a porous cloth and place over the jar; then set it in a shallow basin of water so that the edges of the cloth will be in the water; the evaporation in the cloth lowers the temperature.

WELLS, To Remove Foul Air from.—Throw down a quantity of burned but unslaked lime; when it comes in contact with the water, a quantity of heat is set free from the water and lime, which rushes up, carrying the gases with it, after which the descent may be made in safety; always lower a light before descending; if the light is extinguished, there is still danger, and the operation of the lime should be repeated.

WELL WATER, To Test for Lead. — Evaporate by gentle heat a small sample of the water nearly to dryness in a clean porcelain cup; moisten the residue with acetic acid; add to a portion of it a few drops of strong hydro-sulphuric acid; a black precipitate indicates lead.

WINDOW GLASS, To Prevent Frosting.—Apply a very thin coat of glycerine on both sides of the glass; this will prevent the formation of moisture.

WINDOWS, Old, To Tighten.—Smear the edge with putty, and the sash with chalk, then close very firmly; the putty will fill up the crevices, and the excess, pressed out at the sides, may be removed with a knife, while the chalk prevents adhesion to the sash, letting it move freely.

WINTER PREPARATIONS. — Floors that are open and cold may be improved by covering with old newspapers or thick brown wrapping paper, the thicker the layers the better; over this put a good supply of straw and then the carpet; doors that fit loosely should have strips of list or other thick, soft cloth fastened round the inside of the casing; these must be only thick enough to fill the crack, allowing the door to shut easily; sometimes a very small open space at the bottom of a door will keep the feet cold and aching all day, whether one be sitting or going about; an old carpet folded in several thicknesses, may be fastened on the outside threshold in such a way that when the door is shut, it will lie close against the crack; this is not as elegant as a weather-strip, but keeps out the cold, besides possessing the advantage of being some thing that can be attached at pleasure.

WOODEN BOWLS, To Prevent Cracking. — Place over a good fire in a wash-boiler of cold water; heat to a boiling heat, and boil 1 hour (be sure to have it all covered); then set the boiler off the fire, and let it cool gradually; then take it out of the water; wipe dry, and keep it in the shade; it will never crack or break.

PESTS.

ANTS, Black.—1. A strong solution of carbolic acid and water poured into holes kills all ants it touches, and the survivors immediately take themselves off.—2. A few leaves of green wormwood, scattered among the haunts of these troublesome insects, is said to be effectual in dislodging them.—3. Flour of brimstone, ½ lb; potash, 4 oz.; set them in an iron or earthern pan over the fire till dissolved and united; afterwards beat them to a powder, and infuse a little of this powder in water; and wherever you sprinkle it the ants will die or fly the place.

ANTS, Red. — 1. Set a quantity of cracked walnuts or shell-barks on plates, and put them in the closets and places where the ants congregate; they are very fond of these, and will collect on them in myriads; when they have collected turn nuts and ants together into the fire, and then replenish the plates with fresh nuts; after they have become so thinned off as to cease collecting on plates, powder some camphor and put in the holes and crevices, whereupon the remainder of them will speedily vanish.—2. Grease a plate with lard and set it where the ants are troublesome; place a few sticks around the plate for the ants to climb upon; occasionally turn the plate over a fire where there is no smoke, and the ants will drop off into it; reset the plate, and in a few repetitions all the ants will be caught; they trouble nothing else while lard is accessible.—3. Sprigs of wintergreen or ground ivy will drive them away.—4. They may be kept away from anything by surrounding it by a chalk mark; for instance, a barrel of sugar may have a chalk mark around it below the top.—5. Dishes placed on pie-plant leaves will be protected from ants; they should be replaced every morning.—6. Sprinkle Scotch snuff, red pepper, dry salt or ground cloves on the shelves.—7. Take 2 lbs. of alum and dissolve it in 3 or 4 qts. of boiling water; let it stand on the fire till the alum disappears; then apply it with a brush, while nearly boiling hot, to every joint and crevice in your closets, pantry shelves and the like.

BEDBUGS. — 1. Take the furniture in which they harbor to pieces and wash all the joints with soap and boiling water, carefully exploring all the cracks and openings with a stiff piece of wire; when the wood is dry, saturate the joints with kerosene oil, using a small paint brush; fill up the cracks with a mixture of plaster and linseed oil; if the rooms are papered, saturate the places where the paper joins the baseboard with benzine, using a brush or a sponge and carefully avoid the presence of a light; do the same with the linings of trunks; if the floor cracks are infested fill these with plaster and linseed oil.— 2. 2 oz. of red arsenic; ½ lb. of white soap; ½ oz. of camphor dissolved in a teaspoonful of spirits rectified; made into a paste of the consistency of cream; place this mixture in the openings and cracks of the bedstead.—3. Touch all you can with a feather duster dipped in carbolic acid; remove all clothing and then fumigate the room and bedding with brimstone; close the room tightly, and in 24 hours all bugs will have vanished.—4. Muriate of ammonia, 2 oz.; water, 1 qt.; dissolve and add corrosive sublimate, 2½ oz.; muriatic acid, 2 oz.; mix and

apply with a small brush.—5. Mercurial ointment, 1 oz.; spirits of turpentine, ½ pt.; mix well together until thoroughly incorporated, and use with a feather.—6. Mix together 2 oz. of camphor; 4 oz. spirits of turpentine; 1 oz. corrosive sublimate, and 1 pt. alcohol.

BEES. —Place 2 or 3 shallow vessels—the larger kind of flower pot saucers will do—half filled with water, on the floors where they assemble, with strips of cardboard running from the edge of the vessel to the floor, at a gentle inclination; these they will eagerly ascend, and so find a watery grave.

CRICKETS. — Sprinkle a little quicklime near the cracks through which they enter the room; the lime may be laid down over night, and swept away in the morning; in a few days they will most likely all be destroyed.

CROTON BUGS. — They attack the starch or sizing in the cloth covers of books and often destroy the gold to secure the little albumen used in the work; take a plentiful supply of a powder in which *pyrethrum* is the principal ingredient; with a small bellows, throw this powder among the books on the shelves and allow it to remain; this operation performed once a year will be sufficient to keep them out.

FLEAS.—1. The oil of pennyroyal will drive these insects off; but a cheaper method, where the herb flourishes, is to throw cats and dogs into a decoction of it once a week. When the herb cannot be got, the oil can be procured. In this case, saturate strings with it and tie them round the necks of dogs and cats. These applications should be repeated every 12 or 15 days. —2. Oil of cloves, 2½ drs.; carbolic acid, ½ dr.; cologne, 3 oz.; diluted alcohol, 2 oz.; sprinkle bedding, beds, etc.—3. (*Flea Trap.*) Place a plate of molasses under the house where the animals love to congregate; drive a little stake on each side, and then fasten a sheet of writing paper in a vertical position over the middle of the plate. The fleas will jump against the paper and slip down into the molasses, from which they will be unable to extricate themselves.

FLIES.—1. Infusion of quassia, 1 pt.; brown sugar, 4 oz.; ground pepper, 2 oz.; mix together, and put in small shallow dishes where required.—2. A teaspoonful of pure Persian chamomile, heaped in a little cone and burned in a closed medium-sized room, will kill every fly in it.—3. Cold green tea, well sweetened, and put into saucers, will destroy flies.—4. Black pepper 1 teaspoonful; brown sugar, 2 teaspoonfuls; cream, 4 teaspoonfuls.—5. Pour ½ oz. of oil of lavender into a pt. bottle of cold water and shake it up; scatter the water and oil of lavender on the tablecloth and the flies will go away.

FLY PAPERS.—1. A good kind of fly-paper is that which contains a large quantity of arsenic in its substance. This paper is kept wet when in use, and the flies, by sipping the moisture, are poisoned.—2. Melt resin, and add while soft, sufficient sweet oil, lard or lamp oil to make it, when cold, about the consistency of honey; spread on writing paper, and place in a convenient spot.—3. Boil linseed oil and resin; melt and add honey; soak the paper in a strong solution of alum and then dry before applying the above. — 4. Pour a little simple oxymel into a common tumbler glass, and place in the glass a piece of cap paper, made into the shape of the upper part of a funnel, with a hole at the bottom to admit the flies. Attracted by the smell they readily enter the trap in swarms.—5. Take some jars, mugs or tumblers; fill them half full of soapy water; with a piece of paper, either tied down or tucked under the rim; rub this paper inside with any thing sweet; cut a small hole in the centre, large enough for a fly to enter. The flies will settle on the top, attracted by the smell of the bait, and will then crawl through the hole to feed upon the sweet beneath; the warmth of the weather will cause the soapy water to ferment, and produce a gas which overpowers the flies, and they will drop down into the vessel.

GNATS.—The best preventative against gnats, as well as the best cure for their stings, is camphor.

INSECT POWDER. Persian. — The powder is the pulverized flowers of pyrethrum, carneum and roseum, growing on the Caucasian Mountains. It is not poisonous to man unless inhaled or swallowed in large quantities, but it is known to be death to insect life in all its forms, first stupefying, and then killing. Scattered over the bedstead and clothing, or the person, it destroys bed-bugs, lice, etc. For flies and mosquitoes, the best way to apply it is to burn it. Take a teaspoonful of the powder, in a dish of any kind, and set fire to it. A dense smoke arises, which is certain destruction to all insects with which it comes in contact. A tincture prepared by placing 1 part of the powder in 4 of alcohol, distilled with 10 times its bulk of water, and applied to the body, is said to be a perfect protection against vermin of all kinds. White hellebore answers the same purpose, and is cheaper.

LICE.—Wash with a simple decoction of stavesacre, or with a lotion made with the bruised seed in vinegar, or with the tincture, or rub in a salve made with the seeds and 4 times their weight of lard very carefully beaten together. The acetic solution and the tincture are the cleanliest and most agreeable preparations, but all will destroy both the creatures and their eggs, and relieve the intolerable itching which their casual presence leaves behind on many sensitive skins. White precipitate ointment is also effective.

MOSQUITOES.—1. 3 oz. sweet oil, 1 oz. carbolic acid; let it be thoroughly applied upon hands, face, and all exposed parts, carefully avoiding the eyes, once every ½ hour, when they are troublesome, or for the first two or three days, until the skin is filled with it, and after this its application will be necessary only occasionally.—2. 6 parts sweet oil, 1 part creosote, 1 part pennyroyal. Oil of pennyroyal alone is very efficacious.—3. A camphor bag hung up in an open casement will prove an effectual barrier to their entrance. Camphorated spirit applied as perfume to the face and hands will act as an effectual preventive; but when bitten by them, aromatic vinegar is the best antidote.—4. Drop a small quantity of kerosene on a piece

of cotton; squeeze out the excess as much as possible; then rub the cotton over the face, hands, etc., and they will not alight where the scent has been left.—5. A mixture of glycerine and toilet vinegar rubbed upon the person is a safeguard against mosquitoes.

MOTHS.—1. Steep ¾ lb. of cayenne pepper in 1 gal. of water; add 2 drs. of strychnia powder; strain and pour this tea into a shallow vessel. Before unrolling a new carpet, set the roll on each end alternately in this poisoned tea for 10 minutes, or long enough to wet its edges, for at least an inch. After beating an old carpet, roll and treat all its seams and edges to the same bath; let the carpet dry thoroughly before tacking it to the floor, in order to avoid the accidental poisoning of the tacker's fingers by the liquid. If preserved for future use, carefully label "poison." This preparation will not stain or disfigure carpets or corrode metals in contact with the carpet.—2. 1 lb. of quassia chips, ¾ lb. of cayenne pepper steeped in 2 gal. of water; strain and use as above.—3. Little black carpet moths can be effectually destroyed by a free use of benzine or naptha; poured around the edge of carpet it leaves no stain; the odor soon disappears and so do the moths. All use of either must be attended with care, and applied in the day time and not near an open fire. — 4. Wring a cloth out of hot water; lay it over the bindings and edges, and iron with as hot an iron as can be used without scorching. This will destroy both the moths and their eggs.—5. If fine-cut tobacco be sprinkled under the edge of the carpets, and under places where bureaus, book-cases and the like make it dark, the moths will be prevented from laying their eggs in them, as it will drive them away. — 6. Pour strong alum-water on the floor to the distance of ½ a yard around the edges before laying the carpet; then once or twice during the season sprinkle dry salt over the carpet before sweeping. Insects do not like salt, and sufficient adheres to the carpet to prevent their alighting upon it.—7. Pulverized borax well shoved in all the cracks and seams; if necessary, sprinkle all over the furniture; it will not discolor or injure in any way the furniture or carpet.—8. Sprinkle Persian insect powder into every infested spot and around the edges of the room on tacking down the carpets. Be sure and get a good quality. That which is pure will cause sneezing on the part of the person applying it.—9. 1 oz. gum camphor; 1 oz. of the powdered shell of red pepper; macerate in 8 oz. of strong alcohol for several days; then strain; with this tincture sprinkle the furs or cloths and roll up in sheets; instead of the pepper, bitter apple may be used. — 10. A small piece of paper or linen moistened with turpentine and put into the wardrobe or drawers for a single day at a time, 2 or 3 times a year, is a preventive against moths. — 11. Where the moths have been unusually troublesome, fumigate the room or closet, or even the whole house, with sulphur, removing any articles liable to be bleached by it.—12. Tarred paper, the same as that used in covering roofs, when cut into slips and placed in convenient situations under carpets and behind sofas and chairs in a room, will repel the moth miller from depositing its eggs. If similar strips are placed inside the backs and seats of parlor suits they will render the furniture moth-proof.—13. Sprinkle furs or woolen stuffs, and the drawers or boxes in which they are kept, with spirits of turpentine, the unpleasant scent of which will evaporate on exposure of the stuffs to the air.

RATS AND MICE.—1. When rats refuse to nibble at toasted cheese and the usual baits, a few drops of the highly scented oil of rhodium poured on the bottom of a cage top, will always attract them.—2. Strew pounded potash in their holes. The potash gets into their coats and irritates their skins, and the rats desert the place.—3. Mix corn meal or wheat flour with plaster of Paris or carbonate of baryta. This forms a hard cake in the rat's stomach and kills. Be careful to keep it out of the reach of children.—4. Gather any kind of mint and scatter it about the shelves, and they will forsake the premises.—5. A tincture of Calabar bean is exceedingly efficacious in preserving entomological and other natural history specimens from destruction caused by mice.—6. Place a quantity of red pepper in cotton and stuff the wad into the holes.—7. Sprinkle a little calomel on buttered bread and place where the rats can get it, putting a dish of water close by. This does not kill them but makes them soon disappear.—8. 1 oz arsenic, 1 oz. lard; mix into a paste with meal, and put about the haunts of the rats. They will eat this greedily. Rat poisons are objectionable because the rats are apt to die in their holes.

ROACHES. — 1. Cut up green cucumbers at night, and place them about where roaches commit depredations. What is cut from the cucumbers in preparing them for the table answers the purpose, and 3 applications will destroy all the roaches in the house. Remove the peelings in the morning, and renew them at night.—2. Red lead, 4 oz.; flour, 1 oz; powdered sugar, 1 oz; mix the ingredients well; use by placing some on pieces of paper.—3. Mix finely powdered borax and fine sugar, half-and-half, and spread around where the roaches are most troublesome. For a few days it may seem that the remedy is doing no good, but soon they will begin to die, and in a short time will disappear. — 4. 1 teaspoonful of powdered arsenic, with 1 tablespoonful of mashed potato; crumble this every night at bed-time where the insects will find it; it is an effectual poison.—5. Place a bowl containing a little molasses on the floor at night. A bit of wood, resting on one end on the floor and the other on the edge of the vessel, serves as a bridge to conduct the insects to the sweet deposit.—6. Mix up a quantity of fresh burned plaster of Paris (gypsum, such as is used for making molds and ornaments), with wheat flour and a little sugar, and distribute on shallow plates and box boards, and place in the corners of the kitchen and pantry, where they frequent. In the darkness they will feast themselves on it and die. — 7. Strew the roots of black hellebore, at night, in the places infested by these vermin, and they will be found in the morning dead or dying.—8. Corrosive sublimate sprinkled around the places which the roaches

infest, will kill them quickly. — 9. Equal parts of powdered borax, Persian insect powder, and powdered colocynth, well mixed together, and thrown about such spots as are infested with these insects, will destroy them.

WORMS, On Dried Fruit. — Dried fruit put away with a little sassafras bark (say a large handful to a bushel), will keep for years unmolested by those troublesome little insects which so often destroy hundreds of bushels in a season.

WARDROBE.

REMARKS.—As this is not a treatise on transitory fashions or styles, but for permanent suggestions and guidance, some subjects will appear to be neglected. But due consideration will show that those omitted will, many of them, prove to be concerning such articles of apparel as are constantly changing in cut, or, like underclothing, are so simply made from patterns always on hand, that it would be a waste of space to treat of them. Thus, while the art of cutting and fitting the upper part of the form is treated of as if for ladies only, it should be realized that the same principles can be applied to fitting men's or children's forms. But the drapery and trimmings of fabrics on the human form constantly change, and directions suitable for these to-day would be antiquated to-morrow. Varieties of shape, material and contrivance are limitless. Hints and helps are all that even an encyclopedia can give. (See DRESS in TOILET.)

APRONS. — An old Swiss muslin dress skirt can be converted into little fancy ruffled aprons. These are pretty trimmed with lace or ruffles of themselves. Ornament the pockets with little bows. A kitchen apron is made as follows: Get a piece of cheviot as long as you are from the turn of the bust to the bottom of your dress in front. Hem each end, sew tape at the waist line for strings. A white one can be made in the same way. A sewing apron is made by cutting a small round apron of calico, or any other material desired; make a deep pocket across the bottom; the large pocket may be divided by stitching it through the centre, and smaller pockets may be added at the top. Tennis aprons made of colored sateen, covered with Madras muslin, are very pretty; they are nearly a yard square, and are usually made with one corner forming the bib, and a band around the waist outside; two corners have ribbons sewn on, and these ribbons tie at the back of the skirt; pink, blue and mauve are the most fashionable colors, and there are bows of shaded ribbon on the two pockets, and a frill of cream-colored lace all round; the Madras muslin is 2 yards wide, so 2 aprons can be got out of 1 yard, or 3 smaller ones. There are other aprons made of plain foulard, with 2 flounces of shaded Surah, and a spray of flowers worked or painted to one side of the plain part.

BABY'S OUTFIT.—We here give an economical account of the articles for a baby's outfit; the number may be increased, or they may be made very elaborate or plain, according to the taste and means of the parties: 6 dresses, 6 day-slips, 6 night-gowns, 6 white skirts, 4 flannel skirts, 2 flannel baricotes or pinning blankets, 6 shirts, 6 flannel bands, 6 pairs knitted socks or slippers, 4 doz. diapers, 1½ doz. bibs. These should be prepared before needed. It is also very convenient to have ready a baby basket fitted up with pin-cushion, pockets, fine brush and comb, powder-box and puff, nursery pins, both large and small, etc. Baskets of the most elaborate description are furnished by dealers, but a very neat one can be made at home at a trifling expense, by lining a square wicker basket with a delicate shade of silesia and covering this with dotted Swiss or similar material, with a flounce of the same around it, and trimming with ribbons of a corresponding shade. These can be made more or less elaborate as the fancy dictates. The skirts may be cut either straight or gored slightly, and about 3½ yds. in length. These to be sewed on straight bands of about 6 in. in width, and from 18 to 20 in. in length. Dresses can be cut simply as slips, or gathered and joined to a yoke; or where more ornament is required the entire front may be composed of lace and embroidery. However, simplicity is preferable as a general rule. The best band or binder is knitted of white wool so as to be very elastic and fit closely, with shoulder straps attached. These to be worn winter and summer while the child is teething. Shawls or blankets may be made of flannel or merino, about 1 yard square and trimmed with lace, crochet edges, embroidery, and in a variety of ways.

CAPE. — Take a piece of paper as long as the cape will be required; cut a perfect circle, and another in the centre large enough for the neck; cut it down the middle; try it on the figure it is intended for; should it require any alteration, make it while on, which can be done by taking a plait down each shoulder; when you have succeeded in fitting the pattern perfectly, lay it smoothly on the cloth and cut it out, creasing the seams on the shoulders carefully, which, if neatly stitched, will not be observed when the cape is made; this can be lined; first cut the lining from the pattern, then the material from the lining; put the two faces together; pin it to keep it in place while running the edge inside all round to the neck; then turn it inside out; smooth it on a table; baste it round the edge to keep it in place until it is trimmed, which can be done by putting on a cross-piece, or rows of braid, fringe or frill; then cord the neck; a bow of ribbon to fasten it makes it complete.

CAPS.—These should be made of very fine linen or French cambric; the border either of plain cambric or with a Valenciennes edging sewed on it; the crown of the cap is about 2½ in. in diameter; it is prettier if worked in crochet, tatting or embroidery; the two former are

Baby's Outfit.

very strong, and quite suitable even for night-caps; the cap is composed of 3 pieces, the crown, the head, and the neck; the head piece is 10 in. long and 5 deep; the neck-piece $1\frac{3}{4}$ by 2; it is joined to the other to form a round, in which the crown is set; and the head-piece is then slightly sloped, to shorten it toward the ears; run 6 shirrings, set in pairs, with fine bobbin in them; they should draw at the end, not at the top of the head; the frills are set on one behind the other; very handsome ones are also made of lace and lined with silk.

CAPS, Dusting.—They are prettiest when made of shining cambric and gay ribbons; but may be also made of plain dark calico, using an oval piece 22 in. long and 18 in. wide; bind this with gray plaid, and put on another strip $\frac{1}{2}$ in. wide and 1 in. from the edge; under this run rubber cord and finish with a knot of ribbon in front.

COATS, To Hang. — A heavy garment, like an overcoat, if hung by the loop at the back of the collar, will soon stretch out of shape by its own weight; a piece of hard wood, long enough to reach from the outside of one sleeve to that of the other, will prevent this; it should have a hole bored through centre, or a loop of strong cord to hang it upon the nail or hook; under-coats and vests may be hung in same way.

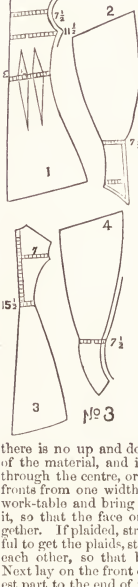
COAT, To Fold. — First, spread it on the table; double the left sleeve from the elbow toward the collar; the other the same way; then the left lappel over the sleeve as far as the back seam, and the other in the same manner; next turn up the left skirt so that the end may touch the collar; do the same with the right skirt; give it a light brushing all over; then turn $\frac{1}{2}$ the coat exactly even over the other half.

COAT, To Make. — To make a coat for a man of medium size $3\frac{1}{2}$ yards will be required. Procure a pattern, either of a tailor or by ripping up a well fitting garment and from it cutting the pattern; it is important that the neck and shoulders fit well; cut out first the body, then the sleeves, and from the pieces the collars, cuffs and facings; cut out the lining in a like manner; with the old coat before you, first sew up the little openings at the top of the coat around the neck; press them; sew the buckram or stiffening on to the lapels and press them; then fit in nicely the stiffening in the front of coat; sew the buttons on the right side; under each button sew to the stiffening a strong piece of brown Holland; mark the button-holes corresponding to the buttons, but do not work the button-holes yet; now prepare the lining, padding and quilting as in model; fit the lining to the outside, basting it carefully to every edge and sew it neatly on the shoulder; now make the sleeves and insert them, taking care to have the fullness on the shoulder or under the arm; press it smoothly; face the lining of the coat down each side of the front with a piece of the goods; now prepare the collar; sew the inside of the collar, with the buckram sewed on it, just as it is on the lappels, to the outside of the coat and the outside of the collar to the lining of the coat; baste the seams together around the neck on the inside; turn the collar over as it is intended to be worn; baste it round the edge; take the binding, begin at the opening of the skirt in the back seam, baste it all around and end where you began; sew it down; press; now work the button holes; put in the pockets; a coat for either lady, child or gent can be made in this way.

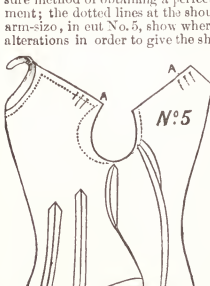
COLLARS AND CUFFS. — Pretty collars and cuffs can be made of any pattern and hem-stitched; cut the pattern and be sure it is a good fit; then cut two layers of white muslin for each collar and cuff; then two of nice linen; take the two pieces of muslin and one of linen; baste them evenly together; if a colored border is desired baste the border around the edge of the three basted together; turn the inside edge in nicely; now baste the second piece of linen on to the first piece; stitch it evenly around the edge; turn, and baste it evenly around the edge; now finish with a neat band if it is a collar; if a cuff, before turning stitch all around with the exception of one little corner; then turn and baste, turning the open corner in neatly; when turned and basted stitch around at the desired depth; if it has a colored border, stitch on the edge of it; they can be trimmed with lace or embroidery if desired; pretty collars for children are made of Paris muslin; cut a strip of sufficient length; put an edging of lace or embroidery on each side, narrow and wide; on the side of the narrow edge run 4 rows of shirring; under the shirring place a straight band, the size of the child's neck and sew the collar on to it; let the wide edge come up to the ends; these are also pretty made of satin, silk or velvet.

CUTTING AND FITTING.—The first thing to be learnt is the measures of the one for whom the dress is to be made. (See *Self-Measurement.*) To illustrate the system of cutting, suppose the following measurements to have been taken: First measurement, length of back, $15\frac{1}{2}$ in.; second measurement, across the back, 14 in.; third measurement, length of waist under arms, $7\frac{1}{2}$ in.; fourth measurement, across the bust, 23 in.; fifth measurement, the chest, 15 in.; sixth measurement, waist, 24 in.; seventh measurement, around the neck, 13 in. Now apply these measurements to the pattern before cutting out the lining. All the alterations are made after seeing that the dart-seams are in the right places. From the front edge to the first dart at the waist line, the measurement should be $2\frac{1}{2}$ in. From the top of the dart to the front of the waist, $3\frac{1}{2}$ in. The bust measurement is 23 in.; the pattern of half the front is $11\frac{1}{2}$ in. As the pattern measures 13 in., to reduce to the proper size, mark at $11\frac{1}{2}$ in., then move the tape up to get the chest measurement. The pattern measures 9 in., therefore mark at $7\frac{1}{2}$ in., taking care to keep the same curve around the arm-size. The double lines show how and where to make the pattern smaller. If the length of the side-body is $\frac{1}{2}$ in. too long, put a plait of $\frac{1}{2}$ in. at the waist. The size around the waist is obtained by placing all the pieces together, and then measuring across them, from the front to the first dart, then between the darts, and from the back dart to the under-arm edge. It measures

13 in., while 12 in. is wanted. Take ½ in. from each side-body, from the arm-side down. (See double lines.) The front edge of the pattern is laid on 1½ in. from the selvage of the lining, this is for turning in for a stay for the buttons and button-holes. After laying the pattern on the lining as it should be, pin each piece in its place smoothly, pinning through both thicknesses of the lining. See that the bottom of the waist comes straight upon a cross-thread of the lining. All waist linings should be cut double, or both sides at once. When the pattern is all pinned on, trace its outline on the lining with the tracing wheel. After tracing the several pieces of the pattern, cut out the lining, allowing ½ in. for seams, except on the shoulder and under the arm, where an inch is to be given. Then remove the pattern from the lining and proceed to cut it in the outside. If there is no up and down to the figure or nap of the material, and if it is not folded down through the centre, or wide enough to get two fronts from one width, lay one end upon the work-table and bring the other end over upon it, so that the face or right sides will be together. If plaided, striped, or figured, be careful to get the plaids, stripes, or figures opposite each other, so that both sides will be alike. Next lay on the front of the waist, with the largest part to the end of the material (as shown in cut No. 4). If there is a right and wrong side, and no up and down, still follow the above; if there is an up and down to the material, either in the nap or the figure, that requires the goods to be cut all one way, then if the material is cloth and folded down the centre, do not unfold or open it, but cut double, with each piece of the lining laid with the upper part toward the top of the nap. Some materials, such as velvet, velveteen and plush cloth, require to be cut the opposite way of the nap. If a material is of a width that will cut to better advantage by cutting it single, do so. In cutting from the single width care should be taken not to get two fronts for one side, or when cutting from the double, not to cut the same piece twice, or instead of two pieces there will be four. To avoid this error lay one-half of each piece of the lining aside, that it may not confuse in cutting. The rule for the cutting of the single width, when there is a right and wrong side, or an up and down face, is to cut the entire pattern to the best advantage; this will give half of the garment; then cut the second half by the first, laying the faces of the material together. After cutting out the body of the dress, such as the waist and overskirt, or polonaise, skirt and sleeves, baste together before cutting the trimming. Begin to baste by separating the lining from the outside, if it has been cut double; then lay the outside down upon the table, with the wrong side up, and put the lining of the same piece upon it with the right side up; be careful to smooth out every wrinkle or fold of both the lining and the outside. If the outside has been pieced, do not baste the lining on it until the seam has been well pressed. Always join the lining and outside together smoothly before basting them; if the material is velvet, silk or satin use fine needles instead of pins; after basting the lining and outside of each piece firmly together near the edge, take the side-body of the left side and pin it in its place on the curve of the back, holding the back a little full, from the arm-size about half way down to the waist, always commencing to baste the side-form in from the arm-size: pin the rest of the seam evenly, and alike on both sides, down to the bottom of the waist; if there are any plaits to be put in, baste them; the right side-body must be pinned in to correspond exactly with the left, always commencing to baste it in from the bottom of the waist, in order that the back piece or full side shall be up; then join the back down the centre, making the seams according to the marks made by the tracing wheel in the lining; do not trust to the outside edges being even, but see that the tracing of the upper and under sides are exactly opposite, and make sure that the needle goes down and comes up in the lines made for the basting; the front should now be basted smoothly on the lining, commencing at the neck and following down the line traced for the hem, then up and down on both sides of the darts. Great care should be taken not to get the outside in the smallest degree tighter than the lining, especially in closely-fitting portions of the waist. The front darts should slope 1 in., and be placed 2 in. from the edge of the front at the bottom of the waist, and 3 in. at the top; the proper distance between the darts is about 3 in. at the top, tapering to 1½ in. at the bottom of the waist; the front dart at the top should be from ½ to ¾ in. shorter than the back dart; while basting let the work lie on the lap; do not pin it down or hold it over the



fingers; after all the seams are basted except the shoulder seams, take the waist by the middle seam in the back, folding it together and putting a pin at each seam, in order to see that the corresponding seams are even; this is the only sure method of obtaining a perfectly fitting garment; the dotted lines at the shoulders and the arm-sizo, in cut No. 5, show where to make the alterations in order to give the short and high



effect to the shoulder seams; letters A A show where to give the required fullness to the front and back of the waist in sewing up the shoulder seams; stretch the front about halfway down the seam, but not enough to have tho back show any fullness when sewed; then reverse the fullness to the front seams, stretching the back the rest of the way to the bottom; in basting the position of the darts and the shape of tho back and side-forms have much to do with making the form appear round or flat; cut No. 6 illustrates how and where to basto the lining on the material; now cut the sleeves by

the pattern and baste the lining carefully on the outside; baste up the inside seam first then tho outside seam; make the outside seam come out even at the top and bottom, and if tho upper side is longer than the under, let it fall in gathers at the elbow; if the sleeve is then to be made tight the armhole should be made small and the sleeve just large enough to fit in without any gathers; if the sleeve is too large it should be cut off along the outside seam. When it is all basted together try it on, wrong side out, and make such alterations as are necessary until it fits the figure perfectly; after having made the basque or waist, measure off first the breadths of the skirt; pin or tack the breadths together, and if gored, be careful that the gores are even, and the sweep of the skirt falls exactly in the centre of the back breadth; be careful that no breadth is turned wrong side out, or with the pattern upside down; allow in the gored skirt for the stretching of the cut edge more than the selvage, or the work will pucker; in a plain skirt begin the seam at the bottom, that any unevenness may come at the top, but in a gored skirt, begin at the top, and let the difference, if there is any, come at the bottom; in case of a cut edge and a selvage coming together, the selvage must be held from you.

We are indebted to Messrs. Strawbridge & Clothier, of Philadelphia, the far-famed dry goods and furnishing emporium, for their courtesy in allowing us to copy these directions in the art of cutting and fitting, as also for other suggestions and illustrations from their handsome *Quarterly*, in which ladies will find a great fund of information, profusely and beautifully illustrated.

DRESSES, For Girls. — For little girls make the dresses as plain as possible; a very pretty style and one that does not change is to make a yoke of some white material, fancy or plain; to this shir a long slip of the same material; make the sleeves to correspond with the yoke; fasten at the wrist with a ribbon, letting a little ruffle fall over the hand; the slip can be tucked and have lace edging and insertion or embroidery to correspond with the yoke; princess dresses, relieved by white aprons, are also pretty; whether of silk or calico, make them plain; for a miss of over 16 the style depends a great deal upon fashion.

DRESS, For Ladies.—For a lady of medium size, 15 yds. of silk will make a neat, plain dress; but if it is trimmed the quantity must be increased accordingly; of double width but half the number of yards is required; for a calico dress, 10 yds. will make a plain suit, 14 a very pretty one; of lawn about the same amount is required; 4½ yds. of lining are needed for a skirt, 3 yds. for a basque; the other articles which are needed for a dress are: 2 spools of buttonhole twist, 2 of silk, 1 of basting thread, 1 braid for the skirt, 2 whalebones, hooks and eyes for skirt, buttons for front of waist; the remaining trimmings depend upon fashion. Always have the materials required ready before the sewing is commenced. After it is all cut and fitted (see *Cutting and Fitting*), stitch the seams carefully right under the basting. Overcast all the seams neatly, putting stays on the darts and under arm seams; next make the collar; if it is a turn-down collar, baste it on the wrong side of the waist, stitch and fell the lining of collar on to the waist goods; if a standing collar, stitch it on the right side of waist and fell the lining of collar on to the lining of waist; now put in sleeves; stitch them strongly and overcast the seams; don't forget to put in an insido belt to support the strain at the waist; sew it to each seam; be sure that it is at an equal distance from the bottom on each corresponding seam. The waist is now done. Now the drapery has to be put on; this depends so much on fashion that no direct rules can be laid down; be sure though that it is faced neatly, that all stitches are small and neat, and that where it is looped up the stitches are made strong, to prevent tearing. If the dress is a summer dress it need not be lined, but a handsomely trimmed or plain corset cover sewed in as a lining makes a great improvement.

HATS AND BONNETS. — Shapes depend on fashion. The best materials should be used in trimmings; cotton velvet or ribbon will soon look rusty; but silk may be used again. An ostrich feather, undyed, is worth many false wings, butterflies, etc. Simplicity shows taste; a wreath of flowers, with a bow, is beautiful; or a feather instead of the flowers; the flowers can go all around with no other trimming; ribbons, silk, velvet, or plush, with flowers, feathers or lace, fixed stylishly, make beautiful hats; summer hats are pretty trimmed with lace or flowers.

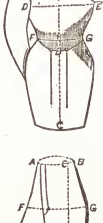
JACKETS. Crocheted. — It takes 4 oz. jacket yarn for a jacket without sleeves; use brown for the jacket and scarlet for border, or chinchilla for jacket and blue for border; the long crochet stitch is the quickest; shape by a basque, knitting the back, then the fronts; crochet together on shoulders and under arms; put on a border of shell stitch, and the same around the arm-holes; leave places for button holes as you crochet; line with a strip of cambric and work with yarn; in crocheting the fronts, make the bias by widening; that is, make a stitch from a loop, shaping by the biases in the basque.

LINEN, To Detect Cotton in. — 1. Boil; then dry; put in common vitriol for a minute; wash in water several times, then in a weak solution of soda or potash; the cotton dissolves, or becomes opaque white, while the linen is transparent. By comparing with a portion not tried, the cotton can be estimated. — 2. Immerse in a mixture of equal parts of hydrate of potassa and water when strongly boiling; take out; press between blotting paper. The dark yellow threads are linen, the white or bright yellow are cotton.

MITTENS. — Use three-threaded Saxony yarn and No. 20 needles; set up 34 stitches on the first needle, 31 on the next and 22 on the third, and knit once around plain; 3d row: Seam 2, knit 1 plain, throw the thread over and knit 1; do the same for 7 additional stitches; this will make 17 stitches from seaming; seam 2, slip 4 stitches on to a hairpin and knit the next 4; slip the stitches from the hairpin back on the needle and knit them; seam 2, knit 1, throw the thread over and knit 1; do the same for 7 additional stitches; seam 2; this is the end of the first needle and forms the back of the mitten; knit 1, throw the thread over and knit 1; do the same for 7 additional stitches; seam 2; repeat until you finish that row and reach the first needle again; 4th row: Seam 2, slip and bind, that is, slip 1 stitch, knit 1 and draw the slipped stitch over the knit one and drop it from the needle; knit 13 plain, knit 2 together; this will give 15 stitches between the seamings; seam 2, knit 8 plain, seam 2, slip and bind, knit 13 plain, knit 2 together; repeat from "seam two"; 5th row: The same as 4th; there will be 13 stitches between the seamings; the 8 stitches which form the twist in the middle of the first needle are never altered; 6th row: Same as 4th, giving 11 stitches between seamings; 7th row: Seam 2, knit 1, throw the thread over and knit 1; do the same for 7 additional stitches; seam 2, knit 8, seam 2, knit 1, throw the thread over and knit 1; do the same for 7 additional stitches; 17 stitches between the seamings; repeat; 8th row: Same as 4th; 9th row: Same as 5th; 10th row: Same as 6th; 11th row: Same as 7th; 12th row: same as 3d; 13th row: Same as 4th etc.; the first needle has two shells with a twist between them; the second needle has 3 shells and the third 2 shells; these shells are begun with 9 stitches, increased gradually to 17, and reduced to 9 again; the twist in the middle of the back is made by slipping the stitches on the hairpin every second time that thread is thrown over increasing the shells to 17; these shells are carried up about half a finger, to form the wrist, after which the second and third needles are knitted plain; the fancy back is continued until seven rows before beginning to narrow; when the shells on the second and third needles are turned into plain knitting it must be when they are reduced to 9 stitches, between the seamings. To shape the mitten, knit 12 rows after these two needles are turned into plain work; then on the third needle widen at the 16th stitch, leaving 15 at the other end of the needle; every third row round, widen at the 16th stitch from one end of the third needle, add the 15th from the other end; this widening, which is for the thumb, must be proportioned according to the shape of the hand; when long enough slip the thumb stitches on a thread, cast on 9 stitches in their place, join the works and continue the hand until long enough to reach the end of the finger; knit eight rows plain all the way round, and the next row narrow every 7th stitch; knit seven rows plain and narrow every 6th stitch, six rows plain and narrow every 5th stitch, and so on until after you narrow every stitch, then bind off and whip the end together on the wrong side; take up the thumb and the 9 stitches that were made between; narrow at each end of these extra stitches every third time round until they are all narrowed away, which will make a little gusset; when the thumb is long enough narrow every 4th stitch; knit four plain rows and narrow every 3d stitch, three plain and every 2d stitch; two plain and every stitch and bind off; if coarser work is desired use No. 18 needles and set up one less shell, or make only 7 stitches in each shell instead of 9.

PANTS, To Make.—It will require about 2½ yds. for a pair of pants. Spread the cloth on a table; pin the patterns down smoothly on the cloth, folded double that both legs may be cut out at the same time; let the nap run down the leg; cut so that the remnants may be left in pieces as large as possible; line from waistband 6 or 8 in. down; sew the facings on the pockets; press these down; insert the pockets; now make the upper front part; baste together the legs; sew the long seams and press them; stitch the legs together on the back seam; baste on the waist bands; sew them; add the triangle at the back; now the strap and buckle; sew on the buttons; now finish the bottom of the leg; examine your model closely; be sure and have the buckram fit nicely and stitch so the stitches will not show through; have a hot iron to press with; dampen the seams with a sponge; sew on a lock-stitch machine.

SELF MEASUREMENTS, For Gentlemen.—*Boy's Suit.*—From nape of neck to heel of boot; round the neck, as for shirt; from H to I for elbow point; on to K for length of sleeve; round the breast, underneath the outside garment; round the waist, underneath the outside garment; length of the trousers inside the legs, measure as in trousers for men, from centre of fork down to K.

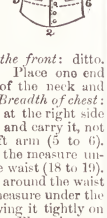


Coat.—Take these measures outside the coat: From A to B and on to C; from H to I for elbow point; on to K for length of sleeve. Take these measures under the coat: From D to E around the breast; from F to G around the waist.

Pants.—From A to B round the waist; from C to D top to bottom; from centre of fork, close up, down to K for length of leg inside, keeping the leg straight down; from F to G round the seat; from H to I round the bottom; L round the knee.

Shirt.—Pass the tape round the neck; take the length of sleeve; measure with arm bent as in coat, from centre of back, round the elbow, to within ½ in. of the knuckle; measure round the hand, now round the chest; each measure to be in inches, and the number of the same to be given.

Vest.—Take these measures over the waistcoat: From 1 at centre of the back round the inside edge of the collar to height required for top buttons; from top button to 2 for length in front; from 3 to 4 round the breast; from 5 to 6 round the waist.



SELF MEASUREMENT, For Lady.—*Length of skirt in the back:* Measure from the waist at the middle to touch the floor. *Length of skirt in the front:* ditto. *Length of waist in front:* Place one end of the measure at the base of the neck and carry it to the waist (1 to 2). *Breadth of chest:* Place one end of the measure at the right side of the chest, close to the arm, and carry it, not too tightly, across to the left arm (5 to 6). *Length under the arm:* Place the measure under the arm and carry it to the waist (18 to 19). *Size of waist:* Bring the tape around the waist evenly. *Arm size:* Slip the measure under the arm and meet it without drawing it tightly on the shoulder. *Length of arm:* Place the tape on the shoulder at 9, carry it down the outside, doubling at the elbow, 10, to the wrist, 11. *Breadth of back:* Draw measure tightly from shoulder to shoulder (16 to 17). *Bust measure:* Draw the tape tightly around the form, letting it lie across the front on the line 3-4. *Length of back:* Place the tape at 14 and carry it to 15. *Shoulder seam:* Carry the measure from 24 to 25.

SKIRT, Infant's. To Knit. — Cast on 82 stitches; purl across; knit across plain; slip off first stitch, narrrow 1, 2 plain, thread over and knit 1, thread over and knit 2, narrow 2, knit 2, thread over and knit 1, thread over and knit 2, narrow 2, knit 2, etc., across; purl across; same as 4; knit across plain; purl across; knit across plain; begin at 4 and so on to 10 until you have 4 times knitted the inclusive rows, and you will have 4 rows of scallops, which form the bottom of the skirt; then knit 2 plain, purl 2, 2 plain, purl 2, and so across; make 45 rows in this manner, being careful to have them match, so as to give the work the appearance of seaming; cast on 16 stitches for the shoulder; then knit across the entire width, shoulder and body; purl across; knit 2, thread over and knit 1, narrow 1, knit 2, etc., across; this last row makes a row of holes, through which narrow ribbon can be drawn to make the neck smaller, if desired; bind off; the sleeve is made of the 4 rows of scalloping in the same way as that round the bottom of the body, and joined to the shoulder.

SHIRTS, To Make. — Baby's shirts should be made of cambric; linen is too coarse; they are a straight piece with the arm-holes cut out and the shoulders shaped; they may be shaped under the arms also; fell the seams neatly so that they will not rub the tender skin. Gentlemen's shirts are made of white muslin with fine white linen for the bosom; the very first thing to do is to set the linen bosom on the front; stitch it twice across the lower edge, and cut out the neck by the shirt pattern; next finish the back. If a yoke shirt is to be made, gather the fullness, and placing it between the front and back of the yoke, sew the seam and turn the yoke, leaving the seam inside; if it be a sack-shirt, face the back for a depth of 12 in. Next sew up the shoulder seams, always leaving the facing of the back or the lining of the yoke, to stitch down on the right side; this makes all smooth and well finished. Then take the sleeves, which have already had the wristbands sewed on, but are still open from wristband to shoulder, sew

them into the body of the shirt, leaving ½ in. to turn down for a facing; this makes unnecessary the troublesome arm-hole facing and gives the requisite strength and finish; now comes the long seam, closing both the sleeve and the body, and almost finishing the garment; this seam must be carefully felled; make the narrowest hem possible round the bottom of the shirt; stay the ends of seams with tiny gussets or a tape stitched firmly across; the pattern ought to be so perfect that the neck will need no trimming out; a circular band is the best fitting, and this requires a pattern; upon the set of the neck band depends the fit of the bosom and the comfort of the wearer; use a tape measure that it may be neither too large nor too small, but just right; shirt bosoms should always be lined. Woolen shirts are the best for farmers, both in summer and winter; they absorb the perspiration, prevent chills and protect the person from sudden change of temperature; the colors are permanent, and with wide turndown collar of the same material, blue flannel makes an appropriate and tidy garment.

SHOES. Creaking. To Prevent. — Rub a little olive oil into the sole, especially about the waist and ball; in boots intended for out-of-door wear, avoid letting the oil get into the seams, as it might, by dissolving the wax on the thread, be the cause of leakage.

SHOES, To Deodorize.—A strong solution of iron and copperas in water will remove the disagreeable smell arising from boots or shoes worn during the summer months.

SHOES. To Dry.—When taken off, fill full of dry oats; this will rapidly absorb the moisture; as it performs this action, it swells and fills the shoe, keeping the form good, and drying the leather without hardening it.

SHOES. To Polish.—Brush off before blacking; never wet, nor allow the blacking to dry before polishing. Patent leather will look handsome if rubbed with unsalted butter, rubbed in with flannel, and polished with buckskin. French kid can be made to look well, if rusty, by a mixture of equal parts ink and sweet oil, applied with camel's hair brush and dried in by the fire.

SILK AND WOOL, To Detect Cotton in. — 1. Unravel and burn the threads; cotton burns freely, leaving little or no black charcoal; wool and silk shrivel up, leave a black charcoal, and give a strong smell. — 2. Put into chlorine water or bleaching liquor. The cotton is whitened, and the silk and wool turn yellow, and can be distinguished by a lens. — 3. Take a thread and break it; if it breaks off brittle, it is cotton; if, in breaking, fibres pull out, it is wool or silk.

SOCKS, Crocheted. — With single zephyr of the desired color and a rather small hook make a chain long enough to go around baby's leg, probably 35 stitches, more or less; join them together to form a round, and work in DC (double crochet), putting the hook through the underhalf of each stitch for about 15 rounds; this forms the leg. Now, for the top part of the foot, raise 13 stitches, crochet tricotee; that is, put in the hook as before, pull the wool through and leave the loop on the hook; work these 13 stitches forward and backward in crochet tricotee for 10 rows, forward and backward making 1 row; on the next row narrow by drawing the wool through the first 3 vertical stitches on the right hand side of the piece, and again through the 3 stitches immediately before the last loop; repeat these narrowings on the next row; there are now 5 stitches; make a DC in each; the top part of the foot is finished. Next, work down the left side of this piece in DC; then around the stitches at the bottom of the leg, and afterward along the right of the foot and around the toe; in doing this be careful about the left side of the foot; the hook here should be put under the last of the afghan stitches down the side and through the stitch below; work round and round the bottom of foot and leg in DC for 6 or 7 rounds; then turn the work inside out, place the 2 sides carefully together, put the hook through 7 stitches at the the end and draw the wool through the whole; crochet in DC the bottom edges of the foot together till only 7 stitches are left; put the hook through all of these, draw them together to match the toe end, fasten off, turn it inside out again, and the foot is finished. Next fasten the wool on the top of the leg; make 3 chains, work 2 treble into the same hole, miss 2 stitches, and fasten with a DC into the 3d stitch; make 2 chains, work 2 trebles into the same hole as DC; miss 2 stitches and work a DC on the 3d; repeat this scallop all around the top of the leg; the work is now complete with the exception of a little chain and tassels, or a narrow ribbon around the ankle. Recapitulation: Cast on 35 stitches for the top of leg; leg 15 rounds deep; top of foot 13 stitches wide, and 10 rows to narrowings for the toe; 2 rows of narrowings, 8 stitches in all; toe, 5 stitches wide; depth of foot, 6 or 7 rounds; finish with scallop on leg and ribbon around ankle.

STOCKINGS, To Knit.—We give the following directions for knitting silk stockings, but the same directions will also apply to wool or cotton, except that the number of stitches cast on will be less in proportion as the size of the yarn is larger: Materials, 2½ oz.; cast on 84 stitches with No. 16 or 17 needles; ribbing 84 stitches, knit 2, purl 2 for 44 rounds; legs, 84 stitches; increase 1 stitch on first round, and knit plain for 10 in., including ribbed top; narrowings, 85 stitches; decrease 6 times with 7 plain rounds between or 12 decreasings in each; ankle, 73 stitches; knit 30 rounds plain; heel, 37 stitches; knit 36 rows; turn the heel Welsh fashion; pick up 19 stitches from each side of heel; foot, 72 stitches; knit 50 rounds, or 5½ in., including heel; toe, 72 stitches; decrease 10 rounds, 40 decreasings in all with 1 plain round between; cast off with 16 stitches on each needle. *Gentleman's plain silk sock.*—Material; 3 oz. silk for 1 pair; needles, No. 16 or 17; cast on 108 stitches; ribbing, knit 2, purl 2 for 50 rounds; leg, 108 stitches; increase 1 stitch on back needle 1st round, and knit 30 rounds plain; narrowings, 109 stitches; decrease on the 40th, 48th, 56th, 64th, 72d, 80th and 88th rounds; ankle, 95 stitches; knit 42 rounds; heel, 49 stitches; knit 38 rows; narrow after the Welsh fashion; pick up 24 stitches on each side of heel;

foot, 95 stitches; knit 90 rounds, or 9½ long including heel, longer or shorter, according to length of foot required; toe, 95 stitches; narrow every 3d round till only 44 stitches remain; knit front and back stitches together and cast off. *Lady's ribbed silk stocking.*—Materials, 4½ oz. of silk for 1 pair; cast on 121 stitches on No. 16 or 17 needles; rib, (knit 3, purl 1) for about 14 in. in length, purling 2 in the centre of the back needle where the seam is; narrowings, 121 stitches, 12 times, decreasing 1 on each side of the seam stitch as in plain knitting with 7 rounds of plain ribbing between the narrowings; ankle, 97 stitches; rib about 2½ in.; heel, 49 stitches; rib 36 rows, knitting 2 together in the middle of the last row; heel turned in Welsh fashion; pick up 20 stitches on each side of the heel; foot, 96 stitches; knit about 8 in. long including heel; toe, 96 stitches; narrow every 3d row 13 times; cast off with 22 stitches on each needle.

TRUNKS, To Pack. — After the trunks are ready, get everything together which is to be packed, and then go quietly and systematically to work; put the heavy things at the bottom, packing them tightly, so that they will not rattle about when the trunk is reversed; put the small articles in the tray; anything which will be scratched or defaced by rubbing should be wrapped in a handkerchief and laid among soft things; if you must carry anything breakable, do it up carefully, and put it in the centre of the trunk, packing clothing closely about it; bottles should have the corks tied in with strong twine; put them near articles which cannot be injured by the contents if a breaking occurs. If the dress is separate from the corsage, it can be laid in the tray with only a slight fold at the top of the skirt; the train is spread out first; then every puff or fold is kept up by soft wads of yellow tissue paper, white having been found to darken white and delicately-tinted satins; this is to prevent the creasing or crushing to which velvet and satin are particularly liable; large sheets of the paper are then placed over the whole. The waist is next taken and laid out flat upon the paper-covered skirt. The sleeves are filled with paper so as to retain the shape made by the arms; every button is covered with paper, and under bead fringes, etc., are laid pieces of paper to prevent discoloration or cutting; over the whole is then placed a final layer. When the top tray is reached, and, perhaps, the next one also, beside the paper a sheet of the finest cotton batting, such as florists use, is placed over it, and, in turn, over this a layer of oil silk. Tack on the trunk a card with your permanent address; as this card is to be consulted only if the trunk is lost, it is not necessary to be constantly changing it.

UMBRELLAS, To Cover.—To cover one sufficiently well for common use, is not a formidable task; if a whole section of the worn-out covering remains, it may be used as a pattern for the new; or, cut a paper circle of about the desired diameter; make the circle 8 sided; cut this into 8 triangular pieces; the base will be for the selvage; now you have a perfect umbrella pattern minus the seams, for which allowance need be made only along the half toward the centre; use old muslin first.

VEST, To Make.—In cutting a vest ¾ yards of material will be required; pin the patterns smoothly on the cloth folded double; after the fronts are cut, cut out the collar, facings and pocket-welts; now cut the back, lining, and pockets; before removing the pattern from the front, mark with chalk the places of the pockets; first stitch up and press the little gore beneath the pocket; cut the places for the pockets; sew on the welts; insert the pockets and press; on the right side baste a strip of strong linen under the buttons; sew on the buttons strongly; sew on the lining of the collar to the outside front of the vest; stitch on the facings down the front and press; also on the bottom; now sew the outside of the collar to the lining of the vest; baste upon it the buckram; fit the outside and lining neatly together; fell all around; proceed in the same way with the left side now; only work the button-holes last; make and baste on the back the buckle strap; sew the back and fronts together at the shoulders and under the arms.

"LA, MISS! HOW SWEET YOU LOOK!"

TOILET.

DRESS.

COLOR.

HARMONY.

REMARKS. — Near the face the utmost care must be used to keep the colors soft and indescribable; for a brilliant color destroys the finest complexion, and the aim of dress is to enhance, not to destroy.

BLACK. — When not worn for mourning, black will bear bright colors, and sets off gold ornaments effectively, as also a fair complexion. Black velvet for diamonds and lace, is very effective, and harmonizes with all bright colors.

BLUE. — This harmonizes with orange and a warm, rich brown; it is discordant with yellow; intolerable with green. Blue requires white next to the complexion. Other harmonious combinations are blue, crimson, gold, salmon, drab, stone, white, gray, straw, maize or chestnut.

CERISE. — This harmonizes well with silver-gray, lilac, or a pale lavender; will bear, in addition, a little gold, and then may allow a point of scarlet or crimson. Blue with cerise is harsh; but blue and gold, arranged in small quantities, will harmonize.

CLARET. — Harmonizes with orange and gold, but not with yellow. Rich if trimmed with black lace.

CRIMSON. — This is often seen with blue in paintings, but it requires white to harmonize. It will bear blue and gold, or orange, combined with discrimination; it will bear orange alone, but is improved by the softening of black or white lace. Crimson and purple are discordant alone, but crimson will bear purple and pale green in small quantities; it is dangerous to the complexion, unless clear or glowing and slightly olive, when white should be placed between the complexion and the color.

DRAB. — The drabs, fawn, mauve and mouse colors, have much the same general character as the grays, but are not so cold in tone. Crimson, blue and green relieve.

GRAY. — The grays adapt themselves to bright colors. Crimson or scarlet is effective upon a dark ground. The grays require white next the complexion when trimmed with their own color.

GREEN. — Grateful to the eye, but difficult to manage. Harmonizes with pale red; better with pale scarlet; but for an evening dress is most effective with gold; in the open air agrees well with white, and may be relieved with scarlet or crimson used sparingly; is dulled in effect by black. Very dark green requires white or crimson; it harmonizes with blue or pink of certain shades. Light green looks well with white; may be used with a darker shade, or a rich brown.

LAVENDER. — Lilac, lavender and mauve harmonize with cerise, used sparingly, and with gold; but are better trimmed with the same color of a shade darker or lighter; white may be used freely; black sparingly; lavender takes black for half-mourning; mauve takes white or black for slight mourning.

MAGENTA. — A variety of claret; improved by contact with black; injured by green; destroys scarlet placed upon it in small quantities.

MAROON — Has a tendency to brown; harmonizes with gold or orange; will bear a little green; heightened in effect by white or black; suits but few, and requires skilful handling.

ORANGE. — Effective in the evening; with purple has a splendid appearance, but suits only a tall commanding figure; black, especially in lace, is an efficient contrast; white is less effective, but looks well by gas light; orange harmonizes well with blue, but would form a doubtful combination in dress; minute points of scarlet, black or white may be added, but for dress orange is best alone, or with purple, black, or white.

PINK. — Looks best alone, or with pure white;

effective with narrow lines of black, or black lace; bears silver trimming, and with dark green or light blue makes a pretty combination.

PUCE. — Requires gold or orange. It is brightened by scarlet; not a good color.

PURPLE.—Has a magnificent effect with gold. A clear crimson or scarlet brightens it, but requires management as to quantity; this combination is improved by gold, or a little orange or amber. A minute quantity of green, as a tiny sprig, suits some shades. White and black may be used freely.

RED — A pale green looks well with it in small quantities, but a pale sea green, pearl or silver-gray, better. Blue and red are of an opposite character, but certain shades look well together.

SCARLET. — This, in an opera-cloak or fancy dress, has a brilliant effect trimmed with gold, and harmonizes well with white; in trimmings it is a valuable addition to gray, or to any of the light neutral tints; will bear black lace or swan's-down.

WHITE. — White muslin is appropriate for the young, and for festive occasions. It admits of the brightest trimmings, though scarlet and blue are most effective. Dull gold is effective with rich white silk or satin. Lace, either black or white, looks well, and colored tulle is effective over a white silk or satin underdress. Faintly tinted whites are effective, with the color of the tint as trimming, but look badly in contact with white.

YELLOW. — Harmonizes best with purple. Black may be used as trimming. Amber, straw, primrose and canary, are feebler in effect than orange; these shades are rendered weaker by contact with any strong color or tone; black looks well in lace only; trimmings of a faint crimson or cerise have a cheerful effect, but require a little dash in the wearer; white may be used as lace, but with care, and will call for the addition of small points of stronger color.

SUITABILITY.

REMARKS. — No complexion can bear every hue; try them all; wear that which is most becoming. Complexions require the colors that enforce their peculiar excellence, and render defects less conspicuous. The pink of the complexion is brought out by a green setting in dress or bonnet; any lady who has a fair complexion, that admits of having its rose-tint a little heightened, may make effective use of green; but it should be delicate, since it is of importance to preserve harmony; when there is in the face a tint of orange, mixed with brown, a brick-red hue will result from the use of green; if any green at all be used in such a case, it should be dark. A lady with a florid complexion should choose bright red, violet, or other colors which will out-shine the high tone of the complexion; for jewels, diamonds, corals, garnets; a diamond pendant on a band of ruby velvet will put a florid face in eclipse at once. A lady of a pale complexion will dress with advantage by choosing grays of all shades, with bows of pale yellow, or black, with relief of pink garnets, lava and cameos. All shades of blue or green, and some tints of purple and red, suit a sallow complexion. Intensely pallid complexions, if shaded by black hair, will not bear a dead white against the face, and only the softest and finest lace in collar or ruffle is becoming. A light, rosy complexion harmonizes with a silver-gray or pearl; gray tints will be found to suit most complexions. A pale complexion, if healthy and natural, is improved by black; black does not suit the extremely pallid complexion. Blue imparts orange, which enriches white complexions and light fresh tints; it also improves the yellow hair of blondes.

BLONDES, Colors Becoming to.—If the hair is dull, light brown, no brilliancy of complexion, the eyes gray or blue, then never wear red, fawn colors or gray. Wear black, creamy white, pale pink, pale blue, invisible green. If the hair is auburn, the eyes brown, choose scarlet, blue, gold or purple. To set off a fair blonde complexion to advantage choose pale pink, rose, lilac, or white, or dark green, dark purple, violet or caroubier. Blue should never approach red hair. Choose for red hair, white, of a creamy tone, black, invisible green, rich bottle green, rich blue green, plum color, amethyst, brownish purple, pale yellow, brown, olive green, gray green, stone gray, claret color, maroon, gold color, pale amber, dark amber, reds approaching amber. The following should be avoided: Blue of all shades, blue white, pale green, scarlet, or all bright reds, bright rose pink, all violet pinks, blue purple, lavender. Chocolate colors, and warm browns partaking of red, may be worn by fair or dark persons, provided they be not too pale, in which case the contrast will render the face death-like. For the golden blonde with hazel eyes the proper colors are, turquoise blue, rose pink, warm greens from dark to light, cream white, reds, yellows, ambers, purple, violet, black, warm grays, fawns, brown, flame color. The colors to be avoided are, cold blues, mauve pinks, cold greens, light pink, blue white, lavender, cold lilacs, cold grays. The golden blonde with gray, green or light hazel eyes, and pale, luminous "matte" skin, must make quite a different choice of colors, namely: Olive green, light and dark, black, cream white, all soft yellow greens, stone gray, blue gray, gray blue, turquoise blue, pale peacock blues, transparent white, mauve pinks, amethyst, light and dark, heliotrope in all shades, pale amber. The colors to be avoided are, orange, brilliant yellow, scarlet, tan color, heavy blue green, blue white, blue purple, cold blues, lavender, fawns, frank pinks, all reds, from dark to light. The following are the colors for a cool blonde: Jet black, blue black, cold dark green, cool pale green, blue white, cool grays, all cold blues, heliotrope purples, cold pale violet pink, cold lilacs, lavender. The colors to be avoided are: Reds, warm blues, yellow greens, olives, browns, yellows, warm violets, ambers, cream white, fawns, tans, russet.

BRUNETTES. Colors Becoming to.— The color which most enhances beauty is decidedly yellow; bright red or green are becoming, as are all bright colors. Diamonds or amber jewelry suit best. For brown black hair, steel-gray eyes and a fair skin, with rosy color, the following colors suit: Green, of all dark or full shades; blue

white, cream white, blacks, fawns, grays, reds, dark to light, rose de chine, gold color, gray-blue, all shades of blue, lilac and violet. Avoid pale green, old gold, ali fade colors, and too subtle tones, like mauves. Perhaps no color surpasses the effect of unrelieved black. Black velvet should be avoided where the contrasts are too startling. With black hair and a high color the effects are rarely in good taste, though often exceedingly brilliant; while a dark green, claret or blue would be more harmonious. For very dark-brown hair, dark-brown eyes and matte complexion the following colors are to be chosen: Black, cream white, purple, violet, amber, olive green, light or dark, rose pink, reds, especially dark reds, all the rich dark-red purples, maroons, some dark-blue greens, like peacock, russet. Avoid blue white, all light and cold blues, grays, mauve, cold yellows, pale greens. Where this color of hair and skin is combined with green hazel eyes, the range of color may be extended to cooler tones. Usually the complexion becomes a little fairer with green or hazel eyes, though the general tone is the same. The brown haired type, with warm brown skin and brown eyes, seems often to have an instinct toward certain barbaric contrasts; blue and red, black and yellow, blue and red and blue and yellow are very fine with it; but avoid black, blue, white and all pale and cold colors; all the blues worn must be warm and rich; the following colors are to be chosen for it: All reds, amber, all yellow, cream white, brown, maroon, olive green, rose pink in small quantities, all warm blues from dark to light, tan colors, fawn colors, tea colors, flame color. Avoid cold and pale blues, light green, all cold greens, pale violets, violet pinks, black, blue white, even the transparent blue white and gray of white muslin. There is a type met sometimes, that is most brilliant. The hair is black, the eyes a very dark brown, a golden-brown skin, with a rich, warm color in the cheek, the teeth often very brilliant. This type should never wear black at all. Nothing is better than the warm, dark browns, the claret colors, the deep ambers, creamy white, and yellows. It should wear no pale colors, but a warm, pale pink or flame color, and for jewels or ornaments, topazes, garnets, amber and diamonds. The most frequent type of the black-haired is combined with black eyes and a sallow complexion; teeth often dazzling white and mouth large; black, relieved with transparent white, a dark, warm gray, and occasionally a flame color or a dull red form the best setting for this type. There is very little color in it, and no color is truly harmonious with it. Especially where the eyes are fine, nothing so good can be done as to dress this type in black, with lace at the throat, white lace, to cast some light upon the face. There is no more beautiful type of the black-haired than that with pale skin and blue eyes; its possible range of color is wide; its most judicious range of color is yellow and green, and, though it may wear purple, nothing will be better than blues and some reds, though the blues are the best; blues of the sapphire shades and blues of the Chinese colors, such as come in the Canton crepes, cannot be improved upon for this type; the reds can be worn, though the lighter reds are too startling, and the dark reds, such as cardinal, are better; very pale shell pink, blue grays and white, both cream and blue white and black, both solid and transparent.

GENERAL SUGGESTIONS.—"No woman is ugly when she is dressed." Only Lord Chesterfield could have been guilty of such a gallant perversion of the truth. If he used the word "dressed" advisedly, and meant clothed with a due regard to the selection of becoming colors and to the cut and style of the gown to suit the individuality of the wearer, he was undoubtedly right—no woman is ugly when she is artistically and becomingly dressed. But so few women seem to know what colors will enhance or destroy their good looks, what style of gown will conceal their defects and heighten their charms and what way of arranging their hair will improve their faces, that dress ofttimes instead of adding beauty to the appearance has the contrary effect. People who are florid must be careful what reds they use even more than the pale people. A deep blue red, that red suggested in a plum or the velvet leaf of a red pansy that has caught a shade from the petals of its near neighbor, the dark blue pansy, is the color for florid complexions. Grown people should be careful not to wear bright red. As Modjeska observes: "As one grows older red is more becoming above the face than below it." Dark cardinal velvet above gray hair and dark eyes has a most charming effect. Pink is most becoming for fair young people. Rose color, combined with black, white or gray, can be worn with impunity by the youthful and fair. Magenta should be suppressed. Only a dazzling beauteous being could survive the uglifying effect of this depraved color, and then it must be combined with white. Dark sage green is an almost universally becoming color. It annuls any tinge of green there may be in the complexion; for this reason brunette people generally look well in green. Only those who have an exquisite complexion should dare to wear pale green. If the complexions are clear, rosy, and fair, pale and dark have equal privileges. Dark green, combined with pale, is becoming to brunettes with clear, pallid complexions. Yellow is a delicious color—a favorite hue of the old masters and Dame Nature. Warm yellow has a good effect on the complexion. It makes the skin look fairer than it really is. It goes pleasingly with many colors. A brunette will look particularly handsome in a green yellow. Mustard color, which is insufferable by daylight, is simply delicious in the gaslight. Pure blue and yellow are harsh. A good rule is never to combine two colors of equal intensity. One of the two colors should be dull and not too pure. People with blue eyes should not wear bright blue. It makes their eyes look faded and detracts from the bloom of the complexion. Every color can be made becoming by being artistically arranged and relieved by another color, or by soft effects of lace or airy tulle. All but people with coarse complexions look exceedingly well in white.

HAIR.

CARE IN GENERAL.

REMARKS.—The hair should be washed once a month, and shampooed every three months; it should afterward be rubbed dry with a towel. To dry the hair before the fire is injurious to its vitality. Once or twice weekly some of the washes recommended for promoting the growth of the hair may be used. Combing and brushing are of great service in promoting the hair's nutrition; soft brushes are the best. Never use a broken, jagged comb, and then go around complaining that your hair is coming out in handfuls. A little—half to one teaspoonful—of scented oil may once a week be rubbed well into the hair and its roots, and the superfluous oil removed by the use of a towel. The daily use of oil, except in some rare cases of obstinate dry hair, is objectionable. If you want a head of thick hair, keep it cut as short as you conveniently can. Clipping the ends about once a month will be found useful in promoting its growth, when it is not desired to shorten too much. Never should a woman allow her hair to grow to the level of her waist, for it will thin the hair and weaken the system. Of the mustache, beard and whiskers, it is eqally necessary to moderate their length, and that it will be found of advantage to occasionally apply a little oil and some stimulating lotion. Combing and brushing will also be of service. Directly hair shows any signs of thinning, shave it off or cut away as much as possible, according to its situation. Brush the eyebrows every day, in their proper artistic line, and occasionally rub in a little olive oil and some preparation. Once every month the tips of the eyelashes may, with advantage, be cut. If properly done, their beauty will be enhanced.

COLOR, To Improve.—A good circulation is essential to fineness. The scalp must be stimulated by brushing and use of the ammonia bath. Hair cannot be glossy, rich colored and thick, unless the bodily vigor is what it should be. The best remedy for poor color is strict care. Never oil red hair to make it darker; it should be kept wavy and light, to show off the lights and shadows with which it abounds. The sun has a good effect on obnoxious shades, if otherwise attended to. Pale hair shows a want of iron in the system, which may be supplied by a free use of beefsteaks, pure beef gravies and red wines. Salt-water bathing strengthens the system and the hair. Hardly any shade is unlovely when luxuriant; it is only when diseased or uncared for that the color appears disagreeable. Sandy hair, when well brushed and kept glossy with the natural oil of the scalp, changes to a golden tinge. Tow-headed children should be sent into the sun that its rays may affect the iron in the blood and change the color to an agreeable shade.

DRESSING.—Few pay enough attention to the shape of their heads and faces in arranging the hair, and the consequence is anything but a graceful appearance. A woman with an oval face, regular features and Grecian head can wear her hair in almost any fashion. A sharp or regular profile admits of the hair being twisted in a coil. A woman with a round, piquant face should wear her hair dressed high on the head. If the hair grows down on the neck very far and the hair is dressed high on the head, little curls should be made about the nape of the neck. It is unwise to wear the hair in one fashion any length of time. That portion exposed to the air will become discolored and brittle, besides producing bald spots. Every night the hair should be taken down and combed out of tangles with a bone comb. A rubber comb will split the hair; then brush vigorously the whole length of the hair. It is impossible for one to do this thoroughly for one's self, but two sisters or friends can exchange services. The hair should then be firmly but tightly braided; two braids are best. Tie the ends with woolen material, never with cotton, and do not put in any hairpins, as, while sleeping, they are apt to become rusty and produce baldness. If you wear a bang, always wear your own hair. The bang should be washed almost every day to keep it in good condition for curling. To cut a bang straight across, comb down sufficient hair, leaving a straight part between the bang and long hair. A bang to curl nicely should be cut straight below the eyebrows. Wet the hair and clip evenly across. A tightly frizzled bang looks unnatural. Loose, natural-looking rings are tasteful. Coarse paper is the best to put the hair up in. Double a piece in the center, catch it in the ends of the hair and roll up, pinning the ends of the paper down. Do not flatten the paper when rolling, or the curls will not be round. When taking the curls out, comb with a coarse comb, and brush all straight hair smoothly back. For crimping the hair there are regular hairpins. Crimped hair is becoming for married ladies, but not for girls. The hair should be crimped on either side of the part, back to the crown of the head. Some young faces with broad foreheads look well with the hair crimped and combed straight back, with a coil at the nape of the neck. There are several washes recommended to stimulate growth of hair, but the best recipe is cleanliness and brushing. Sage tea will darken the hair and make it soft, and has been known to help the growth. Abstain from wetting, twisting, or tightly binding the hair; wetting the hair often, to keep it in place, will produce dryness and a faded appearance. Disentangle carefully, and arrange so as to allow the current of fluid to course along the tubes; where the hair is naturally dry, some greasy substance may occasionally be used. If naturally greasy, no grease is needed. A healthy system should supply oil enough for the hair.

GROWTH, To Promote.—When the hair is in a weakly state, and falls off, cutting it once a month will be found of great service. Ammonia is the most healthful and efficient stimulus

known, and quickens growth when nothing else will. (See TONICS AND RESTORATIVES in this department; also *Baldness* and *Dandruff* in MEDICINE, in HEALTH AND DISEASE.

DEPILATORIES.

REMARKS.—Superfluous hairs are the result of a morbid condition, and must be eradicated as a disease. Care should be taken to brush the back hair upward from childhood to prevent growth of hairs on the neck. Depilatories act either mechanically or chemically. To the first class belong adhesive plasters, that, on their removal from the skin, bring away the hair with them. The second class includes substances which destroy the hair by chemical action. Lime or orpiment, and generally both of them, have formed the leading ingredients in depilatories. The first acts by its causticity, and when an alkali is present by reducing that also, either wholly or in part, to the caustic state. The action of the orpiment is of a less certain character, and its use is even dangerous when applied to a highly sensitive or an abraded surface.

ARSENICAL. — 1. Nitre and sulphur, each, 1 part; orpiment, 3 parts; quicklime, 8 parts; soap lees, 32 parts; boil to the consistence of cream.— 2. Quicklime, 30 parts; orpiment, 4 parts; powdered gum Arabic, 60 parts; mix, and keep in a tightly-corked bottle. When used, form a paste with water. Apply, and let remain 5 or 10 minutes, when the superfluous hair can be removed with the back of a knife.

BOETTGER'S.—Powdered sulphydrate of sodium, 1 part; washed chalk, 3 parts; made into a thick paste with a little water. Let a layer about the thickness of the back of a knife be spread upon the surface. After 2 or 3 minutes the hairs are transformed into a soft mass which may be removed by water. A more prolonged action would attack the skin.

CAZENAVE'S.—Quicklime, 1 part; carbonate of soda, 2 parts; lard 8 parts; mix. Applied as an ointment.

CHINESE.—Crystallized hydrosulphate of soda, 3 parts; quicklime, in powder, 10 parts; starch, 10 parts; mix with water; apply to the skin, and scrape off in 2 or 3 minutes, with a wooden knife.

ELECTRIC. — A moistened sponge electrode from the positive pole of the battery, having previously been placed on the back of the neck, or fixed at some other convenient spot, a 3-cornered needle, with sharp cutting edges, set in a handle and attached to the negative pole of the battery, is made to enter the hair follicle, alongside the hair, care being taken to make the needle penetrate to the depth of the follicle. The action of the current causes a few bubbles of viscid froth to be observed. As soon as this manifests itself, the needle should be rotated a few times, to cause the sharp corners to scrape away the debris, and allow electrical contact with a fresh surface. The operation is continued until the hair becomes loose, and comes away with the slightest traction. The operator then proceeds with the next hair in like manner, and so on.

PLASTER. — Spread equal parts of resin and pitch on a piece of thin leather, and apply; let it remain 3 minutes, and pull off suddenly, when it brings the hairs with it. If the plaster were left on longer, it would be apt to bring the skin.

RAYER'S.—Quicklime, 2 oz.; salt of tartar, 4 oz.; charcoal, ½ oz.

REDWOOD'S.—A strong solution of sulphide of barium, made into a paste with powdered starch; apply immediately; leave a few minutes; then scrape off with the back of a knife.

SPOLASCO'S.—Freshly prepared sulphide of calcium and quicklime, equal parts.

VEGETABLE ESSENCE.— Take polypody of oak, cut into small pieces, and put any quantity into a glass vessel; cover 1 in. in depth with Lisbon or French white wine, and place the vessel in hot water 24 hours; then distil off the liquor. Apply with a linen cloth, and allow to remain on during the night. Oil of walnuts and the distilled waters of the leaves and roots of celandine are also said to be efficacious.

DYES AND BLEACHES.

REMARKS.—Fortunately bleaching and dyeing are such tedious processes that few persons submit to their bondage. Once applied, dye becomes a necessity. Dyes need to be applied once a week, and it is well to touch the partings twice as often with a fine comb dipped in the dye, as the hair always shows the natural color as fast as it grows from the roots.

BLACK. — 1. Oxide of lead, 4¼ dr.; glycerine, 75 dr.; water, 34 oz.; precipitated sulphur, 4¼ dr.— 2. Acetate of lead, 1¼ dr.; hyposulphite of soda, 2¾ dr.; glycerine, 1 3-5 oz.; spirits of wine, 3 1-5 oz.; distilled water, 27 1-5 oz. Dissolve the salts separately, and mix the glycerine and alcohol with the hyposulphite; then gradually pour the solution of lead into the mixture. — 3. Wash the head with spring water, and comb the hair in the sun, having dipped the comb in oil of tartar; do this about 3 times a day, and in less than a fortnight the hair becomes black. The leaves of the wild vine, infused in water, are said to render the hair black and prevent falling off. — 4. Cleanse the hair with dilute ammonia water; then moisten with dilute solution of gallic acid or ammonium sulphide, and go over it with a comb moistened with a solution of 1 part nitrate of silver in 9 parts water, touching the scalp as little as possible. — 5. (*French.*) Melt together in a bowl, set in boiling water, 4 oz. white wax in 9 oz. olive oil, stirring in, when melted and mixed, 2 oz. burned cork in powder. This gives a lustrous blackness to the hair. Apply like pomade, brushing it well in and through the hair. It changes the color instantly. — 6. (*Hager's.*) 10 parts subnitrate of bismuth and 150 parts glycerine are mixed in a glass vessel and heated in a water bath; a solution of potash is then added in small portions, and with continued agitation, until a clear solution has been obtained, to which a concentrated solution of citric acid is added until merely a slight alkaline reaction is observed; enough orange flower water is added to make the whole liquid weigh 300

parts; the addition of a small quantity of a solution of aniline color completes the preparation.

BLONDE. — 1. 1 qt. of lye prepared from the ashes of vine twigs, bryony, celandine roots, and turmeric, of each ½ oz.; saffron and lily roots, of each, 2 dr.; flowers of mullein, yellow stechas, broom, and St. John's Wort, each, 1 dr.; boil together and strain clear. — 2. 5 oz. distilled water; ½ oz., each, acetate of iron and nitrate of silver; 1 oz. nitrate of bismuth; moisten the hair, and after an hour, touch with a mixture of equal parts sulphide of potassium and distilled water. — 3. A strong aqueous solution of sodium sulphite, rendered slightly alkaline with carbonate of soda.

BROWN. — 1. Dissolve permanganate of potash, ½ oz. in 1 pt. rose-water, and after having cleansed the hair with a solution of hartshorn, a teaspoonful to 1 qt. water, and dried it well with a towel, apply. It takes effect immediately and the desired shade may be obtained by applying more or less of the solution. — 2. Acetate of lead, 2 dr.; hyposulphate of soda, 1 dr.; rose water, 14 oz.; glycerine, 2 oz.; dissolve the acetate of lead and the hyposulphate in separate portions of the rose water; filter separately; mix, and add the glycerine. — 3. Add ammonia to ordinary black hair dye made from nitrate of silver. The more ammonia added the lighter the shade. — 4. Solutions of pyrogallic acid in diluted alcohol, are used with good effect.

BROWN, Dark. — 1. Pyrogallic acid, 4 gr.; distilled water, 2 oz. — 2. Crystallized nitrate of silver, 1 dr.; gum Arabic, 1 dr.; distilled water, 2 oz. — 3. Water in which potatoes have been boiled with the skins, forms a speedy dye for hair and eyebrows. The parings may be boiled by themselves, and the water strained for use. Dip a fine comb in the water, draw through the hair till thoroughly soaked. If not satisfactory the first time, repeat with a sponge, taking care not to discolor the skin of the brow and neck. Exposing the hair to the sun will darken this dye. — 4. Walnut bark, steeped a week in Cologne, gives a dye easily applied with a brush each day, and has instant effect; add a small lump of alum to set the dye.

BROWN, For Red Hair. — Oils of nutmeg and rosemary, 1 dr., each; castor oil, 1 oz.; tincture cantharides, 2 dr.; strong brandy, 7 oz.; mix. Use a small portion once a day, and brush the hair with a stiff brush ½ hour.

CHESTNUT. — 1. Permanganate of potash, 1 dr.; powdered gum Arabic, 2 dr.; rose water, 3 oz.; mix. Apply carefully with a tooth-brush.— 2. Fresh slaked lime, 5 dr.; water, 1½ oz.; mix, strain, and pour into a 4 oz. bottle. Dissolve sugar of lead, 5 dr., in water, 3 fl. oz.; add dry slaked lime, 1 dr.; stir together; wash the precipitate with a little soft water; drain off the water; then add it to the milk of lime in the bottle, and shake well and also before use.

GOLDEN. — 1. 17 parts crystallized caustic baryta and 3 parts potassium chlorate; mix in fine powder; melt by a gentle heat. The mass must be washed with cold water to remove the potassium chloride, and the residue shaken in the cold with a solution of 8 parts glacial phosphoric acid in 25 parts water; the whole cooled with ice. When the peroxide of barium is decomposed, the fluid should be decanted. — 2. Moisten the hair, previously washed and dried, with a solution of acetate or nitrate of lead, and follow with a mordant of yellow chromate of potash.

FIXATURES.

FIXATURES are used for stiffening the hair, and to make it curl firmly and remain in place. It is applied either by moistening the fingers and passing the hair through them, or by means of a small sponge.

CURLING FLUID.—Put 2 lbs. common soap, cut small, into 3 pts. spirits of wine; melt together, stirring with a clean piece of wood; add essence of ambergris, citron and neroli, ½ oz. each.

FRENCH CURLIQUE.—Oil of sweet almonds, 1 oz.; spermaceti, 1 dr.; tincture of mastic, 3 dr. Dissolve the spermaceti (white wax is as good), in the oil with a slow heat, and add the tincture. Apply a small quantity.

GUM ARABIC.—1. To common gum Arabic add enough alcohol to make thin; let stand all night; then bottle to prevent evaporating. Put on the hair after it is done up in paper. — 2. Pale gum Arabic (picked), 1½ oz.; rose water, 2 fl. oz.; pure water, 3 fl. oz.; dissolve. — 3. Gum Arabic, 3½ oz.; water, ½ pint; dissolve, and then drop in Cologne gradually until the cloudiness ceases to be removed by agitation; the next day decant.

GUM TRAGACANTH.—1. Gum tragacanth, 1½ dr.; water, 7 oz.; proof spirit, 3 oz.; otto of roses, 10 drops; macerate 24 hours, and strain. —2. ½ oz. gum tragacanth; 1 pt. rose water; 5 drops glycerine; mix, and let stand over night; if the tragacanth is not dissolved let it be ½ day longer; if too thick, add more rose water, and let stand some hours; when it is a smooth solution it is fit for use.—3. Finest packed gum tragacanth, reduced to powder, 1 oz.; rose water, 1 pint; put into a wide-mouthed vessel and shake daily 2 or 3 days; then strain. If required to be colored, infuse cochineal in the water employed, before making.

OILS.

BALDNESS. For. — Boil ½ lb. green southernwood in 1½ pts. sweet oil; add ½ pt. port wine; strain through a fine linen bag 3 times, each time adding fresh southernwood; then add 2 oz. bear's grease and replace near the fire in a covered vessel until the bear's grease is dissolved; mix, and bottle close.

BEAR'S.—Cotton seed oil, 15 gals.; oil of fennel, 3 oz.; oil of lavender, 2 oz.; oil of citronella, 3 oz.; oil of cloves, 3 oz.; no coloring.

BRILLIANTINE.—Castor oil in eau de Cologne, 1 part in 4; or glycerine and eau de Cologne, each, 1 part; honey, 2 parts; rectified spirit, 4 parts.

COCOANUT.—Cocoanut fat, 2½ lbs.; castor oil, 1 gal.; alcohol, 1 oz.; oil of lavender, 4 oz.; oil cloves, 2 oz.; oil cinnamon, 2½ oz.; oil rose geranium, 2 dr. Melt the cocoa fat at a gentle heat;

add castor oil; mix thoroughly; add alcohol, and perfume.

COCOINE.—Oil theobromæ, 3 dr.; castor oil, 15 fl. oz.; 95 per cent. alcohol and glycerine, each, 2 oz.; melt the oils together with gentle heat; transfer them to a bottle, and gradually add the alcohol, then the glycerine, as much as it will take up without becoming milky; perfume.

COLORINGS.—A red tinge is given to oils by allowing the oil to stand for a few hours over a little alkanet root (2 dr. to 1 pint) before scenting. Apply a gentle heat to facilitate the process. Yellow and orange are given by a little annatto or palm oil; and green, by steeping a little green parsley or lavender in them for a few days; or by dissolving 2 or 3 dr. gum guaiacum in each pint by the aid of heat, and, when cold, decanting.

CRESCENT.— Cotton seed oil, 15 gals.; oil bergamot, 8 oz.; oil cassia, 6 oz.; oil cloves, 4 oz.; oil white thyme, 1 oz.; mix; color with alkanet.

CRYSTALLINE CREAM. — Oil almonds, 8 oz.; spermaceti, 1 oz.; melt together. When a little cooled, add ½ oz. bergamot; put into wide-mouthed bottles, and let stand till cold. Camphorated crystalline cream may be made by using camphorated oil instead of oil of almonds.

GLYCERINE. —New rum, 1 qt.; concentrated spirits of ammonia, 15 drops; glycerine oil, 1 oz.; lac sulphur, 5½ dr.; sugar of lead, 5½ dr.; put the liquor into a bottle, add the ammonia, then the other components. Shake occasionally 4 or 5 days.

GOLDEN. — Oil cotton-seed (yellow), 15 gals.; oil bergamot, 8 oz.; oil cassia, 6 oz.; oil cloves, 4 oz.; oil thyme (white), 1 oz.; color with alkanet root.

HICKORY NUT. — Cotton-seed oil, 15 gals.; oil of fennel, 2½ oz.; oil sassafras, 3 oz.; oil thyme, 1½ oz.; oil rosemary, 1½ oz.; oil cinnamon cassia, 4 oz.; oil cloves, 1½ oz.; oil lavender, 1½ oz.; do not color.

HUILE VERTE. —1 dr. guaiacum; 1 lb. olive oil; macerate; strain, and perfume.

LYON'S KATHAIRON. — 2 gals. castor oil; 3 gals. alcohol; mix; ten oz. tincture cauthanile (officinal); 12 oz. bergamot; dissolve in alcohol. Tincture red sanders (strength, 1 lb. to 5 gal. 95 per cent. alcohol), 4 oz. to 30 gallons.

MACASSAR. — Olive oil, 1 qt.; alcohol, 2½ oz.; rose oil, 1½ oz.; then tie 1 oz. chipped alkanet root in a muslin bag, and put it in the oil; let alone some days till it turns red, then remove to other oils. Do not press.

MACE. — Mace (beaten to a paste) and palm oil, each, 1 lb.; purified beef marrow, 3 lbs.; gently melt together, and strain.

MARROW. — 1. Simple marrow oil, scented at will. — 2. Marrow oil, 4 oz.; spirit of rosemary, 1½ oz.; oil of nutmeg, 12 drops. — 3. Cold-drawn nut oil and marrow oil, equal parts; scent. — 4. Clarified beef marrow, lard, pale nut oil and expressed oil of mace, each, 4 oz.; melt together by the heat of hot water; strain into a warm stone mortar; add of oils of cloves, lavender, mint, rosemary, sage and thyme, each, ½ dr.; rectified spirit, 1 oz., in which has been dissolved by gentle heat balsam of tolu, 4 dr.; camphor, 1 dr.; triturate this mixture until it is quite cold, and then put it into suitable bottles.

NIGHT-BLOOMING CEREUS, Phalon's.—Cotton-seed oil, 15 gals.; oil caraway, 4 oz.; oil cloves, 4 oz.; oil sassafras, 2 oz.; oil lavender, 10 oz.; oil rosemary, 2 oz.; color with alkanet root.

PHALON'S.—Cocoanut oil perfumed with oil of almonds.

ROSE.—1. Olive oil, 2 pts.; otto of roses, 1 dr.; oil of rosemary, 1 dr.; mix. — 2. Cotton-seed oil (yellow), 15 gals.; oil red cedar, 3 oz.; oil geranium, 6 oz.; oil rose, 1½ oz.; oil cloves, 6 oz.; oil citronella, 1½ oz.; oil lemon grass, 1½ oz.; oil bergamot, 2 oz.; no color.

ROSEMARY. — Castor oil, 1 pt.; sweet oil, ⅓ pt.; lard oil, ⅓ pt.; alcohol, 1 tablespoonful. Perfume with rosemary.

SILVER. — Cotton seed oil, 15 gals.; oil red clover, 1 oz.; oil geranium, 2½ oz.; oil cloves, 2½ oz.; oil citronella, 1 oz.; oil lemon grass, 1 oz. No color.

POMADES.

AMMONIACAL, For Promoting Growth.—Almond oil, ½ lb.; white wax, ½ oz.; clarified lard, 3 oz.; liquid ammonia, ½ fl. oz.; otto of lavender and cloves, each, 1 dr. Place the oil, wax and lard in a jar; set in boiling water; when melted, allow the grease to cool; stir in the ammonia and perfume, and put into small jars. Apply at night only.

BALDNESS, For.—1. Macerate 1 dr. powdered cantharides in 1 oz. spirits wine; shake frequently during a fortnight, and then filter. Rub together 10 parts of this tincture with 90 parts cold lard; add any perfume; rub well into the head night and morning. — 2. Extract yellow Peruvian bark, 14 gr.; extract rhatany root, 8 gr.; extract burdock root and oil nutmegs (fixed), each, 2 dr.; camphor (dissolved with spirits of wine), 15 gr.; beef marrow, 2 oz.; best olive oil, 1 oz.; citron juice, ½ dr.; aromatic essential oil, to render fragrant; mix, and make into an ointment.

BALSAM OF TOLU. — Prepared lard, 2 oz.; white wax, 3 oz. Melt together; remove from the fire; and, when they are beginning to thicken, add, with constant stirring, balsam of tolu, 2 dr.; essence of bergamot, 30 drops.

BEAR'S GREASE, Imitation. — 1. Almond oil, 10 lbs.; purified lard, 12 lbs.; acacia pomade, 2 lbs.; otto of bergamot, 4 oz.; otto of cloves, 2 oz.; oils of rose, acacia and orange flowers, each, ½ lb. Melt the greases by means of a water bath, and then add the ottos. — 2. Prepared suet, 3 oz.; lard, 1 oz.; olive oil, 1 oz.; oil of cloves, 10 drops; compound tincture benzoin, 1 dr.; mix.

CIRCASSIAN CREAM. — 2 flasks oil; 3 oz. white wax; 2 oz. spermaceti; ½ oz. alkanet root. Digest the oil with the alkanet till colored; strain; melt the wax and spermaceti with the oil; when cool, add 2½ dr. English oil of lavender and ½ dr. essence of ambergris.

COLLANTE. — Oil of almonds, 3 oz.; white wax, ¾ oz.; melt together; add tincture mastic (strong), 1 oz.; essence bergamot, ½ dr.

COSMOS.—1½ parts white wax; 3 parts spermaceti; 2 parts castor oil; 8 parts almond oil;

2 parts glycerine; 9 parts extract of mignonette; ½ part eau de Cologne.

COWSLIP. — Plain pomade, 2 lbs.; essence bergamot, 3 dr.; essence of lemon and essence of orange peel, each, 1 dr.; huile au jasmin and essence de petit grain, of each ½ dr.; essence of ambergris, 6 drops.

CUCUMBER. — Lard, 10 oz.; veal suet, 6 oz.; balsam of tolu, 9 gr.; rose water, 44 minims; cucumber juice, 12 oz. Melt the lard and the suet over a water bath, and add the tolu previously dissolved in a little alcohol, and then the rose water. When clear, decant into a tinned basin; add ½ of the cucumber juice and stir continually 4 hours; pour off the juice, and add another ½; stir as before; then pour off and add the remainder of the juice; separate as much as possible the fat from the liquid; melt by water bath, and after some hours skim, and put into pots.

DE BEAUTE.—Oil of almonds, 2 oz.; spermaceti, 2 dr.; white wax, 1½ dr.; glycerine, 1 dr.; balsam of Peru, ½ gr.; mix by gentle heat.

DIVINE.—Beef marrow, 3 lbs.; put it into an earthen vessel, and cover with cold water; change the water daily for a few days, using rose-water the last day; pour off and press out the water; add 4 oz. each of styrax, benzoin, and Chio turpentine; 1 oz. orris powder; ½ oz., each, powdered cinnamon, cloves and nutmeg; set in hot water; boil 3 hours; then strain.

DUPUYTREN'S.—Beef marrow, 2 oz.; alcoholic extract of cantharides, 8 gr.; rose oil, 1 dr.; essence of lemons, 30 drops.

EAST INDIA.—Suet, 3 lbs.; lard 2 lbs.; beeswax (bright), ½ lb.; palm oil, 2 oz.; powdered gum benzoin, 3 oz.; musk (previously triturated with a little lump sugar), 20 gr.; digest the whole together in a covered vessel, by the heat of a water bath, 2 hours; then decant the clear; and add of essence of lemon, ½ oz.; oil of lavender, ½ oz.; oils of cloves, cassia and verbena, each, ½ dr.

FOX'S CREAM.—Marrow pomatum, 2 oz.; oil of almonds. 2 oz.; melt, and add while cooling, with constant stirring, essence of jessamine or bergamot, 2 dr.

GERMAN.—8 oz. purified marrow; melt in a glass or stoneware vessel; add 1½ oz. fresh bay leaves; 1 oz. orange leaves; 1 oz. bitter almonds; ½ oz. nutmegs; ½ oz. cloves; 1 dr. vanilla; all bruised; cover the vessel, and digest 24 hours with a gentle heat; strain while warm through linen, and stir it as it cools.

HARD. — 1. Purified suet, 1 lb.; white wax, 1 lb.; jasmine pomatum, ½ lb.; tuberose pomatum, ½ lb.; otto of roses, 1 dr.—2. (*White.*) Suet, 1 lb.; wax, ½ lb.; otto of bergamot, 1 oz.; otto of cassia, 1 dr. *Brown* and *Black* are made in the same way, but colored with fine ivory black or umber, ground in oil.

HUNGARIAN, or MUSTACHE WAX. — White wax, 4 oz.; lard, 2 oz.; Canada balsam, ½ oz.; oil of bergamot, 1 dr.; oil of lavender, 15 drops; add the balsam to the wax and lard, previously heated; when nearly cold, add the essential oils, and mold. It may be colored black or brown.

MARROW.—1. 4 oz. ox marrow; 1 oz. white wax; 6 oz. lard; melt; perfume when cooling with oil of bergamot. — 2. 1 oz. beef's marrow; soak in cold water until the blood is out; place in an earthen jar with ½ oz. unsalted butter; put the jar in lukewarm water and let it stand on the fire until the water boils, stirring the marrow and butter till thoroughly mixed.

OIL OF ALMOND. — Melt together with gentle heat 2 oz. purified beef's marrow; 2 dr. yellow wax; 1 oz. spermaceti; oil of almonds; stir until almost cold; and add essence bergamot, ½ oz.; otto of roses, 10 drops, and oil of nutmeg, 10 drops.

ROSE. — Prepared lard, 16 oz.; prepared suet, 2 oz.; melt with gentle heat; add 2 oz. rose water; 6 drops otto of roses; beat well together, and pour into pots. For making jessamine, violet, and orange pomade, put the same quantity of water, and 1 dr. of the essence.

ROYER'S BEARD-CULTIVATING. — An ointment of 1 part pulv. cinchon. rub., and 1½ parts of a hair pomade containing wax.

TRANSPARENT. — Spermaceti, 2 oz.; castor oil, 5 oz.; alcohol, 5 oz.; oil of bergamot, ½ dr.; oil of Portugal, ½ dr.

VANILLA.—Digest ½ lb. vanilla beans, finely cut, in 10 lbs. of a mixture of ⅔ lard and ⅓ beef tallow.

VIOLET.—Purified lard, 1 lb.; acacia pomatum, 6 oz.; rose pomatum, 4 oz.; work it up like marrow pomade.

WHITE.—Benzoinated suet, 1 lb.; white wax, 1 lb.; jasmine pomatum, 8 oz.; tuberose pomatum, 8 oz.; otto of roses, 1 dr. Melt at a gentle heat, and cast in molds.

SHAVING.

REMARKS. — The hair should be softened by soaking it in a lather of soap, which prevents the razor from sticking to the skin, and affords a support to the hair when opposed to the edge of the razor. The soap used should make a strong lather full of small bubbles, and be as free from alkali as possible, to avoid irritating the skin. It is better to wash the skin beforehand, then brush on the lather with the shaving brush, working it well into the skin, and let it remain to soften the hair for a few minutes; apply another coat of lather, and at once proceed to take off the beard with the razor warmed to the temperature of the skin, or rather above it. Most people find it better to stretch the skin by the other hand, but a skilful shaver manages without. The razor should be drawn in a gently sawing manner across the beard, not exactly at right angles to it, but nearly so; the art consisting in getting the two angles correctly, and in avoiding the chop instead of the proper sawing motion. The angle with the skin should be as slight as possible, close contact causing adhesion, and impeding the free play of the blade. When the head is to be shaved, it is better to remove the hair with the scissors to within ½ in. of the scalp, after which the razor may be used as for the beard, following the direction of the hair, and not meeting it.

CREAM. — White soap, 3 oz.; proof spirits, 8 oz.; water, 4 oz.; carbonate of potassa, 1 dr.; oil of lemon, 10 drops; mix; add the potassa and

oil of lemon last. — 2. White wax, spermaceti, almond oil, each, ¼ oz.; melt, and while warm beat in 2 squares Windsor soap, previously reduced to a paste with rose water.

GUERLAIN'S CREAM.—2 lbs. best white palm soap; ½ lb. good common soap; scrape small; dissolve in a copper boiler with 1 qt. rain water. Add 1 pt. 85 per cent. alcohol; 1 gill clean beef's gall; ½ gill rectified spirits turpentine. Boil 5 minutes, stirring slowly. Perfume to suit.

LIQUID.—White soap, 3 oz.; proof spirit, 8 oz.; distilled water, 4 oz.; carbonate of potash, 1 dr.; scent with essence of lemon. Dissolve the soap without heat; add the potash and essence.

RAZOR. Care of.—A razor should be strapped before and immediately after using, and will thus be kept in good order for years without any need for the stone. When a razor has lost its edge or become jagged by neglect, it may be restored on a hone oiled with kerosene oil; but without the greatest care the edge will be wired and spoiled. A strap of common leather glued to a suitable strip of wood is all that is usually necessary. The practice of pressing on the edge of a razor in strapping, generally rounds it; the pressure should be directed to the back, which must never be raised from the strap. If you shave from heel to point of the razor, strap it from point to heel; but if you begin with the point, then strap from heel to point. If you only once put away your razor without strapping or otherwise cleaning the edge, you must no longer expect to shave well; the soap and damp will soon rust the fine teeth or edge. A piece of plate leather should always be kept with the razors. As you strap your razor, strap the two sides alternately, and keep the back of the razor always on the strap, as you turn it from side to side. You thus avoid cutting your strap, and turning the edge of your razor. (See *Razor Paste* in STEEL.)

RAZOR STROP, To Renovate. — 1. Rub clean tallow over the surface, and then put on it the light top part of the snuff of a candle and rub it smooth. — 2. Rub well with a piece of soft pewter or lead.

RAZOR STROP, To Make. — Select a piece of satin, maple, or rosewood, 12 in. long, 1⅜ in. wide, and ⅜ in. thick; allow 3½ in. for length of handle; ½ in. from where the handle begins, notch out the thickness of the leather so as to make it flush toward the end; taper the thickness of the leather; this precaution prevents the ease from tearing up the leather in putting the strop in; round the wood just enough to keep from cutting by the razor in stropping and turning over the same; now select a proper-sized piece of fine French bookbinder's calfskin, cover with good wheat or rye paste, then lay the edge in the notch, and secure in place with a small vise; proceed to rub it down firmly and as solidly as possible with a tooth-brush handle, and, after the whole is thoroughly dry, trim and make the ease.

ROUSSEL'S CREAM.—2 lbs. white soft soap; 1 oz. oil of olives; 2 dr. gum benzoin; 48 oz. alcohol; digest.

SAPONACEOUS CREAM. — Melt 2 dr., each, spermaceti, white wax, and almond oil, in a porcelain-lined vessel; beat in 4 oz. best white soap, and scent.

SOAP. —1. Castile soap (in shavings), 4 oz.; proof spirit, 1 pt.; dissolve, and add a little perfume. — 2. Venetian soap, ¾ lb.; salt of tartar, 1 oz.; benzoin, ½ oz.; spirit of wine, 1 gal. —3. Best soft soap, ½ lb.; boiling water, 1 pt.; dissolve, cool, and add oils of cinnamon (cassia), verbena and neroli, each, 6 drops; dissolved in rectified spirit, 1 pt.; mix well, and if not transparent add a little more strong spirit, or filter through blotting paper.—4. White Castile soap in shavings, ½ lb.; rectified spirit, 1 pt.; 1 gill water; perfume. Put in a bottle and cork tightly, set in warm water for a short time, and agitate occasionally until solution is complete; let stand, pour the liquor off the dregs, and bottle for use. (See *Shaving Soap* in TOILET SOAPS.)

TONICS, RESTORATIVES AND WASHES.

ALPINE HAIR BALM.—10 oz. soft water; 8 oz. alcohol; ½ oz. spirits turpentine; ¼ oz. sulphur, and ¼ oz. sugar of lead.

AMMONIA.—1. When the hair has been neglected, cut it to an even length and wash the scalp nightly with soft water into which ammonia has been poured. This may be strong so it does not burn the skin; afterward put 3 large spoonfuls of ammonia to a basin of water. Apply with a brush, stirring the hair well. Dry thoroughly; comb and shake out the tresses till nearly dry: when it may be done up in a net. 1 teaspoonful ammonia to 1 pt. warm water makes a wash that may be used on a child's head daily.—2. To wash the head thoroughly, drop about 1 5 cts. worth of ammonia into a basin of lukewarm water and soap. If the hair is long, braid it in 6 or 7 loose braids, some coming to the top of the head, and tie firmly. Take a raw egg and rub vigorously into the scalp in every part. This is one of the best remedies for removal of dandruff. After rubbing in the egg, wash the head in the water and ammonia, with a little Castile soap. Wring the braids out and dry with a towel. Then, after the hair is dry, comb out and brush. Care should be taken to go in no drafts while the hair is wet. The ammonia helps it to dry quickly.

BAY-RUM RESTORATIVE. — Oil of bay, 1 dr.; oil of nutmegs, 5 drops; oil of orange, ½ dr.; Jamaica rum, 4 oz.; alcohol, 2 pts.; water, to make 4 pts. Cut oils in alcohol; add rum and water; let stand 2 or 3 weeks, and filter through magnesia and charcoal.

BERNHARDT'S TONIC. — Oil of castor, 3 oz.; oil of bergamot, 3 dr.; oil of cinnamon, 15 drops; oil of cloves, 15 drops; oil of lavender, 1½ dr.; tinct. cantharides, 2 dr.; aqua ammonia, 4 dr.; alcohol sufficient to make 2 pts.

BLACKWELL'S RESTORATIVE. — Glycerine, 1 oz.; tinct. cantharides, ½ oz.; sugar of lead, 2 dr.; lac sulphur, 2 dr.; oil of bergamot, 2 dr.; rain water, 2 dr.; mix; apply once a day. Rub well with the hand.

BORAX. — For cleaning the hair, nothing is

better than a solution of borax. Wash afterwards with pure water, if it leaves the hair too stiff. Use enough borax to render the water soft; ½ oz. to 1 qt. water.

COOLING LOTION. — 2 dr. borax and glycerine to 8 oz. distilled water.

CREOLE TONIC. — Lac sulphur, 1 dr.; sugar of lead, 1 dr.; pulverized copperas, 32 gr.; tannin, 32 gr.; rose water, 1 pt.; mix. Wet the hair once or twice a day, for 2 weeks.

EYEBROWS AND EYELASHES. To Improve. — For causing the eyebrows to grow when lost by fire, use sulphate of quinine, 5 gr. in 1 oz. alcohol. For the eyelashes, 5 gr. sulphate of quinine in 1 oz. sweet almond oil is the best prescription; put on the roots of the lashes with a fine sable pencil; it must be lightly applied, as it irritates the eye to finger it. The eyelashes may be improved by delicately cutting off their forked and gossamer points, and anointing with a salve of 2 dr. ointment of nitric oxide of mercury and 1 dr. lard. Mix lard and ointment well, and anoint the edges of the eyelids night and morning, washing after each time with warm milk and water. This, it is said, will restore the lashes when lost by disease.

FAIRY WATER. — A solution of 1½ parts lead sulphite in about 3 parts sodium hyposulphite, 7½ parts glycerine and 88 parts water.

EAU LUSTRALE. — Castor oil, 8 oz.; tincture cantharides, 1 oz.; alcohol, 48 oz.; oil bergamot, 4 dr.; oil lavender, 1 dr.; oil cloves, 30 drops; mix.

FALLING OUT, To Prevent. — 1. Sherry wine, ½ pt.; elder water, ½ pt.; tincture of arnica, ½ oz.; spirits of hartshorn, 1 teaspoonful; apply with a sponge every night. — 2. Mix 1 oz. gum camphor and 2 oz. pulverized borax; pour over it 2 qts. boiling water; when cold, bottle and keep tightly corked. Apply night and morning, rubbing it into the scalp with sponge or flannel. — 3. Water of ammonia, almond oil and chloroform, 1 part, each, diluted with 5 parts alcohol, or spirits of rosemary, the whole made fragrant with 1 dr. oil of lemon; dab it on the skin after friction with hair brush. — 4. Extract yellow Peruvian bark, 15 gr.; extract rhatany root, 8 gr.; extract burdock root, and oil of nutmegs (mixed), each, 2 dr.; camphor dissolved with spirits of wine, 15 gr.; beef marrow, 2 oz.; best olive oil, 1 oz.; citron juice, ½ dr.; aromatic essential oil to render fragrant; mix; shake into an ointment. — 5. Steep 10 or 15 minutes in soft water 3 oz. pulverized sage; strain off the liquor and add 1 teaspoonful each, pulverized borax and salt: keep tightly corked. Apply daily with a sponge, rubbing it gently over the head; then brush the hair.

GRAY HAIR. To Prevent. — Hulls of butternuts, 4 oz.; infuse in 1 qt. water, 1 hour; add ½ oz. copperas; apply with a soft brush every second or third day. When sea air turns hair gray it should be kept oiled with some vegetable oil; not glycerine, as that combines with water too readily.

HALL'S RESTORATIVE.—Glycerine, 2 oz.; bay rum, 8 oz.; salt, 2½ dr.; Jamaica rum, 4 oz.; lac sulphur and sugar of lead, each, 1 dr. and 15 gr.; rain or distilled water, 16 oz.; mix. Digest 12 hours; shake well before use.

INVIGORATOR. — Bay rum, 2 pts.; alcohol, 1 pt.; castor oil, 1 oz.; carb. ammonia, ½ oz.; tincture cantharides, 1 oz. Mix well.

JABORANDI TONIC. — Glycerine, 2 oz.; jaborandi, 4 dr.; cinchona bark, 1 oz.; alcohol, 2 oz.; bay rum, 2 oz.; rose water, 10 oz.; reduce the jaborandi and cinchona to powder, and exhaust them by percolation with the alcohol, bay rum and water, mixed together; to the percolate add the glycerine, and filter.

LANDERER'S TONIC. — Cloves, 2½ dr.; laurel leaves, 5 dr., in coarse powder; digest with alcohol, 6 fl. oz.; rose water, 3 fl. oz.; glycerine, 2½ dr. After 24 hours, add ether, ½ oz.; oil of lavender, 5 drops; filter.

LAVENDER TONIC. — Alcohol, ½ gal.; castor oil, ½ gal.; tinct. cantharides, ½ oz.; oil of bergamot, ½ oz.; oil of lavender, ½ oz.; oil of thyme (white), ½ oz. Mix.

NEIL'S TONIC.—Tincture cinchona, red, 3 oz.; glycerine, 1 oz.; Jamaica rum, 1 oz.; tannic acid, ½ dr.; tincture cantharides, 2 dr.; tincture capsicum, 1 dr.; cologne to make 9 oz. Mix. Apply twice a day, rubbing well into the scalp.

OWEN'S TONIC.—Rain water, 1 pt.; lac sulphur, ½ oz.; sulphate of iron, ½ oz.; oil of bergamot, ½ oz. Mix. Apply daily.

ST. CLAIR'S TONIC. — Castor oil, 3 oz.; oil of bergamot, 3 oz.; oil of cinnamon, 15 drops; oil of cloves, 15 drops; oil of lavender, 1½ dr.; tinct. cantharides, 2 dr.; aqua ammonia, 4 dr.; alcohol to make 2 pts. Mix.

SHAMPOOING LIQUIDS. — 1. 1½ oz. powdered refined borax; ½ oz. white Castile soap scrapings; dissolve in 1 qt. hot water; when cool, strain through a coarse cotton cloth, and add a few drops of bergamot or other essence. — 2. Powdered borax, 4 dr.; bay rum, 2 oz.; aqua ammonia, 13 oz. Mix. Apply and rub briskly; after the hair is cleansed, rinse with clean water; dry quickly, and apply oil. — 3. Dissolve ½ oz. carb. of ammonia and 1 oz. borax in 1 qt. water; add 2 oz. glycerine; 3 qts. New England rum; and 1 qt. bay rum. Moisten the hair, shampoo with the hands until a lather is formed, and wash off with water. — 4. Carbonate of ammonia, ½ oz.; carbonate of potash, 1 oz.; water, 1 pt.; dissolve, and add the solution to a mixture of tincture of cantharides, 5 fl. oz.; rectified spirit, 1 pt.; good rum, 3 qts. — 5. (*Dry.*) Sulphuric ether, 1 oz.; alcohol, 1 oz.; glycerine, 1 oz.; aqua ammonia, 1 dr.; sliced Castile soap, 2 oz.; rain water 2 pts. Mix.

SIMPLE LOTIONS. — 1. Rosemary tops, 2 oz.; boiling water, 1 pt.; infuse together; add rectified spirit, 1 fl. oz. to the cold strained liquor. — 2. Box leaves, a small handful; boiling water, 1 pt.; digest 1 hour; simmer 10 minutes, and strain.

VEGETABLE WASHES.—1. Salt of tartar, 1 oz.; rosemary water, 1 pt.; burnt sugar, q. s. to tinge it brown; dissolve, filter, and add essence of musk, 20 drops. — 2. Southernwood, 2 oz.; box leaves, 6 oz.; water, 4 pts.; boil gently in a saucepan ½ hour; strain, and to each pint of the liquid add 2 oz. spirit of rosemary and ½ dr. salt of tartar. — 3. Boil 1 lb. of rosemary in 2 qts. water, and add to the filtered liquor 1 oz. spirit of lavender, and ½ oz. Naples soap, or salt of tartar.

WILSON'S LOTION. — 1. Eau de Cologne

(strongest), 8 fl. oz.; tincture cantharides, 1 fl. oz.; oils of rosemary and lavender, each, ½ fl. dr. — 2. Water of ammonia, almond oil, and chloroform, 1 part each; dilute with 5 parts alcohol, or spirits of rosemary; add 1 dr. oil of lemon. Use after thorough friction with the hair brush.

SKIN AND NAILS.

CARE IN GENERAL.

REMARKS. — *Skin.* The best purifiers of the skin are soap and water; the best cosmetic, plenty of out-door exercise, a well regulated appetite, and a cheerful mind. A pure skin is impossible unless regard is paid to diet. Spiced mince pies, rich cakes and sharp pickles show their effects plainly in the face. Plain fare, in small quantity, will do more for the skin than any cosmetics. Full-blooded girls, whose complexions give them trouble, should not eat fat meat except in winter, nor drink milk. The regular use of cosmetics and washes dries the skin and makes it unsightly, and, clogging the pores, is very injurious. The skin hardens by exposure to the sun, or to a high wind. On returning home after such exposure, wash the face with tepid water, and dry it with a soft napkin. If exposed to dust or smoke, the face or neck should be wiped with a handkerchief, if there be no opportunity of laving them. If sitting near the fire, protect the face with a screen. If from any cause there be moisture on the skin, a handkerchief should be applied to absorb, not wipe it away; these attentions, though apparently unimportant, are necessary. Friction to the neck and arms should be performed by means of a flesh-brush, to remove the scaly particles which appear after the application of water. Wrinkles give an appearance of age, and usually come on as people get older, or as a consequence of using large quantities of powder. Knitting the brows produces a wrinkle between the eyebrows. No application will cure this; the effort must come from resolute avoidance of the cause. Living in a dirty atmosphere develops wrinkles; the grime settles in any little hollows that will receive it, and the longer it stays there the more difficult it is to remove. It may be partially kept out by wearing a veil out-of-doors, but the best thing is frequent and thorough washing with hot water, and applying a little sweet oil or cold cream at bedtime. This softens and smooths the skin. A little alum or other astringent lotion applied in the morning does good, but if it makes the skin smart it acts as an irritant, and must be avoided.

Nails. — The finger nails grow out about three times a year. They should be trimmed once a week, leaving them long enough to protect the ends of the fingers. If trimmed too close at the corners there is danger of their growing into the flesh. The "quick" of the finger is sensitive, and will promptly resent any interference by inflammation; hence great precaution should be observed in trimming to avoid lacerating the quick. The secretion under the ends of the nails should not be removed by anything harder than a brush, nor should the nails be scraped with a penknife, as it destroys the delicacy of their structure. To prevent hangnails, the skin should be loosened from the nail once a week, not with a knife or scissors, but with the small end of a tooth brush or an ivory paper cutter. The best way to do this is to first put the ends of the fingers in warm water, then push the skin back gently. The tiny white specks on the nails are made by scraping the nail at the point where it rises from the skin. Biting off the finger nails is an odious practice.

BATHING. — It is by no means necessary to own a bath-room to enjoy its benefits and comforts, for even in a basin an abundant sponge bath may be taken, both healthful and invigorating. The bath must be suited to the organization of the individual. It should always be taken quickly, followed by brisk rubbing. The frequency of the bath should be determined by its effects, and taken as often as the system desires it. The harm is done not so much by bathing often as by staying in the water too long. A hot soap-suds bath once a week is beneficial to persons with moist and oily skins. Bay-rum and camphor may be used by such persons each time after washing the face. None but robust persons should ever take baths except in a warm room. The bath-room should be arranged to be heated in a few minutes; otherwise the bath is best taken in one's own room before the fire. Those who take cold do so often from contact of the feet with the metal bottom of the tub. This may be prevented by standing on a folded towel. Be sure to put on plenty of clothing after the bath, and step about briskly within doors, but do not go out for an hour or so. If the bath produces drowsiness or depression it acts mischievously. To those able to bear the shock nothing is so refreshing as a plunge each morning, summer and winter, into a tub of water fresh from the well. However, this is not advisable, when it is not followed by a warm glow, neither when followed by a rush of blood to the head; in both cases tepid or warm water should be substituted. If not able to forego the pleasure of a cold bath, put into it a tablespoonful of whisky. No one in health should go shivering into a cold bath, and if spirit is unobtainable, wake up your dormant circulation by exercise before submitting to the chilling shock. Cold water is not a cleansing agent; in fact, it tends to make the skin retain the dirt by closing the pores, which shut up to a cold current of air or water; thus the physical evil of dirt is more likely to ensue, for if left to itself the skin would cast off this refuse material in the shape of invisible perspiration. Therefore, as warm or tepid water produces a reverse action on the pores, it is advisable to use that, with a thorough soap scrubbing, followed by a general sponging with cold water. This last may be done with cold water, only when followed by a reactionary glow of warmth; should this not occur, it is unwise

to use it, and warm must be substituted. In the oppressive weather of summer the hot bath is most cooling. The hot water dissolves the matter that clogs the pores, the rough cloth and soap remove it scarchingly, and the towel is hardly laid aside before a delicious coolness passes upon one. People who suffer much in warm weather should reckon this a daily solace. All enervating effects are warded off by an instant's plunge into water of 70°. The bran bath is taken with 1 pk. common bran stirred into a tub of warm water. The rubbing of the scaly particles of the bran cleanses the skin, while the gluten in it strengthens the tissues. Oatmeal is better, as it contains a small amount of oil that is good for the skin. Borax is esteemed for cleansing, removing stains and softening the skin. Many people object to the use of soap for the face, but any who will use the following directions will find that objection removed. Fill a basin ⅔ full with fresh water; dip face in the water, and then hands; soap the hands well and pass them with gentle motion over the whole face; having performed this thoroughly, dip the face in the water a second time and rinse it completely. (See *Bathing* in HYGIENE, in HEALTH AND DISEASE.)

LOUF. — This fibre is the seed-membrane of a gourd. Choose a close, fine (not stiff) one; shave off the ribs inside with scissors; then soak well in hot water; when soaped it makes a speedy and satisfactory lather, better than flannel. One of its advantages is, that it rinses itself the moment it is thrown into water, which only needs shaking out of it as you shake a wet brush; it is the purest thing you can use.

SPONGES. — The kinds most in use are Turkey, rock and sand sponges. Of these the former is undesirable for daily use. The rock or sand sponge, which is the common honeycomb, is the best for bath purposes, and in buying, select a white woolly one, with only a few large holes. After washing thoroughly and beating out the sand, soften by soaking in equal parts muriatic acid and water. Then sew through and through with strong cotton to prevent tearing. Nothing is more unpleasant than a dirty sponge. To preserve it clean never leave it wet, but rinse well and ring hard. No matter if you tear it, it is better to have a ragged clean one than to use a bunch of decaying stuff, which only gives you back human grease and dirt. To wash it use soap, and rinse again and again until it is fragrant. Avoid putting out of the window to dry; sunshine is injurious; a common sponge basket is the best receptacle.

TOWELS. — The choice of towels is a matter of taste, and experience and sensation must guide; each individual skin is differently sensitive, and rough towels are no more advisable than the very smooth ones; but it is well always to have a large towel or bath-sheet to throw over you in coming out of the bath.

DISCOLORATIONS & IRRITATIONS.

BLOTCHED FACE, Wash for. — Rose water, 3 oz.; sulphate of zinc, 1 dr.; mix; wet the face with it, gently dry it, and then touch it over with some cold cream, which also dry gently off.

CHAPPED HANDS, Ointments and Liniments for. — 1. Borax, 2 sc.; glycerine, ½ oz.; water, 7½ oz.; mix, and apply as a lotion twice a day. — 2. Glycerine, 3 fl. oz.; mucilage of quince-seeds, U. S. D., 10 fl. oz.; cochineal powder, 5 gr.; hot water, 1½ fl. oz.; alcohol, 2½ fl. oz.; oil of rose, 8 drops; gum Arabic, powder, 30 gr.; water, 8 fl. oz. Rub the cochineal with the hot water gradually; add the alcohol; triturate the oil of rose well with the powdered gum Arabic, and gradually add the cold water; mix the 2 solutions, filter and add the glycerine and the mucilage of quince seeds; shake thoroughly. — 3. Mix 2 parts white brandy with 1 part rose water and wash the face in it night and morning. — 4. Melt 3 dr. spermaceti, and 4 dr. white wax, with 1 oz. almond oil, and stir in 3 dr. powdered camphor; melt into small gallipots, so as to form hemispherical cakes; color with alkanet. — 5. Glycerine, 1 oz.; spermaceti, 2 dr.; olive oil 2 oz.; mix with the aid of heat. Apply every night and morning. —6. White soap, 1 lb.; spermaceti, 1 oz.; water sufficient to mix; melt together, and add 1 oz. powdered camphor. — 7. Lycopodium, 1 dr.; balsam of Peru, ½ dr.; simple ointment, 1 oz. — 8. Glycerine and rose water, each, ½ oz.; mix, and rub it on the back part of the hands night and morning. — 9. Wash the hands thoroughly before retiring; rub them over with mutton tallow and wear a pair of easy setting leather gloves. — 10. Take ¼ lb. unsalted hog's lard; work it well through clear cold water; drain, and work again, in a wine-glass rose water, the yolks of 2 fresh eggs, and 1 tablespoonful of honey; mix in gradually as much finely powdered oatmeal as will make a paste about the consistency of new butter. Spread on the hands at night, cover with kid gloves and in the morning wash off. — 11. Wash the hands in buttermilk in which some wheat bran has been stirred 20 hours before using, and dry over the fire without a towel. Use at night. — 12. Quince seeds and whisky; put the seeds in a bottle and pour on whisky to cover them; as the mixture thickens add more whisky. — 13. 1 part glycerine; 4 parts witch hazel; 4 parts water; mix and shake well before using. — 14. Rub the hands over with fine soap, and, while the lather is still on, scrub thoroughly with Indian meal. Rinse with tepid water; dry, and wet again with warm water containing ¼ teaspoonful pure glycerine. Dry without wiping, rubbing the hands until the water has evaporated. Do this at night. — 15. Lard, 16 parts; cocoa-oil, 24 parts; spermaceti, 8 parts; yellow wax, 3 parts; alkanet root, 1 part. Melt and keep at a gentle heat 15 minutes; strain through a cloth and mix with oil of lemon and oil of bergamot, each, ½ part; oil of bitter almonds, 1-15 part; pour into suitable vessels and cork.

CHAPPED LIPS, Liniments and Ointments for. — 1. 2 spoonfuls of clarified honey; a few drops of any perfume; mix, and anoint the lips frequently. — 2. Cut 4 oz. fresh unsalted butter into small pieces; place in an earthen vessel; cover with rose water; cover the vessel closely, and stand aside for 5 days in a cool place; then drain off any remaining liquid, and put the earthen

jar in a saucepan of warm water; add 1 oz. grated spermaceti; 1 oz. grated beeswax; ½ oz. powdered alkanet root; 2 dr. pulverized gum benzoin; 1 oz. pulverized borax; ½ oz. powdered white sugar; and 1 tablespoonful clear lemon juice; beat all well together, and place over a slow fire, stirring till it reaches the boiling point; remove from the fire before it boils, and when cool put in china jars. — 3. 10 drops carbolic acid in 1 oz. glycerine; apply freely at night. — 4. White wax, 1 oz.; oil of almonds, 4 oz.; rose water, 2oz.; borax, ½ dr.; oil of roses, 5 drops; by a gentle heat dissolve the borax in the rose water, which is then to be warmed a little and added to the heated oil; lastly, add the oil of roses, stirred.— 5. Wash with a strong tea, made from the bark of the white oak. — 6. 1 gill sweet oil; 1 oz. white wax; ¾ oz. spermaceti; dissolve over the fire and stir till cool.

COMEDONES, To Remove. — These are coagulated lumps, which close the pores of the skin. On the skin immediately adjacent being pressed with the finger nails, they will come from it in a vermicular form, and for this reason they are vulgarly called "flesh worms." They may be removed and prevented from returning by washing with tepid water, proper friction with a towel and the application of a little cold cream. The longer they remain in the skin the more firmly they become fixed; and after a time are converted into spines dense as bristles. With regard to the local treatment the following lotions are serviceable: 1. Distilled rose water, 1 pint; sulphate of zinc, 20 to 60 grains; mix. — 2. Sulphate of copper, 20 grains; rose water, 4 oz.; water, 12 oz.; mix. — 3. Oil of sweet almonds, 1 oz., fluid potash, 1 dr. Shake well together; add rose water, 1 oz.; pure water, 6 oz.; mix. Rub the pimples for some minutes with a rough towel, then dab them with the lotion. — 4. Wash the face twice a day with warm water, and rub dry with a coarse towel. Then with a soft towel rub in a lotion made of 2 oz. white brandy; 1 oz. cologne; ½ liquor potassa. All of these outside applications should be used with caution, for what is perfectly harmless or even healthful in some states of the system will irritate in others. Watch the effect from day to day and you can soon decide whether the remedy will prove effectual.

CRACKED HANDS. To Relieve. — White resin, 1 oz.; melt and add a little lard or oil until the resin is softened, so that when cold, and in a temperature of 80° or 90°, the thumb nail can be indented into it by using a little force. When you have obtained the right consistency by means of the oil or lard, mix the whole thoroughly, and put it by for use. Warm and drop on the hands, and, before it cools, have ready a piece of soft white paper and place it at once on the chap. The paper will adhere, or, if it does not do so, warm it over a lamp. Then moisten the paper and tear off all the outside projecting portions, leaving the wax alone. Do this at night and use no oil or grease first.

FRECKLES. To Remove. — 1. ½ lb. clear ox gall; ½ dr., each, camphor and burned alum; 1 dr. borax; 2 oz. rock salt, and the same of rock candy; mix, and shake well several times a day for 3 weeks, until the gall becomes transparent; strain through filtering paper. Apply to the face during the day, and wash off at night. — 2. 1 oz. alum; same of lemon juice in 1 pint rose water. Apply at night. — 3. Scrape horse-radish into a cup of sour milk (cold); let stand 12 hours; strain and apply 2 or 3 times a day. — 4. Lemon juice, 1 oz.; powdered borax, ½ dr.; sugar, ½ dr.; keep for a few days in a glass bottle and apply occasionally. — 5. Muriate of ammonia, ½ dr.; lavender water, 2 dr.; distilled water, ½ pint; apply 2 or 3 times a day. — 6. Equal parts pure glycerine and rose water, applied every night and allowed to dry. — 7. 1 oz. bitter almonds, 1 oz. barley flour, and sufficient quantity honey; beat the whole into a smooth paste, spread thinly on the skin at night, and wash off in the morning. —8. 2 parts, each, corrosive sublimate, sulphate of zinc, and acetate of lead; 125 parts of distilled water; mix. This preparation being poisonous, care must be taken not to get it in the mouth. — 9. Fine, pale honey, 4 oz.; glycerine, 1 oz.; mix by gentle heat, and when cold, add alcohol, 1 oz.; essence of ambergris, 6 drops; citric acid, 3 dr. — 10. Take finely powdered nitre (saltpetre), and apply it to the freckles by the finger moistened with water and dipped in the powder. — 11. Elder flower ointment, 1 oz.; sulphate of zinc, finely powdered, 25 gr. Apply with the finger night and morning.

MASK. To Remove. — This frightful discoloration can be removed by a wash made from 30 gr. chlorate of potash in 8 oz. rose water.

MOLES. To Remove. — The common mole is situated in the middle layer of the skin; the coloring matter is probably some chemical combination of iron. They are often elevated above the surface, and then the natural down of the skin over them is changed into a tuft of hair. The less they are trifled with, the better; and avoid particularly the use of depilatories to remove the hair from them, as it often causes a fœtid, suppurating wound. When slight they may be removed by touching them every day with a little concentrated acetic acid, by means of a hair pencil, observing due care to prevent the application from spreading to the surrounding parts. The application of lunar caustic is also effective, but it turns the spot temporarily black. When other means fail, the hair may be safely removed by surgical means. They can also be removed with a sun-glass. Seat the patient in a clear, strong sunlight; bring the concentrated rays of the sun to bear on the excrescence 5 or 10 minutes. In 3 or 4 weeks the mole will scale off and new skin form.

MOTH PATCHES, To Remove. — Wash with a solution of common bicarbonate of soda and water several times during the day, until the patches are removed. After the process, wash with some nice toilet soap, and the skin will be left nice, clean and free of patches. Lemon juice is good, rubbed on the skin.

PIMPLES, To Remove.— 1. Barley meal, 1 oz.; powdered bitter almonds, 1 oz.; honey, q. s., to make a smooth paste. — 2. White vinegar, 4 oz.; sulphur water, 2 oz.; acetated liquor of ammonia, ½ oz.; liquor of potassa, 2 gr.; distilled water, 4 oz.; mix, and apply twice a day. — 3. Beat a quantity of houseleek in a marble mortar;

squeeze out the juice and clarify it; pour a few drops rectified spirit on the juice, and it will instantly turn milky. — 4. 6 dr. mercury; 6 gr. flour of sulphur; 2 oz. of hog's lard; mix carefully in a mortar. — 5. 36 gr. bicarbonate of soda; 1 dr. glycerine; 1 oz. spermaceti ointment; rub on the face; let remain ½ hour, and wipe off all but a slight film with a soft cloth. — 6. Wash the face in a dilution of carbolic acid, 1 teaspoonful to 1 pt. water.

PITTING, To Remove. — Simple oil, pomade, or ointment, medicated with croton oil, and of a strength sufficient to raise a very slight pustular eruption, is probably the safest and most effective of all preparations employed for the purpose. Apply at intervals extending over several weeks.

SUNBURN. To Remove. — 1. Dip a bunch of green grapes in a basin of water; sprinkle it with powdered alum and salt mixed; wrap the grapes in paper, and bake them under hot ashes; then express the juice, and wash the face with the liquid. — 2. 2 spoonsful sweet cream; ½ pt. new milk; the juice of a lemon; ½ glass genuine French brandy; a little alum and loaf sugar; boil, skim, and when cool, it is fit for use. — 3. Borax, 15 gr.; lemon juice, 1 oz.; sugar candy, ½ dr.; mix the powders with the juice, and let them stand in a bottle, shaking occasionally until dissolved. — 4. Put a quantity of elder flowers into a jug; pour boiling water on them; let the mixture stand 24 hours; then strain through muslin. Wash the face every morning with the decoction. — 5. Pour 1 qt. boiling water on a handful of bran; let stand 1 hour and strain; when cold add 1 pt. bay rum. — 6. A mixture of lime water and sweet oil; bathe the affected parts frequently. — 7. Powdered borax, ½ oz.; glycerine, 1 oz.; camphor water, 1 qt. Wash the face twice a day.

Paints and Powders.

REMARKS. — Skin paints and skin stains are employed to give an artificial bloom to the skin. They can be of no benefit further than to produce a false beauty, and to a certain extent they must be injurious, because they fill up the pores of the skin, and if they do not prevent, they retard transpiration. Metallic colors should be avoided; those which have white or red lead for their bases, may and often do produce paralysis. Rouge and carmine are the articles generally used to communicate a red color. The first is the only cosmetic that can be employed without injury. The other, though possessing unrivaled beauty, is apt to impart a sallowness to the skin by frequent use. Starch powder is employed to impart a white tint, and generally proves harmless. Several metallic compounds, as the trisnitrate, chloride and oxide of bismuth (pearl white, Fard's white, etc.), carbonate of lead (flake white), white precipitate, etc., are frequently used, but they act as poisons. To insure a beautiful complexion by natural means is better than by artificial ones. Those who live temperately, keep regular hours, are actively employed and take a due amount of air and exercise, will, generally speaking, have no cause to be ashamed of their complexions. But, if some insuperable defect does exist in spite of every precaution, all the nostrums that it is possible to conceive of will not efface it.

ALMOND BLOOM.—1 oz. Brazil dust; 3 pts. distilled water; boil and strain; add 6 dr. isinglass; 2 dr. cochineal; 1 oz. alum; 3 dr. borax; boil again and strain through a fine cloth.

CHINESE BOXES.—They contain each 2 doz. papers, and in each paper are 3 smaller ones, viz.: a small black paper for the eyebrows; another of fine green color, but which, when fresh, makes a fine red color for the face; and a paper containing ½ oz. white powder (prepared from real pearl) for the face and neck. The red powders are best applied by a fine camel's hair brush; the colors in the dishes, wools and green papers are laid on by the tip of the little finger, previously wetted; but as gum is used in their composition, they are apt to leave a shining appearance on the skin.

CHINESE CARD.—Said to be a carthamate of soda; colorless when applied, but, being decomposed by the acid secretions of the skin, acquires a beautiful rose-like tint.

COSMETIC POWDER. — Blanched sweet almonds and beans, each, 18 oz.; orris root, 8 oz.; white Spanish soap, 6 oz.; spermacti, 1½ oz.; dried carbonate of soda, 1 oz.; oils of lavender, bergamot and lemon, each, 6 dr.; mix, and beat to a powder.

FEET, Powder for.—1. A good deodorizer for unpleasant smelling feet is the following: A mixture of equal parts salicylic acid, soap, talc and starch, to be applied in the form of powder. — 2. For excessive perspiration of the hands and feet, the following is recommended: Carbolic acid, 1 part; burnt alum, 4 parts; starch, 200 parts; French chalk, 50 parts; oil of lemon, 2 parts. Make a fine powder, to be applied to the hands and feet, or to be sprinkled inside of gloves or stockings.

FINGER TIPS. Alkanet for. — ½ oz. chippings of alkanet, tied in coarse muslin, and soaked 1 week in diluted alcohol, will give a tincture of lovely dye. The finger tips should be touched with jewelers' cotton dipped in this mixture.

FRENCH WHITE.—French chalk, finely powdered; bottled, and perfumed to taste.

HAND POWDER.—Almond powder, 1 lb.; powdered cuttle-fish bone and white soap, each, 4 oz.; orris powder, 1 oz.; mix. Use to clean the hands, and to render them soft and white.

HARMLESS POWDER. — 2 oz. pulverized starch; 3 dr. powdered orris root; 4 oz. powdered marshmallow root; 2 oz. powdered jasmine flowers (dried); pound in a mortar till mixed, and sift through muslin.

LIPS. Color for.—Color for the lips is nothing more than cold cream, with a larger quantity of wax than usual melted in it, with a few drs. of carmine. For vermilion tint, use a strong infusion of alkanet. Keep the chippings for a week in the almond oil, of which the cold cream is made, and afterward incorporate with wax and spermaceti. Always tie alkanet in a muslin when it is used for coloring.

PEARL POWDER. — The best white is literally

pearl powder, *i.e.*, made from pearls; and this is as safe as its effects are natural and beautiful; a most dangerous compound of bismuth is, however, sold under this name. The following is a good receipt: Pure pearl white and French chalk (scraped fine by Dutch rushes), equal parts, triturated together; some add more French chalk.

PINK SAUCER.—8 oz. dried safflower, previously washed in water, until it no longer gives out any color; 2 oz. subcarbonate of soda; 2 gals. water; infuse and strain; add 4 lbs. French chalk, scraped fine with Dutch rushes, and precipitate the color upon it, with citric or tartaric acid.

ROUGE. — 1. Mix vermilion with enough gum tragacanth dissolved in water, to form a thin paste; add a few drops of almond oil; place in rouge pots, and dry by a very gentle heat. — 2. (*Turkish.*) ½ pint alcohol; 1 oz. alkanet; macerate 10 days; pour off the liquid, and bottle. —3. (*Vinegar.*) Acetic acid, 4 dr.; alum, 30 grs.; rose water, 12 oz.; alcohol, 26 oz.; balsam of Peru, 50 grs.; carmine, No. 40, 2 dr.; water of ammonia, 1 dr., dissolve the balsam of Peru in the alcohol and the alum in the rose water; mix the two solutions; add the acetic acid, and macerate for a few hours; add to it the carmine, dissolved in the ammonia; shake well, and after 10 minutes, decant and bottle.

TALC WHITE. — Briancon chalk; choose a pearl gray color, and rasp gently with a piece of dog-skin; sift through a sieve of very fine silk, and put into a pint of good distilled vinegar for a fortnight; shake the bottle every day except the last, on which it must not be disturbed; pour off the vinegar so as to leave the chalk in the bottle; into which pour clean water that has been distilled or filtered; throw the whole into a clean pan, and stir well with a wooden spatula; let the powder settle again to the bottom, then pour the water gently off, and wash the powder 6 or 7 times, taking care always to use distilled water; when the powder is soft and white as desired, dry it in a place where it is not exposed to the dust; sift it through a silken sieve which will make it still finer; it may be either left in powder, or wetted and formed into cakes; dip the finger, a piece of paper, or a hare's foot, in cold cream, and put upon it about a grain of this white which will not be removed even by perspiration.

VIOLET POWDER. — Wheat flour or starch, 12 oz.; powdered orris-root, 2 oz.; otto of roses, 20 drops; oils of bergamot and cloves, each, 10 drops.

Pastes, Pomades and Ointments.

ALMOND PASTE. — 1. Blanched Valentia almonds, 4 oz.; reduce to a paste by pounding in a clean mortar; adding, towards the last, a little rose water, with some eau de Cologne, or 3 or 4 drops otto of roses or neroli, or any perfume.—2. Powdered bitter almonds, 4 oz.; white of egg, 1 oz; beat to a smooth paste, with equal parts spirits of wine and rose water.—3. Sweet and bitter almonds, blanched, each, 2 oz.; spermaceti, 2 dr.; oil of almonds, ½ oz.; Windsor soap, ½ oz.; rose water, 1 oz.; otto of roses and oil of bergamot, each, 12 drops. — 4. Spermaceti, 4 oz.; white wax (pure) 8 oz.; oil of almonds, 1 pt.: melt together in a glazed earthenware vessel, by the heat of a water bath; when cooled a little, add essential oil of almonds, and expressed oil of mace, each, 2 dr.; stir until cool, and then pour into molds.

AMANDINE.—Fine new white or pale honey, 4 oz.; white soft soap, prepared from lard and potassa, 2 oz.; mix in a marble mortar.; add 1 or 2 teaspoonfuls (if necessary) of solution of potassa, until a paste or cream is produced; then rub in, gradually, oil of almonds, 7 lbs., previously mixed with essential oil of almonds, 1 oz.; essence (oil) of bergamot, ¾ oz.; oil of cloves, ½ oz.; and balsam of Peru, 3 dr.

BISMUTH CREAM.—Subnitrate of bismuth, 2½ oz.; carbonate of magnesia, 20 gr.; gum acacia, ½ oz.; aqua rose, 8½ oz.; orange flower water, ½ oz.; essence vanilla, 10 drops; carmine 2 gr.; mix thoroughly.

CACAO CERATE.—Butter of cacao, white wax and oil of almonds, equal parts; melt and strain.

CAMPHOR CREAM.—White Castile soap, 4 dr.; boiling water sufficient to dissolve it; carbonate of ammonia, 4 dr. camphor, 4 dr.; tincture of opium, 4 dr.; oil of origanum, 2 dr.; water sufficient to complete, 2 pts.

CAZENAVE'S PASTE.—3 oz. ground barley; 1 oz. honey; the white of 1 egg; mix to a paste, and spread thickly on the cheeks, nose, and forehead, before retiring; wash it off with warm water, wetting the surface with a sponge, and letting it soften while dressing the hair or finishing the bath. Repeat nightly till the skin grows perfectly fine and soft, after which it will be enough to use it once a week. Always wash the face with warm water and mild soap, rubbing on a little cold cream when exposed to the weather.

COLD CREAM. — 1. Oil of almonds, 16 oz.; white wax, 4 oz.; melt together in an earthen vessel, and, when nearly cold, stir in 12 oz. rose water. — 2. 3 dr. of white wax; 2½ oz. sweet oil of almonds; 3 dr. spermaceti; 2 oz. rose water; 1 dr. oil of bergamot; 15 drops oil of lavender; 18 drops otto of roses. Place the wax, spermaceti, and oil of almonds, in an earthenware jar, and stand it in boiling water until thoroughly melted; pour off into a warm mortar, and stir in the rose water; when well mixed and cool, add the other ingredients; beat all together, and place in porcelain jars. — 3. Cosmoline, 24 oz.; white wax, spermaceti, each, 12 oz.; glycerine, 3 fl. oz.; oil of geranium, 1 fl. dr.

CREAM OF ROSES. — 1. Compound tincture of benzoin, ½ oz.; almond and Malaga oil, each, 1 oz.; otto of roses, 5 drops; honey, 2 oz.; and enough rose water to make the mixture measure 6 oz. Apply as often as you like. — 2. Spermaceti, 5 oz.; white wax, 2½ oz.; oil of almonds, 1 lb.; rose water, distilled, 6 oz.; melt the wax and spermaceti in the oil with gentle heat; pour into a warm mortar, holding 4 times as much, and never cease stirring with a bone spatula nor change the direction. In a short time commence

adding the rose water, previously warmed; stir briskly while adding it; and, when of a creamy consistence and quite cool, add 20 drops otto of roses, and continue stirring until thoroughly mixed.

CREAM WASH BALLS. — White curd soap, 7 lbs.; powdered starch, 1 lb.; water or rose water sufficient to mix; beat the whole together, and form into balls.

CUCUMBER POMATUM. — Clarified lard, 4 lbs.; veal suet, 1 lb.; juice of cucumbers, 3 lbs.; melt the two former together; beat them up with the juice; next day pour off the juice that has separated, and add the same quantity of fresh to the melted pomade; repeat 6 times, or until the pomade is imbued with the odor of cucumbers; melt the pomade by a water-bath, and mix with it 3 dr. powdered white starch; let it settle, and before it is too cold, pour it off into small pots, taking care not to disturb the dregs.

ELDER OINTMENT. — Fresh elder leaves, bruised, 3 lbs.; suet 4 lbs.; lard 2 lbs.; boil together until the leaves become crisp, and squeeze through a linen cloth.

GLOVES. Paste for. — 1. ½ lb. soft soap; 1 gill salad oil; 1 oz. mutton tallow; boil together; after boiling ceases, add 1 gill spirits of wine and 1 sc. ambergris; rip a pair of gloves 3 sizes too large, spread them with this paste, and sew up to be worn at night. — 2. Spermaceti cerate, 3 oz.; melt; add balsam of Peru, ½ dr.; stir 5 minutes, and, after a few minutes' repose, pour off the clear portion; to this add oil of nutmeg, 15 drops; oil of cassia and essence of ambergris, each, 6 drops; and stir until cold.—3. The yolks of 2 fresh eggs beaten with 2 teaspoonfuls oil of sweet almonds, 1 oz. rose water, and 36 drops tincture of benzoin. Make a paste of this, and either anoint the gloves with it, or spread it freely on the hands and draw the gloves on afterward.

GLYCERINE BALSAM. — 1000 parts glycerine; 120 parts orange flower water; 1 part, each, oils neroli and bitter almonds.

LEMON WASH BALLS. — Cut 6 lbs. soap into small pieces; melt with 1 pt. water in which 6 lemons have been boiled; withdraw the soap from the fire, and add 3 lbs. powdered starch, and a little essence of lemon; knead the whole into a paste, and form into balls the desired size.

LIP SALVE. — 1. Spermaceti ointment, ½ lb.; alkanet root, ½ oz.; melt together until colored; strain, and, when cooled a little, add balsam of Peru, 3 dr.; stir well, and in a few minutes pour off the clear portion from the dregs; lastly, stir in oil of cloves, 20 or 30 drops. — 2. Oil of almonds, 3 oz.; spermaceti, ½ oz.; virgin rice, ½ oz.; melt over a slow fire, mixing with them a little powder of alkanet root, to color it; stir till cold, and add a few drops oil of rhodium.—3. Oil of almonds, spermaceti, white wax, and white sugar candy, equal parts.

ORANGE PASTE.—Orange flowers, 2 lbs.; bitter and sweet almonds, each blanched, 2½ lbs.; beat to a perfectly smooth paste.

ORGEAT PASTE.—Blanched Jordan almonds, 1 lb.; blanched bitter almonds, white sugar and honey, each, ½ lb.; beat to a paste, with orange flower water, q. s., or neroli, a few drops, and put into pots; for use, rub 1 oz. with ½ pt. water, and strain through muslin.

PATE DIVINE DE VENUS. — Mix equal parts washed lard, fresh butter, and white honey; add balsam of Mecca and otto of roses to perfume.

POMMADE DE BEAUTE. — Melt together in an earthen vessel placed in hot water, white wax, 1½ dr.; spermaceti, 2 dr.; oil of sweet almonds, ½ oz.; virgin olive oil, ½ oz.; oil of poppies, ½ oz.; beat them with a few drops balsam of Peru.

POMMADE D' HEBE. — Juice of lily bulbs, 2 oz.; Narbonne honey, 2 oz.; white wax, 1 oz.; rose water, 3 drs.; melt the wax with a gentle heat, and add the other ingredients.

POMMADE DE NINON DE L' ENCLOS. — Oil of almonds, 4 oz.; prepared lard, 3 oz.; juice of houseleek, 3 fl. oz.

POMMADE DE VENUS. — Bears' oil, 4 oz.; honey, 6 oz.; oatmeal, 6 oz.; yolks of 3 eggs; 1 oz. powdered gum Arabic; mix the honey and gum first; then put in the eggs. To the oil add 2 oz. deer suet, and gradually mix with the foregoing; add the oatmeal last. Perfume with essential oils, press in fancy molds like soap, or make into balls. Use more oatmeal if necessary. When made it should be like stiff paste.

POMMADE EN CREME. — Melt together 1 dr. each, white wax and spermaceti; add oil sweet almonds, 2 oz.; pour it into a warm mortar, and gradually stir in rose or other perfumed water, and 1 dr. tincture of tolu.

POMADE, For Whitening and Softening. — 1. Camphor gum, white beeswax, spermaceti, each, 3 oz.; 2 oz. olive oil; melt slowly. If the hands be affected, anoint them on going to bed, and put on a pair of gloves. — 2. Dissolve 2 oz. Venice soap, in 2 oz. lemon juice. Add 1 oz. oil of bitter almonds, and a like quantity oil of tartar; mix and stir until it has acquired the consistence of soap; use it as such for the hands. — 3. Slice ¼ lb. Castile soap, into a pewter jar, and pour upon it 2 qts. alcohol; place the jar in a vessel of water at such a heat as will cause the spirits to boil, when the soap will dissolve; put the jar, closely covered, in a warm place until the liquor is clarified; take off any scum that may appear on the surface and pour it carefully from the dregs, then put it into a jar again, and place it in a vessel of hot water, distilling all the spirits that may arise; dry the remaining mass in the air a few days, when a white transparent soap will be obtained, free from alkaline impurities.

ROSE GLYCERINE CREAM. — Spermaceti, ½ oz.; oil of sweet almonds, 2 oz.; white wax, 1 oz.; glycerine, ¼ oz.; melt the spermaceti, white wax and oil of almonds together; add the glycerine and stir the mixture until cool; perfume with otto of roses.

ROSEMARY OINTMENT. — Lard, 16 oz.; suet, 8 oz.; yellow wax, 2 oz.; oil of mace, 2 oz.; liquefy in a vapor bath; when nearly cold, add oil rosemary and oil juniper, each, 1 oz.

ROSE OINTMENT. — Washed lard (melted), and roses (centif.) each, 2 lbs.; mix, and in 2 days remelt, and press out the fat; to this last add of fresh roses, 2 lbs., and repeat the process; color with alkanet root if required red. — 2. Spermaceti ointment melted and beaten up with

about $\frac{3}{4}$ its weight rose water until they congeal.

RUBEFACIENT PASTE. — Acetate of lead, 1 oz.; bisulphate of potassa, 3 oz.; water, q. s.

SULTANA PASTE. — 2 oz. bitter almonds; blanch, and beat into a paste with 1 oz. rose water; add honey, fine oatmeal, and glycerine, 1 oz. each, and when well mixed, 2 dr. tincture of benzoin. Apply before a fire a short time before retiring.

TAR PASTE. — Mix 1 spoonful best tar in 1 pt. pure olive or almond oil, by heating the two together in a tin cup set in boiling water; stir till mixed and smooth, putting in more oil if too thick to run easily. Rub this on the face when going to bed, and lay patches of soft old cloth on the cheeks and forehead to keep the tar from rubbing off. The black unpleasant mask washes off easily with warm water and soap. The skin comes out, after several applications, soft, moist, and tinted like a baby's.

Washes.

ALBERT'S COSMETIC.—Cucumber pomade, 3 oz.; almond soap, 1 oz.; rose water, 1 qt.; mix the pomade and soap, and add the rose water gradually.

AMYKOS.—105 dr. cloves, boiled in 1 gallon water, in which 105 dr. pure glycerine are dissolved, and to which 42 dr. borax are added.

AQUA COSMETICA.—Emulsion of bitter almonds, 3 oz.; rose and orange flower, each, 4 oz.; borax, 1 dr.; tincture of benzoin, 2 dr.; mix.

AUGUSTIN'S.—Rose water, 8 oz.; salt of tartar, 2 dr.; tincture of benzoin, 3 drs.

BALM OF BEAUTY. — Pure soft water, 1 qt.; pulverized Castile soap, 4 oz.; emulsion of bitter almonds, 6 oz.; rose and orange flower water, each, 8 oz.; tincture of benzoin, 2 dr.; borax, 1 dr.; add 5 gr. bichloride of mercury to every 8 oz. of the mixture. To use, apply on a cotton or linen cloth to the face.

BATH OF MODESTY. — Take 4 oz. sweet almonds, peeled; 1 lb. pine apple kernels; 1 lb. elecampane; 10 handfuls linseed; 1 oz. marshmallow roots; 1 oz. white lily roots; pound to a paste, and tie up in several small bags, which are to be thrown into a tepid bath, and pressed till the water becomes milky.

BLOOM OF ROSES.—1. Dried red rose leaves, 1½ oz.; boiling water, 1 pt.; infuse in earthenware for 2 hours; press out the liquor, and add juice of 3 lemons; the next day filter the clear portion. Keep in a cool place. A little spirit of wine (3 or 4 fl. oz. to the pt.) is sometimes added. — 2. Carmine, ¼ oz.; strong liquor of ammonia (not weaker than .900), 1 oz.; put them into a stoppered bottle; set it in a cool place, and occasionally agitate 2 or 3 days to effect a solution; then add of rose water, 1 pt.; and, after admixture, add esprit de rose, ½ fl. oz.; pure rectified spirit, 1 fl. oz.; well agitate, and set the whole aside for a week; lastly, decant the clear portion from the dregs for use.

BLOOM OF YOUTH. — Boil 1 oz. Brazil wood in 8 pts. water 15 minutes; strain; add ¾ oz. isinglass; ¼ oz. cochineal; 1 oz. alum; ½ oz. borax; dissolve by heat, and strain.

CALAMINE LOTION. — Levigated calamine, 40 gr.; oxide of zinc, 20 gr.; glycerine, 20 drops; rose water, to make, 1 oz. Get the white calamine, not the red.

COSMETIC LOTION. — 1. Make a hole in a lemon, fill it with sugar candy, and close it with leaf gold, applied over the rind that was cut out; then roast the lemon in hot ashes; when desirous of using the juice, squeeze out a little through the hole already made, and with it wash the face with a napkin. — 2. Take a teacupful of cold sour milk; scrape into it a quantity of horseradish; let it stand from 6 to 12 hours; strain and apply 2 or 3 times a day.

EAU D' ATIRONA. — 6½ dr. spirituous tincture of cinnamon and cloves, 1 dr. soda soap, and a drop of peppermint oil.

EAU DE PRINCESS. — ½ dr. calomel, 1-10 dr. corrosive sublimate (so altered by the added perfume that the usual tests do not reveal it), and 30 dr. orange flower water.

ENGLISH EARTH. — English earth, 6 oz.; bay rum, 2 oz.; glycerine, 1 oz.; powdered borax, 2 dr.; extract of violet, 2 dr.; distilled water, 2 pts.; rub the glycerine and the earth to a smooth paste and add the other ingredients.

FACE WASH. — 1. 2 gr. bichloride of mercury; 2 gr. muriate of ammonia; 8 oz. emulsion of almonds. — 2. 2 gals. of strong soap suds; 1 pt. pure alcohol; ¼ oz. rosemary; mix, and apply with a linen rag. — 3. Infuse well sifted wheat bran 4 hours in white vinegar; add the yolks of 5 eggs and 2 gr. ambergris; distil the whole; cork carefully, and it is ready for use in 15 days. — 4. Cascarilla powder, 2 gr.; muriate of ammonia, 2 gr.; emulsion of almonds, 8 oz.; apply with fine linen. — 5. Tincture benzoin, 2 oz.; pure alcohol, 1 pt.; bathe the skin; allow the wash to remain on a few minutes and then wipe off.

GLYCERINE LOTION. — 1 oz. sweet almonds, or pistachio-nuts; ½ pt. elder or rose water; 1 oz. pure glycerine; grate the nuts; put the powder in a little bag of linen, and squeeze it for several minutes in the rose water; then add glycerine and a little perfume. Wet the face with it 2 or 3 times a day; allow it to dry thoroughly, when, if it feel sticky or pasty, it may be washed off with water.

HANDS, Wash for.—4 oz. pulverized borax; 4 oz., each, saleratus and muriate of ammonia; mix with 4 qts. hot soft water; stir well and bottle for use. After washing the hands and face, wet with the above. — 2. Kerosene oil and water, equal parts. When the hands are discolored and soiled by rough work, before washing them dip the fingers in the mixture and rub in the usual way; the darkened skin will be effectually freed from soil and grime; then wash in soap and hot water until the smell of the oil is removed.

ITALIAN WASH.—Melilot water, 12 oz.; tincture of benzoin, 2 drs.

KALYDOR.—Bitter almonds, blanched, 1 oz.; corrosive sublimate, 8 grs.; rose water, 16 oz.

LEMON JUICE LOTION.—Fresh lemon juice, 2 oz.; glycerine, 1 oz.; rose water or rain water with 3 or 4 drops otto of roses added, 1 pt. Anoint the hands and face 3 or 4 times daily; al-

iow to remain on several minutes before wiping.

MILK OF CUCUMBERS. — Slice into ½ pt. blue skim milk, as much cucumber as it will cover, let it stand 1 hour. Bathe the face and hands, washing them off with fair water when the cucumber extract is dry.

MILK OF ROSES.—1. (*French.*) 1 qt. rose water; ½ pt. rosemary water; 2 oz., tincture of storax; 2 oz. tincture of benzoin; ½ oz. spirit of rose. Mix by shaking in a bottle, plunging it occasionally into warm water, but not hot water. — 2. (*German.*) 4 oz. blanched almonds grated; 2 oz. grated white curd soap; 1 qt. rose water. Rub the soap and almonds together with the hand, gradually adding the rose water till thoroughly mixed; warm a few minutes by standing in a vessel in a pan of boiling water; strain and bottle for use.

NAILS, Wash For.—1. Tincture of myrrh, 1 dr.; diluted sulphuric acid, 2 dr.; spring water, 4 oz.; mix. Cleanse the nails with white soap; then dip into the wash.—2. When the nails are stained or discolored, a little lemon juice or vinegar and water, is a good application. Occasionally a little pumice stone, in powder, or a little putty powder, may be used with water and a piece of soft leather or flannel. The frequent employment of these substances is injurious to the healthy growth of the nail.

OFFENSIVE FEET, Washes for.—1. Wash the feet in warm water, to which a little hydrochloric acid, or chloride of lime, has been added. — 2. Bathe every night or oftener in a strong solution of borax. — 3. Bathe in a weak solution of permanganate of potassa; 1 sc. salt to 8 oz. water. — 4. Common kitchen soda dissolved in water.

STAINS, Wash to Remove. — 1. Fruit and ink stains may be taken out by immersing the hands in water slightly acidulated with oxalic acid or a few drops oil of vitriol, or to which a little pearlash or chloride of lime has been added; afterwards rinse them well in clean water, and do not touch soap for some hours, as any alkaline matter will bring back the stains, after their apparent removal by all the above substances, except the last. — 1. To remove acid fruit stains, wash the hands in clear water, wipe them lightly, and while moist strike a match and shut them around it so as to catch the smoke, and the stain will disappear. — 3. Rubbing the hands with a slice of raw potato will remove vegetable stains. — 4. Damp the hands first in water, then rub them with tartaric acid as you would with soap; rinse them and rub dry. — 5. Put ¼ lb. glauber salts, ¼ lb. chloride of lime, and 4 oz. water into a small wide-mouth bottle, and when required for use pour some of the thick sediment into a saucer, and rub it well over the hands with pumice-stone or a nail brush. Stains of nitrate of silver may be removed from the hands by means of a solution of chloride of iron.

SULPHUR. — Break 1 oz. of sulphur, and pour over it 1 qt. boiling water; infuse 12 or 14 hours and apply to the face 2 or 3 times a day, for a few weeks. This application is useful in removing that roughness of the skin which generally succeeds pimples.

VIRGIN MILK. — 1. Dissolve in spirits of wine, gum benzoin and styrax, equal parts; the spirits become a reddish tincture, and exhale a fragrant smell. Some add a little balm of Gilead. Drop a few drops into a glass of clear water, and by stirring the water, it instantly changes milky.— 2. Simple tincture of benzoin, 2 drs.; orange flower water, 8 oz.; vary it by using rose or elder flower water.

WRINKLES, Washes for. — 1. Second water of barley, 1 pt.; strain through a piece of fine linen; add 1 doz. drops balm of Mecca and shake until the water assumes a whitish or turgid appearance. Before applying, wash the face with soft water. —2. 2 oz. juice of onions; 2 oz. white lily; 2 oz. Narbonne honey; 1 oz. white wax; melt in a new earthen pipkin and continue stirring briskly until cold. Apply on going to bed, and allow to remain on till morning. The onion juice may be omitted. —3. Put pieces of court plaster on the face where the wrinkles are inclined to come, just before going to bed, and remove in the morning. Warm water should always be used to wash the face, as it prevents wrinkles. — 4. Sleep with face done up in a mixture of the whites of eggs, sweet almond oil, and alum. — 5. Wrinkles are less apparent under a kind of varnish containing 36 gr. turpentine in 3 dr. alcohol, allowed to dry on the face. — 6. To 1 fl. oz. tincture gum benzoin add 7 fl. oz. distilled rose water and ½ oz. glycerine. Bathe face, neck and hands with it at night, letting it dry on. Wash off in the morning with a very little pure white Castile soap and soft water. If the water is hard, add a little dissolved borax.

TEETH.

REMARKS. — Sound teeth not only promote digestion, but keep the breath sweet and pure. They are bones thinly covered with a fine enamel, which is more or less substantial in different persons. Whenever this enamel is worn or eaten through in any way, the teeth cannot long remain sound. They are to be cleaned, but with precaution, for if the enamel is worn off faster by cleaning the outside than nature supplies it within, the teeth will probably suffer more than by neglect. Many persons injure their teeth by too much scouring. Water used for the teeth should be lukewarm, as hot and cold water are injurious. The brush should be well made, with the bristles very thick but not too stiff. Some teeth can bear harder brushes than others; but the hardness or softness should be a matter of personal taste; whatever it is, let it be rinsed, well dried, and kept uncovered; put away wet, and shut up, they become unpleasant. Straight brushes are impracticable; curved ones with a tuft end, bud shaped or convex, are best. The use of floss silk between the teeth ought to be recommended; also the quill toothpick; those formed of gold, silver, or any metal, should never be used. The mouth should be rinsed and the

teeth brushed with clear warm water both before and after the use of any dentifrice, and after eating, if it is only a cracker. Crosswise brushing is not wise; the upper teeth should be brushed down, and the lower ones up. The teeth are greatly influenced by what is eaten and drunk. All things that are very hot or very cold are bad. When animal food or vegetables are eaten, cleanse the teeth immediately; the first is apt to leave behind it a rancid acrimony, and the other an acidity. Clean them before retiring to rest. With smokers, this practice is obligatory. The decaying of teeth is partly due to chemical decomposition of the food lodged between them. When there is joined to this an unhealthy or weak condition of the ivory, and also the continual pressure of the adjacent teeth, decay is sure to take place. When a cavity is actually developed, the sooner it is filled the better. When it is small and has not opened into the natural cavity of the tooth, gold leaf is the best material. When this cavity is exposed, gold is useless under ordinary circumstances. Mineral as well as vegetable acids act on the teeth. Grapes in 48 hours render the enamel of a chalky consistence. Vegetable substances are inert till fermentation takes place, and acetic acid is formed. Sugar has no deleterious effect only in the state of acetous fermentation. Animal substances exert no injurious effect until putrefaction is far advanced. Dentifrices often put a beautiful pearly surface on the teeth at the expense of the enamel. The solid ingredients used in them should not be so hard or gritty as to injure the enamel of the teeth; nor so soft or adhesive as to adhere to the gums, after rinsing the mouth.

Pastes and Pastils.

These consist, for the most part, of the ordinary substances used as dentifrices, reduced to the state of a very fine powder, and mixed with sufficient honey, sugar, or capillaire, to give them the required consistence. Honey of roses is often used for this purpose, with some agreeable perfume at will. A little eau de Cologne, or rectified spirit, is a useful addition.

CAMPHOR PASTE. — 1 oz. sal ammoniac, 4 dr camphor; powder, and mix with sufficient honey to make a smooth paste; triturate until entirely smooth.

CARBON PASTE.—Chippings of turkey stone, cylinder charcoal and prepared chalk, each, 2 oz.; cochineal and cloves, each, 1 dr.; honey, 5 oz.; eau de Cologne, q. s. Put in pots until the next day, and press ve from the air.

CHARCOAL PASTE. — 1. Chlorate of potassa, 1 dr.; mint water, 1 fl. oz.; triturate until dissolved; add of powdered charcoal, 2 oz.; honey, 1 oz.— 2. Suds of Castile soap and spirits of camphor, equal parts; make into a thick paste with pulverized chalk and charcoal, equal parts.

CINNAMON PASTE. — 1. Cinnamon, 2 oz.; cloves, 6 dr.; fresh lemon peel, 1½ oz.; dried rose petals, 1 oz.; scurvy grass, 8 oz.; spirits, 3 lbs.; macerate 24 hours, and distil in a water bath.— 2. Cinnamon, cloves and nutmeg, each, 1 ar; vanilla, ½ dr.; camphor, 10 gr.; tincture of pellitory, 2 fl. oz.; brandy or proof spirit, ½ pt.

CORAL PASTE. — 1. Prepared coral, 8 oz.; cochineal, 1 oz.; cinnamon, 2 oz.; alum, 3 dr.; honey, 20 oz.; water, 1 oz.; triturate the cochineal with the alum and water; add the honey, then the coral and cinnamon; leave the whole till the effervescence has subsided; then rub it with a few drops of oil of cloves, or other aromatic oil, and put it into covered pots. — 2. Prepared coral, 8 oz.; cuttle-fish bone, 4 oz.; mastic, 2 oz.; cochineal, ½ oz.; honey, ¾ lb.; essence of ambergris, 1 fl. dr.; oil of cloves, ½ fl. dr., dissolved in rectified spirit, 1 fl. oz.

FLORILINE. — Prepared chalk, 5 dr.; starch powder, 2½ dr.; glycerine, 2 dr.; pellitory tincture, ¾ dr.; peppermint oil, 10 drops; and water q. s., colored with Florentine lac.

HONEY PASTE. — 1. 1 oz. myrrh in fine powder; a little powdered green sage; 2 spoonfuls white honey. — 2. 2 sc. myrrh, in fine powder; 1 sc. juniper gum; 10 gr. rock alum; mix in honey. Apply frequently to the decayed teeth.

MAGIC PASTE. — White marble dust, 4 oz.; pumice stone (in impalpable powder), 3 oz.; rose pink, 1 oz.; honey, ½ lb.; otto of roses, 15 drops; whitens the teeth, but should not be used too freely, nor too frequently.

METGES' PASTE. — Metges' tooth powder, 48 oz.; Narbonne honey, 32 oz.; syrup, 64 oz.; cochineal, 1 oz.; alum, 1 oz.; water, 4 oz.; triturate the cochineal and alum with the water and strain; add the honey, then the syrup; lastly the powder.

MOUTH PASTILS. — Dry compounds for perfuming or correcting the breath. — 1. Extract of liquorice, 3 oz.; oil of cloves, 1½ dr.; oil of cinnamon, 15 drops; mix, and divide into 1 gr. pills, and silver them. — 2. Chocolate powder and ground coffee, of each, 1½ oz.; prepared charcoal, 1 oz.; sugar, 1 oz.; vanilla (pulverized with the sugar), 1 oz.; enough mucilage. Make into lozenges of any form, of which 6 to 8 may be used daily to disinfect the breath. — 3. (*Bologna Catechu.*) Extract of liquorice, 3 oz.; water, 3 oz.; dissolve by heat in a water bath, and add catechu, 1 oz.; gum Arabic, ½ oz. Evaporate to the consistence of an extract, and add (in powder) ½ dr., each, mastic, cascarilla, charcoal and orris; remove from the fire, and add oil of peppermint, ½ dr.; essence of ambergris and essence of musk, each, 5 drops; roll it flat on an oiled marble slab, and cut into small lozenges. Used by smokers. — 4. Catechu, 7 dr.; orris powder, 40 gr.; sugar, 3 oz.; oil of rosemary (or of peppermint, cloves, or cinnamon), 4 drops. Make as before.

PELLETIER'S ODONTINE. — Magnesia or pulverized sepia-bone and butter of cacao, aromatised with some essential oil.

ROSEATE PASTE —Chalk, 8 oz.; myrrh and rhatany root, each, 2 oz., orris root, 1 oz.; honey of roses, q. s. to mix.

ROSEMARY PASTE. — Levigated bole, 4 oz.; myrrh, 1 oz.; oil of rosemary, 2 dr.; dissolved in 1 oz. rectified spirit; clarified honey, q. s.

ROSE PASTE. — Cuttle-fish bone, 1 oz.; prepared chalk, 2 oz., cochineal, ½ dr.; honey of roses, 5 oz.; otto of roses, 6 drops.

SALINE PASTE. — Sulphate of potash, 1 oz.; bay salt, ½ oz.; clarified honey, q. s.; eau de Cologne, 2 dr.

SPANISH PASTE. — Castile soap, in fine powder and cuttle-fish bone, each, 2 oz.; honey of roses, 5 oz.

VANILLA PASTE. — 1. Charcoal, 1 oz.; white honey, 1 oz.; vanilla sugar, 1 oz.: Peruvian bark, ½ oz.; and a few drops essential oil. — 2. Red cinchona bark, 2 dr.; vanilla, 1 dr.; cloves., ½ dr. (the last two reduced to powder by trituration with). white sugar, 1 oz.; cuttle-fish bone and marble dust, each, ½ oz.; syrup of saffron, q. s.

VIOLET PASTE.—Prepared chalk and cuttle-fish bone, each, 3 oz.; powdered white sugar, 2 oz.; orris root, 1 oz.; smalts, ½ oz.; syrup of violets, q. s. to mix.

WHITE PASTE. — Orris, sal ammoniac, cream of tartar, each, 2 oz.; tinctures cinnamon and vanilla, each, ½ oz.; oil of cloves, 60 drops; clarified honey and syrup to form a paste. — 2. Precipitated chalk, 4 oz.; sulphate of potash, ½ oz.; prepared honey sufficient to form a paste; add a few drops of otto of roses or oil of cinnamon.

Powders.

REMARKS.—The most useful form of dentifrices is that of powder, but liquids and electuaries are also employed. Care must be taken that the dry ingredients be pulverized, and the harder ones reduced to impalpable powder either by levigation or elutriation. The mixture of the ingredients must be complete; which is most readily effected by stirring them well together to a homogeneous powder, then passing it through a fine sieve. Those which contain volatile substances should be preserved in closely-corked wide-mouth bottles, and those containing acidulous or gritty matter should not be frequently used.

AMERICAN.—Coral, cuttle-fish bone, dragon's blood, each, 8 oz.; burnt alum and red sanders, each, 4 oz.; orris, 8 oz.; cloves and cinnamon, each, ½ oz.; vanilla, 2 dr.; rosewood, ½ oz.; rose pink, 8 oz.

ANTISCORBUTIC.—Extract of rhatany, ½ oz.; prepared charcoal, 2 oz.; cinnamon, ¼ oz.; cloves, ¼ oz.

ANTISEPTIC. — Prepared chalk, 2 oz.; dry chloride of lime, 10 gr.; oil of cloves, 5 drops. Mix.

AROMATIC. — 1. Finely powdered prepared chalk, 2 dr.; pure starch, 2 dr.; myrrh, 2 dr.; ginger, ½ dr.; cuttle-fish bone, 2 dr.; flower of lavender and sugar at pleasure. Mix. — 2. Calamus, 4 dr.; charcoal, 1 dr.; soap, 1 dr.; oil of cloves, 12 drops.

ASIATIC.—1. Prepared coral, 4 oz.; Venetian red, 3 dr.; ochre, 5 dr.; pumice, 5 dr.; musk, 1 gr. Mix. — 2. Bole, 3 parts; chalk, 2 parts; ochre, 1 part; pumice, 1 part; musk, to scent.

BARK. — 1. Charcoal, 4 parts; yellow bark, 1 part. — 2. Red bark and Armenian bole, each, 1 oz.; powdered cinnamon and bicarbonate of soda, each, ½ oz.; oil of cinnamon, 2 or 3 drops.

BEALL'S.—Prepared chalk, 12 oz.; powdered orris root, 2 oz.; bicarbonate of soda, ½ oz.; soft part of cuttle-fish bone, 1 oz.; add a sufficient quantity of rose pink to color it, and mix well.

CADET'S.—Sugar, 1 oz.; charcoal, 1 oz.; Peruvian bark, ½ oz.; cream of tartar, 1½ dr.; cinnamon, 24 gr.

CAMPHORATED. — 1. Camphor (pulverized by the aid of a few drops of spirit), 1 oz.; prepared or precipitated chalk, 3 oz. — 2. Camphor, 1 oz.; precipitated chalk, 2 oz.; cuttle-fish bone, ½ oz.; myrrh, 2 dr.; borax, 2 dr.; lake or rose pink, 1 dr., or q. s. — 3. Prepared chalk, 8 oz.; powdered cuttle-fish bone, 4 oz.; camphor, 1 dr.; oil of cloves, 1 dr. Dissolve the camphor with alcohol; add the remaining ingredients, and mix.

CARABELLI'S.—Cuttle-fish bone, 1½ oz.; prepared oyster shells, 1½ oz.; cinnamon, orris, and lime tree charcoal, each, 3 dr.; vanilla, 10 gr.

CARBONIC.—1. Willow charcoal, 4 oz.; cinchona bark, 4 oz.; cloves, ½ dr. — 2. Charcoal, 8 oz.; cinnamon, 4 oz.; sugar, 8 oz.; oil of mint, ½ oz.; oil of cinnamon, ¼ oz.; tincture of ambergris, ½ dr.

CARTWRIGHT'S.—Prepared chalk, 1 oz.; orris, 1 oz.; Castile soap, ½ dr.

CHALK.—1. 2 oz. prepared chalk; ½ oz., each, pulverized borax and orris root; ¼ oz. cassia powder. — 2. Cuttle-fish bone and prepared chalk, each, 2 oz.; oil of cloves, 20 drops. — 3. Precipitated chalk, 4 oz.; finely powdered charcoal, ½ oz.; powdered orris root, 2 oz.; otto of roses, 10 drops; oil of sandal wood, 5 drops.

CHARCOAL.—The charcoal made in iron cylinders, from willow, is to be preferred, reduced to an impalpable powder, and kept from the air. Charcoal of areca nut is highly commended. That of the shells of cocoa nuts is said to be used for the same purpose. 1. Prepared charcoal, 1 oz.; sugar, 1 oz.; oil of cloves, 3 drops. Mix. — 2. Powdered charcoal and white sugar, 1 oz. each; Peruvian bark, ½ oz.; cream of tartar, 1½ dr.; carnella, 24 gr. Rub together and pulverize in a mortar. — 3. Powdered cuttle-fish, 2 dr.; powdered myrrh, ½ dr.; carbonate of soda, 1 dr.; charcoal powder, 1 oz. Use freely, and allow to remain some minutes in the mouth.

CIRCASSIAN. — Prepared hartshorn, 2 oz.; sulphate of potash, 2 oz.; cuttle-fish bone, 8 oz.; orris, 4 oz.; yellow sandal wood, 1 oz.; rose pink, 3 oz.; oil of rhodium, 30 drops. Mix the ingredients, previously reduced to powder, and add the oil of rhodium.

COCOA. — Pulverized French chalk, 1 lb.; lily white, 1 lb.; white earth, 1 lb.; pulverized sugar, ½ lb.; powdered cocoa soap, ½ lb.; oil of wintergreen, ¼ oz.; oil of rose, ½ dr.; oil of cloves, ½ dr.; oil of sassafras, ¼ dr. Mix, and pulverize thoroughly.

CORAL. — Red coral, red bole and cuttle-fish bone, each, 3 oz.; dragon's blood, 1½ oz.; cinnamon, ¾ oz.; cochineal, 3 dr.; cloves, 1 dr.; bitartrate of potassa, 4½ oz. Reduce separately to fine powder and mix.

DESCHAMP'S.—Powdered talc, 4 oz.; bicarbonate of soda, 1 oz.; carmine, 6 gr.; oil of mint, 12 or 15 drops.

DETERGENT. — Bicarbonate of soda, 1 oz.; powdered Castile soap, ½ oz.; sulphate of potash, ½ oz.; sugar of milk, ½ oz.; orris root, 4 oz.; oil of bitter almonds, 4 drops.

FARINA'S. — Cuttle-fish bone, 2 lbs.; pulverized orris root, 2 lbs.; pulverized white sugar, ½ lb.; otto of rosemary, 4 dr.; otto of orange peel, 2 dr.; otto of lemon, 2 dr.; otto of neroli, ½ dr.; otto of bergamot, 2 dr. Mix, and pass through a silk sieve.

FLORENTINE. — Prepared shells, 14 dr.; orris, 6 dr.; cream of tartar, 3 dr.; lake to color.

FRENCH. — Peruvian bark, burnt crust of bread, and sugar in equal proportions.

GALVANIC.—1. Triturate 2 leaves of gold leaf, and 3 of silver, with 2 dr. sulphate of potash and 1 dr. alum; add white sugar, 2 dr.; common salt, 1 dr.; pellitory of Spain, ½ dr.; prepared hartshorn, 1 oz.; sulphate of quinine, 10 gr.; mix. Color with finest smalts, rose, pink, or lake. — 2. 2 leaves of gold; 2 of silver; alum, 3 dr.; salt, 1½ dr.; white sugar, 1½ dr.; pepper, 15 gr.; opium, 5 gr.; coral, 3 dr.; Peruvian bark, 3 dr. Grind the gold and silver with the salt and alum, and add the latter ingredients. For the double galvanic tooth powder, put twice the above quantities of gold, silver, alum, salt, pepper and opium.

GERMAN.—Peruvian bark, 6 dr.; red sanders, 2 dr.; oil of cloves and of bergamot, 3 drops.

GROSVENOR'S.—Red coral, 3 lbs.; prepared oyster shells, 2½ lbs.; orris powder, ½ lb.; oil of rhodium, 25 drops. Rose pink is now substituted for coral.

HEMET'S.—Cuttle-fish bone, 6 oz.; cream of tartar, 1 oz.; orris root, ½ oz.

JAMET'S. — Orris, 16 oz.; magnesia, 4 oz.; pumice stone, 8 oz.; cuttle-fish bone, 8 oz.; sulphate of quinine, 4 oz.; cascarilla, 1 oz.; sugar of milk, 16 oz.; oil of mint, 1 oz.; oil of cinnamon, 2 dr.; oil of neroli, 1 dr.; essence of ambergris, 1 dr.

KEMMERER'S. — Wood soot, 1½ oz.; strawberry root, ½ oz.; add a few drops of cau de cologne.

LAVENDER.—Crimson lake, 1 dr.; Chinese or Turnbull's blue, 1 sc.; mix, and add bicarbonate of soda, ½ oz.; cuttle-fish bone, 2 oz.; precipitated chalk, 6 oz.; oil of lavender, 8 drops.

LEFOULON'S. — Scurvy grass, horseradish, guaiacum, cinchona, mint, pellitory root, calamus, rhatany, of each, equal quantities; reduce to an impalpable powder; a little calcined magnesia is sometimes added.

LEMON. — Powdered arrowroot, 1 lb.; powdered orris root, 3 oz.; oil of lemon, 20 drops; oil of cloves, 10 drops; oil of bergamot, 12 drops. Rub the oils with the powders until thoroughly mixed; add indigo to strike a violet tint.

METGE'S. — Prepared chalk, 3½ lbs.; lake or rose pink, 1 lb.; orris, 2 lbs.; cream of tartar, 12 oz.; levigated pumice, 1 oz.; sugar, 9 oz.; oil of cloves, 1 dr.

MIALHE'S.—Sugar of milk, 3 oz.; pure tannin, 3 dr.; lake, 1 dr.; oil of mint, 8 drops; oil of aniseed, 8 drops; neroli, 4 drops.

MYRRH. — 1. Myrrh, ½ oz.; cuttle-fish bone, prepared chalk, orris, each, 1 oz.; cassia, ½ oz.; mix.—2 Bole, 1 oz.; myrrh, bark and orris, each, ½ oz.; mix.

PALMER'S.—Prepared chalk, 1 lb.; camphor, 1 oz.; orris, 1 lb.; cuttle fish-bone, 4 oz.; rose pink, 1 oz.

PARISIAN.—Pulverized cream tartar, 2½ lbs.; Pulverized alum, 1 lb.; pulverized cuttle-fish bone, 1 lb.; pulverized carbonate of magnesia, ½ lb.; pulverized cochineal, 3 oz.; pulverized cassia, ¾ oz.; pulverized cloves, 1½ oz.; oil of geranium, ½ dr.; oil peppermint, 1¼ dr.; oil bergamot, ½ dr.; mix.

PEARL. — Heavy carbonate of magnesia or precipitated chalk, 1 lb.; finest smalts, 3 dr.; essence de petit grain, ½ dr.

QUININE.—1. Sulphate of quinine, ½ dr.; pulverized orris root, 4 oz.; pulverized starch, 5 oz.; pulverized chalk, prepared, ½ lb.; pulverize fine and mix thoroughly.—2. Sulphate of quinine, 4 gr.; prepared red coral, 1 oz.; myrrh, 1 sc. For the coral may be substituted levigated bole, 2 dr.; precipitated chalk, 6 dr.

RHATANY. — Rhatany root, 2 oz.; cuttle-fish bone, 4 oz.; prepared chalk, 8 oz.; borax, 1 dr.

ROSE. — 1. Pulverized corn starch, 2½ lbs.; pulverized orris root, ½ lb.; terra alba, 2 lbs.; carbonate of magnesia, ½ lb.; French chalk, ½ lb.; oil of cloves, ½ dr.; oil of rose, 1 dr.; oil of bergamot, ½ dr.; mix and pulverize thoroughly. — 2. precipitated chalk, 6 oz.; cuttle-fish bone, 3 oz.; bicarbonate of soda, 2 oz.; red lake, ½ oz.; otto roses, 20 drops.

RUSSIAN.—Peruvian bark, 2 oz.; orris root, 1 oz.; sal ammoniac, ½ oz.; catechu, 6 dr.; oil of cloves, 6 or 8 drops.

TONIC.—1. 1½ dr. powder of myrrh; 3 dr. Peruvian bark, finely powdered; 10 drops oil of cinnamon; 10 drops oil of cloves; 1 oz. prepared chalk; 2 dr. orris powder; 1 oz. rose pink; mix well together and keep close. — 2. Fine powder of Florentine iris, 6 dr.; ditto pure starch, 3 dr.; quinine, 2 dr.; ditto hyoscyamus, 1 dr.; sugar to the taste; and perfume with otto of roses; carmine may be used to color it.

VIOLET. — Precipitated chalk, 6 oz.; cuttle-fish-bone, 3 oz.; rose pink, 2½ oz.; orris root, 1½ oz.; ess. violets, 1½ fl. dr.; indigo to strike a violet, a sufficient quantity.

WASHES.

ANATHERIN BALSAM.—1. Red sandal wood, 20 parts; guaiacum wood, 10 parts; myrrh, 25 parts; cloves, 15 parts; cinnamon 5 parts; oils of cloves and cinnamon, of each, ⅔ part; spirit, 90 per cent., 1450 parts; rose water, 725 parts; digest and filter. — 2. Myrrh, 1 part; guaiacum wood, 4 parts; saltpetre, 1 part; to be macerated for a night with corn brandy, 120 parts; spirit of cochlearia, 180 parts; distil of this 240 parts, in which are to be digested for 14 days garden rue, cochlearia, rose leaves, black mustard, horseradish, pellitory root, cinchona bark, club moss, sage vetiver and alkanet root, of each, 1 part; strain and filter, and to each 120 parts of the filtrate add 1 part of spirit of nitrous ether.

ANTISCORBUTIC ELIXIR. — Cinchona, 3 oz.; guaiacum, 5 oz.; pellitory, 3 oz.; orange peel, 2 dr.; cloves 5 dr.; saffron, ½ dr.; benzoin, 2 dr.; spirits of wine or brandy, 32 oz.; digest and filter.

ASTRINGENT.—1. Borax, alum, bay salt, of each 1 dr.; spirit of camphor, tincture of myrrh, of each 1 oz.; spirit of scurvy-grass (or of horseradish), 4 oz.; tincture of rhatany, 2 oz.; mix, and shake occasionally for a day or two, then filter. A teaspoonful in a wineglassful of water, to rinse the mouth after cleaning the teeth, or at any other time.—2. Tannin, 1 dr.; rose-water, 4 oz.; spirit of wine, 2 oz.; spirit of scurvy-grass (or of horseradish), 2 oz.; essence of bitter almonds, a few drops.

BALM OF A THOUSAND FLOWERS.—White Castile soap, 2 oz.; honey, 4 oz.; water, 12 oz.; alcohol, 4 oz.; melt the Castile soap and the honey in the alcohol and water with a gentle heat, and then scent with wintergreen, sassafras and rose.

BORAX. — Dissolve 2 oz. of borax in 3 pts. of hot rain water; add 1 tablespoonful of spirits of camphor stirred into 1 tablespoonful of pulverized sugar, to prevent it from curdling; before quite cold, add 1 oz. tincture of myrrh.

CARBOLIC ACID.—Spirit of wine, 2 dr.; carbolic acid, 20 drops; distilled water, 6 oz.; mix. Use the wash after cleansing the teeth.

CHELTENHAM.—Camphor, 4½ oz.; myrrh, 2 oz.; bark, 5 oz.; rectified spirit, 36 fluid oz.; distilled water, 8 oz.

CHLORINATED SODA. — Liquid chlorinated soda, 1 oz.; distilled water, 19 oz.; mix; 1 teaspoonful in a glass of water.

DETERGENT.—Alum, powdered, 30 gr.; simple syrup, 1 oz.; rose water, 3 oz., and mix. Should the mouth be very sore, dilute with water at first, and use pure afterwards.

EAU DE BOTTOT.—Aniseed, 4 oz.; cinnamon, 1 oz.; cochineal, 2 dr.; oil of mint, 2 dr.; spirit of wine or brandy, 8 lbs.; macerate 8 days, and filter. —2. Tincture of cedar wood, 1 pt.; tincture of myrrh, 1 oz.; mixed with the following essential oils: of peppermint, ½ dr.; of spearmint, ½ dr.; of cloves, 10 drops; of roses, 10 drops.

EAU DENTIFRICE DES CORDILLIERES.—360 parts strong spirits; 330 parts water; 2½ parts extract of red or yellow cinchona; 1 part of oil of cinnamon; 2 parts oil of cloves; 3 parts oil of anise; 5 parts oil of peppermint.

EAU DENTIFRICE DE MALLARD.—Star anise, common anise, cinnamon, cloves, of each, 8 parts; guaiacum wood, 10 parts; brown cinchona, 6 parts; rose leaves, 5 parts; nutmegs, 2 parts, are placed in a displacement apparatus, and percolated with 3 parts cochineal; 12 to 15 parts water, 1,000 parts spirits of wine, sp. gr. 860. The tincture is displaced with water, and 1,000 parts are mixed with 7 parts of a mixture of peppermint oil, spirit of scurvy-grass, and tinct. benzoin, allowed to stand and filtered.

EAU DENTIFRICE DE STAHL. — Spirit of wine or brandy, 2 gal.; rose water, 3 qts.; pellitory, 5 oz.; cypress root, 3 oz.; tormentil, 3 oz.; balsam of Peru, 3 oz.; cinnamon, 5 dr.; goat's rue, 1 oz.; rhatany, 1 oz.; macerate for 6 days, shaking occasionally; let it rest for 24 hours, and pour off the clear; add to the clear liquor, oil of mint, 1½ dr.; cochineal, 4 dr.; in 3 or 4 days, filter.

EXTRACT OF PELLITORY. — Take of pellitory root, 5 oz.; cinchona, 1 oz.; benzoin, 1½ dr.; essence of peppermint, 3 dr.; brandy, 1 quart.

FRENCH ELIXIR.—Rose water, 16 oz.; spirits of scurvy-grass, 2 oz.; tincture of galbanum, 1 oz.; color with cochineal.

GREENOUGH'S.—Bitter almonds, 2 oz.; Brazil wood, ½ oz.; cinnamon, ½ oz.; orris root, ¼ oz.; cochineal, alum, salt of sorrel, each, 1 dr.; spirit of wine, 32 fluid oz.; spirit of scurvy-grass, 1 oz.

HUDSON'S PRESERVATIVE. — Tincture of myrrh, tincture of bark, cinnamon water, of each, 3 oz.; arquebusade water, 1 oz.; powdered gum, ½ oz.

LEFANDINIERE'S ELIXIR.—Rasped guaiacum wood, ½ oz.; pellitory, 1 dr.; nutmegs, 1 dr.; cloves, ½ oz.; oil of rosemary, 10 drops; oil of bergamot, 4 drops; brandy, 1 pint; macerate for a fortnight, and filter.

LEFOULON'S ELIXIR.—Fresh roots of horseradish, fresh leaves of scurvy-grass and of mint, of each, 6 dr.; guaiacum, cinchona, pellitory, calamus and rhatany, each, 5 dr.; proof spirit, 1 quart; macerate for 16 days, and strain.

LEMON.—Juice of ½ a lemon; a spoonful of rough claret or port wine; 10 gr. of sulphate of quinine; a few drops of eau de Cologne or oil bergamot; mix and keep in a well-stopped vial for use.

ODONTALGIC ELIXIR.—Pellitory root, 2 oz.; simple spirits of lavender, 16 oz.; muriate of ammonia, ½ dr.; digest for 24 hours, and then filter.

PRESERVATIVE TINCTURE.—4 dr. camphor; 1 oz. tincture of myrrh; 1 oz. tincture of bark, and 1 oz. of rectified spirits of wine; mix, and put 30 or 40 drops into a wineglassful of water.

QUILLAYA.—Star anise seed, 1 oz.; quillaya bark, 3 oz.; cloves, 2 dr.; cinnamon, 2 dr.; oil peppermint, 12 minims; cudbear, 1 dr.; diluted alcohol, 28 oz.; exhaust by maceration or displacement, and filter.

ROSE ELIXIR.—Cloves, 2 dr.; cinnamon, 6 oz.; ginger, 4 oz.; spirits of wine, 5 pints; oil of orange, 2 dr.; otto of roses, 30 drops; essence peppermint, 2 oz.; mix; digest 14 days and then filter.

RUSPINI'S TINCTURE.—Orris, 8 oz.; cloves, 1 oz.; spirit, 32 fluid oz.; essence of ambergris, 1 oz. (or ambergris 1 scruple); macerate 14 days, and filter.

SOZODONT. — Carbonate of potassa, ½ oz.; honey, 4 oz.; alcohol, 2 oz.; water, 10 oz.; oil wintergreen and oil rose sufficient to flavor.

TINCTURE OF MYRRH.—1. Turkey myrrh, 3 oz.; eau de Cologne, 1 quart; digest for 7 days, and filter.—2. Borax, 1 oz.; shellac, ½ oz.; water, 8 oz.; boil together to 4 oz., and add spirit of scurvy-grass, 1 pint; camphor, ½ oz.; myrrh, 2 oz.; digest and filter.—3. Mix ½ pint of Jamaica spirits, ½ teaspoonful each of powdered alum and saltpetre pulverized, and 1 oz. pulverized myrrh. — 4. Tincture myrrh, ½ oz.; tincture of Peruvian bark, 2 oz.; a few drops in water when brushing the teeth. — 5. Balsam of Peru, 2 dr.; camphor, ½ dr.; essence of musk and liquor of ammonia, of each, ½ fluid dr.; tincture of myrrh, 3 fluid dr.; spirit of horseradish, 1½ fluid oz. To sweeten and perfume the breath, a teaspoonful

in ½ wineglassful of tepid water to rinse the mouth. — 6. (*Borated Tincture of Myrrh.*) Myrrh, 1 lb.; eau de Cologne, 16 lbs.; borax, 1 lb.; distilled water, 3 lbs.; syrup, 3 lbs.; essence (or tincture) of roses, 6 dr.; rhatany root, 4 oz.; digest for 10 or 12 days and filter. — 7. Borax, 1 oz.; shellac, ½ oz.; myrrh, 2 oz.; spirit of camphor, 2 oz.; honey of roses, 2 oz.; rectified spirit, 1 pt.; Cologne essence, 2 dr.; orange flower or rose water, 4 oz.; digest for a few days in a warm place, shaking occasionally, and then filter.

AGRICULTURE.

FARM OPERATIONS.

SOILS.

REMARKS.—The kind of trees indigenous to a soil should guide in selecting land. Wherever the hard wood trees flourish, a rich soil and healthy climate are found. Where the sugar-maple, beech, white and black oaks grow, wheat, oats, and similar small grains, will give remunerative crops. Willows, poplars, birch, red maple, black ash, and elms, indicate a wet soil, and while in some instances it may be made available for farming purposes by drainage, it is usually more valuable for grass than grain or fruits. The hickories, buckeyes and black-walnut indicates a strong, rich soil, rather hard to work, but of great fertility when once brought under thorough cultivation. The chestnut takes to the light and rather thin soils, easily subdued and tilled, which, under favorable circumstances, produce good crops of corn, rye and vegetables; but they are not rich enough to produce wheat, oats, or fruit trees in general, without an abundant application of the strongest fertilizers.

ANALYSIS.—Fit a cork into one end of a glass tube, 3 ft. long and $\frac{3}{4}$ in. in diameter; then half fill it with clear water, and pour into it a similar quantity of water in which has been mixed as much of the soil to be examined, as will fill about 6 in. of the tube; place the tube in a vertical position, and let it stand for about 1 hour. An examination will then show the earths deposited in the order of sand, clay, and humus; and the proportion of the latter will indicate the quality of the soil.

CLASSIFICATION.—Soils are classified according to their chief ingredients, as loamy, clayey, sandy, chalky, and peaty soils. Of these the first is the best for most purposes, but the others may be improved by the addition of the mineral constituents of which they are deficient. Sand and lime or chalk are the proper additions to clayey soils, and clay-gypsum, or loam, to sandy and gravelly ones. Clayey soils are expensive to bring into a fertile state; but when well manured, they will yield immense crops.

COMPOSITION.—The principal mineral substances which enter into the composition of rocks and soils are silica—found in quartz, flint, and sand; alumina—a leading ingredient in the composition of clays, giving them that softness, plasticity, and adhesiveness for which they are distinguished; lime—constituting the numerous varieties of limestone, marl, chalk and magnesia—existing in various states of combination with acids and other earths, and found in various mineral springs. The other important constituent of soil is vegetable mold; the three most important items of plant food contained in this are nitrogen, phosphoric acid and potash; these are essential, and if not present should be supplied by the farmer.

FERTILITY.—The most fertile soils are those which are loose in their texture and neither so light as to become too easily dry, nor heavy enough to be too wet in rainy weather. Alluvial soils are the deposits of sand, clay, or gravel, made by river action; they are the most complex and the most widely fertile, as containing a greater variety of the elements needed in the formation of different plants. Fertility is largely dependent upon the amount of nitrogen in the soil; this is stored up only by previous generations of plants. Any severe cropping—in which more nitrogen is removed from the soil in the crop than is formed and stored up in the soil during the same period—will sooner or later bring the most fertile soil to a state of exhaustion. In order to maintain and increase their fertility, and render soils fit for cultivation, ascertain the composition, and add to, or subtract from the ingredients in which it is deficient, or with which it superabounds. A soil of good apparent texture, or peats, containing sulphate of iron, or any acid matter, will be sterile; but this may be remedied by a top-dressing with lime, which converts the sulphate into manure. If there be an excess of limy matter in the soil it may be improved by the application of sand or clay. Soils too abundant in sand are benefitted by a dressing of clay, marl, or vegetable matter.

Light soils are improved by using peat, and peats by a dressing of sand; though the former is in its nature only a temporary improvement.

CLEARING,

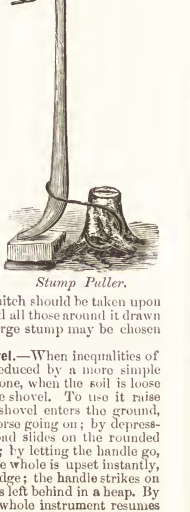
PARING AND BURNING.—Pare off the turf to a depth of 2 or 3 in., generally by a breast plow, worked by hand, or by a turf-paring plow, drawn by a horse; allow it to dry, and then burn in heaps. The result is a mixture of burned earth, charred vegetable fibre, and the ashes of that part which is entirely consumed, thus producing a powerful manure. Insects are also killed by the process. To ascertain whether a soil will be improved by paring and burning, a few sods may be taken and exposed to heat in a closely covered iron pot; the heat should not be so intense as to produce light, but should be kept up for a considerable time, till the sods are consumed. If the ashes are red, and the whole is a fine powder, with particles of charcoal in it, the soil from which it was taken may be safely pared and burned, especially if it forms a mud with water, and the earth is not readily deposited; but if it feels gritty, lets the water readily through, and soon settles when mixed with it, burning will not be advantageous.

STONES, To Remove.—1. Heat the stone to a high degree by means of a fierce fire applied to one part of it only, which will cause it to expand; when the stone has been thus made intensely hot, pour water upon it to make it crack, the effect being increased by powerful blows given with very heavy hammers.—2. Pierce the stone in the direction of its veins, and introduce into the hole a cleft cylinder of iron; then drive a wedge of the same metal in between the two halves of the cylinder.—3. A quantity of water may, during the winter season, be introduced into a hole made in the stone to a sufficient depth, the aperture to be then closed with a stopper closely driven into it. The water contained in this hole, expanding as it freezes, exerts a force sufficient to break in pieces the strongest stone.—4. Very large stones must be blasted. For this work two iron bars are needed—steel bars are lighter to handle and do not cost much more than iron—a long wooden lever, a cable and other chains, and a stone boat. The cross pieces should be fastened to the planks with iron bolts, three in each end of each plank, and for moving large stones, where the ground is not rough, no side pieces are needed, as such stones can be more easily loaded and taken off, and the boat will not be so liable to damage. For raising the larger stones use a rock lifter, which can be operated by two men, or one if necessary; it is simple in construction and easily handled; it will raise stones as large as two teams can draw. When the stones are raised to the proper height put under the stone boat and draw them at once, if possible, to the location desired.—5. When stones cannot be used for any valuable purpose, they may be sunk into the ground. For this purpose a trench, deeper than the stone itself, is dug all around it, and it is laid in the hollow thus formed. This must be greater than the stone, and so contrived that the stone when turned over may not present its edges to the ground.

STUMPS, To Blow Out.—The cheapest and most effective way to get rid of stumps in a field is to blast them out with cartridges of giant powder. This is put up in cartridges about 10 in. long by 1½ in. in diameter, and these can be cut into pieces of the size required with a knife. A piece 2 in. long is sufficient to throw out a good sized stump. A hole is punched under the stump with a crowbar; the explosive, with the proper fuse and fulminating cap attached, is put in the hole; water is poured in as tamping, and the fuse is fired. The explosion throws the stump out in several pieces, leaving the hole to be filled up afterwards.

STUMPS, To Burn.—In the autumn or early winter bore a hole 1 or 2 in. in diameter, according to the girth of the stump, and about 18 in. deep; put into it 1 or 2 oz. of saltpeter; fill the hole with water and plug it close; in the ensuing spring take out the plug and pour in about a gill of kerosene oil and ignite it. The stump will smolder away, without blazing, to the very extremity of the roots, leaving nothing but ashes.

STUMPS, To Pull.—A good stump puller is represented in the illustration. The iron hook being fastened to the stump, power is applied to the upper end of the post, which, being forced from its position, takes the stump with it. Stumps of 6 to 10 in. may be pulled out by a yoke of oxen, by hitching the chain at the top of the stump, and taking 2 or 3 turns around it so as to get a twisting pull upon it. Large stumps, up to 18 in., may all be pulled out by using a block and tackle. Blocks of 3 sheaves should be used, and a rope sufficiently strong for the purpose. A hitch should be taken upon the largest stump, and all those around it drawn out, when another large stump may be chosen to hitch to.



Stump Puller.

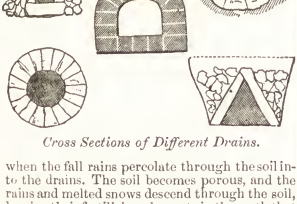
SURFACES, To Level.—When inequalities of surface cannot be reduced by a more simple process, it may be done, when the soil is loose and sandy, by a horse shovel. To use it raise the handle, and the shovel enters the ground, and is filled by the horse going on; by depressing the handle the load slides on the rounded bottom of the shovel; by letting the handle go, retaining the rope, the whole is upset instantly, turning over on the edge; the handle strikes on the bar and the load is left behind in a heap. By pulling the rope the whole instrument resumes

its original position, and is brought back to the place from which the earth is to be taken again, without any loss of time, or the slightest stoppage of the horse.

TIMBER. To Cut.—To clear land of a small growth of trees, without the aid of a stump puller, and at the same time have the land in immediate condition for tillage and cropping, the timber should be cut out by the roots; that is, until the weight of the tree breaks what are left and causes it to fall. The tree can be left for a heavy wind to prostrate it. Just after the frost leaves the ground in the spring is a good time, as the soil is easily removed from about the roots, which should be cut off below the surface of the ground, so that they will not materially interfere with cultivation. Trees and brush may be cut at any time that they will not be liable to throw up a growth of shoots. When only the roots are left in the soil, but little trouble need be anticipated from this source. After two or three plowings they will decay.

DRAINAGE.

REMARKS.—Drainage deepens the soil. The advantages of a deep soil over a shallow soil, are that a shallow soil underlaid with a cold wet subsoil compels the roots of growing crops to seek food near the surface in soil perhaps already exhausted by former crops. The water line must be lowered, then the rootlets will follow down through the little spaces and seams, giving back to the parent stock the necessary food. The air also follows down as the water line is lowered, coming into contact with elements in the earth which dissolve into food for plants, which is taken and appropriated by the small rootlets. Drainage enables the farmer to start his plow from ten days to three weeks earlier in the spring, and to keep it going when lands undrained are unfit to work, as the plow can run later in the season

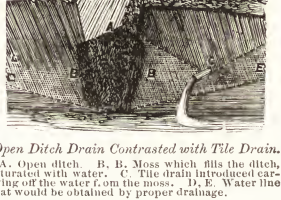


Cross Sections of Different Drains.

when the fall rains percolate through the soil into the drains. The soil becomes porous, and the rains and melted snows descend through the soil, leaving their fertilizing elements in the earth that has acted as a filter, instead of flooding the surface and carrying all their rich freights off the land. Drainage also renders the farm and neighborhood more healthy, obviating malaria. The different kinds of drains in use may be classed into 2 divisions,—drains of conveyance alone, and drains of conveyance and collection jointly. In the former all that is necessary is a channel or passage for the water, of sufficient dimensions, which may be formed by pipes of different kinds, arched or barrel drains, and box or walled drains. The illustrations show different kinds of drains, which, however, tile draining is usually superseding.

HILLS. Drains for.—When the site is on the side or foot of a hill, it is generally necessary to cut off the water that drains from the higher level, by constructing drains across the hill and connecting these with drains at right angles running down through the hill-side. Where the spring has naturally formed itself an outlet, it may frequently only be necessary to bore into it, or render it larger, and of more depth, which, by affording the water a more free and open passage, may evacuate and bring it off more quickly, or sink it to a level so greatly below that of the surface of the soil as to prevent it from flowing into or over it.

OPEN DITCH DRAINS. — Open ditch drains, though better than none at all, are not to be recommended, as they only conduct the water away, and scarcely, if at all, produce the effect of under-drainage; and, besides, are in the way of plowing or similiar operations, readily fill up, and their sides become overgrown with weeds.



Open Ditch Drain Contrasted with Tile Drain.

A. Open ditch. B. B. Moss which fills the ditch, saturated with water. C. Tile drain introduced carrying off the water from the moss. D. E. Water line that would be obtained by proper drainage.

PEAT LANDS. To Drain. — When the drains cannot be carried to a sufficient depth to take the water out of the porous stratum saturated with it, bore numerous holes with a proper auger in the bottom of the drain through the stiffer soil. The water will either rise through these bores into the drains, and be carried off, or it will sink down through them if it lies above. The bottom of the drains is sometimes choked with loose sand, and they require to be cleared repeatedly; this soon ceases after the first rush is past. The surface of the peat, being dried, dressed with lime, and consolidated with earth and gravel, soon becomes productive. When a single large and deep drain will produce the desired effect, it is much better than when there are several smaller; but this is only the case in tapping main springs, for, if the water is diffused through the surrounding soil, numerous small drains are more effective; as soon as there is a sufficient body of water collected, the smaller drains

should run into larger and these into main

Peat Land Drain.

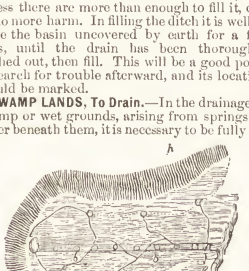
a b, hole sunk into the subsoil.

drains, which should all unite into one principal outlet.

SILT BASIN.—Small particles of soil or dirt always find their way into the drain, and are carried along by the stream and left in depressions of the pipe, sometimes developing a complete obstruction. For this reason a silt basin is placed where the grade is slightest, or at the intersection of mains. A good basin is made by sinking a large tile two-thirds its length in the bottom of the ditch, and making the tile above and below empty into it; or, rather, the drain passes through it. The bottom of the basin should rest upon a flat stone, or solid piece of plank, and the top be also securely covered. The traveling particles tumble into the basin, and unless there are more than enough to fill it, can do no more harm. In filling the ditch it is well to leave the basin uncovered by earth for a few days, until the drain has been thoroughly washed out, then fill. This will be a good point to search for trouble afterward, and its location should be marked.

Silt Basin.

SWAMP LANDS, To Drain.—In the drainage of swamp or wet grounds, arising from springs of water beneath them, it is necessary to be fully acquainted with the nature and disposition of the strata composing the higher grounds, and the connection which they have with that which is to be rendered dry. The line of springs being ascertained, and also some knowledge of the under surface, a line of drain should be marked out above or below them, according to the nature of the strata, and excavated to such a depth as will intercept the water in the porous strata before it rises to the surface. Increase the effect of these drains by boring holes in the bottom of them. When water issues forth from 2 or 3 places, find the chief spring. Remove this, and the outlets will become dry. The highest outlet, if the strongest, may be the leading spring. Determine this before marking out the drains. If the bank is formed irregularly and springs are found around the base of the outlets, carry the ditches up to a higher level in the side of the hill than the wet land. When difficult to ascertain the line of the spring, carry up the conducting drain to carry off the water. When the spring is discovered, form a cross drain on the surface at a sufficient distance on each side of the end of the strata containing the water.



Swamp Land Drain.

h h, represents the sides of a hill; the swampy lot, below, is filled with springs, which are, however, drained by running a ditch (*b b*) across it, and sinking holes into the subsoil. One of these holes is seen in the cut above (*a b, Peat Land Drain*), and the manner in which it conveys the surface water away.

TILE DRAINS.—These are the best of all drains, and are made of 1¼ in. round draining tiles, with collars for the laterals, connecting with 2½ in. tiles for the mains. These tiles are laid jointed together, the water percolating through the joints and passing off through the tiles. The proper depth to lay them is 3 ft., if the drains are 20 ft. apart, and 4 ft. if the drains are 40 ft. apart, with a fall of 6 in. to the 100 ft., although less will do. The drains should run parallel with each other if possible, and down the deepest descent of the land. To lay the tile, begin at the head of the drain, closing the outer end of the first tile with a stone. Place a collar over the other end ready for the reception of the second tile. These collars are simply sections of a larger size of the tile 2 or 3 in. long, which slip over the 2 ends, fitting closely to prevent particles of soil from getting into the drain. The layer walks backward as the work proceeds. If the ends of the tile are ragged, trim them with a hatchet having a point instead of a head. The main tile should be a little lower than the lateral drain, and the opening made as near the top as practicable. Much depends upon the skill with which these connections are made, and too much care cannot be taken in making all of the joinings perfect in every part. 3 in. tile is now being more generally used than smaller sizes, as there is less liability to choke up with silt. To render drains fully effective, the land should be thoroughly subsoiled so as to hold our heavy rains. Much of the labor of draining is now done by horse power or steam. Hammond's mole-drain plow makes a small tube of the subsoil by compression. This mode of draining is effective for a considerable time, is cheap, and can be done over again as required at but little cost. At a recent trial of draining machines very excellent work was performed. One steam tile ditcher cuts 4 feet deep and 10 inches wide, in all kinds of clay and soil, whether it is of a wet or dry character, and grades perfectly at a cost of from 5 to 8 cents per rod.

UNDER DRAINS. —When made of stone, these not only last for all time, but carry off any surface water much sooner than tile. They cannot be choked with debris like open drains. In cutting a ditch for a drain, the most expeditious way is to first run a furrow with a 2 horse plow as straight as possible, where the drain is to be, and on this first furrow backfurrow another, of equal width. After shoveling to one side the earth of which this double furrow is composed, repeat the plowing and shoveling by attaching a short chain between the doubletree and clevis, to increase the distance between the two, and thus cause the plow to run the required depth. Thus a depth of from 15 to 20 in. may be obtained, and of the proper width the drain is to be; hitch the 2 horses tandem fashion to a single coulter plow; with which rip up the sub-soil and throw out as before; repeat the operation until the proper depth is had. In finishing the bottom of the intended drain, care should be taken to have it of uniform smoothness throughout its entire length, only sufficiently inclining towards the mouth to cause the water to flow with equal freedom through every part of the drain. Prepare the stone for constructing the drain by breaking it into pieces not larger than goose eggs; place the smaller ones in the bottom of the drain, and the larger ones throw on promiscuously to within 18 in. of the surface; cover with straw and fill the balance of the drain with the excavated earth. Where low places occur in a field, on which water is inclined to stand so as to interfere with its cultivation, and for which no outlet can be conveniently had by means of a drain, a very good substitute will be found by digging a hole through the clay, some 3 or 4 ft. in diameter, filling the same with stone to within a few inches of the top, and covering with leaves and earth as above directed.

FERTILIZERS.

REMARKS. — Any substance, which, when mixed with a soil, adds to the growth or fertility of plants, is a fertilizer and promotes the growth either by entering into the composition of plants, by absorbing moisture, or by stimulating the vascular system of the plants. The coarse manures should generally be applied to the heavy clays, especially if vegetable matter is lacking. It is always better to spread manure as it is drawn than to put it in heaps. When put in heaps a large portion of the soluble matter is left in the ground under the heap and makes these spots too rich, and deprives the rest of the ground of its proper share. It should be forked over occasionally to make it fine. If it is heating, then muck or loam should be mixed with it to absorb the ammonia which is formed during the process of decomposition. The quantity of each kind of manure in use to be applied to the acre is as follows: Barnyard manure, 5 to 20 tons, or 30 to 40 cubic yds.; bone dust, 16 to 20 bush., or 700 to 1200 lbs.; fresh fish, 25 to 40 bush.; fish guano, 4 to 600 lbs.; guano, 3 to 800 lbs.; gypsum, 5 to 600 lbs.; horn shavings, 25 to 40 bush.; hops, 30 to 40 tons; lime, 50 to 150 bush.; night-soil, 20 bush.; salt, 2 to 6 bush.; soot, 20 to 50 bush.; super-phosphate, 500 to 1000 lbs.; tanner's refuse, 5 to 800 lbs.; wood ashes, 20 to 40 bush.

ARTIFICIAL FERTILIZERS. — 1. Sulphate of ammonia, common salt, and oil of vitriol, of each 10 parts; chloride of potassium, 15 parts; gypsum and sulphate of potassa, of each 17 parts; saltpetre, 20 parts; crude Epsom salts, 25 parts; sulphate of soda, 33 parts; for clover. —2. Dry peat, 20 bush.; unleached ashes, 3 bush.; fine bone dust, 3 bush.; calcined plaster, 3 bush.; nitrate of soda, 40 lbs.; sulphate of ammonia, 33 lbs.; sulphate of soda, 40 lbs.; mix the peat, ashes and bone dust; then mix the nitrate and sulphate of soda and the ammonia, in 5 buckets of water; when dissolved, add this to the first mixture; when mixed, add the calcined plaster.—3. Charcoal, 371 parts; salts of ammonia, 426 parts; salts of potash and soda, 24 parts; oxide of iron, 50 parts; silica, 65 parts; alumina, 31 parts; sulphate of lime, 31 parts; carbonate of magnesia, 2 parts.

ASHES, Wood.—Wood ashes are very valuable as a fertilizer. Their chief value consists in supplying the soil with mineral constituents, and by their action as solvents upon the insoluble salts already in the soil; also by neutralizing acids and improving the mechanical condition of the soil.

BUCKWHEAT. — This is not as valuable as clover, but will grow where clover will not. It contains large quantities of nitrogen, potash and phosphoric acid. Two or three crops plowed down in their green state will make a light soil dark and loamy; success is secured by shallow plowing; by covering only 3 or 4 in. speedy fermentation and rapid decomposition take place.

CARCASSES, To Make Fertilizers of. — For a large animal, draw 4 or 5 wagon loads of muck, sod or mold; roll the carcass on to this; sprinkle freely with quicklime; cover immediately with a generous quantity of soil; 10 or 12 wagon loads will not be too much; in less than a year, without giving offense to any one, quite a number of wagon loads of excellent fertilizing material will be had. Bones alone, or the whole carcass may be speedily decomposed by using sulphuric acid, and a valuable superphosphate produced.

CHARCOAL.—Charcoal is a most efficient manure to all cultivated plants, especially to those under glass. It should be broken into small pieces, about the size of a nut, and, for potted plants, may be mixed in the proportions of 1 part charcoal to 20 parts earth.

CLOVER. — There is no crop so valuable for the renovation of partly exhausted grain lands as clover. Sow 20 lbs. of seed to the acre, and when 6 in. high plow under.

COMPOST HEAP.—There ought to be a compost heap on every farm; into it can be thrown all kinds of refuse material—weeds, straw, ma-

nure, earth, sods, etc. A good compost heap is made by a layer of stable manure and bedding about 1 foot deep, which should be covered immediately with 6 in. of swamp muck or soil. It should be repeated from time to time as the manure accumulates, so that the pile will consist of successive layers of manure and muck. In 6 months the whole pile will be a homogeneous mass of rich manure. It should be kept moist but not wet. If swamp muck can not be conveniently obtained, cover the heap with any loamy soil that is at hand. On the compost heap should be thrown all waste matter about the house. A sprinkling of ground plaster on each layer of manure before it is covered will add much to the value of the compost, but never use quicklime on a compost heap.

COTTON SEED. — Cotton seed mixed with superphosphate makes a cheap and good manure. It contains not only the two leading elements of all good fertilizers, nitrogen and phosphoric acid, but, in addition, like stable manure, all of the elements needed by crops. The ratio of 6 bush. of seed to 100 lbs. of superphosphate makes a good combination. It should be applied fresh.

COW DUNG.—This is one of the least stimulating of all animal fertilizers. Its constituents, nevertheless, are those of most cultivated plants, and as it slowly decomposes in the soil, and does not induce over luxuriant growth, it is very generally employed to mix with the soil for potted plants.

FISH.—Fish generally owe their powerful fertilizing qualities, not only to the oil they contain, but also to the phosphate of lime in their bones. From 25 to 45 bush. per acre are the extreme quantities to be applied broadcast; but if in the drills, with the crop, 16 bush. are ample.

GUANO.—Guano is a powerful fertilizer. Its great value consists in the amount of ammonia it contains. It should always be composted with earth. It is immediate in its effects, and should never be used with ashes or any alkali. Pure guano, owing to its high price, is very commonly adulterated, or is in an advanced stage of decomposition when sold. If pure, it should be light colored and dry, coloring very slightly when squeezed together, and not gritty.

GYPSUM (Land Plaster).—This is a valuable fertilizer and deodorizer too little known and too sparingly used. For use in the stable and poultry yard it is invaluable. It is a complete absorbent of ammonia.

HOPS.—Hops, as the refuse of the breweries, when they can be obtained, are a very powerful manure, considered to be even more valuable than horse manure. They should be rotted down very slowly, for if allowed to ferment strongly they lose a large portion of their value. It is best to compost them with stable manure.

HORSE DUNG.—The fresher the dung is used the more economical; but it is more troublesome and encumbers the tools of the workmen, besides being liable to convey into the land the seeds of weeds. It is most advantageous, therefore, to use half rotted stable manure; it is easily incorporated with the soil, and the seeds of weeds have for the most part so far vegetated, that the moving and digging destroy them.

LIME.—Lime is a valuable manure, having a tendency to render light soils more retentive of moisture, and heavy soils more friable. The quantity to be applied should be determined by the character of the soil. A very excellent manure is formed by mixing 1 bush. of salt with every two bushels of lime. Lime cannot be applied to the soil too fresh from the kiln; for if allowed to absorb carbonic acid from the air, it is rapidly converted into chalk. When crops are devastated by the slug, dress them some evening, so as to render the surface of the soil quite white, with lime.

LIQUID.—The liquid manures, which should be carefully attended to, are especially devoted to those crops which will bear rich ameliorations. Some farmers reserve them for clover and other artificial meadows, or for natural pastures. They are never so advantageous as when applied to sandy soils, which they render tolerably consistent, and more adapted for the retention of moisture. It is the most economical, prompt and efficient form in which fertilizers can be applied to the garden. If, instead of digging in stable manure, each crop were watered occasionally with liquid manure, the produce would be finer and more abundant; 10 gals. of water will readily dissolve, or keep suspended in astate of minute division, about 50 lbs. weight of guano. A good way to save manure in this form is to grade the barnyard into a basin shape, the lowest part under the cow stable window; then settle a cistern 5 ft. deep and 11 ft. square; lay the walls with water cement, so that when done it will be 8 ft. square; make a stout wooden frame and place it in the centre to receive a flagstone covering; put in a rubber chain pump high enough to spout out the drainage into a hogshead standing on a truck; heave the manure right on from the stable to the cistern.

MARL.—A natural mixture of clay and chalk, with sand. It is characterized by effervescing with acids. According to the predominance of one or other of its component parts, it is called argillaceous, calcareous or sandy marl. The quantity applied per acre must vary greatly, according to the object to be attained. To render a light soil more tenacious, 100 tons per acre of clayey marl are not too much; neither is the same quantity of siliceous marl an excess, if applied to a heavy soil to render it more friable.

MUCK.—This is the richness of upland soils washed by the rain down to the low land, where it accumulates. Cultivating exhaustive crops upon the uplands, and washing the remaining richness out by rains, soon renders such lands nearly barren. As the muck, in its passage downhill, has lost the coarser parts of the original soil which make a loose and porous seed-bed, it has become so compact, that the atmosphere is absolutely excluded, and the muck by itself is a mere paste, impervious to air, warmth, and all the invigorating influences of summer rains. To make it again soluble, it must be mixed with the soil by plowing, or harrowing; muck is usually dug in the fall, piled on a slope to drain,

and left to freeze friable during the winter; in spring return it to its proper place in the barren soil, and it at once restores the original fertility. It is most valuable when composted with manure.

NIGHT SOIL.—Human excrements, or night-soil, make a very active manure. The best way of using it is to form it into a kind of compost, by mixing it with other substances, and especially by making it into heaps with turf, and adding a small quantity of burnt lime.

PEAS. — As a fertilizer, peas are reckoned by some to be equal to clover. They produce a heavy and rich crop to be returned to the soil in a shorter period than any vegetable fertilizer known, and they will thrive upon land too poor to grow clover. They produce two crops in one year, and feed but lightly on the soil, thus leaving largely in the soil what is required for the succeeding crop.

SALT.—Salt should never be applied other than in a pulverized state, and never employed on impervious, cold, and humid soils. The best manner to use it, is to combine it with other manures, a dose of 2 cwt. to the acre being sufficient. When selected to destroy insects, it should be applied before sunrise. In the case of cereals, salt strengthens the stems, causes the ears to fill better and favors the dissolution and assimilation of the phosphates and silicates. It acts vigorously on potatoes, and can be detected in their ashes to the extent of ½ or 1 per ct.

SAND.—Sharp drift sand, such as is found by the side of rivers, is a very effectual improver of heavy soils, and may be applied to them in any quantity until they are rendered more friable. Sea sand is used especially when abounding with fragments of shells.

SODA, Nitrate of.—One pound to 30 square yards of land is a sufficient quantity as a fertilizer. Plants probably decompose it. Dissolved in water, 1 lb. to 12 gals., it can be used with advantage as a liquid manure.

SOOT.—Save the soot that falls from the chimneys, when they are cleaned, as it is one of the most powerful and permanent of fertilizers dug into the soil.

TILLAGE.

FALLOWING.—The chief use of fallowing is to liberate the plant food stored in the soil as organic matter. Plowing and stirring admits air, which promotes decomposition as does the turning over of a dung heap. It destroys the roots of weeds, converting them into fertilizing material and allowing the ground to recuperate. In all cases of fallow, the first plowing should be given immediately after harvest, and as deep as the quality of the soil will permit, with a strong team, if the land be very stiff and retentive of water; and in all cases the field should be well ridged and deeply furrowed. Immediately after the stirring time of spring-work is over, if fallow crops are to be sown, the second plowing is to take place, and in the same direction with the former and, lest, by cross-plowing, a fall of rain should stagnate on the surface; in light soils a cross plowing is preferable, even at this early time. The third plowing should be executed in June, and at this time always across the original direction of the ridges; harrowing with a heavy break, if the land requires it, should regularly succeed the summer plowing; the harrowing should be executed by repeated double turns, crossing those of the previous ones, until the land is sufficiently pulverized to admit of the easy collection of weeds; drag the surface and collect as large a portion as possible of the roots of fast growing weeds in the ground. Fallowing is becoming an obsolete custom with many. The plowing in of green crops, such as clover, peas or millet is a superior practice. (See FERTILIZERS.)

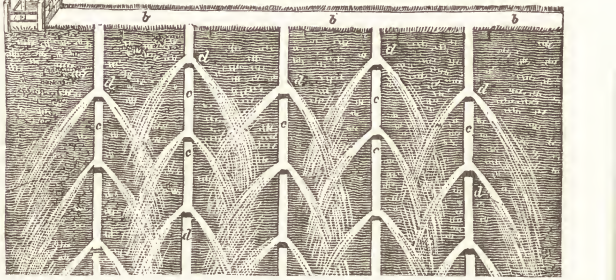
HARROWING.—This has for its object the reduction of the soil to a fine, loose condition, to permit the air to freely circulate through it. It should be done when the ground is moderately dry; it is then in a position to pulverize readily. If worked when wet, the soil becomes rough and lumpy and will remain so during the season.

HOEING. — Plants grow and mature better when the ground is hoed frequently. The loosening of the soil in the operation of hoeing is as beneficial to the plants as the destruction of weeds. The cultivated soil being made porous immediately conveys to the roots of the plants the moisture condensed from the atmosphere, and being cooler than the uncultivated, it is able to cause a greater condensation of moisture and attract a heavier fall of dew. When the surface is kept loose it acts as a mulch, affords actual resistance to the rays of the sun, and keeps the roots of the plants cool; but when it is hard it becomes a good conductor of heat, which deeply penetrates it. In the cultivation of corn, potatoes and similar crops, stirring the soil among the plants can scarcely be repeated too frequently during the early part of the season; in fact, these operations may be continued until the crop is well on toward maturity. The sprouting weeds are thus destroyed in the germ and the work is comparatively easy all the season afterwards.

IRRIGATING.—Watering poor land, especially of a gravelly nature, improves it and makes it fit for cultivation. Land, improved by irrigation, becomes fertile and productive. A channel which receives the water at a point higher than that to which the river flows, may be dug with a much smaller declivity than that of the bed of the river, and made to carry the water much higher than the natural banks; it may thence be distributed so as to descend slowly, and water a considerable extent of ground, in its way to rejoin the stream. This is a common mode of irrigation, and the shape, size, and direction of the channels are regulated by the nature of the surface, and other circumstances, which vary in almost every situation. The illustration is an example of irrigation where the soil is very porous, and gently inclined, the supply of water

being abundant. A main carrier is led from the sluice (*a*) directly across the declivity (*b*), and side feeders (*c*) taken out from it at regular distances. These feeders have stops of turf, at regular distances (*d*), by which means the water is dispersed. After watering a space of from 20 to 40 feet in breadth, it is again collected by the small drains in the furrows, and returned lower down to another feeder. In the preparation of the surface for irrigation, it is usual to form it into low ridges, the feeders being on the crowns of the ridges, and the drains for carrying off the water in the furrows. In the irrigation of lands with considerable inclination of surface, the feeders cannot be carried along lengthwise, but across the line of descent, so that the water flowing from one is intercepted by the next lower, and so on until it has covered the whole of the meadow. Water may be dammed in any break passing through a field and caused to flow back over the adjoining land. Water may also be dammed until it swells high enough to be carried by pipes through the land. Where the character of the surface to be irrigated is such that it has irregular depressions, but a general slope downward from the level of the reservoir, the courses of the distributing channels may be laid so as to irrigate the whole. A soil containing 80 per cent. of sand, may be irrigated every 5 days; one containing 20 per cent. once in 15 days. It is of advantage that the soil should lie on a warm and absorbent bottom; for the subsoil of watered meadows is considered of more importance than the quality or depth of the surface soil. The best watered meadows are sometimes those in which the soil is only a few inches in depth, especially when the bottom is porous. The waters most suitable for irrigation are those of rivers which flow through a rich and cultivated country, as they are enriched by the animal and vegetable matters which are contained in them in a state of solution. Water impregnated with iron has sometimes been used with good effect. By judicious flooding the yield of grass land may be doubled; but by flooding at improper seasons it may be destroyed. Water should not be permitted to lie on the grass more than two days at a time, nor more than 2 in. in depth, and not at all during the winter. It should never be turned on while the soil is heated during the daytime. When the grass has well covered the ground and it is nearly ready for cutting, no water should be given for two weeks before the hay is made. When that is done, watering may be repeated as before until another cutting. No water should be given for a month previous to the winter, as it is very injurious during the frosts. The aftermath should be permitted to die down on the meadow on the approach of winter, as a protection to roots from frost. Under such treatment 4 tons of hay has been gathered from 1 acre.

Plan of Irrigation.



PLOWING. — The medium depth of good plowing may be held to be 7 in., but this varies according to the kind of crop to be cultivated, and the nature of the soil. Clay, underlaid by compact subsoil, should be plowed deeply. If the clay subsoil is allowed to remain within 5 or 6 in. of the surface, it forms a crust at that depth, through which the roots of plants do not easily penetrate, and there is only a few inches of good, mellow soil at the surface for the support of plant-life; when rains fail, this shallow bed of moisture is soon exhausted, and if not soon replenished the plants suffer from drought, and in wet seasons it is soaked and injured by surplus water to an extent unknown in deep soils. In plowing the plow should be held perfectly upright, to get a slice of equal thickness and consequent uniform depth of cultivation. The plowman should walk with his body as nearly as possible upright, without leaning on the handles and without using force to any part, further than may be absolutely necessary to keep the implement steadily in a straight line. He should not shout at or whip his team frequently, as it confuses them, and at length loses its effect. There is much to be gained by plowing the ground in the fall, especially that intended for corn the following season; for if the piece is a sod, which is most excellent for corn, late fall plowing turns up the roots around which quite

an army of cut worms have put up in winter quarters, and the cold freezing weather of winter has an opportunity to destroy them, thus saving the future corn crop from much of their ravages. When the sod is plowed late in the fall the piece must be gone over with an ordinary cultivator or with a sulky cultivator in the spring, to fine up the soil and make it in good order to receive the corn. In tenacious, clayey soil, even in fallow ground, the fall plowing, followed by another plowing in the ensuing spring, is of great benefit in reducing the texture of the ground and in making it more readily worked, as well as making it more suitable for a vigorous plant growth. There may be some cases where it will not do, but in most instances late fall plowing pays well. Inventions for using steam plowing, while quite numerous, have never come into extensive use, except for very large and level fields and in farming on the largest scale. For subsoiling it is superior to other methods on account of its great power. Subsoiling is done by following in the furrow of the surface plow, which loosens up the subsoil, and it is covered by the next furrow made by the surface plow. By subsoil plowing the earth is loosened to a considerable depth and root culture is much improved.

ROLLING.—The roller may be used to a very great advantage on many wheat fields. The thawing and freezing of the ground causes "heaving," drawing the roots out of the ground, and exposing them to drying winds. Passing a roller over the field presses the roots down into the soil upon which they depend for the support and growth of the plant. In closely compressing the particles of earth on light, sandy soils, by excluding cold wind or a parching sun from the roots of young corn, its value is great, and it may be repeatedly performed to grain crops in the spring months, as long as it can be continued without breaking the stems. When the surface of the ground is so dry that lumps of earth will powder under the pressure of a roller, then is the time to use it, for the soil needs to be pulverized, not matted down into a hard paste. Don't use the roller when the ground is so wet that it will plaster down and, with the action of the sun, form a hard baked surface.

ROTATION OF CROPS. — This gives time for the disintegrating action of the atmosphere, rain and frost to prepare new material from the rock particles in the soil, and get it in a form to be used by the plant. One crop may use up the available food of a particular kind faster than it can be prepared by these natural agencies. When properly managed it enables one plant to prepare food for another. The principles upon which a regular succession of crops is based are: 1. That all plants exhaust the soil, though in an unequal degree. 2. That plants of different kinds do not exhaust the soil in the same manner. 3. That all plants do not restore to the soil a like quantity or quality of manure. 4. That all plants are not equally favorable to the growth of weeds. These principles, confirmed by experience, form the basis of an agricultural system not only rich in its products, but rendered highly profitable by the economy of labor, soil and manure. Though the system of rotation is adapted to every soil, no particular rotation can be assigned to any one description of soil which will answer at all times; much depending on climatic changes, and on the demand for different kinds of produce. On clayey soils, beans and clover, with rye-grass, are generally alternated with grain crops; and on dry loams or sandy ground, turnips, beets, potatoes, and clover. On rich soils this system of alternate husbandry is most conducive to the plentiful production of food, both for men and animals. One portion of a farm would thus be always under grain crops, while the other portion was growing roots or cultivated grasses; but, as the major part of arable lands cannot be preserved in a state of fertility with even this kind of management, it is requisite that the portion of the farm which is under cultivated grasses, should be pastured for 2 or 3 years, in order to give it time to recruit. The following is a good rotation of crops: 1st year, clover; 2d, clover; 3d, corn; 4th, oats; 5th, wheat. The clover does well with oats, and after an early mowing can be very well prepared for wheat.

FLORICULTURE.

GARDENING.

GROUND.—Depth is as necessary as firmness. Great depth supplies good drainage and consequently heat. Shallow soils must be fed continually, or the manurial matter will get washed out and the vegetable matter they contain will be dried up by the sun. The sites of flower beds should be trenched by removing all the soil to the depth of 16 or 18 inches. If the soil be poor or exhausted, take it all away and entirely renew the bed with fresh soil, composed of either clay, sand, or turfy loam from a common mixed with a good fertilizer. The roughest of the compost should be placed at the bottom of each bed. All red flowers are greatly benefited by covering the earth around them with about an inch of pulverized charcoal. Turfy loam, turfy peat, leaf mold, and rotten dung are all good fertilizers. A good liquid manure for flowers is made as follows: Put 1 bush. of cow or hog manure into a large barrel, and fill it up with water; let it stand for a week, when it is ready for use. Apply it with a watering pot. All bedding plants can be watered with this liquid every other day if they are not pot bound. Repotted plants should be watered once a week until they have plenty of working roots to take up

the manure. It will also be found excellent for hard-wooded plants if used once or twice a week. Ammonia is also an excellent fertilizer. The best way to apply it to plants is to take a teaspoonful of Peruvian guano and put it in 1 gal. of water; water the plants with this once a day; when the guano and water has been used up, give the plant a rest for a month, and if by that time they have not improved in growth and have not a deep green color, give them a second gallon.

HOT-BEDS are contrivances for the purpose of protecting tender plants from the weather and promoting their early growth. They are made in a frame, covered with glass or some other material, and are composed of earth and any fertilizing material that will ferment and produce warmth; stable manure and dead leaves are generally used, but stable manure is unquestionably the best. To make a hot bed, lay out the ground 6 in. larger than the frame. The frame may be of any size and consists of a box without a bottom, with a movable top, formed of glazed sash; the length or number of the frames is immaterial; but they should be from 9 to 12 in. deep at the front, and 15 to 18 in. at the back. This will give a good slope to carry off the rain. After the frame is made, proceed to build up the bed to the height of 2½ to 3 ft., making it rather firm and watering if the manure is dry. If the seeds are to be sown in the soil of the bed, 2 or 3 in. more soil should be added; but if in pots, no addition will be necessary. After adding the soil put on the lights, and let it stand to settle and exhaust the violent heat. The following is a good substitute for glass coverings; it possesses many advantages over glass, and may be made at about ¼ the cost: Buy unbleached muslin and sew enough together to cover a light frame the size of the top of the hot bed; this frame should have one or two cross-pieces to stay it and be enough larger than the box to fit snugly down over it or around it at the top; after stretching the muslin over the frame tightly and tacking it neatly about the edge; give it a coat of linseed oil, in which 1 or 2 eggs are well beaten or stirred; 1 pt. of oil will coat two quite large covers; let it dry for a day and the cover is ready for use; be careful to keep the cover clean until the oil is well dried. These frames are light, and easily and cheaply repaired.

PLANTING.—*Annuals.*—Should the weather be warm and dry and the beds and borders nicely trimmed, proceed to sow the hardiest annuals as follows: With a small rake draw a portion of soil from the places where the seeds are to be sown, commencing at the border or in the centre of the beds; make as many of these hollows as possible, without unnecessarily treading upon the ground; for the less it is trodden upon the better the flowers will thrive. For large seed make the hollows fully 1 in. deep; for smaller ones ¾ in. will be a sufficient depth. Having made the hollows, take two papers of the tallest annuals of different colors, carrying also as many short pieces of wood as there may be patches of flowers in the two packets of seed. The two kinds may be sown near to each other. Sow of large seeds from 4 to ½ doz. seeds, and of those that are smaller from 12 to 20 in each place; stick one of the short pieces of wood in the midst of the seeds, leaving them uncovered till the whole of the tall kinds are sown. Then with the rake cover them in, and put out all footmarks, making the ground neat and level; proceed then to open other hollows with the rake. If the soil is heavy and wet, for the small seed especially, have some light soil sifted moderately fine and cover the seeds with it.

Biennials.—These are plants raised from seeds, which do not flower till the second year, but which generally die as soon as they have ripened their seeds. Biennials are usually sown in a bed of light, rich earth, in the open year in the reserve ground, and then transplanted, in September, to the place where they are to flower the ensuing year. The finer kinds should have a bed or pit prepared for them, of rich, loamy soil, in which they are planted, with a small quantity of manure. Biennials, as a rule, need some protection through the winter; but often more harm is done by the covering than by the frost. Two things are to be avoided; material that will rot and smother the plants, and material that will serve the mice for nests, and so the plants be devoured for food. Straw is objectionable, as also corn stalks. Leaves are excellent; and very thin sods do well, laid on bits of brush.

Cuttings do not require to be planted deep, but the larger ought to be inserted deeper than the smaller ones. In the case of evergreens, the leaves should be kept from touching the soil, otherwise they will damp or rot off; in the case of tubular stalked plants, which are in general not very easily struck, owing to the water lodging in the tube and rotting the cutting, both ends may be advantageously inserted in the soil, and, besides a greater certainty of success two plants will be produced. Too much light, air, water, heat or cold, are alike injurious. To guard against these extremes in tender kinds, inclose an atmosphere over the cuttings, by means of a hand or bell glass, according to their delicacy. This preserves a uniform stillness and moisture of atmosphere. Immersing the pot in earth has a tendency to preserve a steady, uniform degree of moisture at the roots; shading or planting the cuttings, if in the open air in a shady situation, prevents the bad effects of excess of light. The only method of regulating the heat is by double or single coverings of glass or mats, or both. The degree of heat is decided by the degree of heat requisite for the mother plant. Most species of the erica, dahlia and geranium take root better when supplied with rather more heat than is requisite for the growth of these plants in green-houses. The myrtle tribe and camelias require rather less; in general a lesser portion of heat, and of everything else proper for plants, in their rooted and growing state, is the safest. Cuttings of fuchsias, zonale geraniums, fever-fews, smooth-leaved begonias, and many other plants, may be easily rooted in sand. Fill a flower-pot with coarse, gravelly sand, and stick in the cuttings close to the outer edge and quite near together. Press

the sand tightly around each one; set the pot in a saucer and soak it with water until it will hold no more. Put it in the sunshine and keep it there every hour of the day that you can; but never let the sand get dry or even approach that state. When a slip once withers, it is done for. In two weeks the cuttings should be well rooted and ready for transplanting into thumb-pots and good soil mixed with sand. They must be kept shaded for a few days. After the first watering they will need little, if any, until signs of growth appear. Cuttings of many plants can be readily started in water; in the early spring, if you have not a green-house or hot-bed, it is the safest plan. Fill small bottles or vials with warmish water; remove the lower leaves of the cuttings; be sure to have a bud at the base; put them in the water; hang up the vial to the window sash, tying a string about the mouth for this purpose. If cotton wool is put around the mouth of the vial it will prevent the evaporation of the water and make the roots sprout more quickly by keeping up a more even temperature. As soon as the roots are 1 in. long, the cuttings should be transplanted, taking care to spread out the tiny rootlets as they grow in the water; fill up the bottle with rich earth; let it dry off for 2 or 3 days and then break the glass; pot or plant out the cutting without disturbing its roots in the least degree.

Perennials. — Perennials continue to flower several years in succession. The seed may be sown at times when the ground is moist, but not very wet, from the first of April to August. Many of them may be raised in the open ground, like hardy annuals, and transplanted. As they do not generally bloom the first year, they may be thinned out or removed from the seed bed as soon as they are well rooted, and planted either in different parts of the garden, or into nursery beds, in rows a foot apart.

POTTING. — When this operation is necessary, it should generally be done after pruning, and when fresh growth has taken place. The mold for potting should be light and loamy, the fertilizing material used being well decayed. If the soil is rich of itself, it is better to be either very sparing with the fertilizer or to dispense with it altogether. In potting, drainage must be secured; to assist this place several small pieces of broken crockery in the bottom of the pot, then a little green moss, then the soil. To obtain early bloom, small pots must be used. When rapid growth is desirable, put the soil in rather loosely; when early blooming is wanted, pack it firmly round the roots. When potting plants that are to remain in the pots a number of months without being expected to bloom, pot rather lightly.

REPOTTING. — When the roots of the plant have become pot-bound (that is when the earth shrinks and forms a hard ball around the roots of the plant, leaving a space between the earth and the pot, through which all the water runs without wetting the roots of the plant), it is necessary to repot. Turn the plant out of its old pot by putting the hand upon the earth and turning the pot upside down; if the ball of earth does not come out readily, strike the rim of the pot against the edge of the potting table or shelf. The ball containing the plant will thus drop out into the left hand; the bits of earthenware that adhere to the bottom of the ball having been picked off, and any part of the root that appears decayed having been removed, a little mold is put on the drainage in the new pot; the ball of earth containing the plant having been placed in the centre, the space between it and the pot is filled in with light, rich mold, and made firm with the potting-stick; shake the pot, then take hold of the rim with both hands, and strike the bottom of the pot two or three times, with a jerk against the potting-bench. Then water the plant and set in the shade for the remainder of the day. As a general rule, do not repot when plants are showing bloom.

SEEDS. To Select. — To select seeds from plants having single flowers which will produce double ones, closely examine the bloom upon single wall flowers or single stocks, and here and there a bloom that has one more leaf in it than the ordinary bloom will be found; the presence of this extra leaf is an infallible sign that the seed produced from that bloom will produce a plant bearing double blooms. To mark the seed, a short piece of scarlet silk is loosely tied upon the stem of the extra-leaved flowers, or where the different plants have different colored blossoms, the color of the silk may denote the color of the flower also.

WATERING. — Plants should be watered regularly once a day, except when it is rainy or the sun is not very strong; then they should not be watered till they show signs of needing it. Never water plants when the sun is shining on them; evening is the best time to water them, because the roots have time to absorb their drink all night long, and in the morning the plant is bright with health and vigor. Smooth-leaved and hard plants, as a rule, require less watering than soft-leaved plants. Small pots require watering every day, sometimes twice a day. Rain-water is best for plants; it should never be colder than the atmosphere in which the plant is surrounded; too much water rots the roots, or causes them to perish with cold. Sickly potted plants, even some that have almost died, can be greatly benefited, and sometimes, indeed, entirely restored to vigor, by applying to them warm instead of cold water. Manure waters should be applied with care and not too strong. Syringing is a most valuable mode of applying water, as it promotes cleanliness, and is necessary for removing dust and incrustations from the foliage. In winter it should be done at midday, when the sun shines; in spring and autumn, in the morning; in summer, chiefly in the evening, though at that season frequently give them a dash several times a day.

WINTER CARE. — For winter protection, all tender roses, pampas grass, oleanders, tritomas, bulbs and plants that die down to the ground, may be bent to the ground and covered entirely with coal ashes. Leaves, straw and coarse manure will serve the same purpose. Tall bushes, etc., that will not bear bending down, can be protected by stacking and binding straw around the main stalk, completely covering it.

Tuberous roots, as those of the dahlia, pæonia, tuberose, etc., intended to be planted in the succeeding spring, are preserved through the winter in dry earth, in a temperature rather under than above what is natural to them; but as they do not require light during the winter it is safer to lift and store them in a dry cellar or building from which frost is excluded. A spare closet in a part of the house where there is no danger of freezing is preferable to a cellar for these.

House Culture.

Care of Plants.

REMARKS. — The principal cause of failure with house plants is the attempt to bring under the same treatment plants of diverse character. If flowers are required, sunlight is indispensable, whereas, in partially shaded situations, the so-called "foliage plants" will thrive. If symmetrical plants are desired, turn frequently and pinch back long shoots. The plants intended for winter use should not be left outside till the chilly nights stunt their growth, but they should early be brought inside, and so gradually accustomed to the changes of temperature.

CLEANLINESS.—The leaves of plants should be kept free from dust and impurities, for through these functions perspiration and digestion are carried on. Plants must be removed from the room when sweeping; or have them in a stand with open sockets at the corners, in which the edge of iron hoops may set and a clean cotton cloth thrown over and tied beneath to keep them clean; remove the cloth carefully when the dust has settled, and shake it outdoors.

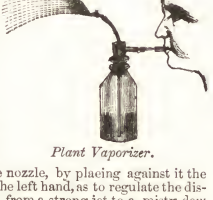
FROZEN PLANTS. — They should not be put near the stove to be thawed out, but placed in the dark where the temperature is nearly freezing, so that they can thaw gradually. If severely touched with frost, it is best to remove the frozen parts, that new stems may be forced out from the buds below. Water freely, and finally bring them to the ordinary temperature for house plants.

GREENHOUSE.—Flues, glass, woodwork and walls should be thoroughly cleaned at least once a year. The house ought to have free exposure to the east, south, and west, and be entirely free from the shade of lofty, overhanging trees. On the north side, however, and also in some degree on the east, there should be ample shelter from the cold, searching winds of spring and winter. Of whatever description the house may be, or of whatever material the stage is composed, it is of the greatest importance that it should be constructed and so situated that the plants will be as near the glass as possible. Ventilation is one of the most essential requisites; to give this, open the windows at the top of the house; never open the side slides in cold weather, but let the air in by the flaps on the roof. There are three modes by which horticultural structures are heated: 1st. The flue, or fire heat; 2d. Heated air, or the Polmaise system; 3d. Hot water. The first of these is the oldest, and by some considered the best. The flue may be built below the level of the walk, but it is best if situated above ground, so that every portion of its surface is free to give out all the heat that is generated into the body of the house. The bottom should be made of paving tiles resting on a brick at their junction with each other, so as to keep them off the ground, and to insure an open space all around them. The flue should be 9 in. square inside; the sides formed of bricks on edge, and covered on the top with tiles similar to those used for the bottom. In constructing it, care must be taken to make it perfectly tight, to prevent anything like an escape of sulphurous vapors, which would certainly destroy the plants; for this purpose the work should be put together with fine lime putty. The practice of plastering the flue is bad, for plaster is a bad conductor of heat. In houses that are used for forcing, or where tropical plants are grown, the flue should be covered with concave bricks, for the purpose of holding water and generating steam, which is necessary for all plants which require a moist atmosphere. The fire-place or furnace should be 18 in. long, 14 in. high, and 10 in. wide, with a grating for the bottom; the whole enclosed by a double iron door, that is, a door with a plate of iron on the inside of it, leaving a space of 1½ or 2 in. between. The fire-place must be a foot lower than the entrance to the flue, for the purpose of insuring a thorough draught. The 2d mode of heating consists in introducing a current of air in such a manner that it will circulate and pass all around fire-place or furnace, and during its progress become highly heated. This heated air is then conveyed into the house by an opening in the back wall, immediately contiguous to the fire-place, and thence diffused throughout the whole house. Towards the front of the house there are openings like traps communicating with an underground drain, which passes all around the inside of the house, and leading to the fire-place; down these traps, and along this drain, the cold air is conveyed to the fire-place, and becoming heated, is forced into the house, and so a continual circulation is kept up. The 3d method is the best, most cleanly, most efficient, and most easily managed; and although the most expensive at first, when iron pipes are employed, is ultimately the most economical, as it is less liable to fall out of repair. There are two varieties of heating by hot water, namely, by iron pipes and by tanks; in both cases a hot water boiler is employed, and the same description of boiler will do in either case, whether for supplying iron pipes or tanks. The boilers are made of various shapes, the preference being generally given either to the saddle or to the conical boiler. The latter is a very excellent and convenient contrivance, and can be employed without being fixed in brick work, as it stands in any position just like a common stove,

with the fire in the centre of it, and the space for the water all round the fire; it is supplied with fuel at the top, and as easily managed as a stove. Small pipes may be employed or houses of small dimensions, in some cases 2 in pipe and 3 in. are made use of; but, as a general rule, the larger the pipes are the better, as when of large diameter they contain more water in proportion to their radiating surface, and will therefore retain their heat longer, after the fire is extinguished. The heating by means o' the tank is effected much in the same way as by pipes; but the medium for conducting the water through the house is by tanks instead of pipes. If applying the tank system to the house, use the whole of the space under the platform where the pipes pass; to do this, brick piers or strong wooden trusses, about 1 foot in height, should be raised, at distances of about 3 ft. apart, and on them a wooden trough or tank erected, which must be perfectly water tight. The dimensions of this tank should be, for the house in question, 2 ft. 4 in. wide outside, and 8 in. deep inside; the length to be regulated by the length of the house. This tank must have a division up the middle by means of an inch thick partition; this partition must be 2 in. shorter than the tank at the opposite end from the boiler, to allow the water to circulate from the one side to the other; one side containing the hot water flowing from the boiler, and the other being its course back to the boiler again. The tank should be covered perfectly tight by means of flat tiles or slates, closely cemented; and when in full operation, it will be found to form a cheap and most effectual mode of heating.

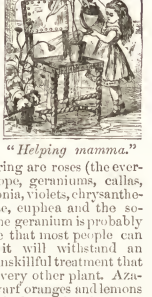
TEMPERATURE.—The average temperature should be 48° at night and 70° in the day time. Care should be taken not to get the temperature too low in cold weather, and too much fresh air should be avoided. Too much heat is just as injurious as a deficiency. If the air is dry and hot the plants will soon be infested with the red spider, green fly and mealy bug. To get the moist air so essential to all plants in rooms heated by a stove, furnace or any dry heat method, water may be evaporated on the stove or in some place near the heater.

WASHING AND SYRINGING.—A good way to occasionally wash a plant, is to spread the fingers and palm of the left hand over the surface of the soil in the pot; turn the head of the plant into a pail of water; move it briskly several times through it; then set it upright, and wash every leaf, upper and lower side, between the fingers and thumb; then swing it again through clean water, and set it once more in its position. If a little soap is dissolved in the first water, and in the washings before the last, so much the better. When on examining the foliage it is found to be supplied with bristly hairs or down on either side, then a sponge will be preferable to the fingers. In all other cases the fingers will be best, as no mechanism can ever be made to equal them. It will also be advisable, in all cases, to have a piece of loose cloth to place over the surface soil of the pot before the palm and fingers are placed across it with one hand, while the other hand holding the pot reverses the top of the plant in the water. If the plant is too large for a pail or tub it is best to lay it down, wet it all thoroughly with a good syringe, a substitute being found in a good-sized boy's squirt, especially when you can so manage the nozzle, by placing against it the forefinger of the left hand, as to regulate the discharge at will from a strong jet to a misty dew when desirable. For the latter, vaporizers, sold at all drug-stores, are often used.



Plant Vaporizer.

WATERING.—Succulents require but little water in winter, simply enough to keep them growing; aquatic or semi-aquatic plants will bear watering to saturation. (See *Ground* in GARDENING; also *Watering* in GARDENING.)



"Helping mamma."

WINDOW GARDENING.—The variety of plants that will thrive under ordinary window culture is not large and may be divided into 2 classes — *flowering* and *foliage*. Among the best plants for flowering are roses (the everblooming sorts), heliotrope, geraniums, callas, begonias, carnations, libonia, violets, chrysanthemums, Chinese primrose, euphea and the so-called Dutch bulbs. The geranium is probably the leading sort and one that most people can grow successfully, as it will withstand an amount of neglect and unskillful treatment that would be fatal to most every other plant. Azaleas, camelias and the dwarf oranges and lemons will also do well, and with those already mentioned will thrive under similar conditions. To secure good results from flowering plants, a sunny aspect is very necessary, for without sunlight the flowers will be few and poor. Among Dutch bulbs, the hyacinth, tulip, crocus and narcissus are indispensable, while anemones jonquils, snowdrops and the numerous other kinds are but of secondary importance. Hyacinths may be grown either in pots or glasses filled with water, but the others must be grown in soil only. Whichever way they are grown, it is necessary to place them in a cool, dark place for about 6 weeks, or until they have formed good strong roots. This is an important element in the successful handling of these bulbs; for on the formation of an abundant supply of good, strong roots before the flower bud starts, depends in large measure the perfection of the flowers. Crocus, tulips and narcissus can only be grown successfully in soil, but they re-

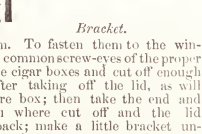
quire similar treatment to the hyacinth. Plants designed for winter flowering should be grown in pots all summer, changing them from one size to another as the pots become filled with roots. The buds should all be picked off, thereby throwing all the strength of the plant into forming a healthy and vigorous growth. For a shaded window, plants of beautiful and varied foliage are best. Among them the crotons, ma-

Window Gardening.

rantas, agaves, palms, ivies and ferns are adapted to window gardening. Very pretty effects may be made by the harmonious blending of the various colors and forms, fully equal to any made by flowers. The potting material should consist of good garden soil mixed with half its bulk of good leaf mold, well rotted manure and sand in about equal proportions. Unless very large pots are used, no drainage will be necessary, as too little water is usually applied to house plants. Do not let the pots become dry before giving water, as every drying checks to a greater or less degree the vitality. The water should be lukewarm, and given in the morning, as the room is usually warmer during the day, and the plants will not then have to contend with cold atmosphere and chilled roots, so frequent at night. The amount of water required varies with different kinds, and experience alone can determine when to give and when to withhold moisture. The temperature should not be allowed to fall much below 40°, for if kept too cold plants will not thrive, but will turn yellow and drop their foliage; this sometimes occurs when they need nourishment. This condition may be overcome by applying some fertilizing element in the shape of liquid ammonia, of which 1 tablespoonful in a pail of water will be found sufficient, or 1 teaspoonful of bone meal or some other chemical fertilizer may be scattered on the top of the pot and then stirred in. Care should be exercised in using guano, as it is highly concentrated and requires but very little to produce good results. There are many plants that will thrive in one situation that utterly fail in another, so that those who start window gardens should not be discouraged over the loss of a few plants, but try others until success is attained.

Stands and Baskets.

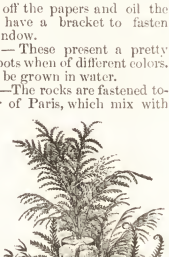
BRACKETS. — 1. These may be made of any required size, to fit any desired place. For the construction of a simple form use ¼ in. iron rod or wire, heat in stove and bend to the size wanted. When a blacksmith is near that part may be done by him. To fasten them to the window frame use common screw-eyes of the proper size. — 2. Take cigar boxes and cut off enough of the box, after taking off the lid, as will make a square box; then take the end and tack on again where cut off and the lid will make a back; make a little bracket under the box; wash off the papers and oil the box, and you will have a bracket to fasten at the side of the window.



Bracket.

BULB GLASSES. — These present a pretty effect among other pots when of different colors. In them bulbs may be grown in water.

FERN ROCKERY.—The rocks are fastened together with plaster of Paris, which mix with dry colors, grays and browns predominating. As fast as the plaster is applied, sand is thrown on it. The effect of the coloring and sanding of the plaster is to destroy its whity glaring look, and to harmonize it with the general colors of the rock work. The cans used for the flower pots are first wrapped in wet paper, to increase them in size, before applying the plaster against them when building up the rock work. In a few hours the paper wrappings will be so dried that the pots are easily withdrawn, after which the paper is removed and the pots put back in their places. This placed on a table makes an effective ornament for the room, or it can be set outdoors.

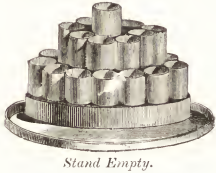


Rockery.

FLOWER STANDS. — These are made of various designs of wire, wood and iron, and are usually painted green. The size depends upon the number of plants and the style. A nice home-made stand may be constructed as follows: Secure an old centre-table and two cheese

boxes of different sizes; place one on top of the other, the smaller one on top; around the side of the lower place fruit-can flower pots; above these on the next cheesebox place more, and on the top of the smallest box place more pots, so that but little of the cheese boxes can be seen; all the pots ornament with burrs, cones, lichens, or barks; the spaces left between the boxes fill in with wood mosses; around the rim of the table nail hooping from a flour barrel; the inner angle formed by the hooping and the top of the table, patch with putty; over the entire top of the table, the hooping and the putty, apply hot asphalt with a brush; a hole bored through the top of the table affords an escape for surplus water; the cheese boxes coat inside and outside with asphalt to prevent them from warping; the open space between the first circle of pots and the rim of the table fill in with earth, on top of which build up moss to the first circle of pots.

Wire Flower Stand.



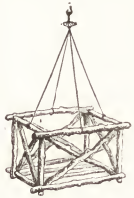
Stand Empty.

Stand Filled.

HANGING BASKETS.—Under this heading are usually classed pots, logs and the various shapes of wire and rustic baskets. A very pretty effect may be made by cutting off 3 or 4 in. of the top end of a carrot, scooping out the interior and filling with water; it will soon start to grow and the leaves will curve upward, completely covering the root. Rustic logs, pots or baskets can be readily made by one possessed of ordinary skill in the use of tools. A hanging log can be made by partially telescoping two cans together, after the opened end has been entirely removed; a section of the side of each can is cut out, to leave an opening for the reception of the soil and plants; the cans are then heavily coated with asphalt, particularly where the cans are joined, so as to strengthen the joint; barks of chestnut and oak trees are used for covering the cans. Wire baskets should be thickly lined with moss before they are filled with soil. A pretty basket may be made of rustic limbs of trees. The branches are collected and cut of uniform size. It should be made longer than it is wide. Then they are joined together, the sticks being laid to form different designs; they may be hung up by wires. When ready for use they must be lined with moss. Care should be taken not to allow the baskets to get dry, as herein lies the root of the difficulty with all hanging designs.

Hanging Log.

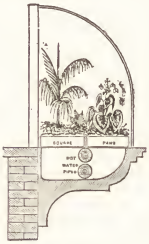
Wire Hanging Basket.



Rustic Basket.

JARDINIERES.—These are very elegant and add much to the appearance of a room. Never put more than one flower in the pot at a time; simplicity is their chief beauty.

PLANT CASES. — A fernery or plant case might be arranged to run the whole length of the front windows of a story and be heated by a small boiler placed behind a fire-place; from this a 2 in. flow and return pipe is taken through the case, so as to heat it when required; the space around the pipes can be filled with bark or water if desirable, so as to produce a moist and genial bottom heat; the ferns, mosses, and other decorative plants, are arranged in flat square pans of zinc or earthenware, and the effect of the whole, especially when seen from within, is very effective, and affords relief to the eye which might otherwise look out on a dismal prospect of blackened roofs and soot-begrimed chimney pots. Wardian cases are very convenient contrivances for the protection of ferns, mosses, and other delicate plants. They were invented by a Mr. Ward and from him receive their name. They were originally quite portable, but now appear in all possible forms and sizes. They consist of a lower portion containing soil for the plants, and of a glass inclosure, which should be very tight to exclude dust, wind, etc., and prevent the escape of moisture. The glazed inclosure is open to the light on all sides and on the top, and is sometimes movable; at other times it can be opened without lifting it. The common square or oblong form is a good one.



Section of Plant Case.

Wardian Fern Case.

WINDOW BOXES. — Window boxes for holding plants can be decorated to look very pretty. The box should be 8 in. high, 10 in. wide, and the length of the window. A design, either conventional or of flowers, birds, and butterflies, is to be painted on the outside, with a background of whatever color may be preferred; let it stand for several days, that the paint may be perfectly dry, and then give it a coat of drying oil laid on quite thin, but evenly; it should be allowed to dry thoroughly before putting in the plants. If painting is not possible, oil-cloth may be used with good effect to decorate it with; select a pattern that will give the appearance of tiling, and cut strips to fit the sides and ends exactly; these should be tacked smoothly on the box round the upper and lower edges; a narrow black walnut molding finishes the top and bottom and the joinings at each corner; the plants are then put in with sufficient earth for their growth, and the top of the earth covered with moss and vines. Small boughs of ash, hazel, or other straight-growing trees, split into halves and nailed on the front of the box in diamonds and other simple figures, are also very effective. Cones and acorns make a pretty decoration for them. Where it is practicable, the effect of the ordinary window box may be much enhanced by the addition of wire netting up each side of the window, so that climbing plants placed at each end of the box may ascend it. Or a light wire trellis arch may have its extremities fixed in each end of the box, so that it will span the window top. A very pretty box consists of a rough pine box, covered with cork shavings of different thickness, the thinner ones forming the panels under the arches, and the thicker ones the arches, pilasters and cornice.

Cone and Acorn Window Box.

Cork Window Box.

(For the preparation of the cork see *Cork Ornaments* in HOUSEHOLD ORNAMENTS.) The box should be painted inside and varnished outside to render it waterproof. The earth for the plants should not be put directly into the box, but into pots which are placed in the box and hidden by it. Boxes faced with encaustic or glazed tiles are very convenient and much used.

Jardiniere.

Pests.

Solutions to antagonize pests are often well applied by an atomizer or vaporizer. (See *Washing and Syringing* in House Culture.)

BLACK ANTS.—Place fresh bones where they congregate; they will gather upon them and may be scalded.

CATERPILLARS.—The varieties of caterpillars are innumerable. Many of them feed on leaves; some species are restricted to a single kind of plant; those which infest flowers and garden plants can only be kept away by watering the plants copiously and frequently, and by examining them often during the spring and summer and destroying the caterpillars.

GREEN FLY. — These are not always green, but vary from yellow to green, according to what they eat. They are very common and easy to get rid of. 1. They may be destroyed by tobacco smoke, or tobacco water.—2. The stems and leaves of the tomato plant are well boiled in water, and this decoction, when strained and cold, is syringed over plants which are infested by the green fly and other insects. The liquor, when once applied, leaves behind a peculiar odor which prevents insects from coming again for a long time. — 3. Take a 2 gal. water pot full of water, put into it 2 wine glasses of paraffine; then mix well with the syringe; afterward syringe the roses with the mixture. It will kill every fly and will not injure the tenderest shoot or the rose blooms.

MEALY BUG. — This species is reddish, and strewed with white dust. At the sides of the 12 segments of the body it is provided with small tubercles. The male is slender and gnat-like, with two rather broad wings, and two long, brush-shaped tail filaments. It attacks a number of species of plants, and can only be diminished in number by brushing them off carefully with soft brushes, and crushing them.

MILDEW.—To prevent mildew on roses and other plants syringe with the following: Mix 1 lb. of flour of sulphur and 1 lb. of fresh lime in 5 qts. of water; repeatedly shake the mixture; and after settling put it into well-corked bottles. For using, 1 gill of this mixture is put in 3 gal. of water.

OLEANDER SCALE.—The female appears as a yellowish, round, flat shield, almost destitute of limbs, which sucks plants with its rostrum. The shield of the male larva is smaller than that of the female, and quite white. The perfect male is brownish-yellow, dusted with white, and white wings. Length, 1-36 of an in. It lives in amazing numbers on different kinds of plants, particularly on oleanders, acacias, aloes, palms, etc., and can only be gotten rid of by careful brushings.

ORANGE SCALE.—This appears like an elliptical nut-brown shield, and is very plentiful on greenhouse plants, particularly on orange trees, fastening itself upon the branches and leaves, particularly when the trees are kept rather warm. It may be destroyed by washing the branches and leaves. If this be done in autumn, it is a great advantage, as the old ones cannot creep up again. Or, they may be destroyed by spraying kerosene through an atomizer over the leaves covered with scale and black fungus.

LICE.—A teaspoonful of ammonia to 1 qt. of water sprinkled every other day over plants will cause lice to disappear and not injure the plants.

RED SPIDER. — It is scarcely visible to the naked eye; has 8 legs; its color changes from yellowish to brown and reddish, and on each side of the back is a blackish spot. In the open air it usually attacks kidney beans. Among trees, the young limes mostly suffer, and the mites are found in thousands on the under side of the leaves. These leaves assume a dirty-yellowish or brownish appearance, and in the middle of summer the trees acquire an autumnal hue.—1. Frequently sprinkling the plants with cold water has been found efficient as a means of destroying these insects. — 2. Repeatedly fumigating the hot houses with strong tobacco smoke injures them in some degree.—3. A teaspoonful of salt in 1 gal. of water; sprinkle with this; in a few days wash the plant with pure water. — 4. Wash the plant with warm soap-suds with a very few drops of coal oil in the water; then remove all dead or sickly leaves and branches. Stir up the soil; syringe the foliage frequently.—5. Fill a barrel nearly full of water; slake in it about ½ peck of lime, and let it stand until perfectly clear; hold the plants in the water, bottom up, for about 5 or 10 minutes, then wash them with pure water.—6. A little flour of sulphur dusted over and under the leaves is efficacious. Separate those that are infested from those not touched; do so as soon as you discover them. They will always be found on the underside of the leaves. The plants should be taken from the window to a place where water can be used freely.

ROSE MOTH. — In early spring, if the new leaf-shoots of the rose tree are closely examined, a little brownish scale is found here and there attached to them, in which a worm, the larva of a small moth, is concealed, which gnaws the tender shoots. The larva which lies in the little case is about ½ in. long; yellow with a black head, and black-spotted collar. It undergoes pupation in its case, which enlarges from time to time, as necessity requires. The moth appears at the end of May. The whole body is silvery shining gray; the upper wings strewed with minute black dots, deeply fringed at the posterior edge; the under wings are narrow, pointed, with very long fringes. The only certain way of preserving rose trees from this enemy is to look for the small cases in early spring, before the foliage is developed, when they must be crushed immediately.

ROSE SCALE. — These live on the stems and old twigs of rose trees, which are sometimes entirely covered with them, and look moldy. Brush them off with strong brushes before the rose trees sprout.

ROSE SLUGS.—This is the name given to the gasteropodous naked mollusc, so great an enemy to our gardens and fields. They are, unfortu-

nately, too well known to require description; they are found in nearly every part of the world, but are more common in the temperate regions. —1. A common plan to prevent their attacking plants is to surround the foot of the plant with soot; this the slugs will not cross.—2. A good way to catch them is to get a few cabbage leaves, and having warmed them well in an oven, rub them over with unsalted butter or dripping, and place them in the haunts of the infesting mollusc. In a few hours the leaves will be found covered with slugs, and they may then be destroyed.—3. Take an ordinary sprinkling pail, with a fine nozzle; put in a few spoonfuls of kerosene and 2 or 3 spoonfuls of hellebore; then fill with water and give the bushes a thorough sprinkling. Take care to have the mixture reach the under side of the leaves as far as possible. Apply as soon as the slugs appear, and you will be entirely rid of them.

SWEET BAY SCALE.—The shield of the female is oval-shaped, brown, with a reddish-yellow elevation before. The male is pale cherry-red; the body flat; the horns or feelers rather shorter than the body. The shield of the larva the same as the female, but narrower. It is difficult to remove, as it is so firmly seated that brushing is not always sufficient; a pointed stick must be used.

THRIP is a nimble black insect, exceedingly pernicious, and very fond of ferns, azaleas, lilies of any sort, callas and the like. Their work is discernible in rusty brownish or yellowish blotches and tracings on the leaves, which they very soon destroy. The old or black ones are hard to kill. They should be bruised to death by the fingers. The young or yellowish ones should be bruised by sponging; then shower with clean water afterwards. In greenhouses thrips are killed by tobacco smoke.

WORMS. — Worms at the roots of plants can be exterminated by watering with a solution made of fresh lime and water. Use after the lime has settled.

VARIETIES.

ABRONIA.—A pretty annual, with long, trailing stems, bearing in profusion clusters of elegant verbena-like flowers of great fragrance, remaining in bloom a long time; very effective in beds, rockwork, or hanging baskets. The seeds are enclosed in a husky covering, which should be removed before planting; can be sown as early in the spring as the ground is ready to work; transplant 1 foot apart. It requires a light soil.

Abronia.

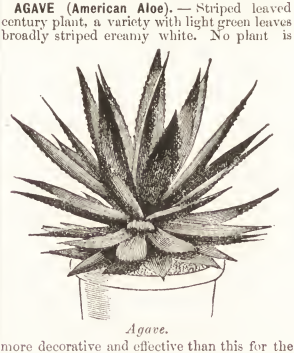
ACACIA.—A genus which supplies, during the winter and spring months, a perfect blaze in the greenhouse and conservatory. They are hardy and evergreen; the flowers are yellow and many of them are fragrant. They continue long in bloom and are generally grown in sandy loam mixed with a little peat and leaf mold; require good drainage, an abundant supply of water, and the soil moist at all seasons. Being liable to become leggy, the best plan is to cut them in after flowering in spring. The plants should be well furnished with shoots from the base, keeping them plentifully branched by frequently stopping the shoots; plant the seeds in March in a hot-bed, soaking the seeds in water at 90° for 24 hours before sowing; or cuttings of the young shoots taken off at a joint, in sand over sandy loam and peat, placing in a hotbed.

ACROCLINIUM. — One of the finest and most beautiful of the everlasting flowers, growing freely in light garden soils, and blooming in August and September; flowers pink and white with yellow centre; very desirable for the flower garden, and a great acquisition for winter bouquets, for which purpose they should be cut as soon as they begin to expand, and carefully dried in the shade. They grow about 1 foot high, and should be planted about 4 in. apart.

AGAPANTHUS (African Lily). — A tuberous rooted plant with recurved leaves. The handsome blue flowers are produced at the top of the flower stems, which grow about 3 ft. high, often bearing from 20 to 30 flowers. The seed produces small tubers which will require two seasons' growth to become of sufficient size to flower. Plant in sandy loam in greenhouse, and transplant to open ground when weather is warm. Secure the tubers from extreme cold.

Acroclinium.

AGAVE (American Aloe). — Striped leaved century plant, a variety with light green leaves broadly striped creamy white. No plant is more decorative and effective than this for the



Agave.

conservatory in winter and lawn or garden in summer. They succeed in 2 parts fibrous light loam, 1 part leaf soil, and ½ part sandy peat, pieces of charcoal, and sand in equal proportions.

ALLEGHANY VINE (Adlumia). — A most beautiful and graceful climber, thriving in a sheltered situation. It is sometimes known as mountain fringe and wood fringe. The beautiful pink and white flowers are produced in abundance during the three summer months. It is biennial, and makes but little growth the first season. Sow the seed in April, and the following autumn transplant to the place where they are to blossom.

ALMOND, DOUBLE FLOWERING. — A shrubby plant, bearing beautiful rose-like flowers in the spring. It is propagated by suckers.

ALTHEA (Rose of Sharon). — This is really one of the most showy and beautiful flowering shrubs; the flowers are of large size, very double and full, and of various brilliant and striking colors. It blooms freely during August and September when scarcely any other tree or shrub is in bloom.

ALYSSUM, SWEET. — A small pure white fragrant flower; grows freely from seed, either under glass or in the open ground, and makes a pretty border. Sow the seed in May or June.

Alyssum.

AMARANTHUS. — An annual plant, with a beautifully variegated foliage of red, green, and yellow. The name means "never withering" and embraces a large class of flowers, including *Love Lies Bleeding, Fountain Plant, Princess Feather, etc.* It requires a rich soil. The seed is found in little tufts about the stalk, and may be sown in April or May.

AMARYLLIS. — This blooms in August; has a strong flower stem 18 in. high; bears in succession from 4 to 8 brilliant purplish scarlet flowers, 2 to 3 in. in diameter; continues in blossom a long time. The bulbs should be potted in a rich sandy loam, with good drainage. They require abundant moisture when growing, but at their season of rest water should be given sparingly.

Amaryllis.

ANEMONE. — A most beautiful flower, both double and single; the single is the most brilliant. It is plain looking during summer, with dark green foliage; but in the latter part of summer flower stems appear, growing 18 in. high, with white flowers. It requires a pure loamy soil well mixed with sand, and is raised from seed or from pieces of the roots. Sow the seed in spring. During the summer, it sends out young roots, which must be taken off and planted out, to become blowers.

ANIMATED OATS. — An annual plant, resembling the common oats while growing. The seeds are clothed with a stiff down, and have appendages like the legs of some insects, with apparent joints. They are affected by the changes of the weather, and are continually moving. If they be wet, they will turn over several times, and twist about. If wet, and held to a lighted lamp, they exhibit such motions of apparent agony as an insect would, placed in a like situation.

ASTER, CHINA. — An annual, producing many splendid flowers. There are several varieties, as red, white, purple, yellow, striped, quilled, etc. The seed should be sown early in the spring. It flowers late, but is destroyed by severe frosts. It requires deep, rich soil, and may be grown in a hot-bed and transplanted, or in an open seed bed; large varieties should be 12 in. apart, and small half that distance.

AZALEAS. — Spring flowering shrubs, universally esteemed for their beautiful flowers, which are produced in great profusion from April to June. The flowers are of all conceivable colors, and for brilliancy are unsurpassed. They need hot-house culture, and the seed should be planted in April in a cold frame, in a turfy peat soil, with a good proportion of sand intermixed; transplant out the seedlings the year following, in beds, 4 in. apart, to remain till they flower. It is well to cover the plants in the fall, with straw or mulch, as the late frosts sometimes destroy the young, early shoots.

Azaleas.

BACHELOR'S BUTTON. — A perfectly hardy border plant, succeeding finely in any common garden soil, but the flowers are more brilliant if grown in gravelly ground. Under cultivation, it is a handsome flower, blooming into varieties of white, purple, pink, parti-colored, etc. It is a hardy annual, 2 to 3 feet high.

BALLOON VINE (Cardiospermum). — A curious half hardy annual, remarkable for its inflated membranous capsules, and sometimes called *Love-in-a-Puff*. The flowers are insignificant, but the plant is a rapid and graceful climber. Sow in open ground, from 1st to 15th of May, and give the plant support to run upon. It is suitable for low trellises and greenhouse decoration; succeeding best in a warm situation.

BALSAM (Lady Slipper). — A beautiful annual plant, with great abundance of flowers. To have them in perfection the plant should be set 12 in. apart and trained to 3 stalks, which will be as thickly laden with flowers as the hyacinth; or the plants can be set 5 or 6 in. apart and trained to only 1 stalk by nipping off every other branch but the centre one, and keeping

every straggling shoot down. Thus trained, all the strength of the roots is concentrated into a very small space, and the flowers will be very large and double. The soil should be very rich and loamy, and the plants will grow better if mulched with strawy litter in July or with grass from the lawn mower.

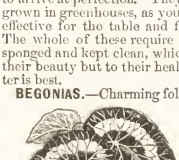
Balsam.

BARTONIA.—A very showy, half-hardy annual. The leaves are somewhat thistle-like in appearance, gray and downy. The flowers of a very bright metallic yellow, and exceedingly brilliant in the sunshine. It likes considerable moisture, and young plants suffer sometimes in a dry time. Sow the seed where it is destined the plants should bloom, as they are transplanted with difficulty; thin to 6 in.

Bartonia

BEAR GRASS (Yucca).—Splendid, showy, hardy plants, with aloe-like foliage, bearing a close panicle of cream-colored, drooping, tulip-like blossoms; plant the seed where it will remain undisturbed, as the plant takes some time to arrive at perfection. They are, however, best grown in greenhouses, as young plants are very effective for the table and for vases in rooms. The whole of these require to have the leaves sponged and kept clean, which adds not only to their beauty but to their health. Soft tepid water is best.

BEGONIAS.—Charming foliage plants. There are many flowering sorts, varying in color from pure white to scarlet. Sow in heat, in February; pot the young seedlings off as soon as large enough, and repot when necessary. In 3 or 4 months the plants begin to display their splendid and continuous bloom. They require a rich soil and an abundance of water at the roots. They may be propagated by cuttings.



Begonia.

BITTER SWEET (Celastrus).—A hardy, deciduous climber, producing yellow blossoms early in the season, and later ripened fruit which is very ornamental, and remains on the vines nearly all winter. Grows about 20 ft. high.

Bitter Sweet.

BLEEDING HEART (Dicentra Spectabilis).—A native of China, with heart-shaped deep pink flowers, a dozen or more borne on a graceful drooping branch. Pot before frost in autumn for blooming in the house.

BOX.—A low, delicate shrub, which may be pruned to any shape to please the fancy. It is an evergreen, hardy, and suitable for borders, and is grown by cuttings, or by dividing the roots. If a plant be placed deep in the earth, and the soil be brought in close contact with the small branches (being spread as much as possible), they will send out roots, and furnish a large number of small plants. In trimming this shrub, let the operation be done well, using the proper utensils.

Browallia.

BROWALLIA.—A lovely little flower; grows wild in South America. It germinates quickly from seeds and is a constant bloomer. If the flowering branches are picked when the frost threatens and are kept in vases of water, they will continue to bloom for weeks, and will also throw out tiny roots, so that they can be planted and kept during the winter. The blue flowering varieties are preferable to the white because blue flowers are much rarer. Although the flowers are quite small, they are peculiar in shape and unsurpassed for vases and bouquets.

CACTUS.—There are several kinds of cactuses: prickly pear (*Opuntia*), with spines ¾ of an in. long; quadrangular stemmed cactus, like the most familiar one in greenhouses; a cactus with rounded ribbed stem, growing in candelabrum-like form (*Cereus*); and a large dome-shaped cactus, 1½ ft. high, and bearing a crown of small red flowers. By their structure the cactuses are especially adapted to a long season of drouth, and in a dry time they take their rest, the same as our plants do during the winter. They need very little water during the winter, and should be kept in a warm place, and where they will not get near the freezing point. In spring, when they start to grow and bloom, they should be freely watered. The exceptions to this treatment are the *Epiphyllums*, Crab's Claw cactuses, and the Rat-tail cactus, *Cereus flagelliform*.

CALADIUM ESCULENTUM.—One of the largest and grandest of the ornamental plants, with leaves 1½ ft. long, and 1 foot wide; of a beautiful variegated or mottled green. It will grow in any good garden soil, and is easy of culture. Roots obtained in the spring will make good plants in the summer, and in the fall they should be taken up and stored in a cellar.

Caladium Esculentum.

CALANDRINIA.—Fine, dwarf plants for grow-

ing in masses, having fleshy leaves and succulent stems like the portulaca, and producing an abundance of blossoms, which, when fully expanded, make a beautiful appearance, and suitable for edgings, rockeries and clumps; in bloom a long time. The seed should be sown in hot-bed, early in spring, and planted out in June, in rich, sandy loam, in masses. They are a tender annual, but perennial if protected in winter, and grow ½ to 1 ft. high.

CALCEOLARIA.—Remarkable for their large, beautifully spotted blossoms, which are very showy, and from which an almost countless number of hybrids have been raised. They are perennial, and are grown in pots in the conservatory, greenhouse and garden. Sow in a temperature of 50 or 60° from January to April, in shallow boxes, in light soil, merely pressing the seed into it and covering with light leaf mold or sifted moss. Transplant into similar boxes as soon as the tiny plants can be handled, and when strong enough into pots. For winter and spring blooming sow from August to September. They are propagated from seed or cuttings. The best time for making cuttings is as soon as the young shoots can be had after flowering. Some of them are herbaceous perennials, others shrubby evergreens.

Calceolaria.

CALIFORNIA POPPY (Eschscholtzia).—Finely cut leaves of a glaucous color, and blossoms about 2 in. in diameter, of many brilliant and showy colors. Sow the seed where the plants are wanted to bloom, as they do not bear transplanting. Thin to 6 in. apart. As the stalks and branches are delicate, they will do better if supported by small sticks. It requires a light rich soil, and is a hardy annual.

CALLIOPSIS.—This is a hardy annual, 2 ft. high, and is a very showy border plant, producing flowers in nearly every shade of yellow, orange, crimson, red, and brown. If the seed pods are removed as soon as they appear, the plant will remain in bloom much longer. Sow where they are to remain, and thin to 2 ft. apart.

Calliopsis.

CALYCANTHUS (Spice Shrub). — This is one of the sweetest of our hard-wooded shrubs. The leaves are slightly fragrant, the bark and flowers exceedingly spicy. The plant makes a bush several feet in height, is hard-wooded, the leaves large, and the flowers abundant, and of a brownish or cinnamon color.

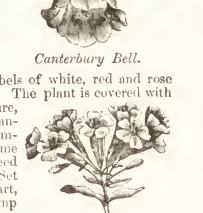
CAMELLIA. — One of the earliest of spring flowers, valued for beauty of color. The best soil is an equal quantity of good sandy loam and peat. They are propagated by inarching, cuttings, grafting, and from seed, the latter being the only method of obtaining new varieties. When the plants are not growing, they should receive but little water, and when growing freely, can scarcely receive too much. A regular succession of flowers may be obtained from autumn till July, if attention be given to removing the potted and growing plants from a warm to a cooler atmosphere. When the growth is completed and flower buds formed, a cool, sheltered situation is best, for they will be seriously injured if exposed to the rays of the sun.

Camellia.

CANNA (Indian Shot). — Stately and highly ornamental plant, desirable not only for the beauty of its spikes of flowers, but for its elegant foliage. The leaves are a rich, deep green, 3 ft. long and 6 in. wide, very handsome as they unfold themselves. Start the plants in hot-bed in pots, and transplant in June, and blossoms will appear in July or August. Soak the seed thoroughly before planting, and keep in a warm spot. The roots can be kept in the greenhouse from year to year, and then it becomes perennial. They are a tender annual, in open ground, 4 to 6 ft. high.

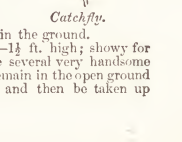
Canna.

CANTERBURY BELL (Campanula).—A biennial plant, bearing large blue flowers which are much admired, and make a fine appearance. Sow in open ground early in the spring; thin out to about 6 in. apart; propagated by division of roots or by seed.



Canterbury Bell.

CATCHFLY.—This is a hardy annual, 1 ft. high, and produces dense umbels of white, red and rose pink-like blossoms. The plant is covered with a glutinous moisture, from which flies cannot disengage themselves; hence the name catchfly. Sow the seed in spring or fall. Set flowers 6 to 8 in. apart, so as to form a clump or border. After having been once grown, the seed will sow itself in the ground.



Catchfly.

CHRYSANTHEMUM.—1½ ft. high; showy for large beds. There are several very handsome varieties. They may remain in the open ground until late in the fall, and then be taken up

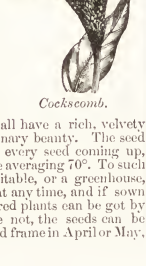
and placed in pots. When the frosts appear, keep them in a warm room until after flowering, and then put the roots in the cellar or open ground. They will flower in the garden, if carefully attended to. Raise by dividing the roots. The ordinary soil is formed of good loam and well decomposed dung, in the proportion of 2 parts of the former and 1 of the latter. The flowers determined upon to save seed from should be protected from wind, rain, and insects; their own pollen must be dusted upon the stigma; and the seeds gathered as soon as they are ripe, and sown in the February following in a gentle hot-bed, in shallow pots, and light, sandy loam. When the seedlings are high enough to be handled, transplant them into the smallest pots, and repot as soon as the pots are moderately filled with roots.

CLARKIA.—An effective, hardy annual, 1½ ft. high, with bright pink, red, white, purple and lilac flowers. It is better to sow the seed in September, and the plants will be large enough by spring to make good bloom.

COBOEA SCANDENS.—A climber of very rapid growth; has large purplish bell-shaped flowers; will grow in the garden during summer, but will not stand frost. Put the seeds in moist earth, edge down, and do not water until the young plant appears, unless in a warm place and the earth is very dry. In the autumn plants can be taken up with care, potted and removed to the house, where they will flourish and flower during the winter. When it becomes too large in the house turn back a shoot and lay it in the ground to root, when it will become a young plant. It will succeed in any rich soil.

Coboea.

COCKSCOMB, or CELOSIA.—One of the most interesting and singular of annuals. In a rich soil with careful cultivation the heads grow from 6 to 18 in. across. The seed should be started in a hot-bed, or in pots in a warm room, and transplanted in a warm, rich soil.



Cockscomb.

COLEUS.—A universally admired ornamental plant. The leaves are of all shapes, shades and colors, and nearly all have a rich, velvety appearance of extraordinary beauty. The seed germinates very easily, every seed coming up, if sown in a temperature averaging 70°. To such as have warm rooms suitable, or a greenhouse, the seed may be sown at any time, and if sown by January, finely colored plants can be got by May. To such as have not, the seeds can be sown in a hot-bed or cold frame in April or May, and when of sufficient size, grown in pots or planted out in the open ground. Seeds sown in April will produce plants 3 ft. high and as wide by September. Slips should be taken from the finest, which will grow finely all winter, if potted and placed in greenhouse or conservatory.

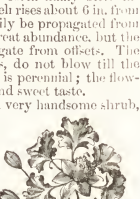
COLUMBINE (Aquilegia).—A very pretty perennial, bearing in June and July red, blue or variegated flowers. It is propagated by seed sown in open border or by separation of the roots in autumn, and thrives best in a strong soil and shady place.

Columbine.

CORAL TREE (Erythrina).—A greatly esteemed deciduous summer flowering plant, producing large spikes of crimson coral-like flowers during the greater part of the summer. The roots are thick and fleshy, but not exactly tuberous, and may be kept in a pit or cellar during the winter. Plants put out in the spring will flower during the summer, and before hard frosts should be taken up, cut back and stored away until the following spring. Start in heat, and transplant out of doors in warm situations, where the plants will grow freely.

COWSLIP (Primula). — This is of a delicate yellow color, and sends forth many blossoms from the same stem, which rises about 6 in. from the ground. It may easily be propagated from seed, which it bears in great abundance, but the easiest way is to propagate from offsets. The plants raised from seeds, do not blow till the second year. The plant is perennial; the flower has a delicate smell, and sweet taste.

CRAPE MYRTLE. — A very handsome shrub, hardy in the Southern States, flowers very freely, almost concealing the plant with blossoms. In the North the plants may be wintered in a cool, dry cellar.



Crape Myrtle.

CRASSULA. — There are many species of this genus, but that which is most generally in cultivation is *Crassula coccinea.* It has showy scarlet flowers in July, and is green in sandy loam, with a mixture of lime rubbish.

CROCUS. — A bulbous-rooted plant, hardy, and early; colors, blue, yellow, white, purple, etc; begins to bloom in March. The yellow are the most vigorous in growth. Plant in the fall, setting the bulbs 3 in. apart and cover with not less than 2 in. of soil. Just before the winter sets in cover the bed with a little straw or leaves, to prevent the bulbs being heaved out by the frost. Beds can be formed by planting different colors, each color in a row. This makes what we term ribbon beds, and the effect is pleasing. Circular beds look best—say 4 ft. in diameter. A few crocuses planted in the lawn at different places (simply by raising the sod with a trowel and inserting the bulb) will give a pretty appearance in early spring.

CROWN IMPERIAL.—Very early in the spring the strong flower stem of the crown imperial begins to appear. Nearly at the top of the stem appears the flowery crown of bell-shaped flowers, and above these a tuft of glossy-emerald leaves, which completes the crown from which its name is derived. Plant the seed 4 in. deep and 1 ft. apart. They do not usually flower the first spring after planting, but once planted they will last a life-time, growing and increasing from year to year.

Crocus.

CUPID'S EAR (Monk's Head).—A fine, vigorous annual, bearing a profusion of pretty blue flowers, during the summer and fall. Propagated by a division of the roots. A very neat plant for the flower garden.

CYCLAMEN. — Well known and universally admired bulbous rooted plants producing exceedingly handsome red and white flowers. The leaves are heart-shaped, while the flowers are of one petal, but deeply divided into 5 segments. After flowering the flower stalk coils itself up in a spiral form, with the seed vessel in the centre, and bends itself towards the ground, in which position the seeds are ripened. The seed should be sown in spring, and by autumn will produce a bulb, which, if potted and placed in conservatory or greenhouse, will blossom the following spring. Propagated only from seed. The soil should be very light and rich, containing a good part of peat and sand, with well-rotted cow manure. They require frequent watering while growing.

Cyclamen.

CYPRESS VINE. — One of the most delicate and beautiful of the tender annuals; foliage very fine dark-green; flowers small, star-shaped, and exceedingly brilliant; vine will grow from 4 to 20 ft. Sow seed in circle 2 or 3 ft. across; set a 10 ft. pole in the centre and run strings 3 in. apart from circle to top of pole, forming a striking cone of great beauty; do not sow until after danger of frost is past; make the soil rich.

Cypress Vine.

DAFFODIL. — A very common flower, but its early blossoming and color make it always welcome in the garden. It looks well in the shady parts of small shrubberies or borders, and if planted in tolerably large numbers makes a great show. It is frequently grown also in pots for the conservatory or greenhouse The soil should be a rich, sandy loam, with a little leaf mold intermixed with it. Should it be required to force any for early flowering, they should be moved out of the ground as soon as the leaves begin to decay, and be kept in a dry place until potting time arrives.

Daffodil.

DAHLIA. — This exceedingly beautiful genus comprises an almost endless number of varieties, all more or less showy in the flower garden in the autumn, when most other flowers have faded. They are all of easy cultivation, grow ing freely in almost any soil, from seed sown in spring. The seed should be sown in shallow pans, in March, and the seedlings transplanted to small pots. As soon as danger of frost is over, plant out, 1 ft. apart. These plants will make a tuber, which should be taken up in the fall and kept through the winter in a cool, dry place, away from frost, and planted out in the spring, when it will blossom the following autumn.

Dahlia.

DAISY. — A small, delicate, perennial plant, producing small but attractive flowers. It is hardy, and will bear flowers through the winter, if kept in pots or boxes, in the house. Not all will come double from seed, and the single ones should be pulled out. Sow early in hotbed, and when large enough, transplant to a rich, cool, partially shaded situation. Set the plants 6 in. apart. Roots can be divided any time. Flowers are most abundant in spring.

DAPHNE. — Evergreen shrubs, with white or purplish pink flowers in April to June. Require to be under rather than over potted. Good drainage is necessary, and equal parts peat and loam, both sandy and fibrous, with a sixth of silver sand; keep moist, but avoid making the soil sodden. Rather moist and slightly shaded when growing, otherwise light and airy position. Propagated by cuttings of firm shoots in sand under a bell glass in a close frame, at the end of summer, or by grafting on a hardy stock. The berries of this plant are highly poisonous, while the juice of it is so acrid as to blister the skin.

DAY LILY (Funkia).—A superb autumn flower, with beautiful, transparent, white trumpet-shaped flowers, one of which opens every day. The blue variety has smaller bell-shaped flowers.

DRAGON TREE (Dracaena).—Very ornamental pot plants, grown for their beauty of form and foliage. They require re-potting about 3 times a year to keep them in a healthy condition. The leaves should be washed with a damp sponge weekly. They are also especially adapted for using in hanging baskets, or vases, as centre plants, for which purpose they are without an equal. In winter keep moist, but not too much so. Use 3 parts fibrous loam, ½ part each sandy peat and leaf soil, with ⅛ of silver sand, and a few pieces of charcoal; supply good drainage. They are better kept rather close and moist when making fresh growth.

ECHEVERIAS (House Leek).—A splendid house plant, also well adapted for rockeries, carpet beds or outer edge of ribbon beds. For pot culture they require a good drainage, small pots, plenty of sand, but not too much water. They will stand all the sun you can give them. After the flower stem is done blooming (or before if you are in a hurry), twist off the leaves which are on it, and insert them slightly in moist sand or sandy earth. These will in a week throw out a young plant which, when strong enough, can be shifted into a small pot and richer soil. From where the leaves are taken off the stem, young plants will now appear, which, if treated the same as above, will soon make fine specimens. Should any old plant get lanky, cut the top off, with part of the stem, and root it in sandy soil.

FERNS.—Ferns require a moderately airy and shaded part of the greenhouse, and are suited to positions which, from shade, moisture and little air admitted in the immediate vicinity, are ill-suited for flowering plants. They need light, but the fierce scorching rays of the sun should be broken by climbers or a light canvas shading from April to September inclusive, there being no sun to hurt them during the winter season of the year; and without air they become drawn and weak, and yet if too dry the growth is stunted and sometimes dries up. In gardens of large extent, the situation of the fernery should be some retired place, with a dense shrubbery or plantation to the north of it. In small gardens, in the suburbs of towns, the habitation for ferns should be in some retired part, the south side of it. to be shaded either with a north wall or shrubbery. Ferns are propagated in three ways: by division, by the viviparous plants, and by spores. Division may be of the crowns, some occasionally having more than one, and these may be separated at the time of potting, and be potted separately. Those with creeping stems are readily increased by taking off the stems or rhizomes, with a branched joint or two, and some roots with soil adhering to them at the time of potting, or when they are beginning to grow, placing them in or on the soil, according to their habit of growth; and those with clustered crowns are readily divided in spring when repotting. The viviparous plants forming on the fronds will in some cases form roots on the plants, in which case there is nothing needed, only to remove them and plant out in suitable positions, or they may be potted and kept rather closer and shaded until established. Those viviparous plants not forming roots on the plants or parent frond should be taken when they are beginning to be shed, the whole frond or part, and pegged to the surface of a pot or pan closely, scattering a little soil over the frond so as to partially cover it, and keeping rather close, moist, and shaded; the young plants will in a short time form roots, and may, when well rooted, be potted off. Ferns may be satisfactorily cultivated in pots plunged in coal ashes, under a wall facing the west, where they will thrive very well. The larger-growing species do not send up such fine fronds as they would do if they were planted out in a proper situation, and in the right soil. Some of the more delicate kinds do exceedingly well in pots, in a compost of peat-earth, light loam, and sand, mixed with very small pieces of broken garden pots. The larger pieces can be used for drainage. Those delicate kinds are such as grow naturally in the crevices of rocks in exposed situations. Should the rains fall ever so abundantly and frequently, the roots of those ferns are never over-supplied with moisture, if the drainage in the pots is so perfect that the superabundant water will readily pass off from the plants. Ferns may be grown on rock work. A nicely put together rockery is a beauty in itself quite independently of its being employed for plants. Another method of rearing ferns is in what is called a Wardian case. For mode of treatment, see *Plant Cases* in HOUSE CULTURE.

Ferns fit for open-air culture.—Male Shield Fern, Mountain Shield Fern, Marsh Fern, Lady Fern, Hard Fern, Oak Fern, Brake or Eagle Fern (*north aspect*); Broad Shield Fern, Common Hart's Tongue, Royal Fern, Parsley Fern, Limestone Polypody, Common Polypody (*south and east aspect*); Crested Shield Fern, Spreading Shield Fern, Soft Prickly Shield Fern, Black Spleenwort, Maiden Hair Spleenwort, Scaly Spleenwort, Moonwort, Common Adder's Tongue (*west aspect.*)

Ferns adapted for culture in pots.—True Maiden Hair, Crested Shield Fern, Mountain Shield Fern, Holly Fern, Marsh Fern, Black Spleenwort, Lady Fern, Smooth Rock Spleenwort, Lanceolate Spleenwort, Sea Spleenwort, Wall Rue, Forked Spleenwort, Maiden Hair Spleenwort, Scaly Spleenwort, Common Hart's Tongue, Hard Fern, Parsley Fern, Limestone Polypody, Brittle Bladder Fern, Mountain Bladder Fern, Beech Fern, Alpine Fern, Oblong Woodsia.

Ferns adapted for culture in close cases.—True Maiden Hair, Alternate-leaved Spleenwort, Lanceolate Spleenwort, Sea Spleenwort, Wall Rue, Maiden Hair Spleenwort, Common Hart's Tongue, Brittle Bladder Fern, Mountain Bladder Fern, Filmy Fern, Wilson's Filmy Fern, Bristle Fern, Beech Fern, Oak Fern, Black Spleenwort.

FEVERFEW (Pyrethrum).—A hardy perennial, producing large quantities of white flowers and continuing in bloom a long time. Sow in box-

es of prepared soil, as early as the season will permit, and transplant to 16 in. apart whenever the plants are large enough. The young seedlings are small and of slow growth, but the older plants hardy and vigorous. The largest crop of flowers is produced the second season. They should be gathered when in full bloom, dried carefully and stored in paper bags. Before using, the flower should be powdered as fine as possible.

Feverfew.

FICUS (**India Rubber Tree**). — Large, smooth, leathery leaves; one of the finest house plants grown; it grows to a large size and produces enormous green leaves; requires plenty of light, and should never be exposed to draughts. Sponge the leaves frequently, to keep them free from dust.

FLAX (**Linum**).—One of the handsomest and most effective and showy of all bedding plants, producing a profusion of beautifully saucer-shaped flowers, of a rich, brilliant scarlet, with crimson centre. Grows 18 in. or more in height. Seeds germinate best in the hot-bed, but do well if sown in the garden in a light soil. Set plants 1 ft. apart.

Flax.

FORGET-ME-NOT. — A hardy perennial, and as it grows very freely it requires, when once planted, only to be thinned out; when it needs transplanting the smallest piece will root. It is exceedingly useful for making a border, and when in blossom the brightness of its blue color forms a pretty variety. It also looks well planted in large masses in shrubberies or large borders, and if well watered will keep in flower a long time. It may be grown in pots for the window or conservatory, and when so done water should always be kept in the saucers. It is propagated by seed or cuttings. The latter should be placed under a hand-glass.

FOUR O'CLOCK (**Mirabilis**). — Fragrant flowers of various colors; open about 4 o'clock in the afternoon, remain open all night, and generally perish before noon the next day. Some of the varieties have beautifully variegated leaves. Plant the seed in the spring, 2 ft. apart. The roots may be taken up in autumn and preserved like dahlias.

FOXGLOVE (**Digitalis**). — Ornamental plants of much beauty, producing dense spikes of flowers on stems 3 to 5 ft. high. The blossoms are thimble-shaped, purple, white and spotted, and very striking. Seed can be sown in spring or autumn, and large roots can be divided. Blossoms the second season.

FRINGE.—A handsome shrub, much admired for their curious fringe or hair-like flowers that cover the whole surface of the plant. They grow from 10 to 12 ft. high, and are very showy. The white variety has large, glossy leaves, and produces its flowers in drooping racemes, about the time the foliage starts. The purple variety flowers later and in erect spikes that remain on the plant all summer.

FUCHSIA.—A well known half hardy perennial plant. Sow or set in March in shallow pots, and in 3 weeks transfer to 4 in. pots. When the plant attains a height of 8 or 10 in., pinch out the centre, and in place of the 1 there will be 3 or 4 branches grow out. Let their branches make about the same growth; then clip the points out, keeping the side branches of equal length, or tapering like a pyramid. Or clip off all the lower limbs and allow the upper ones to droop over, as they are sure to do when loaded with flowers, and you are sure to form a handsome umbrella. Fuchsias, after being exhausted with blooming, should have the terminal shoots of all their branches clipped off; then set aside for 2 or 3 weeks, giving very little water; repot in soil composed of well decomposed leaf mold, mixed with a sprinkle of good garden soil, a few rusty nails and a layer of charcoal at the bottom of the pot to secure good drainage. Water and light should be given freely while flowering, avoiding too strong heat.

Fuchsia.

GERANIUM.—There are many varieties of this much-admired plant. Some give flowers, with little or no leaf; others possess beauty of leaf, as well as of flowers; some give no perfume; others are delightfully fragrant. It is easily propagated by cuttings from any part of the plant, old wood or young, and placed in pots. In a greenhouse, or parlor, they will bloom in winter. Geranium slips should be planted in May, June or July, taking only the last year's shoots, from which the leaves must be stripped. When planted, give them water, and place them in the shade; when they have taken root, let them have the sun in the morning. The slips chosen for cutting should not be such as bear flowers, and they should be inserted about half their length in the earth. Geraniums, except the shrubby kinds, require shelter from frost only, and should have free air admitted to them when the weather is not very severe. In sultry weather they should all be watered liberally every morning, except some few of a succulent nature which must be watered sparingly. Do not let the plants flower too soon, but pinch off the first appearing bloom, and pinch out the eyes of all straggling branches, which will immediately throw out side-shoots, thus forming very healthy and strong as well as good-shaped plants. Give preference to those plants which have their branches close to the surface of the soil. They must have a season of rest during the summer, if they are expected to bloom in winter. Keep the plants in pots out of doors, under the shade of some tree, till September, and water sparingly. In the beginning of September shake the soil from the roots, replant them in rich, sandy loam, and bring them for-

ward to the sun and air; place them in a sunny window, indoors, when there is danger of frost, and when they begin to grow give them an occasional watering with liquid manure.—*Scarlet Geraniums.* Require a light rich soil of loam, leaf mold, and rotted manure and sand. They root readily without glass or bottom heat. —*New Life Geranium.* Each flower on the whole truss is of a beautiful vermillion color striped irregularly with white, but very often the same bunch or truss will be composed of striped flowers, solid red ones, and of flowers of a beautiful salmon color; some of them are often half red and half salmon. It makes a good winter blooming geranium, and any one can increase their number of plants by taking slips and rooting them in sandy soil or water.—*Lady Washington Geranium.* The flowers are large, with deep blotches on the upper petals, and bright spots on the lower. While in bloom during the months of May and June, they are very beautiful and ornamental, either as pot plants or in the garden.

GLADIOLUS (Corn Flag).—Magnificent plants, with sword-like leaves, and long spikes of flowers, of every conceivable color and shade. The plant and flower are from a bulb, which requires 2 or 3 years to produce from seed of sufficient size to flower well. The *Cleopatra* and *Marguerita* are said to be the finest varieties. The one is a fine fresh rose color tinted with lilac with large and effective flowers and broad shaded lines, and the spikes are unusually long; the other is an enormous flower, white, rose and cerise with dark carmine spots and beautiful, softly-shaded throat. Each of these has upward of 20 flowers to each spike. Sow in the open ground (thickly) as soon as the ground is warm in the spring, pressing the seed down 1 in. or so. By planting at intervals, from May first to middle of June, a succession of flowers can be had from July to October. Weeding must be carefully done, or the tiny plants will soon be choked up. If carefully tended they will have formed small bulbs by fall, which must be lifted when ripe and kept under cover like onions or potatoes, to be planted out again the next season.

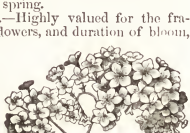
GLOBE AMARANTH (Gomphrena). — A well-known flower, shaped like a clover blossom, purple, white, or flesh-colored. Seed had better be started in hot-bed if possible; transplant to 1 ft. apart. It grows 18 to 24 in. high; fine for garden, as well as for drying; pick for drying only when flower is fully developed.

GLOXINIA. — A choice hot-house, bulbous-rooted plant, producing in great profusion its bell-shaped flowers, of the richest and most beautiful colors, during the summer months. They thrive best in an equal mixture of peat, loam and sand. Sow in March, on the surface, in a warm, moist atmosphere. When the second leaf appears, transplant into shallow pots to grow through summer. Allow them to rest through autumn, and keep in same pots through winter, giving little water. In spring, repot and water freely. They will blossom the second season; bulbs must be kept warm and dry during the winter.

Gloxinia.

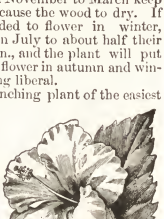
GOLDEN EVERLASTING.—A somewhat peculiar plant, bearing a late, bright yellow flower, which, if taken off before the seed ripens, will retain its brightness for many years. Plant the seed early in the spring.

HELIOTROPE.—Highly valued for the fragrance of their flowers, and duration of bloom, and are to be met with in most gardens. They succeed in any rich, light soil, and cuttings of the shrubby kinds, taken off while young, strike readily. It is a half hardy perennial, 1 ft. high. Plant in March, and water as often as the soil becomes dry, but not till then, giving good supplies. From November to March keep dry, but not so as to cause the wood to dry. If the plants are intended to flower in winter, shorten the shoots in July to about half their length, or to 3 or 4 in., and the plant will put out fresh shoots and flower in autumn and winter, the watering being liberal.



Heliotrope.

HIBISCUS.—A branching plant of the easiest culture, with rather pretty foliage, and large blossoms which are exceedingly showy. It continues to bloom from June till Oct. The seed should be planted early, and the plants thinned to 1 ft. apart each way. If grown in pots will flower well in the house during winter.



Hibiscus.

HOLLYHOCK. — A hardy, perennial plant, showy for a shrubbery. There are several varieties—the single, double, white, red, yellow, dark, etc. Plant the seed in spring; when the leaves are 2 or 3 in. across, transfer the plants to their permanent beds. Hollyhocks serve admirably to crown a knoll, or to form a background, with other stately plants. A bed of pure whites is one of the most charming sights ever seen on a lawn. The latter part of August, in the second year, is the time they should receive careful attention. The stalk should be cut down and the roots carefully divided with a sharp knife; plant them out in a warm, light soil. In this way plants may be kept blooming every year.

HONEYSUCKLE. — This blooms in clusters. There are several varieties. It may be propagated by seeds or cuttings, but best by layers; put into the ground in spring and treat like other wood cuttings.

Hollyhock.

HYACINTH. — A bulbous-rooted perennial plant. It is an early, beautiful, and fragrant flower, and will bloom in glasses filled with water, in a room. If the bulbs show a disinclination to throw out roots, they may be planted for a few days in earth to coax them forward. But they must not remain long there, or the roots will spread laterally, so that they cannot afterwards be forced into a glass. The water should be changed once, and, as soon as the flower has protruded, twice a week. When the water is changed, do not draw the roots out of the glass, but tilt the bulb a little on one side, and so pour the water out and in. If the bulbs are inclined to become soft and putrefy, add a teaspoonful of powdered charcoal, and change it every alternate day. For spring flowering, hyacinths should be planted outside in September, October or November. Plant 3 or 4 in. below the surface of the soil in ground that is well drained, and not likely to thaw and freeze often; give a good covering of leaves before winter sets in. The flowers can be cut freely without injury to the bulb. When the leaves begin to turn yellow after flowering, the bulbs may be taken up, dried and packed away in paper bags or boxes for planting again in the fall. It requires a light but rich soil, sandy loam, well dressed, and mixed with thoroughly rotted manure; but if the soil is not sandy, add $\frac{1}{3}$ of silver sand. The soil for a hyacinth bed must be deeply dug, well mixed and turned over.

Honeysuckle.

HYACINTH BEAN (Dolichos).—A twining evergreen plant, with pea-shaped flowers, purplish red; requires to have the shoots well thinned out in summer after flowering, removing the old and weak growths. Water should be abundantly given, with occasional supplies of liquid manure. Soil 2 parts fibrous loam and 1 part leaf soil; good drainage, and frequent syringing in summer so as to keep down red spider. In winter keep the plant rather dry, but not too much so, otherwise the aftergrowth will be enfeebled. Propagation is best effected by seed sown in spring in a hot-bed, or cuttings of the young side shoots after they become rather hard, in sandy soil, under a glass, affording slight bottom heat.

HYDRANGEA.—A plant much esteemed for its great profusion of elegant rose colored flowers, which under certain circumstances of culture become blue. If grown in brown loam with a little sand, they will preserve their original color; but if grown in swamp earth with a little mold of decayed leaves, they will become blue. It must have a plentiful supply of water when in flower, and be kept in the shade. It is a house plant—will bear some frost, but should be kept, during the winter, in a greenhouse, parlor, or a cellar where there is some light. Propagate by cuttings.

ICE PLANT (Mesembryanthemum). — This is a handsome and curious plant for hanging baskets, rock work, vases, and edgings. The leaves and stems are succulent and fleshy, and appear as though covered with ice crystals, and look like rock candy. The whole plant is peculiarly brilliant in the sunshine. The flower is white, and not conspicuous. Succeeds best in dry, sandy loam, and in a warm situation. Can be grown in pots or open border, the former having preference. Plant the seeds in spring.

IRIS (Flowering Flag). — A hardy perennial plant, comprising many varieties, both large and small; raised by dividing the roots. There are many very useful for borders or rockwork, as their stiff, spear-like leaves contrast agreeably with plants of different habits.

IVY.—A creeping plant with a long branched stem; proper time for trimming is in May. English ivy will succeed better in dry, warm rooms than almost any other plant, and requires very little care. Good, rich loam and plenty of water are all that is required; move the pot as little as possible; once a week wipe off all the leaves carefully with a large wet sponge, fastened to a long stick. As the ivy does not require sunlight it can be grown anywhere, and makes a charming frame-work for doors, windows and pictures. It requires to be watered often, yet the water must not be allowed to stand about the roots. There are varieties with golden and silver variegated leaves; others with lobed, or palmate or heart-shaped leaves.

JASMINE, or JESSAMINE. — A favorite genus of shrubs, for the exquisite fragrance of its flowers, which are white and sweet-scented. Plant in soil 2 parts fibrous loam, and 1 part each of leaf soil and sandy peat. It requires free watering in summer, and to be kept rather dry in winter. It flowers

Jasmine.

early in summer, after which the flower stalks should be cut off, and the old wood thinned out or cut back, encouraging growth by frequent sprinklings overhead. Propagated by cuttings of the half-ripened shoots in summer, in sandy soil, under a glass, in a hot-bed.

LARKSPUR (Delphinum).— An annual plant, blooming from May to September. The leaves are much divided; the flowers are blue, purple, red, white and yellow, with various shades. Sow in autumn or very early spring; thin to 18 in. apart. It prefers a rich soil, plenty of moisture and a little shade. When the plants become large, divide and plant in fresh soil.

LEAD-WORT (Plumbago.)—Flowers are pale blue, produced at the end of summer (August, and later). Its flowers are very fine, but the plant is of straggling growth, for which there is no remedy except stopping, but if that be resorted to after June the flowers will be few. The plant should be cut in rather closely in February, keeping it rather dry for about a fortnight, and then encourage growth by copious waterings and free syringings. A good growth being made, water sparingly, and this check will generally induce flowering. After November keep it dry. Soil, turfy loam 2 parts, 1 part leaf soil, and 1 part sandy peat, with a free admixture of sharp sand, and good drainage. Propagated by cuttings.

LILAC.—A large shrubby tree, hardy, and handsome when in bloom, having large bunches of fragrant flowers. The white and purple may be easily grafted or inoculated into each other, and when the shrub, with a handsome head, is thus managed, some branches producing purple and others white flowers, the show is very fine. It is raised from suckers, of which it sends out a great many, but from which it should be freed as much as possible.—The *Persian* lilac is a neater shrub, bearing delicate white flowers. It is propagated by suckers.—The *Chinese* lilac has much darker flowers than the other varieties and its leaves are dark glossy green.

LILIES.—Autumn is the most favorable time for procuring and planting. The lily does not always flower the first season after being transplanted, but the chances of flowering are much greater if planted in the fall than if removed in the spring. Make the soil deep—say 2 ft.—and in its components put either a lot of well-rotted barnyard manure, or fresh, rich, loamy soil.

Japan Lily.

Lilies, in deep, rich soil, will grow from 5 to 7 ft. high, and give from 7 to 15 flowers on a stalk, while in shallow soil they will only reach 2 ft., 6 in. high, and give 3 to 5 flowers on a stalk. —*Calla Lily* has large wax like flowers, deep green leaves. In spring after frost, set out in the garden, giving plenty of water during the summer and repot in the fall.—The *Japan Lily* has flowers from 10 to 12 in. across, composed of 6 delicate, white, ivory-like petals, each being thickly studded with rich chocolate crimson spots, and having a bright golden band through the centre of each petal, with an exquisite vanilla-like perfume. As the bulbs acquire age and strength, the flowers obtain their maximum size and number. Upwards of 12 flowers have been produced on a stem. It is perfectly hardy in dry soils; also admirably adapted for pot culture.—*The Valley* is a sweet little plant, thriving in any common soil; it will do well in any shaded situation, where few other plants will thrive; can be multiplied by dividing the roots, or by seed.—*Tiger Lily* grows 4 or 5 ft. high, producing gaudy spotted flowers.—*Water Lilies* can be grown in any swampy piece of ground, and even in tubs of water sunk in the ground, or on the surface, and even in aquariums in the house. For ponds, if a soft, muddy bottom, tie the root close to a stone large enough to sink it, and drop it in near the shore in 2 or 3 ft. of water, as the bloom is much better in shallow water. If a hard bottom, dig a small hole and cover it lightly. For tubs, take any strong barrel free from oil, tar or salt (molasses barrels are best); saw in two, put in 6 or 8 in. of fine loam or pond mud, if handy; lay in the roots, being careful to straighten out the small fibers, and cover 2 in. deep; fill the tub gently with water and keep full. This is all the care they need; paint the outside of tubs to suit fancy, and set on a brick or plank platform in any locality you may desire. These tubs should be put in a cellar in the winter, to keep from freezing; fill with water when put away, and they will come out all right in the spring. In warm climates, where the surface of the water will not freeze more than 1 in. or 2, they can remain out of doors the year round.—*Pink Water Lilies* are one of the specialties of Boston culture. Their habits are similar to the white, from which they vary only in color, greater intensity of odor, in being of larger size and remaining longer in blossom.

LOBELIA.—A very interesting genus of flowering plants, alike pleasing to the eye, and useful to the pharmaceutist. Varieties are blue, white, scarlet, pink, and purple blue. The greenhouse, hot-house, shrubby and herbaceous kinds, grow well in a mixture of peat and sand; the shrubby kinds being readily increased by cuttings, and the herbaceous species by division as well as by seeds. The hardy, herbaceous varieties flourish in a light, rich earth; but in the cold weather of the winter season, most of them require the protection of a frame. The greenhouse annuals and biennials must be sown in pots; but those of the hardier plants may be sown in the open border. To propagate lobelias the first bloom should be picked off, and the branches as they extend should be pegged down closely to the surface of the mold. The branches will then take root as they lengthen, and by thus drawing a large amount of sustenance from the soil, they will bloom very freely and cover a large space.

LYCHNIS.—Deservedly popular for the brilliancy of their flowers and ease of culture. The flowers are produced in clusters, and are constantly coming out all summer. Sow the seed in spring, in rich loamy soil, and the following

spring transplant to the border, one foot apart; flowers the second season; hardy perennials; 1 to 3 ft. high.

Lychnis.

MADEIRA VINE.—A beautiful, thrifty climber, with thick, glossy, light green, almost transparent leaves; grows 12 to 20 feet in a season; does equally well in house or out-doors. Bears a small, white fragrant flower in autumn. Plant the tuber where it is to grow, in spring in a warm sheltered place; grows very rapidly on strings; dig tubers and store in the cellar over winter. They are excellent for house climbers.

MAGNOLIA.—A very elegant and showy plant when in flower, and one which deserves extensive cultivation. Being a remarkably handsome shrub, it should be planted in a conspicuous situation, where it will bear a profusion of flowers when it attains a good size. The *Chinese Magnolia* has large pure white flowers, which expand in spring before the leaf buds burst, and the effect produced by large bushes or trees 30 ft. high with, perhaps, 500 white flowers on, may readily be believed to be grand.

MARIGOLD (Calendula).—Tall coarse plants often more than 2 ft. in height. Flowers large, double, in color yellow, orange and brown. There are several dwarf varieties, growing only about 1 ft. in height; easily cultivated and makes a good show. They need a light rather poor soil and plenty of sun. Sow from April till June; when 3 in. high thin or transplant, and in the following May or June they will be in full bloom.

Marigold.

MARSHMALLOW.—A beautiful shrub, requiring a warm and sheltered situation in the Northern States. It is raised from seed or suckers. There are several sorts, as to colors. They should be mixed to make a variety. Save the seed in November or December, and sow in the spring. Seeds produce the handsomest shrub.

MIGNONETTE.—An old and universal favorite; emits a pleasant odor from its flowers. It is usually an annual, but, by greenhouse cultivation and constant pruning, it may be rendered perennial, and even shrubby. Seeds may be sown in all seasons, so as to produce flowers in succession. To obtain a tree mignonette take a vigorous plant of mignonette sown in April, and place it in a flower-pot by itself. As soon as the blossom-buds appear, they must be carefully picked off, and in autumn all the lower side shoots should be removed; cut off so as to shape the plant into a miniature tree; then transplant into a larger pot, with fresh soil formed of turfy loam, broken up very fine, and mixed with sand. When this has been done, remove to a greenhouse, or warm room, and water it regularly every day. It will thus be kept in a growing state during the whole of the winter, and its stem will then begin to appear woody in the spring; treat it in the same manner the following year. Carefully cut off the side branches as soon as they appear, leaving only those that are to form the head of the tree, and by the third spring it will have bark on its tree, and become a complete shrub; then allow it to blossom, and its flowers, which will be exquisitely sweet, will continue to be produced every summer in succession for several years.

MIMULUS.—Beautiful, tender-looking plants, with almost transparent branches. Comprises numerous varieties with white, sulphur and yellow grounds, spotted crimson, scarlet and pink. They luxuriate in damp, shady situations and freely bloom in the early summer months. Culture required about the same as that given for the Aster.

Mimulus.

MOCK ORANGE (Syringa).—A shrub, bearing flowers quite similar to those of the orange, and making a very pleasing appearance when growing with other shrubbery. Propagated by suckers.

MOMORDICA. — A curious annual climber with yellow blossoms, and foliage similar to the Canary Bird Flower. The fruit is the chief curiosity, is egg and pear shaped, and covered with warty excrescences, and when ripe bursts suddenly open, scattering its seeds and showing a brilliant carmine interior. Fine for trellises, fences, stumps, etc.

Momordica.

MORNING GLORY (Convolvulus).—The oldest and best annual climber known; endless in variety and easily cultivated. Sow the seed early in the spring, and provide strings when young.—*Convolvulus Minor*, or *Dwarf Morning Glory*, is a plant of trailing branching habit, occupying a space of 2 feet. At midday it is completely covered with a mass of most brilliant many colored blossoms, which remain open till evening in dry weather. The colors are pure white, blue, passing into white, yellow, red, purple, etc. Will do well in any common garden soil. Thin to 3 ft. apart each way.

MOURNING BRIDE (Scabiosa). — Handsome flowers in hemispherical heads on long stems; of exceeding sweetness, and sometimes called sweet scabious. The colors are deep and light purple, scarlet, white, and dark mulberry red; some of the dark shades are tipped with white. With proper protection of the roots they will bloom

2 or 3 years. Very useful for bouquets, as their long stems work easily, and their striking colors, as well as fragrance, are desirable. Plant in hotbed, and transplant 1½ ft apart.

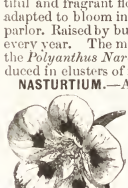
MOSS (Portulaca).—A hardy annual; flowers are both single and double, and are white, orange, yellow, crimson, red striped and pink. Double varieties look like roses and are very handsome. Once make a good bed for this plant and the work is done for years; only keep out the weeds, and give a light top-dressing of manure every autumn. The ground must be warm before planting seed, or else it will not germinate. The first of June is early enough to plant in the open ground.

MUSK PLANT (Nycterinia).—Small half-hardy annuals, about 8 inches in height, with sweet-scented, star-shaped flowers, and during the evening are very fragrant. They produce richer, larger, and more blossoms in light soil. Start in hotbed, and transplant 6 in. apart. They will blossom very early in spring and remain in bloom the whole season.

MYRTLE (Myrtus).—An evergreen vine including several species bearing a pretty blue flower. A favorite plant for ornamental purposes. Prune if needed, after flowering, to form a good plant, and repot in spring before it begins to grow. If much cutting be needed to bring them into form, it should be done in March or April, keeping rather dry until the plants are breaking afresh; and having shoots 1 or 2 in. long, repot, removing most of the old soil and place in the same size pot; succeeds best in sandy loam 2 parts, 1 part each sandy peat and leaf soil, and ⅛ of silver sand.

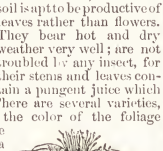
NARCISSUS.—A bulbous rooted plant, managed like the hyacinth. It bears an early, beautiful and fragrant flower. It is hardy, and well adapted to bloom in a pot in the greenhouse or parlor. Raised by bulbous offsets, which increase every year. The most beautiful of the family is the *Polyanthus Narcissus*. The flowers are produced in clusters of from 6 to 18.

NASTURTIUM.—A half hardy annual, requiring but little care. Seed sown in the spring of the year in any fair garden soil will produce plants 10 or 12 ft. in height before autumn. They do not require even a rich soil, for a rich soil is apt to be productive of leaves rather than flowers. They bear hot and dry weather very well; are not troubled by any insect, for their stems and leaves contain a pungent juice which they do not like. There are several varieties, differing as well in the color of the foliage as in the flowers. The leaves of some are a very light transparent green, while in others they are very dark, almost purplish.



Nasturtium.

NIGELLA. — Sometimes called *Love-in-a-Mist*, or *Devil-in-a-Bush*. Hardy annuals with odd showy flowers and finely cut leaves. Sow the seed in spring in open ground.



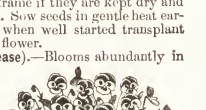
Nigella.

NOLANA. — Beautiful trailing plants, with prostrate stems, much branched; almost equal to the portulaca for growing in masses, and unsurpassed for rock work, pots, baskets, or vases, as the branches hang pendulous over the edge of vase or basket. The blossoms are convolvulus shaped, brilliant, freely produced, of various colors. Sow in open ground, in light, sandy soil, early in spring; plenty of sun, and a dry situation are essential.

OLEANDER (Nerium).—A noble-looking, evergreen shrub, easily cultivated and flowering freely during the greater part of the year. It prefers a fine, mellow, turfy loam and peat, with a little sand, and to be abundantly supplied with water when in bloom. The best way to root them is in a bottle of rain water set in the window. The cuttings should be no deeper in the water than half way up to the second joint, and when the rootlets get to be ½ in. long, carefully pot in rich sandy loam. After the plant blooms, cut back to within 1 ft. or 15 in. of the ground, when three branches will come out; let them grow until it again blossoms, after which cut them all back about 6 in. from the main stalk, and every time it blooms repeat cutting back, and in a few years a very beautiful plant will be the result.

OXALIS.—Pretty herbaceous plants with rich, rose colored blossoms. They thrive well in a mixture of loam and sand; they should not be watered after they have done flowering, until they begin to grow afresh. They are desirable for greenhouse decoration, rock work or baskets out of doors. The plants can be wintered successfully in cold frame if they are kept dry and the frost excluded. Sow seeds in gentle heat early in spring and when well started transplant where they are to flower.

PANSY (Heartsease).—Blooms abundantly in all colors, and is among the first to bloom in the spring. Seed may be sown in open ground in spring or summer, or in a hotbed early in the spring. Young plants produce the largest and best flowers. The plants should always occupy a cool, partially shaded situation, and the ground cannot be too rich; coolness and moisture are necessary. Transplant when 1 in. high. Seed sown in July will blossom late in autumn; if sown in October, will bloom the following spring.



Pansies.

Passion Flower

PASSION FLOWER. — A beautiful and celebrated flower, growing on a perennial vine; the name originating from the large cross in

the middle of the flower, surrounded by appendages resembling a glory. The plant has a succession of flowers for a long time. It is tender, suitable for the greenhouse, but will not endure a northern winter in open ground. It is best raised from cuttings. *Passiflora cerulea*, a species with white and fine flowers, is hardy. *Passiflora Colvillii*, with variegated flowers, and *Passiflora glaucophylla*, having blue flowers, are also hardy varieties.

PEA, FLOWERING.—Flowers ranging in color from white to deep purple. Plant the seed 4 in. deep, early in the spring. It thrives in a moist soil; in rich soil it will grow 5 ft. high.

Flowering Pea.

PEONY. — A perennial plant, bearing a gorgeous but short lived flower. There are several species that are perfectly hardy, and will succeed in any ground, unless water lies on the surface or near the roots in winter. They may be planted in the autumn or spring, and are increased by division of the roots. These divisions should be made either in the autumn, or very early in the spring, and not until the plant becomes large. In Southern countries the peony grows well, but the buds often blast unless grown in partial shade, and liberally supplied with water.

PETUNIA.—The varieties are many. From pure white the flowers shade into pink, some with white throats, and others with white edges, crimson, and a deep rich purple. The plants begin to blossom when quite young, and are never without flowers from that time till cold weather comes. They spread rapidly, often forming clumps 4 ft. across, with dozens of stems sent up from one root, each seam branching freely. The plants form more compact masses, and produce more and better flowers if the ends are cut off. Seed may be sown either in the open ground or earlier in a frame or in boxes in the house. When the plants are transplanted to the bed where they are to bloom, they should be set at least 18 in. apart in order that they may become fully developed. They should never be mixed in beds with other flowers if the best effect would be obtained from them. Sandy soil is the natural home of the petunia, but it takes kindly to richer food, and its colors are brighter, its flowers larger, if it is occasionally treated to a little soluble guano or very weak liquid manure. The single varieties seed plentifully and when hybridized with the double varieties produce many new varieties. But the quickest way to grow double petunias is by cuttings, which should be taken from fresh shoots when they break easily from the plant, and single varieties can be propagated in the season. Take the slip off just below a joint, and remove the lower leaves; then set the shoot firmly into wet sand; do not let more than 4 leaves remain upon the slip, and nip off all incipient buds so as to make 2 shoots grow from the top; keep it shaded from the sun for 3 or 4 days; as soon as the rootlets are well developed take it from the sand and plant, either in the border or in a pot where it will bloom all winter.

PHLOX DRUMMONDII.—These flowers are of extreme beauty, and are greatly admired by all; their long duration in bloom, combined with their almost unequaled richness of color, renders them of invaluable service in the general flower garden. The colors range from the purest white to the deepest blood purple or crimson. Seed may be sown in the open ground in May or in hot-bed or cold frame earlier, or it may be planted in the autumn, but it must be sown so late that the seed will not start in the fall, for the plants will not bear frost. Early spring is generally the best for sowing. In a good rich soil it will grow 18 in. or more in height. Set the plants 1 foot apart.

Phlox Drummondii.

PINK. — A well known perennial plant, fragrant, and embracing many varieties; easily grown by seeds, layers, etc. The beds require shelter in winter, plenty of good manure and frequent stirring in spring. Sow the seed in April; transplant seedlings in June, and have them tolerably strong before the autumn; protect through the winter with hoops and mats, or some other cheap covering. The time for obtaining cuttings depends upon the growth of the plant. As soon as the side-shoots are long enough, they may be taken off and planted. This generally happens about the end of May, or beginning of June. The earlier it can be done the better plants the pipings will make, and the finer they will flower the following season. The Carnation comes into flower about the end of May or the beginning of June and lasts about 1 month or 6 weeks. If sown it does not blow till the second year and is usually propagated by layers. While it is in flower it sends out several side shoots near the root; these are pinned down in August, a little under the earth, leaving the extreme part erect; in a little time they take root, and the new plant must be severed from the old and transplanted. They are rather tender as to frost, and must be covered in the Northern states, to live through the winter; put them into large pots, and keep them in a greenhouse or parlor, or in some place where they can have air and light during winter. *Clove-Scented Carnations* are hardy and charming. The fragrance is delicious. The plants may be kept for years by covering lightly in the winter; but it is best to keep a constant supply of new plants on hand.

POMEGRANATE.—Deciduous shrubs, flowering in summer. Keep dry in winter, and give a light, airy position, and near the glass, repotting in spring after pruning, leaving a majority of the twiggy shoots; keep under rather than over potted; water freely when growing, encourag-

ing growth with a moist atmosphere, and frequent sprinklings overhead. The soil should be sandy loam 3 parts, 1 part leaf soil, and a free admixture of sand; drainage good; cuttings of firm shoots, in gentle heat, are best for propagation; the best plants are those grafted, as it dwarfs them, and they flower more freely and longer. Plants should be removed to the cellar in the fall, and remain dormant until spring.

Pomegranate.

POPPY (Papaver).—An annual plant, admired for its great variety in size and in flower. The double are very showy, but of short duration. The plant grows 3 or 4 ft. high. Sow the seed in open ground; will bloom the first year from seed if sown early; will not bear transplanting well.—The *Oriental* has an intense scarlet flower with blackish or purplish blotch at the base of the petals, and is often 6 in. in diameter.

POPPY, PRICKLY (Argemone). — A curious, free-flowering plant, with large, poppy-like flowers, succeeding well in common garden soils. The leaves resemble those of the thistle, and are of a bluish-green color, with white veins. The plants grow about 2 ft. in height, and make very good low screens or hedges, for which purpose set the plants about 10 in. apart in rows. The foliage is large, pretty in form, and of a pleasant light green color.

PRIMROSE, CHINESE (Primula).—This has pink flowers and blooms almost constantly during winter and spring. Sow the seed in May of each year, in a box or pan, covering lightly, and place in a cold frame. When 2 leaves have formed, transplant into pots having good drainage. Set out the plants during June, in a cool, shady border, where they will continue to blossom nearly all summer. A compost between rich light loam and peat soil is most suitable. The leaves should not be wet in watering.

PRIMROSE, EVENING (Oenothera). — Produces large, showy blossoms, which are fully expanded only towards and during evening. The blossoms are 3 to 4 in. across, usually yellow or white, and very freely and constantly produced. They all do better if seed be started in hot-bed, and the plants transplanted.

ROSES.—Four things are absolutely essential in high rose culture—a rich and deep soil, judicious pruning, freedom from insects, and watering when requisite. They thrive best in a mixture of well rotted manure, sand and garden loam. To raise them in perfection feed well and place them in the full sunlight, and not where they will be shaded by trees and shrubs. After they have bloomed prune them closely, also when they commence to leaf out in early spring. Roses designed for winter blooming, out in the borders, must be carefully supplied with water during the hot or dry days. If allowed to wilt, the white working roots are dried up, and new ones must be formed before the plant will recover. All roses may be propagated from seed; but as the seed seldom comes up until the second year, the usual mode of propagation of all sorts, except the *China* rose, is by suckers. These come out near old stems, during the summer; they are dug up in the fall and planted out. In the spring they are cut down near to the ground, and the next year they blow. Choice roses may be propagated from the slip by rooting them in water and then transferring them to small pots where they can remain until large enough to take their permanent places. The water should be put in black or dark-green bottles, and a little raw cotton wrapped around the slip. The water need not be changed except occasionally, but the bottles must always be kept filled up to the neck. The best season for taking rose slips is in June, just after the profuse bloom of early summer is over. Choose from a good vigorous branch of last year's growth a fresh shoot, containing two or three buds, such as will always be found more or less swollen at the base of the leaf stems; cut the slip from the parent branch diagonally, with a smooth, clean cut that will bring off a little of the old bark as well, in order to make the condition as favorable as possible for the formation of roots; have ready a box or pot of rich mold; with a round, pointed stick make a hole several inches deep, and fill it up with clean sand; insert the end of the slip in this sand to the depth of 1 or 2 inches; be sure to make it firm in the soil; the sand acts as a percolator for moisture, and the slip may be kept well watered; do not remove to a permanent place until it has put out several sets of new leaves. From the last of June to the last of August is the best time for budding roses, as the bark can then be more easily raised from the wood. Take a smooth stalk and make a horizontal cut across the bark through to the wood, but not into it; from the centre of this cross cut make another cut straight down the stem, an inch or more in length; (these 2 cuts should resemble a T); slice off the bud you desire to propagate with 1 cut of the penknife, cutting it close to the main stalk; then, with the edge of the spud, turn back the bark on each side of the straight cut and insert the bud on the wood of the branch to be budded, fitting it tightly to the crossed cut; with a bit of soft yarn bind down the bark, leaving the point of the bud exposed; then bind a handful of dampened moss round the stem, taking care to leave the tiny point of the bud exposed to the air. In six weeks the wrappings can be removed, but all other shoots must be kept from growing on the budded branch. By this means a rose-bush can be made to bear half a dozen different colored roses. Mulching roses in pots to force flowers for the holidays with common moss mixed with a good portion of bone dust, say 1 part bone dust to 30 of moss, has a wonderful effect in bringing forth early roses. In two weeks after the mulch is first ap-

plant a change will clearly be seen, and by the end of May the plants will attain from 4 to 6 ft. in height. They may be protected during the winter, except in the extreme north, by being bent to the ground and a covering of 6 in. of leaves or straw (leaves are best) thrown over them, and a little brush on this to keep them from blowing off. Defer covering for winter until cold weather fairly sets in, as moderate freezing will not injure them. To prevent mildew on roses see *Mildew* in PESTS. The following are the principal classes of roses: *Banksian.* Nearly evergreen, requiring a warm wall and dry border. They should be trained with long shoots, to bloom on the short branches these shoots make, and will then flower very freely and beautifully. The older they are the more flowers they will produce. Any long, strong, extra shoots they may produce, that are not wanted, should be cut away towards the end of June. — *Bourbon.* Not quite as hardy as the *Hybrid Perpetual Roses*; require a slight protection. They are constant bloomers, of vigorous, rapid growth and rich foliage. The last of summer and autumn is the season of their greatest beauty. — *China* (*Bengal*). Dwarf growers, blooming freely and constantly throughout the summer and autumn, making fine plants for pot culture, and for bedding out in flower garden. They can be protected through the winter by a covering of leaves, or removed to the cold frame. — *Climbing Hardy.* Very gorgeous, of rapid, vigorous growth, blooming in large clusters. They are admirably adapted to cover arbors, walls and any unsightly objects, and are always ornamental in every situation. To prune them rightly, thin out the branches severely, but do not shorten much those you leave. — *Evergreen.* These bloom in very large clusters of from 10 to 50 flowers in each. They retain their fine shining foliage the most of the winter; are free growers, and very hardy. They form beautiful weeping heads if on tall standards. Prune them so as to leave the largest previous year's shoots, which will flower in the extreme ends. — *Hybrid Perpetual.* These are entirely hardy. The flowers are of immense size, often 5 to 6 in. in diameter, and of the most beautiful colors, from pure white to the darkest shade of crimson. They flower freely in June and at short intervals during the summer and fall. They are of easy culture, not requiring but benefited by protection at their roots with a mulch of leaves or evergreen boughs during winter. They thrive well in any rich soil. In the spring, cut them back pretty close, and they will send up new shoots, which will make a very strong growth and give abundance of bloom. — *Many Flowered.* The varieties are rather tender, requiring a warm, sheltered situation, and a very gentle use of the knife in pruning. "The seven sisters," is a splendid variety when it has proper treatment. — *Monthly or Everblooming.* These are undoubtedly the most satisfactory, as they bloom continuously from the time they are set out until frost. They are not hardy, north of Maryland, requiring a good covering of straw or leaves, which should be put on about December. This should not be removed until all danger of severe frost is over in the spring. They should then be cut well back, which keeps the plants in good shape and induces stronger shoots. — *Moss.* This class, most beautiful in bud or flower, to succeed well, requires high cultivation in rich loam, and will fully repay this care by their beautiful mossy buds. They require but little pruning, and are perfectly hardy. — *Noisette or Climbing Monthly.* Bloom generally in large clusters throughout the summer and autumn. They are free growers, and fragrant. In a mild climate they become magnificent climbers. — *Tea.* These are celebrated for their peculiar and delightful fragrance, and the delicacy of their coloring. In this class are found the greater part of the roses that are called everblooming; in color they range from the purest white to bright crimson.

SENSITIVE PLANT (Mimosa).—An interesting and curious plant, with globular heads of pink flowers, well known for the extreme irritability of its leaves and foot stalks, which close and droop at the slightest touch, or in cloudy, damp weather, and during the night. The plant is most irritable in the greatest heat, and if the upper branches be touched and droop, touching the lower ones, the whole plant will appear as if wilted and dying. Start in hot-bed, in pots, and transplant into a warm situation, 6 in. apart. A plant or two reserved for the house will afford a good deal of pleasure during the winter. Start a young plant in a pot, and the pot in the earth to the rim, removing to the house in autumn.

SHELL FLOWER (Molucca Balm).—A strong annual, 2 to 3 feet in height, having but few leaves, but such numerous branches that its width is often as great as its height. Within the calyx a button shaped bud appears, which unfolds into a shell shaped flower of a white and purple color. Sow in hot-bed in spring, and about the end of May transplant into dry, warm border, where it will flower freely.

SMILAX.—In cut flowers and for wreaths, etc., this is indispensable. Soak the seed in warm water for 12 hours; plant in pots in February, and keep in a warm, moist place. One plant in a 2 in. pot is enough. After they have completed their growth and the foliage begins to turn yellow, withhold water until August, when the little bulb can be repotted and watered freely, and it will grow all winter.

SNAP-DRAGON (Antirrhinum).—An old favorite border-plant, with dark and glossy leaves, and large, curiously-shaped flowers with finely marked throats. They will blossom the first season from seed sown in spring, but the blossom will be much stronger the second season. When the seedlings have attained 1 or 2 in. in height, plant them 5 in. apart every way, keeping the sorts still separate. If it is desired to have a long season of bloom, cut down the first flowering spikes before the seed is formed; then fresh flower-spikes will push forth from the base of each plant, and there will be a succession of bloom. Succeeds best in a dry, loamy soil.

SNOWBALL.—A well known shrub; attains the height of 8 or 10 ft.; produces its snowy

white flowers in large balls or masses in June.

SNOWDROP. — Blossoms in February or March, the flowers being white, drooping, and having their inner segments of a greenish color. Should be planted in masses, about 2 in. apart, and about the same depth.

Snowdrop.

SUN DIAL (Lupinus).—Pea shaped flowers in long spikes; leaves compound and very pretty. Colors white, blue, and variegated. They are hardy, and seed must be sown in the open ground, having a tap root, and not transplanting well. They will bloom a long time if the seed is removed as soon as the pod forms.

Sun Dial.

SUNFLOWER (Helianthus).—Adapted by its stately growth for a back ground to a lawn, or a screen to hide unsightly places. It is also raised as an absorbent of miasma in damp or ill-drained situations, thus preventing fevers. Plant the seed in spring, where desired, and thin to 4 ft. apart in rows. Large quantities of seed are produced by the single varieties, and they are of considerable value for oil as well as feeding.

SWEET ROCKET.—A very hardy perennial, bearing clusters of single flowers, and fragrant during the evening. The best colors are purple and white. The plant, with fair culture, will grow 18 in. in height, and seed will germinate readily in the open ground. Grows freely in any light rich soil; unlike most plants, they do better if transplanted every second season.

SWEET WILLIAM.—A very beautiful class of plants, of extreme richness and diversity of color. The seed can be planted very early in the spring in open ground, and will blossom the following autumn; or it can be sown in August, and will make fine blooming plants for spring. The plants will bloom several years, but young plants bloom better, and seed should be sown every year.

TASSEL FLOWER (Cacalia).—A showy plant of easy culture, producing beautiful scarlet and golden yellow, tassel shaped blossoms, from July to October. It is sometimes known as *Flora's Paint Brush*. Looks best when grown in clusters. Succeeds best in a mixture of fresh loam and leaf mold. Sow seed under glass, if possible, though they do pretty well in a warm bed in the garden; set plants 6 in. apart. They keep in bloom from early summer until autumn, furnishing flowers for cutting every day; particularly valuable for small bouquets.

TEN WEEKS' STOCK.—Comprises those varieties which, being sown in spring, flower during the summer and fall. The *Pyramidal* probably produce more double flowers than any other sort, and its dwarf habit renders it unequaled for bedding-out work. They delight in cool, dewy nights and moist days. To have them bloom early, start in hot-bed, and transplant when small into pots, and turn out in June to open border, planting 12 in. apart. They will blossom late in the season if planted in open ground. They may be sown in pots late in the season for house use.

THOROUGHWORT (Eupatorium). — Winter blooming plants, with clusters of white and blue feathery flowers. Propagated by dividing the roots. The plants should be plunged in the open ground in the summer. When growing freely they should be topped, as they are apt to grow straggling. They will grow in common soil.

TIGER FLOWER.—A very showy Mexican bulb, growing about 18 in. high. Its flowers are 4 in. in diameter, and of the most gorgeous coloring and curious form. In bloom from July to the first of October. The bulbs may be planted any time in May, or the first of June, about 2 in. deep, in any garden soil, and require no particular care. In autumn, after the tops are killed by frost, take up the bulbs and keep them in a dry place away from the frost until the time of planting in the spring.

TRUMPET FLOWER (Datura).—An ornamental genus of plants, many of which possess attractions of the highest order. In large clumps or borders of shrubbery, they produce an excellent effect. The roots can be preserved in a cellar, like dahlia roots. Plants 3 ft. in height; set the plants 3 ft. apart.

Trumpet Flower.

TRUMPET VINE (Bignonia).—Hardy, rapid, strong grower, with glossy foliage, bright red, trumpet-shaped flowers, 3 in. long; blooms in August. This plant is not only an admirable climber, but on the lawn makes a pretty bush if the tops are cut back, having the appearance of a strong, drooping shrub.

Trumpet Vine.

TUBEROSE.—A beautiful pure white, wax like, sweet scented, double flower; stems 3 ft. in height, each with 12 or more flowers. To cultivate the tuberose, pot the bulbs in 6 in. pots, 3 in each, and use a mixture of equal parts turfy loam, peat and leaf mold, and place in the pit. Give very little water at first, and as they commence to grow freely increase it and keep near the glass. When they begin to push up their flower-spikes they will of necessity require to be placed where they will have sufficient space for the proper development of the tall spikes. These will come into bloom from August to October, when they will require a temperature ranging from 60° to 70°, the latter being preferable. The offsets are ready for bloom after one year's growth. In lifting from the bed the large bulbs

which are to bloom next year, throw them in heaps; cut off the leaves, and put in a dry place; if in the greenhouse, let it be near the heating pipes. For early flowering, in January, put 3 bulbs in an 8 in. pot, and place them in a very warm place, behind the stove if possible. They will stand 100° Fahr.; keep the soil dryish until the green leaves start; then use all the water they want and they will come on rapidly; plant outdoors when it becomes warm, for late autumn flowering. Start some in July and August for flowering at Christmas or New Year's. The later ones planted will not need much care, although a little bottom heat will assist in starting them at any season.

Tuberose.

TULIP.—Perfectly hardy, flourishing under very ordinary care, and has a range of brilliant colors. It is desirable even as a single specimen, but when grown in masses the finest effect is produced. A very rich soil is not necessary, though well rotted manure, rotten sods or leaf mold may be applied when the earth is poor. The ground should be well drained before planting. The usual time for planting is October and November. Spade the soil deep and work it mellow; plant the early sorts 5 in. apart, and the late varieties 6 in.; cover 3 in. deep. After they are done flowering in the spring, they can be taken up and planted close in any corner of the garden until it is time to replant again in the fall, or bedding plants can be set between rows, and before they cover the ground the tulip will be ripe enough to be removed. When the plants show flower, protect them by an awning from the midday sun, but still let them have plenty of air. When the seed-pods form they should be removed; and when the leaves die down and turn yellow, it is time to take up the bulbs and carefully dry them. When it is desired to cultivate tulips from the offset, the latter should be broken from the parent bulb about the middle of July, after the drying has taken place. The old bulbs should be stowed away in bags, but the young ones had better be planted before November. The offset bulbs take fully a year to reach maturity. Care should be taken not to bruise the bulbs in any way.

VALERIAN.—A beautiful perennial border plant, bearing large clusters of small, brilliant, scarlet, white, blue and red flowers. It grows 2 to 3 ft. high, and will bear shade and moisture. Sow in the spring, under glass or in open ground, and transplant. An old, standard border-plant, often called Jacob's Ladder, blooms in June; is of easy cultivation, perfectly hardy and may be increased by dividing the roots.

VERBENA.—A beautiful tender annual, varied in color and much used for bedding; those grown from seed usually give much better satisfaction than those from cuttings. Plant in open border in May, or the seed may be sown in February, March and April, in boxes in the house for early bloom, or in hot-beds. Cover about ¼ in. deep and take care to keep the soil moist and warm until they germinate, which will be in about 2 weeks from sowing. Do not set the plants too thickly in the beds, especially seedlings, which should have at least 2 ft. of space, or even more if the soil is rich, as it should be to produce an abundance of fine flowers. In order to keep verbenas in good flowering condition during the season, pick off the seed vessels. When the flower fades the strength of the plant goes to the seeds, and if they are permitted to remain the number of the flowers will become less and less. A soil composed of 2 parts loam, 2 parts well rotted manure and 1 part sand suits them best. Keep the surface soil loose and porous, to allow air to reach the roots, and provide good drainage.

VIOLETS.—This little plant is perennial; the flowers blue, double, and fragrant, blooming early and long. Propagate by dividing the roots. The soil best suited is a sandy loam and peat. Succeeds best in a shady, sheltered place.

VIRGIN'S BOWER (Clematis Virginiana).—One of the most beautiful and hardy climbers; thrives in almost any situation, and produces masses of beautiful flowers and foliage. They are grown in sandy loam, with a little leaf mold, and are best propagated by dividing the roots.

WALL FLOWER.—Very conspicuous in beds and borders, and very useful in making bouquets; deliciously fragrant; perfectly double, and combines many shades of color, the orange, purple and chocolate predominating. Sow the seed early, in hot-bed, and while the plants are small, prick them out into pots, and sink the pots in the earth. On approach of cold weather, remove the pots to the house, and they will bloom all winter. Cuttings ought to be taken in August, and for a time placed under a hand-glass, and as soon as rooted put in a sandy loam or leafy mold. In spring they ought to be planted in open border.

Wallflower.

WATER CRESS.—An annual plant with showy flowers. The seeds are enveloped in fleshy pods, and should be sown very early in spring. Support the plants from the ground by bushy sticks.

WAX PLANT (Hoya).—An evergreen twiner, with dense clusters of wax-like, pinkish-white flowers. It is a first-rate plant for pillars. Water it freely when flowering and growing, but when at rest keep it dry, only do not allow the leaves to shrivel. The plant cannot be kept too dry in winter. Drain extra well, and afford a compost of equal parts of sandy fibrous peat, fibrous light loam, old cow dung, charcoal in lumps from the size of a hazel-nut to that of a walnut, broken bricks, and old lime rubbish, well mixed. Propagate from cuttings of shoots, in sandy open soil, in a hot-bed.

WISTARIA.—One of the most beautiful and

rapid growing of hardy climbers, growing, when well established, in good soil, from 15 to 25 ft. in a season. Frequently blooms both in spring and fall; the pale blue, pea shaped flowers are borne in long, drooping clusters similar in size and shape to a bunch of grapes. It thrives best in a light, rich soil, and should be trained against a south wall or veranda. Seeds should be sown in mellow loam early in the spring; if a greenhouse or hot-bed is available, start in winter, and when plants are 1 ft. high, transplant into situations where they are to remain.

WOODBINE (Virginia Creeper).—This is hardy, very ornamental, of rapid growth, and the foliage is luxuriant and beautiful. It is often made to cover the walls of houses 40 or 50 ft. high, clinging by its tendrils. The flower is reddish green, not showy, but is succeeded by clusters of nearly black berries, at which time the tendrils and stalk turn to a rich crimson color. It is exceedingly ornamental and conspicuous in October, after the first frost. It can be transplanted at almost any time of the year, though early spring is best, since it blooms in April and it would not be desirable to transplant it after the buds have started.

FRUIT CULTURE.

GARDEN FRUITS.

BARBERRY.—There are several varieties, but the common red is the best known. Its color, when fully ripe, is a deep scarlet with a slightly dark tinge. Its fruit, made into a preserve, is relished by some. It forms a beautiful single shrub or hedge, and may be propagated from seeds, from cuttings, by layering, or by budding or grafting. The seeds are best planted in the fall, as, if kept till spring they are apt to become dry and fail to germinate. If propagated by cuttings or layers, the spring is the best time; grafting is seldom done. If the barberry is left to itself, it forms a dense shrub, with many stems; but when cultivated for its fruit, a portion of the shoots should be annually removed to allow the sun and air to more readily reach all parts of the plant, and assist in developing the fruit-buds. It may be trained to a single stem, and when treated in this manner, some of the varieties will form shrubs 10 to 15 ft. high. The fruit will also be larger and more abundant.

BLACKBERRY.—Any rich, deep soil, well plowed, will suit this fruit. Allow plenty of room and set the plants every 4 ft. in rows 8 or 10 ft. wide. The ground should be well cultivated, and the suckers kept down by cutting them between the hoe whenever they appear between the rows. It is best propagated from cuttings of the roots, which, if carefully kept through the winter in damp sand or soil, grow readily and need no special care. The terminal shoots should be pinched off in August, to check the growth. Prune severely once annually, choosing the early spring. Cut the old canes out as near the ground as possible. The bearing canes should be headed back to 4 ft. and the lateral branches to 1ft. Varieties: *Kittatinny.* Large to very large; deep, glossy black; sweet and rich; plant strong, vigorous and very productive. — *New Rochelle*, or *Lawton.* Yields enormous crops of the largest sized berries and keeps in bearing 4 to 6 weeks. — *Taylor's Prolific.* A new variety, said to be perfectly hardy. A very vigorous grower and exceedingly productive; fruit large and of good quality. — *Wilson, Jr.* The fruit is very large, early and of excellent flavor. If unprotected, zero weather will kill it.

CRANBERRY.—These require a subsoil or bottom of peat, or peaty matter; no cold spring, but a head of water, so that the bog may be quickly flowed at all times, to prevent it from the ravages of insects. The turf or top soil of roots, grass, etc., must be removed down to the peat. Ditches must be made so that the water can be drained to at least a foot below the surface during the growing season; especially the cold water from the borders must be drawn off. The surface of the peat, after the soil is removed, must be covered 3 to 12 inches deep, according to the depth of the subsoil, with sand that contains no loam, grass nor weed seeds; such sand as will not adhere when pressed in the hand. Make holes 4 ft. apart, into which plant the sods, or square bunches of the cranberry roots. Planting by cuttings may be resorted to, the vines being passed through a straw cutter, and chopped into pieces about an in. long; they are then sown like oats upon an evenly prepared surface and harrowed in. This must be done early in the spring, and upon moist ground, so that the cuttings will become well rooted before the heat of summer. To grow them from seed requires a long time for the vines to become productive. Great care should be taken in selecting the vines to procure those which yield large berries. The shape of the fruit is of little consequence. There are some varieties that do well on rich uplands, as the Mansfield Creeper. A northern exposure suits them best.

CURRANT.—A strong, rich, deep loam brings the fruit to its highest state of perfection, but it will thrive in a much poorer soil. High cultivation increases the pulp and lessens the seeds. Wood-ashes make the best fertilizer for the currant. In making the currant cuttings, use only the growth of the present year, cutting it into 6 in. lengths. The cuttings should be set quite close together in a sheltered spot about the end of August or the first of September, and about ¾ of their length. A soon as severe cold weather comes on the cuttings should be covered with a mulch, to be removed early in the spring. The permanent planting should be attended to as soon as the ground can be stirred, as the cur-

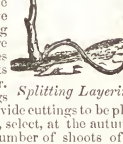
rant buds early. After that keep down all weeds and cultivate thoroughly during the summer. The same autumn or the following spring they may be transplanted into a bed of deep, rich soil, about 4 ft. apart, and receive a mulching about the roots of coarse manure, and the following summer give clean culture, cutting out all the dead wood, etc. Varieties: *Black Naples.* Considered the best of the black varieties, being larger and more prolific. It is not so well suited to a southern clime. — *Fay's Prolific.* Equal in size to a cherry; has very large clusters of a bright red color. — *Lee's Prolific Black.* Large and beautiful; large clusters; hardy, and very productive. — *May's Victoria.* A newly-introduced sort, bearing a large berry, of a brilliant red color. The flavor is very superior, and it is very productive. — *Red Dutch.* An old, well known, thrifty, upright sort; very productive; color red; grows in long clusters. — *Versailles.* Of all reds perhaps the best. It bears well and the fruit remains a long time on the bush. The fruit is larger than the Red Dutch; also more acid, but the flavor is not so curranty. — *White Dutch.* Size large; skin slightly yellowish; flavor mild; quite hardy. A variety much esteemed for dessert. — *Victoria.* Large, bright red, with very long bunches; late, and a good bearer.

GOOSEBERRY.—Cultivated the same as the currant; but while the currant will do under the shade and drip of trees, the gooseberry must have an open, airy situation and northern exposure to avoid the fierce rays of the sun. There are 2 classes of gooseberries, the foreign and native. The foreign varieties seldom succeed, on account of mildew. Only 2 of them can be cultivated for a few years. They are as follows: *Wellington's Glory.* Large, pale yellow, oblong; of fine quality. — *Whitesmith.* Large, white, round, of fine flavor. Native varieties:

Downing.

American Upright. A variety of Houghton's Seedling, but more upright. — *Downing.* Very large, handsome, pale green, and of splendid quality; bush a vigorous grower; very productive, and free from mildew. — *Houghton's Seedling.* Grows very thrifty, and said not to mildew under any circumstances; bears abundantly; though the berry is not so large as some; the fruit is fresh, soft and sweet; skin delicate; color dark. — *Mountain Seedling.* Large, roundish, oval, pale red, thick skinned, medium quality berries; plant a free grower, and very productive.

GRAPE.—Vines are propagated by layers and cuttings. The former is the readier mode. It is accomplished by bending down a vine, or side-shoot of a plant, and burying the middle portion of it in the soil to the depth of 6 in. Roots will strike from the buds of the buried portion. If the shoot is split or cut immediately under a buried bud, the roots will form more rapidly. A slight excavation should be made near the parent plant, in which the layer may be buried and fastened down by a small forked branch. 1 or 2 buds only at the extremity of the layer should be above the ground. Layering should be done before the young wood becomes too hard, if good plants are required the first year.



Splitting Layering.

Propagation by cuttings is the better way. To provide cuttings to be planted at the proper season, select, at the autumnal pruning, a sufficient number of shoots of the preceding summer's growth, such as are well ripened, of a medium size, and moderately short jointed; cut them into convenient lengths of 3 or 4 buds each, cutting square off, close under the lowest bud, and leaving 1 in. of the blank wood for the protection of the terminal bud. Stick these cuttings in the ground, leaving the last bud above the soil, in a warm and sheltered situation, where they will be protected from the severity of the winter. The months of March and April are usually selected for planting out grape vines. Dig the ground deep, but plant shallow. The vines may be set out 8 or 10 ft. apart on almost any good garden soil, spreading out the roots well. Only 1 cane or shoot should be allowed to grow the first season, removing the other buds or shoots when small. The second season cut this cane back to within 2 or 3 ft. of the ground, and allow from 1 to 3 canes to grow. Grapes can be propagated also by means of single eyes, so as to save wood, each eye furnishing a new shoot; cut off the shoot about ½ in. from the eye on each side, so as to leave a cylinder of wood about ½ in. long, with the eye in the centre. In April they are to be laid down, at a depth of 2 or 3 in., in furrows about 6 in. apart, and covered with a little manure, watered in dry weather, and the earth about them occasionally loosened. Grapes grown in a damp, rich, heavy soil are larger, more juicy, and the vines more vigorous and productive than those grown in a porous, dry soil. A deep, loose, red soil, intermixed with rough stones, and a porous subsoil, will produce grapes that will make a wine of the highest excellence and greatest durability. The best exposures are those which slope gently towards the east or south, the northeast or southeast. The southwest or west is the worst exposure, from the action of the winter sun. This is especially the case in the Southwestern states. In pruning the vine, always cut upwards, and in a sloping direction; always leave 1 in. of blank wood above the last bud; leave as few wounds as possible, and let the surface of every cut be perfectly smooth; in cutting out an old branch, prune it even with the parent limb, that the wound may heal quickly; prune so as to obtain the quantity of fruit desired on the smallest number of shoots possible; never prune in frosty weather, nor when frost is expected, but as soon after the first of October as the gathering of the fruit will permit. To graft grape vines, select scions of the present year's growth, and from canes ½ to ⅝ in. in diameter; cut into lengths of 3 in., with a bud near the upper end;

make the lower end into a long, slender wedge; remove the earth about the stock 4 to 6 in.; cut off the vine a few inches below the surface and square off; split it with a chisel or knife, making as smooth a cleft as possible; place the outer edge of the scion even with the outer edge of the wood of the stock; after fitting the scions to the stock, wind a strong cord about the two; pack grafting wax about the stock, entirely covering the wound and the lower end, but leaving the bud uncovered; after the scions have been inserted, invert a flower-pot over them; upon this place a quantity of leaves; cover all with earth, fine sand, powdered charcoal, pine needles, or coffee grounds; early in the spring remove the covering a little back of the bud. Another method, called *inarching*, is as follows: Plant close together 2 plants, 1 each of the variety which is to form the stock, and of the scion; as soon as the young shoots become sufficiently hard and woody to bear the knife, take a shoot from both the stock and scion vine, and at a convenient place, where they may be brought in contact; take a shaving from each of these, on the side next to the other, 2 or 3 in. in length; then fit them snugly together, and wrap securely with some old calico torn in strips; place 1 tie a little below and 1 above the grafted point; tie the united canes to a stake or trellis; look over the grafts after a few weeks; replace such ties which have burst; loosen others which may bind so as to cut the wood; in about 6 or 8 weeks, remove the bandages; leave the grafted portion exposed to the sun; in the fall, cut close below the union of the cane with the stock, which cut close above the connection. Varieties: *Bacchus*. Bunch medium; compact, shouldered; berry below medium, black, with blue bloom; half tender, sprightly, juicy; an excellent wine grape. — *Brighton*. Bunch large, compact and shouldered; berries medium, dark red; skin thin; flesh tender and sweet; vine a vigorous grower and healthy; productive, and ripens early; when fully ripe becomes nearly black. — *Catawba*. Bunches of good size, rather loose; berries large, round; when fully ripe of a dark copper color, with a sweet, rich, musky flavor; requires a long season to arrive at full maturity; excellent both for table and wine. — *Clinton*. Bunches small and compact; berries round, black, pulpy, juicy, of medium quality; valuable for wine and culinary purposes. — *Concord*. A large, purplish black grape, ripening about the middle of September; vine remarkably vigorous and free from disease. — *Delaware*. This is undoubtedly the best table grape, ranking pre-eminently above all others in its pure, rich, sugary, wine-like juice; bunches small, compact, shouldered; berries medium size, fine wine color, translucent; vines hardy, moderately vigorous and very productive; ripens about the 15th of September. — *Duchess*. Bunch medium to large, shouldered; compact; berries medium, pale greenish yellow with a whitish bloom; flesh tender, juicy, sweet, spicy, rich, and of excellent quality, lasting a long time after being gathered; ripens soon after Concord. — *Early Dawn*. An extremely early black grape of superior quality; berry, medium round; flesh tender, juicy, sweet, slightly vinous; ripens a week before Hartford; hangs on well, and is a good keeper. — *Hartford Prolific*. Bunches large; berries large, round and dark, of medium quality. Ripens about 3 weeks earlier than the Isabella. Hardy and prolific. — *Highland*. Bunch large, long, compact; berry large, round, black; flesh soft, juicy, sweet, somewhat vinous; ripens between Concord and Catawba. — *Iona*. A grape of very fine quality; much larger than the Delaware, and as hardy; color a fine red; one of the best. — *Isabella*. Large bunches and berries, not compact, very dark purple; tender, sweet, and juicy; ripens from middle to last of Sept. — *Jefferson*. A pure native; a cross between Concord and Iona, resembling Concord in growth, vigor and hardiness, with fruit much like Iona in color, texture and quality; ripening about with Concord. — *Lady Washington*. A showy and beautiful white grape; bunch and berry large; skin pale yellow, with a tinge of delicate pink; flesh soft, tender, juicy, sweet, very slightly vinous, of good quality; ripens about with Concord and continues a long time in use. — *Moore's Early*. Bunch large; berry large, round; color black with heavy blue bloom; vine exceedingly hardy, entirely exempt from mildew or disease; its earliness makes it desirable for an early crop, and its hardiness particularly adapts it to Canada and the Northern portions of the United States. — *Pocklington*. A white grape; moderate grower; hardy, healthy; with fair sized clusters and large berries; very compact, shouldered; ripens soon after the Concord; has a strong foxy aroma. — *Prentiss*. A new white grape, very prolific; bunches large; grapes medium large; hardy and healthy. — *Vergennes*. Early, healthy, hardy and of good quality; foliage healthy, and vine a rank grower.

HUCKLEBERRY, or WHORTLEBERRY.—Select bushes that produce large sized and good flavored berries; set them near enough to shade the ground; cut off a large portion of the top; mulch the ground with a heavy coat of leaves; keep well mulched until the bushes are thick. When the bushes seem to have too much old wood to bear well, cut them down to the ground; select a moist ground. In many places in the west the ground abounds in limestone, which produces very richly flavored fruit. There are some white fruited varieties.

RASPBERRY.—The raspberry requires a rich and deep loamy soil to be grown to perfection. Thorough preparation of the soil before planting is very important. The modes of propagation are by suckers, by the tips of the canes, or by seeds. The suckers are separated in autumn, either by taking up the whole plant and dividing it, or by slipping them off from the sides and roots of the main stock. Planting in rows and then restricting the plants to hills or stools is the usual method. Make rows 6 ft. apart, and set the plants 3 ft. distant in the rows, which requires 2,500 to an acre. The tops should be cut off within a few inches of the ground when the plants are set. In planting the smaller growing kinds, 2 plants may be set in a hill, placing them about 6 in. apart. A plow or cultivator may be used among the plants for keeping the

weeds down in summer, but keep the soil as nearly level as possible. If they are to be grown in poor sandy land, open during autumn deep furrows with 2 horses, 6 to 8 ft. apart; dig and haul enough tidewater muck to fill in the furrows, which will be thoroughly frozen before spring, and at the approach of warm weather will crumble and become mellow, so as to spread evenly; then apply a good coat of ground bone or hair manure along the rows, and set the plants 2 or 3 ft. apart. Prune the bushes in the summer; pinch or cut off the shoots as soon as they are 4 ft. high; this causes them to branch out with strong laterals, and these are to be cut back, according to their strength in winter; at the same time cut away all redundant branches. During the winter lay the canes down, and cover with earth, where the climate is severe or the variety tender. Varieties: *Amazon.* A very large and finely flavored berry, and one of the most vigorous growers. — *Brandywine.* A large and bright red berry of very beautiful appearance, which makes it a favorite market variety, although not of the highest quality. It does well on all soils, and endures the drought and heat of the south better than most varieties. — *Cuthbert.* A remarkable strong, hardy variety, said to stand the northern winters and southern summers better than any other variety. Berries very large, measuring 3 in. around; conical; rich crimson; very handsome, and so firm they can be shipped hundreds of miles by rail in good condition; flavor is sweet, rich and luscious. — *Delaware.* Medium size, bright red; originated in New Jersey, where it is spoken of as one of the most delicious of berries. — *Doolittle.* Although one of the first introduced, it still holds its place as one of the most valuable.

Gregg.

— *Gregg.* This is decidedly the largest and most prolific black cap, far surpassing in size the famous Mammoth Cluster; averaging when grown side by side, with the same treatment, from ½ to ½ larger. — *Hansel.* Medium to large; color highest crimson; quality best. — *Highland Hardy.* This is an early, strong growing, and very productive variety, thriving in almost any soil. Berry medium, bright red; its earliness, great productiveness, and bright, handsome appearance, make it a favorite market variety. — *Lost Rubies.* Very profitable and delicious; exceedingly vigorous and hardy, enduring severe winters. — *Seneca Black Cap.* Larger than Doolittle, a week later in ripening; firm, sweet and rich; hardy and very productive. — *Shafer's Collossal.* Described as the largest raspberry in the world, and very hardy; it is of the class called hybrids; color of a purplish hue; ripens late. — *Souhegan.* A week earlier than Doolittle; as large as the Gregg; perfectly hardy and enormously productive.

Hansel.

Lost Rubies.

STRAWBERRY.—The best soil for strawberries is a sandy loam containing sufficient clay to prevent leaching. The best artificial fertilizer is Peruvian guano. New plants are best propagated by striking runners in small pots plunged in the soil. As soon as the plants are well rooted, they may be set out in permanent beds, and next season will produce good crops. They may be set out any time during growing season, but the best time is in spring. Strawberries may be grown in hills, in rows or in beds. The latter is the common method, and the beds are formed by planting 2 or more rows 1 ft. or 15 in. apart, setting the plants 12 in. one from another in the rows. In the beds the runners are allowed to grow, and to increase the number of plants indefinitely, so that they are often injured by being crowded too closely together. When planted in hills, they are set 18 in. apart; the space between them is kept perfectly clean, and the runners are cut as soon as they appear. The best way to move old strawberry plants is to wait till after a heavy rain when the ground is soaking wet, and take up clumps of them with the earth attached and carry them where you want them. Stirring the surface of the soil frequently is of prime necessity, and should be continued until the fruit begins to set and mulching is required. Then mulch the whole surface between the rows and up against the hills. When water is applied, let it be done so as to soak the ground well down, lasting for several days. Among practical growers strawberries are classed as European and native, and as having *pistillate* or *imperfect* (female) blooms, that require another variety to fertilize them (marked P), and the *perfect* or *hermaphrodite* blooms. The P varieties are good growers and have large fruit, but are troublesome. Varieties are: *Bidwell.* The plant is a very strong grower and very hardy and exceedingly productive; the number of berries a well-grown stool will grow and mature is almost incredible; the fruit is very large, regular, and handsome in shape; color very bright and showy; flesh very firm,

Bidwell.

and quality of the best; succeeds well on all soils. — *Crescent Seedling* (P). Large, conical, quite uniform in size and shape; bright scarlet; a remarkable grower; very productive; does well on all soils. — *Crystal City.* The earliest variety in cultivation; fruit of medium size, conical; color deep red; flesh moderately firm, good quality; very desirable for early home use. — *Cumberland Triumph.*

Jersey Queen.

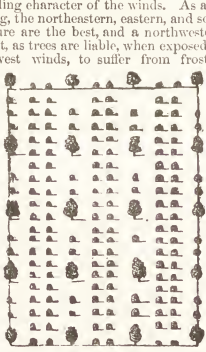
A magnificent variety; berries immense, fine, perfect form, and of fine flavor; plant very vigorous and productive. — *Charles Downing.* Soft, rich, productive, good; bears neglect well; succeeds almost everywhere. — *Glendale.* So far the best late market berry that has been tested; plant very thrifty, with tall, rank foliage, and very productive; succeeds well in both light and heavy soils; fruit of large size, regular, uniform, conical, bright scarlet color; fair quality; very firm, being equal to Wilson for shipping and keeping. — *Jersey Queen* (P). Exceedingly large and beautiful, very firm and of superior quality. It ripens late, continuing until very late; a healthy grower. — *Longfellow.* A variety from Kentucky. Large, late, firm berries. — *Manchester* (P). Vigorous grower, very productive; berries large, uniform size; very firm; ripen medium to late. — *Miner's Great Prolific.* Large to very large; deep crimson; strong grower, and so enormously prolific that the fruit is heaped about the plant. — *Monarch of the West.* Well tested variety; will grow on almost any good soil; stands drought and wet; berry very large, firm, and of delicious flavor. — *Mt. Vernon.* A large, late, very productive variety; a strong, healthy grower, with strong fruit stalks; fruit conical, bright red, uniformly large, and of excellent quality.

Longfellow.

ORCHARD FRUITS.

GENERAL CARE.

ASPECT.—This depends a great deal upon the prevailing character of the winds. As a general thing, the northeastern, eastern, and southern exposure are the best, and a northwestern the poorest, as trees are liable, when exposed to the northwest winds, to suffer from frost. The



Orchard Plan.

banks of lakes, streams or gullies are better locations for trees than any other. For the orchard a sloping surface is an advantage, provided the slope is very moderate and inclines to any of the points from southeast to southwest. The illustration shows a good way to plant orchard dwarf trees, using larger trees as a protection, when hillside shelter is not obtainable.

BUDDING.—Budding or grafting by detached buds, consists in transferring a portion of bark containing a bud, and forming the scion, to the wood of another plant, forming the stock, a portion of the bark of the stock being raised up or taken off to receive the bud. It is performed in

Budding.

the late summer or early fall. A sharp penknife can do duty for a budding knife, and a small piece of goose or large chicken quill, cut like a pen, but without a slit, will answer for a spud to aid in lifting the bark. Take a smooth stalk and make a horizontal cut across the bark through the wood, but not into it. From the centre of this cross-cut make another cut straight down

the stem 1 in. or more in length; these 2 cuts should resemble a *T*; slice off the bud you desire to propagate with one cut of the knife, cutting it close to the main stalk; with the edge of the spud turn back the bark on each side of the straight cut and insert the bud on the wood of the branch to be budded, fitting it tightly to the crossed cut, and pressing firmly into the bottom of the slit; with a piece of soft yarn bind down the bark, leaving the point of the bud exposed; in from 8 days to 2 weeks, according to the growth, the ties should be examined and loosened a little, and in about 6 weeks the wrapping can be removed; all other shoots must then be kept from growing on the budded branch. Next summer, if the bud has pushed and grown well, in July or August, the stock should be cut off close to the shoot. *Annular* budding consists in removing a ring of bark from the stock and a corresponding ring containing the bud, slit open on one side. The ring with the bud is made to fit the denuded space. This method is appliceable to trees of hard wood or thick bark. *Terminal* budding may sometimes be used to advantage. The cut in this case is sloped downward and the insertion made as usual. Care must be taken to apply the whole of the ligature below the bud.

Tying the Young Shoot.

Stick with Bud.

Annular Budding.

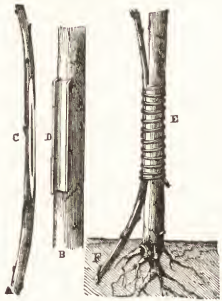
Terminal Budding.

CUTTINGS.—*Green Wood.* Take green shoots 3 to 6 in. long; cut clean off below an eye or joint, and pinch off most of the leaves, but a sufficient number should be left on for the purposes of vegetation. When cuttings are set in pots, they should be placed so as to reach to the bottom and touch the sides throughout their whole length. Green wood cuttings are usually started under glass. In the case of tubular stalked plants, it is advantageous to insert both ends into the soil, each of which will take root, and may then be divided, when 2 plants will be produced instead of 1. The cuttings should be placed in the earth in a slightly sloping position, bottom end down, with but 1 bud above the ground; place 2 at each point where 1 plant is wanted, and if both grow, 1 should be removed. No cutting requires to be planted deep, though the large ought be inserted deeper than such as are small. In the case of evergreens, the leaves should be kept from touching the soil. — *Ripe Wood.* The choice of cuttings should be made from the side shoots, observing to leave a little wood of a former year or season's growth attached to them, as such are found to take root more readily than when they are wholly composed of new wood. The time to take cuttings is before the sap gets into motion. Before setting them they should be cut across, just below an eye or joint, with as smooth a section as possible, observing not to injure the bud.

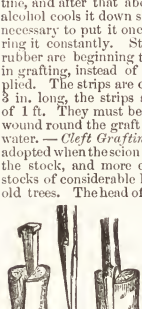
GIRDLING.—This is usually done to fruit trees to promote early and full bearing, by preventing the sap from returning into the roots and forcing it to expand itself among the fruits and flowers. It is done by taking out a rim of bark entirely around the tree, limb or vine, not over ¼ in. wide. Sometimes this space is healed up the first year, but certainly the second year, if the tree be not too feeble and sickly. Another method is to take coarse twine or fine wire and wind it several times around the tree above the lower limbs and tie it as tight as possible. Girdling is also performed in clearing new ground of timber when there is not time to remove it entirely. A portion of the bark 1 or 2 ft. in length is cut out all around the butt in spring. This kills the tree.

GRAFTING.—The objects and advantages of grafting are as follows: *a.* The propagation of varieties which are not increased freely by any other mode. *b.* The quickening of the fruitification, especially of trees which are naturally a number of years before they come into flower. *c.* To increase the vigor of delicate species by grafting them on robust stocks. *d.* To dwarf or diminish the bulk of robust species. *e.* To increase the fruitfulness of trees. *f.* To preserve varieties from degenerating, which are found to do so when propagated by cuttings and layers. *g.* By choosing a stock suitable to the soil, to produce trees in situations where they could not be grown if on their own roots. *h.* To produce several kinds on one kind. *i.* To renew the heads of trees. Thus, if a fruit-tree is cut down to the ground, or headed in to the height of 10 or 12 ft. and left to itself, it will develop a great number of latent buds, each of which will be contending for the mastery; and the strength of the tree, and the most favorable part of the season for growth, will be in some degree wasted, before a shoot is singled out to take the lead; but, if a graft is inserted either in the collar or stool, or in the amputated head, it will give an immediate direction to the sap, the latent buds will not be excited, and the whole concentrated vigor of the tree will be exerted in the production of one grand shoot. Of the many modes of grafting, *whip* or *tongue*, *saddle* and *cleft* grafting are the most common; but no matter which mode is adopted, the graft must be inserted in the stock so that the line of division between the inner wood and bark of the stock and scion shall correspond. The implements necessary are the common knife, for heading down stock; the chisel; a grafting-knife; ligatures of different kinds for tying on scions, and grafting-clay or grafting-wax for covering them.

The ligatures in common use are strands of bast matting, or other flexible bark; but sometimes coarse worsted thread is used, or occasionally shreds of coarse paper, or cotton cloth, covered with grafting-wax. When bast mat is used, it may be rendered waterproof by passing it first through a solution of white soap, and next through one of alum; by which a neutral compound is formed, insoluble in water. These prepared shreds, before being put on, are softened, by holding them over a vessel of burning charcoal, which the grafter carries with him; and when grafting wax is employed, instead of grafting-clay, it is kept in an earthen pot, also placed over live charcoal, and the composition taken out and laid on with a brush. Grafting-wax is universally used in this country instead of grafting-clay. It may be made as follows: Melt 1 lb. of common resin over a gentle fire; add to it 1 oz. of beef tallow, and stir well; take it from the fire, let it cool down a little, and then mix with it a tablespoonful of spirits of turpentine, and after that about 7 oz. of alcohol; the alcohol cools it down so rapidly that it will be necessary to put it once more on the fire, stirring it constantly. Strips of very thin India-rubber are beginning to be used as a bandage in grafting, instead of the wax commonly applied. The strips are cut about $\frac{1}{2}$ in. wide and 3 in. long, the strips stretching to the length of 1 ft. They must be applied dry and tightly wound round the graft so as to exclude air and water. — *Cleft Grafting.* This mode is chiefly adopted when the scion is a good deal larger than the stock, and more especially when grafting stocks of considerable height, or heading down old trees. The head of the stock being cut over horizontally with a saw, a cleft is made in it, from 2 to 3 in. in length, with a stout knife or chisel, or with the splitting-knife. The cleft being kept open by the knife or chisel, or the pick end of the splitting-knife, 1 or 2 scions are inserted, according to the diameter of the stock; the scions being cut into long wedge-shapes, a little thinner on the inside edge than the outer edge, and inserted into the slit prepared for them, when the knife or chisel being withdrawn, the stock closes firmly upon the scions, and holds them fast. The graft is then tied or clayed in the usual manner, and the whole is frequently covered with moss, or some similar substance. — *Layer Grafting*, or *Inarching*, consists in forming a hollow place in the side of the tree into which the scion is to be placed. The side of the scion which comes in contact with the tree must have a piece shaved off, it is then placed in the hollow and tightly bound or clayed. (See *Grapes* in GARDEN FRUITS.) — *Root Grafting.* This method is chiefly used for the apple. The stocks are taken up by the roots, cut off down to the crown of the roots, and the graft inserted in the crown. The grafted root is then covered with wax, and replanted, leaving the bud of the graft just above



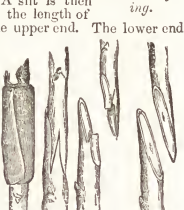
Layer Grafting.



Cleft Grafting.

ground. — *Saddle Grafting* is only applicable to stocks of moderate size, but it is well adapted for standard fruit trees. The top of the stock is cut into a wedge-shape, and the scion is split up the middle, and placed astride on it, the inner barks being made to join on one side of the stock, as in cleft grafting. The tying, claying, etc., are performed in the usual manner. — *Whip* or *Tongue Grafting*, is applicable to small stocks, and for root grafting. The stock is cut close to the ground with a sloping cut. A slit is then made about $\frac{1}{3}$ of the length of the slope from the upper end. The lower end of the graft is then cut so as to match the sloping end of the stock, and a slit made in the end similar to that made in the stock. The sloping surfaces are pressed together, the tongues formed are inserted into the slits in each other, then closely bandaged and sealed. The illustration represents the successive stages of whip or tongue grafting from the sloping cut of the scion and stock to completion of the operation by covering with wax.

Saddle Grafting.



Whip or Tongue Grafting.

MULCHING.—Young trees and plants recently set should be mulched with decaying matter, as straw, rotten wood and leaves. This prevents evaporation from the ground and keeps the soil moist. The gradual decay also furnishes food to the roots.

PLANTING TREE SEEDS.—All nut and hard shell seeds should be soaked in warm water, or milk and water, until the rind is softened, then placed in the ground as follows: Take of good rich loam ½, sand ½, very old decomposed manure ½; mix them thoroughly; then prepare boxes with holes in the bottom for drainage; fill these boxes ⅔ full of this compost and plant the seeds, each in separate boxes and in thickness according to the size of the seed; then sift over them good sand and loam only, about 1½ to 2 in., and over this cover about 1 in. of sawdust; then sprinkle with a fine syringe or water pot; the sawdust keeps the surface from baking. Keep the boxes in a light and cool place, free from the sun till the seeds are up and show 2 or 3 leaves, then bring gradually into the sun and air. When 6, 10, or 12 in. high, transplant to where they are to grow. Or, they may be sown at once in well prepared beds.

PRUNING.—This varies according to the kind of plant or tree operated on and the particular object in view, and its skillful performance must, therefore, greatly depend on the experience and knowledge of the gardener. Fruit trees above all others are benefited by pruning. The object of pruning is to create an abundant supply of sap during summer, by the production of leaf shoots, by which the general strength of the tree is augmented, and to limit the distribution of this sap when it ascends from the roots in the following spring, by diminishing the number of buds. The effect of this is to increase the vigor of the shoots or fruits produced by these buds. In shoots which produce their buds alternately the cut is made at the back of the bud sloping from it, so that it may be readily covered by the bark in the same or in the following year; but in the case of branches where the buds are produced opposite each other, either one bud must be sacrificed or the branch must be cut off at right angles to its line of direction, which is most conveniently done with the pruning shears. The seasons for pruning vary according to the object in view. Where wood is to be cut out or buds removed, so as to throw strength into the remaining parts of the tree, the sooner the operation is performed, after the fall of the leaf, the better. Next to autumn, winter is to be preferred, for the same reason; in this season mild weather is always to be chosen, because the frost, if severe, will seize on the moisture of newly-made wounds, and rupture their surface. For disbudding and ringing, spring is the most suitable season. The summer season is found better than any other for pruning trees which gum, such as the cherry and the plum, provided too much foliage is not thereby taken away; and it is also considered favorable for resinous trees. The autumn, on the other hand, is considered the best for trees that are apt to suffer from bleeding, such as the vine, the birch, and some species of maple. The principal modes of pruning are as follows: *Bruising and Tearing.* This consists in tearing off the sprouts from the stems of the plants at their roots, and in some cases is found to be more effective than cutting them off with a smooth section. — *Close Pruning.* Cutting off shoots close to the branch or stem from whence they spring, leaving as small a section as possible, in order that it may be speedily healed over. In performing the operation, care should be taken to make the wounded section no larger than the base of the shoot, in order that it may be healed over as quickly as possible; and at the same time to make it no smaller, because this would leave latent buds, which would be liable to be developed, and thus occasion the operation to be performed a second time. — *Disbarking.* This includes two distinct operations; the removal of coarse, loose, outside bark, to admit of the swelling of the inner bark and the alburnum by the returning sap, and the removal of a ring of both inner and outer bark, with a view to the interruption of the returning sap. — *Disbudding.* The removal of buds in spring or summer, just when they are beginning to develop their leaves, and is commonly performed with the finger and thumb, the object being to lessen the number of shoots or of blossom buds to be produced, and is the easiest and safest mode of pruning. — *Disleafing.* The leaves by this process are taken off a growing shoot as fast as they are unfolded, in order to throw the growth more strongly into another portion of the plant to maintain a symmetrical balance. — *Foreshortening.* A portion of the extremities of the lateral branches of a standard tree are cut off when they extend too far, the cut being always made close above a branch of such thickness as to form a leader of sufficient strength to keep the branch alive and healthy. — *Heading-in.* All the branches which form the head of a tree are cut off close to the stem, leaving only their base to produce buds. — *Lopping.* A term which is very generally applied to heading-in, but it is generally used to signify the cutting off of large branches from the sides of stems. It is done by shortening the branches to a sufficient size. — *Root Pruning.* This is performed with a sharp spade, and generally only on the main roots, at the distance of several feet from the stem, according to the magnitude of the tree. — *Shortening-in.* A term applied when side-shoots are shortened at the distance of from 2 to 4 or 5 feet from the stem, the cut being always made to a bud. — *Spurring-in.* A lateral shoot of the 1st year is shortened to 2 or 3 visible buds; the 2d and 3d years, the shoots are re-shortened.

SEED, To Preserve.—1. Put them in a sack of coarse material, or in a box or barrel full of small holes, and keep them under water until ready for planting. — 2. Place them with alternate layers of sand in trenches lined with boards. — 3. Store the freshly gathered acorns in a well ventilated room, stirring them frequently, and when tolerably dry, put them in heaps and cover them with a coat of leaves, another of branches and moss, and the whole with straw.

TRAINING.—Training a plant to support or conduct its stem and branches in some form or position, either natural or artificial, for purposes of use or ornament, is effected partly by pruning and thinning, but chiefly by pegging down to the ground, tying and fastening to rods, stakes or trellises, or nailing to walls, and is

termed *Espalier* training. The articles more immediately required are hooked pegs, ties, nails, and lists, with props of various kinds, and ladders. The tie or the list, by which the shoots are fastened to the wall or trellis, should be placed in the space between the points of the stem from which the leaves arise, and always immediately behind a bud or joint. The bast ties are gently twisted before being tied into a knot, in order that it may be the firmer, and not liable to be torn during the operation of tying. Osier ties, which are frequently used for espalier-trees, are fastened by twisting together the two ends, and turning them down. In fastening shoots with nails and shreds, when any restraint is required to retain the shoot in its position, the pressure must always be against the shred, and never against the nail. The shred ought not to be placed in the hollow of a bend in the branch to be attached; for there it is worse than useless. Shreds of woolen are preferred to those of any other cloth, or to leather, as being softer, and less influenced by the weather. The length should be such as to contain a shoot double the size of that for which they are intended, in order that they may never compress the shoots so much as to impede the returning sap, and their breadth may be from ½ to ¾ in. to 1 in. They should be folded up a little at each end, so that in driving the nail through the shred it will pierce four times its thickness, and be in no danger of tearing. The different modes of training bushes and trees in the open garden are chiefly the conical form for tall trees or standards, and some modification of the globe or cylinder for dwarfs. — *Conical Standards* may be produced from trees partially spurred-in; cut in the side branches. — *Fan Training.* Head the maiden plant down to 4 eyes placed so as to throw out 2 shoots on each side; next season head down to 3 eyes, 1 leading shoot and 1 on each side; the 2 lowermost shoots are to be headed down to 2 eyes, so as to throw out 1 leading shoot, and 1 shoot on the uppermost side; there are now 5 shoots on each side; each shoot must now produce 2 shoots on the uppermost side, and 1 on the undermost side; the next season each shoot should produce 1 on the upper and 2 on the under part. — *Horizontal Training* is practiced either with 1 or 2 stems, and either with the upright stem straight or in a zigzag direction, to stimulate the lateral buds to develop themselves. From this upright stem, the branches proceed at right angles—generally at 9 in. apart for apples, cherries and plums, and from 10 in. to 1 ft. or 18 in., for pears. A maiden plant with 3 shoots having been procured, the 2 side ones are laid in horizontally, and the centre one upright; rub all the buds off except 3, 1 next the top for a vertical leader, and 1 on each side, as near the top as possible, for horizontal branches. In the autumn of the first year, the 2 laterals produced are nailed in, and also the shoots produced from the extremities of the lower laterals, the centre shoot being headed down as before. But in the second summer, when the main shoot has attained the length of 10 or 12 in., it may be stopped. — *Spiral.* Prune and manage the tree so as to have from 3 to 6 branches within 6 in. of the ground; fix 6 rods or stakes into the earth in a circle about the roots; bring down each branch; fix it to the rod near its base; carry the branch around in a spiral manner; let all move in the same direction, 1 above the other.

TRANSPLANTING.—The autumn is the most convenient time for transplanting; for the soil is dry and warm and there is time to do the work well. Have the ground ready; never plant where an old tree stood before; dig the hole at least 2 ft. in diameter and have 1 ft. of good, rich soil under the roots; prune off the ends at least ½, with a sharp knife; after digging the hole, make a little mound in the centre, then a little basin; and after the tree is on it, carefully adjust the roots, so that each one is spread out in its natural position; the fine, rich soil is then filled in so that each little root will come in contact with the solid soil. A pair of large wheels and an axle make an apparatus for transplanting large trees. A piece of 4x4 in. studding is tied to the tree with cloths, straw, or something to prevent bruising the bark of the tree, and a rope attached to the upper end. A trench has previously been dug around the tree. When ready to move it, fasten the axle firmly to the studding or timber, seize the rope and pull the tree into a horizontal position, when it is ready for transportation. Some skill is required in digging trenches. They should be cut as far away from the trunk as convenient, in order to destroy as few roots and rootlets as possible. The more earth moved with the tree the more apt will be the tree to survive the transplanting. A good plan is to dig 2 trenches, the first about 2 years before the removal, leaving 3 or 4 strong roots uncut to keep the tree standing, and the second the autumn before moving. Fill the first trench with rich surface soil as soon as dug. Into this myriads of little roots will grow, to give additional insurance of life after the tree is transplanted. The second trench should be cut outside the first, so as not to disturb the rootlets. To water a newly-set tree, dig the earth away down to near the roots; pour in water enough to last a week of dry weather; put the dry soil back over the wet. If the roots are wet, no matter how dry the surface is.

WINTERING.—*Heeling-in.* If the supplies of trees are procured in the fall, choose the driest and cleanest spot in the garden; clear away all rubbish from the vicinity, to save trouble from mice; dig a trench long enough to admit a layer of 10 or 12 trees side by side, and wide and deep enough to let the roots below the surface; throw the soil forward at a right angle from the trench, so the tops can rest upon it; this will raise the tops just a little above the level of the ground; when the first layer is properly placed, proceed by shoveling fine earth among the roots, extending the trench for another layer at the same time; fill carefully all spaces and pack the ground firm, by pressure with the foot; place another layer in the same position, with the roots projecting a little forward of those of the first, but no deeper in the ground. Varieties may be separated by placing small willows across and between, as put in, and a register

should be kept of the whole. To preserve labels distinct, wind them with paper, which should be tied on.

KINDS.

THE success of orchard fruits depends upon climatic conditions. Some fruits that are successfully cultivated in the East will not grow in the West, and those cultivated in the North will not grow in the South, and *vice versa*. It would take more space than can here be spared to give the climate favorable to each kind and variety. The American Pomological Society has published, and will doubtless continue to publish, from time to time, lists in which the latest approved varieties are given, with the localities in which they thrive best. These can be had at any time by applying to the veteran President, Marshall P. Wilder, of Boston, or to whoever may be Secretary of the society for the term.

ALMOND, Hard Shelled. Sweet.—Will succeed where the peach will, and requires the same soil, culture and methods of propagation. It is extensively cultivated. The soft shelled is suitable for the South.

APPLE.—The apple will grow in any common soil neither too sandy, gravelly, nor clayey, on a dry subsoil and free exposure. Any soil that will produce good crops of grain and potatoes will be adapted to the growth of apple trees. The apple may be propagated by seeds, cuttings of the branches and roots, by layers, suckers, grafting or budding; the last two modes are principally for continuing varieties (See *Budding* and *Grafting* in GENERAL CARE), and seeds are used to obtain new varieties. In planting apple seeds, the ground should be plowed, harrowed, rolled and well pulverized. It should be moderately rich, but use no green manure. To get the seed, pick out good, ripe apples from strong growing trees; crush them and wash and sieve the pulp. The good, plump, seeds will fall to the bottom, while the light seeds and pulp will float. The seed should be planted in rows about 3 ft. apart. After the seeds are sown and covered about 3 in. deep, they may rest undisturbed until about December, or till the first slight freeze, when they should be covered in the row with a light covering of barn-yard manure or any mulch. This keeps the ground from cracking, and makes the soil soft in the spring, so that the little sprouts can easily get through the ground; it will also keep the weeds back. After they are up, keep the ground well cultivated and the seedlings weeded; when they are 6 in. high, just after a rain, thin out the weakest where too thick. For the first 3 or 4 years the weeds should be destroyed and the ground kept in good condition by cultivating some low growing hoed crop. Salt hay makes a good mulch. Put a hundred weight or a little more to each tree, extending it 6 or 8 ft. from the trunk all around the tree; it will keep the surface mellow, retain the moisture for a long time and keep down the grass. After the trees have been several years planted the soil should be sown with grass and annually enriched with good stable manure as a top dressing or mulch. October or November are the best months to apply the manure and to give the trunks of trees a good scraping-off of all old bark. To remove suckers, allow them to grow until they are in leaf, then take each separately in the hands; place a thick boot upon it near the tree, and they are quickly separated. If done at that time they will not be likely to sprout again. To make apple trees bear the odd year, enrich the ground heavily in the spring of the even, or full of the odd year, as suits convenience; this treatment induces a set of fruit buds for the odd year. Or, during the even year, when the apples are about the size of a hickory nut, knock them all off with a long pole, breaking the little twigs as well, and the trees for many years will bear full crops. Apple trees should be pruned sparingly; the tops should be kept sufficiently open to admit sunshine and air. Apples may be divided into *Cider, Crab, Fall, Summer*, and *Winter* kinds.

Cider.—The most valuable varieties for the manufacture of cider are the *Harrison* and *Camfield*, extensively raised in the Middle States, being rich in flavor, and bearing very abundantly; *Hugh's Virginia Crab*, small size, but very productive; and the *Red Streak*.

Crab.—*American*. The common wild crab apple of the U. S., growing in glades and frequently forming extensive thickets. — *Chicago*. Fruit small; yellow, with a vermillion cheek; flesh crisp, slightly sub-acid; December to March.— *Gen. Grant*. Fruit large, round, oblate; warm, yellow ground with broken stripes of dark red on sun-exposed side, with light dots; flesh white, not juicy, very mild, sub-acid; late autumn. — *Hyslop*. Large; skin rich purple, covered with a velvety bloom; fruit hanging until heavy frost. — *Lady Elgin*. Medium; skin whitish yellow, nearly covered with bright red and light gray dots; September to December.— *Marengo*. Tree vigorous; fruit red, on yellow ground, with a few russet dots; flesh yellowish white, crisp, juicy; when fully ripe, pleasant sub-acid; carly winter to late spring. — *Montreal Beauty*. Large; bright yellow, shaded with rich red; flesh yellowish, rich and acid. — *Red Siberian*. A beautiful tree, and a great bearer; fruit small, about the size of a cherry, growing in clusters; color bright red; when matured, globular form, long and thin stem; excellent for preserves; September.— *Transcendent*. The largest of the Siberian Crab apples, beautifully colored, red and yellow; tree a very strong grower. — *Van Wyck*. Large; skin mottled with red; sweet and firm; tree vigorous. — *Yellow Siberian*. Similar in habits and appearance to the Red Siberian; fruit a fine clear yellow or a rich golden color; September to October.

Fall.—*Alexander*. A Russian apple, very hardy; fruit large size; deep red or crimson; flesh yellowish white, crisp, tender and pleasant flavor; October. — *Fall Jennetting*. Large, roundish, oblate; greenish yellow with a blush; tender, juicy and very good; October and November. — *Fall Pippin*. Large size, round, oblong; skin smooth, bright greenish yellow,

slightly speckled; flesh white, tender, juicy and of excellent flavor; October to December. — *Gravenstein.* Vigorous tree, and very productive; fruit large; color clear straw or yellow, with stripes of red; flesh pale yellow, crisp, delicious flavor; vigorous, erect, and productive in all localities. — *Jefferies.* Medium size; skin yellow, shaded and striped with crimson, and thickly covered with large whitish dots; flesh white, tender, juicy, with a rich sub-acid flavor; September and October. — *Jersey Sweet.* Medium; greenish yellow, thickly striped with red; very sweet, juicy and tender; good in all localities; fine bearer; September and October. — *Lowell, or Orange.* Large, roundish, oblong; green, becoming rich yellow; surface oily; valuable for its fairness, good quality and great productiveness; tree very hardy; September and October. — *Maiden's Blush.* Medium to large, oblate or flat, with a beautiful blush cheek; fine grained and tender, but not rich; uniformly productive; September and October. — *Porter.* A large and popular variety, very productive, skin bright yellow, with a blush; flesh fine-grained and juicy; last of September to October. — *Primate.* Medium; pale yellow; fine-grained, tender, juicy, mild and sub-acid; August and September. — *Rambo.* Medium, oblate; yellowish ground, streaked with dull, yellowish red, and somewhat dotted; tender, rich, mild and very excellent; fine in nearly all localities; October to January. — *Red Bietigheimer.* A rare and valuable German apple, ripening in early fall; extra large, pale cream ground, mostly covered with red and purplish crimson, very beautiful. — *St. Lawrence.* Large, roundish; striped with dark red on yellowish ground; rather acid, moderately rich and agreeable; a handsome, good and productive apple; tree very hardy; October. — *Sops of Wine.* Medium; color dark crimson; juicy and sub-acid; August and September. — *Stump.* Medium, roundish, conical, smooth, white, shaded with bright red, splashed and striped with crimson; flesh white, tender, juicy, and pleasantly sub-acid; September and October. — *Twenty Ounce.* Very large, roundish, striped with red on yellowish ground; crisp, sub-acid; very productive and excellent for cooking; very profitable market apple; October to January.

Summer. — *Benoni.* Medium size, nearly round; yellow ground, striped or overspread with deep red; tender, rich, sub-acid, and with an agreeable flavor; ripens August. — *California Red June.* Medium size; deep red; flesh white, tender, juicy, sub-acid; tree hardy and productive; bears early. — *Early Harvest.* Medium size, roundish; pale yellow or straw color; tender, rather acid; tree moderate grower and productive; July and August. — *Early Joe.* Medium size; deep red on yellow ground; tree slow, but erect grower and profuse bearer; flesh tender, juicy and excellent; August. — *Early Red Streak.* Below medium size, roundish ovate; skin greenish yellow with dark red stripes; flesh white, sub-acid, rich, agreeable flavor. — *Early Strawberry.* Medium size, striped with deep red; tender, sub-acid and pleasant; erect grower and productive. — *Golden Sweet.* Rather large, roundish; greenish to pale yellow; flesh very sweet and good; tree very hardy, free grower and good bearer; fine for cooking; ripens in August. — *Juneating.* An old, favorite variety, of small size, flat form, long and thin stalk; color a pale green, turning to light yellow when ripe; the skin has an oily feel; the taste is pleasant; bears abundantly in good ground; last of June to the middle of July. — *Keswick Codlin.* Above medium, conical; straw colored; juicy, acid and of pleasant flavor; superior for jelly, and in use from July to October. — *Red Astrachan.* Rather large, roundish; brilliant deep crimson, with a thick bloom, juicy, crisp and acid; a beautiful apple; tree a vigorous grower, very hardy and productive; August. — *Summer Queen.* A popular apple, of the finest quality and appearance; large size; color fine, rich, yellow ground, mixed with red striped; long stalk; large tree; great bearer; flesh rich, yellow, and agreeable flavor. — *Summer Rose.* Medium size; light yellow with a red cheek; tender and delicious; August. — *Sweet Bough.* Large, roundish; pale greenish yellow; tender, delicious, sweet; a moderate and regular bearer; August. — *Tetofsky.* An early Russian apple; fruit handsome, medium to large; yellow, striped with red; juicy, pleasant, acid and aromatic; bears extremely well; July and August. *Williams' Favorite.* Moderate grower and good bearer; large and handsome; skin smooth, nearly covered with a fine dark red; flesh yellowish white, mild and agreeable flavor; July to first of September.

Winter.—*Baldwin.* Large, roundish; bright red; mild, juicy and rich; tree productive but rather tender; it is, on account of its productiveness, one of the most profitable varieties to cultivate, while trees that bear the odd year are doubly valuable; December to March. — *Bellflower, Yellow.* Large; pale yellow, with a deep blush on the sunny side; crisp, juicy and excellent; November to April. — *Belmont.* Tree vigorous, healthy and very productive; fruit medium, of a waxen yellow color, often with a bright vermilion cheek; flesh yellowish, crisp, tender, juicy, of a mild, agreeable flavor; very good; November to February. — *Ben Davis.* Large; very handsomely striped with red; good quality and late keeper; a very popular apple in the West and Southwest. — *Esopus Spitzenberg.* Large, round, ovate; skin deep red, faintly striped and covered with bloom; rich, crisp, and high flavored; December to April.— *Fallawater.* Large, roundish, smooth; yellowish green with a brown blush, tender, juicy, mildly acid and agreeable; December to January. — *Fameuse.* Medium size, round, striped and blotched with deep crimson; juicy, sub-acid, spicy and pleasant; highly esteemed in Canada; tree very hardy; November to January. — *Grimes' Golden.* Large; golden yellow; juicy, sprightly, sub-acid; very good; January to April. — *Hubbardston Nonsuch.* A superior variety; the tree grows large, vigorous, and handsome; bears early and abundantly; fruit large, globular, or conical; color yellow, with stripes of pale red; flesh yellow, juicy, rich, sweet, relieved by a slight acid; November to

January. — *King of Tompkins Co.* A large, handsome fruit, striped red and yellow; crisp, juicy, sub-acid, and of excellent quality; tree rather tender; October to January. — *Lady.* Small and attractive; color red and yellow; flesh crisp, juicy and pleasant; November to May. — *Lankford Seedling.* Fruit large and heavy; color rich red with a tinge of yellow on one side; flesh fine grained, juicy, pleasant and sub-acid; January to April. — *Newtown Pippin, Yellow.* Medium size roundish, a little flattened; when fully ripe, it is yellow, with a lively red cheek; flesh firm, crisp, juicy, with a very rich and high flavor; one of the finest. — *Northern Spy.* Large, roundish; handsomely striped with red; juicy, rich, mild and agreeable; vigorous grower and fine bearer; December to June. — *Ortley.* Large; white or very pale yellow; tender, rich and juicy; very large hollow core; October to February. — *Peck's Pleasant.* Large, roundish; light green, becoming yellow; very tender, with a mild, rich, fine clear pippin flavor; good bearer; tree very hardy; December to March. — *Pewaukee.* Medium size; bright yellow, splashed and striped dull red; sub-acid, with rich, aromatic flavor; perfectly hardy; December to March. — *Pryor's Red.* Rather large, roundish, deep dull red on greenish yellow ground; very tender, mild, rich, sub-acid and agreeable; highly esteemed in the Southwestern States; keeps till spring. — *Rawle's Genet.* Medium size, roundish oblong pale red stripes on light yellow ground; crisp, juicy, rich and mildly sub-acid; keeps through the spring; tree very hardy. — *Rhode Island Greening.* Large, roundish; green, becoming greenish yellow; tender, juicy, rich, rather acid and slightly aromatic; very crooked grower. In the South it becomes an autumn fruit; in the North it matures in March and April. — *Russet, Golden.* Full medium size, tinged with red on the exposed side; flesh crisp, juicy, high flavored, resembling a fine pear when ripe; January to June; tree very hardy, and bears every year. — *Russet, Roxbury.* Very popular, and extensively grown; medium size, roundish, somewhat flat; skin dull green or brownish-yellow; flesh greenish white, compact, slightly acid, but rich flavored; December. — *Swaar.* Large, roundish; greenish yellow, a little russeted; tender, with a very mild rich, agreeable flavor; January to May. — *Talman's Sweeting.* Medium, roundish; clear light yellow; firm, rich and very sweet; fine for the kitchen; vigorous and productive; tree very hardy; November to April. — *Wagener.* Medium or large; yellow ground with dull red stripes; very fine grained, tender, aromatic, mild and excellent; November to April. — *Wealthy.* Fruit medium, with whitish yellow ground, shaded with deep crimson in the sun, broken stripes and mottlings in the shade, covered with light dots; flesh white, fine grained, stained with red, tender, juicy, lively, vinous, sub-acid; very good; December to February. — *Westfield Seek-no-further.* Medium to large, roundish; slightly russeted with dull, red stripes; tender, rich, spicy, and of a fine flavor; great bearer; November to February. — *White Winter Pearmain.* Large; light yellow, very handsome, and good quality; January to April. — *Wine Sap.* Medium size, rather oblong; smooth, dark red; flesh firm, crisp, with a rich, high flavor; December to June. — *Winter Sweet Paradise.* Large, roundish; fair, dull green with a brown blush; fine grained, juicy, sweet, sprightly and very good.

APRICOT.—The soil which suits apricots best is a good sound loam, which will readily crumble by the action of the weather. It must be prepared about ½ yard deep; if a light soil, 2 ft. with turfy matter mixed with it. The apricot tree may be raised from the stone, or by budding, either on its own, plum or peach stocks. In pruning the coarse breast shoots should be pinched off in summer. All immature looking sprays which tend to shade the blossom-buds should be cut away. Young trees should be shortened in order to produce more shoots. Varieties: *Breda.* Small; dull, orange, marked with red; juicy, rich and vinous; good bearer and hardy; August. — *Early Golden.* Small; pale orange; juicy and sweet, hardy and productive; July. — *Large Early.* This is a fine fruit, which also ripens in July; fruit medium size, somewhat oblong; color orange, rather pale; flesh straw color, rich, juicy, easily leaving the stone; an excellent sort. — *Peach.* This is the largest, and by many considered the finest of all varieties; form round, with compressed sides; color a yellowish fawn on the shady side, slightly colored with red towards the sun; flesh yellow, sprightly, juicy and high flavored; August. — *Henskirk, Moor Park, Red Masculine, St. Ambroise* and *Turkey* are also recommended varieties.

BANANA.—The fruit of a handsome plant now grown almost everywhere in the tropics. It is a variety of the plantain, the fruit of which is much like it. Bananas have generally spots on the stems, with dark purple stripes, and the fruit is smaller, less curved, and of a more delicately luscious taste than the plantains. Bananas are generally 4 or 5 in. long, and the plantain from 8 to 12 in. long. The best land for growing bananas is on a side hill, where the sun has great force. After the land is cleared the bananas are planted in rows about 15 or 20 ft. apart. On ground that is used for the first time for bananas, vegetables of various sorts are planted between the rows. These help to keep down the grass. Each tree bears a single bunch, which is ready to cut about 9 months after setting out the plant. After removing the bananas the trees are cut off close to the ground, and from the old stumps 3 or 4 more trees will spring up, each of which will in about 9 months yield a bunch. The trees grow about 15 ft. high. In setting out a new field, the roots of old trees are taken. The bunch of roots is cut into a number of pieces, each piece containing about 1 eye, and from each one of these pieces a new tree starts. The usual time for setting out new plants is the beginning of the wet season. The first crop is always the best. The bananas are larger, and there are more on a bunch. They usually average about 250 per bunch, and yield about 175 bunches per acre.

The second crop is a little poorer in quality, and so each time the trees are cut off the fruit becomes smaller and yields fewer to the bunch, until, in 4 or 5 years, the land runs out. There is no particular season for the fruit, it being as plenteous at one time as at another. Bananas should be cut from 24 to 48 hours before shipping, as they will not keep if cut earlier.

CHERRY.—Cherries will thrive in almost any soil, but prefer a light loam in a free exposure. The soil should not be too rich, as it will then become thrifty in wood, without corresponding fruitfulness. The cherry tree is propagated by seeds and suckers, when stems are wanted; by seeds alone when new varieties are wanted; by scions, when working on old subjects; and by buds, when the trees are young. Keep the ground mellow, spading up for 3 or 4 ft. from the body of the tree. Be careful in digging and grubbing about the trees that no injury is done to the roots or bark, as the least bruise will cause damage that the tree will never outgrow. In the Southern States the stem of the tree should be protected from the direct rays of the sun on the southwest side in winter, by wrapping with sacks or straw, or shielded by two boards nailed at right angles, and set up to shade the stem. Varieties: *Belle De Choisey.* Medium; pale amber, mottled with red; very tender, juicy, melting, sweet and rich; last of June. — *Belle D'Orleans.* Medium size; pale red and white; very juicy, tender and delicious; middle of June. — *Bigarreau* (*Yellow Spanish*). Size large to very large, heart-shaped and flattened; color pale yellow, or straw, slightly dotted; flesh yellowish tinge, firm, juicy, and sweet; last of June; a superior sort. — *Black Eagle.* Large, black; tender, juicy and high flavored; vigorous grower and productive; 1st to 15th of July. — *Black Heart.* Fruit large, heart-shaped; color dark purple to deep black; flesh tender, juicy, sweet and well flavored; last of June. — *Black Tartarian.* Very large, purplish black; half tender, juicy, rich and delicious; vigorous grower and very productive; tree very tender; last of June into July. — *Carnation.* Large; light red, mottled with orange; finer than most of this class; tender, juicy and excellent; from middle to last of July. — *Downer's Late.* Fruit large size, oval; skin smooth, light red; flesh firm, juicy, sweet and delicious; early part of July, lasting a considerable time; certain and productive bearer. — *Early Purple Guigne.* Rather small; purple, tender, juicy and sweet; growth spreading; middle of June.—*Early Richmond.* Fruit medium; red, melting, juicy and acid. The great thing in its favor is its freedom from worms; June. — *Elton.* Large; pale yellow in the shade, nearly covered next the sun with light red; half tender, juicy, rich and sweet; growth vigorous; last of June. — *Governor Wood.* Large; light yellow with a red cheek; tender, sweet, juicy and delicious; one of the best; last of June. — *May Duke.* One of the choicest and most thrifty sorts, and very extensively cultivated; fruit roundish, growing in clusters; color red; flesh soft and juicy, rich, and of fine flavor; June. —*Napoleon Bigarreau.* Very large; pale yellow and deep red; very firm with a fine flavor, juicy and sweet; vigorous grower, and very productive; a favorite; beginning of July. — *Reine Hortense.* Very large; bright red; tender and juicy, nearly sweet; vigorous and productive; middle of July.

Black Heart.

Downer's Late.

DATE PALM.—The palm of the deserts; but may be grown at the far southwest in the U. S. Where the atmosphere is humid or the rainfall considerable, there the date palm will not ripen its fruit. Abundant moisture at the roots, great heat, at least, during the summer, much sunshine and little rainfall, are the most essential conditions. Neither the fiercest heat of the sun, nor the strongest winds injure it. The wind may bend the crown to the earth, or even uproot the tree, but is incapable of breaking its trunk, and it will bear without injury 10° or 12° of frost, as well as very low night temperatures succeeding very high day temperatures. The nature of the soil is of little importance, provided always there is plenty of water, which may be either fresh or brackish. Propagation is usually effected by means of suckers, as they not only perpetuate the variety pure, but come into bearing much younger, and the cultivator runs no risk of overproduction of the male plants. In 5 years they produce fruit, though they do not come into full bearing until they are about 30 years old. After they attain 80 or 90 years the crop begins to diminish, yet they sometimes continue bearing until they are 200 years old. The trunk is of very slow growth, and eventually reaches a height of 70 or 80 ft. An old tree that produces fruit of a superior quality is sometimes rejuvenated by banking up the trunk with mud to the depth of 2 yards. In about a year's time it is rooted in the mud; it is then cut off above the old roots and transplanted.

FIGS.—Almost any well drained soil will suit fig trees, provided that, with its porosity, it also possesses that kind of mechanical texture which, whilst it readily transmits moisture, will also retain sufficient to withstand a hot and dry period in the middle of summer. The trees may be propagated by seeds, layers, cuttings and suckers. The seeds do not uniformly produce the same sorts, and are to be employed only for obtaining new varieties. In setting out plants, give them room according to their size. In the South, spring cuttings of last year's growth are taken off and set in February; and summer or green cuttings in August. In the North, hard wood cuttings are taken off late in autumn and kept moist in a cellar till spring, and then set out. Two crops of fruit are produced from the fig tree, each crop being produced on distinct

sets of shoots. The second crop grows from the eyes or buds of the shoots made in early summer, and, if the season be sufficiently warm and long, the fruit will ripen. The second crop is the most prolific and valuable, and is used in drying for exportation. In climates where the winters are severe the trees are so trained that the branches can be tied in bundles and laid along the ground, when they are covered with litter and earth. More commonly they are kept in tubs and boxes. As far south as Virginia the trees are covered with inverted boxes or large barrels, or protected with a mass of evergreen branches. When the small end of the fruit becomes of the same color as the large one, the figs are ripe and ready to gather. All shoots that are not short jointed or compact should be stopped at the end of August or beginning of September, by merely pinching off or squeezing flat the terminal growing point. This will induce the fruit for the ensuing year to commence forming. A too early stopping with some figs would cause them to develop the fruit for the ensuing year too early, and the period of doing this must be determined by the kind and its condition or habit. Figs most suitable for a garden are the *Black Ischia*, *Brown Ischia*, *Early White Murray* and *White Genoa*.

FILBERT.—Filberts are similar to hazel-nuts, but are distinguished from them by their larger size and lengthened form. They require a deep, light, but naturally fertile soil, without putrescent manures. They are propagated most easily from suckers, but bear from seeds, and should be well pruned. They bear in the 4th and 5th year, and are in season during the months of September and October. Varieties: *Barcelona*, *English*, *Frizzled*, *Large Cob*, *Red* and *White*.

Lemon.

LEMON.—A small tree, with ovate-oblong leaves, pale green with a winged stalk; flowers red externally; fruit pale yellow, with a juicy and very acid pulp. Generally raised from seed in Eastern countries. In the Southern States and California it is raised with great success. It is not so hardy as the orange and is improved by being worked upon the bitter orange stock. Varieties: *Gaeta*, *Imperial* and *Wax*.

LIME.—The lime is related to the lemon, has obovate leaves on a wingless stalk, small white flowers, and roundish, pale yellow fruit, with a nipple-like termination. The leaves and general habit of the plant resemble those of the lemon; but the acid of the pulp of the fruit, instead of being sharp and powerful, is flat and slightly bitter. The seeds are generally planted 15 ft. apart early in spring. The trees require regular pruning, and to be freed from the mistletoe, dodder, and other mischievous parasites; so that their cultivation during the years that elapse before they come into bearing involves a considerable outlay.

Lime.

MULBERRY.—Prefers a moist, deep, loamy soil, and a somewhat free exposure to the south. The soil should not be cold, or wet, and should be well drained. It may be trained against a wall, but this requires much space. It may be propagated by seed, sown in a warm border, but this mode is rarely pursued; by layers; by cuttings, having $\frac{3}{4}$ of their length old wood, and $\frac{1}{4}$ yearling; or by lopping off a straight branch, 8 ft. long, from a large tree—the nearer the trunk the better. Make it clear of every little stem, then dig a hole 4 ft. deep; plant the naked branch firmly in the ground, leaving around it a cavity to hold water, when the season is dry. In 2 years it will bear fruit. The black mulberry requires no pruning, and needs very little care. Varieties: *Black*. A native of Persia, but thrives in a northern climate. It is late in putting forth its leaves, but the fruit forms very quickly. The berry is large, long, black and of a rich aromatic taste. It is used in making wine or cider mixed with apples. — *Downing's Everlasting*. An American variety of great excellence. Color black; sprightly.— *Johnson*. Large, oblong fruit of a mild and pleasant flavor. — *Red*. A native of N. A., and grows wild. The fruit is of a deep red color, but is not as pleasant as the black. — *Russian*. Fruit large, about the size of Kittatinny blackberries, mostly jet black, about 1 tree in 20 producing flesh colored berries; sub-acid to sweet, with a fine, aromatic flavor; immensely productive; perfectly hardy. The original trees were imported from Western Russia. Fence posts made from the timber of this tree lasts as long as red cedar or catalpa. — *White*. A tree on which the silk worm lives. It is grown in China, Europe and N. A., but can not stand frost.

Mulberry.

NECTARINE.—The nectarine is a variety of the peach, but has a smooth, shining surface and is more highly flavored. It is propagated and grown the same as the peach. Varieties: *Boston*. Fruit very handsome, of medium size, and heart-shaped; color bright yellow and red; flesh firm, sweet, pleasant; one of the best varieties for general cultivation; 1st of September. — *Early Newington*. Large; pale green, red in the sun; juicy and rich, with a fine flavor; 1st of September. — *Early Violet*. Medium size; green, and purplish red; flesh pale yellow, and pinkish; soft, rich, sweet, agreeable flavor; good bearer; very superior; last of August. — *Elruge*. Medium; pale yellow, with a dark red cheek; juicy and high flavored; much esteemed; 1st of September. — *Red Roman*. One of

the most hardy; large; handsome, red clingstone; color dark next the sun, the shaded side yellow; flesh juicy, sweet, and vinous; August and September; a good bearer. — *Stanwick.* Resembles in size and shape the Elruge; pale, with a violet tinge next the sun; exceedingly tender, juicy, rich and sugary; in form and appearance surpasses all others; 1st of September.

OLIVE.—The olive grows on a branchy, low, evergreen tree. It has lanceolate or lance-oblong leaves, which are pale green above and rather whitish beneath. The fruit is used for various purposes, but principally as a pickle and for oil. It varies in size from an acorn to a large plum. It requires a warm climate and a dry soil, and is generally propagated by suckers; but when great care is bestowed on it, inarching is practiced. It grows from cuttings. The crop matures at the same time as cotton.

Olives.

ORANGE. — The orange thrives only in a warm climate, though it is quite generally raised in hot-houses in cold latitudes. It rarely grows to any considerable height; has deep green leaves, and, when fruited, makes a fine appearance. May be raised by seed or cuttings. The seeds are planted in early spring or in hot-beds in January. When 1 year old, they are transplanted in a nursery arrangement. At the age of $2\frac{1}{2}$ years they are budded; i. e., the seedlings are of the sour variety, and to produce sweet oranges fully matured buds are taken from bearing trees and inserted. This is done to render the tree more hardy, since the sweet seedlings are subject to a root disease called heel, while the sour seedlings are not. Hence orange growers resort to this means to produce sweet oranges. The trees are transplanted at the age of four years into orchards. At the age of 6, flowers first appear, and at 10 years the trees are called full bearers. Pruning should be done in February, and should be limited to thinning out the wood where too thick, cutting out that which is old and weak. Nothing is gained by crowding the shoots. Varieties: *Bergamot, Bitter* or *Seville, Blood, China, Egg, Mandarin, Portugal* or *Lisbon,* and *Tangerine.*

Orange.

PAWPAW, Common.—Grows in the South and Southwest in rich soil; is of small but most pleasing tropical growth. The fruit is very rich. The bark makes a tie for budding equal to bast, and the poles make fine light handles for hoes.

PEACH.—Peaches thrive best on a rich, deep, sandy loam, but will grow on almost any soil. They may be propagated by seeds and by budding. To raise seedlings plant the stone in the fall, at a depth of 2 or 3 in., and in 1 or 2 years they will be of sufficient size to transplant. Seedling trees are the longest livers, and the most prolific and profitable. Good varieties are obtained by budding. Trees should be transplanted at 1 year old from the bud. By growing low to the ground and heading back well, it is not necessary to set the trees more than 12 to 15 ft. apart. After the trees have attained to a proper size cut back and prevent them bearing; this will cause the roots to spread in the soil. In shallow soils top dressing with manure in the fall, and frequent harrowing, will be found advantageous. Apply lime and ashes before the manure; fork it in and around the trees. To keep the trees from blooming early spread manure, coal ashes or sawdust deeply upon the roots when the ground is hardest frozen, and do not remove until late in the spring. If a tree ceases bearing, dig around the base of the stem a hole 4 or 5 in. deep, scraping away all the worms that can be found burrowing at the junction of the stem and root, and fill the hole thus made with wood ashes from the fire, which retain all their potash; as the defective power of growth is believed to be owing to a deficiency of potash. If this be supplied so that it shall reach the small roots and be absorbed, the fruit bearing power will be restored. In order to harden or ripen the shoots of young and rapidly growing trees, the cultivation of the soil should cease in August. Otherwise they would be likely to keep on growing till frost, and would be left in a green and succulent condition, unfitted to withstand the cold of winter. But bearing trees should be cultivated till the fruit is about to ripen, as the crop continues to consume the strength of the tree after the cessation of the growth of the shoots. Pruning is the life of peach culture. By cutting in the excessive growth at the extremities, the tree is made stronger, and the fruit of better size and flavor. Peach trees on prairies should be permitted to branch near the ground, say from 18 to 30 in., and never more than 3 ft. above it, and should be caused to grow in as compact form as possible. Endeavor to keep the lower branches trimmed and trained at an angle of about 30 or 35°; keep the top rounded up to a flat, conical shape, observing as much as can be, without marring the shape of the tree, to cut back most on the north side in order to balance against

the effect of the south wind that blows so much during the growing season. The centre of the tree should be well pruned so as to admit a free circulation of the air. Thinning out the fruit not only largely increases the size of the fruit, but entirely transforms its character, making it rich, juicy and melting. The thinning should be done before the stone is formed, when the fruit is about the size of cherries, leaving the peaches 5 or 6 in. apart on the limbs. Early varieties as a rule require the most thinning. A few kinds do not need thinning, the late Crawford for instance, which thins itself sufficiently. Varieties: *Alberge.* Size medium; yellow skin, with dark red cheek; flesh yellow, tinged with red, melting, rich, sweet and vinous flavor; deeply indented by a seam running from the stem to the blossom end; last of August. — *Bergen's Yellow.* Large size, round, slightly depressed; freestone; color red and orange, dotted; flesh yellow, tender, rich and luscious; good bearer; first of October; valuable sort. — *Blood Cling.* Most valuable for canning. Is a good bearer, hardy, and the fruit is less liable to be preyed on by insects — *Cole's Early Red.* Medium; free-stone; red mottled; juicy, rich with a pleasant flavor; vigorous grower and good bearer; August. — *Cooledge's Favorite.* Above medium, and nearly white, with red dots, and brilliant scarlet cheek; free-stone; very melting and juicy, with a rich flavor; middle of August. — *Crawford's Late.* Fruit large, round, and handsome; yellow in the shade, deep red towards the sun; freestone; flesh yellow, reddish near the stone, juicy, tender, rich, finely flavored; last of September or first of October. — *Crawford's Early.* Large, round; freestone; yellow in color; juicy and vinous; ripens middle of August; very popular everywhere. — *Early Beatrice.* Very early, ripening about the 10th of July; free-stone; fruit medium size, with a marble red cheek; melting and very juicy. — *Early Louise.* Medium; free-stone; bright red; melting, juicy, and fine; ripens a few days after Early Beatrice. — *Early Tillotson.* Medium size, round; color yellowish white, red, with dots; free-stone; flesh white, red near the stone, juicy, melting, excellent flavor. — *Early York.* One of the earliest and most generally cultivated; free-stone; medium, roundish, slightly oval; skin thin, somewhat dotted; color red; flesh greenish white, tender, rich, lively flavor; middle or last of August. — *George IV.* Large; nearly white, with a red cheek; free-stone; melting, juicy, rich and excellent; crops moderate, one cause of its excellence; last of August. — *Grosse Mignonne,* or *Royal Kensington.* Large; free-stone; white, with a pale, red cheek; juicy, with a very rich, high vinous flavor; good grower and bearer; latter part of August. — *Hale's Early.* Medium size; free-stone; white flesh, juicy, rich and delicious; very early; fine orchard variety. —*Heath.* Large, oblong, terminating in a point at the head; cling; rich cream-colored white, sometimes faintly blushed; flesh rich, tender, juicy and melting; hardy; September to November. — *Jacques Rareripe.* Very large; deep yellow, shaded with red; free-stone; has a high reputation; last of August. — *Large Early York.* Large; nearly white, with a deep red cheek; free-stone; fine grained, very juicy, mild and rich; vigorous and productive. — *Lemon Cling.* Large, lemon shaped; yellow cling, with a brownish cheek; rich, vinous and sub-acid. — *Morris White.* Medium; free-stone; creamy white, tinged red; flesh white, juicy, and delicious; middle of September. — *Noblesse.* Large and handsome clingstone; skin white with a pale blush and dark brownish spots; flesh rich and highly flavored; September. — *Old Mixon Freestone.* A beautiful, large, flat peach, with a white skin and red cheek; flesh rich, juicy and luscious; latter part of September. — *Red Cheek Melocoton.* A large yellow clearstone, with a red cheek; flesh rich and juicy; September—sometimes earlier. — *Red Rareripe.* An excellent fruit, frequently called Morris' Red Rareripe; size quite large, round; color red and white; flesh tender, rich, melting and highly flavored; August. — *Smock Free.* Large; light orange yellow, with red cheek; flesh yellow, red at stone, juicy, rich; September to October. — *Stump-the-World.* Very large; creamy white, with a bright red cheek; freestone; flesh white, juicy and high flavored; last of September. — *Troth's Early.* Little above medium; free-stone; red; flesh white, juicy, sweet and rich; one of the best early peaches; middle of August. *Yellow Rareripe.* Size large, globular; free-stone; color yellow and purplish red; flesh yellow, red near the stone; tender, juicy, vinous flavor; September. — *Waterloo.* Medium to large; whitish green marbled with purple; juicy and vinous; the best flavored of the earliest peaches; August.

PEAR.—The pear will exist in a variety of soils, but clay loam is best adapted to it. If dry, the ground should be rolling; if wet, underdrained and subsoiled. Soils of a sandy or gravelly character are not well adapted to the pear. Seedling stocks are the best to graft or bud. To plant seedlings, the soil should be deep, fertile, moist, and well manured with lime and ashes, and supplied with peat or muck, if not in the soil. Sow the seed by drills, in lines 2 ft. apart. Seedlings taken up in the fall may be kept safely all winter by burying them in a cellar. Or, without taking them up, cover the ground several inches deep with forest leaves. Budding is preferable to grafting, as it can be repeated in case of failure. In 2 years after grafting or budding, the plants may be removed to the places where it is intended they shall stand. Set the plants so that the point from whence the stem and roots proceed in opposite directions will be about 1 in. below the level of the surface of the ground. Dwarfs should be set 12 ft. apart, and standards 25. Animal manure, wood ashes, and farm compost are the best fertilizers, and these should be applied in fall. When thinning pears, they should be left till somewhat grown; as they often fall after they are pretty well advanced. Pears of all varieties are best when ripened off the tree. Some varieties, such as Clapp's Favorite, are worthless, if allowed to remain too long upon the tree, but if picked as soon as mature, and allowed to ripen, are among the best. Late pears, which do not rip-

en until winter, should remain on the trees until hard frosts begin. Varieties: *Bartlett.* A general favorite; fruit large, pyramidal; color yellowish at maturity; skin thin and smooth; flesh white, delicate, buttery, sweet, juicy, highly flavored; hardy and productive; September. — *Beurre Bosc.* An esteemed late sort, high flavored, and much in demand as a market pear; fruit large and long; color light cinnamon russet; flesh white, rich and tender; September and October. — *Beurre Clairgeau.* Very large; clear cinnamon russet, with reddish tint on sunny side; melting, juicy, sprightly, perfumed and excellent; very handsome; tender; October. — *Beurre d'Anjou.* Large, greenish yellow; buttery and melting, with a high, rich flavor; tree very hardy; fruit ripens in November and December. — *Beurre Diel.* Large size; dull yellow and much dotted; sugary, rich and juicy; November and December. — *Beurre Gifford.* Medium; pyriform; fine yellow, with red cheek; buttery, juicy, sweet, high flavored and delicious; a poor grower in the nursery, but one of the best early pears; August. — *Bloodgood.* Large size; form oval; color dull yellow, with darkish spots; flesh soft, melting, agreeable flavor; early and prolific; August. — *Brockworth Park.* Large; pale yellow, flushed, streaked with red on the sunny side; flesh white, buttery, melting; very juicy, vinous and rich; September. — *Clapp's Favorite.* Large and handsome; resembles the Bartlett in all its qualities, except the musky flavor peculiar to that variety; September. — *Dana's Hovey.* Medium size; skin a yellowish russet; flesh yellowish white, juicy, tender, honeyed sweetness, high flavored; productive and hardy; November to December. — *Dearborn's Seedling.* A valuable early sort; small, symmetrical; color light yellow, with a few dots; flesh white, tender, sweet and sprightly flavor; productive; early, ripening from the middle to the last of August. — *Doyenne d'Ete.* Small; clear yellow, with a bright red cheek; juicy, sweet and melting; bears well even when young; August. — *Duchess d'Angouleme.* Large, greenish yellow; sometimes a little russeted; does best grafted on quince; fine market fruit; October and November. — *Flemish Beauty.* Fine large fruit; color, dull yellow and brownish; flesh yellowish tinge, sweet, tender, juicy, sugary, musky flavor; October. — *Howell.* Large and handsome, color yellowish green with a dull red cheek; melting, juicy, with a delicate, perfumed flavor; October and November. — *Keiffer.* Fruit large and very uniform in size; color rich yellow; October and November. — *Lawrence.* A large, rich flavored, melting pear; color golden yellow; pleasant, aromatic flavor; stands among the best early winter varieties; November to February. — *Louise Bonne de Jersey.* Large; yellowish green, with a red cheek; very juicy, buttery, melting and rich; very productive; September and October. — *Seckel.* The richest and highest flavored pear known; small, yellowish brown, with deep brown cheek; sweet, very juicy, buttery, melting; September and October. — *Sheldon.* Large; russet and red; melting, rich, delicious, with a high musky flavor; October. — *Tyson.* A medium-sized fruit; color light straw, with brownish blotches; flesh lightish-white, rich, sweet, fragrant; September. — *Vicar of Winkfield.* A large and long pear, of good quality and great productiveness; does best grafted on quince; tree very hardy; November to January. — *Winter Nelis.* A fine winter variety; size rather above medium; roundish-obovate; color pale straw, slightly brown; flesh white, soft, sugury, rich, musky flavored; November to January.

PERSIMMON.—The persimmon requires but little cultivation. Prune when the branches get too thick. Varieties: *American.* A tree 2 to 3 ft. in height. — *Black Persimmon.* A shrub or middle sized tree. — *Japanese.* An extremely interesting and beautiful fruit; as large as tomatoes, of various forms and colors. Has been fruited in several parts of New Jersey, and in southern New York, but not entirely hardy north of the latitude of Washington, D. C. There are a few seedless varieties that promise to be of great value, not only as dessert fruit, but to dry as dates. The ripe fruit made into a preserve is a specific in summer complaint; the bark and green fruit are employed as astringents, and the wood is used for inlaying.

PINE-APPLE.—Grows in the tropical climates; the best soil is a rich and rather sandy loam, which is often formed from the turf of old pastures, in which dung, peat, and sand are thoroughly mixed. The pine-apple has a number of long, sharp-pointed, rigid leaves, growing from the root, in the midst of which rises a short flower-stem, bearing a single spike of flowers, and later a single fruit. From the top of this fruit springs a crown or tuft of small leaves, capable of becoming a new plant, which is generally used for planting; pine-apples are propagated entirely by crowns and suckers, as in a state of high cultivation, perfect seed is almost never produced. The universal practice, till a late date, was to grow the plants in pots plunged to the required depth in tanner's bark or other fermenting matter, and these were transferred from one department to another according to the stage of advancement, 3 years' culture being considered necessary for the production of ripe fruit. But is now often planted in beds, and fruit of the finest quality is sometimes obtained in 15 months. In the cultivation of the pine-apple great care is necessary, as without it, it is fibrous and coarse, with little sweetness or flavor; but with it is one of most delicate and richly flavored of fruits. The size also depends very much on cultivation, and varies from 2½ to 12 lbs. in weight. Ventilation must be given from time to time, care being taken to keep the atmosphere moist. Apple-pine which has borne fruit is cast away as useless.

PLANTAIN.—(See *Banana*).

PLUM.—The best soil for the plum is a rich loam, though a good, sound mellow loam will suit the majority. Like other stone fruit it is mostly propagated by budding, the stocks being the free growing plum or the peach, raised from seed, or, more commouly, from layers or suckers. Trees should be planted 20 ft. apart. They require but little care save to prevent the ravages of the curculio. All the varieties produce their blos-

soms on small spurs, which are protruded along the sides of the shoots of 1, 2 or 3 years' growth, generally in the course of the 2d or 3d year. These spurs, if duly thinned, and, when necessary, cut in, will continue bearing for 5 or 6 years, or longer. Among all the fruits there is none that require thinning more than the plum. The fruit should be thinned so that each plum shall hang by itself; to do this, oftentimes five plums must be cut off where one is left. Varieties: *Bleecker's Gage.* Medium size, nearly round, very regular; color dark yellow, with deep red spots; flesh yellow, sweet, finely flavored; ripens in September. The tree is hardy, productive, and the fruit much esteemed in some parts. — *Bradshaw.* Very large; dark violet red; juicy and pleasant; tree very vigorous and productive; middle of August. — *Coe's Golden Drop.* Thrifty growth; good bearer; fruit large and handsome, oblong; color greenish yellow, with violet and crimson dots; flesh orange color, rich, juicy, fine flavored; September. — *Chickasaw.* Red; of pleasant, sub-acid flavor; early; quite ornamental; native. — *Damson.* A favorite much used in cookery. The tree grows to a great height, and has a very full, bushy appearance; yields a great quantity of fruit, which varies in color, some of the plums being dark purple, others yellow, blue and black. — *Duane's Purple.* Large, oval or oblong, bulging on one side; color reddish-purple toward the sun, palish-red in the shade, with a few yellow specks and a lilac bloom; flesh light brown, juicy, lively, slightly acid; middle of August. — *General Hand.* One of the largest of the native varieties; pale yellow; juicy, sweet and good; a sure bearer and of high reputation; beginning of September. — *German Prune.* Large oval; dark purple; juicy, rich, sweet and good; very productive; September. — *Green Gage.* Of this there are several varieties. The size in good soils is large; form round; skin green; flesh green, melting, juicy, and exquisitely flavored; August and September. — *Huling's Superb.* Very large; yellowish green; firm, rich, brisk and excellent; good grower and moderate bearer; tree very tender; middle to last of August. — *Imperial Gage.* Large; greenish yellow; juicy, melting and rich; fine grower and great bearer; 15th of August. — *Jefferson.* A superior dessert sort; fruit large, oval, contracting towards the stalk; color bright, deep yellow, with a purplish-red cheek, and a whitish bloom; flesh orange, quite juicy, richly flavored; middle to the last of September; a good bearer. — *Lawrence's Favorite.* Large, yellowish green, melting, juicy, rich and excellent; vigorous and productive;

Bleecker's Gage.

August. — *Lombard.* Medium, roundish oval; reddish purple; good; tree productive; end of August. — *McLaughlin.* Large size; round; color brownish-yellow, with a red tinge; flesh melting, juicy, fine flavor, though not superior; August. — *Purple Favorite.* Large size; roundish; color light brown, with a shading of purple, and bright yellow dots; flesh greenish, soft, sweet; last of August to 1st of September. — *Washington.* Large; green, somewhat reddish; juicy, sweet and fine; vigorous in growth, and very productive; liable to rot on the tree; August. — *Wild Goose.* Skin purple, with fine bloom; flesh, juicy and sweet; well adapted to peach stocks; the last of July. — *Yellow Egg.* Large size; oval, narrow at both ends; color yellow, whitish dots, and a thin white bloom; flesh somewhat coarse, yellow and slightly acid; September; better cooking than eating. — *Yellow Gage.* Medium; golden yellow, juicy and rich; middle of August.

QUINCE.—The tree will grow in any good soil; yet, like the pear, a deep, damp soil, free from stagnant water, suits it best. Quinces are best cultivated from cuttings. These should be from 12 to 15 in. in length, and, unless those of last year's growth are strong and vigorous, it is better to use the 2-year-olds. They may be as large around as the finger. The larger ones give earliest results. To gain time, and also to utilize worthless trees, budding may be done either on the worthless quince-bush or on the thorn. Plant the trees from 10 to 12 ft. apart in full or early spring. The quince needs pruning in order to make the greatest thrift in growth and fruit. In training, if the bush form is preferred, let the limbs start close to the ground; thin out but never cut off the large limbs. Water-sprouts and suckers should be cut back or off, and the bush kept in a close, compact shape. — *Angers.* Large; a little elongated; skin greenish yellow; very fragrant; fine for preserves; also used for stock to graft the pear on; season December to February. — *Apple-shaped.* Also called *Orange*; a well known favorite variety; fruit large, much resembling an apple in shape; color brilliant yellow; flesh solid, and of fine flavor; a very good bearer, and much esteemed as an excellent cooking variety, on account of the flesh becoming soft when stewed. — *Champion.* An early and abundant bearer of large size, fair fruit; quality of the very best; keeps till January. — *Chinese.* Does well in the South, and promises well in the southwest. — *Japan.* Hardy, ornamental variety, with scarlet or white blossoms in the very early spring. — *Portugal.* This variety is more juicy, less harsh, better colored and flavored, than the two preceding; fruit large, oblong; color mild yellow; not very productive; a superior variety. — *Rea's Golden.* Superb fruit, ½ larger than the *Orange Quince*; same form and color and equally as good. — *Rea's Mammoth.* A seedling of the *Orange*; superior in size and equally as good in quality.

PESTS.

DISEASES.

BLIGHT.— 1. Wash the trees with an infusion of about 1 lb. of quassin chips to 8 gal. of water. — 2. Cut the diseased limb out completely and all parts affected by the blight. — 3. Place dry salt near the trunk of the tree, a few in. below the surface. — 4. Root pruning is also performed as a preventive.

MILDEW.—Indicated by the presence of certain minute plants of the order of *fungi*, which grow upon the stem and leaves, and doubtless feed upon and exhaust the juices of the plant. The prevalence of heavy fogs or mist, drizzling rains and sudden changes of temperature, have been assigned as the cause of mildew, and it has been found that open, airy situations are much less subject to it than low sheltered lands. — *Gooseberry*. 1. Sprinkle a weak solution of saleratus, strongly tinctured with alum, over the bushes. — 2. Put 1 qt. of hard wood ashes in a vessel holding 5 gal.; pour 3 gal. of boiling water over them; stir a few moments, and fill with cold water; use as hot as the hand can bear without scalding; throw the hot liquid forcibly into the bush with a garden syringe, drenching every leaf, both upper and lower side; early in the morning while the dew is yet on, is the best time to do this; commence when the fruit is first formed and continue from time to time as signs of mildew appear. —*Grape*. If this appears on the vines, dust them thoroughly with sulphur; their presence is known by white spots. — *Peach*. Affects some varieties of white peaches. A wash of soap-suds will cure it, or lime water and suds.

ROT.—*Apple*. Apples on the trees are affected by a fungus known to botanists as *Sphæropsis malorum*. Small pale spots make their appearance on the apple and in a few days more numerous black pustules or papillæ will appear, and thickly scatter over nearly the whole surface of the fruit. When microscopically examined each one of these black papillæ is found to contain several oblong pale fungus spores, supported on a short stem or foot stalk, from which they soon separate. When this fungus rot makes its appearance remove the affected apples at once from contact with the others.— *Grape*. The cause and cure for this are still unknown. The best preventive is to inclose the bunches in bags of paper. Fumigating with sulphur in the evening will also prevent its appearance.

SUN SCALD.—When apple trees are commencing to open their leaf buds, the terminal ones frequently already opened, there is susceptibility to sun scald. The edges of the terminal leaves will turn to a dark color and the bark from green to black, on the south or southwest side first, and from hour to hour curves around the tree. The best relief is to at once severely crop off below the part affected.

YELLOWS.—Found in peaches and is caused by a minute fungus growth at the roots, gradually spreading through every part of the trees. It is peculiar to the peach and nectarine, and is so poisonous and contagious that a knife used in pruning a diseased tree will communicate the malady to a healthy tree if it is afterwards pruned with it. To cure peach trees of yellows: 1. Apply potash salts to the surface under the tree and rake it in; then mulch with old hay leaves or straw. The German crude muriate of potash will be the least expensive. Use 1 or 2 lbs. according to the size of the tree. Apply 1 lb. in the late fall and same quantity in the spring.—2. Pour boiling hot water over the limbs and body of the trees afflicted with that disease, the remedy to be applied in the spring, summer and autumn. It will not kill the bark.

INSECTS.

APPLE CHERMES.—The eggs are laid in September, on different places of the twigs of the apple tree, usually in the furrows of the knots. In the formation of the body it resembles the pear chermes, but is different in color. The eyes, instead of being red, are of a snowy white, with a black pupil; the back of the thorax is of a light-green, the abdomen is marked with yellow rings, and the membranous wings with strongly-marked snow-white veins. The snout, which contains the bristled tongue, is situated, like that of all the species of chermes, in the middle of the breast. To secure the blossoms and fruit of trees in pots, or dwarf trees, brush away the young chermes with a fine brush, when they appear, or at latest when the first changing of the skin takes place in April. It is also necessary to examine the small apple trees in spring, when the blossoms begin to appear, to ascertain if any insects are upon them, and if so, to destroy them.

APPLE-ROOT PLANT LOUSE.—Forms wart-like excrescences upon the roots of apple trees, which contain in their crevices the insects which suck their juices; is said to be destroyed by an application of boiling hot water. Mulching around the infested trees has been found to have the effect of bringing the lice to the surface of the ground, where they can be more easily reached by the hot water.

APPLE-TREE LOUSE.—Feeds on leaves and twigs of apple trees. The wingless female is pale green, with yellowish head and dark green stripes on the back. The winged ones of both sexes have black heads, green abdomens, and a row of black dots on each side. A mixture of tobacco juice and lime will kill them.

BARK LICE. — Judicious pruning of the branches, draining the land where the trees stand, manuring the soil and keeping it free from grass and weeds—all have the effect to promote vigorous growth, and are therefore useful in preventing the depredations. For killing the lice, the best things are strong lye made of wood ashes, a solution of caustic soda of potash, diluted soft soap, or a mixture of lime whitewash and kerosene oil. If the latter is employed, the proportions of the mixture should be 1 pt. of kerosene to 1 gal. of whitewash. Whatever sub-

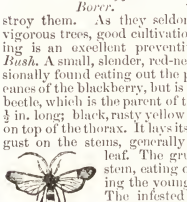
stances are chosen, they should be applied thoroughly. To insure complete destruction of the insect, a second application should be made some days after the first.

BORERS.—*Flat Head Apple Tree.* The larva of a dark green beetle, and is pale yellow in color. The egg is deposited under the loose bark of the tree, from whence the young ones bore into the tree. The presence of the young borer is usually indicated by a discolored spot, a cracking of the bark, or the presence of saw-dust like excrement. To destroy them wash the tree with strong soap suds during spring and early summer.—*Round Head Apple Tree.* Fleshy, whitish grubs, with small, brown heads, and infest the apple, quince, pear, crab apple, hawthorn, mountain ash and juneberry. Kill the grubs by thrusting a wire into their holes. August, September and October are the months to destroy them. As they seldom attack smooth, vigorous trees, good cultivation and low heading is an excellent preventive.—*Blackberry Bush.* A small, slender, red-necked beetle, occasionally found eating out the pith of the young canes of the blackberry, but is not common. The beetle, which is the parent of the borer, is about ½ in. long; black, rusty yellow on the breast and on top of the thorax. It lays its eggs early in August on the stems, generally at the base of a leaf. The grub penetrates the stem, eating out the pith, causing the young canes to wither. The infested canes should be pruned off in the fall and burned.—*Currant.* These are whitish, with brown head and legs, and bore into the stems of currant bushes. The moth is blue black, with yellow on the tips of the fore wings. All infected stems should be cut and burned.—*Gigantic Root.* Pale yellowish white, partly translucent, with bluish shadings. They are 3 in. long and bore in the roots of grape vines and fruit trees, cutting a root entirely off. Difficult to extirpate. If their presence is suspected, they must be searched for and destroyed.—*Grape Root.* Little can be done in the way of extirpating these underground borers, as their presence is only indicated by the approaching death of the vine. Still, every vineyardist should make it a rule to search for them wherever they find vines suddenly dying from any cause unknown to them, and upon finding such a borer should at once put an end to his existence. The beetle, which may frequently be found during the summer months, should also be ruthlessly sacrificed wherever met with. Do not plant a vineyard on land covered with old oak or hickory stumps, nor use oak stakes where those made of cedar can be had as conveniently.—*Peach.* This works on the tree just under the surface of the ground. Scrape away the bark and kill the worm with a probe. Wash with a thin alkaline solution, as far up as the branches, and also apply a small portion to the hollow where the lower branches unite with the stem. Prepare a sheet of brown paper by painting it with grafting wax or coal tar; clean the dirt from the tree as low as possible without interfering with the roots; then wrap the paper around the trunk about 1 ft. from the root; take 1 qt. of slacked lime, and apply to the crown of the tree, heaping a small mound of earth to the trunk. Young trees should be wrapped before they are planted.

Flat Head Apple Tree Borer.

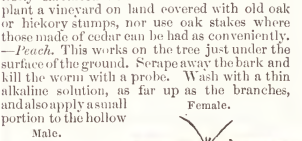
Round Head Apple Tree Borer.

Moth of Currant Borer.



Gigantic Root Borer.

Male Grape Root Borer.



Peach Tree Borer.

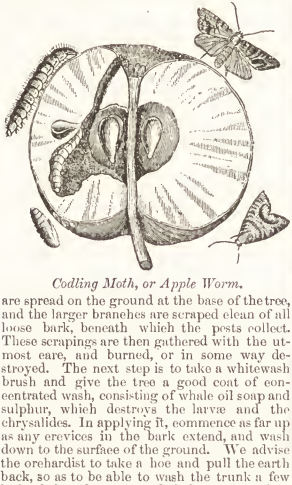
CATERPILLARS.—*Bush.* The ordinary mode of disposing of this pest is to shake the bushes and collect the caterpillars; hellebore powder and foxglove are good destroyers. The latter is made into a strong tea by boiling it in water; water or syringe the bushes with this. As a precautionary measure, open a trench 1 ft. in depth at the extremity of the roots, and then scrape or shovel the surface soil from over the roots for nearly 3 in. in depth into the trench, in the hopes of burying and destroying the chrysalis; the paring of soil should be well trampled down, and the occasion may be seized for manuring the roots in the circle or line excavated; salt and soot might be used to cover the parings before trampling them down, or other strong matters, which are at once fatal to insect life, and a manure to the bushes.—*Apple Tree.* Forms large, cob-

web-like nests in the forks of the limbs of apple and cherry trees during May. Destroy the nest and worms by pressing into the fork of the limb with a rough stick until the nest and the worms are ground to pieces.

Moth of Apple Tree Caterpillar.

CHERRY SLUG.—When quite young they are white, but afterward become olive colored and sticky, with a dark chestnut head. They feed on cherry and pear leaves. Destroy them by dusting with dry lime or fine ashes.

CODLING MOTH, or APPLE WORM.—The codling moth is, perhaps, the most destructive pest to apples known. It lays its eggs in the blossom end of the apple and pear when the fruit is small, and the small white worm eats its way to the core; then the apple falls; the worm escapes, goes through its transformations, matures, and lays eggs upon the half-ripened fruit or remains a chrysalis until spring, where it may then be found in a thin shell beneath loose bark. Provide a triangular bit of steel, some 4 in. in length and width; then grind 2 of the sides in segments of a circle, so that they will fit about the trunk of the trees. These scrapers are then fastened to wooden handles; old sacks

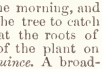


Codling Moth, or Apple Worm.

are spread on the ground at the base of the tree, and the larger branches are scraped clean of all loose bark, beneath which the pests collect. These scrapings are then gathered with the utmost care, and burned, or in some way destroyed. The next step is to take a whitewash brush and give the tree a good coat of concentrated wash, consisting of whale oil soap and sulphur, which destroys the larvæ and the chrysalides. In applying it, commence as far up as any crevices in the bark extend, and wash down to the surface of the ground. We advise the orchardist to take a hoe and pull the earth back, so as to be able to wash the trunk a few inches below the surface. Or hollow cones of tin or zinc, shaped like the body of a funnel, are placed on the stem of a tree to prevent the insects ascending. Still another way is to fasten pieces of light wood together on the flat; lay these at the base of the tree as traps; then kill the insects.

CURCULIO.—*Cranberry.* A troublesome insect found on cranberry bushes. The female deposits its eggs about the middle of May, in the buds of the cranberry. Selecting a bud not quite ready to open, and clinging to it, she works her snout deep into its centre; an egg is then deposited in the hole thus made; the beetle climbs the stem, and cuts it off near where it joins the bud, and the shoot drops to the ground. The larva feeds inside the bud, and the weevil, when mature, eats its way out. The perfect insect is also said to eat into the fruit. The only remedy that could be suggested, should the insect become troublesome, is to flood the cranberry patch, if possible, for a short time, provided it does not occur at a period when the future crop might be injured by being under water. — *Plum.* Dark brown with white yellow shining spots. The wing-cases are adorned with 2 shining black lumps; behind this is a broad band of yellow and white. It measures about 1-5 in. in length, and attacks nearly all important fruits. They begin their work in May or June. — 1. Mix 4 oz. of sulphur and 1 lb. of whale-oil soap; stir well together 4 pk. quicklime in 4 gals. water, and when it settles pour off the clear liquid, and add it to the soap solution, to which 4 gals. of tolerably strong tobacco water are also to be added. When the first mark of the curculio is seen upon the young fruit, take a syringe and drench the foliage thoroughly with the mixture, and in case rain occurs within 3 weeks to wash it off, repeat it. — 2. Jar the beetles from the tree by striking it with a heavy maul, cushioned with leather. This should be done early in the morning, and a white sheet placed beneath the tree to catch the insects. — 3. Plant tansy at the roots of plum trees, or hang branches of the plant on the limbs of the trees. — *Quince.* A broad-shouldered snout beetle, larger than the plum curculio. Ash-gray in color, mottled with ochre-yellow and whitish, with a dusky almost triangular spot at the base of the white thorax above, and 7 narrow longitudinal elevations on the wing covers, with 2 rows of dots between each. Iron plugs stuck into the trees and struck soundly with an ax or hammer, is said to be the most effective way of bringing down the curculio, and is much better than the padded mallet.

Plum Curculio.



Quince Curculio.

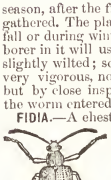
CURRANT WORM.—This is the larva of a saw fly, and is destructive to currants and gooseberries, devouring the leaves and often killing the bushes outright. They may be destroyed and damage prevented by close watching and picking off the leaves when the larvæ are newly

hatched and too young to be injurious. Sprinkling powdered white hellebore upon the leaves will kill the worms that eat it, but when this poisonous substance is used care must be taken to wash the fruit before it is eaten. The 1st brood appears in May, and the 2d about a month afterward. A 3d brood appears later in the

Currant Worm and Fly.

season, after the fruit has matured and has been gathered. The plants should be examined every fall or during winter, and every shoot that has a borer in it will usually be of a brown color, or slightly wilted; sometimes when the shoots are very vigorous, no difference can be observed, but by close inspection the small hole where the worm entered can be found.

FIDIA.—A chestnut-brown beetle, about ¼ in. long, and is densely covered with very short whitish hairs, which give it a hoary appearance. Feeds upon the grape vine. It cuts straight, elongated holes of about ⅛ in. in diameter in the leaves, and when numerous they reduce the leaves to mere shreds. They fall to the ground on the slightest disturbance and can be caught on a cloth.



Fidia.

FLEA-BEETLE.—The color varies from steel-blue to metallic-green and purple. Feeds on the grape-vine, and is found on the upper surface of the leaf. The larvæ can be destroyed by an application of dry lime.

GALL-CURCULIO.—Found on the canes of the Concord grape-vine, in the shape of an elongated knot, just below the joint. It is minutely wrinkled transversely, and covered with minute white bristles; cut off and burn these gall-bearing canes during the winter.

GRAPE CODLING.—The larva of this is distinguished by having 6 scaly legs near the head, 8 fleshy ones in the middle, and 2 at the extremity. Its presence is indicated by a reddish brown color on the side of the grape which it enters. The only way to get rid of these is to keep on the lookout for them and remove the infested parts.

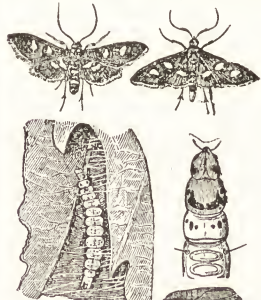
GRAPE VINE WORM. — Distinguished from all others by having a pyramidal hump near the end of its body, of a delicate green color, marked

Grape Vine Worm.

with pale yellow or cream-colored lines and spots; it is easily kept in check by hand picking.

HOPPER.—Attacks grape vines; very small; of a pale yellow color, with 2 red blood bands and 1 dusky band across the wing covers. As larvæ, or when very young, they do not possess any wings, and it is only in the adult state that the perfect wings are acquired. The leaves injured by these insects, appear at first flecked and spotted with whitish marks, showing where the sap has been drawn out by the leaf hopper. They then assume a sickly appearance, and if the insects are very numerous the foliage will finally turn brown and fall to the ground. To destroy them, syringe the vines with strong tobacco water. Dusting the vines with lime, wood ashes, lime and sulphur, is said to be beneficial, and fumigation with strong tobacco, when under glass, will destroy many of them. Light attracts these insects at night; if a lantern were placed immediately over a pail or tub nearly filled with water, on the surface of which a little oil had been poured, whenever the vines were disturbed the insects would immediately fly toward the light and fall into the vessel below and perish by hundreds.

LEAF FOLDER.—The moth of this expands almost 1 in.; length of the body ½ in.; color black, with an opalescent reflection; the under surface is less bright; all the wings are bordered with white; the front wings have 2 white spots on each; the hind ones have only one; the body



Leaf Folder.

has one transverse band and a white dash longitudinally at its extremity. The worm folds rather than rolls the leaf, by fastening 2 por-

tions together by its silken threads; the chrysalis is formed within the fold of the leaf, and by going over the vineyard in October, or any time before the leaves fall, and carefully plucking and destroying all those that are folded and crumpled, the supply for the following year will be cut off.

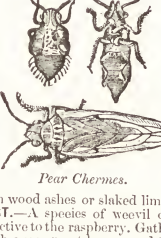
MIDGES.—Gooseberries, attacked by these, turn red prematurely and become putrid, having in them small, bright yellow maggots, of an oblong-oval form, and slightly divided into segments by fine impressed transverse lines; changing to pupæ in the berries, and in the latter part of July giving out a small, 2-winged fly, resembling a mosquito, of beeswax yellow color. The berries should be gathered as soon as they show signs of premature ripening, and destroyed.

NEW YORK WEEVIL.—Ash-gray beetle, marked with black; on each wing case are 4 whitish lines interrupted by black dots, and 3 smaller ones on the thorax. It is from 4 to 6-10 of an in. in length, and damages fruit trees. It gnaws off the tender bark before the buds have put out, and later in the year destroys the tender shoots which start out from the old wood. It cuts out the buds, and frequently gnaws off the leaves at the base of the stem, after they have expanded. It prefers the tender growth of the apple, though it will make free with that of the peach, plum, pear and cherry, and of other fruit, as well as forest trees. This insect is more active at night than day, and is often jarred down upon a sheet or curculio-catcher, for it falls about as readily as the plum curculio.

PEACH WORM, Blue Spangled.—A caterpillar which, entering the twig near the bud, eats out the interior. After the insect leaves the twig, the injured part dries up and breaks off. To destroy them cut off the shoots that appear to be withering, and burn them.

PEAR CHERMES.—Besets the young shoots and bearing wood of dwarf pear trees. It has wings, and is about the size of a large aphis; it has a broad head, terminating in front in 2 cones; but there is no opening for the mouth in the head, it being situated in the middle of the breast. The rostrum stands out perpendicularly, and ends in a point, from the latter issuing the very long delicate tongue with which it sucks its food. To clear the trees from them, brush off the young with a stiff brush, and tread upon them; or, search out and take away the winged chermes from the dwarf pear trees as soon as the blossoms appear and the shoots begin to grow. Their red color and long wings discover them, and as they are not shy, they are easily caught by the hand.

QUINCE WORM.—The principal enemy of the quince is the worm at the root. Remove the earth from around the stem of the tree each spring and fall, and probe for the grub in his hole in the bark with a stiff wire, and fill up around the tree with wood ashes or slaked lime.



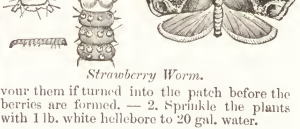
Pear Chermes.

RASPBERRY PEST.—A species of weevil or snout beetle, destructive to the raspberry. Gathering the beetle with a sweep net has proved to be the most efficacious mode of removal.

SAW-FLY.—The green gage and round plums are sometimes attacked, when hardly the size of a pea, causing them to fall off, by a saw-fly, which makes use of the pulp as food for her offspring. It resembles the house-fly, but has 4 wings; the head and body are black, and the feet reddish-yellow. To diminish the number of this insect, take the plums infested by the larva from the tree, and destroy them; these are known by a small black opening in the plum; and convey away all the plums that fall.

SPOTTED PELIDNOTA. — The largest beetle that attacks the grape vine; it subsists on the leaves, and is kept in check by hand picking.

STRAWBERRY WORM.—The larva of a black fly; of a yellowish color. They feed on strawberry leaves and blossoms. 1. Poultry will devour them if turned into the patch before the berries are formed. — 2. Sprinkle the plants with 1 lb. white hellebore to 20 gal. water.



Strawberry Worm.

FORESTRY.

COMMON TREES.

REMARKS.—The universal intelligent opinion, borne out by statistical facts, is that the timber trees of the U. S. are rapidly diminishing. This fact the public at large become convinced of only as rising prices for all kinds of lumber touch its pocket. Whenever the touch is felt with disagreeable strength, Congress and the States will be called on to regulate and encourage the cutting of trees, and forestry—the increase of timber tree culture—will become a regular industry. But it is already a profitable industry. Wild lands at cheap prices still abound, and there are few fields of agricultural effort more promising to the shrewd and far-seeing speculator. A proper study of the lumber market will show any one what timber is in de-

mand at high prices, and an investigation of the conditions of propagation and growth will point to the selection of such rapid growing sorts as will quickest reward the labor and capital expended. The planting of forests also has a most beneficent effect on the rainfall of any region, increasing or diminishing, or regulating, it to the wants of other vegetation, a result fully as important as the timber harvest itself. The general laws observed in the successful growing of field crops extend to trees and other vegetables, and are the foundation of profitable cultivation. Trees appear to have some deleterious influence upon the soil in which they grow, rendering it unsuitable during some time for the growth of the same species on the same ground, and the benefits of rotation of crops are just as evident after a timber harvest as after any other from the land.

To Measure Height of Trees: 1. Place a 10 ft. pole upright against the trunk; then go to a distance from the tree, and employ the breadth of the hand as a measure by holding it out at arm's length; the distance from the tree should be such that the breadth of the hand shall just cover the 10 ft. pole; then remove the hand successively upward, thus measuring 10 ft. at a time, the last portions being measured by the fingers and thumb 2 ft. each. — 2. For determining the height of tall forest trees, where a few rods of open level space can be had, measure them by the shadow of the sun's rays; the length of the shadow is determined, and a 3 ft. pole held upright, and its shadow also measured, then, as the length of the shadow of the pole is to its height, so is the length of the shadow of the tree to its height. — 3. There are instruments made for measuring with great precision. The following is a good and simply made one: A quarter of a circle is made of some light wood, and a small plumb-bob is suspended from what would be the centre of the circle, and a mark made just $\frac{1}{2}$ way of the curved side of the quadrant; 2 small eyes for sights attached to one of the straight edges makes the implement complete; the quadrant is held by the operator, moving backward or forward until he can see the top of the tree through both sights, the plumb-line at the same time hanging over the mark; the distance of the observer from the tree, when he can see the top of it in this manner, will be the height of the tree; allowance must be made for the height of the eye from the ground, and for any difference in the level of the ground between the tree and the observer.

AILANTUS. — Grows very fast; wood hard, heavy, glossy, and susceptible of a fine polish. It is very valuable for interior work and cabinet-making. The wood is at first of a pale straw color, but grows somewhat darker with age. Grows about as rapidly in a poor soil as in a rich one. It will even grow in blowing sand and on the sea coast. It is very easily propagated from seed; the seeds, having a broad wing, are carried to a distance by the wind, and the young plants come up in all sorts of unwelcome places. The tree is also a nuisance from its habit of springing from the root.

ASH.—Belongs to the olive family. It prefers a deep, damp soil and is best raised from the seed, which should be gathered in the fall and kept in a damp, cool place till spring; plant like corn, an inch deep; plant in rows 3 ft. apart and 2 ft. between each tree; the alternate trees will afford fine hoop-poles at the end of 10 years. There is a beautiful weeping form much admired as an ornamental tree. The *European* ash seldom grows alone. Its leaves are gathered as foliage and its timber is valued in carriage making. The wood of the *White* ash has no equal for lightness, elasticity and strength. The *Black* ash is distinguished by the great number of its leaflets and the blunt appearance of its leaves. The *Blue* ash is a large timber tree. Its bark has a bluish tinge when macerated in water.

BASS-WOOD, or AMERICAN LIME.—A highly ornamental tree and sometimes rises to more than 80 ft. in height. The wood is very white when green, but becomes of a light brown hue when seasoned. It is soft, easily worked, and is often sawed into boards, which do not warp like those which are formed of resinous trees. The wood is almost useless as fuel. In cultivation it requires a loose, rich, deep soil and will thrive where the sugar maple, white ash and hemlock spruce grow. All the varieties of this species may be propagated from seeds, by cuttings and by grafting; but, from the facility with which they can be multiplied by layers, the former mode should be rarely adopted.

BLACK WALNUT.—The trees are of large size with alternate unequally pinnate leaves. It is valuable for its timber, which is hard, of a rich deep brown and beautifully marked. It is much used for ornamental furniture, handles of tools, and gun-stocks. Put the seeds in the ground in the fall, or keep them in a damp place through the winter and sow in the spring, but where neither of these things have been done, and the sowing is desired, they will grow very well the coming season if put into cold water until they have become thoroughly soaked. Plant the seeds in rows about 1 ft. apart and from 4 to 6 in. apart in each row. As soon as they are 6 in. high, spade them up and transplant where it is desired they should grow. In digging be careful to leave the nut on the root when it is to be transplanted. They are quite difficult to transplant and it is perhaps best that the seed should be placed in the permanent position at first. The nuts of this tree are much liked by some people; the green ones are used to pickle.

CATALPA.—A fine wide-spreading tree which attains the height of 50 ft., with a diameter of 2 ft. In color, the bark is a light shining gray. It possesses a durability and power of resistance to the influence of the elements possessed by no other wood. The young trees should be set 2 ft. by 4, cut back and cultivated like corn for 3 years. The common or southern form, *Bignonioides*, is tender north of 40°. The western form, *Speciosa*, is quite hardy. The Japan variety, *Kempfers*, is a small growing, hardy, early blooming variety. The *Teases* is a hybrid of great value.

CHESTNUT.—This is a deciduous tree of con-

siderable size. The timber is coarse-grained, strong, elastic, light, very durable, handsome and easily worked. Its natural home is a barren soil. It may be sown in autumn or in spring, and if delayed till the latter season, the chestnuts must be kept from moisture and frost, which is done by placing them, after taking from the burr, in a large box, the bottom of which is covered with straw. They are then put in with alternate layers of straw and sand, till the box is full. The fruit will sprout a little during the winter, and as early as the season will allow, they are carefully taken out without breaking the radicle, and placed in baskets or upon hurdles, to be carried to the place ready for planting, which should be done with as little exposure as possible. Place 2 chestnuts in each hill, and at a time when the soil is not wet, for the chestnut gathers dampness very easily. If planted in autumn they should be covered with some 3 in. of earth. Almost every chestnut that comes up from seed grows but a few years before it begins to show signs of decay and a sprout comes up from the bottom which is better than the parent; cut off the seedlings and let these sprouts grow.

CORK.—A native of Europe; though it may succeed on the Pacific slope and in the states south of 36°, but does not stand our dry inland climate. It is a species of the oak and grows to a height of 30 ft. The wood is of a reddish brown and very tough. It does not begin to bear acorns before it is 12 or 15 years old, and the acorns are not fertile nor the yield abundant until they are 30 or 40 years old. The seeds are fertile when the cork is sufficiently good to make bottle stoppers. The trees which yield small oblong or round and bitter acorns, produce coarse cork; those bearing large and sweet acorns, fine cork. A southern exposure is the most favorable to its growth. Granitic lands and sandy silicious soils are very favorable to the rapid growth of the cork tree, which seems almost to absolutely reject those which are purely calcareous. It grows spontaneously in virgin soils, where silica or silico-argillaceous compounds are abundant. The acorns should be gathered, if perfectly ripe, in the latter part of November or the 1st of December. To protect the young plants from the cold, heat, and excess of light, mix other kinds of seeds with the acorns. About the 12th year, the alien trees may be cut down, and 2 or 3 years later the cork trees should be pruned. Repeat the pruning every 4 or 5 years. Transplanting the young trees should be done in damp or marshy places. This can be done at any time the young trees can be taken up without hurting any roots. As soon as possible after taking from the ground, cover the roots with moss or straw, if they are to be carried far. They should be planted in belts or squares, which is done by cutting out squares measuring 4 ft. each way, in the existing growth of shrubs and young trees, and planting a few acorns in the center of each square. It will not do, however, to follow this latter plan with close soils, for the water would accumulate in the centre and injure the young plants or seed.

COTTON-WOOD.—This is a species of the poplar. For characteristics see the *Poplar*.

CYPRESS.—Next to the yellow pine in importance. It is evergreen, of a conical figure, tapering upwards, with close set branches growing upright. Its lumber finds a variety of applications. It is mostly sawed into planks for exportation; much of it is used in the manufacture of doors, window sashes, and other cabinet work, and in that of shingles. For posts it is scarcely rivaled, resisting the action of water for ages. It grows in immense quantities in the low swampy grounds contiguous to large rivers in the warmer parts of the U. S. The *White Cedar* is a variety of the cypress.

ELM.—A native of the forest, but often grows spontaneously in open fields. The trunk, with a diameter of 3 ft., towers to the height of 30 to 70 ft., perfectly straight and naked, when it divides into 2 or more primary branches. These ascend, gradually spreading and dividing into other long, flexible limbs, bending in broad, graceful curves. The wood is tough and strong, but not easily wrought; used for the naves of wheels, etc. The finest kind of elm wood, that which is hardest and closest in grain and consequently takes the highest polish, is largely used for furniture. The seeds should be sown as soon as ripe; these are mature in the spring or early summer. Cover lightly; keep the ground moist and partly shaded; they favor a soil rich with potash; the seed is easily gathered and requires no skill in handling or planting. There are several species, the chief being the *Cork, English, Red, Rock, Small-leaved* and *White*.

EUCALYPTUS.—The wood is hard, durable, takes a good polish, and is rather pale in color; it is used in ship-building, carriage-making, and the manufacture of poles and railway-ties. The lower leaves are broad and heart-shaped; the upper ones turn edge-wise, long pointed and curved flatwise; leaves emit a strong aromatic odor when rubbed. The trees have the power to absorb moisture to such a remarkable degree, that if a swamp be planted with them, it will be entirely dried up and the malarial influences dissipated. The trees sometimes grow to the enormous size of 400 to 500 ft. in height, and over 80 ft. in circumference. The seeds should be started in wooden boxes large enough to hold 12 or 24 seedlings. When grown enough, carry to the place to be planted; take them out with a curved trowel, and set without disturbing the soil; press down the earth in the hole; cover the roots with fine rich soil; water as soon as planted, and from time to time, until the leaves are well started. It will not endure a temperature much below the freezing point. The blue-gums are the best known species, but the iron-bark withstands frost best.

HICKORY.—Large, beautiful trees, attaining a height of 70 to 80 ft., with pinnate leaves. The timber is very heavy, strong and tenacious, but decays speedily when exposed to heat and moisture. Great quantities are used to make hoops for casks; also for handspikes, musket stocks, shafts of carriages, handles of whips, large screws, etc. It is greatly valued as fuel. The nuts of many species are excellent eating. In planting the seed, plow the ways 4 ft. apart;

follow the marker with a roller which will not efface the mark; do this the first week in October, or maybe earlier; take a sack of nuts with the hulls on, as soon as they get ripe enough to grow; take a hoe, and at each crossing of the check-rows plant a nut about 1½ in. deep, stepping hard upon it; next spring run a harrow over the ground as soon as the frost is well out; when the trees come up cultivate them the same as corn, being careful not to bruise in any way; mulch in the fall sufficiently to keep the weeds out the next spring; if any should come, keep them pulled. To transplant with success, the tap-root must be cut off underground with a long sharp chisel, to cause it to throw out small rootlets; after they are established, the young tree may be removed. The *Pecan* is a variety of the hickory, and requires similar treatment.

HOLLY.—Grows in gravelly, stony soil. It does not need much care after planting. The family includes 3 genera, of which the Ilex is the most important. It embraces 145 species. The *Common Holly* is an evergreen tree. The *Dahoon* grows 25 ft. in height. The *Yaup-on* is a shrub. It is much used for inlaying. The *Mahonia* is the American representative of the family and a shrub of much beauty.

Holly.

HORSE CHESTNUT.—A highly ornamental tree of the largest size. The wood is white, very soft and unfit for use where much strength and durability are required. It requires a deep, free loamy soil, and is always propagated by the nut, sown in autumn or spring, and covered with from 2 to 3 in. of soil.

IRON WOOD.—Grows in the tropics and the warmer parts of the temperate zone. Wood very white, hard and strong, and much used for levers and ship building. In burning it gives out an intense heat, and charcoal made from it is nearly equal to anthracite. It is propagated by seed sown in the spring or early summer. It needs little care, but grows well when a little sheltered by other trees. There are but 2 species, *Ostrya Virginica*, found in the New World, and *Olneya Tesota*, found in the Old.

JUNIPER.—A bushy shrub with evergreen, sharp-pointed leaves; all parts of the plant, when bruised, exhale a more or less agreeable odor. The wood has a reddish color, used occasionally for veneers; also in the manufacture of wooden-ware; soft, light, easily worked, pleasant hue, and of a fine grain, admitting of high finish. Varieties differ greatly. Some require a fertile soil; some grow on hills, in valleys, on open sandy plains, or in moist or close woods. Start them in a nursery; set them in spring with the slightest possible exposure of the roots to the air; water well; in a dry climate protect them on the south side; when old enough, transplant with care. The seeds are hard to germinate and should be placed in a box and mixed with damp wood ashes during the winter before beginning to sow. There are 25 species widely distributed over the northern hemisphere. The principal ones are as follows: *Red Cedar.* Largest and most widely spread; much used for posts on account of its non-decay.—*Western.* Loose, reddish bark.—*California.* A stout shrub or small tree; rarely 30 ft. high.—*Savin.* A prostrate shrub, found in northern latitudes; spreads in dense masses over the rocks and sand. The *Irish, Swedish* and *Chinese* Junipers are beautiful ornamental shrubs that succeed well over a wide range.

LARCH.—A species of the pine and fir family. It attains the height of 60 to 100 ft., and an age of 200 yrs.; ovate-oblong cones 1 in. long and erect; grows rapidly; very resinous; does not readily rot; apt to warp; scales of cones attenuated at the top and do not fall off from the axis of the cone when fully ripe; leaves deciduous and in clusters; wood is remarkable for its durability, and may be used without seasoning when newly cut. If the soil and situation are likely to produce this tree, plant it as a pure crop; but if there is any fear of its being overtaken by disease, plant larch and Scotch fir in equal numbers, 4 ft. apart. Elevated positions are preferable to low ones; the ground should be sufficiently level for tillage. Prepare it, and mark out rows; in planting press the earth firmly over the roots; keep down all vegetation likely to interfere with the growth of the young trees; plant very early in the spring before the leaves begin to appear; if they assume a straggling form, when young, prune severely; cut off all side branches; when 10 or 12 ft. high, cut off all dead or sickly limbs; thin when necessary, at first slightly, removing only worthless or least valuable trees. There are 8 species. The most important are the *Tamarack, Western* and *European.*

LOCUST.—The wood is fine grained, yellowish, hard, and durable; the bark possesses anthelmintic properties. Keep the seed until May, then scald with boiling water, which will cause them to swell, when they will come up in a few weeks; sow in drills pretty thickly, and transplant into nursery rows when one year old, or plant at once where they are to remain. There are many species of this tree The principal varieties are the *Common Locust, Clammy, Rose, Honey, Water,* and *Red Bud.* Some varieties are upright and others have pendant or twisted and deformed branches.

MAGNOLIA.—One of the most highly ornamental trees, growing from 60 to 100 feet in height, in cool, shady places, where the soil is deep, loose and fertile, flourishing best near the great swamps found on the borders of the rivers of the South. It may be propagated by seed or layers. When propagated by layers, the shoots are put down in autumn, and require 2 yrs. to become sufficiently rooted for separation; they are then potted and kept in pits, or under glass, where the climate requires it to be protected, or set in the open air, in a shady place, if the climate is too hot, till wanted for final planting. In whatever manner this tree is treated, all the pruning it will require, after it has begun to grow freely, will be to cut out the stumps from which the flowers have dropped off.

MAPLE.—There are 12 varieties of this tree indigenous to America. The kind known as the *Greater Maple* is most serviceable in arts and manufactures, is extremely hardy in its nature, and grows to a great height. The wood is of a close fine grain, can be cut with ease, and is not liable to warp with heat or moisture. When it displays beautiful markings, with a mottled appearance arising form knots, it is technically called bird's-eye maple, form the supposed resemblance of such knots to the eyes of birds. The *Red Maple* is a rose-colored wood which is admirably suited for cabinet-work; but it is not strong, and when exposed to alternations of temperature and dryness rapidly decays. The *Sugar Maple* is cultivated for the sap, from which maple sugar is made.

MAPLE SUGAR, To Make.—Clear the woods of logs, brush, and other obstructions to the free passage of a team in collecting sap. The boiling house should be so the sap may be drawn down hill. If possible, place near a stream of water, so the vessels can be easily cleaned, etc. The boiling house should be well lighted, so that dirt of any kind may be quickly seen; the boilers should be placed in the centre, so that the attendant can readily pass on either side; have a good supply of seasoned wood, so that steam can be made rapidly, as quick evaporation is a very essential matter; have a reservoir for holding the sap, the bottom of which should be a little higher than the top of the boilers, so that the sap may run into them, with a faucet. It may be made either a square plank vat, or in the form of a broad hooped tub, and should hold at least a gallon for each tree. To prevent the wood from absorbing the sap, and thus producing sourness, the inside should be well painted. It should be covered, to exclude dirt; and for convenience the cover of a trough or vat should be in sections, opening by hinges. In large establishments it will be most convenient to have the reservoir a large tub or cistern, placed low down, so as to be easily filled, from which the sap may be pumped or ladled into a smaller feeding trough placed over the boilers. A partition of thick flannel, set vertically, should be placed near the end of the feeding trough, to strain out leaves, bits of bark, dust, etc., before the sap flows into the boiler. The worst kind of boiler is of cast iron, in the form of cauldron or kettle. The best are made of sheet iron, flat and shallow, so that the fire only reaches the bottom, as they rest at the edges for $1\frac{1}{2}$ in. on the brick or stone walls forming the fireplace. Spouts may be made of tinned sheet iron or of wood. When the former are used, hang the pail up against the tree just beneath the spout on a nail. The spouts should then be 3 in. long; let them be widest where they enter the tree and also concave; drive $\frac{1}{2}$ in. into the sap wood. Wooden spouts can be made of 1 in. board, 4 in. long and shaved large enough at one end to fit the hole in the tree; bore a hole lengthwise through them and $\frac{3}{4}$ in. into the tree. The pails may be tin or wood. If tin they should be largest at the top. The top should be stoutly wired, with a hole under the wire to hang on the nail or hook. Never allow the sap to stand in the vessels 24 hours. The fresher it is boiled the purer will be the sugar. If the sap sours in the wooden vessels at any time, they must be scalded again before using. When the sap is collected by means of horses and sled, simple open barrels or high tubs answer every purpose; if a circular board, 1 or 2 in. less in diameter than the inside of the barrel, float on the sap, it will entirely prevent it from splashing out. In districts of the country where there is much deep snow in the woods, it is sometimes easiest to collect sap in a cask placed on a hand sled, with runners 5 in. wide, made of thin boards, shaved thinner where bent. These are somewhat flexible, and on this account run over the snow with a load more easily. The collector should have snow-shoes, if necessary. Some good manufacturers use lime water to neutralize the minute portion of acid that exists in the fresh sap from the tree; 1 qt. of lime water to a barrel of sap is enough. Where brass or copper vessels are used for boiling, the lime water is indispensable in preventing a slight action on the metal, and dangerous consequences. It should be applied to the sap in the reservoir, before it is run into the boilers. The sap must now be boiled. In the morning fill 2 pans, and then build the fire. The sap in 1 pan will be boiling before that in the other; when it is, put the syphon in its place and gauge it so that it will just keep the first pan full; then start the cold sap from the holder so as to keep the other pan full also; strain it through a flannel, when reduced to 1-20, into a clean barrel; let it stand 12 to 24 hours. Draw it off carefully, through a faucet, leaving the sediment. To save all the sugar in this sediment, more sap is then applied, to dilute the syrup, which in a few hours is drawn off to be returned to the boilers. The next process is to convert the syrup to sugar. This may be done in one of the pans, but many prefer a separate brass kettle. In either case, the fire should be controlled easily, either by a damper in the flue or by hanging the kettle on a crane. When placed in the pan or kettle, to every gallon of syrup add a beaten egg and 1 gill of milk to clarify it, keeping it hot but carefully from boiling till the scum has risen and been skimmed off. If eggs cannot be readily obtained, then milk alone may be used. If it boils, the scum is broken and mixed again with the syrup. In 1 or 2 hours most of the impurities will have risen and been removed by a constant use of the skimmer, the fire having been allowed to slacken. The scum, which contains much sugar, should be saved, the sugar dissolved in sap, and the latter drawn off, as in the case of the sediment, already mentioned. Before the final heating is applied, again strain through flannel. The remainder of the boiling should be carefully but rapidly performed. The precise point of time when it will best granulate, is determined in various ways. When the bubbles rising to the surface burst with a slight or just perceptible explosion, from the tenacity of the thickening liquid; or if a drop hot from the kettle into 1 in. of water forms a distinct solid globule slightly flattened when it strikes the bottom; or if a drop between the thumb and finger will draw

out into a fine thread ¾ in. long—the process has gone far enough. It is then poured into vessels to granulate. To obtain dry sugar, place it in a tub, barrel, or hopper shaped box, with holes for draining off the molasses. To make white sugar, lay a few thicknesses of flannel on the top of the sugar while draining, these flannels to be wet and washed daily with cold water; they thus absorb and wash out the coloring matter.

OAK.—This tree grows on hillsides, along the banks of streams, on the prairies. To raise a good crop of oak trees, it is only necessary to plow the land or dig up portions of it; drop the acorns, and leave them to germinate and grow. They will come up without any pains being taken to prepare the seed, and will require no care. The acorns should be gathered about the month of October, or at the time when they begin to fall of their own accord, and carried to well-aired places where they may be spread evenly and raked 2 or 3 times a day until the dampness is off, when they may be formed into piles a foot deep and left till used. Varieties: *White Oak*, employed in ship building, and regarded as the best of all woods for fuel. The *Turkey, European, Red, Black,* or *Yellow,* are used as timber. The bark of many kinds is astringent and largely employed for tanning purposes.

PINE.—The soils in which the pine thrives are silicious, but not always to the exclusion of the calcareous, when associated with sand and clay. It grows very well in dry soil, but best in soil a little damp, covered with dry heather, where any arborescent growth other than of resinous species would refuse to live, or be of stinted growth, leaving the better soils for trees with deciduous foliage, such as the chestnut or the oak, that require a better soil, and bring an incomparably higher income. Of the 3 modes of forest sowing, in trenches, in drills, or in alternate rows, that should be selected which would best serve the end to be attained. The sowing in successive belts on terraces should be preferred for sloping grounds, and the clear spaces should be sufficiently wide to allow of complete forest growth. The belts should be narrower and the spaces wider as the slope becomes steeper. On level or slightly inclined surfaces, the whole surface may be sown upon a ground that has been worked; or, better, upon that which has been dug from 2 to 3 ft. deep, according to the soil. This may be done either broadcast or in lines spaced from 8 to 10 in. apart; the latter will facilitate the labor of weeding and dressing that will be necessary during the first year of the sowing. Upon maritime coasts and in all places exposed to violent winds, it will be necessary to set these rows in such a way as to break the wind, and not so that it shall take them lengthwise of the lines. Instead of sowing *in place*, the plants may be taken from a nursery and set where they are to grow, when they are 2 or 3 years old. As the young pines come up, they should be thinned out, leaving only those that appear strongest. The plants that are pulled up may be again set elsewhere in holes pricked in the ground, always remembering that evergreen trees should never be transplanted in winter, but before the stopping of the sap, or after its return, that is to say, in September and October, or in April and May. It is barely possible to raise the pines from seeds in the Central States south of 40°, without artificial shelter from the scorching rays of the sun. The best known species of this are the *Cluster, Maritime, Scotch, Riga, Mountain, Pitch, White* and *Yellow.* From the pitch pines are obtained turpentine, rosin and other resinous products, so important in commerce and the arts.

POPLAR. — Grows in a moderately damp soil, and is propagated by seeds, by cuttings of the young wood or roots, and from layers and layers and grafts. The seeds are ripe in the spring or early summer; when planted, cover them thinly with soil, and shade from the sun. All the species are rapid growing timber trees; broad, heart-shaped, ovate, triangular, deciduous leaves. There are about 20 species; the *American, Aspen, White, Lombardy, Large-toothed,* and the *Cottonwoods,* are the chief.

SEQUOIA.—Requires a heavy clay soil, a damp climate and moist subsoil, but prefers high lands to low; likely to be injured by severe frosts and east winds. It is only adapted to the Pacific and Southern coasts. Propagated from seed. Sow the seed in seed-beds in spring; it requires sufficient depth for its penetrating roots, and will not endure their mutilation; it also requires the greatest care in transplanting, which should never be attempted in cold weather, but toward the end of spring or beginning of autumn, and it should then be abundantly watered. There are but 2 species of this genus, the *Giant Tree* of California and the *Red Wood.* They grow to the height of 250 to 300 feet, and have a circumference of 40 to 64 ft.; bark reddish brown, 2 ft. thick; wood soft, strong and durable.

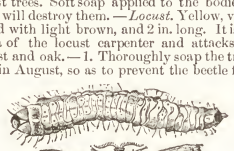
SPRUCE.—Requires a dry soil and southern exposure. Started from seed in the nursery and transplanted, it does not need any more care, with the exception of thinning the trees now and then, to allow the immature to grow to their full size. There are about 12 species of this genus. They have pendulous cones, with the bracts shorter than the scales. The *White* and the *Black* Spruce are the most important species; the wood of both is white, strong and elastic, but coarse-grained; much prized for flooring, building timber, yard arms, and small masts in vessels. *Engelmann's Spruce* much resembles the black; a tall, pyramidal tree, with a thin, scaly bark of a reddish or purplish brown color and a white, soft wood. *Blue Rocky Mountain* is another chief variety, grown to a large size.

TULIP.—An ornamental tree, attaining the height of 60 to 80 ft., with a diameter varying from 18 in. to 3 ft. The wood is fine grained, easily wrought, and polishes well; when employed in wide boards and exposed to the weather, it is liable to shrink and warp. The tree requires a deep, loamy, and extremely fertile soil, such as is found in the rich bottoms, lying along the rivers and on the borders of great swamps. It is seldom propagated except by seed. If the seeds are sown in autumn, they generally come up in spring; but sown in the spring they generally remain in the ground 1 yr.

WILLOW.—In regard to location, the best is that having a deep soil near a stream, where it will be generally soft and humid. The ground should be thoroughly broken up by a plow in February, if the season permits, and then planted at distances of 3 or 4 ft., with cuttings 15 or 16 in. long, and as large around as a finger. These cuttings are put in with the aid of a planting tool, and pressed down $\frac{2}{3}$ of their length. The cuttings of the first year yield sprouts of little value for use; but they should nevertheless be carefully cut, for if neglected they will be good for nothing the next year, except for brush-fires, because they will be too branching for any other use. When, on the other hand, care is taken to cut them down to the level of the roots, the shoots of the second year will be several in number, 4 to 6 ft. high and fit for use. Willows should be cut in February, or at least in March. The finest shoots are often 8 to 10 ft. long. They are cut with a strong cutting hook at a little above the root, which thus becomes a kind of pollard. The rods are used for common work with the peel on, but for fine ware are peeled by hand or machine. It is of utmost importance in peeling that no portion of the wood of the rod is scraped with the peeling tool, as it breaks there in working up and is unsalable. All the varieties are used as fuel, and in the manufacture of willow ware, hoops, poles, sheep-fences, etc. For wagons and wheelbarrows they are much esteemed, as they will not fracture, but will stand the hardest bumps. The *Bedford* is of a rapid growth; wood equal to the white. — *Redwood.* Light, tough and durable wood. — *Round-leaved* or *Goat.* Grows to a large size, with a tough, elastic wood; the bark is used for tanning leather. — *Russell.* Rapid growth; wood much used for poles, basket-making, etc.; the bark also abounds in tannin, and is medically an astringent and a tonic.

PESTS.

BORERS.—*Carpenter Moth.* A large, livid, reddish caterpiller, nearly 3 in. long; greenish beneath, and the head shining black; body somewhat flattened, and with scattered long fine hairs. Bores large holes and galleries in the trunks of locust trees. Soft soap applied to the bodies of trees will destroy them. —*Locust.* Yellow, variegated with light brown, and 2 in. long. It is the larva of the locust carpenter and attacks the locust and oak. — 1. Thoroughly soap the trunk late in August, so as to prevent the beetle from



Locust Borer.

laying its eggs early in September. — 2. Whitewashing and covering the trunks of the trees with grafting composition will prevent the female from depositing her eggs upon isolated trees. Young trees may be headed down to the ground, so as to destroy the grubs boring in them, and also to promote a more vigorous growth. An excellent preventive remedy is to collect these beetles early in September when engaged in eating the flowers of the golden rod. — *Pine.* These attack only dead or decaying trees, into which they bore deep oval tunnels that destroy their value as lumber. The eggs are laid in the rough crevices of the bark. In a few days the larvæ hatch out, and begin to cut their way into the heart of the tree or log. In a few weeks the larvæ are full grown, and assume the pupa form at the closed end of the tunnel, which is near the bark. The beetles soon emerge and cut their way out. Trees kept green and vigorous are safe from attack. Trees burned or cut in August are safe from injury during the same season, but should be sawed or got into water the next spring. Trees cut or killed before August will need attention the same season, and if killed in June are liable to serious damage. Trees can be saved either by peeling off the bark or by immersion in water. Cutting the bark from off the top of the logs only will be effectual, as it causes the bark to peel off. Dampness will not destroy the borers, but if exposed to the hot rays of the sun they die at once. Peeling off the bark not only secures against the attack of the borer, but helps to insure against fire, in case a little pains is taken to remove the bark a short distance from the logs.

ELM-LEAF BEETLE. — A pale, yellowish beetle, more than $\frac{1}{2}$ in. long, with the wing-covers twice spotted with blue; laying its yellow eggs in a cluster on the under side of the leaf in June, the grub appearing a week later, being brown, or yellowish brown, and eating the leaves into rags; towards the end of July or early in August entering the ground, forming an oval cavity a few inches below the surface; assuming the pupa state a week before they appear as beetles in June. Encase the base of each tree in a low, open box, about 1 ft. or 18 in. in height, placed at the same distance from the main trunk, having its lower part sunk 4 or 5 in. below the surface of the soil, the top capped with strips of bright tin, sloping inwards and projecting on both sides like the eaves of a house; paint the upper half of the inside boards every morning with coal tar or some other viscid substance; the larvæ will not be able to crawl over it, and the helpless and motionless pupæ will be found collected in heaps within the inclosure, and can be killed by thousands.

Elm-Leaf Beetle.

OAK PRUNER.—A long-horned, brownish

beetle, which cuts off the branches of the oak, apple, peach, hickory and chestnut. Does not make the incision from the outside of the branch, like the twig-girdler, but the larva cuts the twig from the inside. The egg is deposited in July, on a twig near the extremity of a branch. The larva when hatched penetrates into the wood, and forms a cylindrical burrow several inches in length in the interior of the branch, and, when full grown, eats away parts of the wood of the branch in which it resides, from the inside, leaving only the bark untouched, so that these branches are broken off in autumn by the first strong wind. Destroy it by gathering up all fallen branches under the trees in winter or spring and burning them.

SAW-FLY.—From midsummer until October, and sometimes as late as November, clustering on the twigs and smaller branches of the white pine,

Saw-Fly.

these are soft, smooth-bodied, yellowish-white worms about 1 in. long, with 3, and posteriorly 4, longitudinal rows of large black dorsal spots; late in the autumn transforming in tough brown pod-like cocoons attached to the twigs, within which they hybernate, changing to pupæ about the middle of May, the 4-winged fly with broad pectinated antennæ appearing about the 1st of June. Destroy the slugs by showering with a solution of carbolic acid, petroleum or soap.

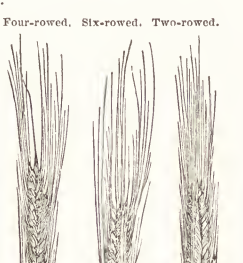
SKIPPER BUTTERFLY.—The larva is a large pale green caterpillar about 2 in. long, with a red neck and a large red head, with a large yellow spot on each side of the mouth, feeding by night on the locust, sometimes pupating between the leaves, and transforming into a stout-bodied, brown butterfly with a skipping, rapid, strong, low flight, and antennæ flattened and bent over at the end; the butterfly is brown; the fore wings are brown with a transverse semi-transparent band across the middle, and a few spots towards the tip of a honey-yellow color; hind wings with a short rounded tail on the hind angles, and a broad silvery band across the middle of the under side; the wings expand from 2 to 2½ in. They may be gotten rid of by hand-picking and collecting the leaves in autumn and burning them.

WEEVIL.—Rolls up the leaves of the oak late in April, forming compact, cylindrical cases containing a single egg; the case dropping to the ground, the larva after hatching feeding on the food around it, and finally transforming into a long-snouted weevil, which is small and highly polished black, with 2 large orange-red spots at the bases of the wing cover. The same methods of catching this weevil may be employed as with the curculio.

FIELD CROPS.

GRAINS.

BARLEY.—This succeeds best on sandy loam, but will adapt itself to almost every soil except a very moist one. It endures drought better than excessive moisture, but requires good tillage. The time of sowing varies with the locality. September is probably the best month in autumn, as the plant becomes in ordinary seasons sufficiently strong to go through the winter. When necessary to sow in spring, sow as early as possible. Drill culture is preferable to sowing broad-cast. Use 2½ to 3 bus. per acre. Barley ought to be reaped before it becomes dead ripe, as the husk then becomes thick and difficult of separation. The time for harvesting may be judged by the yellowness of the straw or drooping of the heads. In favorable weather it soon becomes dry after being cut. Care should be exercised that it does not get wet while curing, for stained barley is worth far less than that well cured and of a bright yellow color. There are 30 kinds of barley; they are divided into 3 sections, 2, 4, and 6-rowed. The 6-rowed is the variety usually sown, as it is hardiest and most prolific.



Barley.

BUCKWHEAT.—This requires a light, warm,

mellow soil; when planted on rich soil the straw is more abundant than the grain. The sowing of buckwheat must be deferred till all danger of cold is over. The middle of May is a good time; if sown later it is apt to be attacked by the white frosts of autumn, before its seed is ripe. Sow ½ to 1 bu. of seed to the acre. By sowing it in 3 or 4 different portions, at different times, a crop may be made sure of. The seed should be covered up with a harrow, and not in furrows, and requires no further attention than guarding it against the depredations of birds. The ripening of the grain is very unequal, for the plant is continually flowering and setting. It must be cut at the time when the greatest quantity of grain is ripe. It sometimes happens that the first flowers do not set, or that they produce nothing but barren seeds, destitute of farina, while those which come out later yield better seed. But the grain will ripen, and even the flowers set, while the crop is lying on the ground after cutting, especially if rain fall. Where it must be threshed by hand, a floor may be prepared in the field by scraping and sweeping a piece of ground, or laying down sheets. Lay over this a bed of rails 1 or 2 in. apart, raised from the ground sufficiently to make room for the grain when it is threshed. On these rails throw the straw as it is brought from the stacks, and thresh out the grain, which falls through the openings between the rails. The straw can thus be removed and separated from the grain very quickly. When all is threshed, remove the rails, and the grain may be cleaned on the ground if desired, without moving it to the barn. It is absolutely necessary to clean buckwheat as soon as threshed, or the chaff, being damp, will heat and spoil the grain in a few hours. There are 2 varieties, the *Broom* or *Black*, and the *Silver Hull*.

CORN, Indian.—Corn will not flourish on a very wet soil, no matter how rich it may be. Manure may be spread broad-cast upon the land previously to plowing, or applied in hills. Wood ashes are an excellent manure, and may be dropped upon the hills. It is common to make a mixture of these with lime and plaster; but no doubt the main benefit of the mixture proceeds from the live ashes. Poudrette is also applied, 1 gill to each hill. Deep plowing is not necessary; use the roller and pulverize thoroughly with the harrow. The closer the planting follows the plow and harrow, the better. Before the soil is dry it should be marked out, either for hills or drills. (For *Corn Markers* see WORK ON THE FARM.) The best results will be found in planting in drills about 3½ ft. apart, and 8 in. in the drill. As soon as the corn begins to push through the ground start the harrow. Go over the piece at least once a week until the corn is of such a height that the harrow will break it off; then use a wheel cultivator, or any of the various implements. Keep the field clear of weeds and the ground loose; begin as soon after planting as possible and harrow until the corn is 1 ft. high; then use the cultivator. The corn is usually cut off at the surface of the ground, as soon as the grain has become glazed, or hard upon the outside, and, while the blades are still green, put immediately into shocks, and thus left some time standing in the field. The corn, after becoming sufficiently dry, is husked and cribbed, and the stalks, with all the attached fodder and husks, are used for provender. Northern varieties: *Early Yellow Canada*. Small, 8-row. — *Holden*. Same as last, but more productive. — *Kingsbury's Excelsior*. Early, 12-row, yellow, growing larger every way than the others. — Southern and Western varieties: *Early Galena* (one of the best for late planting), *Chester County Mammoth, Illinois Yellow, Long John Evans, Proctor Bread, Southern Big Yellow*, and *White Gourd-seed*.

OATS.—This does best on a stiff, loamy soil. Plow deeply and harrow until the pulverized surface soil is 2 in. in depth. Then sow after a single plowing. In regular rotation, oats are chiefly sown after grass. One plowing is generally given to the grass lands, which should be done as soon in spring as the state of the weather and the other labors of the farm will allow. When oats succeed a green crop, the preparation of the land is the same as that for wheat. The seed should be sown just as early in the spring as the soil can be cultivated without lumping. Use the grain drill, and put in from 2 to 3 bus. to the acre. Cover 1 in. deep by thorough harrowing, then roll well. Cut just before the grain is fully matured. The longer it stands, the heavier will be the grain, but the poorer the straw for fodder. It must be cut before the danger of shelling becomes too great. If oats ripen unevenly, the best time to cut is when the latest grains may be shelled by the hand. They are sufficiently matured after passing the milk state, when the straw has turned yellow. Oats may be stacked like wheat, though they keep better in the barn. All that has been said regarding the harvesting, threshing and storing of wheat, applies to oats. They should not be allowed to get wet after cutting, as they discolor easily, and this injures their selling value. The following are the principal varieties: *Dutch Oat*. This is plump, thin-skinned, has white grains, mostly double, and the large ones sometimes awned. — *Egyptian*. This is grown in large quantities in the South.—*Georgian*. Large grained and very prolific.—*Houterson Winter*. This has a heavy grain, with a thin husk. — *Imperial*. A clean, bright, plump, heavy grain; it is hardy, and the heaviest raised. — *Pedigree Poland*. Early and prolific.— *Poland*. Thick, white husk, awnless chaff, solitary grains, short, white kernel, and short, stiff straw. — *Potato*. Large, plump, rather thick-skinned, white grains, double and treble, and with larger straw than any other variety. — *Red*. Brownish-red husk, thin and flexible stem, and firmly attached

Oats.

grains; an early variety. — *Siberian.* Black or brown grain, thin, rather small, straw large, and reedy.

RICE.—There are 2 modes of culture: the water and dry culture. Water culture: Commence planting about the 25th of March; trench the ground shallow, but wide; scatter the seed in the rows in the proportion of 2 bus. to 1 acre; hoe about the close of April; cover the field now with water; if the planting be late, and there is danger of grass, flood before hoeing; the usual depth is 3 in.; when the water is of proper depth, make a notch in the frame of the feed-trunk; if the rains raise the water above the notch, or it leaks out, let it off, or raise it accordingly; if seum or froth appear in 8 or 10 days; change the water by allowing it to run off with the ebb-tide and refilling at the next flood; keep the water on 15 to 17 days; allow the water to leak off for 2 days; then run the whole off and allow the field to dry; in 4 or 5 days hoe the field a second time; then stir up the ground; comb the fallen rice up with the fingers; about the 1st of July hoe the third time and pick it clean; again flood at the same depth as before; if the rice is flaggy and likely to lodge, support it by flooding it deeply. Dry culture: The ground must be thoroughly pulverized; sow the seed in June, in drills 30 in. apart, and cover lightly; after culture same as for any drilled grain. The time of ripening depends on the character of the season. The crop is ready to harvest when the grains at the top have turned yellow, are pretty hard, and the bottom grains still in the dough state. Cut the grain with sickles, bind it in bundles, and stack; in a week or two it will get through the stack-sweat and be ready for cleaning. The husks and grain are very difficult to separate. On regular rice plantations this is done by large stones, but in small quantities warm water and the hominy mortar are used. The operation is effected by means of a machine, which not only divests it of the husk, but polishes it at the same time. There are 4 varieties of rice, the *Clammy*, *Common*, *Dry* or *Mountain*, and *Early*.

Rice.

RYE.—The soil for rye may be inferior to that chosen for wheat, and it will succeed with less culture and manure. The soils best suited to its growth are those which contain the greatest proportion of sand. Those soils which contain a less proportion of sand are preferable; for, though it will grow upon ground of the poorest description, yet the produce will be more abundant upon good land, if it be not of a clayey nature. Any kind of manure serves well for this crop—green, rotted, or chemical. Rye exhausts land less than other grain. It may be sown either in the autumn or in spring, and, as in the case of wheat, the period of ripening is affected by that of sowing. The quantity of seed may be 2½ bus. to the acre, but, when grown for straw phait, this quantity is more than doubled. As it vegetates more slowly than wheat, it should be sown when the soil is dry; otherwise, the grain is in danger of rotting in the ground before it has completely germinated. Rye may be cut once or twice for green fodder before the joints are formed; cut it for grain before it is dry enough to shell; the general directions for raising wheat suit rye also. There is but 1 species which has produced 2 varieties, spring and winter. These are produced by the different periods of sowing, and resemble each other so much, that, when sown together, they cannot be distinguished.

Rye.

WHEAT.—The soils best adapted for the culture of wheat are the rich clays and the heavy loams. The soil should be well manured on a previous crop; then pressed down as compactly as possible with a heavy roller; the surface may be plowed and harrowed to make it mellow, but the ground under it must be compact; before plowing apply salt liberally to the field. For seed select the best heads, shell; then grade them, throwing away all the small seeds. Plant the selected seed in drills about 20 in. apart, dropping the kernels 2 or 3 in. apart in the drills; cover about 1¾ in. deep, and press the covering gently over the seed. Planting broadcast is objected to, because a uniform thickness cannot be obtained in the covering. The ground should be hoed just before planting. To get the best results, it is a good plan to use a machine that both hoes and sows the seed at the same time. The season of sowing wheat depends on the latitude, whether winter or spring wheat, and on the crop to which it succeeds. Where winter wheat is liable to suffer from freezing, spring wheat is much the safer variety; and by the new process of grinding the best quality of flour is obtained from spring wheat. Winter wheat is perfectly hardy, and will endure any amount of frost and cold, but freezing and thawing often play havoc with the crop, resulting in winter-killing. Stable manure with plenty of straw or other litter used as top-dressing serves well as a protection. It is sown before winter, when the land can be then prepared for its reception, as after fallow or potatoes; and it is sown in spring after cabbages, turnips, and such other crops as are not removed from the land till that season. The time of sowing must depend on the state of the land as well as the season. Put it into the ground as early as may be convenient in autumn; on strong soils sow in the latter end of September, in the course of October, and the beginning of November; 1 bus. to the acre of clean, plump seeds, on good land, in good condition, sown broadcast, is ample. When the seed is sown broadcast, cover it by the action of the harrow sufficiently to cover the seed. A double turn along the ridge, a double turn across, and again a single turn along, will generally suffice. As soon as the seed is harrowed in, water-furrow, to carry all excess of moisture off the land, by means of the double mold-board plow, with one horse, passing along

the furrows of the field and the furrows of the head-lands. Open furrows are also to be drawn through such hollow parts as the water might stagnate in, care being taken to sink all inequalities, that a passage may be afforded for the water to run off. The intersection of the furrows of the field with the e of the head-lands are also to be cleared out, and cuts made occasionally through the head-lands. On the lighter class of soils, plowing in the seed may be adopted. The seed is sown broadcast; after which a shallow plowing is given to the land, and, perhaps, a slight harrowing. The grain should be cut immediately after the lowest part of the stalk becomes yellow, while the grain is yet in the dough state, and easily compressible between the thumb and finger. If cut at this time, it will yield more in measure and weight, and a larger quantity of sweet, white flour. If early cut, a longer time is required for curing, before storing or threshing. The latter operation is usually done, by extensive wheat-growers, with a large machine, taken into the field, and driven by horse-power; with small farmers, a small single or double horse-machine, or hand-threshing in winter. If the grain is perfectly ripe, the straw thoroughly dried, and the sheaves free from grass or weeds, the wheat may be cut and shocked. Place the butts of 12 to 16 bundles on the ground; crowd the tops together as much as possible; break 2 bundles over at the band so as to bend them at right angles and place them, reversed, on the top of the shock to shed the rain. When placed in a stack, it should be well elevated from the ground. If the stack be large, a chimney of lattice or open-work should be left from the bottom, extending to the top, to produce circulation. The straw or chaff yields good fodder, when cut or mixed with meal or roots; it is also good for bedding for cattle, for manure, and should never be wasted. The stack must be of a good form in order to shed the rain. A good foundation should always be built at the bottom of the stack out of rails or timber for the grain to rest on. Whenever the butts of the bundles reach the ground it has a tendency to make the grain or that portion of it musty. Place the bundles close together on the outside courses, and then put the loose straw and rough bundles in the middle. Within a few days after the wheat is stacked it may be threshed; much depending upon its condition when stacked; but it is safer to let it go through the sweat in the stack. When it is threshed on the day it is cut, it is generally done by steam; hand threshing is not now much resorted to. The opinion is gaining ground that too new wheat is being used for seed, and that seed a year old, and specially grown and preserved for seed, will be more healthy and productive. The following are the principal varieties of wheat: *Clawson*. A white variety; large heads; large kernel; beardless; straw of medium height and stiff at the bottom. — *Fultz*. A smooth wheat, very evenly 6-rowed; straw stands well; chaff very close and adherent; grains short and plump, of a dark amber color. — *Hard No. 1*. Very hard; wheat giving more satisfaction than the softer grains. — *Harmon's White Flint*. Bran very thin, superior flour. — *Indiana*. White chaff; bald; white and large berry; thin bran. — *Kentucky White-Bearded*. White chaff; bearded; short, but heavy heads; well filled; straw strong; litters a little. — *Mediterranean*. Light red chaff; bearded; red berry and long, flinty, thick bran; inferior flour. — *Old Genesee Red Chaff*. Red chaff; bald; long straw; white and large berry; thin bran; superior flour. — *Red Bearded*. White berry; red chaff; beard standing out from the head. — *Virginia White May*. White chaff; bald; resembles White Flint in its growth and straw, but the heads are more clumped, the berry stands out more and shells easier; berry white and hard. — *Wheatland Red*. Red chaff; bald; heads of medium length; red berry; bright and large straw. — *White Provence*. Heads middling and bald; chaff bluish; large berry; thin bran; straw long, soft, small and liable to fall. — Besides these the *Amber* and *Rice* are new and promise to be very productive and fine sorts. *Dallas* is a fine wheat for the South, being very free from rust. It is somewhat tender in the Middle States. The *Clawson*, *Fultz*, *Mediterranean*, also the *Diehl* and *Golden-straw*, are excellent winter varieties; the *Black Sea*, *Rio Grande*, *Champlain* and *Defiance* are among the best spring varieties.

—o—

GRASSES.

ALFALFA, or LUCERN.—Alfalfa will not thrive in a compact clay, or in any shallow soil with a hard pan subsoil. It prefers a rich sandy loam well drained, with a permeable subsoil. Plow, harrow, roll and pulverize it until you have a fine, mellow, seed-bed. Sow the seed as early as possible and cover slightly. Near the latitude of St. Louis it is proper to sow it from the 10th to the 30th of April; south of the Ohio it can be sown earlier. From 15 to 30 lbs. should be sown per acre. It is very important to get a full stand at once, as its growth is so rapid after it is established that it shades the ground too much for self-seeding to do any good; thick seeding makes fine stalks and thin seeding coarse ones. Broadcasting and drilling are both practiced; but if the soil is foul, drilling is preferable, as it admits of careful culture until the crop is able to displace the weeds. It has two characteristics which adapt it to regions subject to long-continued hot and dry weather. These are its very prolific and rapid growth, by which, after being cut, it quickly shields the surface by a thick green coat, and the astonishing depth to which it sends down its carrot-shaped tap root. Either crop will produce seed if you let it stand, but as the second crop will be freest of weeds and come at the best season of the year to perfect the seed, utilize that crop for seed. Cut when in early bloom, and as often as it comes in

bloom for hay, or yet still oftener for soiling.

BROOM CORN.—This crop takes a rich soil, as free from weeds as possible. A clover sod, turned under early, makes a first-rate bed for the broom corn. When sod is to be planted, some prefer to turn it the June before planting, and then give it a replowing in the spring. On poor soils any well rotted manure will benefit the crop. The fertilizer, whatever is used, should be thoroughly harrowed into the surface soil before planting. A rolling surface should be chosen rather than a flat one, on which water might collect and stagnate during the wet seasons. Broom corn should be planted at the same time of Indian corn, when the ground is warm. Whatever seed is selected it must possess strong vitality, which should be tested before sowing; and it should be chosen from the finest growths. 1½ gals. will plant 4 acres, which will produce on the avearge a ton of corn. Thoroughly pulverize the ground in spring; mark out the row 3½ or 4 ft. apart; distribute the seed with regularity and at equal depths to obvinte cutting a second time. It is sometimes planted in hills, but for general cultivation drill planting is generally practiced. The planting may be done with a drill or by hand. In hand-dropping, shallow furrows are marked out with a small plow, and the seeds dropped in a continuous row 2 in. apart, or at intervals, 5 or 6 seeds every 15 in. Cover with a light harrow or brush. A planter drops and covers the seed at the same time. When the plant is 2 in. high, run backwards and forwards between the rows with a 2-horse harrow, to kill the weeds, loosen the soil, and give the corn a start; then the rows require hand-weeding and thinning out to the proper distances. To prevent the brush falling down and growing crooked, bend down the corn as soon as the heads shoot out; be careful not to bend the stalks so low that the tops will touch the ground, or so much that the joints fracture, else the corn will be ruined; go over the ground and repeat the process until the heads are all out. The stalks left in the field should be plowed well under, to rot for the benefit of future crops. To obtain brush of a bright greenish color the corn should be cut while still green, and when at slight pressure milk exudes from the seed; if left later the tips turn red or brown, and should the ripe standing corn receive a shower, may even become black. Cut off the heads just above the upper joints. As they are cut off, lay the heads in the vehicle all one way, and haul to a dry shed where shelves should be arranged about 18 in. apart. Place the heads in dry stacks, where they may remain until the seed shall be separated. The stalks should be left 4 to 6 in. long, and the brush selected by handfuls and divided into long or short, crooked fine, medium or coarse straight brush. This facilitates scraping and also baling the various grades separately. Broom corn should be cured under cover, as exposure makes it brittle. From 2 to 4 weeks is long enough for curing. A covering and free circulation of air is all that is necessary. The seed may be separated by an ordinary threshing machine. The motion of the machine should be reversed, and the bunches should be held to the cylinder, turning them back and forth till all the seed is removed. Or they may be separated by means of a comb such as is used for flax. Or by means of a spiked wheel moved by a treadle. To prepare the brush for market, after the seed has been extracted, cut it 2 ft. from tip to butts, and pack in bales with the brush lapped in the middle and the butts to each end. The bales are pressed by a lever and are tied by 5 wire bands; weight about 200 lbs. each. Of the various varieties the *Chinese*, *California* and *Missouri Evergreen* are most in demand.

CLOVER.—Sow in February or March, and, if practicable, when snow is on the ground, which, melting, carries the seed down and into crevices left by the frost, there to germinate. Seed frozen will become imbedded in the soil as it thaws, and is soon covered. If not sown early it is better to wait until the frost is out of the ground, and then sow, harrow and roll. The harrowing and rolling will cover the seed and do good to the plants; any disturbed by the teeth of the harrow, will be pressed back in their places by the roller. As a fertilizer, 50 lbs. of plaster per acre will often have as good effect as the larger doses of 100 and 200 lbs. that are recommended. Wood ashes on many soils will be found a useful application. While the quantity of seed depends much upon the weather, the crop is largely increased by mowing or feeding off the first, or hay crop, as early as possible. Clover is frequently turned under in the fall, to enrich the ground preparatory to a crop of wheat, or in the ensuing spring for the benefit of Indian corn. The best time for turning down is in the rankest and most juicy stage of its growth. Clover leaves the field after the second year, unless allowed to seed itself. When timothy has been sown with it, it obtains possession of the field, where it is generally allowed to remain 2 or more years longer. The proper time to cut clover is after it has blossomed and begins to turn brown, about the last of June. It should be cut when dry, free from dew, allowed to wilt, and then turned over until it is evenly wilted all through. The harvesting of the seed crop may be effected with a machine for the purpose, which simply removes the heads, or the cutting can be done the same as it is with the grass crop. Dew or rain will not hurt grass while it is green. The next morning, after it has been cut and the dew is off, rake the partially dried grass into small windrows. Turn them immediately after dinner, and toward night rake into larger windrows and put into cock. Turn or spread out the cocks the next morning, and draw in the hay in the afternoon. When thoroughly cured the crop should be taken to the threshing floor or barn and the seeds beaten out with light flails, or, better still, with a threshing machine, especially a clover huller and separator.

COMMON GRASSES. — To seed down land to any of the well known pasture and meadow grasses, put the land into the best possible condition either by thoroughly summer fallowing, or by growing upon it the previous season some crop, like potatoes or corn, that requires

clean cultivation, in order that all weeds, and the inferior kinds of grasses, may be destroyed; then, at the usual time of sowing grain in the fall, sow on the grass seeds desired and nothing else. The more the ground is harrowed and pulverized, the better. A seed bed for the smaller grasses would be better than for any of the ordinary kinds of grain. Bone dust or tankings or some fertilizer in which the nitrogen is not in the form of ammonia, and not soluble, is the best for late autumn application to grass. Such a manure has some immediate effect, yet is not washed away in solution by heavy rains, but shows its potency in the spring. Leached ashes are also an excellent application on poor grass land. From the middle of August to the middle of September is the best time to sow grass seed. If sown early enough to get the full benefit of the fall rains, the grass will become sufficiently well established before winter sets in to yield a fair crop of herbage the following season, either for pasture or hay. Timothy should always be sown in the fall, and may in some climates be sown with safety as late as the middle of Oct. It seldom does well when sown in spring. All the other grasses must either be sown in spring or not later in fall than the last of August or the 1st of September. The following quantities per acre should be sown; Clover and timothy (alone or together), 1 bus. to 8 acres; clover and orchard grass (together), 1 bus. of the former and 5 bus. of the latter to 10 acres; orchard grass alone, if the seed is perfectly clean, 1 bus. to the acre, otherwise 2 bus. to the acre. The same proportions are observed for Randall grass. Clover, 1 qt. per acre; orchard, 1 pk, per acre; Randall, 1 gal.; red top 1 gal. per acre. Under the term meadow is included all such lands as are kept in grass chiefly for the sake of hay-crop. Meadows situated along the banks of rivers and streams are the most valuable. If the land is liable to the oozing out of springs, it can be remedied by draining. Upland meadows require more attention than valleys and low lands, being more difficult to drain, and requiring frequent manuring, as the roots of grasses never strike deep into the soil. Boggy land is least valuable, but when thoroughly drained and tilled, large crops may be obtained at comparatively small expense. Do not leave any one seeding to lie more than 2 or 3 years before breaking and tilling, so as to thoroughly overhaul the land, and then reseed it, giving it a change of crops and a change of condition, which well agrees with almost any soil. Grass will hold in longer when the land is cultivated a year or two in hoed crops. Sowing turnip seed with grass is sometimes a good practice, if the work is done very early and the turnips are not too thick. By judicious flooding the yield of grass land may be doubled. (For method of flooding, see *Irrigation* in Tillage.) Do not pasture meadows the first season, except slightly by young cattle, as the weight of heavy animals destroys the crowns of the plants. Sheep should never be allowed to run on young grass, as they nip so closely as to kill the plant. If a meadow has been used for years without being manured, either break up the field and cultivate grain or root crops; or loosen the soil by running a subsoil plow 1 ft. deep at intervals of 2 ft.; apply manure generously, and then roll the field. Broken and uneven land often makes very excellent pasture. If a portion of a pasture is high and a portion low, a good supply of feed may be secured from the time the frost leaves the soil in the spring till it enters in the fall. Pastures of nearly uniform surface generally fail to afford a supply of grass during the entire grazing season. The cheapest and most practical manner is to have 2 pastures. Let the grass have a good start in the spring, say 4 in., before turning on the stock, and change pastures as often as the pasture appears to be closely grazed. A variety of grasses and other fodder plants is essential to good pasture. The greater the variety, the larger will be the amount of food produced. The pasture requires constant care. As grasses disappear from any cause, seed should be sown that the full amount of feed may be supplied. The hand-scythe or mowing machine should be used to cut weeds and tall grasses that run to seed. Cultivated grasses should be cut as soon as they are in full blossom. They may yield more lbs. of hay if allowed to remain uncut a few days longer, but it will be of inferior quality. Early cut grass and clover will make more milk and flesh than when they are allowed to remain in the field until the seeds are nearly or fully ripe. When grass and other forage plants are cut while they are yet tender and properly cured, a large proportion of them will be digested. By cutting rank grass and clover early, danger of injury by lodging is avoided, and the prospect of securing a second crop increased. Cut red top, June and orchard grass, and possibly a few other varieties, first. Red clover should then follow, letting the cutting of timothy come last. All the grasses cannot be cut at the same time, for they do not flower at the same time. Close mowing of upland meadows is injurious, as the action of the hot sun and dry weather following harvests affects the roots of the grass most unfavorably when left without some protection. Wet mowing grounds will bear cutting close and be benefited by the same influences which would dry and burn up an upland meadow. Where the practice is followed of top-dressing the meadow immediately after taking off the grass, close mowing is also permissible. Grasses which are cut 2 in. high will start much quicker and thrive much better than when shaved close to the ground. Fine grasses, when the season is not a very dry one, may be cut lower with safety than the coarser kinds. Grass made into hay in such a manner as to retain the most possible of all its natural juices, makes the richest and best hay. In order to do this, it should be exposed to the sun as little as possible, as a bright, clear sun is apt to burn and reduce the quality. Curing hay in the cock is preferable to sun drying. The sweating and fermentation improve and prevent heating in the mow or stack. Put up the hay after the dew is off, in moderately large cocks (4 ft. wide and high), after it has lain spread in the sun 1 full day. It may thus stay safely for a week, if necessary, and a hay cap will protect it from a 24 hours'

rain. The day it is drawn in cocks it should be opened early so as to get a final airing for 2 or 3 hours before it is taken up. The coarser grasses require still longer time to cure than timothy grass. Timothy will dry sufficiently in one day, if the weather be propitious. During the early part of the season 2 days are usually required for properly curing heavy grass. Care should be taken not to cure hay too much, but to get it in stack or in the mow as soon as it will bear it. Hay should be stacked just as near as possible to where it is going to be fed out. Substantial supports, made of iron or timber, and elevated at some distance from the ground, will insure stacks against moisture in the ground, protect them against vermin, and allow a free circulation of air beneath them. Stacks of hay, cornstalks, etc., may be ventilated by making a hole perpendicularly through the centre, with apertures through the base and top of sides of the stack to admit a current of air. The orifice should be constructed when the stack is being built, which can be done by filling a bag of the requisite size with hay or straw, placing it upright in the centre of the stack, drawing it upward according as the stack rises. In this way a chimney will be formed in the centre of the stack, which will carry off the steam, if the hay or corn-stalks should ferment, and by admitting air will prevent damage from mold. The top of the air-tunnel should be protected by a roof, to keep out rain. By the use of a hay elevator, a load of hay may be transferred from a wagon to the mow or stack in a very few minutes. In forming the stacks, a layer of straw is usually spread over the bottom, or stand, and the hay is then regularly spread and trodden down, observing to keep the middle of the stack well raised. In this manner it is carried up to the height of several feet, projecting slightly to the eaves, so as to overhang the sides, to guard the lower part from rain. The roof is then raised to a considerable height in a slanting form, with gable ends, and, being thus formed, the loose hay which projects from the sides and ends of the stack is pulled, until all is smooth and regular, and the stack is then bound down with ropes. Salt, in small quantity, is sometimes strewed upon the hay, as the building of the stack proceeds, to stop fermentation, and render the hay palatable. Varieties: *Annual Spear*. An early, sweet grass, much relished by cattle, but it will not stand drought. — *Barn*, or *Barnyard*. Flourishes on moist, rich, or well manured soils; is very succulent and nutritive. Flowers in the latter part of summer and beginning of autumn. *Black*. Grows luxuriantly along the margins of salt marshes liable to periodical overflow by the tides. When cut early and well cured, it makes a very excellent hay, although not equalling in weight that of many other varieties. — *Crab*. A native of India; is an early grass, which requires a moist, rich soil. — *Crested Dog's Tail*. Grows well in upland pastures, and affords a wholesome food for sheep. It flowers somewhat late, and makes a beautiful covering for lawns in the latter part of summer, forming a close turf and having rather fine foliage. — *Crow-foot* succeeds well in a moist, rich soil, and makes excellent hay. — *Darnel-spiked Fescue*. One of the most valuable grasses in cultivation, either for permanent pasture or lawns; it springs early, is very productive, very nutritious, and improves by age; it thrives on all good soils, and increases in bulk if pastured for many years. — *English Blue* or *Meadow Fescue*. A valuable pasture grass, as its long and tender leaves are much relished by stock. It succeeds well, even in a poor soil, and as its roots penetrate the earth 12 to 15 in., it is not affected, except by exceedingly dry weather, and is as valuable a fertilizer as red clover. When cured like timothy, it yields a very superior quality of hay. — *Evergreen* requires a light soil which is subject to wash with heavy rains, as the roots form such a compact mass as to render injury from this cause almost impossible. It forms a heavy sod, and its long, fibrous roots strike deep into the ground. It grows rapidly from early spring until winter, and remains green and fresh all winter. — *Floating Fescue*. Flowers in June, and delights in very wet grounds. Horses and cows are very fond of it, and the superior excellence of some kinds of cheese is said to be caused by the peculiar richness and flavor which it imparts to the milk of cows fed upon it. — *Foxtail*. Very much resembles timothy, for which it is sometimes mistaken. It is extensively grown in the Middle states, and flourishes on any fertile soil which is not wet. — *Guma*. One of the most prolific grasses under cultivation, and will bear drought when all surrounding vegetation is destroyed. If suffered to go to seed it becomes too coarse for hay; but in its green state, it is eaten by cattle with avidity. — *Guinea*. A most prolific and nutritive grass. It is a perennial plant, and may be cut 4 or 5 times during the summer. — *Italian Rye*. Flourishes best on fertile, well-watered soils; but does not equal timothy in its nutritive qualities. — *Kentucky Blue*. This is known in some sections as *Green Meadow Grass*, and *June Grass*. It makes excellent pasture, succeeding finely on hill lands, and producing the most nourishing food for cattle; retaining its qualities till a late period in winter, and further south affording abundant food throughout the winter. — *Meadow Foxtail*. A perennial grass of early growth and hardy nature. It grows well on soils which are in good condition, and is very productive, continuing to shoot forth flowering stems until late in autumn. — *Meadow Spear*. Flowers late in June; and, being a hardy plant, succeeds as well on low, wet grounds, as it does on light upland soils. It is eaten readily by cattle during the winter season, though it is not much esteemed because of its coarseness. — *Narrow-*

English Blue.

Kentucky Blue.

leaved Meadow. Forms a fine permanent pasture. It flowers in June, and before that time, its leaves, which are soft and succulent, attain the length of 12 in. — *Orchard.* Generally known in England as *Cock's-foot*, and the seed is sold as such in foreign seed stores. It comes to us from Europe, and adapts itself to all varieties of soil. Its stems are very leafy; it does well in the shade of trees; it gives a heavy aftermath; and it is in its best condition in blossom, at the same time as red clover; all of these being in its favor as a meadow grass. For pastures it is quite as valuable, starting quite early in spring; pushing a new growth very rapidly after it has been grazed over; lasting late in the fall, and enduring drought better than almost any other. — *Perennial Rye.* A very valuable variety for permanent pasture, and makes a large return in hay; very nutritious, and stock are very fond of it; succeeds best on moderately moist land, for which it is peculiarly adapted. — *Pony.* Considered one of the best winter grasses for the Western States; grows in close, thick, elevated tufts, and continues green through the cold season. — *Red Top.* A favorite grass on wet, swampy meadows. Its thick, interlacing roots consolidate the sward in such a manner as to prevent the feet of animals from sinking through. As a pasture grass, it is only valuable when mixed with other varieties. — *Reed Meadow.* Grows in wet soils; contains much nutriment, and is greedily eaten by cattle. It is too aquatic in its habits to allow of an extended culture. — *Ribbon.* Well adapted to boggy grounds; yields a large product, either in hay or pasture, and is much relished by cattle; it requires a soil well saturated with water. — *Rice.* This flourishes in swampy lands in the South; may be cut several times during the summer, and furnishes a hay fully equal to the best timothy. — *Salt Marsh.* Grows in muddy spots, overflowed by sea-water. Cut green, and made into hay, it furnishes good food for horses and cattle, which eat it with a relish, on account of its saline flavor. — *Sheep's Fescue.* Forms an excellent pasturage for sheep. It grows from 6 to 10 in. high, and flowers in June. — *Smooth-stalked Meadow.* Makes an excellent hay, and affords the richest of pastures. It delights in a moist soil, but thrives most luxuriantly in rich meadows. It is useful for making a straw plait which very closely resembles Leghorn. — *Sweet-scented Vernal.* Delightfully fragrant. It is of dwarfish habit, and is sown on grounds intended for pasture on account of the early feed it affords, and for its rapid growth after being cut. — *Tall Fescue.* A native perennial; very luxuriant and productive, but not a favorite on account of its coarseness. It grows well in boggy meadows, and flowers in July. — *Tall Meadow Oat.* Blossoms in May. Is preferred by horned cattle before all other grasses, and yields an abundance of good, sweet hay. Mixed with clover, it makes a good upland meadow. — *Timothy, Cat's Tail*, or *Herd's.* Flourishes in all soils except such as are wet, too light, dry, or sandy; is easy of cultivation, hardy, and very productive. For milch cows and young stock, it should be cut while it is juicy. May be sown upon wheat or rye, in the spring or early fall. — *Wood Meadow.* Grows from 1½ to 2 ft. high; has a perennial, creeping root, and an erect, slender, smooth stem. Its chief value is, that it will produce a crop of hay in moist, shady situations, where it frequently grows quite tall. Cattle are fond of it; it is succulent and nutritious, and is perhaps the best variety for sowing in orchards, under trees and shaded situations, either for hay or pasturage.

Orchard.

Perennial Rye.

Sheep's Fescue.

Timothy.

HUNGARIAN GRASS. — This is a species of millet. It has a close head, and millet a looser and more broken one. It will grow on any soil of sufficient richness to raise good corn and potatoes, the richer the better, provided the manure has been applied to previous crops. The ground before sowing should be thoroughly pulverized by harrowing and made smooth and level, that the seed may not be buried too deep. Sow when the ground is warm and dry, or immediately after corn planting. If portions of the field are sown with a few days' interval between, it will not be ready to cut all at once, which may prove a convenience in a large field. Cover the seed with a fine or smothering harrow and then roll the surface. 3 pks. broadcast are enough for an acre. Cahoon's sower is well adapted to doing the work evenly. Hungarian grass smothers all weeds and leaves the land in good condition for wheat. It makes good hay, and a good deal of it if the land is rich. It is a good crop to plow under, to enrich the land. For feeding green, Hungarian grass should be cut as soon as large enough for a good swath. For hay, it should be cut as soon as it is all headed, and before the seed is formed. 2 or 3 days may be required for thorough curing of Hungarian grass, including turning or shaking up before raking, and opening the cocks.

MILLET.—This requires a dry, rich, well pulverized soil. The seed should be sown at the time of sowing corn, and not earlier, in drills 4 ft. apart; when well up the plants should be trimmed out to 2 ft. apart in the rows. 2 lbs. of seed will plant an acre if properly sown. The soil should be tilled to a considerable depth for its reception, and plowed 3 times, besides harrowing, rolling, and weeding. Pearl millet requires light, sandy soil. It may be cultivated in drills, or sown broadcast, and on the richly manured land the yield has reached 100 tons of green or 16½ tons of cured fodder in a season. When cultivated for fodder the seed should be dropped in drills and given plenty of room. As soon as weeds make their appearance among millet which is just shooting above the ground, they must be eradicated; thorough weeding is an indispensable operation in the culture of millet. Millet grows very fast and is ready for cutting in 6 weeks when sown on good soil. If used for green fodder it should be cut before the first seeds have begun to ripen; if for grain, just before the seeds begin to fall. Pearl millet is matured in 45 days after planting, and 3 crops may be cut from the same planting. The fodder is in the best condition for cutting when the stalks are 5 or 6 ft. high; but if used for soiling it can be cut earlier or later. Millet may be cured like hay. That portion of millet which is intended for seed should be preserved in a dry and airy place, and should be threshed when wanted. Varieties: *Golden*, or *German*. Close panicle, broad leaves, and grows very rank and high, giving a heavy burden of fodder. — *Pearl Millet*. Seed larger than any other variety; on very rich lands the stalks grow to ½ in. in diameter.

SAINFOIN. — Sainfoin is best adapted to limy soils, but will grow upon any light soil which has a free or open subsoil. It may be sown with a crop, in the same manner as clovers and grasses. It should be sown broadcast, rather than cultivated in rows, and the seed should be of a good and tried kind, perfectly fresh. If ground is to be mown for successive years for forage, then, on such soils as are suited to it, it is a good crop, being easily grown, hardy and productive. When sown merely to produce 1 crop of hay, and then to be depastured for such a period as may be thought suited to the nature of the soil, it answers well; but in this case it is better sown with a proportion of white clover and rye grass. When used for soiling, it may be cut twice; when used for hay, it should be cut once, and the aftermath depastured. It may be used for herbage as well as for forage. When made into hay, it should be cut just when it comes into full flower. It is not very apt to be injured by heating, and may be put up more quickly than other hay plants.

TARE.—It is regarded as a pest, but is sometimes grown for fodder. This is a hardy annual, best adapted to clay soil, but will grow in any rich soil, not over dry. In a moist climate, the stalks grow so luxuriant, as to rot at the bottom; and in one over dry, it is deficient in length. For an autumnal sowing 1 plowing is sufficient; but for a spring sowing a winter and spring plowing is necessary. The winter variety is sown in September and October; the spring variety should be sown as early as the season will permit. Sow broadcast. The quantity of seed to an acre is from 2½ to 3½ bus., according to the time of sowing, and whether they are to be consumed green or left to stand for a crop. When intended for seed, less is sown than when grown for soiling or drying the stalk. Varieties: *Spring*. Where the land is foul, and requires to be 2 or 3 times plowed in spring, or where a late crop is desired, or crop for seed, this is the better variety. — *Winter*. If the object is to have early feed, the winter variety is to be preferred.

ROOTS.

FOR the cultivation of Beets, Carrots, Horse-radish, Parsnips and Turnips, see same in VEGETABLES, ETC.

PEANUT.—A light, clayey soil, filled with pebbles, is best for peanuts. As the soil affects the color of the peanut, the brighter the clay and pebbles the more valuable the crop. Uplands are better than bottom-lands. Peanuts require a clean soil; they will follow any hoed crop to advantage, with the exception, perhaps, of sweet potatoes. Corn land is generally preferred. Plow the ground with a 1-horse plow, in March or April, to a depth not exceeding 4 or 5 in. If the land is thin and needs manuring, open furrows 3 ft. apart, and strew in 100 to 125 lbs. of Peruvian guano, or from 150 to 200 lbs. of superphosphate of lime; mix intimately with the soil; then ridge over the furrow and throw the whole surface into 3 ft. beds, reduced to within 2 or 3 in. of the general level of the field; mark off rows 2½ or 3 ft. apart; drop 2 kernels, carefully hulled by the hand, at the intersections of the rows, and cover from 1½ to 2 in. deep with a hoe. Fine dirt only must be used in covering, as the plant is very tender at the outset. If the plant does not appear within 10 days of favorable weather, replanting must follow, because the cut-worms or moles have probably destroyed the hill. Red peanuts are generally planted in ridges, the kernels being from 8 to 12 in. apart and 2 in. deep. Keep the ground mellow and clean; throw the soil up to the red, but leave the white level. Cultivation ceases usually about the 1st of August. The time for harvesting the crop is from the 15th to the 30th of October, immediately after the first frost. When the crop is forward, or when it is an object to get a portion of it early in the market, the operation may be commenced in the latter part of September; but the longer the vines continue to grow, the greater will be the number of sound pods. Select a time when the weather is settled and favorable, and with pronged hoes loosen the vines along the rows; pull up the vines, shake the dirt from them, and leave them in the same place. In dry

weather they will be sufficiently cured in 2 days to be stacked. Showery weather, though it may somewhat delay the curing, does no injury. Stack around a pole 8 ft. high, the roots inside; place logs, with the ends on poles, on the ground, to prevent mold from dampness; leave a little space around the pole, that air may circulate from bottom to top; cap with hay or corn-fodder. Put up in this manner, the nuts may be securely kept all winter. After remaining about 2 weeks in the stack the picking should be begun, taking off none but the matured pods, which should be picked off by hand. They are then screened in a cylinder, sunned a few hours, and put into sacks containing 4 or 5 bus., and are ready for market. Varieties: *Red.* Erect stem and few roots; adheres more closely around the stem than the white. — *White.* Grows flat upon the ground, spreading out and forming a rigid and deflexed stalk, from which the forming pods grow into the ground where the nut is formed.

POTATO.—A rich sandy loam is best suited to the potato. In all heavy soils, it is more subject to disease, and the flavor is much inferior. Manure is applied either in rows or hills, or broadcast over the hills and plowed in. If the soil is good but little manure is required. The best fertilizers are plaster, lime and superphosphate of lime. Very early potatoes are sometimes forced by laying tubers in a warm moist cellar; there they grow and form tubers which sometimes obtain high prices in winter and early spring. Or they may be started in a hot-bed, setting them out in rows in open ground after they are furnished with green leaves. Select for seed none but the best. Cut a large potato into pieces of 1 eye, leaving a due proportion of the potato with each eye. Plant as early as the ground can be had in fair working condition, in hills or ridges about 3 ft. apart; covering in light, warm soils about 4 in. deep, but in cold, wet situations, 2½ or 3 in. will be sufficient. Thorough cultivation during the early season is necessary. After the vines begin to bloom, when the potatoes are near the surface, cultivation should cease beyond pulling out any weeds that may make their appearance. Strawing is being adopted to save hoeing and secure immunity from the Colorado beetle. After the potatoes are up 3 to 6 in., straw is put on the ground 4 in. deep. This keeps the ground cool and moist and in dry seasons secures a good crop. The straw leaves some soils in bad condition. Potatoes should be harvested as soon as they are ripe; otherwise the tubers may start into a new growth. They are much more apt to be affected by rot if left long in the soil. The spading fork or the pronged hoe are the most desirable implements for digging potatoes by hand. They do quicker work, and do not bruise or cut as the hoe is apt to do. Allow them to lie on the ground until thoroughly dry. Early potatoes should be marketed as soon as dug, or placed in thin layers or small heaps in a barn or cellar, and turned occasionally if there are signs of heating. If this cannot be done, it is better to leave them in the ground until cool weather sets in. The expense of handling potatoes is so great that, as a rule, those farmers make the most profit, especially in the case of early potatoes, who ship them directly from the field. Varieties: *Beauty of Hebron.* Very productive; white skin and flesh; a good keeper, and excellent for table. — *Burbank's Seedling.* A white skinned, medium, early variety; flesh of fine grain and excellent flavor; produces a large crop of handsome tubers, nearly all of which are marketable. — *Dunmore.* Tubers medium to large; skin white, slightly russeted; eyes few and small, quite even with the surface; very productive. — *Early Ohio.* A few days earlier than the Early Rose, and similar in color and habit of growth; is more productive, and equally as good for table and market purposes. — *Early Rose.* A standard variety for earliness, quality and productiveness. — *Early Vermont.* Similar in color and form to the Early Rose, but much more hardy; a better keeper, more productive, better quality, and from a week to 10 days earlier. — *Improved Peach Blow.* One of the best late varieties; a very vigorous grower, the vines completely covering the ground; tubers round, of medium size, very uniform, resembling the Jersey Peach Blow; fully equal in quality, and will produce nearly double the quantity per acre. — *Magnum Bonum.* Tubers medium to large; very uniform in size, with very few eyes, quite deeply set at the seed end, which is almost square; produces few small tubers, and is of excellent quality. — *Mammoth Pearl.* Skin white; tubers medium to large; eye quite even with the surface; very productive, and for table use or marketing is an excellent variety, being exceedingly flowry and well-flavored. — *Pride of America.* Very productive, growing to a large size; flesh exceedingly fine grained and of snowy whiteness; cooks quickly and evenly, dry and flowry, and has no hard centre or core. — *Snowflake.* Ripens about the same time as the Rose; tubers of medium size, oblong, somewhat flattened, very uniform, eyes quite even with the surface; skin

White Star.

white, with a russety tinge; either baked or boiled it is dry, mealy, and of the finest flavor. — *White Star.* An excellent white potato, with slightly russeted skin; tubers large, long, and of the finest quality; a strong grower, very productive, and may be classed among the best varieties for table use or marketing.—*White Elephant.* Tubers very large, long; color light pink, with a white blotch around the eyes, which are quite numerous and slightly depressed; grows to an immense size; not hollow, very productive, and of good quality.

White Elephant.

SWEET POTATO.—Sweet potatoes succeed best in a light, rich, warm, sandy loam, and are propagated by tubers or by cuttings of the stem. Prepare the soil by plowing and harrowing The latter part of May or the first of June is soon enough to plant sweet potatoes. If the plants are to be set in hills mark out the ground with a plow in rows 3 ft. apart each way; otherwise let the rows be at least 3½ ft. distant. For hill planting apply 1 shovelful of good, very finely composted stable manure at each intersection of the furrow and cover it with 2 or 3 hoefuls of soil. When the plants are to be set in rows, scatter the manure as evenly as possible along each row and cover by turning 2 furrows directly over it. Apply the manure liberally and be certain that it is fine and mellow. Plant in the evening, the plants to be 15 in. apart. With the right hand make a place for the plant; set it so that not more than 2 in. of the top will remain above the surface; press the earth firmly about the roots, leaving a little depression, into which pour 1 pt. or less of water, and when it has settled entirely, go back and draw the dry earth over all. Or simply water the hole thoroughly first, and plant as above. The season must be very dry and hot if the plants need any additional watering. Keep the sides of the ridges clean until the vines cover them. Do not cut deeply in the ridges with any implement. Their shape must be kept intact, for here it is the potatoes form, standing upright in a cluster about the stem, the tops next the surface. If weeds appear after the vines have run somewhat, they may be turned over with the handle of a rake, the weeds killed and the vines replaced. If weeds appear after the vines cover the ground they must be pulled by hand. If wet weather causes the vines to take root at the joints, they may be raised by running a rake-handle under and lifting them up. In the fall the potatoes should be dug before frost kills the vines. If they should happen to be killed by white frost, they must be cut next the root before the sun strikes them to thaw them, if possible, and the crown covered with a mound of earth. In this way the potatoes will continue to ripen for some time if the weather holds moderate. If the blackened vines are allowed to remain when thawed, the potatoes will become blackened, spotted and worthless. Dig the potatoes on some dry, warm day. Allow them to dry somewhat in the sun, and remove them to some moderately warm, dry, airy room, without bruising, to season for 1 or 2 days. They may then be packed in barrels, either with or without dry sand. Thus, if placed where the temperature will not vary much from 50° F. and is dry, they may be kept for use until midwinter. There are numerous kinds of sweet potatoes, chiefly distinguished by size and color, which ranges from a rich yellow to white and red. Varieties: *Brazilian.* A very large, short, thick, truncated sort; often weighs 12 lbs.; of good quality; productive, but from its great thickness difficult to cook. — *Chinese Yam.* Well adapted to the deep, sandy, alluvial soil of the South. It is perfectly hardy; stem 12 to 20 ft. long; blooms small, profuse, fine cinnamon odor; leaves finely heart shaped; produces numerous bulblets at the axils of the leaves which are planted to renew the crop; tuber 2 to 3 ft. long and 2 to 3 in. in diameter, white, brittle, mucilaginous; of the quality and flavor of boiled rice; can remain in the ground for several years, increasing in size. — *Red Bermuda.* Old, and extensively grown; root long, tapering, and of good quality; requires deep, free soil. — *Red Spanish.* Pale red; root small, but good; an old variety, now often sold as *Red Nansemond.* — *West Indian Yam.* A type of the white sorts; has a long root of fair quality; stands drouth well, but requires deep culture; in wet seasons is apt to be boggy. The *Yellow Nansemond, Early Peabody,* and *Southern Queen* are also profitable varieties.

SPECIAL CROPS.

BEVERAGE & STIMULANT PLANTS.

COFFEE.—These plants can be grown in but few of the most southern places in the United States; in Mexico and South America they do well. The soil must be kept moist by means of small artificial canals. It is raised from seed in nurseries, and transplanted when about 6 months old. Plant the trees closely together, so that the thick foliage shelters their roots from the hot rays of the sun; a dry climate produces a better flavored bean than a moist; rocky ground, with rich, decomposed mold, agrees with it best. Place the plants 8 ft. apart, in holes 10 or 12 in. deep. First, clear the land thoroughly; make the soil as friable as possible; divide into beds with narrow paths between; put in the seed row by row; leave the holes

open for some time; when pulled up, throw the plants with crooked roots away; trim the roots with a sharp knife, then press down firmly in the hole; when plants are free from suckers and are 12 or 18 months old, begin tapping; regular pruning and scarching are necessary; no branch should be allowed to bear more than 2, or at the most 3 crops; then remove it to make room for a fresh one. Manures, consisting of bone dust, poonac, guano, lime, salts, wood ashes, burnt clay, pulp and cattle manure, are the best. The next thing is the picking; have the pickers provided with a gunny bag, holding 2 to 3 bus., and similar sacks fastened round their waist; into these the berries should be first put, and then into the larger vessels; the fruit should be gathered when resembling ripe cherries. After being gathered, they should be measured and thrown into a loft above the pulper in a heap; submit it to first process of machinery, the pulper, 24 hours after; let them remain 1 day and night for the process of fermentation; then wash off the mucilaginous matter; in 1 hour remove for the curing; spread out thinly and expose to the sun; in 8 hours it is ready for housing; milling is the next process, by machinery; the parchment and silver skin is removed by means of the friction of a large roller passing over the produce in a wooden trough; now submit it to the fanner; pass it through 2 or 3 sieves, when it comes away perfectly clean. Varieties: *Mocha, Java, Ceylon, Bourbon, Martinique, Rio,* and *Maracaibo.*

HOPS.—The soils most favorable are clays, and strong, deep loams, with a dry and friable subsoil. In preparing, destroy all weeds and have the ground well pulverized. The ridges should also be made level, and dung liberally applied. The most effectual preparation is trenching. Plant generally in rows, making the hills 6 ft. distant, giving a free circulation of air, and admitting the sun's rays. Plant in February or March; but if bedded plants, or those nursed for one summer in a garden, are used, by planting in autumn, some produce may be had the succeeding year. When root sets are used, October is the right time. The cuttings are procured from the old stools, and each should have 2 joints or eyes; from the one which is placed in the ground springs the root, and from the other the bind. Use the most healthy and strong binds, each being cut to the length of 5 or 6 in. Those to be nursed are planted in rows 1 ft. apart and 6 in. asunder, in a garden, and the others at once where they are to remain. In commencing picking, gather those first that are ripe, and not those that are largest. The certain indication of picking time is when the lupulin, or small globules of the bright yellow resin, are completely formed in the head of the hop, at the bottom of the leaves, and the leaves are readily rubbed from the stem. The hops should be picked clean, without leaves or stems, and, if possible, without dew on them; nor pressed too close, nor put in too large quantities, before going on the kiln, or they will heat. To dry hops, place them as they ripen in the drying room until a depth of 1½ or 2 ft. is obtained; then start the fire and open all the air holes; keep the temperature at about 180°; when the second fire is built, place some sulphur upon a pan of coals to bleach the hops. It will take from 8 to 10 hours to dry a kiln. When the stems break in bending, the hops are sufficiently dry. Let the fire go down and the kiln cool for 2 hours before throwing open the doors. The patent kiln is a great improvement upon this method. The *English Cluster* and *Grape* hops succeed best in this country, although there are several other varieties grown.

TEA.—There are a number of places in the Southern States in which the tea plant has been tried with a fair show of success, and its culture may yet be established in the U. S. The tea-plant delights to grow in valleys, at the foot of hills, and upon the banks of streams, where it has the benefit of a southern exposure. The soil best adapted to it is a rich, porous loam, containing a considerable admixture of vegetable mold; and the land must be thoroughly drained. The seeds are gathered in October, packed in sand for preservation during the winter, and in spring sown in rows, distant about 4 ft. from each other. From 3 to 5 seeds are dropped in each place, at intervals of 3 ft. along the rows. With the exception of stirring the earth, and eradicating the weeds, the plants remain undisturbed during the first 2 or 3 years, until they are well established, and putting forth strong and vigorous shoots. On properly managed tea plantations, a regular succession is always kept up, so that the failure of old plants is compensated by the constant maturing of an equal number of new. Plucking the leaves should not be commenced until it is in a vigorous condition. When the plants are in their third year, the first crop is usually gathered; and they continue to yield until they are 10 or 12 years old. The best time for gathering tea is while the leaves are small, young and juicy; and the first gathering should commence about the close of February, when the leaves are young and unexpanded; the second about the beginning of April; and the third during the month of June. Leaves intended for green tea are thinly spread out on trays, where they remain for 1 or 2 hours, in order that the superfluous moisture may be evaporated, when they are thrown into the roasting-pans, placed over brisk wood fires. In these pans they are rapidly moved about and shaken up by the workmen until they become quite flaccid and moist, and give off considerable vapor. After remaining in the pans 4 or 5 minutes, transfer them to the rolling table; take up as many as can be pressed together with the hands; work them up into the form of a ball and roll them upon the table until they are greatly compressed; continue this until all the leaves are used; then shake them out upon flat trays; let them remain thus for a few minutes, then again throw them into a pan; place them over a slow but steady fire and keep them in rapid motion with the fingers. In about 1 hour the leaves are well dried, and exhibit a dull green color, which subsequently becomes brighter. When a sufficient quantity of leaves have been thus treated, they are winnowed through sieves of different sizes, by which sev-

eral varieties of tea are made, according to size, and the whole cleansed from dust and other impurities. During this operation the coarse teas are once reheated, and the finer qualities 3 or 4 times, by which the leaves acquire a dull bluish-green color. The leaves which are to be manufactured into black tea are first heated and manipulated as above described; after which they are transferred to a tubular-shaped basket, somewhat resembling a dice-box, and containing a sieve. This apparatus is placed over a charcoal fire, where it remains but a few minutes, when the leaves are taken out, and again rolled; this operation being repeated a second, and sometimes a third time. When all the leaves have thus been treated, they are replaced in the baskets in bulk, and set over a slow fire, and, being covered over with a flat basket, are allowed to remain thus until quite dry; being carefully watched, however, and occasionally stirred, so as to expose them equally to the heat. A black color is thus produced, which subsequently improves. The other processes of sorting, sifting and reheating are similar to those used with the green teas. Teas are classified under 3 heads, *Green*, *Black* and *Scented*. The principal green teas are *Gunpowder*, *Hyson*, *Young Hyson*, *Twankay* or *Imperial Hyson*, *Japan* and *Java*, colored and uncolored. The principal black teas are *Congou*, *Moning and Kaisow*, *Souchong*, *Oolong*. *Orange*, *Pekoe*, *Canton and Foo Choo*, and *Caper*, and *Imperial* tea from Java. Scented teas have a foreign flavor and odor imparted to them by being placed during the process of manufacture with certain aromatic flowers. The blossoms of the sweet-scented olive are extensively used for this purpose, and impart to the tea a very fragrant and delicate scent. They are never used alone, usually being mixed with a variety of either green or black tea.

TOBACCO.—A dry, warm, deep, rich, sandy loam, containing lime, is the best soil. The land must be protected from winds and well drained. This plant is never raised from seed planted in the field where the crop is to grow, but from transplanting. Seed-beds for raising it are generally prepared by burning a brush-heap in a warm, sunny place, any time during February or March. Rake the brands out, leaving the ashes on the ground, then dig the soil 5 or 6 in. deep; rake smooth, lay off into beds 3 ft wide, and it is ready for sowing. Mix a tablespoonful of the seed with ½ pt. dry ashes, and scatter evenly over the bed. This amount will sow a bed 25 ft. square, and raise plants enough for 5 or 6 acres. Do not rake in the seed, but roll or pack the bed pretty solidly; cover it with brush or straw until spring opens, when it should be removed. The plants will soon after start, and in from 4 to 6 weeks be ready to transplant. Keep the weeds out, and if necessary water occasionally. When the largest leaves are 3 or 4 in. long, if the weather is warm, it is time to place in the field. Transplanting is done very much like cabbages and tomatoes. The hills should be about 3 ft. apart, 1 plant to the hill, and flat. Before transplanting, plow from 8 to 12 in. deep; then harrow until the surface is perfectly pulverized. The soil must be enriched with guano, or any kind of manure thoroughly incorporated. Lay off the field in rows 5 ft. 4 in. each way with a shovel plow. A small hill, at the crossing of each furrow, should be made, say 2 or 3 hocfuls of loose soil, to which give a sharp pat with the hoe in order to better retain the moisture after the plant is set. The after culture consists in giving the tobacco 2 hoeings. The first is performed while the plants are small, or as soon as they have commenced growing nicely, and consists in taking away a thin layer of the surface soil between and around the plants, and substituting mellow soil from between the rows; the second hoeing is done about 2 weeks later. Priming is pulling off the leaves next the ground, which, to the number of 4 or 5, have no value. A good rule is to prime 6 in. and top to 8 leaves; if the land is poor, the plant backward, the season advanced, and frost apprehended, the priming should not be carried higher than 4 in. If the soil is unusually rich, and there is danger that the top will come to the ground, then the priming must rise in proportion. *White Burley* requires the removal of but 2 or 3 leaves. Topping is pinching out the bud of the plant, in order to cause it to spread and mature, and also to prevent it running to seed; it should be postponed as long as the circumstances will allow, so as to top as much of the crop at one time as possible. A week after the plant has been topped, sprouts, or suckers, will start from the stalk at the base of every leaf. These must be pinched off, or they will try to produce seed, spoiling the growth of the plant. Keep them pinched off. This process has to be done 3 or 4 times before the plant's efforts to produce seed is finally overcome. Priming, topping and suckering should not be done during a rain, or when the plant is covered with dew, for rust invariably results, injuring the crop. Tobacco is ready to be cut when the leaves held up to the sun show yellowish, reddish, or brownish spots, feel sticky, and will break off short and clean when bent. It is usually cut with a hatchet, severing the stalks at the ground. Lay the stalks smoothly upon the ground and leave them to wilt until the leaves can be handled without tearing. Do not leave the plants out between 11 A. M. and 2 P. M.; load upon a wagon and drive to the tobacco house as soon as possible. Another method of gathering is to have sticks, 4 ft. long, and 4 in. wide; with a string tie 2 stalks together and hang them over the board; when 1 board is full, hang it in the tobacco house. Spearing is very frequently practiced; the laths are made shorter and narrower, and sharpened at once end and thrust through the stem at a short piece from the end. This method aids the drying out of the stem and saves tying. Principal varieties: *White Burley*. The most profitable filler and cutter. — *Sweet Oronoko* and *Flanigan*. Two of the best old-style bright fillers. — *Hester*, *Hyco* and *Yellow Oronoko*. The best varieties for yellow wrappers. — *Yellow Pryor* and *Gooch*. Good manufacturing varieties. — *Medley Pryor*. A good, dark, heavy variety.

Plants Used in the Arts.

CASTOR OIL PLANT.—The best land for the growth of the castor oil plant, is a light, sandy, loamy soil, with a substratum of clay. Almost any soil that will produce Indian corn will answer. The ground should be put in condition for the seed as for other crops. One thorough plowing, and 3 or 4 harrowings, with a heavy harrow, will be a sufficient preparation; full plowing is desirable, as it more fully exposes the particles of the soil to the influence of the frosts and the atmosphere, thereby pulverizing it and preparing it better for the seed. Lay off the ground in rows 5 or 6 ft. apart each way; except that between every 6th and 7th row, a distance of 8 ft. between the rows is left one way to admit a horse and wagon or slide to pass to take the beans when gathered. Hot water, somewhat below the boiling point, should be poured on the seed, and they should remain in this water 24 hours. The temperature of the water will, of course, be reduced to the temperature of the atmosphere. Applying the hot water once will be sufficient. If planted without this preparation, they are a great while in germinating, many of them not making their appearance for 3 or 4 weeks. Good, sound, plump seed should be selected; ½ bus. will plant 10 acres; 8 or 10 seeds should be dropped in each hill; when the plants are 1 ft. high, thin to 1 in a hill. Care should be taken to have the plants clean until 2 ft. high; they will then be able to take care of themselves, and will grow rapidly. After heavy rains, break up the crust between the rows and loosen the soil, to derive a greater benefit from the atmosphere. When the pods begin to turn brown, it is time to harvest castor oil beans. Pick 3 rows on each side of the wagon, the wagon running over 1 row; cut the pods from the stock with a knife. It is necessary to pick these about twice a week when the weather is dry and warm, or they will waste in the field. The picking season lasts 6 or 8 weeks. The pods are taken to a yard with a clean-swept surface and a tight board fence around it, and spread about; as they ripen and burst and the beans fly out, these are caught by the board fence and prevented from being lost. When the pods are emptied, they are raked up, and others are gathered and treated in the same way, until all are ripe. Do not allow the beans, when drying, to get wet; an open shed is best; if you have no shed, when the weather is threatening, rake into a heap, and cover with a tarpaulin or boards. They should be well fanned and winnowed before being sacked for market. The oil is procured by 2 methods, expression and decoction. 1. *Expression.* The seeds are first slightly heated, and subsequently subjected to powerful pressure under a hydraulic press, when a thick, whitish oil exudes, which is boiled for some time in a large quantity of water, until it dissolves out the mucilage and coagulates the albumen. The clean oil is then removed, and boiled with a very small quantity of water, to drive off the acrid principle. 2. *Decoction.* The seeds are bruised first, and then boiled in water until the oil rises to the surface, when it is skimmed off, and again boiled to remove the acrid principle. This oil is usually of a darker color than the first. Castor oil is used for medicinal purposes; for lubricating larger classes of machinery; for mixing with other oils; for burning purposes; as an excellent oil for the hair, and in mixing with paints.

COLZA.—Succeeds best on a rich, light soil, well manured and carefully worked. It flourishes in soils of a slightly clayey nature, if they are light in texture. Spring colza must be sown during the latter part of May, in drills, or broadcast. Winter colza is sown in 3 ways, broadcast, in rows, and in beds for subsequent transplantation. Drill barrows are used for sowing the seed in rows, which are laid off at a distance of 18 in. from each other—thus admitting of the use of a cultivator for clearing out the weeds. The period of sowing is generally from the 15th of July to the 15th of August, and about 6 lbs. of seed are used to the acre, when sown broadcast, but only about 3 lbs. when planted in drills; the seeds being dropped about 1 in. apart in the direction of the rows. If planted in rows, the cultivator is run through them in the month of March, to clean out the weeds, and loosen the soil; after which they require no farther attention until harvest. Winter colza matures about the beginning of July, and, as the seeds are apt to shed, it is necessary to cut the plants when the seed pods begin to turn yellow and become transparent, at which time the seeds, though still tender, are of a dark brown color, and will ripen in the stack or mow. When over-ripe, the plants are cut only in the morning and evening, while the dew is on them. If the crop is a heavy one, the colza, immediately after being bound in sheaves, is stacked in the field where grown, in cone-shaped stacks, so constructed as to exclude rain, where it remains until the grain has fully matured, which is generally in 8 or 10 days. The fermentation which takes place in the stacks, gives the grain a fine color, and adds to its quality. A small crop is taken at once into the barn, and threshed; but large crops are sometimes trodden out in the field by the feet of horses, the ground being covered with stout hempen cloth. If the seed is kept in bulk after it is threshed, it should frequently be turned and stirred to prevent it from heating, to which it is subject. As it keeps better when mixed with the chaff, it should only be cleaned when about to to be sold or pressed. To procure the oil, put the seed in bags and submit it to the pressure of a powerful press. The refuse is called oil-cake. The oil is used to burn in lamps, as well as for many other useful purposes. The cake remaining after the extraction of the oil, forms an excellent article of food for cattle, and is sometimes used as a manure.

INDIGO.—Indigo thrives best in a free, rich soil, and in a warm situation, frequently refreshed with moisture. In the West Indies it may be grown on comparatively poor, dry soils, but to most advantage in those that are fertile. In the Southern States, the plant requires a good, rich, deep soil. After the ground has been thoroughly plowed and harrowed, the seeds may be sown with a drill, in rows, distant from each other about 12 or 14 in. As the plants shoot up,

they must be frequently weeded, and carefully tended until they spread sufficiently to cover the ground; when cultivated in great quantities, the seeds are merely strewn rather thickly in little shallow pits, hoed up at a distance of 6 or 7 in. apart, and immediately covered with earth. Plants thus raised, thrive better than those sown in drills, but require more care in weeding; 4 bus. of seed will sow 20 acres. From rich land the yield in 12 months will average 500 lbs. of indigo to the acre; if kept free from weeds, the plant will yield 3 or 4 crops each year, as it rattoons, or sends up new shoots after each cutting. It must be replanted every season. They arrive at full perfection in 2 or 3 months. When in full blossom and the lower leaves begin to dry, they are ready to cut; while the morning dew is still on them, cut them off with a reaping hook a few inches from the root and tie up in bundles. After cutting, they are immersed in vats, where they remain until macerated. The liquor is then drawn off into another vat, in which it is beat until the fecula separates, when the latter is let off into a third vat, and allowed to stand for some time; it is then strained through cloth bags, and afterwards evaporated to dryness in shallow wooden boxes, placed in a shady situation. Before becoming quite hard, it is cut into square pieces, and packed in cases for shipment. Fermentation is not essential to its extraction, as a mere infusion of the plant in hot water deposits indigo by standing in the air. The only solvent of pure indigo is sulphuric acid, with which it forms a deep blue pasty mass, soluble in water, and largely used in dyeing. For the manufacture of indigo on a small scale, ordinary barrels will supply the place of vats; and holes bored in them at regular intervals from top to bottom will serve to draw the liquor off as required. The coloring matter of indigo is largely used in manufactures, principally for dyeing woolen and cotton fabrics, and for coloring morocco. Varieties: *Wild*, *Guatemala*, and *French*.

MADDER.—Madder needs a rich, deep, loamy soil, containing a considerable infusion of lime and vegetable matter. It will grow in light soils, if they are fertile and of sufficient depth, but they must be well manured. The sets are obtained from the surface roots of the old plants, or from seeds sown in the previous year, and transplanted in June. The selection of sets from the growing crop should be made when it is dug in the fall; those which grow horizontally, and have numerous eyes, are regarded as the best, and should be separated from the lower roots, and buried in the cellar during the winter; previous to planting, they should be cut into pieces containing from 2 to 5 eyes each. Plow the land deep in September and in October; let it lie in ridges during the winter to be acted on by the frost; when the ground is dry and warm in spring, plow again deeply and harrow well; strike the land off into ridges with a plow, making them 3 ft. wide, with water-furrows 4 ft. in width between. If the ground is moist, raise the ridges 10 or 12 in. above the surface; but if dry, 6 or 8 in.; then level and shape the ridges with a harrow. Plant in May, or earlier if there is no danger of frost. Stretch a line lengthwise the beds; with a hoe, make holes 6 in. from the edge, along both margins of the beds, and in the middle, leaving a space of 12 in. between each hole; insert the sets and cover from 2 to 4 in. deep with fine earth, and press it down with the foot. As soon as the plants appear above the ground, carefully hoe and keep free from weeds; when 10 or 12 in. high, cover the tops, except the extreme ends, with fine mold taken from the alleys; bend them outward and inward, so as so fill all vacant spaces, and repeat as often as the plants become long enough, in order to assist the plants to form new roots. The 2nd year the beds must be freed from weeds and the plants covered as before. Keep the edges of the beds as high as the centres, so the rains will not run off and the plants suffer from drought. The 3rd and 4th years little attention is required. Plow out the roots during September of the 3rd year in warm latitudes, and during September of the 4th year in colder climates. Remove the top of the plants with a sharp edged shovel, then with a plow turn a furrow outward, beam deep, around the edge of each bed; plow another furrow as before inside the last, and proceed until the beds have all been turned over. To cleanse the roots take them to a stream or pump; put ½ bus. at a time into a large sieve and wash well; then lay them on slanting platforms to dry. After the 3rd day's drying protect from dew and rain by covering with boards. In 5 or 6 days they will be sufficiently dry. Or they may be dried in kilns like hops. As soon as the roots are thoroughly dried, they may be kroken in a cast-iron bark-mill, and then cleansed by a fanning machine, after which they may be ground fine in a grist-mill, and packed in barrels like flour. If not packed immediately they gather dampness from the atmosphere, which prevents them from grinding freely. The addition of a little carbonate of lime while grinding improves the color considerably. The best coloring matter is prepared from the heart of the root, and the older roots are preferable to the young ones. Madder is a principal ingredient in nearly all the dyes used by calico printers; and for woolen goods it furnishes blue, black, purple, red, buff, orange, olive, yellow, brown, and many other colors.

RAPE.—The soil best suited to rape, is a rich, deep, dry soil. It is cultivated in the same manner as turnips, but requires less culture and manure. Sow the seed in May, in drills or broadcast. If sown broadcast, 4 qts. will be required; but if sown in drills, ½ that quantity will be sufficient. Keep the plants free from weeds and the soil in good condition. The seed ripens in July, and the plant must be harvested with great care to prevent loss of seed from handling. After threshing, the seed should be divided into small parcels and frequently turned. Oil is extracted from the seed by pressure and grinding, and when purified burns with a brilliant flame. The cake left, after the oil is expressed, furnishes a nourishing food for cattle. The seeds are used for the food of domesticated birds. When they are used as a green

food for cattle, its leaves are unsurpassed.

SAFFLOWER, or BASTARD SAFFRON.—Cultivated in various parts of Europe. Thrives equally well in a light soil, or in a rich, friable, black earth. Sow the seed in rows or in patches, 2 ft. distant each way in spring; after the plants make their appearance above the ground, thin to 1 ft. apart; stir the soil well and keep free from weeds until the flowers begin to expand. The petals of the flowerets are cut off as the flowers expand, and are dried. This operation is performed in the early part of each day until October, when the plants are pulled up, sheaved, shocked and threshed, to obtain the seeds. Some beautiful rose and scarlet colors are obtained from this plant, to be used in dyeing. Rouge is also obtained from safflower. The seeds furnish an oil, which is used by painters and in pharmacy.

SUMAC.—The soil best adapted to its growth possesses little clay, an abundance of lime, and a moderate proportion of silica; is naturally mellow, warm and dry after a rain. A hilly place is preferable to a plain, and a southern aspect to a northern one. It also requires to be cultivated alone and in the open sun. It is propagated from sprouts that come up around the mature shrubs. The best sprouts are those from shrubs in a good state of growth, and from regions where they prosper most. Plant them 26 to 27½ in. apart, in soil prepared by spading holes 26 to 30 in. square and 8 in. deep, or they may be planted in trenches. Begin at the head of the lines and fill in the soil upon the roots; work the spaces between so as to bring up the soil in parallel lines on the plantation. When finished, cut off plants to the height of 5 or 6 in. with a large cutting hook, taking care to put the foot down by the side of the stalk to prevent it from being pulled up. Keep the soil soft and porous around the plants and keep free from weeds. The hoe should be used where the culture is not deep. It gives a crop the 2nd year after setting out, and regularly thereafter. For the purpose of tanning white and delicately colored leather, collections are made in June; while for tanning dark colored leathers, and for dyeing and calico printing in dark colors, where the slightly yellow color will have no injurious effect, the collections are made in July. The plant must be cut in clear weather, and spread on a floor in such a manner as to allow it to dry rapidly; for, when fermentation begins in a small portion of it, the whole mass soon becomes seriously impaired. When dry, the plants may be cut up by a straw cutter, and put into sacks for market, or be ground fine in a bark mill.

SUNFLOWER.—The soil for profitable cultivation should be rich and sandy, but it will grow in almost any soil. Sow the seeds early in the spring in rows, leaving 2 ft. between each row. After the plants have attained the height of 3 ft. they need but little cultivation. Where the plants stand some time after the seeds ripen they will be self-sowing. Each flower will furnish about a gill of seed. The seeds, when fed in moderate quantities, are excellent for horses and poultry. The oil extracted from the seed is excellent for table use, being equal to olive oil for burning in lamps, and for the manufacture of soaps. The green leaves, dried and powdered, make excellent fodder for milch cows, when mixed with bran. The seed receptacles are made into blotting paper, and the inner part of the stalk into fine writing paper; the woody portions are consumed as fuel, and from the resulting ash valuable potash is obtained. The plant or flowers are remarkable for absorbing malarial poison, and should be planted near the house in all sections where malarial diseases prevail. Varieties: *Californian.* A handsome variety, bearing large, double flowers of a rich orange color.—*Green Centered.* A very double variety; the plant grows to a height of 4 ft.—*Helianthus Argophyllus.* A very pretty double sort, bearing a bright yellow flower of fine size with silky white leaves. There are other varieties which bear globular formed flowers of a bright saffron color.

TEASEL.—Requires a deep, rich, moist, loamy soil. Sow the seed in spring; but the plants are not available for use until the 2d year. To procure an annual crop, plant the seed in 2 rows, 16 in. apart, leaving a space of 12 in. between the plants in the row; at the distance of 4 ft. plant 2 more rows in the same manner, and so on over the field; 1 pk. of seed will be sufficient for an acre. Keep the plants free from weeds. In Belgium they are sown in spring; in August or September they are transplanted, and 12 months after this the first crop is gathered. Teasel is of a greenish yellow color when ripe. Harvesting is generally done at 3 different times, with intervals of 10 days each. The operator, whose hands are covered with a pair of stout gloves, is furnished with a short-bladed knife, having a string attached to the handle, which is passed around his wrist. He seizes the ripe heads, cuts them off with about 9 in. of the stem, and ties them up in handfuls with a perfectly ripened stem. In the evening they are placed in a dry shed, and, when the weather is clear, they are exposed to the heat of the sun until they become perfectly dry; they are then sorted for market. The burr must be 1½ in. long to be marketable. The burrs are used to raise the nap on woolen cloth. The seed is useful for feeding poultry.

WELD.—Fertile loams produce the best crops, but it will grow on a variety of soils. Plow and harrow the soil well, then sow the seed, either broadcast or in drills, in May, or later, and cover lightly; 2 qts. to 1 gal. are sown to the acre. If sown in drills, make the drills 12 in. apart, and as soon as the plants make their appearance above the ground, thin out until they are 6 in. from each other. Keep the plants free from weeds and the ground well stirred. The plants flower in July of the 2d year. When the bloom has been produced the whole length of the stems, and the plants are just beginning to turn of a light or yellowish color, they are pulled up by the roots in small handfuls, which are tied round with a wisp of straw or one of the stalks, and set upright in stacks of 4 or 5 bundles each, to dry; when sufficiently dry, which is usually in about a fortnight, they are bound up into larger bundles, ready for market. Used in dyeing.

WOAD.—Deep, rich, mellow soils produce the best crops, but a good crop may be obtained upon alluvial soils. Plow the ground deeply in the fall; replow in spring and cross harrow. Sow the seed broadcast, in March; but a better method is to plant in rows, allowing sufficient space to admit of a cultivator. When sown in rows, 2 lbs. are sufficient for an acre, but if sown broadcast, 5 or 6 lbs. are required. Steep the seed some time before sowing. Keep the plants free from weeds, thin and hoe. If sown early, the leaves of the plants are ready for harvesting in July, which is done as soon as the leaves are full grown, and while they retain their perfect green color. The leaves are collected in baskets, which are proportioned in number to the extent of the crop. They are picked off by hand, being grasped firmly, and separated from the stem by a sudden twist. In favorable seasons the plants often yield 2 or 3 crops of leaves. The after croppings should be kept from the others, as their mixture with the first would injure the value of the crop. To save the seeds, the leaves are allowed to remain on some of the plants during the second year; when it ripens in July or August, it is treated like turnip seed. The leaves are dried, ground to a paste, and after being left in heaps for about a fortnight, the crust formed on the outside of the pressed heaps is rubbed and mixed with the interior portions, and then formed into oval balls which are pressed into wooden molds. When required for the purpose of dyeing, the balls are broken into fragments and allowed to ferment, when a dense fetid fume arises. An infusion may be obtained by steeping the leaves in water, which will impart a green dye, and this green will change to blue on exposure to the air. Woad is used for what is termed "sadkening."

Saccharine Plants & Products

REMARKS.—The principal varieties are cane and beet root. The only difference existing between beet root and cane sugars is in the difference of the size of the crystals, those of the beet root being the larger.

BEET-ROOT.—The soil should be deep, mellow, free from stones, and abundantly rich. A deep, sandy loam, with plenty of vegetable matter, produces a profitable crop. A strong clay is not suitable, neither is a soil that is low and naturally wet and cold. Plant in rows at a distance of 2 ft., 6 in., from each other, and at intervals of 12 in. in the rows. Deep plowing and pulverization of the soil are essential to the full development of the root. Put the seed in the ground during March or April, and carefully tend the plants during the early stages of their growth, clearing out all weeds and thinning the plants where necessary. Moist weather is the most suitable for performing these operations, and a cultivator may be used with advantage. An application of phosphoric acid in the spring materially increases the yield of sugar. Harvesting is done largely with the plow. The beets should not be bruised. They should be thoroughly dry before storing, and are profitable for sugar purposes only when grown within easy distance of a factory. Of all the varieties the *White Silesian* is the best known. It is pear-shaped, penetrates about 12 in. into the ground, and throws out a great many rootlets.

BEET-ROOT SUGAR, Manufacture of. — The first step is to free the roots from foreign matters. For this purpose, they are thrown into a rapid current in a stoning machine. The stones are then collected by the machine and fall to the bottom. The roots are taken up by the current and tossed out of the machine. The roots, thus freed from all stones, are passed through a washing machine. The next step is the extraction of the juice, and this may be done either by rasping and pressing or by maceration. Rasping is accomplished by means of a machine, consisting of a revolving drum, armed with teeth. The roots are introduced by a hopper and are forced against the saw-like teeth. Water is injected at the same time, and the pulp falls into a receptacle below. The pulp is placed in woolen sacks, and these are put in the press with their mouths doubled under, and are separated by iron plates, and the pile is put on a movable plate of a powerful hydraulic press, which expresses 50 per cent. The next step to be taken, is maceration. The pulp is introduced into a press and the remaining juice extracted by an agitator. This must be kept in regular motion, not too fast. The juice thus obtained is passed into a vessel whose strainers detain the ligneous matters held by the juice. The juice is then clarified by simply boiling with the addition of a little lime. Raise the juice to a temperature of 122° to 167° Fahr.; then draw off the juice clear, press the scum, and collect the juice in a boiler, and treat with carbonic acid; produce carbonic acid gas by burning charcoal in a small furnace and injecting it into the mass. The next thing to be done, is the concentration of the thin juice; boil the juice until it becomes thick; then pass it into a cistern, where it must be heated to the boiling point; then filter through animal charcoal; remove the matter obtained by boiling in vacuo. The sticky mass obtained from the vacuum pan must now be crystallized. This is performed by centrifugal machines. The operations are now the same as in making sugar from the canes. (See *Sugar Cane Juice, Concentration and Defecation of, etc.*)

GLUCOSE.—This is sugar manufactured from any carbo-hydrates, starch, dextrine, cellulose, etc., but is generally prepared from corn starch, although potatoes are used largely and economically, especially in a productive year. 1. To manufacture it from corn, soak the shelled corn in hot water for a period ranging from 1½ to 5 days; if it is not to be fermented, the water is changed when it begins to sour; it is then ground with the ordinary burr stones, and with a stream of water running into the hopper with the corn. The mixture is then run on fine, vibratory sieves, with more water added; the finer, starchy part of the corn is washed through the sieves, while the hull, gluten and woody fibre go over the tail of the sieves, and after the water is squeezed from it by rollers is sold for

feed. The portion that went through the sieves is run into tanks and settled; the water is then drawn off, and the sediment again mixed with clean water and treated with caustic soda, to separate any trace of gluten from the starchy matter. It is next run into long, metal-lined troughs or vats; these descend slightly, and most of the water runs off at the lower end, leaving the sediment at the bottom. The sediment is left to settle and dry somewhat, and is then shoveled out, and known as green starch, about 50 per cent of it being water. It is now in a condition to be made either into starch, or into glucose. Water containing .01 of sulphuric acid is heated to the boiling point; a mixture of the starch and water is also heated and allowed to flow gradually into the water. After boiling this ½ hour, chalk is added, to neutralize the acid; the clear liquid is now drawn off and evaporated. The sediment forms the sugar. — 2. Moisten linen or cotton cloth, paper, or sawdust with concentrated sulphuric acid, and a gummy mass will be formed. After a few days dissolve this in a large quantity of water and boil 8 or 10 hours; add chalk, and proceed as if made from starch. — 3. Glucose from potatoes is made by a similar process as the above; the raw potato being grated into water and the feculn treated similarly to that of corn.

SUGAR CANE.—A perennial-rooted plant, attaining the height of from 6 to 12 ft., and surmounted by a terminal panicle, 1 to 3 ft. long, of a grayish color. A rich alluvial soil is best adapted to the sugar cane. It is a very exhausting crop, and the rich lands of Louisiana have become much exhausted by a continuous cultivation of it. It is propagated by cuttings. In Louisiana and the West Indies new canes are not planted every year; the roots retain their vitality for years, and continue to produce canes equally as good as those cut from the first planting. This system of culture is called "rattooning." In selecting plants from which to make cuttings, those with healthy, succulent tops should be taken instead of the hard, woody ones. In renewing a field, the canes are usually planted in rows, a space of 6 ft. in width being left between each row; make a series of holes in the ground in a direct line, in each of which place 2 joints of the cane and draw the earth loosely over them. With the exception of an occasional hoeing, the sugar cane requires little attention. To cut the canes seize them with the left hand, draw them forward, and with a single blow of the cane-knife, cut them off close to the root; then strip off their leaves, and divide them into 2 or 3 pieces, and they are ready for the mill. Varieties: *Otaheite*, and *Brazilian* or *Creole* grow in the West Indies; the *Bourbon*, *Red Ribbon*, *Blue Ribbon*, *Yellow Ribbon* or *Java*, *Green Ribbon*, and *Gray* are grown in the Southern States.

SUGAR CANE JUICE, Concentration and Defecation of, Etc.—To obtain the juice, the canes are crushed between powerful rollers. The juice flows into a pan placed beneath the mill, and it is then conveyed to the clarifiers, or pumped up into a receiver, and distributed where required. The canes, after being properly cured, are useful for fuel. The strength of the juice is tested by a saccharometer, which is plunged into it and the height at which it floats carefully noted. The defecation of the juice is conducted in pans, placed over flues so arranged that the heat can be shut off from 1 of the pans without interfering with the others. When the receiving-tank is full, the juice is conveyed into the defecating pans by a wooden gutter, and, when slightly warm, a sufficient amount of cream of lime is added to neutralize the free acid, and to assist in coagulating the vegetable albumen contained in the solution. When the heat is increased all impurities rise to the surface, leaving the clear juice below. On the appearance of ebullition the dampers are closed, and the juice allowed to stand about 20 minutes, when it is drawn off from the bottom, and conveyed to the first clarifier. The process of clarifying is conducted in 2 iron pans, lined with sheet copper, which are placed much nearer the fire, but higher up than the defecators. They are both in a line with the flue; but the first, which is the largest, and most remote from the fire, is placed about 2 in. lower down than the second. Both pans are surrounded by a gutter, and whatever overflows from the second during ebullition, finds its way back into the first, and all the impurities which escaped removal in the defecators, and which are skimmed from the boiling liquid in the clarifier, pass through an opening at one side of the gutter into a scum-kettle, placed alongside of the train. As soon as it settles, all the good syrup is again returned to the first clarifier by the aid of a pump, with which the scum-kettle is furnished. The juice, after being thoroughly purified, is conveyed to the evaporators, 2 in number, both surrounded by a copper curb, that around the smallest pan being the highest. This prevents the syrup from the first evaporator boiling over into the second, while at the same time it allows the overflow from the second to find its way back to the first. If sufficiently boiled to strike, the fire is withdrawn, and the syrup baled into a gutter, by which it is conveyed into the coolers, distant about 10 ft. from the second evaporator. The coolers are oblong troughs, usually about 10 ft. in length, 5 ft. in breadth, and 12 in. deep, made of 2-in. pine-boards. They are arranged in a double row, parallel with the train, and each has sufficient capacity for 3 "strikes," all of which are not run into 1 cooler consecutively, but into 3 coolers alternately, until that number are filled, when 3 more are brought into use. While cooling, the sugar is agitated with a small wooden rake, which is drawn through the mass once after each "strike." This promotes crystallization, and in a few hours the sugar sets or grains. A few days subsequently the sugar is dug out of the coolers, and carried in tubs to the purging-house, where it is emptied into hogsheads, the bottoms of which are perforated, to allow the molasses to drain away. When it enters the purging-house, it is a dark brown mass, containing about 40 per cent. of molasses; but, if the house be even moderately warm, this soon commences to drip into a tank placed beneath the open joists upon which

the hogsheads rest. As the sugar settles down the hogsheads are replenished, either with sugar which has already been purged, or with fresh material from the coolers. At the expiration of 1 month, or thereabouts, the hogsheads are headed up, and stored, or sent off to the place of shipment. Boiling by steam is practiced on many plantations, and has many advantages over the old process, though more costly.

SUGAR CANE, Chinese or Sorgo, and African or Imphee.—Sandy upland soil is best, black bottom soil is worst. New land yields good syrup. Land freshly manured gives poor syrup. Clay land gives good syrup, but not so large a yield. The soil, unless rich, should be well manured in the fall with vegetable or rotten stable manure. This is especially needed with clay lands. Plant in a ridge rather than a furrow; the seed should be soaked in warm water until an appearence of germination is perceived; let the rows run east and west; plant shallow and not thickly; if in rows, 4 ft. apart; if in drills, allow 4 to 6 in. between each seed; keep the ground free from weeds; the seed may be sown under glass, and planted in the open ground when about 1 mo. old. In sections where the cane is liable to frost in the fall, planting should be done early, as soon as the ground is thoroughly warm. As soon as the plant comes up, destroy the weeds and keep clean until ready for the plow. It is especially important to give the plant every assistance in the early stages of its growth, as it is a slow grower at first, and if left alone will be choked with weeds. As soon as the rows can be followed stir the soil about the hills. When large enough plow and cultivate same as corn. When about 30 in. high it may be turned out, as it is then able to take care of itself, and further plowing would only do damage by cutting the roots and injuring the stalks. The suckers should be pulled off, as they sap the strength of the cane. Cane should be cut when the seed is in the dough, and several days ahead of grinding, as it will be more free from impurities if cured a few days before going to mill. Top the cane by cutting off 1 or 2 joints, then cut and throw into windrows. If it is desired to strip the cane, it can be done now, by catching hold of the top end and drawing the stalks from the heaps. Bind the cane with 2 bands, having from 3 to 50 stalks in a bundle. It is believed by many that it is not necessary to strip the cane; unstripped cane yields more syrup and fuel than stripped. After a week or 10 days, if not wanted for immediate working up, the cane should be removed to shelter. The cane should never be left to be overtaken by frost before it is cut, or it will be seriously injured. When a severe frost is threatened the cane should be cut without stripping, and laid in windrows. The blades should not be stripped until the cane is wanted for grinding. By cutting before frost, and curing with blades on, the cane may be kept for a month, or longer, without injury. It should be protected from rain and frost as much as possible. The tops should be laid in piles convenient for gathering to dry, and may be left until the grinding is over. If not intended for use at once, cross pile the bundles, leaving suitable space for the circulation of air through the pile, or stand them up on ends, if by so doing it can be kept out of the dirt. The principal varieties of the Imphee are the *Liberian*, which has a deep red seed, the *Neeazana*, which has cream or wood colored seeds, and the *Oomseeana*, which has dark brown seed. The *Amber* is a variety of sugar cane which has the characteristics of the Sorgo and Imphee; grows quite tall; head not so open and branching as the sorgo. It receives its name from ripening early, and from the bright amber color which characterizes the syrup when properly made from it.

Sorgo, or Chinese Sugar Cane.

SUGAR CANE JUICE, Chinese and African, Concentration and Defecation of. Etc.—When the cane is to pass through the mill, let the butts enter first. Good work requires 3 rolls in the mill, that the mill be strong, and that the rolls run evenly and remain set in place. Immediately after the juice comes from the mill it must be freed from its surrounding impurities. Its quality will depend on the rapidity and skill with which this is done. The rough stuff can be disposed of mechanically by some such device as strainer wire, or coarse cloth, or straw filter, but the acids and other impurities held in solution can be freed only by chemical action and heat. The use of lime is the best method of neutralizing acids. Its application requires care and judgment. It must be pure and fresh, not used in its caustic state, but slacked frequently during the day, being reduced to the consistency of milk of lime. The exact quantity to be used depends entirely on the amount of acid in the juice and must be determined by an experienced eye, or tests with litmus paper. Next to lime, heat is the chief agent in defecation. Its effect depends upon its prompt application and proper distribution, as well as its withdrawal as required. On account of the rapidity with which the juice changes from exposure to the air, it is important that all the process of defecation should progress rapidly. In fact the defecation with lime and purification by heat should be combined, the juice running directly from the mill into the defecator. The lime is then added. There are 3 methods of concentrating or evaporating the sugar cane juice: 1st. By the direct application of fire only (as in kettles, common pans and the evaporator); 2d. By the use of both fire and steam (as in trains composed of fire evaporating pans, and steam defecating and finishing pans); 3d. By the employment of steam alone (as in the ordinary steam trains, or the steam trains with vacuum pan). While the steam train is complete in itself, a vacuum pan is often used, especially on the larger plantations, as an adjunct to it. In operations on a very large scale the use of steam for evaporating cane juice is preferable to

fire, as it allows perfect control of the heat, and is more expeditious. Through pipes the heating surface is immersed in the liquid, and it can not be injured by burning. It also economizes fuel and effects a great saving of labor. The steam train, as used in the most complete modern sugar works, consists of a series of vessels of different sizes, properly proportioned, and arranged in order, and all supplied within with steam heating pipes, connected by branches with a main pipe from the boiler. This places the successive operations of defecating, concentrating and finishing by steam, under the immediate and convenient control of the sugar-maker. The heat is readily increased or diminished or withdrawn from either vessel at pleasure. As sugar-making by a connected steam train is a continuous as well as rapid process, it is important that proper arrangement and proportions of all the parts be provided, including also the even and reliable working of the mill, so that the continuity of the operations may be harmoniously and effectively preserved to the end. The effectiveness of the steam train may be seriously impaired or totally destroyed by ignorant management, or improper proportions of vessels and pipes. In constructing a steam train, experience and skill are absolutely necessary. If the planter has an engine and boiler of sufficient capacity to run his mill and plenty of steam to spare, he can use steam profitably, either with steam pans entire, or with steam pans for defecating and finishing, and a fire evaporator for concentrating. In the practical operation of the latter plan, the juice is defecated by steam, then passes into an evaporator, where it is concentrated nearly to the sugar point, and then on to the *batterie*, where it is finished by steam. After a thorough defecation of the juice, and its rapid concentration to the sugar point, the next object is to secure crystallization. The liquid should be put into shallow coolers, and kept at a moderate warmth and even temperature. Nature will do the rest. After the sugar has crystallized in the coolers, all that remains to do is to separate it from the molasses. This may be done by draining. The best means is by the use of a centrifugal. This rapidly expels the molasses from the sugar by force, leaving the sugar dry and finished.

Textile Plants.

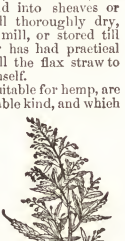
COTTON.—Clay loam and silicious soil, and a clay subsoil, are best for upland cotton. Sea Island cotton grows only on low, wet lands. Deep plowing and underdraining are necessary. Plowing should be done in January, February or March. Lay off rows 4 ft. apart with a shovel plow; double furrow, and put in fertilizers 8 in. deep; ridge with a long scooter, 5 in. wide, where the rows are to be planted; make the beds with a turning plow, and subsoil the furrows with the turn plow; split out the middle with a shallow plow; plant with a cotton seed sower and cover with a board or harrow. The seed should be sown in hills from 8 to 20 in. apart, 6 to 8 seeds to the hill. Planting is generally done after the last frost in spring; 2 to 5 bus. of seed will plant an acre. When the plants are 2 in. high, thin to 2 or 3 stalks in a hill; 10 days after the crop is hoed, or has a little dirt thrown around the plants with a plow; 2 weeks later it is again hoed and plowed, all grass and weeds being removed. In 2 or 3 weeks more, it is again hoed and plowed, after which there is nothing more to do. The bolls of cotton mature and open in July or August. Picking is generally done by the hand as soon as the pods are well open. After picking it is spread out on scaffolds to dry. When a seed pressed between the teeth will crack with some noise, it is sufficiently dry. It should be turned and stirred frequently. In cleansing, the first machine through which the cotton is passed is called a whipper, and consists of a cylinder 6 or 8 ft. in length, made of slats, reeds, or wire. One end is closed, and the other open. The centre of the cylinder is traversed by a shaft, intersected with rods reaching to within 1 in. of the sides. The cylinder is placed in an inclined position, and the cotton fed into it from a hopper resting upon the upper side, near the top, which is closed. The shaft being turned by a crank, the cotton, as it falls from the hopper, is whirled around by the rods until it issues from the lower end of the cylinder—any contained dirt, sand, or leaves having meanwhile escaped through the open sides of the whipper. The cotton is then carried to the gin-house, where the cotton wool is separated from the seed. Gins should not be run with too high speed. As high speed as 450 revolutions may be run without injury to the cotton. A machine should be attached to the gin-house to hull the seed and press out the oil. After ginning it is baled and is then ready for market. Varieties: *Green Seed* or *short staple*, known in commerce by the name of *Upland* cotton. — *Nankin* or *Yellow*. — *Sea Island*, known as *long staple*, from its fine, white, silky appearance, and long fibres. The *Vine Leaved*, *Hairy* and *Spotted-bark* are varieties classified by botanists.

FLAX.—The only soil suitable for flax is a rich, mellow and deep clayey or sandy loam, free from wet. In very dry sandy soils, river bottoms, and wet, low lands, flax will suffer from mildew. Soil that will raise a good crop of grain or potatoes will give a large crop of both seed and fibre, if sown to flax. Flax should not be grown on the same land oftener than once in five years. In the preparation of the soil it should be plowed deeply in the fall; then grub, harrow and roll until the field is in the best state of cultivation. The surface should be pulverized 3 or 4 in. deep. Seeds which are fresh and proper for sowing, should be smooth, slippery, bright, plump, and so heavy as to sink in water; they should also taste sweet, and, on being broken, should appear of a light yellowish green color, and oily. Sow the seed broadcast in April or May; the best time is after a rain when the soil

Flax.

has settled and is warm. Before sowing, soak the seed 2 or 3 hours in water, and then roll in land plaster. The quantity of seed sown will depend on the object in view in cultivating the plant. When the quality of the fibre is regarded rather than the quantity, thick sowing is advisable; but if it be intended to save the seed of the crop for the purpose of reproduction, it should be sown thin, in order that the plants may have room to throw out their shoots, and to have free access of air in the blossoming and filling seasons; 3 bus. of seed may be regarded as the proper quantity; but if fine fibre must be produced, an additional ½ bus. may be added; when the seed is regarded, 2 or 2½ bus. may be sufficient to the acre. Scatter the seed evenly, and cover with a brush harrow. If the ground is wet at seeding time, shallow covering will do; if dry, it will not. If weeds spring up, they should be cut off close to the ground, not pulled up, and be kept down until the flax is 10 or 12 in. high. When flax is grown for seed, cut when most of the bolls and lower parts of the stalks have turned yellow, and the seeds have turned slightly brown, and the lower leaves have dropped off. Be careful not to cut before ripe. Unripe seed can not be properly filled out and must fall short in weight. Use a smooth knife in your reaper. Cut only low enough to get all the bolls. When the seeds are intended to be saved for consumption on the farm, the best period of cutting is shortly after the plants have attained maturity with respect to the formation, but not to the full ripening of the seeds. When grown for fibre, pull by hand or cut very close to the ground. When pulled by the hand the plant should be grasped just below the top and jerked quickly, the different lengths being placed by themselves. When cutting is the method used, set it up as soon as cut in gavels. It may be handled the same as barley or buckwheat; but, better still, bind with the self-binder; shock the same as wheat. Flax cures very fast, and in good drying weather may be stacked the day after cutting. Build a good solid stack, always keeping full in the centre—heads in and butts out—and top off with prairie hay. Stacks must not be disturbed for two or three weeks, or more, until the flax is through the "sweat," which leaves the seed heavier and better. Threshing may be done with a threshing machine, by holding the head of the bundle against the cylinder, but not allowing it to go through the machine. Or by taking the bundle in both hands and whipping the heads upon a large stone. Watering or rotting is the separation of the fibres from the stem by steeping the flax in water, by which the softer part partially undergoes the putrefactive fermentation; the best water being that which is clear, soft, and in standing pools. The bunches of flax should be built in the pool in nearly an upright position, the root-ends being uppermost. They are kept under water by means of stones. When the flax is properly watered, it will sink in the pool, and the fibres will separate freely from the stalk. In warm weather, 8 or 10 days will sometimes be enough, and only a few more, in any case; but if the fibres adhere to the stem so as to be separated with difficulty, it must be continued in the water longer. When sufficiently watered, it is taken out of the pool, and when drained is taken to a grass field, and spread thinly over it in rows, lying on the grass not more than 8 or 10 days; when brittle, it is taken up and again bound into sheaves or bunches, and then left till thoroughly dry, when they are sent to the mill, or stored till wanted. Unless the farmer has had practical experience, it is better to sell the flax straw to the dealer than to rot it himself.

HEMP.—The soils most suitable for hemp, are those of a deep, black, vegetable kind, and which from their location, are slightly inclined to moisture. Mellow, rich, clayey soils do very well, and none answer better than old meadow land. Hemp may be raised on the same ground for successive years without degenerating and without exhausting the soil, especially if the shives are returned to the land in the form of manure. The ground should be plowed in time to receive the influence of frosts, and after a crop of grain; besides a deep plowing before winter, it should be plowed at least twice in the spring, so as to reduce the soil to a fine tilth, as it is important that it be thoroughly pulverized. To insure a good crop the seed must be fresh, which may be known by its being heavy and of a bright reddish color. The best seed is that of the previous year. Sow as soon as danger of a severe frost is past, and just before moist weather. When the object is to make a crop of hemp, the seeds are sown broadcast. The usual quantity is 1½ bus. to the acre. The seed should be plowed or harrowed in and the ground rolled afterwards. The seeds intended to reproduce seeds for the crop of the next year are sown in drills about 4 ft. apart. When they are grown sufficiently to distinguish between the male and female stalks, the former are pulled and thrown away, and the latter are thinned, leaving the stalks separated 7 or 8 in. from each other. The male plant alone blossoms, and, when agitated, throws off farina, a yellow dust or flour which colors the ground or any object with which it comes in contact. A few of the male plants should be left, scattered through the drill, until the farina is wholly discharged. Between the drills a plow is run sufficiently often to keep the ground free from weeds and grass, and between the stalks in each drill the hoe is used for the same object. Hemp should be cut as soon as the blossoms turn yellow and begin to drop their leaves. Cutting may be done with a cradle-scythe; if over 7 ft. with a brush-scythe. As cut, it should be laid on the ground evenly to cure, which will take 3 to 5 days. The seed plants are generally cut after the first hard frost, between the middle or last of September and the middle of October, and carried to a barn or stackyard, where the



Hemp.

seeds are easily detached by the common flail. After threshing, spread the seeds on a floor to cure and prevent their rotting before they are stored for spring use. The next process is rotting the stalks. There are 2 methods of rotting—dew rotting and water rotting. When dew rotted, the plants are usually spread down from the middle of October to the middle of December. Autumnal rotting is more apt to give the lint a dark and unsightly color than winter rotting. The best ground upon which to expose the plants is meadow or grass land. In a very wet and warm spell, 5 or 6 weeks may be long enough for the plants to remain on the ground. If the lint can be detached from the stalk easily, it is properly rotted. If the fibres remain on the ground too long, they lose some of their strength, though a few days longer than necessary, in cold weather, will do no injury. If they are taken up before the lint can be easily separated from the woody part of the stalk, it is harsh, and the process of breaking is difficult. Snow-rotting, that is, when the plants, being spread out, remain long enough to rot (which requires a greater length of time), bleaches the lint, improves the quality, and makes it nearly as valuable as when water rotted. After the operation of rotting is performed, the plants are again collected together, put in shocks or stacks, or under some covering. Breaking and dressing are best performed in February and March; and the best sort of weather is in frosty nights and clear, thawing days. The brake cannot be used advantageously in wet or moist weather.

INDIAN MALLOW. or ABUTILION AVIENCE.—A plant widely extended over the Southwestern States as a pestiferous weed, is taking an important position among textile plants, and gives promise of valuable results. Its culture is as simple as corn, and good corn land is best adapted to its growth. It is handled and marketed much like jute and hemp, and merits attention.

JUTE.—Jute requires a moist, sandy, loamy soil, and is no harder to raise than corn. Sow the seed broadcast in March or April. Cut the stalks as soon as the blossoms fall, before the seed begins to ripen, as the fibre is better than when the plant is older. Tie them in small bundles and throw them into a pond of water; after 5 or 8 days the fibre will fall from the stalk. As soon as dry it is ready for the loom or paper mill.

RAMIE. or WILD HEMP.—Belongs to the nettle family, but is stingless. Its stems grow straight and in bunches filled with pith and surrounded by a fibrous mantle covered by a thick red skin, the fibres themselves bound together by a resinous substance. It is a perennial plant, not annual, like flax and hemp. The strength of its fibre places it in the first rank of usefulness as a textile plant. Age increases its strength and fertility, and it resists drought and wet, though injured by frost except in the roots. It can be produced in any quantity in the South, and can be grown successfully as far north as New Jersey. Except its luxuriant growth requires manuring, its cultivation is simple; hoeing and digging are needed only in the first year, for the plant itself thereafter grows so luxuriantly as to smother all weeds. The process of preparing the fibre is similar to that of hemp. The removal of the glutinous substance inclosing the fibre is the most difficult process, but for that and the separation from the woody tissue, mechanical means are now employed with growing success. The Chinese make the coarsest nets from it and fabrics resembling the finest batiste. Rope and paper are also made from the fibre.

PESTS.

DISEASES.

BLIGHT, Cotton. — Although mistaken for rust, it is of itself a distinct affection. The leaves suddenly wither, droop, change to a brown color, and then fall off; and the bolls shrivel and dry up. The entire plant dies in a very short time; the pith of the root, stem and branches, preserving that blackish-brown appearance which usually accompanies an advanced stage of decay. It may be prevented by a judicious rotation of crops.

ERGOT.—The principal disease to which rye is subject. It is a fungous growth on the heads of the grain, causing them to turn black. This growth is poisonous and used as a medicine; rye affected with it should not be used as food. There is no cure known for it.

ROT.—*Cotton.* Makes its first appearance as a small, dark green, circular spot, on the outside of the boll, and many of them are frequently present on a single boll at the same time. With the advance of the disease, the spots change color, and gradually assume a blackish brown hue, until the entire boll is affected. If suddenly checked, as sometimes occurs from an unexplained cause, only a portion of the boll will be discolored. In the first case the disease has penetrated to the centre of the boll, which ferments, and pours out a white, frothy liquor; after which putrefaction follows, involving the destruction of the seed and immature cotton, when the rind, or the exterior coating of the boll, being exhausted of its juices, hardens and turns black. A careful selection of well ripened seed, from sound and healthy plants, will do much toward eradicating the disease. — *Tobacco.* The sweat, which terminates in rot, takes place after tobacco has partly cured; during continued soft, damp or foggy weather, the outside leaves, which cure out first, become so wilted and soft as to lop down over the green stalk and under leaves, and exclude the air to a great extent; this causes it to heat almost immediately about the stalk, where the under leaves join it, especially if there have been any suckers allowed to remain on the plant at the time of housing. These are unripe, and add greatly to

the trouble, and when the plant comes in contact with the pole, if hung that way, decomposition soon follows the fermentation, when leaf after leaf, and finally the stalk, drops to the ground, or lodges on the tier below, increasing the difficulty wherever they come in contact with each other. The manner of hanging is one of the causes of this disease and should be looked to, for where the plant is kept hard pressed against the pole, with a quantity of bruised leaves between the pole and the stalk, the rot makes its first appearance; this can be remedied by using lath for hanging, a much more desirable way for several reasons; for the stalk is pierced or split through, assisting it to cure out much sooner in time of danger, while it leaves each plant hanging free, touching nothing but the lath it rests upon. If attention is paid to the details of cultivation, rot will not be found on the plant. — *Potato.* This disease is marked by a deepening of color, accompanied by an enlargement of the affected part, and succeeded by weeping or exudation. As the disease advances, the part of the stem affected becomes soft and pulpy, and the color changes to a yellowish-brown. To prevent this, dust over the floor of the bin with lime, and put in about 6 or 7 in. of potatoes, and dust with lime as before, then more potatoes, using about 1 bus. of lime to 40 bus. of potatoes. Or, when the plant blooms, take 2 parts plaster, and 1 part fine salt; mix well together, and put 1 large spoonful of this compound as near the centre of each hill as possible. When ripe, take them out of the ground, have them dry when put in the cellar, and keep them in a dry, cool place.

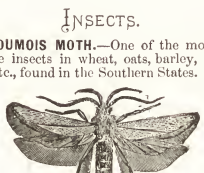
RUST.—*Cotton.* A parasitical fungus grows upon the stem and branches of the plant, which exhausts the sap, and causes the leaves to wither and fall. The leaves assume a yellow color, and are frequently spotted with red. It is generally traceable to defective cultivation, and may be remedied by adopting such a system of agriculture as will restore to the soil its abstracted salts and phosphates. — *Potato.* Affects the leaves and is a preliminary stage of rot. Cut off the tops and burn them. If it appears in the roots, dust them liberally with dry air-slacked lime. — *Wheat.* Appears in June on the leaves of wheat, and is readily distinguished by its reddish-yellow and yellowish-red colors. As a preventive, sometime before sowing prepare a steep of 3 measures of powdered quicklime and 10 measures of cattle urine; pour 2 qts. of this upon 1 pk. seed wheat; stir with a spade until every kernel is covered white with it.

SMUT.—There is nothing in the appearance of wheat to tell of the existence and destructive growth of this disease. If an ear be shelled before ripening, the kernels themselves present a plump green appearance, distinguishable from sound ones only by close comparison when viewed exteriorly; it is only when the kernels are broken open that the enemy is exposed to view, a dark fetid mass, occupying the whole farinaceous part of the kernel. The wheat should be carefully examined before the crop is gathered, by brushing the kernels taken from the heads in different parts of the field, or by having a considerable quantity floured, and watching the results. Whenever this fungus is found to any considerable extent, the grain should be carefully destroyed, for it is unfit and dangerous to use. To prevent smut, dissolve in $3\frac{1}{2}$ gals. of cold water, $3\frac{1}{4}$ oz. of sulphate of copper for every 3 bus. of sowing grain. Throw this quantity of wheat into another vessel, and pour over it the prepared liquid until it rises 5 or 6 in. above the wheat; stir thoroughly and remove all the grains that swim; throw the mixture into a basket so as to drain off the liquid; wash it well in soft water, and dry before sowing.

SORE SHIN.—An affection of the cotton plant, which makes its appearance in the early stages of its growth, during the prevalence of cold nights in a wet and backward spring. The bark of the stem becomes callous, and the sap vessels are dried up, or obstructed, near the surface of the ground. If the plant continues to live, its growth is slow and languid, and it never regains its former strength and vigor. It has been attributed to early planting, but is really caused by the ravages of the cotton louse, which debilitates the plant by abstracting the sap. (See *Cotton Louse* in *Lice.*)

INSECTS.

ANGOUMOIS MOTH.—One of the most destructive insects in wheat, oats, barley, Indian corn, etc., found in the Southern States. It only



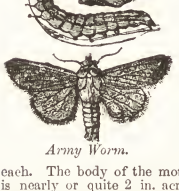
Angoumois Moth.

feeds upon ripe grain, attacking it in the field before harvest, and continuing its operations in the mow and out-door stacks, but being most destructive in bins or granaries, flouring mills and storehouses. The most effective method of destroying them is to subject the infested grain to the heat of about 190° Fahr., without destroying its germinating powers; this will kill all the insects and worms in it.

ANTLER, or GRASS MOTH.—A moth injurious to meadows. It is of middling size; its head and back are yellowish-brown, the collar lighter, almost yellow; the abdomen and legs are brownish-gray, the latter with darker joints; the upper wings are usually brownish-gray, with a darker mixture in the middle; the under wings are yellowish-gray. The caterpillar is brown or blackish, with 5 lighter stripes along the back; the first and last sections are covered with a hard, smooth scale; the stripes meet at the edge of the anus; the abdomen is blackish. The larvæ are 1 in. long, and they undergo their transformation about midsummer, within a light cocoon, under moss, stones,

etc., changing into a blackish-brown, shining pupa. The food of the caterpillar consists of all the soft sorts of grasses. It lives at the roots, and eats all the germs. The only means of diminishing this caterpillar consists in surrounding the attacked pieces, as the ground permits, with shallow ditches, or by means of a plow with deep furrows, as broad as possible, and turning pigs into these places to devour the insects.

ARMY WORM.—The true army worm, when fully grown, is 1¾ in. in length, and is striped lengthwise with black, dull swarthy green, and yellowish lines, intermingled with marginal white hair lines. The head is light or yellowish brown, and has 2 blackish bent lines on the face. It has 16 feet; 6 small black ones in front, 8 fleshy ones along the middle part, and 2 at the hinder end. On the outside of the 8 intermediate feet are conspicuously a black spot on each. The body of the moth is stout, and it is nearly or quite 2 in. across the expanded wings. The front wings are of a dull or dirty yellowish color, faintly sprinkled with blackish dots. The hind wings are partly transparent, with a smoky and purplish appearance. Its ravages begin about the last of May or 1st of June, great numbers of them traveling together. The favorite food-plants of the army worm are grass, the small grains and corn. Timothy, blue grass and winter wheat are more generally injured than any other crop. The worms rarely touch clover, and are not fond of rye; but, when hard pushed, will eat various vegetables, the leaves of fruit trees, and even each other. It is generally more destructive in a wet year following a dry one. The moths are generally called "owlet moths," and belong to the nightfliers, because they usually remain quiet or secreted during the day and fly abroad at night; if luminous traps are set in the fields after the crops are removed, millions of them may be captured. Burning over a meadow, or prairie, or field of stubble, either in winter or spring, effectually prevents the worms from originating in such meadow or field. A ditch with side toward the field to be protected perpendicular or sloping under, will protect a field from invasion from some other infested region when the worms are marching. When they are collected in the ditch they may be destroyed either by covering them up with earth that is pressed upon them, by burning straw over them, by pouring a little coal oil in the ditch, or by crushing with rollers. Where the soil is sandy, so that the ditch cannot be made with a vertical side, it should be dug deeper than in other cases and the side made as nearly perpendicular as possible, so that when the worms attempt to crawl up, the sand will crumble beneath them and cause them to fall back again.



Army Worm.

BLACK-RAT BLISTER BEETLE.—This sometimes appears in swarms upon the potato plant, especially in the more Northern States; it also attacks other plants, but is partial to the potato. The most successful method of destroying them is to place straw between the potato rows and set fire to it. The straw burns very quickly, and does not injure the potato vines.

BOLL WORM.—Color varying from pale green to light brown, striped longitudinally with darker stripes of the same color. It is from ¾ to 1½ in. in length. The moth is pale yellow, or shining ash color. It feeds on green corn in the North, and in the South is found on the tips of cotton plants. The only remedy for corn is to plant it early enough for it to begin to ripen before the appearance of the worm. To destroy them in cotton fields: 1. As the moth makes its excursions only after sunset, large numbers of them may be destroyed by lighting fires on the borders of the fields, to which they are attracted by the light. — 2. Take bottles filled with coal oil, and supplied with a lamp wick; attach them to sticks higher than the growing cotton, with one end stuck in the ground, at suitable distances from each other. The moths will be prevented from depositing their eggs. The lamps should be used as long as it is deemed necessary. — 3. When the moths are frequent over the field, clip off the branches upon which they are likely to have made their deposits. This topping of the plants is believed by some to increase the number of the bolls, and by doing it at the right time great numbers of the eggs may be destroyed.

Boll Worm.

CHINCH BUG.—A small insect less than ¼ in. long; color black and dirty white; body black, covered with a grayish down scarcely visible; legs dark yellow. It attacks wheat, corn and oats. Irrigation is the most effective method of destroying them, but where this is not possible, burn over the infested fields in winter. In timbered sections the leaves should be burned and fence corners cleared out and burned. The practice of plowing land for spring grain the preceding autumn, or if plowed in the spring, rolling it repeatedly with a heavy roller after seeding, is thought to possess advantages for fields pervaded by them. The female bug has to work her way underground in the spring of the year in order to get at the roots upon which she lays her eggs, and the looser the soil at this season the greater the facilities which are offered for the operation. An emulsion of coal oil and milk will destroy them. The emulsion

Chinch Bug.

may be made with soap-suds equally well, 1 lb. soap being added to 10 gals. water, and equal parts of oil and suds being taken. If, then, this emulsion be diluted by an additional quantity of suds, or even of clear water, so that there will be 1 part oil to 19 parts water, the liquid will not injure grain. In its migrations from field to field it may be checked by a line of tar poured on the ground, or by deep furrows or trenches, but the tar must be kept soft and the surface of the furrows friable and pulverized. When congregated on certain spots, dry straw, spread over the place and burned, will destroy numbers; gas lime sown broadcast over infested fields, at the rate of 6 or 7 bus. to the acre, is also recommended; or dropping a handful of gas lime on each hill of corn, when infested.

COLORADO BEETLE.—Body cream colored; 5 black stripes upon each wing case; wings rose color. Both the larva and the perfect beetle prey upon the potato plant. — 1. A few lbs. of carbonate of lime, Paris green, or London purple, dusted from a dredging box, will kill them. — 2. Put ½ bus. dry mandrake root in a barrel; fill with water and let it stand for 2 days, stirring now and then; strain the liquid through a cloth into a garden sprinkler; sprinkle towards sunset those plants on which the young brood hatch, before they scatter to adjacent plants.

CORN MOTH.—A moth injurious to grain laid up in bins. The perfect insect or moth measures, from the head to the tips of the wings, from 6 to 7 lines. The body is brown, with a little white on the back; the head has a thick tuft of whitish hairs; eyes black; upper wings more or less white, with brownish and dusky dots, varying in form and size. This insect appears as a moth in May, June and July, in buildings where grain is stored; it rests in the daytime, and only flies about at night, attacking rye, oats, barley and wheat. To destroy them, fill up the cracks and holes, sprinkle the floor with a mixture of strong white-wine vinegar and salt before laying up the corn, sweeping the floor and walls thoroughly before storage, and, if the moth has laid her eggs on the grain, common salt may be mixed with the grain.

COTTON ARMY WORM.—Color green; 2 black stripes on the back and sprinkled with black dots along a yellowish sub-dorsal line. This worm is furnished with 6 fore, 8 middle, and 2 hind feet; the 2 first of the middle feet being small, imperfect, and apparently useless for the purposes of progression, which is effected by alternately stretching out the body, and again contracting it in the form of an arch. When touched, the worms double themselves up, and spring to a distance several times their length; but if undisturbed when not feeding, they rest on the leaf with the forepart of the body elevated and slightly curved, sometimes varied by a sidelong swinging motion. They appear from June to September, and may be destroyed as follows: 1. Dissolve ¾ lb. London purple in 40 gals. water; sprinkle on the bottom of the leaves during the infancy of the worms, and it will effectually destroy them. — 2. Mix 1 lb. Paris green in 40 gals. of water, and apply to the under surface of the foliage, where the poison will not be washed off by the rain. — 3. Add to 5 gals. water, 5 lbs. arsenic and 1 lb. soda; boil until the arsenic is dissolved. This makes a solution of arsenic that will keep for any length of time without the slightest depreciation; put 1 qt. of this in 40 gals. of water, and sprinkle over the infected field. — 4. Kerosene and other oils are very deadly to the insects in all of their stages, and are the only substances which effectually destroy the eggs. The oils should first be made into an emulsion with fresh or spoiled milk, and this emulsion can then be diluted as much as one pleases with water, as the oils will be held well distributed in suspension. A fountain pump, or hydronette, is the best instrument with which to apply the solution, as the under side of the leaves can then be sprinkled.

COTTON STAINER.—A very destructive insect on a cotton plantation, as it clusters in large numbers on the opening boll, and so discolors the cotton as to render it unfit for the fabrication of white goods. They may be collected from the plants by depositing in their vicinity small slips of sugar cane, on which they will cluster; and they may also be reduced in numbers by burning out all stumps and dead trees standing in the fields.

GRAIN WEEVIL.—The true wheat or grain weevil is a slender beetle about ⅛ in. long; preys upon all kinds of grain in the bin and the corn-crib. This weevil being quite small, is liable to be overlooked, particularly in a dark bin. Its mode of operation consists in piercing minute holes in the kernel and there depositing its eggs, from which are hatched small maggots that eat out the heart of the grain. In due time these grubs undergo transformation and come out of the hulls in the beetle state to lay their eggs for another brood. When possible avoid storing grain in bins that have been infected. When it is inconvenient to change the place of storage, fumigate the granary thoroughly with burning sulphur. Fumigation should not only be done before the grain is placed in the bins, but repeated in the course of 1 or 2 months after it has been stored. The larvæ of the weevils that are in the grain may be destroyed by heating the grain where one has ovens or kilns at hand for the purpose. Scattering lime among stored grain may be practiced, if care is taken to remove it when the grain is taken out for use. Running it through a fanning mill, if the grain is dry, will blow out the dry lime. Grain that is stored in a cool place, if well ventilated and frequently moved, is said to be exempt from attacks.

Grain Weevil.

HESSIAN FLY.—Tawny or black body, with pale brown or red eyes and black feet; wings blackish or tawny. It deposits its eggs on the young wheat plant at the first joint or crown; maggots are hatched, which work between the leaf and the stalk, live on the sap and destroy the plant. If the fly is present, burn over the stubble as soon as possible after the wheat is

eut; thresh out the wheat before stacking and before it enters the sweating stage; then scatter the straw over the stubble and burn as

Hessian Fly.

thoroughly as possible, and follow after with the plow. Another way of destroying them, is to turn the horses and cattle on it while the ground is frozen; let them graze it down close to the ground. Quicklime strewed over the field, immediately after the grain is eut, will destroy the pupæ. If an attack of the fly is threatened, delay the time of sowing.

JOINT WORM FLY.—Little more than $\frac{1}{8}$ in. long; pale yellow color, with the exception of the jaws, which are dark brown. It preys on

Barley and Joint Worm Fly.

the stalks of small grains, which, when attacked, present a blistered appearance. To destroy them, burn the stubble after the grain is cut, and the straw after threshing.

LICE.—*Corn.* The wingless are dark green in color. The winged have head and thorax of shiny black; abdomen pale greenish yellow, dotted along the lateral margin with black. In larvæ they prey upon the roots of corn and upon the tassels. Tobacco

Corn Louse.

will destroy them.— *Cotton.* A species of aphis which pierces the outer coatings of the leaves, principally on the under side, and, by constantly draining the sap from the plant, enfeebles it and causes the leaves to curl up, turn yellow, and drop off. Brisk cultivation, and a top-dressing of ashes and plaster of Paris are the best remedies. — *Wheat Plant.* Inhabits corn crops, barley, oats and wheat. In July and August it

Winged Wheat Plant Louse.

is sometimes very abundant on the ears of wheat, sucking the stem and impoverishing the grain. No remedy has yet been found, but there are a number of insects which slay and feed upon it.

MAGGOTS.—*Seed-corn.* Small, white maggots. The fly is yellow or dusty brown. The larvæ destroy the heart of seed corn soon after planting. Soaking the seed in gas-tar is a preventive. — *Wheat.* Works in the stems of the wheat next the joint; it is less than $\frac{1}{4}$ in. long, rather slender; footless; largest at the anterior end, and tapering to the other extremity; of a pale cream yellow color, and easily recognized by the 2 brown triangular hooklets on the under side of the longer or head end. Burning off the stubble is a remedy.

Wingless Wheat Louse.

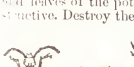
Corn Maggot.

RYE GRASS MOTH. — A moth injurious to the different species of grass and other meadow herbage. The moth is of middling size; the male, with extended wings, is nearly 1 in. broad, and black, with yellow notches on the abdomen; the wings are thin, black, and fringed with the same color. The female has a thick, long abdomen, which is whitish-gray, and woolly at its exterior; wings small, slender, brownish-gray, and not adapted for flying. The caterpillar is found in April and May, living on rye grass and many other plants in meadows; its ground color is velvety-black, yellow at the incisions and sides, with a black head and small yellowish warts, having ash-gray hairs on them. The destruction of this caterpillar is very difficult, as it prefers living in long grass in the daytime, or in the ground. Breaking up the meadows in autumn is the best method of destroying the pupæ concealed there.

STALK WEEVIL.—Bluish or ash-gray color, distinguished by having 3 shiny black impressed spots at the lower edge of the thorax. Burn all the potato vines which wilt from its at-

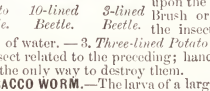
tacks, roots and all, for it always works below ground.

STRIPED POTATO BEETLE.—1. Dull yellow, striped with black. They feed upon young shoots and leaves of the potato vine, and are very destructive. Destroy them by placing dry straw on the ground between the rows; drive the beetles into it, and then set it on fire. — 2. *Ten-lined Potato Beetle.* An enemy that preys upon the leaves. Brush or shake the insects into a pan of water. — 3. *Three-lined Potato Beetle.* An insect related to the preceding; hand picking is the only way to destroy them.

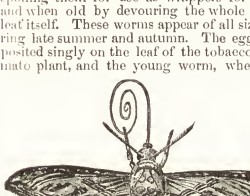


Potato Beetle. *10-lined Beetle.* *3-lined Beetle.*

TOBACCO WORM.—The larva of a large moth which is very destructive to the leaf of the tobacco plant, by eating holes in the leaves, thus spoiling them for use as wrappers for cigars, and when old by devouring the whole of the leaf itself. These worms appear of all sizes during late summer and autumn. The egg is deposited singly on the leaf of the tobacco or tomato plant, and the young worm, when first hatched out by the heat of the sun, commences to eat holes in the leaf of the plant, and sheds its skin several times before attaining its full size; it then goes into the earth, and the pupæ is formed in a subterranean cell, the late broods remaining as pupæ all winter, and coming out as the perfect moth the following spring. There are several parasites, and one in particular, that is very useful in destroying the potato and tobacco worm; it is a minute, 4-winged fly, which deposits its eggs in the caterpillar, and eventually kills it. The eggs of this parasite, to the number of 100 or more, are deposited in the back and sides of the caterpillar, in small punctures made by the ovipositor of the fly. The simplest and best way of disposing of the tobacco worm, is to pull their heads off as quickly as possible. The following is also a successful method: A number of artificial jimson flowers; made of tin, and stuck upon poles in different parts of the tobacco field. Bait the flowers with sugar and arsenic, and the tobacco fly will eat it and fall dead close by; but this plan has the fault of killing friendly insects.



Tobacco Worm.



Tobacco Worm Moth.

UNSPOTTED LADY BIRD.—An insect injurious to many of the artificial grasses. It has been observed on the common tare, sainfoin, and the different sorts of clover. This larva is only ⅛ in. long; yellowish-white, with single green spots, and the upper side of the body covered with prickles. Its transformation takes place on the leaves. The pupa is light yellow, covered with minute hairs of the same color. The perfect insect is almost globular, yellowish-red on the upper side, with a brownish-red spot on the thorax. The abdomen is brownish-black, and the legs reddish, or reddish-brown. A good soil and moist weather which will cause the herbage to grow quickly and luxuriantly, and to be often mown, are the chief requisites for diminishing the insect. By often removing the cut fodder from the field, the insect will be disturbed in its propagation.

WHITE-LINE DART MOTH.—A moth injurious to buckwheat and autumn-sown grain. The caterpillar is upwards of 1 in. long, and of the thickness of a slender writing-quill. On the back it is dirty-olive green, with a mixture of yellow. The head is brown; the abdomen and feet are dirty yellow. It lives in the daytime in the earth, coming out only at night. To destroy them, hand-pick, and apply a strong dressing of lime to the land in the spring; or strew the ground with ashes, rolling the fields with heavy rollers, and lastly driving flocks of sheep over the field.

WINTER, or DART MOTH.—A moth that injures winter grain. The caterpillar attacks both the leaves and the roots of the corn; also the roots of lettuce, turnips, and spinach. It appears generally in August, sitting quietly on the ground in the daytime, and flying about and pairing at night. When at rest, its wings are folded together flat over the body, and is then nearly 1 in. long and ⅜ in. wide. Its colors are dirty-gray, and dark brown, or earth color, except on the under wings, which are covered as it sits, and which are sometimes whitish-gray, sometimes cream color. On the upper wings, a faint blackish ring-like mark is seen, and a cone shaped spot on a wavy line, a kidney-shaped stain almost in the middle, and towards the lower edge 2 other wavy or notched transverse lines. The most simple and certain mode of extirpating them is to repair to the fields, and collect the caterpillars as soon as they appear. They lie in the daytime under stones, clods or buried in the earth; these must be carefully turned up in search of the enemy. When they are changing their skins, they come out of their lurking places, even in the daytime, and can easily be gathered. Immediately after sunset they come

out in great numbers, and feed greedily on the young corn. At this time, the work must be carried on vigorously, and even until late at night with an artificial light.

WIRE WORMS.—These are the larvæ of the snapping beetle, which is covered with short, fine, prostrate, ash-gray hairs, its wing covers having rows of punctures resembling the stitches of a garment; they are hard, shining worms, of various sizes and colors, that breed in manure and in decaying vegetable matter, and gather under stones, clods, and lumps of manure. They attack corn, wheat, potatoes and other plants, but are especially destructive to corn and potatoes. 1. An easy way to kill them, is to poison them in traps, consisting of pieces of board or shingles laid upon the ground with a few small pieces of potato sprinkled with Paris green or other poison under them.—2. When very numerous, summer fallowing thoroughly done so as to permit no weeds of any kind to grow, is the most effective and cheapest remedy.

Wire Worm.

KITCHEN GARDEN.

HERBS.

ANISE.—A half-hardy annual, used for garnishing or seasoning. Sow during April, in pots buried in a hot-bed; remove to a warm light border, in May; thin to 6 in. apart; the seed is ripe in August and September.

Anise.

BALM.—A hardy plant, with square stems, rising 2 ft. high or more, with large leaves growing by pairs at each joint; propagated by parting the roots, preserving 2 or 3 buds to each piece, or by slips, either in autumn or spring; plant in common earth, from 18 in. to 1 ft. apart, watering in dry weather; gather when coming into flower; when the leaves are entirely free from moisture, dry them; and when cool, press into packages.

Balm.

BASIL.—The *Sweet-scented* and the *Dwarf Bush* are the varieties. A rich, light soil is the best; sow the seed in a gentle hot bed, early in April; thin, and those removed prick out at the close of the month in a similar situation, to be finally removed when the weather is settled, in open ground; when thinned, the seedlings must be kept at 3 in. apart, and those removed pricked out at a similar distance; water at every removal, hoe, and keep clear from weeds; gather seed from the earliest raised plants.

Basil.

CAMOMILE.—A creeping plant, cultivated for its flowers. The double-flowered variety is the most common, but the single possesses more of the virtue of the plant, according to its weight; it requires a poor soil, planted in rows 1 ft. apart, and hoed between, and produces an abundance of flowers annually, from June to Sept.

CARAWAY.—A biennial plant, with taper root, stems rising from 1½ to 2 ft.; spreading branches, and finely-cut deep-green leaves; a clayey loam is the best soil, which should be well plowed; sow in March, directly after the plow, harrowing well. In 10 weeks after, hoe, and repeat hoeing 2 or 3 times before cutting, which may be done in July; after which, thresh it upon a cloth.

Caraway.

CORIANDER.—A small rooted annual, with branchy stems. Sow in a light, rich soil, in the fall, with fresh seeds, 20 lbs. to an acre; thin the plants to 6 or 8 in. apart every way; stir the soil with a hoe; the seeds ripen in August, when they must be carefully cut and gathered; a few strokes of the flail will get the seeds out clean.

Coriander.

DILL.—Cultivated for its leaves and blossoms, which are used for pickling, and in soups and sauces. Soil rather dry; sow as soon as the seed ripens, in drills 1 ft. apart; thin to 10 in. asunder, after 3 or 4 weeks' growth; keep clear of weeds; and, for seed, cut in September.

FENNEL.—Resembles the dill, but is larger; grown for its stalks and leaves. 3 or 4 plants are sufficient for any garden. The variety called the *Finochio* may be grown in rows, on light, rich soil, and earthed up to the height of 5 or 6 in., which blanches the stalks in 10 days or a

Fennel.

fortnight; may be watered in very dry weather.

FOXGLOVE.—A perennial medicinal plant, comprising two varieties, the *Large* and the *Small*; when raised in gardens, it is easily propagated by seed; it prefers a gravelly, sandy, or chalky soil; every part of it is poisonous.

HOARHOUND.—A perennial, 2½ ft. high; stools somewhat; sow seeds in early spring, thinly; a few stools will furnish a supply after the first or second season; gather when in bloom and dry in the shade; when dry, put in paper bags or boxes; it is readily increased by divisions of the roots, or by seeds.

Hoarhound.

HYSSOP.—There are 3 varieties, the *White*, *Red*, and *Blue*, distinguished by the color of the flowers. A dry soil is the most appropriate. It is propagated by seed and slips of the shoots, as well as by offsets; may be sown from early spring until June; rooted offsets may be planted in March, April, August, and September; cuttings of the branches in April and May, and slips of young shoots in June or July; sow broadcast, or in drills, 6 in. apart, and not deeper than an inch.

LAVENDER.—A dwarf, odorous shrub, of 3 or 4 years' duration. The soil should be a poor, dry, limy gravel; the seeds being sown in a garden in spring, may be transplanted in September or March following, in rows 2 ft. apart. The second season they will yield flowers, and a full crop the fourth, after which the plants will continue productive for years; the spikes are gathered in June and dried in the shade. In many localities it is tender and treated as a house plant.

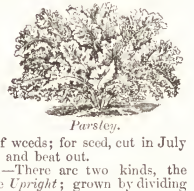
LICORICE.—A deep-rooting plant, with stems 4 or 5 ft. high; use a deep, sandy loam, trenched 2 or 3 ft. deep, and manured; the plants consist of side roots, having eyes or buds; plant in the fall or spring, in rows 3 ft. apart, and from 18 in. to 2 ft. in the row; hoe, stir, and weed, and carry off the stems every autumn, after they are completely withered.

MARJORAM.—The *Sweet Marjoram* is a biennial, and long in use for many culinary purposes; this species, being somewhat tender, is commonly sown on a slight hot-bed towards the end of March, or on a warm border about the middle of April; in the former case, transplanting into rows 1 ft. apart, and the plants 6 in. distant; and in the latter case, thinning out, without transplanting.

Marjoram.

MINT.—The *Common* or *Spear Mint* is a creeping-stemmed plant, the leaves of which are used in salads, soups, etc.; propagate by dividing the roots before they begin to grow in the spring, and bury in shallow drills, or slip off the young shoots when they are 3 or 4 in. long, and plant in beds a few inches apart; to produce tender stalks and leaves, water liberally; to dry, cut the stalks when just coming into flower.

PARSLEY.—A biennial, with a large, sweet tap-root. There are 2 varieties, the *Plain-leaved* and the *Curled-leaved*. Sow at monthly intervals, from February until middle of June, in drills 9 in. apart; when of tolerable growth thin to 9 in. asunder, and keep clear of weeds; for seed, cut in July or August; dry, and beat out.



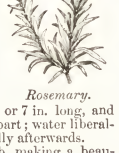
Parsley.

PENNYROYAL.—There are two kinds, the *Trailing* and the *Upright*; grown by dividing the roots in the spring; the best soil is one that is strong and moist; of very easy cultivation.

PEPPERMINT.—A well-known creeping-stemmed plant, growing spontaneously; propagated by dividing the roots early in the spring, and planting in a soft, rich soil; the stalks are gathered when in full flower.

PURSLANE.—There are 2 sorts, the *Green* and the *Golden*, the latter being used mostly as a garnish, the former for a salad; also for potherbs and pickles. In most of our soils this is a troublesome weed that forms good food for cows and pigs. Where a constant supply is required, the first sowing should be made on heat in February, and the others monthly, on a warm border, till August; the shoots are gathered when from 2 to 5 in. high, and well leaved.

ROSEMARY.—The *Green*, *Golden-striped*, and *Silver-striped*, are the varieties cultivated, the first-named being the most used. It has a fragrant aromatic smell like camphor, of which its oil contains ½. The best soil is a poor, light limy one; propagate by cuttings and rooted slips, during the spring, or by layers in the summer; sow in March or April, in drills 1 in. deep, and 6 in. apart; the slips and cuttings must be 5 or 7 in. long, and planted in rows 8 or 10 in. apart; water liberally at planting and occasionally afterwards.



Rosemary.

RUE.—An evergreen shrub, making a beautiful garnish for table dishes, but of very strong odor and taste; thrives best in a poor, clayey soil, and is propagated by slips, cuttings, and seeds in the spring, the seed being sown in drills 1 in. deep and 1 ft. apart; the slips or cuttings may be planted on a poor, shady border, and watered occasionally.

SAFFRON.—Also called the *Autumn Crocus*; a bulbous-rooted perennial, of medical and culinary uses. Plant the bulbs on a prepared soil, not poor nor a very stiff clay, in July, in rows 6 in. apart across the ridges, and 3 in. distant in the rows; the flowers are gathered in September, the stigmas picked out, together with a portion of the style; these are dried

Saffron.

between layers of paper, under the pressure of a thick board, to form into cakes.

SAGE.—A half shrubby plant, seldom more than 2 ft. high, with wrinkled leaves, and a very strong aromatic smell. In cookery its chief use is in stuffings for subduing the richness of certain kinds of meat, such as goose and duck; the common red and the green variety are most employed; for medical purposes the small-leaved sages are used. Propagated by seeds or cuttings, the plantation being renewed every 2 or 3 years; otherwise, the winter may destroy it; grows best in a dry soil, shaded from the sun.

Sage.

SAVORY.—Known commonly as summer savory; annual; grows 12 to 15 in. high; leaves opposite; branches in pairs; flowers flesh-colored, growing from the base of the leaves near the upper portion of the plant; seeds small, retaining germinative properties 2 years; sow seed in May, in light mellow soil, in shallow drills, 16 in. apart, and thin the plants to 6 in. in the drills; gather by cutting the plants by the ground when they begin to show flowers, and dry in an airy, shady place. If the dried leaves are pulverized and put up in junk bottles corked tight or in sealed tin cans, they will preserve their aroma for a long time.

Savory.

TANSY.—A perennial plant, from 2 to 4 ft. high, with a profusion of deep green leaves and small yellow flowers; both leaves and flowers possess a strong aromatic smell and a bitter taste. The *Curled* or *Double Tansy* is the kind chiefly grown for culinary use. It is raised by rooted slips, or divisions of its roots, planted in spring and in autumn, in rows 1 ft. apart each way.

TARRAGON. — A hardy perennial plant, grown for its leaves and the tips of the young shoots; used for flavoring. It seldom produces seeds; therefore it is generally propagated by division of the roots; set these out in any good garden soil, in April, in rows 15 in. apart, and the plants 10 or 12 in. apart in the row, covering the sets 2 or 3 in. deep. Sow the seeds in April or May, in cold frame or in a nursery bed; the drills should be 6 or 8 in. apart, and when the plants are 3 or 4 in. high, they should be set out as directed for the roots.

Tansy.

THYME.—The *Common* and *Lemon Thyme* are the 2 varieties principally cultivated, but the *Golden* and *Silver-leaved* are quite ornamental and useful. They are increased by seeds, cuttings, or divisions, and the plants should be renewed by one or other of these modes, every year, in the spring; the lemon is a trailing evergreen; sow seeds in April or May, in shallow drills 12 in. apart, and thin to 2 to 4 in.; roots may be divided and reset in April; make as many parts as the roots and tops will admit of; cut and dry the leaves and shoots, in August or September.

WORMWOOD.—This is a flowering herb of a disagreeable odor and intensely bitter taste. It contains a volatile oil of a green color, and a bitter tonic principle, called absinthium. It is propagated by seeds, cuttings, or division of roots. Sow in March; transplant in July to 18 in. apart. A dry, poor soil is best suited for growing this plant.

Wormwood.

VEGETABLES, ETC.

ARTICHOKE.—This requires a deep, rich loam; manure should be applied every spring. It should always have an open exposure, and is best propagated from seed or from offsets; if by the former, sow in rows 1 ft. apart, as soon as the frost is out of the ground; thin the plants to 1 ft. apart, in the row; and in the autumn, put out in clumps of 4, in rows 3 ft. apart, and the rows 6 ft. asunder. In winter, when the frost sets in, cover 5 or 6 in. thick with leaves, seaweed, or long manure to protect from frost, and keep free from stagnant water. When the plants are about 9 or 10 in. high they should be transplanted where they are to be permanently grown. As the roots penetrate deeply and require very rich soil, the soil should be heavily manured, deeply spaded, and well pulverized. There are 3 distinct kinds, viz.: *Conical or French.* These are of a milky green color, with scales spreading. — *Globe.* A thistle-like plant which grows on a stem from 2 to 3 ft. high. The head of the flower only is eaten, and is regarded as a great dainty.—*A small sunflower,* with nutritious tubers less in size than potatoes, and treated similar to them.

ASPARAGUS.—Raised by sowing the seeds in September or April. The seed bed should be composed of good, rich soil, well pulverized and manured with well rotted manure. The seed, of which 1 oz. will produce about 1,000 plants, or be sufficient for 50 or 60 ft. of drill, should be thinly sown in drills 12 in. apart and 1 in. in depth; it is best to keep them in water 180° to 200° for 24 hours, before sowing. After the plants come up, the bed should be kept thoroughly clear of weeds by repeated hoeings; the

plants, if well cared for, will be large enough to plant out in permanent beds when a year old, but some prefer to let them remain until 2 years old. It will succeed in any rich, deep, dry and porous soil, through which water can readily drain away; but does not succeed well in heavy, close soils. The end of March or early in April is the best time to make the bed. Trench the space intended for the bed, and mix with the soil as much rich, thoroughly decayed dung as can be worked in; have only 2 rows of plants in each bed, as this enables them to be cultivated and cut from easily; set the rows out 2 ft. apart, and the crown of the plant 3 in. deep. Every spring give them a top dressing of rotted manure, superphosphate of lime or guano. A liberal application of liquid manure may also be used to great advantage. A spading fork is preferable to a spade in turning in the manure, as it is less liable to cut or injure the roots; even this should not be inserted more than 5 or 6 in. deep. In forcing asparagus, such plants may be inserted in hot-beds as are 5 or 6 years old, and of sufficient strength to produce vigorous shoots; the first plantation should be made about the first of October, and, if it works well, will begin to produce in the course of 4 or 5 weeks, and continue to do so for about 3. The hot-bed may be made in the usual way, and topped with 12 in. of light rich earth, and kept at about 60° in the day time, and never below 50° at night. In planting, a furrow is drawn the whole length of the frame; against 1 side of it the first row or course is to be placed, the crown upright, and a little earth drawn on to the lower end of the roots; all round on the edge of the bed, some moist earth must be banked close to the outside roots.

Asparagus.

BEANS.—The following are the principal varieties of *Bush* or *Dwarf* beans. These will grow in any good garden soil moderately enriched; if too highly manured it will cause them to run to tops too much. The proper time for sowing is after the 10th of May until the beginning of August; sow them in drills about 2 in. deep, and from 2 to 3 ft. apart. The beans should be dropped from 2 to 3 in. apart on the row: *Black Wax.* The pods, when ripe, are of a waxy yellow, transparent, very tender and delicious; an excellent variety.—*Crystal White Wax.* A variety of very rich flavor; pods waxy white, transparent and stringless. The pods, although growing to good size very rapidly, do not harden soon, and snap beans of this variety can be had tender and sweet for a long time.—*Early China.* A very excellent variety both for string and shelled beans, green or dry; pods medium size and full; seeds white, with a bright red eye; round oval shape.—*Early Mohawk.* Considered the hardiest bean, for first planting; will endure a light frost, and continue a long time in bearing if the green pods are gathered often. Pods pale green, long and flat; seeds large, kidney-shaped, brown and purple marbled.—*Early Red Valentine.* A most excellent variety, used principally for snaps, having round, fleshy pods, which remain a long time brittle and tender; beans long, light red and salmon-color marbled; very early, a good bearer, and extensively cultivated.—*German Wax, Black Seeded.* An excellent variety for cooking in the pods, which are delicious when fully grown; beans nearly round, black; pods white; a good bearer.—*German Wax, White Seeded.* The color of the seeds being white, it is by some preferred to the preceding for cooking. With the exception of the color, it is identical with it.—*White Valentine.* A selection from the Red Valentine, it possesses all the good qualities of its parent and of more sturdy growth; the pods are green, round, stringless, succulent, curved in form and of highest excellence; pods reach maturity 35 days after germination.

Pole Beans require a light, somewhat sandy soil, well enriched with manure in the hills; sow the seed deep in hills 3 to 4 ft. apart, with a stake or pole 8 or 9 ft. high set in the centre of the hill at the time of planting. The planting should not be done before the 15th of May and may be continued until the end of June. If planted too early they will rot in the ground; 5 or 6 beans should be sown in each hill, and when they have attained their second leaf, all but 3 or 4 should be pulled up. The after cultivation consists in one or two hillings up and keeping them clear of weeds; nipping off the ends of the shoots after they have reached the top of the poles makes the plants fruitful. If it is desired to have them earlier than they would produce in the open air, plants can be raised from beans sown 1 each in ½ pt. pot in April and kept in a cold frame; these will be ready for transplanting by the end of May. Good ways to train pole beans are as follows: Plant the beans about 4 ft. from the fence; take common poles or laths long enough to reach to the top of the fence; stick one end in the bean row, and with a single nail fasten the other end to the top of the fence; after the vines reach the top pinch off the terminal shoots and the side shoots will grow rapidly.—2. Plant a sunflower or corn by each hill of beans; the stalks will answer the same purpose as the ordinary pole.—3. Take 3 good common laths to every 2 hills, 2 for the beans, and the 1 for a brace, set in the form of a tripod, letting the tops cross about 1 in. or more, and 1 four-penny nail will hold them together. The following are the principal varieties of pole beans: *Butter or Large White Lima.* Vines vigorous but tender and late; seeds white, veined with green, very large, broad, thin, and surpassed in quality by no other variety. A general favorite wherever the season is long enough to mature it.—*Deer's Improved Lima.* The distinctive improvements are its earliness, remarkable productiveness, delicious flavor, and the forming of the bean closely in the pod.—*Dutch Case-knife.* The earliest variety of pole beans. Pods long and flat; beans white, flat, kidney-shaped, and of excellent flavor; good green or dry.

BEETS.—A deep, rich soil is best for beets. They may be sown as early as the first week in April, and should be gathered before severe frost occurs, and pitted or put in cellars for winter use. The thinning of beets must be done while they are young, and the young plants are excellent for greens. The ground should be prepared by deep plowing and harrowing, until it is fine. Open 2 furrows 2 ft. apart, and put in a sufficient quantity of manure, according to the state of the ground; cover the dung with the plow by throwing a furrow of earth upon it, ridging as high as can be well done; level the surface of the ridge over the dung, taking care that there is a full proportion of earth over the manure for the seed to vegetate in. Drop the seeds about 2 in. apart; then cover in, and roll or press down to set the earth firmly about the seeds. For succession crops, sow every 2 weeks, from the first of April until the first of June. The crop will be more tender and delicate when thus sown in succession, as those first sown become harder and not so well flavored as the hot weather approaches. The principal varieties of beets are: *Bassano.* An early, good beet, tender and juicy; flesh white and rose; grows to a good size; when sown late, it keeps well in the winter.—*Blood Turnip.* Turnip-shaped, smooth, tender and good; about 10 days after Bassano.—*Egyptian Blood Turnip.* The earliest variety grown, and valuable on this account; not very productive.—*Henderson's Pine-Apple.* Compact, short-top variety, roots medium sized and of a deep crimson.—*Imperial Sugar.* The sweetest and best sugar beet.—*Swiss Chard.* This variety is cultivated solely for its leaves. The midrib is stewed and served as asparagus, the other portions of the leaf being used as spinach. If often cut, new and more tender leaves will be reproduced. — *White Sugar Beet.* Attains a large size and is extensively grown for feeding; largely cultivated in France for the manufacture of sugar. — *Yellow Globe Mangel Wurzel.* Roots of large size and globular form; very productive; keeps better than the long red, and is better adapted for growing in shallow soil.—*Yellow Turnip.* Similar to the blood turnip, but differing in color; flesh yellow, tender and sweet.

Blood Turnip Beet.

White Sugar Beet.

BORAGE.—A light, dry soil is best suited to this. It is propagated by seed, sown in March or April in shallow drills ½ ft. apart. Transplanting is not advantageous or necessary.

BROCCOLI.—Similar to cabbage; requires a cool manure and very rich soil. A top dressing of lime and salt or a mulching of seaweed, is very useful. Sow the seed rather sparingly in drills ½ in. deep, and from 4 to 6 in. apart in seed beds in the open air. ¼ oz. of seed will sow a piece of ground 4x4 ft. and produce about 1,000 plants. The varieties are: *Large Early White.* Large white head resembling cauliflower.—*Purple Cape.* Head purple in color.—*Purple Sprouting or Branching.* These do not form a solid head, but numerous distinct purple heads, sprouting out somewhat after the manner of Brussels Sprouts.

Borage.

BRUSSELS SPROUTS.—Cultivation same as cabbage. Cultivated for the small heads, which are produced in great numbers on the main stem of the plant, and are in perfection in the autumn. They are very tender, and of fine flavor. As soon as the plants reach their height, and the top begins to cabbage, cut out the cabbage; this throws all the strength into the sprouts down the stem, making the bottom ones as good as those on the top.

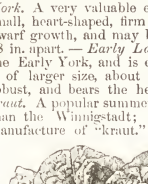
Brussels Sprouts.

CABBAGE.— The best soil is a strong, rich, substantial one, more clayey than sandy, though it will grow in any soil, if it be well worked and manured. They may be grown either from hot-bed plants, or from seed planted in the open ground. If the seed of the earlier sorts has been sown in a hot-bed, they will be ready for removal when 2 or 3 in. high. In this case, as soon as the season will permit, prepare a bed, by digging out the ground 1 ft. deep, 4 ft. wide, and to as great a length as the extent of your operations will require. Fill this up with dung, cover with earth to the depth of 4 in., and set your plants upon it in rows 4 in. apart, and 2 in. apart in the row. Water them lightly, and, if convenient, shade them for a day or two, and shelter them at night. For the late or autumn crop, the seed should be sown in a prepared bed in the open ground during the month of May, the drills being 3 or 4 in. apart. In all sowings, see that the plants do not stand too thickly together, so as to guard against their being drawn up. In the second or third week of July they should be transplanted into the permanent bed, in rows 3 ft. apart, and 2 ft.

from plant to plant. As they progress in growth, they should receive 3 or 4 deep hoeings, and be slightly earthed up. The principal varieties are as follows: *Early Blood Red.* An early variety; will make fine winter cabbage if sown late in the open ground.— *Early Dwarf Flat Dutch.* An excellent second early sort which does particularly well in the Southern States. Head of medium size, solid, flat, grows low on the stump, and is of good flavor. — *Early Sugar Loaf.* A very compact growing variety, and the plants may be set as close as 16 in. apart each way; very early, but is more affected by the heat than most early varieties. — *Early Wakefield.* A great favorite with market gardeners for the New York market; the earliest, and sure to head; the seed is true and the best. — *Early Dwarf York.* A very valuable early variety. Heads small, heart-shaped, firm and tender; of very dwarf growth, and may be transplanted 15 or 18 in. apart. — *Early Large York.* Succeeds the Early York, and is equally desirable. It is of larger size, about 10 days later, more robust, and bears the heat better. — *Filderkraut.* A popular summer sort, a little larger than the Winnigstadt; largely used in the manufacture of "kraut." It is equally good for early or late use, and heads up hard with few side leaves. — *Green Globe Savoy.* Does not make a firm head, but the whole of it being very tender and pleasant flavored, is used for cooking; leaves wrinkled and dark green; is very hardy, and improved by frost. — *Henderson's Early Summer.* An old popular sort. It follows the Wakefield and resembles the Early Flat Dutch; should be sown in hot-bed in February or March; when sown in the fall are inclined to run to seed. — *Large French Ox-heart.* A fine, heart-shaped cabbage, coming in use after Early York and other earlier sorts; very tender and fine flavored, and heads freely. — *Marblehead Mammoth.* A very large winter cabbage; heads freely, and with good soil will grow to an enormous size. — *Netted Savoy.* The leaves of this are netted to an unusual degree, and it forms a solid, compact head; one of the finest flavored of all the cabbage tribe. — *Quintal Drumhead.* An exceedingly large variety, of French origin. Heads quite flat on the top, with few side leaves; solid, firm, hard, and of good flavor. — *Winnigstadt.* A fine tender variety, sugar-loaf in form; one of the best summer sorts; if sown late, good for fall or even winter.

Early Dwarf Flat Dutch.

Early York.



Netted Savoy Cabbage.

Winnigstadt.

CARDOON.—A species of artichoke. The stalks of the leaves being thick, fleshy, and crisp, are blanched, and used for salads, soups, and for stewing. Sow about the last of April, in deep, light, moderately rich soil, in trenches about 6 in. deep, 12 wide, and 4 ft. apart. Drop 3 or 4 seeds together, at intervals of 18 in., and when they come up, thin them out to single plants. Water frequently, and in a dry day, about the end of October, commence blanching by tying up the leaves with twisted hay-bands, after which earth may be heaped around them, in the manner of earthing celery.

CARROTS.—These prefer a light, loamy soil, that has been well manured for the previous crops and does not require fresh manure; if the soil is too rich or the manure too fresh, the plants have a tendency to run to leaf and not to form roots. The soil should be deeply spaded and well pulverized. Do not plow the ground until it has become thoroughly dry. Throw it up into slight ridges 3 ft. apart and leave until ready to sow the seeds. Rake off the ridges just previous to sowing the seeds, so as to have fresh, moist soil for them. For sowing, a calm day should be selected; the seeds should be separated by rubbing them between the hands, with the admixture of a little sand or dry coal-ashes. Sow thinly in drills 8 or 12 in. apart and the beds not more than 4 ft. wide. The larger weeds must be continually removed by hand, and when the plants are 7 or 8 weeks old, or when they have got 4 leaves 2 or 3 in. long, they should be thinned—those intended for drawing young to 4 or 5 in. apart, and those to attain their full growth to 10; at the same time the ground must be small-hoed. If the weather is cold and there is danger that the ground will freeze, this work may be done before the roots attain their full growth. The tops should be cut with a light, sharp hoe. If a little of the crown is removed, the roots keep just as well and are not so likely to sprout in the water. The best varieties of carrots are: *Danvers.* In form midway between the Long Orange and Early Horn class; color a rich shade of orange, growing very smooth and handsome; yields the greatest bulk,

with the smallest length of root, of any now grown. Under the best cultivation, it will yield from 25 to 30 tons per acre. — *Early Half Long Scarlet, Stump Rooted.* A popular early market variety, growing in favor. Of medium size; flesh bright scarlet, brittle and of fine flavor; will do well in shallow soil. — *Early Scarlet Horn.* The best early variety. It is shorter than most sorts; flesh deep orange color; fine grained and agreeably flavored; top small. It is best for table use, and will grow well on shallow soil. Sow 6 in. apart, in 14 in. drills. — *Earliest Short Horn.* (For forcing.) The earliest variety in cultivation; used mostly by market gardeners for forcing. Is small, but of excellent quality. — *Large White Belgian.* Grows ¾ out of the ground; root pure white, green above ground, with small top. It will grow to very large size on light, rich soil, and is very easily gathered. Flesh rather coarse; is raised extensively for stock. — *Long Orange.* A well known standard sort. Best for field culture, because of its excellent qualities for feeding purposes and its coloring effect upon the product of the dairy.

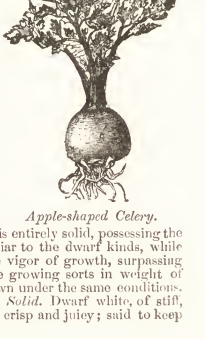
Long Orange.

Early Half-long Scarlet.

CAULIFLOWER.—This requires a cool and moist climate, and a very rich soil, to succeed well. For spring eating sow about the middle of September. Prepare the ground by opening small trenches, and dig in some earth in good compost, to receive the plants. When of a proper size, the plants should be pricked out in a careful manner, and for them the warmest part of the garden should be selected. Being very tender they should always be put under glass in severe weather. They should not be covered until the weather is severe, and in the meanwhile the hoe should be frequently used between them, to keep the earth dry about their stems. From their beds they may be planted out in rows, like cabbages, at rather greater distances, and taking care to move a little earth with them about the middle of spring. When the flower heads show themselves, some of the leaves should be broken over them, in order to protect them from the rain and sun, and to keep the heads close and of a pure white color. They will be fit for use during the month of June or the beginning of July. Important varieties are: *Early Snowball.* Highly esteemed by market gardeners, for earliness and reliability as a sure header. — *Erfurt Earliest Dwarf.* Seed grown in Erfurt; the earliest variety in cultivation, very dwarf, with solid, pure white heads, and superior quality; one of the surest to head; seed very scarce. — *Extra Early Paris.* Heads large, white, compact and solid, of excellent flavor, tender and delicious; leaves large, stalk short. Being early, it is a favorite with market gardeners. — *Le Normand's Short Stem.* Considered by the French one of the very best sorts. The plant is hardy; semi dwarf, producing numerous leaves which protect the close, solid curd, keeping it well blanched. — *Veitch's Autumn Giant.* A distinct and valuable late variety. Heads very large, beautifully white, firm and compact, and being well protected by foliage remain a long time fit for use. The plants should be started and transplanted early in the season, to insure their full development.

Erfurt Earliest Dwarf.

CELERY.—This thrives best on a deep, mellow, sandy loam, rather moist in character. It will thrive, however, in drained clay land, if heavily manured. Dig a trench; place 1 ft. of rich soil in the bottom; set the plants in a row, about 5 in. apart; avoid breaking or drying off the roots, and when possible set out the plants in cloudy weather. Shelter from drying wind and hot sun when first transplanted and water often. In earthing up care should be exercised to close the stems well together with the hand, so that no mold can get between. Earthing up should be sufficiently frequent to keep the mold nearly level with the leaves of the outside stems. A good and simple method is to plant after early potatoes in the furrows, and have the blanching done in the storing pit in which they are kept for winter. The following are the principal varieties of celery: *Apple-shaped.* Very regular, almost spherical shape, with a fine neck and small leaves; may be planted very thickly, and will yield a heavy crop. — *Boston Market.* This forms a cluster of heads instead of a single large one, and is remarkably tender and crisp. The best variety for light soils. — *Crawford's Half Dwarf.* When blanched, this is of rather a yellowish white, and is entirely solid, possessing the nutty flavor peculiar to the dwarf kinds, while it has much more vigor of growth, surpassing most of the large growing sorts in weight of bunch, when grown under the same conditions. — *Dwarf White Solid.* Dwarf white, of stiff, close, habit, solid crisp and juicy; said to keep



Apple-shaped Celery.

in good order later in the season than any other variety. — *Golden Heart, or Golden Dwarf.* Resembles Crawford's Half Dwarf, but the heart is of a beautiful golden yellow. It is very solid, of excellent flavor, and one of the best for either home or market use. — *Incomparable Crimson.* A dwarf-growing, rich colored variety, very crisp eating, and of delicious flavor. — *Turnip-rooted.* The root is turnip shaped, tender, and narrow like, having a sweeter taste and stronger odor than other varieties. Used principally for seasoning meats and soups.

Incomparable Crimson.

CHERVIL.—An annual plant, and should be sown in March, April and May, in drills about ¼ in. deep, and 9 in. apart. Cover lightly and press firmly with the foot; rake evenly and give a gentle watering in dry weather. The leaves are fit for use when 2 to 4 in. high. Cut them off close; they will come up again, and may be gathered in succession throughout the season. One species is grown as parsley for garnishing, and is known as *Curled-leaved*; the other, known as the *Turnip-rooted*, is grown for its roots, which resemble an early horn carrot in size and shape, the flesh being white and mealy, with the flavor of a sweet potato.

CHICORY.—Chicory possesses aromatic oil, starch, sugar, nitrogenous substances, and salts; and though inferior, its action is in the same direction as coffee. When mixed with the last-named, it imparts both color and body, and is considered by most people to improve the beverage, so that it can scarcely be called an adulteration. The seeds should be sown in May, in drills ¾ in. deep and about 15 in. apart. The soil should be rich, mellow and well trenched 12 or more in. deep. When the young plants are 2 or 3 in. high, they should be thinned out to 8 in. apart. The soil should be kept frequently stirred and clear of weeds. Before being used as a salad the leaves should be blanched, which is done by inverting boxes or flower-pots over them about 12 in. deep, or by placing boards, nailed together at right angles over the rows. When wanted for winter use, the plants are to be taken up late in the fall and planted thickly in a box filled with sand or light earth, and then placed in a cool cellar, watering them after planting. When wanted for use, a box full of them should be placed in a dark room where the temperature will be from 50° to 60°; or they may be placed in the kitchen, and another box, such as a soap box, inverted over them. They will soon start into growth, and afford a supply of blanched leaves for salading purposes. Varieties: *Large Rooted, or Coffee.* Much used as a substitute for coffee, and large quantities of the prepared root are annually exported to this country for similar use. In the fall, the roots require to be taken up and cut into small pieces and put where they will dry, requiring the same treatment used in drying apples. When required for use, it should be roasted and ground like coffee.—*Paris.* This variety produces the *Barbe de Capucin*, a salad much used in France. Sown in June, the roots are transplanted in autumn into sand, in a cellar, and the shoots soon come up.

Chicory.

CHIVES.—These are small and not very important members of the onion tribe, quite hardy everywhere. The leaves are slender and appear very early in the spring, and may be shorn several times during the season. They are propagated by divisions of the root. The chives make the very best border for beds in the vegetable garden, and are not only ornamental, bearing pink flowers and masses of green leaves, but equal to the onion for flavoring soups and salads.

CRESS, or PEPPERGRASS.—This should be sown in a hot-bed or in a sheltered spot in the garden, quite thick, in shallow drills, and in a short time it will be fit for cutting. It gives a pungent relish to lettuce and other salad plants. A fresh lot should be sown every week, as it matures very rapidly and is useful only when young.

CRESS, Water.—Cultivated by sowing the seeds by running water, near springs which are not severely frozen in winter. Transplanting, however, is always surer than sowing. This may be done from March till August. The distance between the plants should be 10 or 15 in. Stirring the earth about the roots is useful; but having once taken root, no further care is necessary. There are three varieties of watercress: The *Green-leaved*, the easiest to cultivate; the *Small Brown-leaved*, the hardiest; and the *Large Brown-leaved*, the best for deep water.

CUCUMBER.—For open air raising, cucumbers should be planted in hills about 4 ft. apart, early in May; those intended for pickling may be planted till July 15th. Before planting, prepare the ground by mixing well rotted manure with the earth of each hill. 2 or 3 plants are enough to a hill. The seed should be sown about ½ in. deep; the plants must be kept free from weeds, and in very dry weather they should be watered. To have cucumbers earlier than by the ordinary way, make a hole under a warm fence, and put some hot dung in it. On this put 6 in. of fine, rich earth, and sow some seed in it. Cover at night with a carpet or other article. When the plants come up, and before they show the rough leaf, plant 2 in a pot; or let the seeds

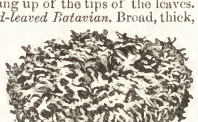
be originally planted in one, or in some large turnips, scooped out and filled with earth. The first pots may be put into a bed prepared for them, and covered as before, where they are to stand until cucumbers sown in the natural ground come up, when they may be turned out with the ball of earth and planted. When planted in turnips, put the whole into the ground. Varieties: *Bismarck.* Very constant in color and uniformly well formed and handsome. — *Early Cluster.* A popular early sort, very productive, producing its fruit in clusters; fruit about 5 in. long; skin prickly; flesh white, seedy, tender. — *Early Frame.* Plants vigorous, healthy and productive; fruit straight and well formed; flesh tender and somewhat seedy, although the young fruit makes excellent pickles. A good variety for forcing. — *Early Green Cluster.* Next in earliness to the Russian; small, prickly, in clusters, productive. — *Early Russian.* One of the earliest and hardiest varieties, and desirable for first planting. Fruit 3 to 4 in. long, and generally produced in pairs; flesh tender, crisp and well flavored. — *Early White Spine.* One of the best sorts for table use. Vines vigorous, fruiting early and abundantly; fruit uniformly straight and handsome, light green, with a few white prickles; flesh, tender and of excellent flavor. — *Gherkin.* Not a cucumber proper, but a little, rough, prickly fruit, that grows on a pretty vine, with leaves something like the watermelon. It is liked for pickling, and is known as the *West India Gherkin.* — *Improved Long Green.* Produced by selection from the London Long Green. Vines vigorous and productive, forming fruit fit for the table nearly as early as the shorter sorts; fruit about 12 in. long, firm and crisp, with very few seeds. The young fruit makes one of the best of pickles, and when ripe is the best of any for sweet pickles. — *Russian Netted.* Exceedingly prolific, and in hardiness surpasses all other varieties; of medium size, white flesh, skin covered with a pretty, white net-work, which imparts to the fruit a peculiar and handsome appearance.

Improved Long Green Cucumber.

DANDELION.—When cultivated in good rich garden soil it makes admirable spring greens, and when blanched, a salad resembling endive. The seed should be sown in May or June. Sow in drills ½ in. deep, and 12 or 15 in. apart, and in July thin out to 3 or 4 in. apart. The following spring they will be fit for use. For a salad, blanch the heads as with endive.

EGG PLANT. — Cultivation similar to musk melon. The soil cannot be made too rich. When about 1 ft. high, hill as with any other vegetables; Varieties: *Black Pekin.* Quite early and large. Very prolific and desirable for market gardeners. Fruit nearly round; skin smooth, black and glossy; flesh white, fine grained and delicate.—*Early Long Purple.* One of the earliest varieties; very hardy and productive; fruit long, and of superior quality; good for general culture.— *Improved New York Purple.* Very large and fine; the best.

ENDIVE.—Endive is one of the best salads for fall and winter use. Sow for an early spring about the middle of April. As it is used mostly in the fall months, the main sowings are made in June or July from which plantations are formed 1 ft. each way, in Aug. and Sept. It requires no special soil or manure, and after planting is kept clear of weeds until the plant has attained its full size, when the process of blanching begins. This is effected by gathering up the leaves and tying them by their tips in a conical form with bass matting. This excludes the light and air from the inner leaves, which in course of from 3 to 6 weeks, according to the temperature at the time, become blanched. Another and simpler method consists in covering up the plants as they grow, with slats or boards, which serve the same purpose by excluding the light, as the tying up of the tips of the leaves. Varieties: *Broad-leaved Batavian.* Broad, thick, plain or slightly wrinkled leaves. Principally used for cooking; preferred for stews and soups. If the outer leaves are gathered and tied on the top, the whole plant will blanch nicely, and make an excellent salad for the table.— *Green Curled.* The hardiest variety, with beautifully curled, dark green leaves, which blanch white and are very crisp and tender.— *White Curled.* Grown chiefly for summer and autumn.



Endive and Flower.

FETTICUS, or CORN SALAD.—Chiefly grown as a winter and early spring salad, but is sometimes used boiled, as greens. It requires a rich soil. The seed may be sown towards the end of August or the beginning of September, in drills 6 or 8 in. apart and ½ in. deep, rolling after sowing. When the plants are well up, thin out to 3 or 4 in. apart. Keep them well hoed and clear of weeds, and when severe weather sets in, give them a slight covering of straw or salt hay, as is done with spinach, removing it in March or April. It can also be sown early in the spring, and will be ready for use in 6 or 8 weeks.

Fetticus.

GARLIC.—This belongs to the onion family, and is the most pungent of all. The varieties

cultivated are the *Large* and the *Small*. It is grown by planting the bulb, root, or seed, in drills 2 in. deep, 6 in. apart, and 4 in. from plant to plant; plant early in the spring on light, rich ground; it should be well hoed. The bulbs attain their full size about the 1st of August, when the leaves wilt.

HORSE-RADISH.—Propagated from seed and sets, the latter obtained by cutting the main root and offsets into lengths of 2 in.; the tops or crowns of the roots form the best. Each set should have at least 2 eyes. The soil should be rich and mellow. The best time for planting is in October, for dry soils, and in February, for moist ones. The sets must be inserted in rows 18 in. apart each way. The ground should be trenched between 2 and 3 ft. deep, the cuttings being placed along the bottom of the trench, and the mold turned from the next one over them, or inserted to a similar depth. The shoots make their appearance in May or June. The only culture required is to hoe and rake the ground, and destroy the weeds. In taking up the roots, it should be done regularly, instead of a root here and there, as is often practised.

KALE, or BORECOLE.—Cultivation same as cabbage. Sow the seed in May; set out plants in July; they are better when touched slightly by the frost, and may be kept in the same manner as cabbages, during winter. The stocks, in spring, send out numerous tender shoots; and 1 oz. of seed will produce nearly 4,000 plants. The two best varieties for winter use are the *Dwarf Green Curled* and the *Purple-leaved*. The first seldom grows more than 18 in. high, and the plants may be set that distance apart. The last grows about 30 in. high, and should be planted 2 ft. apart on the rows. Other varieties: *Green Scotch, German Curled, Purple, Jerusalem*, and *Thousand-headed Cabbage*. The two last grow to 4 ft., and yield large numbers of sprouts.

Scotch Kale.

KOHL-RABI.—Belongs to the cabbage tribe, and the culture is the same, but the stem swells out, assuming a globular form resembling a turnip, this being the edible part. It is best sown thinly in drills, where it will remain. Varieties: *Green*. Large and excellent; raised both for table and cattle use.—*Purple*. Purple bulb, very tender, excellent for table.—*White Vienna*. Bulb light green, rapid in growth and symmetrical in form.

White Vienna.

LEEK.—Belongs to the onion tribe, but is more delicate. The culture is similar to that of the onion, but it requires more water. Put the rows 8 in. asunder, and thin the plants to 3 in. apart in the row. Hoe frequently between the plants until the middle of July, then take them up, and cut their roots off to 1 in. long. Make trenches for them like those of celery, only not more than ½ as deep, and ½ as wide apart. Manure the trenches with rotten dung, or other rich manure. Put in the plants as you do celery plants, and about 5 in. asunder. As they grow, earth them up by degrees. 3 leeks planted out for seed will ripen in August, and be enough for the next year. The chief varieties are: *London Flag*. This variety is more generally cultivated in this country than any other; it is hardy and of good quality.—*Musselburgh*. A remarkably large and showy variety.

Leek.

LETTUCE.—All sorts grow freely on any rich, mellow soil, where the subsoil is dry. Raise it on beds set apart for it, keeping the varieties separate; to multiply the supplies throughout the summer, portions may be sown, thinly intermixed with principal crops of leeks, onions, carrots and spinach, which will come off before the lettuces are fully grown. Sow from February to July, for the main summer or autumn crops. For an early crop, sow in the beginning of February, on a gentle hot-bed; care must be had to water them frequently with tepid water, so that they may be kept in a constantly growing state; and when the plants are 1 or 2 in. high, in March or April, prick a portion either into a warm border, or else let them be shielded with mats, during nights and bad weather, transplanting to a slender hot-bed, to bring them more forward. According to their progress in April or May, transplant them into the open garden, from 6 to 12 in. asunder to remain for heading. Varieties: *Brown Dutch*. An old sort, noted for its hardiness; leaves large, thick, green, tinged with brown. It forms a large, solid head with the inner leaves beautifully blanched, exceedingly sweet, tender and good flavored.—*Early Tennis Ball*. Very hardy and the best variety of head or cabbaging lettuce for growing under glass. Leaves dark green, thick, crisp and tender, forming under glass a compact head, but apt, unless planted very early, to be loose and open in the open air.—*Early White Head*. An excellent variety for hot-bed as well as open air culture; early and hardy. Heads small, white, crisp, very compact, and closely cabbaged.—*Green Fringed*. Exceedingly ornamental inside, the leaves are white, the edges a delicate green, and beautifully fringed and crimped; worthy of cultivation for table decoration though the quality is inferior.—*Hanson*. A very fine heading

Brown Dutch Lettuce.

variety of the largest size and standing the sun better than any other. The heads are very large, solid, sweet, tender and crisp throughout, and entirely free from any bitter taste. — *Large Drumhead.* Heads remarkably large, somewhat flattened, compact; pale green without, and white at the centre; crisp and tender; one of the finest summer varieties; seeds white. — *Simpson's Early Curled.* One of the best early sorts for market or family use; all the leaves tend to produce a large, loose head. Leaves beautifully crimped, dark green, very tender and crisp. — *White Paris Cos.* The heads are long, upright, with oblong leaves. It is very hardy, of large size, and long in running to seed; tender, brittle, and highly flavored.

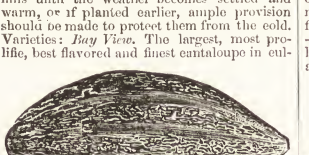
White Paris Cos.

MARTYNIA.—Seed-pods of this plant are used for pickling when in their young, green state, and by many persons are preferred to cucumbers. The seed should be sown in an open border in April or May, and in June should be transplanted into the permanent bed at a distance of 2 or 2½ ft. apart each way. In many soils it is apt to become a vile pest. Gather the pods before becoming woody.

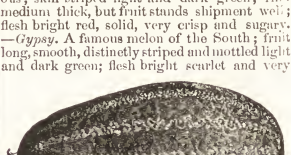
MELON, Musk.—A warm, moist, rich, loamy ground is most suitable for this crop. Hills should be prepared by digging out the soil from 1½ to 2 ft. deep and 2 or 3 ft. broad; add a very liberal quantity of the best decomposed stable manure, and mix well with the soil, filling up a little above the general level. By this mode, good melons may be raised on almost any soil. Plant in hills 6 ft. apart each way, 8 or 10 seeds in each, and thin out to 3 or 4 plants when well up. After cultivation, similar to that of the cucumber. Seeds should not be put into the hills until the weather becomes settled and warm, or if planted earlier, ample provision should be made to protect them from the cold. Varieties: *Bay View.* The largest, most prolific, best flavored and finest cantaloupe in cultivation; luscious, sweet, and very hardy; picked green, it will ripen up finely, and carry safely for a long distance. — *Casaba Citron.* Very showy cantaloupe, quality variable, in many instances, not surpassed by any known variety; flesh orange in color; sometimes produces fruit twice as large as an ordinary cantaloupe. —*Early Yellow Cantaloupe.* The earliest; of good size, nearly round, slightly ribbed. Flesh yellow, thick, but quite variable in quality. —*Green Citron.* Handsome fruit, roughly netted all over; flesh thick, green, melting and very sweet. —*Jenny Lind.* A very small, early variety, flattened at the poles; healthy, and of surpassing quality; recommended for family garden, but small for market. — *Montreal Green Nutmeg.* Nearly round, flattened at the ends; deep, regular ribs; skin densely netted; flesh thick and of a delicious flavor. —*New Surprise.* An excellent new variety; skin cream colored and thickly netted; flesh deep salmon color, of excellent flavor; very prolific. —*Nutmeg.* Of large size; flesh green, rich, sugary. — *Pine Apple.* Dark green; of medium size; rough netted; flesh thick, firm and sweet. — *Skillman's Fine Netted.* A small, very early, rough netted variety; flesh, green, thick, firm, sugary and of delicious flavor.

Green Citron Melon.

MELON, Water.—Requires a light, sandy soil, not over rich. Plant in hills, as directed for musk melons, giving more room, as the vines extend much farther. If wanted of large size, 3 or 4 melons to each plant will be sufficient, and when only one is allowed to grow from each plant, they will grow to 20 or 30 lbs. weight each. If they are planted near other varieties of vines, they will hybridize, and greatly injure the flavor. Varieties: *Black Spanish.* Vine small, so that they may be planted closer than most sorts. Fruit round, very dark green, with scarlet flesh and black seeds. It is not so large as some of the other sorts, but has a very thin rind and a rich, sugary flavor. — *Cuban Queen.* One of the largest melons known. Vine vigorous; skin striped light and dark green; rind medium thick, but fruit stands shipment well; flesh bright red, solid, very crisp and sugary. —*Gypsy.* A famous melon of the South; fruit long, smooth, distinctly striped and mottled light and dark green; flesh bright scarlet and very sweet. —*Ice Cream.* Medium size, nearly round; color pale green; white seed, thin rind, flesh solid, scarlet, crisp and of delicious flavor. —*Mountain Sweet.* One of the very best for general culture.



Casaba Citron Melon.



Gypsy Water Melon

Color dark green; rind thin; flesh scarlet, solid, very sweet and delicious.—*Orange.* Oval melon; skin green; flesh scarlet, of good quality, and may be easily separated from the rind. —*Peerless.* Rind thin, light green; flesh solid, bright in color, sugary.—*Phinney's Early.* Very early; medium and uniform size, and beautiful form; skin smooth, with uniform, narrow, white mottled and dark green stripes; flesh light red or pink, very sweet and delicious. For an early melon for family use it has few superiors, but does not bear carriage well, on account of its thin, brittle rind.

MOREL.—Chiefly used fresh or dried, to flavor sauces. Garden culture may be by collecting the spawn in June, and planting in dung-beds or ridges. It grows on wet banks, in the woods, and in moist pastures, and under old apple trees, and should be gathered when dry.

MUSHROOMS. — Grows spontaneously and very luxuriantly, and numbers several varieties, some of which are very poisonous. It needs great care to raise it artificially and to do so successfully requires a special training. It is raised in hot beds and otherwise. None but those familiar with the different species should collect the article at all, on account of the great resemblance between the good and the poisonous. The crown or hat is at first hemispherical, then convex, and at last flat, fleshy; about 2 to 5 in. broad; white, or very light brown, slightly scaly; the scales soft and fibrous; gills pink, changing to brownish black; the flesh when divided, changes generally to a reddish hue.

Mushroom.

MUSTARD.—Any free and open space in the garden will do for this plant. Sow from the beginning of November to March in a gentle hot-bed, or in the corner of a stove. From the close of February to the close of April it may be sown in the open ground, in a warm, sheltered border, and from thence to the middle of September in a shady one. Sow in flat bottomed drills, about ¾ in. deep, and 6 in. apart, very thickly. The earth should be very fine. Water in dry weather. Sow once or twice in a fortnight, according to the demand. The young plants, when about 3 in. high, are used as a salad, like cress, and the seeds are used in pickles. There are 2 species of this plant, the *Black* and the *White.*

NASTURTIUM. — The unripe succulent seed-pods are used for pickling, being an excellent substitute for capers. (For cultivation, see same in VARIETIES in FLORICULTURE.) The plants should have pea-brush set to them when they are about 6 in. high, on which they may climb. The pods should be gathered when of the size of a small pea; if left on too long, the seed within them becomes hardened and unfit for use. Sometimes the young shoots are used as a salad, or for mixing with lettuce. The *Dwarf* is the best variety for kitchen garden purposes. The *Tall Mixed* is useful and ornamental.

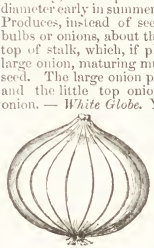
OKRA.—It may be sown, with certainty of success, at the time of planting Indian corn. Draw drills about 1 in. deep, and 4 ft. asunder, into which drop the seeds at the distance of 2 in. from one another, and cover them 1 in. deep. As they advance in growth, earth them up like peas. Varieties: *Dwarf.* Grows from 2 to 2½ ft. high and is best adapted for the garden. — *Long Green.* Long pale green, and ribbed. — *Tall or Giant.* This grows 5 or 6 ft. high, taking up too much room in the garden.

Okra.

ONIONS.—For a general crop, the ground should be well prepared by digging in some of the oldest and strongest manure that can be got. Plant in April or May, sowing the seed moderately thick, in drills 1 in. deep and 12 in. apart. The plants should be hoed 3 times during early growth. Beds to stand for ripening should be thinned out, while young, to 2 or 3 in. apart. When the greenness is gone out of the tops, it is time to take them up, for from this time the roots decay. After being pulled they should be dried, and removed to shelter. The small onions may be planted in the following spring. Even an onion which is partly rotten will produce good bulbs, if the seed stems be taken off as soon as they appear. Most varieties are propagated by seed. The potato onion, however, does not produce seeds, but increases by the root. One onion, slightly covered, will produce 6 or 7 in a clump, partly under ground. The bulbs are generally planted in the spring, 12 to 18 in. apart, though they are apt to yield better when planted in autumn, as they will survive the cold, if covered with dung or litter. Varieties: *Extra Early Red.* Ripens about 10 days earlier than the Large Wethersfield, and is rather smaller in size, but close grained and heavy. —*Giant White Italian Tripoli.* A large, beautiful, pure white, flat onion of mild and excellent flavor; to attain the full size, the small bulbs should be set out the next spring. — *Large Red Globe.* A handsome globular onion, of mild flavor and a good keeper. — *Large Red Wethersfield.* The standard variety, and the favorite onion in the East, where immense crops are grown for shipment. Large size; skin deep purplish red; form round, flat; flesh purplish white; stronger flavored than any of the other kinds. Very productive and the best keeper. — *Large Yellow,* or *Yellow Dutch.* One of the oldest sorts.

Extra Early Red.

and, as a market variety, probably better known than any other. Flesh white, fine grained, mild, and well flavored. — *Marzajola.* Probably the earliest variety grown in the warm climates; seed sown in autumn produces bulbs in spring. — *New Queen.* Silver skinned; of quick growth and remarkable keeping qualities. If sown in February, it will produce onions 1 to 2 in. in diameter early in summer. — *Top Set*, or *Button.* Produces, instead of seed, a number of small bulbs or onions, about the size of acorns, on the top of stalk, which, if planted, will produce a large onion, maturing much earlier than from seed. The large onion produces the top onion, and the little top onion produces the large onion. — *White Globe.* Yields abundantly, producing handsome and uniformly globe shaped bulbs. The flesh is firm, fine grained, and of a mild flavor. — *White Portugal.* A large flat onion; skin loose; of a mild flavor; fine for early winter use, and much esteemed for pickling; the best keeper of the white varieties.—*White Silverskin for Pickling.* This is of small size, silvery white, and, on account of its small size and handsome appearance, is preferred for pickling. — *Yellow Danvers.* Mild flavored, very productive, ripens early and a good keeper.



White Globe.

PARSNIP.—Sow the seed in drills, and leave in thinning, 8 in. apart in the rows; keep clean by frequent hoeings, and in the autumn they are fit for use; they improve in quality by being exposed to the frost, and will remain in the earth without injury; those intended for spring use may be left in their beds, and are usually found in a fine state in the spring months. The seed of this plant vegetates with some difficulty, and in a light, dry soil should have the earth pressed upon them with a roller immediately after sowing. The drills in which these are planted should be about 1 in. deep and 14 to 15 in. apart, sowing the seeds quite thickly. When grown as a field crop, the rows should be 20 in. apart, so that they can be readily worked with a cultivator or horse hoe. Varieties: *Early Round.* An early variety of small size. — *Guernsey.* A coarse growing variety; valuable for stock food, for which it is alone recommended. — *Hollow Crown.* Roots oblong, ending somewhat abruptly; with a small tap root; grows mostly below the surface; has a very smooth, clean skin, and is easily distinguished by the leaves arising from a cavity on the top or crown of the root. — *Long White Dutch*, or *Sugar.* Roots very long, white, smooth, tender, sugary, excellently flavored. Very hardy, and will keep through winter without protection.

PEAS.—For early peas, the soil should be light, warm and sheltered, but for general crop a moderately heavy soil is preferable. Sow as early as possible a few of the earliest varieties on warm quick soil prepared the fall before. The general crop can be delayed until later, but better success is obtained from sowing all the varieties comparatively early, depending for succession on selecting sorts that follow each other in ripening. The very earliest may be covered only 1 in. deep; the other sorts should be covered from 2 to 6 in. deep, the deep planting preventing mildew, and prolonging the season. Fresh manure or wet, mucky soil should be avoided, as they cause the vines to grow too rank and tall. Gather the crop as fast as it becomes fit for use. If even a few pods begin to ripen, young pods will not only cease to form, but those partly advanced will cease to enlarge. All wrinkled peas are superior to, and more delicate in flavor than those that present a full and perfect form. Varieties: *American Wonder.* A highly improved variety, whose stout, branching vines grow only about 9 in. high, and are covered with long, well filled pods. The peas are of the best quality. — *Blue Peter*, or *Blue Tom Thumb.* An early, dwarf, blue pea, of robust habit and strong growth. It grows about 9 in. high, and needs no sticks; it is a great producer, and perhaps, with the exception of the American Wonder, the most dwarf of any. — *Champion of England.* One of the richest and best flavored grown, and very productive; height 4 or 5 ft.; seed whitish-green and much shriveled. — *Dwarf White Marrowfat.* Similar in general character and appearance to the Large White Marrowfat, but of stiffer habit and dwarfer growth, being only 3 or 4 ft. high. — *Large White Marrowfat.* Cultivated more extensively for the summer crop than any others. 5 ft. high, of strong growth. Pods large, round, rough, light colored and well filled; seed large, round and yellow or white, according to the soil in which they are grown; excellent for summer use, but inferior to some of the newer sorts; the greatest bearer. — *McLean's Little Gem.* A very desirable early, dwarf, green, wrinkled variety, growing about 15 in. high. When in a green state, it is very large, sweet, and of delicious flavor.

PEPPER.—Sow early in a hot-bed, in the Northern and Middle States, or in the open ground, in a seed bed, about the middle of spring, in light warm soil. Transplant when 3 in. high, 1 ft. apart, in 18 in. drills, and earth up a little at 1 or 2 hoeings. Guano, hen dung, or any other bird manure applied upon the surface and hoed in when the plants are about 6 in. high will be found to increase the product. Varieties: *Chili.* Used in the manufacture of pepper sauce. Pods sharply conical, nearly 2 in. in length, and ½ in. in diameter; brilliant scarlet. Requires a long, warm season, and plants should be started quite early in hot-bed. — *Large Bell*, or *Bull Nose.* A very large sort, of square form, mild, thick and

Large Bell Pepper.

hard, suitable for filling with cabbage, and for mixed pickles; less pungent than other sorts, and one of the earliest varieties. —*Long Red Cayenne.* A long, slim pod, rather pointed, and when ripe, of a bright red color. Extremely strong and pungent.

Long Red Cayenne

PUMPKIN.—This is not so particular in regard to soil as melons or cucumbers, but in other respects is cultivated in a similar manner, though on a larger scale. It is generally raised on cultivated farms between hills of corn, and may be planted with success in fields by themselves. Varieties: *Cashaw.* A great favorite in the Southern States, but too tender for general cultivation in Northern climates. In form much resembling the Winter Crookneck Squash, though growing to a very large size, frequently weighing 70 lbs.; color, light cream, sometimes slightly striped with green; flesh salmon colored; very productive.—*Large Yellow.* Grows to a large size, and is adapted for cooking purposes and feeding stock. It is irregular in shape and size, some being depressed and flattened at the ends, others round or elongated; of deep rich yellow color; of fine grain and excellent flavor.

Cashaw Pumpkin.

RADISHES.—Sow for the earliest productions, during December, January and February, in a hot-bed; and in the open ground once a month during winter, and every fortnight during the other seasons of the year; In the open ground sow thinly in drills; bury ½ in. deep; drills for the Long-rooted, 3 in. asunder; for Turnip-rooted, 4 or 5; and for the Spanish, 6 or 8; when the seedlings are advanced to 6 or 6 leaves they are ready for thinning. In dry weather they ought to be watered regularly every night. The early and late crops that have to withstand the attacks of frost, should be kept constantly covered with dry straw to the depth of about 2 in., or with matting, supported by hooping, until the plants make their appearance, when the covering must be removed every mild day, but renewed towards evening, and kept on constantly during frosty or tempestuous weather. The bed should have a good watering the morning before that on which they are taken up, but none afterwards until subsequent to the drawing. The *soil*, a light loam, and moderately fertile, should be dug a full spade deep, and well pulverized. Manures should not be applied at the time of sowing. The situation should always be open, but for early and late crops warm and sheltered. Varieties: *California Mammoth White China Winter.* This was introduced into California by the Chinese; it grows to a large size; flesh, white, firm, and of good flavor. — *Early Long Scarlet, Short Top Improved.* This is unquestionably the best standard variety for private gardens or market use. It grows 6 or 7 in. long, ½ out of ground; is very brittle and crisp, and of quick growth; color bright scarlet; small top; tapers regularly to the root, and is uniformly straight and smooth. — *Early Scarlet Turnip-rooted.* Small top; quick growth; mild and crisp. — *French Breakfast.* A quick growing variety, and one of the best for early forcing. It is of oval form; color, scarlet, tipped with white. — *Olive-Shaped Scarlet.* An early and handsome variety, of a lively rose color and oblong shape. — *Scarlet China Winter.* Form rather conical and very smooth; of a lively rose color; flesh firm and pungent. — *Spanish Winter, Long Black.* Of very large size and firm texture. Store in sand in the cellar for winter use. — *White China Winter.* Except in color, this is similar to Scarlet China.

Long Scarlet Short Top.

French Breakfast.

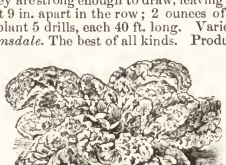
RHUBARB, or PIE PLANT.—Succeeds best in deep, somewhat retentive soil. The richer its condition, and the deeper it is stirred, the better. Sow in drills 1 in. deep. Thin out to 6 in. apart. In the full trench a piece of ground, and manure it well; then transplant the young plants into it, 3 ft. apart each way. Cover with leaves or litter the first winter, and give a dressing of coarse manure every fall. In the spring hoe the bed, and if to be blanched, dig a trench between the rows, and the earth from it place about 1 ft. thick over the stool. This covering must be removed when the cutting ceases in June, and the plants may then be allowed to grow at liberty. The more they are cut from the less productive they are the next year. As the earth in wet seasons is apt to induce decay, the covering may be advantageously formed of coal-ashes or drift sand. Chimney-pots and butter firkins make good coverings for blanching. The finest flavor is obtained by exposing the stalks to the light and air. Varieties: *Giant.* Very large and late green variety, with round stalks of great length and thickness. — *Linnæus.* The earliest variety, and very productive and high flavored. It produces little acidity and is very thin skinned. — *Victoria.* Very large leaf stalks, 2 or 3 in. in diameter at the broadest part, and often 2 or 3 ft. in length. They are stained with red at the base, and finely spotted to the nerves of the leaf.

SALSIFY, or OYSTER PLANT.—This plant, when properly cooked, has a flavor like that of oysters. Cultivation same as parsnips.

SEA-KALE.—The soil should be good, well manured, trenched, and pulverized. If intended to be raised from seed, lay the ground level in April after winter's trenching; draw drills 3 ft. apart, and finally thin the plants to 2 ft. apart in the rows. If the ground is to be planted with sea-kale to stand permanently, choose one-year old plants from a poor piece of ground; no matter how small they are, so long as they are clean from canker and from the distorted crooked swellings caused in them by wounds from the grub. Plant in rows 3 ft. apart, and the plants in the rows 2 ft. apart. Insert the plants singly. A cellar, or the bottom of a dark cupboard, or any dark corner, are excellent places for producing early shoots of it, if planted in sand, old tan, leaf, or other light vegetable soil, or even in common garden earth. The plants should be kept as much in darkness as possible if intended to be well blanched. Strong plants should be taken up, and no matter how thickly they are placed. Water them occasionally with tepid water, and 2 or 3 crops of excellent sea-kale may be obtained in succession before the plants are exhausted.

Sea-Kale.

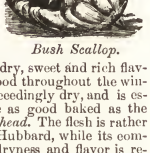
SPINACH.—This is best developed and most tender when grown in rich soil. It should be heavily manured and deeply trenched. Sow early in March for summer crop in drills, which method renders the cultivation and gathering of the produce more convenient. Encourage the growth with frequent hoeing, which draws the moisture to the roots. For a succession a few seeds of the summer varieties may be sown, at intervals of a fortnight, from April to August. Sow from the middle of August to the beginning of September, for the winter crop, in a light, sandy soil, on raised beds, which enables it better to stand the severe frost. Thin the plants as soon as they are strong enough to draw, leaving them about 9 in. apart in the row; 2 ounces of seed will plant 5 drills, each 40 ft. long. Varieties: *Bloomsdale.* The best of all kinds. Productive



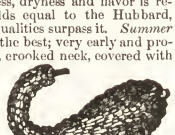
Round-leaved Savoy Spinach.

in leaf, thick foliage and corrugated like a Savoy cabbage.—*Prickly Winter.* The hardiest variety and will withstand the severest weather, with only a slight protection of leaves or straw. The seed is prickly; leaves triangular, oblong or arrow-shaped. It is employed for fall sowing, which is made about the 1st of September. —*Round-leaved Savoy.*—Produces large, thick, dark green leaves, somewhat crumpled, and possesses the valuable quality of standing a long time before running to seed.—*Round Summer.* This variety is generally preferred for early sowing; leaves large, thick and fleshy; not quite so hardy as the Prickly, but stands winter very well.

SQUASH.—This is cultivated the same as pumpkin. The principal varieties are as follows: *Boston Marrow.* A fall and winter variety. Oval form; skin thin; when ripe, bright orange; flesh rich salmon yellow, very dry, fine grained, and for sweetness and excellence, unsurpassed, but not as dry as the Hubbard.—*Early Bush Scallop.* An early, flat, scallop-shaped variety; color yellow or white; flesh pale yellow and well flavored; very productive; used when young and tender for boiling, and at maturity for pies.—*Hubbard.* This is a superior variety, and the best winter squash known; flesh bright orange yellow, fine grained, very dry, sweet and rich flavored; keeps perfectly good throughout the winter; boils or bakes exceedingly dry, and is esteemed by many to be as good baked as the sweet potato.—*Marblehead.* The flesh is rather lighter color than the Hubbard, while its combination of sweetness, dryness and flavor is remarkable. It yields equal to the Hubbard, while its keeping qualities surpass it. *Summer Crookneck.* One of the best; very early and productive. It is small, crooked neck, covered with warty excrescences, the more the better; color bright yellow; shell very hard when ripe.—*Turban.* An excellent variety for use in the autumn and early winter. Flesh orange yellow, thick, fine grained, sugary and well flavored. Generally a light yellow color, but occasionally greenish yellow, striped with white. In form resembling a turban or Turk's cap; not to be confounded with the French Turban, which is more showy but inferior.



Bush Scallop.

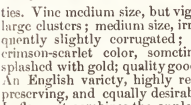


Summer Crookneck.

SWEET CORN.—Requires a rich soil; sow in hills about 3½ ft. apart, from the last of April to the 1st of July; manure each hill, and have only 2 or 3 stalks in each hill. Varieties: *Crosby's Extra Early.* A remarkably early, excellent variety; ears large and produced very low on the stalk; medium length; sweet, rich and delicate.—*Early Minnesota Sweet.* Excellent and very early; ears rather small, long and pointed. —*Early Red Narragansett.* The best red variety of sugar corn; early; kernels shrivelled, and

very sweet and tender. — *Early Sweet.* Ears good size, tender and sugary; plant productive, hardy and quite early. — *Excelsior.* Ears medium in size, but remarkably sweet, succulent and tender; plant small, but very productive. — *Mammoth Sweet.* This variety produces the largest ears of any sort, a single ear sometimes weighing 2 or 3 lbs. The quality is sweet, tender and delicious. — *Stowell's Evergreen.* Intermediate in its season, and if planted at the same time with earlier kinds, will keep the table supplied till October. It is hardy and productive, very tender and sugary, remaining a long time in a fresh condition, and suitable for boiling.

TOMATO.—Tomato is raised from seed, which should be sown in hot-bed in March, or in pots in a warm window. They should be started as early and forwarded as rapidly as possible, whether by hot-bed or open-air culture. When about 2 in. high they should be transplanted in single plants, to warm, light, rich soil. Water freely at the time of transplanting, and shelter from the sun a few days, or until well established. Train upon trellis work, or support by driving sticks in the ground and tying to them. Varieties: *Canada Victor.* Very early; vines large, spreading, productive; fruit of light scarlet color, round, smooth, of medium size, solid, and ripening up well. — *Early Conqueror.* One of the earliest and most productive varieties. Vine medium size, but vigorous. Fruit in large clusters; medium size, irregular, and frequently slightly corrugated; of a beautiful crimson-scarlet color, sometimes dotted and splashed with gold; quality good. — *Green Gage.* An English variety, highly recommended for preserving, and equally desirable for the table. In flavor it combines the apple and tomato; is piquant and highly agreeable; medium size, plum-shaped, and of a bright yellow color. — *Paragon.* Vine very large, vigorous and productive, and continuing so until killed by frost. Fruit large and round; of a very dark, rich crimson-scarlet color, with occasionally a purplish tinge. It ripens evenly, and the flesh is thick and fine flavored. — *Red Cherry.* A small, round, red tomato, of the shape and size of cherries; cultivated mostly for pickling; is very early. — *Trophy.* Well known as one of the best; vines of medium size, but producing compact clusters of fruit in immense quantities; fruit large, smooth, of bright red color; solid, and of good flavor.

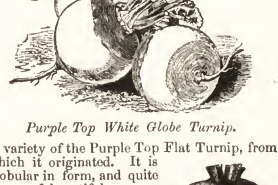


Canada Victor Tomato.

Paragon Tomato.

TURNIP.—Grows best in highly enriched, sandy, gravelly or light loamy soils. Commence sowing the earliest varieties in April, in drills from 12 to 15 in. apart, and thin out early to 6 or 8 in. in the rows. For a succession, sow at invals of a fortnight, until the last week in July, from which time to the end of August sowings may be made for the fall and main crops. Varieties: *Cow Horn* or *Long White.* This variety is carrot like in form, growing nearly half out of the ground, and slightly crooked. It is pure white except a little shade of green near the top. It is delicate and well flavored, of a very rapid growth, and has obtained favor as a market sort for fall and early winter use. — *Early Purple Top Strap-leaved.* Similar to the preceding, except in color, being purple, or dark red on the top. — *Early White Flat Dutch.* A medium size, white, flat turnip, of quick growth, juicy, and of excellent quality when young; sow in spring or fall. Designed for table use; is spongy and inferior when overgrown. — *Purple Top White Globe.*

Cow Horn.



Purple Top White Globe Turnip.

A variety of the Purple Top Flat Turnip, from which it originated. It is globular in form, and quite large; of beautiful appearance; of most excellent quality, and equally desirable for table or stock. It keeps well, and is a fine market sort. — *Ruta Baga, Swedish* or *Russian.* Extensively grown for a farm crop; the roots are close grained, very hard, and will endure a considerable degree of cold without injury. The roots are best preserved in a pit or cellar during the winter; excellent for table early in spring. Sow from the 20th of June to the middle of July, in drills 2 ft.

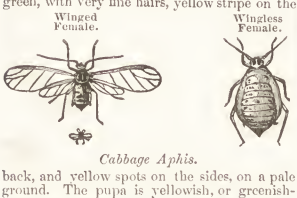
White Egg.

apart, and thin out to 8 in. — *White Egg.* A quick growing, egg-shaped, perfectly smooth, pure white variety, growing half out of the ground, with small top and rough leaves. Its smooth, white skin and quick growth make it particularly adapted for fall market purposes. The flesh is very sweet, firm and mild, never having the rank strong taste of some varieties.

VEGETABLE PESTS.

ASPARAGUS BEETLES.—These are troublesome pests found on asparagus. There are 2 kinds: one, blackish-green, the thorax red, with 2 black dots, yellow wing-cases, the suture and 3 spots united to it on both sides being black; the other, called *Twelve-spotted Leaf-beetle*, red, the wing-cases lighter, each having 6 black dots; the horns, eyes, breast, edge of the abdomen, tips of the thighs and palpi, black. The larva is spindle-shaped, flat beneath, arched, fleshy, wrinkled, covered with single hairs, bordered at the sides, of an olive-color; the head and legs black. The only remedy is to pick off and kill both beetles and larvæ.

BUTTERFLIES.—*Green-veined.* Attacks cabbage. Its wings are white, with the tips of the upper ones black. The male has 1 black spot, the female 2 or 3. The veins on the outer edge of the female's under wings are black. The under wings are yellow on the under side, with greenish-powdered veins. It flies about in April and July. The caterpillar is finely haired, of a faint or brownish green, lighter at the sides, with reddish-yellow spiracles, small white warts, and black punctures. The pupa is yellowish-green, with points on the head. To destroy them, pick off and kill the caterpillars, as well as the pupæ, excepting those which have a brown appearance, as these are full of the larvæ of ichneumons and other allied parasites. — *Large White.* White wings, upper wings with broad black tips, and the female has 2 black spots on the middle. The under side of the under wings is light yellow. Appears from May to October. The caterpillar is bluish-green, thinly-haired, sprinkled with black dots, having a yellow stripe on the back, and some on the sides; found on all sorts of cabbages. The pupæ are yellowish-green, with black dots, with a point on the head, and 5 on the back. Same cure as above. — *Small White.* This also attacks cabbage. It resembles the former insect, but is smaller, and the black tint at the points of the upper wings is fainter, and not visible on the outer edge. The caterpillar is of a dull green, with very fine hairs, yellow stripe on the



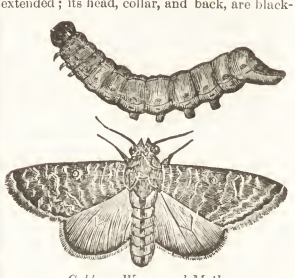
Cabbage Aphis.

back, and yellow spots on the sides, on a pale ground. The pupa is yellowish, or greenish-gray, with 3 yellow stripes. Cure same as that prescribed for the green-veined variety.

CABBAGE APHIS.—Early in June the cabbage aphis makes its appearance on young cabbage plants, and before long becomes very numerous. Tobacco smoke or infusion will destroy them.

CABBAGE FLY.—An ash-gray insect; the thorax has 3 indistinct black streaks on the back; the wings are clear, like glass; the abdomen is linear, with black stripes on the back of the male, or entirely ash-gray on the female; the length is 3 lines. The larva much resembles that of the onion fly, but is thicker. To diminish this, pull up sometimes and carry away the plants attacked by the larvæ, which may be known by their dull lead color, and the withering of their leaves in the sunshine.

CABBAGE MOTH and WORM.—The moth is of middling size, 1½ in. broad, when the wings are extended; its head, collar, and back, are black-



Cabbage Worm and Moth.

ish-gray, intermixed with whitish and yellowish hairs. The back has a thick double crest; the abdomen is dark ash-gray, the upper ½ beset with black tufts in the middle. The upper wings are gray, with a mixture of yellow and white; the under wings are light gray, with dark veins, and central spots, blackish towards the outer edge. The moth appears in May and June, sits in the day-time, and flies only at night. The caterpillar is green, more or less covered with gray or black; it has a dark stripe on the back, on which there is a pale, indistinct line. Above, it is sometimes furnished with dark or pale spots, placed lengthwise. At the sides is a dirty-yellow stripe, which becomes reddish above; close above this spot are 2 white spiracles, surrounded with black, each in a small black spot. Sprinkle over the parts where the worms usually operate, a pinch of cayenne pepper. Or, sprinkle air-slacked lime on the plant

in the morning, on the dew, till the plants are white with it.

CLUB-FOOT.—A disease common to cabbage grown in moist, mucky land. It is caused by a maggot or worm that infects the fine rootlets of the plant, and produces a thickening of the root. Salt, applied 2 or 3 times during the season, is recommended as a remedy. An application of lime to the soil will prove of benefit, or the use of sulphur is good. Another remedy is to boil leaves and twigs of the scarlet-berried alderberry to a strong decoction, and pour 1 gill, cold, on the centre of the plant; 1 application is generally sufficient. On heavy soil it may be necessary to loosen the earth about the stem of each plant. As a preventive, water the plants once or twice with the decoction after setting out.

FLAT-BACKED CENTIPEDE.—This attacks the roots of cabbage. Pieces of boards and chips scattered around the garden will gather a number under them, and they may be destroyed by cutting them to pieces. Or, place a hen with small chickens under a coop in the garden.

Flat-backed Centipede.

FLEA BEETLE.—This is a small black insect which destroys small plants. Soot, tobacco-water, solution of whale-oil soap, infusion of wormwood, Mayweed, pennyroyal, or slaked lime are all good remedies. Toads and snakes do more towards destroying these than all else combined.

LETTUCE FLY.—This insect is blackish brown; the under part and sides of the segments of the abdomen vary ang gray; length nearly ¼ in.; flies in July. The larva is small and smooth, and its color varies into yellow. It is almost impossible to get rid of these insects.

MELON PESTS.—1. To remove from the vines, dilute fresh cow manure until of a paste-like consistency and pour on the vines.—2. Plant a tomato vine in each hill.—3. Put ½ gal. of sharp sand immediately around them.

NEGRO FLY.—Slightly haired, shining black, rather of a metallic-green; head reddish yellow; legs light yellow; balancers white; wings clear, like glass; ¼ in. long. The larva is cylindrical, pointed anteriorly, like parchment, shining, smooth, bare, pale-yellow. Pull up the sickly infested carrots, known by their yellow outer leaves and early withering, and destroy the insects contained in them, before changing into pupæ.

ONION FLY.—The eggs of this fly are laid on the leaves, close to the earth, and the larvæ destroy the root, and cause the plant to turn yellow, wither and die. The larva state lasts about 2 weeks, the pupa is formed in the bulb itself, or in the earth near it, and the fly appears in 2 or 3 weeks afterward. Tar and water, wood ashes, lime, powdered charcoal, flour of sulphur, lime water, soot, petroleum, soapsuds, and pyroligneous acid, are all good remedies. As a preventive sow the seeds deeper than usual.

Onion Fly.

PARSNIP or PARSLEY WORM.—A large thick-bodied, apple-green worm, with black bands, which finally becomes a beautiful butterfly. It appears in July and August. To destroy pick off by the hand and kill.

Parsnip or Parsley Worm.

PICKLE WORM.—A pale green worm, which produces a peculiarly marked moth of yellowish brown color with an iris-purple reflection. It bores holes into cucumbers, squashes and melons in the garden, and after being gathered. The vines should be carefully watched and all infested fruits cut and destroyed immediately.

Pickle Worm.

Moth of Pickle Worm.

SKIP-JACK.—This insect attacks lettuce. It is a light yellow, 6 to 7 lines long, of the thickness of a pigeon's quill; its body is cylindrical, somewhat flatly compressed at the head, rather pointed behind, with strong, black, and shining jaws. The pupa or nymph is shorter than the larva, paler in color, and thicker. The beetle, which is developed from the pupa in 14 days, is from 4 to 5 lines long, 1½ lines broad, and has the usual form of spring beetles; it is slightly curved; head and thorax dark-brown; wing-cases yellowish, striped, with dots; the feelers are slender, notched, and yellowish-brown; the under side of the body also brownish. To get rid of this pest, pull up every plant that begins to wither, and kill the enemy within, or in the earth near the plant.

SQUASH BUG.—Very destructive to squashes and pumpkins. It is a little over ½ in. long, of a rusty-black color above and dirty yellow beneath. It gives off an odor like that of an over-ripe pear. They may be destroyed by pressing and cracking them between the thumb nails, or the clusters near the edge of the leaf may be torn off and trampled on, or destroyed by fire. The *Spotted Squash Bug* feeds upon the leaves of the squash, eating them in large circular holes. It is commonly called *Lady Bug.* The larvæ

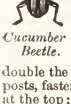
Squash Bug.

after attaining their growth, change to pupæ, enclosed in the dry and thorny skin of the larvæ. They remain in this state for a week, when the beetles crawl out. To destroy them, brush from the leaves into a pan of brine or boiling water. Encourage toads, lizards and snakes.

Spotted Squash Bug.

Larva Spotted Squash Bug.

STRIPED CUCUMBER BEETLE.—Feeds upon the leaves and tender shoots of the cucumber and melon. The larvæ work upon the stem generally below the ground. They are bright yellow with black stripes and black head. To destroy them, set 4 stakes 1 ft. high out of the hill; fold a stout newspaper



Cucumber Beetle.

Larva of Cucumber Beetle.

double the longest way and wind it around the posts, fastening tightly with pins; leave it open at the top; cover 1 or 2 in. of the bottom all around with dirt, or sprinkle the vine with Paris green.

STRIPED FLEA BEETLE. — Perforates small holes in the leaves of young cabbage. To destroy it, dust the plants with ashes, sulphur, lime, plaster, or snuff.

Striped Flea Beetle.

TOMATO PESTS.—To remove the pests from the tomato vine, take 1 bus. of newly slaked lime, and mix therewith ½ bus. wood ashes; mix and blend the whole intimately together, and sift the powder lightly along the top of the drills. Liberal sowing and rapid growth best insure the plant from injury; and to effect this, the seed should be plentifully sown in a rich soil, and, if possible, when the ground is moist. Before sowing, the seed should be steeped in some preparation, which experience has shown will the most quickly develop the germ. Hand-picking the worms is the easiest and surest mode of destroying them.

WEEVIL.—This deposits its eggs on the surface of the pods of beans and peas. It is about ¼ in. long and black in color. As soon as the eggs are hatched, the larvæ bore directly through the pod, 1 entering each pea or bean, and making a puncture smaller than a pin-hole. As the pea and pod enlarge, the puncture closes up, and the larva excavates a small cavity in one side of the pea, leaving its outer coating whole. In this cavity it assumes the pupa state, and comes out a perfect beetle the next year, usually about the time the young peas are in bloom. If the weevils are in the peas when sown, they remain in the ground till the proper time to come out and deposit their eggs. Inclose the peas, after they are perfectly dry, in a tight cask, and keep them over to the 2nd year before sowing, which will kill the weevils; put them into water just before sowing, when the sound ones will mostly sink, and those containing the weevil will rise to the surface. Also immerse them in hot water for 1 or 2 minutes, by which most all the weevils will be killed and the sprouting of the peas not injured. Beans and peas can be preserved by mixing with them, when being stored away, a few drops of crude carbolic acid.

Weevil.

LANDSCAPE GARDENING.

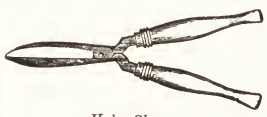
REMARKS.—In landscape gardening, aim to separate the accidental and extraneous in nature; preserve only the spirit or essence. This subtle essence lies in the expression more or less pervading every attractive portion of nature; and it is by eliciting, preserving or heightening this expression that landscape gardening has a higher charm than even the polish of art can bestow. The two principal things to be aimed at are the production of the beautiful and the picturesque. The beautiful is nature or art obeying the universal laws of perfect existence, freely, easily, harmoniously and without the display of power. The picturesque is nature or art obeying the same laws rudely, irregularly, and sometimes displaying power only. Unity, harmony and variety are the great principles in landscape gardening. Unity, or the production of a whole, is of the highest importance. The mind can only attend, with pleasure and satisfaction, to one object, or one composite sensation at a time. In the arrangement of a large extent of surface, where a great many objects are necessarily presented to the eye at once, the principle of unity will suggest that there should be some grand or leading features to which the others should be merely subordinate. Thus, in grouping trees, there should be some large and striking masses to which the others appear to belong, instead of scattered groups, all of the same size. Variety is a great source of beauty in landscape gardening. It should be considered as belonging to details, and not to the production of a whole. Introducing trees and shrubs, different species of vegetation, or kinds of walks, and ornamental objects, buildings and seats, have a pleasing effect. Harmony is the principle presiding over variety and preventing it from being discordant. If unity only were consulted, the ground might be planted with but one tree only, the effect of which would be sameness. Variety might be carried so far as to have each tree of a different kind, which would produce a confused effect. Harmony introduces contrast and variety, but keeps them subordinate to unity, and is the highest principle of the three.

ARRANGEMENT OF GROUNDS.

APPROACH.—Roads and walks are directly connected with operations on the surface of the ground and with the disposition of plantations. The approach is the most important of these routes. It is the route leading from the highway directly to the house itself. It should bear a proportionate breadth and size, and exhibit marks of good keeping, in accordance with the dignity of the house. The point where the approach is to start from should be chosen so as to afford a sufficient drive through the grounds, before arriving at the house, to give a stranger some idea of the extent of the whole property. The house should generally be approached so that the eye shall meet it first in an angular direction, displaying the beauty of the architectural facade and the end elevations, thus giving a complete idea of the size, character and elegance of the building; instead of leading in a direct line from the gate to the house, it should curve in easy lines through the park or lawn. In the approach, the curves should never be so great, or lead over surfaces so unequal, as to make it disagreeable to drive upon them, and the road should never curve without some reason, either real or apparent.

DRIVES.—These may be made an agreeable feature at a small expense. They should generally commence where the approach terminates; that is, near the house; and then proceed in the same easy manner through various parts of the grounds, farm or estate.

HEDGES.—Fences are unsightly and offensive objects. The close proximity of fences to the house gives the whole place a confined and mean character. Verdant or evergreen hedges are elegant substitutes for stone or wooden fences. To plant a hedge, if the sod is new, break it up in the fall, and in spring plow it, throwing the furrows outward, so as to leave a broad furrow in the middle, in the line of the intended hedge. If the ground is rough, it must be very thoroughly harrowed at planting time, and the earth, thrown into the centre by plowing from both sides, must be allowed to settle for a few days before planting the hedge, to prevent subsequent exposure of the roots. As it is requisite in order to have a handsome-looking hedge, to plant the sets in a straight line, the ground should be staked off at regular distances, and a cord run from one stake to another as a guide. When the plants are ready, they may be set in the ground with but little trouble by inserting a spade to the depth of 5 or 6 in., close to the line, pressing it outward, and dropping a plant into the hole thus made. The spade may then be withdrawn, and inserted a short distance behind its first position, by which the ground is pressed forward against the plant, thus fixing it firmly in position. A double row, with the plants alternating, is preferable to a single-row hedge. In no case should they be planted nearer than ten inches asunder in the rows, and the rows should be at least 8 in. apart. Many of the hedge-plants will require to be planted at even a greater distance from each other, or they will not thrive. The first year, keep the ground mellow, and clear of weeds. Throw a furrow against the plants on each side, and subsequently plow from them when weeds and grass spring up. Repeat this operation as often as any obnoxious vegetation makes its appearance, and late in the autumn, plow two heavy furrows against the hedge on each side. Trim frequently with shears during the summer, keeping the shoots down to within 3 or 4



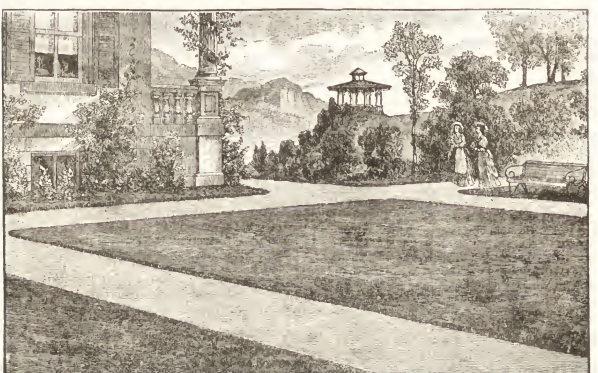
Hedge Shears.

in. of the ground. The second year replace all the plants which have died, setting them carefully, so as to insure their successful growth; cultivate as during the first year. Cut the plants down to the ground in the spring with a scythe, and in June trim all the vertical shoots down to 4 in., but allow the horizontal branches to extend as far as they will. Protect the plants from the frost by throwing a furrow against them, and leave them until the spring of the third year; then trim down the plants to within 5 in. of the last cut, and cultivate as before. The hedge now being very wide, but little vegetation will grow beneath it, consequently so much labor will not be required in clearing out weeds. Prune again in June within 5 in. of the spring cutting, and trim the hedge in a pyramidal, round, or square form. The principal varieties of hedge plants are, *Osage Orange, Honey Locust, Buffalo Berry, Buckthorn, Cockspur, Red Cedar* and *Flat Cedar.*

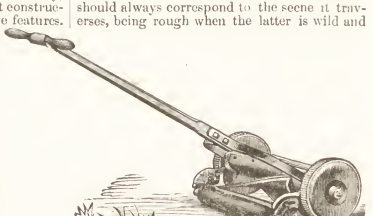
LAWNS.—Soft, velvety, elastic turf, smoothly shorn and of fine color, is always pleasing, but not always attained. The primary requisite is thorough preparation of the soil. A good foundation must be laid by draining and subsoiling, trenching, manuring, or otherwise loosening or enriching the soil. With limited lawns, spade-trenching will be at once thorough and permanent; but where a plow and other implements can be used, the work may be executed more economically, and, by using the subsoil plow in connection with the common surface turning, a depth of 18 in. will be reached. A lawn properly prepared should always receive a coating of gypsum, for this agent is the peculiar pabulum of the white clover plant, one of the richest, densest and most beautiful of our lawn grasses. There are two seasons for sowing—autumn and spring—either of them appropriate. A top-dressing of thinly sprinkled manure will protect the young plants during the winter, and a good thick-set lawn will be secured early in the following summer. After dry, hot weather, the grass-plots will, especially if newly laid, suffer for want of moisture; let plenty of water be poured upon the lawn freely, early in the evening, so that the roots will have time to absorb the water all night long. Should any cracks appear, fill them up with some finely

sifted soil. Roll previously to mowing. Mow early, if the scythe is used, before the dew evaporates, the grass being then more tender, and consequently more easy to mow; besides, the labor is not so much felt by the operator in the cool morning air. But, for lawns, the lawn mower is now well nigh indispensable to produce that even, velvety appearance ever to be desired. The well-known "Philadelphia," from the manufactory of Graham, Emlen & Passmore of that city, always gives satisfaction by its perfect construction and work and nicely adjustable features. Sweep the grass up, and convey it away, either to line a hot-bed or to decay amongst soil in the compost yard. Trim the edges of the walks and flower beds, and remove all the rubbish into the compost yard. Among the many grasses used on lawns, the *Little June* is superior to all others, especially for ornamentation of small areas, like door-yards, terraces, borders of flower beds, and fancy forms. It is one of the very earliest to start in the spring; has a vivid blue tint, a small leaf with capacity for close setting, making a velvet-like cushion, and is also of small and slow growth, thus requiring less clipping. — *Kentucky Blue* is also often used. It is reliable during drought, and winters well, but requires clipping every few days. The *Red Top* also forms a good sward where the soil is good, and the summers comparatively cool and moist; but during dry, warm weather it becomes hard and wiry. The timothy grass vegetates quickly, and greatly assists the growth of the others. The clover is also valuable in rapidly producing a thick, close sod, and getting ahead of the weeds.

WALKS.—These are laid out for similar purposes to drives, but are more frequent and may be introduced into very limited scenes. They should be dry and firm at all seasons. They may be open to the south, sheltered with evergreens, and made dry and hard for a winter promenade; or they may be formed of closely mown turf, shaded by a leafy canopy of verdure for a cool retreat in summer. The walk should always correspond to the scene it traverses, being rough when the latter is wild and picturesque, and more polished as the surrounding objects show evidences of culture or high keeping. Like the approach, it should take easy flowing curves, though it may often turn more abruptly at the interposition of an obstacle. When walks are out of order, with pickaxe and shovel loosen all the rubbish the walk may be made of. If the walk is not drained, or badly drained, have either some draining tiles or bricks with covers ready. Let all the old rubbish



The Lawn.



"*Philadelphia*" *Lawn Mower.*

be sifted, and the rough laid in a ridge at one side of the walk. The fine stuff that passes through the sieve will do well to mix with dung to manure the garden with, especially where the general soil of the garden is heavy, or of a clayey nature. Where there is plenty of room to lay the rough rubbish, the whole may be sifted at once; but where that is not the case, the work may be done in lengths of 10 or more yards at a time. After the rubble is removed, make and lay the drain, provided the walk is deep enough. To make a thoroughly good dry walk, there ought to be at least 9 in. deep of open rubble; the drain should be in the centre of the walk; $\frac{1}{2}$ of its depth ought to be below the bottom of the rubble. Lay short drains from the sides of the walk to the centre drain; upon them, close to the edging, lay 4 bricks to receive a grating, to take in the top water in heavy showers; where the walk is pretty level, these gratings need not be nearer to each other than from 10 to 15 yards; if the walk is steep, or of a moderate slope, the gratings ought to be much more numerous; in extreme cases, as near as 5 yards to each other. The clay, or earth, under the rubble, should be made smooth and sloping from each side, down to the drain. As soon as the drain is laid and the bottom made smooth, the rubble should be put in carefully, so as not to disturb the drain. This should be put in to within 2 in. of the level of the edging. If the edging be out of order, in this state of the walk it is a very good opportunity to renew it; but great care must be taken not to mix the earth with the rubble. When all this work is well done, and the rubble beaten down with a rammer, or well rolled with a garden roller, it is then ready for the gravel. Lay on a coating of rough gravel first, rounding it up in the centre, so that the top of the centre should be as high as the edging, and the sides $1\frac{1}{2}$ in. below it. This rough gravel would be better to lay as it is for a few days, or even weeks, so that it may settle, and become in a degree solid. Then lay on the last coat of moderately fine gravel, the pebbles amongst it not being larger than hazel nuts. This should be laid on pretty nearly level with the edging, and rounded up to the centre. This will, after it has been well rolled and has become solid, allow the water to run to the lowest part of the walk—the sides, and from thence into the drains. All the drains ought to have a gentle descent. If the walk is steep, it is best to lay the bottom of the drain with slate or flat tiles, to prevent the water working away the substratum, which will soon choke up the drain if this precaution is not adopted. In places where the walks are on a steep descent, it is a good plan to pick out of the gravel, or to procure them on purpose, as many pebbles about the size of hen's eggs as will pave each side of the walk 6 or 9 in. wide, laying them rather hollow, so as to form a conduit. This will prevent the gravel washing away.

EMBELLISHMENTS.

ARBORS.—Arbors may be either purely natural, partly natural and party artificial, or entirely the result of art. To the first class belong those trees which send down many branches, such as the weeping-ash, willow, etc. These trees, with their lithe and tenuous branches, waving with every breeze, are the most natural and perhaps the most delightful of arbors. To the second kind belong all those which are formed by the hand of man, such as an aged forest tree with climbing plants placed at its roots, so as to run through its branches and foliage, and descend gracefully from the extremities, until they nearly touch the ground. The construction of the third kind of arbor depends much on the situation; there are many designs for these. The various forms of the Turkish tent are very effective.

FLOWER-BEDS.—It is a mistake to lay out flower beds in exact geometrical forms, unless one has the means to adopt the geometric style of landscape gardening. This style has a bed in one part of the lawn, balanced by a similar bed in another corresponding part; has trees in straight and balanced rows, and walks with straight borders and acute, straight angles. It admits of few curves and no irregularities. It calls for an exactness of detail which is expensive and to most persons displeasing. This style of gardening is going out of date, to be superseded by the more free, graceful and informal natural style. It is better to scatter flower beds wherever a suitable place occurs for locating them. It is poor taste to plant directly in front of the house. A straight walk from the front gate directly to the front door, is not in good taste, and still less so if it is bordered with flowers or shrubs. Most individuals make the mistake of planting too many flower beds. The beauty of a clean lawn is enhanced by a few tasty beds, while it is spoiled by too many. Make the beds wide. If they are narrow, or have long, narrow points or appendages, the grass roots from each side will be sure to join feet under the bed and choke out the flowers. A sharp-cut sod is the neatest border for a flower bed. Stones, shells, bricks and beer bottles do not make tasty borders. It is a mistake to plant too many kinds of plants. A bed with nothing but phlox is far prettier than one with a dozen species of plants. The massing of colors is more effective than scattering them. In the front of most private houses there is usually a single round or square bed. One row or circle of blue, a second of yellow (as the calceolaria), a third of red dwarf geraniums, is a pretty arrangement, which may be varied by the use of dwarf variegated geraniums, etc., where the white leaf is an advantageous foil to the blue and red. In the centre there may be some thick, leafy evergreen.

FLOWER STANDS.—These are very effective when placed in the corners and angles of a garden; the most common form is the vase; but a rustic or any other is just as pretty, provided it is appropriate to its situation.

FOUNTAINS.—In a large garden these add much to the effect. In selecting them the surroundings must be considered, and the color or design should be such as to add to the brightness of the scene, if placed among shrubs and green foliage; if among flowers, bronze is very

effective; white marble is best where the background is green. In deciding where they should be placed, consider the general effect of the whole garden when done.

GARDEN SEATS. — These add much to the beauty and attractiveness of a flower garden, placed either in arbors or under an embowering shade, or in the open garden; they may be composed of hazel rods, or straight small branches of any other tough wood. On the lawn, rustic or wooden benches, painted green or red, add to the general comfortable look; iron ones are also pretty and much used.

HAMMOCKS are convenient during the warm months, and form comfortable beds or resting places during the afternoons. They may be hung between two trees, or on the porch. The disposition of hammocks to sag, can be obviated by placing sticks at each end with hooks along their length, which will catch in the meshes and spread them out flat. 1. Take 4 yds. of strong, unbleached muslin; make a wide hem at each end; slip ropes through, fasten to a tree, and by changing your position a trifle, you have an easy chair, a bed or cradle. — 2. Take a piece of manilla matting, from 2 to 3 yds. long and $1\frac{1}{2}$ yds. wide; bind or hem the ends firmly; fasten each end to a piece of timber; these pieces should be 5 ft. long, 2 in. thick, and should have holes bored about 3 in. apart the whole length; fasten by passing heavy twine from the matting to the hole, back and forth. For each end of the pieces of wood larger holes are bored, through which pass ropes to hang the hammock between two trees.

ROCK BEDS. — After deciding upon the position, excavate the beds, first ascertaining the nature of the soil; if wet, clayey, sandy, or otherwise improper, throwing it aside, to be utilized elsewhere. Let this excavation reach 16 in. below the level, according to the size of beds; throw in a few rough slabs of rock, placing them in various natural positions along the edge of the bed so that about $\frac{2}{3}$ of the stone is hidden when the chasm is filled in, and serving to raise the bed somewhat, here 1 ft., yonder 6 in., and occasionally jutting out to 18 in. Next arrange according to size of bed; if large, it may be built up to a height of 4 ft., or more; but if small it is best to make no attempt to form an imposing structure, rather depending upon tasteful planting, giving the appearance of a mere woodland break among the rocks. In a large bed, let the second layer of stones fall back so as to leave 1 ft. or more of soil exposed in one part, and 3 or more in another, thus forming a diversified and luxuriant vegetation between the rocks. As an approach to such a shady nook, place banks and braes, using care to mark out an irregular line in semicircles and ellipses, so as to give bold sweeps and connecting blocks, which may be made to jut out and divide one portion from another. Dig out a trench and fill in with clay or loam, the former answering especially well, inasmuch as any tree or shrub planted in the upper strata of rich loam will root firmly in it, and prosper continuously. Have banks in the rough, some high, some low, some straight, some crooked, with here an open space and there a deep bay. Face the banks with large blocks of sand and limestone, with huge burrs from a brick kiln or furnace, and when a straight line becomes necessary a rough wall of tree stems and roots will make ample amends. These must be laid horizontally and kept in place with stout uprights, driven down or planted in front, and carried about 2 ft. higher than the level of the bank of clay. On this a bed of fine loam, sand and old rotted manure, or, better still, of peat, will afford a bank on which to grow anything that will live outside a hothouse.

WATER. — When appropriately introduced, the effect of water in pleasure grounds is always pleasing; frequently it is strikingly beautiful. Of all the materials that enter into the composition of natural scenery, there are none that produce a greater amount of varied interest and beauty. It is desirable as an adjunct to the more artificial improvements of private residences, public institutions and city parks, where it can be secured. To form an artificial lake, the first requisite is an ample supply of water at all seasons. Water for ponds is sometimes procured from the discharges of underground drains; where the drained area is extensive enough to furnish all the water necessary, which can be ascertained by observations during summer, a pond may be excavated at the lowest point, allowing the surface of the water to be on a level with the discharge pipes of the drains. The excavated soil can be used in forming the banks of varied heights and configurations. The outline of the pond, like that of a belt of trees or shrubbery border skirting a lawn, should be varied and irregular, with bold points and deep indentations, and these should be a level lawn, surrounded by curved outlines of shrubbery, and that of a smooth sheet of water in a pond or small lake, with jutting banks and retiring bays, is very close, so far as relates to their artistic treatment in ornamental planting. The most natural position for water is in a hollow or low ground, occupied by a constantly running stream. It frequently occurs that small streams are so situated that by skilfully throwing a dam across the valley hollow through which the water runs, a large surface may be flooded and the water permanently retained. The water level on the surrounding ground will probably show a beautifully varied outline, which may be increased or rendered more definite by deepening bay-like recesses and adding to prominent or jutting points. This, together with the effects that may be produced by planting, will give a variety to otherwise monotonous outlines. In geometrically arranged flower gardens, simple basins of water may be introduced with good effect, either with fountains or without them. In these situations the marginal finish or connection between the grass and the water should be of an architectural description. Any attempt made toward a rugged, or what is usually termed a natural looking finish, will prove unsatisfactory. A fountain in the centre of a pond or lake, adds greatly to its beauty. A cascade is the most charming feature of natural brooks and rivulets. A small

cascade may be made by damming up a stream with a few large projecting stones, studiously avoiding any formal or artificial disposition of the stones or rocks employed.

Trees and Shrubbery.

CLASSIFICATION AS TO EXPRESSION. — Trees with relation to form may be divided into *Round-headed*, *Oblong*, *Spiry-topped*, and *Drooping*. *Round-headed*. This includes all trees which have an irregular surface in their boughs, more or less varied in outline, but exhibiting in the whole a top or head comparatively round, as the oak, walnut, etc. They are generally beautiful when young, from their smoothness and the elegance of form; but often grow picturesque when age produces its effects upon them. — *Spiry-topped*. Distinguished by straight leading stems and horizontal branches, which are comparatively small and taper gradually to a point. The foliage is usually evergreen. The evergreen trees comprising the spruce and fir families, most of the pines, the cedar, and among deciduous trees, the larch, belong to this class. These trees, when planted in large tracts or masses, give less pleasure than round-headed trees, yet their general expression when single or scattered is extremely spirited, wild and picturesque. — *Oblong-headed*. Heads of foliage more lengthened out, more formal and generally more tapering than round-headed ones. They have upright branches instead of horizontal ones. The Lombardy poplar is a representative of this class. Its great use is to relieve and break into groups large masses of wood. — *Drooping*. Though these are sometimes classed with oblong-headed trees, they differ from them so much that they deserve to be ranked under a separate head. To this class belong the weeping willow, drooping elm, etc. Their characteristics are gracefulness and elegance, and they are unfit to be employed to any extent in scenes where it is desirable to produce a picturesque character. They are in excellent keeping as single objects, or tastefully grouped in beautiful landscape.

PLANTING AND GROUPING.—It should be the aim in planting to produce not only natural beauty, but higher beauty of expression and individual forms than is found in nature. Create variety and intricacy by various modes of arrangement; introduce rare and foreign plants, and conceal all defects of surface, disagreeable views, unsightly buildings, or other offensive objects; but be careful not to hide the house from all points along the road, nor to place too many trees near it, as they produce dampness. Leave vistas through which to see the house. The group is the key-note of the modern style. A small place, having only a few trees, should have these connected in groups. Many a tame level with scarcely a glimpse of distance, may be rendered lovely by charming grouping of trees. Groups, to be natural, should be full of openings and hollows, of trees advancing before, or retiring behind each other; all productive of intricacy, of variety, deep shadows and brilliant lights. Care should be taken in the formation of groups not to place them in any regular or artificial manner, but they should be disposed so that the whole may express the variety, connection, and intricacy found in nature.

PLANTING FOR THE BEAUTIFUL.—Choose trees of graceful habit and flowing outlines, such as the elm and maple. In disposing them, they should be planted rather distant in groups, and often singly. Close groups may occasionally be formed, but in general the trees should be grouped at a distance from each other to allow a full development of the branches on every side. When a close group is planted the trees composing it should be of the same or a similar kind. Trees or groups where the beautiful is aimed at should be pruned with great care and only to remedy disease, or to correct a bad form. The fall and droop of the branches should never be warred against by trimming the lower branches. Clean, smooth stems, fresh and tender bark, and a soft rounded pyramidal or drooping head, are the characteristics of a beautiful tree.

PLANTING FOR THE PICTURESQUE.—All trees are allowable in a picturesque place, but those trees called picturesque trees, such as the larch, fir and some species of the oak, should be most employed. Everything depends upon intricacy and irregularity, and grouping should be done in the most irregular manner and with different species. There should be a wildness in the disposition of the trees; sometimes planting them closely, even 2 or 3 in a hole, at others more scattered. They should often be mixed with smaller undergrowth of a similar character. Bright vines should be allowed to clamber over trees occasionally in a negligent manner. There should be the same open glades in picturesque as in beautiful plantations; but in the former these openings should be bounded by thickets and groups of every form, and of different degrees of intricacy, while in the latter the eye will repose on softly rounded masses of foliage or single open groups of trees with finely balanced and graceful heads and branches. Pruning, where it is at all necessary, is directed towards increasing the naturally striking, and not to assisting the development of a form of unusual refinement and symmetry.

SHRUBBERY.—The manner in which shrubs are disposed depends in a great degree upon the size of the grounds, the use or enjoyment to be derived from them, and the prevailing character of the scenery. On account of the beauty and abundance of their flowers, shrubs are generally placed near the house. Where a place is limited in size, and the whole lawn and plantations partake of the pleasure-ground character shrubs of all descriptions may be grouped with good effect; the finer and rarer species being disposed about the dwelling, and the more hardy and common sorts along the walks, and in groups, in different situations near the eye. In planting shrubbery in beds or clumps, the taller-growing kinds should occupy the centre or background and those of dwarfer habits the front. With respect to soil, hardy shrubs may be conveniently considered as constituting two

great divisions; one requiring any common garden soil, and the other requiring a large portion of peat or leaf-mold. With regard to the first division, a rich, light, hazel loam is suitable to the greater number of the plants, though some will thrive in the poorest soils; but in this there is great diversity. After having taken out the original soil of the border, about 1½ or 2 ft. deep—though 3 ft. will do no harm—fill in the vacancy thus formed with peat or compost raised above the garden level, to allow for subsequent sinking. With respect to shrubs that shed their leaves on the approach of winter, they may be removed with safety as soon as the leaves have begun to fall in October. Shrubs which do not shed their leaves and are evergreen may, if carefully taken up, be planted at any season of the year, provided advantage is taken of dull or dripping weather. But, notwithstanding, there are particular seasons when they will thrive better and grow more freely than at others. If the situation be dry, and the soil light and sandy, evergreens, with the exception of hollies, should be planted as late in November as the season will permit. But in the case of a bad situation, with a soil retentive of moisture, May is the preferable season. When the plants are large or rather old, good balls should, if possible, be taken up with them, and all the fibres of the roots that can be got up without bruising or injury. Whatever may be the state of the weather, it is important to keep the roots as short time exposed to the air as possible. If only a few minutes, so much the better. In all seasons, situations, and soils, the plants should be well soaked with water as soon as the earth is put about the roots. As soon as a plant has been put into its place, the earth should be filled in and well firmed by pounding or tramping, leaving a sufficient hollow around the stem, and as far as the roots extend, to hold water, which should then be poured in, in sufficient quantity to soak the ground down to the lowest parts of the roots. If the season be very dry, it will be important to lay around the roots a quantity of moss, or cut grass. While the plants are small, care must be taken not to let them be stifled or choked with rank-growing weeds, nor by the increasing growth of contiguous shrubs, and to clear away all rubbish that might retard their shooting; also stir the surface of the ground frequently with a hoe, to prevent the surface becoming hard and caked in dry weather. The branches must be trimmed off as they grow too large or luxuriant, or overhang and smother each other. Among the numerous kinds of ornamental shrubs, the following are a select assortment: *Rose Acacia, Horse Chestnut, Strawberry Tree, Double-flowering Almond, Snowball, Japan Sophora, Spice-bush, Rose of Sharon, Lilac, Carolina Syringa, Spirea, Mountain Rose, Mountain Laurel, Azalea, Calycanthus, Honeysuckle, Hawthorn, Prim, Juniper, Storax, Halesia, Fringe Trees, Cyrilla, Suartia, Clethra, Weigelias, Golden Bell, Fire Bush, Magnolias, Hydrangeas,* and *Upright Honeysuckle.*

PESTS IN GENERAL.

REMARKS.—Insectivorous birds, lady bugs and toads are great devourers of insects, and should always be encouraged in a garden. The birds not only devour the living insects, but also devour the insect eggs, of which they are very fond. Lady bugs live upon the plant lice, and toads live upon small winged insects, of which they catch large numbers. In plant-houses, especially forcing-houses, where insects increase their numbers so rapidly at all seasons, the toad's services are especially valuable; and if a suitable ladder, made of a narrow board with bits of lath tacked on it 2 in. apart, be set in a corner, slanting from the floor to the stage, he will climb it, and thus be able to make himself still more useful. The swallow, swift and hawk are the guardians of the atmosphere. They check the increase of insects that otherwise would overload it. Woodpeckers, creepers and chickadees are the guardians of the trunks of trees. Warblers and flycatchers protect the foliage. Blackbirds, crows, thrushes and larks protect the surface of the soil. Snipe and woodcock protect the soil underneath. Lizards and black snakes are great insect consumers.

ANIMALS.

MICE.—The most satisfactory way of trapping the various species of mice that infest meadows, grain-fields and fruit orchards is, to sink several old barrels in the ground, about ⅔ their length, at different parts of field, and bore 3 or 4 1½ in. holes in the staves, say 6 or 8 in. from the top of the barrel, or at that point of the barrel which will come even with the surface of the ground. When the mice run along, they will be attracted by the barrel, enter the holes and jump into it. As they cannot climb up the inside of a barrel they can easily be disposed of. If a few inches in depth of water should collect in the barrel, field mice will plunge into it and be drowned—provided the surface is covered with dead grass and leaves. If the top of the barrel is left uncovered, and if there should be no water in the barrel, cats will soon learn to take every mouse from the trap. To keep mice from trees, a smooth compact mound of mellow earth, free from grass, made 1 ft. high, late in autumn, is best. A roll of sheet tin or sheet iron coated with gas tar, will be found convenient. Roofing tin, 14 by 20 in. will make to each sheet 4 protectors 7 in. high and 3 in. in diameter. They may be applied after some snow has fallen, with a little pressure and turning about. Tarred building paper is a cheap article, durable and easily applied.

MOLES.—1. To destroy moles, take castor beans, and where they have recently been passing along their underground passages, make a small hole in the passage with the finger or some other way, drop in a couple of beans and cover up the hole with dirt carefully, so as to disturb their track as little as possible. This course, persevered in for a few weeks, will exterminate them. The striped leaf variety that bears a speckled bean is best. — 2. Make a stiff dough of corn meal, mixing with it a small quantity of arsenic; make a hole with a finger in the runways, drop in a lump of dough about the size of a marble, and then cover over with a lump of earth to exclude the light. After the first rain, go over the field again and deposit in all freshly made roads. — 3. Sink a glass or stoneware jar into the ground under the mole-runs. The moles, while running along, fall into the jar, and the vertical, slippery sides of the jar prevent their getting out again.

POCKET GOPHER, or POUCHED RAT.—A prairie animal, confined to the Western States and Territories, and throws up a mound of earth on the prairie, in which it constructs a nest and rears its young. An effectual mode of getting rid of this animal is by trapping. Or, place a short barreled shot gun on a triangular frame, so that the muzzle points to the mound of the gopher; in the mound place a small cross piece, and attach it by a wire to the trigger, which is set at full cock. The motion of the animal discharges the gun. Poison has been successfully used, in the form of strychnine or arsenic, introduced into vegetables, and placed in their subterranean quarters.

PRAIRIE DOG.—To destroy them, mix corn meal with water to form a dough; add strychnine and bake it to form a cake; break the cake into small pieces, 1 of which is put into each prairie dog's hole, taking care to roll it well down and out of the way of domestic animals. Corn or wheat soaked to receive the poison may also be used.

RABBITS.—If bothered with rabbits lurking about and gnawing trees, a ferret will catch the last one. Find where a rabbit has taken to a hole in the ground, and place a sack over the hole; let in the ferret, and in a short time the rabbit will be in the sack.

RATS.—1. Where rats harbor numerously, take 4 joist posts about 4 ft. long and nail 12 to 13 ft. boards to them, about 2 in. apart from bottom to top. This pen should be set near where the rats are most abundant. In setting the pen put 4 in. square blocks under the posts, so that the rats can run under the lower board easily into it; now spread corn, oats or anything they are fond of over the ground inside the pen; then lay down 3 4-in. square joists equidistant, and floor these with boards; let the pen remain thus for a week or so, by which time the rats will have made it a great harbor for themselves; now take the blocks from under the posts and the lower boards of the pen will come so near to the ground that the rats cannot escape underneath it, and it being so high they cannot leap over; put in 1 or more terrier dogs, take out the floor boards and you will see rare sport. — 2. Put a shovelful of dry sand over each hole. The rats soon come up through this, but in doing so let half the sand into the burrow, which, unlike earth, they cannot either force or carry up again, and by repeating this at every fresh opened place their runs become filled up, and they make up your foundations again. All their burrows being at last filled with sand, they will be compelled to betake themselves elsewhere.

SLUGS AND SNAILS.—Great enemies to every kind of garden plant, whether flower or vegetable; they wander in the night to feed, and return at daylight to their haunts. Lay cabbage leaves about the ground, especially on the beds which they frequent. Every morning examine these leaves, and you will find a great many taking refuge beneath. Search for their retreat, which you can find by their slimy track, and hunt there for them. A pinch of salt will kill them, and they will not touch fresh lime; it is a common practice to sprinkle lime over young crops, and along the edges of beds, about rows of peas and beans, lettuce and other vegetables; but when it has been on the ground some days, or has been moistened by rain, it loses its strength.

INSECTS.

BASKET or DROP WORM. — They are ashy brown or black and white, and deposit their eggs in little cases, which may be seen hanging to trees in winter. The eggs hatch in May, and the worms begin their work. They feed alike on forest and fruit trees, and have been found attached to raspberry canes. The best way to destroy them is to pick off the cocoons in winter and burn them.

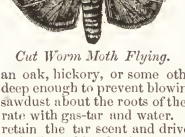
BLACK-VEINED WHITE BUTTERFLY.—A four winged insect. It is large, wholly white, excepting that the ribs or veins of the wings, and a short, oblique stripe from the 2d to the 3d vein of the upper wings, are black, which distinguishes it from the cabbage butterfly. At the beginning of June the butterfly appears and propagates its species. The best way of destroying these caterpillars on low fruit trees, is by seeking out the eggs or young caterpillars on the branches, and killing them. On high trees the mode of destruction must be delayed till the leaves have fallen off, when the nests of the caterpillars will become visible.

Black-Veined White Butterfly.

CANKER WORM.—When young they are of a blackish or dirty-brown color, with a yellow stripe on each side of the body. When full grown they are ash colored on the back and black on the sides. They are most abundant on apple, elm and oak trees; but cherry, plum

and lime trees, as well as some others, and many shrubs, suffer from them. They feed on the leaves about 1 month and then descend to the ground, burrowing into the earth 3 or 4 in., where they form small cells, in which they undergo their transformation and remain until the following season. To destroy them, dig around the trees and lay the earth smooth; then take air-slaked lime and strew 1 in. thick around the trees, to the extent of 2 to 3 ft. from the roots; then scrape or shave off the rough, shaggy bark round the body of the tree to the width of 2 or 3 in., and with a brush apply cheap printers' ink to the scraped part, forming a belt around the tree. This must be put on every 10 days during the fall and spring, and whenever a long thaw seems likely in the winter. The slightest contact with the ink is death to the insect.

CUT WORM. — Feeds on cabbage plants, corn, strawberries, peas, melons, cucumbers, tomatoes, in fact every green thing that is tender enough to suit their palate. 1. To destroy them, surround each plant with



Cut Worm Moth Flying. *Cut Worm Moth at Rest.*

an oak, hickory, or some other strong leaf, set deep enough to prevent blowing away. — 2. Put sawdust about the roots of the plants, and saturate with gas-tar and water. The sawdust will retain the tar scent and drive the pests away. — 3. Late fall plowing, followed by an early spring plowing, exposes the worms to the frost; 1 or 2 seasons of this treatment will kill them out effectually. — 4. The most deadly trap consists of a barrel in which is 1 ft. of water, covered with a film of kerosene oil. A large stone is placed in the barrel with the top level with the surface of the water; a lantern lighted is placed on the stone at night, and the light attracts the moths, which fall into the water and are killed.

EARWIG.—Varies in size according to its age and sex; when fully grown, it measures almost 1 in. The body is light brown, free from hair; it has very short wing-cases, under which the wings lie concealed, folded both longitudinally and transversely. It is usually under the bark of trees, in the hollow stems of trees, in rolled-up leaves and under stones. In orchards it injures fruit trees. In flower gardens it destroys carnations, pinks, and dahlias, in particular. The only certain method of destroying them is by catching them, which is best effected by hollow tubes, laid here and there, in orchards and flower gardens. The hollow stem of the sunflower is fit for this purpose, as the insects are eager in the pursuit of the remains of the sweet pith. They are also easily caught between the folds of paper, or in pieces of cloth and linen laid on the ground.

FALL WEB WORM.—Found in the fall on a great many kinds of trees, though on some more abundantly than others; but with the exception of the different grapevines, the evergreens, the sumachs and the ailantus, scarcely any tree or shrub seems to come amiss to its voracious appetite. The twig or branch containing their web should be cut off and burned.

Fall Web Worm.

GARDEN FLEA.—A very small leaping insect which gathers along the edges of a wound in a leaf made by other insects. To destroy them, dust the plants with lime ashes or soot.

LIME LOOPER, or MOTTLED UMBER MOTH. — Takes its name from the lime tree, on which it likes to feed, as also on fruit trees. This caterpillar, when full grown, is of a reddish color, and has a yellow stripe on each side. It goes into the earth in May or June, and is transformed into a brownish red pupa. The moth comes out of the earth in the beginning of November, and lays her eggs on a fruit tree. The male is as large again as that of the winter moth; its broad fore wings are of a reddish yellow, covered with blackish dots; the under wings are dirty white, dotted with brown, and in the middle of the wings is a black dot. The female has no wings, is much larger than that of the winter moth; the head and body are whitish, covered with black streaks and dots, and the feet annulated with yellow and black. To guard against its ravages, strike the branches of the tree with a long pole in May, to throw down the caterpillars.

Garden Flea.

MAY BEETLE, or WHITE GRUB.—Color chestnut brown, covered with minute punctures. Feeds on leaves, and flies with a humming noise, in May and June. The larvæ (white grubs with brown heads) feed on the roots of grass, and are found on fruit and forest trees, and sometimes do great injury to strawberry plants, Indian corn, wheat and potatoes. Great numbers of beetles can be destroyed by shaking them from the trees early in the morning. The grubs may be destroyed by turning hogs into the field. They take 3 years to undergo their transformation, hence their great danger.

PLANT LOUSE (Aphis), or GREEN FLY. — Sometimes becomes quite numerous upon the roots of the strawberry, when the soil is loose and open; it also attacks plants when grown under glass. A liberal application of dry ashes or refuse from a tobacco factory will destroy them; or fumigate with tobacco smoke.

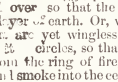
ROCKY MOUNTAIN LOCUST, or WESTERN GRASSHOPPER.—The female locust, in the autumn, deposits her eggs in small holes or cells made in the earth by means of her ovipositor.

Most of these eggs remain all winter uninjured by the frost, and hatch the following spring, earlier or later, according to the influences of climate. Cold rains in the spring, however, are said to destroy the young insects. The grass-

Rocky Mountain Locust.

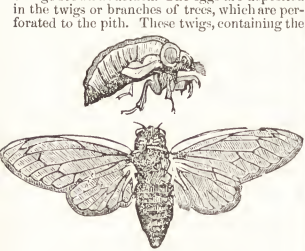
hoppers, when first hatched, exactly resemble the old insects in form, with the exception that they have no wings or wing-cases. When young they feed near the place where they were hatched, and upon whatever vegetation is growing in the vicinity. When fully grown, with perfect wings, they collect together, pair and emigrate in countless myriads to other places in search of food and proper places in which to deposit their eggs for the next year's crop, after which they soon die and disappear. This insect, from the egg to the perfect state, is injurious, devouring almost any vegetable substance. As soon as the grasshopper has laid its eggs, plow the fields and turn the soil over so that the eggs will be buried under 2 inches of earth. Or, when the young grasshoppers are yet wingless and the grass dry, set fire to 2 circles, so that the insects cannot escape from the ring of fire, but be driven by the heat and smoke into the centre, where they will eventually perish in the flames.

SADDLE BACK CATERPILLAR.—Bright green with an oval, reddish brown spot on the back. Is 1½ in. in length, and feeds on corn, rose bushes and fruit trees. Pick them off and destroy them.



Saddle Back Caterpillar.

SEVENTEEN-YEAR LOCUST.—Black, with transparent wings and orange brown abdomen. The eggs are deposited in the twigs or branches of trees, which are perforated to the pith. These twigs, containing the



Seventeen-year Locust.

eggs, drop off. The eggs hatch and the young insects enter into the ground to pass their 13 or 17 years, according to the brood. The larvæ feed on soil.

STALK BORER. — Leaden color, with light stripes. Bores into stalks of corn, wheat oats and tomato, and currant and peach twigs. Cut it from the stalks, and burn the stalks to prevent increase.

Stalk Borer.

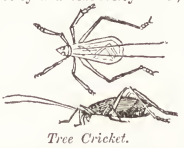
STRIPED TURNIP BEETLE.—Black, with a wavy yellowish stripe on each wing cover. It is less than 1-10 in. long, and feeds on mustard, turnip, and other plants. The larvæ feed on plant roots. 1. Sprinkle the young plants with lime, while covered with dew—2. Water them with strong soap suds.—3. Sprinkle the ground with lime or ashes as soon as the seed is sown.

Striped Turnip Beetle.

TENT CATERPILLAR.—White and yellowish on the back, with black and yellow stripes on the sides from ½ to 1 in. in length. It spins its web around leaves of fruit trees and some forest trees, and on most plants belonging to the rose family. 1. While the nests are small they are easily destroyed in the following manner: Procure a light pole, long enough to reach to the top of the trees (along rod of bamboo is the best), and tie to the end a small brush, or a wisp of broom corn; dip this into a mixture of kerosene oil and water, and twist it about the nest, gathering both the nest and worms at once into a mass; then clear the brush and crush every worm. Care should be taken to touch the fork of the branch all over with the oily water, which kills all it comes in contact with.—2. Cut off and burn the egg clusters during winter, and examine the trees carefully in the spring for the nests from such clusters as may have eluded the winter search.

Tent Caterpillar.

TREE CRICKET.—A green cricket that punctures grape, raspberry and blackberry canes, and the twigs of peach, white willow, and a variety of other trees. Sometimes bunches of grapes are entirely severed by them. Search thoroughly for them, and destroy by hand. In winter search for all punctured twigs and burn them; this will prevent their increase.



Tree Cricket.

TWIG BORER.—These insects measure from

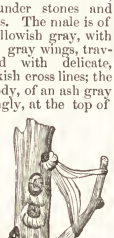
.25 to .35 of an in. in length. and are small, dark, chestnut colored beetles, of a cylindrical form, having the front part of thorax roughened with elevated points; the male having 2 little horns, and the tip of the wing covers above provided with 2 prickle-like points curving inward. Attacks apple, pear, hickory and cherry trees, and also grape vines, by boring into the twigs and young branches. When the insects attack twigs and branches, cut them off some distance below the place injured, and burn them immediately, with the beetles inside.

TWIG-GIRDLER.—Light brown. The eggs are deposited in the branches of trees, the female first gnawing a groove around the branch, above and below the eggs, so the larvæ may feed on the dead wood. It attacks hickory, elm, persimmon, peach, plum and pear trees. Kill by hand.

WINTER MOTH.—The green-looped caterpillar produced by this moth is injurious to fruit trees. It appears late in the autumn, and proceeds from a light-brown pupa, which lies from June to the end of October, either a few inches under the earth, or under stones and clods. The male is of a yellowish gray, with pale gray wings, traversed with delicate, darkish cross lines; the female has a much thicker body, of an ash gray color. The eggs are laid singly, at the top of the tree, and are small and greenish. The caterpillars are hatched in spring; are at first gray, and then light green; black head, without ventral feet. They devour the leaves, buds and fruit. To prevent their attacks, surround the base of the stem with a wooden frame, or box, and daub it on the outside with tar. Or, place a layer of bird-lime around the trunk of the tree.

Winter Moth.

VINE SCALE INSECT.—This insect forms a longish, marbled-brown scale. In old age the scale becomes blackish-brown, hemispherical and wrinkled. The eggs, which are laid under the body of the female, are covered with long white wool. They are found on vines, particularly in gardens. Their destruction is best effected by dry brushing in autumn or spring.



Vine Scale Insect.

WEEDS.

REMARKS.—Weeds are only "plants out of place," and many of the most common have elements of utility that are entirely overlooked. Their hardiness, great vitality, or structure and appendages, are matters of interest to the inquiring mind. But few fields are exempt from all kinds of weeds, and not only is the quantity of feed lessened, and greatly, but the quality is hurt. A great variety of weeds impart their taint to the milk; this is worse with hay than with pasture, as the objectionable flavor is disseminated through it when in bulk. Many of the seeds of weeds are sown with those of the crop, especially those that are nearly the size, color, etc., of the grains and grass seeds. Some weeds may be effectually exterminated by cutting off the stalks close to the ground with a scythe. The proper time to do this work is soon after they have attained their growth, but before the seeds have matured. The branches of some weeds are so close to the ground that they can only be severed from the roots by a hoe, which should be very sharp. The stalks of large weeds must be cut several inches below the surface of the ground or they will throw up suckers in the same manner as trees and bushes. A sharp spade or a spud is the best implement to use. After the stalk is cut and removed drop a handful of salt on the stump that may remain in the earth. A drop of sulphuric acid applied with the end of a stick is effectual in destroying the life of the roots of weeds. The fallow is the best means for successfully clearing the land, working the soil often enough to prevent any plants from seeing the light. Weeds on gravel-walks may be destroyed and prevented from growing again by a copious dressing of the cheapest salt. This is a better method than hand-pulling, which disturbs the gravel and renders constant raking and rolling necessary. One application early in the season, and others as may be needed, while the weeds are small, will keep the walks clean and bright. Or, carbolic acid, largely diluted with water, and applied with a brush or watering-pot, may be used.

BURDOCK.—A coarse, rank, bitter weed, with very large burrs. Cut the leaves off near the ground and pour a small quantity of coal oil into the crown of the plant. In some cases it will take years to completely exterminate it.

CANADA THISTLE.—This is the most troublesome of all the weeds. As soon as the pests appear in the spring, strike them off with a sharp hoe below the lower leaf, or even with the solid earth; repeat every time a sprout starts and they will be almost totally eradicated the first season. A few may appear the second year after this treatment; if so, repeat the cutting of the stalks, and if thoroughly done sure death is the result.

CHESS, CHEAT, or BROWN GRASS.—This is one of the most troublesome weeds which infest wheat fields. Sow nothing but perfectly clean seed and it will gradually disappear.

CHICKWEED.—An annual which is often very troublesome on damp soils. Underdraining and frequent cultivation will destroy it.

CLOT BURR, or COCKLE BURR.—An annual that is frequently quite troublesome, the burrs adhering to the fleece of sheep. It is easily exterminated by cultivation.

COUCH, or QUACK GRASS.—One of the most difficult pests to eradicate; ordinary cultivation,

that which answers for most weeds, only causes it to grow with unusual vigor. The leading methods of eradication are: 1. Use a flat-toothed cultivator, one that will shave the ground instead of running deep, and pass it 1 in. or so below the surface; this cuts off all shoots as they start up, but does not divide the horizontal running root-stocks. The plants die of exhaustion in endeavoring to throw up stems to bear leaves and seeds. — 2. Use a grubber, and tear the plants bodily from the soil, when they are gathered by the use of a long-toothed rake, and burned.

ELDER BUSH. — A troublesome bush. If it is cut early in summer, and the brush burned upon the stubs, and then all the sprouts pulled up the moment they appear, the roots perish.

HORSE NETTLE.—A very troublesome weed, and more so at the South than at the North. Thorough cultivation and pulling it by hand is the only way to destroy it.

OX EYE DAISY.—A perennial plant; yet if it is not allowed to ripen its seed, the vitality of the root is soon exhausted. Constant cutting and thorough cultivation will destroy it.

PLANTAIN may be destroyed by constant cutting, not allowing it to go to seed. The best way is to go over it with a long knife and cut it out, root and all.

PURSLANE.—A troublesome summer weed. It is easily killed when it first breaks ground, but once it gets rooted it will grow just about as well with its roots in the air as any other way, and will blossom and ripen seed after it has been hoed up and turned with roots upward. The only way to get rid of it, is to cart it off and bury it in a hole. Hogs and hens eat it greedily, but they do not destroy all the seeds.

RAG or BITTER WEED.—One of the most troublesome weeds. Clean culture and rotation of crops are the best means to destroy it.

RED ROOT, or WILD AMARANTH.—An annual, more difficult to exterminate than Canada Thistle. It is a great enemy to the wheat crop. A good plan for extirpating this weed is as follows: For the first wheat crop, plow the ground very deep, at least 8 in. This will throw the seed down beyond the reach of vegetating, and the wheat may be sown on the inverted surface and escape 1 year. In the fall plow as deep as for the wheat, which will throw the seed again to the surface. Harrow well and the seed will germinate. The next spring turn the weeds under with a gang plow, or cut them to pieces with a large steel-tooth cultivator, and sow oats, barley, spring wheat or peas; the latter is best. By way of rotation plow or harrow again in the fall, to start another crop of weeds, and plant corn, cultivating it thoroughly. The following spring plant clover or grass, and when wheat is again introduced in the rotation, the weeds that are discovered can be pulled by hand.

ST. JOHN'S WORT.—A very troublesome weed, and in neglected pastures often greatly diminishes or excludes the grass crop. Good cultivation and rotation is the best means to exterminate it.

SORREL.—This field pest may be eradicated by the judicious application of either lime or ashes. The souring principle of sorrel is oxalic acid; if this be removed from the soil, sorrel cannot grow.

TOAD FLAG, or WILD SNAP-DRAGON. — A very destructive weed, common in many places along the roadside, fences and in pastures. Cattle will not eat the grass that grows with it. Repeated plowing and harrowing will destroy it.

WILD CARROTS.—Kills out all grass, and the seeds are so light that they are wafted by the wind in every direction. After a heavy rain they may be pulled up by the roots, and as soon as any blossom, they should be pulled, as the seeds spread rapidly.

WILD RADISH.—An annual, propagated by seed. The plants should be pulled as soon as the flowers appear.

STORING AND CURING.

FIELD CROPS.

ENSILAGE.—The process of preserving grain and fodder green through winter, is very simple and easy. 1st. The preserving receptacles should be wholly air-tight, so that when sealed the air cannot come in contact with the food to be preserved. 2nd. The pits should be of such form and dimensions as will best facilitate the settling and compacting of the food into a solid mass, and when opened for feeding will expose as small a part to the atmosphere as practicable. 3d. The fodder must be cut green when in the best condition or in bloom, passed immediately through the cutting machine to reduce it to uniform short lengths of not more than 1 in., at once be deposited and trod firmly into the pit, and sufficient salt be used to render it palatable, but no more. As fermentation, which will commence at once, proceeds and the mass settles, the cutting and treading in of fresh fodder must be continued from day to day, after an interval of about 36 hours, until the pit is filled and settling has nearly ceased. 4th. The pit, as soon as completely filled and settling has ceased, must be securely sealed to exclude the air wholly and arrest fermentation, and must be kept sealed until opened for use. The pit may be made of hard brick, with 12 in. perpendicular walls. If the ground is sandy, the outside of the walls, next to the earth, is covered with a coat of cement. The bottom should be laid with brick. The deeper the pits the more they will contain in proportion to measurement, owing to the greater density of the contents from the weight of the mass above. In all cases where practicable, the pits should be made at least 20 ft. deep. The walls are made so smooth upon their inner

sides as to offer no obstacle to the settling or compacting of the food by friction of the sides. These pits are made open at the top and covered with a roof, or arched over under ground, with 2 necks to each coming up to within 1 ft. of the surface of the ground, through which they are filled and the necks then sealed with earth. The green fodder is drawn from the field as fast as cut, and may be cut in any weather except during rain. After running through the cutting machine it is deposited and trod into the pit firmly until it is full. The doorway at the end of the pit having already been closed, by placing boards across it upon the inside as the filling progressed, is now sealed tightly by placing other boards properly fastened across it upon the outside of the jambs and filling the space between the jambs with well compacted earth, so that no air can pass into the pit through this doorway; the outer covers are then placed temporarily upon the necks of this pit above. After the pit has been closed 36 hours, the necks must be uncovered and opened. The contents will be found very warm and thoroughly wilted, and upon being now trodden down will occupy less than $\frac{1}{2}$, and if clover not more than $\frac{1}{4}$ of the pit. The pit should then be filled again, trodden firmly and covered again temporarily as before. The pit should now be opened and refilled as before at intervals of from 24 to 30 hours, the contents at each time being trodden down as firmly and evenly as possible, and this should be continued until settling nearly or quite ceases and the pits are full. The pits being now full, and settling having nearly or quite ceased, must be immediately and thoroughly sealed over the whole top surface of the fodder by a well compacted layer of clear earth not less than 6 in. thick. If the pits are arched over, they should be filled fullest along the centre line of the arch, and must be sealed from the spring of the arch upon the curve, which will be caused by this fullness in the centre to prevent the earth from falling away or opening cracks in the sides in further settling. This covering of earth should be afterward examined at least twice at intervals of a week or 10 days, and any cracks that appear, be closed with fresh earth. In feeding, the fodder should be cut down and fed from one end of the pit in sections of convenient width, the earth being first removed from each section. If open pits are used, a layer of hay or straw may be put over the pit, when filled and sealed, to protect the contents from frost in winter, if necessary.

GRAIN. To Store.—In storing grain, a plentiful amount of air must be let in by some good system of ventilation, and great care taken to exclude rats and mice. Absolute freedom from moisture is necessary for the perfect preservation of wheat, and in storing it is about the only thing to be considered, save convenience. Every well regulated barn should have its granary, with accessible apartments for wheat, rye, oats, barley, buckwheat, etc. All grains, however well stored, should be occasionally examined to ascertain whether or not they are keeping well. (See *Granaries* in BUILDING.)

HOPS, To Dry.—(See *Hops* in SPECIAL CROPS).

TOBACCO, Curing of.—After the tobacco is cut, carry it to the scaffold or barn; hang 6 to 8 plants on a 4 ft. stick. If it is scaffolded, it is best to have the scaffold near the barn, so that it may be taken under shelter in case of rain. Tobacco should not remain longer than 5 or 6 days on the scaffold in good weather, and if there be rain or excessive heat, a much shorter time is required. Many of the best planters never scaffold, but carry the tobacco from the field and hang in the barn as they cut. Hang on the scaffold so that the plants touch, on sticks, say 6 or 8 in. apart; but if hung in the barn, plants must not touch; sticks must be 8 to 10 in. apart. But, as the tobacco cures, if room is needed, it can be stored closer; but never crowd too close. Never allow tobacco to lap tails and butts in the tier, nor hang close enough to exclude the air, as by either, the risk of dark cure and house-burn is incurred. No fire is admissible now in curing any sort of tobacco, except wrappers, and then only by flues. After this point is reached in the crop, good weather will almost surely give a good, bright, sweet cure. But if the weather is unfavorable, good judgment in the use of ventilators is all that can save a crop unhurt, as fire cannot be used under any circumstances, except for wrappers. When the plants are sufficiently dried, which may be judged of by the stems becoming hard, the leaves may be stripped from the stalks. A damp spell during the winter or spring is the best time for this operation, as the moisture in the air prevents the leaves from crumbling. They must then be sorted into 3 classes: 1st, comprising the best quality and color; 2d, that which is inferior; 3d, the ground leaves. The leaves may then be neatly tied up in bundles called "hands," each containing either 4 leaves of the 1st class, or 6 of the 2d and 3d classes. The "hands" must then be packed in large bulks, with the tails in the middle and the heads on the outside, and subjected to heavy pressure by weights. In this state it undergoes a sweat; but as soon as it commences to heat it must be taken out, and hung up to dry, and there left until a rain shall again bring it into case. It should then be put down in very large bulk; the number of courses being 6, 8, or any higher number, and the whole enclosed by soft straw, the walls of the house, and plank, so as to exclude the air entirely. In this condition it may be kept for any length of time, and will always be ready for hauling to market in the "hand" or "prizing." When the cover of the bulk is removed, with the view of taking out a part of the tobacco for prizing or sale, the entire top course or courses should be smoothly separated from the rest, and the cover carefully replaced. Prizing should be done in weather when the condition of the tobacco will not change. Each bundle should be straight, and closely packed in hogsheads in the usual way. When prizing in summer, some elder bushes may be spread over the bulk to keep the tobacco damp. Flue cured fillers command nearly or quite as much as sun cured, and the risk is much less. To cure fillers with flues, let the tobacco be placed in the barn as soon as cut, and raise the heat in the barn to 85° or 90° F.

Kindle fires in the flues every morning, raising the heat to 90°, and then leave as before, and continue to do this for 4 or 5 days, until the tobacco is thoroughly yellowed. If the tobacco has much sap, it may be necessary to continue the yellowing process from 5 to 7 days, to yellow properly. When the leaves have assumed a mottled, piebald appearance, run the heat to 100°, and let it remain at that point for 3 hours; then raise the heat 2½° an hour until 130° is reached. Keep the heat at this point until the leaf is cured, and then move up gradually to 170° or 180°, and thus cure stalk and stem. If cured properly there will be much of the leaf mahogany, while the remainder will run from a bright dapple to a cherry red. Dark heavy shipping may be cured with flues better than in any other way. Smoke from the open wood fire is objectionable, and with the flue you get the heat without the smoke, which is all that is wanted. There are 2 modes for curing yellow tobacco: one with charcoal and the other with flues. The first is gradually giving place to the latter, which is cheaper and more efficient. The chief agent in either mode is a dry, curing heat, to expel the sap from the leaves, stems and stalks of the plants, and catch the color, yellow, next to nature's color, green, and to fix it indelibly. By the process of nature, leaves drying descend in color from green, first to yellow, then orange, then red, and finally lose all color as they go to decay. A quick, dry heat, so regulated as to dry out the heat, and catch the yellow, and fix it, is the object in view. Charcoal produces an open, dry heat, well suited for the purpose; but its preparation is costly, its use tedious, dirty and laborious, and it deposits a black dust on the leaf that is objectionable. The flue process, if properly conducted, is free from smoke. The first step in curing is called the *steaming* or *yellowing* process. Medium tobacco will require from 24 to 30 hours steaming at about 90° to yellow sufficiently; but tobacco with more or less sap, larger or smaller, will require a longer or shorter time to yellow. Here the judgment of the curer must be his guide. The next step is called *fixing the color*. When the tobacco is sufficiently yellowed, the best leaves of a uniform yellow, and the greener ones of a light pea-green color, increase the heat to 100°; observing the leaves closely, to detect sweating, which will soon redden and spoil the color, unless driven off. To do this, open the door and let it stand open; and if after an hour the sweat has not disappeared, open a space between the logs on opposite sides of the barn to let in more air, and permit it to remain open until the tobacco has dried off all appearance of the sweat. Right at this point more curings are spoiled than at any other stage of the process. The thermometer will now indicate a fall of 5° to 10°; but a little cooling is necessary; then close up the opening and raise the heat to 100°. But a skillful curer detects the first indications of sweat, and prevents it by regulating the heat. Keep the heat at 100° for 4 hours, and then advance 2½° every 2 hours until 110° are reached. Here you have reached the most critical point in the difficult process of curing bright tobacco. The condition and appearance of the tobacco must now be the curer's guide. No one can successfully cure tobacco until he can distinguish the effects of too much or too little heat in the appearance of the leaf. Too little heat in fixing the color, operates to stain the face side of the leaf a dull brown color, and is called "sponging," and may be known to the novice by its appearance only on the face side of the leaf. Too much heat reddens the leaf, first around the edges and then in spots which are visible on both sides. To prevent sponging on the one hand and spotting on the other, is the aim of the experienced curer. No definite time can be laid down to run from 110° to 120°. Sometimes 4 hours will suffice, then again 8 hours is fast enough. While it is usual at this stage to advance about 5° every 2 hours for medium tobacco, the condition of the tobacco often indicates to the practiced eye the necessity for slower or faster movement. But it is safe not to advance above 110° until the tails begin to curl up at the ends. Arrived at 120°, this is the curing process. The heat should remain at or near these figures until the leaf is cured, which will require from 6 to 8 hours, according to the amount of sap in the leaf to be expelled. When the leaf appears to be cured, advance 5° every hour up to 170°, and remain until stalk and stem are thoroughly cured. To run above 180° is to endanger scorching the tobacco, and perhaps burning barn and tobacco. If, after the tobacco is cured, the weather remains dry and it fails to get soft readily, so that it can be moved, it may be brought in order in the following way: Place green bushes, with the leaves on, over the floor, and sprinkle water over them copiously; if the tobacco is very dry and the atmosphere contains but little moisture, and if the weather is cool, a little fire kindled in the flues will assist in making the tobacco soft. Straw, wet or made so, will answer the same purpose. If the weather is damp there will be no necessity to use either straw, brush or water. But when it is necessary to use any means to order tobacco, it is best to apply them in the afternoon, so that the tobacco may be removed next morning.

FRUITS.

REMARKS.—Fruit, which is to be kept beyond the natural period of ripening, must be gathered before fully ripe; all sudden changes in temperature and moisture are productive of decay, and should be avoided. A dry, cool place, where the temperature is even, is best calculated to retard decay and improve the keeping qualities. 1. The following preparation is unequalled for preserving apples, pears, lemons, etc.: Rosin, 2 lbs.; tallow, 2 oz.; beeswax, 2 oz.; melt slowly over the fire in an iron pot, but don't boil. Take the fruit separately, and rub it over with pulverized chalk or whiting, to prevent the coating adhering to the fruit; then dip it into the solution once, and hold it up a moment to set the coating; then pack away carefully in barrels, boxes, or on shelves, in a cool place.—2. Glycerine of purest quality has been recommended for the

preservation of fruits; previous to eating which, the glycerine should be removed, by immersing the fruit in water. — 3. Using wheat bran for packing tender specimens of fruit, to prevent bruising, has been long practiced, but an improvement has been made by which, in addition to this protection, the fruit is preserved from decay. The bran is slightly charred by a patented process. — 4. Dry sand is one of the best articles in which to pack fruit; packed in this way it will keep all the year round. The fruit must be sound when stored, and the sand must be quite dry. The chief advantages of packing in sand are the exclusion of air currents, the preservation from changes of temperature, and the absorption of moisture.

APPLES, To Dry.—1. Pare and cut the apples in slices; then spread them on cloths, tables or boards, and dry them out-doors. In clear, dry weather, this is the most expeditious way. It is a good plan to use frames. These combine the most advantages with the least inconvenience of any way, and can be used either in drying in the house or out in the sun. In pleasant weather the frames can be set out-doors against the side of the building, or any other support, and nights, or cloudy and stormy days, can be brought into the house and set against the side of the room near the stove or fireplace. Frames may be made in the following manner: 2 strips of board, 7 ft. long, 2 or 2½ in. wide; 2 strips, 3 ft. long, 1½ in. wide; the whole ¾ in. thick. Nail the short strips across the ends of the long ones, and it makes a frame 7x3 ft., which is a convenient size for all purposes. On one of the long strips nails are driven 3 in. apart, extending from the top to the bottom. After the apples are pared, quarter and core, and with a needle and twine, or stout thread, string them into lengths, long enough to reach twice across the frame; the ends of the twine are then tied together, and the strings hung on the nails across the frame. The apples will soon dry so that the strings can be doubled on the nails, and fresh ones put on, or the whole of them removed, and others put in their place. As fast as the apples become sufficiently dry they can be taken from the strings, and the same strings used to dry more on. Dried apples are bleached by exposure to the fumes of burning sulphur. This may be done by making a tight box with shelves to slide in or out at the front. The shelves should have wire gauze bottoms on which the dried fruit is to be placed. The box is set up on legs 1 ft. high. Under the box is a sheet iron close receptacle, from which a pipe passes into the bottom of the box. A quantity of ignited charcoal is put into the iron vessel and covered with sulphur, the fumes of which pass into the box and through the fruit, making them very white and clear. Any other convenient arrangement, which will answer the same purpose, may be adopted, but the fumes must be confined in a close receptacle, and the fruit should be arranged so that they pass through it.

APPLES, To Keep.—1. The fruit must be free from bruise and blemish, and should be spread out on shelves or packed in barrels, and kept in an atmosphere of 40° to 45°. Some cellars are just the thing, and preserve them beautifully; others are too moist. Where this is the case a few bushels of stone lime should be used. Sliding shelves, 6 in. apart, latticed bottom, with single layer of fruit, are extremely convenient, as they allow of constant examination without disturbing the fruit. — 2. Fall apples may be preserved in pits made as follows: Choose an elevated piece of ground in the orchard and scoop out a shallow basin, in which heap the apples in quantities of not more than 10 or 12 bus.; cover them with straw laid lengthwise from top to bottom of the heap; leave them thus for 2 or 3 days, during which they will heat and sweat; after they have dried, cover the straw with a light coating of earth, except in 3 or 4 small places at the bottom and at the top, where a large wisp of straw should be inserted and bent over to make a water shed. The apples will keep much longer in this way than in barrels, and winter apples may be kept until spring in fine order. If the apples are picked before they are quite ripe they will keep much longer.

APPLES, To Pack.—1. Assort them so as to run uniform in size and quality. Pack in new, sound barrels of the standard size, flat hoops preferred; only one variety in a barrel; turn the upper end of the barrel down; take out the lower head, and commence packing by placing a tier of apples snugly, with stem ends upon the head; then fill up the barrel without bruising the fruit; shake down gently, but thoroughly, and fill so full that the head must be pressed in with a level or barrel press, flattening the last tier of apples; then, fastening the head, turn the barrel over, and mark plainly with a stencil plate, or red chalk or ink, the variety contained. — 2. Wrap each one in manilla tissue paper; then pack as solidly as possible; putting a layer of soft chaff at the bottom of the barrel, and sifting more over every layer; when the barrel is full, place plenty of packing on top, and press the head firmly down. In this condition apples will travel months without injury.

CHERRIES, To Dry.—1. Stone, spread on a flat dish, and dry in the sun or a warm oven; pour whatever juice may run from them over them, a little at a time; stir them about that they may dry evenly. When perfectly dry, line boxes or jars with white paper and pack close in layers; strew a little brown sugar and fold the top of the paper over them, and keep in a dry, sweet place. — 2. Take large cherries, not too ripe; remove the pits; take equal weights of cherries and sugar; make a thick syrup of the sugar, put in the cherries and boil them a minute, and spread them on an earthen platter till the next day; strain the syrup; boil it down thick; put the cherries in, and boil 5 minutes; spread on a platter as before; repeat the boiling two more days; then drain; lay them on wire sieves, and dry in a nearly cold oven.

CRANBERRIES, To Keep. — Cranberries will keep all winter in a firkin of water in a cellar.

CURRANTS, To Dry.—Beat up the whites of eggs, or a little gum Arabic in water; and, after dipping in the bunches, and letting them get a little dry, roll them in finely-powdered

loaf sugar. Lay them on a sieve in a stove to dry, and keep turning them and adding sugar till they become perfectly dried. Not only red, white and black currants, but even grapes in bunches may be thus dried and preserved. They should be carefully kept dry, in boxes neatly lined with paper.

FIGS, To Dry.—When ripe, the figs are picked and spread out in the sun to dry; those of the better quality being much pulled and extended by hand during the process. Thus prepared, the fruit is packed closely in barrels, rush baskets, or wooden boxes.

GOOSEBERRIES, To Dry.—To 7 lbs. of red gooseberries, add 1½ lbs. of powdered sugar, which must be strewed over them in the preserving pan; let them remain at a good heat over a slow fire till they begin to break; then remove them. Repeat this process for 2 or 3 days; then take the gooseberries from the syrup, and spread them out on sieves near the fire to dry. This syrup may be used for other preserves. When the gooseberries are quite dry, store them in tin boxes or layers of paper,

GOOSEBERRIES, Red, To Keep.—Pick gooseberries when fully ripe, and for each quart take ¼ lb. of sugar and 1 gill of water; boil together until quite a syrup; then put in the fruit, and continue to boil gently for 15 minutes; then put them into small stone jars; when cold, cover them close; keep them for making tarts and pies.

GRAPES, To Dry.—1. The grapes are allowed to remain on the vine until of a golden color and translucent; they are then picked and put on wooden trays, 2 by 3 ft. in size, placed between the rows, sloping to the sun. When half dried they are turned by putting a tray on the top, and by inverting them both, are transferred to the new tray. When the grapes lose their ashy appearance, and after removing the green ones, the rest are put into large sweet boxes, placing sheets of paper between every 25 lbs. of raisins. They are left there for 2 weeks; when the stems are tough and the raisins soft. The packing follows, in which iron or steel packing frames are used, the raisins being assorted, weighed, inspected and made presentable.—2. The grapes are allowed to ripen and dry on the vine. After being plucked and cleaned, they are dipped for a few seconds into a boiling lye of wood ashes and quick lime at 12° or 15° Baume, to every 4 gals. of which a handful of culinary salt and 1 pt. of salad oil has been added; they are then exposed for 12 or 14 days in the sun to dry; lastly, they are carefully garbled, and packed for exportation. The sweet, fleshy kinds of grapes are those selected for the above treatment; and, in general, their stalks are cut about ½ through, or a ring of bark is removed, to hasten their maturation.—3. Place the grapes in boiling water for the purpose of scalding them. As soon as they boil the skins will burst, and the seeds rise to the top; they must then be skimmed off immediately, or they will sink again among the grapes. After skimming, remove from the fire, and stir in sufficient sugar made into a syrup to sweeten them, and then spread on dishes to dry.

GRAPES, To Keep.—Grapes, in bunches, are preserved by wrapping them in silver paper, and packing them in dry bran. Each bunch is suspended by the stem with the fingers of one hand, while the bran is poured round it with the other; the jar being occasionally gently shaken as the process of packing proceeds. Some paper is then laid over the top of the jar, the mouth or cover of which is, lastly, firmly tied over with bladder to exclude the air and moisture.—2. Grapes may be kept in shallow drawers, spread upon paper, and covered with the same material. Some varieties, in this way, can be kept in good condition until midwinter, and sometimes until toward spring.

LEMONS, To Keep.—1. Cover them with buttermilk or sour milk, changing it once a week. Even lemons that are quite dry will seem fresh if kept in this way.—2. Lemons can be kept sweet and fresh for months by putting them in a clean, tight cask or jar, and covering with cold water. The water must be changed as often as every other day, and the cask kept in a cool place.

LEMONS AND ORANGES, To Pack.—Examine each one carefully to see that it is perfect; then wrap in tissue paper, and pack closely in boxes.

PEACHES, To Dry.—Let the peaches get mellow enough to be in good eating condition; put them in boiling water for a moment or two, and the skins will come off like a charm; let them be in the water long enough, but no longer.

PEACHES, To Keep.—Peaches can be kept several weeks beyond the usual time, if carefully gathered when hard, and each peach at once wrapped in thin paper such as is used for keeping oranges, and then packing in stone jars; and storing in a cool, dry place, where the temperature does not rise above 60°.

PEARS, To Keep.—Summer pears, gathered a few days before fully ripe, and wrapped in thin paper, and kept in a cool place away from the changes of light and air, may be kept in good condition for several weeks.

PRUNES, To Dry.—These are mostly imported from France, where several sorts of prunes are raised especially for drying, among which are *German Prune, St. Catharine, Brignolles,* and others. The fruit is not gathered until the sun has dried off the dew; it is then picked by hand, and spread in shallow baskets, which are kept in a cool and dry place; when they have become soft, they are shut up close in spent ovens, and left for 24 hours; they are then taken out, and replaced after the ovens have been slightly reheated; on the next day they are taken out and turned by slightly shaking the sieves on which they have been laid; the ovens are heated again, and they are put in a third time; after remaining 24 hours they are taken out and left to get quite cold; after some manipulations, they are submitted to oven heat twice more, and then packed in boxes and jars for sale.

RASPBERRIES, To Dry.—Black raspberries and blackberries are dried whole, and care must be taken that they be unbroken; dried red raspberries never sell well.

VEGETABLES.

REMARKS.—To enjoy palatable and wholesome vegetables during the winter months, proper care and attention are essential in harvesting and storing. Most house cellars are too warm for the best preservation of vegetables, and it is therefore advisable to store only a limited quantity for immediate use in the house, while the main stock should be kept in a cool barn, cellar, or in an outdoor pit. Where a pit is not practicable and the entire crop has to be stored in a cellar, the roots intended for late keeping should be carefully selected. Only sound, solid roots will keep well. These should be laid loosely in thin layers, into bins or barrels, and each layer covered with sand, so that none of the roots are exposed to the light. The purer the air can be kept in the cellar, and the cooler without freezing, the better the vegetables will keep in it. A good way to keep vegetables, is to sink a barrel, box or cask, ⅔ its depth into the ground; heap the earth around the part projecting out of the ground, with a slope on all sides; place the vegetables in the barrel; cover the top with a watertight cover, and when winter sets in, throw an armful of straw on the barrel. If the bottom is out of the barrel, so much the better. Cabbage, celery, and other vegetables, will keep in this way as fresh as when taken from the ground. Celery should stand nearly perpendicular; the celery and earth alternating. Freedom from frost, ease of access, and especially freshness and freedom from rot are the advantages of this plan.

BEANS, Lima. To Dry.—Gather them while green and tender, and spread them in the sun to dry.

BEANS. String. To Dry.—Cut the beans up in the usual lengths; dry them; put them in a bag. In winter soak them and cook them in the usual way.

BEANS. To Keep.—Take a wide-mouthed stone jar, lay on the bottom of it some freshly-pulled snap beans, and over them put a layer of salt; fill the jar up in this manner with alternate layers of beans and salt. The beans need not all be put in at the same time, but they are better if the salt be put on while they are quite fresh. They will keep good all through the winter. When going to use them, steep for some hours in fresh cold water.

BEANS, To Pack.—The principal points to be looked after in packing beans are, the different kinds must not be mixed; they must be hand-picked, that is, looked over, and the dark-colored and imperfect beans, pebbles, etc., removed; they should be perfectly dry, otherwise they will become musty. Barrels should be used, and well filled.

CABBAGE, To Keep.—1. Gather them before the severe fall frosts. Let the coarse, outside leaves remain on them. Fix a strong string around the stalk, and suspend the cabbage from the timbers of the ceiling, heads downward. The cellar should be cool and dry. This will preserve them with certainty.—2. Pack in sawdust in the barn, and allow the whole to freeze, the sawdust being such a non-conductor of heat that once it becomes frozen through it will not thaw out again until well in April, and cabbage will come out almost as nice as when put in.—3. Cut the head from the stump; pack close in a cask, taking care to fill up all the vacancies with dry chaff or bran, and keep in a dry cellar.

CAULIFLOWER, To Keep.—1. They can be kept in a cellar, by covering the roots and stalks with earth, till February. Or they may be placed in a trench in the garden, roots down, and covered with earth, up close to the heads, and then cover with hay or straw, 4 or 5 in. thick, placing just enough soil on the straw to keep it in position.—2. Make a trench 12 in. deep; cover the stalk and part of the head with earth, and cover the whole with 4 or 5 in. of straw.

CELERY, To Keep.—To keep celery through the winter: About the last of October dig a trench 18 in. deep and 12 in. wide, in some dry place where drainage is perfect, so that no water can stand in it. Lift the celery with considerable soil about the roots; stand the branches upright, as they grew in the trench; pack them as close as possible; draw the earth close against them; then lay on them boards, and on the top of these coarse straw or leaves, or both.

CORN, To Dry.—Clean the silk carefully from the corn. Put it in a steamer, over a kettle of hot water. Steam 10 minutes; then draw a knife through each row of kernels, and scrape out the pulp, leaving the hulls on the cob. Spread on plates, and carefully dry without scorching.—2. Husk the corn and silk it; then shave it off with a sharp knife. To 6 qts. of the shaved corn add 1 teacup of sugar, and stir it up all together. Put it on a pie platter and plates, and set in the oven. Let it scald 10 minutes; then take it out and put it on a clean tablecloth, and spread in the sun and let it dry. When dry, put in a jar or box to keep.

ONIONS, To Keep.—Gather in the fall, and remove the tops; then spread upon a barn floor, or in any open shed, and allow them to remain there until thoroughly dry; put in barrels or small bins or boxes, and place in a cool place, and at the approach of cold weather cover with straw or chaff, if there is danger of very severe freezing. Onions are more frequently injured in winter by keeping them in too warm a place, than by frost. It is the alternate freezing and thawing that destroys them; and if placed in a position where they will remain frozen all winter, and then thawed out slowly in a dark place, no considerable injury would result from this treatment. Onions should always be stored in the coolest part of the cellar, or put in chaff and set in the barn or some outhouse.

PARSLEY, To Dry.—To have nice, bright, crisp parsley for winter use, spread thinly, as soon as gathered, on a piece of paper, and place in a cool oven, leaving the doors open; as soon as dry, powder it and put it into a bottle, corking to exclude the air. Dried in this way, it will retain its color and flavor.

PARSNIPS, To Keep.—The roots should be dug up late in the fall, leaving all the tops on, then carefully heeled in thickly together in rows, after which they should be covered with

a little coarse litter, and they can be reached whenever wanted during the winter.

PEAS, To Dry.—Look the peas over, and remove any that are bad; then place them in the sun until they are dried.

PEAS, Green, To Keep. — When full grown, pick and shell; lay them on dishes or tins in a cool oven, or before a bright fire; do not heap the peas on the dishes, but merely cover them; stir them frequently, and let them dry very gradually. When hard, let them cool, then pack in stone jars, cover close, and keep in a very dry place. When required for use, soak them for some hours in cold water, till they look plump before boiling; they are excellent for soup.

POTATOES, To Dry.—The potatoes are to be washed clean, placed in trays, and thrust into a steam box. At the end of 35 minutes they are removed and the skins stripped off by hand. Great care is necessary that the potatoes are not too much cooked, or they are worthless for drying. After peeling, they are placed in a press with a tight-fitting plunger and a perforated bottom and pressed through upon trays, which move on a tramway so as to secure an equal distribution. They are then ready for the dryer, and after being dried hard are placed in a grinder and coarsely pulverized. They can then be cooked in 15 minutes in a little boiling water.

POTATOES, To Keep.—1. A cave, dug in the side of a hill, or a pit in a sandbank, affords an excellent place for storing potatoes. If piled on top of the ground and covered with straw and earth, care should be taken not to leave them exposed to the light. A dark cellar is preferable to a light one for keeping potatoes.—2. To prevent potatoes from rot, dust over the floor of the bin with lime, and put in about 6 or 7 in. of potatoes; then dust with lime as before, then add more potatoes, using about 1 bus. of lime to 40 bus. of potatoes. The lime improves the flavor of the potatoes, and effectually kills the fungi, which causes the rot.

PUMPKINS, To Dry.—Take ripe pumpkins, pare, cut into small pieces, stew soft, mash and strain through a colander, as if for making pies; spread this pulp on plates, in layers about ½ in. thick; dry it in a stove oven, which should be kept at so low a temperature as not to scorch it; in about a day it will become dry and crisp. The sheets thus made can be stowed away in a dry place, and are always ready for use, either for pies or stewing. The quick drying after cooking, prevents the souring, which is almost always the case when the uncooked pieces are dried, while the flavor is much better preserved and the after cooking dispensed with. When ready to use, soak portions of the article in a little milk over night, when it will return to as delicious a pulp as if made of a pumpkin when fresh.

RHUBARB, To Dry.—The best method is to strip it of its epidermis. This is a long operation; but both time and expense are spared in the end by the promptness and regularity of the drying. Many cultivators of rhubarb on a large scale have repeated the experiment and have met with the most decisive results.

SALSIFY, To Keep.—Salsify is improved by being frozen.

SQUASHES. To Keep.—Squashes are injured by the lightest frosts, and should be kept in a warm, dry store-room, rather than in a cellar; if hung up by the stem in a cool place, they will keep for many months.

SWEET POTATOES. To Keep. — There is no better way than to pack them in dry sand, in boxes, and keep the temperature of the place where they are stored at from 45° to 60° Fahr. Where one has but a few, dig when thoroughly ripe; handle them as carefully as if they were eggs; dry them well, and then pack in ½ bbls. or small boxes, and place them in the kitchen near the stove, or some other warm place. The sand will absorb heat during the day and give it off slowly at night. In this way danger from freezing is obviated.

TOMATOES, To Dry.—To every gal. of peeled tomatoes put 1 teacupful of salt, and 1 tablespoonful of pounded black pepper. Boil all well until it becomes a marmalade. Then sift in 1 pt. of flour, and let it cook a few moments longer, in order that the mixture be thickened. Now take off the tomatoes, and spread them over dishes slightly greased. Dry them in the sun 3 or 4 days, then roll them into balls; sprinkle with flour, and expose to the sun a week or two longer. Put away in paper bags. One ball the size of a small apple is enough for a tureen of soup in winter.

TOMATOES, To Keep.—Pick the green tomatoes before the vines freeze; place in a cool, dry place, where air can be admitted and the frost can be kept out.

TURNIPS, To Keep.—Of all the roots turnips are the most affected by heat. They will sometimes grow in a cellar of not over 40° temperature. There is a natural heat about the roots, and when they are piled together, this accumulates and the roots sprout. A little frost does not hurt turnips. Place them in small lots in stalls where the frost can get at them, and cover with straw to prevent thawing.

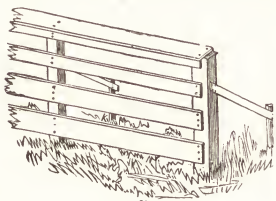
WORK ON THE FARM.

FENCES AND GATES.

BOARD FENCE.—This is an easily constructed and neat fence. In most cases it will prove to be the cheapest. To build 10 rods of fence, 4 boards high, requires 56 boards 12 ft. long and 6 in. wide.

BOARD-HOLDER.—The illustration shows a handy contrivance for the farm. The peg at the top is adjustable to any width of board or

any distance apart. It takes the place of one man in building board fences, and costs nothing.



Board Fence.

GATES.—To make a cheap farm gate: Take a round post and set it firmly in the ground; then make a gate with a scantling 3x3 at one end, and 2x2 at the other. For the top rail, make the heel piece of 3x4 scantling. Let the top rail of the gate run over the top of the post. Put a ¾ round iron pin through the top rail and into the centre of the post, thus forming the top hinge. For the bottom hinge, match upon the heel piece, about 6 in. from the bottom, a piece of 3 in. plank, 15 in. wide edgeways, hollowing it out so as to fit the round post. This gate will swing open both ways. Where there are obstructions to swinging-gates, a sliding gate is a good form. There are no hinges to this gate, or braces. It should be made of 6

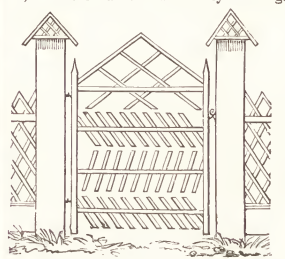
Board Holder.

A Cheap Farm Gate.

bars, mortised and pinned into the scantlings forming the end pieces. Set 2 posts in the ground, and connect them by 2 boards, on which the upper and next to the last rail of the gate is to rest. Place the posts at any easy distance apart for the gate to slide between easily, having the inner post 4 or 5 in. the rear of the other. At the other end of the gate place a post to which the gate is to be latched. This gate is easily opened by unlatching it, pushing it back on the supports at the other end, and swinging it to the right or left. A pretty front gate can be made of rustic branches or boards; these to be arranged in any design, according to the taste of the builder. The illustration is fanciful, cheap and serviceable. The design requires no explanation. There are various styles

Sliding Gate.

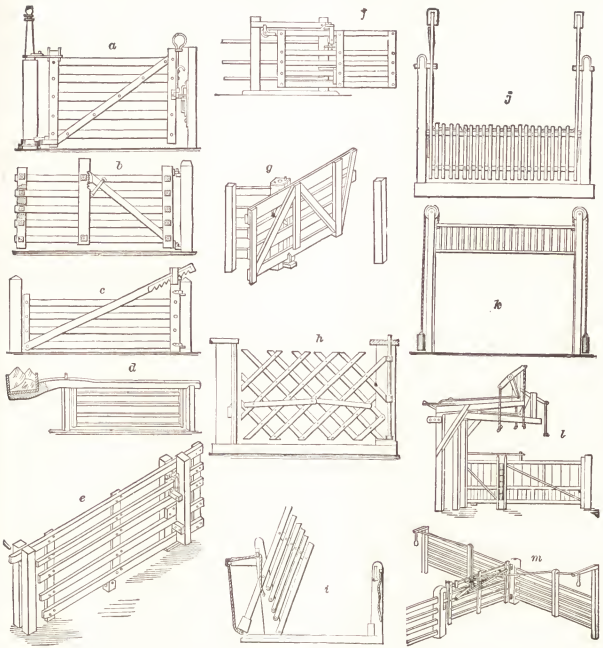
of making gates, not only in regard to appearance, but in the manner in which they are hung.



Fancy Gate.

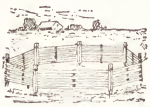
a, represents a gate which has adjustable hinges operating on rings on the post; the fastening consists of a movable latch and staple; *b*, represents a good method of hanging a gate when the loose end sags, by means of a diagonal strip; *c*, represents a method of preventing a gate from sagging, by a tie slat; *d*, represents a gate whose top bar is pivoted to the post, the whole gate being counterbalanced by a box filled with stone, placed on the extended bar; *e*, is a gate whose slats traverse on rollers, thus sliding longitudinally; *f*, is a sliding gate which has rollers to keep it level; *g*, slides half its length, and then rotates on a bar at its middle point; *h*, is a gate of pivoted bars; *i*, is a gate having a set of pivoted slats, which assume a vertical position when the top slat, being counterbalanced, is allowed to oscillate; *j*, is a suspended gate which swings upward in a vertical plane; *k*, is counterbalanced and suspended from pulleys; *l* and *m*, are complicated gates, so arranged as to be easily opened by pedestrians, equestrians, or persons in vehicles, by means of ropes.

HOOP-IRON FENCE.—Hoop iron makes as durable a fence as any kind of wire, and if tarred will last a lifetime; if painted white, it makes a beautiful light fence, besides a harmless one for any kind of stock. Old, sound rails would be good for supports or standards; 1½ in. hoop is the best size to use.



Forms of Gates.

MOVABLE FENCE.—Make lengths or frames of fence out of boards; at each end of each frame have the posts sharpened, in order that they may be driven into the ground. When all the frames are made and placed in position, fasten them together at the top by means of wire or rings of iron.



Movable Fence.

PICKET FENCE.—Useful to inclose the kitchen garden or hen-park. It takes from 900 to 950 pickets to make 10 rods. It also takes 28 posts, 6 ft. apart, and 14 pieces of scantling, 12 ft. long.

POSTS. To Set.—As posts, standing in the ground, decay a few inches below the surface, and in many cases become entirely rotten, it is best so to set them that these evils will be overcome. To preserve the posts, coat 6 or 8 in.

Picket Fence.

above and below the surface of the ground with crude petroleum, raw paint oil, or coal tar. Another method of preserving the posts, is by setting them above stone drains. For this purpose the stones may be laid in several ways. The bottom of the ditch may be covered with cobble-stones, capped with flat ones, upon which the post is set (*Fig. 2*), or the stones

may be laid as in *Fig. 1, 3* or *4*. *Fig. 1* is the best one shown, if properly laid on a hard subsoil.

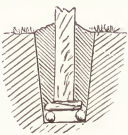


Fig. 1.

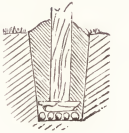

Fig. 2.

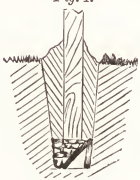

Fig. 3.

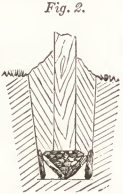

Fig. 4.

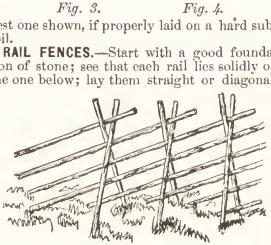
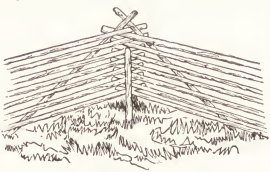
RAIL FENCES.—Start with a good foundation of stone; see that each rail lies solidly on the one below; lay them straight or diagonal,



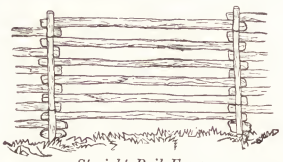
Diagonal Rail Fence.

in which case the end of each pole will be on the ground and more stakes will be needed; if



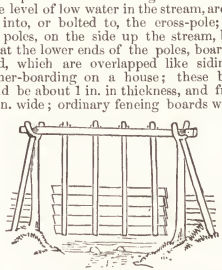
Zig-zag Rail Fence.

laid straight, the zigzag form is preferable; if the zigzag is not desired, drive the stakes in from 4 to 6 in. apart; place a stone 4 in. in height between them; upon this pile the rails; place a piece of annealed wire around both stakes; twist the ends well together; upon this place more rails; near the top use another piece of wire. Galvanized wire will not rust easily.



Straight Rail Fence.

WATER GATES.—Upright forks of heavy, durable timber, are placed on either side of the stream. These are set firmly in the ground, and securely braced. The gate swings, and is made as follows: A heavy pole rests upon the forks reaching across the stream; a small groove is made around the pole where it rests in the fork, which serves to keep it in place; 4 or more poles of sufficient length to reach down to the level of low water in the stream, are mortised into, or bolted to, the cross-pole; upon these poles, on the side up the stream, beginning at the lower ends of the poles, boards are nailed, which are overlapped like siding or weather-boarding on a house; these boards should be about 1 in. in thickness, and from 6 to 8 in. wide; ordinary fencing boards will answer; they should extend up the poles to the height of an ordinary fence above the bottom of the stream; when the water rises, this gate will swing upward, offering no obstruction to floating drift or ice, but effectually keeping animals from passing.



Water Gate.

WIRE FENCE.—1. A cheap, substantial, and sufficiently strong fence, can be made of No. 8 wire, 4 strands, with posts set 16 ft. apart. This requires 4 lbs. of wire to the rod. The wire is fixed to the end of the fence, where the post is strongly braced to the foot of the next one, set about 10 ft. from it, by means of a screw eye bolt, by which the wire may be loosened or tightened, as may be required by the contraction in winter or the expansion in summer. It is fixed to the posts by staples first loosely driven in, and is drawn tight by a winch and a binding cam attached to a rope, and then the staples are driven in firmly, so as to hold the post. The last post is braced as the first one, so that it will stand the strain firmly.—2. A good wire fence is formed by planting maple or cedar trees along the line, 30 to 40 ft. apart; then put up lines of barbed wire between them.

FUEL.

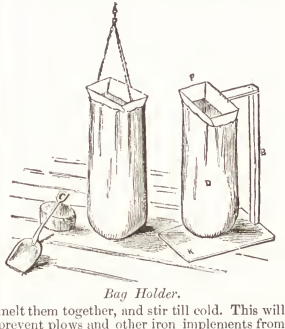
CHARCOAL.—This is made by the combustion of wood so confined that air is not admitted in sufficient quantities to make a blaze. The top soil is cleaned off, and the wood piled in pyramids, leaving small spaces between the different tiers, in which dry chips and brush are placed; the pile is then covered with earth, which is packed in closely, small openings being left immediately over the spaces in which the chips and brush are placed. The pile is then ignited below, the small holes acting as flues, creating a draft. The pile must be watched, to prevent blazing, and whenever a blaze is discovered, the hole from which it issues should be immediately closed with earth. When the white smoke which issues from the heap changes to thin blue, it is an indication that the charcoal is made, and all the openings should be closed; it should not be disturbed until thoroughly cooled, which will take a week or 10 days.

CORN.—Two bus. of corn will make a fire, which will keep a family warm all day; it makes a good and durable fire, and can be burnt in either hard or soft coal stoves, and is especially choice fuel for the cooking stove. Save the corn-cobs for kindlings. To prepare them, melt together 60 parts resin and 40 parts tar. Dip in the cobs, and dry on sheet-metal heated to about the temperature of boiling water.

FIREWOOD.—Among the first things to be considered during the winter, is to provide for a supply of fuel sufficient for the year's need. As soon as the fall work is over, it is a good time to commence in the woods the preparation for fuel. Cut down all trees come to maturity and those not growing any better from year to year; cut them into 8 ft. lengths; haul to the house; saw into stove lengths; split, pile in the wood house. Save all limbs of trees and scrubs. Oak, pine, hickory, dogwood, white ash, white hazel, red oak, hard maple, poplar, butternut and white birch, are all good as fuel.

IMPLEMENTS AND TOOLS.

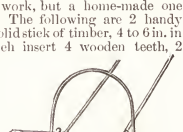
BAG HOLDER. — Useful in gathering potatoes and fruits. Take a 1 in. plank (K) for the bottom; bore a hole in the middle of one side; insert an upright stick (B) in this hole; to this fasten a short plank to which is attached 4 pieces of board, nailed together by their ends forming a square (P); on the outside place hooks or nails on which to hang the bag (D); the bag is hung, so that the square formed by the boards forms the opening. The opening can be made separately and attached by ropes or chains to the wall or ceiling.



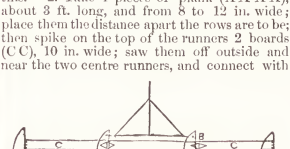
Bag Holder.

CARE OF IMPLEMENTS AND TOOLS.—When not in use, have them sheltered from the sun, wind, rain and snow. By this means, sleighs, wagons, carts, plows, threshing machines, harrows, and the like, would last twice as long as they would if left in the open air, swelling from moisture one week, and shrinking the next from the influence of the sun and wind. When put away for the season, paint the wood work well, and oil the iron to keep it bright. Take of rosin an amount equal to ½ an egg, and 1 lb. lard; melt them together, and stir till cold. This will prevent plows and other iron implements from rusting, when rubbed on. For general purposes on the farm, castor oil, with a little kerosene added, is a good lubricator and preserver.

CORN MARKERS.—There are several patent machines for this work, but a home-made one does just as well. The following are 2 handy ones: 1. Take a solid stick of timber, 4 to 6 in. in diameter, in which insert 4 wooden teeth, 2 ft. long; these should be round, strong and blunt. A pair of poles wedged into the sticks serve as thills. On the top of the pole, nail two hooks, firmly, to hitch to. Add a piece of sapling that, when bent, will come up about breast high. The operator guides the machine by this. — 2. Take 4 pieces of plank (A A A A), about 3 ft. long, and from 8 to 12 in. wide; place them the distance apart the rows are to be; then spike on the top of the runners 2 boards (C C), 10 in. wide; saw them off outside and near the two centre runners, and connect with 4 hinges (B B B B); put in a tongue, and it is ready for work on any kind of land; should a



Home-made Corn Marker.



Another Corn Marker.

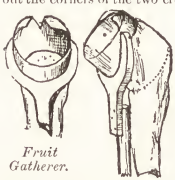
tree or stump be in the way, raise the right or left wing, as the case may be; if going through a narrow place, turn up both wings. To get the rows perfectly parallel, mark but three at a time, by allowing one runner to run in the last mark.

CORN HORSE. — Used to shock corn. The following is a good one. The cut shows the construction. The stock or rod in the centre is movable. It is placed in corn, with 3 rows upon each side, making 36 hills to a shock. The corn

Corn Horse.

is placed equally in the 4 corners formed by the cross-piece, and after tying the shock, this stock or rod is removed and the horse drawn out for the next shock.

FRUIT GATHERER.—Small fruits, or orchard fruits lying on the ground, can be gathered by a rake or by hand. But, for fruit on the tree, the following is a good invention: Take an old fruit can; place it on a bed of hot coals, and carefully melt off the top without loosening the side seam; cut the bottom ⅔ around and straight across, leaving on one side a crescent-shaped piece of tin, an in. or two wide at the widest part; through the middle of the crescent, extending down the side of the can, cut a V-shaped notch and bend out the corners of the two crescent pieces; next

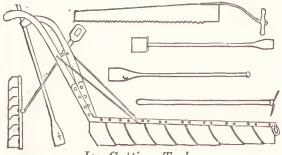


Fruit Gatherer.

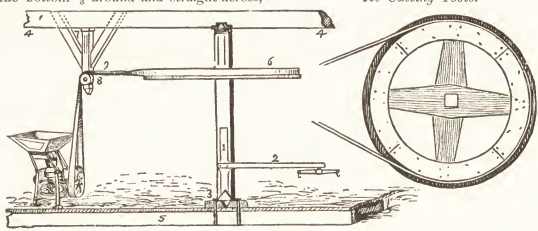
whittle or saw a fork out of a board and nail it to the pole, by means of nails or screws inserted from the inside; fasten the can in the fork; place the can over the fruit in such a manner as to bring the stem through the notch; draw down on the pole, and at the same time give the can a motion toward you; this will detach the fruit, which, falling into the can, will roll through the open end into a bottomless bag resting on the basket, fastened to the can by means of holes punched in the tin; hold the lower end of the bag up with the left hand until it gets heavy, then let the fruit pass carefully into the basket.

HORSE POWER.—The machine consists of an upright shaft, 6 by 6 in., 8 ft. high; bolt to this shaft a sweep to which the horse is to be attached; nail a pole also to the shaft to lead the horse; at the top and bottom of the shaft place iron journals; these, driven in firmly, turn with it and in the step below; erect in the barn; attach to the upright a pulley or wheel, 6 ft. above the floor; attach a strongly braced frame with 2 pulleys to the beam; over this pass a belt to the machine to be run.

ICE CUTTING TOOLS.—These are an ice-saw,



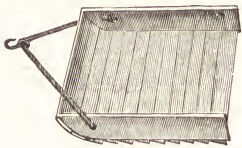
Ice Cutting Tools.



Horse Power.

an ice-hook or pole, and an axe. The ice-saw resembles somewhat the single or one-man cross-cut saw, for which the cross-cut saw may be substituted. The ice-pole or hook, is a long pole pointed with iron, and having a sharp iron hook near the point.

SHOVELS.—These are always in demand and



Surface Shovel.

3 or 4 are never out of place on a farm. A good

surface shovel is also needed. It consists of a wooden shovel, shod with iron. It may have a long handle or a cord and hook to which the horse is to be attached. It is needed in harrowing or in leveling a field or garden.

SLEDS.—These are convenient in hauling

Log Sled.

wood, etc. They can be easily constructed of boards or logs. Any form will do, but weight and size are great considerations. The less weight the better. The cut shows a good strong sled, made of logs. A horse may be fastened to the chain.

SOLDERING IMPLEMENTS.—A soldering iron, with the necessary accompaniments of resin, acid and solder, is another economical institution which dairymen, especially, find very convenient, for if every milk pan, can, pail, etc., had to be carried to the tinshop whenever a

Soldering Implements.

leak had to be stopped, a great deal of time, if not money, would be consumed by it. Then, every time a lead pipe can be mended by home talent, enough is saved, if far from a village, to nearly cover the cost of an iron. Implements like those shown in the illustration are convenient, and can be bought of agents.

ROADWAYS.

ROADS.—Very much of personal comfort and pleasure in rural residences depends upon good roads. A smooth, firm, dry road, is one of the greatest conveniences and enjoyments; while a rough, soft, or muddy road is one of the greatest drawbacks and annoyances of country life. Bad roads form the greatest obstacles to progress and permanent improvements. After locating the road and marking out its course, the sides should be brought to the proper grade and finished by a layer of sod as a guide to further operations. The road-bed is then formed by excavating and removing the soil to a depth of 6 in. at the sides, curving slightly higher in the centre, and made perfectly smooth by rolling, producing a uniform surface upon which the material of the road is to be placed. The best stone for road metal is tough granite. Hard, brittle stone is more readily reduced by pressure, but in a well-kept road this difference is not important. It is, however, all-important that the stones should be broken. The largest stones should be laid first. The road should be filled to a level with the sides. When it is necessary to branch a secondary road from the main line, it should leave the latter at as nearly a right angle as convenient, and at the same time be somewhat narrower, so that its appearance may convey the proper idea of its being subordinate, and so avoid confusion and mistake. A thin layer, not more than 1 in. in thickness, of fine clayey gravel, should then be evenly distributed over the stones, and the roller again applied until the surface becomes homogeneous, firm and close. Where stone cannot conveniently be obtained, the road-bed may be filled with refuse matters of many kinds, such as coal ashes, clinkers from furnaces, and shells. Oyster shells are plentiful in many places near the seaboard, and form an admirable road; but the permanency, as well as the efficiency of these materials in a road-bed, will depend altogether upon the care of surfacing with proper gravel. Where it is impracticable to procure, or deemed inexpedient to use, any of the foregoing materials, an earth road may be rendered very serviceable by proper attention to keeping it dry. In this case, instead of excavating a road-bed, slight excavations should be made at the sides and the material spread over the centre; and that surface water may pass to the sides more rapidly and thoroughly, a greater convexity may be given to the curve.

WALKS. Gravel. To Make.—Lay the bottom with lime rubbish, large flint-stones, or any other hard matter, for 8 or 10 in., to keep weeds from growing through, and over this lay the gravel 6 or 8 inches thick. This should be laid rounding up in the middle, by which means the larger stones will run off to the sides and may be raked away, for the gravel should never be screened before it is laid on. It is a common mistake to lay these walks too round, which not only makes them uneasy to walk upon, but takes off their apparent breadth; 1 in. in 5 ft. is a sufficient proportion for the rise in the middle; so that a walk 20 ft. wide should be 4 in. higher at the middle than at the edges, and so in proportion. As soon as the gravel is laid, it should be raked, and the large stones thrown back again; then the whole should be rolled both lengthwise and crosswise; and the person who draws the roller should wear shoes with flat heels, that he may make no holes. The walks should always be rolled 3 or 4 times after very hard showers, from which they will bind more firmly than otherwise they could ever be made to. (See also *Walks* in LANDSCAPE GARDENING.)

TABLES.

BINS AND PILES, Measurement of.—To ascertain the number of bushels in a bin of any dimensions, find the number of cubic ft. by multiplying the 3 dimensions of the bin in ft.; deduct 1-5, and the result will be the number of bushels. To find the cubic contents of a pile in the usual form of a cone, find the area of the base by the old arithmetical rule of multiplying the square of its diameter in ft. by .7854, and this product, multiplied by $\frac{1}{3}$ the height of the cone, will give the cubic ft.

DRAINS REQUIRED FOR AN ACRE OF LAND.—The following table shows the number of tiles, of the different lengths made, which are required for 1 acre, and will be useful to those who may desire to purchase just enough for a particular piece of ground:

DISTANCE APART.				12 Inch Tiles.	13 Inch Tiles.	14 Inch Tiles.	15 Inch Tiles.
Drains	12 ft.	apart	require	3630	3351	3111	2934
"	15	"	"	2904	2681	2489	2323
"	18	"	"	2420	2234	2074	1936
"	21	"	"	2074	1914	1777	1659
"	24	"	"	1815	1065	1556	1452
"	27	"	"	1613	1480	1386	1291
"	30	"	"	1452	1340	1245	1162
"	33	"	"	1320	1218	1131	1056
"	36	"	"	1210	1117	1037	968

In reference to tile pipe drains, it must be remembered that the ditch may be much narrower than when stones are used, thus making a considerable saving in the expense of digging. The upper part of the earth is taken out with a common spade, and the lower part with one made quite narrow for the purpose, being only about 4 in. wide at the point.

ELEMENTARY SUBSTANCES IN A CROP OF ONE ACRE.—

HAY, To Measure.—Weighing is the only accurate method of measuring hay. It is difficult to do this unless it is baled or made otherwise compact. On account of this difficulty it is sometimes weighed by the cubic contents, a mode which is only approximately correct. Equal bulks of different kinds of hay vary largely in weight. The following rules are useful for estimating the amount in meadows, mows or stacks. About 25 cu. yds. of average meadow hay in windrows make a ton; 15 or 18 cu. yds. make a ton, when well settled in mows or stacks; 20or 25 cu. yds., when it is loaded on wagons from mows or stacks; 25 cu. yds. of dry clover make a ton. 1. The number of tons of meadow hay, raked into windrows, may be found as follows: Multiply together the length, width and height of the windrow in yds., and divide by 25. — 2. To find the number of tons in a mow, multiply the length, height and width, in yds., together, and divide the product by 15. — 3. To find the number of tons of hay in old stacks, find the area in sq. yds. of the base, by the table of areas of circles in this volume; then multiply the area of the base by ½ the altitude of the stack in yds. and divide the product by 15. — 4. To find the number of tons in long, square stacks, multiply the length, width, and half the altitude in yds. together, and divide the product by 15. — 5. To find the number of tons of hay when taken out of the mows or old stacks, multiply together the length, width and height of the load in yds., and divide the product by 20. These estimates are for medium sized mows or stacks. — 6. To ascertain the value of a given number of lbs. of hay, at a given price per ton of 2,000 lbs., multiply the number of lbs. of hay, or any other article which is bought or sold by the ton, by ½ the price per ton, pointing off three figures from the right hand. The principle is the same as in interest: dividing the price by 2 gives the price of ½ ton, or 1,000 lbs.; and pointing off three figures to the right is dividing by 1,000. A truss of hay, new, is 60 lbs.; old, 56 lbs.; straw, 40 lbs.; a load of hay is 36 trusses; a bale of hay is 300 lbs.

LAND, To Measure.—Each section has four quarter sections, as here designated, each containing 160 acres. The township is 6 miles square, divided into 36 square miles or sections, numbered as in the following diagram, and each containing 640 acres.

A SECTION.

N.W.	N. E.
S.E.	S. E.

A TOWNSHIP.

6	5	4	3	2	1
7	8	9	10	11	12
18	17	16	15	14	13

30	29	28	27	26	25
31	32	33	34	35	36

Every farmer should have a light, stiff pole, just $16\frac{1}{2}$ ft. (1 rod long), with division marks on it of 1 yd. each, making it $5\frac{1}{2}$ yds.; then, by proceeding according to the rules below, the area in acres of each lot can be obtained. 1. Where the field is a square, a parallelogram, a rhombus, or a rhomboid, multiply the length in rods by the breadth in rods, and divide the product by 160, and the result will be the number of acres. —2. Where the field is triangular, multiply the base or longest side, in rods, by the perpendicular height (the greatest width), in rods, and divide $\frac{1}{2}$ the product by 160, and the result will be the number of acres. —3. Where the field is a trapezium or a trapezoid in shape, divide it diagonally by a line running from one extreme corner to the other, which will cut the field into two triangles; then proceed with each as in the preceding rule, and add the areas of the two triangles together; the result will be the number of acres in the field.—4. Where the field is an irregular polygon, draw diagonals to divide the field into triangles; find the area of each separately, and the sum of the whole will be the number of acres. There are very few lots which cannot be measured by cutting them into triangles; and proceeding by the above rule. In fact, all approximately straight-sided fields can be so measured, nearly enough for practical purposes.—5. Where the field is long, and the sides crooked and irregular, take the breadth in rods in a number of places, at equal distances apart; add them, and divide the sum by the number of breadths for the mean average or breadth; then multiply that by the length in rods and divide the product by 160, and the result will be the number of acres. —6. Where the field is long, and the sides and ends crooked and irregular, find the mean breadth in rods by the preceding rule, and proceed in the same way to find the mean length in rods; then multiply the mean length by the mean breadth, and divide the product by 160, and the result will be the number of acres.—7. Where the field is a circle, take the diameter in rods, and find the area of the circle in our table of the areas of circles in this volume, and divide by 160, and the result will be the number of acres. To lay off small portions of ground, we give the following table:

Parts of 1 Acre.	Square Feet.	Feet Square.	Parts of 1 Acre.	Square Feet.	Feet Square.
1-16	2722½	52½	½	21780	147½
⅛	5445	73⅝	1	43560	208⅛
¼	10890	104⅝	2	87120	295⅛
½	14520	120½			

The following table will assist in making an estimate of the amount of land in fields and lots:

*	10 rods by 16 rods	1	acre.
†	5 yds. by 968 yds	1	"
‡	220 ft. by 198 ft	1	"
	25 ft. by 125 ft	.0717	"
	4,356 sq. ft., .10 acre.	10,890 sq. ft., .25	"
	21,780 " .50 "	32,670 " .75	"

* Or any two numbers whose product is 160.
† Or any two numbers whose product is 4,840.
‡ Or any two numbers whose product is 43,560.

WAGON BEDS, Capacity of. — 1. If the opposite sides are parallel, multiply the length inside in in. by the breadth inside in in., and that again by the depth inside in in., and divide the product by 2,150.42, (the number of cu. in. in a bus.), and the quotient will be the capacity in bus. — 2. Should the head and tail boards, or either of them, be set in beveling, add the top and bottom lengths together and divide by 2 for the mean length, and proceed by the foregoing rule; should the sides be sloping, add the top and bottom widths, and divide by 2 for the mean width, and proceed by the foregoing rule. — 3. Should the contents be required in cu. ft., divide the product by 1,728 (the number of cu. in. in a cu. ft.), instead of 2,150.42, and the quotient will be the contents in cu. ft.

WHEAT, Depth of Sowing. — The depth of sowing wheat must vary with the soil. A thinner covering is required in a heavy than in a light soil. Experiments give the following results:

	Appeared above ground in	No. of days.	No. of plants
Seeds sown to the depth of	½ in.,	11 days.	¾
" " "	1 "	12 "	all.
" " "	2 "	18 "	¼
" " "	3 "	20 "	⅛
" " "	4 "	21 "	⅛
" " "	5 "	22 "	⅛
" " "	6 "	23 "	⅛

VEHICLES.

EVERY farm needs a buggy, a spring wagon, a hand-cart, and a heavy farm wagon of some kind. A carriage is also a great addition to the comfort of the household. These all need a certain amount of care and should not be neglected, but kept in perfect order.

AXLE GREASE.—1 lb. tallow; ¼ lb. castor oil; ¼ lb. black lead; melt the tallow, and rub the whole together until cold and well mixed. —2. Water, 2 gals.; soda 1 lb.; palm oil, 20 lbs.; mix well by heat, and stir till nearly cold. Just enough grease should be applied to the spindle of a wagon to give it a light coating.—3. Tallow, 8 lbs.; palm oil, 10 lbs.; plumbago, 1 lb.

CARRIAGE AND BUGGY, Care of.—Never under any circumstances put them away dirty. In washing, keep out of the sun, and have the lever end of the "setts" covered with leather. Use plenty of water, which apply with a hose or syringe, taking care that the water is not driven into the body to the injury of the lining. When forced water is not attainable, use for the body a large soft sponge. This, when saturated, squeeze over the panels, and by the flowing down of the water, the dirt will soften and harmlessly run off; then finish with a soft, wet chamois leather and an oiled silk handkerchief. The same remarks apply to the underworks and wheels, except that, when the mud is well soaked, a soft mop, free from any hard substance in the head, may be used. Never use a "spoke brush," which, in conjunction with the grit from the road, acts like sand-paper on the varnish, scratching it, and of course effectually removing all gloss. Never allow water to dry itself on the carriage, as it invariably leaves stains. Aprons of all kinds should be frequently unfolded. Enamel leather tops should be first washed with Castile soap and warm water, then oiled with neat's-foot oil; or if sweet oil and a coat of enamel varnish are put on, the leather will look like new. Dashers may be cleaned in the same manner, but varnish color is not very beneficial to patent leather; however, when old and cracked, it may be colored to improve the appearance. Be careful to grease the bearings of the fore-carriage so as to allow it to turn freely. Examine a carriage occasionally, and whenever a bolt or slip appears to be getting loose, tighten it up with a wrench, and always have little repairs done at once. Never draw out or back a carriage into a coach-house with the horses attached, as more accidents occur from this than from any other cause.

TIRES, To Tighten.—Procure a number of small pieces of leather, from 1½ to 2 in. in diameter; with a sharp knife and a compass, or a cutting punch, make round holes in the centre of these pieces, and make a straight cut from the hook to the outer edges of the pieces, so as to form open rings; the holes must be made of a size that will nicely fit the tenons on the out ends of the spokes. Place a fulcrum on the top of the hub, on which place your lever, with the short end under the felloe, near a spoke; have an assistant bear down on the other end sufficiently to raise the felloe, and expose the shoulder and tenon of the spoke; open your leather and fit it nicely around the tenon, holding it to its place while your assistant relaxes the lever and settles the felloe firmly upon the spoke by a blow or two upon the tire. Having repeated the process with a sufficient number of spokes to make the tire all right, trim off the projecting leather even with the surface of the spokes, and your task is done. If the pieces of leather should be spongy, hammer them down before using.

WHEELS, To Prevent Shrinking. — Apply a mixture of petroleum and linseed oil to the felloes with a brush, several times over, where they are dry.

WEATHER INDICATORS.

ANIMAL CREATION. — Rain is sure to come when the cattle snuff the air and gather together in a corner of the field with their heads to leeward, or take shelter in the sheds; when sheep leave their pastures with reluctance; when the goats go to sheltered spots; when asses bray frequently and shake their ears; when dogs lie much about the fireside and appear drowsy; when cats turn their backs to the fire and wash their faces; when pigs cover themselves more than usual in litter; when cocks crow at unusual hours and flap their wings much; when hens chant; when ducks and geese are unusually clamorous; when pigeons wash themselves; when peacocks squall loudly from trees; when the guinea-fowl makes an incessant grating clamor; when sparrows chirp loudly, and clamorously congregate on the ground or in the hedge; when swallows fly low and skim their wings, on account of flies upon which they feed having descended toward the

ground; when the carrion crow croaks solitarily; when wild waterfowl dip and wash unusually; when moles throw up hills more industriously than usual; when toads creep out in numbers; when frogs croak; when bats squeak and enter houses; when singing birds take shelter; when the robin approaches nearest the dwelling of man; when tame swans fly against the wind; when bees leave their hives with caution, and fly short distances; when ants carry their eggs busily; when flies bite severely, and become troublesome in numbers; when earth-worms appear on the surface.

CHEMICAL BAROMETER.—Put a small quantity of finely pulverized alum in a long ½ oz. vial, and fill it with spirits of wine. When the atmosphere is dry and clear, the spirits will be clear as crystal; but on the approach of rain or bad weather, the alum will rise in the centre in the form of a spiral cloud, which is an infallible indication of rain or bad weather.

CLOUDS.—1. The cirrus consists of fibres or curling streaks, which diverge in all directions. It occupies the highest region, and is frequently the first cloud which is seen after a continuance of clear weather. While the cirrus remains nebular in structure and indistinctly defined against the sky, no rain need be expected. Under the low barometer, however, it develops by accretion, becomes smooth and compact in structure and much enlarged in volume. It now sinks lower and becomes more sharply defined against the blue sky. Rain may now be expected, especially if it unite with the cumulus, which is a convex aggregate of watery particles, increasing upwards from a horizontal base, and assuming more or less of a conical figure. If the cirrus, instead of forming the nimbus or rain-cloud, reascends, it dissipates, and no rain may be expected until it lowers again, which generally is in 24 hours.—2. If the clouds are soft, undefined, and feathery, the weather will be fine; if the edges are hard, sharp and definite, it will be foul. Generally speaking, any deep, unusual hues betoken wind and rain, while the more quiet and delicate tints bespeak fair weather.

LUNATIONS OF THE MOON.—The following table and remarks, originally made by Herschel, the astronomer, and approved with some alterations by Dr. Adam Clarke, are the result of many years' close observation, the whole being a due consideration of the attraction of the sun and moon, in their several positions, respecting the earth, and will, by inspection, show the observer what kind of weather will most probably follow the entrance of the moon into any of its quarters. It has seldom been found to fail. 1. The nearer the time of the moon's changes, first quarter, full, or last quarter are to *midnight*, the fairer will the weather be during the seven days following.—2. The space for this calculation occupies from 10 at night till 2 the next morning.—3. The nearer to *mid-day* or *noon* the phases of the moon happen, the more foul or wet weather may be expected during the next 7 days.—4. The space of this calculation occupies from 10 A. M. to 2 P. M. These observations refer principally to the summer, though they affect spring and autumn nearly in the same ratio.

If the new moon, the first quarter, full moon, or last quarter happens

Moon.	Time of Change.	In Summer.	In Winter.
	Between midnight, and 2 in the morning.	Fair.	Hard frost, unless the wind be S. or W.
	Between 2 and 4 morning.	Cold, with frequent showers.	Snow, and stormy.
	Between 4 and 6 morning.	Rain.	Rain.
	Between 6 and 8 morning.	Wind and Rain.	Stormy.
	Between 8 and 10 morning.	Changeable.	Cold rain, if less the wind W.; snow, if E.
	12 morning. At 12 o'clock at noon and at 2 P. M.,	Frequent showers	Cold and high wind.
	Between 2 and 4 P. M.,	Very rainy.	Snow or rain.
	Between 4 and 6 P. M.,	Changeable.	Fair and mild.
	Between 6 and 8 P. M.,	Fair.	Fair.
		Fair if wind N. W.; rainy, if S. or S. W.	Fair and frosty, if wind N. or N. E.; rain or snow, if S. or S. W.
	Between 8 and 10 P. M.,	Rainy, if wind S. or S. W.	Rain or snow, if S. or S. W.
	Between 10 and midnight,	Fair.	Fair and frosty.

PLANTS.—Trees and their branches fall just before a severe storm; the common English bindweed and the English pimpernel, spread their leaves at the end of wet weather, while the different species of clover contract them; the chickweed, at 9 o'clock in the morning, if the weather is clear, straightens its flowers, spreads its leaves, and keeps awake until noon; if, however, there is a prospect of rain, the plant droops and its flowers do not open; if they open a little, the coming rain will be of short duration; the same with *Pimpinella saxafraga*; the marigold opens between 6 and 7 in the morning, and generally keeps awake until 4 in the afternoon; in such cases the weather will be steady; if, on the other hand, it has not opened by 7 o'clock in the morning, you may look that day for rain; the hog thistles indicate fine weather for tomorrow if the head of the blossom closes for the night; rain, if it remains open; again, rain is certain if the *Bladder ketmi* does not open its blossoms; if the stemless thistle closes; if clover and most allied kinds droop their leaves; also, if the nipple-wort does not close its blossoms for the night; if the whitlow grass lets its leaves hang drooping; if *Gallium vernum* swells and exhales strongly; also, if birches scent the air; the crowfoot anemone tells the coming rain by closing its blossoms; while *Anemone mentalsa* carries its flowers erect when the weather is fine, and droop when overcast.

SKY, Color of.—An intensely blue and serene sky indiactes heavy rains and severe storms in from 12 to 48 hours. A gray, hazy sky, indicates continuous dry and generally hot weather. A bright sunset presages fair weather. A bright yellow, in the evening, indicates wind; a pale yellow, wet; a natural gray color constitutes a favorable sign in the evening; an unfavorable one in the morning.

SMOKE.—Dense smoke and haze in the early

morning portend falling weather. If the smoke arises, the weather will be clear; if it falls, the weather will be rainy.

STRAW AND CATGUT.—A simple hygrometer can be made by a piece of catgut and a straw. The catgut, twisted, is put through a hole in a dial, in which a straw is also placed. In dry weather the catgut curls up; in damp, it relaxes, and so the straw is turned either to the one side or the other.

WIND.—Wind veering from N. or W. to S. and S. E., precedes falling weather; if the wind is in S. W. and rain sets in, the rain is of short duration and light yield; as a rule, if the wind touches N. E. or E. for 2 or 3 days, it is a sure indication of rain; an immediate cessation of rain occurs as soon as a N. W. wind sets in; the W. wind brings 3 or 4 clear days.

STOLEN SWEETS ARE SWEETEST.

BEES AND SILKWORMS.

BEE-KEEPING.

ANATOMY AND RACES.

REMARKS ON RACES.—The bee is a resident of any climate of the globe. It will prosper in hollow trees in Canada, where mercury will freeze in the open air, as well as at the equator. The following are the principal varieties or races of bees: *Albinos.* These are a pure, highly bred and distinct race of bees, and surpass all others for gathering honey; as for beauty, they can't be excelled in the world, and they are among the most gentle bees known to mankind. About the eyes they approach nearer a purplo than the Italian. Beginning at the waist, they first have 3 distinct yellow bands, then 3 distinct white bands—the white is pure, the wings are fino and of a bright silvery color. Their shoulders and the under part of the abdomen are very thickly coated with white hair. The queens are large and beautiful. They are a bright reddish yellow and generally havo the white hair as described of the workers. They are very prolific. — *Black* or *Common.* These bees are not really black, but a grayish black. South they are so very light in color as to be taken for a distinct race. — *Cyprian.* Yellow and undoubtedly a variety of the Italian. The Cyprian queen is lively, and of a very light yellow color under its body. This often approaches a straw color. She is ferocious when attacked, and resists vehemently. Her workers are much more hardy than either the Italian or black bee. It is said that in Cyprus she will live for 6 yrs.—*Egyptian.* Broadly banded with yellow, and smaller, more slender and yellow than the Italian. They are supposed to be the ones mentioned in the Scriptures. — *Italian.* These bees have 3 bright rings at the base of the abdomen. They are the best natured of any race of bees. The best color for Italian worker bees is a golden hue. They are superior to the common or black bees, in the prolificness of their queens. Italian hives will be strong in spring and throw off swarms from 1 to 2 weeks before the common bee. The great preventive of the ravages of the moth is to keep the hives strong, and this very prolificness of the Italian queen answers this purpose.

ABDOMEN.—The abdomen of the bee contains the honey-bag, the stomach, the wax-bag, the venom-bag and the sting. The honey-bag is not used for the purposes of digestion; it is a small bag, about the size of a pea, with 2 pouches behind, and is properly only an enlargement of the gullet. This receptacle receives the honey from the probocis; a small passage leads from it to the stomach, which receives and digests the food of the bee. Wax is derived from the saccharine matter consumed by the bee. It is secreted from vessels on the surface of their pouches. After the wax has remained there for a time, it appears externally in scales, 8 in number, below the medial rings of the abdomen, and is removed by the bee itself, or one of its fellows.

EYES.—In front of the head are 2 eyes, which are protected by hairs from any substances that might otherwise injure them, and on the top of the head are three smaller eyes. This visual apparatus renders the bee's power of sight a very extended one. Simple as the tiny instrument seems, it is composed of about 3,500 perfect hexagonal lenses, fitting closely together and disposed in regular rows.

FEELERS.—Two feelers spring from between the front eyes, and curve outwards on each side; these are endowed with a very acute sense of touch, and perform many of the offices of eyes, in the dark recesses of the hive. It is by the assistance of these delicate and highly sensitive organs that these insects form their combs, fill their cells, and feed the young.

LEGS.—The bee has 3 pairs of legs, of which the posterior are the longest, and the anterior the shortest. These are formed and articulated much like the same limbs in man, and are attached to the thorax; at their extremities we find 2 lit-

tle hooks, which appear like sickles or reaping hooks, and have their points opposed to each other. By means of these the insect suspends itself to the top of the hive, or in any other position it may desire.

MOUTH.—The bee's mandibles or jaws, when separated, resemble a pair of toothed pincers; they are composed of the same horny substance as constitutes the rings of the body, and are extremely powerful. Besides these there are a second pair of jaws composed of 2 long-pointed blades, whose thin edges work together after the manner of a pair of scissors. It is with these latter instruments that the bee cuts and molds its wax in its work of cell making. The mouth of the bee is further provided with a tongue of a curious sort. It is capable of protrusion considerably beyond the jaws, and covered along its whole length with regular and symmetrical circlets of fine hairs. From root to tip it is traversed by a tube, through which, in all probability, the nectar is conveyed to the mouth. When the insect is in a state of repose, the whole of this complicated apparatus folds under the head.

STING.—Seen through a microscope of low power, the sting presents the appearance of a tiny thorn, slightly curved and tapering to inscrutable fineness. This, however, is not the actual sting, but the mere scabbard which contains a distinct pair of darts. Seen under a very powerful microscope, the 2 darts are found to bear 8 notches or barbs, which prevent them from being released too quickly from the part attacked. But the puncture made by this complicated set of instruments, is the simplest part of the affair. Situated at the root of the sting there is a little bag filled with an acrid fluid, generally supposed to be formic acid. At the moment when the double dart enters the wound made by the sheath, there is expressed from the poison bag a drop of the fluid which is conducted in a groove to the end of the sheath, and from thence into the wound. When human beings are stung, they can instantaneously obtain relief by pressing upon the point stung with the tube of a key; this will extract the sting, and relieve the pain, and spirits of hartshorn will completely remove it.

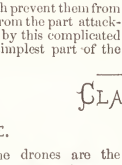
THORAX.—Interiorly the thorax contains the gullet, which traverses its extent on its way into the abomen, where it dilates into, first, the honey-bag, which is furnished with 2 pouches posteriorly, and a muscular apparatus, by which it is enabled to give forth its saccharine contents; and, secondly, into the true stomach, in which digestion goes on, for the nourishment of the insect and the secretion of wax.

WINGS.—Four wings are attached to the superior portion of the thorax, which consist of 2 pairs of unequal size. These wings are hooked together in order that they may act simultaneously, and not only serve to convey the insect from place to place, through the air, but by the humming, buzzing noise their motion produces, to give notice of their departure from, and return to, the hive, as well as possibly to animate their fellows in their mutual labors, and by their fanning motion at the entrance, cool and ventilate the hive.

CLASSES.

DRONE.

CHARACTERISTICS.—The drones are the males, and larger in body than either the queen or the working-bees. Their head is rounder, proboscis shorter, eyes fuller, and they have no sting; they also make more noise in flying, and do no work.



Drone.

COMB.—Drone comb cells are larger than those of the worker. Four inches of drone comb is enough for any hive of bees. By removing it the raising of drones may be prevented to a certain degree, but the bees will always find some little corner in which to raise a few drones. A hive with a young queen builds worker comb almost entirely.

HATCHING.—The drone passes 3 days in the egg, and about 6 in the worm, and changes into a perfect insect on the 24th day after the egg is laid. Much depends upon the strength and heat of the colony, which should be about 70° Fahrenheit for their speedy development. They lie in rather a dilatory state for several days, after they hatch, before taking wing.

LONGEVITY.—The age of the drone depends on the condition of the colony and the supply of honey, but it is something less than the age of the worker. If kept constantly in a queenless hive, they might live for 3 or 4 months. At the end of summer they are expelled from the hive.

QUEEN.

CHARACTERISTICS.—The queen-bee may be recognized by her greater length of body, which is of a blackish color above, and of a yellowish tint beneath. She is sometimes of a larger size than either of the other classes; her abdomen contains 2 ovaries, or receptacles, for eggs, and her sting is of a curved form. She receives the greatest attention and respect from the other bees; none of them appear to be willing to turn their backs upon her, but all are watchful to offer her food and anticipate every want.

Queen.

CHOICE.—Preference should always be given to the dark or orange colored, rather than the bright yellow.

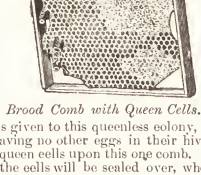
CLIPPING THE WINGS.—The wings of all queens, as soon as they are fertile, may be clipped; but it is an erroneous idea to suppose that clipping the wing of the queen will keep the

bees from swarming. They are just as likely to swarm, but the queen being unable to accompany them, will prevent their leaving for parts unknown. It is only necessary to clip the tip of one front wing; this will prevent her flying, and does not disfigure her. The queen should be handled as little as possible. Take her by the thorax, between the left forefinger and the thumb; raise the point of the wing with the scissors and clip, being careful not to catch her foot, as she is liable to throw her leg up around the wing while held. Never take her by the abdomen, as a slight squeeze is likely to injure her.

FERTILIZATION.—A fertile queen is one that has paired with the drone and is capable of laying eggs that will produce workers, drones, or queens. A queen's fertility lasts from 3 to 5 yrs. In the spring and summer young queens leave the hive to meet the drones for impregnation, usually on the 5th day; in the fall months they very seldom leave until 7 or 8 days old.

FERTILIZATION. Artificial.—A wire cloth dish cover, 10 in. in diameter, is just the thing for a fertilizer. It can be easily fixed by fitting a piece of thin board in the bottom, in which a door, large enough to put in one's hand should be made. Fasten on the inside of the fertilizer a piece of empty drone comb, 3 or 4 in. square; when required for use, fill with honey and water, taking pains not to drop any honey in the fertilizer, or the queen and the drones will become daubed up so as to prevent them from flying. On the morning of the day that a queen is to leave the hive, put her with 4 or 5 drones into the fertilizer. In selecting the drones to be put with young queens, great care should be taken to choose only those that are strong, vigorous, and well marked, and they should be caught as they are about to leave the hive. Having got the queen and the drones in the fertilizer, and everything fixed, lay it over the frames of the hive to which the queen belongs, so that the heat from the hive can get into it. Leave her there 36 or 48 hours. When a dead drone is found, examine it, and if the generative organ is gone, the queen can be released, when she will go down into the hive and begin to lay in a few days, or she can be introduced into a nuclei hive, which can be done in a minute by giving the bees in the nuclei a dose of smoke, where she can be kept until wanted.

HATCHING.—Queen bees and the ordinary worker bees are produced from the same kind of eggs. The difference is, that the workers are reared in small cells and fed sparingly while in the larval state of their growth, which leaves them undeveloped females. The queen is reared in a large cell, produced by uniting several ordinary cells into one, and fed very plentifully with a rich food, called "royal jelly," and the result is a perfectly developed female, capable of laying eggs and becoming the mother of a colony. When a colony is deprived of its queen, the bees proceed at once to repair their loss, by constructing from 3 to 15 or 20 of these queen cells. The first queen that hatches bites into the sides of the remaining cells—the bees often joining with her—and destroys her imprisoned sisters. Knowing these facts, the breeder of queens, when he wishes to rear some, removes both the queen and all the royal brood from some strong colony. Then a comb of eggs from some choice



Brood Comb with Queen Cells.

queen is given to this queenless colony, and the bees, having no other eggs in their hive, build all the queen cells upon this one comb. In 5 or 6 days the cells will be sealed over, when they will, in shape, resemble peanuts projecting from the side of the comb. In about 10 days more, or 16 days from the time the eggs were laid, the queen will hatch; but after the cells are sealed over, all that is required is heat; therefore the apiarist removes the comb upon which are the cells, and brushes off the bees, and hangs it in a lamp nursery. He then gives the colony another comb of eggs, and the bees proceed to build another batch of queen cells.

INTRODUCING.—Queens cannot be introduced to colonies that have been queenless a few hours without caging several days, and sometimes a week may elapse before they can be released with safety. When a colony is deprived of its queen, the bees realize their loss, and at once prepare to repair it. To introduce an Italian queen to a colony of common bees, inclose her in a wire cloth cage and insert the cage in the centre of a comb where the bees will cluster upon it. In 36 hours release the queen, smear her with honey, and allow her to crawl down among the bees.

LAYING.—As soon as the cells are in readiness, intimation of the fact is conveyed to the queen bee, who at once proceeds to lay her eggs. She has 3 sorts of eggs to deposit—worker, drone, and princess eggs, and the cells prepared for the reception of each differ in shape from the other. The worker cells are smaller and neater than the drone cells, and those intended for the reception of royal eggs are more commodious still. She deposits an egg in every cell, and should she, by accident, leave 2 in a cell, the extra one is quickly destroyed by her attendants. The eggs are long, slightly curved, and of a bluish color; when laid, they are covered with a gelatinous matter, which instantly dries, attaching them to the bottom of the cell. The queen bee commences depositing her eggs when 5 days old; during the heat of the season she lays from 150 to 200 eggs per day, and lays with little or no intermission from early spring to the middle of autumn.

LONGEVITY.—Queens are the only bees that live more than one season, and they sometimes live 3 years, and they have been known to exist for 5 years. If a queen survives her second year, it is best to remove her to give place to a younger and more vigorous one.

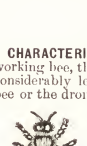
RACES, Changing.—The queen deposits all

the eggs, and it follows that all the bees will be like her. If the queen be taken from a colony of common black bees and an Italian queen placed there in her stead, it follows that all the eggs thereafter laid will produce Italian bees.

REARING QUEENS. — Provide some small boxes on the plan of a simple movable frame hive, with a loose top and rabbeting for the frame; and just sufficient size to accommodate from 3 to 5 of them. When eggs have been deposited in the combs, set up one of the small boxes with them as a miniature hive, and inclose therein from 1 pt. to 1 qt. of bees. They will immediately commence work, and construct queen cells, and the hive may then be opened. In this manner a large number of queens may be had.

WORKER.

CHARACTERISTICS. — The third class is the working bee, the most interesting of all. It is considerably less in size than either the queen bee or the drone; is about ⅓ in. in length; of a blackish-brown color, and covered with closely-set hairs over all the body, which aid in carrying the farina which it gathers from the flowers. The workers are imperfect females. Every worker egg, or grub, not more than a few days old, is capable, by appropriate treatment, of becoming developed into a perfect female, or mother bee.



Worker.

FERTILE WORKERS. — The workers are undeveloped females, but sometimes they may be sufficiently developed to lay eggs. Some account for this by the possibility that the larva may have been adjacent to the queen cell and received some of the pabulum, given so plentifully to the queen. When this occurs it is a great annoyance. Any bee-keeper is liable to be bothered with fertile workers once in a while. As soon as discovered, if in the brood-rearing season, make a small division of a stock that is in good condition, set it close beside the infested colony, with entrances in the same direction. As soon as the division has a fertile queen (one may be introduced at the time of making it) well established and laying, move it to the farthest side of the brood chamber of its hive, at the same time reducing its number of combs to 3 or 4; then proceed gradually to break up the infested colony by going to them at sundown and spraying both stocks liberally with diluted honey or thin sugar syrup, and placing a few of the outside combs with adhering bees of the fertile worker stocks in the side of the hive containing the queen; remove every other evening until all are united; remove the empty hive, and the work is done.

HATCHING. — The bee's egg is a small, colorless speck, and is deposited at the very bottom of its cell. The worker and drone cells are used not only for brood rearing, but also for storing honey and pollen, or bee bread. At the end of 4 days, there emerges from the egg a little dingy-white worm, possessing, as far as the naked eye can observe, no sign of external members; and by this time, the bees, whose duty it is to nurse the little strangers, have poured into each cell a drop of diluted honey, and in this the little maggot lies curled up. When the nurses know that the worm is approaching bee-hood, they plaster over the mouth of its cell and leave it to itself. It then sets about spinning for itself a silken cocoon (the worker in not less than 36 hours), and in this it lies enveloped till the metamorphosis is complete, and becoming a perfect bee, it comes forth from its cell. Its first journey is to the lighting board in front of the hive, that the sun may dry its damp body; while an old bee busies itself to straighten and smooth the hairs that cover its limbs. The time occupied from the deposition of the egg to the final appearance of the worker bee is about 20 days. (See *Hatching* in QUEEN.)

HABITS OF YOUNG WORKERS. — After filling itself with honey, to supply the demands of hunger, the bee goes to work at partially digesting food and feeding the larvæ, not leaving the hive till 6 days old, at which time, if the weather is propitious, the first flight is taken, which happens about 2 o'clock in the afternoon. In taking leave of the hive for the first time, the bee, as it rises on the wing, turns its head toward the hive and commences to describe small circles in the air, each circle increasing in diameter until it is lost from sight. This they do to mark their location, so as to be enabled to return to the exact spot they started from, and so accurately do they do this, that they will return within a few inches of the exact place from which they started, ever after, unless by swarming or long confinement they are compelled to mark their location anew. After the first flight the bee still remains in the hive the most of the time, till it is 16 days old, building the comb (if any is to be built), feeding the young bees, taking the honey from the field bees as they come in with their loads, evaporating the honey and storing it in the cells, and, in short, doing all the duties of the hive. At 16 days old the bee goes into the field to gather honey and pollen, and thereafter rarely ever performs any of the labors belonging to the inside of the hive.

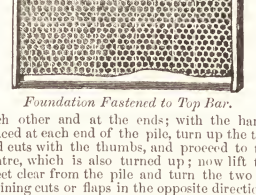
LONGEVITY. — It is difficult to decide how long a worker bee would live, if kept from wearing itself out by the active labors of the field; 6 months, and perhaps 1 year; but the average life during the summer time is not over 3 months, and during the height of the clover bloom, not over 6 or 8 weeks. The matter is easily determined by introducing an Italian queen to a hive of black bees at different periods of the year. If done in May or June, the hive will be composed entirely of Italians in the fall. If the Italian queen is introduced in September, you will find black bees in the hive until the month of May. It is also pretty well established that black bees will live longer than Italians; probably because the latter are more inclined to push out into the fields when the weather is too cool for them to do so with safety; they seldom do this, however, unless a large amount of brood is on hand, and they are suffering for pollen, or unless they are in need of water.

COMB FOUNDATION.

ADVANTAGES.—In olden times the bees were allowed to make the honey and all the comb; but it has been found that the workers consume about 20 lbs. of honey to construct 1 lb. of comb, and that by supplying the bees with an artificial comb foundation, much labor is saved, and a great deal more honey stored. A perfect comb foundation is a sheet of pure wax, put in in such shape as will enable the bees to utilize the greatest amount of wax in the construction of their cells in the least time, of sufficient strength when used in brood frames to retain a perfect shaped cell, and be handled safely in extracting or moving. With broad sheets of foundation, every bee has an opportunity either to draw out the foundation or to bring honey, and the result is surprising. Comb foundation has another and far greater merit than that of saving labor to the bee; it secures a perfectly even, straight comb for each frame. Or, into the large frame there may be set 8 little 1 lb. frames, each with its foundation "starter," and if these are placed in a second hive set on the top of the first, the bees will very rarely rear brood in them, but fill them with clear honey.

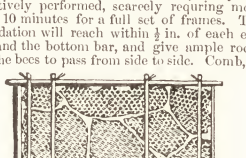
DESCRIPTION.—Comb foundations consist of sheets of beeswax, formed by dipping wooden plates into melted wax; the sheets, thus molded, being removed and rolled through a machine, have inuendations made on both sides that form the foundation of cells. There are many styles and many machines for their manufacture. There are foundations with triangular-shaped cells, with flat-bottomed cells, with high side walls, and with no walls at all; with linen, cotton, wood, paper, tin-foil and woven wire for a base. There are also foundations with fine wires imbedded therein, and frames of foundation with wires pressed therein. A medium heavy sheet, say 4½ or 5 sq. ft. per lb., with a thin base or septum, and heavy, prominent side walls, is most desirable for economy in the use of wax, and rapidity in comb building by the bees.

FASTENING IN.—Use the Langstroth frames, with a V-shaped top bar; the foundation is just as wide as the inside of the frame from the bottom bar to the lower point of the top bar, and is 1 in. shorter than the frame from end to end. When ready to use a set of frames, the foundation is placed on clean paper, evenly piled, with the straightest edge next to the operator; now, with a sharp knife, make 4 incisions or cuts, ½ in. long, down through the foundation to the paper, and at equal distances from



Foundation Fastened to Top Bar.

each other and at the ends; with the hands placed at each end of the pile, turn up the two end cuts with the thumbs, and proceed to the centre, which is also turned up; now lift the sheet clear from the pile and turn the two remaining cuts or flaps in the opposite direction; lay the sheet down with the top edge nearest to you; place the frame with the lower or sharp edge fitting closely to the joints, formed by alternately bending up and down the flaps, and press the foundation to the top bar with the thumbs, drawing to you. When warm, and the wax quite pliable, the work is very easily and effectively performed, scarcely requiring more than 10 minutes for a full set of frames. The foundation will reach within ½ in. of each end bar and the bottom bar, and give ample room for the bees to pass from side to side. Comb, in



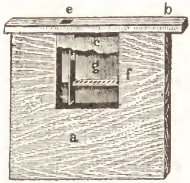
Utilizing Pieces of Comb.

pieces, may be used by a little cutting and fitting, and temporarily fastened with wire, tied top and bottom, until the bees secure it, which they will do in a day or two.

FOOD.

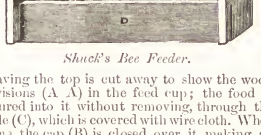
ARTIFICIAL.—The best kind of food that can be given to bees is honey liquefied with a small portion of warm water; but where honey is scarce and dear, an excellent substitute will be found in lump sugar; 3 lbs. of sugar to 1 pt. of water, boiled for 2 or 3 minutes, and then mixed with 1 lb. of honey, will make 5 lbs. of excellent food, which the bees appear to like quite as well as honey alone. Barley sugar is excellent food when honey in the comb cannot be had. A good mode of feeding is to put the honey or syrup into a shallow box; lay on the top of the sweet liquid a thin board with ⅜ in. holes in it, through which the bees can suck the syrup without falling into the mass or becoming clogged by it; place the box in the top of the hive; the bees will soon make it out, and remove the stores to their cells. For feeding inside the hive, the division board feeder may be used to advantage. The top bar of this is 2 in. wide; from the upper central portion, beneath the top bar, a rectangular piece, the size of an oyster can, is

replaced with an oyster can (*g*), after the top of the latter has been removed. A vertical piece of wood (*d*), is fitted into the can, so as to separate a space 1 in. square on one side from the balance of the chamber. This piece reaches within $\frac{1}{8}$ in. of the bottom of the can. In the top bar there is an opening (*e*), just above the smaller space below. In the larger space is a wooden float (*f*), full of holes. On one side, opposite the larger chamber of the can, $\frac{1}{2}$ in. piece of the top (*c*) is cut off, so that the bees



Division Board Bee Feeder.

can pass between the can and top bar on to the float, where they can sip the feed. The feed is turned into the hole in the top bar (*e*), and, without touching a bee, passes down under the vertical strip (*d*), and raises the float (*f*). The can may be tacked to the board at the ends near the top; 2 or 3 tacks through the can into the vertical piece (*d*), will hold the latter firmly in place; or the top bar may press on the vertical piece so that it cannot move. The feeder is placed at the end of the brood chamber. When about to feed, with a teapot pour the feed into the hole in the top bar. Shuck's bee feeder feeds at the entrance any time in the day, without danger from robbers, as the food can be reached only from the inside of the hive; it is placed on the alighting board, with the side (D) nearly covering the entrance. In the en-



Shuck's Bee Feeder.

graving the top is cut away to show the wood divisions (A A) in the feed cup; the food is poured into it without removing, through the hole (C), which is covered with wire cloth. When done, the cap (B) is closed over it, making all tight.

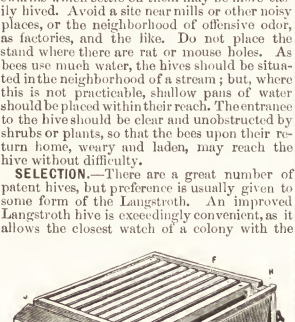
PLANTING FOR FOOD.—As fast as the apiary is increased, plant or scatter self-propagating seed, which will provide good honey-secreting bloom. The following are some of the best plants for bee pasture: *Alsike Clover* is a good honey plant. The bees have no trouble in finding the honey, as the blossoms are short and the head no larger than white clover. It ripens in the latitude of Chicago, in the latter part of July.—*Basswood.* The bees are fond of this, and it produces most excellent honey.—*Box Elder.* A great favorite with bees, and yields a superior honey; it blooms between the basswood and tulip.—*Buckwheat.* The honey from this, though dark and strong, is highly prized for manufacturing and other purposes. It furnishes an excellent winter food for bees, and when well ripened will allow the producer to avail himself of all the white grades of honey stored earlier in the season.—*Catnip.* Can be planted any time and anywhere. Bees work on it early and late, and the honey is excellent.—*Eucalyptus.* A superior and beautiful honey producer.—*Figwort.* Furnishes honey plentifully, but is of slow growth.—*Honey Locust.* The most certain of honey producers. Although the duration of bloom is but limited, it yields a bountiful supply of rich honey, and bees will gather thickly around the highly perfumed blossoms. The time of the year in which it blooms, nearly filling the interval between the late fruit bloom and the white clover, makes it very valuable. It is a most profuse honey bearer, and the honey is of a superior quality. When in the liquid state its color is of a rich pale red; but, in the shape of comb honey, its appearance is little inferior to clover honey. It becomes exceedingly thick if left with the bees till the cells are thoroughly sealed, and its keeping qualities are most excellent.—*Mammoth Mignonette.* Grows and blooms, and yields a rich return of beautiful honey under the most adverse circumstances.—*Motherwort.* An excellent honey plant. Its blossoms make their appearance early in July, and it remains constantly in bloom till frost. It is not a favorite with grazing animals, and may be planted on the roadsides, where stock are allowed to run at large.—*Mustard.* There are several varieties of mustard which furnish honey. The length of season for bloom is quite extended, and where a dearth of honey pasturage prevails, bees will work on them vigorously. They bloom during July and August.—*Sweet Clover* or *Melilot.* One of the hardiest plants and the best honey producer.—*Tulip Tree.* As a producer, it ranks only second to the basswood.—*White Clover.* Honey almost equal to the sweet clover.—*Willows.* There are 2 or 3 varieties of willows, all of which are good honey producers.

WATER.—Bees use a large amount of water in preparing food for their young, and when they themselves are secreting wax. If no water is near the apiary, shallow troughs, with floats in them, should be kept constantly filled with water for their use, and in this way much time and labor may be saved them.

HIVES.

LOCATION.—The east is the most favorable aspect for boxes and hives; this, however, may be modified or varied according to the season. The arrangement of the hives should be in line, or singly, under trees. Never set a hive upon benches close together, as the bees are continually quarreling and interfering with one another. Set the hives within 4 to 6 in. of the ground and have the alighting board to reach down to the ground, so that if a bee happens to fall on the ground, he can run right into the hive. The place for fixing the stand should be on dry soil, and a sandy one is best. It should slope towards the front in order to carry off the surface water produced by occasional rains, and should not, on any account, be exposed to the droppings from the eaves of houses, or even hedges. Shelter is essential, especially behind and on the east of the hives; a house or high wall is the best; it is also recommended that the stand be placed in a sort of small, open shed, well painted on the outside, to protect it from the weather; a few shrubs about the stand are also good as additional shelter. Whatever trees are planted in the immediate vicinity of the hive, should be of low size, with bushy heads, in order that the swarms which settle on them may be more easily hived. Avoid a site near mills or other noisy places, or the neighborhood of offensive odor, as factories, and the like. Do not place the stand where there are rat or mouse holes. As bees use much water, the hives should be situated in the neighborhood of a stream; but, where this is not practicable, shallow pans of water should be placed within their reach. The entrance to the hive should be clear and unobstructed by shrubs or plants, so that the bees upon their return home, weary and laden, may reach the hive without difficulty.

SELECTION.—There are a great number of patent hives, but preference is usually given to some form of the Langstroth. An improved Langstroth hive is exceedingly convenient, as it allows the closest watch of a colony with the



Improved Langstroth Hive.

greatest ease. By turning the thumb screw (L) and opening the movable side (which takes but an instant), the frame can be examined; and by removing the loose side board (M) the bottom board may be cleansed; giving all the advantages of a loose bottom board, without its disadvantages. The new Langstroth hive is peculiarly adapted for the production of comb honey; its honey rack is the best in use, and perfectly adapted to the use of prize boxes. It holds 18 prize boxes, with separators between them. A wedge holds all with a vise-like grip. The outer boxes are glassed as they stand on the hive. By removing the wedge, any box may be instantly removed, examined, returned or replaced by an empty one, the space between the rows readily admitting the fingers for that purpose. The Langstroth hives are made of different sizes to suit those who use them. The standard size is 14x18⅝ in. inside and 10 in. deep with 4 in. portico. The second story is the same as the first, but only 6 in. deep. The frames are 9½x17⅜ in. outside. *Home-made Hive.* The shape of the box should be long from front to rear, 15 in. deep, 12 wide, and 12 high. Inch boards unplaned are the best, and the boards should be well seasoned and carefully put together. The hive should be set in a groove in the bottom board and not be fastened to it. Place 2 or 3 ⅜ in. sticks, crossing each way, in the middle of the hive to support the combs; ¼ in. from the top of the hive fasten slats 4 to 6 in. in width of ⅜ in. stuff, leaving cracks from ¼ to ⅜ in. in width between them. Over the top of the hive place a cover projecting on every side, and fasten the same to the hive by small hooks, which not only gives you a movable top and bottom board, but also a honey board. This will answer for a movable hive.

WINTERING. — For wintering on summer stands, all preparations should be made early enough in the fall to admit of ample feeding in case of a scarcity of stores, as they can not often be fed afterward without great disturbance. Put the hive into a box some 6 in. larger than it; provide a winter passage out from the entrance, and fill with sawdust, forest leaves or chaff; leave the cover off the hive; fill in on top, and then cover the box. In all cases of packing on summer stands, a passage-way should be made through each comb, a little above and back of the centre, or ⅜ in. square sticks laid over the tops of the frames, to afford the bees a passage from comb to comb, to reach their stores without going to the extreme ends of the frames to pass around. In wintering bees in the cellar the first thing to be assured is, that it is sufficiently warm to prevent the freezing of potatoes, etc., and that it is sufficiently ventilated to allow of the escape from it of noxious gases and heat generated by the bees. The bee apartment should be separate, and not so situated as to be subject to constant invasion by individuals or vermin. The covers should be removed from the hives, 1 or 2 thicknesses of woolen or cotton cloth spread over the frames, 2 or 3 in. square sticks laid crosswise of the hive, and the next one set on top and treated the same way, proceeding thus till all are neatly and

carefully piled up. This work should not be done till the fall is so far advanced that the bees will be quite chilled, and exhibit but little activity when slightly disturbed. The work should be done gently, so that the bees will not know they are being moved. When all are piled away, darken every nook and crack, so that should the bees venture to the entrances of the hives, they will think it is night. Every fortnight enter the bee apartment with a dark lantern, and see that all progresses favorably. If the thermometer indicates above 45°, admit cold air at night; if below 40°, partly close the ventilators.

HONEY HARVEST.

TAKING THE PRODUCT.

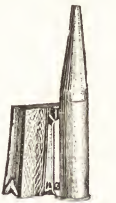
DEFENSE. — The best protector is a veil, made of net or tarlatan, with one side sewed up, and an elastic in the end to be placed over the hat; the veil must be long enough to allow the vest or coat to be put over it. Rubber gloves should be used on the hands.

Bee Veil.

HANDLING.—Nothing is either more offensive or more irritating to bees than the human breath; therefore breathing upon them must at all times be most carefully avoided. Avoid, also, all sudden jars, quick, active motions, and never fight them. It is a part of the nature of bees to gorge themselves with honey when alarmed, and, when in this condition, they rarely if ever sting unless pinched. Use the smoker judiciously, and avoid being stung. Never allow a hive to become infuriated and then left alone; for if a hive gets the better of you once, it is likely to show its temper through the whole season. If a colony proves unmanageable, get up a big smoke, and give them as much as is needed; strike on the side of the hive; it will scare them, but will tame them. In mid-summer, from early morning till 10 A.M., is the best time to handle bees, when many of them are out. They should never be disturbed at night or when the air is damp and chilly, or when it is windy.

REMOVING GLASSES.—At noon, upon a clear fine day, pass either a very thin knife or fine wire between the hive and the glass intended to be taken. If this precaution be neglected, a piece of comb is frequently left projecting from the top of the one left, or the bottom of that taken, which will cause much trouble to the operator. The glass must be lifted very gently, kept in the same position, and placed upon 3 inverted flower pots, or something of the kind, in a shaded place, about 30 or 40 yds. from the hive, and the bees will make their escape in about 10 or 15 minutes. The glass being thus placed, a loud humming noise is first heard, and the bees are then seen to leave it, and in 5 or 6 minutes all, except a few stragglers, that may be brushed out with a feather, will have left it; but should the queen be in the glass, which very rarely happens, quite a different appearance presents itself, no noise will be heard, nor a bee scarcely seen to leave it; but the hive from which it has been taken will in a very short time appear in great confusion. Whenever this occurs, the glass must be returned immediately, and taken off again the next day.

REMOVING HONEY FROM HIVES.—The best time is the month of July. When a part of the honey only is to be taken, the full hive should be inverted, and an empty one placed over it, and the two fastened together by a large sheet or table cloth. The hives being thus arranged, beat the sides gently with a stick, being particular not to strike those parts where the combs are attached. After a few minutes the bees will have ascended into the new hive, and it may then be placed on the pedestal formerly occupied by the old hive. Having extracted the requisite quantity of comb, the hive may be returned to its former position, reversing the hive which contains the bees; and placing the deprived hive over it, they may be left in that position for hours, by which time the bees will be once more in possession of their old habitation. Smoke is often used in removing honey from the hive. With a good smoker, blow some smoke in at the entrance of the hive; after a while open it and take out the frames of honey to be extracted; shake the bees from each frame by one or two sudden jars, brushing the remaining ones off, right over the frames into the hive, or down in front of the entrance, with a large feather or small turkey wing; place empty combs, or a frame furnished with comb foundation, in place of what is taken from the hive. Always cut the comb with a knife ground to a "wire edge"; never hone off the wire edge.



Bee Smoker.

Extracting Knife.

TREATMENT OF THE PRODUCT.

CANDIED HONEY.—Much of the honey received, is candied or granulated and turned to sugar. This may be from adulteration, but

the principal cause is taking the honey from the comb before it is ripe. The bee, having filled the cell with honey, does not directly close it up, but for a time leaves a slight aperture for the action of the air upon the honey, after which the cell is sealed up by the insect. If this interval has been allowed to elapse and the bee has closed the cell, the honey extracted will keep for almost any length of time without crystallization; but if the honey is extracted before the period is complete, solidification is almost certain. Granulated honey can be made liquid by immersing the can in boiling water, but the process has the effect of darkening the honey, and granulation again speedily ensues. A small quantity of cream of tartar, added to the honey, on being put in jars, will prevent granulation.

CLARIFYING HONEY.—1. The honey is mixed with an equal weight of water, and allowed to boil up 5 or 6 times without skimming; it is then removed from the fire, and after being cooled, brought on several strong linen strainers, stretched horizontally and covered with a layer of clean and well-washed sand, 1 in. in depth; the sand is rinsed with a little cold water, and the mixed liquor is finally evaporated to the thickness of syrup. —2. Dissolve the honey in water, as last; clarify with white of an egg, and evaporate to a proper consistence. —3. Dissolve in water; add 1½ lbs. of animal charcoal to every ¼ cwt. of honey; gently simmer for 15 minutes; add a little chalk to saturate the excess of acid, if required; strain or clarify, and evaporate. —4. Honey, 1 cwt.; water, 9 gals.; fresh burnt animal charcoal, 7 lbs.; simmer for 15 minutes; add a little chalk to saturate free acid; strain or clarify, and evaporate as before.

DRAINING HONEY FROM THE COMB.—Place a sieve, either of hair or canvas, over an earthen jar; cut the combs containing the honey into small pieces, and put them into a sieve; let them be cut in a horizontal direction. It is better to slice them at the top and bottom, than in the middle. Crushing, or pressing, should be avoided; for as a portion of brood and bee-bread generally remains in the comb, pressure would force it through the sieve, and the honey would thereby be much injured, both in color as well as flavor. It is very desirable to have 2 sieves, for in every hive there will be 2 kinds of honey—the one, almost colorless and fine flavored, found at the sides of the hive; the other, dark and not so good, stored in the centre. These should always be kept separate. The draining process may occupy, perhaps, 2 days; but the largest quantity, as well as the best quality, will be drained off in 3 or 4 hours. The honey should be put into jars immediately and the jars filled and tied down with bladder; for exposure to the air, even for a few hours, very much deteriorates its flavor.

EXTRACTING HONEY.—Extracted honey is obtained by the use of the extractor, a modern invention which has cheapened honey by saving much of the labor of the bees. The extractor is a contrivance by which a knife is made to shave off a very thin slice from each side of the comb, opening each cell, from which the honey drains out. By this means the comb is available for second use by the bees; all they have to do being slightly to repair it, when it is ready to be again filled with honey.

IMITATION HONEY.—1. 10 lbs. of good brown sugar; 4 lbs. of water; gradually bring it to a boil, skimming it well; when it has become cool, add 2 lbs. of bees' honey, and 8 drops of peppermint. A better article can be made with white sugar instead of common, with 1 lb. less of water and 1 lb. more of honey. —2. To 20 lbs. of coffee sugar, add 6 lbs. of water, 4 oz. cream of tartar, 4 tablespoonfuls of vinegar, the whites of 2 eggs well beaten, 1 lb. of bees' honey, and 20 drops of Lubin's extract of honeysuckle. Place the water and sugar in a kettle, and put it over a fire; when lukewarm, add the cream of tartar, stirring it at the time; then add the egg; when the sugar is melted, put in the honey, and stir well until it comes to a boil; then take it off; let it stand 5 minutes; then strain, adding the extract last; let it stand over night, and it is ready for use. —3. Take 10 lbs. of Havana sugar, 4 lbs. of water; 40 grs. of cream of tartar, 10 drops essence of peppermint, and 3 lbs. of honey. First, dissolve the sugar in the water over a slow fire, and take off the scum arising therefrom; then dissolve the cream of tartar in a little warm water, and add, with some stirring; then add the honey, heated to a boiling point; then add the essence of peppermint; stir for a few moments, and let it stand until cold, when it will be ready for use.

Honey Extractor.

WAX. To Bleach.—Melt yellow wax in a kettle, and then dip out into a long tin vessel that will hold 2 or 3 gals., and which has a row of small holes about the diameter of a knitting-needle, in the bottom. This vessel is fixed over a cylinder of wood, 2 ft. in length and 15 in. in diameter, which is made to revolve like a grindstone, in one end of a trough of water, 2½ ft. in width, 10 to 15 ft. in length, and 1 ft. in depth. As the melted wax falls in small streams on this wet revolving cylinder, it flattens out into a thin ribbon, and floats off toward the other end of the trough of water. It is then dipped out with a skimmer (that may be made of osier twigs), spread on a table with a top made of small willow rods, covered with a clean white cloth, and then exposed in this way to the sun until bleached.

WAX, To Color.—¼ lb. best roll annatto to 1 cwt. wax, depending on the paleness of the latter, is put into a clean boiler with about 1 gal. of water, and boiled till it is perfectly dissolved, when a few ladlefuls of the melted wax are added, and the boiling continued until the wax has taken up all the color, or till the water has mostly evaporated. The portion of wax thus

treated has now a deep orange color, and is added in quantity as required to the remainder of the melted wax in the larger boiler, till the proper shade of color is produced; when cold, observing to mix well the whole, and to cool a little now and then to ascertain when enough has been added. The copper must then be brought to a boil, and treated with vitriol, etc., as before.

WAX, To Refine.—The usual method of refining crude beeswax, is to melt it after adding about 5 per cent. of water to the quantity of wax. When the mixture becomes perfectly liquid, and has boiled for some minutes, oil of vitriol in the proportion of 5 or 6 oz. to every 100 lbs. of wax, is sprinkled over the whole surface of the wax. Great care must be observed during this operation, as the wax froths up, and will run over the sides of the vessel, if not carefully attended to. The wax is then covered over and left to settle until cool enough to mold, when it is gently skimmed off with a hot ladle, care being taken not to disturb the sediment. When no more can be drawn off, the impurities are scraped off from the under sides of the cakes, which are then to be remelted and strained through canvas.

SWARMING.

REMARKS.—A colony of bees that have been well wintered, with a vigorous laying queen, is induced to enlarge the brood, and the workers are enabled to scatter through the hive, which they could not do in cold, unfavorable weather. The hive is soon filled with brood and honey, and young bees begin to hatch. Being provident of the future, the bees construct queen cells. The queen, seeing the sealed queen cells, becomes restless, and on the first beautiful day this restlessness of the queen causes a commotion in the whole colony; the workers, in contemplation of an early removal, fill themselves with honey before making their exit in search of a new home. The queen always goes out with a swarm, and if by accident she becomes lost the bees immediately return to the hive which they had left. The oldest of the bees in the hive are the ones to swarm, because the very young bees are not ready to leave yet. The natural swarming instinct is so strong, that great care and many precautions must be taken to prevent over-swarming. The swarm is led off by the old queen, and her place supplied with a young queen. An old queen will seldom go out with a swarm except about the middle of a fair day. While swarming is by no means to be forced, yet if symptoms of a swarm present themselves early, say in April or May, it may be permitted to take place, provided the parent stock be still sufficiently strong in numbers; otherwise it is highly disadvantageous to the well-being of the hive, as well as to emigrants. The indications preceding a first swarm are the rapid increase in numbers clustering or hanging out, and drones becoming numerous and unusually active. Those of an after-swarm are much more certain, for 9 or 10 days after the departure of the first swarm, a singular noise, called "piping," may be heard in the stock.

ARTIFICIAL.—Artificial swarming may be easily effected by the use of the movable comb hive. As soon as signs of swarming are detected in a hive, a portion of the comb sheets, with queen cells in them, may be removed to a new hive. In the hive where the old queen remains, the queen cells should be destroyed. Let the old hive then be removed a little to one side of its former position, and the new hive placed a little to the other side. When the bees return, not finding the hive in its place, they will divide about equally between the old and new hives. The new hive is called a nucleus colony. After a swarm has been once divided in this way, it can be prevented from swarming again by destroying the queen cells, whenever any indication to swarm is detected.

CATCHING.—A swarm of bees will always settle, if let alone, and then send out scouts. If they are hived before the scouts return, all is right; if not, the spies will lead the swarm off to a new location. When hiving bees, go among them clean and calm; not dirty, and in a state of perspiration, nor flurried and afraid; work coolly, calmly, and slowly; avoid, as much as possible, the killing of any of the bees; it makes the others cross and more apt to sting. Never set a hive over a cluster of bees without stirring them up;

Swarming.

they will cling to whatever they pitch on, even if there be a dozen hives over them, and are just

as likely to fly away as though there was no hive within a mile of them.—1. When the swarm settles, the bees collect themselves in a heap around the queen, hanging to each other by means of their feet. When thus suspended from a tree, hold an empty hive under them, and tap the branch. See that all the bees enter the hive. Every bee may be in except one, and if that one be the queen, you have lost your time and swarm. They should then be confined for about 12 hours. When a swarm divides and settles separately, it is probable there are two queens. One of them must be secured. If a second swarm comes off, as soon as it is hived, secure the queen, and return the swarm to the hive; deprived of its queen, it will usually immediately return of its own accord.—2. When the bees swarm out, place an old hat on a brown stick, and hold in the midst of them, and in a few minutes they will be clustered upon it.—3. A swarm catcher, like the one in the illustration,

Swarm Catcher.

is useful in swarming time; it consists of a bag made of factory, having a handle of cloth on the inside as well as the out—making it reversible. With a long wooden pole it will reach any swarm, and when the bees are emptied in front of the hive, the handle on the outside gives the apiarist control of it, and when turned inside out, a handle is still on the outside, as it has two.

DIVIDING.—It sometimes happens that a swarm divides itself into different clusters, this is a certain sign that there are several queens, each cluster having one. These clusters should not be molested, but quietly watched until they incorporate, which they will presently do. It is a disadvantage to have swarms from different hives unite; but, in case they do, the swarm being collected into one hive, a sheet must be spread on the ground, the hive held over it, and giving it a smart knock the bees will all fall upon it; no fear need be entertained of their flying away, and the queen should be immediately sought. Having detected a queen in the midst of a group, cover it with a small bell glass, and then proceed to divide the bees as nearly as possible into two equal portions. For this purpose two hives must be in readiness, and having allotted a proper number to the queen, who is at large, the hive should be placed in a remote part of the garden, and as far as possible from the parent hive. The imprisoned queen is then set at liberty and conducted to her hive with that proportion of bees which has been assigned to her. The whole being placed in the hive, it is placed, as far as limits will permit, in a contrary direction to the former hive. No further fear need be entertained of their quietly though busily adapting themselves to their homes.

DRONES.—When a stock has too little honey to afford to rear drones until the flowers yield it, they will occasionally swarm before drones appear. The appearance of drones is not a certain indication of swarming. When honey is scarce, the workers take the drones out of the hive and sting them to death; no swarms need be expected at such a time. If it occurs late in the season, they may not swarm, though they may rear drones. A hive that has not reared any drones until the flowers yield honey, is much more likely to swarm than one that has destroyed them once. The queen does not lay drone eggs exclusively at any time, but a number of both drone and worker eggs daily for months in some seasons. Drones do not appear to control the swarming.

HIVING.—Whatever system be adopted, let everything be in readiness for the reception of swarms; watch the swarm in silence, and after it has once collected, lose no time in housing it in a new, clean, and dry hive; and let it be placed where it is to remain, within 10 or 15 minutes after the time of its being hived; it will not be necessary even to wait till the bees, clustered in front or on the sides of the hive, are reunited to their companions inside, as they are never long in being so.

PREVENTING.—Immediately after the issue of the first swarm, open the hives; destroy every royal cell but one. If at the end of 5 days this has not hatched, look over the combs again, and destroy every royal cell that may now appear, excepting the one saved at first. The best way is to make the first swarm an artificial one, before or soon after queen cells are started; then, at the end of 9 days, destroy all cells but one, as above. To prevent first swarms, clip the wing of the queen, and put in front of the hive a shallow box, some 2 ft. square, with edges of tin projecting inward, so that no bee can get out and away from the hive without flying. This will, of course, prevent the escape of the queen, and swarms will return.

PUTTING ON GLASSES.—The best time for putting the bell glass, or small hive, or box, upon a swarm, will be from the 18th to the 21st day after their being hived; and should it be quickly filled, and more room required (which may be known by the crowded state of the bees inside the glass, and by their being seen to cluster at the mouth of the hive at 9 or 10 in the morning), let no time be lost in lifting up the glass, and placing between it and the stock hive a small hive or box with a hole in the top. It is necessary to use this precaution at all times, but more especially in a rainy season, as a greater disposition amongst the bees to swarm then prevails.

UNITING.—When two 2d swarms, or a 2d and 3d, come off on the same day, hive them separately, and leave them till before sunset; then spread a cloth upon the ground, upon which, by a smart and sudden movement, shake all the bees out of one of the hives, and immediately take the other and place it gently over the bees that are heaped together upon the cloth, wedging up one side about ½ in., that the bees outside

may pass under, and they will instantly ascend into it and join those which, not having been disturbed, are quiet in their new abode. Next morning, before sunrise, remove this newly united hive to the place in which it is to remain. Two 2d swarms, or a 2d and 3d, may be joined in the same manner, although one of them may have swarmed some days or even weeks later than the other; taking care, however, not to make the 1st one enter the 2d, but the 2d the 1st. A 3d and a 4th swarm of bees may be joined to them at different times in the same way, till the stock becomes strong.

WORKING CALENDAR.

JANUARY.—Look well to the ventilation of the boxes. Mice are very apt to take up their winter abode inside the hives; hence the necessity of a frequent examination. Combs will grow moldy where a hive has no upward ventilation, but more especially if the swarm is small. It is a cold atmosphere that kills bees and molds comb. The vapor exhaled from the bees settles on the outside of the combs, and after a time finds its way into the cells and lodges in small drops against the septum of the cells, and creates a fungus in a very short time. See that the entrances of the hives are narrowed and that during the time snow remains upon the ground they are wholly closed, so that not a single bee can escape; for the sun shining upon the snow will bring the bees out of their hives, and, settling upon the snow, they are chilled and die; but upon the disappearance of the snow, no time must be lost in unstopping the entrances, and giving the bees full liberty. See that the entrances are clear, and not filled up with dead bees, which, after a long confinement, sometimes happens. Should a very warm spell of weather occur at any time in the winter, the mercury rising to 60°, ventilate the hives thoroughly.

FEBRUARY.—Look to the covers and see that they be all sound, and that no moisture comes upon the tops of the hives. Towards the end of the month, particular attention must be given to keeping the interior of the hives free from damp, which a frequent changing of the floor boards will tend very much to effect. About the 15th clean the hive, and if any of the stock have exhausted their stores, they should be replenished. Let the food be given, if possible, at the top of the hive; if at the bottom, not till after sunset, carefully stopping up the entrance of the hive, and removing the vessel in which the food was given before sunrise the next morning. The chief enemies to guard against at this time are mice and birds; cold, if the floor boards and hives are dry, affects them but little.

MARCH. — Should the hives be found to be at all damp or moldy, take the precaution of raising them a little for a few hours on a dry day. Remove all incumbrances from the mouth of the hive, and make every part thoroughly clean. Supply the bees with fresh water. Make an addition to such hives as are strong and heavy, and remove such combs as are old and discolored. The effects of long confinement and poor food are the causes of dysentery. If bees partake of sour pollen, even in the smallest quantity, they will be affected by it to a greater or lesser extent. The time has now arrived for all careful apiarians to possess themselves of as many hives, glasses, boxes, bee-dresses, etc., as they are likely to require during the coming season; and those who prefer the use of straw hives should never put a swarm into an old hive. Where the population is low, and little or no food in store, the bees are very likely, upon a fine and mild day towards the end of the month, to forsake their hives entirely, and to join themselves to more populous and better stored communities. As a rule, bees should be kept in until they can gather some pollen from the soft maple and willows. Give the bees plenty of water. Look out this month and next for queen wasps, and destroy every one. March and April are the best two months for purchasing stocks, and May for swarms. It is better to obtain them from such a distance only as they can be conveyed by hand.

APRIL.—This is the best time to remove a leaf or two of comb from old hives; select those of very dark color and thickened cells. It is probable that at the end of the month some of the most populous hives may require glasses, but it is best not to add them till the bees have shown evident signs of want of room, for it is desirable that the stock should ascend into the glass immediately. Guide combs being fixed in glasses of every kind that are to be placed either on hives or boxes, the bees are induced thereby to commence working in them sooner than they otherwise would do; and it must always be remembered that simply putting on a glass, a box, or a small hive, will not prevent swarming except the bees commence working in it, which a small piece of comb fixed at the top induces them to do more readily. A very large quantity of food is consumed by the young bees while in the larvæ or maggot state, which draws very heavily on the store of food in the hive. It is therefore necessary to look attentively to all weak stocks, and more especially to swarms of the last year, and let them have a regular supply of food. Moths now begin to make their appearance, and they are, by far, the most dangerous enemies the bees have to contend with. It is the caterpillars of these moths which gnaw and destroy the combs; and they would soon be ruined by these insects, if the bees did not offer the greatest opposition to their ravages. The female moth is distinguished from the male by her bill-like head. She deposits her eggs in and around the warm portions of the hive, which soon hatch worms. The worms feed upon the wax, and work in the centre of the combs edgewise, enveloped in a kind of tubular covering of web, so that it is difficult for the bees to remove them. Strong stocks will generally protect themselves. The best way to keep rid of them, is to attend often to the bees and destroy all the millers and

worms found about the hive or apiary. Place blocks or sticks under the hive, with little troughs cut in them, and turned down upon the bottom board, with frequent openings for the worms to crawl under; these form good hiding-places; remove these every day or two; mash all the worms, and replace the blocks for more.

Bee Moth.

MAY.—Inspect the hives and clean away everything offensive. Weak stocks must still continue to be fed. When the bees are beginning to work in a glass, a cold night generally obliges them to forsake their newly-made combs, and to discontinue their labors, which are seldom resumed till the middle of the next day. To prevent this delay, the space between the glass and the covers should be filled with fine tow or wool, the temperature of the glass being thereby kept up, and the bees enabled to carry on their labors without interruption. Putrid foul-brood is a disease which attacks the young brood of the hive about this time, showing itself fully after the larvæ have been sealed up. It may be known by the viscous, gelatinous and yeast-like appearance of the decomposing brood, the unpleasant odor arising from the hive, and by the sunken covers of the cells. There is no cure for this disease when it has once obtained headway. Destruction of the bees and honey, and thorough purification of the hive, is the only remedy to prevent the spread of the disease. As a means of preventing the disease, feed no fermenting honey; feed no meal, especially when the hive is threatened with disease; destroy carefully every particle of dead and moldering matter; and avoid weakening colonies during the brooding seasons, so that they will not be able properly to maintain the heat necessary for the development of the brood. Premature swarming generally happens early in May. The best plan that can be adopted in these cases is to unite the bees to another stock, if they should not join one of themselves; for, if put into a hive, they generally leave it or die. The cause usually arises from poverty, or the old age of the queen. Should there be a dry May, swarms may be expected at the end of the month, therefore it will be a good policy to have every arrangement for their reception made in good time. Give plenty of ventilation this month. Queen wasps and moths should be killed, and the swallows watched.

JUNE.—The system of management for the present month must be determined by the intentions of the bee-keeper. If box honey is desired, the boxes should now be properly arranged upon the hives. If the extractor is to be used, extra combs should be supplied for this purpose. If increase of swarms is the object, rather than surplus honey, preparations for additional swarms should be made. It will now be time to place glasses or small hives upon such stocks as are not intended to swarm, and it will be well not to do it until the bees show evident signs of want of room. A glass should never be put on without having a piece or two of guide-comb placed at the top, which may easily be effected by first warming the glass, and then attaching the comb to it while in that state. It is not at all unusual at this season to see the bees of some hives, although possessing a good store of honey, quite inactive, carrying in no pollen, and basking in the sun at the edge of the hive, but still giving smart resistance to a robber if he venture to make an entry. This arises from the old age or death of the queen; and if the bees are numerous, will go on in the same manner nearly through the summer. But if the numbers be few, robbers will attack them and little or no resistance will be offered; but frequently the bees themselves will assist in carrying off the store to the pirate's home, where the queenless bees will meet with a ready welcome. The best method to adopt in such a case is to introduce a piece of comb from a strong hive which contains both brood and eggs and queen or queen cell, and they will ultimately do very well. The time for swarms is now near; but in weak stocks it is not very desirable. However, if they come, the best must be made of them. By all means let the new swarm be placed where it is to remain as soon as it is settled in its new hive, which rarely exceeds 10 minutes. This will save the bees much loss of time, as well as numbers of them their lives. Honey stored in June and July is thicker and contains less acid than that stored later in the season, and for this reason is a better winter food than fall honey; hence during these months, full frames of honey should be removed from the hives and put away in a dark, dry and airy room for winter purposes, and their places in the hives be filled with frames full of comb foundation set in the centre of the hive. Now begin to look out for the woodpecker and sparrow, as they are enemies to the bees; the woodpecker draws the honey out of the hive with his long round tongue. Bees are sometimes now troubled with lice. They are small parasitical insects, of a red color, which adhere to the body of the bee, and derive their nourishment from her juices. They are about the size of a grain of mustard-seed, or rather smaller; Morocco tobacco will kill the lice without injuring the bees. Millipedes, or woodlice, sometimes now make their appearance; they are often produced by the stand being made of decayed wood, or the hive being placed too near an old hedge. Let the stand be of new wood, and strew soot on the ground under and about the hive. This will also serve in part as a protection against the attacks of ants. All ants' nests that are found in the neighborhood of a hive should be destroyed.

JULY.—The hives should always be shaded from the hot sun, in such weather as that of the middle of July, and more especially so for swarms of the year. The necessity for returning swarms in some seasons, will be apparent to every one at all acquainted with bee management. The manner of performing the operation will be as follows: As soon as the swarm has left the parent hive, proceed immediately to open the hive and take out the bars, one by one, and cut from each comb every queen cell that is seen upon it, and replace the comb again in the

hive. This operation of removing the royal cells will take about 5 minutes; when done, return the swarm immediately to the hive. The old queen, which led it off, finding, by this process, that there is no royal brood left in the hive to succeed her, will not again attempt to leave it. Persons who have never practiced this method will be surprised to find how easily it is accomplished. In some cases the help of a puff or two of tobacco smoke may be useful, should the few bees left be angry, or the operator feel at all timid. The readiest way of returning the swarm will be to lay a board upon the floor-board of the hive, and parallel with it, upon which, by a smart and sudden movement, shake the swarm, and as nigh to the entrance of the parent hive as can be done conveniently, and with the finger, or piece of wood, guide a few bees to the entrance, and the remainder will follow immediately. Swarming is frequently much later than usual, if May be wet and cold, and the stocks be very weak. It is very probable that 2d and 3d swarms will be coming in July, and should it prove so, we would recommend their being united to late swarms, or 3 or 4 of them being put together.

AUGUST.—It will be quite useless to give additional room to any colony of bees, be they ever so prosperous, after the month of July is ended; for the honey season is fast drawing to a close, and the population of the hives very much upon the decrease, not only from the killing of the drones, but by the death of numbers of the workers. Where 2d and 3d swarms have been hived by themselves, they will generally be found too poor to live through the winter, even with feeding. Late swarms and stocks that are weak, must be closely watched, and if the least appearance of robbing is discovered, the entrance of the hive must be closed, so as to admit but one bee at a time. Weeds or small brush set up before the entrances to hives, will prove considerable of a barrier against robber bees, as they dislike very much to approach the entrance by winding passages. For very bad cases of robbing, a wet cloth hung over the entrance and kept dripping, is generally very effective. Too much heat is always injurious to bees, and they should not be exposed to the sun in sultry weather; it renders them irritable, and exposes the comb to the danger of being melted. Those persons who have been so fortunate as to get their glasses filled with honey, will now be preparing to take them off. Do this with great caution. Weigh the hives, and if it can be satisfactorily proved that they will contain 20 lbs. of honey each when the glasses are removed, all well; but, if not, let the glass or box remain upon the stock hive until the bees have emptied it of its honey; as soon as this is ascertained, let it be removed.

SEPTEMBER.—About the middle of September examine the hives; at all events, do not, whatever may be the aspect of the season, neglect this necessary operation until October. It is now quite time to remove glasses from hives intended for stocks, and to see that each one contains at least 20 lbs. of honey; if not, they had better at once be made up to that weight by feeding. The end of the month will be a good time to examine the pedestals upon which the stocks are placed; for it is not unusual to hear of a stock being destroyed by the pedestal decaying just below the surface of the earth, so that by a strong wind, or anything accidentally going against it, it is broken, and the combs by the fall so misplaced as to render the stock of little or no value.

OCTOBER.—In most northern sections, bees that are to be kept indoors should be placed in winter quarters this month. Those to be wintered out of doors, should be properly packed and protected. A system of wintering, by which one shall have nothing but good strong stocks in the spring, will go further in insuring a profitable season than anything else connected with bee-keeping. Defending them effectually from wet, is of first importance. Narrowing the entrances, to prevent the ingress of mice, is also necessary, as well as their destruction in the neighborhood of the apiary. Having done this, and taken effectual means for keeping the hive free from damp, very little fear need be entertained of their being safely carried through the winter without any further attention beyond that of occasionally cleaning the floor-boards and shutting up the hive while snow lies upon the ground.

NOVEMBER.—Remove the top story of the hive; take off all surplus honey boxes; place the lids on the brood chambers, and they are read to wheel into winter quarters as soon as the proper time comes, which varies with latitude, but in Central Illinois is, as a rule, about the middle of November. Select a nice cool day or evening, about the middle of November, soon after the bees have had a good purifying flight. Close up the entrances of the hives, and place as many as is desired into the repository, and stack the hives one upon another as high as you can lift them, always being very careful as you stack them up to raise each lid 1 in. above the hive all around, by slipping under the lid a suitable number of $\frac{1}{4}$ in. pieces prepared for the purpose. Avoid placing the hives against the walls of the building, as this might produce a concussion among the bees from an outside jar of the building. Look into the hives as they begin to stay indoors. If there is not enough honey to carry the colony through the winter, give it a frame of honey from another hive, or, in case all are found to be short, feed a little syrup every warm day. In hives of wood, it is necessary, during the winter months, to withdraw one of the slides at the top of the hive, and place over the opening a feeder or small glass for the purpose of carrying off the condensed vapor, which would otherwise run down the sides of the hive, and cause dampness and moldiness to the combs, and sometimes the entire destruction of the stock.

DECEMBER.—The population of the hives will now be found to be very much reduced; but alarm for their safety on that account need not be entertained. Stocks will require but little attention during this month beyond cleaning the floor-boards, and seeing that there is neither damp nor mold in the hives; and if the

floor-boards are observed to be quite dry, it will be a pretty sure indication that all is right within. During this month bees should not be interrupted, unless there come a warm day. All hives should have the brood chambers contracted to just what combs the bees can cover, and a good quilt or piece of carpet placed just above the combs with some absorbing material on it. Have the hive covers well secured, so that the wind may not blow them off, and place a few boards over the hives, to keep off the snow and rain. The west and north winds should not strike the hives.

SILK CULTURE.

BREEDS.

REMARKS. — Domestication has produced numerous varieties of the silkworm, every different climate into which it has been carried having produced some changes in the quality of the silk, or the shape or color of the cocoons, or altered the habits of the worm. The wild silkworm is much more prolific than the domesticated. The latter has almost lost its generative power, reproducing only once a year. The wild species is therefore of much greater value than the domesticated, for breeding purposes.

ATTACUS ATLAS.—The larva, when hatched, is black, with long, white soft spines. In the subsequent stages the larva appears almost entirely white; this is due to a white powder, which covers not only the tubercles, but the greater part of the body. In the 2d and 3d stages, the color seems orange on the parts of the body from which no farina is secreted.

ATTACUS AUROTA. — Found in Brazil and equatorial America. Various names are given to different races of *Aurota*, as if they were distinct species. *Attacus speculifer*, found in Brazil, is so much like the true type *Aurota*, that it seems but a variety, if it be even a variety. The male moth of the *Aurota* is blotched all over with reddish brown; the female is pale green. In French Guiana they have 6 generations every year.

ATTACUS CYNTHIA. — The larva of *Attacus cynthia* (ailantus silkworm) is covered, but not so thickly, with a white farina, in its last stages. On removing the powder, the skin of the larvæ is green. There are 6 rows of spines on the larva, the 2 rows on the top of the back being the longest; the 2 lateral rows are very small and almost filiform. The farina on the 4 top spines is so thick that they look as if covered with hoar frost. In the 5th stage the larva seems of a yellowish green, the tips of the spines blue; the anal segment is blue, with small black spots, and has on each side an orange red ring.

ATTACUS PERNYI.—This most valuable oak silkworm, now thoroughly acclimatized in Spain, where it is double-brooded, has been reared in the United States. Worms, which had left oak trees, the foliage of which had become dry and tough in consequence of the heat, have been found feeding on hawthorn bushes growing close to the oak trees. Other *Pernyi* larvæ were found on apple trees in a garden, where they reached an enormous size.

BOMBYX CYNTHIA.—A new variety of the silkworm introduced into Europe from the East Indies and naturalized in Malta. They will thrive upon the leaves of the castor oil plant, lettuce, wild endive, weeping willow, etc. It reproduces itself several times in the course of a year. The cocoon, not being entirely closed, the chrysalis may emerge from its cell without injuring the value of the cocoon. The aperture is covered in a very novel manner. On the side from which the moth issues, the cocoon is terminated in the form of a cone, formed by the convergence of a crown of stiff, continuous threads, running in such a manner as to prolong that part of the cocoon, and render the entrance impassable from the outside, while it is easily traversed by the imprisoned grub, which, as it is transformed, pushes its way out, by stretching the elastic sides of this cone. The stiff threads constituting the cone-shaped appendages of the cocoon, are glued, doubled, and folded on each other in such a manner as to retain their primitive integrity after the hatching of the moth.

GATURNIA CLEANOTHA. — This variety was recently discovered in California. It is of the same species as the Chinese silkworm, but superior. Silk of excellent quality has been produced from it.

PROMETHEA.—This worm is very closely allied to the *Cynthia*, and is spared by the sparrows.

SAMIA CLEANOTHI.—A native of California. The ground color of the wings is of a uniform reddish brown; the bands and markings are pure white. The cocoon has the open end very pointed and pear-shaped; its color is iron-gray. The inside cocoon is brown and small compared to the outside envelop. The moths emerge from the 3d of April to the 18th of July.

SAMIA GLOVERI.—This fine species has only been found in Utah and Arizona. The cocoons were collected in plantations of a species of willow with small, narrow leaves. The cocoon is of a silvery gray outside; the rough envelop adheres to the cocoon inside, which is of a very dark brown. The *Gloveri* moths emerge from the middle of April to the middle of July.

TELEA POLYPHEMUS.—This silkworm produces a closed cocoon, a little smaller than that of *Pernyi*, and is the best of the silk producers of the United States. The silk is white, very fine, and of a superior quality. It is double-brooded in Alabama and in the Southern States; in the Northern States it is single-brooded.

CARE AND MANAGEMENT.

THE silkworm exists in 4 stages: Egg; larva or caterpillar; chrysalis; and adult, imago or moth.

EGG STAGE.

CHARACTERISTICS. — The eggs are laid by the moth, and are numerous, about the size of a pin's head, and are not attached together. The color, when first deposited, is yellow, and this color they retain if unimpregnated. If impregnated, they soon acquire a gray, slate, lilac, violet, or even dark green hue, according to variety or breed. They also become indented. When diseased, they assume a still darker and dull tint. With some varieties they are fastened to the substance upon which they are deposited by a gummy secretion of the moth produced in the act of ovipositing. As the hatching point approaches, the egg becomes lighter in color, which is due to the fact that the fluid contents become concentrated into the centre, forming the worm, leaving an intervening space between it and the shell, which is semi-transparent.

HATCHING.—The eggs are laid at the end of summer, and hatched at the beginning of the next summer. When the buds of the mulberry begin to burst, remove the eggs from the ice, and put in a cool place for 2 or 3 days, so that they may be brought gradually to the temperature of the air. As soon as the mulberry leaves have begun to open, spread the eggs on clean white paper; 1 oz. will require 1 sq. ft. of surface. The temperature should be about 70°, and may gradually increase about 1° or 2° a day to 75° or 80°. They will hatch usually in 5 days, but the higher the temperature the sooner the hatching. The worms hatch out in the morning for 3 or 4 successive days. Those who wish to rear worms in June, can rub the new eggs with a whisk broom for about 10 minutes, or until a shiny appearance has been produced; then, if the weather is warm, they will hatch themselves; otherwise, they require artificial heat: 1 oz. of the eggs will produce about 40,000 worms.

PRESERVATION.—The eggs are best preserved on the cloth where originally deposited, as they are protected by a natural coating of varnish, and, being fastened, the worms, when hatching, eat their way out better. For commercial purposes, they are usually detached during the winter by immersing the cloth containing them in cool soft water for a few moments; the moisture is drained off by means of blotting paper, and the eggs gently removed with a paper knife; they are then washed in soft water, thoroughly dried, and put away for safe keeping. The eggs are usually kept at the temperature of ice until hatching time. The Japanese producers sell their eggs on cards or cartoons made of coarse silk. The cards are placed in wooden frames, the rims of which are varnished, so that the moths, disliking the varnish, are made to confine their eggs upon the cards, which are consequently covered in a very regular and uniform manner, as is desirable.

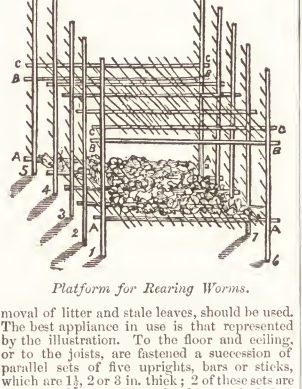
WINTERING.—There is little danger of premature hatching until December, but from that time on the eggs should be kept in a cool, dry room, in tin boxes, to prevent the ravages of rats and mice. They are most safely stored in a dry cellar, where the temperature rarely sinks below the freezing point, and they should be occasionally looked at to make sure that they are not affected by mold. If at any time mold be perceived upon them, it should be at once rubbed or brushed off and the atmosphere made drier. If the tin boxes be perforated on two sides, and the perforations covered with fine wire gauze, the chances of injury will be lessened. The eggs may also be tied up in small bags and hung to the ceiling of the cold room. The string of the bag should be passed through a bottle neck, or a piece of tin, to prevent injury from rats and mice. The temperature should never be allowed to rise above 40° F., but may be allowed to sink below freezing point without injury. Indeed, eggs sent from one country to another, are usually packed in ice. They should be kept at a low temperature until the mulberry leaves are well started in the spring, and great care must be taken as the weather grows warmer to prevent hatching before their food is ready for them, since both the mulberry and osage orange are rather late in leafing out.

CATERPILLAR STAGE.

COLOR. — The color of the newly-hatched worm is black or dark gray, covered with long, stiff hairs, which spring from pale colored tubercles. Different shades of dark gray will, however, be found among worms hatching from the same batch of eggs. The hairs and tubercles are not noticeable after the first molt, and the worm gradually gets lighter, until, in the last stage, it is of a cream white color. It never becomes entirely smooth, as there are short hairs along the sides, and very minute ones, not noticeable with the unaided eye, all over the body. While feeding, the worm is of a light green color, and soft as velvet to the touch.

COCOONERY.—Any sort of a house or room may be used for hatching and raising silkworms provided it is well lighted, well aired, and can be kept tolerably uniform in temperature: fire will be needed on cool nights and rainy days. Direct sunshine should be excluded, which may be done by window blinds on the sunny sides of the room. For a small crop, a room on the north side of the house is best. Ventilation should be secured from the upper part of the room, to avoid direct draughts upon the worms. A close, hot air is injurious, and any sudden or great change of temperature. Cleanliness is very important. Rats and ants must be excluded, as they are very fond of the larvæ. The odors of smoke and tobacco are fatal. Both the room and the apparatus should be arranged to secure as nearly as possible the same condition which the worm finds on the tree. A frame or plat-

form which will allow the free circulation of air from below and on all sides, and the ready re-



Platform for Rearing Worms.

moval of litter and stale leaves, should be used. The best appliance in use is that represented by the illustration. To the floor and ceiling, or to the joists, are fastened a succession of parallel sets of five uprights, bars or sticks, which are 1½, 2 or 3 in. thick; 2 of these sets are represented as touching the floor at 1, 2, 3, 4, 5, and 6, 7, etc. The uprights are about 1 ft. apart in the sets, and the sets running the length of the room, about 5 ft. apart, and the whole should be not less than 2 ft. from the wall. The uprights have sloping pins or nails driven into them 4½ or 5 in. apart. On these, as at A, A, A, A, and C, C, C, C, are laid a series of 5 bars or sticks, and across these little rods or straight twigs; the first of these platforms may be 5 or 6 in. from the floor, and the next (C, C, C, C,) say 2 or 3 ft. above that, and so on, as high as one chooses to go; but 2 are as many as can be easily managed without steps. On these platforms are placed the papers or frames containing the young worms, up to the 3d or 4th age, and after that the twigs or small branches of mulberry leaves with the worms. All the timber of both room and apparatus must be seasoned. The papers containing the young worms may be laid on these platforms directly, but it is perhaps better to use frames like that represented in the illustration. The bars (A, A, and B, B,) are ¾ in. thick; the cross slats, or laths (*a*, *b*,) are ½ in thick, 1 in. or less wide, and 1 in. apart. It is better to make these frames 2½ ft. by 5, so that 2 of them will occupy, crosswise, 1 platform. The only additional apparatus

Frame.

needed is perforated paper and netting (mosquito or other) about the size of the frames, for the younger stages of the worms. The paper should have sufficient strength and stiffness, so that it can be lifted with the worms on it without huddling them. A good quality of merchants' wrapping paper will do.

FEEDING.—The worms should be fed as soon as hatched and removed, by sprinkling young and tender leaves over the tray. Repeat the feeding every 2 hours during the first age, and afterwards every 3 or 4 hours. Give the first feed at 5 o'clock in the morning, and the last at 10 or 11 at night. Before each feeding, spread a net or paper over the worm and place the leaves on it. About every 2 days lift the net with the worms to a new frame and remove the litter. The space must be increased as the worms grow, so as to avoid crowding. They will need double space the second day. To accomplish this in feeding, when about ⅓ the worms have come through the net or paper, remove and place a second paper with leaves for the remainder; in the same way the space may be trebled by removing ⅓ at a time. The leaves should be spread evenly so that the worms may get the same amount of food and keep together in their growth, as it is important to have them molt together. The leaves must be fed fresh and dry, never wet or wilted. Gather the leaves in the evening for the next morning's meal, and, when rain threatens, gather a day ahead, and keep in an airy, cool place, stirring occasionally to prevent heating and fermentation, which will ruin them. When food is scarce, lower the temperature of the room and the worms will eat less. For young worms, gather only the small leaves. After the second age, small twigs or branches may be cut with the leaves. Cut up the mulberry leaves on a chopping-board; they can not be chopped too fine, because the more the leaf is chopped, the more fresh-cut edges there are to which the young insects fasten themselves. In this manner, a few oz. of leaves will present so many edges and sides that 100,000 insects may feed in a very small space. In this state they bite the leaf quickly, and it is consumed before it becomes withered. It is better to keep the silkworm a day without food than to give it wet. If gathered wet, the leaves should be spread on the floor, and afterwards dried, by a few lbs. being shaken at a time in a sheet, which speedily absorbs all moisture. If the weather is very warm, feed lighter and oftener. If the worms do not eat all their feed, give them less at a time.

FOOD.—The *Chincapin oak*, growing in the California mountains, will feed the wild Chinese silkworm; some of the other kinds of oak, that grow upon the coast, can be utilized for food.—*Lettuce.* The silkworm will eat lettuce leaves, if given before it has tasted those of the mulberry.—*Mulberry.* There are 11 varieties of the *Morus alba*, or white mulberry. Among them are the *Morus multicaulus*, *Morus tartarica*, *Morus maretta*, *Morus japonica*, English white, and others. The *Morus tartarica*, from Russia, where it has long been grown and used for silk, is one of the favorites. It produces a red-

dish-white fruit of inferior quality, and is easily propagated. It flourishes best in light sandy or gravelly soils. One full grown tree will yield from 200 to 300 lbs. of leaves; 200 trees may be planted on 1 acre of land. In 3 years they will yield, under fair conditions of soil and cultivation, 10 to 12 lbs. of leaves each, or more than 2,000 lbs. per acre; 1,800 lbs. suffice for 1 oz. of eggs, and will produce 100 to 120 lbs. of cocoons. At 7 or 8 years the yield will be 10 fold.— *Osage Orange.* This affords a good substitute for the mulberry, and will make excellent cocoons. Those who use this plant as silkworm food, must bear in mind that the shoots from a hedgerow become very vigorous and succulent by the time the worms are in the last age. These more milky and succulent terminal leaves should be thrown aside and not used, as they are apt to induce flaccidity and disease. In avoiding these more tender leaves, and using only the older and firmer ones, especially when the worms are large, consists the whole secret of the successful rearing of silkworms on this plant; and if care be had in this respect there will be no appreciable difference in the silk crop from osage orange as compared with that from mulberry.

LONGEVITY. — The time of the silkworm's life in the caterpillar stage is generally from 6 to 8 weeks; about 5 days are occupied in the spinning of the cocoon; about 2 or 3 weeks elapse before the perfect insect or moth comes forth. The life of the caterpillar is commonly divided into 5 "ages," these ages being defined by the same number of "molts."

MOLTING.—The 1st age of the caterpillar extends from the 1st to the 6th day, or to the end of the 1st molt. The 2d age extends from the 6th to the 10th day, or to the end of the 2d molt. The 3d age extends from the 10th to the 16th day, or to the end of the 3d molt. The 4th age extends from the 16th day to the 23d, or to the end of the 4th molt. The 5th age extends from the 22d to the 28d day, or to the end of the 5th molt. When the time for their sleep approaches, the worms lose appetite and raise their heads with a waving motion. When any of the worms are seen in this state, give a light fresh feed to hurry up the tardy ones. During their torper they eat nothing. As soon as their skin is shed their activity and appetite return. This process is usually over in about 30 hours. No food should be given until about all of the batch are through the molt and ready to make an even start; or if the last are much delayed, give a light feed to the first, and feed the last more copiously, and keep them warmer for a day or so, that they may overtake the first. This rule need not be observed after the 4th molt. After molting, the space will generally need to be doubled. The worms usually pass through the 1st molt without difficulty. The 2d and 3d casting of the skin takes place with but little more difficulty than the 1st; but the 4th is more laborious, and the worms not only take more time in undergoing it, but often perish in the act. At this molt it is perhaps better to give the more forward individuals a light feed as soon as they have completed the change, inasmuch as it is the last molt and but little is to be gained by the retardation, and it is important to feed them all that they will eat, since much of the nutriment given during the last age goes for the elaboration of the silk. At each successive molt the color of the worm has been gradually whitening, until it is now of a decided cream color. Some breeds, however, remain dark, and occasionally there is an individual with zebra-like markings. During the last few days the worms require the greatest care and attention. All excrement and litter must be often removed, and the sickly and diseased ones watched for and removed from the rest. The quantity of leaves which they devour in this 5th age is something enormous, and the feeding will keep the attendant busily employed. Summed up, the requisites to successful silkworm raising are: 1st. Uniformity of age in the individuals of the same tray, so as to insure their molting simultaneously; 2d. No intermission in the supply of fresh food, except during the molting periods; 3d. Plenty of room, so that the worms may not too closely crowd each other; 4th. Fresh air and as uniform temperature as possible; 5th. Cleanliness; the last 3 are particularly necessary during the 4th and 5th ages.

MUSCARDINE.—A worm about to die of this disease becomes languid, and the pulsations of the dorsal vessel, or heart, become insensible. It suddenly dies, and in a few hours becomes stiff, rigid and discolored; and, finally, in about a day, a white powder or efflorescence manifests itself, and soon entirely covers the body, developing most rapidly in a warm, humid atmosphere. No outward sign indicates the first stage of the disease, and though it attacks worms of all ages, it is by far the most fatal in the 5th or last age, just before the transformation.

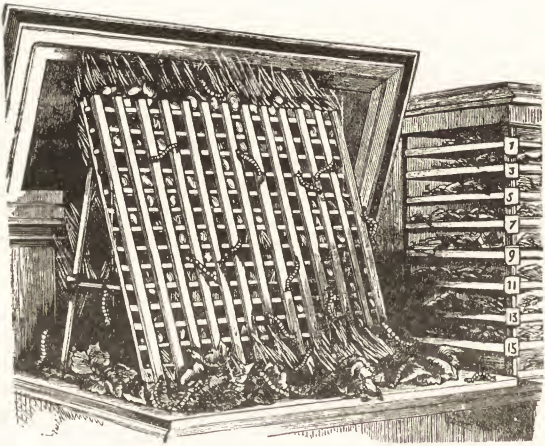
PESTS.—Silkworms are subject to many casualties, besides suffering severely from want of cleanliness, cold apartments, moisture and tempests. Large numbers are every year killed by the operation of some or all of these causes; but more disastrous than any other is the effect of thunder. The most beautiful worms which have passed safely through all their molting seasons, are frequently killed by the operation of electricity. Red ants are great enemies of the silkworm, as also spiders, mice and rats.

SPINNING.—With 8 or 10 days of busy feeding, after the last molt, the worms will begin to lose appetite, shrink in size, become restless, and throw out silk, and the arches for the spinning of the cocoons must now be prepared. These can be made of twigs of different trees, 2 or 3 ft. long, set up upon the shelves over the worms, and made to interlock in the form of an arch above them. Interlace these twigs with broom corn, hemlock, or other well-dried brush. The feet of each arch should be only about 1 ft. apart. The temperature of the room should now be kept above 80°, as the silk does not flow so freely in a cool atmosphere. The worms will immediately mount into the branches and commence to spin their cocoons. They will not all mount at the same time, and those which are more tardy should be fed often, but in small

quantities at a time, in order to economize the leaves, as almost every moment some will quit and mount. There will always be a few which altogether fail to mount, and prefer to spin in their trays. It is best, therefore, after the bulk have mounted, to remove the trays and lay brush carefully over them. The fact that the worms already mounted, make a final discharge of soft and semi-fluid excrement before beginning to spin, makes this separation necessary; as otherwise the cocoons of the lower ones would be badly soiled. As the worms begin to spin, they should be carefully watched to guard against 2 or 3 of them making what is called a double or triple cocoon, which would be unfit for reeling purposes. Whenever one worm is about to spin up too near another, it should be carefully removed to another part of the arch. In 2 or 3 days the spinning will have been completed. The cocoon, when finished, is much shorter than the body, which, being bent, is completely inclosed in it. The cocoon is about the size of a pigeon's egg, 1 to 1½ in. long, and of a bright yellow color.

neither heat nor cold hurts them, but want of air will smother them at once.

Spinning a Cocoon.



A Cocoonry.

VENTILATION.— The worm needs pure air, and must have an abundance of it; therefore, if the weather is at from 75° to 80°, keep the windows and doors wide open, avoiding strong draughts, as they will give the worms cold, and surely kill them. During the month of May

Chrysalis Stage.

CHRYSALIS.—The chrysalis is a brown, oval body, which is inclosed in a bright yellow cocoon; it is considerably less in size than the full-

Chrysalis.

grown worm. In the external integument may be traced folds corresponding with the abdominal rings, the wings folded over the breast, the antennæ, and the eyes of the inclosed insect—the future moth. At the posterior end of the chrysalis, pushed closely up the wall of the cocoon, is the last larval skin, compressed into a dry wad of wrinkled integument.

COCOON.—The cocoon consists of an outer covering of loose silk, known as floss, which is used for carding, and is spun by the worm in first getting its bearings. The amount of this loose silk varies in different breeds. The inner cocoon is tough, strong and compact, composed of a firm, continuous thread, which is, however, not wound in concentric circles, as might be supposed, but irregularly, in short figure of 8 loops, first in one place and then in another, so that in reeling, several yards of silk may be taken off without the cocoon turning round. In form the cocoon is usually oval, and in color yellowish, but in both these features it varies

Cocoons.

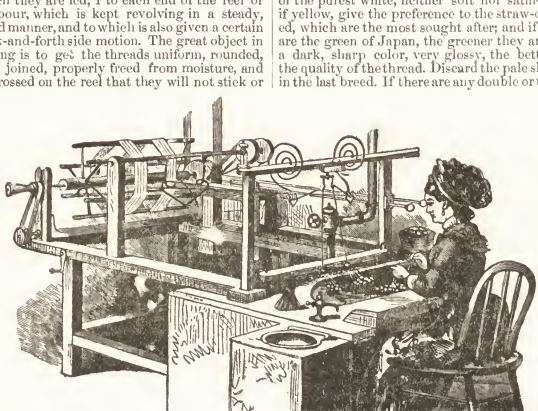
greatly, being either pure silvery white, cream or carneous, green, and even roseate, and very often constricted in the middle. It has always been considered possible to distinguish the sex of the contained insect from the general shape of the cocoon, those containing males being slender, depressed in the middle, and pointed at both ends, while the female cocoons are of a larger size and rounded form, and resemble in shape a hen's egg, with equal ends. Eight days from the time the spinning commenced, it will be time to gather the cocoons. The arches should be carefully taken apart, and the spotted or stained cocoons first removed and laid aside. Care should be taken not to stain the clean ones with the black fluids of such worms as may have died and become putrid, for there are always a few of these in every cocoonry. The hardest, brightest and most substantial cocoons are saved for seed, strung on threads by means of a long needle, so passed through them as not to injure the occupant, and hung up in a moderately warm position. Both male and female cocoons are kept.

CHOKING THE CHRYSALIS. — When the cocoons are intended for reeling purposes, the chrysalis should be killed before it is time for it to burst the shell and come forth as a moth; for by so doing the thread is cut and the silk injured for the reel. There are several methods of killing or choking the chrysalis, which are as follows: *Dry Heat Method.* The cocoons are placed in shallow baskets, and slipped on iron drawers into an oven, which is kept heated to a temperature of about 200° F. This should not be increased for fear of burning the silk. This operation lasts from 2 to 24 hours. A certain humming noise continues so long as there is any life, and its cessation is is an indication that the chrysalides are all dead. Where the choking is well done, there is little loss, only about 1 per cent. of the cocoons bursting at the ends. After choking in this manner, the cocoons should be strewn upon long wooden shelves in the shade, with plenty of air, and, for the first few days, frequently stirred. After remaining on these shelves for about 2 months, with occasional stirrings, the chrysalides become quite dry, and the cocoons will preserve indefinitely. Choking may also usually be effected by exposing the cocoons to the hot sunshine, from 9 o'clock till 4, for 2 or 3 days. A longer time is needed if there is much air stirring, or the sunshine is not strong. And the process is surer if conducted in a shallow box under glass, with a crevice for the escape of moisture. In either case guard against ants. The stifling should be attended to as soon as the cocoons are gathered, lest cloudy weather intervene. In this case the result may be reached by packing the cocoons in a barrel, carefully lined with paper, so as to be nearly air-tight, with alternate sprinklings of camphor, roughly granulated with the hand, beginning with camphor on the bottom, then 3 or 4 in. of cocoons; again camphor, and so on, finally closing the barrel for 2 or 3 days; using about 1 lb. of camphor to the barrel. After 3 or 4 days, spread the cocoons on boards or shelves to dry, in an airy room or attic, stirring frequently the first 2 or 3 days, and afterwards occasionally for about 2 months, when they will be thoroughly dry, and may be packed for market. Guard must be kept against rats and mice, ants and smaller insects, which will penetrate the chrysalides and injure the silk. The latter may be expelled by a sprinkling of camphor or other insectifuge drugs, or by the bark of sassafras root, or chips of red cedar, tobacco stems, etc.—*Steam Method.* This is a much quicker process than the dry heat method. The cocoons should be put into a bag of coarse flannel, or a basket, and steamed for $\frac{1}{2}$ hour over boiling water, exactly in the same manner as potatoes are steamed. When sufficiently steamed, they should be spread on a cloth on the same frames upon which the worms have been fed; these being net-work, the air passes through and dries the cocoons; they should be turned and moved occasionally to prevent fermentation, and should not be heaped upon one another above 2 in. deep. — *Vacuum Box Method.* In the colder climates it has been suggested that the chrysalides could be well choked, with no injury to the cocoons, by placing them in a vacuum box and exhausting the air. Chloroform has also been used to a certain extent.

LONGEVITY.—The chrysalis state continues from 2 to 3 weeks, when the skin bursts and the moth emerges.

REELING.—The cocoons are plunged into water, when it is near the boiling point, and

moved about so that the gum which fastens the threads becomes uniformly and thoroughly softened. They are then beaten with a small birch-en broom, having the tips split, so that the loose threads readily fasten to them. After beating a short time, the operator gets all the cocoons fastened, and, taking the bundle of threads, shakes the cocoons till each hangs but by a single one. She now takes up 5 or more threads, according to the quality of silk wanted, unites them, and introduces the combined staple or strand into a little glass eye on one side of the basin. She then forms a 2d similar strand, and introduces it into a 2d eye on the other side. The strands are then brought together, twisted several times, separated above the twist, and introduced into 2 other glass eyes or ringlets through which they are led, 1 to each end of the reel or tambour, which is kept revolving in a steady, rapid manner, and to which is also given a certain back-and-forth side motion. The great object in reeling is to get the threads uniform, rounded, well joined, properly freed from moisture, and so crossed on the reel that they will not stick or



Reeling the Silk.

glaze, as it is termed. These objects are attained by the twisting and the to-and-fro lateral movement of the reel, as also by properly regulating the distance between reel and basin. The uniformity of the thread depends on the skill of the operator, who must supply a new thread as soon as one begins to give out. This is called nourishing the silk, and is done by dexterously casting with the thumb the new thread upon the combined strand, to which it immediately adheres. In this she must use much judgment, for the silk of a cocoon gradually gets lighter and finer as it approaches the end, and the uniformity of strand does not entirely depend on the uniformity in number of the individual threads forming it. Whenever the silk rises in locks, the temperature of the water is known to be too hot, and when it unwinds with difficulty, the temperature is, on the contrary, too low. The operator is supplied with a skimmer with which to remove all chrysalides and refuse silk; also with a basin of cold water in which to cool her fingers, which are being constantly dipped in the hot basin. This constitutes the whole operation of unwinding.

SEED.—The very best of the firm cocoons should be chosen as seed for the next year, unless the raiser prefers buying his eggs to the trouble of caring for the moths and keeping the eggs through the winter. Eggs bought from large establishments are apt to be untrustworthy, and it is well for all silk raisers to provide their own seed. These cocoons should be chosen for their firmness, and the fineness and color of the silk, rather than for their size. If white, take them of the purest white, neither soft nor satin-like; if yellow, give the preference to the straw-colored, which are the most sought after; and if they are the green of Japan, the greener they are, of a dark, sharp color, very glossy, the better is the quality of the thread. Discard the pale shades in the last breed. If there are any double or triple cocoons in the batch, of the right color, quality and consistency, they should be used before the others, as they are just as good for breeding purposes, though unfit for reeling.

IMAGO STAGE.

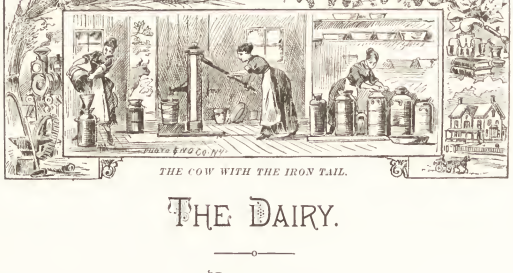
BURSTING THE COCOON.—In from 12 to 20 days from the time when the worm commenced to spin, the moths begin to issue from the cocoons laid aside for breeding purposes. They issue most abundantly during the early morning hours, from 4 to 8 o'clock, and, as they appear, they should be taken by the wings, and the sexes kept apart for a short time. The males may be readily distinguished from the females by their broader antennæ and smaller bodies,

as also by the incessant fluttering of their wings. The females remain comparatively quiet, their abdomens being heavy and distended with eggs.

REPRODUCTION.—A few hours after issuing, the sexes, in equal numbers, may be placed together, great care having been taken to destroy any that are at all deformed, in order to keep the breed as fine as possible. They should be placed upon paper or card-board, and the room should be kept as dark as possible, in order that the males shall not uncouple themselves. For the complete impregnation of the eggs, the sexes should be kept together for 6 hours, neither more nor less, and occasionally visited in order to replace those males which may have become separated. Should however, they may be thrown away. These last, as soon as separated, should be placed for a few minutes upon sheets of blotting paper, where they will free themselves of a quantity of greenish-yellow fluid. From the blotting paper they should be transferred to trays lined with cloth, upon which the eggs are to be laid. This cloth should be of the smoothest sort of woolen stuff rather than of linen or paper, if it is desired to remove the eggs at a future time, as they will stick so fast to the latter that it will be difficult to remove them without bruising. Upon these trays they may be placed in rows, and will immediately commence depositing. It is advisable to tip up the trays at one end, so that they incline a little, as the moths are then more apt to

Moth Laying Eggs.

there, on this day, more males than females issue, the superfluous males may be put in a closed box and kept till the next day, when this state of things may be reversed. Should there, on the other hand, be a superfluity of females, a sufficient number of the strongest and most vigorous males should be uncoupled at 4 hours and placed with the unpaired females for 6 hours more. As the pairs are uncoupled at the end of 6 hours, care should be taken not to injure either sex. The female should be held by the wings with one hand and the abdomen of the male gently pressed with the other. The males may then be laid aside in a box, as there may be use for them before all the moths have appeared. After all the females are impregnated, lay their eggs uniformly. They should also be kept in the dark, in accordance with the nocturnal habit of the moth. The temperature of the room should be kept at about 75°, and plenty of air given during oviposition. All of the thoroughly impregnated eggs will be laid in about 24 hours, and the moth should be removed after that length of time. She may continue depositing a short time longer, but the eggs should be kept by themselves and not mixed with the others. It will be well, also, if the best and purest breed be desired, to keep the eggs of those moths which were coupled with males that had been used before, separated from the eggs laid by those which where coupled with virgin males.



THE COW WITH THE IRON TAIL.

THE DAIRY.

BUTTER.

REMARKS.—To make good butter, requires good cows; those not necessarily giving a large flow of milk, but a regular flow of rich milk, which will make butter of a waxy texture; and, to please the eye, of a deep yellow color. While improved systems of setting, and improved churns, workers, and salt, may save much time, labor and anxiety, and secure more uniformity, good butter can be made without the improved machinery; but good butter cannot be made without good cows. The only difference between creamery and dairy butter is, that creamery butter is made in large quantities, and according to uniform and scientific rules, while dairy butter is made by different farmers in their dairies, from varying material, and no scientific system followed.

BUTTER, To Make.—Set the milk according to the directions for *Setting* in MILK; then skim (see *Skimming*, in MILK). Stir the cream every day; and the day before churning, put the pot near the stove, to allow the cream to warm and get sour. To sour the cream, take the milk after it has stood 9 or 10 hours, and place it over a clear, slow fire, but do not boil it. The earthen pan, having its bottom much smaller than its top, when the milk is sufficiently heated, throws up the form of its bottom on the surface of the cream; it is therefore preferable to the tin pan, which, if almost as big at the bottom as at the top, gives no criterion to judge by, except the wrinkles on the cream become smaller, and the texture somewhat leathery. In summer, the process of scalding ought to be quicker than in winter, as in very hot weather, if the milk should be kept over too slow a fire, it would be apt to run or curdle. Now turn all the cream into the churn. The coloring (if any is to be used) may be added now, or worked into the butter after churning; but, by adding the color in the churn, it is easier and more evenly mixed with the butter. In churning, care should be taken that the agitation is not too rapid, or so violent as to injure the grain of the butter. In filling the churn, leave out whatever milk may be found at the bottom of the cream crock, as its sour taste will be sure to promote acidity in the butter, and give it a cheesy flavor. Churning should occupy from $\frac{1}{2}$ to $\frac{3}{4}$ of an hour; if the butter should be hard and granular, refusing to come together well, throw in a little warm water, churning all the while, and the butter will be gathered and ready to take up. When the butter is well churned, rinse it with cold water until the water runs off clear; then churn it together again and press the water out; instead of washing it, the buttermilk may be worked out. When it is taken out of the churn, work with the hand, which presses out most of the milk. Press a cloth repeatedly down upon it, to absorb all the remaining milk; the less it is beaten or worked, however, the better. Care must be observed not to work enough to destroy the grain, or the butter will become sticky and adhere to the knives. 1 oz. of fine, purified dairy salt should be used for each lb. of butter. Salt is added by being sprinkled over the butter after it has been spread out in layers; a few turns should be given to the mass with the butter worker. The quality of the salt should be strong marine, free from the brine of mineral salt; the quantity may be that of about 10 oz. to 14 lbs. of butter; rather more or less, according to the length of time which the butter is intended to be preserved; but it is generally thought that the butter made during the summer months is the most suitable for salting, and that the sort which is made in the latter part of the season, not taking it so well, requires rather more. Some farmers use saltpetre, in the proportion of $\frac{1}{2}$ oz. of salt to $\frac{1}{2}$ of saltpetre to the lb. of 16 oz.; and although this forms a valuable pickle, if the salt be really good, yet it would unquestionably be much improved if 4 oz. of raw sugar were added to each lb. weight of salt. A compound of 1 part of sugar, 1 part of nitre, and 2 parts of the best Spanish salt, beat together into a fine powder, and mixed thoroughly with the butter, in the proportion of 1 oz. to the lb., has been

found to keep the butter in every respect sweet and sound during 2 years that it was in the cask; it is also said to impart a rich, marrowy flavor that no other butter ever acquires, and tastes but very little of the salt.

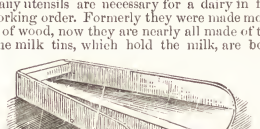
BUTTER, To Make Come.—To 20 lbs. of butter, add 1 teaspoonful of carbonate of soda, and 1 teaspoonful of powdered aluminate of sodium; put into the cream at the time of churning. It is claimed that this powder makes the butter come firm and solid, and gives it a clean, sweet flavor, and that the yield of butter will be increased and the process of churning shortened; but this method is not advisable, as it adds to the butter a part of the curd that belongs properly to cheese-making only.

BUTTER, To Color.—1. Annatto, 4 oz.; curcuma, 1 oz.; sweet, nice lard, 4 lb.; put 1 lb. of the lard in an iron kettle on the stove, with the annatto; stir all the time to prevent burning; put the curcuma and 1 lb. of lard in another iron kettle; stir constantly to prevent burning; when the lard, which settles on top, looks of a bright clear amber color, turn off the clear lard from both kettles into a jar, leaving the sediment at the bottom in the kettle; put the rest of the lard on this and heat and stir again until it is all dissolved; strain it all together through toweling.—2. Annatto, 5 oz.; pulverized turmeric, 6 oz.; saffron, 1 oz.; lard oil, 1 pt.; butter, 5 lbs.; the butter is first melted in a pan over the water-bath, and strained through a fine linen cloth; the saffron is made in ½ pt. tincture, and together with the turmeric and annatto, is gradually stirred into the hot butter and oil, and boiled and stirred for about 15 minutes; it is then strained through a cloth as before, and stirred until cool.—3. Annatto, 10 parts; caustic potassa, 1½ parts; borax, 1 part; water, 100 parts; tincture of turmeric, 20 parts; mix and filter.—4. Take 2 large-sized carrots; clean them thoroughly, and then with a knife scrape off the yellow exterior, leaving the white pith; soak the yellow part in boiling milk for 10 or 15 minutes; strain boiling hot into the cream; this gives the cream the desired temperature, colors it nicely, and adds to the sweetness of the butter.

DAIRY AND CREAMERY, Construction of.—The only respect in which a creamery is different from a dairy, is that it does the work of several dairies, and greatly reduces the cost of making the butter. If the first requisite of good butter is the cow, the second is the dairy-room; for it is useless to produce good milk if it is spoiled in the keeping. The best situation for a dairy is on the north side of the dwelling-house; one that is partly underground and has an apartment over it for churning, and washing pans, etc., is preferable, as it will need no artificial heating by a stove. One with brick walls, whitewashed with lime, plastered overhead, and with a cement or flag-stone floor, is best; have the windows above ground, and facing the south and west; cover the windows with fine wire gauze outside, and hinge them at the top, so that they may be opened by raising and hooking up the sash. The windows being close up to the ceiling ventilates the room completely. Small dairies have only 1 or 2 rooms; but large dairies, where both butter and cheese are made, have 3 or 4 rooms: the milk-room, the churning-room, the cheese-room, containing the cheese press, and the drying-room, where the cheeses are placed to harden; to these may be added a scullery, furnished with boiler, water, etc., for scalding and washing the dairy utensils, when it is not desirable to perform these operations in the churning or cheese rooms. If room and means will not allow of a dairy, a substitute may be found, for keeping the milk fresh 48 hours, in the following: A box or covered trough, 2 ft. deep, 18 in. wide, and long enough to hold 4 cans of milk, should be placed under some shade trees in the back yard, a few yds. from the house well. Wooden pump tubing should lead from the pump into this trough; the milk cans, each holding one milking, are stored in the trough, which should be kept filled with water to within a few inches of the top, where the overflow passes through an orifice into open troughs, and hence to a large trough in the stock-yard. Thus, in watering the stock, the water in the milk trough is changed several times a day.

DAIRY AND CREAMERY, Management of.—It is very necessary that every article should be kept perfectly clean. All utensils that have held milk or butter, should be scalded, scrubbed, and rinsed with cold water, before being used a second time. Ample means should be provided to insure thorough ventilation, by means of suitable windows; but flies and other insects must be excluded. The temperature must be preserved as much as possible in an equable state, ranging from 45° to 55° F. In the summer, the heat may be lessened by sprinkling water upon the floor, which will produce a considerable degree of cold by its evaporation. Should the temperature rise too high, it may be reduced by suspending a piece of ice at a considerable distance from the floor, or by hanging up a wet sheet where the air will strike upon it. If in winter the cold should become too great, and the room is not provided with a stove, a barrel of hot water, closely covered, or a few hot bricks placed upon the floor, will prevent all mischief. A charcoal stove should never be used. Abundance of pure water is essential. Dampness does no harm if the dairy is kept fresh and clean.

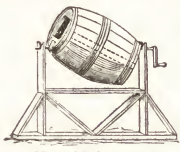
IMPLEMENTS AND UTENSILS.—A great many utensils are necessary for a dairy in full working order. Formerly they were made mostly of wood, now they are nearly all made of tin. The milk tins, which hold the milk, are both



Butter Worker.

large and small, as larger ones are generally required in summer than in winter. A good-sized tin is 6 ft. long by 3 broad, and 5 in. deep. The

curd-breaker, used to grind the curd, is an instrument about 1 ft. square, being a frame-work of tin cutters with 1 in. mesh, the handle 4 ft. long. Then there are vats of all sizes, which are usually made of elm, the cheese-press, the milk-warmer, bowls, strainers, coolers, girth butter-boards, markers, cloths, brushes and various other pots and pans. The butter-worker is also an important article in the dairy. It can be made entirely of wood, and is light to handle and move about. There are innumerable patent churns in the market, the preference being much a matter of choice. A good home-made churn, like the



Home-Made Churn.

one in the illustration, may be made of any water-tight cask or barrel. The cover is held in place by a bar screwed loosely at one end to the head of the churn, and the other end falls into a hook, after the cover is adjusted. The second illustration also represents a churn, moved by dog-power. A cream still is an important addi-

Dog Power Churn.

tion to a dairy. It is simply a kind of refrigerator to maintain a temperature of about 60°. The ice-chambers are above the pans, and the pans rest on slats, except the lower tier. It will prove serviceable to those who keep a small number of cows, and who have no proper appliances for setting milk, but who can have ice at their command during summer.

PACKING, STORING AND MARKETING.—The best package for keeping butter through the summer is a white oak pail, varnished on the outside, and made with a tight-fitting cover; or, for larger quantities, a white oak firkin should be used. The pails should be thoroughly scalded, next soaked in clean brine before being used, and then dusted with dry salt on the wet sides before the butter is put in. The butter should be packed solid, without any air spaces, and if the tub is not filled at once the butter

Cream Still.

should be covered with a little clear brine until the next packing is put in. When the tub is filled to within ½ in. of the top, a piece of clean muslin, dipped in brine, should be placed over it and pressed down; dry salt is then laid on a level with the edge of the pail, and the cover is pressed down and fastened. The package is then kept in a cool, sweet cellar. Stone crocks, which hold 10 or 12 lbs. each, are also excellent vessels in which to pack butter. Fill them to within ½ in. of the top. A good plan is to make a long box; put 1 in. of salt in the bottom; put in the filled crocks; place 1 in. of salt all around the packages, and on top of the butter pour 1 pt. or more of clear brine as strong as can be made from the best dairy salt; over this place a common plate, projecting over the edge of the crock; over the plate place 1 in. or more of salt; put all in a cool, clean cellar, and cover with paper and a board. Some butter goes into market in the form of rolls; some pine-apple, and other fancy forms for the table. Every person should be guided by circumstances in his choice of styles for putting up butter, always being careful to give it a neat and attractive appearance.

RANCID BUTTER, To Purify.—1. Melt in twice its weight of boiling water and shake well; pour the melted butter into ice water to regain its consistence. — 2. Wash in good, new milk, in which the butyric acid, which causes the rancidity, is freely soluble. Wash afterward in cold spring water. — 3. First agitate the butter with hot water. On standing it soon separates from the water, when it is again agitated for some time with an equal volume of fresh hot water, and a few oz. to the lb. of fresh animal charcoal, in coarse powder and free from dust. It is freed from charcoal by straining through a cloth while hot, and from the water by the difference in specific gravity. The butter, when cold, is well washed with fresh milk to which a little sulphite of lime has been added; then re-

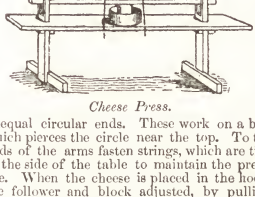
worked, salted, and colored with a small quantity of annatto. An objection to this receipt is that so much working tends to destroy the grain and make the butter oily.

CHEESE.

REMARKS.—Cheese is composed of the curd, or congulated milk, and may be obtained from the caseous part alone, after the milk has been skimmed. If thus deprived of the cream, this "skim milk" cheese is, however, of a poor quality; and if intended to be good, the whole milk should be used, without any loss of cream. Cheese differs vastly in quality and flavor, according to the method employed in its manufacture and the richness of the milk of which it is made. *Limburger* cheese is not considered ready for consumption until it is partly putrefied. Much depends upon the quantity of cream milk contains; consequently, when a superior quality of cheese is wanted, cream is frequently added to the curd. The addition of a pound or two of butter to the curd for a middling size cheese also vastly improves the quality of the product.

CHEESE. To Make.—In making cheese, put the greater portion of the milk into a large tub, to which add the remainder, sufficiently heated to raise the temperature to that of new milk; whisk together, then add the rennet or rennet liquor, and cover the tub. It is allowed to stand until completely turned, when the curd is gently struck down several times with the skimming dish; after this it is allowed to subside. The cheese hoop, covered with cheese cloth, is next placed on a horse or ladder over the tub, and filled with curd by means of the skimmer; care being taken to allow as little as possible of the oily particles or butter to run back with the whey. The curd is pressed down with the hands and more added as it sinks. This process is repeated until the curd rises to about 2 in. above the edge. The newly-formed cheese, thus partially separated from the whey, is now placed in a clean hoop, and a quantity of salt, to taste, added, as well as of annatto, when that coloring is used, after which a board is placed over and under it, and pressure applied for about 2 or 3 hours. The cheese is next turned out and surrounded by a fresh cheese-cloth, and then again replaced in the hoop, and submitted to pressure in the cheese-press for 8 or 10 hours, after which it is commonly removed from the press, salted all over and again pressed for 15 to 20 hours. The quality of the cheese depends on this part of the process, for, if any of the whey is left in the cheese, it rapidly becomes bad-flavored. Before placing it in the press the last time, pare the edges smooth; then wash the outside of the cheese in warm whey or water; wipe it dry, and cover the outside of it with annatto or reddle.

CHEESE PRESS.—A good cheese press may be made at a trifling cost. The uprights are 2 by 4 in. scantling, 4 or 5 ft. long, with pieces of the same fastened to the bottom as braces; 30 in. from the floor stout cleats are nailed firmly to the uprights, upon which rests a 2 in. plank, which serves as a table. Upon this plank is a cheese hoop, with a cheese inside to be pressed. Above this is a stout strip of 2 by 2 stuff, with ends resting in mortises cut in the uprights. This strip should be 5 or 6 ft. in length. Under it, in the centre, is a block which rests upon a round follower the exact size of the cheese to be pressed. The power is furnished by the eccentrics, or arms, which are merely levers with



Cheese Press.

unequal circular ends. These work on a bolt which pierces the circle near the top. To the ends of the arms fasten strings, which are tied to the side of the table to maintain the pressure. When the cheese is placed in the hoop, the follower and block adjusted, by pulling down upon the eccentrics a pressure of any required degree is applied upon the cheese; both the board and strip being elastic, the pressure is maintained as long as applied.

CHEESE, To Store.—Store in a cool cellar, neither damp nor dry, and one which is uninfluenced by changes of weather. The temperature should not be permitted to exceed 50° or 52° Fahr.; an average of about 45° is preferable.

ANTI-ACID.—Draw the whey off while it is still sweet, and place the curd so that it shall not in the least soak whey, but be cleared from it as fast as it exudes, because of the action of the rennet. Depend on the rennet to perform the work of cheesing, with the aid of the oxygen in the atmosphere, to which the curd should be thoroughly exposed; pay no attention to the degrees of acidity, but be guided, in the dipping of the curd, by the stage to which the action of the rennet has developed it.

ARTIFICIAL.—Oleomargarine is used to adulterate and cheapen cheese. In manufacturing cheese, the oil is mixed with skim-milk; it can be handled then as if all milk, and the product can scarcely be detected from ordinary cheese.

BELLUNESE.—Made by heating the milk, pouring in rennet, letting it congulate, breaking it into medium-sized pieces, re-heating it in wooden tubs, salting, and placing it on stands for daily turning and re-salting.

BRICKBAT.—Made of new milk and cream. This name is given to it from its being made into forms resembling brickbats.

BUTTERMILK.—Buttermilk, after being boiled and allowed to stand until cool, is placed in a cheese form or heavy linen bag until the whey

is drained off, when it is salted, spiced according to taste, and thoroughly mixed; a spoonful of wine or cognac is then added for each lb., and the mass is thoroughly kneaded and formed into cheeses of any desired size or form, which are dried in the air, and then wrapped in clean linen cloths that have previously been moistened with hot whey, and packed in a well-covered cask and stored in a warm place; 4 days suffice to render it fit for use, but it improves by age. The small hand cheeses, which especially become dry in winter, may be rendered palatable by simply wrapping them, when dry, in horseradish leaves, and packing them very closely in a cask.

CACCIO CAVALLO. — The cows are milked once daily; their milk, when poured into large vats, is divided, and ½ heated to a point which will make it and the unheated, mixed, when tested by hand, 100° Fahr. Whey of goat's milk is shaken in it, and while curdling it is covered with a cloth to keep up the temperature. When curdled, it is broken, stirred till in filbert-sized pieces, placed with whey in a vat, re-beaten, wet, and covered with warm whey to grow. When, by heating on hot coals, ductility is obtained, the curd is called "grown." It is next cut, the pieces thrown into a pail, where they are wet with hot water, re-united, manipulated, pulled into thread, and made into as many balls as there is cheese to make up. These thread balls are immersed in the water which served to make them manipulated, until homogeneous and compact, formed by hand into proper shapes, and salted daily for 2 or 3 days.

CHEDDAR.—A fine kind of cheese, with a spongy appearance, the eyes or vesicles of which contain a rich oil. It is made up into thick, round cheeses of considerable size. Its manufacture is based on the method of drawing the whey from the curd while it is yet sweet, and of setting the curd at a low temperature. The milk is heated to only 78° or 80°, when the rennet is added, and no further heat applied until the curd is set and broken up. The curd is then heated to 100°, and the whey is drawn off before any acidity becomes apparent without the closest test by an experienced dairyman. The curd is then aired in the vat; this is, in fact, a process of oxidation, by which a certain degree of acid is produced. When this point is reached, the curd is gathered up and pressed for a few minutes, to get rid of the whey; then ground, salted, and put to press.

CHESHIRE.—The best is made from new unskimmed milk. Mix with the morning milk that of the preceding evening, previously warmed, so that the whole may be brought to the heat of new milk. To this add a little less rennet than is used for other cheese. A small piece of dried rennet put into 1 pt. of water over night, and allowed to stand until the next morning, is sufficient for 18 or 20 gals. of milk. The curd is now broken down and separated from the whey, after which it is put into a cheese vat and pressed very dry, then broken in small pieces, and mixed with a proper quantity of salt, and about ½ its weight of curd from the day before, kept for the purpose; now press the mixed curds, with the hands, into a cheese vat, previously lined with cheese cloth; press 4 or 5 hours, then take out, turn, and again put into the press, and leave for the night. Take out the next day; salt well, and leave until the salt is quite melted; then wipe dry and place in a dry, cool situation; turn every day, until it becomes fit for the market.

COLORING.—Spanish annatto, 3½ dr., is sufficient for a cheese of 50 lbs. weight. If a considerable part of the cream of the night's milk be taken for butter, more coloring will be requisite; the leaner the cheese is, the more coloring it requires; tie up in a linen rag the quantity deemed sufficient, and put it into ½ pt. of warm water over night; this infusion put into the tub of milk in the morning with the rennet infusion; dip the rag into the milk, and rub it against the palm of the hand as long as any color runs out.

COTTAGE.—Also called *Schmeer Kase* and *Clabber* cheese. Skim the sour milk on the stove in a milk pan, and let it gradually warm till it is lukewarm all through; stir it occasionally to prevent its hardening at the bottom; when it is a little warmer than new milk and the whey begins to show clear around the curd, pour it all into a coarse, thin bag; tie it close, and hang it up to drain; let it hang up 2 or 3 hours in a cool, shady place; then take from the bag the contents and put in a covered dish.

CREAM. — Procure some molds made of blocks of maple or beech, 6 in. long, 3 in. wide, and 3 in. deep, inside measurement. Mats of common green rushes are sewed together to fit into the mold; sweet cream, as thick as can be procured, is the material of which the cheese is made; the mold is laid upon a dish; a rush mat is placed at the bottom of the mold; this is covered with a piece of fine muslin, rinsed in brine; the cream is put into the mold, and a piece of muslin dipped in brine laid upon it; then a rush mat is laid upon the cloth, and a small block is laid upon the mat; this pressure is enough. The dish and all are set away in a cool place for 2 or 3 days, when it will have become compact, slightly acid and of a cheesy flavor.

DUNLOP.—When a number of cows are kept, so that a cheese of any tolerable size may be made every time they are milked, the milk is passed, immediately as it comes from them, through a sieve into a vat, and, when the whole is collected, it is formed into a curd by the mixture of the rennet. Where, however, the cows are not so numerous as to yield milk sufficient to form a cheese at each meal, the milk of another meal is stored about 6 or 8 in. deep in coolers, and placed in the milk-house. The cream is then skimmed from the milk in the coolers, and, without being heated, is put into the curd vat, along with the milk just drawn from the cows, and the cold milk, from which the cream has been taken, is heated so as to raise the temperature to about blood heat. If coagulated much warmer, the curd becomes too adhesive, much of the butyraceous matter is lost in the whey, and the cheese will be found dry, tough and

tasteless; but if too cold, the curd, which is then soft, does not part readily with the serum, and the cheese is so wanting in firmness that it is difficult to be kept together. When the utmost pains are taken to extract the whey, and give solidity to the cheese, eyes frequently break out, rendering them rancid or insipid. About 1 tablespoonful of the liquid rennet is generally thought sufficient for 25 gals. of milk, and the curd is usually formed by it within 12 or 15 minutes. The curd is then broken with the skimming dish, or with the hand, and the whey ought to be taken off as speedily as possible, though without pressing. When quite freed from the whey, and the curd has acquired a little consistence, it is then cut with the cheese knife, gently at first, and more minutely as it hardens, after which it is put into the drainer.

DUTCH. — Allow the milk to thicken, then heat gently over a fire in a large kettle, till the curd separates from the whey; then dip out into a colander, so that the whey can be pressed out of the curds as dry as possible; after the curds are pressed out, crumble up with the hands as fine as can be done; press them down in an earthen vessel; let it stand a few days till it becomes thoroughly heated; stir it throughout daily, afterwards pressing it down, so that every portion of it may become heated alike; now take it out, and salt to suit the taste; a small quantity of butter makes it richer, but it is not positively necessary, as it is very good without it. Take a deep basin, or basins; grease them well; press them even full of cheese, and set them in a stove or oven, and bake till they are slightly brown on the top.

FROMAGGIO DE GRANA.—Milk is poured into caldrons and placed on the fire. If mature, it is warmed to 88° Fahr.; if retaining the whiteness and sweet taste of freshly milked, it is heated to 90°. At this temperature, as tested by the hand, it is removed from the fire and mixed with rennet; ½ oz. of rennet is used for 720 qts. of milk. The rennet is dissolved with a pestle in wooden cups, and filtered through horsehair sieves, the oozing going into the caldron of milk. To prevent hardness, the curd formed is broken and turned with the cream turner; this is continued for ¾ of an hour, while concretions appearing on the surface are removed by hand. Turning is stopped for 2 or 3 minute intervals to consolidate, but not harden, the now softened or dissolved curd. The whey is removed, and ½ oz. of saffron for 110 qts. of milk, thrown into the caldron; the curd is replaced, and left for 1 hour on the fire heated to 122° Fahr., but not higher, and continually stirred. A cup is filled with the curd for examination as to the minuteness of its particles; if small enough, the caldron is removed, and the curd sinks and forms on its bottom. To hasten this, the cooled whey, before drained off to enable the adding of the saffron, is poured into the caldron, the bottom of which is pressed with the rotella, to unite and incorporate the curd. The curd is loosed with a stick from the sides of the caldron, lifted, drawn on the surface, collected in a cloth, placed and left for 1 hour in a vat, then wet with whey, and pressed for drainage, by hand, in a box of narrow beech boards, bound with hoops and packthread and covered with linen, a wooden disc and a heavy stone. When dried, these coverings are removed, and it is re-wet with whey, and then covered with buckram, which, under the pressure of the disc and stone, makes reticulated imprints on its circular surface; after some hours the buckram is cut, and the clippings removed to permit the whey to dry in; it is covered and rubbed on an oak bench with salt; dipped in salt water, and repressed between the beech-boards. It is re-salted every other day for 2 weeks.

FRIULANI. — Friulani cheese is made with milk tepified in heaters, and thence poured into wooden vats for coagulation. The curd formed, is wet, broken into large lumps, re-wet with hot whey or water, gathered, and pressed in wooden hoops.

GLOUCESTER.—The double Gloucester are made entirely from new, unskimmed milk; the single Gloucester, from ½ new and ½ skimmed. A smaller proportion than usual of rennet is used in turning the milk for these cheeses, and it is this that renders them so delicate and mild in flavor. They are often made up into large, round cheeses, from 100 to 200 lbs. in weight.

GORGONZOLA.—The milk, while warm from the cow, is well curdled with rennet. The quality of the cheese depends much on that of the rennet, and experience guides as to the quantity required. In 15 or 20 minutes, when the milk is coagulated, and the whey separated, the curd is hung in hemp cloth bags to drain. The morning-drained curd, inclosed in light, flexible wooden bands, covered on their inside surface with hemp cloth, is placed on an inclined board, strewn with rye chaff. Being of 2 milkings, the curd is partly warm, partly cold, and, though mixed, care is taken to form the upper and lower strata of the warm, because it is cementitious. As hot and cold curd never perfectly unite, minute interstices remain in the cheese, and, while maturing, green mold, known as parsley, forms and gives the stracchino the delicious taste for which it is famous. The curd is further drained during the first day of the process, by 2 or 3 turnings. On the following morning, when of some consistency, the cloth being removed, its value is determined by weighing. After 3 or 4 days, fermentation begins, and the wooden bands are removed; it is then, once daily, for 8 or 10 days, alternately salted on its upper and lower sides, 4 oz. of pulverized salt being, on an average, used per form of 33 lbs. The color changes in a month to pinkish-white, if good; to black, if bad; when black, the crust is soft and the cheese perishable in summer; if the crust is sufficiently hard, the shade is improved by 1 or 2 dippings in salt water. The time of maturity depends upon the temperature (which is best from 10° to 15° Centigrade), manner of making, and the quality of the milk.

GREEN or SAGE. — Steep over night in a proper quantity of milk, 2 parts of sage, 1 part of marigold leaves, and a little parsley, after they have been bruised; on the following morning the greened milk is strained off, and mixed with about ½ of the whole quantity intended to

be run or coagulated; the green and white milks are run separately, the 2 curds being kept apart until ready for vatting; these may be mixed, either evenly and intimately, or irregularly and fancifully. The management is the same as for common cheese.

NEUFCHATEL. — A variety of Swiss cheese. The rennet is added to the milk in pots, holding about 3 gals., at its natural temperature as it comes from the cow; various devices are resorted to for preserving this temperature in winter without warming the milk. The rennet being added to the milk, it is left for many hours for the curd to be fully deposited; the curd is afterward placed in a linen cloth, which is suspended from the 4 corners of a skeleton box, and it is then left several hours to enable the whey to drain off; it is then transferred to a clean cloth, in which it is carefully folded up, and is submitted to pressure for about 12 hours, or at least until the whey ceases to run out; but the pressure is neither very great nor very even; the curd is next passed through cylindrical molds, and the small cylindrical cheeses thus formed are at once salted on the outside; the cheeses being then made, are put into a cellar on boards, each one being quite separate from its neighbors; in a few days, more or less, according to the temperature, the first mold, thick and white, makes its appearance, and soon afterwards, especially in summer, the cheeses are sold fresh.

PARMESAN.—The cheese is made of the evening milk, after having been skimmed in the morning, and at noon, mixed with the morning milk, which is also skimmed at noon; both kinds of milk are poured together into a large copper caldron, of the shape of an inverted bell, which is suspended on the arm of a lever, so as to be moved on and off the fire at pleasure; in this vessel the milk is gradually heated to the temperature of about 120°, after which it is removed from the fire and kept quiet for a few minutes, until all internal motion has ceased; the rennet is then added; within about 1 hour the coagulation is complete, and then the milk is again put over the fire and raised to a temperature of 145°; during all the time it is heating the mass is briskly stirred, till the curd separates in small lumps, when a part of the whey is taken out, and a few pinches of saffron are added to the remainder, in order to color it; when the curd is sufficiently broken, nearly the whole of the whey is taken out, and 2 pailfuls of cold water are poured in; the temperature is thus lowered, so as to enable the operator to collect the curd by passing a cloth beneath it and gathering it up at the corners. It is now pressed into a frame of wood, placed on a solid platform, and covered by a round piece of wood fitting into the mold, with a heavy weight at the top. In the course of the night it cools, parts with the whey, and assumes a firm consistence. The next day, one side is rubbed with salt, and the succeeding day the cheese is turned, and the other side rubbed in like manner; this alternate salting being continued for about 40 days; after this period, the outer crust of the cheese is pared off, the fresh surface is varnished with linseed oil, the convex side is colored red, and the cheese is fit for market.

POTATO.—Potatoes of good quality are boiled in a caldron, and, after becoming cool, they are reduced to a pulp, by means of a grater or mortar. To 5 lbs. of this pulp, add 1 lb. of sour milk and the necessary quantity of salt; the whole is kneaded together and the mixture covered up, and allowed to remain 3 or 4 days, according to the season; at the end of this time it is kneaded anew, and the cheeses are placed in little baskets, when the superfluous moisture escapes; they are then allowed to dry in the shade, and placed in layers in large vessels, where they must remain for 15 days.

RASCO.—Cow's milk, when coagulated and lightly broken, produces a semi-solid excretion or discharge, which forms the essential substance of *Rasco* cheese. This is placed in hoops, slightly shaken, and dipped quickly 3 or 4 times in hot whey; removed, and replaced when sufficiently solid, upper side down, in these hoops, and there kept for 24 hours; slightly salted, and taken to cool, dry rooms for keeping. It is soft, white, and soluble at a low degree of heat.

RENNET, To Prepare for Cheese. — Rennet is employed to curdle milk, and is the fourth, or true digesting, stomach of the calf. A piece of the requisite size is cut off and soaked for some hours in whey or water, after which the whole is added to the milk for curdling. A large quantity should be made at a time, as it should never be used until it has stood at least 2 months. It is prepared for use as follows: 1. Take the maw of a newly-killed calf, and clean it of its contents; salt the bag, and put it into an earthen jar for 3 or 4 days, till it forms a pickle; take it from the jar, and hang it up to dry, after which it is to be replaced in the jar, the covering of which should be pierced with a few small holes to admit air, and let remain there for about 12 months; when wanted for use, a handful, each, of the leaves of sweet briar, dog-rose and bramble, with 3 or 4 handfuls of salt, are to be boiled together in 1 gal. of water for ½ hour, when the liquid is to be strained off and allowed to cool; the maw is then to be put into the liquid, together with a lemon stuck around with cloves; the longer it remains in it, the stronger and better will be the rennet; ½ pt., or less, of the liquor is sufficient to turn 50 gals. of milk.— 2. Fresh rennet, 12 oz.; salt, 2 oz.; proof spirit, 2 oz.; white wine, 1 qt.; digest for 24 hours, and strain; 1 qt. of milk requires 2 or 3 teaspoonfuls. The membrane of the stomach is to be cut with scissors and kneaded with the salt, and with the rennet found in the interior of that organ; the whole left in a cool place in an earthen pot, till the cheesy odor is replaced by the proper odor of rennet, which will be in 1 or 2 months; then add 16 parts of water and 1 of spirit; filter, and color with burnt sugar.

ROCHEFORT. — This is made of ewe's milk. The evening's milk is heated almost to boiling, and set aside; in the morning it is skimmed, heated to 98°, and mixed with the morning's milk for coagulation. After the curd has been divided, by stirring with a paddle, and the whey

drawn off, it is kneaded with the hands and pressed in layers into molds with perforated bottoms, and usually a thin layer of moldy bread, made of summer and winter barley, sour dough and vinegar, is put between the layers of curd to hasten the ripening of the cheese, by supplying the germs of the green mold peculiar to cheese. The curd remains under pressure for 3 or 4 days, after which the cheeses are wrapped in linen and put to dry.

SKIM MILK.—This article, made of milk from which the entire portion of the cream has been taken, is more or less palatable in proportion to the time during which the milk is allowed to stand. The milk should, if possible, not be allowed to become sour, and the moment it has been skimmed, it should be heated to no more than animal heat, or about 90°; for, if put together too hot, its toughness will be increased, and as the curd coagulates more readily than that of full milk cheese, the same degree of heat is not necessary. This is the chief perceptible difference in management, except that the curd is more difficult to be broken, and that the cheese needs less of the press; but in all other respects the mode of making is the same.

STILTON.—Put the night's cream, without any portion of the skimmed milk, to the milk of the following morning; those who wish to make it very fine add a still greater quantity of cream, and of course the richness of the cheese depends upon the amount which is used. Butter is also sometimes added. The rennet is then added without any coloring. When the curd has come, it is taken out without being broken, and put whole into sieve or drainer, where it is pressed with weights until entirely cleared of whey; when dry, it is put, with a clean cloth, into a cheese hoop, and placed under the press, the outer coat being first salted. When sufficiently firm to be removed from this mold, the cheese is placed upon a dry board and tightly bound in a cloth, which is changed daily in order to avoid all danger of cracks in the skin, until this is found to be tolerably well coated, after which it is no longer used, and the cheese requires no further care than being frequently turned upside down and occasionally brushed.

SWISS.—The milk, partly skimmed, or not, according to the quality of the cheese desired to be made, is put into a kettle over a gentle fire, where it is allowed to attain a temperature of 77° Fahr., when rennet is added to the milk. When coagulation has advanced far enough, the curd is cut into as fine pieces as practicable with a large wooden knife; the kettle is then swung over the fire again, and the curd is taken up in small quantities and poured back through the fingers, where it is still more finely divided. Great importance is attached to this division of the curd, in order that each particle may be fully exposed to the action of the heat in the "cooking" process, which ensues up to a point when the temperature of 90° has been attained; the kettle is then immediately swung off the fire, and the waste of curd and whey stirred for some 15 minutes longer; and if the cooking has been properly performed, the particles of curd have the appearance of bursted grains of rice swimming in the whey; the curd is then collected in a cloth, and great care is taken to expel all whey. The salting of the cheese is also considered a delicate and important process; the salt is rubbed from time to time on the outside of the cheese, care being taken to discern when enough shall have been absorbed.

MILK.

REMARKS.—Unless cows are fed with good, sweet, nutritious food, it will be folly to suppose that their milk will be good; and the best cows, well fed, will still furnish milk of an undesirable quality, unless great care is taken to keep them perfectly clean, and also particular attention paid to the keeping of the barn clean and free from bad odors, and all the vessels sweet and clean; for there are but few, if any, liquids that will absorb bad odors more readily than milk. Buttermilk is the liquid that is left after the butter or fatty matter has been separated from the cream. It contains the sugar, caseine, and salt of milk, and when it is procured from sweet cream, is both delicious and nourishing, besides being easy of digestion.

COW, To Milk.—Cow milking machines have been invented, but have not succeeded in displacing the hand as the best method. The udder should be washed before milking. The milker should work his hands rapidly, keeping up a constant flow till the udder is clean, when, except in severely cold weather, the milk will be crested with a fleecy foam. Cleanliness is one great point to be had always in view. The best time to milk is either before or after feeding; never while the cow is eating. Drawing the milk with a strong, downward pull—in fact with a jerk—should never be allowed; it irritates the cow, and often injures the bag. Fill the teat, and with a firm pressure of the last 3 fingers empty it, drawing slightly on the teat and udder at the same time; so proceed alternately with each hand until the milk supply is exhausted. The cow should be milked regularly and stripped quite clean. The milk will be thin in quality when near calving, and it is not customary to use the milk for some days after calving, as it is considered fit only for the calf.

SETTING.—Strain the milk into the cans and set them into cold water as fast as the cows are milked. The cans can be placed in a cream still, or in a trough, as described under *Dairy and Creamery, Construction of.* Never mix the night's milk with the morning's. If the cream is wanted for immediate use, enough will rise in 2 or 3 hours; for butter, let it set at least 24 hours; 36 is the time in which all the cream will rise.

SKIMMING.—The cream should be taken off

either early in the morning or in the evening after sunset. Take it off carefully and neatly with a skimmer; deposit it in clean stone crocks or tin pail, if for butter, or in the cream jug, if for immediate use. If the cream is for supper, skim that from the morning's; if for breakfast, skim the evening's milk.

SOURING, To Prevent.—To prevent the milk souring by thunder storms, start a fire in the dairy; this should be done even in the hottest weather. Another good remedy, which answers at all times, is to add to each qt. 15 gr. of bicarbonate of soda. A thin iron chain, passed through the milk pans, and the ends of the chain kept in cold water, will prevent souring.

"ON THE CONTRARY, I FEEL QUITE LIGHT."

HEAVY LIVE STOCK.

REMARKS.—The laws which govern the raising and management of the brute creation for the service of man need to be well understood by the farmer, breeder and user of all descriptions of live stock. The demand for improved breeds is constantly growing, and no department of farm work is more profitable. It is the effort in the following pages to give comprehensive and practical, though condensed directions in all important particulars. In the descriptions given of the different breeds of all the animals, will be found sufficient to guide in selection for specific purposes. It should be here remarked that the greater humanity (or analogy of treatment between what is accorded to domestic animals and what would naturally be given to a human being) that is exercised in the health or diseases of all, the greater the success in stock raising. It is apt to be forgotten that there is a close analogy between the physical structure and requirements of both man and beast; that whatever psychological differences may exist, both possess bones, sinews, muscles, senses, organs of nutrition, absorption, circulation and respiration; and last, though not least, brain and nerves susceptible to fright, exquisite pain, and intelligent teaching. It therefore follows, that success with the animal creation depends largely on common sense and the observance of the golden rule, which is the attribute of all true humanity.

GESTATION OF ANIMALS.—

KIND OF ANIMAL.	Proper Age for Reproduction.	Period of the Power of Reproduction.	No. of Females for 1 Male.	Period of Gestation and Incubation.

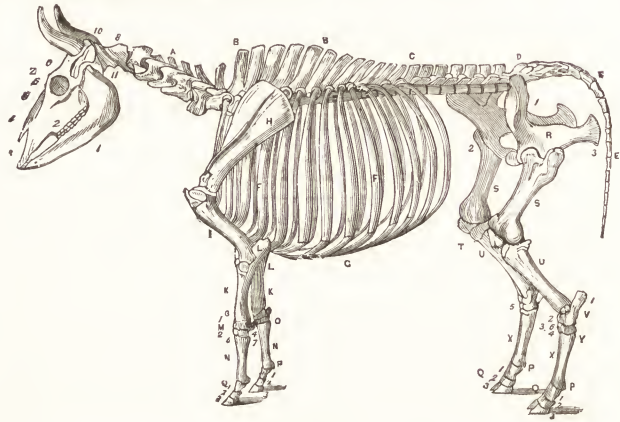
CATTLE.

A YOUNG castrated male bullock, after the 1st year, is called a stot, stirk, or steer; at 5 years old, an ox. A female, after the 1st year, is called an heifer, or quey; at 5 years old, a cow; and afterwards a castrated female is called a spayed heifer or cow. Bullock is the general term for any full-grown cattle, male or female, fat or lean.

ANATOMY.

BONY STRUCTURE. — The skeleton is the foundation of the animal, upon which is built and attached the muscles and other soft parts. These are then all covered by the skin. The only weapons of offense and defense used by a bullock are the horns, which are very firmly attached to the frontal bone. The whole skeleton of the animal is admirably adapted to its purposes—to

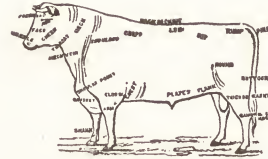
its usually peaceful and sluggish habit. A good form of bullock is solidly rectangular, from whatever point it is viewed. Massiveness and strength of foundation and superstructure, are the prevailing characteristics. The following illustration shows the location and scientific names of the principal bones of cattle.



Skeleton of the Cow.

A, cervical vertebræ; B, B, dorsal vertebræ; C, lumbar vertebræ; D, sacrum; E, E, coccygeal bones; F, F, ribs; G, costal cartilages; H, scapula, 1, humerus, K, K, radius; L, ulna; M, carpus, or knee; 1, scaphoid; 2, semilunar; 3, cuneiform; 4, trapezium; 5, trapezoid; 6, os magnum; 7, uneiform; 8, pisiform; N, N, large metacarpal, or cannon; O, small metacarpal; P, P, sesamoid bones; Q, Q, phalanges; 1, os suffraginis, or pastern bone; 2, os coronæ; 3, os pedis; R, pelvis; 1, ilium; 2, pubis; 3, ischium; S, femur; T, patella; U, tibia; V, fibula; W, hocks; 1, os calcis; 2, os tragalus; 3, cuneiform magnum; 4, cuneiform medium; 5, cuneiform parvum; 6, cuboid; X, large metatarsal; 1, 2, 3, phalanges; Y, small metatarsal; Z, head; 1, inferior maxilla; 2, superior maxilla; 3, anterior maxilla; 4, nasal bone; 5, molar; 6, frontal; 7, parietal; 8, occipital; 9, lachrymal; 10, squamous; 11, petrous.

POINTS. — The accompanying illustration shows the points of cattle. In judging of, or selecting an animal, the following will be found useful: The animal's flesh should be elastic to the touch, having the power to replace the parts when pressed. The skin should be thick, soft, and elastic, thus allowing room for the animal



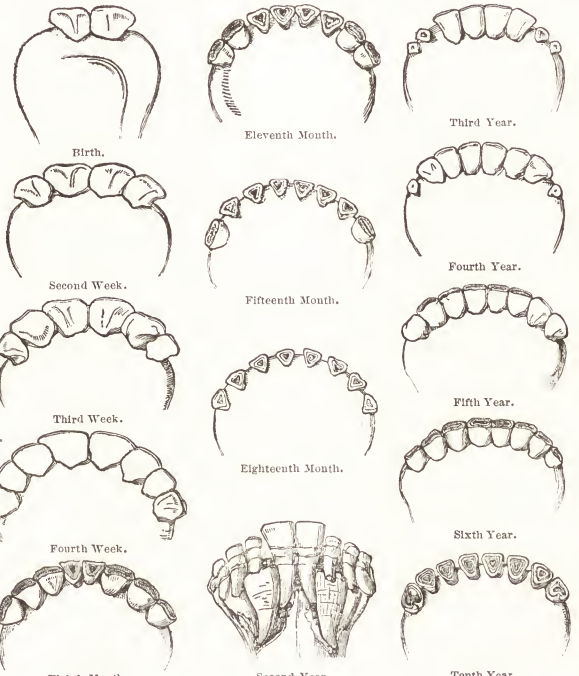
Points of Cattle.

to fatten. The general form of the body should be square; the back straight, and the belly nearly so; the flanks low; ribs, barrel-shaped; the rump, long and wide, and the loins wide; the thigh, long and wide, and the back wide; legs, short and small, standing well under the animal, and the hocks directly in line with the body; tail, light; hair, fine, color unimportant; the head should be small and wide above the eyes; small, dark, eyes, surrounded by a circle, with large face above, show a vicious and bad-tempered animal; a bright, yellow circle around the eyes is a good indication; the eyes should be quiet, yet bright; the lips thin and the nostrils elastic; ears, medium size; neck, strong and muscular upon its sides, covering the points of the shoulder well at the base; it should be long enough to allow the taking of food easily. If the animal is broad in the crops, it shows a good back, and also a good rib beneath the shoulder-blade, thus giving width to the chest and greater play to the lungs.

RINGS ON HORNS, To Determine Age by. — The ages of horned cattle may generally be known by the rings on the horns till their 10th year; but after that time they give no indication of age further than that the animal has passed its 10th year. The 1st ring appears on the

horn after the animal is 2 yrs. old. During the 3d year the ring gradually increases, and at 3 years of age it is completely formed. The 2d ring appears during the 4th year, and at the end of the 5th year it is complete. After that period an additional ring is formed each year.

TEETH, To Determine Age by.—The calf is generally born with 2 fore or cutting teeth; 2 central incisors has begun to wear, the osseous portion of the tooth appearing where the enamel is abraded; this increases, and in the course of 2 months, the next teeth will begin to show signs of wearing, and in about 3 months the next in succession; till, in the course of 4 months, or a little more, the whole set show the effects of use, but the 4 central teeth by far the most decided-



Age of Cattle Shown by the Teeth.

at the close of the 2d week, a tooth on each side of this central pair cuts the gum, making the number 4; at the end of the 3d week the number will be increased to 6; at the termination of the 4th week the full number of the deciduous, or milk incisors, will be complete. At this time the upper line of the sharp edges of the

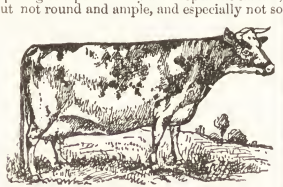
ly. At this time, independently of their wearing down by attrition, the 2 central teeth begin to diminish in size; at first this is not very perceptible, but, in the course of a few months, the change will be very palpable. This diminution is the result of a process of absorption, which goes on with increased rapidity as the

new teeth, in their nutrient cells beneath, become more and more developed; the worn surface of the teeth in question assumes a triangular form, with an oblique inclination inwards, the osseous portion appearing as a distinct central mark. At the age of about 8 months the diminution and wearing down of the 2 central incisors is very decided; and before the close of the 12th month, the next incisor on each side will show the same appearance, and the 4, instead of being close together, will be separated from each other, especially at their base; at the close of 15 months the number of teeth thus diminished by absorption, worn by use, and separated from each other, will extend to 6; and at the close of 18 months the whole 8 will appear as little worn rudiments. During these changes the ox experiences increasing difficulty in cropping herbage, and from this cause, and the action connected with the formative process of the permanent teeth, the animal is subject to many disorders and is liable to become out of condition, especially where the herbage is not abundant and succulent. Still these rudiments of teeth remain for some months, their decrease continuing, first more especially in the 2 central teeth; till at the commencement of the 2d year the 2 central permanent teeth shoot up and push out the mere relics of their predecessors. Towards the close of the 2d year the next incisor on each side takes the place of its temporary predecessor; at the close of the 3d, the next in rotation succeed. The corn, or milk teeth, give place at the close of the 4th or beginning of the 5th year, to their successors; the last teeth obtained are smaller than the rest, and can scarcely be said to be fully grown until a few months have elapsed. The whole set is complete, but while the outer teeth have been growing, the 2 central permanent teeth first, and then the next, have been wearing, and show the marks of attrition, which, at the age of 6 yrs. will have extended to the whole set. The teeth become flattened at the top with a dark, central mark, bounded by a line of bone, and this by the layer of enamel. As yet the 4 middle teeth are the largest; but, again, by slow degrees, a change takes place, and the process of absorption and wearing down goes on. First the 2 central teeth show this, then the next on each side, till at the age of 10 the 4 middle teeth are smaller than the outermost 2 on each side, which, nevertheless, are greatly worn. The animal has then turned the grand climacteric, and the teeth continue more and more to show the ravages of age. At 16 the ox is old, but there are many instances in which the cow will give milk to the age of 18 or 20.

BREEDS.

ALDERNEY.—This breed is almost identical with the *Jersey*, which see.

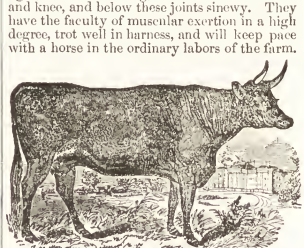
AYRSHIRE.—This breed has been much improved. It is short in the leg, the neck a little thicker at the shoulder, but finely shaped towards the head; the horns are small, but clear and smooth, pointing forwards and turning upwards, tapering to a point. They are deep in the carcass, but not round and ample, and especially not so



Ayrshire Cow.

in the loins and haunches. The Ayrshire cow is a valuable dairy cow, the quantity of milk yielded by her being very great, considering her size; 5 gals. daily for 2 or 3 months after calving, may be considered as not more than an average; 3 gals. daily will be given for the next 3 months, and 1½ gals. during the succeeding 4 months; 3½ gals. of this milk will yield about 1 lb. of butter.

DEVON.—Well recommended for workers and for beef, but not for milk. Their shoulders have that obliquity which enables them to lift freely their fore extremities; and their quarters behind are relatively long. Their bodies are light, their limbs long, muscular to the hock and knee, and below these joints sinewy. They have the faculty of muscular exertion in a high degree, trot well in harness, and will keep pace with a horse in the ordinary labors of the farm.



Devon Cow.

The horn of the Devon bull ought to be neither too low nor too high, tapering at the points, not too thick at the roots, and of a yellow or waxy color. The eye should be clear, bright and prominent, showing much of the white, and it ought to have around it, a circle of a variable color, but usually a dark orange. The forehead should be flat, indented and small, the purity of the breed being very much determined by the latter characteristic. The cheek should be small, the muzzle fine, the nose clear yellow, the nostril high and open, the hair curled about the head, and

the neck quite thick. Excepting in the head and neck, the form of the bull does not materially differ from that of the ox, but he is considerably smaller. There are few things more remarkable about the Devon cattle than the comparative smallness of the cow. The bull is a great deal less than the ox, and the cow almost as much smaller than the bull. But though small, the Devon cow possesses that roundness and pro-

Devon Bull.

jection of the last 2 or 3 ribs, which renders it more roomy than a careless examination would lead one to suppose. She is particularly distinguished for her full, round, clear eye, the gold-colored circle around the eye, and the same color prevailing on the inside skin of the ear; countenance cheerful, muzzle orange or yellow, but the rest of the face having nothing of black, or even white, about it; jaws free from thickness, and the throat free from dewlap. The points of the back and the hind quarters differ from those of other breeds, having more roundness and beauty, and being free from most of those angles by which good milkers are sometimes distinguished.

FRIESIAN.—These are a Dutch breed, and at home are valued both for beef and milk; but, in this country, milk is the object. As bred here, the best are black and white, very large, well-

Friesian Cow.

formed, broad and deep, wedge-shaped, with enormous udders, which are very well quartered and placed; fine bones, with long heads, broad muzzles, thin withers and thighs, and of enormous digestive capacity.

GALLOWAY.—The Galloway cattle are a hornless breed, native to Scotland. They are a medium-sized, compactly built, beef cattle, mature early, and have good flesh; in color mostly black, occasionally red and red brindled. They have not been esteemed specially as dairy cattle.

GUERNSEY.—Similar to the *Jersey*, which see; has richer milk and more highly colored butter; it is also larger, making a very fair animal for the butcher, when well fatted.

HEREFORD.—The countenance cheerful, pleasant, open; the forehead broad; eye full and lively; horns bright, tapering and spreading; head small; chap lean; neck long and tapering; chest deep and full; bosom broad and projecting forward; shoulder-bone thin, flat, full and mellow in flesh; loin broad; hips standing wide and level with the chine; quarters long and wide at the neck; rump even with the level of the back, and not drooping, nor stand-

Hereford Cow.

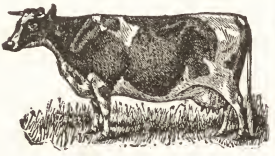
ing high and sharp above the quarters; tail slender and neatly haired; barrel round and roomy; the carcass throughout deep and well spread; ribs broad, standing flat and close on the outer surface, forming a smooth, even barrel, the hindmost large and full of length; round bone small, snug and not prominent; thigh clean and regularly tapering; legs upright and short below the knee; hock small; feet of middle size; flank large; flesh everywhere mellow, soft, and yielding pleasantly to the touch, especially on the chine, the shoulder and the ribs; hide mellow, supple, of a middle thickness, and loose on the neck and huckle; coat neatly haired, bright and silky; color a middle red, with a bald face, characteristic of the true breed. They fatten to a much greater weight than the Devons, and at an early age. They are far worse milkers, but will thrive and grow fat where a Devon would scarcely live. A cross of the Devon and Hereford will

Hereford Bull.

often improve each other, the former acquiring bulk and hardihood, and the latter a finer form and activity. The Hereford cow is apparently a very inferior animal. Not only is she a poor milker, but her form is defective, small, delicate

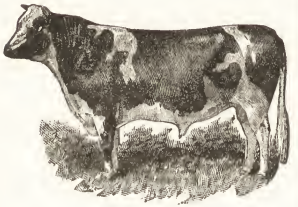
and ill-made. She is very light-fleshed when in common condition, and beyond that, while she is breeding, she is not suffered to proceed; but when she is actually put up for fattening, she spreads out and accumulates fat at a most extraordinary rate. The Hereford ox fattens speedily at a very early age, and it is therefore generally more advantageous that he should go to market at 3 yrs. old than to be kept longer to be employed as a beast of draught.

HOLSTEIN.—This breed has been introduced into this country from Holland, where they have been bred for centuries for dairy purposes.



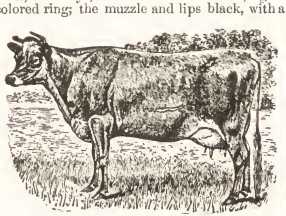
Holstein Cow.

They are large, resembling the shorthorn somewhat in shape and size; black and white in color, and great milkers in quantity and quality.



Holstein Bull.

JERSEY.—The Jersey is well fitted to thrive in all climates, and upon all kinds of food. She is singularly docile, with the graceful head of a fawn, a soft eye, surrounded with a clear, light-colored ring; the muzzle and lips black, with a



Jersey Cow.

light band above, and crumpled horns; the skin is very thin, of an orange color; the ears small and thin, and lined with a deep orange tinge. The limbs of the Jersey cow are very slender and fine; her hips broad and well developed; her neck graceful and rather long; body rotunded with sufficient angularity to insure milking qualities; the veins full and prominent; the udder broad, running well forward and well up behind; teat squarely placed and of a fine yellow tint. For butter making, the Jersey is now the most popular breed among those who take an interest in improved stock. The cows

Jersey Bull.

of this breed are remarkable for their gentleness, their graceful form, and especially for the richness of their milk. They do not give so large a quantity of milk as other improved breeds, but much more than the best common cows; 4 gals. is not considered an extra yield for a Jersey, and this will make 2 lbs of butter.

NEW LEICESTER.—The fore end long, but light to a degree of elegance; chap clean; the head fine but long and tapering; eye large, bright and prominent; the horns of the bulls comparatively short, of the oxen extremely long, as are also those of the cow, and most of them hang downward by the side of the cheeks; shoulders fine and thin as to bone, but thick as to flesh, without any protuberance of bone; girth small compared with the short-horns and middle-horns; chine quite full when fat; loin broad; hip quite wide and protuberant; quarters long and level, the nache of a middle width, and the tail set on variously; round bones small, but thighs fleshy, tapering; legs small, clean, somewhat long; feet neat, middling size; the carcass as nearly a cylinder as the natural form of the animal will allow; ribs standing out full from the spine; belly small; hide middling thick; the color quite varied. The fattening quality, when the breed is in a state of maturity, is indisputably good. As beef stock, they rank high. The principle of the utility of form has been strictly attended to. As dairy stock, their merit is less evident. As beasts of draught, many of them are sufficiently powerful, and are more active than some other breeds used for the plow or on the roads; but their horns form an objection to such use of them.

POLLED ANGUS. — The Angus cattle are black, but at times the evidence of other colors in ancestral breeding will show itself. Their size does not equal the shorthorns, but their

flesh is perhaps unequalled wherever known. They are rivals of the Durham in hardiness, and thus peculiarly fit for exposure on the range. On account of having no horns they are of great merit in shipping; a car will hold 2 more steers, if they are hornless.

RED POLLED NORFOLK.—These are an English breed. They are excellent as dairy cows, and resemble the Devons in their deep red color, and in the fact that they are remarkably good beef cattle also, on an average surpassing that breed as milkers, and not quite equalling

Red Polled Norfolk Cow.

them as economic beef producers. The thoroughbred bull calves sell quickly at high prices for use on the plains. The grade calves are usually hornless, and much more tractable, less dangerous, and less liable to hurt one another when shipped on railway cars.

SHORTHORN, or DURHAM.—This is an English breed, and is one of the most popular imported into this country. In color they are red, red

Shorthorn or Durham Cow.

Shorthorn or Durham Bull.

with white spots, roan, or pure white. They attain a greater size than any other breed, mature early, and make most excellent beef. They are also good milkers, but are bred almost exclusively for their beef.

SUSSEX. — The points wherein the Sussex cattle seem to excel other breeds, consist in their size, deep flesh, thick (though supple) skin, hard hair, and activity; but they carry an excess of horns, and are unamiable animals.

SWISS.—These are hardy milk givers, bearing all the vicissitudes of weather, and yielding rich and abundant milk. Among these breeds is one of a silver-gray color, like one of the most fashionable colors of Jerseys, and in fact resembling

Swiss Cow.

them in other points also—the mealy muzzle, the richness of the milk, etc. The cows are stronger boned and carry more flesh than the Jerseys, and will sometimes approach the average short-horn in weight; 20 quart cows are common, and those giving 28 to 30 qts. are not very rare.

BREEDING AND REARING.

REMARKS.—In breeding, always have a definite aim in view. Indiscriminate breeding always leads to poor results. When a line is established suitable for the purposes in view, continue in that line and work each change of the sire, producing a grade higher in the same line than before. In this way the good qualities of a breed may be perpetuated, and desirable characteristics cannot be maintained without. The breeder of cattle should know that blindness is an hereditary disease, and that the progeny of a bull that has any defect of sight is very apt to become blind.

BULL.

AGE, Procreating. — The age at which bulls should be employed, and the number of seasons they should be allowed to serve, are points regarding which practice is by no means uniform. Sometimes the bulls are pretty commonly allowed to leap while yearlings, and if good stock getters, are kept on as long as they can serve, perhaps till they are 10 or 12 years old; in some places they are employed only 3 seasons, for the first time at 2 yrs. old.

BREEDING-IN.—If milk be the object, select

a yearling bull from a good stock of milkers; if beef be the object, select one with barrel-shaped ribs, well sprung out and ribbed close to the hips, and with large loins, rump and thighs. (See *Choosing the Bull.*) For this bull select from the best cows on the farm, 10 2-year old heifers. The result of this intercourse will be 10 calves; castrate the bulls when about 3 or 4 weeks old. When the heifers are 2 yrs. old, they should be bred to their sire, and the offspring of this union again bred to the same animal, and this continued through 4 generations, if the bull still remains vigorous. The 4th generation will inherit 15-16 of the blood of the sire. Select from these the strongest and most vigorous, and follow this down through the intermediate grades, but keep the families distinct. Great care should be exercised in breeding closely, and whenever the feeding qualities or constitutional vigor seem to be impaired, breeding-in should be discontinued. If the progeny does not improve in the essential qualities, take what is called a "line cross," by choosing another sire with the same qualities as the old sire; this is called "breeding-in." Breed this bull again with select heifers for 2 generations; then take another line cross similarly as before.

CHOOSING THE BULL.—In the bull, the head should be well set upon a broad, deep, muscular neck; having the horns short and not too bright; the ears long, and situated near the head; the inside skin have an orange tint; the forehead should be broad at this point, with a somewhat concave appearance between the eyes; the eyes themselves large, mild, lustrous and prominent; fine flesh-colored muzzle, with nostrils well dilated; the shoulder blades well set toward the rib behind, and yet stretching out finely toward the "crop," leaving no deep hollow between it and the ribs; chest deep; ribs well rounded, and stretching backward to the hip bone, so as to leave no very wide space there; the breadth between the hip bones proportionate to the length from them to the point of the fleshy rump, and tail set on within this outline; the thighs should be well developed and touching each other inwardly to near the hock; the skin covered with thick, soft, somewhat curly hair, and should be to the touch, when the animal is in store condition, soft, elastic, mellow and pleasant; but when the animal is fully fat, the skin itself should be very firm, resisting and resilient to the pressure, like the feel of a well distended hair cushion.

CROSS BULL, Treatment of.—Never pat a cross bull about the head. A firm command, promptly enforced, is the only treatment he should receive; over kindness makes a bully of him.

STABLING.—Keep bulls constantly well fed and in proper inclosures. If designed for breeders, they should be kept as much as possible in an open lot, and not in the stable or box-stall, and should be kept in only in very bad weather, and then only during the prevalence of a storm. Exercise in the open air is conducive to strength, while lying on the ground has a tendency to keep the system cool, which is necessary when an animal is living on stimulating food. Attention must be paid to the feet of bulls kept up, as the hoofs are apt to grow too much, and inconvenience them in walking.

Cows.

AGE FOR BREEDING.—It is best to bring heifers into breeding condition as soon as possible after they are a year old. The first calf should come at 2 yrs., or soon after. To effect this the calf should be well fed after weaning, have good pasture in the summer, with a mouthful or two of bran daily, to push them forward. Unless the calf has been pushed in this way, it will be slow in breeding until it is 2 yrs. old. After the birth of the first calf, the heifer should be coupled with the male again in from 60 to 90 days, and not sooner, so that she may produce the second calf just a year after the first, and so on through her entire breeding period. The great majority of cows cease to breed at the 12th yr., but some have been known to breed when they were 15, 16, 17, or 20 yrs. old.

CALVING, Season for.—The most desirable season for putting cows to the bull is midsummer, in order that the calves may be dropped in the spring, and have the whole of the grass season before them, thus becoming sufficiently strong for enduring the change to a dry food the ensuing winter. Where no regular system is followed, and the cows are sent to the bull merely because they are in heat, calves will be dropped at all seasons. A calf, newly weaned, seldom thrives well during the cold period, unless it is pampered with better food than usually falls to the share of young animals. By midsummer the cows are readier to take the bull than at any other season, and will bring calves in proper time. If a cow goes till after May before she calves, the calf will be too weak the winter following, and the dam will not be so ready to take the bull again, but will often grow barren.

CALVING, Treatment before.—Prevent all excitement to the system. Keep the cows in fine condition during the period of non-lactation; feed very sparingly just before coming on, giving only cooling food; the food richest in muscle-forming elements, and poorest in heat and fat-forming elements, is called cooling food. Nice clover hay, malt sprouts, a little bran, etc., may be given, but no food very rich in oil or starch. But if a pt. of oil meal has been given through the winter, no harm will come of continuing this small quantity, for this is cooling food and slightly loosening, but must be given very cautiously near calving. A roomy stall or loose box should be provided, in which the cow may remain at night without being tied. Milch cows should be milked up to within 4 weeks of calving. Be particular not to allow coming-in cows out among young cattle and oxen, where they may be injured; and do not drive them over ice or allow them to drink a great amount of water.

CALVING, Treatment during.—The average duration of pregnancy is 280 days; but various causes may prolong or shorten this period by a a week or two. When, from the enlargement

of the udder and vulva, and the spreading of the hips, her time is evidently near, the cow should be secluded in some sheltered yard, or in a box stall in the barn, where she may be quiet, and as free as possible from noise and other disturbing influences. If not delivered within an hour after labor pains are fairly established, her case should be examined, and, if necessary, assisted. And, in order to render intelligent aid, the first requisite is to understand the natural and proper presentation; then, in what respect there may occur deviations and how these deviations can be remedied: 1. The natural presentation is that of the 2 fore feet, and the nose following along between them. All the malpresentations, where help is needed, are those in which 1 or both feet, or the head, fail to come forward, and are turned back or on one side—except 2 or 3 breech presentations, which will require separate notice. In order to assist the delivery, or even to examine thoroughly what the presentation is, the hand and arm must be introduced; and, in order to do this, the cow must be supported in a standing posture, and with the hind feet preferably a little higher than the fore feet; because it is almost impossible to introduce the arm when the cow is lying down. Before introducing the hand and arm, the presenting part, whatever it is, should be noosed with a strong cord or small rope, in order that it may not be lost while the fœtus is being pushed back during the operation; for, during the introduction of the arm of the operator, either for examination or for operation, the fœtus must be pushed back. — 2. If, therefore, on examination, one foot does not come forward, or the foot and the head are both turned back or to one side, first move the presenting foot, then push back the fœtus, introduce the hand and arm, noose the other foot and also the head, by putting the cord in the calf's mouth or around his jaw, and pull gently and steadily, till these parts are brought as nearly as possible into the position of a natural presentation; taking special care in all cases to interpose the hand between the hoof of the fœtus and the cow's womb, as you draw the hoof forward, so as to avoid laceration of the womb by the sharp point of the hoof. — 3. As to breech presentations, the one least dangerous is where both the hind feet present. In this case, the chief danger is to the life of the calf; for, unless the labor is hastened as much as possible by a judicious pulling of the presenting limbs, and a lifting of the buttocks of the calf over the rim of the cow's pelvis by the hand of the operator, there is great danger that the calf will suffocate in consequence of the long pressure on its navel-string before its head can be delivered so as to enable it to breathe. The calf lives, either by the pulsations of its navel-cord or by breathing; if, therefore, these pulsations are stopped by pressure, the calf must breathe within about 4 minutes, or suffocate. The other 2 presentations of the breech, where the hind feet of the fœtus are either turned backwards and up against the loins of the cow, or downwards towards her belly, are remedied by introducing the hand and arm, noosing the hind feet, and drawing them as nearly as possible into the breach position, first mentioned, and then delivering as speedily as possible. There is one more presentation, and it is the worst possible—that of the neck or shoulder of the calf, while its feet are turned towards the cow's abdomen. This is usually owing to hydrocephalus and ascites, or head dropsy, and abdominal dropsy of the fœtus; and delivery can only be accomplished after letting out the water, first, by a short trocar plunged into the calf's head, and then by a long one to reach its abdomen. A dead fœtus is, of course, the result.

CALVING. Treatment after.—The calf should not be taken away immediately, and the mother should be allowed to cleanse its offspring in its own way. After calving, the food should be light and cooling. The oil meal may be increased to 1 qt., as it is desired to keep the bowels open. Feed 1 pt. of oil meal through the winter. Simple hay and a thin bran slop is sufficient for 6 or 8 days after calving, as it is necessary to ward off all danger of milk-fever in fleshy cows. After the system has recovered from parturition, then the food should be gradually increased up to a full ration. It is usual to take away 1 qt. of the first milk, called the "beastings," before the calf is allowed to suck. After this the young animal may be allowed access to the cow, but regulated by the plan of suckling, or bringing up, on which the raiser may determine. The calf should remain with the mother during a few days at least, or until the milk is proper for the purposes of the dairy; 9 months in 12 is as long as any cow should give milk. In case the animal becomes too fat, exercise, and not starvation, should be used to reduce her.

CHOOSING FOR BREEDING.—Extra milkers should be kept to breed from, their milking qualities alone entitling them to this preference. More attention should be paid to what the cow has done and can do, than to the fact that its parents through a long line may have their names in the herd-book.

SEX AT WILL.—The practicability of this is maintained by Fiquet. The following are experiments which led to his conclusions: Choosing 8 cows, he fixed upon 1 from which he desired a bull calf, the other 7 were to produce heifers. Having carefully noted the dates of the periods of the 8 cows he allowed them to pass 1 œstrum, and thus was able to anticipate the return of the period in each. The cow destined to produce a bull calf came in first. Mr Fiquet began to feed her most bountifully upon grain, corn, oats, meal and rich hay. A few days before the reappearance of her period, she was withdrawn from the herd and well stabled. As anticipated, her passion came strongly. The bull, meanwhile, had been fed upon green and cooling food, which moderated his usual passion, and the difference between the animals was plainly discernible. His theory was, that the cow being far more desirous for the bull than was the latter for the cow, nature was thus calling more loudly through the female than through the male for the natural gratification of her desires; that the services of a male were more necessary than that of a female. This he supposed to be the desired

disturbance of a uniformity in nature, and consequently, that in her very economy nature required the production of a bull calf. The cow was served by the bull twice, and the result was the desired bull calf. The remaining 7 cows were submitted to a castrated bull, who, though impotent, served as a never failing detective of the periods of the cows. Previous to his introduction to each of the cows, the other bull was generously fed on various rich grains and clover hay. On the other hand the several cows were kept cool by light food—grazing, green fodder, and bran. When their periods arrived, the animals were allowed to run temporarily with the castrated bull, and their frenzy was thus partially allayed. Being finally coupled with the service bull, the conditions in each case were a rampant bull and a moderately excited cow—the reverse of the conditions in the first experiment. The bull, being more anxious for the cow than the cow for the bull, the result was the birth of 7 heifer calves.

SUCKING BY CALF, Injury from.—Allowing a calf to suck long after birth is a great injury to a cow. The udder of a young cow, thus treated in the full flush of her yield, loses capacity to hold a large quantity of milk, if it ever had it, and older cows, becoming accustomed to the steady half-hourly draughts of the calf, fall off in their yield rapidly after the calf is sent to the market. Calves, it is true, usually fatten better on the cow than as fed in general practice in this country, but the practice is wrong. Take the calf away when 4 weeks old; it can be fattened after that even on skim milk, if properly cared for.

TWINS.—Cows seldom bring more than one calf at a time. When they produce twins, one of them a male and the other a female, the latter, which is called a "free martin," is commonly considered incapable of procreation, though there are a few instances to the contrary.

CALVES.

CARE IN GENERAL.—The calf should be allowed to suck for a day or two to get enough of the mother's milk to physic it. Then shut it up in the apartment assigned. Fasten up, at a proper height, a V trough large enough to hold 2 gals. It is no use to offer a calf milk until it has fasted 24 hours. When the calf gets hungry it will generally be little trouble to teach it to drink. For a week or 10 days give the calf new milk; then substitute warm skim milk, with a little flaxseed tea or oil meal added. When the calf is about 4 weeks old, put a little shelled corn in its trough, and it will soon learn to eat it. It is essential in feeding to change the food as much as possible and to have it of a nourishing quality. A good substitute for milk is bean soup, made thin enough to drink, to which has been added cornmeal and a small portion of salt. If it is possible to add milk to the bean soup, it will be much better for the calf. For older calves the following mixture is good: 100 lbs. wheat middlings; 50 lbs., each, of corn, oats and linseed cake meal, ground together. Give 1 qt. a day of this in a dry state to a calf on pasture after it is weaned from milk. Salt should be given sparingly to young animals; but plenty of water must be supplied. After grain has been cut, calves may be turned into fields that have been seeded to clover and true grasses, to excellent advantage. At first they should be allowed the range of a field of young clover a few hours at a time, and should be supplied with some dry food to prevent bloat or hoven.

CASTRATION.—If bull calves are to be raised for beef or draught, the best time to castrate is when they are about 4 weeks old. Tie the calf's head close to a post or fence; or the animal may be thrown on its left side for the operation. Grasp the scrotum in the hand, between the testicles and the belly, and make an incision on one side of it, near the bottom, of sufficient depth to penetrate through the inner covering of the testicle, and long enough to admit of its escape. The testicle immediately bursts from its bag, and is seen hanging by its cord; compress the blood-vessels with ligatures, and prevent after hemorrhage, and thereby save a great deal of unnecessary torture by including them alone in the ligature, and afterwards dividing the rest of the cord. The other testicle is proceeded with in the same way, and the operation is complete. The length of the cord should be so contrived that it shall immediately retract into the scrotum, but not higher, while the ends of the string hang out through the wounds. In the course of about a week the strings will usually drop off, and the wounds will speedily heal. It will be rare that any application to the scrotum will be necessary, except fomentation of it, if much swelling should ensue. Another mode is as follows: The spermatic artery is exposed, and seized with the forceps, which are then closed by a very simple mechanical contrivance; the vessel is drawn a little out from its surrounding tissues, the forceps are turned round 7 or 8 times, and the vessel liberated. It will be found perfectly closed; a small knot will have formed on its extremity; it will retract into the surrounding substance, and not a drop more blood will flow from it; the cord may then be divided, and the bleeding from any little vessel arrested in the same way.

SPAYING.—If the heifers are to be raised for beef, it is best to spay them; i. e., to remove the ovaries, when 1 yr. old. Get 3 ropes, 16 ft. long, and $\frac{3}{4}$ in. thick; tie a 2 in. iron ring in the end of 1 rope; take $\frac{1}{2}$ in. rope, 30 in. long; put a 2 in. ring on it and tie the ends together, making a loop 12 in. long; tie the animal to a tree or post, by putting a rope on its head, also by a rope on the left hind leg, below the hock, to another post; put the long rope through the ring around the right fore ankle; put the short rope around the right hind leg, with the ring through the loop for a pulley; now pass the end of the rope on the fore leg through the ring on the hind leg, and then under the belly to the left, where it is pulled hard, while a man on the right pulls the tail to the right. Now grasp the flank, and push it downward. Cut a gash through the hide into the red flesh; make the gash about 4 in. long; draw the skin and mem-

brane back 2 in. toward the hip; stick a knife through the flesh at this point into the abdominal cavity; with the right thumb and left forefinger tear an incision to admit the hand to feel for the ovaries; remove them with curved, pointed scissors; then sew up the cuts by the skin only, and smear the wound with pine tar.

STABLING.— When they are suckled, if the stable be roomy enough, stalls are erected for them against the wall behind the cows, in which they are usually tied up; or they are put into large loose boxes at the ends of the stable, and unfastened at stated times to be suckled. When brought up by hand, they are put into a separate apartment from that of the mother, and each confined in a crib, where the milk is given to them. The crib for each calf should be 4 ft. square and 4 ft. in height. Abundance of light should be admitted, either by windows in the walls or skylights in the roof; thorough ventilation and a regular supply of fresh air should also be attended to. The crib should be fitted up with a manger to contain eut turnips or carrots, and a high rack for hay, the top of which should be as much elevated above the litter as to preclude the possibility of the calf getting its feet over it.

General Management.

BREACHY CATTLE, Treatment of.—When cattle jump out of inclosures, take an old headstall with a browband, throat-latch, and noseband, going all around the nosc; get an old boot-leg, (or any piece of leather that is wide enough to extend beyond the eyes), split it open, and with copper rivets fasten this to the browband and the noseband. The animal can see in front of him by bending to the right or left, but he will never jump with his neck bent, or when he can not see his way clear.

BREAKING OXEN TO THE YOKE.—It is best to begin with them as calves, and let the boys play with them, and drive them, tied or yoked together, taking care they are not abused. When a pair of old steers are to be put together and broken to the yoke, or a pair of bulls, it is best to yoke them and tie their tails together, in an extempore stall, in a well-fenced yard, and then turn them loose in the yard, which should not be large enough for them to run in and get under much headway. If the tails are not tied together, they will frequently turn the yoke, which is a very bad habit. The daily lesson should be given after they have stood yoked a while. They should not be taken from the yard until they have become used to the yoke, and are no longer wild and scary. All treatment should be firm but mild, and no superfluous words should be employed.

COOKING FOOD.—Connected with the cattle sheds and feeding yards, there may be an apartment for boiling or steaming food, in which a steaming apparatus is placed. For this purpose our illustration shows a good form. The boiler is so constructed as to generate steam in a few minutes. The water barrel or tank is connected with the boiler by 2 pipes; the upper one conveys the steam into the barrel, thus forcing the water through the lower pipe into the boiler. The lower one is provided with a cock, by which the flow of water is stopped at pleasure. The pipe on the other side of the boiler connects with the cooking apparatus, conveying the steam to the food to be cooked. To cook corn for cattle, soak as many barrels, ½ full, as are desired, from 15 to 24 hours; turn these at the end of this time into the cooking apparatus; turn on the steam, and cook until done. To make mush, fill the barrel ½ full of water, and bring it to a boil; then stir in from 1½ to 1¾ bus. meal, until well mixed; then cook till done. To cook vegetables in general, fill the barrel full, chop the top fine with a shovel and cover with meal; then

Apparatus for Steaming Food.

cook till done. To cook hay, put a false bottom in the barrel; press down the cover tightly, after the hay has been cut, wet and put in. Pass the steam under the false bottom. Warm water may constantly be had from the boiler, and the superfluous steam may be usefully applied for heating, and other purposes of domestic economy.

FASTENING CATTLE IN THE STABLE.—When a farmer is about to build a barn or stable for his cattle, the question always arises which method of fastening is best, for there are various devices in use and each one has its advocates. The old fashioned stanchion seems to be the most popular; but better than any other mode of fastening are proper stalls. Cows, as well as man, must be allowed a change of position to be comfortable and continue healthy. These requisites can not be had, if the cattle are fastened. If stalls are not used, a humane way to fasten the cattle is as follows: Use small posts, 4 by 6 in., set up where the stanchion would be, 3 ft. 2 in. from centre to centre. On the inside of these posts, 14 in. above the floor, drive a ⅝ staple, 12 in. long, into each post. A ¼ inch cable chain, stretching from staple to staple with a ring on each end, slides up and down on the staples, and has a ring in the middle to which the cow is to be fastened; a leather strap, 1½ in. wide, with a strong breast

strap slipped on, is placed around the cow's neck and riveted on with 3 small copper rivets. The cow is brought between the 2 posts, and the snap fastened to the ring in the middle of the chain, which holds the cow in the centre between the 2 posts, but the slack of the chain, and the chain slipping back and forth upon the neck, enables the cow to move forward and backward, to turn her head, and she may lick or scratch herself from shoulder to rump; when she lays down, it may be in the natural position with her head upon her shoulder. The cow carries the strap upon her neck, and it is not as much work to fasten her as with a rope.

FATTENING.—The age at which cattle are fatted depends on whether they are being employed in breeding, in labor, for the dairy, or solely for the butcher. In the latter case the most improved breeds are fit for market when about 3 yrs. old, and very few of any large breed are kept more than a year longer. As to cows and working oxen, in most instances the latter are put up to feed after working 3 yrs., or in the 7th or 8th year of their age. When fattening an animal for beef, let the process be as quick as possible. Any stint in feeding will make the meat tough and dry. Fattening stock will thrive most when fed only such a quantity as will be eaten readily with good appetite. A variety is desirable. One feed daily should be some esculent, as potatoes, turnips, or beets. Feed and water should be given at regular times, by one feeder, who will soon learn what each animal requires, and salt must be placed where they can take it at will. An ox may be fatted on hay and potatoes, boiled, and given half warm with cornmeal. Give 1 bus. of potatoes and 8 qts. of meal daily, and all the hay that will be eaten clean. Feed 4 times a day and give water only moderately. Another good fattening ration is made as follows: 8 bus. of corn, soaked in 10 pails of water 2 days; then simmered for 1 hour or so; afterwards mixed with 14 lbs. of coarse, cheap sugar or glucose, and mixed with cut straw, hay or other fodder. It is often necessary to dry up the milk when cows are wanted speedily to fatten, and this is sometimes found difficult with large animals. The best time is very early in the spring, when they are eating dry food. A good dose of physic, followed by mild, astringent drinks, will usually dry her, especially if she is moderately bled before the physic is given. The cow may be milked clean when the astringent is given, and then turned on some dry, upland pasture; 2 days afterwards she should be examined, and if the udder is not overloaded, hard or hot, the milking may be discontinued; but, if the udder is hard and full, and especially if it is hot, she should be milked clean, and another astringent drink given. The common method of fattening calves is to allow them to suck. The period necessary varies from 5 to 9 weeks, the time being much shorter where milk is very valuable. Another method is, to give them the milk to drink, morning and evening, warm from the cow; the quantity increased according to their age and strength. They should be kept in pens in a close house, well littered, kept clean, and enjoy a due quantity of fresh air. Meal, linseed boiled into a jelly, and such like articles, are also given to calves while fattening.

FEEDING MILCH COWS.—Grass is the best milk-making food. In summer give the cows plenty of good, rich pasture, free from weeds, and plenty of water. The transition from summer to winter food should be gradual; as the grass becomes shorter, give hay in increasing quantities. For milch cows, barley meal is probably better than any other, when fed alone. Equal quantities of corn, oats and barley, mixed and ground together with the same weight of wheat bran added that there is of each kind of grain, makes the best kind of feed. The meal for cows in cold weather, should be scalded, using enough water for the purpose to make it like thick porridge, and fed to them while it is warm. Bran or ground feed is best fed to cows upon moistened hay; it being mixed with the hay, all will be eaten together, and mixed and masticated. But, if it is not fed with cut hay, it should be fed dry and in a small quantity each time. The drumhead cabbage and cotton-seed meal are the richest vegetable substances that can be given to a milch cow. The disagreeable flavor liable to be imparted to the milk by the cabbage, may be removed by dissolving 1 oz. of saltpetre in 1 qt. of spring water, and mixing ¼ pt. of it with 10 or 12 gals. of milk, as it comes from the cow. Cotton-seed, 1 qt., combined with bran and cornmeal, of each 3 qts., then mixed with hay and thoroughly saturated, makes a splendid feed, given twice a day. If the cow shows a desire to chew old bones, give her phosphate manures. If 30 lbs. of pumpkins are fed to a cow each day, the yield will be increased; but more should not be given.

HEIFER, To Break.—If in winter, it is best to milk in the stable, make as little fuss and as few alarming motions as possible; handle her very gently. Be careful not to pinch the teats. A cow naturally wishes to be rid of her milk. She stands quietly until some careless milker has given a squeeze that hurts, when she kick and runs. The best way to manage, if you have no stable, is to have a well-fenced yard, and teach the heifers to stand for milking in that; or, next best, to tie them, using them very quietly. As a rule, by letting the calf suck 2 or 3 days and milking at the same time, with patience and gentleness, heifers will become docile to the milker, and stand even quietly untied in the open yard to be milked. Occasionally comes the exception. In that case, loop a rope around the near hind leg above the ankle, and draw it back till it becomes impossible to bring it near the pail or to disquiet the milker, milking with both hands. At first the animal kicks ferociously, but daily it grows less, till all becomes quiet, when it will do to make a trial of the heifer without the rope. The heifers should be daily handled and petted, and made so familiar with the persons who have them in charge as not only to show no fear, but exhibit a fondness for persons and a desire to be caressed.

HOOKING FENCES, To Prevent.—Take ½ in. annealed wire 10 in. long, make a ring in one end 1½ in.; grind the other end sharp, and punch through the gristle into the nose. The animal's head has to be fastened securely in the stanch-

fons in order to bore the holes through the horns, which should be done with a $\frac{3}{8}$ bit; then punch

To Prevent Cows from Hooking Fences.

the wire through and make the same sized ring in the sharp end. Now take a cord that will run easily through the holes in the horns; tie one end to the ring on one side and pass the cord through the holes in the horns to the other ring. The wire should be bent above the nostrils to prevent the breath from the nostrils rotting the cord. The cord should not be very tight when put on, as it will shrink a little.

JUMPING FENCES. To Prevent.—Nail a horse-shoe on one forward foot. This prevents the hoof from spreading, and renders the animal unable to spring. Make it a rule, whenever cattle are made to pass a fence, whether through bars or slipgap, to leave 1 rail for them to pass under. This gives them a downward tendency, and lessens their inclination to jump or look upward, as they are sure to do when a lazy attendant throws down part of the rails, and makes them vault the rest.

MILCH COWS, Selection of.—A good native cow should yield an average of 7 qts. of milk per day for 10 months, that is, equal to about 2,000 qts. in the year; of this, if she is a good cow, and well fed, 160 or 170 lbs. of butter should be made, or about 5 lbs. a week. A good Jersey cow should give about the same amount of milk, but twice as much butter. A cow is in her prime at from 4 to 6 yrs., and the best paying time to buy is just after the birth of her second or third calf. A good milch cow should have a thin, hollow neck, light fore quarters, with little dewlap; a well-rounded chest; broad loins and hips, and not show indications of putting on fat. The udder should be full and round, yet thin to the touch, and of equal size and substance throughout. If it shows more behind than before, it is deemed a sign of the milk falling off soon after calving, and if it feels coarse and lumpy, the bag will be found not to contain a large quantity. The teats should stand square, at equal distance, and should neither be very large nor thick towards the udder, but nearly equal, yet tapering. Draw milk from each teat to see that it is in good working order. When the large vein running forward from the udder on the belly just under the skin, called the milk vein, is very large, crooked, and enters the abdomen through a hole that will allow the entrance of a man's finger; it is a sign that the cow will yield a large quantity of milk. The famous Guenon system of judging of the value of cows for milk by the "escutcheon" or "milk mirror," is an external mark on cows, whereby their good qualities or defects may be known. Great diversities exist among cows in respect to the shape of the bearded ears, or quirls, which produce the dandruff found in spots on her hind parts, where the hair grows upward. Escutcheons are different in size, shape and quality of the skin and of the hair growing on them. These differences indicate the different milking qualities of the cows, including quantity and quality of milk, and the length of time they will give milk after being with calf. On the edges of the escutcheon, where the upward and downward growths of hair meet, a feather is formed, and this is most conspicuous on the back part of the thighs, where escutcheons extend that wide. The hair on the escutcheon is shorter and softer than elsewhere, and sometimes nearly resembles fur. There is one general shape to which they

A Good Mirror.

The Best Mirror.

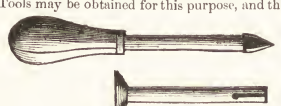
conform, they are wider below than above, and at or near the top of the udder they narrow in abruptly; some continue up as far as the vulva, and even above it, and others but a little distance above the udder. The larger the escutcheon, the better. All great milkers have very large escutcheons. In large ones the upturned growth often begins on the belly, in front of the udder, extends along between the teats and up the back part of the udder, over the whole width. A good escutcheon is symmetrical. The feathers on the two thighs are at equal distance from the middle line of the body and extend up to equal heights on the back part of the thighs. A broad and high escutcheon indicates a superior milker. There is nearly always another sign accompanying such an escutcheon, and that is one or two ovals just above the hind teats, on which a fine coat of hair grows downward. These may be large or small, may be one or two, and may be alike in size, or unlike, but they are always good signs. Two are better than one, and the larger and more uniform they are, the

better. **The quality of hair and skin of the escutcheon** indicates the quality of the milk. There are 10 classes and 6 orders to each class of escutcheons. To each class one more is added called the "bastard." The first 4 orders of each class and the marks of the bastard are all that require notice. The classes are as follows: 1st class, or Flanders; 2d class, or left Flanders; 3d class, or Selvage; 4th class, or Curveline; 5th class, or Bicorn; 6th class, or Double Selvage; 7th class, or Demijohn; 8th class, or Square Escutcheon; 9th class, or Limousine; 10th class, or Horizontal. The orders in each of these classes are designated by their appropriate numerals. Each class is better than the succeeding one, and each order better than the following one of the same class, but may be better than the preceding order of the next class.

MILK, Holding Back, To Prevent.—Place a weight on the back of the cow while milking her, or lay a wet rag on her back.

PASTURING.—The best grass for pastures is orchard grass. This stands the drought beyond all the good grasses, and is never seriously hurt. Besides, it is an early grass, and will maintain itself in a late growing season, on good soil, pushing forward very rapidly, making 1 in. a day. It is also highly nutritious and relished by stock. Pastures that have been fed a few seasons will generally produce more milk or make more fat than those which have been newly seeded down. Mow orchard grass 3 times in a season, and in October an aftermath will be had, which furnishes good pasture. The meadow pasture can be kept in good condition by this method, if it is occasionally re-seeded, harrowed, and other varieties mixed in. Do not cut too low, and add a light top-dressing of some fertilizer after cutting. The following is a good plan to follow in pasturing, in case of a scarcity of land: Plant a strip 14 rods long and 4 rods wide, with timothy and clover, which cut twice, and sometimes thrice a season. As soon as it will do to cut, feed it regularly to the cows twice a day, and it will last till the corn is ready to use. Plant a strip 14 rods long and 10 rods wide with sweet corn for fodder; make the stalks about 2 in. apart in the row; plant at 3 different times, so as to have it early and late. About the 1st of July commence to thin it out, leaving about 1 stalk per ft. Soon after, commence cutting it up clean. When ½ cut up, plow the ground and sow winter rye; sow the balance as soon as the corn is on. This makes good pasture late in the fall and early in the spring. The average amount required in this case is 2½ acres to one cow.

RINGING. — Bulls should have a good ring placed in their nose before they are 1 year old. Tools may be obtained for this purpose, and the



Tools for Ringing Bulls.

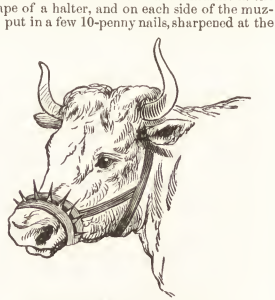
ring is easily inserted. Whittle a piece of wood that it may be placed in the nostril to meet the blow to be given to the punch; let an assistant hold the wood in place; tie the bull securely; then place the punch in the opposite nostril; give it a smart blow, and then put the ring in the hole thus formed.

RUBBING POSTS.—There should be posts set up in the pasture for cattle to rub themselves, and they will use them and thus save the fences and gate-posts.

SELF-SUCKING COW, To Cure. — 1. Take a halter, with a nose-piece just tight enough to allow the cow to eat well; fasten on each side, with wire, sticks made of good hickory, 2 ft. 3

Device to Prevent Self-sucking.

in. long; make a girth of No. 9 wire, with eyes bent a little above the middle of the sides, to which fasten one end of short wires, 10 in. long; fasten the other ends to the sticks; place a leather pad under the wire on the back. —2. A good device is as follows: Make a muzzle in the shape of a halter, and on each side of the muzzle put in a few 10-penny nails, sharpened at the



Device to Prevent Self-sucking.

points. —3. A good method is to take a stick about the size of a large pitchfork handle and about 3 ft. long; insert in or near each end, stap-

les, such as are used on light neck-yokes for 2-horse buggies; put a strap, long enough to reach around the cow's neck, through 1 staple, and one long enough to pass around the cow's body, just back of the fore legs, through the other staple; buckle the shorter strap around the neck; pass the other end of the stick between the cow's fore legs and buckle the surcingle around the girth, both rather loosely.—4. If their teats are rubbed frequently with strong, rancid cheese, it will prove an effectual remedy.

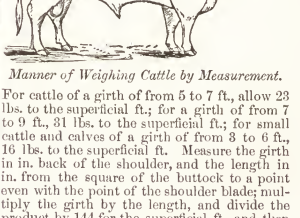
SHADE AND SHELTER.—To cattle in summer time left to roam about sunburnt pastures, a few shade trees are a luxury. There are generally odd corners where trees may be left to advantage, especially a wet place, perhaps near a spring, where a willow would grow. A shed, open to the north side, will furnish a great protection to the cows that are kept in the pasture through the day, and provide safe shelter from sudden showers.

STABLING.—Cleanliness should be the rule, instead of the exception, in the case of the stable, and the animal should be kept clean by the use of a card and brush. The bedding should be frequently renewed; the fodder in the bin kept fresh, and not allowed to become moldy and emit foul odors. The floors should be kept swept, and occasionally be allowed the privilege of the hose; but the stable must be kept dry. Cows need plenty of air and a warm temperature. If they have not a warm shelter, they consume an unusual amount of food to keep warm. A temperature of 45° should be maintained. Very good ventilation can be secured through the windows or small doors, placed at intervals in the walls in front of the cows. These small doors can be swung up so as to let in more or less fresh air, as the wind and weather may demand. The air should always come in near the cows' heads, where they can breathe it, and the outward ventilation should be in the rear, through tunnels running up in the walls; or, if the cattle stand in 2 rows, running up from the alley-way between them. Care should be taken that there be no perceptible draught on the cows. For keeping cow stables clean and sweet, fine, dry earth is superior to any other bedding. It absorbs all smell, and saves the loss from evaporation of the liquid manure. Dry sand is another good bedding; it is easily procured, and acts as an absorbent. Sawdust, however, is considered the best; it makes a more comfortable bed, completely absorbs the urine, and the cow is kept clean with less labor than when anything else is used. All animals, to be kept in good health, must have exercise and sunlight. The light of all stables should come from behind, never from the front.

SOILING.—The meaning of the word "soiling," as understood among cattle feeders, is the practice of confining animals to the stake or small lots, and feeding them on green clover, corn, grass, etc., cut as needed, and not allowing stock to graze on the ground where the food grows. By this system, land may be utilized which would be kept barren by the cattle being constantly pastured on it. The crop can be much more easily manured to better advantage, and a careful rotation of crops is kept up; also, a more uniform system is provided as regards quantity.

TETHERING.—This mode of pasturing saves the fence and grass. A tether chain, 20 ft. long, with a leather headstall, by which the chain is fastened to the cow, and an iron peg to drive into the ground, are all that are required. The cows should all be pegged in a line; then they will eat in a circle. Move them forward a few feet at a time, so as to give only a narrow strip of grass at the end of their chain. They thus stand principally on the ground eaten over. When the cows have eaten across the field, bring them back, and repeat the process. If a pole is used in place of a chain or rope, as far as the animal's body extends, and a piece of rope to admit of the animal holding its head up, is attached to one end, and the desired length of chain to the other, there is no danger of injury by tangling.

WEIGHING CATTLE BY MEASUREMENT.—To obtain the girth, pass a cord around just behind the shoulder blade, under the fore leg; to find the length, measure along the back from the foremost corner of the shoulder blade, in a straight line to the hindermost part of the rump.



Manner of Weighing Cattle by Measurement.

For cattle of a girth of from 5 to 7 ft., allow 23 lbs. to the superficial ft.; for a girth of from 7 to 9 ft., 31 lbs. to the superficial ft.; for small cattle and calves of a girth of from 3 to 6 ft., 16 lbs. to the superficial ft. Measure the girth in in. back of the shoulder, and the length in in. from the square of the buttock to a point even with the point of the shoulder blade; multiply the girth by the length, and divide the product by 144 for the superficial ft., and then multiply the superficial ft. by the number of lbs. allowed for cattle of various girths, and the product will be number of lbs. of beef in the four quarters of the animal.

TREATMENT OF DISEASE.

REMARKS.—When cattle stretch themselves on rising from the ground, and when they chew the cud, they are well and hearty. When their coats stare, and their eyes are dull, if the nose is dry and scurfy, and especially if their hide sticks close and hard to the ribs, pass the hand

with something of pressure along the back; if they shrink down from the touch, they are ill; have either caught cold, or have internal disorder coming on, which, taken in time, may be checked by warm nursing and a dose of salts, well seasoned with some cordial mixture, or with ginger. As soon as an animal is discovered to be unwell, let it be placed in a house by itself; this is necessary, both for the welfare of the sick animal and for the safety of others. The house that the animal is placed in, ought to be warm, well lighted and ventilated, and kept scrupulously clean. In acute diseases, no food ought to be given until improvement has taken place, and then only in a sparing manner; the articles of diet most suitable are, bran, oats, hay, carrots, turnips, and green food, either grass or clover; the bran may be given either dry or wetted, whichever way the animal prefers; oats may be given mixed with the bran, either raw and crushed, or whole and boiled; it is necessary to keep the animal without food or water ½ hour before and after administering medicine. In acute diseases, it is necessary to repeat the dose every 5, 10, 15, or 20 minutes; in less acute diseases, every 2, 4, 6 or 8 hours; in chronic diseases, once in 24 hours is sufficient. Physical symptoms and diseases of the brute creation should be treated generally on the same principles as those in man. There is no more mystery about the ailments of one animal than another. With the exception, perhaps, of cattle, the quantities of doses should be proportioned to those given to man, as weight to weight, somewhat reduced for safety. Cattle have 4 stomachs, and need to be treated with medicine in larger quantities, and always in fluid form, so that it may pass from one stomach to another without injury and in the shortest possible time. Similar rules of proportion should also be followed in the administration of doses to early ages of animals, to those given in *Administration of Doses* in MEDICINE.

ABORTION.—The premonitory signs are an irritable, excited state of the animal, staggering when walking, a discharge from the vagina, looseness and fullness of the external organs of generation, and occasionally sudden enlargement of the udder. Abortion may be caused by fright, injury, improper food or water, a diseased male, and commerce with him after conception. *Treatment*: These symptoms may continue for several days, and if noticed before straining or other signs of calving have appeared, the animal should be placed in a comfortable loose box, away from the herd, kept as quiet as possible, moderately supplied with soft, laxative food, and, if the bowels be costive, with 1 or 2 lbs. of molasses daily. Powerful purgatives are too irritant, and must be avoided; 2 oz. of laudanum, with the same quantity of sweet spirits of nitre, should be given twice a day, until all danger is over.

ALBUMINURIA.—This corresponds to Bright's disease in the human system, and is caused by impoverished blood in consequence of low diet. There is generally constipation, straddling gait, stiffness, and the urine is thick and dark. *Treatment*: If the bladder is full, evacuate it. Regulate the bowels and kidneys by giving 1 dr. of blue mass at night, and the following the next morning: Epsom salts, ½ lb.; sulphur, 4 to 6 oz.; ginger, ½ oz.; gentian, ½ oz.; warm water, q. s.; and with injections, when necessary. Make also a complete change of diet. If it still continues, give 1 dr. of muriated tincture of iron (tincture of chloride of iron) in ½ pt. of water, 3 times a day.

ANEMIA.—This is a weak condition of cows, and is sometimes called poverty of blood. The symptoms are whiteness and clearness of the lining membranes of the nose, mouth and eyes. When this condition occurs as an effect of some disease, the animal will become hectic, and die in a month or so from the first attack. *Treatment*: Give the following powders, night and morning, in cut feed: 3 dr. powdered gentian root; 3 dr. powdered ginger root; mix, and make into 1 dose. If these powders improve the animal in a week, give 2 dr. sulphate of iron in addition. The iron may dry up the milk considerably.

ANGLE BERRIES.—Little warty tumors, growing on various parts of the skin, which sometimes become very sore. *Treatment*: 1. Tie a piece of waxed silk firmly around the base of each, and tighten it every day; the tumor will drop off, and rarely grow again; there will be no bleeding, and the neighboring parts will not be inoculated. — 2. If attended to before they have reached any considerable size, they will gradually disappear when they are daily touched with nitrate of silver, either in substance or in the form of a strong solution; strong nitric acid will answer the same purpose.

APOPLEXY.—In this disease the animal drops suddenly, and is incurable.

BLACK-LEG.—The symptoms are: Extension of the neck, red eyes, hot breath, dry muzzle, quick pulse, heaving, moaning, loss of appetite, and lameness. *Treatment*: Give a strong purgative dose, composed of 1½ lbs. Epsom salts, 1 pt. linseed oil, and 3 pts. water. A seton, occasional doses of physic, and frequent careful examinations by the owner, are better than all else to prevent this disease. The following drench has been recommended: 1. Sweet spirits of nitre, ½ fl. oz.; powdered cascarilla, 2 oz.; solution of acetate of ammonia, 4 fl. oz.; yeast, 8 fl. oz.; given every 3 or 4 hours. — 2. Laudanum and sweet spirits of nitre, of each, ½ fl. oz.; solution of chloride of lime, ¼ fl. oz.; prepared chalk, 1 oz.; warm gruel, 1 pt.

BLADDER, Inflammation of.—In cows that are near parturition, a discharge of urine is not infrequent, which arises from irritation of the bladder, caused by the pressure of the fœtus, or from sympathy with the uterus, now much excited, and not from actual inflammation. When the cow has calved, this will gradually cease. *Treatment*: If it continues, give a dose of salts, followed by 1 or 2 of the following powders: Antimonial powder, 1 sc.; camphor, ½ dr.; nitre, 1 oz.; mix; and give twice a day in gruel.

BLADDER, Prolapsus of the.—Among cows, during and after difficult calving, there will be sometimes observed a white, shining, watery bag protruding between the lips of the vulva;

this is the bladder; it is twisted at its neck, and cannot be emptied. *Treatment*: Carefully examine the distended bag, its shape and size. Having determined that it is the bladder, carefully cleanse it, if dirty, and pass the hand, previously oiled, along its surface, ascertaining which way the turn or twist is made; then take the bladder by the other hand, and reverse the turn or twist, and carefully push it back into its place. Should it again protrude, plug up the vulva, for 1 or 2 hours, with a roll of soft cotton cloth. If this is not sufficient, with a small packing or darning-needle, pass a suture of stout saddler's silk, or other strong material, through each side of the vulva, and allow it to remain for a few days.

BLAIN.—The animal appears dull and languid, the eyes red and inflamed, with tears trickling from them. A swelling begins about the eyes, and occasionally appears on other parts of the body; there are generally blisters under the tongue or at the back part of the mouth; the pulse is quicker than natural; there is more or less heaving of the flanks; and the bowels are sometimes constipated; there is often a copious flow of saliva from the mouth, mixed often with a purulent, bloody, stinking discharge; the animal becomes extremely weak and reduced, and is in danger of being suffocated by the rapid enlargement of the tongue. *Treatment*: Cut deeply from end to end, the bladders that are found along the side of and under the tongue; they will appear to be filled with a glutinous matter; although there may not be much bleeding from them at first, considerable bloody fluid will gradually ooze out, the swelling of the mouth and head will subside, and the animal will be very much relieved. If much fever has accompanied the enlargement of the tongue, give a physic drink. Wash the mouth with a solution of chloride of lime in water, in the proportions of 1 dr. of the chloride to 1 pt. of water, while the mouth is very offensive; and with equal parts of tincture of myrrh and water afterward, to promote the healing of the ulcer. Thin gruel should always be placed within reach of the animal, and plenty of thick gruel administered with a horn.

BLOODY MILK.—Results from violent jerking of the udder, racing about, a blow, cold in the organ, or other similar accidents. Some heavy milkers are subject to it occasionally. *Treatment*: 1. Freely bathe the udder and flank with cold water until soreness departs, and milk regularly and gently. — 2. Give 8 oz. of salts, or 4 dr. of saltpetre, or both together.

BONE DISEASE.—*Treatment*: 2 oz. bone meal in 1 pt. bran, 3 times a week, during early summer and fall feeding, accompanied by plenty of salt, will cure this disease.

BOWELS, Inflammation of.—Sometimes called *Enteritis* and *Fardle-bound*. The animal is continually lying down and getting up again immediately, and, when up, strikes at its belly with the hind feet; the bowels are obstinately constipated; the dung, if any is voided, is in small quantities, hard, covered with mucus, and sometimes streaked with blood; the urine is generally voided with difficulty; the pulse is quicker than natural, and there is much heaving at the flanks. It is distinguished from colic by the great degree of fever that attends it, the muzzle being dry and the mouth hot. The animal becomes speedily weak, falls or throws itself down suddenly, and when it rises, does it with difficulty, and staggers as it walks. The lowness and weakness appear more speedily and decidedly than in almost any other disease. *Treatment*: For the pain and inflammation, give doses of calomel and opium, 2 or 3 times daily—calomel ½ dr.; opium 5 gr. Give for a purge: Epsom salts, 1 lb.; hot water, 1 qt.; dissolve, and add linseed oil, 1 pt.; to be repeated in 6 hours, till the bowels are well relieved, with injections of warm gruel. In very severe cases, bleeding will sometimes aid the operation of the medicine.

BRAIN, Inflammation of.—This is due to overfeeding in long, wet grass or clover, and distension of the stomach. *Treatment*: Give 1 lb. of Epsom salts and 1 lb. of table salt, dissolved in 4 qts. cold water, and sweetened with molasses. Apply ice to the forehead, warm water bandages to the legs, and tightly clothe the body.

BRONCHITIS.—This is inflammation of the windpipe and its branches. In no case of pure bronchitis is the breathing painful, but short and quick, the thoracic as well as the abdominal muscles being brought into full play; this distinguishes it from the breathing characteristic of pleurisy, in which the ribs are more or less fixed and the respiration abdominal. In ordinary cases of bronchitis, the animal is dull, listless, sometimes semi-comatose; hangs its head; is generally thirsty; ropy saliva fills the mouth, which is hot and moist; the visible mucous membranes are affected, and present a varying degree of lividity, due to non-oxidation of the blood; the animal stands in a corner, or moves listlessly about. If in a box, and the door be open, it stands with its head to the open air, from which it evidently obtains relief; the bowels are generally somewhat constipated, the feces covered with mucus; the urine is high colored and scanty. *Treatment*: Give tincture of aconite, 3 times a day, 25 drops to a dose, when there is fever. Give once or twice daily, ½ oz. of commercial sulphuric acid, mixed in ½ bucket of cold water. Apply warm poultices of slippery elm, on the surface of which is sprinkled powdered lobelia, to the throat; and give internally as an expectorant, tablespoonful doses of tincture of lobelia 2 or 3 times a day, as long as the cough is tight.

CATARRH.—*Treatment*: In slight cases, house and give a dose of Epsom salts. In malignant cases give a mixture of Epsom salts, 12 oz.; ginger, 1 oz.; gentian, 1 oz.; syrup, 4 oz; and water, q.s. Then administer the following: Whisky, 2 oz.; iodide potash, 2 dr.; gruel, 1 pt.; powdered cinchona, 1 oz.; give as 1 dose. Foment the head with hot water and rub in the following: Oil of turpentine, 1 oz.; linseed oil, 1 oz.; liquor ammonia, 1 oz.; mix.

CHOKING.—In choking, the accumulation of gas (chiefly sulphurreted hydrogen) is the cause of the animal's death. *Treatment*: This gas can be decomposed by forcing a strong solution of salt and water down the animal's throat; or force the beast to jump over the bars

of a gate or fence; when she touches the ground on the opposite side, the obstruction will be ejected. Another way, is to use 4 or 5 ft. of $\frac{3}{4}$ in. rubber hose, and push the obstruction down. If the obstruction is low down, and this operation be attempted, 1 pt. of olive or linseed oil should be first turned down the throat, which will lubricate the parts and greatly assist the operation. The power applied must be steady, but not violent, for if the gullet is torn, the rupture is generally of serious consequence. Or a hollow tube may be used, and after the obstruction has passed into the stomach, the tube should remain for some time to permit the escape of the gas. A dose of chloride of lime or ammonia may be given, and the animal kept on fluid diet for several days afterwards, to prevent a recurrence of the choking.

Malignant Catarrh.

CLUE-BOUND. — An affection of the third stomach of cattle, induced by their unduly partaking of coarse, indigestible food. The symptoms vary greatly in intensity, and are often some days before they definitely manifest themselves. The animal ceases to ruminate, refuses food, and, if a cow, the secretion of milk is stopped. Then, after a day or two, fever (indicated by heat and dryness in the nose and mouth) comes on, with somewhat quickened circulation and breathing, the breathing by the second or third day being accompanied by a grunt at the beginning and end of respiration, which is very noticeable when an attempt is made to move the animal. *Treatment:* $\frac{3}{4}$ lb., each, of Epsom and common salt, 20 croton beans, and 1 dr. of calomel, will suffice for a full-grown, middle-sized ox or cow, and must be administered in 3 or 4 bottles of water or very thin gruel. In this disease there is little fear of giving too much medicine.

COLIC.—The animal is evidently in pain, and appears very restless; it occasionally turns its head, with an anxious gaze, to the left side, which seems to be distended more than the right; there is an occasional discharge of gas from the mouth and anus. *Treatment:* Powdered aniseed and powdered cinnamon, of each, $\frac{1}{2}$ teaspoonful; mix, and give in 1 qt. of spearmint tea. Repeat if necessary. If the animal suffers much pain, apply fomentations to the belly, and give the following injection: Powdered ginger, $\frac{1}{2}$ oz.; common salt, 1 tablespoon; hot water, 1 gallon.

COSTIVENESS.—*Treatment:* For simple costiveness, the best remedy is the milk that comes from the cow for the first 4 days after calving; but in confirmed cases, doses of warm water, containing 2 or 3 oz. of Epsom salts, should be frequently administered.

COW-POX.—This is identical with small-pox in the human subject. It shows itself by a slight fever for 2 or 3 days, then breaks out in pimples on the teats, udder, flanks, and around the vulva, nose, mouth and eyes. These are first red, then they enlarge and become yellow. *Treatment:* Foment the udder, and apply poultices of spent hops; give laxative and saline medicines, and draw off the milk.

CUD, Loss of.—A species of indigestion, and may be brought on by the animal's eating greedily of some food to which it has not been accustomed. *Treatment:* 1. Give the animal 1 pt. raw linseed oil.—2. Golden seal, powdered, 1 oz.; caraway, powdered, 2 oz.; cream of tartar, $\frac{1}{2}$ oz.; mix; divide into 6 powders and give 1 every 4 hours, in a sufficient quantity of chamomile tea; also, give as a drink Epsom salts, $\frac{1}{2}$ lb.; powdered gentian, $\frac{1}{2}$ oz.; powdered caraway seeds, 1 oz.; powdered ginger, 2 dr.; mix, and give in warm gruel.

DIARRHEA.—If this becomes chronic, it is hard to cure. *Treatment:* 1. If milk, thickened with fine flour and boiled for some time, fine and free from lumps, like starch paste, be added to the daily ration, in the proportion of 1-5 to $\frac{1}{2}$, according to the severity of the attack, and fed by pouring it from a bottle down the calf's throat (if he will not drink it), a cure will be promptly effected in most cases. — 2. Prepared chalk, powdered, Winter's bark, and laudanum, of each, 1 oz.; water, 1 pt.; give 2 or 3 tablespoonfuls, according to the age and condition of the animal, 2 or 3 times a day.

DROPSY. — The first symptoms are short breath, followed by stretching on the ground. If it is abdominal dropsy, the swelling will show about the abdomen; if general dropsy, it will appear over the whole body and legs. The swelling will feel doughy to the touch. *Treatment:* In order to carry off the water, and reduce the swelling, use occasionally and alternately one of the two following hydragogue cathartics: 1. Calomel, powdered jalap, powdered squill, of each 1 dr.; podophyllin, 15 gr.; $\frac{1}{2}$ oz. powdered nitre, and 2 dr. powdered ginger; mix, and make a powder, to be administered mixed with meal.—2. $\frac{1}{2}$ lb. of Epsom salts; 4 oz. of cream tartar; 1 oz. of nitre, and 2 dr. of ginger, to be given in warm gruel. Make a free use of vegetables, potatoes, carrots, parsnips, etc., in the diet.

DROPSY OF THE CHEST, or HYDROTHORAX. —This is the result of neglected or badly managed cases of pleurisy, the chest filling with water from the excessive effusion. *Treatment:* See that the bowels are kept free, and then apply blisters to the sides, and give the following: 2 dr. gum camphor; 1 oz. spirits nitre; dissolve the camphor in the nitre, and add 4 dr. saltpetre and 1 pt. of water or gruel. Give as 1 dose, and repeat every 4 or 6 hours. Administer stimulants freely, and tap the chest early, repeating it if necessary.

DYSENTERY.—This is one of the most dangerous diseases cattle are subject to. It is often mistaken for diarrhea, but can be easily distinguished by closely observing the following symptoms: The efforts to expel the dung are frequent and accompanied by evident pain; the animal is restless, frequently lying down and rising again. If the loins are pressed with the hand, the animal will shrink. The discharge will be thin, and have an offensive smell. *Treatment*: 1. ½ lb. Epsom salts; 2 to 4 oz. sulphur; ½ oz. nitre; 2 dr. ginger; 1 oz. spirit of nitrous ether; dissolve in warm water or gruel, and repeat once a day for several days. Give frequent injections of starch gruel, each containing 1 oz. opium. — 2. 1 lb. mutton suet; 2 qts. new milk; ½ dr. powdered opium; 1 dr. ginger; melt the suet in the milk by boiling; when dissolved, add the remaining ingredients. Feed lightly and nurse carefully.

DYSPEPSIA.—The symptoms are changeable appetite, staring coat, belching from the stomach, emission of gas from the rectum; the manure is small in quantity, dry and glazed; the skin and hair are dry and coarse, and there is rapid loss of flesh. *Treatment*: Give a dose of bran twice a week, and daily a bitter tonic, in which rhubarb and gentian, or Peruvian bark, are prominent ingredients; and also 1 tablespoonful of bicarbonate of soda. The skin should be kept clean, and rubbed and curried a good deal.

ECZEMA.—A skin disease. The skin becomes hardened, dry and sore, and cracks into fissures. The discharge continues, and becomes greasy and offensive. *Treatment*: Cleanse the bowels with 1 dr. of calomel and 1 oz. of rhubarb, mixed. Apply hot linseed meal poultices till all inflammation and soreness are gone; then embrocate freely with the following: 1 dr. pure carbolic acid, in from 6 to 12 oz. of water. When all soreness has gone, apply the following: 4 oz. lard; 1 oz. alum; and 1 dr. carbolic acid; mix.

ERYSIPELAS.—*Treatment.* The bowels must be kept gently open, by small doses of medicine, and laxative glysters. If there be any fevcrish symptoms, saline diuretics should be administered; and as a lowering treatment is objectionable, tonics and stimulants should be had recourse to at an early stage of the disease. The affected parts should be kept constantly moist with a lotion composed of rum, or alcohol diluted to about the strength of rum. Nutritious food, fresh air and general comfort must not be neglected. Cold applications are hurtful.

EYELIDS, Torn.—*Treatment*: Bring the edges neatly together; sew with fine silk, and dress 2 or 3 times a day with the following: 1 dr. white vitriol; 1 pt. water; mix, and use the lotion.

FITS, or EPILEPSY.—*Treatment*: Animals subject to fits, should not be driven, excited, or agitated. Give ¼ oz. doses of bromide of potash daily.

FLOODING.—A discharge of blood from the uterus of the cow after calving. *Treatment.* 1. Apply very cold water to the loins. If it continues, raise the cow's hind parts; give 2 dr. tincture of opium every hour; keep the patient quiet; take her calf. — 2. Injections of alum water—1 oz. of alum to 1 qt. of water—will be useful in this disease.

FOOT-ROT. — This disease makes its appearance sometimes between the claws of the foot, often in the heel, and, extending up the leg, causes extreme lameness, loss of flesh and loss of milk. *Treatment*: Give 1 lb. of salts, and, when that has operated, give 1 oz. of hyposulphite of soda daily; wash the sore spots with water and soap, and dress them with an ointment as follows: Melt 4 oz. of lard and spermaceti together; add 1 oz. of acetate of copper (verdigris); and stir thoroughly; and, while still fluid, add 1 oz. of turpentine, and stir until cold. Keep for use.

GLANDS, Inflammation of.—Inflammation of either of the glands may be known by the heat, tenderness, enlargement, and difficulty of swallowing. *Treatment*: In the inflammatory stage, teas of marshmallows or slippery elm, and poultices of the same, are the best means yet known to reduce it; they relax constricted or obstructed organs, and by being directly applied to the parts affected, the more speedily and effectually is the object accomplished; 2 or 3 applications of some relaxing poultice will be all that is needed, after which apply 1 gill olive oil or goose grease; 1 oz. spirits of camphor; 1 oz. oil of cedar; ½ gill vinegar; mix, and rub around the throat as occasion may require. Or, the parts may be well rubbed with coal oil or petroleum. Give tonics, as iodide of potassium, gentian, etc., and pay particular attention to the bowels.

GLOSSITIS (Inflammation of the Tongue.)—*Treatment*: Examine the mouth carefully, and remove offending matter. If the tongue hangs pendulous, foment it with hot water. Apply the following lotion 4 or 5 times a day; honey, 2 oz.; borax, ½ oz.; water, 1 pt.; mix.

GRAVEL.—*Treatment*: Wash out the bladder with tepid water. Inject into the bladder a weak solution of hydrochloric acid. Then, twice a day, give internally the following: 2 dr. gentian; 1 dr. tartrate of iron; 1 dr. ginger; mix, and give in 1 pt. gruel.

HOOSE. — A cough caused by a species of worms, the eggs of which are swallowed in grazing. *Treatment*: Give linseed or cotton cake, with the most nutritious diet. Let the animal breathe the fumes of turpentine burned on pine shavings.

HORN, Ail in.—This disorder usually attacks cattle in the spring, after a severe winter; likewise, those that are in poor flesh, or those that have been overworked and exposed to severe storms, or reduced by other diseases, are predisposed to take it. Symptoms, eyes dull, discharging yellow matter, dizziness, loss of appetite, shaking of the head, bloody urine, coldness of the horns, stupidity, and great debility. *Treatment*: Give nourishing and relaxing food, as cotton-seed, or flax-seed meal.

HORN, Broken.—*Treatment*: If the shell is broken, leaving the inner core bare, wrap it in an oiled cloth, or even in a bandage wetted with water, to protect the horn from the air. A new horny covering will grow over the core, and although it will never again be wholly repaired, yet the horn will become hard and solid again.

HOVEN, or BLOATING.—This often follows the feeding of a large quantity of green fodder. When partly wilted and with very succulent forage, as alfalfa, clover, or green corn fodder, the danger is increased, as partial fermentation has already begun and is greatly quickened by the warmth and solid packing in the stomach. *Treatment*: 1. If the cow is able to stand alone for 10 minutes, tie her by the head, so as to hold her head up; then press down on the sides just forward of the hip bone on both sides; gently at first, but continuing the pressure harder and harder. In a few moments you will hear the cow commencing to belch up gas, the escape of which will relieve her.—2. Give 1 lb. of Epsom salts, with 4 oz. of cream of tartar, repeating the dose till a movement of the bowels is obtained.—3. Once a week give a dose of calomel and jalap, 1 dr. each.

HYDROPHOBIA.—*Treatment*: There is no cure; the best thing is to destroy the animal as soon as the disease is sufficiently plain. Care should be taken that the saliva of the rabid ox is not received on a wound or abraded part, for it has produced the disease in other animals. Any wound on which it has fallen should immediately have lunar caustic applied to it. When a mad dog has been known to bite an ox or a cow, there is a possibility of their escape, for the hide is thick, and the hair is thick too, and the skin may not be penetrated, or the tooth may have been cleaned in passing through the hair. They should be most carefully examined, and especially about the part on which they were seized by the dog, and if the minutest scratch can be found the hair must be cut off round it, and lunar caustic applied.

JAUNDICE.—This affects cattle, giving rise to a tawny hue of the skin and membranes, yellow eyes, skin and urine. *Treatment*: If there be fever, give Epsom salts, 1 lb.; powdered ginger, 4 dr.; warm water, 3 pts. After the bowels are well opened, give every day, for a purge, madder, 1 oz.; flour of sulphur, 2 oz.; powdered caraway seeds, 1 oz.; Epsom salts, 2 to 4 oz.; warm water, 3 pts.

KIDNEYS, Inflammation of.—The symptoms are a constant desire to void the urine, which is thick and dark; great pain, as shown by the expression of the countenance, and by frequent wistful looks at the loins, straddling gait, and arching of the back; the appetite is poor and fever high. *Treatment*: Apply hot water to the loins, and give large quantities of linseed tea or slippery elm water to drink, with warm water injections. Give the following as 1 dose: 20 drops tincture aconite root; 3 oz. Mindererus' spirit; 1 pt. linseed tea; mix. Keep the animal quiet, and feed on sloppy food.

LIMBS, Broken.—*Treatment*: By means of plaster of Paris (not land plaster), and some bagging strips, the limb may be set and supported until the bone unites again. Wind the strips about the broken limb; plaster over with calcined plaster, mixed to a thin paste; wind another over that, and apply more plaster, the leg being fastened to splints of wood until the plaster sets. The animal will limp around for a few days on three legs, but will recover.

LIVER. Inflammation of.—The symptoms are, fever; reclining on the right side; fullness on that side of the belly; urine yellow or brown, and sometimes bloody. *Treatment*: If there is much fever, give calomel, 1 dr.; powdered opium, 10 gr.; powdered ginger, 2 dr.; rub together, and give in 1 qt. gruel, and repeat it twice a day; give, in 6 hours after first dose, a purge of Epsom salts, 8 oz.; water, 1 qt.; dissolve, and add linseed oil, 1 pt.; repeat till the bowels are open. If purging takes place from the first, give the calomel, opium and ginger, and give the drench as in diarrhea, at the same time blistering the right side; if great weakness ensue, give for a tonic powdered gentian, ½ oz.; powdered caraway seeds, 1 oz.; powdered aniseed, 1 oz.; Epsom salts, 4 oz.; mix, and give in 1 pt. warm brandy.

LOCKJAW.—The symptoms are, a stiffness of gait in the animal; he will walk unusually wide behind; there will be difficulty of turning; permanent cocking of the tail, except when that is interrupted, or accompanied by a singular tremulous motion of it. The animal can scarcely, and, after a while, not at all, bend his neck to graze, but he will stand with his head protruding and his ears stiffened and unnaturally fixed in a somewhat backward direction; rumination gradually ceases, or is performed slowly and painfully; the jaws become firmly closed, and neck perfectly stiff; the eyes are strangely fixed, and with some degree of squinting, and the expression of the countenance is peculiarly anxious; the breathing is considerably affected, and there is much labor of the flanks. *Treatment*: Give for a drink, Epsom salts, 1½ lbs.; flour of sulphur, ½ lb.; warm water, 2 qts.; mix, and repeat in ½ lb. doses every 6 hours, assisted by injections every 4 hours, composed of Epsom salts, ½ lb.; linseed oil, ½ pt.; warm water, 4 qts.; when well operated, give 1 dr. opium, dissolved in warm water, twice a day, and put a seton in the dewlap.

MANGE.—Mange in calves is caused by a mite burrowing in the skin. *Treatment*: 1. Dress the part with an ointment composed of 4 oz. of lard; 1 oz. of sulphur; 1 dr. of creosote; mix well together; rub into the skin every morning, and give each calf 1 teaspoonful of sulphur, daily, for 2 weeks.—2. 4 oz. of pyroligneous acid; 1 pt. water; mix, and apply daily; at the same time take 2 oz. powdered sassafras; 1 handful powdered charcoal; 1 oz. sulphur; mix well together, and divide into 6 parts; 1 to be given in the feed night and morning. As the mange is infectious, the cattle troubled with it should be removed from the rest of the herd.

MILK FEVER.—A disease of the blood consequent upon a disordered circulation, and is a sort of apoplexy, the brain being inflamed and congested, and the nervous system prostrated. Usually, a cow afflicted with this disease, lies still, with the head on the flank, but sometimes dashes the head about violently. *Treatment*: 1 lb. of sulphate of magnesia; 2 oz. of pulverized Jamaica ginger; divide into 6 powders, 1 to be given 3 times a day, dissolved in ½ pt. of tepid water, alternating every 6 hours with 1 of the following powders; 1 oz. chloride of potas-

sa; ½ oz. pulverized digitalis leaves; ½ dr. tartarized antimony; mix, and divide into 6 powders. Place the cow in a large, well-ventilated box-stall, well supplied with clean, dry straw, and kept clean. If the weather is cold, protect her with warm clothing. The milk should be frequently drawn off, and when unable to rise, she should be turned occasionally, which will afford her temporary relief.

MURRAIN.—A dangerous disease, and seems to attack the entire system of the animal at the same time. The symptoms are, fever, quick pulse, cold horns, swollen eyes, sometimes accompanied with diarrhea. *Treatment*: The first thing to be done, is to separate the sick from the well, as this disease is very contagious. First, bleed the animal freely; then administer a purgative drink, ½ lb. of Epsom salts, dissolved in soft water, twice a day, for several days. If tumors appear upon the body or teats, wash with the following solution: 4 dr. of sulphate of zinc to a qt. of rain water. Everything depends upon good nursing.

NAVEL ILL.—*Treatment*: When the naval bleeds, tie a ligature a short distance from the belly; a pledget of lint, dipped in friar's balsam over it, confined with a bandage, and changed night and morning; and keep the bowels open with linseed oil; then give a cordial drink in a little gruel, once a day, made of powdered caraway, 2 dr.; powdered gentian, 1 dr.; powdered ginger, ½ dr.

PALSY.—*Treatment*: Keep the bowels well open by a drench made of Epsom salts, 1 lb.; powdered caraway, 1 oz.; powdered aniseed, 1 oz.; powdered ginger 2 dr.; mix, and give in 1 qt. warm beer, and use the following liniment: Opodeldoc, 4 oz.; spirits of turpentine, 4 oz.; powdered hartshorn, 4 oz.; mix well together.

PATELLA, Dislocation of.—*Treatment*: Pull the foot forward by a rope passed around the pastern, and push inwards on the patella. It will then be replaced in position. If the joint is injured, fasten the leg forward with a rope fastened around the neck. Foment the joint with hot water, and when the inflammation is reduced, blister with the following: Lard, 4 oz.; powdered cantharides, 1 oz.; mix.

PERITONITIS.—Inflammation of the peritoneum, a serous membrane lining the cavity of the belly, and covering the bowels and other abdominal viscera. The symptoms are, fever; labored breathing, done mostly with the chest; shivering around the flanks and hind parts; the animal paws or crouches with pain. *Treatment*: Give a mild purgative, and in 6 or 8 hours give the following: 2 dr. powdered opium; 1 dr. calomel; 1 qt. gruel; mix and give as 1 dose. Give frequent injections of soap and water. If great weakness follows the action of the purgative, give the following: 2 dr. camphor, dissolved in ½ oz. sulphuric ether; add 4 oz. acetate of ammonia, and give as 1 dose, in ale or gruel.

PLEURISY.—This is an inflammation of the membrane covering the lungs and lining the chest. The symptoms are, fever; breathing quick and painful, and done by the abdominal muscles; the animal shows pain by frequently turning its head to its sides; pressure on the ribs causes intense pain and a peculiar grunt; there is a hacking cough, and the animal remains standing, with its head hung low. *Treatment*: Apply blisters or mustard plasters to the sides. If much fever exists, give the following: 2 dr. tincture of aconite root; ½ oz. fl. extract of belladonna; 3 oz. spirits nitre; 2 oz. nitrate of potash; 2 oz. muriate of ammonia; 1 qt. of water; mix, and give ½ teacupful every 2 or 3 hours. If the animal appears to be much distressed, give 4 oz. of liquor ammonia acetatis, in 4 oz. rose water, 3 times a day, until the animal shows improvement. When the fever is subdued, give the following: 2 dr. gentian; 1 dr. tartrate of iron; 1 dr. ginger; mix, and give in 1 pt. gruel. Give good nourishing food, and good ventilation.

PLEURO-PNEUMONIA.—A contagious disease of the lungs. The first symptoms are a dry, husky cough, of a peculiar character, first heard in the morning, or while the animal is drinking; the appetite becomes sluggish; rumination ceases; staring coat; slight shiverings; scanty urine, of a dark color; the milk becomes smaller in quantity, thin and blue; breathing hurried and accompanied with moans; coughs more frequently; later there will be a discharge of matter from the eyes, and rapid weakening of the system. *Treatment*: In first stages give heavy doses of castor oil, or raw linseed oil, 1 pt. at a time. If a veterinary surgeon can not be obtained, it is best to kill the animals attacked and bury them, as the disease is very contagious and generally regarded as incurable.

PNEUMONIA.—Coughing is the first symptom. The nose is dry, and the animal stands with its back arched and elbows turned out. If forced to move briskly about, it will cough and pant. The disease seems more severe during a thaw than when the weather is colder. There is some running from the eyes. The appetite is invariably good up to 24 hours before death. From 6 to 24 hours before death occurs, the animal is unable to stand. As death approaches, the animal groans quite loudly, the breathing becomes accelerated, and the cough seems to come from a more or less solid body. In coughing, a calf will extend its nose on a level with its neck. *Treatment*: Give a dose of salts, and then the following: Tartar emetic, 1 dr.; camphor, 1 dr.; nitre, 4 dr., in one qt. thick gruel. Sometimes bleeding is necessary; but the chief reliance should be upon tartar emetic; the former to loosen the cough and relieve fever, and the latter to quiet the cough and pain.

RED WATER.—Also called *Hæmaturia*, *Bloody Urine*, *Brown Water*, *Black Water*, and *Moor*. The symptoms are: Bloody urine, loss of appetite, languor, apathy, seclusion, constipation. *Treatment*: Bleed copiously; then give Epsom salts, 1 lb. in 2 qts. of water, every 6 hours, in ½ lb. doses, till the bowels are relieved. The pasture should be changed. If there is considerable fever, or the animal should appear to be really ill from the discharge, she should be taken under shelter and fed on mashes, with a very little hay; or a few turnips or carrots may be allowed her, if they are in season.

RHEUMATISM.—The early symptoms of this complaint are those of common catarrh, with no great cough, but more than usual fever; by

degrees the animal shows some stiffness in moving; and if the hand is pressed upon the chine, or any part of the back, the animal will shrink, as if this gave him pain. In 2 or 3 days the animal appears stiffer in the joints; these afterwards begin to swell, and are evidently painful, particularly when he attempts to move. Sometimes the stiffness extends all over the body, and to such a degree that he is unable to rise without assistance. *Treatment*: Give for a drench, to keep the bowels open, Epsom salts, ½ lb.; powdered caraway seeds, 1 oz.; flour of sulphur, 4 oz.; warm water, 1 qt.; also give once or twice a day, tartar emetic, 1 dr.; camphor, ½ dr.; nitre, 2 dr.; powdered aniseed, 1 oz.; rub well together, and give in 1 qt. thick gruel; if the joints continue much swollen, use for a liniment, spirits of hartshorn, 2 oz.; opodeldoc, 2 oz.; camphor liniment, 4 oz.; laudanum, 1 oz.; mix for use.

RING-BONE. — *Treatment*: Paint with tincture of iodine, or with a solution of corrosive sublimate, 40 gr. to 1 pt. of water.

ROPY MILK.—When cows are suffering from any functional disorder, the milk is at once affected. Sometimes the milk is acid, and soon becomes thick and ropy; is often clotted in the udder, and is drawn in strings and clots. *Treatment*: 1 lb. of Epsom salts, or 1 qt. of linseed oil, may be given, and afterward repeated doses of 1 oz. of hyposulphite of soda daily until the trouble is removed.

RUPTURE, or HERNIA.—This occurs in young colts and calves, and consists in the protrusion of a portion of the bowel and intestine through the navel, forming a small tumor. *Treatment*: 1. Force the bowel up into the belly; gather the loose skin together; tie a well-waxed cord tightly around it, close to the belly, and a strong pin may be forced through the skin below the ligature or cord, to keep it from falling off before the loose skin comes away. In a few days the skin will fall off, leaving a healthy sore. —2. Place a bandage round the body, and a pad over the rupture.

STINGS.—The stings of hornets, wasps and bees, in some cases produce much temporary swelling and pain. *Treatment*: Rub the part with warm vinegar or aqua ammonia. When stung by a reptile, 1 qt. of olive oil should be given to the animal, mixed with 1 oz. of hartshorn. Oil of turpentine may be used when hartshorn cannot be procured.

TEATS, Leaking.—*Treatment*: Leaking teats may be cured by the application of collodion to the teat immediately after milking. To apply it, wipe the teat perfectly dry, and with a small brush or camel's-hair pencil paint the end of the teat over with 3 or 4 coats of collodion. It dries instantly, and, contracting as it dries, closes the orifice. — 2. Another method, is to clip away the skin around the edges of the hole, then cut a small slit across the hole and a little above and below it, and bring the edges together with a stitch. As the wound heals, the hole will close. This should be done when the cow is dry, or a milking tube should be used to draw the milk.

TEATS, Sore.—*Treatment*: 1. Take a full pail of cold water, and wash and rub the sores well. Use the whole pailful of water before milking, which cools the teats and reduces the fever, and the cow will stand perfectly still. After milking, use ½ as much more cold water, cleansing the bag and teats well, and in a few days the sores will be healed. — 2. Take 1 oz. of glycerine, and ¼ as much turpentine; mix, and rub it on the teats after milking. It is not advisable to wet the teats with milk; it is better to wipe them with a wet cloth, or wash them with water and soap and a sponge before milking.

TEXAS FEVER.—A disease accompanied with sympathetic fever. It is usually prevalent from the close of the summer months to the end of autumn. It is impaction of the manyplus with withered and dried grass and herbage, containing no moisture. The stomach refuses to digest it, causing heat, dryness and fever. *Treatment*: Give large doses of Epsom or Glauber salts, dissolved in great quantities of molasses water. If no relief follows in 24 hours, repeat the dose. Large drenches of water with the salts, do not only assist their action, but in many cases wash and dissolve the dry feed into a soft mass or pulp, which will readily pass away.

THROAT, Inflammation of. — *Treatment*: In many cases, if attended to immediately, nothing more will be necessary than confining the animal to a light diet, with frequent drinks of linseed tea, warmth and moisture applied locally in the form of a slippery elm poultice, which may be kept in close contact with the throat by securing it to the horns. In severe cases, steep mullein leaves in vinegar and apply to the parts, with an occasional stimulating injection, together with a gruel. Coal oil or petroleum rubbed on the throat is invaluable.

UDDER, Inflammation of.—Inflammation of the udder appears to result from various causes: Indigestion, over driving, the too long retention of the milk in the udder, and cold. *Treatment*: If the disease be constitutional, as indicated by the suddenness of the attack, administer at once a good dose of Epsom or Glauber salts, combined with a little ginger, and give copious doses of nitre. A modified form of this treatment should be kept up for some little time by means of gentle aperients, and smaller doses of nitre. In the milder form of inflammation use spirit lotions or refrigerant applications, such as ice water, or a mixture of chloride of ammonium and nitre applied immediately after mixing with water. When there are lumps in the udder, the continuous application of warm water is advisable. Whether the cold or hot treatment be indicated, it should be diligently kept up for a day at least. If there is much swelling, support the udder by a bandage passed around the body over the loins. The milk should be removed every 3 or 4 hours; if the milking operation causes pain, a syphon should be used. The hard lumps, or cakes, will be found to disperse best under gentle friction applied by the hand twice a day, for an hour each time, the hand being previously anointed with lard or coal oil. When the surface pits or becomes soft and very hot, liberate the confined pus by means of the lancet.

URINE, Retention of.—The animal attempts frequently, but ineffectually, to pass urine; has

colicky pains, and the hind legs are raised and moved about restlessly. *Treatment:* If the cow is constipated, or not decidedly relaxed, give a castor oil or a saline cathartic (Epsom salts, etc.); and then follow with laudanum injections in ½ oz. doses for a few hours. If there is no relief at the end of 3 or 4 hours, draw off the urine with a catheter. This must be done by a regular surgeon. After using the catheter, repeat the injection and give a light diet and linseed tea for a few days.

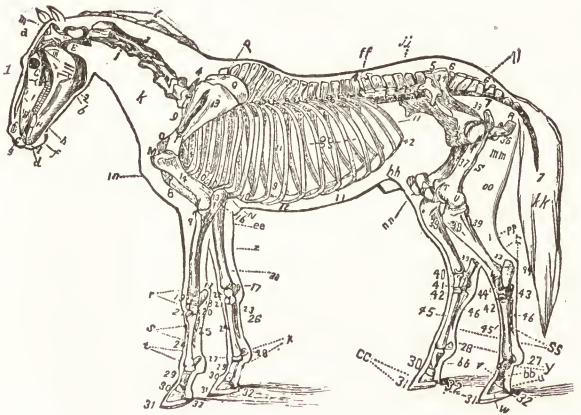
WARBLES. — These are caused by a certain species of gadfly depositing its eggs beneath the skin along the back of the cow during summer. *Treatment:* Extract the larva, and foment with hot water, and when the tenderness has abated, apply a lotion of strong vinegar, 1 pt.; rectified spirits of wine, 2 oz.; extract of Goulard, 1 oz.; spirits of turpentine, 1 oz.; mix together for use.

WOMB, Inflammation of.—Occurs after calving or bulling. The symptoms are great irritation and pain. *Treatment*: Give for a drench. Epsom salts, 1 lb.; powdered caraway seed, 2 oz.; warm gruel, 3 pts. Bathe the womb with Goulard water, or vinegar and water mixed equally.

WOUNDS. — *Treatment*: Clean the wound from all dirt and gravel which would cause irritation and prevent healing of the part, by warm water; then wash several times a day with a 40 per cent. solution of carbolic acid.

THE HORSE.

ANATOMY.



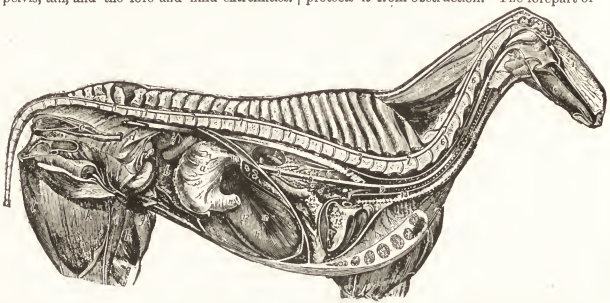
Skeleton and Points of the Horse.

BONES.—1, cranium; 2, lower jaw; 3, cervical vertebræ; 4, 4, dorsal vertebræ; 5, 5, lumbar vertebræ; 6, 6, sacrum; 7, 7, coccygeal vertebræ; 8, sternum; 9, 9, true ribs; 10, 10, cartilages of true ribs; 11, 11, false ribs; 12, 12, cartilages of false ribs; 13, scapula; 14, humerus; 15, radius; 16, elbow; 17, os pisiformes; 18, 19, 20, 21, 22, 23, carpal bones; 24, large metacarpal bone; 25, outer small metacarpal bone; 26, inner small metacarpal bone; 27, 28, sesamoid bones; 29, os suffraginis; 30, os coronal; 31, os pedis; 32, wing of pedal bone; 33, 34, 35, 36, os innominatum; 37, femur; 38, tibia; 39, os calcis; 40, astragalus; 41, 42, 43, 44, tarsal bones; 45, large metatarsal bone; 46, small metatarsal bone.

JOINTS, TEETH, ETC.—A, molar teeth; B, H, canine or tush; C, I, incisors; E, atlas; G, orbit; M, carniform cartilage; N, ensiform cartilage; O, coracoid process of scapula; P, spine; Q, cartilage; R, trochanter major; S, sub-trochanteric ridge crest; T, trochlea; U, external condyle; V, patella; W, hock joint.

POINTS.—a, forehead; b, jaw; c, temples; d, lips; f, nostrils; g, top of nose; h, beard; i, chin; j, neck; k, throat; l, mane; m, fore top; n, chest; o, shoulders; p, withers; q, arm; r, knee; s, shank; t, fetlock joint, u, pastern; v, coronet; w, hoof; x, fetlock; y, back sinews or main tendons; z, plate vein; a a, ebesnut; b b, quarters; c c, toe; d d, heel; e e, elbow; f f, reins; g, g, ribs; h h, flanks; i i, belly; j j, fillets; k k, tail; l l, rump; m m, buttocks; n n, stifle; o o, haunches; p p, thighs; q q, hock; r r, point of hock; s s, instep.

BONY STRUCTURE. — The skeleton of the horse is composed of 247 separate bones, which are united by joints to form the spine, thorax, pelvis, tail, and the fore and hind extremities. inclosed in the horny box of the crust, no inconvenience can arise from an outward pressure; for the bone allows free passsge to the blood and protects it from obstruction. The forepart of

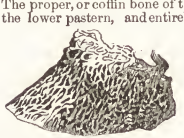


Internal Organs of the Horse.

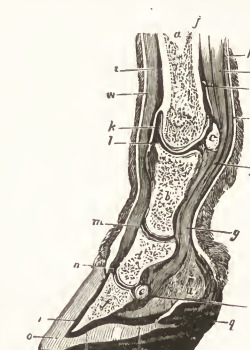
a, stomach; *b*, spleen; *c*, left kidney; *d*, broad ligament of the uterus, with left cornu and ovary displayed; *e*, rectum; *f*, anus; *g*, *h*, *i*, *j*, *k*, *l*, internal muscles of the thigh; 1, occiput; 2, cerebellum; 3, cerebrum; 4, nasal membrane; 5, tongue; 6, 6, cervical vertebræ; 7, 7, 7, 7, spinal cord; 8, pharynx; 9, 9, 9, œsophagus; 10, cardiac orifice of the stomach passing through the diaphragm; 11, pylorus; 12, 12, posterior surface of the diaphragm; 13, 13, trachea; 14, lungs; 15, heart.

The spine is finished anteriorly by the head, which is divided into the cranium and face, and contains the teeth. Suspended from the head is the *os hyoides*, which completes the number of bones. The bones are composed of a tissue peculiar to them, enveloped by a membrane, the *periosteum*. They contain a semi-fluid of a fatty nature, the marrow, and are pierced in various directions by blood-vessels and nerves.

FOOT.—It is necessary to examine the structure of the foot most carefully, not as an object of curiosity connected with the sense of touch, but on account of the numberless diseases and accidents to which it is subject. No part of the horse is so liable to the effects of hard work and mismanagement as this, and there is none which more requires our care both in health and disease. The proper, or coffin bone of the foot, is beneath the lower pastern, and entirely inclosed in the hoof. It fills about ⅓ of the forepart of the hoof, to which it is fitted. It is light, spongy, and filled with numerous holes, through which pass the blood vessels of the foot. These are numerous, considering the important and various secretions there going on; and the circulation could not be kept up if these vessels did not run through the substance of the bone. The holes about the coffin bone carry the blood to the little leaves with which it is covered; those near the lower part go to the sole. As this bone is the coffin bone, besides being thus perforated,



Mesh-work of Veins, without Valves, just under the Secretive Membrane of Hoof.



Vertical Section of the Lower Leg and Foot.

a, cannon, or large metacarpal bone; *b*, large pastern bone; *c*, one of the sesamoid bones; *d*, smaller pastern bone; *e*, navicular bone; *f*, coffin bone; *g*, *g*, *g*, penetrating tendon; *h*, *h*, *h*, penetrated tendon; *i*, extensor tendon; *j*, suspensory ligament; *k*, *k*, capsular ligament; *l*, fetlock joint; *m*, pastern joint; *n*, coffin joint; *o*, horny crust of hoof; *p*, horny sole; *q*, the frog; *r*, sensible lamiæ; *t*, sensible frog; *u*, cushion; *v*, navicular joint.

is curiously roughened for the attachment of numerous little leaves. On its upper surface is a concavity for the head of the lower pastern. In front is a prominence, into which is inserted the extensor tendon of the foot. At the back it is sloped for articulation with the navicular bone; and more, underneath is a depression for the reception of the flexor tendon, continued down the leg, passing over the navicular bone, and then inserted into this bone. On either side are projections, called the heels of the coffin bone, and the bottom is hollowed to match the internal part of the sole. The crust, or wall, is that part which is seen when the foot is placed upon the ground, and reaches from the hair to the ground. It is deepest in front, where it is called the toe; shallower at the sides, which are called quarters, and of least depth behind, where it is termed the heel; it is placed flat upon the ground, but ascends obliquely backward, and possesses different degrees of obliquity in different feet. In a sound hoof, the proper degree of standing is calculated at 45°, or the fourth part of a semicircle. This crust is thicker in front, being about ½ in., and at the quarters and heel is very much thinner. It is also thinner at the inner than the outer quarter, where the most weight is thrown upon. It is under the inner splint bone, on which so much weight rests, and being thinner, it is able to expand more—its elasticity is called more into play, and concussion and injury are avoided.

MUSCLES. — The bottom of the chest at the girth place and between the fore legs, is clothed by the very large pectoral muscles. When these muscles are large and the withers high, the fore part of the trunk is very deep. The muscles of the shoulder are for support and speed. There are very small muscles which stretch from every bone of the spinal column to the next bone in front of it, and are said to clothe the spinal column. These muscles of themselves cause the wriggling movement of the column. The column, however, is acted upon by other muscles than those little ones stretched from bone to bone. The principal muscle of the back extends from the shoulders to the haunches; it is used in raising the fore and hind quarters. The muscles of the hind quarters straighten the legs and give speed. The bones of the extremities are clothed by muscles which act by lifting and extending them in the different gaits. If the bones of the extremities are of proper length and stoutness, then, except in disease, the muscles will either be in good condition, or will be capable of being made so, and they will be massive and present bold, beautiful curved outlines. The muscles of the ear are not easily observed. One of them extends from the base of the ear and turns the ear forward; the second, placed behind the eye, turns it inward and backward; and the third occupies the back of the cheek, and turns the ear outward. One of the most important muscles of the eye, is the iris. It is a very delicate moving muscle, flattened like a sheet of paper and ovoid, having an ovoid hole in its very centre, which is the pupil of the eye through which the light passes. There are 5 or 6 muscles to move the eye. The ends of each muscle are attached, one to the bony socket, the other to the white outer tunic. One muscle is attached to the upper part of the eye; one to the lower; one to the inner or nose side; one on the outer side; so that when the top one contracts, the eye looks upwards, and so forth. There are 2 other muscles, obliquely placed for rolling the eye. The 4 muscles named are called the straight muscles. The superior triangle of the neck is occupied by muscles which are attached to the last 5 bones of the neck. The nostrils are made up of muscles which are covered with skin and hair; are for the purpose of regulating the width of the opening; and are thrown into action the moment the horse has to breathe more quickly.

BREEDS.

REMARKS ON AMERICAN HORSES. — The American and Canadian horses consist of judi-

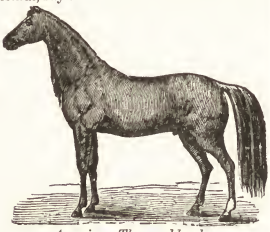
Morgan Horse.

iously-made crosses amongst English, Arabian, Barb, Spanish, and other stock; the climate of the American continent, apparently, having the same effect upon the horse, as respects wiriness of frame, that it has upon the human subject. American trotting horses are celebrated. The Conestoga horse often rises 17 hands; light in the body, with great length of leg; it is a great deal used as a riding horse, and for hunting when of suitable calibre. Among the American roadsters, the Morgan family stand first. They are exceedingly compact, deep-chested, strong-backed, fore legs set wide apart; head small, high and graceful; eyes fine, and well set. The family comprises several varieties, among which the Goss and Gifford rank very high. The Gold Dust Horses of Kentucky are elegant, staunch, fast-going horses, and are good for light farm work; and for the light carriage, in double harness, they are excellent.

AMERICAN SCRUB.—These are horses which are less than half-breeds of any recognized strain, and include the light-weight mongrel,

native, Indian pony, mustang and others. In the market they are also denominated "plugs."

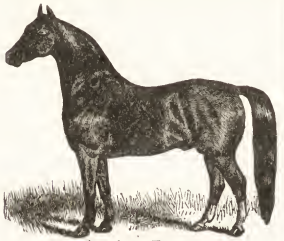
AMERICAN THOROUGHBREDS.—This breed of horses originated in England, and is the oldest and purest breed in existence. They are very valuable to the farmer on account of the reproduction of their leading characteristics to a remarkable degree in their descendants. For energy, endurance, resolution and speed, they have no equal. They are light-boned, and have a long body, with thin neck, small head, wide between the eyes. They have long legs and a deep chest. They are of various colors, but chestnut, bay and brown are the most common.



American Thoroughbred.

They are of great value for crossing upon other breeds, but are not used for any purposes besides racing and breeding.

AMERICAN TROTTING HORSE.—This horse is not a distinct breed, but is generally a cross between a thoroughbred and some hardier native



American Trotter.

horse. In lower Canada, there is a breed of hardy, spirited horses, descended from the larger Percheron horse, which they resemble in form and appearance, though smaller.

ARABIAN.—This horse possesses an elegant frame. The ear is small and beautifully shaped; the neck is light, the shoulders good, and the fore arm very strong. The hind quarters are narrow, indicating speed rather than strength. The legs are strong, less bone and more back sinew than in American horses. The pastern joints are long and fine—too long for strength, and the long pastern causes the horse to trip even on level ground. They seldom exceed 15 hands in height;

Arabian.

their colors being either black, gray, or bay; there being said to be 3 distinct breeds of Arab horses: The Attechi, which does not rank high in general estimation; the Kochlani, highly prized and very hard to procure, of undoubted pedigree; and the Kadischi, a mixed breed. Most of the thoroughbred horses have had some of their best points transmitted to them from Arabian blood.

ASS.—The ass is naturally humble, patient and quiet. He is extremely hardy, both as to the quantity and quality of his food, contenting himself with the most harsh and disagreeable herbs. In the choice of water, he is very nice, drinking only of that which is perfectly clear. He requires very little looking after, and sustains labor beyond most others. He is seldom or never sick, and endures hunger and thirst most resolutely. The milk of the ass is the lightest of all milks, and is excellent for persons in a debilitated condition. But the ass is mainly bred in this country for raising mules, the Maltese jack being most favored for the purpose. Fine jacks are scarce; those crossed with the Spanish variety have the largest size, activity and spirit. The quality of the jack is important, as he mainly controls the quality of the mule offspring. (See *Mule.*)

BOULONNAIS.—This is the most important French draught-horse. His characteristics show that he has a vigorous constitution, and in point of strength he is a Hercules among horses. He is as gentle as he is strong. For so heavy an animal, he is free and quick in his movements. He is endowed with a vigor and energy which is reflected in his gait.

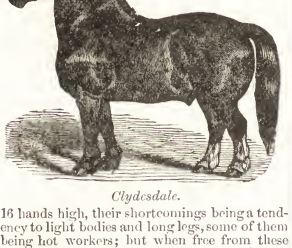
CLEVELAND BAY.—This breed receives its

Cleveland Bay.

name from a district in Yorkshire. The breed

has been so much crossed, with the object of obtaining greater speed, that the original race appears to be fast dying out; they were always a useful horse for those purposes where bulk and power were required, coupled with quick stepping action. The standard color is a bright blood bay, with black legs, mane and tail. When pure, they generally stand from 16 to 17 hands high. The carcass is lengthy, the shoulder lofty, and the withers tapering; the thighs are deep and sinewy; legs longer than in some improved breeds; bone thin and flat, with much muscle; the neck is long, but not very well arched; head long and projecting forwards; the eye uncommonly pert and bold. The whole animal denotes a figure for activity rather than for symmetrical form and points. They carry less flesh than any other breed, and their muscular power is proportionately increased; they have abundance of bone of the right sort.

CLYDESDALE.—As a draught horse of great strength, perhaps the Clydesdale stands unequaled. Scarcely any horse is so well adapted for single-horse carts, to draw heavy loads, and get through such a large amount of work in a single day. They are extremely active, standing about



Clydesdale.

16 hands high, their shortcomings being a tendency to light bodies and long legs, some of them being hot workers; but when free from these defects, they are useful for agricultural purposes. The fashionable color is black or black-brown, with the two hind feet white a little above the fetlock; the fore feet are sometimes white, but it is not liked. A white stripe in the face runs from the muzzle to near the ears, widening between the eyes. The body is short, but very deep, compact and strong. The chest is very wide and capacious; the arm strong; and the legs straight set; the thigh is very deep and sinewy; the barrel round; the ribs closely joined home near to the hook-bone. The neck is of a very proper length, finely arched, showing a very uncommon depth from the bottom of the chest, in a line slanting upwards to the top of the withers. The head is fine, tapering to the muzzle, the ear, small and erect; the eye, prominent and lively.

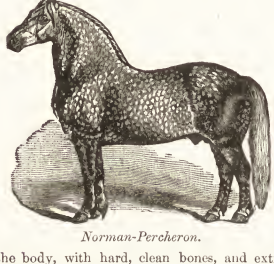
COSSACK.—An inferior race. They are small in size, rough in appearance, and are literally a useful kind of pony, being rough and wiry, and resembling most ponies in their endurance and general qualifications, combined with spirit and a brisk and lively action.

ENGLISH DRAFT.—The old black cart-horse of England was one of the distinctive breeds of English horses from an early period. They are divided into three sub-families; first, the heavy, massive horse raised in the rich marshes and plains of the midland counties expressly for the London brewers; second, the smaller sized, but tolerably heavy horses, generally employed for agricultural purposes, a strong compact animal, but slow in action; and, third, a lighter and more active animal, possessing either some admixture of blood of a smaller breed, or being the descendants of the Flemish discarded coach-horse. The prevailing color among these animals is black, but the large dray horse is not confined to those of a black color. There are many of a bay, and still more of a brown color, as well as numerous grays and roans. The largest are seldom less than 17 hands high, when 2½ yrs. old, at which age they are usually sold.

MULE. — Strong, well-limbed, large, sure-footed, and capable of carrying great burdens and traveling great distances. They are much hardier and stronger than horses, less subject to diseases, capable of living and working to almost twice the age of the horse, and cost very much less to keep. The white mule is the least hardy, though an iron gray is generally a serviceable animal. Cream mules with hair, mane and tail all the same color, are frail; but those with black mane and tail, striped legs, and a black stripe across the shoulders and back, are more hardy; spotted mules are the least valuable of their race. The color is various; action bold, square, free and easy; the walk 4 to 5 miles per hour, the trot 6 to 8, on a dry and moderately level road, but capable of being pushed much faster on the latter gait when required. As mules are hybrid, they are infertile and not bred together. A large, well-made jack is best for breeding. Male colts should be castrated as early as from 4 to 6 months old. (See *Ass.*)

NORMAN-PERCHERON.—These are from two well-known classes, the Norman and the Percheron. The Norman horse is heavy, muscular, closely-built, and weighs sometimes 2,200 to 2,300 lbs.; it is capable of carrying great weights and of going at a good pace. The Percheron of to-day has a clean, bony, and small head; ears short, mobile, erect, and fine pointed; eyes bright, clear, large, and prominent; forehead broad; nostrils large and open, and bright red within; jaws rather wide; chin fine; lips thin; teeth sound and even; neck a little short, yet harmoniously rounding to the body; throttle clean; crest rigid, rather high and gracefully curved; mane abundant, with silky hair; breast broad and deep, with great muscular development; shoulders smooth and sufficiently sloping for the collar to set snug to them; withers high; back short and strongly coupled; body well ribbed up; round, full and straight on the belly, which is much longer than the back; rump broad, long and moderately sloping

to the tail, which is attached high; hips round and smooth at the top, and flat on the sides; quarters wide, well let down, and swelling with powerful muscles; dock strong; tail long, heavy, and gracefully hanging out from the croup when the animal is in full motion; legs flat and wide, standing square and firm, and well under



Norman-Percheron.

the body, with hard, clean bones, and extra large, strong joints, cords and tendons; short from the hocks and knees down; pasterns upright; fetlocks thin; hoofs full size, solid, open, tough and well set up at the heels; color, usually mottled gray; height 15 to16½ hands; weight 1,300 to 1,700 lbs.

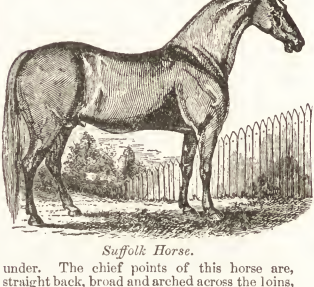
PERSIAN.—The Persian horse is of elegant shape, and ranks, perhaps, next to the Arabian,

Shetland Pony.

being his equal in speed, though not in staying qualities, and is similar in size, seldom rising above 14½ hands.

SHETLAND.—These are of small size, varying from 7½ to 9½ hands in height. Many of them are extremely handsome, and they are very docile, and contented with the hardest fare. They possess enormous strength in comparison with their size, and are useful animals to mount children upon, or draw a small carriage. The head, almost concealed by the shaggy mane, appears smaller than it really is; the shoulders are slanting and muscular; the color generally bay-brown or rusty black.

SUFFOLK.—The Suffolk is a small horse, seldom exceeding 15½ hands in height, and often



Suffolk Horse.

under. The chief points of this horse are, straight back, broad and arched across the loins, with short couples, full and lengthy quarters, with sinewy fore arms and an open chest, though somewhat wanting in depth; the shoulder low, but well set for the collar.

WELSH.—The Welsh pony is about 13 hands in height and possesses a neat head, good shoulders and strong legs and feet. Many of them are of a dun or cream color; and, if the former, marked with a dark stripe down the back, which color extends to the mane and tail. It is often a very handsome little animal, being well shaped, and capable of any amount of endurance. It is contented also with the humblest fare.

Breeding and Rearing.

REMARKS.—The first thing to be acquired, is the knowledge of the parts or points that are supposed to constitute the different qualities; and this can only be done by acute and frequent observation. Without this knowledge, it is useless to proceed, for blunder would only succeed to blunder, and the whole business terminate in failure. For the want of this knowledge, bad breeds of animals of every kind are continued, which is wholly chargeable to the ignorance and apathy of the breeder. In acquiring this knowledge, he must inquire most anxiously into the practice of those who have succeeded; ascertain correctly the causes which have produced the known results, compare them with his own observations, and then try to discover the applicability, in his own case, of similar causes, in order to produce similar results. Pairing should have strict reference to correcting the imperfections of one animal by the corresponding excellence in the other. Bays and chestnuts, with dark manes and tails, are the best colors to breed from; some breeds, however, have characteristic colors. The sire impresses

outward form and color, and the mare the inner and physical form. A pure-blooded sire, coupled with a mare of mixed blood, will produce a foal which resembles the sire more than the mare. Some sires have the power of impressing upon their offspring their characteristics in a remarkable degree; and some mares bring young much resembling the sire. The oftener the mare is served by the same sire, the greater will be likeness of the offspring to the sire. The dam is impressed with the blood of each of her sires, but the first impress is stronger than the succeeding ones. When the sire is changed, often the progeny will be varied. In breeding up to a higher standard, be sure that the sire is of the purest and most strongly-marked characteristics. To keep a stock pure and retain the characteristics of a breed, breed in line with animals having just the points required. Breeding in-and-in, is the breeding of animals closely related. In founding a breed, or refining certain points, breed in-and-in for 3 generations, then take an out cross. (See *Breeding-in* in CATTLE.) Crosses are not always objectionable, but violent crosses are not good. Great care should be taken to preserve the purity of breeds; for this reason pedigrees are established. Kind treatment and careful training have great influence upon hereditary traits; and blindness, and many other diseases, are hereditary in horses.

STALLION.

ADAPTATION TO THE MARE.—To be successful in breeding, care must be taken that there is mutual adaptation in size and form, and also to avoid using a horse which is defective in any particular when the mare has the same defect. A somewhat finer quality may be allowed in the male, but not so far different as to form an unseemly distinction. The qualities of animals that are assorted for propagation should be much alike. The properties will be more usefully developed in the process of like qualities, advancing step by step to better, than in the ill-consorted adaptation of extremes, which in the process of meeting may be expected to yield many irregularities.

AGE FOR BREEDING.—The time of maturity, longevity of the breed, and stamina of the individual, must determine this; but the stallion should be at least 7 or 8 years old; if a very young mare is chosen, the horse should not be less than 8, 10 or 12 years old. If both are very young or very old, the produce is generally small and weakly; but by using a young mare and an old stallion, the services of young and old may be fully utilized.

CHOICE FOR BREEDING. — The stallion should be at least medium sized. He should be masculine in appearance, and possess the beauty, fire, strength and courage of the male. In breeding to a feminine-looking male, the outcome will always be a failure.

MARE.

AGE FOR BREEDING.—A mare is capable of breeding at 3 or 4 years old, though some people commence to breed before the form or strength of the animal is sufficiently developed; and this early breeding is adverse to her proper development, and materially interferes with her growth. If a mare has done but little more than ordinary farm work, she may continue to breed until she is nearly 20 years of age.

CHOICE FOR BREEDING.—The mare exerts an important influence over the quality of her offspring, and great horses usually come from superior dams. The form, disposition, and general character of the colts, are often counterparts of the dam. The breed should be taken into consideration. If it is desired to raise a carriage animal, select a mare with a good, animated countenance; sprightly, not too nervous, nor too sluggish, but with a good muscular structure. The head of the brood mare is a point which should be always regarded; for a mare that has a large head, with a dull, stupid countenance, will not breed a good foal, unless it might be from a very sprightly, ambitious horse. The shoulder blade should be wide and long, extending nearly to the top of the withers, and so well covered with muscle as not to present any undue prominence. The neck should come out from the top of the withers and not low down. The fore leg should be perpendicular, so that the point of the shoulder and the toe will be in a right line. The foot should be sound, and of good, symmetrical shape. The hips should be long, oval, and broad. The hock-joint should be well formed, and not of the "cow-hock," or "sickle-hock" kind.

FOALING, Treatment before.—All mares are better for slow work up to within 2 months of foaling; but they should not be ridden or driven so fast as to occasion exhaustion. Work mares are generally used to within a few days of their time, taking care to keep them at light work and to avoid straining them. When nearly half the time of pregnancy has elapsed, give a little better food. The food should be good clover, and timothy hay, well cut and salted; ground oats and a bran mash, mixed with potatoes and other roots. Feed some corn or meal, but not too much, in order to guard against milk fever. If not intended to be kept at work, she should be turned out into good pasture; but it should not be so rich and succulent as to disagree with the stomach, or make them unwieldy from fat. The former mistake is a constant cause of miscarriage, the bowels becoming relaxed from the improper nature of the food. On the other hand, if it is not sufficiently good, the mare will become thin, and will starve her foal in growth. Mares that have been corn-fed highly all their lives, should have a feed or two daily, after they are 6 months gone, and especially if the autumnal grasses are not rich and plentiful. Excitement of every kind is a fertile source of "slipping" the foal, and everything which is likely to have that effect, should be carefully avoided. The smell of blood and other bad odors, have a very prejudicial influence in this way; and there is no doubt one mare miscarrying, will, in some way, affect others in proximity to her. If a mare has "slipped" a

foal in a previous pregnancy, double care must be taken, as she will be very likely to do so again.

FOALING, Treatment during.—The period of pregnancy varies from 44 to 56 weeks. Small mares generally go a shorter time than large ones, and a mare usually carries a horse colt longer than one which is a female. If the mare has been cared for as suggested above, and be in good health while in foal, little danger will attend the act of giving birth to her young. Should there be, however, false presentations of the fœtus, consult the directions given under cattle. (See *Calving, Treatment during*, in Cows.)

FOALING, Treatment after.— As soon as the foal is born, the mare should be allowed to clean it, and the secondaries be removed by the attendant; a little warm gruel should be given to her; and, if much exhausted by the act of parturition, 1 pt. of strong ale should be given with it as well. It sometimes happens that a mare will not take to her first young foal. In order to cause her to do this, her usual attendant should soothe and quiet her as much as possible, and milk her; and when her udder has been made somewhat empty, she will then usually allow the foal to suck; and until this point is satisfactorily settled, they should not be left alone together, for the mare might do the foal an injury. Nothing but warm gruel and a little hay should be given to the mare for the first 24 hours, in order to prevent heating of the system. For after pains, remove clots from the parts and raise the hind quarters. Give clysters of lukewarm linseed tea, and laudanum or belladonna extract. Syringe out the parts with warm water. Give internally belladonna, opium, or chloroform. Draw away the milk. In a healthy state, the mare very soon recovers from the efforts made in bringing forth the foal. In fine weather she may be allowed to enter her pasture on the second day afterwards. Occasionally the young animal is very active within 6 hours after it comes into the world. For a couple of months, the mare and foal are better kept in a pasture by themselves. Until the mare can get plenty of grass, she should have carrots, bran mashes, and a feed or two of oats. Rye grass is cultivated and cut for mares, daily, by those who raise early foals.

TIME FOR SERVICE.—The time for sending the mare to the horse will vary with the purposes for which her produce is intended. If for racing, it is desirable that she should foal as soon as possible after the 1st of January; and, as she carries her foal about 11 months, the first time of her being in use after the 1st of February, is the period chosen for her. All other horses take their age from the 1st of May. A mare will almost invariably be in heat on the 9th day after foaling, if she is healthy and has received no injury in giving birth to her foal; and in most cases it is best that she should receive the horse at that time, if it is desired that she should be kept for breeding purposes. If she refuse the horse then, try her again on the 7th day following; if she refuse again, try her on the 6th day after that; if she refuse then, she may be considered to probably be with foal.

TURF, Breeding for the.—The first step of the breeder is to decide what kind of stock he wants to raise. If he decides to raise trotters, the next step is to trace out his mare's pedigree. If he finds that she has 5 or 6 generations of trotting ancestors in her pedigree, he can not fail to produce their kind, agreeable to hereditary law. The dam may trot in 2.20; still, if her gait is not hereditary, but acquired, there is no certainty that she will breed her equal; while a mare that cannot trot half as fast as that come down from a very speedy family, will be far more likely to breed trotting colts than the fast mare without any pretensions to the trotting inheritance. In selecting brood mares, preference should be given to a young one.

Foal.

CARE IN GENERAL.—A day or two after the foal is dropped, providing the weather is fine, it may be turned with its dam into a sheltered pasture, in which there is a shed for security from wind and rain. The foal, if separated from the dam, must be put into a yard in the homestead, properly provided with a shelter shed and a supply of fresh water. No more than two animals may be put together, as the smaller the number of any animals that is put into one shed, the better. Colts should be broken to harness at 3 yrs. old, and used in light work for 2 yrs., when they will become matured and fit for full work. If they are used for hard service before their joints become settled or surrounded by a full-grown texture of muscle and sinews to support them, they will become sprained, causing spavins or bony enlargements, that will destroy their future usefulness. Shelter from the weather should be afforded colts of all classes during the winter season; and unless they have this, they soon grow out of form and lose flesh, however well they may be fed. A colt neglected in its first winter never recovers its proper shape.

CASTRATION.—The best time for performing this operation is just before weaning, provided the weather is mild. If, however, his neck is very light, and the withers low, its postponement till the following spring will give a better chance for the development of these parts. Midsummer should be avoided, as the flies prove troublesome, and the colt needs to be kept as quiet as possible, taking only the moderate exercise which he will get in grazing. A large and well-ventilated box is used by many, and to this there is no objection. The colt should first be cast, or thrown, by the use of hobbles. Attach a strong $\frac{3}{4}$ in. rope, 18 ft. long, to one end of a D-shaped ring. There are also 4 loops, 13 in. in length, each of which is attached to a similar ring. Fasten the long rope around the left fore pastern, by drawing it through the ring attached, and inclosing the leg in the loop thus formed. Fasten one of the short loops on each of the other pasterns, by drawing the ring through the loop; thus making a slip-noose around the leg, with the ring hanging clear; the

remaining short loop fasten around the right fore leg, just below the knee. The long rope pass through the rings on the different legs successively, beginning with that on the right fore pastern, thence through on right hind pastern, thence on left hind pastern, and thence through the ring at the knee of the right fore leg. Then throw the rope under the horse's belly to the left, and draw upon it until the feet are pulled together, the colt being backed gently from the head at the same time. This compels him to sit down upon his haunches, and then he can be easily pushed over on his right side. The feet are then drawn closely together, and the rope wrapped twice around the left hind ankle. The colt is then turned on his back, the rope brought under the rump and wrapped around the other ankle. He is now perfectly secure, and may be turned on either side, or left on his back for castration. Grasp the bag or scrotum over the testicle, so as to draw the skin quite tight; make an incision on each side of the seam, well forward, and press the testicles out; the clamp, or ecraseur then put on above the testicles and above the epididimus, or "prides." Care should be taken not to pull on the testicle more than sufficient to admit of the clamp or ecraseur being put on. If the clamp is used, the cords are then cut. If the ecraseur is used, the cords are cut with that instrument. If the clamp is used, it should remain on one day. If, after the operation, the wounds swell, the gashes should be opened at their lower ends with the fingers, so as to admit the discharge of the serous liquid. Keep the horse at work, or in action, as though nothing had happened to him, as in this way the wounds are kept open and the serum cannot accumulate. If there should be excessive bleeding after the operation, this can be checked by tying a string around the scrotum close to the body.

EXERCISE. — Colts should be permitted to gambol as much as they please. Exercise develops muscle, makes an animal active and spirited, and increases the capacity of the lungs and chest.

FEEDING.—Hay, corn, and bran mashes, must be allowed, if it is early in the season, or the grass has scarcely begun to shoot. There is nothing so detrimental to the colt as insufficient food. It is a fundamental principle in breeding, that if the growth of the colt at any time is checked by starvation, beauty, energy, and stoutness will rarely be displayed in after years.

WEANING.—The foal may be weaned in 5 or 6 months after its birth, according to its strength and growth, when it should be either turned into some distant rick-yard, or be housed for 3 weeks or 1 month; or, it may be tied in the adjoining stall, with the partition so open that the dam and colt are in plain view of each other. The first day let the colt nurse twice; the next day once. Feed him upon new mown grass, or fine clover hay, and give him 1 pt. of oats twice per day, and in about 2 weeks he will be weaned.

General Management.

Breaking and Training.

REMARKS.—In managing a horse, the chief point is to teach him confidence in man. It is necessary to be calm, cool, brave and fearless; to be quiet, for then the horse will be put off his guard; to be firm, and to give the animal no advantage, but crowd him up to doing invariably what is wanted.

BACK, Teaching to.—Put the cord (described in *Driving, Breaking to*) upon the horse, using the small loop; draw it with a steady pull; this brings the horse's nose towards his body. Keep a firm hold upon the cord until he steps back a little, using at the same time the word "back." The utmost gentleness must be observed in order not to excite him, and the lesson should not be long enough to tire him; 5 to 10 minutes being the best length, repeated at intervals of a few hours. As soon as he understands what is desired, he will back promptly at command. At first nothing should be behind him; next, he may be tried with a light, empty cart, and afterwards with a loaded cart, great care being taken not to hurt his mouth.

BITTING.—The true way to bit a colt, is to let him bit himself. When the colt is 1 yr. old teach him to hold the bit in his mouth. Use a large, smooth snaffle, so as not to hurt his mouth, with a bar at each side, to prevent it from pulling through either way. This should be attached to the headstall of the bridle, and put on the colt without any reins to it, and let him run loose in a large stable or shed some time, until he becomes a little used to the bit, and will bear it without trying to get it out of his mouth. Repeat this several times before doing anything more with the colt; and as soon as he will bear the bit, attach a single rein to it, without any martingale; also, have a halter on the colt, or a bridle made after the fashion of a halter, with a strap to it, so that he can be held or led about without pulling much on the bit. A horse should be well accustomed to the bit before putting on the bitting harness, and when he is first bit rein his head up to the point where he naturally holds it. The horse will soon learn that he cannot lower his head, and that raising it a little will loosen the bit in his mouth. This will give him an idea of raising his head to loosen the bit; then draw the bitting a little tighter every time it is put on, and he will still raise his head to loosen it. By this means his head and neck will gradually get in the position in which he is wanted to carry it. After some days of this usage a small string of bells may be attached to the girth. Take the colt out of doors with harness on, and, first in the lot, and afterwards in the street, teach him handily to be driven by the reins, and to turn out on meeting teams and turn around corners. Go different routes daily. Always, on returning

home, teach the colt to stand still while being unharnessed. Three week's daily lessons of this kind, and the colt will be fit to hitch to a light but strong sulky.

CARRIAGE, Hitching to.— Lead the horse to and around the carriage; let him look at it, touch it with his nose, and stand by it until he does not care for it; then pull the shafts a little to the left, and stand the horse in front of the off wheel. Let one stand on the right side of the horse and hold him by the bit, while another stands on the left side facing the carriage. This will keep him straight. Run the left hand back and let it rest on his hip, and lay hold of the shafts with the right, bringing them up very gently to the left hand, which still remains stationary. Do not let anything but the arm touch his back, and as soon as the shafts are square over him, let the person on the opposite side take hold of one of them, and lower them very gently to the shaft bearers. Hitch very slowly and deliberately. When the shafts are placed, shake them slightly, so that he will feel them against each side. As soon as he will bear them without scaring, fasten braces, etc., and start him along very slowly. Let one man lead the horse to keep him gentle, while the other gradually works with the lines until he can get behind and drive him. After he has been driven in this way a short distance, get into the vehicle, and all will be right. It is very important to have the horse go gently when he is first hitched; after he has been walked awhile there is not so much danger of scaring.

CATCHING A HORSE.—Besides the old-fashioned way of catching a horse, by shaking in a measure a little grain, the following is a good way: Take finely-grated castor, oils of rhodium and cummin; keep them in separate bottles, well corked; put some of the oil of cummin on your hand, and approach the horse on the windy side. He will then move toward you. As soon as you can reach him, rub some of the cummin on his nose; give him some of the castor on anything he likes, and get a few drops of the oil of rhodium on his tongue. After this, you can make him do nearly everything you want. Treat him kindly, feed well, handle gently, and your victory is certain.

COLTS, To Break.—Colts are generally allowed to run entirely too long before they are taken in hand for breaking, and the consequence is, that when breaking becomes necessary, they are wild and unmanageable, and are only reduced to obedience by a series of violent and barbarous devices, by which they frequently suffer irreparable bodily harm, and learn evil and mischievous habits. The breaking should begin so early and proceed so gradually that the horse should grow up in those habits of obedience and docility which give him in reality his highest value. The colt should be made docile and fearless by familiar handling and petting. No such thing as a whip should ever be allowed to touch the very young foals. Be firm, but not overbearing; it will be found better to overlook the fault than to attempt to correct it and fail; never lose your temper, for the moment you do so, you at the same time lose the advantage you should always have over him. If a colt is never allowed to get an advantage, it will never know that it possesses a power that man cannot control, and if made familiar with strange objects, it will not be skittish and nervous. Never try to beat a colt into doing a thing, for, if nervous, he may turn out a vicious horse, and, if stupid, he may become stubborn. Never trifle nor deceive. When you must draw the whip to compel attention, remember to reward obedience with sugar or some pleasing gift. Condescend to talk to the horse, and be clear in language, for he can hear, and is glad to be coolly and intelligently directed. "Go on!" "Steady!" "Whoa!" are magic words, which should be used to start, to moderate, or to stop the movements of a colt. Repeat them clearly when having occasion to use them, for just what they mean, and the colt will soon obey them, and be proud of his knowledge. As soon as weaned, break to the halter; then commence to take up all its feet and clean the hoofs, thus preventing thrush and slipping, and getting it well used to having its feet handled preparatory to being shod. By the time he is 1 year old, he should allow you to place light articles on his back without any resistance, and should be taught not to be afraid of straps hanging loosely either about the body or heels. This education is best done in the winter, and should be repeated until perfectly broken, and, when harnessed for the first time, he will quietly permit himself to be driven alongside of a quiet horse. Commence breaking to harness when about 1½ yrs. old. Put on all the harness, and spend considerable time in adjusting each part, and buckling and unbuckling everything. Tie traces into breech-rings, pretty closely drawn; buckle both girths; use no blinders on the bridle, and only a loose check-rein. Let the colt stand several hours at a time with the harness on.

DANCE, Training to.—Fasten the animal with 2 side reins between the posts supporting the leaping bar. Take a whip, and as the music plays, gently touch him with it, using the "jik, jik," of the groom, while going on. The horse, being tied to the posts, can move neither backward nor forward; but he will be induced to lift his legs, and thereby gain the rudimentary movement of his lesson. After a while the teacher must mount on his back; the horse being fastened by the side reins. Just when he is to raise his leg, a gentle pull must be given to the rein at the proper side to help the movement. In course of time, the reins must be loosened, and the horse, if tolerably ready, will soon learn to mark time, quick or slow, in answer merely to a slight jerk of the bridle. The rider must then dismount, and, coming before the horse, teach him to dance or keep time, with a wave of the hand, or by a pat on the foot which he is wanted to lift.

DRIVING, Breaking to.—Take a cotton cord, of fine strands, such as is sometimes used for a bed-cord or clothes-line, usually about ⅜ in. thick; hemp, or anything of the kind that is strong enough, will answer the same purpose; let it be about 15 ft. long; tie one end into a hard knot, as would be done to prevent its raveling; tie

another knot about 10 in., or a little more, from the one on the end; but, before drawing it tight, put the knot on the end through. There is now a loop that will not slip, made on the same principle that a rope is tied around the neck of a horse to hitch with, so as not to tighten upon the neck by pulling upon it. This loop should be just large enough to slip over the under jaw of the horse it is desired to train. Put this loop over the lower jaw, then, while standing on the near side, take the cord in the left hand and bring over the neck, by passing the left hand under the neck to the opposite side towards the mane; bring the right hand over the neck, and take the cord from the left and pass back to the loop, and put through from the top side, until the part over the neck is drawn down like a check-rein; then take hold of the end of the rein.

FEAR, To Overcome. — Whatever the horse understands to be harmless, he does not fear; consequently great pains should be taken to cause him to examine and smell such things as are likely to frighten him in after life. This should be attended to in his early education, since early impressions are strong in the horse. A log or stump, by the road-side, if regarded with suspicion, should be approached slowly or cautiously; to the imagination of the horse, such things are supposed to be some great beast that may spring upon him, but which he will soon comprehend to be harmless, if obliged to examine its nature in his own way, by advancing to the object and allowing him to understand it fully by smelling and breathing with the nose. There is a singular fact connected with taming the horse. If he is accustomed to any particular object by seeing it on one side only, he will not be afraid when he sees it with the eye on that side; but he will be afraid if he approaches it on the other side; it is therefore necessary to pacify him on both sides in all cases. After he is accustomed to whatever he is to be made familiar with, on his right side, repeat the operation on the left side in the same manner, as if he had not approached it at all. Whenever the horse is noticed directing his ear to any point whatever, or indicating the slightest disposition to become afraid, instead of pulling the rein to bring the horse forward toward the object causing its nervousness, it should be pulled on the other side. This will instantly divert the attention of the horse from the object which is exciting his suspicion, and usually the horse will pay no more attention to the object, from which he would fly away if forcibly driven on to it by pulling on the wrong rein. To accustom a horse to a drum, place it near him on the ground, and, without facing him, induce him to smell it again and again, until he is thoroughly accustomed to it; then lift it up, and slowly place it on the side of his neck, where he can see it, and tap it gently with a stick or the finger; if he starts, pause and let him carefully examine it. Then re-commence, gradually moving it backwards, until it rests on his withers, by degrees playing louder and louder, pausing always when he seems alarmed, to let him look at it and smell, if needful. In a very few minutes it may be played upon with great force, without his taking any notice. When this practice has been repeated a few times, the horse, however spirited, will rest his nose unmoved on the big drum while the loudest sounds are being produced. To break horses to stand the firing of a gun, place something in the nostrils, to prevent him from smelling the powder; then load the pistol, but very light, so as to make the report as faint as possible; every time it is fired, give him a small piece of apple, with some powder on it; then rub and pat him on the head and neck. When the pistol is first fired, stand close to the horse's shoulders, and rest the arms on his withers. After firing a sufficient number of times, mount the horse and shoot from his back. Keep up this practice for a short time, and the horse will get so used to it that he will not care anything about the firing of a gun at any time or place.

FOLLOW, Teaching to. — Turn him into a large stable, or shed, where there is no chance of escape, with a halter or bridle on him. Go to him, and coax him a little; take hold of his halter, and turn him towards you, at the same time touching him lightly over the hips with a long whip. Lead him the length of the stable, rubbing him on the neck, saying in a steady voice, while leading him, "Come along, boy!" or use his name instead of "boy." In turning, touch him lightly with the whip, to make him step up close to you, and then caress him with the hand. He will soon learn to hurry up, to escape the whip and to be caressed, and can be made to follow around without taking hold of the halter. If he should stop and turn away, give him a few sharp cuts about the hind legs, and he will soon follow, when he must be caressed. When excited, the colt is not in a condition to understand what is required of him, or to be submissive. Be careful not to train the colt till heated and confused. But little should be required at a time, and hold to that point until it is gained thoroughly, before undertaking to do more.

HALTER, To Use.—Never use a rope halter. The cords of the rope are hard, and appear to aggravate and excite distrust rather than confidence; but by all means procure a leather halter, made of bridle leather, so it will feel soft and pliable to the touch and fit tolerably tight on the head, so as not to feel uncomfortable. Before putting a halter on the colt, he must be rendered familiar with it, by caressing him and permitting him to examine the article with his nose; then place a portion of it over his head, occasionally giving it a slight pull, and in a few minutes he will be accustomed to these liberties, and then the halter may be fastened on properly.

HUNTER, To Train for a. — In breaking in a horse that is intended to be a hunter, the necessary routine is very little different to that ordinarily given, except teaching him to jump, and this is done by buckling the reins higher, and keeping the horse at it till he learns to bend himself well, and the rider is enabled to bring him back on his haunches. The main object sought in the education of the intended hunter,

is to get him to bring his hind legs well under him, and, thus carrying a good share of his weight, he is safer in awkward places, and when crossing ridge and furrow in the hunting field, and ordinarily across the country. A fixed bar should be used for him to jump over, and when he has progressed fairly well, he may be ridden over a few low fences; but no high jumps should be allowed to be taken without the hounds, he being brought up gradually to his intended future work. Hunters should be carefully handled at a very early age, if they are intended to become temperate and hardy. They may be ridden gently by a light weight, with good hands, at 3 yrs. old, over small fences. At 4 they ought to be shown hounds, but should only be allowed to follow them at a distance, after the fences are broken down, for, if put to large leaps at that age, they are apt to get alarmed and never make steady fencers afterwards. Above all things avoid getting them into boggy ditches, or riding them at brooks; but they should be practiced at leaping small ditches, if possible, with water in them, the rider facing them at a brisk gallop, for this gives a horse confidence and courage. No matter how carefully a hunter may have been trained, it is hard to say whether the right stuff be in him until he is tried in the field. In a hilly country, nothing has a chance against a pure thoroughbred. Lengthy horses always make the best jumpers, if they have good hind quarters, good loins and good courage. The most dangerous of all horses in the field, is the star-gazer. A hunter should carry his head low, as by so doing he is less liable to fall, and gives his rider a firmer seat. All wild horses lower their crests in leaping. It is, however, the peculiar excellence of going well through dirt which decides the real value of a horse. No matter how wide a horse may be, if he is not deep in the girth, he cannot carry weight, and is very seldom a good winded horse, even under a light man. One of the best things that can be said of a hunter is, that at first sight he appears 2 in. lower than he really is. Short-legged horses leap better and safer than long-legged, and go faster and farther under hard riders. Horses with straight hind legs never can have good mouths. They should have well placed hind legs, with wide hips, well spread gaskins, well knit joints, short cannon bone, oblique pasterns, and large feet. The bone of a hunter's hock cannot be too long.

JUMPING.—The colt should be at least 4 yrs. old before he is taught jumping. Do not urge a horse to a leap which he cannot perform, for failure will discourage him. To commence with, place a bar about knee-high. Begin the instructions by letting one man lead the colt, while another man follows with a whip. The former walks over the bar, encouraging the colt with his voice to follow. The man with the whip is only to prevent the horse backing; the whip should never be applied unless the animal is positively restive. With a little coaxing, he will soon go over, and having once done so, he will readily repeat it. A few pieces of apple may be advantageously used to induce him to leap the bar, and to reward him for doing so. Leading the horse over ½ doz. times will suffice for the first lesson. The next day he may be trotted up to it, or more lessons may be devoted to teaching him to leap at command. With each succeeding lesson the bar may be raised until it is as high as the horse's breast, but beyond this, there is no necessity with common animals intended merely for private riding. Neither should the horse be wearied and disgusted with too long lessons. When perfect in his lessons, a boy may be placed upon his back to ride him over. The boy must be a good rider, or the horse may stop suddenly at the bar and throw him.

MULE, To Break.—Approach and handle him the same as an animal already broken, and, by kindness, in less than a week, the mule will be more tractable and better broken than he would in a month had the whip been used. In commencing to break mules, kicking is the first thing to guard against and overcome. The young mule kicks because he is afraid of a man. He has seen those intrusted with their care beat and abuse the older ones, and he very naturally fears the same treatment as soon as man approaches him. Most persons intrusted with the care of these young and green mules have not had experience enough with them to know that this defect of kicking is soonest remedied by kind treatment. Long experience with the animal will show that, in breaking the mule, whipping and harsh treatment almost invariably make him a worse kicker. He must be convinced, by kindness, that he is not going to be hurt or punished.

PACE, Training to.—Pacing is a favorite gait for a lady's horse. The animal should be taught to start out with the right leg, the left being uncomfortable to the rider as she sits the horse; and the breaker must persevere until the colt habitually starts off with the right leg. To teach the colt to pace, buckle around each hind leg 3 lbs. weight (lead is best); after which ride the animal briskly, at the same time twitching each rein of the bridle alternately; soon he will be thrown into a pace. After training him in this manner several times, detach the weights, and in their stead place 2 lb. weights, and use these several times; then change for something still lighter; leather padding, or even something still lighter, will answer the purpose, and these let him wear until he is perfectly trained, and you will have a smooth and even pacer.

RIDING, To Break for.—The muscles of a colt's back must be gradually trained before permitting much weight to be carried. Keep in mind that he is not accustomed to carry weights, and that to put 150 lbs. on him would be entirely wrong. Give the colt to understand that you are his friend. It will require but a few days to thus train the muscles; then he will bear the weight more easily. After the first 3 days, the horse will carry 125 lbs. easier than at first he could carry 40. Now fasten the saddle on, but not too far forward; buckle the girths tight, and let him remain a few minutes; then approach him gently, pat him on the neck, and draw up the reins tight with the left hand to the withers;

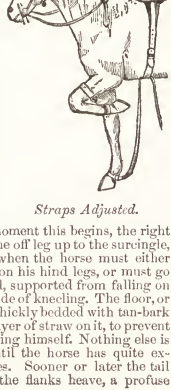
put the foot in the stirrup, and bear gently on the saddle, then pat him gently on the back and rump, speaking very low during the time. Then rise gently, throwing the right leg over the saddle, and sit perfectly still for a few moments; then dismount and caress him, patting his head and back, and after doing so a few times, he will be as submissive as a lamb. To start the colt, do not touch him on the side with the heel, or do anything to frighten or make him jump. Speak kindly to him, and if he does not start, pull him a little to the left until he does so; then let him walk off slowly with the reins loose; walk him around the stable until he gets used to the bit, when he can be turned in any direction and stopped when desired. After taking him out of the stable, be very gentle with him, as he will feel a little more at liberty to jump or run, and be easier frightened than while he was in the stable. When first mounting a colt, take a little the shortest hold on the left rein, so that if anything frightens him he can be prevented from jumping by pulling his head around. If he is stubborn, and will not go, he can be made to move by pulling his head around to one side, when whipping him would have no effect. Turning him around a few times will make him dizzy, and then, by letting him have his head straight, and giving him a little touch with the whip, he will go along without any trouble. Never use martingales on a colt when first driving him; every movement of the hand should go right to the bit in the direction in which it is applied to the reins, without a martingale to change the direction of the force applied.

STAND, Teaching to.—After he is well broken to follow, place him in the centre of the stable. Begin at his head to caress him, gradually working backward. If he move, give him a cut with the whip, and put him back to the same spot from which he started. If he stands, caress him as before, gentling him in this way until it is possible to get round him without making him move. Keep walking around him, and only touch him occasionally. Enlarge the circle when walking around, and if he then moves, give him another cut with the whip, and put him back to his place. If he stands, go to him frequently, and caress him, and then walk around him again. Do not keep him in one position too long at a time, but make him stand in another place, and proceed as before.

STOP, Teaching to.—The word, "whoa!" should be used only to stop a horse when he is in motion; never use it when you approach a horse standing quietly. Horses soon learn to distinguish any word often addressed to them, and they should learn to associate it with some definite and exact duty which they are desired to perform. If any word of command is used indiscriminately, or out of its proper place, the animal becomes confused, and loses the association between the word and the object desired. To teach a horse the meaning of the word "whoa!" the leg-strap may be used; or put a rope around his near fore foot, passing it under the girth; and, as the animal walks along, pull up the foot, saying at the same instant, "whoa!" He will be brought to a stop, and by repeating the lesson he will soon raise the foot and stop, even though the rope is not pulled upon. The object of this lesson is to teach him, that if he jumps when one foot is up, he is liable to be thrown down. The fear of being thrown, seems to be greater than almost any other fear which horses are subject to.

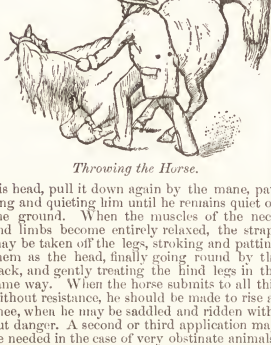
THROWING.—The following is a description of the celebrated Rarey method of taming a horse, and is based upon the fact that there is nothing a horse dreads so much as being thrown. Take a common bridle strap or rope; fasten the end carefully to the forward foot, below the fetlock; pass the other end over the belly-band of the harness and carry it back on the left side to the sulky over the hold-back strap of the breechin, and hold as a third rein in the hand. This strap, or cord, connected with the foot, is a means of control with which the horse can be governed, while moving in the harness, very easily. If the horse attempts to run away, simply pulling upon the strap, throws him instantly upon 3 legs, and he has to stop. If he attempts to kick, his attention is attracted forward instantly, and he finds it impossible. With a violent horse, it is better to let him feel his want of power for doing mischief with the near fore leg strapped up, and the slight degree of fatigue which a few minutes hopping will produce, before a second strap is called into play. When this is done, and the second strap is applied and put through the surcingle, the left rein is taken in the left hand and gently jerked, using, if necessary, the usual slight stimulus with the tongue to make the horse move, which he can only do by raising the off fore leg from the ground in the action known as hopping. The moment this begins, the right hand firmly draws the off leg up to the surcingle, and keeps it there, when the horse must either bound into the air on his hind legs, or must go down on the ground, supported from falling on his side in the attitude of kneeling. The floor, or ground, should be thickly bedded with tan-bark or manure, with a layer of straw on it, to prevent the horse from injuring himself. Nothing else is to be attempted until the horse has quite exhausted his energies. Sooner or later the tail begins to tremble, the flanks heave, a profuse

Leg Straps.



Straps Adjusted.

perspiration breaks out, and the horse lies, or is easily pulled over on his side. If he raises



Throwing the Horse.

his head, pull it down again by the mane, patting and quieting him until he remains quiet on the ground. When the muscles of the neck and limbs become entirely relaxed, the straps may be taken off the legs, stroking and patting them as the head, finally going round by the back, and gently treating the hind legs in the same way. When the horse submits to all this without resistance, he should be made to rise at once, when he may be saddled and ridden without danger. A second or third application may be needed in the case of very obstinate animals.

TROT, Training to.—Use rollers on the front feet. These rollers should be made of wood or horn; made round, about the size of a hickory nut, with a small hole bored with a gimlet in the centre of each, and about a dozen of them strung on a string or narrow strap. The string or strap should be much smaller than the hole. Then tie or buckle very loosely around the fetlock joint, next to the hoof, so that they can play loosely up and down when the animal is moving. As soon as the horse finds that there is something on his feet, he will naturally think that there are stones in his road, and will lift them up higher, and throw them out farther, and soon he will learn to be a good trotter.

TWO-WHEELED VEHICLES, To Train for.—A long-gaited horse gives an unpleasant motion to a chaise, dog-cart, or two-wheeled vehicle of any kind. Now all horses of good action will make good chaise horses if their gait is shortened. To do this, a net must be used. This net is like a breast-collar; it must be 2 or 2½ ft., and should be fastened to the collar and harness, and worn long, reaching to the knees; the cords in the fringe to this, must be about 4 in. apart, and on each cord there must be 4 balls, 1½ in. in diameter. There must be a similar net on the breechin, reaching round the flank and meeting the front one; the net must hang below the gambrils; then use a string of smaller balls on the fore feet, these to be 1 in. in diameter. They will effectually shorten the gait. Care should be taken in the first exercise after putting on the net. Drive or lead the horse around after the harness and net are on, before putting him in the chaise. After a few days' practice he will be a fine chaise horse. There are many horses that are very gentle after starting, but that will not stand to let more than one get in; they will then rear up and start very suddenly, and, if stopped, they become stubborn, and refuse to start when called on. People usually punish them with the whip, or by kicking them sometimes in the belly, which is very dangerous, as they have thus been ruptured. After he is hitched, caress him about the head; then take hold of the reins, and put the foot on the step, and shake the carriage; if he starts, pull gradually on the reins, and at the same time speak low, "Whoa! my boy," or something like it. Then approach his head, and give him a piece of apple; caress him on the head, between the eyes and on the nose and neck; continue this kind of treatment a few minutes, and, when in, don't allow him to start off in a hurry, but walk him off. After a few repetitions of this exercise he will be submissive.

VIOLENT HORSE, To Control.—The velvety nose and lips of a horse are his tenderest parts, and so instantly retroactive upon the whole nervous system as to afford to the skilful trainer a powerful means of control over the most violent animal. It is enough to touch the nostrils, simply passing the finger along the sides of the nose, to stop the activity of the heart and respiration, and stop consciousness in a measure; interchange between tissues and blood is also stopped. Sometimes the fingers may be passed inside the mares. Merely touching these parts may produce some effect; pressing hard upon them has far more effect. It is not essential that the application be made there, as a pressure of the lip only may produce the same thing.

Feeding.

REMARKS.—Horses need feed regularly, and as often as once in 6 hours, at regular times in the day; but they should never be crammed full of hay, especially after a long drive, when they have been without all day, nor just before a hard day's work or a long journey. Long intervals without food produce hunger, and hunger begets voracity; food is bolted, and indigestion and colic follow. This is doubly true and dangerous with horses doing hard work. They come to their long-deferred meal not only hungry, but exhausted; not only is the food bolted, but the stomach is in such a state as to be incapable of thoroughly active digestion, and is overpowered by half the amount of food it could otherwise digest. The kind of work which the horse is intended for, affects not only the quantity of food required, but also its quality. Hay, alone, be it ever so good, is not fit feed for horses, whether working or idle; they need grain; with an occasional feed of roots, bran mash, or something to keep their bowels open. The best feed for horses is about 12 lbs. of hay, and from 3 to 10 qts. of oats, given in regular feeds daily, with a feed of raw potatoes once in the week, when idle or at gentle work, and a small increase when at hard work. In winter, when horses return from work in the evening, a warm feed of roots, such as steamed potatoes, will be useful. In winter horses can work from 8 in the morning to darkness in the

evening, with 1 hour's rest and a feed of corn at noon.

APPLES.—These stimulate the appetite, and give the animal a fine glossy coat. The ration should be small at first.

BARLEY.—This may be given advantageously to horses when mixed with other food. Barley, given to horses just recovering from sickness, has been found to recruit their strength and tempt their appetite. It is best given in the form of mashes, hot water being poured upon the grain, and the vessel kept covered over with a cloth for ½ hour or so. In this form it is easily digestible, and promotes assimilation of other food, in conjunction with which it may be used.

BEANS, English Horse. — These are fed to horses in England. They are injurious when given alone, and should never be used for animals that are not working. They may, however, be given to great advantage when mixed with oats and other grain, and should always be crushed. Beans are heating and astringent in their nature, and may often be given with advantage to animals liable to purge, though too stimulating and binding by themselves. An occasional feed of beans, mixed with his other food, will improve the stamina and spirit of the working horse. Beans should be at least 12 months old before they are used, and care should be taken to keep them from becoming damp and moldy.

BEANS. Locust.—These are a doubtful article of food to have recourse to, not being very digestible, and when given whole are apt to accumulate in the intestines; on this account they should always be split, otherwise severe diarrhea is occasionally produced, which is very difficult to stop at times, the kind of shell in which the bean is enclosed resisting the digestive fluids of the animal's system.

BRAN MASH.—Put ½ peck of bran or pollard into a bucket, and pour on it enough scalding water to wet it thoroughly; stir well with a stick, or work with the hands, and let it stand covered up until new milk warm. If a horse is not in work on Sunday, give it on Saturday evening a bran mash, in lieu of a feed of corn. Bran mash is cooling, and slightly laxative. The bran should always be freshly ground. When intended to be nutritive, oats should be scalded with the bran.

BREAD.—Oat or rye meal, 3 parts; mashed potatoes, 2 parts; a little salt and yeast, to ferment; mix, and bake. Give 4 lb. rations daily. This method effects a great saving over the common plan of feeding horses.

BISCUIT.—This is made of crushed oats and the flour of gray peas, mixed with hemp-seed oil and salt, and is 4 in. in diameter. A day's ration weighs about 4 lbs., and is equal to 10 lbs. of oats. Horses like the biscuit when soaked in water; but, if fed exclusively on them, they lose in flesh, though they are still fit for fatiguing work.

CHAFF.—The proper proportion of hay and straw to be used in the composition of chaff for horses, is generally considered to be 2 bales of clover or meadow hay to 1 of straw, either wheat or oat straw: 8 lbs. of oats and 2 of beans, are considered also to be the proper quantity to add to 20 lbs. of chaff. Large horses, such as are usually employed in wagons, may require 40 lbs. of this mixed food per day; but for the ordinary farm or cart horse about 36 lbs. is considered sufficient. By giving chaff and corn together, the horse is obliged to grind his food, and properly masticate it before swallowing. Horses which eat greedily, often swallow the corn entire, which may be seen in the dung, and which consequently does not do them the good it ought to do.

CLOVER.—Clover, in its green state, is usually considered inferior to the artificial grasses. For soiling horses, though, clover hay is often preferred for chaff to meadow hay, and it will sometimes tempt a sick horse to eat that has neglected his food.

CORN.—In midwinter, when the weather is cold, corn is the best feed for promoting plumpness and warmth in horses; but it is heating, and not good for summer feed, if the horses are idle. Using crushed corn is an injudicious practice; for, to prepare the food for the act of swallowing and for its reception by the stomach, it is not only necessary that it should be broken up, but that it should be thoroughly softened and saturated with the saliva. The horse, finding his corn crushed, and requiring little chewing to break it up, and particularly if he be a greedy feeder, swallows it but partially mingled with the saliva, and not fully prepared for what is to follow. In some cases, bruising the corn is to be recommended; in such, for example, as a horse with some disease of the masticatory organs, or where a horse invariably swallows the greater part of his corn whole; although, in the latter case, he may frequently be prevented from doing so by having a little chaff mixed with the corn. Damaged corn is exceedingly injurious as food for horses, because it brings on inflammation of the bowels and skin diseases.

CORNMEAL.—This is easily penetrated by any liquid. When cornmeal is masticated by a horse, it becomes saturated with saliva, and takes the form of a plastic, adhesive mass, and in this form goes into the stomach of the horse. The muscular movements of the stomach can only move or roll this mass about; but cannot separate or loosen its particles, so as to render it sufficiently porous for the circulation and operation of the gastric juice. It is for this reason that whole corn, or that coarsely ground, may be fed alone to a horse, with less danger of colic or other diseases induced by a fevered stomach, because, in the form of cracked kernels, it cannot adhere into such a solid, plastic mass, and what is not digested will be passed in the droppings. And when this finely ground cornmeal is mixed with a little more than ½ its weight, but several times its bulk, of cut hay, this fibrous hay so completely separates the particles of meal as to form a spongy, porous mass that fluids can pass through freely. When the horse masticates the meal, he also masticates the hay, and the whole goes into the stomach together.

COTTON-SEED MEAL.—This is being used in cut feed to great advantage. Begin with 1 tea-

cupful at a meal, and it can be increased to 1 qt. It produces fat, and a fine, glossy coat. It is apt to ferment in bulk, and must be used fresh. It is a cure for hide-bound.

HAY.—Good, sound hay, is a very important article of food to the horse, but its qualities vary considerably. If allowed to stand too long before cutting, when it has shed the greater portion of its seeds, the value is considerably less than when it has become full of herb and flower. Moldy and inferior hay should never be given to horses, as colic and irritable coughs are often produced by its use. Good upland hay contains twice the nutritive qualities possessed by the inferior sorts that have been harvested too late in the season. The hay should be sprinkled with water in which salt has been dissolved, as it very materially aids the process of digestion. Old hay is more nutritive and wholesome than new hay, on account of its having undergone that slow process of fermentation which sweetens it and develops its saccharine qualities. By feeding on new hay, there is no real sickness, but a general weakness, frequent sweats, loss of appetite, digestion disturbed, diarrhea, relaxation of the muscles, weariness, etc. New hay can replace old hay in the regular rations without injury, and perhaps with advantage; but to feed exclusively on new hay is injurious to horses. Good timothy, blue-grass, or red-top hay, with plenty of oats, may be considered excellent food for both horses and mules during the winter. Kansas prairie hay, though coarse and cheap, is a favorite in the West. It contains a weed that acts favorably on the kidneys. Clover hay, when fed unmixed to horses, often produces a cough. This can always be removed by substituting timothy for a few weeks, after which the feed may consist of ½ clover and ½ timothy, with little or no danger of producing a cough. When the clover hay is fed from large troughs or mangers, instead of racks above the head, horses escape the dust, and consequently the cough.

LINSEED.—This has been a good deal employed in feeding farm horses, boiled with roots or mixed with cut feed, the best method of doing this being to keep it in a bag by itself, so as not to let it get mixed up with the other food in the vessels in which the bulky food is prepared. Although very nourishing, it is of a laxative nature, but possesses assimilating properties that cause it to be very useful. The skins of horses, that are fed upon linseed, are generally very fresh and bright looking. Too free use of linseed is, however, injurious, and must be avoided.

LINSEED OIL.—This is not only a valuable restorative for sick horses, but it is exceedingly useful in cases of inflammation of the membranes peculiar to the organs of respiration and digestion, which it shields and lubricates. Put 2 handfuls of seed into a bucket, and pour 1½ gals. of boiling water upon it; cover it up a short time, then add 2 qts. of cold water, when it will be fit for use. In case of an irritating cough, add some honey.

LUCERNE AND SAINFOIN.—These are very similar in their nature, and when well got make a capital hay, but are chiefly used in their green state, the latter being considered preferable. They are easily digested; the horses thrive that are fed upon them, and put on fat and muscle. They are very efficacious when horses have become hide-bound, for which they are a capital remedy.

OATS.—It is the best plan to bruise the oats that are given to horses, though a strong horse in his prime will be able to masticate his food readily enough; but in the case of old horses, which are not in the full possession of their masticatory powers, and in the case of greedy horses that bolt their food, the bruised oats is certainly preferable. When oats are mixed with bran, it is much less heating. Bad oats become a powerful diuretic, and increase the secretions of the kidneys; and, although the musty smell of oats can be removed by kiln drying, the kiln-dried oats acquire a heating quality, and are not so good for animals as sound oats. Although new oats are much heavier than old ones, the difference is simply caused by the presence of watery matter, which is gradually evaporated; and it will be found the best and safest plan not to tamper with doubtful or inferior food, but supply that of the best quality.

OIL CAKE, Of Linseed or Cotton Seed.—A little oil cake or meal, given to the farm team about the time when shedding the winter coat, will be of great advantage. It will act as a gentle laxative and stimulant, and render more active the various secretive organs of the system, and better fit them for the arduous labors of the season.

PASTURING.—One of the benefits derived from pasturing, is exercise. The slow but constant exercise, thus rendered, is highly beneficial to lame horses; but the exertions demanded by a bare pasture, are very unfavorable to any sprain or lameness arising from disease in the ligaments. Horses that have any disease about the head should not be sent to pasture. Even healthy horses are liable to attacks on the brain when turned to grass, particularly when the weather is hot and the herbage abundant. Horses that have been for more than a year in the stable, and those that have been reined up in harness, often experience difficulty in grazing. The neck is rigid, and the muscles which support the head are short. Very old coach horses, that have short, stiff necks, should not be turned out when they can be kept in. Pasture alone will not be enough for horses at night, that are kept at work through the day. A run in the pasture will be beneficial, but a feed of grain should be given before turning them out. Nothing will do so much good to a horse as turning him out in the spring, but the condition of matters alters very much as the summer advances. The grass gets dry and loses its succulent and aperient quality, while the ground, instead of being soft and moist, is, perhaps, baked hard and made hot by a summer sun. Such is often the result with a horse left out at grass during the entire summer, so that by the end of it he comes back to the stables quite out of condition. To avoid these results, let him enjoy to the full the months of May and June; but when the ground becomes hard, and the flies make their appearance upon the scene, he is then best taken away.

By that time he will have derived the benefits to be had from the change, without being exposed to the disadvantages that afterwards ensue from a too long run at grass. A horse requires no physicking at that time, as the grass acts as a gentle aperient, which carries off various little humors, the result of dry food and partial confinement, and the breathing of an artificial atmosphere.

PEAS.—These are not so heating as beans, and are in a slight degree more nourishing, while they are at the same time easier of digestion. White or Canadian peas are considered the best kind for the use of horses by some. Peas, also, are better crushed, as, on account of their round shape, they are apt to be swallowed whole at times and escape the grinding to which it is necessary they should be subjected. It is not considered advisable, however, to give peas to horses that are required to maintain their full speed, answering better with horses of slow draught. Some horses will eat peas very greedily whenever they get a chance, the result being painfully distended stomachs, which have sometimes actually burst when they have become fully gorged with them, which is to be as much guarded against as the megrims or staggers caused by beans.

ROOTS.—These become a necessity as a winter stock food, and their great value in this connection should commend them to those who have not engaged in their cultivation. *Carrots* are excellent when employed as a tonic for old horses, in order to purify and strengthen the blood; but dangerous for young horses, and especially for stallions; they give them too much blood, make them nervous, irritable, spiteful or vicious, when at work, and predispose them to apoplectic fits if they do not take enough exercise. Horses eat them with avidity, especially when they are mixed with coarse bran.—*Parsnips* are very healthful, and when fed instead of carrots and oats, give great vivacity of spirit and sleekness of coat.—*Potatoes* are frequently given to farm horses, raw, sliced with the chaff; but they form much better food when given boiled, some horses eating them with great relish. When cooked, a proportion of 1 part of potatoes to 3 parts of other food, is about a proper quantity to give; and, as potatoes contain much water, when horses are fed upon them to any extent, it will be prudent to curtail the supply of water somewhat. If the potatoes are kept frozen until they are cooked, the only difference in them is a partial change in the starch to sugar, which goes on slowly even at low temperatures. They thus acquire a sweet taste, but are in no way injured for feeding. By being boiled and cooled, they may be fed to horses with benefit; and if any grain food is used with them, it should be bran or oats, rather than cornmeal.—*Turnips.* These are healthful for horses, and should be cut in slices, or, what is better, pulped finely and mixed with a little meal and some salt. They assist in maintaining the sleek, healthy condition which the horse has acquired on good grass. Rutabagas are better than white turnips.

STRAW.—This may be fed to horses in small quantities without injury. The nutriment should be supplied mainly with grain, for the purpose of the straw is to distend the stomach and aid the animal economy to maintain thrift otherwise than by the nutriment contained in the straw.

WATERING.—A horse needs much more water during a day and night than most people suppose. When a horse wants water, if he does not receive a supply, he endures intense suffering. After being driven until he perspires freely, there will be an imperative demand for water to supply the place of the liquid that has passed off through the pores of the skin; and, after he has filled his stomach with dry feed, a little water is needed to promote digestion, especially when the animal did not receive a generous supply before being fed. When horses are watered frequently they will drink only a few qts. at each draught. This is infinitely better than to allow them to gulp down at one draught 2 or 3 pailfuls. Horses require 4 lbs. of water for each lb. of dry substance in their food. Have the stable fitted with a small water tank, from which the horse may drink as often as he feels inclined. If pure water does not flow at the barn, look into the means for securing it. It is better, however, to water horses from a pond or stream, rather than from a spring or well, because the water from the latter is generally hard and cold, while from the former it is soft and comparatively warm; the horse prefers soft, muddy water, to hard, clear water. A sudden change of water may induce a severe attack of colic. To avoid any ill effect, it is best to mix a handful of oatmeal or bran in strange water, and, if possible, warm it a little. The temperature of springs and wells varies very much, and a difference of 10 or 15° is quite frequent; that is quite sufficient to affect injuriously the condition of the horse, which is an animal that easily suffers from disturbance of the digestive organs. Never give a horse large draughts of cold water when he is overheated. Lukewarm water may be given in small quantities without injury.

WHEAT.—This is occasionally given to horses, but it is not a safe grain to resort to, being somewhat difficult of digestion, and apt to cake in the stomach, so that it requires to be bruised and always given with chopped feed. A horse should not be allowed to drink water immediately after eating wheat, and at first it should be given in small quantities, if the necessity should arise that the horses need to be fed upon it; they will thrive after having become accustomed to it, and when it is used with discretion.

GROOMING.

REMARKS.—Punctuality in all the daily operations appertaining to the stable should be strictly observed. Not only should the horse be watered and fed at regular times, but his entire management should be conducted upon a system of thorough routine. Stable operations ought to begin at the latest at 6 A. M., and in fine weather the door, upon the first entrance of the groom or stable-keeper, should be left open

to admit fresh air; and each animal should receive an inspection in turn, to see if they are all right, particularly those which have been tied up. Little accidents may have happened during the night; a shoe cast, or the first signs of indisposition may be exhibited by an animal; and these should all be carefully noted, in order that necessary remedies may be applied without loss of time. Good grooming to the stable horse is essential; the use of the brush opening the pores of the skin and promoting circulation of the blood, without which the horse cannot be preserved in good health; and good grooming will take the place of exercise in promoting free perspiration. Heat will have the same effect, and thus indolent grooms like a hot stable, because it saves them a great deal of trouble, but at the expense of the constitution of the horse. Much grooming, however, is not required for the farm horse, kept constantly at work, which requires mainly to have all the dirt well brushed off, too much grooming in his case being likely to render his skin more sensitive to the weather. The dandruff which accumulates at the roots of the hair of horses which are turned out altogether, acts as a protection against the cold winds; they thrive best when let alone under such conditions. Grooming, when it can be avoided, should never be done in the stable, but in an adjoining shed; the dust will get upon the hay and corn, fall upon the other horses, and soil the appointments of the stable. A thorough washing with clean water, not too cool, will greatly aid in keeping the working horses in good condition; it removes the dried sweat and dirt much better than dry rubbing. When brought in from work warm with exertion, the horse must be rubbed down and then blanketed; the feet and legs, in muddy weather, must be washed and carefully picked; but, unless they are rubbed quite dry afterwards, it were better not to wash them at all; the safest plan being to rub off the loose dirt with a soft broom, and afterwards wisp them till they are dry; after which curry-comb or rub off the dust entirely.

BALLING. To Prevent.—When the snow upon the roads is cohesive and packs firmly, it collects upon the feet of horses, forming a hard, projecting mass, known as "balling." The trouble may be prevented very easily by the use of gutta-percha. For this purpose the gutta-percha should be erude; to apply it, place the gutta-percha in hot water until it becomes soft, and, having well cleansed the foot, take a piece of the softened gum, and press it into the shoe and foot in such a manner as to fill the angle between them, taking care to force it into the crack between the two. The ball of snow thus has nothing to hold it, and it either does not form or drops out as soon as gathered. When the gutta-percha is applied and well smoothed off with the wet fingers, it may be hardened at once to prevent the horse from getting it out of place by stamping, by the application of snow or ice, or more slowly by a wet sponge or cloth. To remove the gum, apply hot water by means of a sponge or cloth, which will soften it. The same material will last for years. For a horse of medium size ¼ lb. is sufficient for all the feet.

BITS.—The compound bit is composed of 5 principal pieces, viz.: The mouth-piece, the branches, the rings, the curb, and the cross-bar. A compound bit, however, is not always requisite, many ponies and horses being ridden with a simple snaffle, which should be in the corners of the horse's mouth without pressing against it. The curb bit powerfully controls the horse, but with the snaffle he can take a natural position and act with more freedom. The snaffle is preferable for common use in every way; but if the rider cannot control his horse, he must resort to the curb bit, which should be knotted underneath the snaffle. Care should be taken that the bit does not press unnecessarily hard upon the horse's mouth, nor that it is so sharp as to wound it. It may be necessary to have a sharp bit for the headstrong and obstinate animal; yet if it is severely and unjustifiably called into exercise, the animal will, in all probability, plunge and rear and endanger both himself and his rider. The torments which the trappings of the mouth often inflict upon the docile and willing horse, are useless and cruel, and only serve to render the mouth hard, thereby destroying all the pleasure of riding, as well as causing the horse to become fretful and vicious. Rubber bits are the best for winter use on horses. Warm the bit on the bridle, in frosty weather, before putting it in the horse's mouth. The bit, full of frost, coming in contact with the tongue and lips, adheres to these soft tissues the same as it would do if red hot, leaving the animal with a sore mouth.

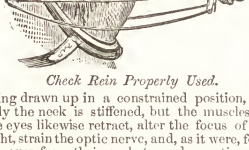
BLINDERS.—Blinders should never be used, and the sight of the horse, for many reasons, should not be interfered with in any way. Horses are only fearful of objects they do not understand, or are not familiar with, and the eye is one of the principal mediums by which this understanding and this familiarity are brought about. Horses can be broken in less time, and better without blinders; but horses that have always worn them will notice the sudden change, and must be treated carefully on the first drive; after that they will drive better without blinders than with them. The horse, when permitted to see, uses his eyes with great judgment; and, if allowed the free use of them, would often save himself by the quickness of his sight from collisions, when the driver would fail to do so by a timely pull on the reins. It would also save many accidents to pedestrians in the streets, as no horse will run over any person he can see.

CHECK-REINS.—When used properly there is no objection to the check-rein. It keeps the horse in shape and prevents him from putting his head to the ground when standing. When the check is drawn so as to derange the natural incline of the head, it causes a stiffness of the neck and a pressure of the cervical and dorsal vertebræ, changes the natural position of the windpipe, and interferes with free respiration. The neck being raised, curves the vertebræ of the back, making it hollow, which has a tendency to draw the hind legs forward under the body, or to thrust the body backward upon them. This is a prolific cause of the knuckling

over the pasterns and springing of the knees. Besides, an undue bearing is brought on the lumbar vertebræ, serious strain is produced on

Check Rein Improperly Used.

the loin and rear parts, and a disordered state of these members is the consequence. Hence come lumbago, spinal meningitis, and other diseases of the spine, contracted heels, navicular joint disease and leg disorders. Moreover, the head



Check Rein Properly Used.

being drawn up in a constrained position, not only the neck is stiffened, but the muscles of the eyes likewise retract, alter the focus of the sight, strain the optic nerve, and, as it were, force the eyes from their sockets, and sometimes so distort them as to prevent the closing of the lids.

CLIPPING, SINGEING AND TRIMMING. — *Clipping.* The coat of the horse is changed twice a year; the long hair of winter coming off in April and May, or sometimes earlier when the stables are warm, and there is no exposure to severe cold. The reason for clipping the hair off horses at the beginning of cold weather, is this: The hair becomes so thick, that when a horse is driven very fast he naturally becomes heated and wet with perspiration, and the hair, holding the moisture, does not permit the horse to dry, and so leaves him very liable to take cold. Clipping is mostly practiced on blooded horses. Horses that are kept moving all the time while out of doors in cool weather, may be clipped with advantage, but no clipped animal should stand exposed, even blanketed, to the cold. Horse clipping should not be performed by any but the professed artist. When a horse is well clipped, his skin should look as level and almost as glossy as if he had on his ordinary summer coat. It should not be done till the new hair has attained nearly its full length, for it cannot be repeated at short intervals like singeing. If it is attempted too soon, the new coat grows unequally, and the skin in a fortnight's time looks rough and ragged. A comb, and 2 or 3 pairs of variously curved scissors are all that are required, with the exception of a singeing lamp, which may be used at last to remove any loose hairs which may have escaped the blades of the scissors. Two men generally work together, so as to get the operation over in from 16 to 20 hours, which time it will take to clip the averaged sized horse properly. While the process is going on, the horse ought to be clothed as far as possible, careful men removing only so much of the covering used as is sufficient to expose the part they are working at, and no more. As soon as the whole body is gone over, as well as the legs, the singeing lamp is lightly passed over the surface, which will leave the hair burned to such an extent as to require a rapid washing with soap and water, followed up by a good strapping and plenty of warm clothing.—*Singeing.* About the end of September is generally the best time for singeing, but much depends on the condition of the horse's coat when these operations should be performed, some animals shedding their coats much earlier than others. Accidents sometimes happen in singeing, the skin being not unfrequently burned, and sometimes the mane and tail are disfigured; and where a coat has been left on too long, or is of a coarse nature, the horse should be clipped first, and then afterwards lightly singed. Singeing should be repeated every 10 days or a fortnight till the coat has done growing, which will thus be kept short and present its natural color. When clipping and singeing are performed, the condition of a horse is vastly improved, and he is much more vigorous and healthy than one that is allowed to keep on his natural winter coat, which often gets wet and dirty, the animal at the same time being dull and lifeless. The horse should have a gentle sweat, be well washed, and rubbed dry after singeing, and then be clothed up, and the next day he will be found ready for his usual work, which he will do in a brisker manner than before the operation was performed. Singeing requires less practice than clipping, but it cannot be done without some little experience; a novice generally burns the skin as well as the hair. On account of so many applications of the lamp, the professed singer is not so often employed as the clipper. The lamp used, is attached to a wide copper comb, made like a rake in principle, and is so arranged that the teeth raise the hair and draw the ends into the flame. Where gas is available, the comb is attached to the gas-pipe by a flexible tube, and the lamp consists merely in a number of holes perforated along the edge of the comb, so that a series of jets of gas are lighted and burn so strongly that the coat is completely removed as near the skin as the teeth of the comb can raise it. If gas cannot be obtained, a wide wick of cotton is inserted in a flat holder, the ends protruding to the level of the teeth, while a reservoir filled with naphtha supplies a constant flame, but not nearly equal in strength to that from gas. In the winter, the arms and backs of the knees, as well as the bosom and the insides of the quarters, will generally want singeing, whether the body is

submitted to the lamp or not; but in the summer, even if any long hairs are left there, they are easily removed by the hand armed with resin. Unless general clipping or singeing is practiced, the front surfaces of the legs do not require trimming at any season of the year.—*Trimming.* The jaws, nostrils and ears are singed, the last named not being touched inside, as the internal hairs are a protection of the delicate lining membrane of the ear from the cold and wet. The long bristles of the nostrils may be either cut off, pulled out, or singed off, but the first plan is the easiest and the most humane. There are, also, some bristles about the eyes, which are generally removed. The hair which grows 1 in. or more in length beneath the jaw, being of the same nature as the rest of the coat, can only be singed off with advantage, and it should be done as fast as it grows, especially if the singeing is not universal, or there will be a different color presented in these parts. The legs are trimmed partly by singeing, and partly either by clipping or pulling out the hairs. Great dexterity is required to manage this performance in a workmanlike manner, so as to avoid the stale and post-like appearance which is presented by a leg clipped all over (without a corresponding clipping of the body), and at the same time to remove all, or nearly all, the superfluous hair. In the summer, a clipped leg is totally inadmissible, and even from the legs of a badly bred horse, the hair may be pulled by gradually working at it for a little time every day with the fingers armed with powdered resin. This prevents the hair slipping through them, and by its aid such a firm hold may be obtained, that perseverance will clear the legs entirely, with the exception generally of a strong lock of hair behind the pastern. When this is very obstinate use the scissors to clear away the hair below the horny growth which is found there; but there should always be left a slight fringe round this, so as to avoid the stiff and sharp outline presented by the clipped leg. A small lock of mane is generally cut just behind the ears where the head of the bridle rests, as it would otherwise lie beneath that part in an untidy manner. In trimming the tail, it is carefully combed out; then held by an assistant's hand placed beneath the root of the dock, as nearly as may be in the position which it assumes in the animal out of doors. While thus poised, the operator takes a pair of sharp scissors, and holding the blades horizontally open, he insinuates one of them through the middle of the tail at the place to be cut, passing it straight backwards and cutting the hair quite level from the central line to the outside on his own left. Then reversing the blades, and keeping to the same level, he cuts towards the right. To make the mane lie smoothly on its proper side, it must be plaited in small locks, and the ends loaded with lead if it cannot be made to lie down without.

CLOTHING.—Horse covers are regarded by many as necessary to protect the animals from cold draughts of air, and are often in a great measure useful in keeping dust from their coats. Horses, however, are clothed too much in some stables, a single sheet being sufficient in summer time, and one good woolen cover all that is required for winter; but keeping them constantly covered makes them tender and liable to take cold. It is far better to give them a warm stable and plenty of straw for bedding, and good food, and leave the blankets to be used only when they are compelled to stand for any length of time out of doors on a cold winter's day; also when they come in from work, steaming hot, they should be allowed to stand a very short time until they are partially cooled off; then put the blankets on for an hour; but be careful and not delay putting on the blanket until they are chilled.

COLLAR. — The collar is a most important thing to look to, and which should be always deep enough to prevent the horse's shoulders from suffering; the usual way to test a fit being to lift the horse's head up to the height he usually carries it when going along, sufficient space being left to insert the hand comfortably between the collar and the horse. It should fit like a comfortable shoe. An excellent plan to secure a good fit, and one that will not injure the collar, is to dip it in water until the leather is thoroughly wet, then put it on the horse, securing the hames firmly, and keeping it there until it becomes dry. It is all the better if heavy loads are to be drawn, as that causes the collar to be more evenly fitted to the neck and shoulder. If possible the collar should be kept on for 4 or 5 hours, when it will become perfectly dry and retain the same shape ever afterwards; and, as it is exactly fitted to the form of the neck, will not produce chafes or sores. In young horses, sweeney, or wasting of the muscles of the shoulder, is often a consequence of unsteady pulling with an ill-fitting collar.

EXERCISE.—Regular exercise is essential for keeping horses in health, as it enlarges the muscles and removes from them the fat which gets into their interstices when well fed and very much confined to a stable. A stable-fed animal needs to have 2 hours exercise daily, if he is to be kept free from disease and in perfect health and working condition; exercise promoting vigor and strength; whereas, if he is kept idle in the stable for 2 or 3 days out of the week, his health will inevitably suffer. Young horses require more exercise than old ones, and the amount of exercise given should be proportioned to the age of the horse. Working horses should be exercised for at least ½ hour every day for which they are not required for work.

FEET, Care of.—There is nothing more necessary to be observed than the feet of horses, which ought to be objects of particular attention. Each morning the feet should be carefully picked and examined, so that it may be seen whether the shoes are fast, and their condition; whether the clinches are not raised so as to cut the horse, and that the heels do not press on the foot. Whether the shoes are worn out or not, they ought to be taken off once in 3 weeks, when the feet grow fast, to see if the hoof requires some attention. Immediately the horse's hoof becomes too high, it begins to contract, and in hot weather, especially if the feet are of a hot and dry description, they should be stop-

ped every night; cow-dung or even horse-dung being better than clay, and the former is improved by having a small quantity of tar mixed with it.

FIRE, To Save from.—Horses are frequently burned to death when barns or stables are on fire, owing to the impossibility of leading or driving them out of the building while their eyes are dazzled by the blaze. But, by simply covering their eyes with a bag, a coat, or a pocket handkerchief, they may be led out of danger without trouble or difficulty. They will the more readily come out if the saddle and bridle, or harness, to which they are accustomed, be thrown over them as usual. Goats ought always to be kept in large stables, because they will face fire, and horses will follow them out, though they would not go out by themselves.

FLIES, To Rid from.— The flies which infest stables are not the common flies, as is generally supposed, but a savage, biting fly. It is this which causes the constant stamping upon those nights when the air is close and heavy. This may be prevented as follows: 1. The horse may be brought into the yard, and a pailful of water, a sponge, and a piece of carbolic or whale-oil soap provided. First, with a corn-broom, the legs of the horse should be washed down, and then the whole body rubbed off with a handful of straw dipped in water; the sponge is then well soaped and passed over the whole body, leaving some soap-suds to dry upon the skin.— 2. Moisten the hair, especially of the tail and nostrils, with a strong decoction of hazel-nut leaves. By means of this decoction, the eggs which the flies lay on the skins of horses are also destroyed.—3. Darkening the stables during the day will keep out many flies. — 4. Kerosene oil, slightly sprinkled on the floor of the stables, will also serve to abate the nuisance. It may be shaken out of a bottle through a hole in the cork. A pint will last a week for the purpose.

HALTER.—There are two kinds of halters, the common halter and the head collar. The common halter is more generally used; but for unruly horses the head collar is best, as it passes around the neck and renders it impossible for the animal to get loose.

HARNESS.—This should always be of the best description and quality; cheap and indifferent harness is apt to give way when any severe strain is put upon it, and the user has to rely upon it most. A good harness is somewhat expensive at first, but if kept in good condition it will last for a long time, and any part that shows signs of wearing should be carefully renewed without loss of time. The harness should be kept clean and soft, that it may not gall the animals. A little powdered aloes rubbed in with the oil will keep away any insects that are likely to infest the harness, and will do no injury to the horse. In cleaning, unbuckle all the parts and wash clean with soft water, soap and a brush. A little turpentine or benzine will take off any gummy substance which the soap fails to remove. Then warm the leather, and as soon as dry on the surface, apply the oil with a paint brush or a swab. Neat's foot oil is best. Hang up the harness in a warm place to dry, but do not let it burn. Keep the leather soft and pliable, by keeping it well charged with oil and grease. The grease should sometimes be preceded by blacking, or the leather will turn red. (See LEATHER AND SKINS.) Water destroys each one of these; but mud and saline moisture from the animals are even more destructive. Mud, in drying, absorbs the grease and opens the pores of the leather, making it a ready prey to the water, while the prespiration from the animals injures the leather, stitching and mountings. It therefore follows that to preserve a harness, the straps should be washed and oiled at intervals as required, and then rubbed with a woolen rag. The rubbing is important, as it, in addition to removing the surplus oil and grease, tends to close the pores and give a finish to the leather. In hanging harness, allow all the straps to hang their full length. Light is essential to the care of leather, and when the harness closet is dark the door should be left open at least half the time during the day. All closets should be well ventilated, and when possible lighted. To clean plated mountings, use a chamois skin with a little tripoli or rotten stone, but they should be scoured as little as possible. A teaspoonful of cayenne pepper, mixed in 1 qt. of oil, if rubbed on the harness, will effectually protect it against the gnawing of rats.

NICKING.—This operation is for altering the carriage of the tail when it is too low for the taste of its owner. The horse should be confined in stocks fitted for that purpose. The tail then should be plaited up and clubbed at the end, turned over a small stick and securely tied with a string. Being provided with a knife, made for that purpose, turn the tail up within a direct line with the back; commence the operation by making an incision about 1 in. from the rump close to the hair; cut the cords in one place on each side, leaving an incision only the size of the knife blade; be very careful not to touch the bone with the knife, for if so, it would create inflammation, and the hair would come out. Great pains should be taken to have the weights equal, in order to keep the tail in a perpendicular direction, and prevent it from turning to either side during the time of healing, as a horse that carries his tail to one side instead of being elegantly nicked, is ruined. The horse many times has had a crooked tail before he has been nicked. To straighten the tail, cut the top cord; the under cord depresses the tail, and the top one raises it. When standing, the tail is straight; you will see at once that it is the top cord. In cutting the cord to straighten, cut the long cord, and the short cord will pass by on a lap and grow together, leaving the tail as strong as ever. Pulling is not required in straightening the tail. A more humane way of setting up the horse's tail, to give him a more stylish appearance, is by simply weighting it, for a few hours each day in the stall, until it attains the desired elevation. This is done by having 2 pulleys at the top of the stall, one at each side, through which are passed 2 ropes, which come together and are fastened to the tail, the ropes having at their other ends weights (bags of sand or of shot are very good for the purpose), which must

be light at first, and may be increased from day to day. The weighting should be continued until the tail has taken a permanent position as desired. This method requires a somewhat longer time than that of cutting the muscles, but while it is being done the horse is never off his work, and suffers infinitely less pain.

SADDLES.—Saddles for riding horses are made of various sizes and weights, some people preferring plain flaps, and others padded ones. To the majority of riders the padded flaps are found the most convenient, as the knee is kept more firmly in its place, and the leg is consequently maintained in firmer position at those times when the horse has occasion to exert himself somewhat violently, as in jumping in hunting, or when the rider has to recover a stumbling horse. The saddle should be sufficiently long and broad to carry the rider's weight fairly distributed over it, so that an equal pressure is applied to the back of the horse; otherwise, if extra weight is thrown upon any one particular part, saddle-galls will be produced, which often take a long time to cure when a horse is constantly ridden, and are often very hard to get rid off. There should be 2 girths to every saddle, the broad girth being used with 2 buckles at each end, which is put on first, and then a narrower one over it, with 1 buckle at each end, about half the width of the other. When this description of girth is not made use of, but the ordinary kind, with a buckle at each end, 2 girths should always be used. Stirrups should always be of sufficient size and not too small, so that the foot may be easily and quickly disengaged. The best saddles are made with spring bars, which release the stirrup-leather when an accident occurs, and these should be kept oiled so as to be always in good working order. The leather of which the stirrups are made should be fine grained, of close, tough texture, as strong as may be, without being too clumsy and heavy. When a horse returns from a long journey, or becomes hot in his work, the saddle must have absorbed a good deal of moisture, and unless it is carefully wiped and cleansed, it soon becomes hard, and not in a proper condition to be made use of by those who value their horses and study their comfort and well-being; for without care the saddle will remain damp, and, if put on in that condition the next day the horse will very likely take cold. To escape this risk, wear a cloth beneath the saddle, which can be easily dried, and, with a little care, it never gets hard.

STABLE UTENSILS.—The implements used in the stable should always be kept ready at hand, for immediate use, in one definite, appointed place; so that either the curry-comb, the body-brush, the dandy or whalebone brush, the mane-comb, or rubber, may be taken up in a moment without search having to be made for them, as well as a wisp of two sorts, one made of straw for rough purposes, and another of soft hay, to be damped and used at a later stage of the horse's grooming. In addition to these, there should be a picker, which is a blunt instrument that should be always ready at hand for the purpose of removing the stones and grit from the horse's feet, to which sharp pieces of flint will sometimes be found attached, as well as the loose particles that are commonly taken up. A sponge is needed to dry the legs after washing, which should never be left wet. Leathers and rubbers are required to rub the horse down after he returns from his work, and wipe him after

Stable Utensils.

dressing. A singeing lamp and a pair of scissors are necessary to remove the long hairs which often give the horse an untidy appearance. A wooden box should be provided to hold the stopping of cow-dung, mixed with tar, for the horse's feet; and there should be a tin can to hold oil, and an oil-brush, to oil the horse's hoofs before leaving the stable to go to work. A pitchfork is wanted to make up the horse's bed, which requires to be equally spread over the floor of the stable, and for the purpose of removing soiled or dirty litter, while a shovel is necessary for taking up the more solid and smaller particles that need removal. These must be supplemented by a good brick broom or two, to sweep up, and make things clean and straight, while a manure basket must needs be provided for the removal of the droppings which should be taken away as soon as possible, and before they get trodden about, which not only causes the stable to be much dirtier, but makes it a more difficult matter to clean it. A stable pail is required for water, which should never be used for any other purpose; and a sieve is wanted for the purpose of cleaning the provender and separating any small stones, dirt or other objectionable matter from it, while quart, peck, and ½ peck measures, should always be at hand with which to measure out each horse's allowance of food.

Stocking.

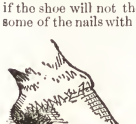
STOCKING.—This stocking is intended to contribute to the comfort of the horse and to its support. It consists of a snug-fitting, elastic

anklet of india rubber, molded to fit the horse's leg, and ribbed and reinforced to prevent sagging and slipping down at the top. It is also perforated to allow free exit for perspiration, and is laced in front as shown. The object of the invention is to provide a support, not always of the length shown, but longer or shorter as may be necessary in sustaining and protecting the tendons, ankles and knee joints of trotting and racing horses, and horses in general, so as to prevent injuries from overstraining or bending in stepping upon stones or rut holes.

SHOEING.

REMARKS.—Colts should never be shod until they are 2 yrs. old; for the feet increase in size with the rapidity of other parts of the frame, and hence the fettering with iron is sure to produce contraction. The time at which a horse's shoes should be reset, must depend very much upon circumstances. If a horse wears his shoes out in less than a month, they had better not be removed; and horses with thin, weak horn, which grows slowly, are, likewise, better left alone between each shoeing, unless their shoes last 7 or 8 weeks, in which case they should be removed once within the time; but horses with strong feet and plenty of horn, that wear their shoes 4 or 5 weeks, should have them removed at the end of a fortnight; and when the horses are doing so little work, or wear their shoes so lightly that they last over 2 months, they should be removed every 2 or 3 weeks, and at the second removal the shoes should be put in the fire, and refitted, or the feet will outgrow the shoes, as the horn grows much quicker when a horse is idle than when he is in full work. In shoeing horses, begin by taking off 1 of the old shoes; the others should always be left on, for the horse to rest upon. All horses stand quieter on shod feet than they can on bare ones; and they are less likely to break the crust; many tender-footed horses are in positive agony when forced to rest on a bare foot, while the opposite one is held up to be shod. First raise all the clinches with the buffer, and if the shoe will not then come off easily, loosen some of the nails with the punch; but never tear

Shoe Left on Too Long.



Properly Shod.

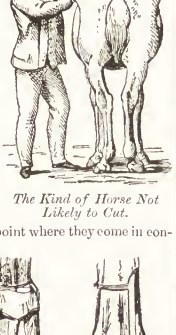
Foot Rasped to Make the Shoe Fit.

the shoe off by main force; it splits the crust, widens the nail holes, and destroys the horn. Rasp down the foot level, watching that the heels are not cut down too low, and take out any stubs that may be left in the crust. The object in preparing the foot for the shoe should be to remove any undue accumulation of horn, designed to prevent its natural bearing, and the free, healthy action of its parts, and this requires the cutting away of about the proportion that contact with the ground would have worn off or so much as had grown since being shod last. Before paring out a foot, think of the state of the roads; and if they are dry, and covered with loose stones, or have been lately repaired, take very little off the sole of any foot, because, if thin, the stones will bruise it; but when the season is wet, and the stones worn in, the sole of a strong foot may be pared a little, until it will yield in a very slight degree to the heaviest pressure made on it with the thumbs. The frog should be allowed to come to the ground, which will prevent, to a certain extent, the concussion which would otherwise take place. The frog should not be cut down, nor should it be touched when healthy, except for the purpose of cleansing. Have the shoe so formed as to size, weight, fitting and fastening, as to combine the most advantages of protection and preserve the natural tread of the foot the best; in weight it should be proportioned to the work or employment of the horse. If the horse walks principally upon the road, his shoes should be rather heavy, and must have a concave surface corresponding with the concave surface of the foot. The shoe should not have high calks at the heels, as they throw the entire bearing forward on the toe, thus, sometimes, causing contraction of the tendons. The shoe should be as big as the foot, so as not to require any cutting down of the hoof to make it fit the shoe, and the heels of the shoe should not be allowed to project backwards beyond the heel of the hoof more than about $\frac{1}{8}$ in. Never put hind shoes on fore feet. Practice cold fitting; a thick shelled foot is not injured by touching it with a red hot shoe that was previously fitted, but a thin shelled foot should never be pressed with a hot shoe. A hot shoe makes the hoof brittle instead of tough. It is better to heel first and put on the toe calk when ready to use the shoe. If the toeing is done last there will be heat enough in the shoe after welding the calk to fit the shoe. Let the heels, which are nearly cold, drop on the walls of the foot, and hold the toe, which is red hot, 1 in. away from the foot while fitting. After the toe is fitted and level, harden the toe and nail on. Put the point of the nail in the middle of the hole, keep the nail upright and drive it straight; it must come out in the right place, low down in the crust without the possibility of wounding the sensitive parts of the foot. Nails should never be driven high, and then in 6 or 8 weeks the foot will have grown sufficiently to enable the shoer to cut out the old nail holes, leaving sound hoofs. If the nails, however, are driven high, at the next shoeing the hoof will not have grown

High Calk.

enough to cut down to the old nail holes, and the water and mud will soak into these holes and cause the hoof to become rotten and brittle. The shank of the nail will pass straight through the substance of the crust, and gain a good, firm hold of it, leaving the strongest part from which to form a clinch. The clinches should be short and broad, and not thinned by rasping away any of their substance, but hammered at once into a slight notch made in the hoof under each; and the rasp should never be allowed to go over them after they have been hammered down, for the sharp steel rasp is almost sure to cut through the soft iron clinch just where it turns down, and leave the appearance of a clinch, when in truth it has been cut off at the bend, and the loose end only remains buried in the notch. Much time is often wasted in polishing the shoe with the file before it is nailed on; but all that is really needed is to remove the burs about the nail holes, file off the sharp edges of the shoe, and round the heels, taking care to apply the file hard to that part of both heels which comes next to the frog, so as to slant it from the ground upward away from the frog; but be careful not to make the ground surface of the web at the heels narrower in so doing.

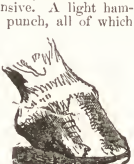
INTERFERING, or CUTTING, To Prevent.—To prevent interfering, pare the foot a little the most on the outside. This will have a tendency to roll the ankles further apart. A side calk on the outside heel will prevent the foot sliding under as it touches ground. The shoes should be light and of narrow web on the inside, with the nail holes near the toe. They should be straight at the point where they come in contact with the opposite leg. In some instances a small piece of leather placed between the sole and the shoe, and allowed to project outwards, has a very good effect in preventing interfering. In the hind leg ¾ shoes will prevent cutting when other plans fail; for here the part that cuts is not situated so far forward as in the fore feet, so that the removal of the iron altogether from the inside quarter, will often accomplish the aim. It sometimes happens that every plan that can be adopted will not prevent cutting, and then the only resource is the adoption of boots or straps. The illustration shows a horse with wide-set legs which will not cut.



The Kind of Horse Not Likely to Cut.

Ankle Boots for Cutting.

LOOSE SHOE, To Replace. — A job like the replacing of a "thrown" shoe, can be done at home. It is not a difficult one, and the needed tools are few and inexpensive. A light hammer, a pair of pincers, a punch, all of which every farmer's workshop should contain for other uses, and a few horse shoe nails, are all that are necessary. If the shoe is only loose, it may be tightened by driving up the old nails and clinching them anew, but if quite loose, it had better be taken off, which can be done with the pincers, care being taken not to break the hoof. All the old nails should be removed by using the punch.



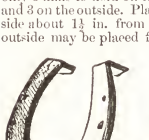
Loose Shoe with Nail Piercing the Foot.

NAILS.—Many of the nails in common use are badly formed; short, wedge-shaped heads, wide at the top and narrow at the bottom, with shanks springing suddenly from the head without any shoulder and ending in a long narrow point, are most unsafe to trust a shoe to. Nails should have heads which are straight-sided at the upper part, and gradually die away at the lower part into the shank so as to form a shoulder which will entirely block the bottom of the nail hole; the point at the end of the shank should be short and broad to form good stout clinches, which will assist in keeping the shoe firmly in its place until it is worn out. The nails should be made of the very best nail rods, and they should not be cooled too quickly, but left spread about to cool by degrees.

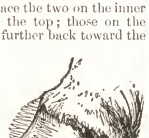
PRICKS, To Cure.—Pricks in shoeing occur from the want of skill in the smith, who drives the nail too near the lamina, and sometimes wounds them. It may be that the nail in its passage upwards is not within ¼ in. of these delicate parts, and the horse may not have flinched during the driving of it, but when he is put to work the nail opposes a hard, unyielding fine to the soft parts, inflammation is established, and possibly even matter is formed, which may end in quittor. When, on the day after shoeing, a horse, which was previously sound, goes lame, and the foot is hot to the touch, it may generally be assumed that a nail or nails have been driven too near to the quick, unless there is evidence of laminitis from other causes. On tapping the crust with a hammer, the horse will flinch at some particular spot, and there is the

nail which is in fault. Sometimes there is little inflammation as yet set up, but the pressure of the nail is sufficient to cause lameness, and in either case the shoe should be taken off. Then, if there is reason to suppose that matter has formed, the opening from which the nail came out should be enlarged, and the matter allowed to escape. If, however, the foot has been merely "bound" it may be either left to nature, with a shoe lightly tacked on, and a wet "swab" round the coronet, or it may be placed in a bran poultice, which last is the safest plan.

SUMMER SHOEING.—The summer shoe needs to present a flat surface to the ground. Make it of the same width and thickness from the toe to the heel. Have the seating deep, so as to prevent the sole pressing upon the shoe as it descends. Have a clip at the toe to prevent the shoe slipping back, but none at the sides, as they not only destroy too much of the hoof, but prevent expansion. Have the fullering deep to receive the nail-heads, and have the nail holes straight—neither inclined inwardly or outwardly. Have only 5 nails to hold on the shoe—2 on the inner and 3 on the outside. Place the two on the inner side about 1½ in. from the top; those on the outside may be placed further back toward the



Shoe With a Clip at the Toe.



Incision for Receiving the Clip.

heel. By placing the nails far back, expansion is prevented, thereby cramping the foot, which makes the animal step short and quick, like one with tight boots. By this plan of shoeing, the whole of the inner quarter and heel are left free to expand, and in consequence of this freedom of expansion, corns, however long they may have existed in the feet, disappear altogether after a horse has been shod a few times in this manner, and never return while the same plan of shoeing is continued. The hind shoe need not be so broad, but a little higher at the heels; in this put 7 nails, as the hind legs propel, and the front legs receive the weight.

SHOE. To Make Durable. — When a horse wears his shoe hard at the toe, turning up the toe makes the shoes last much longer, and is a better practice than welding on a lump of steel. A strong foot will bear the toe to be turned up a good deal; but a flat foot is always weak at the toe and cannot bear removal of any of the horn from it. The best way, therefore, of dealing with a very flat foot is to fit the shoe to it without turning up the toe, then to make the toe of the shoe red hot, and place it in the vice with the ground surface toward you, and in that position rasp the iron away from that part of the toe which would have rested on the ground. A very handy tool can be made for turning up the toe of a shoe, by "shutting" a piece of iron 5 in. long and 1 in. broad, crosswise on to each blade of a pair of smith's tongs; with this tool both limbs of the shoe can be grasped at once, and not only turn up the toe over the end of the anvil, but restore the seating at the toe without bending the shoe or putting it out of shape, which could not be done without a great deal of trouble by holding one limb at a time in the common tongs. Take care that the web is not too narrow, and that the shoe is not too light. A light shoe is apt to bend before it is half worn out; and the pain caused by the pressure of the bent nails against the tender lining of the hoof, throws the horse down and most likely breaks his knees. If the foot should be flat, with a weak, brittle crust, choose a stout shoe; for a horse with such a foot could not go at all on a bent shoe; and the shoe must have a wide web, because the sole is sure to be thin, and will need plenty of cover to protect it. The seating must also be examined, for, if the foot is weak and flat, the shoe must be well seated out, to prevent its pressing upon and bruising the sole; but, if the foot be strong, and the sole arched, there need not be more seating than will allow the point of a picker to pass freely around between the sole and the shoe: otherwise dirt and small stones will get in and bruise the sole as much as the shoe would if it pressed on it.

TENDER FEET, To Shoe.—Many tender-footed horses travel best with a covering over the sole, and leather is commonly used for this purpose. The shoe must be fitted to the foot with as much care as if nothing were to be put under it, and when it is filed up and ready to be put on, lay it with the foot surface downward on the covering, whatever it may be, and mark the form of the shoe upon it with the end of the drawing-knife; then cut the piece out, put it in its place upon the shoe and fix them both in the vice, which will hold them close together while the edge of the covering is carefully cut until it agrees with the edge of the shoe; then turn them in the vice together, so as to bring the heels of the shoe uppermost, and cut out a piece from heel to heel, slightly curved downward in the centre, that nothing may be left projecting for the ground to lay hold of. The next thing to be done, is to smear the whole of the under surface of the foot with common tar, mixed with a little grease, but be sure that gas-tar, instead of the common, is used. Take the oakum, dipped in the tar, pressing it well into the hollow, until the mass rises above the level of the frog on each side, but never put any oakum upon the frog itself, excepting a piece in the cleft to prevent the dirt working in; very little is ever wanted on the sole in front of the frog. The use of the oakum is to protect the foot, but more especially the navicular joint, which lies above and across the frog, from being jarred by stones on a hard road. The ends of the oakum that are placed in the cleft of the frog, are collected together and carried across the body of the frog, to be mixed with the oakum on one side, which keeps it in its place in the cleft and prevents its working out behind. Now nail on the shoe with 5 nails, exactly as if there was nothing under it,

and if the fitting has been attended to, there will be no fear of the shoe shifting or coming off.

WINTER SHOEING.—The winter shoe needs toe and heel pieces to prevent the horse from slipping. Have the inner calk not quite so sharp as the outer one, so that if he steps upon the other foot it will not cut it. A good plan to prevent horses slipping is as follows: The smith, when finishing the shoe, should punch a hole in the 2 ends, and when the shoe is cold tap a screw thread and screw into the shoe when on the foot, a sharp-pointed stud, 1 in. in length, and with shoes thus fitted the horse can travel securely over the worst possible road. When the horse comes to the stable, unscrew the pointed stud, and screw in a button so that no damage can happen to the horse, and the screw holes are prevented from filling.

STABLING.

REMARKS.—The stable should be situated on a well-drained site; but where, from circumstances, it is necessary to occupy a somewhat low position, some substance impervious to water should be interposed between the foundations and upper walls. Stables should be placed in such a position that ready access may be had to them, without the necessity of passing through courts or yards where any animals are kept. They may have a court in front for containing the dung and soiled litter; but it is better that they be contiguous to the yards where the cattle are kept, so that the dung may be mixed with that of the other animals. If circumstances allow, there should be an adjoining cistern for holding water. It is better, for the regularity of superintendence, that all the farm houses be under one roof, and, if more than one stable is necessary, that all the stables be together.

BEDDING.—Every horse should be bedded down at midday. As regards economy of straw, it is essential not to give the horse a chance of eating it. With this view no fresh straw should be placed within his reach. The fresh straw should be brought in first, and put not merely at the bottom, but also in the rear of the stall; then the old litter should be brought in and put at the top and in the front. The horse will not readily eat it, and by the following morning the new straw will have become somewhat tainted, and may then be mixed and dried along with the rest. Great care should be taken in the morning to thoroughly shake up and cleanse the bedding from dung; and any parts which may have become rotten should be thrown out. Good straw rapidly deteriorates if these precautions are not taken. On the other hand, good bedding is often thrown away with the bad, which might be used again. Sawdust makes a good bedding on account of its resinous odor and its repellent effect against vermin.

BOXES.—Loose boxes ("box-stalls") should be attached to every stable where any number of horses are kept, and although a loose box often adjoins the ordinary stalls in many well-arranged stables, they are better situated at a distance, when practicable, in case an animal may have a contagious disease; and sick horses are better away from the healthy ones. A loose box is preferable to a stall in many cases, but the room they take up is against their common use. For a young horse that is only partially worked, or for a sick animal, a loose box is invaluable, where the inmate can lie down comfortably; and for spirited animals which chafe under the confinement of too narrow space. Working farm horses do well enough in stalls; but hunters and riding horses are better in a loose box. The doors should be made to slide along outside, instead of being hung upon hinges, and, as fresh air is always desirable, a rail or bar door is very appropriate; but half doors should be avoided.

CLEANLINESS.—A large mass of dung, unless frozen or kept near the freezing point, will undergo decomposition, and gives off, besides steam, ammonia and other gases. These tend to soften and injure the hoofs of animals, and especially horses, that may be forced to stand continously upon the accumulation of dung. They cause inflammation of the eyes, and injure the general health, interfere with the digestion, and reduce the vigor of the animal. There should be no mass of manure in a stable where horses are kept. A clean floor and pure air are requisites for the best health of the animals. A gutter should be provided to carry off drainage and a tank or pit, filled with absorbents, should be made to receive it. Once a day a few pails of water should be dashed on the floor to wash it off. Then a shovelful of plaster should be scattered about before fresh litter is spread. This will add at least $100 to the value of the manure from a pair of horses in a year, for the urine is worth more than the solid excrement, and would thus be saved, even that portion which escapes into the air or is carried into the house and elsewhere by those who attend the stables. The result of this care will be to keep it free from those odors which attract flies in vast numbers, and which have a very injurious, irritative effect upon the eyes and lungs of the occupants. Sawdust, wetted with sulphuric acid, diluted with about 40 parts of water, and distributed about the stable, is a good deodorizer. Keep the mixture in shallow earthenware vessels. A healthy mode of cleansing the stable and sheds, is to give them a coat of lime wash, applied hot.

FLOORS.—Where it can be done, have a hard clay or earth floor for horses to stand on, in preference to stone, brick, mortar, or wooden floors, the latter being perhaps the most injurious. The cool, moist earth, is the most natural, while it is the pleasantest kind of floor for a horse's feet, keeping them in a sound, healthy condition, if ordinary care is taken of the animal otherwise.

HAY LOFTS.—It will be found more advantageous to the health of the horse, inasmuch as his food will be sweeter and more appetizing, to have as little open communication as possible between the hay loft and the stable, the space which is often left for access to one and the other being best closed with a trap-door. This, also, keeps out the dust.

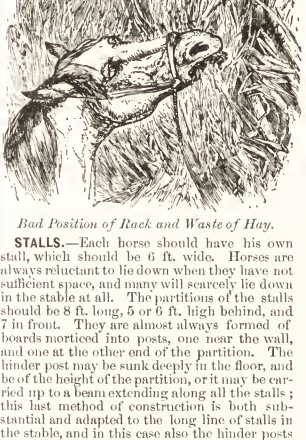
LIGHT.—Stables should be moderately well

lighted; but throwing the direct rays of the sun on the horse's eyes from the front should be avoided. If too dark, the eyes become habituated to this, and, in the absence of the customary stimulus of light, become less able to bear it; and, when suddenly taken into the glare of sunshine, and especially of sunshine reflected from the winter's snow, they are liable to suffer from irritation and inflammation. If, on the other hand, the light falls directly on the horse's eyes from a window in front, the constant glare may, of itself, injure the eyes. The light should be abundant, but should fall from the windows placed behind or to one side of the stables, and not in front.

MANGER.—Its dimensions may be 15 in. wide at the top, 12 in. at the bottom, 9 in. deep, and $2\frac{1}{2}$ ft. long. In this box the corn for the horse is placed at stated times and in a given quantity; and when boiled or prepared food is given, it is likewise placed in it. What is not occupied by the manger, is occupied by the lower rack. The outer edge of both the manger and the rack should be formed of a continuous bar of stout wood, 3 in. thick and 4 in. deep. Into this bar is fixed a ring, through which is to be passed the end of the halter which attaches the horse, with a little iron or large wood weight at its extremity, to keep it tight. Often, however, though not so properly, the end of the halter is merely tied to the ring.

PADDOCK.—A paddock is almost a necessary adjunct where there are many horses, and especially for colts when the breaking is performed at home; a small paddock may be more easily obtained than fields to be placed at the service of horses. Contraction of the feet very often occurs to young horses at training, and this will be in a great measure avoided by the use of a nice shady paddock with good turf. If the colt is turned out into this for an hour or two each morning, and the same time each evening, the middle of the day being devoted to his breaking-in education, he will gradually be preparing himself for the alteration in his diet which will ultimately have to take place; eating his hay in the night, and picking up a little grass during the time he is in the paddock, the little change making him relish his corn when he gets it. For an overworked or tired horse, or one that is a little ailing, if his disorder is of such a nature as may be benefitted by turning out, a paddock is often found to be invaluable. The gentle exercise that is taken by the horse in the natural manner does him a great deal of good, and the change from the stable may be made highly beneficial to him.

RACKS.—These should not be above the level of the animal's head, so that dust and hay seeds may not fall into the eyes. If the hay is supplied from the floor above, it should be passed through a closely-boarded funnel, so that the animal may not reach the hay and pull it down, thus causing great waste. The rack may consist of 2 horizontal rails, into which are fixed upright pins slightly inclining outwards from the lower rail. The pins may be 2 in. in diameter, and 3 in. apart, and the lower rail may be $4\frac{1}{2}$ ft. from the floor. This rack should extend the whole width of the stalls, in every case.



Bad Position of Rack and Waste of Hay.

STALLS.—Each horse should have his own stall, which should be 6 ft. wide. Horses are always reluctant to lie down when they have not sufficient space, and many will scarcely lie down in the stable at all. The partitions of the stalls should be 8 ft. long, 5 or 6 ft. high behind, and 7 in front. They are almost always formed of boards morticed into posts, one near the wall, and one at the other end of the partition. The hinder post may be sunk deeply in the floor, and be of the height of the partition, or it may be carried up to a beam extending along all the stalls; this last method of construction is both substantial and adapted to the long line of stalls in the stable, and in this case also the hinder posts are not sunk into the ground, but let into stone sockets.

TEMPERATURE AND VENTILATION.—When stables are kept hot, the great difference in the temperature within and without, causes horses to catch cold when issueing from them into the open air; and, while a stable should be kept moderately warm, it should be always well ventilated at the top, the foul air always ascending. A horse requires 2,446 cu. ft. of fresh air per hour. There are several modes of ventilating a stable when there is a loft over, the best plan being to resort to tubes carried through the loft to the roof; or, where there is not a loft, by gratings close to the ceiling; but wherever these gratings exist, they should be so arranged as to allow of being enlarged or contracted at pleasure by shutters or coverings. It will be found a good plan to regulate the heat of the stable by a thermometer, which should be always hung up in it; 50° to 55° Fah., is usually considered an appropriate temperature during winter, and 65° a fitting summer heat. The heat of a stable is always found to have a very material effect upon new comers, especially horses that have been turned out to grass; and it will be found the best plan to accustom these, by different stages, to the confinement of the stable, by putting them first into a shed, and gradually bringing them into work and the stable by degrees, as these sudden changes have a great

effect upon the life and constitution of the horse.

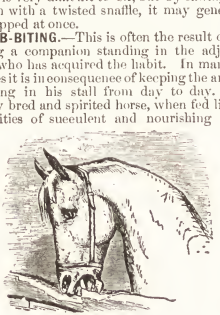
Vices and Habits.

BALKING.—When a horse balks in harness, it is generally from some mismanagement, excitement, confusion, or from not knowing how to pull, but seldom from any unwillingness to perform all that he understands. High-spirited, free-going horses, are the most subject to balking, and only so because drivers do not properly understand how to manage them. Almost any team, when first balked, will start if they are allowed to stand 5 or 10 minutes, as though there was nothing wrong, and then speak to them with a steady voice, and turn them a little to the right or left, so as to get them both in motion before they feel the pinch of the load. A good remedy is to catch up a handful of dirt, and force it into the mouth of the animal. Another is to pass a twine around the lower jaw below the tongue, and tie it quite tight over the top of the head, leaving an end of 2 or 3 ft., by which to pull at, walking in front of the horse. This will be found to be a remedy in all cases, if properly done.

BITING.—This has its origin in horses being teased. If at first only done in play, it should be at once checked and discouraged, or otherwise it will become a habit that will ultimately take the form of viciousness. A muzzle should be used to horses that have this habit confirmed, which neither kindness nor severity will cure.

BUCKING.—This may be described as a series of bounds into the air, which, when they are made up and down in the same place, or nearly so, are called "bucking," from their resemblance to the playful antics of the deer. A bucking horse is very difficult to sit, but by sawing the mouth with a twisted snaffle, it may generally be stopped at once.

CRIB-BITING.—This is often the result of imitating a companion standing in the adjacent stall, who has acquired the habit. In many instances it is in consequence of keeping the animal standing in his stall from day to day. The highly bred and spirited horse, when fed liberal quantities of succulent and nourishing food,



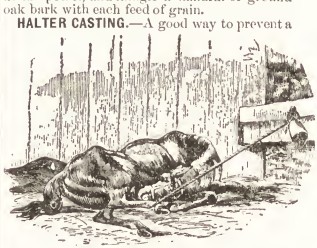
Cribbing.

must be in some mischief when his time is not employed. It is caused, in some instances, in young colts, by partial starvation, or by not keeping sufficient provender before the animal when confined in the stable, to allow him to pick it over at will. In consequence of this neglect in his stable management, he acquires the habit of cribbing on the manger. It is, also, the result of feeding unsound, and consequently unpalatable diet, which no horse will eat unless forced to it by starvation. Lastly, it is occasionally caused by the groom dressing his spirited charger in his stall, or other narrow compartment connected with his stable, where he can and will bite on the partition walls located on either side of him; and this biting at anything within his reach may often be observed in a spirited and nervous horse, when the brush or rubbing cloth is applied to his body or legs by the groom. In the early stage of the acquired habit of cribbing, rubbing common yellow bar soap on the top of the manger rail daily, will often prove an efficacious remedy, or nailing a fresh sheepskin, flesh side up, on the top and outside edge of the manger, will have the same effect. But when the animal cannot be cured by any of these methods, he should be muzzled.

Muzzle to Prevent Cribbing.

EATING THE LITTER.—This is a peculiar appetite, which chiefly occurs either in those horses which are kept short of hay on account of their tendency to fatten, or when the animal possessing it has been stabled for a long time and requires change. In the former case, nothing but the muzzle will be of the slightest service; but, in the latter, a run at grass, or soiling in-doors, for a month or two, will remedy this disorder of the stomach. Rock salt in the manger will sometimes have the desired effect, producing a degree of thirst that will make dry litter distasteful. The stable should be well ventilated, and if the rock salt should fail to effect a cure, add a piece of chalk; if this also fails, dampen the food, and, when feeding it, sprinkle some magnesia upon it, and mingle a handful of ground oak bark with each feed of grain.

HALTER CASTING.—A good way to prevent a

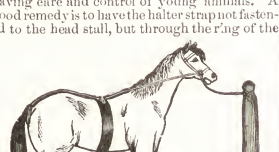


Halter Cast.

horse from getting his foreleg over the halter

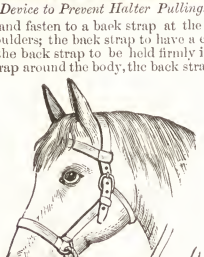
strap, is to pass the halter strap through the hole in the manger, and, instead of tying it to the manger, tie it to a block of wood or other light weight. The weight will take up the slack in strap, and usually prevent this annoyance. But, sometimes, in pawing with his foreleg, or in endeavoring to rub his head with his hind foot, the leg gets over the halter, and in struggling to free himself, the leg is often seriously wounded by the rope, halter, or chain. The spring catch, although it will not prevent this accident, will mitigate its effects, especially when 2 collar reins are used. When neither of these methods will prevent their being cast, they should not be tied, but left loose in box stalls.

HALTER PULLING. — 1. It is usually a habit contracted by the bad management of those having care and control of young animals. A good remedy is to have the halter strap not fastened to the head stall, but through the ring of the



Device to Prevent Halter Pulling.

halter and fasten to a back strap at the top of the shoulders; the back strap to have a crupper to it; the back strap to be held firmly in place by a strap around the body, the back strap pass-



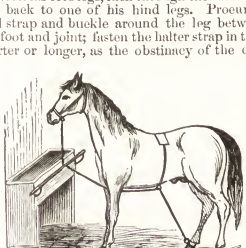
Device to Prevent Halter Pulling.

ing loosely through a loop in it. In this way the horse, in pulling back, pulls on his own tail, and will only make a few efforts of the kind. There is no inconvenience or danger in keeping such an apparatus on until the horse is thoroughly cured. — 2. Another contrivance consists of an ordinary ring halter, with the 2 side rings connected by a strong, flexible cord. Whenever the horse pulls, the inner part of the cord is drawn forcibly against his jaw, and the effect is a severer punishment than he is willing to endure.

HALTER SLIPPING.—This is a trick at which many horses are so clever that scarcely a night passes without their getting loose. It is a very serious habit, for it enables the horse sometimes to gorge himself with food to the imminent danger of staggers; or it exposses him, as he wanders about, to be kicked and injured by other horses, while his restlessness will often keep the whole team awake. If the web of the halter, being first accurately fitted to his neck, is suffered to slip only one way, or a strap is attached to the halter and buckled round the neck, but not sufficiently tight to be of serious inconvenience, the power of slipping it would be taken away.

JIBBING.—Moving restlessly from side to side, or backwards. Bad breaking very often has been the occasion, and it is a very dangerous vice. When horses, that do not commonly show this vice, display it upon occasions, there may be some reason for it, as the withers being wrung or the shoulders galled, and the animal should then be treated with consideration; but a confirmed jibber had better be got rid of as soon as possible. When a horse jibs, in harness, a stone put behind the vehicle will sometimes cause him to go forward, as he finds it much easier than going backward.

JUMPING. — Put a good, stout surcingle around his body; put on his halter, and have the halter strap long enough to go from his head between his fore legs, then through the surcingle and back to one of his hind legs. Procure a thill strap and buckle around the leg between the foot and joint; fasten the halter strap in this, shorter or longer, as the obstinacy of the case



Device to Prevent Jumping and Kicking.

may require. It is also useful to keep colts from running where there is likely to be danger from the result; if the thill strap should cause any soreness on the leg, it may be wound with a woolen cloth, and it would be well to change it from one leg to another occasionally.

KICKING. — A good way to prevent kicking, is to use the device explained in *Jumping*. Kicking in harness may be prevented by attaching to a common halter head-stall a strap about 6 ft. long, over which put a 2 in. ring, then tie

the end of this strap back into the halter; now pass this double strap down between the fore legs, so that the ring will extend just back of the belly-band; then buckle round each hind foot below the fetlocks, short straps with rings attached; to these rings attach a rope, which is passed through the ring upon the halter, just enough to enable the horse to stand naturally. In this condition the horse has sufficient freedom to walk and trot, but the moment he attempts to kick, he reproves himself by the attachment to the head. In cases of kicking the stall, fasten a short trace chain, about 2 ft. long, by a strap to each hind foot. A better way is to have the stalls made wide enough, so that the horse can turn in them easily. Close them with a door or bars, and turn the animal loose. After a while he will forget the habit, and stand tied without further trouble. When the horse is given to kicking, while being shod, he should be humored as much as possible, and the blacksmith should not be allowed to use a horse roughly, or to twitch him, except the latter is strictly required. In shoeing, it is better to let him follow in his turn some steady old horse which goes through the operation quietly, whose example will be beneficial to him. Connect the animal's head and tail by means of a rope fastened to the tail and then to the bit, and draw tightly enough to incline the horse's head to one side; this makes it almost impossible for the horse to kick on the side of the rope.

MANGER, Leaping into. — Some horses that are allowed to remain too long in the stable without exercise, acquire this habit, which, if likely to become confirmed, should be prevented by the use of a short halter, that will not allow him to raise his head high enough to effect his purpose. If a horse should happen to get himself awkwardly fixed in this position, the groom should go up to his head and push him to the opposite side of the stall, and back at the same time.

MANGER, Lying under.—Young horses, that have not long been accustomed to a stable, are most given to this vice; when getting their heads under the manger, they are prevented from rising. To get them out, they need to be drawn backwards by a girth round the breast. The remedy to prevent a recurrence of this, is to board up the space beneath the manger flush with the outer edge of the top.

PAWING. — Short-tempered, irritable horses, paw the floor of the stable sometimes violently, not only making the stable untidy, but wearing out their shoes, and sometimes bruising their feet and spraining their legs. The best plan, when this is carried on to a great extent, is to shackle the 2 legs close together with 2 padded straps, united like a pair of fetters, by a small chain about 1 ft. long.

REARING. — A deep curb and small bit will sometimes make horses rear. The instant one is about to rise, slacken one hand and bend or twist his head with the other, keeping the hands low. This bending compels him to move a hind leg, and of necessity brings his forefeet down. Instantly twist him completely round 2 or 3 times, which will confuse him very much, and completely throw him off his guard. After twisting him around, place his head in the direction he is desired to proceed; apply the spurs, and he will not fail to go forward. If the situation be convenient, press him into a gallop, and apply the spurs and whip 2 or 3 times severely. The horse will not, perhaps, be quite satisfied with the first defeat, but may feel disposed to try again for the mastery. Should this be the case, twist him, etc., as before, and in the second struggle he will be still more easily subdued.

ROLLING.—This is a pleasant and perfectly safe amusement for a horse at grass, but cannot be indulged in in the stable without the chance of his being dangerously entangled with the halter rein and being cast. Yet, although the horse is cast, bruised and half strangled, he will roll again on the following night, and continue to do so as long as he lives. The only remedy is not a very pleasant nor quite safe one, yet it must be had recourse too if the habit of rolling is inveterate. The horse should be tied with length enough of halter to lie down, but not to allow of his head resting on the ground; because, in order to roll over, a horse is obliged to lay his head quite down upon the ground.

RUNNING AWAY.—1. Put on the foot strap, described in *Throwing*, and when he attempts to run, take up his foot, make him run, and trip him every time he will not stop instantly at the word, "whoa!" Should he be of the extremely willful character, he may run on 3 legs. If so feared, attach another strap to the opposite foot. Then make him run, and if he will not run after the taking up the second (which will destroy his confidence at once), then 1 strap will answer just as well. Make the lesson thorough, so that the horse will stop every time you call "whoa!" —2. Place a cord with a running knot around the horse's neck, near the neck strap. To this slip noose attach a pair of reins, which must be thrown over the dash board, ready to be seized at once. When the horse starts and becomes unruly, take up the cord and tighten his throat so that he cannot breathe; he will stop instantly, and will not fail or kick.

TEARING CLOTHES.—This is an unusual sta-

Device to Prevent Tearing the Clothes.

ble habit, and very difficult to cure. There are 2 effectual preventives, one of which consists

in the regular employment of a rough horse-hair cloth, made like that for hops, outside the rug, and which is so disagreeable to the teeth that no horse will attempt to tear it. The other is a pole of ash, about ¾ in. in diameter, with an iron eye attached to each end. One of these is fastened by a short leathern strap or buckle, to the side of the roller pad, while the other has a strap or chain about 1 ft. long, which attaches it to the head collar. The pole should reach about 15 in. beyond the point of the shoulder, and should be fixed on the side which is generally uppermost when the horse lies down, so as not to be under him in that position.

SHYING.—With some young horses, this fault is the result of nervousness, and when that is the case the remedy is in strengthening the nervous system. A young horse given to this fault, must be handled gently but firmly. No better direction can be given for remedying this fault, than to gently lead or drive the horse up to the object, when it is practicable. (See *Fear, To Overcome*, in BREAKING AND TRAINING.)

TONGUE, Lolling of.—Rivet a section of a knife from a mowing machine on his bit; dull the edges and make everything smooth. The knife, running up in his mouth, prevents him from drawing his tongue far enough back to get it over the bit. Carelessness in breaking colts is the cause of this.

JUDGING AND BUYING.

REMARKS.—The buyer must know what he wants, whether a saddle horse, draught horse, racer, hunter, or a horse for family use. And in order to make a selection (especially as the seller's word is rarely to be taken), it is necessary for him to have some knowledge of the points required for these different purposes. This will include the study of the anatomical structure of the horse, and modes of ascertaining his age, defects and vices.

POINTS TO OBSERVE.

ACTION, To Test.—Having attentively looked over the horse as he stands, and found nothing objectionable to the eye, it is prudent to see him through his paces before proceeding to ascertain, by careful examination, the defects, blemishes, etc., which have a tendency to produce unsoundness. He should first be walked, and then trotted, without any whip near him, slowly down the road, allowing him to have the whole of the halter to himself; his head will then be entirely unconstrained, and irregularities in action may be easily detected. The action should be scrutinized most attentively when he steps off, as defects are then most visible. Good action is observed when he starts easily and promptly without stiffness, and when the limbs are moved evenly and in accord one with the other, the hinder limbs being kept well under. The action should be square in walking and trotting, with no paddling with the front legs or straddling behind. The carriage of the head and tail are points to which the eye of a good judge will be directed. If the tail goes to and fro when in action, like a pendulum, it is a good sign of blood and steadiness. He should also be mounted, and the trial be repeated on the stones or hard road, or a rough and stony declivity; for there are many cases of slight lameness which do not show on soft ground at a walking pace, or when the horse is unburdened.

AGE.—Horses, as a rule, are considered at their best from 5 to 10 yrs. of age; much depends on the age at which they are put to work. One method for ascertaining the age of the horse is said to be as follows: After the horse is 9 yrs. old, a wrinkle comes in the eyelid at the upper corner of the lower lid, and every yr. thereafter he has one well-defined wrinkle for each yr. of his age over 9. If, for instance, a horse has 3 wrinkles, he is 12; if 4, he is 13. Add the number of wrinkles to 9, and the age will be obtained. But the safest way of determining the age of a horse is by the appearance of the teeth, which undergo certain changes in the course of years. By the end of the 1st yr. the colt has cut his 12 nippers and 16 grinders, which usually pierce the gums at the following mos. Before birth, the 8 anterior grinders have generally shown themselves, followed about a week after foaling by the 2 central nippers. At the end of the 1st mo. another grinder makes its appearance all round, and in the middle of the 2d the next nipper shows itself. By the end of the 2d mo. the central nippers have attained their full size, and the second are about half grown, requiring another mo. to overtake their fellows. Between the 6th and 9th mos. the corner nippers are cut, and towards the end of the 1st yr. reach their full size. This first set of nippers consists of teeth considerably smaller in size than the permanent teeth and somewhat different in shape. They are more rounded in front and hollow towards the mouth, the outer edge being at first much higher than the inner. As they wear down, these two edges soon become level, but the corner nippers maintain this appearance for a long time. At 6 mos. the central nippers are almost level, with the black mark in their middle wide and faint; and about the 9th mo. the next nipper on each side above and below is also worn down almost to a level surface. In the first mo. of the 2d yr., and sometimes towards the end of the 1st yr., a 4th grinder is cut all round, which commences the set of permanent teeth, the 3 first molars only being shed. At 1½ yrs. the mark in the central nippers is much worn out, and has become very faint; the 2d is also worn flat, but is not so faint; and the corner nippers are flat, but present the mark clearly enough. In colts which have been reared on corn and much hay, the wearing down proceeds more rapidly than in those fed upon grass alone. The 3d yr. is occupied by the commencement of the 2d dentition, which is effect-

ed in the same order in which the milk teeth made their appearance. Both sets are contained within the jaw at birth, the permanent teeth grows very slowly, and the central nippers above and below fall out, and are replaced by permanent ones, which are larger sized and different

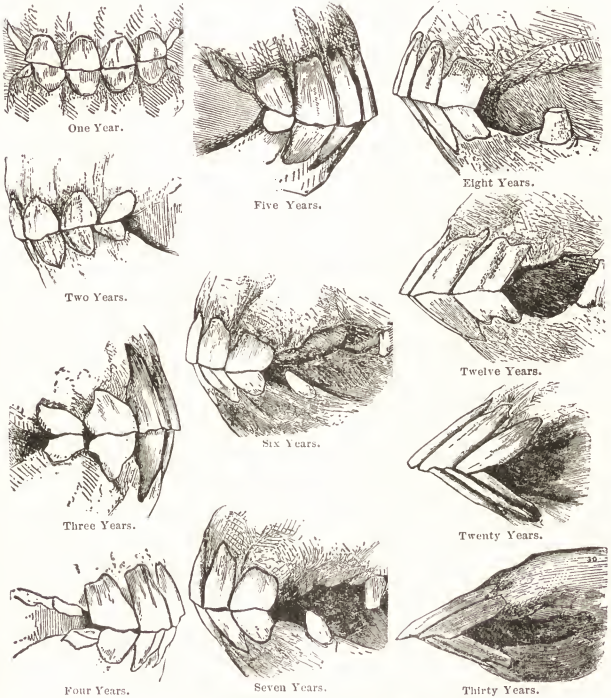
Age of the Horse Indicated by the Teeth—Mouth Open.

being small and only partially developed and lying deeper than the milk teeth. Towards the end of this yr. the 6th grinder shows itself, but in form. At about 3½ yrs. the next nipper all around falls out, and is replaced by the permanent tooth. The corner nippers are much worn,

and the mark in them is nearly obliterated. About this time, too, the 2d grinder is shed. At 4 yrs. the central nippers begin to lose their sharp edges, and have grown considerably in substance. The next nipper all round has grown nearly to its full size, but not quite, and its edges are still sharp, with the mark deep and very plain. The corner milk nippers still remain, unless they have been knocked out for purposes of fraud, which is sometimes done to hasten the growth of the permanent teeth, and give the horse the appearance of being 4 or 5 mos. older than he is. Between 4½ to 5 yrs., the corner nippers are shed, and the tush protrudes through the gum. At 5 yrs. the mouth is complete in the number of its teeth; and from this date it becomes necessary to study their aspect in both jaws. In the lower teeth of the same mouth, the edges of the central cavities are much more worn away, the central nipper having only a small black speck in the middle of a smooth surface, while the next is much worn, and the corner teeth, though showing the mark very plainly, bear evidence of having been used. The tush is much grown, with its outer surface regularly convex, and its inner concave, the edges being sharp and well defined. The 6th molar is at its full growth, and the 3d is shed to make room for the permanent tooth in its place. After 5 yrs. no further shedding occurs in any of the teeth. The 6 yr. old mouth is the last upon which any great reliance can be placed, if it is



Age of the Horse Indicated by the Teeth—Mouth Closed.

desired to ascertain the age of the horse to a nicety; but by attentively studying both jaws, a near approximation to the truth may be arrived at. It is ascertained that the nippers of the upper jaw take about 2 yrs. longer to wear out than those of the lower; so that until the horse is 8 yrs. old, his age may be ascertained by referring to them, nearly as well as by the lower nippers at 6. But as different horses wear out their teeth with varying rapidity, it is found that this test cannot be implicitly relied on; and in crib-biters or wind-suckers, the upper teeth wear out wonderfully soon. Up to this age, the nippers stand nearly perpendicular to each other, the 2 sets presenting a slight convexity when viewed together. Afterwards the nippers gradually extend themselves in a straight line from each jaw, and, in the very old horse, from an acute angle between them. At about the 8th yr. the upper nippers present the same appearance as the lower nippers at 6 yrs. old. Both tushes are considerably worn away at their points, and the upper ones more than the lower. At 9 yrs. the upper middle nippers are worn down completely. The next pair have a slight mark left, but their surfaces are quite level, and the corner nippers have only a black stain without any central depression. After 9 yrs. the age of the horse can only be guessed at from his teeth, which gradually grow in length and more in a line with the jaw. The section of each nipper presented to the eye becomes more and more triangular instead of being oval. After the 12th yr. the triangular section disappears, and the tooth becomes nearly round. In very old horses the color of the teeth becomes a dirty yellow, with occasional streaks of brown and black. The tushes wear down to a very small size, and very often one or both drop out.

BACK.—The first thing to notice in judging of a horse, so far as his back is concerned, is the length of it. A long back is a weak one. By superior excellence of structure in other respects, the weakness of the back may, in some measure, be made up, but the horse can never be the horse he would have been, had his back been a shorter one. A horse's back, if short, has strength, and is sure evidence that he can carry or drag a heavy weight a great distance, and not tire; neither will 2 or 3 seasons of turf experiments break him down if he is a speedy animal. There must be length somewhere, or else the horse cannot stride far, but it should be put in below and not above. The length should be between the shoulder-point and the hams of the horse. He should be backed to ascertain if he has received any injury of the spine. If he backs with difficulty, his hind quarters swaying from side to side, and when compelled to retrograde suddenly he appears as if about to fall, he has received some injury.

BELLY.—Ask what the horse is living upon. If it is green food, expect to find a larger belly than when living upon harder and more concentrated food. When the gas in the bowels is much less than common, it gives to the animal an unsightly appearance, and he is said to be "tucked up in his flanks;" but it is easy to be deceived in this. If a horse is pained in moving his hind legs, he will be tucked up in the flanks on the side on which the lame leg is, and tucked up on both flanks, of course, if lame in both hind legs. In this case, the gas in the bowels may not be proportionately less, unless he is otherwise in bad health, but it is more compressed and pushed forwards and encroaches upon his breathing area. Some horses have habitually an appearance of less residual gas in their bowels even when in health. This gives their belly an unsightly, tucked up appearance, but it is not in itself a blemish. This will sometimes occur from overwork.

COLOR.—The best color is dark brown, with black points; the next best color is bay, with black points. Light chestnuts are good; but dark chestnuts are objectionable, as, after 7 yrs. old, their fore feet are often contracted. Grays and whites are not bad colors, but are difficult to keep clean looking; black is a hardy color; white stockings, if they exist largely on the same horse, are objectionable, especially if the absence of pigment or coloring matter extends to the horn of the feet. Of all colors, yellow or Cleveland bays, piebalds, and dark red chestnuts are the most objectionable. But, if the color does not offend the eye, and the horse is otherwise desirable, it ought not to be an obstacle.

EYE.—Pass the hand suddenly before the eyes, and if the horse does not wink, he is blind. Viewed in front, the depths of the eye should be looked into, then sideways, which will assist in ascertaining the clearness and absence of specks on or within its surface. A full and clear eye, with soft, gazelle-like expression, is scarcely ever associated with a bad temper, and will most frequently continue sound if the management of the horse is proper. The eyes should be as large as possible, and not obliquely set in the face, as in the Chinese. The white of the eye should not be too conspicuous. When so, it gives the horse a wild stare, and is an almost unfailing sign of mental aberrations, which lead to biting, kicking, etc. The white of the eye is seen, not on account of there being more of it than usual, but on account of the eyelids being wider apart. When the eyes appear full, with a fleshy circle around them, it is a symptom of badness of eye and the forerunner of blindness, particularly in the heads of coarse and fleshy horses, with heavy countenances, who usually go blind with cataract at 7 yrs. of age. Slight thickenings of the lid or puckering towards the inner corner of the eye, a difference in size, a cloudiness or dullness of the iris, are indications of disease, that a purchaser should beware of. If there is an excess of tears, it denotes debility; all horses with weeping, dull, cloudy eyes, should be rejected as unsound.

FEET.—Always have a horse shown quietly; when there is much noise and bustle, there is generally something wrong, and when the animal is agitated, slight lameness will escape the eye. If one foot is more upright than the other, that foot is diseased; if it is of a different temperature, active disease is going on; if an old standing complaint, the feet will be of different size, and possibly the muscles of the arm and shoulder

diminished in size. Carefully examine the hoofs for cracks, as jockeys have acquired great skill in concealing cracks in the hoofs. If cracks are observable in any degree, reject. Also, both look and feel for ringbones, which are callosities on the bones of the pastern near the foot. If apparent, reject. Examine the front feet, and if the frog has fallen, or settled down between the heels of the shoes, and the heels are contracted, reject him, as he, if not already lame, is liable to become so at any moment. The frog, in its healthy state, must be firm, yet pliable and elastic. If there is any smell, or, if on squeezing the frog, matter exudes, there is thrush. A horse that goes with his forefeet low, is very apt to stumble, and there are some that go so near the ground that they stumble on even roads; and dealers, to remedy this, put heavy shoes on their feet, for the heavier a horse's shoes are, the higher he will lift his feet. To enable the purchaser to arrive at a sound decision, he should know that the inclination of the pasterns is governed by the major flexor tendons, which are situated underneath or behind them. Their slanting, therefore, is regulated by no peculiarity in the forms of the bones themselves, but is controlled by and dependent upon the condition of another structure. A short,

Upright Pastern.

Overshot Pastern.

upright pastern, if it can bear any evidence at all, testifies to a stubborn and unyielding state of the great flexor muscles, the weight being then thrown upon the osseous supports. The play of the pastern denotes nothing more than the healthy elasticity of the flesh upon the tendon proper and on which the osseous structures repose. The bones have no motor power belonging to themselves. The upright and the overshot pastern suggest no change in the more solid frame; but such alterations prove that excessive work

Long Slanting Pastern.

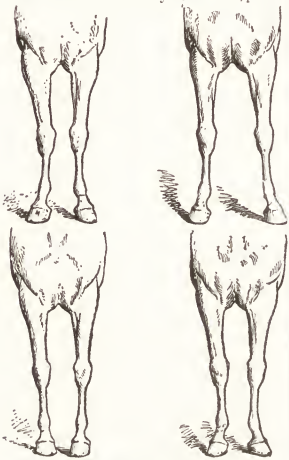
Natural Pastern.

has strained the great flexors of the limb, and destroyed the inherent property of elasticity with which every muscle is endowed by nature. The burden being then supported by an osseous pillar instead of an elastic band, of course jar or concussion ensues upon abnormal change. Thus, alteration in the natural position of an oblique bone, is of great importance to the purchaser; and to judge properly of the pastern joint, the substance swelling forth beneath the elbow must be regarded. Should this portion of the body be mean or wanting in development, hard work will probably induce it to become rigid, or labor may, ultimately, cause the pastern joint to shoot forward and out of its proper position. When the profile of the hoof is irregular, i. marks what is called a "shelly foot." This is decidedly bad. If there are any protuberances or rings round it, the feet have been affected with fever to such a degree as to produce an unequal growth of horn, which frequently leaves some injurious consequences in the internal part of the hoof. If there is any depression or hollow, it betrays separation of the foot from the hoof, and sinking of the coffin bone, and the sole will be found bulging. If the toe of the hind foot is found to extend a little over the shoe, it is to prevent "hammer and click" from being audible. If the toes of the hind feet drag, or the shoe is squared off or worn, disease of the hocks may be suspected; and if the inside of the shoe is beveled off, it is the sign of a cutter. If the foot appears to have been cut unusually deep at the angles where the shoe meets the inside heel, or if there is any peculiarity of shoeing at that part, the examiner may infer that he has corns.

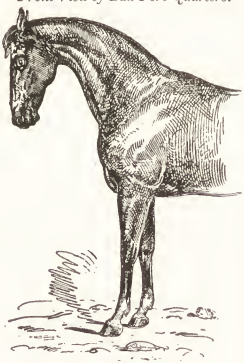
FORE QUARTERS.—The chest should be large and spacious. It may vary somewhat in shape according to the service to which the horse is to be put. A draught horse should have a deep, circular chest; but passing through the different degrees of speed up to the racer and trotter, the chest will increase in depth compared to its roundness, until for the highest rate of speed, the chest must be as deep as a greyhound's, and at the same time not lacking in strength. The chest and breast should be searched for marks of rowels, setons and blisters, for the remains of them render it probable that the horse has been under treatment for inflamed lungs or chest affections. The shoulder blade must in all classes of horses be of good length and breadth to afford space for the attachment of the many powerful muscles which take their origin from it. In the race horse it must be placed very obliquely, in order that the great length of arm required can be placed sufficiently downwards and forward, so as not to interfere with the saddle girth. For draught horses the shoulder blade has need of being extremely broad, and placed more upright, in order to fill the upper half of the collar well when the body is thrown forward. The arm bone must be short

Good Fore Quarters.

and stout, and at a less angle with the scapula. The remaining long bones of the limb from the elbow downwards, cannot be too short and thick in order that the horse may be on short, power-

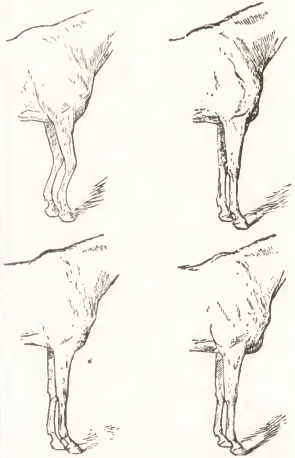


Front View of Bad Fore Quarters.



Side View of Good Fore Quarters.

ful legs. The fore arm and the shins thus appear of nearly equal length. The hunter must have a lengthy scapula, of good breadth, and set well back. The arm must be in length longer than the draught horse, but not so long as the race horse; it also must be placed at an angle with the shoulder blade greater than the work horse, but less than in the race horse. The forearm must be of medium length, also the shin. The shoulders should be examined for tumors. If there are any marks of setons or blisters about the points, it is probable that he has been treated for shoulder lameness. The withers are usually desired high and thin, but they are very commonly too much developed, and if the bony processes stand up like the edge of a razor, without muscle on them, they are to be regarded as objectionable rather than otherwise. Examine the withers for bruises from the saddle. The fore limbs should be set on, so that when the horse is standing, the limb may be neither turned in nor out. The fleshy-legged horse being generally subject to grease, and other infirmities of that kind, should not be chosen. The

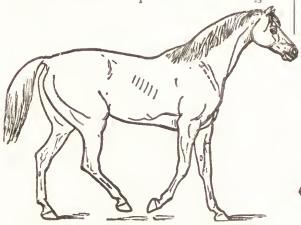


Side View of Bad Fore Quarters.

knees should be examined with the utmost care; 1st, that they correspond in shape; and, 2d, to ascertain whether the skin has been broken by falls; but it does not follow that a mark or scar indicates a stumbler, and an accidental blemish should not at once condemn a well-formed animal. When a scar on the knee is observed in connection with low withers, a thick and upright shoulder and pasterns, with the legs inclined under the bone, it is evident that the faulty formation has produced its natural consequence.

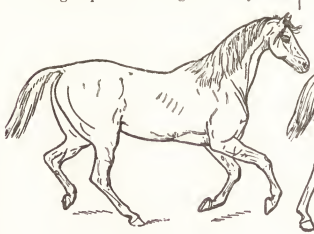
GAITS.—The natural gaits of the horse are the walk, trot and gallop. Whatever the pace may

be in moving forward, the hind quarters are the main propellers and thrust the body forward on the fore legs. This forward motion is effected by one hind leg at a time, as in the walk, trot, amble and rack, or by the two almost simultaneously, as in the canter, gallop and leap. The *Walk* is performed in 1–2–3–4 time, and in regular cadence. The 4 legs move separately, and not by 2's, as in the trot and amble. The hind foot is raised from the ground and moves forward ½ its stride before the fore foot moves. The illustration shows the position of the legs in



Correct Manner for Starting the Walk.

starting to walk. The hind foot is just being placed where the fore foot has just moved from. The other hind foot next follows in succession, and then the other fore foot completes the cadence. The *Amble* is sometimes classed as a modified pace, and is in reality a slow gallop. It is performed by 2 legs alternately moving in exact correspondence with each other; these are of the same side, and one lateral half of the body is moved forward while the weight of the whole is supported on the other. The *Canter* is a slow gallop. There is a great variety in the

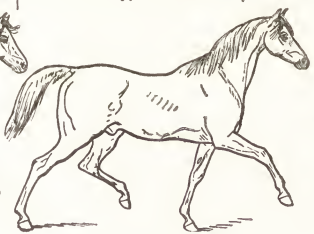


The Canter.

manner of performing the canter, and when it is performed with the right leg leading, it is an extremely elegant and well adapted gait to the female seat. The *Gallop* is performed in 1–2–3–4, but the faster the strides, the more nearly simultaneously will the fore and hind feet be brought down; and when the horse is running at speed, the movement seems to be in 1–2 time. The horse in full gallop, when carefully watched, will be seen to extend himself very much, but not nearly so much as represented by artists. To give the idea of speed, the hind legs are thrust backward, and the fore legs forward in an unnatural position. The *Rack* or *Pace* is a fast kind of amble. It is performed by 2 legs of the same side acting simultaneously, as in the amble, but they are moved with much more rapidity, and the result is a speed greater than the fastest trot by several seconds in the mile. (See *Pace, Training to*, in BREAKING AND TRAINING.) The *Run* is a kind of gallop, but by some it is defined as a trot, in which the limbs each seem to act independently, as in the walk. It is impossible for the rider of a running horse to rise in his stirrups, but as the action is

The Gallop.

very easy there is no occasion for this relief. It cannot be performed at a slow rate. The *Trot* may be described under 3 heads; the jog trot, the true trot, and the flying trot. In each of these, the diagonal legs move together; in the 1st, the time during which each foot is on the ground is much greater than that in which it is in the air; in the 2d, the contrary is the case; and in the 3d, the horse is completely carried off his legs for a considerable space of time, between the several bounds which are made by the 2 feet of opposite sides as they touch the



The True Trot.

ground in succession. The jog trot comes natural to the horse when he is first mounted; and, as long as he is fresh and fiery, the colt will maintain this pace, unless he is permitted to exceed it. The chief difference between the 3 varieties of the trot consists in the rapidity of the propulsion which is going on. In the first, this is very slight, and the more elastic the fetlock joints, the better and softer is this pace. The

feet are raised, but the body is not thrust forward; the consequence is, that the feet are deposited again very close to the spot from which they are taken, and the pace is as slow as the walk. In the true trot, the hind legs move as rapidly as, and with more force than, the fore legs, because they have more work to do in propelling the body, the latter having only to sustain it during the operation.

HEAD AND NECK.—The face should have an intelligent and good-tempered expression, and this is usually found in horses with a broad,

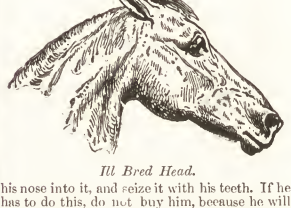
A Well Bred Face.

A Low Bred Face.

flat forehead, a straightly-inclined nose, a moderately square muzzle, with some expansion of nostril, full and prominent eyes, and thin lids. A small, sunken eye, particularly with a Roman nose, gives a horse a sulky, piggish expression, and often denotes obstinacy and bad temper. Again, the sub-maxillary space, or distance between the branches of the lower jaw, should be moderately wide, and not bulging or lumpy toward the chin, otherwise a profile view is considerably depreciated. The side face should be deep. Length of head is not of such importance. It cannot well be too short, so far as the chief requisites are concerned. In order that large quantities of well-masticated food may be swallowed, the back teeth, or grinders,

Well Bred Head.

must have large, flat and regular masticating surfaces. So, also, with the jaw; if there is not ample width between the 2 sides for the development and play of the larynx and windpipe, the wind is sure to be affected, and, in addition, the head cannot be nicely bent on the neck. A defect in this last point is the usual cause of that straight and inelegant setting on of the head which is so common, and which is alike unsightly and prejudicial to the wind and the mouth; for a horse which cannot give way to the pressure of the bit, will become dull in his mouth, and therefore unpleasant to ride or drive. All badly treated gatherings or abscesses are apt to leave behind them 2 evidences of their former presence, viz.: thickening of the skin and parts beneath, and ragged scars. Therefore, always look for these between the jaws of a horse. The skin, in this situation, should be fine, and the hair silky. See that the space between the jaws is not flush with the lower borders of the jaw. See that the lips are not swinging about like pendulums. Very old horses sometimes have pendulous lips from debility. If about to buy such a one, give him a feed of hay, and watch him to see if he can grasp the hay with his lips, or if he has to push



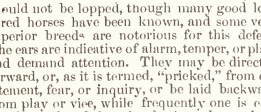
Ill Bred Head.

his nose into it, and seize it with his teeth. If he has to do this, do not buy him, because he will spoil more food than he will eat, from its dropping out of his mouth while chewing; he will take twice the time to feed, and he will never keep in good condition. Sometimes he swings the lips about in trying to seize a morsel, showing that some power in them remains. If this be so, present a pail of water to him, and watch him drink. If he cannot keep his lips pursed, and so keep up a steady drinking effort, and if they are so powerless that he has to dip his whole muzzle into the water, nearly up to his eyes, do not buy him. Hold the nostrils open, and look inside. The pink, or bluish-red membrane which is seen, ought to be covered with drops of water like dew. There ought not to be any ulcers or abrasions seen, or raw spots of any kind. There is always found, however, a very small opening, like a punched-out hole, but this is natural, and no notice need be taken of it. Each nostril should be alternately closed by the hand, to ascertain that the air-passages are not obstructed by polypus, or enlargement of the turbinated bones. If there be any discharge from the nostrils, save a slight watery discharge, it may be that the horse is suffering from a cold, or he may be glandered. The color of the discharge must be noticed, also its thickness; also notice whether it comes from both nostrils, or only one. If it be from cold, it may

be variously colored, even green, as when the horse is feeding on green food in summer. It also may be of any thickness, from wateriness to ropiness, and yet may be from a harmless cold. If, however, it be thick and gluey, and sink when put into cold water, or be tinged with blood, it is most likely that the horse is glandered. The suspicion of glanders is strengthened, if the discharge is coming only from one nostril.

Ill Bred Head.

When buying a horse, see that a discharge from the nose is not cleaned away when the attention is withdrawn. The muzzle should have no streaks of discharge upon it, neither should it be wet as if sponged. A large nostril cannot be dispensed with in horses intended for fast work, and should be desired even in the work horse, for, in drawing heavy loads on a hot day, his breathing may be rendered almost as laborious as that of the highly tasked race horse or hunter. The ear should be of medium size, and should not be lopped, though many good lop-eared horses have been known, and some very superior breeds are notorious for this defect. The ears are indicative of alarm, temper, or play, and demand attention. They may be directed forward, or, as it is termed, "pricked," from excitement, fear, or inquiry, or be laid backward from play or vice, while frequently one is carried forward, and the other backward, especially while going. This is for the purpose of collect-



Young Horse.

Old Horse.

ing all sounds, and such an animal is usually attentive to all that goes on around him. The channel or space between the branches of the lower jaw should be wide. In old age the edges retract, the channel narrows, while the lower margins of the bones appear to the fingers of the examiner, accustomed to handle young horses, to be positively sharp. The neck should be of moderate length, even a moderate-sized head, at the end of an extremely long lever, being too much for the muscles to support. It should come out full and muscular, with a sweep between the withers and the bosom, and should gradually diminish till it runs into the head, with an elegant bend just behind the ear. A very narrow throat, suddenly bent at the upper part, marked as the thropple, is apt to be connected with roaring, and on that account is objected to by horsemen. The neck should be searched to ascertain that both jugular veins are perfect, which is discovered by pressing on the lower part of the neck with sufficient force to stop the return of blood from the head; if the vein be perfect, it will fill and swell from that point upward toward the head.

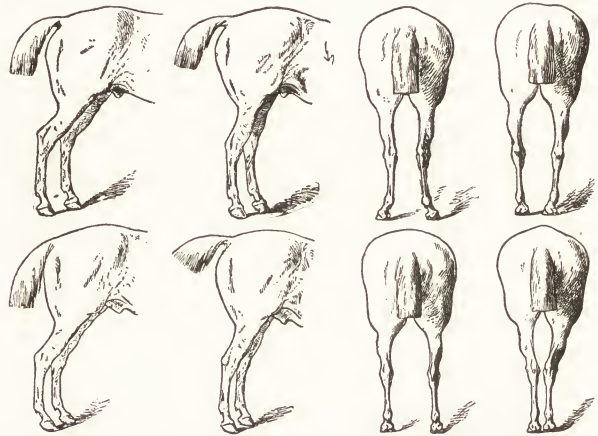
HIND QUARTERS.—For high speed, there should be plenty of length in the 2 bones which unite at the stifle-joint, without which the stride must be more or less limited in extent. In inspecting the leg, the eye alone should not be trusted; but, after minutely comparing the appearance of the 2 limbs, the hand should be passed down both shanks before and behind; any difference, before or behind, points to a deviation from health. In the sound, flat limb, the tendon is well defined, perfectly distinct, and has a hard, tense feel, that resembles the touch of a cord tightly strung. If the back sinews feel thick, the flexor tendons and their sheaths swelled and rounded, leaving no distinctive marks as it were between the one and the other, but all swelled into one mass with the bone, great mischief has, at some time, happened. The hock is one of the most important joints, and should undergo a rigid examination. When standing behind the horse, if one of the hocks is diseased, the bone does not incline gradually as in the sound limb, but there is an abrupt prominence. Though to the unpracticed eye this is not always perceptible on comparing them, yet, by passing the hand down on the inside of both hocks, this abruptness will be felt. If there is any tenderness or heat on pressure, or the marks of recent cutting on the inside of the fetlock, or unequal wear of the shoes, especially at the toe, spavin may be suspected. Sometimes both hocks present an enlarged appearance, though there is neither heat, pain, nor lameness (for hock lameness is frequently intermittent); such hocks are unsound. Certain forms of hock are more subject to disease; those approaching each other, termed low hocks, are predisposed to spavin and curb; those in which the point of the

Good Hind Quarters.

hock inclines too much backward, are liable to spavin; and when the hock is too upright, narrow and straight, it is subject to thoroughpin.

Good Hind Quarters.

LEGAL POINTS.—The inexperienced purchaser can always exact a definite warranty from a responsible seller, or, in default of such warranty, can insist upon a chance to try the horse. In any case where an honest dealer wishes to sell a horse for what the animal is undoubtedly worth, he cannot refuse to warrant a horse in any required particular. Any other course savors strongly of an attempt to deceive one who has no sufficient means of acquiring a knowledge of defects and faults easy to be concealed. Any honest dealer can have no objection to any course that will give the fullest information to the intending purchaser. When a horse is returned, he must be in the same condition in which he was received, except so far as the disease for which he is returned may have progressed in the meantime. Inquire of the seller how he has been accustomed to diet and clothe the animal; whether his feet were stopped; and the same treatment should be pursued till his soundness is ascertained. Note the temperature of the stable; if his new habitation should be hotter, it is probable an inflammatory attack of the lungs may be induced. Beware of putting a saddle on a new horse that does not fit him; while the question of soundness is still doubtful, it is far better to use the saddle he has been accustomed to. If his back becomes galled while trying him (which is not an unusual occurrence), the dealer will object to take him back, unless full compensation is made; and reasonably so, for he is unfitted for sale or for work till it is healed; and it is also a point for calculation whether he may not chance to fall sick while standing in high condition in the stable, in which case the dealer would be subjected to heavy loss. It is, therefore, not prudent to remove his shoes, or in fact do anything with the animal which may cause doubt or cavil, until it is finally decided to keep him. When horses are sold at public auction by dealers, it is usual when a warranty is given, to limit any objection to it to some short period, during which time the auctioneer holds the purchase money in his hands, which is paid over to the vendor if no complaint is made within the time specified, when the transaction is considered closed. If a horse turn out otherwise than according to the warranty given, the horse should be formally tendered to the seller, and the purchase money demanded back. If this is refused, the horse should be sent to a livery stable, and sold by public auction, due notice having been

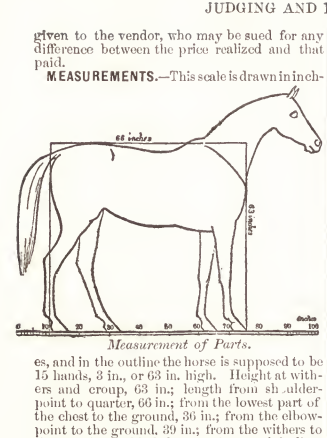


Side View of Bad Hind Quarters.

Back View of Bad Hind Quarters.

given to the vendor, who may be sued for any difference between the price realized and that paid.

MEASUREMENTS.—This scale is drawn in inch-



Measurement of Parts.

es, and in the outline the horse is supposed to be 15 hands, 3 in., or 63 in. high. Height at withers and croup, 63 in.; length from shoulder-point to quarter, 66 in.; from the lowest part of the chest to the ground, 36 in.; from the elbow-point to the ground, 39 in.; from the withers to the poll, just behind the ears, in a straight line, 30 in.; the same measured along the crest, 32 in.; length of head, 22 in.; width across the forehead, 9½ in.; from the withers to the hip, 22 in.; from the stifle to the point of the hock, in the attitude shown in the plan, 28 in.; from the root of the tail to the stifle-joint, 26 in.; from the point of the hock to the ground, 22½ in.; length of arm from the elbow to the pisiform bone, 19½ in.; from the pisiform bone to the ground, 19½ in.; girth varies from 76 to 79 in.; circumference of fore cannon bone, 7½, 8, 8, 8, 8¼ and 9 in.; circumference of arm just below the elbow, 16½ to 18 in. The height of a horse is estimated by the hand of 4 in., a scale of measurement which is confined exclusively to horses. Having regard to most speed there should be the largest dimensions possible, and therefore the greatest height compatible with perfection and symmetry. The greatest power also requires the greatest bulk. A combination of speed and power, as exhibited in the hunter, has its highest expression in horses about 15½ hands high, ½ hand, more or less, being unessential. In a flat outline the length will come to 24 in. in a horse of 15 hands, 3 in., but, measured round the surface, it will be 2 in. more. Again, the lower thigh, or gaskin, should be of about the same length; but if measured from the stifle to the point of the hock, it will be fully 28 in. in a well made horse of high breeding. These measurements, however, will be much greater in proportion than those of the work horse, who requires strength before all things, and whose stride is of no consequence whatever. In him, the length of the upper, or true thigh, is generally as great as that of the thoroughbred, but the lower thigh is much shorter, and the horse stands with a much straighter hind leg, and consequently with his hocks having a very slight angle. Muscular quarters and gaskins are desirable in all breeds.

SKIN.—The skin should feel smooth and look glossy, and the muscles of the body feel hard, not spongy to the touch. In the old horse, the head grows lean and fine, and the features more striking and blood-like; the neck fine, withers short, and the back sinks; the lips exhibit a lean and shriveled appearance, and the lower lip hangs considerably below the upper. In youth they are round and plump, and meet together, and the ridges of the roof of the mouth will be found prominent. In age the middle of the nose will sometimes be found indented by the long-continued pressure of the nose-band of the head-stall. When the skin is rough and harsh, and does not move easily and smoothly to the touch, the horse is a heavy eater, and his digestion is bad. If the hair is rubbed off, especially about the head, flanks and tail, or he is observed rubbing himself against the stall, there is danger of his being mangy, and in this case his coat will be found rough and staring. The skin of the thoroughbred is extremely thin and delicate, and allows the veins to be seen through it, and is covered with fine hair. That of the draught horse is thick. That of the hunter, or power and speed representative, is between the two extremes. Much mane and tail is a sign of low breeding; while, on the contrary, a slight, silky mane, with or without a little wave in the hair, is a desirable thing. The same may be said of the tail.

WIND.—Avoid a horse whose respiratory organs are at all impaired. Any animal so affected should be considered unsound, for impediments in breathing injures him for drawing or any other active service. To test them, ride or drive the horse briskly about ¼ mile; place the ear at the side of the heart, and if a wheezing sound is heard, it is an indication of trouble. Wind may also easily be judged of by the motion of the flanks. A broken-winded horse pinches in his flanks with a very slow motion, and drops them suddenly, which may be easily perceived. Many horses breathe thick that are not broken-winded; indeed, any horse will, in foggy weather, or if foul fed, without sufficient exercise; but, if a horse has been in good keeping, and had proper exercise, and yet has these symptoms, there is some defect, either natural or accidental, such as a narrow chest, or some cold that has affected the lungs. When inspiration appears to be performed readily and quickly, as in health, by a single action, but expiration with difficulty, by an irregular and prolonged movement or double action, the respiratory muscles appearing as if interrupted in the act of expelling the air, and then the flank drops suddenly, it is a symptom of broken wind. The cough should then be tried. The cough of a broken-winded horse, is a peculiar, low, hollow grunt, difficult to describe, but when once heard, easily recognized. The cough can generally be elicited by pinching the larynx or trachea, though occasionally this fails, for some sound horses, as well as broken-winded ones, cannot be made to cough at all.

TRICKS OF DEALERS.

AGE, To Disguise.—A horse is made to appear young by giving the following: Tincture of asafœtida, 1 oz.; tincture of cantharides, 1 oz.; oil of cloves, 1 oz.; oil of cinnamon, 1 oz.; antimony, 2 oz.; fenugreek, 1 oz.; 4th proof brandy, ½ gal.; let it stand 10 days, and then give 10 drops in 1 gal. water. The process of filling up the depressions over an old horse's eyes, is another matter that requires the art of an adept. This is termed "puffing the glims." The skin over the cavity is punctured, and the jockey then fills it with air from his mouth; the aperture closes, and the brow becomes as smooth as that of any young horse.

COLORING.—Jockeys go so far sometimes as to paint a horse all over, if his color is bad; and dyeing in spots for the purpose of producing matched teams, is a common practice. This is a clever trick and not easily detected. The white hairs which appear about the head and eyes of aged animals are frequently pulled out. Black spots may be put on a white horse, by taking powdered quicklime, ½ lb.; litharge, 4 oz.; beat well, and mix the litharge with the lime; put into a vessel, and pour sharp lye over it; boil, and skim off the substance which rises to the surface. This is the coloring matter which must be applied to such parts of the animal as are wished to be dyed black. Red hair may be dyed black with a very similar composition, thus: Boil 4 oz. of lime with 4 oz. of litharge, in fresh water; the scum that rises will have the same effect. If the hair be entirely free from grease, one night will be sufficient to stain it black.

FLESH, To Produce the Appearance of.—It is a custom among horse men who want to sell an inferior animal, to mix antimony, arsenic, and various forms of mercury with their feed. These cause them to make fat rapidly and become sleek and glossy, but often result in terrible blood poisoning, producing slow and agonizing death. A horse may be made to stand by his feed and not eat, if the front teeth and roof of the mouth are greased with common tallow.

GLANDERS, To Hide.—Dealers, at fairs and other places, will frequently endeavor to pass off a glandered horse upon an unwary customer. The usual trick is to stimulate the nostrils till the horse has snorted away all the matter lying in them, and then by injections of an astringent nature, producing a temporary suppression of the discharge. Others cram a pledget of tow up the nostrils. These tricks may be detected by the animal's uneasiness, tossing of his head, efforts to sneeze, the red and vascular appearance of the interior of the nostril, but especially by the fetid breath. A horse is made to appear as if he had the glanders by pouring butter that has been freshly melted into his ears.

HEAVES, To Hide.—To disguise the heaves, the horse is sometimes given ½ lb. of small bird shot, and he will not heave until it passes through him.

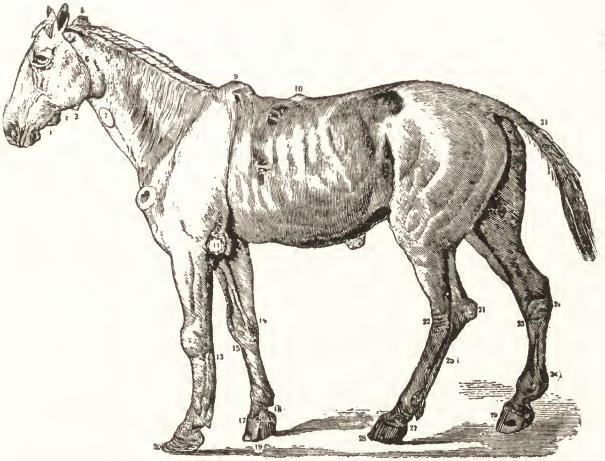
LAMENESS, To Conceal.—About ½ way from the knee to the joint, on the outsides of the leg, make a small incision, and at the back part of the shin bone you will find a small white tendon or cord; cut this tendon or cord off, and sew up the incision with a stitch, and the horse will walk off on the hardest pavement without a limp. A horse is made to appear lame by taking a hair from the tail and passing it through the eye of a small needle; press the skin between the outer and middle tendon or cord of the front leg; shove the needle containing the hair through, then cut off the hair on each side, and let the foot down. In 20 minutes' time the horse will go lame.

LYING.—Of all the means by which the jockey prosecutes his trade, there are none so much relied on or so effective as bold and ingenious lying. This is his great resource. It supplies pedigree, history and warranty. If there be blemishes on the animal, they can be easily explained away by plausible lies; if the horse is lame, it arises from a slight sprain, bad shoeing, or other easily remedied cause; if he stumbles, it is because he has been ill-shod; if he balks, the harness is on wrong, or the horse has an attack of some acute complaint arising from over-feeding, over-driving, or it comes of bad handling; if he kicks, he is only playing; if he leers and bites, it is a sign of courage and vitality; if his coat "stares," he has just been brought in from the country, where he has been running out during the winter; if he is thin and bare, there are a thousand explanations handy; while every good point is exaggerated and held up with art and eloquence.

SPAVIN, To Conceal.—Tincture of cayenne, 1 oz.; laudanum, 2 oz.; alcohol, 1 pt.; the shoulders are rubbed well with warm water, then the above mixture is rubbed on the shoulders and backbone; the horse is then given 1 oz. of laudanum and 1 pt. of gin; his feet are put in warm water as hot as he can bear it; a little spirits of turpentine is rubbed on the feet with a sponge after taking them out of the water; he is then driven about ½ mile or so, when he is found quite limber. If he does not surrender to his pain, a thin cord is tied around the end of his tongue.

STAR, To Make.—Take a piece of coarse towline, just the size of the proposed star; spread on it some warm pitch, and apply it, first shaving the place; leave it on for 4 days, then wash the spot with smart water or elixir of vitriol, 4 times a day, until well; when the hair grows, it will be white.

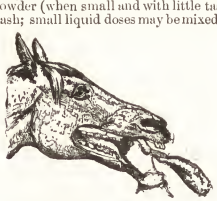
TREATMENT OF DISEASE.



Diseases of the Horse.

1, caries of the lower jaw; 2, fistula of the parotid duct; 3, bony excrescence or exostosis of the lower jaw; 4, swelling by pressure of the bridle; 5, poll evil; 6, inflamed parotid gland; 7, inflamed jugular vein; 8, fungous tumor produced by pressure of the collar; 9, fistula in the withers; 10, saddle gall; 11, tumor of the elbow; 12, induration of the knee; 13, clap of the back shews; 14, malanders; 15, splint; 16, ring-bone; 17, a tread upon the coronet; 18, quittor; 19, sandcrack; 20, contracted or ring-foot of a foundered horse; 21, capped hock; 22, malanders; 23, spavin; 24, curb; 25, swelled sinews; 26, thick leg; 27, grease; 28, a crack in front of the foot, called sandcrack; 29, quarter-crack; 30, ventral hernia; 31, rat-tail.

ADMINISTRATION OF DOSES. — Medicine may be given to the horse as a ball, a drench, or as a powder (when small and with little taste) in the mash; small liquid doses may be mixed in the



Correct Way of Giving a Ball.

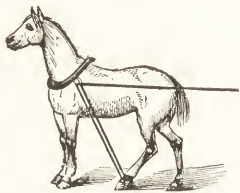
food. In giving a ball, catch firm hold of the tongue with the left hand and draw it down between the incisor teeth; then holding the ball in the right hand, with the fingers inclosing it like a cone, and the arm bare, carry it rapidly to the back of the mouth and deposit it there; withdraw the hand, close the mouth, elevate the head a little, and watch on the left side of the neck for the ball to go down. The nose may be rubbed somewhat roughly in order to divert the horse's attention. Drenches may be given out of a strong-necked bottle, or a horn. Two persons are necessary, the operator standing at the right shoulder, while the assistant is ready to steady the head and aid him on the left. The operator raises the head with his left hand beneath the jaw, and with his right he forces the lip of the horn into the side of the mouth, and, raising the small end, pours the contents in. If the horse is violent, a twitch must be placed on the nose. Do not pass the horn far into the mouth, or use violence, lest a cough should arise, in which case lower the hand instantly. (See *Remarks* in DISEASES OF CATTLE.) To examine the hinder parts, the horse may be

Mode of Distracting the Horse's Attention.

kept quiet by the use of the following: A soft collar with a metal ring is put over the horse's head, and a hobble is fastened to the foot to be

Manner of Giving a Drench.

elevated. By the side of this ring a strong rope is attached; the cord is then passed through the D of the hobble; then it is brought back and run through the side ring or loop; by pulling the rope gradually the leg is brought forward, and he cannot kick. Sometimes lines are attached to both feet to throw the horse, but this is not thought as good a method as that described in *Throwing*, in BREAKING AND TRAINING.



Side Line.

ABORTION.—This is usually the result of accident or overwork. In this disease the parts usually come away naturally and leave no bad results, except, perhaps, a nervous prostration, and a slight rise in pulse and temperature during 1 or 2 days. *Treatment:* The mare should have perfect rest for several days, with soft food and chilled water; if fever ensues, a teaspoonful of saltpeter may be given in the mash morning and evening.

ABSCESS OF THE HEAD.—Generally caused by external injury. A wound is formed on the head, from which issues a watery fluid; the horse becomes dull, refuses his food, and at last falls, and commences knocking his head against the floor, and continues thus until death. *Treatment:* Apply a bran poultice to the abscess till it is brought to a head; then, if it does not break spontaneously, open it with a broad-shouldered lancet. Keep the part clean, trim the hair, and inject into the wound the following: Carbolic acid, 1 dr.; water, 4 oz. If the cavity does not soon fill up, inject a wash of ½ oz. of blue stone with 1 pt. of water.

ANEURISM.—A weakness and consequent expansion or bulging out of the arteries. The large arteries in the abdominal cavity are the ones most commonly affected. If it is suspected, examine the internal parts, by inserting the hand in the rectum; if it exists, a large bulge and distinct pulsation will be felt. *Treatment:* There is no cure when it occurs internally; but, if it is external, cold water, ice, and a compress should be applied to the swelling.

APHTHA (Thrush or Sore Mouth).—This is accompanied by dullness and refusal to feed; both lips swell, the tongue tumefies, becomes red, and generally hangs out of the mouth; around the mouth little lumps appear, which, at first, are stony hard; and others, of a larger size, may be felt upon the tongue; vesicles are developed from these spots, which contain a clear liquid. *Treatment:* Wash the mouth with the following: Borax, 5 oz.; honey or molasses, 2 pts.; water, 1 gal.; mix. Regulate the bowels by a dose of 2 oz., each, of rhubarb and bicarbonate of soda, once or twice a week; and give as a tonic ½ dr. of quinine every morning. Give soft, nourishing food, and keep the animal quiet.

Aphtha or Thrush.

APOPLEXY.—The result of a sudden pressure on the brain, and is usually caused by over exertion, or anything which produces a rush of blood to the head. The horse is a little off his feed; more than usually dull; has a somewhat staggering gait; the last act of voluntary motion is to drink; has little power over the muscles of swallowing, and the fluid returns through the nostrils; foams at the mouth; breathing laborious and loud; death speedily ensues. *Treatment:* Immediately open the jugular vein (see *Bleeding*), and give the following to act on the bowels: Barbadoes aloes, 1 oz.; Epsom salts, 1 oz.; water, 2 pts.

BAGS.—Soft, puffy swellings of the membrane of the mouth. *Treatment:* Cut off a portion of the swelling with a pair of scissors or a knife; after which dress the parts with a little salt or powdered alum.

BITES.—Horses are liable to be bitten by different insects. The bites of the gadfly are sometimes very troublesome in their effects. *Treatment:* Make a strong infusion of the green bark of the elder, and wash the flanks, etc., with it before going out; or with dilute carbolic acid.

BLADDER, Eversion of.—Caused by protracted labor, or straining, in inflammation of the bladder. The bladder will be seen protruding from the lower part of the vulva. *Treatment:* Bathe the bladder with the following: Laudanum, 1 oz.; water, 1 pt. Press the bladder carefully and gently till it is returned to its place. If it is inclined to come out again, put on a compress to hold it in.

BLADDER, Inflammation of (Cystitis).—Commonly caused by the too free use of fly blisters to the back, acrid plants in the food, and reten-

tion of urine. The symptoms are a quick pulse, pain in the hind quarter, evinced by the looks of the animal in that direction, and constant straining to pass the urine, which is thick and mixed with mucus, or, in aggravated cases, with purulent matter. *Treatment:* Purge with linseed or castor oil; then give 2 dr. of laudanum (tinct. of opium), every hour, till pain is relieved.

BLADDER, Stone in the.—The symptoms are a desire to urinate, without any discharge; afterwards the urine flows with ease, but suddenly stops; the stone having been carried to the outlet, blocks up the passage. The animal, after attempting for some time to evacuate the bladder, groans, sighs, and lies down in a careful manner. *Treatment:* The animal should be placed upon his back, with the hind legs drawn well forward; a whalebone staff is passed up the urethra, which may be felt a little below the anus; an incision, 1½ or 2 in. in length, is made directly upon it, obliquely to one side, cutting through the urethra and the neck of the bladder; the forceps are next introduced, and the stone removed; after which the parts are carefully closed by means of the quill suture.

BLEEDING.—This is valuable in cases of congestion, when there is a full, strong pulse, and no fever. When it is necessary to lessen the whole quantity of blood in the system, open the jugular or neck vein. If the inflammation is local, bleed where it can be conveniently done, either from the part affected, or in its vicinity,

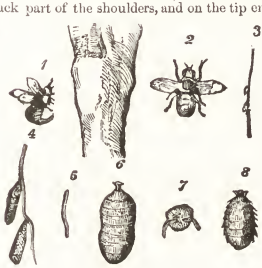
Bleeding.

as by opening the plate vein, superficial vein of the thigh, or temporal arteries. The instruments used, are either the lancet, or the fleam and the blood-stick; but the former requires some practice to manage it properly. In bleeding from the jugular vein the horse must be blindfolded, if the fleam is used, to avoid his shrinking away from the blow; then, with the finger, press upon the vein, to make it fill; place the blade of the fleam upon the vein, as shown in the illustration, and strike it with the blood-stick; then press the blood-pail against the vein, which will cause the blood to flow freely. The quantity of blood to be taken varies according to the age, size, condition and constitution of the horse, and urgency of the symptoms. From a large, strong horse, 4 or 6 qts. of blood will generally be requisite; and this may be repeated in smaller quantities if the symptoms demand it. When the desired quantity has been drawn, the vein must be carefully closed by passing a pin through the centre of the opening, taking up the skin upon both sides, and tying with hair from the mane or tail, or with tow. The pin may be removed in about 24 hours.

BLEEDING, To Stop.—*Treatment:* The best remedy to stop bleeding is a piece of iron simmered for a few minutes in hot water, applied to the wound for a moment, which will at once stop further loss of blood.

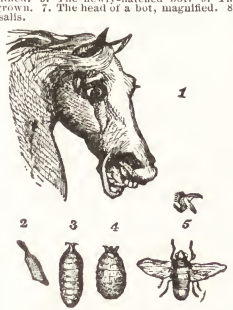
BONY GROWTHS (Osteophytes).—These bony deposits are the result of hard work, which makes the bones sore and inflamed. A bony enlargement can be seen and felt; more or less lameness exists, and the animal is knee sprung. *Treatment:* Give the animal a long rest, and apply the following blister: Biniodide of mercury, 2 dr.; lard, 2 oz.; mix, and rub well in.

BOTS.—There are 2 species of horse bots, the *Œstrus equi* and *Œstrus hæmorrhoidalis*. The female of the 1st deposits her eggs upon the hair on the inside of the knee, on the sides and back part of the shoulders, and on the tip ends



Œstrus Equi.

1. The female fly about to deposit an egg. 2. The male fly. 3. The egg, its natural size. 4. The egg, magnified. 5. The newly-hatched bot. 6. The bot full grown. 7. The head of a bot, magnified. 8. The chrysalis.



Œstrus Hæmorrhoidalis.

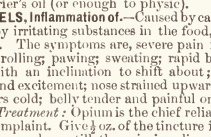
1. The female about to deposit an egg. 2. The egg magnified. 3. The bot. 4. The chrysalis. 5. The male fly.

of the hairs of the mane. The female of the 2d, selects the hair on the lips. The eggs are made to adhere by means of a glutinous liquor secreted with them. The horse licks the spot irritated by

Bots Attached to a Horse's Stomach.

the fly, and gets 1 or more eggs into his mouth; it is hatched by the heat and moisture, passes down the gullet, and attaches itself to the coat of the stomach by its hooks, where it remains until the next spring and then passes out with the dung. On reaching the outer air, it assumes the chrysalis condition, and in 3 or 4 weeks bursts its covering to become a perfect insect. The symptoms are, occasional nipping at the sides; red pimples on the inner surface of the upper lips; rough, unthrifty coat of hair and loss of flesh. *Treatment:* Give 2 qts. new milk in 1 qt. molasses; then 15 minutes afterwards, 2 qts. very strong sage tea; 30 minutes after the tea, 3 pts. of currier's oil (or enough to physic).

BOWELS, Inflammation of.—Caused by catching cold, by irritating substances in the food, or by poison. The symptoms are, severe pain in the belly; rolling; pawing; sweating; rapid breathing, with an inclination to shift about; great fever and excitement; nose strained upward; legs and ears cold; belly tender and painful on pressure. *Treatment:* Opium is the chief reliance in this complaint. Give ½ oz. of the tincture in ½ pt. water, every hour, till the pain is relieved. If there is much fever, give 10 drops tincture aconite root every 2 hours. Apply blankets, wrung out of hot water, to the abdomen, and renew them every 15 minutes. Give 1 pt. linseed oil, and follow with injections of warm (not hot) wa-



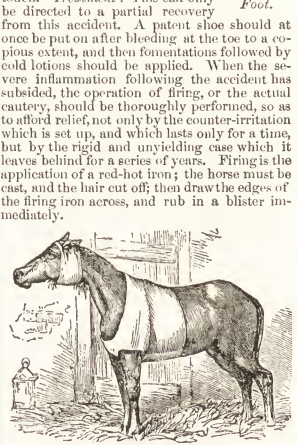
Symptom of Inflammation of the Bowels.

ter, Castile soap, and 1 oz. table salt, every ½ hour, until the bowels move. After the fever has subsided give a few powders of the following: Mix pulverized licorice root, fenugreek and gentian, 2 oz. of each; divide into 6 powders, and give in feed 2 or 3 times a day.

BRAIN, Inflammation of.—It arises from blows over the head, overfeeding, particularly with corn; a tight collar will sometimes produce it. The symptoms are a disinclination to move about; loss of appetite; lining membrane of the eyelids much reddened; eyes present a dull and sleepy appearance; to these succeed delirium or madness. *Treatment:* Bleed freely before the delirious stage comes on. Apply cloths wet in cold water to the head, or bags of broken ice. Open the bowels with the following ball: Barbadoes aloes, 1 oz.; croton oil, 6 drops; pulverized ginger, 1 dr.; mix with water, molasses or honey. Give injections of Castile soap and water. Give no food of any kind for 24 hours, but small quantities of water may be given. After recovery feed lightly.

Broken Down Foot.

BREAKING DOWN. — This is caused by a partial or entire giving way of the fetlock joint downwards, so that the back of it either touches the ground, or nearly so, when the weight is thrown upon it. Usually after the horse is pulled up, he hops on 3 legs, and refuses to put that which is broken down to the ground. In a very few minutes the leg "fills" at the seat of the accident, and becomes hot and very tender to the touch. *Treatment:* This can only be directed to a partial recovery from this accident. A patent shoe should at once be put on after bleeding at the toe to a copious extent, and then fomentations followed by cold lotions should be applied. When the severe inflammation following the accident has subsided, the operation of firing, or the actual cautery, should be thoroughly performed, so as to afford relief, not only by the counter-irritation which is set up, and which lasts only for a time, but by the rigid and unyielding case which it leaves behind for a series of years. Firing is the application of a red-hot iron; the horse must be cast, and the hair cut off; then draw the edges of the firing iron across, and rub in a blister immediately.



Horse Dressed for Bronchitis.

BRONCHITIS, Acute. — Generally caused by exposure. It commences with a chill, fever, harsh cough, labored breathing, mouth hot and dry, with loss of appetite, and in 1 or 2 days a discharge from the nostrils will be observed. *Treatment:* Place the horse in a large, loose box; fill the place with steam; apply scalded hay to the throat by means of an 8-tailed bandage. Fix flan-

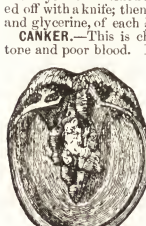
nels, wet with cold water, to the back and side, by means of a waterproof jacket. When the flannels become warm, change them; do this for 2 hours. After that space the flannels may remain on, but must not become dry. Give 10 gr. of tartar emetic, dissolved in 1 tablespoonful of water, with 2 dr. tinct. of opium, 3 times a day. Keep the bowels open with castor oil or Epsom salts, and give as a tonic ½ dr. quinine every morning.

BRONCHITIS, Chronic. — The result of bad treatment of acute bronchitis, and when the attack has been prolonged for some time. It is characterized by a cough which seems to be confirmed, and discharge from the nostrils. The cough is worse after drinking and in the morning. *Treatment:* Take of pulverized gentian and sulphate of iron, 8 oz. each; mix thoroughly and divide into 35 powders, and feed twice a day until all have been given; then make an ointment of red iodide of mercury, 1 dr.; lard, 1 oz.; mix well; apply down the course of the windpipe, and the next day apply sweet oil or lard to keep the skin from cracking. Repeat the application of the ointment in one week.

BURNS AND SCALDS. — *Treatment:* If the burn is severe and there is much pain, use linseed meal poultices locally, and give internally ½ oz. doses tinct. opium till the pain is relieved; then use as a lotion, a saturated solution of bicarbonate of soda, till the burn is healed.

CALLUS, or INDURATION OF THE KNEE.— This is caused by pressure or friction, and sometimes by an injury, which, after remaining sore for some time, finally heals, leaving a thick, hard and enlarged surface. *Treatment:* Paint with tincture of iodine, 3 times a day; in a few days the hardened substance may be scrapped off with a knife; then dress with carbolic acid and glycerine, of each ½ oz.; linseed oil, 1 pt.

CANKER.—This is characterized by want of tone and poor blood. It often follows bruises, punctures, corns, quittors and thrush, and is very difficult to cure. It is more frequently connected with neglected thrush than with any other disease of the foot. It consists of destructive inflammation, with ulceration, which destroys the connection between the sensitive and horny sole and the frog. After a time a foul fungus sprouts from the ulcerations, accompanied with an exceedingly disagreeable discharge. The horn of the sole and frog becomes disorganized and breaks down. *Treatment:* This consists in tonics internally. Take powdered gentian, and powdered sulphate of iron, 8 oz. each; mix, and divide into 35 powders; give 1 powder twice a day. For local treatment, remove all loose horn, and allow all pent-up matter to escape; the exuberant granulations must be carefully cut away, and the parts then washed with a tepid lotion of sulphate or chloride of zinc. After drying the surface, dust it with oxide of zinc; apply tow, dipped in a mixture of tar and lime, and keep it in firm contact with the parts by means of a leather sole, or strips of hoop iron underneath a shoe lightly tacked on. Dress in this manner daily, keeping up the dry pressure for a week.



Confirmed Canker.

CARBUNCLE.—Carbuncle is a gigantic boil. There is a great uneasiness, high fever, and marked prostration. *Treatment:* Move the bowels with Barbadoes aloes, 5 dr.; ginger, 1 dr.; gentian root, 1 dr.; and syrup to combine; mix; make a ball, and give at 1 dose. Apply a linseed poultice locally; and, as soon as evidence of formation of matter exists, do not wait for sloughing, but open at once and freely with a knife or broad lancet. As soon as the sore begins to granulate, change from the poulticing to the following lotion: Carbolic acid, 4 dr.; water, 1 pt.; mix. For the prostration, use the iron powders recommended in *Bronchitis, Chronic*; and for pain, give occasionally ½ fl. oz. of tincture of opium.

CARIES.—Caused by the injuries inflicted by the use of long levers to curb bits, together with tight curb chains. It may be known by a peculiar sore; there is a depression, and in this lies a mass of proud flesh, which is not attached to the surrounding surface, being only fixed to the bottom of the cavity or partially on one side. A watery discharge goes on constantly, and there is continual bleeding from the mouth, on contact with the bit. *Treatment:* This should consist in the adoption of a bit, pressing upon another part of the mouth, changing the curb for a snaffle. Keep the wound open by the use of lunar caustic, daily, which should be pushed deeply into it for a couple of seconds, and it will destroy the unhealthy granulations. Care should be taken not to use the caustic more than is necessary to keep down the fungous growth.

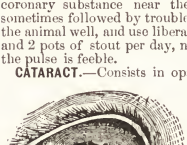
CARTILAGES, Ossified. — A conversion into osseous structure of the cartilages of the foot. The symptoms are, more or less enlargement of the back of the coronet and heel, the part feeling hard and irregular, or lumpy. To ascertain

Test for Ossified Cartilages.

whether the cartilages are ossified, grasp the foot just above the coronet, as shown in the illustration, the fingers on one side, and the thumb upon the other; if the hand is sensible of something hard, and the substance does not yield to pressure, the cartilages are ossified, or approaching this change. *Treatment:* 1. If the horse has recently gone lame, apply a blister to the coronet; repeat it, if necessary. When there is much heat in the part, bleeding from the foot may be adopt-

ed; and afterwards the application of cloths dipped in cold water, with the addition of a wineglassful of tincture of arnica to 1 pt. of water. In confirmed cases, where the parts have become callous, a leather sole to the shoe will take off the vibration, and should be used during the summer season. — 2. Scarification of the skin covering the enlargement with a lancet, encouraging the bleeding by warm water, and followed by the use of cold water as soon as the bleeding has ceased, will sometimes do wonders in recent cases. The scarification should be repeated at intervals of 5 or 6 days, taking care to avoid injury to the coronary substance near the hoofs, which is sometimes followed by troublesome sores. Feed the animal well, and use liberally. Perfect rest, and 2 pots of stout per day, may be allowed if the pulse is feeble.

CATARACT.—Consists in opacity of the crystalline lens, and is generally the result of inflammation of the iris. The progress of the disease is generally marked by an unusual timidity; the animal is alarmed at objects advancing on the road, and covered carts and wagons, of which he formerly took no notice, cause him to shy in the most timid manner. On examining his eyes carefully, instead of the beautifully clear pupil, there is seen either a mass of dull white, generally more opaque in the centre, or an appearance of mottled, semi-transparent soap, or, lastly, 1 or 2 distinct white spots, not quite circular, with irregular edges. *Treatment:* In the early stage, clean the eye by using a lotion of nitrate of silver, 10 gr.; water, 1 oz.; mix, and apply twice a day; give internally, potassium iodide, nux vomica, fenugreek, of each 1 dr.; mix, and give in 1 dose, morning and night for 3 or 4 weeks. Give also the following purgative; 5 dr. Barbadoes aloes; 1 dr. ginger; 1 dr. gentian root; syrup or soap enough to combine with the foregoing powder; make into a ball, and give as 1 dose. Complete cataract can be remedied only by the operation of couching or extraction.



Partial Cataract.

Complete Cataract.

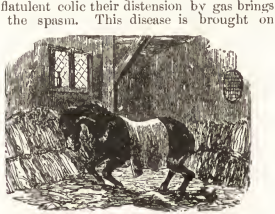
CATARRH, or COLD.—Attended with a slight discharge from the nose, now and then, a slighter weeping from the eyes, increased labor of breathing and cough. *Treatment:* If mild, a little green food, a few mashes, an extra rug and a slight rest, generally accomplish a cure. If severe, give no active medicine. Apply the steaming nose bag 6 times, daily; allow cut grass and mashes for food, with gruel for drink. If weak, give 3 feeds of crushed and scalded oats and beans, daily, with a pot of stout, morning and evening. Good nursing, with pure air and warmth (without exercise) till the disease abates, are necessary.

CHOKING. — This is not of frequent occurrence, but sometimes happens when horses are fed with dry, ground food, and swallow it before it is properly moistened with saliva, and it accumulates in the gullet. *Treatment:* Use a flexible tube, gently; if the choking matter can be felt externally, pour 1 pt. of sweet oil down the throat, and rub outside with the hand.

Steaming Bag.

Choking.

COLIC. — In this disease there is spasm of the muscular coat of the intestines, generally confined to the cæcum and the colon. Various names have been given to its different forms, such as the fret, the gripes, spasmodic colic, etc.; but they all display the above feature. In spasmodic colic the bowels are not unnaturally distended, but in that of flatulent colic their distension by gas brings on the spasm. This disease is brought on by too much food and water at one time, and then immediately putting the horse to work. *Treatment:* Place the horse in a loose box; or remove the carriage from its house, and place a bar across the entrance, and arrange bundles of straw against the walls (as shown in the illustration) to prevent the horse from injuring himself.



Second Stage of Spasmodic Colic.

Give the following drench: 8 oz. raw linseed oil; ½ fl. oz. laudanum; 1 dr. powdered nitre; 8 fl. oz. peppermint water; mix well, and give slowly. If entire relief is not given in 1 hour, repeat the drench. Give proper attention to the diet of the horse, and feed him with sound, sweet and nutritious grain and provender.

CONSTIPATION.—Sometimes caused by the horse not drinking enough, or by inactivity of the liver and other glands that supply the bowels with juices. It may be known by the small amount of fecal matter passed, what is passed being dry and hard; colicky pains are also felt at intervals. *Treatment:* Administer 4 dr. aloes and 1 dr. calomel, rubbed down with gruel; inject soap and water every hour; let the horse have walking exercise, and apply friction to the belly. If, after 12 hours, no effect is produced, let the aloes and calomel be repeated, with the addition of 3 or 4 drops of croton oil, and a wineglassful of spirit of nitre, ether, gin or whisky.

CORNS.—There are 4 varieties of corns, the old, the new, the sappy, and the suppurating, all caused by bruises to the sole, the result, in a vast majority of cases, of bad shoeing. Corns are generally produced at the heel of the forefoot in the corner formed by the outer crust and the frog. The hoof at this point is soft and sensitive and the faulty shape of the shoe causes this sensitive part of the sole to rest upon the shoe, the web of which is too broad. In the angle between the bars and the quarters, the horn of the sole has sometimes a red appearance, and is more spongy and soft than at any other part. The horse flinches when this portion of the horn is pressed upon, and occasional or permanent lameness is produced. *Treatment:* Pare out carefully the seat of the corn, removing all reddened and diseased horn; reduce the crust of the quarter slightly, where it is unduly strong, but leave the bars and frog untouched. They must be preserved, especially in weak feet, to afford a wide bearing for the bar shoe that should afterwards be used. To soften the parts, apply, in bad cases, a poultice for a day or two, and a few drops of nitric acid when the horn is dry and scurfy; keep the hoof soft with soft soap and lard, or any emollient dressing, and pare out the corn every fortnight. In horses subject to corns, shoe and pare out frequently; and along with leather pads, use a bar shoe made with a wide heel on the inside quarter, and nailed only on the outside, or with one nail toward the inside toe.

Small Scarlet Spot Showing a New Corn.

Aspect of Old Corn on a Large Flat Foot.

COUGH.—This is not a disease, but a mere symptom of irritation of the mucous lining of the throat and nostrils by catarrh, dust, gusts of air, etc. *Treatment:* Same as that of *Catarrh*, which see.

CRAMP, Of the Hind Leg.—Quivering or excitement of the muscles of the thigh, accompanied with irritation and fever. It is often mistaken for dislocation of the patella. The muscles will be drawn up in knots, and the horse will be unable to move. *Treatment:* 1. Move the animal, if possible, and the cramp will give way.—2. Bathe the leg with hot water until the muscles relax. Rub dry, and bathe the leg with arnica, or with the following liniment: 1½ oz. arnica tincture; 1 oz. tincture opium; 1½ oz. liquor ammonia; 1 pt. water; mix.

CURB.—Generally caused by a strain from galloping on uneven ground, wrenching the limb, prancing and leaping, etc. It is one of the evils which occur among the better breed of horses, and is one of the many diseases of the hock joint. It consists of an enlargement, or gradual bulging out at the posterior part of the hock. *Treatment:* Apply as a cooling lotion, to reduce the inflammation, 2 oz. sal ammoniac; 2 oz. powdered nitre; 1 pt. vinegar; 1 qt. water; mix for use, and afterwards apply a fly blister.

Clean Hock.

Curby Hock.

A Curb.

DEAFNESS.—Sometimes caused by a blow on the external ear, which produces inflammation, and an abscess forms. *Treatment:* Open the abscess as soon as the presence of matter is ascertained; and keep scrupulously clean with the following lotion: 4 dr. carbolic acid to 1 pt. water.

DEBILITY.—Caused by bleeding in treating diseases, and insufficient and improper diet given to sick horses, when they should have been supported by good and sufficient food during sickness. The symptoms are swelling of the legs, breast, belly and sheath. The horse is very weak, and staggers as he walks. *Treatment:* Give the following tonic balls, once or twice a day, with a liberal amount of good feed and water, and allow him to recover wholly before putting him to hard work: 2 dr. ginger; 1 dr. gentian; ½ oz. Peruvian bark; 1½ oz. fenugreek; mix, and form a ball.

DIABETES.—Frequently caused by kiln-dried oats or new-burnt hay. The symptoms are excessive stalling, and a tendency of the liquid evacuations to be of a sugary nature. *Treatment:* Give wholesome food, and the following ball twice a day: 10 gr. powdered opium; 1 dr. sulphate of zinc; 2 dr. gentian; 1 dr. ginger.

DIAPHRAGM, Spasm of.—Caused by severe runs or rapid harness work, and also by tetanus. It may be known by a spasmodic movement of the body, and a dull, thumping sound arising from the abdomen; small, weak pulse, and difficult respiration. *Treatment:* Give the following ball: Carbonate of ammonia, 1 dr.;

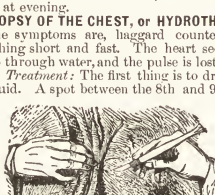
camphor, ½ dr.; powdered ginger, 1 dr.; linseed meal and boiling water sufficient to make into a ball; repeat the dose every 3 hours.

DIARRHEA.—Caused by over exertion, exposure to cold, drinking freely of pump and spring water, and over doses of physic; new oats and hay will sometimes produce it. *Treatment:* Rice or flour milk may be administered as food, and the following drench given every time there is a discharge: 1 dr. powdered opium; ½ oz. tinct. of catechu; 1 pt. chalk mixture; mix.

DISTEMPER.—(See *Throat, Sore.*)

DROPSY, General (Anasarca).—Also called *Moor Ill*; occurs chiefly among horses turned out in marshes or low commons, and may be known by the general swelling of the body, increasing by gravitation in the legs during the standing posture, but showing itself chiefly in the lower side of the body in the early morning, when the horse has been lying down all night. *Treatment:* 1. Give the following to act on the kidneys: 4 dr. nitre; 3 dr. powdered resin; 1 dr. ginger; 1½ oz. spirit of nitrous ether; 2 pts. warm water; mix, and give as a drench every night.—2. Give 1 dr. calomel, once a week, in bran, at evening.

DROPSY OF THE CHEST, or HYDROTHORAX.—The symptoms are, haggard countenance; breathing short and fast. The heart seems to throb through water, and the pulse is lost at the jaw. *Treatment:* The first thing is to draw off the fluid. A spot between the 8th and 9th ribs



Tapping the Chest.

is chosen, and the skin is pulled back; a small slit through the skin is made (see illustration); into that opening a trocar, armed with a stilet, is inserted, and so much force applied as suffices to propel it onward. When there is no resistance felt, the thorax has been entered; the stilet is withdrawn, and the water flows forth. Use a fine trocar; take all the fluid you can obtain. Should the horse appear faint, stop the flow for a few minutes, and then let it proceed more slowly. Give the following ball, night and morning: 1 dr. iodide of iron; ½ gr. strychnia; ½ dr. sulphate of zinc; extract of gentian and powdered quassia, of each a sufficiency. Boiled oats and beans may be allowed in any quantity which the animal will consume. If he will not eat, drench him with oatmeal gruel.

DYSENTERY.—Caused by neglected diarrhea, some acrid substance in the stomach, and foul atmosphere. The symptoms are obscure at the commencement. As in nearly all disorders of the intestines, so in this, there is pain in the abdomen. The pain may be slight at first, or it may be so violent as to be confounded with the pangs of colic; the thirst is excessive; the stench offensive. *Treatment:* Give soft boiled rice; if it is not taken voluntarily, give as a drench, mixed into a thin, liquid form with warm water. If the case is severe, ½ oz. of laudanum may be added to 1 qt. of rice milk, and given every time the bowels act with violence. Or a thin gruel may be made with wheat meal, and the laudanum mixed with that instead of the rice. Once in 2 or 3 days the bowels should be cleared of foul matter, by ½ pt. of linseed or castor oil, aided, if necessary, by large injections of warm saleratus water. If the horse is very much exhausted, 1 pt. of port wine may be substituted for the laudanum with advantage.

DYSPEPSIA.—Generally caused by the animal being constantly fed on the same articles. The symptoms are a cough, staring coat, and loss of appetite; the manure has an offensive smell, and is yellowish in color. *Treatment:* The horse should have a complete change of food, apples, turnips, carrots, scalded oats and bran mashes. If the right time of year, give him 3 or 4 months at grass.

ELBOW, Capped.—Caused by direct pressure against the calk or heel of the shoe. It is an abscess or tumor on the side of the chest just behind the shoulder. *Treatment:* If the tumor is soft and shows signs of containing pus, it should be opened and the matter allowed to escape. Syringe with warm water, and afterwards apply the following lotion: Carbolic acid, ½ oz.; water, 1 pt.; mix, and use 3 or 4 times a day. Keep the bowels in order by an occasional pint dose of linseed or castor oil, if needed; support the strength with the tonic balls, recommended in *Debility*, which see.

A Capped Elbow.

ELEPHANTIASIS, or WATER FARCY.—Usually caused by the animal being fed too highly and not worked enough. The leg is hot, painful and sore, and, when touched, the horse raises it as high as possible. There is also high fever, quick pulse, and mouth hot, with great thirst. *Treatment:* Improve the diet, and never allow the horse to remain a day in the stable without exercise. Saturate the swollen limb with cold water every morning, and have it afterward thoroughly hand rubbed until it is perfectly dry. Should lameness remain after the first day, a few punctures may be made into the limb, but only through the skin. Give the following ball every morning: 1 dr. iodide of iron; 2 gr. powdered cantharides; 1 gr. powdered arsenic; 1 sc. cayenne pepper; 1 dr. sulphate of iron; molasses and linseed meal, a sufficiency; mix. The delay of even a day in treatment, is attended with danger in this disease.

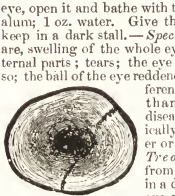
ERYSIPELAS.—This is sometimes caused by the weather being damp, hot and oppressive, and by the animal being neglected and poorly fed. The symptoms are fever, constipation, scanty and high colored urine, loss of appetite, hot and painful swelling. *Treatment:* Tonics and stimulants should be given internally: Epsom salts, 4 oz.; nitrate of potash, 2 oz.; linseed meal, 4

oz.; mix, and give 1 teaspoonful in soft feed, twice a day. Give, also, tincture of iron, 1 oz.; tincture of gentian, 1 oz.; water, 10 oz.; mix, and divide into 12 portions, giving 1 in soft feed, night and morning. Make, locally, a free use of rum or diluted alcohol.

EYE, Cancer of.—The symptoms are, blindness; water flows copiously from the eye. On examination, brilliant yellow substances will be found in the eye. *Treatment:* None is of any service.

EYE, Inflammation of, or OPHTHALMIA.—*Simple.* The most common cause is the introduction of foreign bodies into the eye, or it may occur from a slash of the whip across the head. The symptoms are, closed eyelid, tears; the ball of the eye becomes entirely or partially white. *Treatment:* Remove any foreign body. Insert a flaxseed under the lid several times a day. Fasten a cloth across the forehead, and keep it continually moistened with a decoction of poppy heads, to which some tinct. of arnica has been added. If a small abscess should appear on the surface of the eye, open it and bathe with the following: 5 gr. alum; 1 oz. water. Give the animal rest, and keep in a dark stall.—*Specific.* The symptoms are, swelling of the whole eye, lids, and all internal parts; tears; the eye is closed, or nearly so; the ball of the eye reddened from the circumference; the iris lighter than is natural. The disease appears periodically, terminating sooner or later in blindness. *Treatment:* Remove from the stable and put in a dark shed. Open the eye vein, and puncture the lid if needed; put a cloth, saturated with cold water, over both eyes. Give the following ball twice daily; 2 dr. powdered colchicum; 1 dr. iodide of iron; 1 sc. calomel; make up with extract gentian; as soon as the ball affects the system change it for the following: 3 oz. Fowler's solution of arsenic; 5 oz. muriated tincture of iron; give ½ oz. in a tumbler of water, twice daily. Open the bowels by a gentle purgative; give no hay or grain for several days; bran mashes are all that are needed.

First Appearance of Specific Ophthalmia.



The Eye in Specific Ophthalmia.

EYE, Thread Worms in (Filaria Oculi).—This is a white worm which floats around in the aqueous humor of the eye. There is great pain and inflammation, the horse constantly tossing his head. *Treatment:* An oblique incision should be made into the cornea, when the aqueous humor will pass out, and with it the parasite itself.

EYELIDS, Closing of.—*Treatment:* Apply warm water with a sponge for a period sufficiently long, so as to dissolve or dilute the mucus which causes the lids to stick together. To prevent a recurrence during some diseases of the eyes, smear the lids with sweet oil or cold cream, every night, while the disease lasts.

EYELIDS, Eversion of, or ECTROPIUM.—Caused by an inflamed and thickened conjunctiva, which produces a turning out of the lids. *Treatment:* An elliptical section of the conjunctiva must be removed by an operation, and the eye afterwards treated according to the directions for *Ophthalmia*, which see.

EYELIDS, Inversion of, or ENTROPIUM.—Caused by excessive thickening of the eyelid, which causes the eyelashes to turn in upon the eyeballs, giving rise to irritation. *Treatment:* An elliptical section of the skin must be cut out, and the wound sewed up again.

EYELIDS, Torn.—This is often caused by injuries or accidents. *Treatment:* The wounds may be closed by using fine wire or silk; to heal the wound, apply a solution of pure carbolic acid, 1 dr., and water, 4 oz.; and secure the animal in some way to prevent his rubbing the parts.

EYES, Weakness of.—Generally caused by the unnecessary amount of grain used. *Treatment:* Horses with weak eyes should have light, well ventilated stables, but the windows should not be placed in a position to throw the direct rays of the sun upon the animal's head. Wash the eyes out daily with the following solution: Sugar of lead, 1 dr.; water, 1 pt.

FALSE QUARTER.—This is the result of an accident; the coronary substance is permanently injured; it ceases to secrete sound horn, and a stripe of the crust, defective in strength, runs all the way down from the coronet to the plantar edge. This generally happens at the inner quarter, and is owing to the horse treading on his coronet; but it may also occur on the outside, either from the tread of another horse, or from some kind of external violence. *Treatment:* In cases of crack and granulations, treat as is advised for *Sandcrack*, which see. Put on a bar shoe, with a clip on each side of the false quarter. Pare down the edges of the crack, and ease off the point of bearing on the false quarter. A piece of gutta percha fastened over the false quarter has done good.

False Quarter.

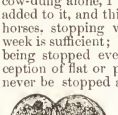
The Only Relief.

FARCY.—Sometimes produced by hard work, bad provender, or bad treatment; poorly ventilated stables overcrowded with horses; inoculation from the virus of glandered or farcied horses. The hair looks rough and unhealthy; one of the legs will swell to a large size (generally the fore leg), become painful, and in a short time break out in small running sores, discharge a thin, unhealthy fluid, and sometimes the discharge is thicker. *Treatment:* give the follow-

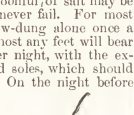
ing ball; 1 dr. sulphate of iron; 1½ dr. powdered gentian; ½ dr. powdered pimento; 20 gr. iodide of potash; 1½ dr. cascarilla bark; mix with molasses. Cut the hair from the enlarged absorbent and rub in a mixture of mercurial and iodine ointment; open the bowels with vegetable food, and give a liberal diet. Open the farcy buds, and cauterize with nitrate of silver.

A Farcy Bud.

FEET, Dryness of.—*Treatment:* Prevented by the use of stopping, which is composed either of cow-dung alone, or cow-dung and clay mixed, or of cow-dung and pitch. The first is, by far, the most powerful application, but it moistens the sole too much if applied every night, and then produces the opposite evil in the shape of thrush. A mixture of equal parts of cow-dung and clay may be used every night with advantage. It should be kept in a strong box of wood, about 1 ft. long and 8 in. wide, with a handle across the top, and should be applied the last thing at night to the soles of the forefeet only, by means of a thin piece of wood, 1 ft. long and 2 in. wide, with which the space within the shoe is completely stuffed. If the feet are obstinately dry, in spite of repeated stoppings with cow-dung alone, 1 tablespoonful of salt may be added to it, and this will never fail. For most horses, stopping with cow-dung alone once a week is sufficient; but almost any feet will bear being stopped every other night, with the exception of flat or pumiced soles, which should never be stopped at all. On the night before

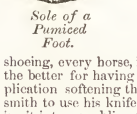


Sole of a Pumiced Foot.

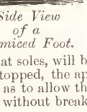


Side View of a Pumiced Foot.

shoeing, every horse, if he has flat soles, will be the better for having his feet stopped, the application softening the horn, so as to allow the smith to use his knife to slice it without breaking it into crumbling fragments.



A Weak Foot.



Sole of a Weak Foot.

FEET, Pumiced.—Caused by the animal being used too soon after an attack of inflammation of the feet, undue work, and from much battering of the feet on the pavement. It may be known by the sole being bulged down towards the ground, and becoming convex, instead of concave; the crust being uneven and furrowed, and much increased in obliqueness. *Treatment:* Relief may be given by putting on a shoe that will guard the sole from receiving pressure, and which will yet protect it from injury. The feet should be anointed with a mixture of tar and grease, to promote the growth and elasticity of the horn.

Dish Shoe for Severe Pumiced Foot.

FEVER.—The symptoms are dullness, and a reluctance to move; a staring coat, and cold legs and feet, with increased warmth of the body. The pulse is quick, soft and variable; breathing a little accelerated, but not much; appetite entirely lost; bowels confined, and urine scanty. *Treatment:* Give 10 drops tincture of aconite root every 2 hours.

FITS, or EPILEPSY.—Occurs only in the foal, and is caused, probably, by debility and solar heat. The young thing will perhaps gallop after its dam, round and round its paddock, and then all at once stop and fall to the ground, where it lies struggling with more or less violence for a few minutes or longer, and then raises its head, stares about, gets up, and is apparently as well as ever. Death seldom takes place during the first attack, but sometimes after 2 or 3 repetitions; the convulsions go on increasing, and the foal becomes comatose and dies. *Treatment:* Give 1 dr. bromide of potassium dissolved in ½ pt. water, 3 times a day until cured.

FOOT, Contraction of.—The causes are neglect and oversight in paring the sole; the too frequent lowering or cutting away of the bars of the foot and heels, and then burning with hot iron; a weak and defective horn; want of moisture and nourishment; and internal laminæ. *Treatment:* This will principally consist in abating any inflammation that may exist, by local bleeding and physic; paring the sole to the utmost extent that it will bear; rasping the quarters as deeply as can be, without their being too much weakened, or the coronary ring at all injured. The horse should be made to stand during the day in wet clay, and at night should have his feet bound up thickly in wet cloths; or he should be turned out into wet pasturage, with tips, or, if possible, without them, and his feet frequently pared out, and the quarters lightly rasped. In 5 or 6 mos. the horn will generally have grown down, when he may be taken up and shod with shoes unattached by nails on the inner side of the foot, and put to gentle work.

FOOT, Nail in the.—(See *Pricks, to Cure*, in SHOEING.)

FROST BITES.—This is a state of numbness or torpification of a part of the body caused by intense cold, which, unless relieved by proper remedies, is liable to be followed by death of the part. Horses are most liable to be troubled with frost bites on the heels and the back part

of the hind legs, which swell badly and are sometimes mistaken for scratches. *Treatment:* Heat should not be applied suddenly, but snow or very cold water. The frozen parts should not be rubbed until the frost has been extracted. After the heat has returned to the parts, use a lotion of rum or diluted alcohol, several times a day, for 3 or 4 days, to prevent soreness.

GALL STONES.—These are the result of incrustations on the walls of the ducts, and may be known by a yellow, bilious appearance, colicky pains, and frequent looking around to the right side. *Treatment:* Give as 1 dose, ½ oz. tinct. opium; 1 pt. linseed oil; mix, and repeat in 2 or 3 hours if necessary.

GLANDERS.—The cause of this disease may be attributed to filth, starvation, or to debilitating diseases, as lung fever, catarrh, or any disease capable of generating pus, which being absorbed into the circulation forms a ferment within the blood. The membrane lining the nostrils assumes a leaden or purple color, accompanied by a thin, acrid, transparent and odorless discharge; the discharge grows thicker, and sinks when placed in water; the membrane lining the nostrils will have sores, ragged and depressed at the top, with varicose veins leading to them from all sides. The appetite fails, and the horse assumes an emaciated and dull appearance; he will be hidebound, and his legs swell during the day, and the swelling go down at night. The ulceration is very bad, and the sores spread into his throat; the body is also sometimes afflicted with sores. *Treatment:* This disease is generally considered incurable, but if the following is adopted early it may prove successful: Give from ½ to 1 oz. doses of sulphite of soda at night, in cut feed, for several weeks, and 5 gr. powdered Spanish flies with it; also every morning and noon a powder consisting of 3 dr. powdered gentian, and 2 dr. powdered sulphate of copper. The tendency is to improve the general health. Give good liberal feed and change it often.

Proof of Glanders.

1. Termination of the lachrymal duct—a natural development. 2. A discolored membrane, disfigured by ulcerative patches.

GLASS EYE (Amaurosis).—Caused by paralysis of the optic nerve. The symptoms are a full dilatation of the pupil, and the iris is so insensible to light that when exposed to the direct rays of the sun it does not contract. *Treatment:* Give the following ball: 6 dr. Barbadoes aloes; 1 dr. pulverized ginger; 2 dr. pulverized gentian root; mix with molasses. In 24 hours after, give ½ dr. doses of pulverized nux vomica, mixed in the feed night and morning, and apply a blister under the ears.

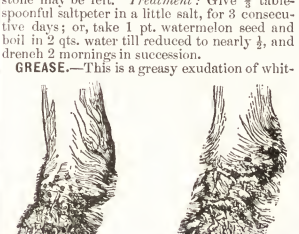
GLAUCOMA.—This is inflammation of the globe of the eye. It may be known by a dilated pupil, sea green color of the interior of the eye, and muddiness of the vitreous humor. *Treatment:* Give 1 dr. calomel and 1 dr. rhubarb once a week; also give 1 dr. iodide of potassium, dissolved in ½ pt. water, every morning.

GOITRE (Bronchocele).—An enlargement of the thyroid gland, and is situated on and in front of the windpipe, about 3 in. from the lower jaw. *Treatment:* Give the following night and morning: ½ dr. iodide of potassium; 1 dr. liquor potassæ; ½ pt. distilled water. Rub the swelling with the following ointment: 1 dr. iodide of lead; 1 oz. simple cerate.

Goitre.

GRAVEL.—This may be known by the animal straining in the effort to pass urine, which escapes in driblets, or not at all. Blood is often passed in clots, and, by introducing the oiled hand into the rectum, up to the bladder, the stone may be felt. *Treatment:* Give ⅔ tablespoonful saltpeter in a little salt, for 3 consecutive days; or, take 1 pt. watermelon seed and boil in 2 qts. water till reduced to nearly ½, and drench 2 mornings in succession.

GREASE.—This is a greasy exudation of whitish, offensive matter from the lower part of the legs. Neglected scratches often run into grease (see *Scratches*); but it is just as likely to appear in warm weather, when it is the result of surfeit. The symptoms are scurfiness and itching of the legs; rubbing the leg with the hoof of the opposite limb; the legs are swollen to the knees, and matter oozes from the pores; lameness; granulations form in ragged bunches; their points becoming like horn. *Treatment:* Cut off all the remaining hair. If hot and scurfy, cleanse with mild soap and hot soft water. Saturate a cloth with the following lotion: Animal glycerine, ½ pt.; chloride of zinc,



First and Second Stages of Grease.

½ oz.; water, 6 qts. Lay it upon the leg. When this cloth becomes warm, remove it and apply another, also wet with the lotion; thus continue applying cool cloths to the limb till the heat abates; afterwards moisten the leg thrice, daily. When cracks and ulcerations are present, adopt the wet cloths, but subsequently use 1 of the following to the sores: Permanganate of potash or phosphoric acid, 1 pt.; water, 6 qts.; or chloride of zinc, 1 oz.; water, 1 gal.; employ thrice, daily. If the granulations have sprouted, remove them with a knife, in 3 operations; likewise, always place in a loose box. Feed liberally; allow old beans; give a handful of ground oak bark with each feed of oats. Night and morning give liquor arsenicalis, 1 oz.; tincture of muriate of iron, 1½ oz.; porter or stout, 1 qt.; 1 pt. for the dose. Chopped roots, speared wheat, hay tea, cut grass, and exercise, are all good for grease.

Third Stage.

GRUBS.—These are the larvæ of some beetle, causing a lump about the size of a raisin, usually on the back. *Treatment:* They may be squeezed out as soon as the head is visible. When discovered previously, an opening may be made with the point of a penknife, and then the larvæ may be gradually squeezed out, avoiding too much haste in the operation, which will only retard the process.

HAIR, Loss of. — Sometimes caused by faulty digestion, disease of the skin, or by blisters, burns, etc. *Treatment:* 8 gr. quinine; 10 gr. finely powdered galls; 5 gr. powdered capsicum; oil of almonds and pure lard, of each, 1 oz.; 20 drops oil of lavender; mix thoroughly, and apply a small quantity to the denuded parts, 2 or 3 times a week. Where there is a falling out of the hair of the mane and tail, take 2 oz. glycerine; 1 oz. sulphur; 2 dr. acetate of lead; 8 oz. water; mix well, and apply by means of a sponge.

HEART, Atrophy of. — This is a wasting away of the substance of the heart. The walls become soft, and do not perform their work in a healthy manner. It may be known by emaciation, listlessness and pallor of the mucous membranes. *Treatment:* Give the following powder in soft food, night and morning: Nux vomica, 1 dr.; sulphate of iron, 1 dr.; fenugreek seed, 1 dr.; mix.

HEART, Enlargement of.—The symptoms are irregular pulse; uneven temperature of the body; one side of the body may be cold, and the other warm. *Treatment:* Iodide of potash, powdered nux vomica, and fenugreek seed, of each, 1 dr.; give as 1 dose in a bran mash, morning and night, for 3 or 4 weeks.

HEART, Inflammation of (Carditis). — An inflammation of the muscular structure of the heart. The animal will be lame generally in the off foreleg, but upon examination no cause will be found sufficient to account for it. This lameness may appear and disappear several times previous to the attacks, leaving the impression that the lameness was rheumatism; then the animal refuses to eat; his heart palpitates violently; he occasionally gasps and gnashes his teeth; has a full, hard and frequent pulse; quickened respiration, and a wild expression of the eyes. *Treatment:* Give cold water freely; also, 1 dr. tinct. digitalis, 3 times a day; if there is high fever, give 10 drops tinct. aconite, once in 2 hours.

HEART, Palpitation of, or THUMPS.—An inflammation of the lining membrane of the heart. The symptoms are, violent palpitation of the heart; pulse full and hard, but not quickened. *Treatment:* Give 1 of the following powders every 3 hours: 1 oz. nitrate of potassa; 2 dr. pulverized digitalis; mix, and divide into 6 powders. Subsequent attacks may be warded off by keeping the bowels regular.

HEAVES, or BROKEN WIND.—The symptoms are a peculiar double-bellows motion of the flanks; respiration quicker than natural; a short peculiar cough, and frequent passing of wind. *Treatment:* If, by rubbing the sides of the throat, a cough is excited, the chances for a cure are favorable; but if the windpipe requires a squeeze in order to produce the cough, there is little use in attempting a cure. Use upon the throat 3 times a week, for 5 or 6 weeks, the following salve, well rubbed in: 2 oz. iodine ointment; 1 oz. blue mercurial ointment; mix well together, and make thin with oil. Give internally, every night, 1 of the following powders: 1 oz. each of sulphate of copper and pulverized ginger; 2 oz. pulverized gentian root; divide into 16 powders. Never give water before work; no hay should be allowed, but give wheat or oat straw. Carrots are peculiarly suited to this disease, and a diet of bran, mixed with carrots, sliced, has sometimes been known to relieve a broken-winded horse most materially.

HIDE-BOUND.—This usually arises from the diseased condition of the secreting vessels; slow inflammation of the liver; the presence of worms; exposure to cold and starvation. It may be known by the skin being extremely tight on the body; the hair, which all stares the wrong way, is dry, and the skin dirty. *Treatment:* Give mixed feed (cut hay, bran, and cornmeal), wet with just enough water to cause the whole to keep together. Give the following powders in the feed every night, for 2 weeks: 3 dr. powdered gentian root; 2 dr. powdered sulphate of iron; mix, and give for 1 dose.

HIP-JOINT LAMENESS. — (See *Strains and Sprains.*)

HOCK, Capped.—This is the result of a bruise of the superficial bursa, which is situated on the point of the hock immediately beneath the skin. The swelling is sometimes slight, being just sufficient to show the point slightly enlarged, and to give a soft, puffy sensation to the fingers, where there ought to be nothing but bone felt beneath the skin. The bursa always rolls freely on the bone, and when large it can be laid hold

Capped Hock.

of and shaken like a bladder of water. *Treatment:* First, draw out the fluid from the bursa with a hypodermic syringe, having a needle of large calibre; then inject the bursa with a mixture of tincture of iodine, 1 dr., and water, 2 dr. After the operation, dress with cold lotion, which there is some difficulty in doing, owing to the prominent nature of the part. A piece of stout calico or fine canvas may, however, be shaped into a cap, carefully fitting the point of the hock; and this being tied by several pieces of tape in front of the leg will allow not only of the application of cold lotions, but of pressure also.

HOOF, Brittleness of. — This is produced by frequent standing in pools of decomposing liquid manure and rotting dung heaps. *Treatment:* Mix 3 oz. of oil tar with 6 oz. of common fish oil; rub this well into the crust and hoof.

HOOKS.—(See *Eye, Inflammation of.*)

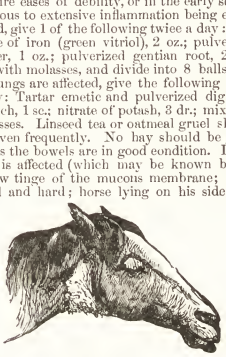
HYDROPHOBIA. — Generally produced by a bite from a rabid animal. The symptoms are a depressed and anxious countenance; inquiring gaze, suddenly lighted up and becoming fierce and menacing from some unknown cause; there

Countenance of a Horse in Hydrophobia.

is a peculiar dread of water, and an irrepressible desire to bite those within reach. *Treatment:* The horse should be shot as soon as the disease is discovered, as it is incurable.

HYSTERIA.—Caused by irritation of the uterus, or some of its nerves. The symptoms are excitement and incapability of standing, and it appears as if some of the bones of the back were broken. *Treatment:* 1. Give 20 drops tincture aconite root, every 2 hours, while the symptoms last. Give the following to build up the strength of the mare: Sulphate of iron, 3 dr.; 3 dr. gentian root; mix, and give in 1 dose, every day, for 1 week or 10 days. Feed well. —2. Give the following purgative ball: 5 dr. Barbadoes aloes; 1 dr. ginger; 1 dr. gentian root: syrup or soap to combine; give as 1 dose. Give also the following anodyne: 3 gr. sulphate of morphia; 1 dr. water; dissolve and inject with hypodermic syringe under the skin of the neck.

INFLUENZA, or EPIDEMIC CATARRH.—Also called *Pink-Eye Distemper* and *Epizootic.* Generally prevails in wet and damp seasons, or when horses are crammed together in stock yards and stables, and filthiness is allowed to predominate. The symptoms are a cough slight watery or thin mucous discharge from the nostrils; eyes become very red; water collects in the inner corner of the eye; pulse very quick; appetite fails; excessive debility; heart sometimes violently agitated; flanks heaving, and feet sometimes hot; in the early stages the membranes of the nose will be found pale, or of a leaden color. In some instances the disease is ushered in with a chill. *Treatment:* If inflammation runs high, give for several days the following: Tartar emetic and nitrate of potash, of each, 2 dr.; make into a ball with molasses, and give at night. Give also in a pail of water, 1 oz. spirits nitre, twice a day, or 2 dr. extract belladonna, dissolved in water. When the inflammation is reduced, give 1 of the following balls, night and morning: Pulverized gentian root and nitrate of potassa, of each, 1 oz.; pulverized Jamaica ginger, ½ oz.; ground fenugreek seeds, 6 dr.; mix with molasses, and divide into 8 balls. In pure cases of debility, or in the early stages, previous to extensive inflammation being established, give 1 of the following twice a day: Sulphate of iron (green vitriol), 2 oz.; pulverized ginger, 1 oz.; pulverized gentian root, 2 oz.; mix with molasses, and divide into 8 balls. If the lungs are affected, give the following twice a day: Tartar emetic and pulverized digitalis, of each, 1 sc.; nitrate of potash, 3 dr.; mix with molasses. Linseed tea or oatmeal gruel should be given frequently. No hay should be given unless the bowels are in good condition. If the liver is affected (which may be known by the yellow tinge of the mucous membrane; dung small and hard; horse lying on his side, and



Blistered Throat.

occasional fits of uneasiness), give the following, but it must not be repeated: 3 dr. Barbadoes aloes; calomel and pulverized digitalis, of each, ½ dr.; make into a ball with molasses. When there is soreness or swelling of the throat, the parts should be freely blistered. If the cough continues troublesome afterwards, a seton should be inserted in the throat in the position shown in the illustration. This disease often spreads rapidly. Green food must be given as early as possible; and in a neighborhood where the

Seton in the Throat.

attack has commenced, each horse should be given 1 or 2 oz. of hyposulphite of soda (according to size), once a day, in water, as a precautionary measure.

INTERFERING, or CUTTING.—Caused by bad shoeing, weakness, malformation, or thinness in flesh. The point where the foot is struck is generally plain; there is a smooth surface on the foot and blood on the hoof. *Treatment:* This requires a nicely-fitting boot placed on the bruised leg to prevent injury. (See *Interfering* in STOCKING.) Have the horse well shod, and apply the following lotion, 3 times a day: 1 oz. muriate of ammonia; 1 oz. nitrate of potash; 1 qt. water; mix.

IRIS, Inflammation of (Iritis). — Caused by cold and exposure. The symptoms are, redness of the eye, and muddy color of the cornea. The iris is a little changed in color. *Treatment:* Apply moist poultices to the eye to allay irritation. Give the following ball: 1 dr. calomel; 1 dr. ginger; 5 dr. Barbadoes aloes; 1 dr. gentian root; molasses or soap, to mix; give as 1 dose. Apply 3 times, daily, with a small camel's hair brush, the following mixture: 12 gr. nitrate of silver; rain water, 4 oz. The brush to be dipped in the mixture and drawn lightly across within the eye. Cover the face of the horse with a green cloth.

ITCH.—(See *Mange.*)

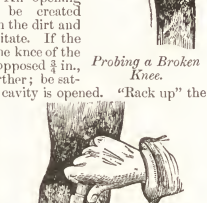
JAUNDICE.—This is the result of an obstruction of the gall duct, causing a yellow discoloration of the mucous membrane. The animal hangs his head, is dull and mopy, and becomes very poor in flesh. *Treatment:* Give 2 dr. calomel, made into a bolus with flaxseed meal and molasses, followed in 24 hours by the following purgative ball: Barbadoes aloes, 5 dr.; ginger, 1 dr.; gentian root, 1 dr.; molasses or soap, to combine; give as 1 dose. The animal should have moderate exercise daily; his body should be kept warm; and if there is pain in the right side, apply a blister. If necessary, the calomel may be repeated in scruple doses once a week.

JUGULAR VEIN, Inflammation of.—(See *Vein, Inflammation of.*)

KIDNEYS, Inflammation of.—Caused by bad provender, hard work, slipping, taking a sudden cold after a hard day's work or drive, or after being under the saddle for a long time; and also by an indiscriminate use of nitre or other diuretics. The symptoms are, quickened and short breathing, suggestive of pain; more or less fever, with quick hard pulse; unwillingness to move the hind legs, which the animal straddles apart when he walks, looking anxiously around to his flanks; urine scanty and high colored, and sometimes bloody. The horse seldom lies down, almost refuses to move about, and crouches beneath pressure made over the kidneys. *Treatment:* Use hot fomentations over the kidneys, and change the cloths often. In the 1st stage, give 10 gr. powdered opium and 15 gr. calomel, sprinkled on the tongue; repeat every hour or two, for a few times, or while the acute stage continues. No food will be necessary during the acute stage, but set before the horse a pailful of good linseed tea, and allow him to drink all he will. If the pulse is quick and hard, give 20 drops aconite root, either between doses of opium and calomel, or after it has been given, and repeat until the pulse becomes slower and softer. Give the horse one month's rest, and use carefully for some time.

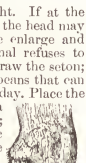
KNEE, Broken.—Knees are always broken by falling on them. There will be a ragged wound, the skin hanging off, the ends of the tendons protruding, and sometimes the white bones of the joint can be seen and felt. *Treatment:* Procure a pail of milkwarm water, and a large sponge. Dip the sponge in the pail, and squeeze out the water above the knee. Continue to do this, but do not dab or sop the wound itself. The water, flowing over the knee, will wash away every impurity. Then, with a probe, gently explore the bag. If dirt has entered it, place a large spatula under the knee; then take a knife with a sharp point, but with its edge blunted the 2 posterior thirds of its length; guard the point with a lump of beeswax; introduce this into the sac, and drive the point through the bottom of the bag. An opening will thereby be created through which the dirt and pus will gravitate. If the probe enters the knee of the flexed leg unopposed $\frac{3}{4}$ in., push it no further; be satisfied that the cavity is opened. "Rack up" the horse's head, and get some cold water, to every qt. of which add 2 oz. tincture of arnica. Pour a little of this into a saucer, and then dip a sponge into the liquid. Squeeze the sponge dry above the joint. Do this every $\frac{1}{2}$ hour, for $3\frac{1}{2}$ days, both by day and night. If at the end of that time all is going well, the head may be released; but should the knee enlarge and become sensitive, while the animal refuses to put the foot to the ground, withdraw the seton; give no hay, but all the oats and beans that can be eaten, with 2 pots of stout each day. Place the horse in slings; apply the arnica lotion until a slough takes place; then resort to the chloride of zinc lotion, 1 sc. to the pt., and continue to use this as has been directed.

Probing a Broken Knee.



Manner of Opening the Dirt Sac.

KNEE, Capped. — This consists in inflammation and effusion of fluid in the superficial bursa under the skin in front of the knee. *Treatment:* The same as that for *Hock, Capped,* which see.



Capped Knee.

KNEE, Sprung. — The cause of this is sprain of the suspensory ligaments, soreness of the feet and joint. It may be known by a deviation from the straight line at the knee and thickness of the back tendons. *Treatment:* Clip the hair from the back tendons and shower with cold water several times a day. Rub well in the following blister: Powdered cantharides, ½ oz.; lard, 2 oz.; mix. The shoes should be removed, the feet pared down, and the heels opened.

LACHRYMAL DUCT, Obstruction of. — This small canal leading from the eyes into the nose to carry away superfluous moisture, is sometimes closed from inflammation, and the water of the eyes flows over the face. *Treatment:* Swab the nostrils with weak tobacco water and afterwards with clear water. If this does not effect a cure, inject warm water up the nasal termination of the duct by means of a fine pointed syringe.

LAMPAS.—Generally occurs in young horses that are kept up and fed upon solid food, which causes irritation of the stomach. *Treatment:* Give a dose of 1 pt. of linseed oil and repeat in 2 days; then give 1 dr. of gentian root, powdered, in the food twice a day. The swollen parts may be scored slightly with a sharp knife and rubbed with powdered borax.

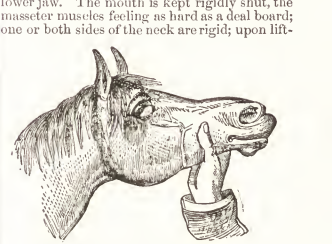
LEG. Fracture of. — The horse has not the power to move, and is in great pain; excitement, sweating, etc. *Treatment:* If in the summer season, place the horse in the field or yard, but in winter in a large, comfortable stable or in the barn-yard, if well protected from wind and storm. Do not give too much bedding nor allow anything to be in the way of the foot, so that it can be carried without interruption. Give 25 drops tinct. aconite root every 5 hours, for the first 20 or 25 hours, to lessen the fever and pain. Place the broken leg in a position as near like the other as possible in shape and also (by actual measurement) to be of the same length, for it is by neglecting the measurement that some are left to unite shorter than the sound leg. When the leg is placed in the same shape and length of the sound one, apply a good coating of tar to the leg, around, below and above the point of fracture. Then wrap the whole leg in carded cotton or coarse tow, and place over this splints cut out of pieces of boards, which will rest evenly upon the leg prepared as above, and fill all unevenness with tow or cotton. Have 3 or 4 splints, so as to hold the leg in position constantly. Secure the whole by carefully applying a strong bandage or by tying with soft cord, and make it perfectly secure, so that the horse will not move the leg where fractured before it has time to unite. Examine the splints daily and see that they do not get loose. The horse may also be suspended in a sling, if thought best to do so.

LEUCOMA.—Consists in more or less opacity of the cornea, existing as a scar resulting from a wound or ulcer, or is the result of acute inflammation of the eye. *Treatment:* Keep the animal in a dark place; give laxative food; also 1 dr. dose of calomel once a week; apply continually the following eye-lotion; 10 gr. nitrate of silver; 1 oz. water; mix.

LEUCORRHŒA. — This is caused by an attack of inflammation which produces a discharge from the vagina or womb; it often follows difficult parturition. *Treatment:* To open the bowels, give the following draught: Linseed oil, 8 oz.; infusion of aloes, 3 oz.; tincture of gentian, 2 oz.; mix, and administer after a fast of several hours; give easily digested food and the following powders in the food morning and night.: Sulphate of iron, 3 oz.; carbonate of soda, 1 oz: ground gentian, 3 oz.; apply the following dressing to the vagina: Tannic acid, 2 dr.; spirits of wine, 1 oz.; laudanum, ½ oz.; water, 1 pt.

LICE.—*Treatment:* They may be destroyed by rubbing into the roots of the hair white precipitate, in powder, taking care to avoid sweating the horse or wetting his skin for some days afterwards.

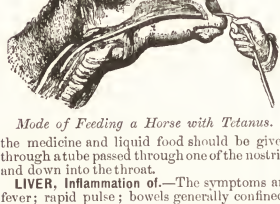
LOCK-JAW, or TETANUS. — This almost always follows some operation, or a severe injury in which a nerve has been implicated, the most frequent causes being the piercing of the sole by a nail, or a prick in shoeing, or the operations of docking, nicking, castration, etc. The symptoms are a permanent rigidity of certain voluntary muscles, and especially of the lower jaw. The mouth is kept rigidly shut, the masseter muscles feeling as hard as a deal board; one or both sides of the neck are rigid; upon lift-



Test for Tetanus.

ing the head, the haw projects over the eye; the nostrils are dilated; the ears erect and stiff, and the countenance as if horror-struck; at first the extremities are seldom involved, but as the disease progresses their control is first lost, and then they become rigid like the neck and head; the patient is scarcely able to stand, and plants his feet widely apart to prop himself up, while at last the tail also becomes a fixture; the pulse varies a good deal, in some cases being quick, small and hard, and in others slow and labored. *Treatment:* Administer a strong purging ball or drink, assisted by injections of 1 pt. linseed oil to 1 gal. warm water, at the same time applying a strong blister from the poll to the rump, and even on the side; when the physic begins to act, give a hypodermic of 3 gr. of sulphate of morphia, dissolved in 2 dr. of warm water, under the skin of the neck every ½ hour, until narcotism is performed; and aid the effect of this anodyne by inhalations of chloroform vapor, as may be needed for relaxation of the symptoms. Place a bucket of cold, thin gruel where the horse can get at it, without an effort to him-

self to reach it. Renew it once a day, and keep it sweet. If the horse is unable to open his mouth,



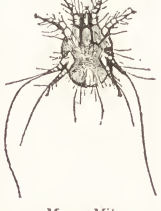
Mode of Feeding a Horse with Tetanus.

the medicine and liquid food should be given through a tube passed through one of the nostrils and down into the throat.

LIVER, Inflammation of.—The symptoms are fever; rapid pulse; bowels generally confined; legs cold; mouth hot; membranes of nose and eyes much reddened; respiration rapid; there are no intervals of rest, the horse is up and down, rolling and pawing continually. *Treatment:* Give 1 pt. linseed oil, with 10 drops croton oil added; and apply a blister over the loins; follow the oil with five drops tincture of aconite root every hour for 5 or 6 hours; then every 3 hours, until about 10 doses have been given. Apply blankets wrung out in scalding water to the belly, and keep up for several hours, and give injections of Castile soap and water. Repeat the oil if necessary. The diet should be confined to green food if possible.

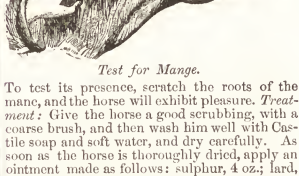
LUNGS, Congestion of.—(See *Pneumonia.*)

MALANDERS AND SALLENDERS. — These eruptions are both of the same nature, differing only in the locality where they are displayed. The former shows itself in the flexure at the back of the knee, and the latter at the bend of the hock. The symptoms are shown in the appearance of a foul scurf mixed with a few thin scabs, the skin underneath being stiff and unyielding. They are generally brought on by washing the legs and leaving them undried. *Treatment:* Wash the parts well with Castile soap, and rub well in the following every night: Cerate of superacetate of lead, 2 oz.; creosote, 10 drops; mix. If the skin continues to be very hard and stiff, a little glycerine should be brushed on 2 or 3 times a week.



Mange Mite.

MANGE, or ITCH.—Due to the irritation and ulceration caused by the burrowing of minute insects. Various causes predispose animals to afford development to the mange parasites and to aggravate their ravages, such as neglect, dirt, starvation, ill-usage, etc., and in curing the ailment these must be remedied. The first symptom is an excessive itching, causing the horse to rub himself eagerly against any obstacle; the skin becomes scabby, the hair falls off in patches, leaving the skin at first smooth, with a few small red patches, each of which contains one of the parasites, technically known as *Acari*; in time the pimples multiply, harden into scabs, under which the acari may be found like mites in cheese. The constant irritation makes the horse feverish, thin and wretched.



Test for Mange.

To test its presence, scratch the roots of the mane, and the horse will exhibit pleasure. *Treatment:* Give the horse a good scrubbing, with a coarse brush, and then wash him well with Castile soap and soft water, and dry carefully. As soon as the horse is thoroughly dried, apply an ointment made as follows: sulphur, 4 oz.; lard, 10 oz.; carbolic acid, ½ oz.; mix.

MEGRIMS.—(See *Brain, Inflammation of.*)

MENINGITIS, Cerebro-Spinal.—This is the result of badly ventilated stables and a plethoric condition of the body. It may be known by the animal exhibiting great uneasiness; excited breathing; inability to swallow; staggering in his gait. *Treatment:* Give the following: 4 oz. bromide of potassa; 2 oz. tinct. belladonna; 2 pts. water; give 2 oz. every 2 hours. Keep hot blankets along the spine, after bathing it well with mustard and water, well rubbed. If the throat is sore, apply a good blister. If the animal does not show signs of improvement in 2 or 3 days, give the following: 4 oz. pulverized capsicum; 1 oz. camphor; mix, and divide into 12 powders; give 1 in a teacupful of water, 3 times a day. Make him a good bed, and turn him over occasionally. If a horse survives the 4th or 5th day he generally recovers.

MOUTH, Excoriated Angles of.—Caused by an

Excoriated Angles of the Mouth.

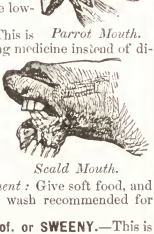
Sensibility of Mouth Destroyed.

abuse of the reins. The bit injures the lower jaw bone, so as to kill a portion of it. The corners of the mouth become very sore, and if allowed to continue doing harm, the mouth loses all sensibility. *Treatment:* Apply the following wash, gently, after every feeding and watering: 2 sc. chloride zinc; 2 pts. water; 2 dr. essence of aniseed.

MOUTH, Parrot.—The upper incisors project over the lower ones, and meeting with no antagonist, they grow very long, and from their form are likened to the bill of a parrot. The horse is unable to graze. *Treatment:* File off the teeth even with the lower ones.

Parrot Mouth.

MOUTH, Scald.—This is caused by giving strong medicine instead of diluting it as directed. The whole inside of the mouth will be found to be swollen; saliva flows from it with constant motion and repeated smacking of the lips; if it is very bad, it will skin in spots. *Treatment:* Give soft food, and use 3 times a day the wash recommended for *Aphtha*, which see.

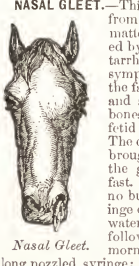


Scald Mouth.

MUSCLES, Atrophy of, or SWEENY.—This is a shrinking of the muscular tissue, and may be known by the hollow surface which will be found in the place of the muscle, and is caused by sprains, bruises or severe pressure. *Treatment:* Frequent applications of the tincture of cantharides will generally re-develop the muscles; but if it does not, after 3 or 4 weeks, setons should be inserted over the shrunken portions, about 2 or 3 in. apart, the extent of the atrophy; about twice a week apply a fly blister to the setons; let the setons remain in 3 or 4 weeks; give gentle exercise.

MUSCLES, Rupture of.—This is the result of severe sprains or over exertion. The symptoms are lameness, pain and swelling, and inability to move. *Treatment:* To allay the inflammation, bathe with warm water, and apply the following liniment: Tincture of arnica, 1 oz.; tincture of opium, 1 oz.; water to make 1 pt.; mix, and apply 3 times a day; when the inflammation is subdued, apply tincture of cantharides till the part is blistered; grease the part till it is healed, after which blister again, and repeat this treatment during several weeks, giving mild exercise.

NASAL GLEET.—This is a chronic discharge from the nostrils of a whitish matter, and is generally caused by neglecting to treat catarrh and colds properly. The symptoms are, distortion of the face; partial enlargement and softening of the facial bones; irregular discharge of fetid pus from one nostril. The discharge is increased or brought down by feeding off the ground, or by trotting fast. *Treatment:* If there is no bulging of the bone, syringe out the nostril with warm water, and inject a little of the following lotion night and morning for a month, using a long nozzled syringe: 2 dr. carbolic acid; 1 pt. water; mix. Give the following ball, once every 24 hours: ½ oz. balsam copaiba; 4 gr. powdered cantharides; cubebs, a sufficiency. If the foregoing should affect the urinary system, change it for ½ dr. doses of extract of belladonna, dissolved in 1 wineglass of water. Give these every 4th day, and on such occasions repeat the belladonna every hour, until the appetite has been destroyed.



Nasal Gleet.

NAVICULAR DISEASE.—Caused by hard work upon pavements, producing slight inflammation, which is neglected, and the horse is kept at work, so that the inflammation continues until it ends in ulceration. The symptoms are, an undue amount of heat in the foot, the pointing of the toe, and a peculiar rounding forward of the fetlock joint. *Treatment:* Bleed the foot, pare the sole thin, and cover the foot with linseed poultices for a week; keep a seton in the foot for a month; the pastern also may be blistered. In bad cases, resort to neurotomy, but do so upon the second attack of lameness; because continued disease disorganizes the internal structure of the hoof, and also occasions the sound foot to be attacked by navicular disease.

Navicular Disease.

NECROSIS, or DEAD BONE.—This is the result of external violence, which causes the bone to perish. It may be known by openings in the skin and flesh, from which pus exudes and sometimes a piece of dead bone will pass out with the pus. Caries is present when the bone is impaired only, and necrosis when the bone is entirely dead, and the functions have entirely ceased. *Treatment:* Make the openings large, to allow the pus to escape freely; keep the parts clean, and, if the disease is on the surface, dress 3 times a day with the following lotion: Carbolic acid, ½ oz.; linseed oil, ½ pt.; mix. If the cavities are deep, inject the following lotion: Carbolic acid, 1 part; water, 30 parts; mix, and inject 3 times a day.

OVERREACH.—A tread upon the heel of the coronet of the fore foot by the shoe of the corresponding hind foot, and either inflicted by the toe, or by the inner edge of the inside of the shoe. *Treatment:* The weight of the fore shoe should be mostly on each side, and the web at the toe as narrow as possible. The hind shoe must be set back from the toe about ½ in., and the toe calk as far back on the web as possible; the toe of the hoof should project over the shoe. The bruises may be treated by the application of tincture of arnica in full strength, which

Tread upon Hind Foot, Heavy Horses.

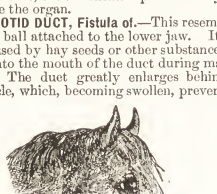
Tread upon Hind Foot, Light Horses.

will dry them up and prevent suppuration. If, however, the heel is very much bruised, a poultice must be applied; but even then a little tincture of arnica should be sprinkled on it. When the bruise is so severe that a slough or core comes away, the wound may be dressed with a piece of lint, dipped in a solution of nitrate of silver, 8 gr. to the oz. of distilled water, and over this a bran poultice. In most cases it is better to foment the part well and then apply the tincture of arnica.

PARALYSIS, or PALSY.—Usually the result of lead poisoning, injuries to the back, sunstroke, etc. The horse lies helpless, and while he can move himself forward, is powerless behind, and the muscles are as soft and quiet as they would be after death. *Treatment:* Open the bowels if they are the least costive and give internally 1 of the following powders night and morning; nux vomica, 1 oz.; pulverized gentian root, 2 oz.; Jamaica ginger, 1 oz.; mix, and divide into 12 powders. Apply warm sheep-skins to the loins, succeeded by the following application: 1 pt. of linseed oil; 4 oz. spirits hartshorn; shake well before using. Perfect rest and moderate diet are necessary.

PARAPHIMOSIS.—In this disease the penis protrudes from the sheath, and on account of the constriction of the prepuce, the animal is unable to retract it. It may be caused by an accident, an operation, by castration, or debility. *Treatment:* It should be bathed with cold water, and the following lotion applied 3 times a day: Sugar of lead, 1 oz.; water, 1 pt.; mix; pass a bandage across the loins to support the penis. If this fails to cure, slit the sheath up a little ways and replace the organ.

PAROTID DUCT, Fistula of.—This resembles a round ball attached to the lower jaw. It may be caused by hay seeds or other substances getting into the mouth of the duct during mastication. The duct greatly enlarges behind the obstacle, which, becoming swollen, prevents the



Parotid Duct Distended by Salivary Calculus.

secretion from entering the mouth. Great agony is occasioned by every mouthful masticated. The duct bursts, and a fistulous opening is established, through which the saliva jerks at each motion of the jaw. From the absence of a secretion important to digestion, the flesh wastes, and the animal soon assumes a miserable appearance. *Treatment:* Make an adhesive fluid with gum mastic and spirits of wine; or with india rubber and sulphuric ether. When the horse is not feeding, pare the hardened edges from the wound; cover the orifice with a piece of strained india rubber; over this put a layer of cotton; fasten one end to the horse's cheek by means of the adhesive fluid; that having dried, fasten the other end tightly down. Place other layers of cotton over this, allowing each layer to cross the other, and fastening all to the cheek. Fasten the head up; allow the horse to remain thus until the cotton falls off, and only give gruel for food. Put tan under the feet; and should the first trial not succeed, repeat it.

PAROTID GLAND, Inflammation of.—Usually caused by cold or from injury. It may be known by the swelling, soreness, hot, dry mouth, and more or less fever. *Treatment:* Bathe the swollen glands with hot water and place linseed poultices upon them; give the following mixture: Tincture aconite root, 1 dr.; fluid extract belladonna, 2 dr.; sweet spirits nitre, 2 oz.; carbonate of ammonia, 1 oz.; nitrate of potash, 1 oz.; water to make 1 pt.; mix, and give a teaspoonful every 2 hours.

PATELLA, Dislocation of.—This is displacement of the whirlbone of the stifle, and may be known by the horse being unable to bring the leg under his body. *Treatment:* Attach a rope to the pastern of the leg which is dislocated; carry the end of the rope through a ring, or over a beam at or about the horse's head; place the ends of the rope in the hands of 1 or 2 strong men (telling them not to pull till a man is placed at the head of the horse to keep him steady); have another man at the leg with 1 hand placed firmly on the point of the hock-joint pulling towards himself, and the other pushing firmly against the dislocated joint; then let the men on the rope pull firmly and gently, till the foot is brought fairly in under the horse's body; after which remove the rope, and keep the horse quiet for a day or two.

PHARYNX, Inflammation of.—This is usually the result of an inflammation of the top of the gullet; caused by some obstruction lodging there. The symptoms are pain in swallowing, violent coughing, and when liquids are poured down they are quickly forced out through the nostrils. *Treatment:* Pass the hand to the back of the mouth, and remove the foreign substance, if it can be seized, but, if not, the forceps or a piece of hooked wire must be used, and the obstruction removed in a gentle manner, as it will require much time and patience.

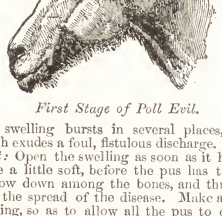
PHIMOSIS.—This is a constriction of the prepuce or sheath at its extremity, which may entirely prevent the passage of urine, and is caused by wounds or blows inflicted on the sheath, swelling of the sheath in castration, or by the sting of venomous insects. *Treatment:* Give plenty of exercise, fomentations, diuretics, and hand friction; if these fail to relieve, divide the constricting prepuce just so far as to allow of the escape of the penis, and promote free urination.

PLEURISY.—Caused by exposure to cold when the body is in a heated condition, or by broken ribs or wounds. The symptoms are a chill, fever, and occasional painful and short cough, and careful breathing, and a disinclin-

ation to turn short; a peculiar line will usually be seen running from the haunch, round the belly to the breast bone. *Treatment:* Blister both sides of the chest, and bathe the legs in hot water; or boil bran, and then put an old pantaloon leg on over his, and fill in around with hot bran; this will get up a circulation in the extremities. Then give 10 gr. tartar emetic; 2 dr. laudanum; 2 dr. tincture digitalis; and 1 dr. nitre, once in 2 hours, till relief is experienced. Keep well covered with warm clothing; keep the legs warm by hot applications and bandages. Use 1 oz. cream tartar, in 2 qts. tepid water, for a drink.

PNEUMONIA, or LUNG FEVER.—One of the most frequent causes of this disease, is to drive against a cold wind after being taken from a warm, tight and poorly ventilated stable, where several horses have remained through the night; or some different alterations of heat, cold, or moisture in an animal not accustomed to work, or in one not in proper condition to work. The horse will often have a discharge from the nostrils; a chill, followed by fever, which is increased for a short time; cold legs and ears, quick and wiry pulse, quick and difficult breathing, pain in the chest, which is aggravated by coughing, and a quivering of the muscles of the side and breast. *Treatment:* Give tartar emetic, every 3 hours, in 10 gr. doses, with 2 dr. of laudanum and 1 dr. of nitre, to increase the action of the kidneys; apply mustard to the chest externally, or, if the disease is severe, blister both sides of the chest. The diet should consist of bran mashes, gruel, and a little hay or green food; the bowels must be kept open by salts or oil. A cool, airy stable, and warm clothing are indispensable.

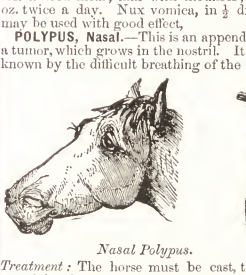
POLL EVIL.—Produced by a blow on the prominent ridge at the top of the poll. It may be known by a painful swelling on the poll. The nose is protruded, and the head kept as motionless as possible; the animal hangs back when it is feeding from the manger. Pressure, or enforced motion, excites resistance and swelling.



First Stage of Poll Evil.

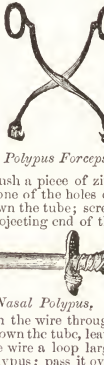
The swelling bursts in several places, from which exudes a foul, fistulous discharge. *Treatment:* Open the swelling as soon as it has become a little soft, before the pus has time to burrow down among the bones, and thus prevent the spread of the disease. Make a large opening, so as to allow all the pus to escape, and clean out well, if necessary, with a swab, so as to remove all the pus, and do this twice a day, as long as any pus remains. Syringe out with a solution of carbolic acid, ½ oz. to each pt. of soft water. Give internally the following: 4 oz. pulverized Socotrine aloes; 4 oz. soft soap; 1½ lbs. linseed meal; mix with molasses; dose, 1 oz. twice a day. Nux vomica, in ½ dr. doses, may be used with good effect,

POLYPUS, Nasal.—This is an appendage like a tumor, which grows in the nostril. It may be known by the difficult breathing of the animal.

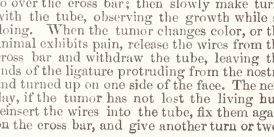


Nasal Polypus.

Treatment: The horse must be cast, the side containing the polypus being uppermost. Catch firm hold of the polypus with the forceps for the purpose, then revolve them several times, which motion will twist and rupture it. Or, procure a fine hollow tube, 18 in. long, having at one end a cover made to screw on and off; the opposite extremity must be open, and should have a cross bar attached externally, 1 in. from the termination. Upon the cover bore 2 holes, sufficiently large to admit a fine wire; push a piece of zinc wire, 1½ yds. long, through one of the holes on the unscrewed cover and down the tube; screw on the cover; fasten the projecting end of the



Polypus Forceps.



Tube for Removal of Nasal Polypus.

wire to the cross bar; return the wire through the other hole, and passing down the tube, leave it hanging free; form of the wire a loop large enough to surround the polypus; pass it over the head of the polypus; by means of the tube work the loop forward, tightening the wire as the size of the polypus diminishes. When the wire is round the pedicle, fix it by winding it also over the cross bar; then slowly make turns with the tube, observing the growth while so doing. When the tumor changes color, or the animal exhibits pain, release the wires from the cross bar and withdraw the tube, leaving the ends of the ligature protruding from the nostril and turned up on one side of the face. The next day, if the tumor has not lost the living hue, reinsert the wires into the tube, fix them again on the cross bar, and give another turn or two;

when the tumor appears dead, twist the tube till the pedicle gives way.

POX.—This disease usually attacks the limbs, but sometimes other parts of the body. It shows itself by slight fever for 2 or 3 days, and swelling of the affected part; then lumps break out, which are at first red, and then enlarge and become yellow. *Treatment:* Bathe the parts with warm water, once or twice a day, and then grease them over when dry. Give a laxative diet. If fever runs high, give the following ball: 1 dr. gentian root; 1 dr. ginger; 5 dr. Barbadoes aloes; syrup enough to mix; make as a ball, and give as 1 dose.

PRURIGO, or ITCHING SKIN.—The causes are generally a most liberal use of nutritious food, such as beans, salt, etc., and also a want of exercise and work. It may be known by the skin becoming thickened and scaly, which is attended by constant itching. *Treatment:* Take away some hay. Give 2 bundles of grass per day. Allow 2 bran mashes each day till the bowels are open. Apply either of the following washes: Animal glycerine, 1 part; rose water, 2 parts. Or, sulphuric acid, 1 part; water, 10 parts. Or, acetic acid, 1 part; water, 7 parts. Drink: Liquor arsenicalis, 1 oz.; tincture of muriate of iron, 1½ oz.; water, 1 pt.; ½ pt. to be given every night. Withdraw the drink a week after the disease has disappeared. Allow a pot of porter and an extra feed of oats each day.

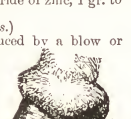
PUERPERAL FEVER.—This disease follows parturition, and is rendered worse by neglect and exposure to cold. There is fever, quickened pulse, ears and extremities cold, constipation and inflamed udder. *Treatment:* The animal should be kept warm, and have good ventilation. Give soft food and pure water, in which mix a tablespoonful of sweet spirits of nitre, morning and night. Give 1 dr. calomel, and 10 gr. powdered opium, 3 times a day. If there is constipation, give ½ pt. raw linseed oil every other day.

PURPURA HEMORRHAGICA.— This is often the result of typhoid catarrh, and also arises from defective ventilation, uncleanliness, bad water, etc. The attack is sudden. The body, head and limbs enlarge; consciousness is partially lost. The horse stands, and the breathing is quickened. Through the skin there exudes serum, with blood. The nostrils and lips enlarge, and part of the swollen tongue protrudes from the mouth. The appetite is not quite lost, though deglutition is difficult. Thirst is great. *Treatment:* Bleed till the animal appears relieved. A second bleeding may be demanded, but it should be adopted with caution. Give ½ oz. of chloroform in 1 pt. linseed oil, in the 1st stage; repeat the dose in ½ hour. No amendment following, give 2 oz. of sulphuric ether in 1 pt. of cold water; in ½ hour repeat the dose, if necessary. Perform tracheotomy, to ease the breathing. Incise the protruding tongue; then squeeze out the fluid, and return the organ to the mouth. Should the skin slough, bathe the part with a solution of chloride of zinc, 1 gr. to 1 oz. of water.

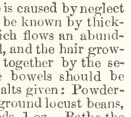
Purpura Hemorrhagica.

QUINSY.—(See *Bronchitis.*)

QUITTOR. — Often produced by a blow or tread from another horse, but will take place from any severe bruise, an abscess forming in the coronet, mostly on the inside, and often affecting the cartilages. The symptoms are lameness, heat and tenderness of the part, occasional redness of the horn, and absence of puncture. *Treatment:* Remove the animal's shoe, to cut away any dead or discolored horn, so as to reach the seat of the suppuration, and to allow it to escape by a more direct outlet; then apply hot water fomentations and poultices for a few days. Should the sores show an indisposition to heal, the parts should be washed with a tolerably strong solution of sulphate of zinc, or of bichloride of mercury, 25 gr. of the latter to 1 oz. of water. The application of strong caustics is to be avoided.



Quittor Before the Pus Has Broken Out.



Quittor After the Pus Has Broken Out.

RAT-TAILS.—This disease is caused by neglect of simple eczema. It may be known by thickening of the skin, from which flows an abundant fluid; scales are formed, and the hair growing from the parts is glued together by the secretions. *Treatment:* The bowels should be opened, and the following salts given: Powdered nitrate of potash, 4 dr.; ground locust beans, 1 oz.; ground coriander seeds, 1 oz. Bathe the affected parts, and apply the following lotion: Goulard's extract, 2 fl. oz.; carbonate of ammonia, 1 dr.; laudanum, 2 fl. oz. Give the following dose internally: Sulphur, 12 oz.; arsenic, 1 dr.; bruised coriander seed, 6 oz.; divide into 12 powers, and give 1 daily.

RHEUMATISM, or FOUNDER.—It is of 2 kinds, acute and chronic. *Acute.* This may be caused by sudden changes of temperature, over exertion on hard roads, over feeding, large draughts of cold water, standing in snow or ice water while warm; or it may be a sequel to strangles, influenza, etc. The horse stands upon his heels, with fore feet and legs stretched out as far as he can get them, so as to throw the weight off as much as possible; and he can scarcely be made to move; has fever and considerable constitutional disturbance; is extremely excitable, and breathes fast and laboriously. The coronet and hoof feel very hot, and, when wetted, may be seen to steam. *Treatment:* 1. Put the horse in a sling; to the end of the cord append weights; soak the feet in warm water, in which a portion of an alkali has been dissolved. As soon as the hoof is softened, release the feet from the water and remove the shoes. Cut down the rim of the hoof all round to such an extent that only the

sole and the frog touches the ground. Do not pare away anything from the sole or frog. Then place him on an earthen floor and not on a plank floor, unless it is kept well littered. Envelop the feet in large, soft, cold poultices of equal parts of bran and linseed meal. If much tenderness prevails, scarify the skin above the hoof and place the feet in warm water to stimulate bleeding. Give 5 dr. of aloes, and 1 dr. each of podophyllin and capsicum, made into a ball. Give every hour from the beginning of the attack, 10 drops tincture of aconite root, until 6 doses are given. If after 2 or 3 days the fever and pain in the feet do not decrease, thin down the sole at the toe, and make an incision sufficiently deep to start bleeding, and encourage by immersing the feet in warm water; then apply a blister

Soaking a Horse's Feet for Rheumatism.

round the pastern. Give loosening food. Subsequently give liberty out of doors when the weather permits. — 2. Bed the horse well in a roomy box-stall, so that he can lie down; give 20 drops tincture aconite root, in ½ pt. cold water, every 4 hours, until 6 or 8 doses have been given; apply a cloth, wet with ice water, to the feet, and keep wet with the same for several days until pain is allayed. Give plenty of cold water to drink, and rest until recovered; feed on grass and mashes. *Chronic.* First shown by a slight soreness or lameness, generally appearing in both fore feet. *Treatment:* Put the horse in a sling, as directed for acute form, and proceed in the same manner to remove the shoes. Omit all bleeding. If the bowels are costive, allow a portion of green food until the evil is removed; but do not produce purgation. Give night and morning, 1 qt. of stout; allow 2 drinks, each containing 1 oz. ether, in ½ pt. water, during the day. Give ½ dr. doses of belladonna to allay any symptoms of pain. Give sound oats previously ground, and a moderate allowance of old beans. The water should be whitened and all hay withheld.

RIBS, Broken.—The ribs are often broken by colliding with objects while running away, and by blows or kicks from other horses. There is displacement; there will be either bulging in or out; sometimes bleeding from the nose; loss of appetite for a day or two, and more or less fever. *Treatment:* Move the horse carefully to his box, and place a bandage with sureingle directly over the fracture, drawing them middling tight to prevent working of the ribs. To control the fever, the following mixture may be used: 1 dr. tincture aconite root; 2 dr. fl. extract of belladonna; water, to make 4 oz.; mix, and give 1 teaspoonful every 2 hours. Give soft food; let the horse have perfect rest for several weeks.

RICKETS, or BIG HEAD. — A disease of the bony structure. It is a gradual softening and enlargement of the bones, which become spongy and porous from want of proper nutrition. *Treatment:* Give the animal liberal, wholesome and very nutritious food, such as oats, barley and bran, mixed or steamed, as chewing is often slow, painful and difficult. During the summer season pasturage is beneficial. For internal use, tonic remedies may be employed, such as 1 dr. of peroxide of iron, and 2 dr., each, of powdered boneset and gentian, mixed together, and such a dose given among food, morning and evening, during every other week.

RINGBONE.—Usually the result of weakness, hereditary predisposition, concussion or sprain of the joint. The symptoms are, lameness, soreness and swelling, which either forms lumps on the pastern, or runs in a circle clear around the joint. *Treatment:* Pare off the toe; then apply wet bandages to reduce the inflammation; and for every qt. of water used for this purpose, add 1 teaspoonful, each, of arnica and alum. Give the animal at the same time a dose of physic, 5 dr. aloes, or 1 lb. Glauber salts. When the tenderness has subsided, apply a blister, composed of 1 dr.

Severe Ringbone.

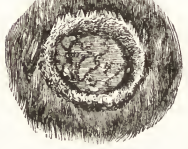
1. The joint between the pastern bones, showing the groove in which the tendon of the extensor pedis muscle reposed.
2. The joint between the lower pastern and the bone of the foot.

of cantharides; 1 dr. of iodide of mercury; 5 gr. of camphor; 1 oz. lard; mix all together. Cut off the hair from the front and back of the joint, and apply rubbing in thoroughly. When the blister is well formed, wash off and dampen the surface daily with a lotion composed of 1 part compound tincture of iodine, and 3 parts water. In very bad cases the blistering may have to be repeated.

Aggravated Case of Ringbone.

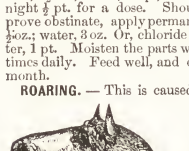
Horse with Ringbone Straining Up-hill.

RINGWORM.—This is produced by the formation of a fungoid crust in a circular form, which causes the hairs to break off and become stumpy; the crust becomes white and soon breaks down into a powdery condition; and there is itching and irritation of the skin. *Treatment:* Be very clean. Wash night and morning, and, afterwards, apply the following ointment: Animal glycerine, 1 oz.; spermaceti, 1 oz.; iodide of lead, 2 dr. A drink is likewise of use when employed with the ointment. Liquor arsenicalis, 1 oz.; tincture of muriate of iron, 1½ oz.; water, 1 qt.; mix, and give every night ½ pt. for a dose. Should the ulceration prove obstinate, apply permanganate of potash, ½ oz.; water, 3 oz. Or, chloride of zinc, 2 sc.; water, 1 pt. Moisten the parts with a soft brush, 6 times daily. Feed well, and do not work for 1 month.



Ringworm.

ROARING. — This is caused when a partial obstruction to the passage of air to and from the lungs takes place, which thus causes the noise that gives its name to the disease; in the case of carriage-horses, it is often caused by tight reining. The symptoms are a hard, dry, and frequent cough; difficult swallowing, the fluids returning by the nostrils; mucous membrane red, and pulse frequent. *Treatment:* If it is caused by an obstruction in the air-tube, from an injury or from the effect of an operation, relief may be obtained by the application of a blister or seton. If it arises from a thickened state of the membrane of the bronchial tubes, apply irritants, such as biniodide of mercury, to the exterior of the part affected, or insert a seton on both sides.



Listening for the Sound Indicating Roaring.

RUPTURE. or HERNIA.—Generally the result of kicks, blows, strains in jumping, falling or pulling. It may be known by a soft swelling on a surface that should be smooth. *Treatment:* Push the part back; introduce skewers crosswise through the skin over the opening, and wind silk round the skin below the ends of the skewers, middling tight; put on a compress, and give the part considerable pressure. Other operations are performed by veterinary surgeons, such as opening the skin and sewing up the opening in the abdominal wall with cat-gut sutures, injecting salt and water under the skin, etc.

SADDLE AND HARNESS GALLS.—*Treatment:* 1. Arrange the harness so as to give an even bearing on the back or shoulders. Bathe the parts several times a day with 1 pt. water, and ½ pt. tinct. myrrh.—2. Dress the parts with common salt dissolved in water, and the brine mixed with ¼ its bulk of friar's balsam. When the sores become firm and hard like warts, apply the following ointment: 1 part of red iodide of mercury to 8 parts of hog's lard, well mixed together; rub well into the parts; if they do not disappear in 5 or 6 days, repeat the application; apply lard once a day between each application, and occasionally wash the parts with warm water, and lard or oil the part when dry.

SANDCRACK. — Caused frequently by bad shoeing, a false step, or by over exertion when drawing a load. It may be known by a fissure in the hoof, which begins at the coronet, the thin edge first breaking away. *Treatment:* Always pare out the crack, so as to convert it into a groove. When the crack is partial, draw a line with a heated iron above and below the fissure. If the separation is all the way down the hoof, make a semi-circular line near the coronet with the hot iron, or draw lines from the coronet to the crack, in the shape of a V, with the hot iron. If the split is not clear through the hoof, the edges may be drawn together by pushing thin wire in short pieces through the holes across the fissure, and bending the ends over so they will meet; then melt a little beeswax, by means of a heated iron, into the crack. When it occurs at the toe, cleanse the wound with chloride of zinc lotion, 1 gr. to the oz. of water, and then cut them off. Afterward place the foot in a poultice. Subsequent-

ly, pare down the edges of the crack while the horn is soft. Use the lotion frequently. Draw lines from the coronet to the crack, so as to cut off communication between the

Split Hoof.

Bar Shoe for Toe Sand Crack.

newly-secreted horn. Shoe with a bar shoe, having the seat of the crack well eased off, and also a clip on either side. If the horse must work, lay a piece of tow saturated with the lotion into the crack; bind the hoof tightly with wax-end; tie over all a strip of cloth, and give this a coating of tar. When the horse returns, inspect the part. Wash out any grit with the chloride of zinc lotion. Feed liberally on prepared food.

Foot Dressed for Toe Sandcrack.

SCRATCHES, or CHAPPED HEELS. — This disease is generally caused by filthy stables, where the animal stands constantly in manure; by overwork, or by traveling long in the mud, and by not being properly groomed at night. The symptoms are a dry and scurvy state of the skin of the heel, accompanied by redness, heat, and itching. (See *Grease.*) *Treatment:* Give a dose of 12 oz. Epsom salts, then 1 oz. hyposulphite of soda, daily, for 2 or 3 weeks. The part should be dressed with acetate of lead, a little of which should be rubbed in every night. Next morning some glycerine should be brushed on at least an hour before the exercise, and renewed before the daily work is commenced. This will prevent all risk of the skin cracking, while the ointment will act beneficially on the vessels of the part.

Scratches.

SCROTUM, Dropsy of. — The symptoms are enlargement, tenderness and softness. *Treatment:* The water should be drawn off with a small trocar and canula, and tincture of iodine injected into the dropsical cavity, so as to cause it to close up by provoking adhesive inflammation.

SEEDY TOE. — This is caused by inherent weakness, undue shocks, or founder. It may be known by tapping the toe with a hammer, and if it is disunited, it will give a hollow sound. *Treatment:* Find the extent of the separation with a thin probe; cut away the whole of the detached horn; place the horse in a loose box, and feed liberally; once every fortnight, for 2 months, cut away so much of the outer wall as may be still disunited. It will take 3 or 4 months for the hoof to grow down.

Seedy Toe after Removal of Shoe.

Hoof after Removal of Seedy Toe.

Section of a Horse's Foot Affected With Seedy Toe.

SHEATHS, Foul. — *Treatment:* Pare the nails of the right hand smooth, and take as much clean lard, free from salt, as can be held by the points of the fingers and thumb; insert the hand to the bottom of the sheath, and as the hand is withdrawn leave all the lard. Repeat the operation 2 or 3 times at intervals of about 2 days, and in 9 cases out of 10 the horse will be all right. If not, wash out carefully with lukewarm water.

SIDE BONE. — Generally caused by severe bruises or other injury to the feet. It may be known by striking near the lateral cartilages with a hammer, when the animal will show signs of pain; the cartilages become stiff, hard and enlarged, the action stilty, and the feet contracted. *Treatment:* Bathe with water continuously and place the following fly blister on the spots: Spanish flies, coarsely powdered, 8 oz.; oil of turpentine, 2 qts.; steep for 3 weeks; strain, and add 1 qt. of olive oil.

SKULL. Fracture of.—Commonly caused by bruises, kicks and blows. It may be known by the external marks of violence, fever, and either stupor or delirium. *Treatment:* Remove the portion of bone that presses into the skull, by trephining the bone, and treat as for a simple wound. If fever sets in, apply poultices of chopped ice and bran.

SPAVIN. — There are several forms of this disease. Sickle-hocked or cow-hocked horses, are said to be most subject to it. To examine

The Manner in which to Feel for a Spavin.

a horse for spavin, view the suspected joint from before, from behind, and from either side. After-

A Sickle-Hocked or Cow-Hocked Horse.

wards feel the hock. *Bog* spavin, generally caused by bruises, sprains, or by wounds or pricks from nails. It may be known by the extension of the bursa or sheath of the true hock joint, and by the soft, yet firm swelling. *Treatment:* Bathe it continually with water, and apply a hot, soft oil meal poultice for 2 or 3 days. When the pain and lameness have disappeared, the following ointment should be applied: Tincture of iodine, 3 oz.; aqua ammonia, 1 oz.; turpentine, 1 oz.; glycerine, 1 oz.; mix; and, after the skin has become sore, grease with lard until it heals. *Bone* spavin may result from eonstitutional causes, hard work, or bad shoeing. It is characterized by an objection to put the heel to the ground; by frequent stumbling or knuckling under of the lower joint; and by stepping on the toe when running, causing the undue wearing at the toe of the shoe. *Treatment:* Bathe the parts with warm water, and let the animal have rest or cessation from hard work, or putting to moderate work on soft ground. The bony deposit, or inflammation, may be removed by repeated blisters. Use a hot iron only as the last resort. *Blood* spavin. Similar to bog, but more extended, and generally involves the front, inside and outside of the joint, giving it a rounded appearance. The swelling is soft and fluctuating. Young horses and colts, especially if driven or worked hard, are more liable to have this form of spavin than older horses. *Treatment:* ½ lb. blood root; 1 qt. alcohol; 2 oz. tannin; ½ lb. alum; mix, and let it stand, shaking it several times a day till the strength is all in the alcohol, and bathe the spavin twice a day, rubbing it in with the hand. *Occult* spavin. Similar to bone in its nature, the difference being that the location is within the joint, so that no enlargement is seen, which makes it more difficult to come to a definite conclusion as to its location, and consequently the horse is often blistered and tormented in nearly all parts of the leg but in the right place. The causes and effects are the same as

Position of a Spavined Foot. *Position of a Healthy Foot in Trotting.*

bone spavin, and it should be treated in the same way. When convalescent, give the following: ½ oz. pulverized fenugreek seed; 1 oz. sulphate of iron; 2 oz. gentian root; ½ oz. nux vomica; mix, and divide into 12 powders; give 1 night and morning in the feed. Give a few carrots, and a little new grass, if it is to be had; a little walking exercise every day will be beneficial. Do not put to work for several days after recovery.

SPLINT.—This is produced by inflammation of the shank bone from fast driving, or from the animal having been overworked when young. The symptoms are heat, tenderness, pain, and often lameness. Dishing, or carrying the front leg outward, when trotting, is thought by some to be an indication of splint, but many horses do this that have no splints. *Treatment:* The periosteum must be cut down and divided by a small narrow knife, to relieve the tension and irritation. Cut the hair short; rub a little of the following ointment into the skin, covering the splint every night, until a free, watery discharge is produced from the surface: Biniodide of mercury, 2 dr.; lard, 1 oz.; mix. If, after a fortnight, the splint does not appear much reduced in size, the ointment should be re-applied, and repeated at similar intervals.

Different Kinds of Splint.

1. A high splint near the knee.
2. Low splint far from the knee.
3. A small bony growth on the front of the leg, which is also called a splint.

Serious Splints.

1. A splint, involving the bones of the knee joint.
2. A splint, interfering with the action of the back sinews.
3. A small splint situated under the tendon of an extensor muscle.

STAGGERS.—(See *Brain, Inflammation of.*)

STOCKED or SWOLLEN LEGS.—(See *Debility.*)
STOMACH, Inflammation of.—(See *Bowels, Inflammation of.*)
STONE BRUISES.—The symptoms are lameness, and a tender and painful spot on the foot. *Treatment:* Same as that for *Overreach*, which see.

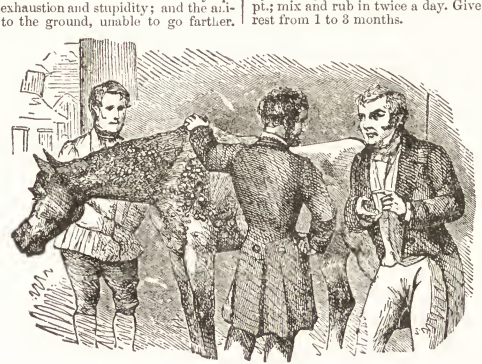
Dishing.

Stone Impacted Between the Sole and the Web of the Shoe.

STRANGLES.—(See *Throat, Sore.*)
SUNSTROKE.—Caused by over exertion or exposure to the sun in hot weather. The symptoms are exhaustion and stupidity; and the animal falls to the ground, unable to go farther.

Fractured Hip.

lock, hip, back, stifle joint, flexor tendon, suspensory ligaments, etc., caused by slipping, falling, overwork, etc. Whatever part is affected the treatment is essentially the same. Fracture of the hip also requires the same treatment, as the bones cannot be got at to be set. The animal will always remain one-sided; but he may be just as useful as ever for ordinary work. *Treatment:* Apply cold douches to the part, pouring the water sometimes from a height; keep the affected part swathed in cloths, wet with rum or diluted alcohol. After the inflammation has somewhat subsided, use the following liniment: Tincture of arnica, tincture of opium, aqua ammonia, of each 2 oz.; water, 1 pt.; mix and rub in twice a day. Give the horse rest from 1 to 3 months.



Surfeit.

Treatment: Remove the horse from the harness to a cool, shady place. Give 2 oz. of sulphuric ether, 20 drops of tincture of aconite root, and a bottle of ale, or porter, as a drench, to sustain the vital powers, and to act as a stimulant in equalizing the circulation. Chopped ice should be placed in a coarse towel, or bag, and laid between the ears and over the forehead. If the legs are cold, swathe them in woolen bandages.

STRAINS AND SPRAINS.—These are accompanied by swelling, heat and tenderness. Every joint is liable to sprain, but the more common sprains will be found in the pastern or fetlock, hip, back, stifle joint, flexor tendon, suspensory ligaments, etc., caused by slipping, falling, overwork, etc. Whatever part is affected the treatment is essentially the same. Fracture of the hip also requires the same treatment, as the bones cannot be got at to be set. The animal will always remain one-sided; but he may be just as useful as ever for ordinary work. *Treatment:* Apply cold douches to the part, pouring the water sometimes from a height; keep the affected part swathed in cloths, wet with rum or diluted alcohol. After the inflammation has somewhat subsided, use the following liniment: Tincture of arnica, tincture of opium, aqua ammonia, of each 2 oz.; water, 1 pt.; mix and rub in twice a day. Give the horse rest from 1 to 3 months.

SURFEIT.—Sometimes caused by indigestion, or by sweating the horse when he is in a plethoric condition, and then exposing him to a chill. It may be known by numerous small scabs on the skin, matting the hair, and chiefly met with on the loins and quarters. *Treatment:* Regular exercise and grooming must be fully attended to, using the wisp only in dressing the skin, when eruption shows itself, and avoiding the brush and curry-comb. Give 1 oz. nitre, with a mash, twice a week, or the following balls: 3 dr. nitre; 3 dr. sulphur; 2 dr. sulphuret of antimony; linseed meal and water to form 2 balls.

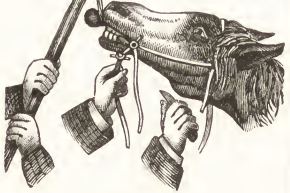
THOROUGHPIN.—This is generally the result of too hard work where the strain upon the hind legs is very great. It may be known by soft swellings just in front of the point of the hock. *Treatment:* This should be by pressure, kept up for a long time, by means of a carefully adjusted truss, alternated with cold affusion, and the use afterwards of tincture of arnica, diluted with water, as a wash.

Thoroughpin.

THROAT, Sore, or LARYNGITIS.—The symptoms are perpetual deglutition of saliva; want of appetite; inability to swallow a draught of liquid, the fluid returning partly by the nostrils, and each gulp being accompanied by an audible effort; in some cases a purulent discharge issues from the nose, and it is then called strangles. *Treatment:* House in a large, well-littered, loose box, and clothe warmly. Give gruel for drink; green food, with 8 feeds of bruised scalded oats, also beans daily. If the bowels are obstinate, give a drink composed of the following: 4 oz. solution of aloes; ½ oz. ess. aniseed; 1 pt. water. Should the throat not amend, steam the nostrils by securing a nose-bag on the head, placing bran and boiling water in the bottom of it. Soak soft hay in boiling water, and fix it upon the throat by means of an 8-tailed bandage. Give 2 pots of stout daily, and blister the throat. No alteration ensuing, mop out the fauces with a sponge wet with nitrate of silver, 5 gr.; water, 1 oz. Give a ball, daily, composed of oak bark and molasses, a sufficiency of each to form a mass. Should the swollen glands of the neck suppurate, open with a lancet. A twitch on the nose will be sufficient to keep the horse quiet. Keep it thoroughly clean by sponging with the following: 2 dr. carbolic acid, 1 pt. water.

Appearance of Strangles.

Eight-tailed Bandage.



Opening the Abscess.

THRUSH.—This disease is generally caused by moisture, bruises or filth, and may be known by the disagreeable discharge of offensive matter, if a stick or blade is run into the fissure. *Treatment:* First poultice with linseed meal, put on hot, and let it remain 12 hours. then use the following paste: 2 oz. blue vitriol; 1 oz. white vitriol; powdered as finely as possible; mix well with 1 lb. of tar and 2 lbs. of lard; apply this in the cleft, by putting it on tow and pushing it in; let it remain 12 hours; then cleanse out with soft water and soap. When dry, make a second application; also renew the poultice at night, until all inflammation disappears.

Thrush in Hind Foot.

Thrush in Fore Foot, with Thick Crust, Concave Sole, and Small Frog.

TONGUE, Sore.—Sometimes caused by injuries from the halter chain, or by striking against the teeth. *Treatment:* Wash with a saturated solution of borax. If the tongue bleeds, apply turpentine as an astringent.

TOOTHACHE.—Caused by carious teeth, and may be known by the head being depressed, the eyes closed, and tears running down the face. *Treatment:* To safely examine the mouth, a balling iron should be used to keep the jaws open. If the tooth is ulcerated, extract it at once; if not, it may be cleansed and the cavity filled with gutta percha. If tender, destroy the nerve with crystallized carbolic acid and powdered opium, before filling.

TYPHOID FEVER.—This disease may be known by the strength becoming reduced; the breath fetid, and the mouth loaded with a black discharge from the tongue and gums. *Treatment:* As few cases recover, it is best to leave the animal chiefly to nature, simply regulating the bowels by injections, and supporting the strength by 1 dr. of quinine every morning, and ½ pt. whisky, 2 or 3 times a day. For nourishment, give freely as a drink a strong infusion of hay and oats.

URETHRA, Inflammation of.—Generally caused by small stones, gravel, or irritating substances in the urinary passage, or injury to the penis. It may be known by the passage of urine being slow and painful, soreness and swelling in the sheath and penis, and by the discharge of pus. *Treatment:* Give 1 pt. raw linseed oil, and foment the sore part with hot water; rinse out any gravel, and inject once or twice a day with a lotion made as follows: ½ oz. sugar of lead; 1 oz. vinegar; 1 qt. water; mix.

URETHRA, Spasm of—(See *Bladder, Inflammation of.*)

URETHRA, Stricture of.—Produced by irritating substances in the urine. It may be known by painful urination, the urine being passed in

a fine stream. *Treatment:* A small catheter should be passed in every day, gradually increasing the size of it, and gently pushing it by the stricture.

URINE, Bloody.—Caused by violence, affecting the bladder, loins or kidneys, or by abscess, tubercle, or cancer in the kidneys. The symptoms are, the existence of bloody urine, unaccompanied by pain or irritation. *Treatment:* Little can be done in severe cases, and mild ones only require rest, and a dose of physic. Green food should be given, and the diet should be attended to as for *Diabetes*, which see.

URINE, Retention of.—(See *Bladder, Inflammation of*; *Bladder, Stones in the*, and *Gravel.*)

VEIN, Inflammation of. — Generally caused by the operation of bleeding being performed in a clumsy manner, or with a blunt or rusty instrument. It may be known by great pain, heat and tenderness; the inflammation spreads to surrounding parts, and there is considerable tumefaction. *Treatment:* Give the following every 8 hours: Nitrate of potash, 2 dr.; tepid water, 6 fl. oz.; tincture aconite, 10 drops; mix. Apply linseed poultices over the vein, and tie up the animal's head to prevent him from rubbing the parts.

WARTS.—These are small tumors which form on any part of the body. *Treatment:* Take corrosive sublimate and red precipitate, powdered and mixed, equal parts. If the wart is large and loose, tie a fine, strong cord around it close to the skin. In a short time the wart will come off; then apply the powder until the wart is eaten down below the skin; then wash off and rub on a little sweet oil, and it will soon heal over. If the wart is dry, scratch it with a pin or point of a knife until it bleeds, then rub on the powder. It will make a dry scab; pick off the scab, and put on the powder again until it is all eaten off.

Warts.

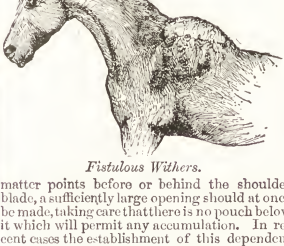
WINDGALLS. — The symptoms are, small enlargements, generally upon the hind legs and below the hocks; no lameness; 2 windgalls appear above the pastern, 1 beneath that joint; after extraordinary labor the round swellings disappear and the course of the flexor tendons becomes puffy. Sometimes continued irritation will cause the windgalls to greatly enlarge and ultimately provoke their ease to change into bone. During these changes, the horse is very lame. *Treatment:* Fold pieces of rag; wet them; put these on the windgalls; place on the rags pieces of cork, and over the cork lace on an india rubber bandage. Mind this bandage is constantly worn save when ridden or driven. Rest is the only alleviation for the change of structure.

Situations and Shapes of Windgalls.

WIND SUCKING.—This generally arises from feeding on chaff, bad hay and musty oats. The horse smacks his lips, attempting to confine air within the mouth, arches his neck, and, with a belching action, inflates the stomach. *Treatment:* Place a strap around the throat, tightening it sufficiently to prevent the animal from distending the neck and straightening the pharynx.

Windgalls as They Appear Dissected.

WITHERS, Fistulous.—When a saddle has been allowed to press upon the spinous processes of the dorsal vertebræ, it produces inflammation, which, neglected, leads to the formation of an abscess. But the situation of the part is such that matter cannot escape, even if the skin over the points of the bones is perforated, and it has a tendency to burrow down among the muscles connecting the shoulder blade with the trunk. The consequence is, there is extensive inflammation, often lameness of the shoulder, and a constant discharge comes from the swelling. *Treatment:* An opening should be made as low down as possible on the right side, taking care that it will allow all the matter to run out as fast as it forms. The reason why the right side should be chosen is, that most horses lie down on that side; but if the subject of fistulous withers is in the habit of lying on the left side, the opening should be made there in preference. When the matter points before or behind the shoulder blade, a sufficiently large opening should at once be made, taking care that there is no pouch below it which will permit any accumulation. In recent cases the establishment of this dependent opening will alone suffice to effect a cure; but in those of long standing the lining of the fistulous passage or passages has become converted into a substance almost resembling cartilage, and refuses to throw out healthy granulation, so as to lead to adhesion of its walls. Here a stimulus must be applied to their interior, which may be either mechanical, in the shape of a seton tape passed through from end to end and left



Fistulous Withers.

there; or, chemical, by means of injections. The latter are best composed of chloride of zinc, diluted with water; 1 dr. of this should be mixed in 1 pt. of water, and carefully injected into every part of the sinus twice or thrice a week.

WOLF-TEETH.—These are small supernumerary molar teeth, which do no harm, except perhaps causing a slight irritation. *Treatment:* They may be removed very easily, being but slightly inserted in their sockets.

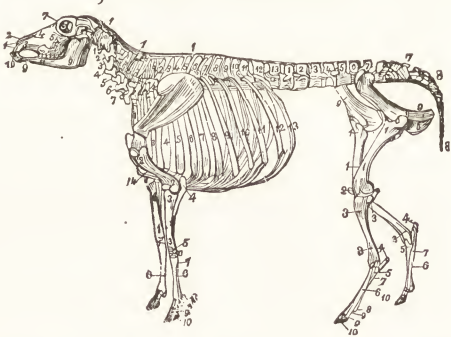
WOMB, Inflammation of. — The symptoms and treatment are the same as those of *Puerperal Fever*, which see.

WORMS.—There are several kinds of worms which infest the horse: *Lumbrici.* Long, round worms, which are sometimes 18 in. long. They prey upon the weakly, whether old or young. *Treatment:* 3 dr. calomel; 1 dr. tartar emetic; make into 3 balls; give 1 every night for 3 nights; 1 day after the last ball, give the following purgative ball: 1 oz. aloes; ½ oz. cream tartar; ½ oz. Castile soap; mix with molasses. *Pin Worms.* This variety inhabits the rectum, and causes great itching posteriorly; which causes the horse to rub its hair off against the wall. *Treatment:* 1 oz. catechu; 1 qt. water; dissolve and give as an injection; repeat for 7 mornings. On the 8th day, give a mash; at night follow with ½ oz. aloes, and 1 dr. calomel. Repeat the above if necessary. Injections of tobacco smoke work well. *Tænia* or *Tapeworm.* These trouble the young mostly; are usually caused by starving the mare when with foal, and by breeding from old animals. The symptoms are, checked development, large abdomen, ravenous appetite, unhealthy coat, thin body and fœtid breath. *Treatment:* Give spirits of turpentine. For a colt, 3 mos. old, give from ¼ to ½ oz.; 6 mos. old, ½ to 1 oz.; 1 yr., 1 to 1½ oz.; 2 yrs., 1½ to 2 oz.; 4 yrs., 3 to 4 oz. Take 1 lb. quassia chips, and pour 3 pts. of boiling water on them; then mix a proportional dose of the quassia infusion with the turpentine, and mix together by stirring in well, with yolks of eggs; add 20 gr. powdered gum camphor, and give the dose the first thing in the morning. Feed well, and give every morning until the coat is glossy, 1 dr. muriated tinct. of iron, and 1 dr. Fowler's solution.

WOUNDS.—*Treatment:* Foment frequently with hot water, and apply tincture of friar's balsam, 2 oz.; compound tincture of myrrh and aloes, 2 oz.; if unhealthy granulations arise, wash, previously to using the tincture, with blue stone, 1 oz.; soft water, 1 pt. Wounds generally heal better without sewing, if it can be avoided. If suppuration is inevitable, use carbolic acid combined with glycerine or linseed oil, in the proportion of 1 to 20; apply night and morning with a feather. The wound must be kept clean, and, in the case of backs and shoulders, all pressure removed by small pads of curled horse hair, sewed on the harness above and below the sore.

SHEEP.

ANATOMY AND BREEDS.



Skeleton and Points of the Sheep.

HEAD.—1, intermaxillary bone; 2, nasal bones; 3, upper jaw; 4, union of nasal and upper jaw bone; 5, union of molar and lachrymal bones; 6, orbits of the eye; 7, frontal bone; 9, lower jaw; 10, incisor teeth or nippers; 11, molars or grinders.

TRUNK.—1, ligament of the neck, supporting the head; 1 to 8, several vertebræ or bones of the neck; 1 to 14, 13 vertebræ or bones of the back; 1 to 7, 6 vertebræ of the loins; 7, sacral bone; 8, bones of the tail, varying from 12 to 21; 9, haunches and pelvis; 1 to 9, 8 true ribs with cartilages; 9 to 14, 5 false ribs; 14, breast bone.

FORELEG.—1, scapula or shoulder blade; 2, humerus or lower part of shoulder; 3, radius or bone of forearm; 4, ulna or elbow; 5, knee; 6, metacarpal or shank bones; 7, a rudiment of the smaller metacarpal; 8, one of the sesamoid bones; 9, two first bones of the foot, the pasterns; 10, proper bones of the foot.

HIND LEG.—1, thigh bone; 2, patella; 3, tibia or bone of the upper part of the leg; 4, point of the hock; 5, other bones of the hock; 6, metatarsal bone or bone of hind leg; 7, rudiment of small metatarsal; 8, sesamoid bone; 9, two first bones of the foot, the pasterns; 10, proper bone of the foot.

BONY STRUCTURE.—The structure of the sheep resembles that of the ox and the horse, having a corresponding number of joints in the limbs, with the exception of the 4 bones below the fetlock being double. The sheep, when full grown, has 8 incisor teeth in the lower jaw, none in the upper, and 24 grinders, 6 on a side in the upper jaw, and 6 in the lower; in all 32 teeth. At birth, usually, the 2 central incisors are through, and in 5 or 6 weeks all the incisors will appear. The 2 first, or milk incisors, will be shed at 12 or 15 mos., and 2 permanent ones appear. At 2 yrs. and past, 2 more permanent teeth appear; at 3 yrs. and past, 6 permanent teeth, and at 4 yrs., 8.

BLACK-FACED HIGHLAND.—The oldest breed known in Scotland, and noted for great hardiness. The face black; muzzle thick; horns of the ram massive and spirally curled; eyes bright and wild; body square and compact; docile, easily handled, and herd well. Mutton of fine flavor, and when fat, weigh from 60 to 70 lbs. The ewes are careful mothers.

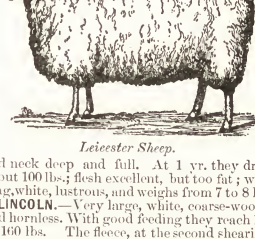
COTSWOLD.—Hardy, heavy shearers, quick feeders, and mature early; wool strong, white and mellow, but rather coarse; averaging 7 or 8 lbs. per fleece. By crossing them upon Merino, or native ewes, the first cross will be nearly equal to that of the thoroughbred, both in size and quality, and the fleece is in demand at prices beyond the Merino or pure-bred Cotswold. They will go to market under liberal keep at 18 mos. old, weighing 150 to 200 lbs., live weight, and will command top prices in the best markets. There is no mutton breed that will feed out at so early an age and cross with as much profit. Being a pure-bred sheep, the rams are better for crossing than any other of the English breeds.

Yearling Cotswold Sheep.

DORSET.—Hardy, strong, active; heavily horned; larger than the Highland; prolific; both rams and ewes are horned; they produce twice in the season. At 2 yrs. they dress 100 lbs. The fleece is close, soft and white, and weighs about 6 lbs.

HAMPSHIRE-DOWN.—A mixed breed, originated by crossing the Southdown on the native breed of Hampshire. Lambs at 1 yr. weigh 100 lbs. Their fleece weighs 6 to 7 lbs., and is excellent combing wool. The mutton is excellent in flavor, and juicy. They are hornless; have black faces, a Roman nose, a large head, and a massive, compact, and well-formed frame.

LEICESTER.—A much esteemed English breed. The sheep are hornless; head small and clean; eyes prominent and animated; shoulders and neck deep and full. At 1 yr. they dress about 100 lbs.; flesh excellent, but too fat; wool long, white, lustrous, and weighs from 7 to 8 lbs.



Leicester Sheep.

LINCOLN.—Very large, white, coarse-wooled and hornless. With good feeding they reach 120 to 160 lbs. The fleece, at the second shearing, weighs from 10 to 15 lbs.; the fiber measures 9 in. in length; hardy and prolific; large feeders, and require succulent grasses and skillful care.

MERINO.—The Merino sheep is, so to speak, a cosmopolitan animal, and may be met with in the most widely-divided latitudes, for it has been introduced into Germany, France, England, at the Cape of Good Hope, Australia, Canada, and the United States of America. It is distinguished by the fineness and felting quality of its wool and weight. Its defects are unprofitable and unthrifty form, voracity of appetite, tendency to barrenness, neglect of young, and inferior flavor of mutton. The wool,

Merino Sheep.

lying closer and thicker than in other breeds of sheep, and being abundant in yolk, is covered with a dirty crust, often full of cracks. Legs long, small in the bone; breast and back narrow; the sides somewhat flat; fore shoulders and bosoms heavy. The horns of the male are comparatively large, curved, more or less spiral; head large; forehead rather low. Male and female have a peculiar coarse growth of hair on the forehead and cheeks; the other part of the face has a velvety appearance. Under the throat there is a looseness of skin, which gives the appearance of throatiness, or hollowness in the pile; the pile, when pressed, is hard and unyielding, on account of the thickness with which it grows upon the pelt, and the abundance of yolk detaining the dirt which falls upon it.

OXFORD-DOWN. — A comparatively new breed; a cross between the Cotswold and Hampshire-Down. They mature early; dress 80 to 90 lbs. of excellent mutton at 14 mos.; are hardy, herd well, and are good feeders. The fleece is thick and curly, averaging from 10 to 15 lbs.; wool even in quality and excellent for worsted manufactures; and is from 6 to 7 in. long.

ROMNEY-MARSH.—A native of England; hardy; improved by crossing with the Leicester. They have a thick, broad head and neck, and a tuft of wool on the forehead; wool long, somewhat coarse, but sound, bright and glossy.

SHROPSHIRE-DOWN. — Originally horned, but crossing with Cotswold, and later with Leicester and Southdown, has produced a sheep without horns. Face and legs spotted gray; head small and firm; ears handsome; neck thick but handsome. The fleece is long, glossy, and will yield about 7 lbs. of washed wool. Ewes prolific and good mothers.

SOUTHDOWN.—This is probably the most popular breed in England with the butcher and consumer, and the prices fetched at the annual lettings and sales prove that it is still considered one of the most generally useful sorts. It is noted for fine mutton; ewes very prolific: wool fine and curled, with spiral ends, and well adapted to carding. The head of medium length; lips thin; under jaw fine and thin; ears tolerably wide apart, and well covered with wool; neck of a proportionate length, thin

Southdown Sheep.

next the head, and enlarging toward the shoulders; breast wide and deep, projecting well forward between the fore legs.

WHITE-FACED HIGHLAND. — A native of Wales. Mutton superior in quality; weighs 8 to 10 lbs a quarter. Hardy; good nurses. Face white, rusty brown, or speckled with gray. The fleece is famous for not shrinking, but seldom weighs more than 2 lbs.

—o—

Breeding and Rearing.

REMARKS.—Sheep are one of the principle sources of agricultural wealth, and furnish, both to commerce and manufacture, products of no inconsiderable importance. Flocks of sheep, from the dung which they leave behind them, are wonderful improvers of the soil. The folding of these animals in a field intended for the cultivation of corn causes beneficial effects which are felt for three consecutive years. Thus their utility in rural economy has long been known. Their wool, for a very considerable period, was considered their most valuable production; but now they supply so vast a quantity of wholesome, agreeable, and very nourishing food, that it is doubtful in which way they most benefit the human family. The fat of sheep, which forms tallow, is likewise one of their most important products; in some breeds it forms a layer from 7 to 8 inches thick along the ribs and around the loins. Their skin, deprived of the wool, is also applied to numerous purposes. Of this integument are made most of the thin leathers which are used in the manufacture of shoes and gloves. When prepared by other processes, it takes in commerce the names of chamois, parchment, vellum, etc. Lastly, milk and cheese are other useful products which are furnished to us by these useful creatures. Ewe's milk, which is remarkable for its richness, is used in many countries as an article of food, but it is more generally applied to the manufacture of cheese. The most valuable commodities which are produced by sheep, both in a manufacturing and agricultural point of view, may be summed up as wool and meat. In order to supply these two products in perfection, it is necessary that the animal should present a certain type of conformation. With regard to the months and seasons named in this department, they are of course modified by the climate and location of each country. We acknowledge our indebtedness to Mr. Armatage's valuable and more complete works, "The Sheep Doctor," and "The Sheep; Its Varieties and Management in Health and Disease."

SELECTION, Rules for. — 1. When buying rams, select always from the same breeder whose reputation is guaranteed. — 2. Avoid flocks only recently established, and thus escape the consequences of wide crossing.—3.

Avoid all animals having the tendency to,or evidence of, hereditary ailments and defects. A delicate constitution is equally as hereditary as physical perfection.—4. Systematic in-breeding is the only source of excellence: that is, a rigorous rejection of faulty sheep, male or female, and breeding only from perfect animals.—5. In-breeding, even with close relations, as sire and daughter or son and mother, if so be that each have perfect health and sound physical qualities, is in keeping with the principle of producing excellence and sound stock. Experience proves that a good ram lamb, excelling his sire, put to his own mother, will produce better stock than even himself or his sire.—6. In-bred animals do not "throw back;" therefore close breeding preserves the strain and acts as a barrier to the introduction of foreign tendencies of every kind.—7. The prominent conditions of successful reproduction are judicious selection and in-breeding. Without these the flock-master may work for a lifetime unsuccessfully.—8. The experience derived from the mating or in-breeding of wild animals is wide of the mark. They do not select, but intermingle, the worst animal having the unopposed opportunity of begetting offspring worse than himself. This applies to form, habits and vice, equally with all physical defects and qualities. —9. If there be no good and suitable rams on the station, they should be purchased from some well-known breeder, and a fair price paid for them, for it is false economy to purchase inferior rams at any price. The more you pay for rams they will (or at least should) be, and of course the more you will get for your wool. When the first dropping of these ewes by the rams you have purchased are about 20 mos. old, select 50 of the very best of them, and purchasing from the same party who supplied you with your first rams a very superior one, put him to your 50 selected ewes, or to 100, if you can find that number of sufficiently good quality. If you breed from the 50 only, you will possibly have, at weaning-time, 20 or 22 ram lambs; from these select the very best one, and when the proper time arrives, put him and his sire to the first selected 50, together with the 22 or so of his own age, provided the whole of the 22 are good; but should any of the 22 be inferior, in consequence of their dams throwing back, cull them at once, and keep only such as are faultless, or nearly so. By these means, as the old rams give up, you replace them with better stock, as the father of the young rams was worth about $225, whilst the old ones cost probably no more than $22.50 or $27 each. Thus, in the first instance, you buy better sheep than your own; consequently, the first lambs of that drop must be better than their mothers; and these again, being put to rams very much superior to either father or mother, must improve your flock rapidly.

RAM.

CHOICE FOR BREEDING.—It is of great importance that the ram be thoroughbred, whether the breeder's object be wool or mutton. In choosing a ram, the following points are requisite: The maximum wool with the minimum of yolk; the greatest amount of muscle done up in the least wrapping of skin; an animal that will reproduce himself the greatest number of times—constitution, wool, mutton.

INFLUENCE UPON PROGENY.—Males do but little influence the number of the young, the female having the power; but a male, being a twin or a triplet, will sire a daughter or daughters which will breed twins or triplets. Every male conveys the qualities of his dam to his daughters because they follow their sire's mother in ability to produce young.

SERVICE.—Keep the ram apart in an inclosure with a couple of ewes only; have the ewes brought singly, and allow only one leap to each. By this method a ram impregnates twice the number of ewes he would do, if turned loose among them, especially a young ram. The period during which the ram is to go with the ewes must be regulated by climate, and the quantity of spring food provided. The rams should be shorn about a fortnight previous to being turned among the ewes, and kept in an open shed up to that time, in order that they may gradually become accustomed to the loss of their coats, otherwise, in case of their being turned into the open field when recently shorn, they suffer in health and condition during the night frosts, which often happen in the early part of the month of May. In the south of England the ram is turned with the ewes in August for the main crop of lambs. In the later districts of England the ram is put with the ewes—1 to 60 or 70—and both are put in good pastures, and kept in good condition by ample feeding. The rams are not taken from among the ewes in ordinary farm practice in the autumn; and on the moorland farms of Scotland they are not generally admitted to the ewes until November. The ram is generally removed from among the ewes in lowland districts toward the end of this month.

EWE.

FOOD.—Ewes that are to bear lambs, should be well fed, and begin winter in good condition A little grain will do much to insure strong lambs. Keep nursing ewes by themselves, and give scalded bran and oatmeal daily. Sugar beets or potatoes, sliced and sprinkled with 1 qt. of middlings or bran, for each, will produce abundant and rich milk.

LAMBING, Time for.—The ewe flock needs constant care in March, which is in most districts the chief lambing season. The lambing season commences on all lowland farms in February, and the constant care and attention of the shepherd are then required. Ewes of some breeds of sheep will lamb in January. They should be provided with shelter, food and attendance. They seldom need turnips till near the end of the year, most farmers having grass sufficient for the ewe flock till they are

near lambing, when they should have turnips regularly given them. If it is desirable to obtain early lambs, they should come in January or February; but it is indispensable to have suitable accommodations, where the ewes may be kept separate and comfortable, and not pinched by cold. To secure lambs early, the sheep should be coupled in August or September, if it is desirable to raise early lambs for market; and, as the best prices are obtained early in the year, it is important to have the lambs come as early as they can be well looked after.

LAMBING, Treatment Before.—To enable the ewe to produce her lamb with safety, she should not be too well fed; high condition will dispose to fever; and with too poor keep the ewe will not have strength to go through safely, nor will she have milk enough; 1 pt. of bran or oats, or an ear of corn every day, will be useful. Ewes that will have early lambs should be separated and carefully tended; and, at night, they should be folded in a sheltered place. Ewes in lamb are likely to take cold, and when exposed to wet and cold, or allowed to lie on the ground, are apt to suffer abortion. One point is also deserving of much attention, which is, that few things contribute more to the health and well-doing of ewes in lamb than by causing them to take a fair amount of exercise every day. About three weeks before lambing, mix with the pulped turnips and chaff brewer's grains, bean meal, crushed oats, or some other extra food, to bring the milk upon them; and the same feeding is continued after they have lambed until there is a full bite of grass for them. Also allow them a limited quantity of hay some weeks before they lamb, so that the lambs may be fat and ready for market as early as possible. It is requisite to provide suitable lambing paddocks or pens for the lambing season, to which the ewes can be taken every night. In them, and also about the pasture fields, or adjoining fields, shelter pens should be constructed, into which a ewe about to lamb, or immediately after she has lambed, should be put, if the weather is unfavorable. These pens are made with straw-wattled hurdles, five hurdles making a double pen, three being set down parallel with each other, and so near that the other two hurdles form the back and front. As the season draws nigh every preparation is made, and the allowance of food is increased. The ewes being heavy with lamb, require additional support. When their "time is up," ewes should be constantly watched for a few days upon the pastures where they have been wintered. As soon as the lambs begin to fall, they are collected into a roomy field, provided as above, in the corner of which, adjoining the shepherd's house, are the lambing paddocks, into which they are driven every dark and unfavorable night. In fine open moonlight nights they are sometimes left out, as it is desirable that the paddocks or lambing pens should be freed from taint, *i. e.*, be sweetened occasionally. Tainted straw or gangrenous droppings are sometimes fatal to ewes if they come in contact with the wounded uterus. On many large farms in parts of the country, ewes are generally if not universally lambed while on turnips. In such cases lambing-yards, or pens of sufficient capacity, should be provided, with a temporary house for the shepherd. It is constant and untiring attention that is required. It is only in special cases that the shepherd's skill and experience are brought into requisition.

LAMBING, Treatment During.—The ewe goes with the lamb for 5 mos. The period of lambing having commenced, the attendant should observe every ewe that appears to be in labor, but should not be in haste to render assistance, until the strength of the ewe appears to be declining. If she is to be driven to the fold, let it be done gently. Before assistance is given see that the fœtus is coming properly, which is with the head crouched between the forelegs; if wrong, it must be turned to the proper position. In case of twin lambs, the one which is least advanced must be put back, and the extraction of the other assisted. If the fœtus be dead, extract immediately. The following are useful to produce parturition:—1. A decoction of horsemint, or any other kind of mint.—2. Bruised ergot of rye, 1 dr.; boiling water, 1 pt.; infuse for ½ hour, and give ½ part; repeat if necessary. The ewe is occasionally subject to after-pains; 20 drops of laudanum should be given in a little gruel, and repeated every 2 hours till the pains abate. It will always be prudent to bleed if not better soon after the second dose.

LAMBING, Treatment After.—Ewes should be allowed rest, quiet, and good feed. If any do not seem to give milk enough, separate them from the rest and give oatmeal gruel, roots, bran slops, and, if possible, second-growth grass. As the ewes lamb, they should be drafted off to other pastures, and the lambs ought there to have access to a fenced enclosure, where they can enjoy a ration of corn and cake to themselves. Ewes should be well treated on the pastures, receiving cut mangolds, and oats and peas daily, until there is a full bite of grass, and the lambs are well grown and able to help themselves.

LAMB.

CARE.—After the lamb is dropped, the ewe will generally lick it dry; if she refuses, it should be wiped dry. The lamb will soon attempt to suckle; if it does not, assist it. If the ewe refuses the lamb, she should be held while it suckles; repeat a few days until she owns it. If the lamb is intended for market, let it eat while young. Feeding may begin at about 3 weeks of age; Indian meal or oatmeal gruel may be given. The ewe should be fed bran, oil cake or oatmeal; heating food, like corn, should not be given.

CASTRATION. — Castration should be performed when they are 10 days or 2 weeks old. They should be in health, and the weather fine, but no twarm. An incision is made into the scrotum on each side, through which the testi-

ches are successively protruded, and they are taken away by severing the spermatic cord. A simple operation.

CHILLED LAMBS, To Relieve. — Bring the lamb into the house, and lay it on a warm blanket on the floor before the fire, so that it may receive all the warmth possible. Beat up 1 egg, and place the cup containing it in a basin of hot water, and stir until warm; feed it to the lamb, and in less than 1 hour it will be ready to go back to the yard.

FEEDING.—Lambs should be fed very lightly at first, for fear of starting the wool. Oats are better than corn, and the feed for each may be increased so that at the end of 2 or 3 weeks it reaches ½ pt. If corn is fed instead, less will suffice. A small amount of grain during winter, with plenty of hay, straw, pure water, good shelter, dry litter, ventilation, and a little salt once a week, will keep lambs growing and in health through winter. A mixture of 1 part of oats and 2 parts of bran is excellent to feed lambs. When the ewe has no milk, feed the lamb on condensed milk diluted with warm water, 2 parts water to 1 of milk.

TRAINING.—By training a pet lamb to come at call, and afterward putting it with the flock, the owner can call his sheep wherever they hear him, and the pet will come, followed by the other sheep.

WEANING.—The period of weaning differs according to the locality of the farm, and the quality of pasture. In a mountainous situation, and where the land is inferior, weaning often takes place when the lambs are not more than 3 mos. old; it requires all the time to the beginning of winter to bring the ewes ready for the ram or fat for market. The time is from the 1st to the middle of July, and the lambs are separated from the ewes. Take away a portion of the ewe's milk at intervals, to prevent distension of the udder; dry them by degrees. Put the lambs into a good pasture in the summer, to make up for the loss of milk. When the grass begins to fail, supply with turnips, which, with hay are to be their food during winter.

General Management.

Feeding and Fattening.

REMARKS.—A sheep, to be well and hearty, must not be starved at any period. It must feel comfortable to grow wool every day. A sheep out of condition is subjected to ailments that, in good condition, would not have affected him. September and October are favorable months for fattening stock, as severe storms are then few. The temperature is neither very warm nor very cold. During this season a larger proportion of food consumed by animals is converted into fat and muscle. Exercise during hot weather is fatiguing and requires the expenditure of muscular power. During severe cold a large proportion of the food consumed is employed in the production of heat, where animals have little or no shelter. Sheep must be kept dry, have a ration of roots or grain, and be kept from fields in the spring, if lambs are expected to live. No good farmer should allow the first blade of grass to entice his sheep. Coarse wooled, large sheep, will thrive in confinement, and it is wrong to imagine that, after running in the fields through the winter, in the spring they can be fatted up by extra food all at once.

FEEDING.—When sheep are well fed in winter, the wool starts to grow, but if any starving takes place, the fibre will have a weak place in it, and be unfit for combing wool. Those intended for the butcher after shearing in May should receive from the 1st of November, peas, oats, or oil-cake, commencing with ¼ pt. of the first, ¾ pt. of the second, or ½ lb. of the third; and increasing gradually up to ¾ pt., 1 pt., and 1 lb., respectively each. They will eat with these from 15 up to 25 lbs. of cut Swedes each daily, according to the weight of the animals. It is a fair rule to go by, that an animal when full grown will eat daily of green food a weight equal to ¼ the weight of its carcass when in fair condition; and it may be assumed that the oil-cake given will reduce the quantity of Swedes required by about 8 lbs. of the latter for every pound of the former. A good crop of Swedes pulled and cut, the sheep being folded on the the land, will keep 10 sheep for 5 months per acre; the same crop may be assumed as equal to the keep of 13 or 14 under shed.—*Beans.* There is no more valuable food than beans. In the production of fat they are inferior to corn and the small grains, but superior in the production of flesh. All young animals are benefited by beans.—*Bran.* Breeding ewes thrive better upon bran than upon corn. Bran supplies nourishment better. Oats are next in value. Mixed food is the best; 1 bush., each, of corn, rye, buckwheat, oats and bran, mixed, combine the most nutritious food elements; 1 pt., daily, will be a fair allowance.—*Buckwheat* may be fed, but it should be given lightly; ½ gill the first few days, gradually increasing the amount.—*Corn.* Sheep may be carried through an average winter with the food furnished by the corn field.—*Clover Hay.* Sheep fatten readily on good clover hay, if cut in full bloom, to retain the juices.—*Pine Boughs.* If given once or twice a week, they will create an appetite, prevent disease and increase health.—*Potatoes.* Sheep thrive upon raw potatoes.—*Salt.* Sheep are fond of it, and it is said to be a preventive of rot, worms, braxy and other diseases. It increases appetite, promotes digestion, modifies their natural timidity, and may be given in moderate quantities 2 or 3 times a week. It is said to improve the quantity and quality of the wool. Sheep fed on roots or succulent food are benefited by salt, which prevents swelling or flatulence.—*Water.* Give plenty of water at all seasons, and have it ac-

cessible to them. Where it cannot be furnished by streams, springs or wells, the flock should be allowed to drink for some length of time every night. Where such is the custom, sheep will seldom frequent impure ponds, and will remain at the yard under sheds until daylight, when they will return to the pasture without a shepherd. If water cannot be given more than once a day, it should be given at night, as grazing takes away the desire for water, and thirst does not begin to be felt until after the effects of morning feeding are past and the grass is dry and parched.

FOLDS.—A considerable quantity of manure may be saved by folding at night during the winter, though such practice would be injurious in warm weather. As a rule, sheep carefully sheltered from severe weather, will be in better condition, and their wool finer and softer than if left exposed. The objection to folding at night is that in warm weather they feed at night time, and it is an objection to have to withdraw them from their feeding grounds just when they feed best. They can be taken in at the close of twilight and put out at daybreak, and thus have the cool of the day to feed in. See that they have a dry and soft bed. Plenty of bedding is very important. The buildings must be clean, and the floor strewn with straw for bedding. At least twice a week this should be carted out. To prevent the yard from becoming a slough of mud, the eaves of the shed can be guttered with 2 planks, nailed edges together, forming a trough, which will convey the water from the yard through the means of other troughs arranged for the purpose. Place the racks in a line, facing the open part of the sheds, leaving a space for the sheep to pass in and out. Make each rack of a single plank, 20 ft. long, 12 in. wide, and 2 in. thick, into each edge of one side of which, rounds 3 ft. long may be inserted to incline outward at the tops. Leave a space of 5 in. between each round, and set in 2 or 3 at each end, to prevent the sheep from jumping into the racks. Mount each one upon 4 legs, 2 feet high, giving them a sufficient spread. Place the troughs convenient to the root house, make them of plank, giving a length of 20 feet, a width of 12 in., and a depth of 4 in., to each. Over each trough, fix a plank on supports, rising from each end, and tenoned to fit into mortice holes in the plank. A long nail, passing through each tenon, will keep the cover in its place, thus preventing jumping into the troughs. Before the hay racks are filled, the sheep must be turned out, to keep them from getting seed in their wool; and if the racks are well filled in the morning, each will feed 100 sheep during the day, provided they can pick at a little green food.

HERDING.—The practice of close herding to keep sheep from running themselves poor, is erroneous. Sheep thrive when traveling 5 to 7 miles per day; but they should not be driven. All that is necessary is to keep them headed in the desired direction, and they will feed as they go. If this method is adopted with a flock that has been accustomed to close herding, they will run furiously for the first week, but when they see that they are not stopped, they soon settle down so as to consume ½ day going out from 2 to 4 miles, and the other ½ coming home. The herder should refrain from following so closely as to annoy the sheep by the presence of his dog. Sheep should not be driven unless it is urgently necessary, as in fetching them home against a storm, or when they become stubborn. To protect from dogs, put a bell upon about 15 or 20 sheep in a flock of 100; 2 goats can drive away a dozen dogs. As soon as dogs enter the field at night, the goats attack them. Horses and sheep pasture well together, the horses protecting the latter from dogs.

PASTURING.—The pasture should be changed every few weeks. In pasturing sheep and lambs the benefit is not only to the animal, but to the pastures, which are greatly improved. Sheep are indiscriminate feeders, and will bite grass, shrubs, weeds and every green thing that starts in spring, and thus destroy and keep down most of the foul stuff that usurps the place of grass; and they tend to leave pastures clean for grass to grow. Their manure, also, is absorbed by the earth and becomes plant food, and accomplishes what cannot well be done by grubbing or top-dressing to renovate land. If sheep graze wheat during the winter and early spring they will destroy numbers of the eggs and larvæ of chinch bugs, army worms and Hessian fly, which lay their eggs in spring and fall, and hatch the first warm spell. In many instances wheat has been saved from destruction by the grazing of sheep. Blue grass affords excellent winter pasturage, but early sown rye is a good substitute for this. The value of winter pasture can scarcely be estimated too highly. The idea that distaste for ordinary winter food is created, finds no warrant in the experience of those who have tested the policy. The advantages of winter pasture are found in the wholesome effect upon the animal system, by mingling the green and the dry food. Another consideration is the fact that exercise, which is essential to thrift, is secured while the few bites are being snatched from the frozen ground. It is important that the fences around sheep pastures should be close and well kept, especially that walls should be well laid up and gaps in rail fences stopped.

SHEARING. — This is an annual operation, usually taking place at the end of May or 1st of June, the precise period depending on the state of the animals, those in high condition being ready sooner than are lean, the wool coming off readily at that time. It is best not to wash sheep, as they are apt to catch cold, and the wool often becomes dirty before shearing. But if they are washed, the first object is to provide a convenient place. It is common for men to stand in the water for it, by which they sometimes get bad colds and rheumatic complaints, and must besides be supplied with gin; so disagreeably situated, they hurry over the work, and the wool suffers. A stream or pond offers the requisite opportunity for doing it well, and at the same time comfortably to the men. Rail off a portion of the water for the sheep to walk into by a sloped mouth at one end, and to walk

out by another at the other end, with a depth sufficient at one part for them to swim; pave the whole; the breadth need not be more than 6 or 7 feet; at one spot let in on each side of this passage, where the depth is just sufficient for the water to flow over the sheep's back, a cask, either fixed or loaded, for a man to stand in dry. The sheep being in the water between them, they wash in perfection, and pushing them on, they swim through the deep part, and walk out at the other mouth, where is a clean pen, or a very clean, dry pasture, to receive them. Of course there is a way to the tubs, and a pen at the first mouth of the water, whence the sheep are turned into it, where they may be soaking a few minutes before being driven to the washers. The shearing is done after a few days, during which the sheep should be kept in a dry meadow. The best method practiced is to lay the sheep on a bench or scaffold as high as suits the shearer, with the hind legs stretched out and tied; then put a rope or strap over the neck and through the bench, so as to keep the sheep from floundering or throwing its head up, with the feet toward you; then begin on the hind leg, and shear toward the head and back. When the first side is done, turn the sheep, with his feet under, so as to bring the back to you, and complete the shearing. This leaves the fleece whole.

WOOL.—The wool covering the ribs, back, shoulders and side of the neck, is considered finest; and next, that clothing the upper part of the legs and thighs, and extending up to within a short distance of the haunch and tail. A coarser kind covers the uper part of the neck, throat, breast, belly, and lower parts of the legs. Temperature, pasture, food and management, exert great influence on the fineness of the wool; and the value of the sheep is in proportion to the equal quality of the wool on all parts of the body. Soundness and elasticity are important properties, especially in long wool, in which they are indispensable. Fine wool has a regular fibre, free from coarse hairs; fineness of staple is always accompanied by an equal growth of wool over all parts of the animal, and marked by an absence of shaggy spots seen on poor and half-fed sheep. Felting on the back of sheep very much injures the quality of wool; and though this occurs among heavy breeds, yet it is commonly the result of a scanty supply of food. A desirable quality is softness of pile. This depends on the fineness of the fibre; and as the yolk imparts richness and pliability, as well as nourishment to the wool, it necessarily exerts some influence on the softness of the pile. The color of wool is of importance; for the purchaser never loses sight of purity and perfect whiteness. Sheep should never be lifted by the wool. When about to catch one, move carefully toward the one to be taken, until you are sufficiently near to spring quickly and seize the animal with both hands; then pass one hand round the body, grasp the brisket, and lift the sheep clear from the ground. The wool must not be pulled. If the sheep is heavy, let one hand and wrist be put around the neck, and the arm pressed against the leg.

WOOL, To Clean.—Make a hot bath composed of water, 4 parts; urine, 1 part; enter the wool, opening it out, to admit the full action of the liquid; after 20 minutes' immersion, remove from the liquid, and allow it to drain; then rinse it clean in running water, and spread out to dry. The liquid is good for subsequent operations; only keep up the proportion and use no soap.

TREATMENT OF DISEASE.

ABORTION.—Various causes produce it, such as exposure to severe weather, fatigue in snow, leaping ditches, crowding through narrow gateways, being worried by dogs, over-driving, a too free use of salt; but mostly by the unlimited use of turnips and succulent food, so as to cause diarrhea. It may occur at all periods of pregnancy, more especially when the ewe is about half gone. The first symptoms are dullness and refusal to feed; the ewe will mope and be heard to bleat unusually; followed by restlessness, often trembling, with slight labor pains, and in the course of 12 hours by abortion. *Treatment:* Prevent, by avoiding the causes mentioned above.

ANEMIA.—This is vulgarly called *Pale Disease.* Most common in young stock from 3 mos. to 1½ yr. old. There is weakness, loss of appetite, drooping head, the skin loses its reddish cast, the nose becomes pale, the eyes are devoid of the minute blood vessels seen under the eyelids in health. As the disease approaches death, the blood turns to water, and a ghastly whiteness is visible throughout. Sheep, when attacked are found infested with long, flat worms, which look like the tape-worm of the human family, only not as large. These worms increase in numbers and gradually destroy the blood, sooner or later ending in death, if the cause is not removed. *Treatment:* For 3 mornings give ¾ tablespoonful turpentine, with 2 tablespoonfuls raw linseed oil, to each lamb or sheep; skip 3 mornings; then give the same dose 3 mornings again. Continue this until the worms are removed. During this time give liberally of tincture of iron, ½ teaspoonful, once or twice a day. The animal should be removed to comfortable quarters during the above treatment.

APOPLEXY, or STAGGERS.—Cerebral apoplexy is the result of high feeding, and the system adopted for producing extraordinary plethora. Thus high-class sheep prepared for exhibition, and excited by traveling, have been known to fall dead in the show-yard. Hot weather, luxuriant grass, and over-exertion, or long journeys by rail, operate fatally on over-plethoric animals. Sudden as this disease usually is, there are however, premonitory signs, such as refusal to feed, loss of the cud, dullness,

congested membranes, hurried and heaving respiration. In acute cases the animal is first seen to stagger, or reel, fall, and after violent struggles dies, the whole of the stages being often completed within 15 or 20 minutes. At the commencement of the usual attack the signs are as follows: pulse full and somewhat accelerated, breathing loud and stertorous, nostrils dilated, blindness is evident, the eyes being open, but amaurotic, and as he moves about he falls over anything in the way. Some sheep will stand persistently, and ultimately will fall and die on the spot, others succumb when forced to move, and after falling, seldom move, and die very shortly. In all such fatal cases there is room for more than a secret belief that the accepted causes minister to some occult form of tissue degeneration within the brain. *Treatment:*—1. Bleeding, only while the pulse is full; in later stages it hastens death.—2. Strong purgatives, with enemas; and strong derivatives to the loins and spine, as liniment of ammonia, etc. Belladonna, nitro-glycerine, and bromide of potassium, to dissipate cerebral congestion, or injection of atropia hypodermically, and when tonics are required, strychnia or nux vomica to restore tone to the nerve tissue. —3. Give, for a purging drench, Epsom salts, 2 oz.; linseed oil, 2 oz.; warm water, 4 oz.; repeated every 6 hours, if the bowels are not well opened, and give once or twice a day tartar emetic, 2 gr.; nitre 1 dr.; gruel, 2 oz.; mix.—4. The advent of one or more such cases should induce the owner to investigate the causes, and he must discriminate carefully between this disease and others which also exert their effects through the medium of luxuriant pastures and highly nutritious food. The apparently healthy should be bled and purged, means of daily exercise also given, and food somewhat less stimulating be provided, a dose of saltpetre or chlorate of potash being placed in the troughs daily. Sheep recovering from the immediate shock of apoplexy are exceedingly liable to an attack of phrenitis, and ultimately succumb to that disease.

ANTHRAX.—Blood-poisoning among sheep, taking the various forms of anthrax, may have their origin in the organic impurities of water, food, etc. Pastures near the farmyard, laid down during many years, are often loaded with the putrid elements of manure to an extent far beyond its power to assimilate, and they are taken up unchanged by the vegetation, to its great detriment as food for stock. The importation of wool, coming from foreign countries never free from anthrax, largely contains the poisonous germs. The hoofs, horns and hides of cattle transmitted from similar places are equally dangerous commodities. But refuse wool proves a most widely destructive agent, as it is turned out of the cloth manufactories of the United Kingdom in the form of shoddy manure. Land fertilized with these preparations is often constituted a permanent home of the disease, the most virulent and fatal forms being developed among cattle, and even mankind. Palliative and preventive measures are recommended rather than active remedies, including the removal of dead animals, and separation of diseased from healthy ones, as well as small doses of purgative medicine, followed by small doses of nitre.

BLADDER, Weakness of.—Sheep in low condition, having passed through a trying winter, or the effects of protracted disease, are sometimes unable to discharge efficiently the contents of the bladder in a continuous stream. There are no evidences of pain, but the attempts to urinate are frequent; the animal stands passively prepared, without straining, and succeeds only in discharging a small quantity in an intermittent flow. The cause is want of tone in the bladder, notably the muscular coat, arising from general debility of the system or a previous attack of inflammation. *Treatment:* Promote regular action of the bowels by means of enemas; give linseed mucilage as a drink, and let the food be composed of the best kinds, supplied judiciously, with ample opportunity for exercise. The remedies should comprise tonics, as saccharated carbonate of iron, 1 oz.; gentian and ginger, of each, 2 oz.; linseed mucilage, 1 pt.; divide into 4 or 6 doses. The iron, gentian and ginger may be mixed and divided into 4 or 6 powders, 1 of which may be given in manger food, morning and night; 1 or 2 gr. of finely powdered cantharides may be added to each dose of the tonic powders, and continued a few days, missing 1 or 2, and renewing the dose in like manner as required, until the full tone and functions of the bladder are restored. Uncertain and dangerous results are common where cantharides are administered incautiously and irregularly, or when continued too long. Careful attention to the directions already given are therefore essential.

BOTS.—The symptoms are nausea, weakness, sneezing, slow pace, turning the head, holding it down, and pushing against the nearest object; a shining, pus-like matter flows from the nostrils, often adhering so firmly to the apertures as to close them up, and cause difficulty of breathing; dullness, indifference, swelling of gums and mouth, ulceration and convulsions. It also makes the sheep turn round frequently, as if they were infested with hydatids, which occasions the disease called the gid. *Treatment:* They are either taken out alive, by trepanning the skull, as for hydatids, or an attempt is made, by injection into the nostril of animal oil, diluted with water, to kill them.

BOWELS, Inflammation of.—The symptoms are, restlessness; resting on one side, and then on the other; walking up and down, as if looking for a place to lie down. *Treatment:* 2 oz. castor oil; 5 gr. calomel; 2 dr. laudanum; 2 oz. molasses; beat up with an egg and as much water as will be sufficient for a small drench. Repeat in $\frac{1}{2}$ doses every 6 hours.

BRAIN, Hydatids on, or GID.—A complaint proceeding from the presence of bladder worms (a species of tapeworm) in the brain, lodged in a sac or bladder, which presses upon the brain. *Treatment:* When once seated, nothing can be done, though the skull is often examined for a

soft spot on the bone, where the water is collected. Perforate the skull with a trocar, accompanied by a tube, through which the water may escape; after which, apply a few drops of essence of myrrh to the aperture; shelter the animal and dress the wound.

BRAIN. Inflammation of. — Often attacks the healthiest sheep of all ages, more frequently in hot weather. The eyes protrude, are bloodshot and bright; the countenance eager and ferocious. The animal is in constant motion; he gallops about, attacking his fellows, the shepherd, and sometimes a post or tree; he is laboring under delirium, and this continues until he is exhausted. He then stands still, or lies down, panting dreadfully, when he starts afresh, as delirious and as ungovernable as before. *Treatment:* Bleed from the jugular vein until the animal falls; then give a purging drench. The sheep should be removed into a less luxuriant pasture.

BRAXY.—A blood disorder, having special manifestations due to sudden changes in the quality of the food, as when sheep are folded on turnips, rich pastures, etc., and otherwise forced in order to prepare them speedily for the butcher. The symptoms, as a rule, are very speedily developed, and very few premonitory signs are observed. When such are present, they consist of unusual excitement, bloodshot eyes, full and rapid pulse, accelerated respiration, mouth, body and limbs are hot, costive bowels, deficient and highly colored urine, with a peculiar staggering gait, in which the creature takes short steps. Colic, as indicated by uneasiness, lying down and rising repeatedly, is characteristic of some cases; while others separate themselves, and stand persistently with the back raised, head depressed, hanging ears, clapped fleece, dull eyes, and swollen abdomen. In the more violent cases, the above mark the commencement of the critical stage, when the feces are voided with pain and covered with mucus, or even blood; the heart throbs violently, and colic causes great uneasiness, between the paroxysms of which sudden insensibility comes on, and passes into distressing convulsions, in which the animal expires. In some instances the final struggle takes place while the animal stands, or has just risen to its feet. He then throws the head upward and backward, the fore limbs refuse their support, and he falls forward, death speedily following more or less painful convulsions. *Treatment:* Accumulated experience not only declares the uselessness of medical treatment, but strongly condemns it. When the symptoms are sufficiently recognizable the fate of the animal is already sealed, the termination, by a rapid and agonizing death, being very near at hand. The advent of the disease in one or more animals should prompt the owner to make a strict examination of the whole flock. Those in which the premonitory signs are even but slightly present should have immediate attention, a sharp run of 200 yards or more having the effect of stimulating the circulation as well as the digestive organs, at the termination of which it is a judicious proceeding to extract blood from the facial vein, jugular, plate or saphena vein. Purgatives with stimulants should immediately follow, the action of these being promoted by enemas of soap and warm water. A proper action of the bowels, with an improvement in the general appearance of the animal, will suggest a change of diet, some of the forms of a less nutritious quality, conjoined with the use of cooling salts, as the nitrate or chlorate of potash, being regularly supplied, and with these the opportunity for free exercise daily must not on any account be omitted.

BRONCHITIS.—This affects adult sheep when subjected to severe wet and cold, especially after being washed or shorn. Other conditions of exposure also bring it on, especially when food runs short in quality as well as quantity. Lambs are peculiarly liable to it, as a result of being too early subjected to cold, and especially prolonged wet weather. The symptoms comprise severe constitutional disturbance—fever, in which the circulation of blood is rapid, as denoted by the pulse, accompanied with a corresponding elevation of temperature. The first will number probably 100 beats, and the latter, as registered by the thermometer, may be 106° to 107° F. The cough is persistent, wheezy, troublesome, and even distressingly painful; the inspirations are short and difficult, and loud breathing sounds are heard in the bronchiæ by applying the ear to the bottom of the windpipe in front of the chest. *Treatment:*—1. Bleeding robust patients is tolerated only at the very outset, and when the pulse is full and strong. All depletive measures are hurtful beyond this stage.—2. The following proves a good fever draught: Take solution of acetate of ammonia, 1 fl. oz.; extract of belladonna, 20 gr.; cold water, 5 fl. oz. Make an emulsion by rubbing the extract of belladonna with successive portions of the water, then add the ammonia. This must be prepared as required. Stimulants may be added when necessary, as nitrous ether, or aromatic spirits of ammonia, when there are signs of prostration. The usual requirements for shelter, warmth, good bedding, and comfortable quarters must not be omitted as important factors in the cure of the patient.

CATARRH.—Sheep run at the nose sometimes on account of cold, but often it is chronic catarrh, which is not easily cured. The symptoms are, a thick yellow discharge from the nose. It clings to the nostrils, and obstructs the air passages, and is frequently accompanied by a cough. *Treatment:* If sheep are made to inhale the steam from hot vinegar, or a decoction of hops, they will throw out a great deal of mucus, which will be loosened by inhalation. The steam may be made by dropping a live coal into a vessel containing the liquid, or by inserting a hot iron. After the mucus has been discharged, smear the nostrils with pine tar. Scotch snuff dropped into the nostrils will cause the sheep to throw out the mucus, but this remedy is not so effective as the steaming. A hood may be put on the head of the sheep to prevent the steam from escaping, and the head of the animal must be held over the vessel.

Sheep affected with catarrh should not be exposed to cold storms or winds, as either will increase the malady.

CHICKEN-POX.—This affection bears close analogy to the *Varicella Bovum*, or chicken-pox of cattle, and has been described by various Continental writers. The symptoms arise in the form of slight constitutional disturbance, with the formation of pustules on the coronet of the hind feet, and on rare occasions only on the fore feet or lips. They are constantly found on the udder and teats, at first being minute, hard, and inflamed knots in the skin, which eventually suppurate, dry up, and leave a scab on the site. The duration of the disease lasts from 12 to 14 days. The disease has been described as an acute form of ecthyma, and is also considered by some as a variety of true sheep-pox. *Treatment:* Very little satisfaction arises from the best efforts in this direction. During constipation in the early stages the following drench may be given:—1. Take linseed oil, 4 or 5 fl. oz.; solution of the acetate of ammonia, 1 fl. oz.; sulphuric or chlorie ether, 1 fl. dr.; mix, and administer slowly.—2. The mouth may be dressed with the following: Take of alumn, in fine powder, ½ oz.; tincture of myrrh, 1 fl. oz.; sulphurie acid, 20 drops; soft water, 1 qt.; mix the alum with ½ of the water, add the acid, and stir with a stick until a clear solution is obtained; then put in the tincture and fill up with the remainder of the water, when the lotion is ready for use.

CHOKING.—This accident occasionally arises from the accumulation of food, or the lodgment of a portion of root in some part of the throat or gullet, when signs of severe distress are developed. Rupture of the gullet, or even the stomach, may ensue, the first arising from the obstruction, the latter in consequence of gaseous distension and interference with the functions of distension. When the obstruction is in the upper part of the throat, it may be reached by a long iron spoon, etc., and withdrawn; and at the outset, when situate within the upper portion of the gullet, the substance being small, it may be caused to pass downwards by gentle mechanical pressure outside with the hand, especially if a small quantity of the mixture about to be referred to is poured into the mouth and allowed to reach the spot. When the obstruction is still lower down in the gullet, and apparently fixed, a dose of the mixture, in conjunction with gentle manipulation, may cause it to descend. The most suitable remedy for this purpose is composed of 4 oz. of raw linseed oil, to which ½ oz. of sulphuric ether has been thoroughly mixed; 1 oz. of the mixture may be first tried, and the manipulation resumed, other portions being administered as required until the whole has been given. When this fails, the probang must be used with as little delay as possible, and in the following manner, avoiding force as much as possible, otherwise the gullet may be seriously wounded, an event which terminates fatally. The sheep is turned on his rump by a stout person, who from behind holds the fore feet in his hands, and with his knees grips him firmly at the shoulders. The operator, standing in front, fixes the gag in the mouth, or uses his hand for the purpose, and gently passes the probang, bulb end downwards, toward the obstruction, which, when reached, may be steadily pushed downwards into the stomach. During this operation the course of the mouth and gullet must preserve a straight line as far as is possible, which will greatly assist the operation. When this fails, the practitioner opens the gullet, providing the situation of the offending body is quite visible, and removes it through the incision. The wound is then closed by sutures, and usually heals without trouble, the animal being fed on soft diet for some time, and the wound protected by a bandage. In the absence of a suitable probang, one of which should always form part of the accessories of sheep industry, a stout cane or rod of hickory, elm, etc., about 5-16th of an inch in diameter, may answer efficiently, the end being protected by means of a piece of stout chamois leather, covering a piece of cork trimmed to form a ball-shaped protuberance about ¾ in. in diameter. To insure an easy passage, the whole should first be smeared with oil.

CHOLERA.—Hundreds of lambs die annually with this disease. Few flocks escape without a loss of 3 or 4, and many lose from 25 to 50. A thin lamb, or one poorly suckled or hand fed, seldom dies with cholera. *Treatment:* Stir as much salt into ½ gal. of pine tar as it will take. The lambs will then soon learn to lick the tar.

COLIC, Wind.—Also called *Blown* or *Bloat*. When sheep are first turned on a pasture more nutritious than that to which they have been accustomed, if they are not watched and kept moving during the day, and folded elsewhere at night, they are apt to overload the paunch, so that it can no longer contract upon and expel its contents; fermentation ensues, and the expulsion of gas; the paunch is extended to the utmost, and the animal often suffocated. *Treatment:* Pass a common elastic tube down the gullet into the paunch. Give a hypodermic of 1 gr. sulphate of morphine in solution under the skin of the neck, repeated every half hour, until evident narcosis. When a sheep is first seized, he will often be relieved by being driven gently about for an hour or two and put into a bare pasture. In the act of moving, these pillars will be occasionally separated a little from each other, and the gas will escape; but the animal must not be galloped or driven by dogs, lest the stomach be ruptured. After relief of the painful distension, give the following: Glauber's salts, 1 oz.; hot water, 1 oz.; peppermint water, 4 oz.; tincture ginger, 1 dr.; tincture gentian, 2 dr.; every 6 hours till the bowels are opened, and ½ the quanty the next 4 mornings.

CONSTIPATION, or STRETCHES.— Derangement of the stomach and intestines, as known by non-passage of excrement, is common to ovine animals of all ages. Adult sheep suffer on land of very dry nature, especially when the pasturage contains grasses and plants possessing astringent characters. An abnormal hardness, with scarcity of feces should lead to close examination, or enteritis, dysentery, etc., may

supervene. Injections of warm water (oil is preferable) or soap and water should be used, which will direct attention to the state of the anus, and consequently suggest the removal of feces, wool locks, etc., and other obstructions. Linseed oil is a safe and effective remedy for sheep of all ages, both as a purgative and injection. In young animals constipation may be treated by a mixture of warm milk, about 100° F., to which molasses has been added, to produce a reddish-brown color. A small syringe must be used, and 2 or 3 oz., according to size of lamb, must be injected. During the operation the lamb is held by the hind legs, and raised to a perpendicular position, the fore feet only being allowed to touch the ground. Some flock-masters use 2 or 3 spoonfuls of hog's lard as a purgative. Constipation in young lambs is a common result of being fed on cow's milk; sometimes the first milk of the mother brings about the same result; and young lambs allowed to drain the udder of the ewe after a long fast often suffer acutely. In addition to injections for this complaint, linseed or castor oil are safe purgatives, and are beneficially combined with rhubarb, ipecacuanha, ginger, gentian, etc., by which combined useful effects are derived. For constipation in newly born lambs, purge the ewe, and unload the rectum of the lamb by mechanical means. In more severe cases the lamb must be treated direct, and with promptitude, as constipation is frequently the precursor of serious and fatal complaints. An infusion of Eupatorium perfoliatum and pumpkin-seed tea are sometimes employed as laxatives in doses of 6 teaspoonfuls, and their action is said to be prompt and efficient. It is important to observe that on the removal of constipation the return to ordinary kinds of food must be observed with the greatest care. Small and frequent allowances of moist, laxative aliment only should be allowed, until the stomach has resumed its natural functions and the system has regained its usual tone.

COSTIVENESS.—This is not an infrequent complaint, and must be speedily attacked; for it is either the accompaniment of fever, or it will speedily lead to fever. *Treatment:* If there is fever, give tinct. of aconite root in 10-drop doses every 2 hours. Then give 1 sc. calomel; 1 oz. Epsom salts; 1 sc. ginger; 1 dr. gentian; 2 oz. warm water; 1 oz. linseed oil; give either alone or with gruel, to a full-grown sheep; and from ½ to ¾ to a lamb, according to age. After the operation of the cathartic, give as a tonic simple doses of quinine twice a day for 1 week or more.

CROUP.—This is common to lambs bred in localities subject to cold and damp, and also to those in high exposed situations. A severe form of sore throat—laryngitis—attacks the animal suddenly; the breathing is described as painful and wheezy, being seriously intensified by changes of temperature, and notably at morning or night. At these times the attendant cough is aggravated by spasms of the larynx, producing serious distress. Fever is intense; pulse will number from 90 to 100 beats, and the thermometer registers 107° F. or more. The specific sign in this malady consists of the formation of false membranes on the inner surfaces of the larynx, or throat—albuminous shreds—as a result of the violent inflammation in the mucous surfaces. These, in ordinary course, are discharged, on or about the third day, by the violence of coughing. *Treatment:* When a number of animals are affected, their effectual treatment is a somewhat doubtful matter, unless careful individuals take up the task as a special duty. Fresh air and perfect ventilation, with freedom from cold draughts, are all-essential. These being secured, warmth to the skin should be maintained by suitable clothing. The next essential is a suitable degree of moisture in the atmosphere, which is readily liberated from heated water. A smart blister should be applied to the outside of the throat; this may consist of the usual oil of cantharides or mustard, to which turpentine has been added. The activity of the cough may be mitigated by aconite, chloric ether, chloral hydrate, tincture of opium, lobelia, etc. The mucilage of marshmallow, slippery elm, etc., are also available for the same purpose. In extreme cases it may be needful to dress the affected parts of the throat internally with a mild caustic, for which nitrate of silver is most useful, about 8 or 10 gr. being dissolved in 1 oz. of water. This should be applied by means of a roll of tow or piece of sponge firmly secured to the end of a suitable cane, piece of stick, or whalebone. Sudden prostration of strength is not an uncommon stage in the progress of this disease, which requires the administration of stimulants, as the aromatic spirits of ammonia, and tonics, as gentian, quinine, etc.

DIABETES, or PROFUSE URINATION.—An abnormal discharge of urine, probably not in all cases meriting the term diabetes, may exist in consequence of mere functional derangement, the original cause being the irritant properties of plants, etc.; forming the food of the animal. In such cases the odor of the plant may prove a guide to the cause. Diabetes, however, attends upon wasting diseases, especially those which result from improper food and defective management generally. The symptoms comprise a chronic form of dyspepsia, rapid loss of flesh, pale membranes, irregular bowels, unequal temperature, small, weak, and irregular pulse, abnormal appetite, and inclination to eat rubbish. The prominent symptom is profuse urination, coupled with increasing weakness. The animal wanders away alone, and is eventually found dead in some isolated spot, or has fallen into a brook, river, pit, or over the rocks. In these cases the cause is not always properly made out, death being ascribed to the accident instead of the disease. *Treatment:* Rarely successful. Mild aperients are needed to correct the prevailing dyspepsia, which are to be followed by iodine, phosphate of iron, etc., the food being of the best and most nutritious character, as well as of easy digestion, and supplied with sound judgment. Warm and sheltered quarters, good beds, and efficient nursing are pre-eminently necessary.

DIARRHEA.—Frequently attacks lambs when

they are but a day old and carries them off in a day. Oftener it does not appear until they are nearly a week old, and the lambs have not then a much better chance. But if they are 2 or 3 mos. old, and have gained a little strength, they may, perhaps, weather the disease. Sheep changed from dry food to grass, frequently have it. *Treatment:* Remove the sheep from dry pasture and give only dry food for a few days. For lambs give the following:—1. 2 oz. prepared chalk; 2 dr. powdered canella bark; ½ oz. tincture catechu; ½ oz. laudanum; 1 pt. water.—2. 2 oz. castor oil; 2 dr. laudanum; ½ to ½ is a dose for a lamb.

ECZEMA.—A form of erythema attended with the formation of numerous small vesicles or bladders. These by bursting leave the skin and wool moist with their contents, and occasion great irritation, causing the animal to rub the affected parts against some object, as a wall, post, etc., eventually producing a sore. Newly washed or shorn animals are affected, especially as a result of cold weather succeeding the operation. Successive crops of vesicles appear for a time, invading fresh skin, and thus the disease is continuous. Plethoric animals are the common subjects. *Treatment:*—1. Administer an aperient; Epsom salts, 4 to 6 oz.; gentian, 1 to 2 dr.; ginger, 1 to 2 dr.; mix, and administer in linseed mucilage. Follow with daily doses of the nitrate of potash in the food.—2. Laudanum, water, and glycerine may be used as a lotion.—3. An ointment of morphia, belladonna and lard is exceedingly efficacious.—4. Regular diet, exercise, cleanliness, etc., are important auxiliaries in the process of cure.

EPILEPSY.—In this disease the animal suffers from convulsions. The duration of the fit varies; sometimes it terminates at the expiration of a few minutes; at other times, ½ hour elapses before it is perfectly conscious. *Treatment:* Give dr. doses of bromide potassium, 3 times a day, dissolved in gruel.

EYES, Inflammation of.—*Treatment:* When there is much inflammation, bleed slightly from the facial vein, that is the vein which runs down obliquely from the eye, and bathe the eyes with the following: Nitrate of silver, 5 gr.; water, 1 oz.; laudanum, 15 drops; dissolve the nitrate of silver in the water; add the laudanum, and mix.

FLEAS.—*Treatment:* Mix 10 parts benzine, 5 parts common soap, and 85 parts water. Generally one or two applications to the fleece are enough.

FLEECE, To Prevent Diseases of.—To prevent sheep from contracting disease, wash them twice a year. The following is a good contrivance: Have a ditch dug 8 ft. in depth, a little over 1 ft. wide and 100 ft. long; in this put 600 gals. water; 200 lbs. sulphur; 100 lbs. lime; 6 lbs. soda; all of which heat to 130°; for a small flock, this size and the quantities of materials can be reduced *pro rata*. Drive the sheep into a trap at one end, and they will be compelled to swim through to the other side, thus securing a bath and taking their medicine at the same time.

FOOT ROT.—A disease where the hoofs unite with the bony structure, and in the cleft between the hoofs. If not attended to at once, it suppurates and the hoofs come off. The first symptom is lameness. The foot is hot, and the animal shrinks if it is firmly pressed. It is particularly hot and painful in the cleft between the two hoofs; and there is generally enlargement about the coronet. There is an increased secretion, usually fetid, and often there is a wound about the coronet, discharging a thin, stinking fluid; sometimes there is a separation of horn from the parts beneath, and that too frequently preceding the dropping off of the hoof. *Treatment:*—1. Pare off all the diseased portion; wash off the matter and apply the following: Turpentine, 2 oz.; sulphuric acid, 2 dr.; lard, 1 lb.; tar, ½ pt. After treatment, the animal should be kept on a dry footing. As soon as the disease appears in a flock, the sheep affected should be isolated at once.—2. 1 oz. corrosive sublimate; 1 oz. blue vitriol; 1 oz. spirits of salts; 1 oz. verdigris; 1 oz. horse turpentine; ¾ oz. spirits turpentine; 4 oz. mercurial ointment; mix well, and keep tied down in a bottle when not in use. Apply every 2 days.

HEAD, Grubs in.—Caused by the worm hatched in the nostrils from eggs of the sheep gadfly. The eyes become weak, watery and swollen, and the sheep makes violent efforts to clear the nostrils. *Treatment:* Prevention is the best remedy. Set traps for the flys, and smear the sheep's nose with tar during fly-season. Scattering slaked lime about the feeding places causes the sheep to sneeze, which expels the grubs. Scotch snuff injected into the nostrils will also expel them.

HEART, Dilatation of the.—This condition consists of an enlargement of one of the cavities of the heart, without material addition to the substance of the organ. The causes are those which produce enlargement. The symptoms comprise absolute lack of power, appetite, and energy; difficult breathing, increasing weakness, palpitations, tendency to faint, coldness of the limbs, etc. In this, as in enlargement of the heart, the animal must be kept very quiet; the forcing system of feeding must be abandoned, and preparation for the butcher accomplished slowly.

INDIGESTION and DEBILITY.—(*See Costiveness.*)

INFLUENZA.—This may be distinguished from a cold, or from bronchitis, by the discharge from the nostrils being more profuse and the eyes nearly closed, great uneasiness of the head, and a sudden prostration of strength. *Treatment:* The same as for *Catarrh*, which see.

ITCH, or SCAB.—An ailment that will spread rapidly through a large flock, causing the animals afflicted by it to lose flesh rapidly, and besides this they lose ½ their fleece. It is purely of a local nature, and due to an insect which attaches itself to the skin, and, in the movements necessary for the purposes of life, produces violent irritation, destruction of animal tissue, suppuration or formation of matter, ending in a subsequent incrustation over the affected parts. The skin of the affected parts first assumes a red appearance, shortly followed by a feeling of roughness under the finger,

which is due first to the slight raising of the cuticle, and very shortly to the formation of small white and hard spots, from the points of which yellow exudation rapidly follows; or they may be replaced by many small hard nodules, which successively become vesicles and pustules. The latter furnish the material for the scab or crust in the form of pus, which dries, and in the process becomes an isolated, round, and hard mass. In a subsequent stage further pustules form within the intermediate spaces, their contents uniting with the previous crop, that is, becoming confluent or running together. In this way the continued invasion of the acari produce new and large surfaces of diseased skin, constituting the state from which the vulgar term "scab" has been applied to the disease. Other changes also take place. The presence of pustular states cannot exist without calling into action the natural active processes for the removal of the diseased products. The lymphatic vessels and glands commence to absorb the effusion, the nature of which sets up some irritation within; they swell and become enlarged. This is especially aggravated by the extent of the abraded surfaces and subsequent attacks of the fly. *Treatment:*—1. Apply a mixture of 1 part of mercurial ointment with 11 parts of sulphur ointment.—2. Another useful remedy, which is more cleanly and agreeable, is composed as follows: Take "Sanitas" oil, 1 part; olive oil, 10 to 15 parts. Apply freely by means of a brush, taking care to break up the scabs and insure the entrance of the dressing beneath.—3. Take sulphur, 2 oz.; powdered sassafras, 1 oz.; honey sufficient to make into a paste. Dose, a tablespoonful every morning. Use, at the same time, a wash made of 1 gill pyroligneous acid, and 1 qt. water, mixed. Apply with a sponge. If a few applications do not remove the difficulty, take ½ pt. fir balsam, and 1 oz. sulphur, well mixed, and anoint the sores daily.—4. Use for a lotion, corrosive sublimate, 1 oz.; sal ammoniac, 4 oz.; spirits turpentine, 1 pt.; hot water, 2 gals.; dissolve the sublimate and sal ammoniac in water; then add the turpentine; separate the wool, remove the scab, and apply the lotion.

JAUNDICE, or ROT.—Consists of a superabundant discharge of bile, or an obstruction of the biliary tubes; and in either case a quantity of bile enters into the circulation, penetrates the capillary vessels, and tinges the skin. *Treatment:* Give repeatedly for a purge, 2 oz. Epsom salts; ½ dr. powdered ginger; 2 dr. aniseed; ½ pt. warm water. If this be too weakening, give 2 dr. powdered gentian; 1 dr. powdered Peruvian bark; ½ dr. powdered ginger; ¼ pt. warm water.

KIDNEYS, Inflammation of.—A derangement of these organs may result from external violence, or it may depend on the animal having eaten stimulating or poisonous plants. Its symptoms are, pain in the region of the kidneys; the back is arched, the walk stiff and painful, with the legs widely separated; there is a frequent desire to make water, and that is highly colored or bloody; the appetite is more or less impaired, and there is considerable thirst. *Treatment:* Give 1 oz. poplar bark, finely powdered; 1 teaspoonful finely powdered pleurisy root. Make a mucilage of the poplar bark, by stirring in boiling water; then add the pleurisy root; the whole to be given in the course of 24 hours. The diet should consist of a mixture of linseed, boiled carrots and meal.

LARYNGITIS.—Inflammation of the throat is of common occurrence during the repeated changes, and especially the ungenial states of the weather during spring and autumn. The usual signs of fever are observed, more or less intense, with proportionate increase of respiration, sometimes giving rise to panting; the head is held low and the muzzle protrudes, an attempt to obtain a free, straight passage for easy breathing; there is difficulty in swallowing, and it occasions a hard, tickling cough. These signs soon acquire intensity; the cough is troublesome and painful; the throat is also painful under pressure, the cough being reproduced by it. These conditions prevent the animal from taking food, or, if he attempts to feed, he cannot swallow, and the aliment is retained in the mouth, which is liberated in conjunction with much saliva if the jaws are separated by the insertion of a finger. The trachea or windpipe is also more or less affected, as shown by slight pressure inducing a cough and inconvenience in respiration. Sometimes swelling of the throat is seen externally. Under ordinary circumstances, weather being more genial and shelter, etc., available, the disease declines, and terminates by resolution, convalescence being established in a week or 10 days. Unfavorable cases terminate in bronchitis or sporadic pleuro-pneumonia. *Treatment:*—1. Ample protection from wind and wet is all-important, especially when the changes are severe and continued, affecting numbers of animals. Move the bowels by frequent warm enemas. Do not attempt to cause the animal to swallow medicines, or the result may be death by choking the passage to the lungs, etc.—2. The following may be used as an electuary: Take boratic acid, 1 part; linseed meal, 1 part; treacle, a sufficiency; mix the acid and meal in a mortar, afterwards add treacle to make a stiff paste; ½ teaspoonful to be placed on the back of the tongue, or between the teeth, 3 or 4 times a day.

LICE.—They run up and down over the body of sheep, causing a separation of the wool from the skin. They may be occasioned by dirt, insufficient food, or want of bodily exercise, or by previous disease. *Treatment:*—1. Use the following washes: 2 lbs. arsenic; 4 lbs. soft soap; dissolve in 30 gals. water.—2. 1 oz. corrosive sublimate; 2 oz. spirits of wine; rub the corrosive sublimate in the spirit until it is dissolved, then add 1 oz. cream of tartar; 4 oz. bay salt; dissolve the whole in 2 qts. water, and apply a little of it with a small piece of sponge wherever the lice appear.—3. Apply freely a mixture of 1 part sulphur with 7 of salt.

LIVER, Yellow Atrophy of the.—This form of derangement, unmistakably due to dietetic irregularities, constitutes a widespread source of loss among the flocks of New Zealand. The

symptoms are snatching movement of the right fore limbs after rest, with occasional lameness; dropping of both ears, at first only when at rest, afterwards constantly; a watery discharge from the eyes, and a peculiar and striking expression of face; disinclination to move, and apparent inability to bring the hind limbs forward, the feet seeming to be put down almost from whence they were lifted. The nose is protruded, the breathing becomes labored; the wool may be easily pulled out; and the sheep, having usually selected a quiet and shaded place, sinks and expires. Frequently from 36 to 48 hours elapse between the early marked symptoms and death, though often the time is much shorter, and a sheep will be found sometimes dying or dead which had previously shown no marked signs of illness. In all paddocks where these deaths occur it has been found that there is present in enormous excess food in which the albuminoid ratio must be probably 1.35. So great indeed is the profusion in which trifolia are found, that a sheep may almost lie down and obtain all it can consume without moving. Sheep will suffer from acute and extensive degenerative changes in the liver when kept under such conditions, especially in a climate like this. *Treatment:* The sheep should be removed to a paddock in which there is not a great profusion of food, and in which they will take exercise in search of it. Food must be at their disposal in such variety as will insure the presence of the well-known ingredients which are absolutely essential to the maintenance of a proper nutritive balance. Beyond this, a dose of laxative medicine, and a convenient supply of water, in which a little chlorate of potash may be dissolved, will be the only treatment necessary. When changes of pasture cannot be effected, the affected flock should be quietly driven into a stock-yard, or into sheep-pens, where such are available, each night, and only allowed on the pasture by day. Care must be taken to avoid overcrowding in the pens.

LOCKJAW, or TETANUS.—Caused by wounds on some part of the body. The jaws become set and the animal soon dies. The malady is usually fatal, and treatment is of little avail. *Treatment:* Keep the sheep warm and quiet; move the bowels as soon as possible with castor oil, and follow this with belladonna; when the animal begins to recover, give gruels.

LUNGS, Inflammation of, or PNEUMONIA.—The symptoms are dullness, hanging of the ears, quick breathing, cough, and discharge from the nostrils. *Treatment:* Dissolve 1 dr. tartar emetic in 2 oz. hot water; add 2 oz. laudanum; give 2 tablespoonfuls 3 times a day. After this a dose of salts should be given.

MEASLES, or RUBEOLA.—The manifestations of the disease are irritative fever, accompanied with elevation of temperature, catarrhal states, swelling of the head and throat, constipation, loss of appetite, etc. On or about the second or third day an eruption appears on the thin parts of the skin, chiefly confined to the inner sides of the thighs, also the sides of the body, chest, face, etc., consisting of perceptible elevation, with redness, which disappears on pressure. At the central part the swelling is also hard, from which point in the course of another day, arises a wheal or pimple, others also arising more or less on the surrounding surface, where such points of hardness were first observed. In 2 or 3 more days the acute signs are allayed, the spots become brown, the cuticle peels off, and the disease subsides by the ninth or eleventh day under ordinary circumstances. A peculiar odor of the skin is exhaled in the earlier stages, and the disease is propagated by the discharges from the nostrils and the scales from the skin. Fatal terminations are marked by the setting in of diarrhœa, on or about the ninth day. *Treatment:* From these characters the need of a definite method of segregation is indicated. The bowels should be moved during constipation by means of mild cathartics, as Epsom salts, followed by daily doses of saltpetre, hyposulphite of soda, etc., and a most essential proceeding is the daily application of "Sanitas" to the affected portions of the skin. Animals having recovered from the disease should be dipped in a "Sanitas" bath at the earliest and most suitable opportunity.

MICROBES.—Rural districts, islands of the sea, and mountains are free from microbes. In other words, fresh air, oxygen, kills them admirably. Open the windows and admit the health-giving breezes, which is death to all germs the result of filth. Lakes and rivers, free from sewage and decomposing refuse, do not contain bacilli. The direct or diffused rays of sunlight effectually destroys the pests. This is the universal remedy. As a sanitary arrangement, it is said that an open drain for conveying the fluids, etc., from houses is a sure preventive of disease. This old truth remains the same—given fresh air, pure water, with suitable food and exercise, health is preserved. Danger lies in the tendency to overlook or cover up the sources of disease, which are fairly well known, and, as a rule, may be suitably dealt with. Accept the axiom of the scientists, viz., "Mortality is lessened by hygiene," which simply means cleanliness in habitations, persons, and clothing, with pure air and water: and, as far as domestic animals are concerned, purity of stables, cow-sheds, sheep-folds, etc.

RICKETS.—This may be defined as inability to bear the weight of the body or the strain of muscular exertion. In this affection, as it occurs in sheep, the softening of the bones, arising from a want of earthy material, more particularly the earthy phosphates, with greater or less deformity, is the natural result of impaired function, having its origin in causes both remote as well as of a predisposing character. *Treatment:* That most likely to be of benefit will be of the character which will afford the necessary material for bone construction. Food rich in phosphates, as the cereals and oil-cakes, and even special forms of the salt as medicine, should be supplied, young lambs and sheep being additionally fed with fresh cow's milk. Rams and ewes apparently of rickety constitution should be rejected for breeding, especially if they have been known to yield offspring

tainted or affected with the malady. The number of the ewes for putting to the ram should be carefully estimated, and regulated so as to insure conservation of the vital powers. This is too frequently overlooked in the eagerness for gain. Ewes and rams at the time of mating should be in perfect health; liberal feeding with sufficient exercise are also called for during pregnancy, and when the yeaning time comes on, these precautions should not be relaxed, but regulated as the wants and condition of the animal may suggest.

ROT.—(*See Jaundice.*)

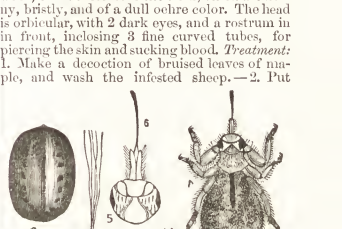
RUPTURE, or HERNIA.—This consists of the appearance, usually, of a tumor on the outer side of the abdomen, the contents of which are a portion or portions of the abdominal viscera. The most common form in sheep is situate at the navel, and is known by the term Exomphalus. The usual characteristics are a well-defined swelling, usually soft and fluctuating, which under ordinary manipulation disappears within the abdomen, and returns to its former size when pressure is removed. *Treatment:* Various methods are adopted. The most common consists in laying the animal upon its back, returning the bowel, and placing a ligature round the sac formed by the skin, which must be close to the abdomen. The circulation being thus cut off, the lower portion dies, and healing of the upper part ensues with adhesion to the orifice, thus closing it entirely. The orifice also may contract when pressure of the intestine is removed.

SHEEP LAUREL, Poisoning by.—When sheep eat of this shrub in great quantities, a disease is contracted called *Hoven*, with impactation of the rumen, accompanied by staggering gait, sleepiness, and inability to walk. *Treatment:* Give 2 dr. spirits ammonia in 1 tumblerful of cold water, once every hour, till 3 or 4 doses are given; withholding the medicine when the animal recovers, though only 1 dose has been given.

SMALL-POX.—This disease, although bearing the same name as that which attacks the human subject, is a perfectly distinct malady, and incapable of being communicated to man. In about 10 days from the time of the animal's having imbibed the contagion, feverish symptoms set in with a mucus discharge from the nose. Red inflammatory pimples begin to develop, first appearing where the skin is thin. After the pimples have been out about 3 days they assume a white appearance, and are filled with serum and pus. Some of the vessels dry up, leaving brown scabs; others, especially in the severer cases, run together, and the scarf skin is detached, leaving an ulcerated surface. It is in this ulcerated stage that the prostration reaches its height, and that most sheep die. *Treatment:* The affected animals must be kept separate from the healthy ones. Give 30 gr. chlorate potash, 3 times a day. Give nutritious food to tempt the appetite, such as bruised oil-cake, bran, and steeped oats.

SORE HEAD.—Often produced by the striking of the fly, especially in woody countries. Next to the tail, the head is most frequently and seriously attacked, and in defending themselves, the sheep are continually striking their heads with their hind feet, until at length a considerable sore or ulcer is formed. No sooner is this done than the fly persecutes the poor animal with tenfold fury, anxious to lay its eggs on or near the wound; and the ulcer will often spread so rapidly as to be difficult to heal, and occasionally it will destroy the sheep. *Treatment:* Procure a covering for the head, made of soft leather or brown paper. This should be cut so as to protect the whole of the head, and yet not to come too close to the eyes; then use the following lotion: 2 dr. carbolic acid; 1 pt. water.

TICKS.—This is one of the most annoying pests of sheep, and is not easily got rid of. When it becomes numerous it affects the health, lessens the growth of wool, and absorbs the vitalizing oil thrown out. The pupæ (shining bodies, like the pips of small apples, and similar in color) may be found attached to the wool; from these issue the ticks, which are horny, bristly, and of a dull ochre color. The head is orbicular, with 2 dark eyes, and a rostrum in in front, inclosing 3 fine curved tubes, for piercing the skin and sucking blood. *Treatment:* 1. Make a decoction of bruised leaves of maple, and wash the infested sheep.—2. Put



Sheep Tick.

1. Pupa. 2 Pupa magnified. 3. Tick. 4. Tick magnified. 5. Head. 6. Rostrum.

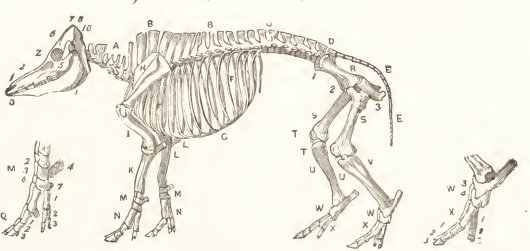
brown snuff into the wool. This is sure death to ticks.—3. Use mercurial ointment carefully, and in small quantities.

WOUNDS AND FRACTURES.—*Treatment:* If any sheep is hurt, catch it at once and wash the wound; and, if it is fly-time, apply spirits of turpentine daily, and wash with something healing. A broken limb must not be roughly stretched or handled, but the divided edges of the bone brought gently and as perfectly opposite, close and fitting again to each other as possible, and kept together by some strips of adhesive plaster, or pitch, spread upon leather, wound round the part. Over this splints should be placed, reaching a little beyond the joint above and below, and these confined with more plaster or waxed thread. A little lint or linen rag should be placed under the end of the splints, to prevent injuring the part beneath. This being done, the leg should not be meddled with until the bandage becomes loose, which will be in about 10 days. The splints must be replaced once, and, at the expiration of another 10 days, the edges of the bone will generally be found to

have united; the animal should be kept a little while longer as quiet as possible, and if the bone is not quite firm, apply the starch bandage to keep all firm, until perfectly healed. If swelling takes place after the splints have been employed, they have been put on too tight, or they do not press equally. They should not be taken off at once, but with a sharp and strong pair of scissors, 2 or 3 notches should be cut through the edge of the bandage above and below. This will afford sufficient room for re-establishment of the circulation, and the swelling will subside without the fracture having been disturbed.

SWINE.

ANATOMY AND BREEDS.



Skeleton of the Hog.

A, cervical vertebræ; B, B, dorsal vertebræ; C, lumbar vertebræ; D, sabrum; E, E, coccygeal bones; F, F, ribs; G, costal cartilages; H, scapula; I, humerus; K, K, radius; L, ulna; M, carpus or knee; 1, scaphoid; 2, semilunar; 3, cuneiform; 4, trapezium; 5, trapezoid; 6, os magnum; 7, unciform; 8, pisiform; N, N, large metacarpal or cannon; O, small metacarpal; P, P, sesamoid bones; Q, Q, phalanges; 1, os suffraginis or pastern bone; 2, os coronæ; 3, os pedis; R, pelvis (fore leg phalanges, 1, 2, 3); I, ilium; 2, pubis; 3, ischium; S, femur; T, patella; U, tibia; V, magnum; 4, cuneiform medium; 5, cuneiform parvum; 6, cuboid; 3, 6 cubo cuneiform; X, large metatarsal (hind leg, phalanges 1, 2, 3); Y, small metatarsal; Z, head; 1, inferior maxilla, 2, superior maxilla; 3, anterior maxilla; 4, nasal bone; 5, molar; 6, frontal; 7, parietal; 8, occipital; 9, lachrymal; 10, squamous-temporal; 11, petrous-temporal.

Swine have 44 teeth: 12 incisors, 6 upper and 6 lower; 4 canines or tusks, 2 upper and 2 lower; 28 molars, 14 upper and 14 lower. The pig is born with 4 incisors and 4 tusks On the 8th or 10th day, the 2d or 3d temporary molars appear. The 4 nippers, 2 on the upper and 2 on the under jaw, appear at 4 weeks old. The 1st temporary molars appear in the 5th or 6th week. At the age of 3 mos., the intermediate incisors appear. At 6 mos. the wolf teeth appear, and the 3d permanent molars. At 9 mos. the permanent tusks, permanent corner incisors, and the 2d permanent molars appear. At 12 mos. the permanent nippers appear; and at 18 mos. the 3 temporary molars will have shed, and the permanent ones appear. At 18 mos. the permanent intermediate incisors and the permanent rear molars will appear, and at 21 mos. these will be fully developed. After this, the age can only be determined by the wear of the teeth and the increasing length of the tushes.

BERKSHIRE.—One of the most popular of modern breeds. It came from the shire of that name in England, but has been much modified. It is now uniformly black, with some white on the face, feet, and tip of the tail, and these white markings are important. The hogs vary from medium to very large size; have a short, slightly dished face, with erect ears; short neck; noticeably broad back, straight, or slightly arched, with strong but finely boned legs. They

Berkshire.

have great vitality, fatten readily, and the meat is of fine quality, having a large amount of lean in proportion to fat. They require more feed in proportion to their weight than the breeds abounding in lard.

CHESHIRE.—One of the offshoots of the race common to the northern part of England. They are excellent bacon pigs, the sides being long, broad, and thin, and the flesh and fat streaked. They are good grass eaters, but by feeding on

corn have become more inclined to fat than the English races.

CHESTER WHITE.—One of the few American breeds. It took its name from its color and a county in Pennsylvania, in which, by various crosses, it was produced. Its size is large, nose straight, ears drooping, body long and deep, hams good, flank frequently light. In almost every State there are experienced breeders who prefer this breed to any other.

Chester White.

CHINESE.—Originally from Asia. There are 2 species, white and black; the former better shaped than the latter, but less hardy and prolific. Both are small limbed, ears and head fine, round in the carcass, thin skinned, and, when quite fat, the end of the snout only can be seen. They seldom reach great weight; are rather difficult to rear, and the sows are bad nurses. Their flesh is somewhat tender for bacon, rather fat, and their hind quarters so deficient in proportion to the size of the other parts, that they cut up to considerable disadvantage for hams. But their great aptitude to fatten, and the extreme delicacy of their meat, render them very valuable. The black are thrifty, and fatten on a small quantity of food. They are crossed with other breeds to considerable advantage, producing several kinds possessing properties superior to those of the parent stock. They are very prolific. There is also a mixed breed, patched with black and white; some with thick, pointed ears, like the true species, which they otherwise resemble in form; while in others the ears are rounded, and hang down.

ESSEX.—A small to medium sized, pure black breed, with fine dishing face, fine bones, great disposition to lay on flesh, and very quiet. It is admirably suited for crossing on coarse, rough hogs, but is counted too small for the great pork regions of the West.

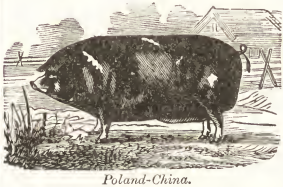
JERSEY RED.—The name most commonly given to a breed of large, strong, slightly coarse,

Jersey Red.

very hardy, healthy, and prolific hogs of a red or dark sandy color. They are sometimes called Durocs and Red Berkshires, although it is claimed by some that these are distinct breeds. Hogs of this general type have long been bred in New Jersey. They sometimes weigh from 500 to 600 lbs.; do not mature as soon as some other breeds; but are great favorites with many.

LANCASHIRE.—Divided into the short-faced, the middle breed, and the large. The short-faced are white, with short face, prick ears, and small bones. The middle breed partakes of the quality of the small breed and the size of the large. The large breed is the largest breed of swine known. They are short haired, hearty, and have flat backs, with large, square hams.

POLAND-CHINA.—Originated from various crosses and good selection by breeders in southwestern Ohio, and has been steadily improved for ¼ century or more. It is nearly black, often with the Berkshire markings, but white is not an evidence of impurity. The ears droop; the

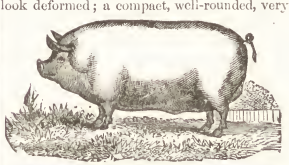


Poland-China.

size is that of the largest; the form like that of other good large breeds. It is quiet in disposition, matures early for a large breed, fattens well when young, and its flesh is of fair quality.

SIAMESE.—The animals are small, and have a cylindrical body, with the back somewhat hollow, and the belly trailing near the ground, on account of the shortness of the limbs. The bristles are soft, the color is usually black, and the skin externally of a rich copper color. The ears are short, small, and somewhat erect. The animals are not over hardy or prolific, and the females do not yield the same quantity of milk; but they arrive very soon at maturity; fatten on a small quantity of food, and their flesh is white and delicate.

SUFFOLK.—A small to medium-sized white hog, with peculiarities readily distinguishable. They have short, dished faces, so much so as to look deformed; a compact, well-rounded, very



Suffolk.

deep body on short legs and with heavy hams. They lay on fat with readiness; are quiet; mature early, but are sometimes shy breeders.

YORKSHIRE.—One of the best breeds. They are well haired, hardy, vigorous, prolific, and are good nurses, and weigh from 200 lbs. upwards.

Breeding and Rearing.

Boar.

AGE FOR BREEDING. — The boar may be coupled at from 6 to 8 mos. old, but it is better not to allow him to serve until 10 mos. old.

CHOICE FOR BREEDING.—Look to constitutional vigor; perfect form, without this, will degenerate the whole herd. The ideal boar has a short head, wide between the eyes; fine muzzle; lively eyes; silky ears; long, fine abundant hair, without bristles; short, well knit, straight legs; high, arching, short, full neck; full and rather compactly built body; strong masculine appearance.

Sow.

AGE FOR BREEDING.—Sows should not be allowed to breed until they are 1 yr. old, and if the female is kept much longer, it improves the size and vigor of the pigs.

CHOICE FOR BREEDING.— A brood sow should be a good milker; if deficient in this, she should not be retained as a breeder. An abundance of milk for the first 8 or 10 weeks of existence is the best preparation young pigs can have to fit them for profitable growth. Milking qualities in swine are as transmissible to progeny as in cattle. This trait may be greatly improved by retaining only good milkers for breeders, as well as by feeding them when young with a view to their development as milk producers rather than as fat producers. Spring and early summer litters are usually the best from which to select young brood sows. They can be kept through summer almost entirely on grass, which will make them grow nicely, and the exercise required in grazing will keep them in good health. At this period all animals naturally lay up fat which afterwards goes to enrich the milk. Hence, while not allowed to become over fat, they should yet be so fat as to supply this demand of nature, and retain the general vigor of the system.

FARROWING, Season for. — The best season for sows to farrow is April or early in May; an April pig is worth ¼ more than a July pig, and more than double a September pig. Some breeds can be fattened at any age, but will not fatten as well at 1 yr. or as much as at 15 to 18 mos.; a hog must arrive at full maturity before it is fattened. An April pig can be kept till a year from the following January at less expense and trouble than a September pig.

FARROWING, Treatment before. — Breeding sows are generally kept too fat. They will not bear when in this condition either so large or healthy pigs, and they are more liable to a wrong presentation, which is dangerous to both mother and young. A breeding sow should never be fed so liberally that she will attain her full growth. This is a condition for a porker and not for a breeding animal. A condition of half fat or thrift is the right one. There is large loss in making unnecessary growth with breeding sows in food which is thus wasted, and causing the sow to be too large and unwieldy, which makes her more liable to lie upon her pigs and crush them. Such sows will be slow to move, whereas, if lighter and more active, they would get up quicker when they heard the cry of a little one.

FARROWING, Treatment during.—Two litters of pigs may be obtained from the same sow in 1 year. The sow usually goes with pig 4 months. A week or 10 days before pigging, the sow should be separated from others, or the young may be devoured. If the mother shows any signs of devouring her young, muzzle her, and smear the little ones with whale oil and aloes.

FARROWING, Treatment after. — Sows should be fed lightly for a few days after the pigs are born, or there may be a surfeit of milk, which will cause the pigs to scour, taking more than they can digest, and causing caking of the udder and fever, which will check the flow of milk, and make it dry up. When this is the case, they should be thoroughly bathed with water, or vinegar, as hot as it can be applied. Thorough rubbing is also beneficial. Sometimes the mother's milk will not flow for a number of hours after the pigs are born. This condition may be known by the pigs appearing hungry and unsatisfied, and not lying quietly in the nest after sucking. Excellent food for increasing milk may be prepared by grinding corn and oats together in equal quantities by measurement, and making a slop of the mixture. To this may be added a little oilmeal with profit.

Pigs.

CARE.—The young animals, being tender, are liable to be destroyed after birth by the motion of the sow; to guard against this, they should be watched and the young ones removed as they are brought forth. During the 1st and 2d days after birth, or until they acquire strength, they should be removed from the sow, and occasionally admitted to suck.

CASTRATING.—The males may be castrated when about 1 mo. old; and a like operation, though not necessary, may be performed, at the same age, on such females as are not intended for breeding.

FEEDING.—Pigs need careful attention the first 3 or 4 weeks; about this period the pig reaches a point where the milk of a sow is not sufficient to keep up healthy growth, and, unless taught to eat before this time, there will always be trouble. The way to avoid it, is to teach them to eat and drink at the earliest age. This may be done by placing a little milk or other food, in liquid or semi-liquid form, in a

trough near them, but where the sow can not get at it. By the time the pigs are a week old they will learn to eat heartily. Give them plenty of nutritious food from this time on, and there will be no difficulty.

WEANING.—When they have been liberally supplied with food, weaning need not be deferred longer than 6 or 7 weeks; when delayed beyond this, the sow will be in low condition as the time of bringing forth young again approaches. When weaned, the young pigs should be fed 3 times a day on nutritious and chiefly farinaceous food, combined with milk or whey; and, in a few weeks, they will consume ordinary roots. Pigs, after being weaned, are sometimes allowed to go through the pastures, and depend on these for their food. In this case they frequently do great injury. The best plan is to confine them in pens, allowing them occasionally to go through the feeding-yard, to pick up any food scattered through it; and, in addition, supply them with a little green food, as clover during summer, and turnips or potatoes during winter.

General Management.

COMPARATIVE COST OF RAISING PORK AND CORN. — By the results of experiments, 1 bush. of corn, weighing 56 lbs., will produce 10½ lbs. of pork. Deducting 1-5 to come at the net wt., would give 8 3-5 lbs. of pork as the product of 1 bush. of corn, or 1 lb. of pork as the product of 6⅔ lbs. of corn; 3 4-5 lbs. of cooked cornmeal make 1 lb. of pork. Allowing that it requires 6⅔ lbs. of corn to make 1 lb. of pork(exclusive of the labor of the care of hogs), the proportion which the price of corn bears to that of pork, is exhibited as follows:

Corn per bush. Cents.	Pork per lb. Cents.	Corn per bush. Cents.	Pork per lb. Cents.
12½	1.50	38	4.52
15	1.78	40	4.76
17	2.	42	5.
20	2.38	45	5.35
22	2.62	50	5.95
25	2.96	55	6.54
30	3.57	60	7.14
33	3.92	65	7.74
35	4.	70	8.57

By reversing the above, the price of corn per bush. can be obtained at different prices per lb. for pork. The use of the above comparison is obvious. For instance, should corn be selling for 50 cts. per bushel, and pork for only 5 cts. per lb., it would be most profitable to sell the corn; but should corn be selling at 40 cts. per bush., and pork for 6 cts. per lb., it would be most profitable to reduce the corn to pork, and sell the latter. To find the price of pork per lb., taking the price of corn per bush. as the standard, divide the price of corn by 8.40 (the number of lbs. of pork produced by 1 bush. of corn). To find the price of corn per bush., taking the price of pork per lb. as the standard, multiply the price of 1 lb. of pork by 8.40.

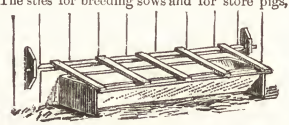
FEEDING AND FATTENING. — Feed about 3 times each day. When fed once or twice, hogs eat too ravenously, impair digestion and make themselves uncomfortable. Never add fresh food to any left in the trough from a former meal. If worth preserving, take it out, work it up with fresh food, and clean out the trough. When the substances employed in fattening have been juicy rather than nutritious, the flesh will be improved by feeding with bran meal, mixed with the other food. This is essential for bacon, as it hardens the flesh, and renders it mellow and firm. Some time previous to killing, the food may consist of about ⅔ steamed potatoes or roots, and ⅓ ground peas, barley, oats, bran, or corn, enlarging the quantity of farinaceous food as the animal fattens. *Apples*, boiled with meal, are good.—*Artichokes* are nutritious, and are said to prevent cholera. — *Ashes*, given in small quantities to pigs while fattening, are very beneficial, as their food is generally rich in phosphoric acid and deficient in lime.—*Beans* will be eaten by pigs, if thoroughly boiled, though they are not fond of them. Swine, fed on beans, will produce soft, spongy pork.—*Bran*, except in small quantities, is not valuable for fattening pigs. But, when rich, concentrated food is given, such as corn, barley, peas, or oil-cake, pigs should be allowed all the bran they will eat, placed in a separate trough. In this way it becomes useful and almost indispensable to the pig feeder. It is also very useful for breeding sows. — *Cabbage* contains a large per cent. of phosphoric acid, and is valuable food for young pigs. — *Charcoal* is a useful medicine, the best regulator of the stomach, correcting acidity and imparting appetite to the human patient. As the principal forte of the hog is to eat as much as possible, his organs of digestion are liable to derangement. Charcoal is perfectly harmless, and aids digestion. — *Corn* will produce the largest amount of fat when ripe. While the foliage is green, nearly every portion of the stalk will be eaten. Ears of corn sufficiently matured for the table make admirable food for hogs. If at any time they refuse to eat dried corn, try coarse ground cornmeal instead of corn on the ear; it may be that continued feeding of whole corn has made their teeth sore, and grinding it will help them along. — *Hay*. Cut the hay as short as oats, and mix with bran shorts or middlings, and feed as other food. Hogs learn to like it, and if soaked in swill, it is highly relished. In winter, use for hog feed the same hay that is fed to the horses, and while it saves bran shorts, or other food, it puts on flesh rapidly. —*Oil Cake*, fed in large quantities, injures the quality of the pork, but small quantities of it can be fed with advantage to the health and growth of the pigs, without any apparent injury to the lard or pork. It is useful for breeding sows, keeps the bowels loose, and increases the quality and quantity of milk. — *Peas*. Hogs are fond of peas, and, when cheap, they should be given, as they afford rich manure; ½ peas and ½ corn are better than either alone. Peas make

firm pork. — *Potatoes.* Pigs will not always eat and never can be fattened upon raw potatoes; while, if they are boiled, next to boiled peas, perhaps, they will bring them to the greatest weight, and greater perfection than anything, admitting that 3 or 4 weeks' feeding upon corn, oats or barley is necessary to make the pork firm and impart flavor. — *Pumpkin,* raw, is excellent for intestinal parasites, and hogs are fond of it. — *Water* should always be within their reach. — *Salt* should be placed where they can get it. It is a necessary ingredient of the blood and gives tone to the digestive organs.

PASTURING. — A pasture surrounded by a strong fence is essential for keeping hogs that are to rely on green food during summer. Every farmer who is not able to fence a pasture, may get a few boards, build a portable fence and make a small inclosure for hogs and move it as circumstances require. It will make pork-raising more profitable than to keep hogs confined in pens all the time. Hogs cannot be herded like cattle, and it is not well to keep them in an inclosure with other stock. An acre should be allowed for every 5 hogs and pigs. Hogs are more likely to remain healthy if they have the run of a large lot that is clean and well supplied with water, than if kept in close quarters, filthy and poorly supplied with water. Clover will produce most food, and the kind of green food that is best relished. As it does not come forward very early in the spring, and is liable to suffer from drouth that usually occurs in midsummer, a hog pasture should contain a plat of one of the true grasses.

RINGING.—It is not best to ring swine, except those intended for fattening. Breeding swine should never have rings. To ring a swine, have a strong cord, 6 or 8 ft. long, with a ring on the end, for making a noose that will slip freely. Now get the swine into a close place, and make a running noose with the cord and ring; step beside the hog to be caught, and drop the noose down at the point of the nose on a line with that of the mouth, and draw back gently and steadily until the cord enters the nostrils at the mouth like a bit in the mouth of a horse. As the hog moves back, so must the operator, and keep his place beside the animal until his nose is drawn up close back of the tusks, when the cord may be thrown over a post and the animal drawn up just so as not to draw the feet off the floor. Let the open ring be placed astride the gristly part of the nose, and when it is ready to set in the gristle of the snout about $\frac{3}{8}$ in. back, close it firmly and promptly, and unloose the squealer and he will go and root no more until the ring comes out, which may be in 1 mo. and perhaps not for 6 mos. But the farmer must not allow swine to run on good sod land without rings. Care must be taken not to insert the ring so as to touch the bony part of the nose, or the nose will swell and keep sore, and the pig will lose flesh. If the rings are properly inserted, there is no loss of appetite.

SHELTERING.—Upon whatever scale the piggery is erected, it should be raised upon a little declination, to allow of drainage of urine, to keep the animals dry, and divided into sties of between 6 and 7 ft wide, and 14 or 15 ft. long; the back part should be covered with a low roof, sufficiently large to allow a fatting hog to lie down conveniently. Sties are sometimes left open in front; but although ventilation should be attended to in cold weather, they should be boarded nearly to the top, allowing only of a door to enter, and 2 in. open space at the bottom to carry off urine. The boards, if placed in a groove of the frame work, can be removed at pleasure, to clean the sty or to render it cool. A good place for the food is a trough outside the front paling of the pen, with a hole in it just large enough to admit the head; by which waste may be avoided, and the trough can be cleaned and then filled without entering the court. The illustration shows a good way to make troughs. The sties for breeding sows and for store pigs,



Hog Trough.

may be wider, and the trough should have a sufficient number of apertures for the little pigs' heads, together with a separate trough, having a larger opening, for the sow, as well as high enough to prevent the sucking pigs from getting into it. It is a good plan to have a small spout of water directed through the sties, not only for easy cleansing, but to afford opportunity to drink. A cool, airy, nearly dark place to lie in during summer can be provided at a small cost, and it will pay largely in the increased growth of the hog, and prevent loss of fat. Hogs sleeping in straw never become rough and scrawny, but their skin and hair are clean, sleek and healthy. An earth bed (not mud) is good for hogs; and, if dusty, there is little danger of vermin. A warm, dry pen, with a dirt floor, and banked up so as to keep out wind, is a safe place for hogs, and can be cheaply constructed. A heap of stable manure is a bad place for a bed. It is impossible for them to inhale the gases arising from it, night after night, and remain healthy. Such a bed is a prolific source of weak backs and rheumatism. The filthy state in which many fattening hogs are kept, has a tendency to give a rank taste to the meat and render it positively unwholesome. A common mode of penning hogs is a rail pen, without protection from the weather. Such pens are not fit to keep animals in. Hogs, so kept, will not take on fat, and a great part of the food fed is wasted, while the hogs will consume a considerable amount of filth, which is detrimental to their health and to the health of those who consume the meat.

TREATMENT OF DISEASE.

REMARKS.—It is very difficult to get swine to take medicine. The best mode of administering it, is to mix it in the food or drink. If too sick to eat, put them in a pen; pass a slip-noose over the upper jaw, and, the mouth being open, pour down the liquid from a horn or bottle. Salt and ashes mixed in the drink of hogs has a tendency to ward off disease. A solution of copperas is also useful to purge them from worms. Charcoal is one of the best remedies for the disordered state into which they drift. A good way to administer it is in the form of burnt corn.

APOPLEXY.—A hog, in the act of feeding, or when moving across the sty, falls suddenly. He will be motionless for a while, and then convulsions come on; the eyes seem protruded, the head and neck swell, and the veins of the neck will be brought into sight. *Treatment:* Bleed copiously, then give 2 or 3 oz. Epsom salts. Diminish the quantity and heating character of the food, and give daily 2 dr. sulphur in the 1st meal.

BRAIN, Inflammation of.— Vulgarly called *Blind Staggers*. The symptoms are, foaming at the mouth, rearing on the hind legs, champing and grinding of the teeth. *Treatment:* Bleed; then give cathartic medicine according to the state of the bowels.

CATARRH.— *Treatment:* Give a liberal allowance of gruel made with powdered elm or marshmallows, and 1 teaspoonful of balsam copaiba, or fir balsam, every night. The animal must be kept comfortably warm.

CHOKING. — Often produced by feeding on roots, particularly uncut roots, like the potato. The animal slavers at the mouth, tries to raise the obstruction from the throat, groans, and appears in great pain. Then the belly begins to swell, from the amount of gases in the paunch. *Treatment:* The obstruction, if not too large, can sometimes be thrust forward by introducing a flexible rod, or tube, carefully into the throat. If the obstruction is low down, and a tube is to be inserted, 1 pt. olive or linseed oil first turned down the throat will so lubricate the parts as to aid the operation, and the power applied must be steady. A hollow tube is best, and if the object is passed on into the paunch, the tube should remain a short time to permit the gas to escape. In case the animal is badly swelled, give 3 dr. chloride of lime, or ammonia, in 1 pt. water. Care should be taken to allow no solid food for some days.

CHOLERA.—During the last few years this disease has become prevalent and fatal, and thus far nothing has been established as a specific for its cure. The symptoms are, drooping of the head and ears; great thirst; refusal of food; the hair looks dead and is loose on the skin; drawing up of the back, and falling in of the flank; wasting away of the flesh; in some cases there is vomiting and diarrhea, with copious discharges of dark, bilious, and offensive matter; in other cases the discharges are hard, black balls; the animal becomes weak. The disease sometimes proves fatal in a few days, and in other cases runs several days. *Treatment:* Remove the sick hogs from others and use disinfectants liberally; put them in good, clean pens with plenty of fresh slacked lime sprinkled in them. The following are well recommended remedies: 1. 1½ lbs. pure chlorate of potash; 1 lb. sub-carbonate of iron; 1 lb. powdered may-apple root; 1 lb. Prussian blue; 1 lb. powdered worm seed; 12 oz. pure arsenious acid; powder well and mix; to full grown hogs give 1 teaspoonful twice per day; pigs ½ the amount, for 3 days, then once per day until they are well. When diarrhea is present, give each hog ½ teaspoonful powdered alum once a day, until the bowels check up, in connection with the above treatment. When cholera is prevalent, give the medicine 3 times a week as a preventive. Give for food boiled vegetables, or boiled oats, rye or barley.—2. Take 1 lb. pure hickory ashes, 1 lb. black antimony, 2 lbs. sulphur, ½ lb. fenugreek, ½ lb. resin, ½ lb. saltpetre, ½ lb. ginger, 2 lbs. cream tartar, and 1 pt. fine salt; pulverize and mix well together. To prevent the disease, give each hog 1 teaspoonful 3 times daily. If the hog can not eat, drench him with the medicine. To destroy the cause, the hogs should have a sheltered place of rest, with plenty of dry absorbent earth to lie on; good air, sheds sweetened by whitewashing once in 3 mos., clean water to drink, and salt, sulphur and sulphurous soft coal or charcoal accessible. An entire change of food from corn to potatoes, mangolds and carrots, cooked and raw as often as once a week.

COLIC.—*Treatment:* 1 teaspoonful powdered caraway seeds; ½ teaspoonful powdered asafetida; 1 teaspoonful laudanum. Give as 1 dose, and repeat in 1 hour, if relief is not obtained.

COSTIVENESS.—Caused by confining hogs. *Treatment:* Give Epsom salts, or 10 gr. calomel in the animal's favorite food.

DEBILITY.—(See *Indigestion.*)

DIARRHEA.—This disease rarely attacks old hogs, but is often fatal to young pigs if not attended to in time. *Treatment:* 1. Give fresh skimmed milk, thickened with wheat flour.—2. Charred corn cobs, or charred corn have a good effect.—3. If the pigs are large enough to eat, give them dry, raw flour or corn, rye or wheat whole.

DROPSY.—The animal is sad and depressed, the appetite fails, respiration is performed with difficulty, and the belly swells. *Treatment:* Keep the animal on a light, nutritive diet, and give a handful of juniper berries, or cedar buds, daily. If these fail, give 1 tablespoonful of fir balsam daily.

EAR, Grubs in.—Caused by a fly depositing its eggs in the ear. *Treatment:* Put a few drops of nitric acid in some water and fill the ear with it.

EAR, Sore.—There are very often troublesome cracks and sores at the back of the large lop-ears of some breeds. *Treatment:* Wash the ears 2 or 3 times a day with a solution of nitrate of silver, 10 gr. to 1 oz. water.

EPILEPSY.—*Treatment:* Put the animal in a well ventilated and clean situation; give a bountiful supply of valerian tea, and sprinkle a small quantity of scraped horseradish in the food; or give 1 teaspoonful bromide of potassium 3 times a day.

EYE, Inflammation of, or OPHTHALMIA.—Caused by sudden changes in temperature, unclean sties, want of pure air, and imperfect light. *Treatment:* Keep the animal on thin gruel, and allow 2 teaspoonfuls of cream of tartar per day. Wash the eyes with an infusion of marshmallows until a cure is effected.

FEVER, Contagious.— This disease is very contagious and may be carried quite a distance in the air. The symptoms are, refusal of food; lying under the litter; great thirst; heat and soreness of the skin, with black spots and red patches; sunken eyes; staggering gait; rapid and weak pulse; belly very sore and tender upon pressure; the bowels are sometimes costive, but generally about the 3rd or 4th day diarrhea sets in, and slime and blood are passed. *Treatment:* Burn or bury deeply all dead animals. Give to the sick ones pure well water, acidulated with sulphuric acid, to drink. If constipated, give 2 oz. castor oil, and an injection of warm water; then give the whole of the following 2 or 3 times a day: Nitrate potassa, bisulphate of soda, of each, 20 gr.; mix in 1 pt. gruel. When blood is passed give 20 drops oil of turpentine twice a day. When they shows signs of improvement give tonics twice a day.

HEART. Palpitation of, or THUMPS.—Usually this disorder affects pigs when confined in a close pen. The symptoms are heaving of the sides, which increases to such an extent that pigs thus affected will not eat and rapidly become emaciated and soon die from weakness. *Treatment:* Give 1 dr. bromide of potassium, dissolved in 1 gill water, mixed with the food, twice a day.

INDIGESTION.—*Treatment:* 1. Give prepared chalk, or a small amount of magnesia in the food.—2. Let the hogs have access to the following: 1 peck ashes to 1 pt. salt; 2 lbs. pulverized copperas; ½ lb. black antimony; ½ lb. sulphur; 1 peck charcoal; mix and put where it will be kept dry.

INFLUENZA, or EPIDEMIC CATARRH.—Caused by the introduction into the system of a poison germ, which propagates itself, and increases in the blood and tissues in a manner allied to the growth of a ferment in a saccharine solution. The symptoms are, difficult breathing; short hoarse cough; fever; constipation and sometimes diarrhea; the head is stretched out and drooping. The duration of the disease is about 15 days. *Treatment:* If the disease is far advanced, kill the hog and bury it deep. If any of the animals show slight indication of the disease, separate them from the others and give the following: 20 gr. powdered white hellebore; ½ pt. milk. When this has vomited the animal, give 2 gr. tartar emetic, 3 times a day, till the disease subsides. If there is costiveness, give 10 gr. calomel once a week.

ITCH, OR MANGE.—*Treatment:* 1. Anoint with equal parts lard and brimstone.—2. 1 lb. flour sulphur; 4 oz. Venice turpentine; 2 lbs lard; 4 oz. mercurial ointment; rub well together.

JAUNDICE.—Distinguished by a peculiar yellow tint in the white of the eye, and sometimes in the lips, accompanied by loss of appetite. *Treatment:* ½ oz. powdered golden seal; ½ oz. powdered sulphur; ½ oz. powdered blue flag; 1 lb. flaxseed; mix and divide into 4 parts; give 1 every night; also once a week give 5 gr. calomel. The food must be boiled, adding a little salt.

LICE.—*Treatment:* 1. Wash the pig all over with crude petroleum; the next day give him a thorough washing with warm water and soap, using a scrubbing-brush.—2. Lard and Scotch snuff, mixed, and rubbed along the back and behind the ears, will destroy them.—3. Rub kerosene on with a woolen rag wherever lice are seen; 2 or 3 applications are necessary, as some eggs may hatch. Pigs should be provided with scratching-posts, having holes bored for pegs at different heights, to accommodate pigs of different sizes.

LUNGS, Inflammation of, or PNEUMONIA.—The early symptom is a cough. The disease rapidly progresses; the animal heaves at the flanks; has a distressing cough, which sometimes almost suffocates him; he refuses to eat, and fever runs high. *Treatment:* Give 2 gr. tartar emetic 3 times a day, and 1 dr. laudanum every night.

MEASLES.—The skin is red and pimpled. It shows that there has been general inflammation resulting from the fattening process being carried too far. The hog rubs himself more than usual, while the skin is free from pimples and scurf. *Treatment:* Remove the animal to a warm place; feed gruel; give 1 teaspoonful sulphur daily with a drink of bittersweet tea; if the eruption does not reappear on the surface, rub with the following: 1 oz. oil cedar, in sufficient alcohol to dissolve it; then add ½ pt. whisky and 1 teaspoonful sulphur.

PARALYSIS.— Caused by cold and damp quarters or exposure to cold rains; more frequent in young pigs than in older ones. *Treatment:* Rub turpentine, or mustard paste upon the loins, over the spine.

PNEUMO-ENTERITIS. Contagious.—A form of hog cholera; inflammation of the lungs and bowels, with red or purple blotches on the skin; caused by filthy pens and foul water. There are 2 forms. In one, the animal is dull and without appetite; there is cough, an attempt to vomit, and constipated bowels. The ears, neck, throat and breast are covered with dark red or purple blotches; breath labored, and the hind limbs become paralyzed. Fetid diarrhea sometimes sets in before death. The other form of this disease commences similarly, but there is great difficulty in swallowing; and a red and purple line about the throat. The throat becomes so swollen that the animal may die in 1 hour. *Treatment:* Give castor oil; when it operates, give nitrate of soda, 20 gr.; nitrate of potash, 20 gr.; mixed with gruel. When the parts are swollen, foment with hot water and sulphate of iron. Keep up the strength by 10

gr. quinine every morning, and ½ dr. laudanum every night.

QUINSY.—(See *Influenza.*)

RED ERUPTION.— Analogous to scarlet fever, and appears in the form of red pustules on the back and belly, which extend to the whole body. *Treatment:* ½ oz. powdered bloodroot; 1 pt. boiling vinegar. When cool, rub on the external surface. Diet with boiled vegetables, coarse meal, etc.; give a small dose of sulphur every night.

RHEUMATISM. — Caused by exposure and wallowing in filth. The symptoms are muscular rigidity of the system; loss of appetite and unwillingness to leave the sty. *Treatment:* Keep the animal on a boiled diet, given warm; avoid exposure and filth, and give a dose of the following: Equal parts powdered sulphur, powdered sassafras, powdered cinnamon, and powdered saltpetre, or nitrate of potash; give ½ teaspoonful in warm gruel. If this does not give immediate relief, dip an old cloth in hot water, and fold it around the animal's body; repeat if necessary, until the muscular system is relaxed. Wipe the animal dry and place in a warm situation, with a good bed of straw.

ROT.—The tails of young pigs drop or rot off. *Treatment:* Give a little sulphur in the food; or rub oil or grease daily on the affected parts. It may be detected by roughness or scabbiness at the point where separation is likely to occur.

TRICHINA.—This is a small worm in the flesh of the hog. When the infected pork is eaten it produces a disease called *Trichinosis.* The cause of trichina in hogs is attributed to eating dead rats, mice, cats, etc. A trichinous hog can never be detected in life, but after death the parasite can be seen through a powerful microscope. Trichinosis is generally fatal; the only preventive is to eat no pork unless thoroughly cooked.

SLAUGHTERING AND CURING.

PRESERVING MEAT FRESH. — 1. To 6 lbs. salt, add 1 lb. brown sugar, 2 oz. saltpetre, 3 oz. saleratus, and ½ lb. finely powdered charcoal; dissolve in sufficient water to cover the meat 2 in. with brine; pack close and weight down. Sufficient for 50 lbs. of meat. By soaking the meat in cold water a few hours before using, it will add to its freshness. — 2. It is said that meat will be preserved fresh for 2 weeks in sour milk or buttermilk. — 3. As soon as the animal heat is out of the meat, slice it up ready for cooking. Prepare a large jar by scalding well with hot salt and water. Mix salt and pulverized saltpetre in the proportion of 1 tablespoonful saltpetre to 1 teacupful salt; cover the bottom of the jar with a sprinkle of salt and pepper; put down a layer of meat, sprinkle with salt and pepper, the same as if just going on the table, and continue in this manner until the jar is full; fold a cloth or towel and wet it in strong salt and water, in which a little of the saltpetre is dissolved; press the cloth closely over the meat and set in a cool place. It is a good plan to let the meat lie over night after it is sliced, before packing. Then drain of all the blood that oozes from it. It will be necessary to change the cloth occasionally, or take it off and wash it, first in cold water, then scald in salt and water, as at first. In this way farmers can have fresh meat the year round.

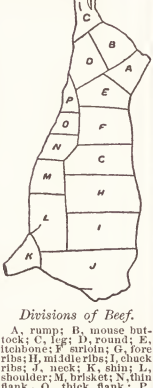
CATTLE.

REMARKS ON KILLING.—The veal from a calf, less than 4 weeks old, is unfit for food and is unwholesome; after 6 weeks the calf requires more food than the mother can give it, and the change to grass, or hay, or meal, materially alters the character of the flesh, which becomes darker and less juicy. Calves are sometimes bled; this makes the meat white, but detracts from its flavor. The amount of meat obtained from a domestic animal sold by its live weight, is variable; animals yield as much as 70 per cent. of meat, while others give 50 per cent.; the mean weight produced is calculated at 58 per cent. of the live weight in beef cattle. An ox of the live weight of 1,332 lbs. yields meat, 771.4 lbs.; skin, 110.2; grease, 87; blood, 55.1; feet and hoofs, 22; head, 11; tongue 6.6; lungs and heart, 15.33; liver and spleen, 20.05; intestines, 66.15; loss and evaporation, 154.352; making the total 1,332 lbs. (See *Weighing Cattle by Measurement*, in HEAVY LIVE STOCK.) Cattle may be killed by firing a rifle ball into the forehead, between and above the eyes. Another method is to stun the animal by a blow with the head of an ax in the same place. When he has fallen, cut the throat with a sharp butcher knife; make the gash square across the front of the throat, and deep enough to reach the spinal column. Now hang the animal on a frame by the hind legs. A good frame can be made of strong oak wood. A heavy gambrel should be placed under the large tendons above the hock joints. Place the gambrel over the hooks, or attach it to the cross nail of the frame by strong cords; then raise the frame by drawing forward the uprights, until the carcass leaves the ground.

CUTTING BEEF.—This should be commenced as soon as the blood ceases to flow. Cut the skin from the throat along the centre of the brisket and belly into a line between the centre of the thighs to the tail; divide the skin of the legs in the same manner on the inside, the cuts running down to the former cut; sever the fore feet at the knee joints and the hind feet about 3 in. below the hock-joints; remove the skin from the upper side of the animal to the back-bone; turn him over and skin the other side; remove the entrails while lying, or first hang up the carcass by the hind legs, and then remove them; now wash the carcass; after cooling divide it into halves by splitting the back-bone; leave it hanging from 12 to 24 hrs.; then divide accord-

ing to the divisions figured in the illustration.

CANNING.—Remove the bones from fresh meat, parboil the flesh, put into a clean tin can, and fill up with rich soup; solder on the lid, piereed with a small hole. Next put the tin into a bath of brine and heat until steam issues from the hole; then solder up and remove the can from the bath. In a short time the pressure of the air will induce a slight concavity of the top and bottom of the can. If the process has been successfully performed, this concavity will be permanent; but if, at any future time, the concavity has ceased, or the ends become slightly convex, it is a sure sign that the meat has become putrid.



Divisions of Beef.

A, rump; B, mouse buttock; C, leg; D, round; E, itchbone; F sarloin; G, fore ribs; H, middle ribs; I, chuck ribs; J, neck; K, shin; L, shoulder; M, brisket; N, thin flank; O, thick flank; P, veiny piece.

CORNING.—1. Put into a cask 12 gals. water, 12 qts. salt, and 1 lb. saltpetre; stir until all is dissolved. Salt your meat, rubbing it well, and lay it in a separate tub, taking care to have the skin side down. Let it lie thus for 10 days; then put into the brine (still with the skin side down), weighting it down with boards and a large stone. This brine will keep from November to Mareh. Meat may be added from time to time, always taking care to have salt rubbed over it and the blood drained off.—2. A pickle for beef is made as follows: 6 lbs. salt, 1 lb. sugar, and 4 oz. saltpetre, are boiled in 4 gals. water, skimmed, and cooled. The meat is packed closely in a barrel or vat and the pickle poured over it. The pickle may be preserved and used year after year, by boiling and skimming it to remove the coagulated albumen which comes from the meat, and which would soon cause it to spoil, and also adding some salt and sugar to replace that which the meat has absorbed.

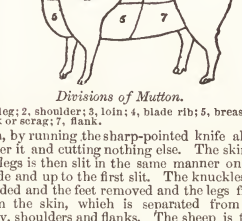
CURING TONGUE.—Throw a handful of salt over the tongue, seeing that it is sprinkled on both sides, and let it remain to drain until the following day; make a pickle of 1 tablespoonful common salt, ½ that quantity of saltpetre, and the same quantity of coarse sugar as of salt; rub this mixture well into the tongue, every day for a week; it will then be found necessary to add another tablespoonful of salt; in 4 more days the tongue will be cured sufficiently. Sometimes the tongue is merely left in the brine and turned daily; this method will be found to occupy a month or 5 weeks before it is cured. When the tongue is to be dried, affix a paper to it with a date; smoke over a wood fire 4 days, unless wrapped in paper, and then as many weeks will be required to cure the tongue.

TALLOW.—(See same in SOAP AND CANDLES.)

SHEEP.

REMARKS ON KILLING.—To obtain the best mutton the sheep should be killed between 3 and 5 yrs. of age. The quality depends on the feeding and the breed. The veins and arteries of the neck are cut with a sharp pointed knife thrust through the throat. In dressing sheep the 4 legs are tied together and the sheep laid on a bench, with the head and neck projecting.

CUTTING MUTTON.—The carcass is turned on the back, the legs loosened, and the skin divided from the root of the tail along the belly to the



Divisions of Mutton.

1, leg; 2, shoulder; 3, loin; 4, blade rib; 5, breast; 6, neck or scrag; 7, flank.

chin, by running the sharp-pointed knife along under it and cutting nothing else. The skin of the legs is then slit in the same manner on the inside and up to the first slit. The knuckles are divided and the feet removed and the legs freed from the skin, which is separated from the belly, shoulders and flanks. The sheep is then hung up by the gambrels on a cross-stick, which stretches them apart, and the skin flayed off from the rump to the head. When the skin is removed the belly is opened carefully and the intestines taken out without breaking them. The sheep is usually cut up according to the above illustration.

DRYING.—Cut the flesh into slices from 2 to 6 oz. in weight; immerse a small portion at a time in boiling water for 5 or 6 minutes, using only just water enough to cover the meat, and adding water to keep the liquor up to its original quantity. Lay the meat to dry on open trellis-work in a drying stove, keeping the temperature at about 122° Fahr. In about 2 days the meat will be completely dry, having lost about ½ its weight. Add a little salt and spice, especially coriander, to the liquor in which the meat was immersed, and then evaporate it to a gelatinous consistence. When the flesh is dry, dip it, piece by piece, in the gelatinous matter liquefied by a gentle heat, and replace it in the stove to dry, repeating this varnishing and drying 2 or 3 times, so as to get the coating uniformly thick. Meat thus dried will keep good for a year.

MUTTON HAMS. To Cure.—Choose fat, sound mutton; rub thoroughly with a mixture in the proportion of 1 part sugar to 2 of salt, adding ½

oz. each saltpetre and black pepper to each lb. of the mixture; place the meat in a covered vessel and turn and beat it twice a day for 3 consecutive days; on the 4th day wipe the scum from the meat, wash it with strong vinegar, and again rub it with the mixture; the day after beat and turn it; repeat these alternate operations for 10 days, being careful to remove the scum before each rubbing, and to turn the meat every time; after this it must be soaked for 10 days. To be used the same as smoked venison or dried beef.

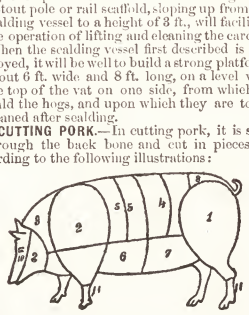
MUTTON HAMS, To Pickle.—1. Rub the hams with a mixture of sugar, pepper and saltpetre, allowing 4 oz. of the former and 1 oz. each of the 2 latter to every 12 lbs., and 1½ lbs. salt to the same quantity; after the meat is thoroughly rubbed, cover it with the salt, and turn and beat it every day; at the end of a week add a teacupful of vinegar to the brine and continue the turning and beating; after 3 weeks take it from the brine, wash with fresh water, then with strong vinegar, and hang in a cool cellar for a week or less according to the weather. It should be soaked in cold water about 1 hour before boiling. — 2. 3 gals. soft water; 1 lb. coarse sugar; 3 lbs. of common salt; boil and remove the scum, and, when cold, pour over the meat. In 2 or 3 weeks the ham will be excellent for baking or boiling. It may be smoked if preferred.

TALLOW.—(See same in SOAP AND CANDLES.)

SWINE.

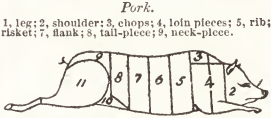
REMARKS ON KILLING.—It is better to kill early than late. As soon as cold weather comes, pigs will gain little, if any, and often lose during cold storms. A cold northwest wind, with a clear sky, indicates suitable weather for the slaughtering; but an east wind, no matter how low the thermometer may fall, implies unsettled weather with prospect of moist temperature. While a very cold temperature is not desirable, it should be sufficiently low to secure a freeze at night. A mean daily temperature of 40° is considered favorable for killing. Let the hog out of the pen, which is apt to be a hard place for a scuffle. He will soon tire of running, and may be seized by the hind leg, the noose slipped over his snout and he laid on his back ready for sticking. The blood may be drawn by an insertion of the knife a little before the front legs directly down towards the spine. Further cutting is useless, injuring the meat. At the great slaughter-houses the victims are dispatched by a single stab. As soon as bleeding ceases, dip the hog in a scalding vat. A barrel or cask is insufficient in which to scald a hog. A good scalding vessel consists of a box 6 to 7 ft. long, 30 in. wide at the top, and 24 in. deep, with the sides flaring. This should be provided with a sheet iron bottom, well supported on the under side, and set over a stone or brick foundation, in which there is a chamber for making fire to heat the water in the vessel above, and by which it can be kept heated for any number of hogs. At its rear should be a pipe or chimney, and the sides banked up with earth. On the bottom of the vat must be laid wooden strips on a slatted frame to prevent the hog coming in contact with the iron bottom. When this is not practicable, a box sunk into the ground, or a hogshead partly let into the ground and slightly inclined, will answer, though it is difficult to keep water at the right temperature. With the latter arrangement a stout pole or rail scaffold, sloping up from the scalding vessel to a height of 3 ft., will facilitate the operation of lifting and cleaning the carcass. When the scalding vessel first described is employed, it will be well to build a strong platform, about 6 ft. wide and 8 ft. long, on a level with the top of the vat on one side, from which to scald the hogs, and upon which they are to be cleaned after scalding.

CUTTING PORK.—In cutting pork, it is split through the back bone and cut in pieces according to the following illustrations:



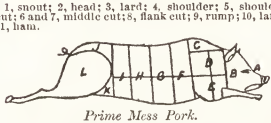
Pork.

1, leg; 2, shoulder; 3, chops; 4, loin pieces; 5, rib; 6, brisket; 7, flank; 8, tail-piece; 9, neck-piece.



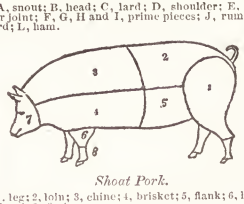
Mess Pork.

1, snout; 2, head; 3, lard; 4, shoulder; 5, shoulder cut; 6 and 7, middle cut; 8, flank cut; 9, rump; 10, lard; 11, ham.



Prime Mess Pork.

A, snout; B, head; C, lard; D, shoulder; E, shoulder joint; F, G, H and I, prime pieces; J, rump; K, lard; L, ham.



Shoat Pork.

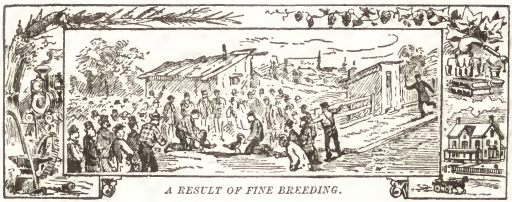
1, leg; 2, loin; 3, chine; 4, brisket; 5, flank; 6, hocks; 7, head; 8, feet.

HAM AND BACON, To Cure.—As soon as the animal heat is gone, salt with plenty of the purest salt and about ½ oz. saltpetre to 100 lbs. pork. As soon as the meat is salted to taste,

which will generally be in about 5 weeks, take it out, and if any of it has been covered with brine, let it drain a little. Then take black pepper, finely ground, and dust all over as much as will stick; then hang it up in a clean, dry, airy place. If all this is done as it should be, you will have no further trouble with it. Another way is to dry-salt the hams, and prepare for the smoke house in the usual way. When the time for smoking comes, instead of lighting a fire, buy a bottle of pyroligneous acid, at the drug store, and, with a clean brush or rag, rub it over the fleshy surface of the meat. Repeat this in 2 weeks, and then lay the meat aside. The room where it hangs will smell like smoke for weeks; for pyroligneous acid is nothing else than bottled smoke. After the meat has taken sufficient salt, which will be in 4 to 6 weeks, according to the size of the hogs, and counting out any weather cold enough to freeze the meat in the meat house, take it up, knock the salt off, and string each piece ready for hanging; then wash clean in tepid water, and while wet roll it in hickory ashes before hanging. Smoke it well with billets of green hickory, and about the 1st of March put the joints in cotton bags, tie closely, and hang up in the house. Never use pine, oak or walnut, or any other quite strong scented wood. A smoke house ought to be dark, and the smoke so supplied as not to heat the meat.—3. To each green ham of 18 lbs., apply 1 dessertspoonful saltpetre and ¼ lb. brown sugar, to the fleshy side and about the hock; cover the fleshy side with fine salt ½ in. thick, and pack in tubs, to remain from 3 to 6 weeks, according to size. Before smoking, rub off any salt that may remain on the ham, and cover well with ground pepper, particularly about the bone and hock. Hang up and drain for 2 days; smoke with green wood 8 weeks, or until the rind assumes a light chestnut color. The pepper is a very effectual preventive of the fly.—4. Dissolve salt in cold water until it will float a potato; then for 12 lbs. ham, add 1 oz. saltpetre dissolved in water, and add it to the brine as you pour it on the meat. Have a kind of skewer made of iron a few in. long, a little wider than thick, sharp at one end, with a hole in it large enough to pass stout twine through; with it put strings in the leg end of the hams before putting in the brine, then pack tight in the cask, with the string end up. They will be ready to smoke in 6 weeks, but standing longer will do no harm. Have them smoked and packed away either in oats or marsh hay before the first fly makes its appearance in the spring. The animal heat must be all out before putting in brine, or they will be tainted.

HAM, To Keep.—1. Take an old flour barrel, or other dry cask; put a good layer of coarse salt in the bottom, and then put down a ham; cover with coarse salt, and put down another; and so on till the cask is full, or all put in; put the cask in a cool, dry place; and the hams will come out good.—2. Put the hams in thick paper sacks, such as millers use to put flour in, made of manilla paper; wrap the ham in several thicknesses of old paper, to keep moisture from striking through and spoiling the sack; tie up tightly, first twisting the top around well; then hang it anywhere; the fly will not find its way into the ham. This paper is strong enough to bear the weight of the ham.

LARD, To Render.—1. To render leaf lard, skin carefully, wash, drain, cut into bits, put into a tin pail, and set into a pot of boiling water. After melting, throw in a small quantity of salt to make the sediment settle, then simmer ½ hour or until clear. Strain through a coarse cloth into jars. Tie over with bladders or paper and cloth, the latter dipped in melted grease. The other fatty portions, wash, drain, cut into bits, and put into an iron kettle over a slow fire. Add a teacupful of water to prevent burning. When the bits of fat are reduced, take out the fibres with a skimmer. Watch, and toward the last stir constantly. The fire should be moderate from first to last. Sprinkle in a little salt, and when the fat looks clear take from the fire; when cool enough strain through a sieve or coarse cloth into jars. When straining, do not press the cloth as long as the clear fat will run through, and when you do squeeze it strain that part into another jar. Lard keeps best in small vessels. Keep covered in a cool, dark place.—2. Cut the fat up into pieces 2 in. square; fill a vessel, holding about 3 gals., with the pieces; put in 1 pt. of boiled lye, made from oak and hickory ashes; strain before using; boil gently over a slow fire, until the cracklings have turned brown; strain, and set aside to cool.

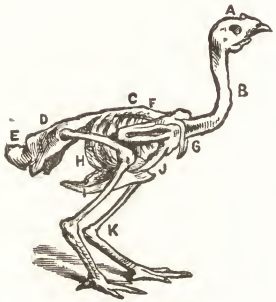


A RESULT OF FINE BREEDING.

POULTRY.

CHICKENS.

ANATOMY AND BREEDS.

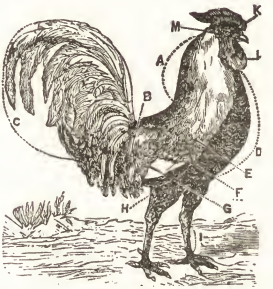


Skeleton of a Fowl.

A, head; B, neck; C, back or spine; D, hip; E, rump; F, shoulder; G, collar bone; H, chest; I, breast-bone; J, wing bones; K, leg.

Leg and Foot of a Fowl.

The leg is composed of *d*, thigh bone; *e*, shin bone; *f*, bone of the foot; *g*, claws; *h*, knee; *i*, heel.



Points of a Fowl.

A, neck hackle; B, saddle hackle; C, tail; D, breast; E, upper wing coverts; F, lower wing coverts; G, primary quill; H, thighs; I, legs; K, comb; L, wattles; M, ear-lobe.

BANKIVA. — A native of Java. Has a red indented comb, red wattles, and ash-gray legs and feet. The cock has a thin indented or scalloped comb and wattles under the mouth; the tail elevated above the rump, and the feathers disposed somewhat in the form of titles; neck feathers long, hanging, rounded at the tips, and of fine gold color; head and neck fawn color; wing-coverts dusky brownish and black; tail and belly black. The hen is of a dusky ash-gray and yellowish color; comb and beard much smaller than the cock, with no feathers on the neck beside the long hackles.

BANTAM. — So called on account of their small size. All cocks over 28 oz., and hens over 24, are disqualified. They are distinguished by

their stylish bearing; are chiefly valued as pets; were formerly prized according to the amount of feathers on their legs, but this is now considered their defect. The characteristics of a well bred bantam are a beak short and curved; the head narrow, with a rounded forehead; bright eye; small ear lobes; short back; breast prominent; round, full body, and carriage erect. A rose comb is considered essential in most varieties, and always to be preferred. The male bird should not weigh more than 20 oz.; the female not more than 15. From their tender flesh, they are substituted for chick-

Seabright Bantam Hen.

Bantams.

ens, and their eggs are considered a delicacy for weak stomachs. The varieties are *Game, Golden Seabright, Silver Seabright, Rose-combed Black, Rose-combed White, Japanese, Pekin,* and *Booted White.*

BRAHMA.—A breed of large size, the cocks weighing from 10 to 12 lbs. It is divided into dark and light. The dark are characterized as follows: The head of the cock is surmounted by a pea-comb; wattles full; beak strong; neck short and curved; back short, wide and flat; tail small, upright; back almost white; saddle feathers white, striped with black; breast broad, full and carried well forward; legs short and well feathered. A standard light brahma hen has a pea comb, bright red wattles, a good sized neck; the neck hackle feathers are edged with white, with a broad, black stripe down the centre; back broad and white; tail small and black; legs yellow and well feathered. The cock resembles the hen in color, has no distinct sex markings, but is built on a masculine model. They are good setters and mothers; fine winter layers, and fatten easily.

Brahma Hen.

BREDA.—A long, thin fowl, with black plumage and feathered legs; wattles, large; both cock and hen, combless; eggs, size of a duck's, and very often unfertile. Weight of cock, 6 lbs.; of hen 5½ lbs.

COCHIN, or SHANGHAI. — Imported from China. They fatten easily, and the hens are good winter layers. The male is from 22 to 25 in., and the female 18 to 22 in. high. There are several varieties, of which the favorites are buff and cinnamon colored; there is a white variety, for which large sums have been realized. The *Black Cochin* is, without doubt, the most profitable of the Cochin varieties. They are not so large as the buff or partridge, but large enough to make a fine table fowl, and better layers. The cocks when 18 mos. old weigh from 10 to 12 lbs., and hens from 7½ to 9 lbs. They are active, and less subject to disease and less inclined to set. They are a rich, glossy black; have a single comb, medium size; short neck, curved, and covered with a rich, glossy hackle; broad back, with a gentle slant toward the tail, which is short; breast full and broad. The *Buff Cochins* have a clear buff head; hackle, wings, saddle and back of a rich, deep golden buff; comb and wattles, brilliant red. *Partridge:* The cock

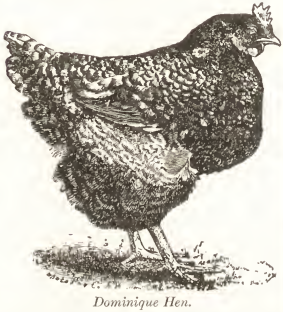
Partridge Cochins.

has bright red hackles and saddle feathers, with a well defined black stripe down the middle of each feather; the back and wing-bow of a dark, rich red, with a wide, lustrous, greenish-black bar across the wings; the quills rich bay on the outer webs, the secondaries ending in black tips; the tail glossy black. Not unfrequently, some white appears at the base of the feathers. Fashion demands a black breast. In the hen, the neck-hackle feathers are bright gold, each having a broad black stripe down the centre. The remainder of the plumage light

brown, well and distinctly pencilled with dark brown. It is important that the pencilling should reach well up the front of the breast; the shafts of feathers creamy-white, contrasting with the darker colors of the webs of the feathers. These fowls are of a domestic disposition. A very low fence, 3 or 4 ft. high, prohibits their straying. They are hardy, if not over-fed. The chickens are raised without difficulty. One of the best varieties for laying eggs in winter, if properly managed. The *White Cochins* are heavy and among the best foragers. The face, comb, and wattles are red; plumage white throughout; legs bright yellow.

CREVE COEUR.—Prolific egg producers, grow rapidly, and have white juicy flesh; non-setters. Not surpassed for whiteness of flesh by any. Their black legs are objected to, but they have no effect on flavor or tenderness of flesh. Young birds fatten when 3 mos. old, and have been made to weigh 4 lbs. at that age; at 6 mos. they weigh 7 lbs.

DOMINIQUE.—Their qualities are extreme hardiness, fast growers, among the best of lay-



Dominique Hen.

ers, and form that of the ideal fowl. Quality of flesh good, plump, and of a nice yellow skin. With an ordinary good run 12 or 14 laying hens can be bred to 1 cock; closely confined, 8 is enough. The eggs are fertile.

DORKINGS.—The color is pure white, and their distinctive mark is 5 claws on each foot, the 5th claw being little more than an apology. They are large, well shaped and good layers. No fence lower than 7 ft. will keep them in; they will not bear neglect, are long arriving at maturity, seldom come to full size until after the 2nd molt, need a long season, and should be early hatched. They require warm quarters in cold weather, remain longer in egg production, and when not producing eggs they are making most juicy, white, and delicate flesh. Capons and poulardes are frequently made of these fowls, which grow to an enormous size when castrated. The other varieties are the *Blue, Brown, Red, Silver Duck-wing, Yellow Duck-wing, Ginger Red, Gray, Red Pile, White Pile, Spangled* and *White*, with combinations.

Dorkings.

FRIZZLED.—A native of Java and Japan. All the feathers are turned and frizzled; smaller than the common species, more wild, and less suitable for domestic purposes. Flesh, firm and delicate.

GAME.—Rather slender in body, neck, bill and legs; and the colors, particularly of the cock, are bright and showy. The flesh is white, tender, and delicate; eggs small, but, like the flesh, much esteemed for delicacy. The plumage, especially that of the *Red*, is beautiful and rich; size below common, and symmetry of limbs comparable with those of the race-horse and the deer. They are pugnacious and will fight till they die. The *Black-breasted Red* is the most favorite.

Game Cock.

Guinea Fowl.

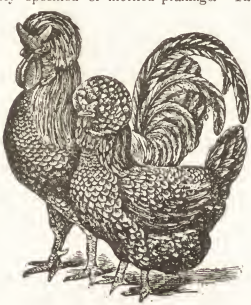
GUINEA FOWLS.—Not strictly speaking a breed of, but they assimilate with the domestic

species in habits and feeding. The cocks and hens are nearly alike. They have a peculiar gait and cry. The head is covered with a kind of casque, with wattles under its bill; plumage either black or dark gray, sprinkled with uniform white spots. They are natives of Guinea and South America. They are active destroyers of the Colorado beetle, and lay an abundance of eggs, smaller than those of the common hen, and speckled.

HAMBURG.—These have a handsome plumage and form; are great layers and non-setters; tender and require good care. They are about the size of the common fowl and their flesh is dark. *Silver-Spangled* and *Black* are best. The other varieties are the *Golden Penciled*, *Golden Spangled*, *Silver Penciled* and *White Hamburg*.

Silver Spangled Hamburg.

HOUDAN. — Large, heavy, short legged, five-toed fowls, with small light bones, and irregularly speckled or mottled plumage. Their merits as table fowls are of the highest excellence. They mature with rapidity, feather early, and are hardy. The old birds are robust, the eggs are numerous, and almost invariably fertile. They have a bulky appearance; plumage black and white spangled; a crest of the same color; comb triple. They are of extraordinary fecundity; lay large white eggs, and the chickens are fit for the table at 4 mos. old. The weight of adult is from 7 to 8 lbs. in which bones figure only for $\frac{1}{3}$. The chickens weigh, when 4 mos. old, without the intestines, about $4\frac{1}{2}$ lbs.



Houdans.

JAVA. — Resembles the Malay in shape, but somewhat colored like the Dorking; probably a cross. In qualities resemble the Malay, but not so valuable as a cross with other breeds.

Java Hen.

LA FLECHE.—Resembles the Spanish, but exceeds it in size; cocks often weigh from 8 to 10 lbs. Both sexes have a large, long body and powerful legs; plumage dense black, with green reflections; excellent layers and non-setters; the flesh white, and of good quality.

LANGHSHAN. — The plumage is black, of a greenish lustre; they have a stately walk; combs straight but small. They are as large as the Brahmas and feathered on the legs; lay early; have white flesh; feather quickly; are hardy, and good winter layers. They are superior market chicks. They have one fault (if it can be so called)—black legs; but, as they dress white, and the meat is fine-grained, the objection is a small one compared with their excellence in every other respect.

LEGHORN.—A quiet, hardy and docile fowl; legs and skin usually yellow; wattles full and large. There is no fowl among the improved breeds cultivated in this country that will produce so large number of eggs as the *Brown* and *White Leghorns*. The *Black Leghorns* are prolific in this respect. Leghorns are the dependence for eggs, but when flesh is desired, size is against them.

White Leghorn Cock.

MALAY. — They have long legs and large

bones; flesh finely flavored, when properly fattened; and their eggs are so large and rich that 2 of them are equal to 3 of those of ordinary fowls. The color of the feathers is black, or dark brown, streaked with yellow; legs large and coarse; tall, strong-beaked, and powerful; the cock has a harsh crow. It is said that a cross between the Malay and common fowl produces a breed superior to its progenitors. They look the very brigands of poultrydom; egg about 2½ oz., its shell pale chocolate-colored; moderate layers; good setters and mothers if they have roomy nests. Chickens feather slowly and should not be hatched after June.

OSTRICH.—This breed are hardy and lay

Ostrich Fowls.

from 40 to 50 eggs before setting; weigh from 7 to 9 lbs.; have short legs and plump, thick body; color, blue-black.

PLYMOUTH ROCK.—Came into prominence within the last 10 years, because of its adaptation for farmers and market. They are a made-up breed, and originated in New England by crossing a Dominique cock on a black hen of the large Asiatic stock. Careful breeding has resulted in an evenly barred, and hawk-colored fowl, with clean yellow legs and single comb. They have plump bodies and short shanks; skin not so yellow as the Cochin, and when dressed for market, does not look so clean as the Cochin, but they are more desirable for the table. A well bred Plymouth Rock will be in good form at 5 mos. old and in its prime at 6 mos. A cock and hen, when matured, weigh, alive, 18 lbs. The average weight is probably 2 lbs. less. They are good layers.

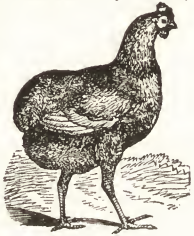
Plymouth Rock Cock.

POLAND.—Imported from Poland. Their color is shining black, with white tops on the head of cock and hen; head flat, surmounted by a fleshy protuberance, out of which spring the crown feathers, white or black, with the head in the

Black Polands.

centre of the crown. They are kept as ornamental, but are one of the most useful varieties, and called everlasting layers. They require more warmth, and attention than the common breed, and are more subject to disease. Their topknots should be occasionally clipped, or they grow into the eyes and nearly blind them.

RUMPLESS, or RUMPKIN.—They are entirely without tail and without that lump terminating the spine, from which the tail feathers issue; and the saddle feathers fall over behind in profusion. They are moderate layers; the eggs average 2⅜ oz.



Rumpless Hen.

SPANISH.—A large size; lay enormous eggs, but do not set well; plumage black; comb loose; and the skin behind the ears white. Two breeds, remarkable for beauty,

Spanish Cock.

are the *Gold-spangled* and *Silver-spangled Po-* | *lands*, sometimes mixed with the Spanish.

Care and Management.

REMARKS.—Fowls feel changes from moderate to extreme weather. Over this stage the Brahma appears to pass with little difficulty, if well fed, and comes into laying early in Dec.

BREEDING.—A cockerel mated with 3 adult hens will give a larger number of male than female chicks—especially with the earlier broods. Later broods will be uncertain. Mating an adult cock with not more than 3 pullets will be uncertain, one sex as likely as the other may predominate. Mating an adult cock with 5 pullets will give an excess of pullets, but, as in the first instance, there will be most male birds from the earlier eggs. Young birds, or adult birds mated together, will give uncertain results, but the fewer the hens and the more vigorous the cock, the greater the proportion of males, and the most numerous from early eggs.

CAPONIZING.—This will cause the fowl to grow fully ½ larger than the ordinary male fowl. Their flesh is delicate and juicy, and they command prices higher than common poultry. To prepare cockerels for caponizing, shut them up without food or drink for 24 hours previous to operation; if the intestines are full the operation will be difficult and dangerous. Cockerels should be operated upon between 3 and 4 mos. of age. Those of any breed may be caponized, but larger breeds are best. A cross between the Light Brahmas and Partridge Cochins produce extra large cockerels, but only the first cross is desirable. A set of caponizing instruments consists of a pointed hook, a steel splint with a broad flat hook at each end, a pair of tweezers, and a pair of concave forceps. First kill a young cockerel and examine it, so that you will be able to tell the position of the organs to be removed. They are within the cavity of the abdomen, attached to the back, one on each side of the spine, are light colored, and the size varies much with age and breed. Practice on chickens that have been killed, until sure that it can be performed quickly and safely; then try the living bird.

Position of the Fowl in Caponizing.

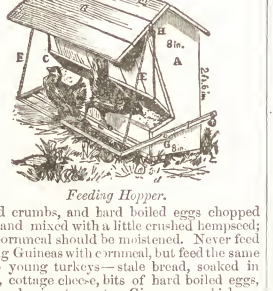
Confine the fowl to a board, left side down, by weights or straps which will securely fasten legs and wings, the latter being drawn well over the back, and the legs extended backward, the upper one drawn farthest out; head and neck free. Remove the feathers from a spot a little larger than a silver dollar, at the point near the hip, upon the line between the thigh and shoulder. Draw the skin back while you make a cut 1½ in. long between the last 2 ribs, and lastly through the thin membrane that lines the abdominal cavity. In making the last cut take care not to injure the intestines. Now take the splint and separate the ribs by attaching one of the hooks to each rib, and then, allowing the splint to spread, push the intestines away with a teaspoon handle; find the testicles; take hold of the membrane that covers them and hold it with the tweezers; tear it open with the hook; grasp the spermatic cord with tweezers; then twist off the testicle with the forceps. Remove the other in the same way. The left testicle is usually farther back than the right, and should be removed first. Take care not to injure the intestines or rupture the large blood-vessels attached to the organs removed. The operation completed, take out the splint, allow the skin to resume its place, stick on some of the feathers that were removed, which will absorb the blood and cover the wound. Give plenty of drink, but feed sparingly on soft cooked food for a few days, or until they begin to move around pretty lively.

EGGS, To Pack.—Eggs are best packed in boxes with divisions of stiff paper to keep them from touching, or being injured by jarring. The following are good ways to preserve eggs:

EGGS. To Preserve.—1. Coat the eggs with lard or clean grease; pack in bran.—2. Wrap each egg in soft paper, twisting each end of the paper so that it can not loosen from the egg; take a bag of coarse muslin, made in the shape of a pillow-slip, draw up one end in your hand, tie strong string around it tightly, leaving the ends long enough to tie a loop; place the eggs in this bag, ends down. It does not matter which end, but be sure not to have them on the side. Put 50 in one bag. Draw up the open end of the bag firmly against the eggs, and tie it like the other end.—3. Put 12 or more eggs into a small willow-basket and immerse this for 5 seconds in boiling water, containing about 5 lbs. brown sugar per gal.; place the eggs on trays to dry; pack, when cool, small ends down, in an intimate mixture of 1 part of finely powdered charcoal and 2 of dry bran. They will last 6 mos., or more. Scalding water causes the formation of a skin of hard albumen next the inner surface of the shell, and the sugar closes the pores.—4. Cover the eggs, by means of a bit of wool, with butter in which has been dissolved 2 or 3 per cent. of salicylic acid. Each egg, after coating, is placed in a box, filled with fine, dry sawdust. If care be taken that the eggs do not touch, and are perfectly covered with sawdust, they will keep fresh for months.—5. As the eggs are taken from the nest, brush each one with a thin solution of gum Arabic, being careful to leave no portion of the shell uncovered. The ½ of each egg must first be done, and left to dry before the remainder is touched, that the gum may not be rubbed off any part by contact while wet with the hand as it is held to be var-

nished, or with the table when laid down to harden.

FEEDING.—Keep chickens for the first fortnight upon alternate feedings of cornmeal,



Feeding Hopper.

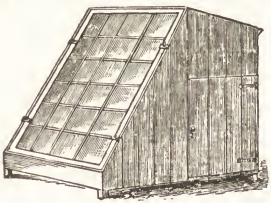
bread crumbs, and hard boiled eggs chopped fine, and mixed with a little crushed hempseed; the cornmeal should be moistened. Never feed young Guineas with cornmeal, but feed the same as to young turkeys—stale bread, soaked in milk, cottage cheese, bits of hard boiled eggs, chopped onion tops, etc. Give young chickens, when feathering, wheat, grits, or rice boiled dry, green food, cabbage, and lettuce. Remember, that a little food, given every 2 hours, is a chief rule. Food should be given warm in cold weather. The gain is 20 per cent. by feeding cooked food. Corn can be cooked to advantage. But fowls tire of a cooked diet entirely; substitute grain occasionally. Vary the cooked food, as potatoes 1 day, cabbage or onions another, etc. Cracker crumbs are good to mix with the meal. *Bran*, alone, should not be fed, on account of its swelling and caking in the crop. Moisten it with warm water, add powdered charcoal, 1 teaspoon to 1 qt. bran, and give scraps of fat or cooked vegetables; as an egg producing food, it is unequaled.—*Buckwheat* is fattening, an egg producer, and is relished.—*Cabbage* is best given whole.—*Charcoal* should be liberally fed, broken in small lumps and put where the fowls can get it.—*Lime and Bone.* Air-slaked lime should be scattered over the floor of the chicken house to remove unhealthy odors, and scattered around the yard. Laying fowls need bone for eggs and shells. For old fowls feed finely ground bone mixed with feed, or coarsely ground into bits; in the latter form it assists the gizzard. Ground oyster shells are valuable.—*Meat.* Feed scraps 3 or 4 times a week, with other food, when there are no worms or insects.—*Milk* may be given with coarse cornmeal, scalded together until a stiff mass; or it may be curdled, separated from the whey and given dry, but not sour.—*Millet* is excellent, and easily swallowed.—*Oats* may be used to advantage for breeding fowls, especially Asiatic varieties.—*Red Pepper* has a beneficial effect on fowls.—*Salt* in small quantity is good, but if not used to it, a very moderate quantity is poisonous.—*Sand and Gravel* should be used during the breeding season to act as grinders for hard food. Sprinkle sand over the floor of the house after cleaning, and on the droppings if the house is not cleaned every week or two.—*Sunflower* seeds may be fed freely; they promote laying and health.

FEEDING HOPPER.—The illustration shows a feeding hopper. A, shows the end view, 8 in. wide, 2 ft. 6 in. high, and 3 ft. long; B, roof, which projects over the perch; C, lid of the manger; E, E, cords attached to the lid of the manger and to the perch; I, end bar of the perch, with a weight attached to the end to balance the lid; H, pulley; G, fulcrum. When a fowl wants food, it hops upon the perch, and its weight raises the lid. When the fowl jumps off, the lid closes.

FATTENING.—Fowls should be fed liberally from the time they are hatched. It is a mistake to suppose that they can be kept low when young, and got up to great size by feeding when put up to fatten. With liberal feeding they become fit for fattening at the age of about 4 mos. in summer, and from 5 to 6 in winter. Cramming is sometimes practiced with a feeding machine, which is made to expel its contents through a tube of rubber, in response to pressure of the operator's foot upon a pedal; the amount passing through the tube is indicated on a dial. The operator seizes with the left hand the neck of the chicken, and, pressing on each side of the beak, the bird is forced to open its mouth, while with his right hand he introduces the nozzle of the tube communicating with the reservoir of food, and conveys into the stomach the food. A skillful operator can cram 400 chickens per hour. In this way it requires an average of 15 days to fatten a duck, 18 for a chicken, 20 for a goose, and 25 for a turkey. The pullets are fed 3 times a day and the ducks 4 times. The food used for chickens is barley and cornmeal, mixed with milk into a dough so thin that no liquid is necessary; the ordinary quantity given is from 7-10 to 1 4-10 gill each time. Pullets are not allowed drink, but ducks are given water at intervals. Only birds between 3 and 6 mos. old are treated thus.

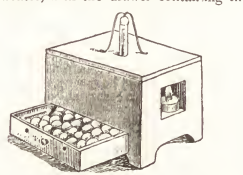
HATCHING, Natural.—Eggs of average size are best for hatching. Rough-shelled eggs should not be chosen, as they are often sterile. Smooth-shelled eggs are proper. Observers claim that sex can not be determined by the shape of the egg. The hen testifies her desire to set by clucking, searching for eggs to set upon, and restlessness. When this is not naturally excited, some breeders promote the disposition by applications, such as nettles, to the belly. Hens that have molted early often set before November. When a hen desires to set, give her a few nest eggs and let her alone for a day or two until the fever is well on, then remove her after dark to the nest and put her gently on the eggs; fasten a board in front of the box, leave it there till after dark the next evening, then remove it. In 9 cases out of 10 the hen will come off the next morning, eat her breakfast and return; then you may give her the eggs you desire to hatch. If she refuses to return, put her back, and fasten her in for another day and night. The setting hen needs feed and water once a day. Setters are sometimes shut up by them-

selves to keep others from disturbing them. A setting hen should be started right, and left much to herself. If early chicks are to be raised, a warm house is needed; a small yard should be attached to each nest, so that the hen can wallow in dirt and ashes placed for that purpose. If a hen is not set until April 1st, set her in a barrel, placed on the warm side of a fence; the barrel should be tight and set in the ground 6 in.; the end that is to be left open should be lower than the other end to let water run out, if any should get in. The nest should be made by first covering the middle of the barrel with fine moist loam several inches in length. In this the nest should be made with soft hay. From fresh eggs the chicks are usually all out by the morning of the 22d day; the strongest first. Remove shells and addled eggs, but leave the chickens in the nest for 1 day; feed the hen and give water; give nothing to the chickens; warmth is what they need. Giving young chickens a peppercorn, or other stimulant, is a bad practice. When 24 hours' old, place the hen under a coop in a dry out-house open to the south, and upon a surface of dry sand 3 or 4 in. deep, so that she can bask at pleasure. Put water outside, within reach of the hen, and give her the same food as the chickens. The difficulty that interferes with rearing early chickens is to overcome the long night of from 15 to 16 hours, when they are without food. There is only one substitute, and that is warmth, derived from the hen. She should not have more than 5 chickens; if she have 9 they would, while small, be covered; but they grow, and she cannot cover them during the night. Allow a hen 5 chickens, and she will rear 4. She can cover them till the nights get short and warm. The hen should be under the coop till the chickens are at least 10 weeks old; and at night cover the coop with matting or a piece of old carpet. Let the chickens have plenty of curd, egg chopped fine, oatmeal mixed with new milk, and some onion tops. Feed often. Let them have milk to drink. Feed the hen the same. No warmth is so beneficial as that from generous feeding. Guinea eggs are best hatched by putting them under a game fowl or bantam; when the chicks appear, keep them under cover where they can have plenty of air and dry gravel; feed once every 3 hours at least. Early chickens are desirable, but they are troublesome to raise in winter. To overcome this and keep the chicks warm during cold weather, a few coops of the style shown in the engraving are necessary. They are 4 ft. long, 3 wide, and 4 high, and large enough to give ventilation when closed. The nest is made in one corner of the coop, and when the young are hatched they may be confined in it. The front is a common hot-bed sash, 3x4 ft., and can be raised at pleasure. The coop is placed in a corner of the poultry house, near the glass front, and being thus warmed during the day, will retain warmth through the night. In the coldest weather a blanket may be thrown over it.

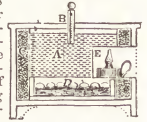


Hatching Coop.

HATCHING, Artificial.—The construction and operation of the hatching box and artificial mother, are so simple that any one can make and use them. The 1st illustration represents the incubator, with the drawer containing the eggs partly drawn out. The 2d shows a section of the same. The upper part of the box contains a zinc reservoir (A) with a space left (E) for the introduction of the lamp, and a small tube (B) passing through the top of the box, which serves for filling it with water, and holding a thermometer, which, plunged into the water, indicates the temperature. Thermometer tubes may be held in position by inserting through a perforated cork; the temperature of the water may then be seen at a glance. The drawer for the eggs (D) is immediately beneath the reservoir; it is provided with two small holes for ventilation, and holds about 40 eggs. A small thermometer is also kept in the drawer to indicate the temperature of air surrounding the eggs. A space is left around the reservoir, and on 3 sides of the drawer, for a filling of sawdust or other non-conducting material. A flat tin lamp with 2 round wicks, is used, but a properly constructed kerosene burner would answer. Soft hay is spread in the bottom of the drawer; the eggs are put in, it is then closed and warmed by the water above. The temperature of the water is kept at 122°, or enough higher or lower to keep the eggs at 104° to 106°. Once or twice each day the drawer is opened, the eggs turned and left for ¼ hour in the open air before replacing. At the end of 21 days, the chickens come out,

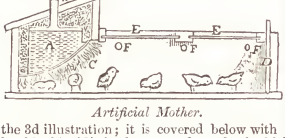


Artificial Incubator, with Drawer Partly Open.



Section of Incubator.

and are left 24 hours in the drawers, without feed, before being taken to the artificial mother. This operation follows the natural method; the eggs receive their heat from above; are turned each day, and ventilated, as in the case when under the mother. The holes for ventilation in the drawer are small, and probably could be dispensed with. The artificial mother is provided with a zinc reservoir (A) of the shape shown in



Artificial Mother.

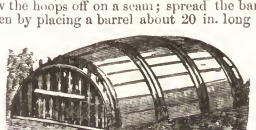
the 3d illustration; it is covered below with a lamb's skin (C), in the warmed wool of which the chickens nestle themselves. This reservoir is only filled in cold weather, once a day, the water being first brought to a temperature of 160° to 175°. The tube (B) passing up from this reservoir is used for filling, and the one at the side (D) for emptying. The top of the box (F, E) is of glass, arranged to slide open at pleasure; there are three ventilating holes on each side the box (F, F, F), and a gate at the end. The chickens are placed in this when 24 hours old, and kept there 1 week; they are then gradually habituated to the outside air, the gate being constantly open for them. Fresh water and feed are given 5 times each day, it being considered essential to give only small rations, and frequently.

LAYING.—Hens lay from early spring, to midsummer, when they cease; then commence again; again cease toward mid-winter, and commence again. When the period of laying approaches, it is known by the brightening of the red in the combs and wattles, archness of gait, glistening eyes, and frequent cackling. She then looks for her nest, and after going in and out of it for some days, and making a hollow in it, she lays. Nests may be made in boxes in which a chalk egg or two should be put. They may be made of short straw. In some instances, a hen makes choice of a nest, and when she finds this preoccupied, she will wait until it is vacated. Some hens lay 1 egg every day, and others 1 every other day. Eggs ought to be taken from the nest every afternoon, for, if left, the heat of the hens when laying the next day will corrupt them. The supply of eggs depends on the food furnished. Never over feed. Hard food, such as corn, barley, wheat, buckwheat, etc., once a day, is necessary; but the principal supply should be soft food, scalded. Corn and oats ground together, and wheat bran, mixed in equal proportions, well scalded, is best. Give this in the morning and grain at night. Never feed oftener than twice a day, and if they have fields to roam feed ½ what they would naturally eat. Occasionally give a little ground mustard, ginger or pepper, but do not always be doctoring.

MARKETING.—Fatten the fowls, and let them remain 24 hrs. without food previous to killing. Instead of wringing their necks, cut their heads off; hang them up by their legs to bleed; pick while warm; do not tear the skin; the wings should not be cut off, but picked; if the head be cut off, the skin of the neck should be tied over the end. Cut off the heads of ducks and geese. All the offal should be taken out from behind. Never send to market with the intestines in; this does great injury to the flesh. After removing the intestines, wipe out the blood with a cloth; but no water should be used. With a moist cloth take off the blood upon the carcass; hang in a cool, dry room until ready to market. Do not remove the gizzard; if the fowl be fat, make a larger hole, turn the leaves out, and fasten with a small skewer. Prepared in this way, poultry will be nicer and entitled to a better price.

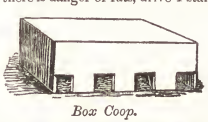
SETTING, To Prevent.—Put water, 2 in. deep, into a barrel; place the hen in it, and cover with a board; leave her 24 hrs., when the setting fever will have left her.

SHELTERING.—An open, airy fowl house is best, provided neither rain, snow, nor wind reaches the body. Pure air is essential to the health; close quarters and high feed are sure to make them sick. Roosts protected from storms and currents of air should be provided, and the fowls bedded down during cold weather. Spring pullets will lay regularly during winter; so also will mature hens of large breeds, and non setters, provided they recover from molting, which takes place between August and November. With larger breeds, such as the Brahmas and Cochins, high roosts are objectionable; use low roosting benches, made of 2 in. strips, laid flatwise, rounded off for the top, and with legs spread apart at the bottom, to prevent tipping over. They are made 18 in. high, and 4 to 5 ft. long. The following are good home-made coops: 1. Take an old barrel; tack the hoops on each side of every seam. After clinching the nails, saw the hoops off on a seam; spread the barrel open by placing a barrel about 20 in. long for



Barrel Coop.

the back of the coop.—2. Take an inverted box, saw out places in one side for doorways. When there is danger of rats, drive 4 stakes, 1 or



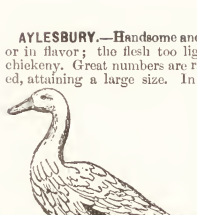
Box Coop.

1½ ft. long, into the ground; on these place inverted tin basins; then place the coop on them.

Ducks.

Breeds.

AYLESBURY.—Handsome and strong; inferior in flavor; the flesh too light colored, and chickeny. Great numbers are raised and fattened, attaining a large size. In ordinary condition they range from 10 to 15 lbs. a pair, and are largest at 2 to 3 years old. Towards spring, and during breeding, all ducks lose flesh and become light. These are hardy, easy to raise, and the eggs usually fertile if the ducks are not kept too fat. No breed excels this for laying; they commence in March and lay till July or August. They mature early; and at 6 weeks old are fit for market, weighing about 3 lbs.



Aylesbury Duck.

BLACK, or DUSKY.—They breed from Canada to the Gulf of Mexico, in any lake or marsh. The nest is built under bushes, beside logs, and often on high ground a distance from water. They cover the eggs when leaving the nest, to conceal them from crows and other birds. Only 1 brood is raised a year at the North, though 2 are common at the South. The young are covered with brown down, are taken to water as soon as hatched, grow rapidly, and at 4 or 5 mos. equal their parents. They feed on bugs, seeds, and roots of grasses. In captivity they lose all activity and grace, retaining but one instinct, fidelity to one mate. Several generations of crossing are required to destroy this characteristic. The body is brownish black, margined with reddish brown; head brownish yellow; upper part black, with green cast at the sides; wing coverts grayish brown; tail short, and rounded. The length of the male 22 in.; weight, 3 lbs.

CALL.—Round and compact in form; gray or white; the gray resembles the Rowen, while the white resembles the Aylesbury.

EIDER.—Perfectly tame. The duck is mottled gray and brown, and hardly to be distinguished at a short distance when upon her nest. It is she who fur'shes the eider down. The drake has a showy back, white plumage, and is a conspicuous bird, but not so tame as his mate. When the nest has been repeatedly robbed of the down, and the duck finds difficulty in replacing it, the drake comes to the rescue, and supplies her with down from his own breast.

MUSCOVY.—A distinct species; larger than the common duck; has a red membrane covering the cheeks and behind the eyes; has a musky odor. In a wild state, the drake is brownish-black, with a broad white patch on the wings; the female is smaller and more obscurely colored. In the domestic state it exhibits every variety of color. It is easily fattened, a prolific breeder, a voracious feeder, but profitable to rear. The male will pair with the common duck.

Muscovy Ducks.

PEKIN.—Their color is snowy white; very handsome for small bodies of water or the lawn. They have yellow colored bills and legs, free from black spots. They can be raised anywhere; do not require much water until several months old, and even then they will do well with a small trough of water, if they have grass range. They mature early and can be marketed in July and August at high prices. It takes in warm weather 3 weeks to hatch them. At birth they are larger and stronger than other varieties and when developed weigh about 18 lbs. to the pair. They lay 150 eggs per year. During the summer they require but little food, if they have a good range and access to the chicken yard.

ROWEN.—One of the most useful and hardy; plumage dark and rich; awkward in gait, and dull in countenance; especially adapted for putting on flesh, which is dark, but excellent; prolific layers. They ought to be of the largest size, for, if small, it is probable they are not far removed from the wild breed, and in that case will be apt to stray away, and be less prolific in eggs, though both eggs and flesh will be higher flavored.

Care and Management.

EGGS.—The eggs of the duck are known from the common fowl by their bluish color and larger size, the shell being smoother, not so thick, and with fewer pores. When boiled, the

white is never curdy, like that of a new-laid hen's egg, but transparent, while the yolk is darker in color; the flavor not so delicate. For omelets, puddings and pastry, duck eggs are better than hen's eggs, giving a finer color and flavor.

FEEDING.—Young ducks should be fed upon cornmeal or curds, kept in a warm place at night and not let out early in the morning. They should be kept from water to swim in, as it always does them harm. When ducks grow large they will provide for themselves a considerable part of the year. They live on grain strewed about the poultry-yard, the sweepings of barns, mealy substances, the residue of breweries, herbage, roots and fruits. They are fond of boiled potatoes, and these have been substituted for maize and barley. Every kind of flesh or offal forwards their growth. Ducks often try to swallow a whole fish, or a frog, which heats them, if they do not immediately throw it up. Slugs, spiders and toads suit their appetite.

FATTENING.—When ducks are being fattened allow no pond, only a trough of water. Butchers' offal is excellent and does not give the flesh a rank flavor. Acorns injure the flavor, and barley renders it insipid. It expedites fattening to have coops, quiet, and darkness. Ground malt, mixed with water, is excellent. When ducks have been rendered tolerably fat by being at large, they are cooped in a dark place and taken out morning and evening to be crammed. This may be done by crossing their wings on the knees, opening their bills with the left hand, while with the right they are stuffed with boiled maize. Many are suffocated by the operation; but their flesh is not the worse, provided they are bled. It requires a fortnight for the process. The sign of their being fat enough, is when the tail opens like a fan, from the fat pressing on the roots of the feathers.

HATCHING.—The domestic duck is not disposed to hatch; to induce it to do so, towards the end of laying, 2 or 3 other eggs may be left in each nest, taking care every morning to take away the oldest laid, that they may not be spoiled; 8 to 10 eggs may be given; they should not be sprinkled with cold water. The duck cannot go to her food and it must be placed before her. First broods are usually best, because the summer helps to strengthen the ducklings. The ducklings are no sooner excluded than the mother takes them to the water, where they dabble and eat, and many of them perish, if the weather is cold.

LAYING.—Ducks begin to lay towards the end of February, and earlier; some will lay 50 and even nearly double that number. They do not lay later than May, unless they be well fed. In the wild state there is only one duck to a drake, therefore in domestication the fewer the better. At the laying season, ducks require to be looked after, for they are not so easily brought to lay in nests as common fowls, but stray away to lay, and sometimes drop their eggs in water. As ducks usually lay at night or early in the morning, to secure their eggs, confine them, when they must lay.

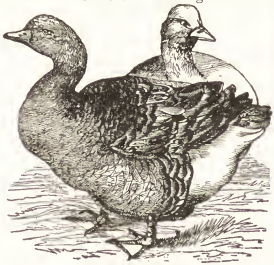
PONDS.—In order to keep ducks a pond should be provided, if there be no water convenient; and, if the pond will admit, have an island in it, planted with aquatic plants.

SHELTER.—Ducks should have a house with a brick or stone floor, which should be frequently washed. Give straw for bedding every 2 days.

GEESE.

BREEDS.

AFRICAN.—A large goose, with straight neck, and head carried level in walking. The head



Common Geese.

is brown, and bill hooked. Rare in the U. S.

CHINESE.—A well known variety embracing several kinds; the geese smaller than Toulouse, but fine birds; the white variety with red legs is beautiful; flesh good; fatten easily, and are prolific.

COMMON.—These are divided into large and small, and white and gray. The gray are the best and prove the most prolific.

EMBDEN.—The most valuable domesticated breed. They have heavy bodies, strong necks; white plumage and blue eyes. They are heavy, weighing 20 lbs.

HAWAIIAN.—These geese commence laying in April. In the wild state they lay but 2 or 3 eggs, while in domestication they sometimes lay 8 or 10. They are fond of human society; are less aquatic than other geese, rarely remain in the water long, and show little disposition to fly.

TOULOUSE.—Chiefly remarkable for size. The head is a slaty blue, marked with bars; neck dark brown; breast slaty blue; belly white; bill orange red, and feet flesh color; of a mild and easy disposition, which conduce to fattening, at little cost; flesh tender and well-flavored.

Care and Management.

FEEDING. — Feed young goslings cornmeal ground with the cob, mixed into dough, rather

Toulouse Goose.

dry, with a little salt; teach them to eat regularly; throw a morsel at a time, in the midst of a flock, or the old geese will get the most. Goslings soon become tame and will eat as long as one will feed them. At the end of the 3rd week feed twice a day; after the 6th not at all, till ready to fatten them for market. If goslings are taught to eat, well fed, and kept dry till feathered, success is certain. The older geese should be fed corn and wheat screenings; put their grain in water, so that they will have to put their heads in to get at it.

FATTENING.—Geese may be brought to great fatness; at which period kill them, otherwise they become lean and many of them die. Geese may be fattened when young, and after they have attained full growth. The methods at each period are nearly the same. Give boiled oats 3 times a day, with plenty of milk; this will fatten them in a month. For stubble geese, besides oats, give split beans, meal and water, and coop them up in narrow pens, so low that they can neither stand upright nor move; keep clean, by renewing the litter. A few feathers are previously plucked out from the rump, and from under the wings. The maize required for feeding is boiled and put into a trough, with clean water, and they are permitted to eat when they feel inclined; they eat a great deal, but in about 3 weeks their appetite falls off. As soon as this is perceived, they are crammed. A lean goose is confined in a small coop, narrow enough to prevent it from turning. Water is supplied in a trough, having some bits of charcoal in it. A bush. of maize is enough food for a month. It is soaked in water and the goose crammed morning and evening, but allowed to eat and drink as much as it chooses. About the 22d day, a quantity of poppy-oil is mixed with the maize. In a month, it is seized with difficulty of breathing, and a lump of fat under each wing indicates that it is time to kill it, lest it should be choked with fat, and die.

HATCHING.—Geese are good mothers, but not good hatchers; 2 to 4 are enough for 1 gander; eggs may be set under hens; 3 or 4 are enough for a moderate sized hen. When a goose appears tractable, let her hatch 1 brood, and when those hatched under hens are big enough, they will all go together. While geese are setting, dust them with dry sulphur, to cleanse them from vermin. After the 28th day the eggs should be put in milkwarm water a few moments each day. This softens the shell, enables one to throw away the rotten, and to count the goslings. Goslings are a month hatching, and must be taken from the mother; for, feeling the young under her, she might leave the rest unhatched. Having separated them, they must be kept in flat wicker pens, or baskets, covered with a cloth and lined with wool. When the whole brood has come forth, the first hatched may be returned to the mother. Sometimes, when the eggs are nearly hatched, the shell is broken to help the goslings out. Have the nest tight, and keep the goslings in over 1 night after all are hatched. Make a triangular pen where the grass is short, and move to a new place every day. Put in a shallow dish of water, and keep it fresh. Feed little and often, while small, and at the end of 1 week they may be turned into a pasture; but shelter at night. If a gosling gets wet and begins to droop, carry it to the fire and dry it.

LAYING.—When well kept, geese will lay 3 times a year, from 5 to 12 eggs each time; if the eggs be removed as soon as laid, a goose may be made, by proper feeding, to lay from 20 to 50 eggs. They begin to lay in March; it may be known by her carrying straws to form her nest. They should be watched, lest they lay in some by-place. As soon as geese want to lay, coop them up under their roof, where nests made of straw have been prepared. If they can once be induced to lay in this nest, they will continue to do so till their number of eggs is completed. To have early goslings, geese should be brought to lay early by keeping them in a warm, clean place, and feeding them on stimulating food.

PONDS.—To raise geese successfully, have a pond, or running water, into which they may go at pleasure.

SHELTERING.—Geese need a clean, dry place to sleep in. It is not well to keep geese with poultry; for, when confined in the poultry yard, they will harrass the hens and turkeys.

Turkeys.

REMARKS. — In selecting a turkey cock, see that he is large and majestic. Both cock and hen should have short legs, full shapes, energy in movement, and be healthy. A turkey cock is in his prime in his 3d year, and the hen in her 2d year.

BREEDS.—Diversity of color is about all that constitutes varieties, the *Black, White, Copper, Brown, Bronze, Dusky Gray,* etc. As to relative value, there is doubt. The brown and ashy gray are not remarkable; but the black are superior as regards hardiness, rearing and the quality of flesh; and they are very prolific.

FEEDING. — Turkeys nearly feed themselves in the farmer's yards and fields; if not so fortunate, scatter oats or corn among them, or feed boiled potatoes or Swedish turnips: feed only so much corn as they will eat up clean. For summer feeding use buckwheat, barley, or screenings of wheat.

Turkey.

For autumn and for fattening, yellow corn, as that gives a rich color to the skin; give milk regularly; chopped onions, bread crumbs, corn bread, cheese curds, or any clean food to insure health.

FATTENING. — Feed meal, boiled potatoes, oats, and mix pulverized charcoal with their food. After 6 mos. cram, like fowls, with the same kind of food, but they need not be closely confined, though a dark place is recommended. It requires 6 weeks to fat, and it would be barbarous to confine them in pens; they may be left in close farm yards. To have large turkeys, cocks should be kept over for fattening until nearly 2 years old; but a young turkey hen, in spring, is much better in flavor. Early feeding of young turkeys is similar to that recommended for fowls; egg is a favorite food; they may soon have nettles and parsley, made into balls, and grits or meal boiled thick, which they will peck from the hand.

HATCHING. — It is better for turkeys to be hatched early. The earliest eggs must be hatched under a common hen, for the turkey, when young, seldom sets on her first clutch, and it is not profitable for her to do so. Never keep over 2 or 3 breeding females ordinarily; if a business, one can keep as many breeders as accommodations admit. Turkeys do not want to be cramped; they like extensive grounds and freedom; the more there are, the greater area required. The male should be changed every year; or, if reserved, the females should be of distinct blood. Choose a quiet hen for a setter, and a quiet place for her nest. A hen will cover from 15 to 18 eggs; while sitting, she should not be disturbed, nor taken from the nest after hatching, for at least 24 hrs.; if contented, allow her to stay longer. The young turkeys gain strength by being quiet for a day or two at first. Watch the hatching, and if a chick is not likely to come out strong, the shell may be broken, and the chick saved. After the hen and her brood is taken from the nest, give her a large, airy coop, where the grass is closely mown off, and the chicks can bask in the sun, run, and pick up bugs and insects.

LAYING.—Hens that have been well kept, lay before they are 1 yr. old, if the season be open. The laying period comes on at 9 mos., and seldom later than 10 mos. from the shell. One fecundation, it is said, renders all the eggs of that laying fertile; some allow 1 cock to every 12 or 14 hens. The laying season is known by the liveliness and strut of the hen, and a peculiar cry. This takes place in March. When let out in the morning, examine the hens, and keep in such as are about to lay. While the hen is laying, the cock should be kept from her. The eggs must be taken as soon as laid, and they will keep if put in a basket and kept dry. The hen will hatch other eggs than her own.

SHELTERING.—In keeping turkeys, let them have a large shed, protected from the weather. The perches should be high, and a ladder must be supplied, as they are apt to injure themselves in their descent. During warm weather let them select their roosting places, but watch, lest they stray, and in cold weather get their toes frosted. Young turkeys, not well feathered, should not be allowed to run in the dew, for a chill will prove fatal. Allow them to roam, but long before night pen them in a roomy coop, after feeding.

TREATMENT OF DISEASE.

APOPLEXY. — Cause, a full habit of body; occurs in overfed birds, and most common among laying hens. Without warning, they fall, roll on their backs, struggle for a minute or two, then rise, stupid and giddy, and return to their food. *Treatment:* Wash the head in cold water, and keep a wet rag on the head. Give 2 gr. calomel, mixed with 5 gr. rhubarb; if it does not operate in 3 hours, give 1 dessertspoonful castor oil. Keep the bird warm and quiet, on light food, and in a dark coop, until recovery.

ASTHMA. — Gaping, panting, and difficult breathing. *Treatment:* Give warmth, with small repeated doses of sulphur, mixed with butter and cayenne pepper.

BALDNESS. — Loss of feathers from the head and neck; caused by want of wholesome and green food. *Treatment:* Rub the place with mercurial ointment, and give a 5 gr. Plummer's pill every 2d day for 1 week. Give green food.

BLINDNESS.—*Treatment:* Wash with warm water; then put a few drops of green tea into the eyes.

BUMBLE FOOT.—A large bunch on the sole or heel, which sometimes suppurates and forms a callosity. Caused by alighting from a high perch, or from perching on a flat pole, the whole weight coming on the ball of the foot. *Treatment:* Prevent by proper roosting poles. Round perches are best. The pole for a full-grown fowl should be 1½ in. in diameter. One sufficiently large to bear the weight is all that is neces-

sary. When roosting on a tree, fowls seek the branches that are small and easy to clasp the toes around. Square or large perches cause crooked breast bones.

CANKER. — In this disease the mouth and throat become filled with a cheesy substance of offensive odor, sometimes causing stoppage of windpipe, suffocation and death. *Treatment:* Take out all cheesy matter with a small spoon and pincers, and wipe out the mucus from the mouth, nostrils and eyes. Prepare a solution of chlorinated soda; dilute it with 6 parts water; wash the head, eyes, nostrils, mouth and throat out, using a soft swab; in 20 minutes give a feed of chopped meat, mixed with bread soaked in ale or spirits and water, and sprinkled with cayenne pepper; keep up this diet until well.

CATARRH.—Cause, cold and dampness. The symptoms are a watery or sticky discharge from the nostrils, and swelling of the eyelids; in worse cases the face is swollen at the sides, and the disease has the appearance of roup. *Treatment:* Remove to a dry, warm situation. Give mashed boiled potatoes, dusted with black pepper. In severe cases, treat in the same manner as roup.

CHILLS.—*Treatment:* Give ground malt and barley-meal in equal quantities, adding a little powdered caraway or coriander seed.

CHOLERA.—*Treatment:* Mix with skim milk and place in small troughs, whenever there is any appearance of the disease, 2 tablespoonfuls of the following: 2 oz. each flowers of sulphur, powdered alum, resin, cayenne pepper and copperas. Let these be stirred into 6 qts. cornmeal.

CONSUMPTION.—Cause, confining chickens in unhealthy places. The symptoms are not strongly marked in the early stages, but in the advanced state there is wasting, cough, and expectoration of matter. *Treatment:* Prevent by wholesome diet, and good housing. In advanced stages it is incurable. Give cod-liver oil mixed with barley meal. Temperature is the principal thing to see to.

COSTIVENESS.—Cause, dry diet, without access to vegetables, and want of good water. *Treatment:* 1. Give soaked bread, with warm skim milk.—2. A meal of fresh meat, or hot potatoes, mixed with lard.

CRAMP.—Cause, damp and cold. The feet are contracted and the fowl unable to move its legs. *Treatment:* Dryness and warmth, with oatmeal mashed with ale for diet.

CROP-BOUND.—The crop is overcharged, and unable to expel its contents into the stomach. The bird being hungry stuffs his crop until it becomes a mass. *Treatment:* With a sharp penknife cut through the skin and upper part of the crop, and remove the impacted mass by some blunt pointed instrument. If it has remained many days and is offensive, pour some warm water into the crop. The incision, if small, may be left; but if large, a stitch or two should be taken. Give soft food for a day or two. Sometimes a dessertspoonful of gin will stimulate the crop to overcome the mass, and render the knife unnecessary.

CROUP. — *Treatment:* Remove the croup membranes from the mouth with a feather; then touch the parts with a feather dipped in a solution of nitrate of silver, 10 gr. to 1 oz. of rain water. Feed no raw grain, but well boiled oatmeal or cornmeal will be excellent. Put ½ oz. carbonate of soda in every qt. of water drank, and change their roosting-place to a new building. If this last cannot be done, clean the place, and wash it over with a solution at the rate of 1 oz. carbolic acid to 1 qt. water.

DIARRHEA.—*Treatment:* When brought on by green or soft food, the diet must be changed, and water given sparingly. Give powdered chalk and rhubarb, of each 5 gr.; 3 gr. cayenne pepper; if this does not check it give the following every 4 or 5 hours: Powdered opium, and powdered ipecacuanha, of each, 1 gr.

DISTEMPER.—An affection of the head and throat of young fowls. The symptoms are listlessness; remaining on the roost; face and comb red, and puffy under the eyes; no appetite. A white froth appears in the corner of the eye the 2d day. *Treatment:* Wash the head and beak clean, and clear the tear tube by blowing through the nose into the throat; bathe the head and wash the throat with a solution of carbolic acid—1 part of acid to 10 of water. Keep quiet and allow only water for a day or so. In aggravated cases, steam the head and throat, give a dessertspoonful of castor oil, and repeat the carbolic acid treatment at short intervals.

EGG ORGANS, Inflammation of.—Cause, overfeeding. The symptoms are, going on to the nest without laying; laying shell-less eggs; dropping eggs from perch or elsewhere. *Treatment:* Low diet of boiled mashed potatoes and boiled rice for a week or more; give a dessertspoonful of castor oil, and a pill containing 1 gr. calomel, and 1-12 gr. of tartar emetic every 2d day for a week.

FEATHERS, Loss of. — *Treatment:* Give, internally, cayenne pepper and sulphur, ¼ each, mixed with fresh butter. Let the fowls have access to plenty of lime. The diet should be changed, and cleanliness and fresh air secured.

GAPES. — A worm infesting the windpipe. Cause, impure and stagnant water. The symptoms are gaping, coughing and sneezing, inactivity, ruffled feathers and loss of appetite. *Treatment:* 1. Take the chicken in the hand, and insert a small-sized wing feather, dipped in kerosene oil, down the throat; turn it round 2 or 3 times, and you will find a small red worm attached to it. Feed wheat screenings and cracked corn or dry feed.—2. Give water to drink impregnated with camphor.

GIDDINESS.—(See *Apoplexy.*)

INDIGESTION.—Cause, overfeeding and want of exercise. *Treatment:* Give less food; turn the fowl into an open walk, and mix powdered gentian and cayenne pepper in the food.

LEGS, Scaly.—Resulting from debris left by small lice in the shank of fowls. They burrow between and under the feet and legs, and the deposits seen are dead insects and the destroyed scales of the parts. When the insects are left to work for a long time the excrescence becomes irritating, and, in an old fowl, sore. It is transmissible from a hen to her chicks. An affected

fowl on the roost will infect others. *Treatment:* Before hens become broody, smear their shanks with carbolic soap, every 2 or 3 days. Treat the perches in the same way.

LEG WEAKNESS.—A disease of young fowls. The symptoms are moping, squatting and staggering. *Treatment:* 1. Remove to a dry, warm place and give cayenne pepper daily in the food. —2. See that that the fowls have lime, and give bone meal in the food.

LICE. — The symptoms are refusal of food, rumpled feathers, comb dark blue at the end. *Treatment:* 1. Grease the fowls under the wings, over the vent and on the head, with ointment made of lard and sulphur. Examine the roosts and wash thoroughly with coal oil.—2. Dissolve 1 oz. carbolic acid in 1 gal. hot water and wash the roosts, and throw the remainder of it over the floor.—3. 2 or 3 lbs. copperas, dissolved in 2 gals. water, will cleanse roosts, and keep poultry in health.—4. Mix a few sprigs of cedar bush with hay or any kind of litter for hen's nests.—5 Syringe the roosts and poultry with pennyroyal tea.

PARALYSIS. — Cause, overstimulating diet. *Treatment:* Incurable. Give plenty of exercise, mixed diet and well ventilated, dry quarters.

PIP.—Cause, want of water or bad water. A dry, horny scale appears upon the tongue. The beak becomes yellow at the base, plumage ruffled, the fowl mopes and finally dies. *Treatment:* Frequently moisten the mouth; if the scale of the hardened membrane is loose, remove it. Do not scrape the tongue, nor use rough modes; apply borax, dissolved in pure water, and tincture myrrh, with a camel-hair brush, 2 or 3 times a day. Give onions or parsley chopped and mixed with potatoes and a little Indian or oatmeal; give pure water; also, a teaspoonful castor oil, according to age.

POX. — A contagious eruption of the comb, face and wattles. The symptoms are yellowish white rash, bleeding profusely when the crests are removed. It takes from 5 to 7 days to run its course. *Treatment:* Remove the crests and bathe in hot water and carbolic acid. When the bleeding ceases, apply citrine ointment; take off the scales after 60 or 72 hours. Take 1 tablespoonful each of common flour, and flour of sulphur; 1 teaspoonful cayenne pepper; 60 gr. hyposulphite of soda; milk enough to mold into 20 pills; dose, 1 pill each morning. Dissolve 4 gr. quinine in $\frac{3}{4}$ pt. of milk, and give in 3 equal doses during the day. Feed boiled onions and rice mixed with oatmeal.

RHEUMATISM.—Cause, exposure to cold and wet. The fowl is unable to move. *Treatment:* Give good food and warm, dry quarters.

ROUP. — Cause, dirt, too hot feeding, and want of exercise. The symptoms are difficulty of breathing, constant gaping, dimness of sight, lividity of the eyelids, a discharge from the nostrils that gradually becomes purulent and fetid, loss of appetite, and thirst. *Treatment:* 1 part powdered gentian and powdered ginger; 1½ parts Epsom salts; ½ part sulphur; make up with butter and give every morning. If the discharge becomes fetid, bathe the mouth, nostrils and eyes with the following: 1 part chloride of lime; 1 part acetate of lead; or with an infusion of chamomile flowers.

SPINAL CURVATURE.—This causes the tail to be carried on one side. It arises from overgrowth when young, caused by high feeding and too much confinement. *Treatment:* Nourishing but not animal food, a good run, and green food, are the best preventives.

STOMACH, Inflammation of. — Cause, overstimulating food. When a fowl mopes and refuses to eat, or selects only soft food, and gradually pines and becomes thin, inflammation of the stomach may be suspected. *Treatment:* Give an occasional gr. of calomel, at intervals of several days, and a wholesome diet.

ULCERS.—*Treatment:* Dress with a little lard, or wash with a weak solution of sugar of lead. If they appear sluggish, touch them with bluestone.

VERTIGO.—(See *Apoplexy.*)

WHITE COMB. — *Treatment:* ¼ oz. turmeric powder; 1 oz. cocoanut oil; apply to the comb.

WINGS, Drooping. — Caused by *Lice,* which see.

WOUNDS.—*Treatment:* Wash with a solution of 1 dr. carbolic acid in 8 oz. water.

DOG VERSUS BABY.

PET STOCK.

ANIMALS.

CATS.

BREEDS.

ANGORA, or PERSIAN.—Remarkable for great size, length and delicacy of hair, especially of the belly and throat. Color usually white, yellowish, or grayish, while the soles and lips are sometimes flesh color. Its temperament lethargic, which is generally due to excessive petting.

BLACK.—These are remarkable for clear, yellow eyes; coat rarely entirely black, having generally white hairs on the throat. When young they show striped markings.

GRAY.— Very rare; a tabby, without black stripes, except 2 large ones over the forelegs.

MALAY.—Found in Pegu, Siam and Burmah. Their tails ¾ the ordinary length, and contorted in a sort of knot.

MALTESE (Blue or Carthusian).—This breed has long, soft hair of a uniform dark, grayish blue tint; black lips and black soles.

ROYAL SIAMESE.—This cat is fawn color of a dark tinge, with a tendency to darker color about the muzzle; remarkable blue eyes, and sometimes 2 bald spots on the forehead.

TABBY.—This may be the result of crossing of the domestic cat by the wild cat. That they do breed together, sometimes, is certain.

TORTOISE-SHELL. — Fawn colored, mottled with black. Cats thus marked are generally females, while sandy colored ones are males. It seems that the sandy tomcat is the male of the breed of which the tortoise-shell is the female—the litters being so divided.

WHITE.—Have blue eyes, or eyes of the ordinary color (an obscure yellow), with a tinge of green. Those with blue eyes are generally deaf. It sometimes happens that the eyes of a white cat are not always alike in color; one may be blue and the other yellow.

CARE AND HABITS.

FOOD.—Cats will eat any kind of fresh meat, fish, birds and insects, and are very fond of cow's milk.

LONGEVITY.—The length of the lives of cats varies; 12 years is probably its limit; but, in some cases, 18 yrs. may be attained.

REPRODUCTION.—The domestic cat begins to be ready to reproduce by the end of the 1st year, and is prolific to her 9th. She carries her young from 55 to 56 days; has generally 5 or 6 young at a birth, and sometimes 8 or 9.

DOGS.

BREEDS.

ALBIAN.—About 27 to 28 in. high, with long pointed muzzle, powerful body, muscular limbs, and a long, bushy tail, like that of the Newfoundland. The hair of a silky texture and fawn color, clouded with brown. Used for hunting wild boars and wolves and for guarding sheepfolds.

BLOODHOUND.—Named from his power of scenting the blood of a wounded animal, so that once on his trail he could hunt him through any number of his fellows, and thus single out a wounded deer from a herd. He has been used to trace human beings. His height is 24 to 26 in.; forehead long and narrow; ears 8 to 10 in. long; lips hanging; throat loose and roomy; deep in the brisket, round in the ribs; loins broad, legs and feet straight; color black and tan, or deep and reddish fawn.

BULL-DOG. — The bull-dog and bull-terrier are fighting dogs. They have short, broad muzzles; head massive and large, and the frontal sinews broad; lips thick and pendulous; ears pendent; neck short; legs short and thick. When properly domesticated they are harmless.

DALMATIAN, or COACH DOG.—Resembles the pointer; has fine muzzle, small ears, dark eyes, sparkling and small; ears spotted, not black, nor any black upon his muzzle, head, or body, except in spots. Black on the head or ears not unfrequent, but it detracts from his beauty. Black

Coach Dog.

and tan on the head is not uncommon and occasionally tan spots, mingled with black, on the legs, feet and hips. The tail is like the pointer's, but inclined to coarseness. The feet small, well split up, close and firm. His chief beauty consists in his marks.

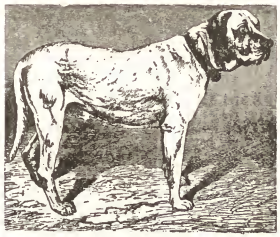
FOX-HOUND.—Prevailing colors: Black and white with tan; mixed or blended colors, known as red pie, blue pie, yellow pie, gray pie, lemon pie, hare pie, and badger pie; the last 3 are handsome. Height of male from 23 to 25 in., female from 21 to 23 in.

GREYHOUND.—The greyhound is used in the chase; and, as he hunts by sight, rather than by smell, his eyes are placed more forward than in other dogs. His head is slender and finely shaped; muzzle long and pointed; ears droop at the points; back is broad and muscular; body lank, and much contracted in its lower parts; legs long and muscular, while the chest is capacious; tail slender and curved upward at the end. The principal varieties are the *English, Rough Scotch, Italian, Persian, Russian,* and *Turkish.*

Italian Greyhound.

HARRIER.—A dwarf southern hound, with a slight infusion of greyhound; is more throaty than the foxhound, and has more ear, with a broader head, more fully developed flews, and a heavier and less active frame. Height 18 in.

MASTIFF. — A large variety; head large, and muzzle broad; ears moderate size and pendent.



Mastiff.

His strength is great, and his vigilance as a house dog unrivalled.

NEWFOUNDLAND.—There are several varieties: A smooth breed, with small head; white spotted with black, which seems to be extinct; a large breed, with broad muzzle, head raised, noble expression, curly hair, thick and bushy

Newfoundland.

tail. He is the water dog *par excellence*. The purer, the better water dog he will be; yet many dogs, possessing Newfoundland blood, make excellent dogs for ordinary sporting. His education comes by nature. In his infancy he may be taught to bring a glove and lay it down; and by practice, his various duties will follow. With judicious exercise of authority, he becomes very docile. They have been known at 4 mos. old to fetch a duck, but they should not be put too early at hard service.

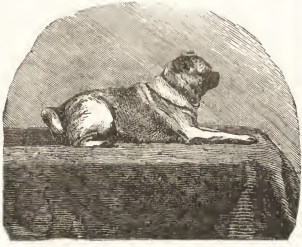
POINTER.—A valuable sporting dog. When it scents game, it stops motionless, until the sportsman comes near, and is prepared to shoot; he then gives the word and the dog springs upon the game. It requires but little training. Its scent and sight are acute.

Pointer.

POODLE.—This dog is covered with long, silky hair. It is considered the least useful of any variety, and is only kept as a pet.

Poodle.

PUG.—A diminutive bull-dog,



Pug.

having a bushy tail. It is cleanly, sensible, and somewhat intelligent and affectionate. It is small, of a fawn color, with black muzzle, and curled tail.

RETRIEVER.—A cross breed. The head is long, ears small, and set close; eyes and mouth large; chest broad and powerful; color, black or black and tabby. They are good tempered, and are used to bring in birds that are shot.

SETTER.—Probably a large species of spaniel. He is intelligent, docile, and courageous. He is taught to set or stand at birds, and is held in great value by sportsmen. He is not a clean house dog, and should be confined to his kennel. There are three kinds: *English*, *Irish* and *Russian*, the latter more like a poodle.

SHEPHERD.—There are 2 varieties: 1 short-haired, black on the back, white on the breast, belly and feet, with tan-colored spots on the cheeks, shoulders and thighs; the 2d, large and rough, with long hair; in color resembling the 1st. Crosses between these breeds have produced numerous races of dogs, doing duty in every sheep country. As soon as his strength allows, he applies himself to the care of sheep with fidelity. With little training he learns the will of his master. Training should commence when the pup is 5 or 6 mos. old; the older, the more difficult. In training, the services of an experienced dog will be indispensable. The

Retriever.

ardent temperament of the young dog must be subdued, and there is no better mode, than by compelling him to accompany a well-trained dog. A long line in the hands of the trainer, attached to a collar or belt, on the neck of the young dog, is generally necessary.

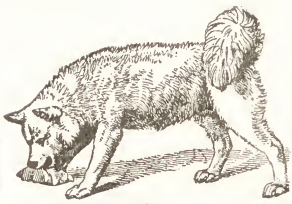
Setter.

SPANIEL.—There are several varieties, more or less elegant: The *Irish Water Spaniel* stands 21 in. at the shoulder, with long ears, round forehead, elegant sharp muzzle, and a comical face; body adorned with long ringlets, and though the face is bare, a few ringlets hang over the forehead; legs well covered with curls; color red, or dark mahogany. The *Clumber Spaniel* is long, heavy looking, short on the legs, strong, white in color, with orange markings; the coat straight and silky; head large and foolish-looking, but the eyes thoughtful. The *Sussex Spaniel* is from 30 to 35 lbs., of a beautiful golden liver color, with long head, dark brown nose, and well developed nostrils; mouth large, and the lips long and hanging; legs rather short and the body strong; coat short. The *Norfolk Spaniel* is liver and white color, at times black and white; legs and nose white, with brown freckles; shaped like the Sussex, but larger. The *Cocker Spaniel*, somewhat similar to the Sussex. The *English Water Spaniel* stands 19 to 20 in. at the

shoulder; color liver and white, with a collar of white; the dog is the only spaniel, except the Irish, on which a curly coat can be tolerated.

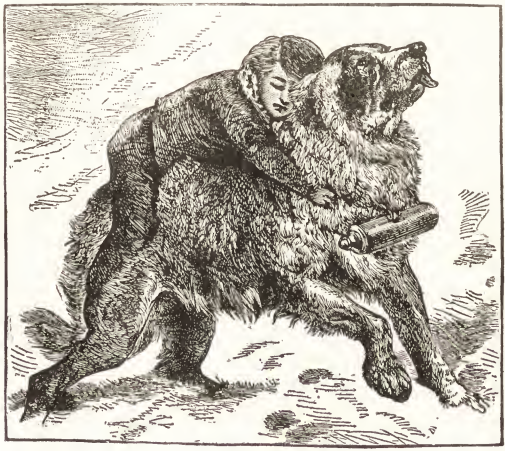
Spaniel.

has a stately carriage; tail heavy and well carried; they vary in intelligence; but a dog of moderate ability will learn to discover the dying and dead beneath the snow.



Spitz.

TERRIER.—A number of varieties, prominent among which are *Fox*, *Bull*, *Skye*, *Scotch*, *Dandy Dinmont*, and the smooth *Black and Tan* terriers. Noted for sagacity and power of scent; they will lie about and dig into a rat



St. Bernard.

SPITZ. — A breed of medium size, covered with long, thickly coated white hair; of hardy stock; active, sagacious, but rather cross; their bite thought to be dangerous; considered subject to rabies; when small, they afford amusement to children, and are often pets.

ST. BERNARD. — A mastiff capable of high training; could be educated as a retriever, but is almost too massive; reaches great weight; hole for days. They are of great assistance in hunting foxes and animals that burrow. The *Bull Terrier* is a cross between the bull and the terrier. Half bloods make good fighting dogs, while less of the bull produces a dog that will learn tricks. They are obedient, affectionate and courageous. Color white, or white patched with black; the under jaw does not project; fore legs straight and hind quarters strong. The

Fox Terrier was once used in fox hunting, but at present his place is taken by faster dogs. They weigh about 16 lbs.; head flat and nar-

Bull Terrier.

Black and Tan Terrier.

Fox Terrier.

row between the eyes; ears small and set back; jaw smooth, strong, and armed with strong teeth; eyes small, black and keen; nose black; shoulders straight; chest full; color white with black, or black and tan markings about the head; coat fine. Of all classes of terriers, perhaps the Fox terrier has greater intelligence; he is small, clean and attractive. The *Skye Terrier* is beautiful; the short haired variety is among the most valuable, being sagacious, hardy, energetic and courageous; color generally dark.

Breeding.

AGE FOR BREEDING.—The best age to breed from, is soon after maturity. When the result is desired to be small, the older both animals are

Scotch Terrier.

Skye Terrier.

the more likely this sequence; except in the last litter, which being often composed of one or two, they are not smaller than the average, but sometimes larger. All should be allowed to breed. The period varies according to size. Small dogs are adult at 1 yr.; large ones take fully twice as long to develop. The mastiff is barely full grown at 2 yrs.; large hounds and greyhounds at 1½ yrs.; pointers and setters from 1½ to 1¾ yrs.; terriers and small pet dogs at 1 yr. and even earlier.

CROSSING. — Crossing has 2 objects: 1. To prevent degeneration by keeping the same blood,

or what is called in-and-in breeding; 2. To improve the breeds when deficient in any desirable quality, by crossing with others which have it.

TIME FOR BREEDING.—The best time of the year for breeding is from April to September; for in the cold of winter the young are apt to become chilled, whereby growth is stopped and disease developed.

WHELPING, Treatment before.—When it is ascertained that the animal is in whelp, exercise should be increased freely till the 6th week, after which it should be given with care, to avoid strains. During the last few weeks the food should be regulated by her condition, which must be raised, if too low, or reversed, if too fat, the medium being such as is compatible with health, and neither tending towards exhaustion or inflammation. Excessive fat interferes with the birth of the young and the secretion of milk. It is better to separate her from other dogs during the last week or 10 days, as she becomes restless, is constantly looking for a place to whelp in, and if prevented from occupying any desirable place, she is uneasy. At this time the food should be of a sloppy kind, chiefly composed of broth, and milk and bread.

WHELPING, Treatment during.—The best way to prepare a place for the animal to whelp in, is to nail a piece of old carpet over a smooth boarded floor, to a regular bench, if in a sporting kennel, or on a flat board, raised a few inches. When a regular wooden box or kennel is used, she may as well continue to occupy it, as she will be more content; but it is not so easy to get at her or the whelps if anything goes wrong. A board, according to the size of the animal, with a raised edge to prevent the young rolling off, and supported by bricks a few inches from the ground, is all that is required; and if a piece of carpet is nailed upon this, and some straw placed upon it, the height of comfort is afforded. During whelping, the only management is in regard to food and quiet. While labor is going on, no food is required, unless it is delayed unnaturally. When completed, some lukewarm gruel, made with ½ milk and ½ water, should be given, and repeated every 2 or 3 hrs. Nothing cold should be given for the first 2 or 3 days, unless in the height of summer. Milk or broth should be given, until the secretion of milk is established, when a generous diet is to be allowed of meat.

TRAINING.

THERE is not space to give a long description of various tricks, but the most common, useful, and amusing ones are here explained.

CARRYING.—This consists of placing the article in the dog's mouth, and when he lets go of it, give him a slight box on the ear, and replace the article in his mouth. Whatever is given him to carry should be of such a form as to be grasped easily. The weight should at first be very light, and never more than he can carry. Dogs take pleasure in carrying articles, and feel the responsibility. When teaching them to carry food, care should be taken to keep them from eating it. Place the article in a covered basket, and when the dog has learned to carry a parcel give him this. If he attempts to get at the food, box his ears. By-and-by reward him with food, and then try him with a basket from which he can abstract the contents; if he tries to do so, punish him slightly, never permitting him to steal.

DANCING.—Taught by attaching a piece of meat to the end of a long switch; with this trace out in the air, in proximity to his nose, the figures you wish him to take, and you may depend upon his instinct leading him to follow the motions of the switch. Reward him with the meat after he has danced enough, and after a few lessons the switch may be used without any bait. He will at first follow its motions in the hope that there is something attached, and if he be rewarded, he will soon comprehend that following the switch means meat.

HUNTING.—As soon as the pups feed apart from the mother they should be called to their meals by firing a gun, commencing for a few days while engaged in eating their food. At first they will be terrified, but will soon associate the sound with enjoyment. Leave off when this object is attained. They must be taught from the first to come to heel at a call or whistle, and as soon as they understand the command, made to obey it by temperate chastisement for neglect. When old enough to walk out into the fields, they should be taught to obey the word "down." The command should be uttered with the whelp at the feet, forcing it down by pressure of the hand; repetition soon teaches the pup obedience, which may be occasionally rewarded by a bit of bread. When obedient at the feet, the pup should be ordered "down" when at some distance, and if a steady pointer can assist, he will soon obey; but, if not, walk quickly up and repeat the command in a stern voice. On the second disobedience a scolding is added; and if a third time the order be neglected, a cut with the whip accompanies the "down," and impresses it. This lesson is of great consequence. Teach the dog to drop at a wave of the hand. The animal must never be allowed to rise till ordered to "hold up," or simply "up." The next step is to teach the pups to drop at the report of the piece by ordering them "down" after discharging it, by degrees omitting the command, meeting any neglect at first by rebuke, and the second time by chastisement. On no account must they be allowed to rise until the piece is reloaded, checking any attempt by an imperious "down." To prevent the other dogs, when a comrade has found game, from rushing in upon the scent, the trainer must wait till the first dog has made a decided point, and then, if another runs in, his name and the word "soho," or other word of caution, must be shouted in a stern voice, at the same time waving the hand. If the game should run and the dog follows, the others will naturally approach, and they may be allowed to follow on the scent. But if any pup attempts to go before the one that found, he must be checked and punished if he disobeys. Young dogs should be allowed to play with the first game they see

chilled; with every successive bird they mouth, their ardor seems to increase, while they rarely injure it much. Dogs may be trained with very little correction, which should never be administered wantonly. If any dog is obstinate, it is best to fasten a light line to his collar, and just when he has gathered full speed, fetch him up sharply, which will send him tumbling over, and a few cuts of the whip will bring him to order. Any hunting dog may be taught to retrieve. Great patience is required, but the result amply compensates for the trouble. In teaching a dog to retrieve, an old glove, or other soft substance, should be used, and after allowing the pup to play with it, toss it from you and he will rush to get it. Call him after he has got it, and take it from him, rewarding him with kind words. Repeat this plan, using the command, "hie fetch," when you wish him to go, and "come in," when you wish him to return. By using the command, "come in," when he is a little distance from you, he will learn to obey. He will regain the glove. After practicing, you may drop the glove unobserved. He will follow your track for a distance to recover a lost article, by receiving the command, "hie fetch." You may now give the glove to another person to hide, first permitting the dog to see it in his possession, and he will be almost certain to find it. In first lessons, be careful to place the glove where the dog will be certain to find it. He should be taught to follow closely at the sportsman's heel when they are out together; this may be done by saying, "back, back," and striking him gently with the whip when he attempts to press forward.

LEAPING.—Extend a line from any support so high that the dog cannot step over; hold a morsel of meat near his nose, but a trifle above it, and induce him to approach to the line. With a sudden movement extend the hand beyond the barrier, saying "hip," or any quick exclamation. This will generally cause him to jump the barrier; when repeated several times he should be given the morsel. After a few repetitions, he will leap over, at a motion of the hand and the word of command. He should be rewarded for obeying, and it is well to have a switch to give a gentle cut, should he attempt to run under. The height of the barrier may be increased daily, taking care never to overtask his powers. When he has learned to leap, a hoop may be held in the hand, and he will jump through it. The hoop may be lessened in size until the dog leaps through one hardly bigger around than his own body, but, to do this, the trainer must display skill in conforming the motions of the hoop to those of the dog as he passes through.

PAW, To Give.—If the same paw is always given, the dog may be taught to offer the other one, when you ask for the "other paw," by taking it a few times when you make the request. It is easy for a dog to learn the difference between "right paw" and "left paw." It is well to lay extra stress upon "right" and "left" while training.

SITTING AND LYING DOWN.—Raise one hand over his head, and make a motion as though about to strike him on the top of his head with your palm; as you do so, use the word "down" distinctly and commandingly with each motion of the hand. While this is done, press firmly with the other hand upon his back, just over the hips. When he has done so, he should be patted. Repeat until he obeys the command readily. Then teach him to lie down, forcing him into a recumbent posture as you command him to "lie" down.

SITTING UP.—When the dog has learned to stand erect, he may be taught to sit up by pressing him down in the desired position. If he attempts to leave it, a gentle tap on the head with the switch will suffice. He may be taught to sit up without learning to stand erect; in this case he may be made to sit down, and, then, pressing his haunches down to prevent rising, tap him under the chin till he takes the right position. Repetition is necessary until he learns what is desired.

WALKING ERECT.—Hold a bone above the nose, but not so high as to lead him to jump up. As he reaches for it, raise it to induce him to rise on his hind feet, saying, "up, up." When he reaches the proper point, let him remain a moment or two, and then let him have the bone. Soon he will stand up by merely holding the hand in proper position, and saying "up, up." He may be taught to walk in this position by slowly moving the bone, or your hand, slightly in advance. These exercises should not be tedious, for the position is fatiguing. After he understands, you may check any attempt he may make to regain his natural position, by a tap under the chin or under the fore paws.

Treatment of Disease.

REMARKS.—The effect of medicines on dogs is much the same as on man; but there are exceptions. The dog can take a dose of aloes 6 or 8 times larger than that given to man; but the administration of ½ as much calomel or oil of turpentine would be of serious injury to the animal. Dogs have a short and strait alimentary canal, and purgative medicines act more quickly. The facility with which dogs can be made to vomit, is another peculiarity. Vomiting may arise by swallowing unpalatable matters. A good plan to prevent the vomiting of medicine, is to keep the head well raised for 1 hr. after administration, by attaching a cord to the collar, and fixing it at the requisite height. The kidneys are acted upon with more difficulty than with the horse, while the skin seems nearly incapable of being affected. The variety in the sizes of dogs should enjoin caution as to quantities in doses.

ASTHMA.—Dogs shut in damp cellars, and deprived of air and exercise, are attacked with asthma; old dogs are more liable than young. *Treatment:* Powdered bloodroot, lobelia, marshmallows, licorice, of each, 1 teaspoonful; mix; divide in 12 parts, and give 1 night and morning. If they produce retching, reduce the quantity of lobelia. The object is not to vomit, but to induce nausea or relaxation. Let the animal take exercise. Feed cooked vegetables; a small

quantity of boiled meat may be allowed; raw meat should not be given.

BOWELS, Inflammation of.—The symptoms are acute pain in the abdominal region; signs of suffering when moved, and the bowels constipated. *Treatment:* Put the animal into a warm bath for about 5 minutes; then take out, rub dry, and give the following injection: 4 oz. linseed oil; 1 gill warm water. To allay irritation give the following: 1 teaspoonful powdered pleurisy root; 1 tablespoonful powdered marshmallows; mix, and divide into 3 parts; give 1 every 4 hours. Should vomiting predominate, give a small quantity of saleratus in spearmint tea. If this does not give relief, make a fomentation of hops and apply to the belly, and give ½ oz. manna. For food, give barley gruel and mush. If the dog betrays heat, thirst, panting and restlessness, a little cream of tartar may be added to the gruel. The bath and clysters may be repeated, if necessary.

BRUISES, or SPRAINS.—*Treatment:* 1. Rub opodeldoe into the part frequently during the day.— 2. Bathe with rum or diluted alcohol.

COLDS AND COUGHS.—*Treatment:* Give a purge of oil, less food, and keep warm.

CONSTIPATION.—*Treatment:* Give a large dog ½ oz. castor oil, and repeat in 10 hours if the bowels have not moved. Give injections of soap and water frequently. If these means do not succeed, give the following: 1 dr. jalap; 1 dr. ginger; 1 dr. gentian; syrup to make a pill; give as 1 dose, and continue the injections. Mixed food and exercise will prevent it.

DISTEMPER.—Commences frequently with white mucus running from the nose. If it begin with a dry, hot nose, it is not so good a sign. The dog is restless, disinclined to move, has loss of appetite, looseness of the bowels, dry cough, debility, and wasting of the flesh. Some have only a part of these symptoms. *Treatment:* Give an emetic; feed beef soup, with rice, and a little meat well cooked. The 2d day give a teaspoonful to a dessertspoonful of castor oil every 2 hours until it operates, if costive. If his bowels be loose give a dessertspoonful of spiced syrup of rhubarb every 2 hrs., until the passages are colored by it. Give rich soup, little and often. If he still grow weak, give a teaspoonful of whisky in each pt. of soup. With patience and care he will be apt to recover.

DROPSY.—Preceded by loss of appetite, cough, diminution of urine, and costiveness. The abdomen shortly after begins to enlarge. *Treatment:* Powdered flagroot and male fern, of each, ¼ oz.; scraped horseradish, 1 teaspoonful; mix; divide into 8 parts, and give 1 night and morning. Give nutritious diet.

EAR, Internal Abscess of.—The affected side is turned downwards, and the dog shakes his head. *Treatment:* In the early stages foment the part twice a day with an infusion of marshmallows. As soon as the abscess breaks, wash with an infusion of raspberry leaves, and if a watery discharge continues, wash with an infusion of white oak bark.

EAR, Ulceration of.—*Treatment:* External ulcers should be washed twice a day with the following: 2 oz. pyroligneous acid; 8 oz. water, mix; as soon as the ulcers assume a healthy appearance, touch them with tincture gum catechu.

EPILEPSY.—*Treatment:* 15 gr. bromide of potassium, 3 times a day, dissolved in water. If the disease is caused by worms give the medicines ordered in such cases. (See *Worms.*)

EYE, Inflammation of.—*Treatment:* Bathe the eyes 3 times a day with green tea. Keep the animal in a dark place on a light diet; and if the eyes are very red and tender, give a pill composed of 29 gr. extract of butternut, and 10 gr. cream tartar. If a purulent discharge sets in, bathe the eye with the following: 5 gr. alum; 1 oz. water. Give the following: Equal parts powdered pleurisy root, bloodroot and sulphur; mix, and give ½ tablespoonful daily in honey. When the eyelids adhere together, wash with warm milk, and grease their edges with lard every evening.

FLEAS.—*Treatment:* 1. Bathe with an infusion of lobelia for 2 successive mornings, and afterwards wash with water and Castile soap.— 2. Rub the skin with powdered resin and bran.—3. Take tobacco stems and put them in the dog's bed.

HYDROPHOBIA.—2 days after madness has seized a dog, he becomes agitated, restless, and turns continually in his kennel. If at liberty, he goes and comes, and seems to be waiting for something; then he starts and bites the air, and dashes himself, howling and barking, against the wall. His voice undergoes a change; he then begins to fight with other dogs. These last symptoms indicate an advanced period of the disease, and the dog may become dangerous at any moment. *Treatment:* When a dog acts suspiciously, chain him up. If it proves to be hydrophobia, shoot him.

LUNGS, Inflammation of.—*Treatment:* Give a purgative; afterwards the following: 12 gr. digitalis; 3 gr. tartar emetic; 1 dr. nitre; mix, and divide into 6, 9 or 12 powders. Also give 5 gr. Dover's powder every evening.

MANGE.—*Treatment:* 1. 7 parts flour of sulphur; 2 parts sulphate ammonia; 1 part sulphate copper; pulverize the 2 latter ingredients to a fine powder, and mix the whole to the consistency of paste; rub well over the parts affected, and repeat on the 3d day.—2. Sulphur, 1 lb.; soft soap, 4 oz.; oil of tar, 1 oz.; whale oil, ½ pt.; mix for use, and rub in with the hand.

PILES.—Generally brought on by confinement, over feeding, etc., and show a red sore and protruded rectum. Dogs subject to constipation are likely to be attacked. *Treatment:* Give ½ teaspoonful sulphur, 2 or 3 mornings, and wash the parts with an infusion of white oak bark. If they are very painful, wash 2 or 3 times a day with an infusion of hops, and keep the animal on a light diet.

SCALDS.—*Treatment:* Apply, with as little delay as possible, a saturated solution of bicarbonate of soda.

ST. VITUS' DANCE.—*Treatment:* 8 gr. nitrate silver; 10 gr. ginger; syrup to form a mass; divide into 64 pills; give 1 or 2 morning and night.

THORNS.—*Treatment:* Extract with pliers, if they can be grasped. If too far in, bind up the

place with a plaster of shoemaker's wax, or a bread poultice, and it will soon come out.

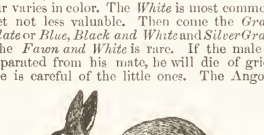
WORMS.—Dogs occasionally suffer with these, and the worms will be seen in the passages. If the animal starts in his sleep, is troubled with itching at the nose, and does not gain flesh on his fair allowance of food, worms may be suspected. *Treatment:* 5 gr. calomel; 40 gr. aloes; give at night, and follow the next morning with castor oil and turpentine, if necessary.

RABBITS.

BREEDS.

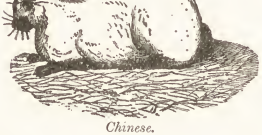
ANDALUSIAN.—With care this will reach 16 to 20 lbs. weight. The most robust variety known. The breeding of this rabbit is deserving of attention. It is a wonderful producer of flesh, rendering it the most profitable for food. At 8 or 10 weeks old it weighs as much as the common tame rabbit at 8 or 9 mos.; besides, the flesh is more tender, juicy and delicate.

ANGORA.—A rabbit of medium size, with erect ears. It differs from the common in fineness of fur, skin, habits and flesh; not so tender as others, and not so often used for the table. Its fur varies in color. The *White* is most common, yet not less valuable. Then come the *Gray, Slate* or *Blue, Black and White* and *Silver Gray*. The *Fawn and White* is rare. If the male is separated from his mate, he will die of grief. He is careful of the little ones. The Angora



Angora.

loves society. The young are never ill-treated, and respect the aged. This variety is bred for its long, silky fur; the old furnish it more abundantly and is more valued. In France their fur is combed every 2d or 3d month, and, as this operation makes them chilly, they should have warm lodgings, with bedding more abundant and clean.



Chinese.

BELGIAN.—Attain large size; not so fruitful as many varieties; ears large; head small; and in color they are similar to a hare.

CHINESE.—Also known as *Polish, Russian Warren* and *Himalayan*. They have red eyes; fur whiter and finer than the common white rabbit; nose, ears, feet and tail black or rich brown; they do not arive at this perfection till 6 mos. old. They are hardy, and are bred for their fur, which is valuable and the best imitation of ermine.

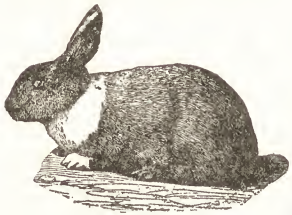
DOUBLE. or FULL LOP.—Lop eared rabbits are pets of the fancier. In breeding, there are 7 points to aim at: Length of ear, measuring from the tip of one ear to the tip of the other across the head; width of ear; position of ears; color; size of eye (the larger the better); carriage of body; and size. Both ears should fall near to the inner corner of the eye. The convex surface of the ear should be outwards, and the concave inside surface nearly concealed; the ear should be of the prevailing color; it

Double or Full Lop Ear.

should be thick and strong, though round and narrow at its root, becoming broad to the tip and not angular. The fashionable colors are *Black and White, Blue and White*, and *Tortoise-shell*. Good *Yellow and Whites* are admired, but are scarce. The nose is marked at each side with some dark color, having a dark mark running up the face; the eyes surrounded with coloring which joins the ears. The chain is a line of spots at each side of the shoulder, running from the ears to the saddle, which is a large patch of color, and should be large and unbroken by any other color. The saddle should be free from any but the prevailing color. The carriage should be low at the shoulder, high at the rump, head resting on the dewlap when sitting. They should not be less than 18 in., but 20 to 21 are good lengths.

DUTCH.—Known in France under the name of *Nicard*; very prolific, hardy, and largely

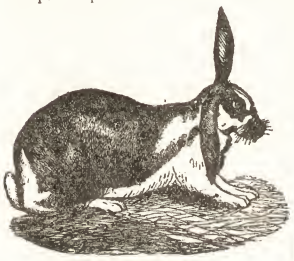
bred; useful as nurses, to bring up young fancy rabbits; of all varieties of color; many of them



Dutch.

have a white collar around the neck, and their chief excellence is diminutive size.

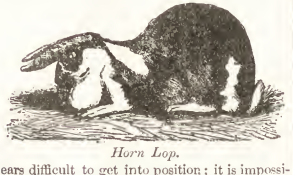
HALF LOP.—Derives its name from the carriage of its ears. It may be divided into 2 classes: One bespeaks impurity of blood; in the others, we find numbers descended from parents of pure blood. It is difficult to breed a litter from perfect specimens without 1 or 2 of them



Half Lop.

being half lop. In the first class the rabbit holds one ear erect, in the other both fall over one side. In the former, the ear will be found deficient in length; in the latter they often turn out longest eared and best lopped.

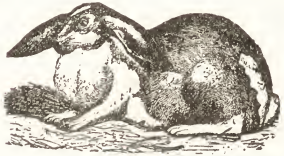
HORN LOP.— The horn lop is not so often met with, is ungainly in appearance, and the



Horn Lop.

ears difficult to get into position; it is impossible to make perfect lops of horn lops either by capping or stitching. Stitching is practiced by fanciers; that is, the ear is placed in position and stitched to the side of the face and allowed to remain for a week, when the stitch is drawn; but the cap is best. In color, form, and size, the Horn Lop resembles the other varieties of the lop-eared rabbit.

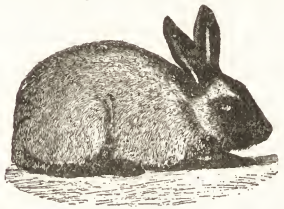
OAR LOP.— So called from the ears in this position resembling the two oars of a boat resting in the rowlocks. This is admired by some fanciers, but condemned by others. It bears a more close resemblance to the perfect lop than any other variety of this breed. Many rabbits carry their ears in this position, but are unfit for



Oar Lop.

exhibition, unless to compete for weight. The ears being thus carried should not be a reason for rejecting stock rabbits fine in every other respect.

SILVER GRAY. — Also known as *Chinchilla Silver Gray*, so called from the skin resembling that animal and being sold as a substitute. It is more developed in form than the wild or domestic rabbit. Its fur is dark, part silvery gray, and part slate color. The head and ears black, with a few white hairs; white hairs numerous on the neck, shoulders and back; on all the lower parts the number of white hairs is greater than those of a blue or black color. The young are quite black, and continue thus from 2 mos. to 9 weeks old, when white hairs show about the neck and loins. These hairs increase until 4 to 6 mos. old, when they assume the silver gray character. It is bred for its flesh and fur, but in cold climates it becomes iron gray instead of remaining silvery. The fur of the males is finest. To obtain a finer fur, castration of the males is in use, which should be performed when the animal is 3 mos. old. It not only improves the fur, but increases size. In climates where temperature alters its qualities, it requires great



Silver Gray.

care to profit by its skin. The temperature of burrows that suit the wild rabbit is suitable for tame rabbits. The darker and warmer the burrows, the finer, longer and more lustrous will be the fur.

Breeding.

AGE OF DOE.—The doe should not be allowed to breed at less than 6 mos. old; it is better, however, to wait till they are 8 or 9 mos. If under 6, they produce weak and delicate young.

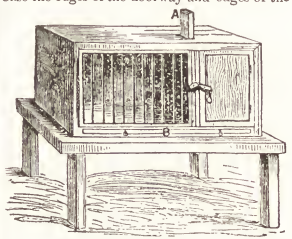
BREEDING-IN.—It has been proved that multiplication by son and mother, or between brothers and sisters, is a powerful cause of degeneracy in fur, fecundity and health. Rabbits of one color, that multiply in their own family, offer from the 3d generation white spots on the fur prejudicial to value. Fecundity diminishes, and weak rabbits are produced, subject to internal derangements, seldom living over the 1st molt, and dying at from 4 to 6 weeks old.

CHOICE FOR BREEDING.—The females must be strong, body long and well developed, hind legs large and well apart, teats apparent, and filled with milk at the approach of birth. The most gentle should be chosen, as the turbulent often destroy the young. The males should be bold and vigorous.

DELIVERY, Treatment before.—Pregnancy continues from 30 to 31 days, and a memorandum should be made to indicate the doe's fecundation, in order to separate her from the young she is suckling. Clean the hutch out, and give litter for her new family. If she is suckling and pregnant at the same time, she must be fed with succulent food, and occasionally a little salt given. Females suckling and breeding at the same time, are often so thirsty that they devour 1 or 2 of their young, to allay thirst. Give them, at least twice a day, a good handful of green food, and water once a day. Four or five days before birth, the litter should be removed and the rabbit left alone in her hutch to prepare her nest.

DELIVERY, Treatment during.—When the rabbit is vigorous, she is delivered without violent pain. The successive births sometimes last 24 hours. During parturition she loves quiet and secrecy, and it is customary to cover the door of the hutch over with a cloth, from the 28th day of gestation. Rabbits frequently die from a laborious birth or from weakness, the result of bad food, or from too watery green food. Delivered, she closes the opening of her nest and watches her new family. She suckles several times a day, but chiefly at night. If she is surprised, she starts away suddenly, and drags with her several little ones out of the nest. The mother does not replace them, unless the feeder does it for her.

HUTCHES.—Place them on stands 3 ft. high, around the sides of the rabbit house. Each hutch for breeding should have 2 apartments, a bedroom and a dining-room. The floor must be smooth, so that the wet will run off. They should be 2 ft. high, 2 ft. 6 in. deep, and 4 ft. long. Separate ⅓ of this length by a panel and arched doorway, dividing the dining-room from the bedroom. Above this there should be a sliding door, to shut the doe into either compartment. Case the edges of the doorway and edges of the



Breeding Hutch.

feeding trough with tin, and any other part that the rabbit can get at with its teeth. The front of the hutch has 2 doors: one, belonging to the inner apartment, made of boards; the other, belonging to the feeding room, is open, having wire-work in front; both doors are fastened by buttons in front, but open in a contrary direction. The bottom of the hutch should have a long, narrow piece of wood in front, below the wires (at B), which should be movable, and this, upon being removed, will permit an iron rod or scraper to be introduced for cleansing the hutch of any loose matter. Place the hutch on the stand a little aslant backward, and drill a few holes at its back partition, to let all liquids pass off as soon as voided. During warm weather, a hutch under the trees does very well; but when cold weather approaches the rabbits must have comfortable quarters. This is especially true of young lop-eared rabbits, warm quarters making material difference in the length of earage.

WEANING.—At the age of 5 or 6 weeks wean, by removing from the mother. The young are finer if left till 7 or 8 weeks old with their mother; but the number of young is diminished by allowing the mother to bear less frequently. The weaned rabbits should be placed with others of the same age, in spacious, warm hutches, with plenty of broken straw for their bed; cleanliness assists their development. Feed with tonic, succulent food, a little barley meal 4 times a day, and what they leave give to the older and less dainty.

Care and Management.

FEEDING AND FATTENING.—The principal thing is always to give more dry than succulent food; weeds and refuse vegetation should be banished, except the roots and leaves of dandelion, sow thistle and hog weed. The most nutritious food is the tops of carrots and parsnips, cabbages, parsley, fine grass, clover, tares, coleworts, and the tops of furze plant, cut up with their dry food. The grain proper for rabbits, are oats, peas, wheat or buckwheat; to

these may be added bran, dry clover, pea and bean straw. Rabbits, full grown, which have as much corn as they will eat, never take harm from an abundant supply of vegetable food; but to young rabbits especially, very little vegetable food should be given. The greater the impossibility to change the green food, the more necessary to season it. Parsley, fennel, coriander, aniseed, peppermint, bitter chicory, wild thyme, pimpernel, etc., should be mixed twice a week with other green food. Salt, as a seasoning, should be mixed with meal once or twice a week. Rabbits should be fed at daybreak, and from 11 in the morning till 1 in the afternoon, and 1 hour before sunset. The best food for fattening is barley meal, oatmeal, soaked gray peas, and boiled linseed, mixed with meal; but they must be varied. Oil cake will fatten to a great size, but the difficulty is to get them to take it, which is only done by starving them into it, and by giving very little at first, pounded and mixed with meal; the cake should be put near the fire, and when warm can be pounded easily. A large quantity of green food is not advisable. Dandelions, thistles, or any plant of the same family, are good, but when not to be had, give a little water once a day, or a little milk sweetened with sugar. Much exercise is not good for them at this time; but if placed for a few hours a day in fine weather, on dry, gravelly ground, and given a little green food, it will promote health. In selecting for fattening, young males should be sacrificed before the females; they become amorous sooner, and their flesh loses flavor.

SHELTERING. — The rabbit house should stand upon a dry foundation, and be well ventilated. A spare loft will be a good place. If rabbits are to be kept in a place already built, fill all crevices with pieces of brick and cement; then mix 1 part cement with 2 parts fine sand and water, till thick like cream; spread it on the floor 1½ in. thick. This should be done quickly, for cement dries rapidly, and becomes hard as stone, through which vermin cannot penetrate. The sides of the building that have been stopped, should be plastered with the same, but thicker than for the floor. Where tiles, stones, or bricks are used for paving, see that joints are well filled with cement to avoid filtration of urine under the pavement. (See *Hutches* in BREEDING.)

TREATMENT OF DISEASE.

CONSTIPATION. — Dry food, deprivation of greens and water, and cold temperature, occasion constipation so obstinate, as to be accompanied by irritation of the genito-urinary organs. *Treatment:* 1. Give a few greens, or a little salt and water. — 2. Dissolve 15 dr. sulphate of soda in 1 qt. water, and give 5 oz. twice a day.

DIARRHEA. — Caused by an excess of green food, and by cabbages and vegetables of too watery a nature. *Treatment:* Change the diet; banish objectionable food; place in a warm hutch, and give a little peameal and oatmeal mixed into a stiff paste; also, sweet hay, crushed oats, and a little carrot.

DROPSY.—Caused by damp, dark hutches, and damp, green food. A soft tumor appears in the neck, disappears, and returns. *Treatment:* Give corn to eat, 1 lb. dry bran, and a mixture of rosin in powder. The powdered leaves of the juniper tree may be given as a preventive.

EAR GUM. — *Treatment:* Loosen the scurf formed upon the ear, by means of a quill; then sprinkle into the ear dry sulphur, which will, after 1 or 2 applications, clear all off. Do not be afraid of a little sulphur, as the rabbit will shake out a great portion of it. Examine the ears every week.

EYE, Inflammation of.—Occurs in young rabbits bred in hutches. The eyes are closed, and lids covered with little red pimples, from which matter is discharged; these pimples often extend over the head, neck, and part of the body. *Treatment:* Give air, clean the hutches, and wash the floors with water in which sorrel has been boiled. If the rabbits are valuable, wash the parts with the following: 2½ dr. alum; 1 qt. water; mix.

LIVER COMPLAINT.—Caused by damp beds, foul hutches, want of exercise, etc. *Treatment:* There is no cure, but it is easily prevented by dry hutches and bedding, and wholesome food.

MANGE.—This attacks the roots of the ears, eyelids, nose and legs. Caused by uncleanliness, want of air, and too much dry food. *Treatment:* Rub sulphur among the hair. Separate the affected rabbits from the rest.

MOLTING.—About the age of 30 or 40 days the fur falls off, and is replaced by permanent fur. This crisis passes if the rabbits are kept warm and clean, and the mother well fed. Convulsions occur when it does not take place naturally, and is often preceded by paralysis. *Treatment:* For paralysis rub the loins with camphorated brandy, or apply a small blister. Keep them warm with 15 gr. camphor a day; as soon as they can eat, give water cress, and boiled barley, with a little salt.

SNUFFLES.—Caused by damp hutches and exposure to cold. There is a discharge at the nose, dullness of the eye, and a stupid appearance. It is fatal if not taken in time. *Treatment:* Give to a full grown rabbit 2 gr. sulphate of copper 3 times a week, or mix it with bran. Give more bran than usual as food; keep the hutch warm, and separate the affected rabbits.

WOMB, Tenderness of. — *Treatment:* Wash the parts affected every alternate day with the following: 15 gr. carbolic acid to 1 oz. water.

WORMS.—Frequent in rabbits kept in damp hutches, fed on much watery green food, and that lie on damp litters. Round worms are found outside the intestines, the loins, bladder and heart. The flesh becomes soft. *Tænia*, or *Tapeworm*, is seldom found. *Treatment:* Change the male or female breeders. Give dry hutches, and tonic food, seasoned with salt; employ condiments mixed with bran and composed of the leaves of heather, juniper, sage, wormwood, thyme, green parsley, etc., dried and powdered.

OTHER FOUR-FOOTED PETS.

FERRETS. — These are useful to poultry keepers. They should never be teased. They cannot bite if held by the neck and shoulders. Wherever rats are, ferrets will go and drive them out. Ferrets need a hutch to prevent them getting out; their quarters should be cleansed twice a week. Pine sawdust is best for litter, but eut straw or dry earth will do. Feed with bread and milk, slightly salted; if they become too fat, mix water with the milk. Feed twice a day, and keep water by them. Feed meat once or twice a week. They will eat rats, birds, or anything fresh. They breed in spring, and have 6 to 9 at a litter. After copulation the male must be kept from the mother, who needs quiet, and after birth her young should not be disturbed until their eyes are open. A few days before delivery fill the nest with soft, clean straw. The period of gestation is 6 weeks. They breed twice a year if well cared for.

GOATS.—The *Angora* goat is a native of Asia Minor, of square build, straight back, large wavy horns, and grayish white color. It has a tuft of hair under the chin, an undercoat of short hair, and an outer one of long, silk hair, termed mohair. The *Cashmere* goat is a native of Central Asia, of medium size, and grayish white color; ears long, and horns small. It has a coat of outer hair, and an undercoat of soft, silky wool, weighing about ½ lb., used for cashmere shawls. The different varieties of the *Common* goat are believed to have originated from wild stock. The milk is superior and plentiful. Goats feed on what cows could not subsist. The female bears 2 or 3 at a birth. Its hair and skin are valuable, especially the skin of the kid, whose flesh is equal to lamb. The male will gender at 1 yr. old, and the female at 8 mos., but good stock must come by parents not so young. The goat is capable of attachment, and may be used in harness and taught to go where desired.

GUINEA PIG.—A native of Brazil; feeds on grain and fruits, and may be kept on sopped bread and vegetables, with an occasional slice of apple. They are less than a rabbit; the upper lip half divided; ears broad and erect; colors, *White*, *Black* and *Fawn*. The *Tortoise-shell* is generally preferred. Some of the white ones have red eyes. Their flesh resembles the rabbit in flavor.

MICE.—The mouse is a lively but timid animal. The *Brown* mouse can rarely be tamed, but *White* mice are domesticated. The female has 6 to 8 broods in a year, but at these times must be separated from the buck, who destroys the young. The cage is like a squirrel's, but smaller. The principal food is bread and milk, oatmeal grits, or any common food, excepting cheese. They should be kept clean, and their beds made up every day, to enjoy health.

MONKEYS.—These are divided into 3 groups: The *Catarrhines* or *Simiadæ* have an oblong head, oblique, flat nostrils, the anterior members longer than the posterior, and provided with thumbs; natives of the old world. The *Platyrhines* or *Cebidæ* have a round head, wide nostrils, the anterior members longer than the posterior, and without distinct thumbs; have long tails, and are natives of the New World. The *Strepsorhines* or *Lemuridæ* have a pointed head, curved nostril openings, the posterior members usually the longest, have long tails, large eyes, soft wool, and are mostly nocturnal; natives of the East Indies and Madagascar. The monkey is easily trained. During instruction he has a small leather belt around his body, to which is attached a cord, which the trainer holds. The first thing taught is to stand on the hind legs; this is done by holding the cord tight and the gentle application of a switch under the chin. Walking the tight rope is easily accomplished, and, when furnished with a balancing pole, he will go back and forth under the guidance of the "leading string." Jumping barriers and leaping through hoops is taught by jerking the string and giving the monkey a slight cut with the whip. Hoops, covered with tissue paper, may be substituted for open ones after a few lessons. Nuts, bread, and an occasional bit of candy, may be given as a reward. To break a monkey to ride a horse, carry a flag, and hold on by the reins, is considered remarkable.

OPOSSUM.—Sometimes a pet with country boys. He uses his tail for climbing, and swinging from branch to branch. He is hardy, and it is almost impossible to kill him. He feeds on insects, birds, eggs, etc. His length is about 22 in., and his height that of an ordinary cat. He should be watched, as he is destructive among the hen roosts, like his neighbor the raccoon.

RACCOON.—About the size of a common dog. If taken young, he can be domesticated. He is very amusing. Feed him with green corn and vegetables.

SQUIRREL.—One of the most engaging of all pets; elegant in form and cheerful in disposition. It breeds generally in May or June, and brings forth 4 or 5. In captivity it will eat nuts and fruit, sip milk and eat bread; it generally sits upon its hind legs, and uses its fore paws in eating. Some squirrels are difficult to tame, and must be taken from the nest at an early age. With care the squirrel may be brought to love and obey its keeper. The *Flying Squirrel* is frequently carried in his young master's pocket. He is fed and treated like others of his kind. He has an expansion of the skin, by which he takes enormous leaps.

AQUARIA.

FRESH WATER.

REMARKS ON MANAGEMENT.—For fresh water, the simplest and least expensive aquarium is the bell glass. It is preferable to the globe, exposing a larger surface to the atmosphere. It is also free from any contaminating influences. Where space is no object, an oblong tank may be selected. The framework may be of wood, zinc, iron or glass pillars, with glass sides; but the best are slate, with glass fronts or slate ends, with a glass front and back. If not made of slate, the bottom should be lined with glass or slate, embedded in a layer of Portland cement. Wood frames are least durable, and soon leak. Sand or pebbles may be used for the bottom, but sand is to be preferred. Wash the sand till the water runs from it clear, and then lay it in the bottom of the tank to the thickness of 2 in., to hold the plants and allow them to root. Or, the plants may be fastened in one of the terra cotta ornaments sold for that purpose, with enough sand or broken rock to cover the bottom. The plants will root readily if the aquarium has light. A few large pebbles improve the appearance, and afford sheltering nooks to which the fish may retire. Shells and corals are out of place. Floating islands may be made of pieces of cork, on which may be grown small ferns. For rock-work or caverns, pile up small blocks of granite, fastening them with Portland cement (other cements are apt to injure the fish); this cement must remain in water for a week, in order that it may part with any soluble matter it may contain. Having laid your sand and gravel, and built your rockery, let the cement get firm, then add water, and empty and refill till the water is clear, when it will be fit to receive plants. These must be put in the aquarium several days before the fish, to enable the plants to commence growing vigorously. Do not put the fish in till this is the case, and then put in only a moderate number. The most important consideration is light. A certain amount of sunlight is necessary. Frequent removal of sediment is required. For this purpose use the lifting tube, which is a simple glass tube, ½ in. in diameter, and 2 or 3 in. longer than the depth of the water, and drawn in a little at one end, so that the finger may cover it more easily. Hold it in the right hand, with the finger over the smaller end; insert it into the water, placing the open end over the object to be removed. Then remove the finger, when the air will escape, allowing the water to rush into the tube, carrying the dirt with it. By placing the finger again over the opening at the top, the tube may be lifted out with its contents and emptied into a vessel held in the other hand, by again removing the finger from the opening. Never take fish in your hand. If the aquarium needs cleansing, make a net of mosquito netting, and take the fish out in it. Keep the aquarium clean and the water clear. Watch the fish, and you will find out when they are all right. Feed them with worms, meat, fish wafer or fish spawn. Dace, roach, and other cyprinidonts are vegetable feeders, and may be kept in good condition on wafer food, sold by dealers. The addition of shreds of lean meat and oysters, or small worms, will be enjoyed. Sun fish may be kept healthy on meat, oysters, or worms; the oysters should first be washed. Where a brook is accessible, a small net, dipped among the plants, dead leaves, or sedimentary deposits, will furnish crustaceous larvæ, on which all classes of fish feed. The sticklebacks require this, and will not thrive on dead food. All food which is not eaten within 2 or 3 hours, should be removed with the lifting tube. The aquarium should have such an even balance, and every occupant so adjusted as to number and variety, as to present a miniature aquatic world harmoniously displayed.

Bell Glass Aquarium.

ANIMALS.

CADDICE WORMS.—These may be put into the tank with safety. To protect their bodies, they inclose themselves in cases formed of straw, sticks, pebbles, and small shells, kept together by threads, which they spin. When about to assume the pupa state, the larvæ fix their cases to some solid substance, and close the extremities with a grating. When nearly arrived at the perfect form, they eat through the grating, swim to the surface, and undergo their final change in the air.

COBITIS, or LOACH.—A small fish, found in running streams. It seldom exceeds 4 in. in length; head, back and sides clouded and spotted with brown on a yellowish white ground; fins spotted with dark brown; belly white; and scales spotted olive. They are restless on the approach of rainy weather and become barometers.

CRAWFISH.—A species resembling the lobster, but smaller; found in fresh water streams.

DACE.—A small fish, found in clear streams; head small, and muzzle pointed; back slightly elevated, and tail forked; color silvery gray.

EELS.—Small eels look well; their sinuous movements give variety. They feed on any sort of food, but prefer animal food.

FROGS.—Young frogs and tadpoles are interesting. They thrive well on meat and oysters.

GOLD FISH.—Live for months without introduced food; are hardy, and stand remarkable changes in temperature.

GUDGEON.—A small fresh water fish, 6 to 8 in. long; back pale brown, spotted with black; belly white, and tail forked. It is easily caught.

MINNOW. — No fish thrives better in the aquarium. The top of the head and back are of a dusky olive color; sides of the body pale and mottled; belly white and silvery. After a short residence in the aquarium, the minnow becomes bold and intelligent.

NEWT, or WATER LIZARD.—Found in ponds and streams. They soon grow tame, and will feed from the finger.

RED SALAMANDER.—Presents a curious appearance, having an elongated body, 4 in. long, and a long tail, which gives it the form of a lizard.

ROACH. — A fresh water fish; color silver white, with greenish back. Suitable only for a large aquarium.

SNAILS.—Introduced into an aquarium, they will reduce the growth of fungus; and where the different elements of the aquarium are balanced, 2 or more snails are sufficient.

Snail.

STICKLEBACK.—A fine fish, 2½ in. long. A pair is necessary, for they will breed in the tank. He builds his nest somewhat like a hanging-bird's, and is a lively, spirited fellow. He is a fine fish for the aquarium.

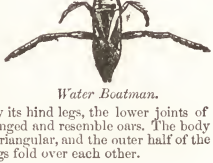
Large Water Beetle.

SUNFISH.—A small fresh water fish, and will answer only while small; but when older he is apt to disturb the others.

TENCH. — Though common in ornamental waters, it is sparingly found in pools and rivers. Its length is 10 in.; color, greenish brown or olive. It is peculiarly adapted to the aquarium, where the quantity of oxygen is never over plentiful.

TURTLE.—The *Chrysemys picta*, or painted water turtle, should be procured when young, as they are destructive when old.

WATER BEETLES.—The large water beetle is useful as a scavenger, and is perfectly harmless. It is better to buy these than to catch them; for if, by mistake, one of the *Dytiscus maginalis* family were put into the aquarium, it would kill the other animals. The *Water Boatman* beetle is very interesting, and may be distinguished by its hind legs, the lower joints of which are fringed and resemble oars. The body is thick and triangular, and the outer half of the superior wings fold over each other.



Water Boatman.

PLANTS.

BROOK LIME.—A plant with sky-blue flowers in loose, lateral spikes; very pretty.

FORGET-ME-NOT.—A well-known blue flower. It may be cultivated on the projecting rock.

FROGBIT.—A plant of the lily kind in appearance. It will thrive well and bloom freely. The body of the plant derives its nourishment from the roots by means of its long spiral stalks; its foliage accommodates itself to the surface of the water. This plant dies away in the winter; but during the autumn a series of eones are formed; these, in due time, are detached and float on the surface; but, on the approach of winter, gradually sink. At the approach of spring they unfold themselves, and assume the shape of the perfect plant.

SOLDIER PLANT.—Admirably adapted, as it affects water of the stillest kind. Its broad, saw-edged leaves form capital lurking places for fish.

Soldier Plant.

TAPE GRASS.—This is found in some rivers; two plants should be obtained, male and female. They may be distinguished by the flowers—the male being borne on short and straight, while the female are on long, spiral foot stalks.

VALLISNERIA.—Well suited on account of its long, bright green leaves. It has perennial roots, and requires but slight depth of soil. The female flowers are borne on long foot stalks, which rise and float on the surface. The male flowers are on short stalks, and at maturity detach and

ascend to the surface, float among the female flowers, and impart to them their pollen.

Small Water Lily.

WATER CROW FOOT. — Known by its white flowers and yellow petals. The plant may be set in the sand, or simply placed in the water. It may be found on the surface of pools in April.

WATER LILY. — Plants of the lily kind are pretty objects. The *Yellow* and *White*, with their handsome leaves floating on the surface, serve as rests for the smaller amphibia. It should have an appropriate situation in every aquarium.

WATER VIOLET.—Fleshy, aquatic, perennial herbs, with pectinate-pinnatifid submersed radical leaves. It is found in swamps and stagnant waters, and may be added with pretty effect to the aquarium.

WATER WEED. — A species of *Anacharsis*, which may be found in ponds and slow-running streams. It is a necessary, as well as a handsome plant; but it multiplies so fast that you will be obliged, occasionally, to remove some.

MARINE.

REMARKS ON MANAGEMENT. — The best form of tank for a marine aquarium is the oblong square tank, with the back sloping inwards towards the bottom, all (except the glass front) being made of slate. The hexagonal shape is ornamental. Artificial sea water may be used, by mixing 100 oz. fresh water with 3 oz. common salt, 1 oz. Epsom salts, 200 gr. chloride of magnesium, and 40 gr. chloride potassium. Sea water may be imitated as follows: Mix with 970,000 gr. rain water, 27,000 chloride of sodium, 3,600 chloride of magnesium, 750 chloride of potassium, 29 bromide of magnesium, 2,300 sulphate of magnesia, 1,400 sulphate of lime, 35 carbonate of lime, 5 iodide of sodium; all, finely powdered and mixed, are to be stirred into the water, through which a stream of air may be caused to pass from the bottom till the whole is dissolved. On no account heat the water. In arranging rockwork avoid hiding places. The stones should be piled to form a shelving background, which will shade the light and prevent the creatures getting out of sight. Immovable objects, such as serpulæ, should be placed so as to be easily seen. Mussels, if deposited against the glass, will cling to it and creep up the side, and afford observation for the magnifying glass. Limpet shells may be embedded in the shingle at the bottom, or placed on rocks. When the hermit grows too large for his shell, he goes in search of another, and an empty shell, larger than the one inhabited, should be placed in the aquarium. If the aquarium has been in preparation for some time, and green growth has commenced, the live stock may be introduced. If not, the water must be aerated, by taking some out with a cup and pouring it back from a distance. All the creatures are accustomed to shallow water, which is aerated by the lashing waves. Imitate this every day for 5 minutes by moving a stick backwards and forwards in the water. A mark should be made on the glass where the water reaches, and when evaporation causes the water level to descend below the mark, fresh rain water should be poured in.

ANIMALS.

BARNACLES. — Found upon the sea shore, drifted upon the wood of a wreck, or other floating body. They live in clusters, each barnacle consisting of a membranaceous branch, fixed to some body, the animal being invested with compressed shells, attached to the pedicel. They are furnished with tentaculæ, with which they gather their food. The shell is clear and brittle, of a white color, tinged with pale blue. The shell is at the end of a long fleshy stalk, generally of a purplish red, but sometimes of a bright orange color.

Barnacles.

CORALLINES, or ZOOPHYTES.—Are compound animals, that live upon one general structure of a plant-like form. Those commonly known are named *Moss Corals*, from their moss-like appearance, and *Polyps*, many of which closely resemble sea weeds. Viewed under the miscroscope they are exceedingly interesting objects.

Corallines.

CRAB.—An animal whose body is covered by a crust-like shell. It has 10 legs, the front pair terminating in claws. *Hermit Crabs* are soft-tailed, and occupy the empty shells of whelks, or other mollusks, as they happen to find them. The crab acts as a scavenger.

Hermit Crab.

FISH LOUSE, or ROCK LOUSE.—Frequently seen running over rocks, where the crevices afford safe retreat. They resemble the common wood louse.

LIMPETS.—Eligible for the salt water aquarium. They are quiet animals. Those should be chosen that are found adhering to the rocks, with the shell raised a little from the body, and with seaweed growing from the shell; the latter being pretty marked sometimes.

Limpets.

MUSSELS.—These live in strong shells, of an oblong triangular form, terminating in a point. The head of the animal is situated toward the point near the hinge. Mussels abound on rocks, to which they attach themselves by strong fibres. When they move, they thrust a tongue-like foot out of the shell, and draw themselves onward. It is hardy, and should always have a place in the aquarium.

Mussel.

PERIWINKLE.—A well-known shell fish. Its eyes are placed at the base of the tentacula. Their tongues are long and armed with teeth. Members of this group inhabit all regions of the sea, but the greater number live near the shore. They are useful as scavengers.

Periwinkle.

SEA ANEMONES.—There are many varieties. The handsomest is the *Carnation-like* sea anemone. There are other kinds, known as *Daisy*, *Wheatsheaf*, and *Crass*. A little below high water mark plenty of specimens of the carnation anemone may be found. The pale pink varieties are sought for nearer to low water mark, where overhanging weeds or stones shelter them. The crass is generally sought for in crevices behind bunches of overhanging weeds. Choose 2 or 3 that have fixed themselves to bits of rock that you can chip off and bring away. The smaller specimens are best, for they live the longest.

Crass.

SEA HEDGEHOG, or SEA URCHIN.—A great treasure for the aquarium. They are of a conical shape, divided into 5 segments, covered with minute holes, from which project tentacles. The surface of the body is covered with shelly spines. The mouth is in the centre; they feed upon marine productions.

SEA MOUSE.—Its appearance is much like an enormous caterpillar. Its upper surface is covered with a double row of broad membranous plates, beneath which are the gills. These plates are covered with hair; and besides these the upper surface is beset with bundles of irridescent bristles, brilliant as the plumage of the humming bird. After a gale of wind, many of them are thrown upon shore.

Sea Mouse.

STAR FISH. — Small specimens are very interesting. They have very peculiar colored rays and extraordinary motions. The brittle star fish is one of the handsomest specimens. It is called brittle from the property of separating into pieces with wonderful quickness. They are affected by the presence of light, and will grow lively when a lighted candle is brought near them.

Star Fish.

PLANTS.

ARTICULATED CHYLOCLADIA.—Found growing upon rocks, or attached to larger plants. Its fronds are tubular, looking like the cells of an orange, united at their extremities; the branches spring from some of these constructions, and the plant grows in tufts, rising from 1 to 6 in.; they are of a tender substance, and purplish or pinky red colored.

BLUNT RUSCOUS-LIKE DELESSARIA. — A red fronded species, growing upon rocks and the

larger marine plants. Remarkable for small leaves from the midrib of the fronds.

BUCK'S HORN FUCUS.—This is destitute of air vessels, but the extremities of the fronds are inflated, forming terminal receptacles. The fronds are from a few inches to 1½ ft. in length; olive green color, with yellow at the extremities.

DICHOTOMOUS DICTYOLA.—Grows upon rocks. The fronds are from 2 to 9 in. in height, green in color, and forming a beautiful specimen when dried.

ESCULENT IRIDÆA.—Consists of a subcartilaginous cuneiform frond, attenuated below into a short stipe; it is found near low water mark. The fronds are 4 to 8 in. long, deep blood red or purple, changing to greenish or yellowish white upon exposure.

FEATHERED PTILOTA.—This is of a red color, characterized, with some 3 or 4 varieties, by the feathered form of the frond. It is frequent on rocky coasts, grows from 3 to 6 in. long, and is attached by a small disc. The younger branches are pale crimson or pink; the older deep purplish red, passing into brown.

Feathered Ptilota.

LACERATED NITOPHYLLUM.—Frequently met with on rocky coasts. The plant is thin and delicate, of a pale pinkish red, varying to reddish brown. The lower part of the frond is marked with dark veins, originating at the base, and disappearing at the length of 2 or 3 in. It flourishes well in the aquarium.

PEACOCK'S TAIL PAVONIA.—A curious species, growing in rocky pools. The frond is membranous, presenting shades of brown, and yellowish or reddish olive, which, with the numerous darker and concentrical lines, and a white, bloom-like powder, spreading over and modifying the hues, renders this a most beautiful plant. Several generally rise from the same base in tufts, seldom more than 2 or 3 in. high.

Peacock's Tail Pavonia.

RED ROCK-LEAVED DELESSARIA.—Beautiful plants of fragile texture, rarely found entire, unless growing in rocky pools; the leaves of a rich red color and satiny texture, from 3 to 12 in. in length.

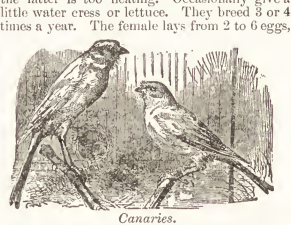
SARGASSUM.—An interesting specimen found on the American shores of the Atlantic. The stems are 1 ft. or more in length, alternately pinnated with simple branches; dark olive color, changing to reddish brown on exposure to air.

SEA WEED.—In making a selection of sea weeds, brown and olive must be avoided; they cannot endure the narrow limits of a tank, and will die; red and green are the sturdiest and the most beautiful varieties. Always choose the smaller and finer kinds; the larger are too strong and will cover the aquarium with slime. The delicate specimens are found under the shelter of the larger kinds. Remove them gently, taking care that a portion of the rock on which they grow is detached with them. Endeavor to obtain specimens of as many various forms and colors as possible.

BIRDS.

BLACKBIRD.—A native of Europe, but being hardy, it is generally able to stand the climate of the United States. Of all birds (excepting the American robin) it is most capable of instruction. His song is rich, and contains deep notes like those of the nightingale. When free, he sings from March until July; but in the cage during the whole year, except when molting. His memory is good; he will learn various airs, and even imitate words. He will eat bread, meat and such food as comes on the table. The young may be raised upon roll steeped in milk. The blackbird must be kept in a large cage and not allowed to associate with other birds, or he will peck them to death, especially the young ones. He will live from 12 to 15 years, if his food is varied, bathing facilities allowed, and his cage kept thoroughly clean.

BULLFINCH.—A pretty bird, about the size of a sparrow; common in many parts of Europe. Its bill is strong and black; the upper part of the head, the ring around the bill, and the margin of the neck are glossy black; the back ash gray; breast and belly red; wings and tail black; legs dark brown. The male has a red tinge upon the breast. The food for those that are allowed to run about, may consist of German paste and a little rape seed. Those kept in a cage must have rape and hemp seed, with a little biscuit occasionally. Rape seed, soaked in water, without hemp seed, increases longevity; the latter is too heating. Occasionally give a little water cress or lettuce. They breed 3 or 4 times a year. The female lays from 2 to 6 eggs,



Canaries.

of a bluish white. The young hatch in a fortnight. The bullfinch may be taught to whistle

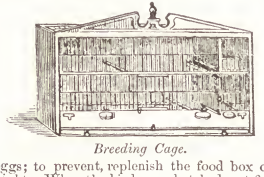
many airs, in a soft, pure tone. The diseases are costiveness, diarrhea, epilepsy and the effects of molting. Change and regulation of food will generally work a cure.

CANARY. — A native of the Canary Islands.

Pets in the Household.

The male has a streak of bright yellow over the eyes and under the throat, his head is wider and longer, his feet are larger, and he is much higher colored than the female; he sometimes begins to warble at the end of a month. Canaries mate in March. Put a cock and hen into the breeding cage, which should be large. Place 2 little wicker nests in the cage. The hen sometimes has a second brood before the first are fit to fly, leaving them to the care of the father bird. When the birds are pairing, feed, besides the usual seeds, with yolks of hard boiled eggs, bread moistened, and pounded almond meat.

The hen lays commonly 4 or 5 eggs, and the time of setting is 13 days. They frequently eat their



Breeding Cage.

eggs; to prevent, replenish the food box over night. When the birds are hatched, cut fine a hard boiled egg, and add some roll soaked in water and squeezed dry. Give fresh every day. If the little birds should be left orphans, keep the nest warm; grate up plain biscuit, and pound some hemp seed; mix together, and moisten with raw yolk of egg and water, and drop morsels into their mouths with the end of a quill. This must be done once every hour. The quantity administered to each at a meal should not exceed ½ teaspoonful. In a fortnight the birds will be able to feed themselves. When they are a month old take them out of the breeding cage, but continue the soft food. Canaries thrive on a mixture of canary seed with rape. A little hemp seed should be occasionally given, but not mixed continually. Groundsel or chickweed, watereress, lettuce and dry sponge cake, may be given occasionally. Food for singing birds may be made as follows: Blanched sweet almonds, pulverized, ½ lb.; pea meal, 1 lb.; saffron, 3 gr.; yolks of 2 hard boiled eggs. Reduce to powder by rubbing through a sieve. Place the mixture in a frying pan over the fire, and add 2 oz., each, butter and honey. Slightly cook for a few minutes, stirring well; set off to cool, and preserve in a closely corked bottle. To keep canaries in health, the cage and perches must be washed often, and fine sand scattered over the sliding bottom; clean water given daily for drinking and bathing; a piece of cuttle fish bone put handy for them to pick at, and a small lump of sugar given occasionally. The cage should not be hung more than 5 feet high, and out of the way of draughts. When hung out doors, have a part of the cage in the shade. Canaries may be trained by stupefying them with oil of bergamot, and made to hop from one finger to the other. Canaries are subject to the following diseases: *Decline* is indicated by roughness of the feathers, inordinate appetite and wasting of the flesh. The bird should be forced to swallow a spider, and a rusty nail should be put into the water. Give green food, especially watereress. *Epilepsy* is caused by excess of food, and deficiency of exercise. Give a few drops of olive oil, but if inefficacious dip the bird once or twice in ice cold water, and cut the claws so close that they let blood. *Giddiness* is the result of looking upwards. Cover the top of the cage with a cloth. *Molting* is an annual recurrence. The food should be varied; all draughts excluded, and cleanliness observed. Put a sprig of saffron or a rusty nail into the water. *Pairing Fever* attacks birds in May. The birds cease to sing, their feathers become rough, and waste away. Hang the cage before a window, so as to cheer the bird. *Pip* is caused by cold. The symptoms are yellowness at the root of the beak, dryness of the tongue, roughness on the feathers of the head, and frequent gasping. A pill of butter, garlic and pepper, with occasional sipping of infusion of speedwell, will cure; and to assist the remedy a fine feather should be drawn gently through the nostrils. *Lice* may be exterminated by using hollow canes for perches; knock out mornings into water. Or, cover the cage with a white cloth at night, and in the morning it will be covered with red spots; these are lice.

CROW.—The crow family comprises birds that have a strong bill, covered at the base with bristly feathers; plumage dark, sometimes gray. They are caught when young and tamed. They have many amusing tricks, and may be taught a few words with patience. They are thievish, and, like the English magpie, hide many things.

GOLDFINCH.—About 5½ in. long; the bill is white, forehead and throat scarlet, head black, back brown, belly white, wings black, edged with white, and crossed with yellow. Kept in a cage or allowed to run about the room. A square, flat cage is best. When allowed to run about the room, a place separated by a grating, or a small tree or bush should be provided for a sleeping place. The female lays once a year 5 or 6 pale green eggs, spotted red. The males have a white ring round the beak. When taken from the nest, rear on poppy seed, and bread soaked in milk and water. The diseases are *Epilepsy*; to this the goldfinch is most liable. *Sore and Swollen Eyes* may be cured by applying unsalted butter. *Stupor and Giddiness*, produced by hempseed, may be cured by substituting soaked lettuce and thistle down. It will conduce to health, if they are allowed now and then to pull the seeds from a thistle head.

LINNET, or REDPOLE.—Found in the northern, temperate and arctic regions. The bill is short, wings long and pointed, and tail forked. Its winter plumage is brown; in the spring the crown of the head is deep crimson. The males have more brown on the back; and if, on stretching out the wings, the white on several feathers extends up to the quills, it is proof that the bird is a male. The food consists of rape and canary seed, groundsel, plantain, seeded chickweed, and hemp seed may be given occasionally. They may be taught to perform many tricks, and require the same care as canaries.

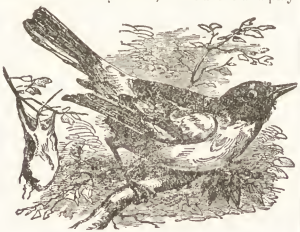
MOCKING BIRD. — It receives its name from being able to imitate the notes of other birds. The female lays from 4 to 5 eggs, of an ash blue color; sets 14 days; is very jealous of her nest, and apt to desert it if disturbed. Their food consists of thickened meal and water, or meal and milk, mixed occasionally with minced fresh meat. Animal food, finely divided, and soaked in milk, is at first the only nutriment for raising nurslings. Young and old require berries from time to time, and any kind of wild fruits, if not given too freely, are useful. A few grasshoppers, or other insects, as well as gravel, are necessary; spiders will often revive the drooping or

sick. The following is a good food: Mix 1 part cornmeal, 1 part pea meal, and ½ part moss meal; add a little melted lard and sweeten with molasses. Fry for 4 hours, stirring constantly; this makes it keep. Put in a covered jar. The moss meal is prepared by drying and grinding

Mocking Bird.

the imported German moss seed. During molting, saffron should be put in the water or a rusty nail. To keep insects out of the cage, tie up a little sulphur in a bag, and suspend it in the cage. This is essential to health.

ORIOLE (Baltimore).—A native of America. It is 7½ in. long. The plumage of the male is brilliant, the under parts being a bright orange yellow. Head, throat, back and tail black; legs and feet lead colored. It can be kept on meal and water, with occasionally a piece of sweet fruit. It is easily tamed, and is docile and play-



Baltimore Oriole.

ful in captivity, and can be taught to imitate the notes of other birds.

PARROT, PAROQUET and COCKATOO.—True parrots have the upper mandible toothed, and longer than it is high, and the tail is short and rounded at the end. The tongue is fleshy, obtuse, and entire; the feet and bill are used in climbing. The *Gray Parrot* is remarkable for its loquacity, docility and distinctness of articulation. It is about the size of a pigeon; its color ash gray, tail bright crimson; bill black, and legs cinerous. It is said to live nearly 100 yrs. The *Green Parrot* is larger than the gray. Plumage fine green; base of the bill bright red; cheeks blue; top of the head yellow; all the quill feathers and wing coverts deep blue; legs and feet dusky. It is affectionate, and may be taught to talk distinctly. The *Paroquet* belongs to the parrot family, but is distinguished by being smaller and having a longer tail. It is graceful in its actions and prettily colored. It is a native of Continental India and some of the islands of the Indian Ocean; it is also found in the woods of Australia. When well cared for, it is easily domesticated. The *Cockatoo* may be distinguished from true parrots by a crest or tuft of elegant feathers on the

Gray Parrot.

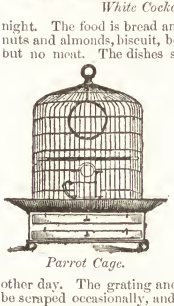
Green Parrot.

head, which it can raise or depress at pleasure. A native of Australia and the Indian Islands. There are several varieties, the *Great White Cockatoo* being the most common. It is about the size of a common fowl; color white. The head has a handsome crest of feathers, which are scarlet underneath; bill bluish black, and strong. It is of a docile disposition, but can rarely be taught any words. Cages for parrots should be large and strong; from the top of the cage there

should hang a wide ring, swinging well clear of the perches, for exercise by day and roost at

White Cockatoo.

night. The food is bread and milk, varied with nuts and almonds, biscuit, boiled corn and fruit, but no meat. The dishes should be porcelain or thick glass. The greatsecret of keeping parrots well is in careful feeding and perfect cleanliness. The feet must be washed, and the plumage occasionally syringed with warm water. The cage should have a grating at the bottom, and a drawer for sifted gravel, which should be put in fresh every other day. The grating and the perches must be scraped occasionally, and the cage cleansed once a month, taking care that it is quite dry before the bird is put into it. The water must be fresh every day, and the food of a moist nature. To train a parrot, take him alone; caress him a little, then utter the word in a distinct tone, and repeat at intervals of a few moments. Soon the parrot will attempt to repeat the word. Caress him and reward him. Repeat this until he has learned the word thoroughly. When he desires anything, make him repeat his lesson before his wishes are gratified. It is essential that the trainer should be on good terms with the parrot in order to insure success. Under favorable circumstances they copy the words and even the voice of their trainer. Parrots are subject to several ailments. *Asthma* is caused by cold, or too much hempseed. The symptoms are shortness of breath and frequent expansion of the beak. Give extra warmth and change of food. In severe attacks, give a paste, made by boiling a piece of white bread, the size of a walnut, in 4 tablespoonfuls of milk, stirring until it becomes



Parrot Cage.

a pulp; mix with it a few grains of cayenne pepper, and keep the bird entirely on it for 2 or 3 days; it must be prepared fresh as wanted; as an aperient, give twice a week lettuce or watercress. *Atrophy* or *Wasting* is caused by improper food. The body becomes emaciated, feathers rough, and the bird disgorges its food. Put a rusty nail into the water, and give same treatment as for asthma. *Consumption* or *Decline* is known by loss of appetite, swelling of the lower parts, and falling away at the breast. Give a bread and milk diet, with seed about twice a week; no water on the seed days; juice of white turnip to drink, and a red or black peppercorn, occasionally, are the best remedies; if taken in time, this disease can be cured. *Convulsions* or *Fits* should be treated as follows: Take the bird up; open the beak, and put into it a few drops of cold water; if this does not restore it, plunge it into a cold bath; this failing, draw out one of the tail feathers, and lay the patient on some cold substance. If recovery takes place, wrap the bird in flannel, and put it in a warm place until dry; afterwards feed it as directed for asthma, and give it a few drops of spirits of nitre occasionally in its water. *Costiveness* may be detected by frequent and useless efforts of the bird to void its excrements. Give bread and milk diet, with a few shreds of saffron boiled in the milk; if this is not effective, give 4 drops castor oil, and introduce into the vent the head of a large pin dipped in linseed oil. *Diarrhea* is caused by sudden change of diet, or improper food. The symptoms are frequent evacuations of fluid chalky matter, which causes irritation in the parts. Keep the bird warm; feed it with soaked bread and corn boiled in a decoction of lettuce seed; anoint the irritated parts with palm oil, and give water impregnated with iron to drink, mixed with a little milk; chillies are good, and the yolk of a hard boiled egg. *Diseased Eyes* proceed from various causes; when inflamed wash with warm green tea. *Diseased Feet* result from want of cleanliness and from cold. Soak the feet in lukewarm water for ½ hour, daily; put the bird in a small dry cage, in a warm situation. If sores are observable, sprinkle with powdered loaf sugar. *Inflammation* is caused by draughts. The bird becomes dull and listless. When this is the case great care must be taken. Give bread and milk and oatmeal grits boiled, yolk of egg boiled hard, and corn boiled in an infusion of rape seed twice a week; remove all food at night, and place a little magnesia mixed with water in a shallow vessel; remove in the morning, after the patient has taken a dose. When *Molting* give extra warmth and nourishment. Give hemp seed, corn and canary seed, separately, twice a week; bread and milk, with chillies cut small, and mixed, once; on seed days put a little saffron in the water; warmth is the grand requisite. *Surfeit* is usually the effect of neglect; it shows itself in head eruptions, which discharge an acrid humor. Apply a solution of salt in spring water, wiping the parts dry after it, and anoint with palm oil. The diet should be scalded bread and ground rice, mixed with milk, in which has been boiled a little licorice, and keep the bird warm.

Tumors may be removed by passing strong silk around them close to their junction with the part to which they are attached; tie the silk so as to gradually tighten it, and the tumor will eventually drop off.

PEACOCK.—A native of the East Indies. It is now domesticated all over Europe and the U. S. The head is adorned with a crest of green and gold; the body variegated; its distinguishing feature is its train, which, when erect, forms a circular fan of resplendent hues. The plumes are shed every year, and, when molting, the bird keeps out of sight. The female lays 5 or 6 eggs, which she hatches in 27 to 30 days. The plumage is in its perfect state the 3d year. It lives 25 years. It feeds chiefly on corn, preferring barley, however; at times it seeks insects, and is very mischievous in gardens.

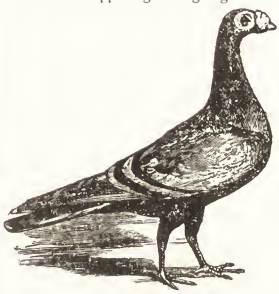
PIGEONS.—The *Archangel* is rich in its coloring; the head, neck, and fore part of the back and body are chestnut, or copper color, with

Common

changeable hues; tail, wings and hinder parts are blue black; but many of the feathers on the back and shoulders are metallic and iridescent; iris orange red; feet clean and bright red. It has a turn of feathers at the back of the head, similar to the trumpeter, and its size is that of the

Archangel.

rock dove. The *Barb* or *Barbary* pigeon was introduced from that part of the African coast. It has a tuft of feathers sprouting from the back of the head; plumage dusky, or black; short, thick beak; insides of the eyes are pearl-colored, and there is a circle of incrusted flesh round the eyes, of a red color. The *Carrier* has been employed as a messenger from the earliest ages; is larger than the common pigeon; measures 15 in. in length, and weighs about 1¼ lbs. The neck is long, and the pectoral muscles large. An appendage of naked skin hangs across its bill. The value of the bird is estimated according to its size and shape. Those are considered best that have the appendage rising high on the



Carrier.

head, and of considerable width across the bill, and a wide circlet round the eyes, destitute of feathers. The *Cropper* has a thick, short body; legs feathered down to the feet. It has also a large pouch or bag under the beak. The crop hangs low, but is large, and it is loose breeched on the thighs. The *Dragoon* is bred between a tumbler and a horseman. It is a serviceable pigeon, and sometimes invaluable as a nurse. A good flyer, but not so strong as the

Fantail.

horseman. The *Fantail* takes its name from spreading its tail in the shape of a fan. There

are 2 sub-varieties, the broad-tailed and the narrow tailed shaker. The former ought to have a tail of at least 24 feathers, a swan-like neck, a full breast, and quivering motion of its tail, which gives it the second name of shaker. The plumage is white, red, blue, or cream color. The narrow-tailed shaker is produced by pairing the broad-tailed shaker with the stock dove. The tail is not so wide as its name imports, while it is also a shorter, thicker and less graceful bird. The *Helmet* is much coveted; it is smaller than the nun, which it resembles, but has no hood; a tuft of white tinted feathers overshadows its head; head and tail black. The *Horseman* resembles the carrier in appearance and qualities, but is smaller, and has a shorter neck. He may be trained like the carrier, and is scarcely inferior. The *Jacobin* or *Jack* has inverted feathers on the back part of the head, like the cowl of a monk. The *Mawmet* is of a cream color,

Jacobin.

with black bars across its wings; the part nearest to the body is black; has black wattle on its beak; and the eyes are circled with black flesh. The *Nun* has a tuft of feathers rising from the head like a hood; bill small; pearl eye; color

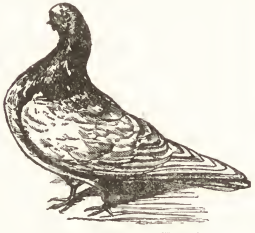
Nun.

of body white; head, tail, and the 6 flight feathers red, yellow or black. The *Owl* is odd-looking; has a purl on its breast; short beak, and a pearly eye; color varies, being red, blue, yellow, black, or silver; the yellow and red, when handsomely formed, are rare and valuable. The *Pouter* is handsome, and distinguished by the size and form of the crop. It is about 18 in. in length; has a hollow back; carries its wings close; legs well covered with feathers; front of the crop white, surrounded with green; head, neck, back and tail uniform in tint. If a pouter

Pouter.

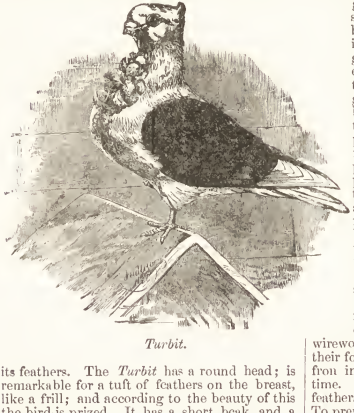
is unable to distend his crop handsomely, it is considered a defective bird. They are difficult to rear, and require great care to prevent overfeeding. Every bird should be kept in a separate coop, lofty and capacious; when the young are hatched, as the old birds pay little attention to them, they should be carefully watched. Some fanciers never suffer pouters to rear their young, but put their eggs under a hen dragoon. The *Ruff* is like the jacobin, but is larger, and a distinct variety. The hood and span are larger. The *Runt* is full breasted, with tail turned up. It has a long, thick neck; beak short; has a small wattle over the nostril; plumage grizzled, and ermine round the neck; those esteemed are black, white, red or mottled. The Leghorn is the most valued, but is a bad nurse; their eggs are often put under the hen horseman. The Friesland runt is larger than the common runt, and its feathers stick out the wrong way. The Spanish runt is short, thick legged, and has a long body. The Smyrna runt has feathers growing from the outside of the feet. The Roman runt is large and unwieldy. The *Swallow* resembles the nun in having a tuft of feathers rising from the back of the head; but has a large bill and feathered legs and feet. It is not a universal favorite. A perfectly feathered bird has the colored portions clean cut and free from white feathers; the colored portion of the head extending back to the base of the crest. The feathers of the feet are the same color as the wings and top of the head, and extend no further than the hock joint; the hock feathers are pure white; and the entire wing the same color as the head. The *Trumpeter* derives its name from the sound it utters after playing. It has a tuft of

feathers sprouting from the root of the beak, and the larger this is, the greater the value of the bird. The legs and feet are feathered; it is pearl eyed; to be valuable, it ought to have a hood at the back of its neck. The *Tumbler* has its name from its habit of turning over in the air. The finest variety is the bald-pated, having



Ermine or Almond Tumbler.

a snow white head and pearl like eyes. Another, called the Ermine or Almond, is a beautiful bird, distinguished by the colors and marking of



Turbit.

its feathers. The *Turbit* has a round head; is remarkable for a tuft of feathers on the breast, like a frill; and according to the beauty of this the bird is prized. It has a short beak, and a tuft behind its head. It varies in color, some being red, some dun, while others are blue and black. The most valued have their body plumage white, or of one color. The blue have black bars across their wings. They are called yellow shouldered or blue shouldered, according to the tints of the shoulders or wings. The original blue turbit has a blue tail, and the black turbit a black tail. In erecting a pigeon house, care should be taken to fix it in some quiet and secure spot. A small one is easily made from a wine cask, which has holes cut in its sides, and the interior apportioned into chambers, and a small platform, made of wood work, before each hole forms a place for the birds to alight upon. The cask should be elevated on a stout scaffolding pole or the trunk of a straight tree, and made secure. The top of the cask may be thatched, and should come well over the holes and sides. In arranging the chambers, they should be large enough for the birds to turn round with ease; and if 2 holes can be allowed for each compartment for egress and ingress, it will be of great advantage. Sometimes there is a little trouble attending the mating of pigeons, and it is of importance that they should be comfortably matched. Coops should have a thin lattice-work partition between them, so that the birds may become acquainted; they should be allowed to feed out of the same vessel, and in a short time the observer will find the birds selecting their choice, when they may be placed in one pen. When mated, they may be left to build their nests. When pigeons are fed, accustom them to one particular call, and the best is that of a common pea whistle. Pigeons will eat any kind of grain; pigeon's beans are the best food, but this may be varied, by mixing with it tares, gray peas, and buckwheat; the tares should be very old and good, and the buckwheat sparingly given. Hemp seed is stimulating, and should be sparingly given, except in very cold weather. Pigeons are fond of lime and salt. Prepare the following for their use: Take sifted gravel, brickmaker's earth, and the rubbish of an old wall, ½ peck each; add to these 1½ lbs. cummin seed; ¼ lb. saltpetre; let these be mixed with as much natural animal brine as will make a stiff paste. Portions of this mixture may be placed in flower pots and stationed where the birds can get at them. Gravel should always be scattered plentifully about the floor of the house, and a little salt allowed. Fresh water, daily, is necessary to keep them in health and feather. They must never be exposed to damp or cold. Cleanliness is necessary, and their houses should be cleansed once in 6 months, care being taken to have them well dried before the birds are readmitted. The dishes must be kept clean, and covered with wirework to prevent the birds from scattering their food. A little hemp seed, and a little saffron in their water, help them about molting time. If annoyed with vermin, fumigate their feathers by puffing tobacco smoke into them. To prevent vermin, attention must be paid to cleanliness, both in the birds themselves and in every part of their houses.

ROBIN. — The common robin of America is about 10 in. long. It is a common and most interesting bird, coming to the temperate districts in spring, and remaining late in autumn; some remain the whole winter, even in New England. Its song is among the sweetest. It builds in hedgerows, or at the foot of old trees, and lays

4 or 5 eggs. It is also very easily domesticated.

Robin.

SPARROW.—There are 2 species—the house sparrow and the tree sparrow. The house sparrow builds in holes, eaves of houses, or in deserted chimneys; the tree sparrow in trees. The nest of the latter is large. It is distinguished from the house species by its chestnut colored head, and having a black patch on the cheek. The sparrow feeds upon grains and seeds, and sometimes upon insects. Some are prized for their song and others for their flesh.

SWAN.—The most graceful of aquatic birds when gliding over the water, with its neck proudly arched, and the wings partly spread. Wild swans are found in nearly all the northern regions of the globe. There are numerous varieties of tame ones, the jet black being rare and the white common. They are seldom seen but in parks and gardens. They feed upon the roots and seeds of aquatic plants, are easy to manage, though often vicious; are hardy, and live long.

THRUSH.—Of this family, the song-thrush is smallest and most attractive. It thrives well in the cage. It may be fed on German paste, or paste made of oatmeal moistened with milk, with now and then a few snails and worms. It needs to be kept clean, and to have plenty of water for drinking and bathing. The young are hatched in spring, and should at first be fed on a little raw meat cut small, and bread steeped in milk and mixed with a little hemp seed. When they can feed themselves, give German paste and an allowance of raw meat.

WREN.—This genus is distinguished by having the bill nearly as long as the head, and the wings about equal to the tail. There are several species; the best known is the house wren. It is nearly 5 in. long; the wings over 2 in.; the color above reddish brown, barred with dusky. It builds in holes in the timbers or walls of dwellings, or in a hollow tree in the garden The nest is formed of twigs and grasses, and lined with soft materials. The wren lays 5 or 6 eggs of a pale reddish color.

FORMS OF BEAUTY.

FISH CULTURE.

REMARKS. — There are few enterprises that promise more profit than the multiplying of food fishes in fresh water ponds. It is believed by those who have investigated the facts, that fresh water fishes can be multiplied indefinitely, and improved in quantity, quality and cheapness. Every one, who has water sufficient to form a pond, can make it yield fish food profitably, with a moderate outlay.

CARP.

CLASSES. — Carp are divided into 3 chief groups: The *Scale Carp*, which has regular, concentrically arranged scales, being the original species improved; the *Mirror Carp*, so named from the rows of large scales along its sides, the rest of the body being bare; the *Leather Carp*, having only a few scales, or none, and a soft skin, velvety to the touch.

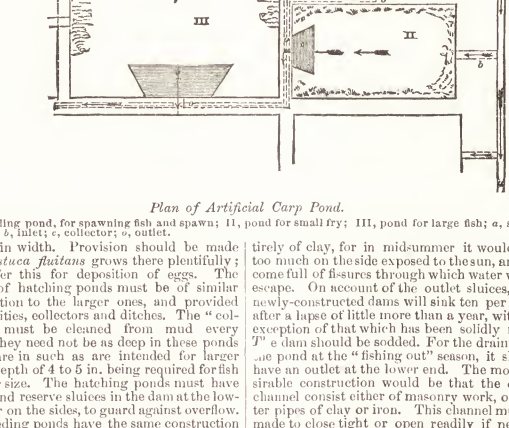
CHARACTERISTICS AND HABITS.—The carp is partial to sluggish waters, with a loamy bottom, and deep places with vegetation. In the temperate zone, at the beginning of cold, they seek deep water. This occurs at the beginning of November if winter sets in early. From 50 to 100 make a cavity in the muddy bottom, called a "kettle;" in this they pass the time until spring, huddled in concentric circles, heads together, the posterior part of the body raised and held immovably, scarcely lifting the gills for breathing, and taking no food from October until the end of March. It will not, however, be safe to depend on this habit when transporting them for propagation, in spring or winter, especially young carp.

CROSSING.—The carp sometimes crosses with related species; and hybrids result, resembling the genuine so much that it is difficult to recognize them. Such are valueless on account of bad and bony flesh. The spawning season of the crucian and the true carp coincide, and if kept together hybrid races may result. The spawning season is from March until August, according to latitude.

FEEDING.—The carp lives on vegetable food, worms and larvæ of aquatic insects, and is fond of cabbage, lettuce, boiled potatoes, corn, turnips, pumpkins, and melons. The refuse of brewer's malt is good. The pisciculturist, who has a pond of only ½ acre, can feed his fish on refuse from the kitchen and stable. Not every pond has the essentials of a good soil at the bottom and is capable of producing fish food. If these are wanting, the fish must be fed. This is a general rule for ponds with a sandy bottom. Never feed in the same place; distribute the food in different places near the banks. If food is always put in one or two places, the carp will stay near those places, and instead of scouring the pond in search of food, will remain at the bottom. It will grow fat, but never have firm flesh nor much length; and, besides, such feeding attracts the turtle, who will lie in wait and destroy the carp. Never give much at one time, or during the day, but in the morning or evening. During the hot season feed late at night, because the carp, if it has eaten sufficient in the morning, remains at the bottom all day, while it is necessary that it should swim and get a change of water. It is, therefore, useful to place in ponds containing large carp a limited number of pike, smaller than the carp. The carp fears the pike and flies from it.

PONDS.—To carry on carp culture in a judicious manner, 3 ponds are required: The hatching pond, breeding pond, and regular carp pond. A gravelly ground is not appropriate. Small ponds with a sandy bottom may be improved by supplying them with loam. An undulating country, with slight elevations, where the valleys are easily closed by dams for forming reservoirs, is favorable, the construction involving only a trifling expense. Ponds must not be too deep, or the water will be cold and harbor fewer insects, larvæ and worms; besides, this fish does not grow quickly in cold water. A depth of 3 ft. in the centre is sufficient; toward the outlet sluice it may be 6 to 8 ft. deep, but only for an area of 200 to 1,000 sq. ft. In the depths of this "collector" the fish seek their resting place for winter, and in summer, when the water is too warm near the edge. The outer part of the pond should not be deeper than 1 ft. for the distance of about 70 or 100 ft., so that the water may be warmed by the sun. Toward the centre of the pond, and in accordance

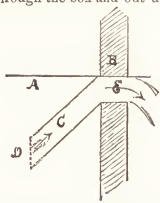
with its size, a cavity of from 20 to 50 ft. in length and 2 feet deeper than the rest of the ground, should be dug. This cavity is sometimes called a "kettle." From the entrance of the pond to the other end, where the "collector" and the outlet sluice are situated, 2 or 3 ditches of 2 ft. in depth and 4 ft. in width, must be dug. These are to carry the fish into the "collector," when the pond is drained. The "collector" is a place of from 20 to 40 ft. in length and breadth, near the outlet sluice, 1 ft. deeper than the remaining bottom of the pond. In ponds of superior construction, it has a wood floor, and is cleaned of the mud every year, so that the fish may not become too much soiled. The hatching pond should not be as large as the breeding pond; its depth 1 or 1½ ft.; the outer portion, or low water margin, 2 to 5 in. in depth, and 30 to 40 ft. in width. Provision should be made that *Festuca fluitans* grows there plentifully; fish prefer this for deposition of eggs. The bottom of hatching ponds must be of similar construction to the larger ones, and provided with cavities, collectors and ditches. The "collectors" must be cleaned from mud every spring; they need not be as deep in these ponds as they are in such as are intended for larger fish; a depth of 4 to 5 in. being required for fish of minor size. The hatching ponds must have outlets and reserve sluices in the dam at the lower end or on the sides, to guard against overflow. The breeding ponds have the same construction as the hatching ponds; they have dams, reserve sluices, outlet channels, collectors and ditches, the only difference being that they are deeper and larger. They have an average depth of 1 ft. 9 in., and the width of their shallow borders is from 70 to 80 ft. The "kettles" have a depth of 4½ ft. from the surface; their borders are from 6 to 8 in. deep. The growth of grass should be advanced in these ponds. Culture ponds should have a shallow border; the depth accords with the size 1 ft., in regular carp ponds, ½ ft. in breeding ponds, and ¾ to ½ ft. in hatching ponds. The borders should be of considerable width, and a great number of shallows be contrived for feeding places. If the size of the principal and supplementary ponds has been decided, the height, depth and width must be measured, and the levels of the ground and dams carefully taken. The leveling of the bottom is required to assist in determining the depth of the ditches, kettles, collector and outlet. In the erection of the required dam, it must be of the best material, to make it secure against the destructive influence of water. It ought to be 3 times as wide at its base as it is high, and at the top the width should be the same as the height. The interior or water side should be less inclined than the exterior. The dam should not be entirely of clay, for in midsummer it would dry too much on the side exposed to the sun, and become full of fissures through which water would escape. On account of the outlet sluices, etc., newly-constructed dams will sink ten per cent. after a lapse of little more than a year, with the exception of that which has been solidly made. *T* e dam should be sodded. For the draining of ..e pond at the "fishing out" season, it should have an outlet at the lower end. The most desirable construction would be that the outlet channel consist either of masonry work, or water pipes of clay or iron. This channel must be made to close tight or open readily if needed, and provided with two or threefold gratings to prevent the escape of the fish upon opening the sluice. There should also be an outlet channel, several feet in breadth at the side of the pond, to allow the water to run off, secured by grating, but kept open, so that in case of storms no overflow may be possible through rising of the water in the pond. The illustration shows a good plan for an outlet in the dam: A, shows the surface of the pond; B, the dam; C, the outlet, which



Plan of Artificial Carp Pond.

I. breeding pond, for spawning fish and spawn; II, pond for small fry; III, pond for large fish; *a*, supply of water; *b*, inlet; *c*, collector; *o*, outlet.

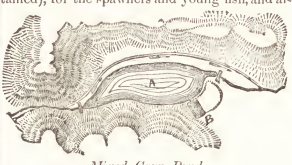
is a wooden box, extending from the surface to a distance under the water, and must be large, so as to allow the surplus water to flow off. The water enters through the perforations (D) and flows up through the box and out at the outlet



Outlet Channel through the Dam.

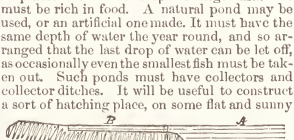
in the dam (E). The advantage is that the water flows out from the bottom of the pond, preventing the grating from becoming clogged by leaves, etc. If it be desirable to use natural ponds, see whether they can be put in proper condition for regular culture. This can only be done if the influx of water can be regulated, and drainage made possible. An intrenchment will be required to make them dry. Trunks of trees should be taken out; if too deep, they should be filled up, or brought into connection with the sewers on the bottom of the pond. If this is not done, many fish will remain embedded in the mud when the pond is drained. Should any brooks fall into such ponds, they must be kept under strict observation on account of possible overflow. If practicable, turn off, and conduct alongside the pond, when the latter can be supplied with water, if required. Spring water direct, is not favorable; it should be conducted a few hundred yards through wide, shallow ditches, to receive nourishing components from the air and earth, and be warmed by the sun. The inflow of water into the pond should not be direct, like a brook falling into it, causing the water to rise, thus carrying into the pond other fish, especially the rapacious pike. The carp has a disposition to swim toward the inflowing water, away from its feeding places. The water should be conducted into the pond sideways from the stream; and if a small brook only, it may be turned off and carried alongside of a pond, from which point the latter can be supplied with water. The inlet sluices from the stream must be of strong construction, so that overflow is impossible, and provided with gratings to prevent other fish from intruding. It is indispensable for fish culture that the ponds allow of being thoroughly drained, so that the fish can be taken out without difficulty. The bottom of the ponds should permit of their being dried up for agricultural purposes when necessary. The fundamental rule in carp culture is that the water be of the same depth in summer and winter. If the supply of water is too plentiful, great quantities of mud are carried into the pond, embedding the grass and causing it to rot and poison the water. The carp deserts such water for depths which are deficient in food.

PONDS FOR MIXED CULTURE.—Sometimes only 1 pond is used instead of 3. When this is the case it must combine the characteristics of the class ponds, and have shallows with grass or aquatic plants (*Festuca fluitans* and *Phellandrium*, when it is possible for them to be obtained), for the spawners and young fish, and al-



Mixed Carp Pond.
A, pond; B, breeding place.

so places 8 to 10 ft. deep for larger fish. It must be rich in food. A natural pond may be used, or an artificial one made. It must have the same depth of water the year round, and so arranged that the last drop of water can be let off, as occasionally even the smallest fish must be taken out. Such ponds must have collectors and collector ditches. It will be useful to construct a sort of hatching place, on some flat and sunny



Cross Section of Carp Pond through Breeding Place.
A, pond; B, breeding place.

spot, near the bank (a cut in the bank), 40 to 100 ft. long, 30 to 50 ft. wide, and 5 in. to 1½ ft. deep, planted with aquatic plants, and it ought to be the only place where carp can ascend to deposit eggs and engage in spawning; as soon as this has taken place, the entrance is closed with a net, so that the eggs cannot be eaten. This net may be removed when the young have hatched; but it is safest to leave it for some days, that they may feed undisturbed.

STOCKING PONDS.—The hatching pond is for propagation, by placing a number of male and female fishes therein. The females drop the eggs upon the aquatic plants, where they are impregnated by the males; 1 female is calculated to 2 males, per acre. When young fish want food for a length of time, the gristle and bone harden, and the fish is crippled for life, even if placed in ponds with an unlimited supply of food. It is better to place fewer young fish in the ponds, then they will grow rapidly, develop, and during the first year reach 5 to 6 in. in length. Strong fish can thus be placed in the growing ponds, and they will grow rapidly. If there are too many young fish for the water area, place them in some lake, brook or river; on no account keep them in the pond. In ponds

of a few acres, it will be found advantageous to surround them with a close board fence sunk 4 to 6 in. into the ground. This will exclude the snapping turtle, the most dangerous enemy. At night it seizes the fish with its fangs and kills them. It is a peculiarity of the carp to keep at the bottom during the night, and in cold and gloomy weather; the snapping turtle would, therefore, have many an opportunity of destroying them. Large iron fish hooks, with meat as bait, at suitable places on the banks, will catch the turtle; this should be done from spring to October. The pieces of meat should be of such a size that large carp cannot bite them. The hooks should be fastened with strong brass wire. In placing spawners in ponds, caution must be had in selection, so that healthy fish may be introduced, and not such as are affected by fungous growths, the gelatinous polyp, or other disease. The newly obtained fry are left in the hatching ponds during winter, to be transferred to the larger ponds in spring. In catching the young fish, it must be done carefully, the water being drained off through the outlets slowly, so that none remain in the mud; for, if a new hatching operation is contemplated in the pond, the newly hatched fish will be retarded in their growth on account of scarcity of food, this being consumed by any remaining larger ones. Young fish must be handled carefully, for the slightest injury proves fatal. The stocking of the breeding ponds takes place in spring, after emptying the hatching ponds; it lasts from the latter part of March until April. An advantage will be gained in northern sections by leaving the young fish 2 summers in the breeding ponds; that is, they are transferred to a larger pond, and from this pass into the real carp pond. This answers well where the bottom of the pond is poor, or if feeding has not the desired effect. In the spring of the 3d year, those fishes which have been 1 year in the breeding pond are transferred to the carp pond. Fish kept in the breeding pond for 1 summer, without being fed, will weigh, at the expiration of that time, 1 to 1½ lbs.; while those which remained 2 summers, will show a proportionally greater increase. To stock a culture pond of 1 acre, 400 to 500 carp, of 1 lb., will be required, and in the autumn of the same year, when taken out for market, they will weigh 2¾ to 3 lbs. each.

SPAWNING.—The fish show signs of spawning about March 1st. Some days before, they increase in vivacity, and rise to the surface more often; 2 or more males keep near the female, which swims more swiftly on a sunny morning. Spawning does not take place at once; days and weeks may pass before the fish leaves her last egg to the care of nature. In rainy, cool weather, it is interrupted, but is resumed when the water grows warmer. Culturists dislike cold weather at this time, as not only the eggs, but the young fry suffer. The great abundance of eggs in the carp explains its extraordinary increase in natural waters. A fish of 4 to 5 lbs. contains about 400,000 to 500,000 eggs. The eggs of the carp adhere in lumps to the object upon which they have fallen. The moment she drops her eggs they are impregnated by the milter. As soon as the egg has left the fish it swells a little, the mucus which surrounds it, serving to fasten it upon some aquatic plant, stone, or brushwood. The eggs which have no such object to cling to, are lost. Eggs develop quickly in warm weather. As early as the 5th or 6th day, the first traces of the eyes will be visible, and toward the 12th or 16th day the little fish break through. This rapid development takes place only in shallow, thoroughly-warmed breeding ponds. If these ponds are deep and the water colder, the hatching process may require 20 days. In 3 to 5 days the young fish has absorbed the yolks, and seeks food. If the breeding pond be productive enough to furnish the food for so many young, they will grow rapidly. The weight which a carp may attain to in 3 years, is from 3 to 3¼ lbs.; that is, a fish which has lived 2 summers, will weigh 2¾ to 3¼ lbs. the year following.

TRANSPORTATION.—The assertion that the scale carp is better for transportation than either the mirror or leather carp, by reason of its scales being a protection against transfer and hurtful attacks in ponds, is not correct. In transportation, scales are not only inefficient, but frequently cause death, especially in the so-called breeding fish, for, if a scale be torn off in part only, ulceration and death will ensue. The leather carp, having no scales, will bear more ill-usage, whether young or old. Its smooth, slippery skin, suffers much less from transportation, and any slight wound will heal more easily. The emptying of ponds demands great caution. The water must flow gradually through the outlets, all of which must be kept open at the time; requiring from 10 to 18 days to draw off the water. The fishes are driven carefully and slowly with boats into the principal ditches. They must not be chased on any account, or they will bury themselves in the mud. To guard against such an emergency, preparations must be made for an immediate supply of water to save the fish. If the fishing out progresses in the regular manner, the fishes will, by degrees, draw off from the ditches into the collector. The collecting takes from 5 to 6 days in large ponds, containing 100 to 400 tons of fish. Avoid crowding them. On the evening previous to the fishing out, when the water has been diminished to the depth of ½ ft., those fish which have been collected are shut off from the pond by a large net, and at dawn they are caught. (See *Transportation* in SALMON.)

SALMON.

CHARACTERISTICS AND HABITS.—Under the head *Salmon*, may be included salmon, trout, lake trout, white fish, grayling, and the fresh water herring. The mode of culture for each is essentially the same. They spawn in autumn and winter, with the exception of the California salmon, which spawns in summer and the first of autumn. The salmon comes in from the sea as soon as the ice breaks up, and seeks fresh water in which to spawn. Trout, also, pass from ponds and lakes into fresh water streams. Salmon and trout form nests. The female digs out

the bottom with her fins and tail; and when the nest is made, she deposits her eggs, which are then impregnated by the male. They are covered with gravel by the female, while the male drives away any intruders of his own sex. When the spawn falls from the fish, it adheres to whatever it touches. As soon as this operation is completed, and the fish are exhausted of milt and spawn, they seek deeper water, leaving the eggs measurably unprotected from numerous enemies; the worst of whom is the eel, which devours the eggs and young voraciously. The eggs remain in the water from 2 to 5 months, according to the temperature of the water, before hatched. Many fail of impregnation, and the nest is often disturbed and the eggs eaten by other fish seeking places for a nest. When the eggs have hatched, the fry are about $\frac{3}{8}$ in. long, and are furnished with a sac of provision 3 times their bulk. For nearly 30 days after birth, the salmon and trout are sustained by the absorption of this sac or stomach. During this period they are beset on all sides by hungry enemies, and being very shy they try to hide in every imaginable place.

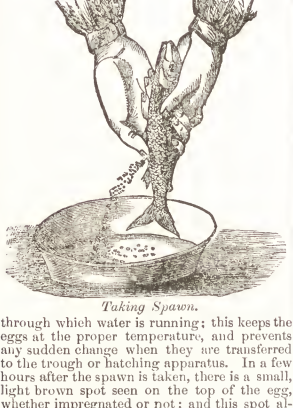
Trout Ponds.

PONDS, Trout.—Those who raise trout as a crop, have a series of ponds connected by raceways, the latter being used for spawning grounds. Three ponds are necessary: The 1st pond is for the young fish, from the time they are hatched until they attain the age of 18 or 20 months. For if left with the older ones they will be devoured. The 2d pond is for the same fish, until they are $3\frac{1}{2}$ years old. The shape of the ponds should be oblong and the width about $\frac{1}{4}$ of the length. The raceways should be 5 to 6 in. deep, and 2 to $3\frac{1}{2}$ ft. wide, according to the size of the ponds and the supply of water; the bottom of the raceways should be covered about 3 in. in depth with fine gravel for nests, and the sides be of boards 1 in. thick, 12 in. wide, and furnished with screens, to prevent the fish going from one pond to the other. These screens may be made of common wire, painted with tar, or copper wire, or of galvanized iron wire; the last being most durable. The screens for keeping the fry, should be 14 threads to the inch, and for 1 yr. old fish, 5 to 6 threads to the inch. Incline them at an angle of 45°, the top farthest down stream. The bottom of the pond may be of mud, clay or moss; gravel must be avoided, as the fish would spawn on it, and the eggs be lost. The ponds must be arranged so that they can be entirely drained.

PONDS, Salmon.—To hatch salmon it is necessary to have ponds where they can be retained till they are ripe; but it is impossible to keep them throughout the year, as they are migratory. The ponds must be larger than for trout, and have larger raceways. They are manipulated as for trout, and the eggs hatched in the same way.

HATCHING, Artificial.—When the fish ascend the raceways and seem to be seeking for a place to make their nest, they may be taken and the spawn pressed out. At the entrance of the raceway there should be grooves to receive a frame, on which is tacked a net of coarse bagging, 8 or 10 feet long. One corner of the bagging should be narrowed, left unsewed, and tied with string. The raceways should be covered in spawning time, so that the fish will not be frightened. As soon as there are fish in the raceway, the net is gathered in one hand, and the frame held in the other, so as to put in the grooves quickly. Go quietly to the spot, and put the net in the groove quickly. The water running down will swell the net to its full length. The covers may be removed and the fish frightened down from the head of the raceway into the net. As soon as they are in, the frame may be lifted out and the fish inclosed in the bag. A tub of water being ready, the end of the net can be lifted into it and untied, when the fish will fall into the tub. The fish should then be immediately taken to the hatching house, lest they die in this small quantity of water. While the fish lie quiet in the tub, there is sufficient air to sustain them, but, if they begin to come to the surface, the air is exhausted and the water must be replenished. Provide a milkpan for the spawn, and a tub of water in which to put the fish after they are deprived of the spawn. Wet the milkpan with water; hold the fish as shown in the illustration; slip the right hand gently down from the head, and press the belly with the forefinger and thumb. If the fish is ripe, a few drops of pearly colored milt, or orange-hued eggs, will be expressed into the pan. If the milt is not of this color, it is not good, and another male must be treated in the same manner. Press the female more slowly and oftener than the male. If, when the hand is pressed lightly over the belly, the eggs are felt to be hard, they are not ripe. When ripe, the belly is soft, and the eggs feel loose and change position at the touch. Stir the eggs at intervals by moving the pan, so that they will

all come in contact with the milt; when the operation is completed, pour about ½ pt. of water on them and set the pan in a hatching trough,



Taking Spawn.

through which water is running; this keeps the eggs at the proper temperature, and prevents any sudden change when they are transferred to the trough or hatching apparatus. In a few hours after the spawn is taken, there is a small, light brown spot seen on the top of the egg, whether impregnated or not; and this spot always rises to the top. When the egg is held before the light in a small vial, this speck looks about the size of the head of a small pin elongated upwards. Looking down on the egg, the speck is seen in the centre, apparently on top. Seven days after the ova is taken, a small circle is seen around the speck, whether the egg is impregnated or not. It is difficult to know which eggs are fecundated; the fecundated egg has a clearer speck in the centre, and the ring around the speck is larger. When 9 days old, the circle in the impregnated egg has enlarged, a slight brown or bluish gray tinge pervading the interior. The unimpregnated do not change after the 9th day, unless to become opaque. On the 11th, the first formation of the fish is seen, a brown line extending from the circumference towards the centre of the circle, and covering ¼ the egg. When 12 days old, the circle covers ⅓ the egg. On the 13th the circle has passed ⅔ around the egg. On the 14th the circle covers entirely the egg, and the trout is formed. On the 25th, the eyes, heart, arteries, red blood, and circulation of blood and motion will be observed. About the 50th day the trout come out of the shell. In a couple of weeks they move about, become more agile as the sac is absorbed, and begin to look for food. They should now be fed twice a day on chopped raw liver, coagulated blood, thick milk, or bonny-clabber, boiled liver or lean meat grated, and the yolks of eggs boiled hard and powdered.

HATCHING APPARATUS.—A great many inventions are in use for hatching. Below are given a few approved methods: 1. A wooden trough, 12 to 15 in. wide and 4 in. deep, is divided into nests or apartments, 16 to 18 in. long, by placing strips across; over these strips, the water slightly ripples, and the force of the current is broken. The bottom of the trough is covered with clean gravel to the depth of 1 in., to receive the eggs, over which the water, 1 in., deep, flows in a gentle current. — 2. A floating box for hatching is also used. It is made of boards, ½ in. thick; the bottom covered with fine, painted wire gauze; on this the eggs are distributed. If the box does not set deep enough to allow the water to cover the eggs 1 to 1½ in., weights should be placed on the cover to sink it that depth. If the bottom of the box is made of boards and gravel strewn over it, 2 or 3 rows of large gimlet holes should be bored in each end below the water line. These boxes are 2 ft. long, 18 in. wide, and 6 in. deep, and are tied to a strip extending across the raceway, and allowed to float in the current. Success in hatching depends on the purity of the water, and even the purest should be filtered. A sq. in. of water divided into 4 jets, and flowing through the same number of troughs, will suffice for 300,000 to 400,000; but about 3 times the supply will be required to sustain the same number of young fish for any great length of time in the nursery. An extra supply must, therefore, be provided for the fry, after they have absorbed the umbilical sac.—3. The Holton hatching box is an excellent incubator, and was constructed especially for white fish. It is about 20 in. sq. and 2 ft. deep, and will hold eighteen wire trays, placed one upon another. The water enters from the bottom, passes up through the box, falls evenly into little troughs, which run around 4 sides, and is thence carried into a reservoir. The trays are lifted for cleaning by arms at 2 sides of the box, fastened into a lower frame. The trays are made of wire cloth of so small a mesh that the eggs will not pass through, but large enough to permit the passage of the white fish fry, which, as soon as they break the shell, are carried up by the current into the reservoir, from which they may be taken as required.—4. Coste constructed an incubating-box, which it is claimed will remedy the defects of the other boxes. This box measures 60 in. in breadth and depth. Its sides and bottom are of solid wood. Its top is formed of a lid in 2 parts, in the centre of which is a grating of metal wire; each end is closed by a door, whose opening is larger than that of the lids, and is also supplied with grating. Both doors and lids move on hinges, open outward and are closed by 2 small bolts fastend with strings, and supplied with padlocks. There are no subdivisions in the inside of this box, but running along the sides are small ledges to support the frames. These frames are of wood and glass sticks. As these frames are intended to be put one over the other, the box must be higher than in the trough apparatus, and at the ends there must be large notches for the free passage of water. To render the process easier, their surface must not (if the box has the length mentioned above) represent more than ¼ its

capacity, so that 4 of them may be on the same floor. This box, which should be used in running water, can be used for free eggs and for eggs adhering to foreign bodies. It can hatch a large quantity, and permits manipulations which in other apparatuses are hurtful. For observing what is going on inside, and to clean the gratings, when obstructed by sediments, the lids and doors can be opened without taking the apparatus out of water or disturbing the frames or eggs. Whether attached to a floating frame by clamps, or by strings attached to pegs driven in the ground, it must present to the current one of its extremities when the current is moderate, and one of its angles when it is very rapid. A bed of pebbles and fine sand, at the bottom, receives the fish, which either fall or descend on it as they are hatched, and offers favorable conditions for their development, till the gates can be opened and they set at liberty in some river or pond. Fish of small size will escape through the meshes of the wire grating and disperse through the water. When the hatching process is finished, the frames are removed from the box, so that it can be cleaned, and also that better care can be bestowed on the young fish.

SMELT.—This fish is a variety of the salmon. The eggs are very adhesive, and must be treated differently from those of trout. The fish spawn in March, and the eggs should be deposited upon trays, previously dipped in water, and then placed in a tin pan without any water in it; then the milt should be added, and just enough water to cover the tray, and the whole shaken till the eggs are evenly distributed. In a few minutes they will adhere firmly, and must remain undisturbed till hatched. With a temperature of 35° to 40°, they will hatch in about a month. The trays are removed to hatching boxes (see *Hatching Box* in SHAD), after the eggs have adhered by the hardening of the mucous matter that surrounds them, and are then treated as trout eggs.

TRANSPORTATION.—Trout, or any other kind of fish, may be transported in a cask, with a cover which has a hole 1 in. in diameter, and the cask filled to within 6 in. of the top with water. Tie some ice in a piece of flannel, and fasten it to the side of the cask near the top, so that it cannot swing about and bruise the fish. If the journey be long, insert a bellows with a tube long enough to reach the bottom of the cask, and by blowing occasionally the fish may be supplied with air and carried a great distance.

SHAD.

CHARACTERISTICS AND HABITS.—Shad are migratory, but spend much of their time in the sea. They spawn from February to August, and ascend into fresh water to deposit their eggs, but do not go as far as salmon. They seek some rocky ledge, where there is a gentle current, and, uniting in pairs, press their vents together and extrude the spawn and milt. They build no nests, and spawn while in rapid motion. The eggs are left to their enemies, the only precaution being that they are deposited at night. A little increase of current will wash 9-10 of the eggs off the rocky ledge into the muddy flats, where they perish for want of air. A heavy rain will rile the water, and on its subsidence there will be deposited upon the eggs a thin covering of sediment, which will destroy them all absolutely and without exception. Eggs of fish, in order to hatch, must be continually surrounded with fresh water; they require the oxygen of changing water just as land animals require the oxygen of changing atmosphere. So great are these risks, that shad could never have held their own, were it not for the compensation of their wonderful fecundity. They produce 10,000 eggs to each lb. of weight, which is 10 times as many as salmon or trout, and it is not unusual to obtain 60,000 eggs from a single mature female. This is their protection, that among the vast number laid some will hatch, and although the percentage is small, the aggregate has been large enough to maintain the supply. When spawning is over, the fish at once return to the ocean to recuperate.

HATCHING, Artificial.—Shad eggs are lighter than those of trout, and will almost float in water. They are less than $\frac{1}{2}$ the size of trout eggs, and require a temperature of from 65° to 75° for hatching. They will hatch at a lower temperature, but in such cases mature slowly, while 80° of heat are as much as they can possibly endure. In artificial manipulation the fish are taken in seines at night from their spawning beds, and stripped at once, as they will die very quickly. The eggs are caught in a pan with a little water in it; after being allowed to stand for a few minutes until impregnation is complete (which is shown by their swelling in size), and reducing the temperature of the water 10°, they are poured into the hatching boxes and allowed to remain. In 24 hours the black eyes of the young fry will be visible through the shell. In from 3 to 10 days the fry will hatch. Instead of trusting to good fortune to get ripe spawners from the nets, these may be obtained in a way similar to the treatment of salmon and trout. A pond may be built by damming up a stream running into the main river; in this the shad may be confined till they are ripe. It has been supposed that shad were so timid a fish that they would hardly ascend fishways, and could not be kept in confinement; but such does not turn out to be the case. There is no difficulty in ponding them and in examining them from time to time till they become in proper condition to strip. They are not more timid than other fish.

HATCHING BOX.—This is a simple box with the bottom knocked out and replaced by a wire gauze netting. It is suspended by floats of wood nailed on the sides so that the bottom is presented at an angle to the current, the degree of inclination being determined by the velocity of the current. The water striking against the screen enters the minute interstices and keeps the eggs in motion. Attach these boxes one behind the other in a long row; fill with impregnated spawn and anchor them in the river.

"STICK TO IT!"

ADHESIVES.

REMARKS.—Quite as much depends upon the manner in which a cement is used as upon the cement itself. The best will prove worthless if improperly applied. Cement should be brought into intimate contact with the surfaces to be united, by heating the pieces to be joined, as in using resin, shellac, marine glue, etc. Glue must never be used upon hot wood, or hot cauls used to veneer with, as the wood will absorb the water in the glue too suddenly, and leave only a little residue, with no adhesiveness. Always glue both surfaces, excepting in the case of veneering. Where solutions are used, the cement must be rubbed into the surfaces with a soft brush (as in the case of porcelain or glass), or by rubbing the surfaces together (as in making a glue joint between two pieces of wood). As little cement as possible should be allowed to remain between the united surfaces. To secure this, the cement should be as liquid as possible, and the surfaces pressed close, until the cement has hardened. Time should be allowed for the cement to harden, particularly oil cements, such as copal varnish, boiled oil, white lead, etc. When two surfaces are joined by a layer of white lead between them, 6 mos. may elapse before the cement in the middle of the joint has become hard. When the article is to be used immediately, the only safe cements are those liquefied by heat, and which become hard when cold. A joint made with marine glue is firm an hour after made. Next to cements that are liquefied by heat, are those dissolved in water or alcohol. A glue joint sets firmly in 24 hrs.; a joint made with shellac varnish becomes dry in 2 or 3 days. Oil cements, which do not dry by evaporation, but harden by oxidation (boiled oil, white lead, etc.) are slowest of all. The hotter the glue, the more force it will exert in keeping the parts together; in long joints the glue should be applied after boiling; glue loses its strength by remelting; newly made is preferable to that reboiled. Glue of good quality should contain no specks, and be transparent. Good glue, when put in cold water, swells without dissolving, and resumes its original condition on being dried. In preparing glue, break it into small pieces; soak in water 10 to 24 hrs.; put over the fire in a glue pot; heat until dissolved, stirring frequently. Never melt glue in a pot subjected to the direct heat of the fire. Glue used by cabinet makers is of an amber color, and of superior quality. Fresh glue dries more readily than that which has been reheated. The quality of glue is determined by the amount of cold water it will absorb. From experiments it has been found that after 24 hrs. immersion in water at 60°, the finest glue absorbs 12 times its weight of water; that from dark bones absorbs 9 times its weight, and ordinary glue absorbs 3 to 5 times its weight of water. Glues that take the longest to dry are preferred to those that dry quickly; the slow drying glues being strongest. Powdered chalk, added to glue in small quantities, makes it hold stronger. Common adhesives are so indiscriminately called cements, lutes, glues, or pastes, that any classification under these heads has little value; the terms are merely those of popular usage, and are too general in their own meaning to be clearly separable. Common usage is, therefore, the uncertain guide in the following analysis and nomenclature.

CEMENTS.

BUILDING.

BRICK DUST. — Brick dust, 1 part; lime, 1 part; sand, 2 parts; mix dry, and temper with water in the usual way.

BRIMSTONE. — Melted brimstone, alone or mixed with resin and brickdust.

CONCRETE, Gravel. — To 8 barrows slaked lime, well deluged with water, add 15 barrows sand; do not use river or beach sand, as this will absorb dampness. Mix to a creamy consistency, and add 60 barrows coarse gravel; work well. You can throw stones into this mixture of any shape, from 9 to 10 in. in diameter. Form moulds for

the walls of the house by fixing boards horizontally against upright standards, which must be braced so as not to yield to the pressure of the material as it settles. Set standards in pairs around the building where the walls are to stand, 6 to 8 ft. apart, and so wide that the inner space shall form the thickness of the wall. Into the molds thus formed, throw the concrete, and the more promiscuously the better. In a short time the material will get hard as solid rock. If the gravel is free of dirt, the sand clean, and the weather dry, the walls can be raised 1 ft. a day. Some make the gravel and sand into mortar, press into bricks, and then lay into walls; but the walls will be stronger, if laid up solid in board frames made to raise up as required.

DRAIN TILE. — 1 bush. Rosendale cement should be evenly mixed with 3 bush. sharp, clean sand, and 4 bush. washed gravel, not very coarse, but not fine. When all is carefully mixed, water should be added to make a soft mortar, and the cement rapidly worked until mingled, and immediately used. It sets quick.

EXTERNAL.—1. (*Pen's.*) Used to cover buildings. Powdered quicklime, 1 part; powdered baked clay, 2 parts; mix; then add 1 part freshly baked and powdered gypsum to 2 parts powdered baked clay; after mixing, add them to the former powder, and incorporate the two. It is mixed with water, and applied like mortar.—2. Sand, 1 part; ashes, 2 parts; clay, 2 parts; mix with linseed oil. Hard and durable, and resists the weather almost like marble.—3. (*Hamelin's.*) Siliceous sand, 60 parts; Portland stone, in fine powder, 40 parts; lime marl, 20 parts; litharge, 8 parts; grind together. For use, mix with linseed oil, and use like mortar. Wash the surface of the building first with linseed oil.

FIRE-PROOF.—Used for walls, and to mend broken pieces of stone, steps, etc. Fine river sand, 20 parts; litharge, 2 parts; quicklime, 1 part; linseed oil sufficient to form a thin paste.—2. (*Beale's.*) Chalk, 60 parts; lime and salt, each 20 parts; Barnsey sand, 10 parts; iron filings or dust, and blue or red clay, each 5 parts; grind together, and calcine.

FLOOR.—1. Used for houses, especially malt houses. Take $\frac{2}{3}$ lime and $\frac{1}{3}$ coal ashes, well sifted, with a small quantity of loamy clay; mix the whole together; temper with water, making it up into a heap; let it lie a week or 10 days, and temper it again. Heap it up for 3 or 4 days; repeat the tempering till it becomes smooth and gluey. The ground being leveled, lay the floor therewith $2\frac{1}{2}$ or 3 in. thick; smooth with a trowel; the hotter the season the better. — 2. To make floors look better, take lime of ragstones, well tempered with whites of eggs; cover the floor $\frac{1}{2}$ in. thick before the underflooring is too dry. If well done and thoroughly dried, it will look, when rubbed with a little oil, as transparent as metal or glass. In elegant houses, floors are made of stucco, or of plaster Paris, beaten and sifted and mixed with other ingredients.

MORTAR, Gloucestershire. — Used for stone and brickwork. Collect road scrapings; slake lime, and mix thoroughly together. Carefully pick out, as the mass is worked over, stones or other foul matter. For stone work, this is quite sufficient; for brick work, pass the materials through a sieve previous to being made into mortar.

MORTAR, To Make.—Reduce quicklime and sand to a paste with water; the lime pure, free from carbonic acid, and in fine powder; the sand free from clay (partly fine sand and partly gravel); the water pure, and if previously saturated with lime, so much the better. The proportions are 3 parts fine and 4 parts coarse sand, 1 part quicklime, recently slaked, and as little water as possible. The addition of burnt bones, rye straw, or hair, improves mortar, by giving tenacity, but should not exceed $\frac{1}{4}$ of the lime employed. Sawdust has been recommended as superior to hair for preventing cracking and peeling off of rough casings by storms and frost. Mortars improve with age, and attain maximum hardness and strength after a long time. A chemical union takes place between the lime and the silica of the sand, requiring years to complete. Black mortar is made by mixing with lamp black.

PORTLAND. — Gray chalk, mixed with $\frac{1}{4}$ its weight of clay in a pug mill supplied with warm water, and run off into a settling pond where the superfluous water is removed. The sediment is dried on a floor provided with flues, then burned in a kiln, and ground between millstones.

ROOFING.—1. Melt together in an iron pot, 2 parts by weight of common pitch, and 1 part gutta percha. This forms a homogeneous fluid more manageable than gutta percha alone. To repair gutters, roofs, etc., clean out of the cracks all earthy matters; warm the edges with a plumber's soldering iron; then pour the cement upon the cracks hot, finishing by going over the cement with a moderately hot iron, so as to make a smooth joint.—2. Mineral coal tar, pulverized coal (charcoal is best), and fine well slaked lime; the coal and lime to be well mixed together; 4-5 coal, and 1-5 lime; the tar to be heated, and, while hot, thickened with the mixture of coal and lime, until it can be spread upon a board and not run. The cement must be applied warm with a trowel.

ROMAN.—Genuine Roman cement consists of *puzzolene* (a ferruginous clay from Puteoli, calcined by the fires of Vesuvius), lime and sand, mixed with soft water. The only preparation which the puzzolene undergoes, is pounding and sifting; but the ingredients are occasionally incorporated with bullock's blood and oil, to give more tenacity.

ROMAN, Artificial.—1. A mixture of clay or loam, broken pottery, flints, or silicious sand, or broken bottle glass and wood ashes, exposed to heat in a furnace, until it becomes partially vitrified; then ground to powder, sifted, and mixed with $\frac{1}{3}$ its weight quicklime in fine powder; then packed in casks to preserve from air and moisture. For use, mix with water, and apply like Roman cement.—2. Drift sand, 94 parts; unslaked lime, 12 lbs.; and 4 lbs. poorest cheese grated; mix well; add hot water to reduce to a consistency for plastering. Work well and quick, with a thin, smooth coat.—3. Slaked lime, 1

bush.; green copperas, 3½ lbs.; fine gravel sand, ½ bush. Dissolve the copperas in hot water, and mix all to a consistency; use the day it is mixed, and keep stirring while in use.

SLATING FLUID. — Dissolve water glass in boiling water to a syrup, and form into a paste with a mixture of equal parts dry plaster Paris and fine calcined clay passed through an 80 in. sieve.

STUCCO.—Used for coating walls and ornamenting ceilings. A compound of powdered gypsum or strong gelatine. It takes a high polish, and colored designs can be painted on it. When employed on walls a coarser kind is first laid on, followed by a coating made of choicer specimens of gypsum, or glue, or isinglass. Fine stucco is the third or last coat of 3-coat plaster, and consists of fine lime and quartz ore sand, which is "twice hand floated" and well trowelled. When the outer coat is dry, it is polished with pumice, tripoli and linen. The color is incorporated with the outer coatings by mixing metallic pigments with it, and applying it to the wall, after which a very thin coating of gypsum and isinglass, or oil is given, and when the whole is partially dry the tint is brought out by polishing. Generally the finest effect is obtained by oil.

WALL FINISH. — 1. (*Sorel's.*) For coating walls of rooms. A coat of oxide of zinc, mixed with size, made up like a wash, is first laid on, and over that a coat of chloride of zinc, prepared as the first wash. The oxide and chloride effect a combination, and form a cement as smooth as glass, and said to be superior to plaster Paris. —2. Slack 1 pk. lime, and while hot and thick like cream, add 1 pt. linseed oil, and ½ lb. dissolved glue. Let it stand ½ day before using. This, for interior walls, is superior to simple lime and water.

WATERPROOF, or HYDRAULIC. — 1. Good gray clay, 4 parts; black oxide of manganese, 6 parts; limestone, reduced to powder by sprinkling it with water, 90 parts; mix, calcine, and powder. — 2. Mix white iron ore, 15 parts, with lime, 85 parts; calcine and powder. Both this and the preceding must be mixed up with a little sand for use. A piece thrown into water rapidly hardens. — 3. Fine clean sand, 1 cwt.; quicklime, in powder, 28 lbs.; bone ashes, 14 lbs. The above are beat up with water for use. — 4. (*Bruyere's.*) Clay, 3 parts; slaked lime, 1 part; mix, and expose to a red heat for 3 hours, then grind to powder. — 5. (*Vicat's.*) Stir into water a mixture 4 parts chalk and 1 part clay; mix with a vertical wheel in a circular trough, letting it run out into a large receiver. A deposit takes place, which is formed into small bricks, which, after being dried in the sun, are moderately calcined; it enlarges about ⅔ when mixed with water.—6. (*Gad's.*) Clay, well dried and powdered, 3 parts; oxide iron, 1 part; mix, and make into a stiff paste with boiled oil. — 7. Slake lime with water, containing about 2 per cent. gypsum, and add a little sand. Gypsum tends to delay the slaking of the lime, and to harden the substance formed after slaking. — 8. Used in constructing edifices constantly exposed to the action of water. When a little manganese is added to the mortar, it acquires the invaluable property of becoming hard under water. Limestone is often combined with manganese, when it becomes brown by calcination. — 9. Used for uniting large stones in cisterns. Equal parts red and white lead, with drying oil, spread on tow or canvas. — 10. Used for making the hard joints of wooden cisterns and casks air and water-tight. Melted glue, 2 parts; linseed oil, 4 parts; boiled into a varnish with litharge; hardens in 48 hours.

MECHANICAL.

ACID PROOF.—1. This cement resists boiling sulphuric acid. Take caoutchouc; melt by gentle heat; add from 6 to 8 per cent. of the weight of tallow; keep the mass stirred; add dry slaked lime, to make the fluid mass the consistency of soft paste; then add 20 per cent. red lead, whereby the mass becomes hard and dry.—2. Used for cementing troughs for holding acids. Resin, 6 lbs.; dried red ochre, 1 lb.; calcined plaster Paris, ½ lb.; linseed oil, ½ lb.; incorporate by stirring together when melted. — 3. For smaller purposes, an alcoholic solution of shellac, or a solution of bitumen in benzol, answers well. To render this latter less brittle, add a few drops solution of india-rubber.—4. (See *Fireproof*, 4, in BUILDING.)

ALABASTER.—Used to join or mend pieces in alabaster, white marble, Derbyshire spar, porphyry, and other like substances, and to fill up cracks, supply chips out of corners, etc. Apply hot, the surfaces having been previously warmed. 1. Yellow resin, 2 parts; melt, and stir in plaster Paris, 1 part. — 2. Yellow resin, beeswax and plaster Paris, equal parts. — 3. Resin, 8 parts; wax, 1 part; melt, and stir in plaster Paris, 4 parts. — 4. Sulphur or shellac, melted with sufficient plaster Paris, or coloring matter to give the desired shade.

AMBER. — Used as a cement for glass and earthenware. Fragments of amber are cautiously heated in an iron pot; as soon as it becomes semi-liquid, an equal weight of hot pale boiled linseed oil is gradually stirred in and the whole thoroughly blended.

AQUARIUM.—Used for the marine as well as the fresh water aquaria, as it resists the action of salt water. 1. 1 gill litharge; 1 gill plaster Paris; 1 gill dry white sand; ½ gill finely powdered resin. Sift, and keep corked tight until required for use, when it is made into a putty by mixing in boiled linseed oil, with a little patent drier added. Never use it after it has been mixed with the oil over 15 hours. The tank can be used immediately, but it is better to give it 3 or 4 hours to dry.—2. Mix equal quantities white and red lead, to a paste, with mastic varnish, and use soon as mixed. — 3. Resin, 1 lb.; tar, 4 oz.; linseed oil, about 2 oz.; melt together over a gentle fire, and pour into the angles of the aquarium in a liquid state, but not when boiling, as this would crack the glass. The cement becomes firm in a few minutes. If too liquid after cooling under water, add more tar to the cement and heat again; if not sufficiently fluid, add

more oil. The cement will not affect the water, and will set the glass water tight. (See *Waterproof* or *Hydraulic.*)

ARCHITECTURAL.—Used for making entire models, busts, ornaments, etc. It is light, and takes a good polish, but is affected by moisture. 1. Reduce paper to a pulp by boiling in water, and work it over. Squeeze this paste dry, and add an equal bulk of whiting; mix the whole into a paste of the required consistency with good size or a solution of glue. — 2. Same as the above, but with plaster Paris instead of whiting. —3 (See *Japanese.*)

ARMENIAN, or DIAMOND. — Used to unite bits of glass, polished steel, and for cementing precious stones on jewelry. 1. Dissolve 5 or 6 bits gum mastic, each the size of a large pea, in as much rectified spirits of wine as will render it liquid; and in another vessel dissolve as much isinglass, previously softened in water (though none of the water must be used), in French brandy or good rum, as will make a 2 oz. vial of strong glue, adding 2 small bits gum galbanum or ammoniacum, which must be rubbed till dissolved; mix the whole with sufficient heat, and keep in a vial closely stopped; when used, set the vial in boiling water. — 2. Isinglass, 6 oz.; gums mastic and olibanum, each, 2 oz.; pure water, 9 oz.; rectified spirits wine, 12 oz.; dissolve the isinglass in the water; then stir in the mastic, previously dissolved in the spirits wine; and, lastly, stir in the olibanum in the state of an impalpable powder. — 3. Isinglass, 1 oz.; distilled vinegar, 5½ oz.; spirits wine, 2 oz.; gum ammoniacum, ½ oz.; gum mastic, ½ oz.; mix well.

BADIGEON.—Used for filling up holes and defects in mechanical work. The most common is putty, colored to suit. Statuaries use a mixture of plaster and freestone; carpenters, a mixture of saw dust and glue; coopers, a mixture of tallow and chalk. The same name is given to a stone colored mixture used for fronts of houses of which the published composition is wood-dust and lime, slaked together, stone-powder, and a little umber or sienna mixed with alum water to the consistency of cement. The composition is probably some good hydraulic cement, colored to suit.

BUCKLAND'S.—Used for all the purposes of mucilage, and as a cement for labels. It does not become brittle and crack. White sugar, 1 oz.; starch, 8 oz.; gum Arabic, 4 oz.; all be separately reduced to fine powder, and rubbed together in a dry mortar; then, little by little, add cold water until of the thickness of melted glue; put in a wide-mouthed bottle and cork close. The dry powder itself, ground and mixed, may be kept for any length of time in a wide-mouthed bottle, and when wanted a little may be mixed with water.

CAP.—Used for chemical and electrical purposes; cementing glass tubes, necks of balloons, etc. 1. Resin, 5 lbs.; beeswax and dried Venetian red, of each, 1 lb., melted together. — 2. Equal weights of red lead and white lead.

CASE-HARDENING.—Used as cement mixture for the manufacture of steel, to convert iron into steel and to utilize the waste bone in the process of the manufacture of cosmoline. A combination of bone carbon and hydrocarbon oils. The bone carbon is impregnated with hydrocarbon oil. The wrought iron is case-hardened by immersion in the bone carbon heated to redness. The surface of the iron is of extreme hardness, and the metal is not blistered.

CHEESE, or CURD.—Used to unite glass, earthenware, etc. It is made into a paste with a little water, and applied immediately. 1. Curdle skim-milk with rennet or vinegar; press out the whey; dry the curd by a gentle heat, as quickly as possible; when quite dry, grind in a pepper or coffee mill, and triturate in a mortar until reduced to fine powder. Mix 10 parts by weight of this powder with 1 part quicklime, in powder; to every oz. of the mixture, add 5 or 6 gr. camphor; triturate the whole together, and keep in vials well corked. — 2. Add ½ pt. vinegar to ½ pt. skimmed milk; mix the curd with the whites of 5 eggs well beaten, and sufficient powdered quicklime to form a paste. It resists water and a moderate degree of heat.

CHEMICAL GLASSES. — Used for mending glasses. 1. Mix equal parts wheat flour, powdered Venice glass, pulverized chalk, and a small quantity of brick dust, finely ground. These ingredients, with a little scraped lint, are to be mixed and ground with the whites of eggs; it must then be spread upon fine linen cloth, applied to the crack, and allowed to get thoroughly dry before the glasses are put to the fire. — 2. Used for sticking things temporarily together. Melt yellow beeswax with its weight of turpentine, and color with powdered Venetian red. When cold, it has the hardness of soap, but is easily softened and molded with the fingers. The consistence of the cement may be varied by changing the proportions of turpentine and wax, and if a firm cement is needed, a little resin may be added. — 3. Used for mending stone ornaments. Finely scraped old cheese, 1½ parts; quicklime, in fine powder, 1 part; mix thoroughly; moisten with milk to a paste, and use at once, as it hardens quickly. Instead of milk, a strong aqueous solution of water glass or borax may be used. White lead (in oil) applied on cotton gauze, may be used advantageously. It is nearly colorless, quick setting, can be applied without heat, and will stand outside weather.

CHINA.—Used for mending all kinds of crockery. 1. Take 10 oz. isinglass, and dissolve in a wineglass gin before the fire. It should be warm when applied, and put on with a camel's hair brush; the pieces joined, and then bound with strips of cloth. — 2. Take a very thick solution of gum Arabic and water; stir in flour of plaster Paris until it becomes a thin paste; apply with a brush to the broken edges, and put them together; let them dry; its whiteness renders it valuable. — 3. Take the white of an egg and a little flour, which make into a light paste; clean the parts to be joined from all dust and dirt; spread the paste on each piece and press together; wipe off exuding portions, and let it dry. — 4. A transparent cement. Take 1 lb. pulverized white shellac; 2 oz. clean gum mastic; put these into a bottle, and then add ½ lb. pure sulphuric ether. Let stand ½ hour, and then add ½ gal. 90 per cent. alcohol; shake occasion-

ally till dissolved. Heat the edges to be mended, and apply the cement with a camel's hair brush; hold the article together until the cement cools. — 5. The expressed juice of garlic is a good cement for glass or china; it is better if mixed with a little of the ash of a burnt oyster shell. — 6. Equal quantities of gutta-percha and shellac are melted together and well stirred. This is best done in an iron capsule placed on a sand bath, and heated. It possesses hardness and toughness. The articles to be mended must be warmed, and kept in position until cool. — 7. 4 lbs. white glue; 1½ lbs. dry white lead; ½ lb. isinglass; 1 gal. soft water; 1 qt. alcohol; ½ pt. white varnish. Dissolve the glue and isinglass in the water by gentle heat; stir in the lead; put the alcohol in the varnish; mix the whole together. — 8. A cement that cannot be dissolved or broken from the part that is repaired. 5 parts gelatine to 1 part acid chromate of lime; put on the edges with a camel's hair brush; press the edges together, and expose to the sun. — 9. This cement will make crockery as good as new. Dissolve 1 oz. common salt in 1 qt. water; bring to a boil, and put in 1¼ lbs. gum shellac. When dissolved, pour into cold water, and work like wax; make into small sticks. Warm the articles to be cemented till they melt the sticks brought into contact with them. — 10. Freshly burnt plaster Paris, 5 parts; freshly burnt lime, 1 part; white of egg, as needed. Reduce the 2 first ingredients to a fine powder, and mix well. Moisten the parts to be united with white of egg; then mix the powder rapidly with white of egg, and apply the mixture; the pieces are then pressed together, and left undisturbed for several days. — 11. This is unbreakable. Pure white lead, or zinc white, ground in oil, and used very thick; but it takes a long time to harden.—12. Put a piece of white flint stone into the midst of a fierce fire; when it is of a white heat, take it out with a pair of tongs, and suddenly drop into a pan of cold water, which should be placed ready for the purpose. This will destroy the powers of adhesion in the flint, and precipitate the stone to a fine powder, from which you must carefully pour off all the water; next melt white resin in an iron or earthen pipkin, and stir the flint stone powder into it till it is of the consistence of thick paste. Warm the edges of the glass, stone, china or earthenware, and rub it thereon; then carefully and neatly place them together; when quite cold, with a knife scrape off as much of the cement as remains outside.

CHINESE. — Used to mend china, glass, and fancy ornaments. 1. Dissolve shellac in enough rectified spirits to make a liquid of the consistency of molasses. This will join wood so strongly that it will resist the flexion of a bow. The fluid is thinly smeared over each face to be united, a thin piece of muslin interposed, the whole pressed tightly together, and left to the next day. — 2. Dissolve 6 oz. shellac in 1½ pts. water, containing 2 oz. borax, and evaporate to the consistency of molasses.

COLLODION.—Ordinary collodion is made by dissolving 8 parts gun cotton in 125 parts ether and 8 parts alcohol. When used as a cement or varnish, it becomes hard, cracks and peels off. It may be rendered elastic by the addition of 4 parts Venetian turpentine, and 2 parts castor oil.

COPPERSMITHS'.—Used to secure the edges and rivets of copper boilers, to mend leaks from joints, etc. 1. Bullock's blood, thickened with finely powdered quicklime. It must be used as soon as mixed, as it rapidly gets hard. It is extremely cheap and very durable. — 2. Boiled linseed oil and red lead, mixed together into a putty. The washers of leather or cloth are smeared with this mixture in a pasty state.

CUTLERS'.—1. Used for handling knives and forks. 1 lb. colophony, and 8 oz. sulphur, melted together, and kept in bars or reduced to powder. 1 part of the powder is to be mixed with ½ part iron filings, fine sand or brick dust, and the cavity of the handle filled with this mixture. The stem of the knife or fork is then to be heated and inserted in the cavity, and when cold it will be found fixed to its place with great tenacity. — 2. Shellac, 2 parts; prepared chalk, 1 part; powder and mix. The opening of the blade is filled with the powder, the lower end of the iron heated and pressed in. — 3. Resin, 4 parts; beeswax, 1 part; brick dust, 1 part. Fill the hole in the handle with the cement; heat the tang of the blade, and press in. — 4. Pitch, 4 parts; resin, 4 parts; tallow, 2 parts; brick dust, 2 parts. Melt the first 3 ingredients, and add the brick dust hot and finely powdered. — 5. Chopped hair, flax, hemp, or tow, mixed with powdered resin, and applied as above.

CRUCIBLE.—Used to join the covers to crucibles, or for similar purposes, so as to keep them air tight when hot. Made of glass, of borax (fused borax), brick dust and clay, finely powdered together and mixed with a little water when used. No very great nicety is required in the proportions, but about 1-10 of borax is quite sufficient to bring the earths to that state of semi-vitrification which is desired. Litharge may be used instead of borax, but the latter is by far the best, as it promotes that thin spreading fusion which is most efficient.

DRUGGISTS'.— Used for cementing stoppers. 1. Composed of finely ground litharge and concentrated glycerine, painted around the cork or stopper; quickly dries, and becomes hard, but easily scraped off when necessary to open the bottle. — 2. Used to close vessels containing the vapor of acids, or highly corrosive substances. Beat and sift finely dry pipe clay; add painter's drying oil, and mix in a mortar to a molding consistency. Use this lute in cylinders, flattened and applied to the joinings. The points to which it is applied must be clean and dry. — 3. For corks and apparatus use. Zinc white rubbed with copal varnish to fill up the indentures; when dry, cover with the same mass thinner, and lastly with copal varnish. — 4. Used as a temporary stopping or lute for the ends or joints of tubes, which are not exposed to much heat. Yellow wax, 4 parts; turpentine, 2 parts; Venetian red, well dried, 1 part; melt together.

EARTHENWARE.—1. A good cement is made by dissolving gum shellac in alcohol; apply the solution, bind the parts together, and let it dry.—

2. White of egg, thickened with powdered quicklime.—3. Fire-proof. Used for metallic or earthen vessels, which should be dried with heat in the open air. Coagulate 2 lbs. fresh milk by means of a little vinegar; remove the whey, and beat this with whites of 4 or 5 eggs, or with fresh bullock's blood; mix with powdered slaked lime. — 4. 2 parts litharge; 1 part, each, unslaked lime and flint glass; pulverize separately and mix. To use it, wet up with old drying oil. — 5. (*Botany Bay.*) Used to cement coarse earthenware. Yellow gum and brick dust, equal parts, melted together. The liquid is spread thin over the parts, a thin gauze interposed, the whole pressed together, and confined so until the next day.

EGG.—(See *China.*)

ELECTRICAL MACHINE. — 1. Black resin, 7 lbs.; red ochre, 1 lb.; plaster Paris, ½ lb.; both dried and warm; melt together until frothing ceases, and the liquid runs smooth; withdraw from the fire, and stir until cooled sufficiently. — 2. Melt together 5 lbs. resin and 1 lb. beeswax; stir in 1 lb. red ochre, dried and warm, and 4 oz. plaster Paris, continuing the heat a little above 212°, and stir till frothing ceases. — 3. (See *Acid Proof*, 2.)

ELASTIC.—Used for cementing leather, cloth, etc. 1. Caoutchouc, in small pieces, 1 part; chloroform, 3 parts; dissolve. — 2. Caoutchouc, 5 parts; chloroform, 3 parts; dissolve, and add powdered gum mastic, 1 part. Elastic and transparent. — 3. Gutta-percha, 3 parts; caoutchouc, 1 part; both cut small; bisulphide of carbon, 8 parts; mix in a close vessel, and dissolve by the heat of a water bath. Gently warm before applied. — 4. Gutta-percha, 1 lb.; caoutchouc, 4 oz.; pitch, 2 oz.; shellac, 1 oz.; linseed oil, 2 oz.; melt together. Melt before being applied. — 5. Used for cementing leather and india-rubber. Bisulphide of carbon, 4 oz.; fine india-rubber, in shreds, 1 oz.; isinglass, 2 dr.; gutta-percha, ½ oz.; dissolve. The parts must be coated thinly, and allowed a few minutes to dry; then heat to melting; place the parts together, and hammer the air bubbles out.

EMERY, To Wood. — Melt together equal parts shellac, white resin, and carbolic acid in crystals; add the last after the others are melted. The effect of the carbolic acid is surprising.

ENGINEERS'. — Used by engineers to make metallic joints; also, for joining broken stones. A washer of hemp, yarn or canvas, smeared with cement, is placed in the joint, which is then screwed up tight. It dries hard as stone. 1. Ground white lead, mixed with as much red lead as will make it the consistence of putty. — 2. Equal weights red and white leads, mixed with boiled linseed oil to a proper consistence.

ENTOMOLOGISTS'.— Used by entomologists in rejoining the dislocated parts of insects. To a solution gum ammoniac in proof spirit, add best isinglass, and unite with gentle heat. The value of this consists in the readiness with which it melts, and the little tendency it has to be affected by moisture.

FIRE-PROOF.—1. To 4 or 5 parts clay, dried and pulverized, add 2 parts fine iron filings free from oxide, 1 part peroxide manganese, 1 part common salt, and ½ part borax. Mix thoroughly; render as fine as possible; then reduce to a thick paste with the necessary quantity of water, mixing well; use immediately, and apply heat, gradually increasing almost to a white heat. — 3. Pulverized litharge, 5 lbs.; fine Paris white, 2 lbs.; yellow ochre, 4 oz.; hemp, cut into shreds, ½ oz. Mix to the density of thick putty with boiled linseed oil, and it is ready for use. — 4. Used for making joints, fitting tups, connecting pipes, and filling cracks in retorts. Is said to be of great service in the manufacture of nitric and sulphuric acids, and other products, because it can be easily made and applied, hardening rapidly, and preventing the escape of acid vapors. It consists of asbestos powder made into a thick paste with the liquid silicate of soda.

FRENCH. — Used by naturalists in mounting specimens; by artificial-flower makers, and by confectioners to stick ornaments, wafers, etc., on cakes. Mix thick mucilage of gum Arabic with powdered starch; a little lemon juice is sometimes added.

GASFITTERS'.—Mix together, resin, 4½ parts; wax, 1 part; Venetian red, 3 parts.

GAS RETORT. — Finely powdered barytes and a soluble water glass; or the barytes and a solution of borax. The joints are to be coated several times with this cement, by means of a brush. The addition of ⅔ part clay improves the cement, and the retorts will then stand a red heat very well. Instead of the water glass, a solution of borax may be used, or even finely powdered white glass.

GLASS.—1. Pulverized glass, 10 parts; powdered fluor spar, 20 parts; soluble silicate of soda, 60 parts. Both glass and fluor spar must be in the finest possible condition, which is best done by shaking each in fine powder with water, allowing the coarse particles to deposit, and then pour off the remainder, which holds the fine particles in suspension. The mixture must be made by quick stirring, and when thoroughly mixed, must be at once applied. — 2. Dissolve 1 part india-rubber in chloroform, and add 16 parts by measure of gum mastic in powder; digest for 2 days, shaking the bottle frequently; apply with a fine camel's hair brush. — 3. Used for mending broken china. Red lead, 3 parts; fine white sand, 2 parts; crystallized boracic acid, 3 parts; mixed and fused; it is levigated and applied with thin mucilage of tragacanth. The repaired article must be gently heated, so as partially to fuse the cement. — 4. Take a thick mucilage of gum Arabic, and stir into it plaster Paris (the broken images are best) made very fine, to form a paste, and apply to the edges with a brush; press firmly together, and confine there 2 or 3 days. — 5. Used for repairing valuable objects in glass. A strong solution of gelatine, to which has been added for every 5 parts gelatine, 1 of a solution acid chromate of lime. The mixture becomes insoluble in water under the action of light, in consequence of the partial reduction of the chromic acid. With a fresh preparation of the solution, cover the surfaces to be united as evenly as possible; press them together, and tie them. Expose the glass to the sun for a few hours. Boiling water has no effect

on the oxidized cement, and the fracture can scarcely be recognized. — 6. Used to stop cracks in glass vessels to resist moisture and heat. Dissolve cascine in cold saturated solution borax; with this solution paste strips hog's or bullock's bladder (softened in water) on the cracks of glass; dry at gentle heat; if the vessel is to be heated, coat the bladder on the outside, before quite dry, with a paste of a concentrated solution of silicate of soda and quicklime, or plaster Paris.

GLYCERINE.—Used to mend coarse earthenware, stop leaks in tin, tighten joints of wood and iron, etc. Mix together litharge and glycerine to the consistency of fresh putty. The articles should not be used until the cement is hardened, requiring from 1 day to a week. This resists the action of water, hot or cold, and acids.

GRINDERS'.—Used to fix pieces of glass while grinding and for lenses. 1. Pitch, 5 parts; wood ashes and hard tallow, of each 1 part; melt together. — 2. Black resin, 4 lbs.; beeswax, 1 lb.; melt, and add of whiting (previously heated red hot and still warm), 1 lb. — 3. Shellac, melted and applied to the pieces slightly heated.

GUTTA-PERCHA.—Used for cementing metal, glass, porcelain, ivory, etc., and as putty in glazing. Melt together, in an iron pan, 2 parts common pitch and 1 part gutta-percha; stir well together until incorporated; then pour into cold water. When cold it is black, solid, and elastic; but it softens with heat, and may be used as a soft paste, or in the liquid state. It does not crack.

HENSLER'S.—Used for china, glass, etc. Litharge, 3 parts; quicklime, 2 parts; white bole, 1 part (all in fine powder); linseed-oil varnish, q. s. to make a paste. It is very tenacious, but long in drying.

INDIANITE.—Used for uniting pieces of india-rubber. 1. 100 parts finely chopped rubber, 15 parts resin, 10 parts shellac, dissolved in sufficient bisulphide carbon. — 2. India-rubber, 15 grs.; chloroform, 2 oz.; mastic, ½ oz. The 2 first-named to be mixed, and, after the rubber is dissolved, add the mastic in powder; macerate for a week.

IRON.—1. Used for cast-iron ware. 5 parts fire clay and 1 part fine iron filings, mixed into a paste with linseed oil. When hard, it resists heat, but does not close cracks in a stove unless these are held by means of a plate and rivets, as the expansion caused by red heat causes the cement to crack. — 2. Clean borings or turnings of cast iron, 16 parts; sal ammoniac, 2 parts; flour of sulphur, 1 part; mix together in a mortar, and keep dry. When required for use, take of the mixture 1 part; clean borings, 20 parts; mix thoroughly, and add sufficient water. A little grindstone dust added, improves the cement. — 3. Common salt and sifted wood ashes, equal parts; make into a paste with water; this may be applied hot or cold. — 4. Used for repairing damaged places in cast-iron tanks, cisterns, etc. 5 parts brimstone; 2 parts black lead; and 2 parts cast-iron filings (previously sifted), are melted together, taking care that the brimstone does not catch fire. The damaged place is well heated by placing a piece of red hot iron upon it, and it is then stopped with the cement, previously heated in a ladle. — 5. Used for luting. Take 16 parts steel filings; 3 parts sal ammoniac, and 2 parts flowers of sulphur. This mixture can be preserved any length of time in dry packages. In order to lute with it, add to 1 part of the mixture 12 parts iron filings, and enough water, previously acidulated with sulphuric acid, to form a paste. This is now ready to be applied to the surfaces of the metal. For fine castings and small holes, the pulverized iron can be substituted for iron filings. — 6. Used for iron joints. 4 parts fine borings or filings of iron; 2 parts potter's clay; 1 part pounded potsherds; make into a paste with salt and water. When this cement is allowed to concrete, it becomes very hard. — 7. (See *Fire-proof.*)

IVORY.—Dissolve 1 part of isinglass and 2 of white glue in 30 of water; strain and evaporate to 6 parts; add 1-30 part of gum mastic, dissolved in ½ part alcohol and 1 part white zinc. When required for use, warm and shake it. Used also for mother of pearl.

JAPANESE.—This elegant cement is made by mixing rice flour intimately with cold water, and then gently boiling it. It is white and transparent. Papers pasted by this cement will not separate at the joining, which makes it useful in the preparation of curious paper articles, as tea-trays, ladies' dressing boxes, etc., which require layers of papers to be cemented. It is preferable to common paste. It answers well for pasting into books the copies of writings taken by copying machines on unsized silver paper. With this composition, made with a small quantity of water, that it may have a consistency similar to plastic clay, models, busts, statues, bas-reliefs, etc., may be formed. When dry, the articles made of it are susceptible of a high polish, and are durable.

JET.—Shellac is the only cement used by jewellers for jet articles. The edges should be warm before applying the cement. Should the joint be in sight, by smoking the shellac before applying, it will be rendered the same color as the jet.

JEWELLERS'.—1. Dissolve 5 or 6 pieces gum mastic, the size of a large pea, in just as much methylated spirit as will render it liquid. Soften isinglass, by steeping in water; having dried it, dissolve as much in good brandy as will make a 2 oz. vial of strong glue, to which add 2 small bits of gum ammoniacum, rubbing until dissolved. Mix the two solutions; keep in a close vial; and when used, set the vial in boiling water. — 2. Put in a bottle 2 oz. isinglass and 1 oz. best gum Arabic; cover with proof spirits; cork loosely, and place the bottle in a vessel of water, and boil it till a thorough solution is effected; then strain it for use.

LAMP. — The cement, commonly used for fastening the tops on kerosene lamps, is plaster Paris, mixed with alum water to the consistency of paste; this is porous and quickly penetrated by the kerosene. A cement which has not this defect is made with 3 parts resin, 1 part caustic soda, and 5 parts water. This is mixed with ½ its weight plaster Paris. It sets firmly in about ¾ hour, and is said to have great adhesive pow-

er, not to be permeable to kerosene, a low conductor of heat, and but superficially attacked by water. Zinc white, white lead, or precipitated chalk, may be used instead of the plaster, but when they are used the cement will be longer in hardening.

LEATHER. — 1. Common glue and isinglass, equal parts; soak 10 hours in enough water to cover. Bring gradually to boiling heat, and add pure tannin until the whole appears like white of an egg. Buff the surfaces to be joined. Apply this cement warm, and clamp firmly. — 2. Used by shoemakers for invisible patching. To 10 parts bisulphide carbon and 1 part spirits turpentine, add enough gutta-percha to make a tough, thickly flowing liquid. The surfaces to be joined must be freed from grease, by laying a cloth upon them, and applying a hot iron for a time. The coat is applied to both surfaces, and pressure made till the joints are dry. — 3. Used for earthenware, china, glass, or leather; for harness, belts for machinery, and cloth belts for cracker machines for bakers. Ale, 1 pt.; best Russia isinglass, 2 oz.; put into a glue kettle, and boil until the isinglass is dissolved; then add 4 oz. best common glue and dissolve it with the other; slowly add $1\frac{1}{2}$ oz. boiled linseed oil, stirring while adding, till mixed. When cold, it appears like india-rubber. To use, dissolve what you need in a suitable quantity of ale to the consistence of thick glue. If for leather, shave off as if for sewing, apply with a brush while hot, laying a weight to keep the joint firmly pressed for 6 to 10 hours, or over night. — 4. A mixture of india-rubber and shellac varnish; or a strong solution of common isinglass, with a little diluted alcohol added to it, makes a very adhesive cement. — 5. Gutta-percha, 1 lb.; india-rubber, 4 oz.; pitch, 2 oz.; shellac, 1 oz.; oil, 2 oz.; melt, and use hot. — 6. Used for invisible patching on shoes. Put 2 oz. sulphuret carbon and $\frac{1}{2}$ oz. gutta-percha into a wide-mouthed bottle. Shake occasionally till the latter is dissolved. Dust the shoes with finely powdered rosin; shave the edges of the patch thin and roughen them; apply the cement, and press with a warm iron.

LEATHER, To Gutta-Percha.—Used for uniting sheet gutta-percha to leather, such as soles of shoes, etc. Gutta-percha, 50 lbs.; Venice turpentine, 40 lbs.; shellac, 4 lbs.; caoutchouc, 1 lb.; liquid storax, 5 lbs. The Venice turpentine should be first heated; then the gutta-percha and shellac added; the order in which the other materials is added is not important; incorporate thoroughly and do not burn the mixture.

LEATHER, To Metal.—1. Steep the leather in an infusion of hot nut-galls; wash the metal with hot gelatine, and press the leather firmly on the surface. — 2. Take 56 lbs. good common glue; melt, and add $3\frac{1}{2}$ lbs. gum ammoniac; stir well, till reduced to an even mass; remove from the fire, and pour in gradually $3\frac{1}{2}$ lbs. nitric acid, and incorporate with the rest. This has been proved to be the best among metal binders, because not susceptible to the action of oil. Gelatine dissolved in acetic acid, forms a cement that will fasten leather to metal, and that will not be affected by bisulphide of carbon.

LUTES. — Used to make tight joints without really effecting a tenacious union between the parts. — 1. Linseed meal, either alone or mixed with an equal weight of whiting, and made into a stiff paste with water. It soon becomes hard and tough. — 2. Ground almond cake, from which the oil has been pressed, mixed as the preceding. It is capable of resisting the action of the fumes of volatile oils, spirits, weak acids, etc., for some time. This, and the preceding, are much used for stills, retorts, and other vessels, that are not exposed to a heat higher than 320° F. — 3. Used as a coating for glass vessels, to preserve them from injury from exposure to the fire. Pipe clay and horse dung, made into paste with water. This composition is used by the pipe makers, and will stand unharmed the extremest heat of the kiln for 24 hours. Applied by spreading on paper. — 4. Dissolve 1 part india-rubber in 2 parts linseed oil, by heat, and work into a stiff paste with 3 parts, or as much as is sufficient, of stiff clay. — 5. Powdered clay or whiting, made into putty with water and boiled linseed oil. Commonly known as "fat lute." — 6. Used for joining crucibles which are to be exposed to a strong heat. A mixture of powdered clay and ground bricks, made up with water, or a solution of borax.

MAHOGANY.—1. Used to fill cracks and holes in furniture. Melt 4 oz. beeswax, and add 1 oz. red lead, and enough yellow ochre to produce tint required. — 2. Shellac, melted and colored as above. Red putty is also used.

MAISSIAT'S.—Used as a waterproof and air-tight covering for corks, bungs, etc. India-rubber, melted with about 15 per cent. of either beeswax or tallow; quicklime, in powder, is gradually added; and the heat continued until change of odor shows that combination has taken place, and until a proper consistence is obtained.

MARBLE. — 1. (*Keene's*). Admirable for internal decorations, and from its extreme hardness is durable. Baked gypsum, or plaster Paris, steeped in a saturated solution of alum, and then recalcined, and reduced to powder. For use it is mixed up with water, as plaster Paris. It may be colored or tinted of any shade, by diffusing mineral colors (levigated, if in powder) through the water which is used to mix the cement. A pleasing tint is given to this cement by adding a little solution of green copperas to the alum liquor. — 2. Water, 1 gal.; glue, 3 lbs.; white lead, 4 oz.; alcohol, 1 qt.; mix. If cold weather, warm the bottle until the cement is dissolved; then rub on the broken parts; put together, and retain in place until dry. — 3. Gum Arabic, 1 lb.; make into thick mucilage; add to it powdered plaster Paris, $1\frac{1}{2}$ lbs.; sifted quicklime, 5 oz.; mix; heat the marble and apply the mixture. — 4. Melt together 8 parts resin, and 1 part wax; when melted, stir in 4 or 5 parts plaster Paris. The pieces to be joined should be made hot. — 5. Procure a small piece quicklime fresh from a newly burnt kiln; slake with white of an egg; wash the fractured parts clean, and apply. — 6. Used for mending marble or stone. Mix 20 parts litharge and 1 part freshly burned lime in dry powder. This is made into a putty

with linseed oil. It sets in a few hours, and appears like light stone.

METAL, To Fibrous Material.—An amalgam composed of good glue dissolved in hot vinegar, with $\frac{1}{3}$ its volume of white pine pitch, also hot. This composition, it is said, will give a sure and certain result with any metal. — 2. Used for brass and wood. Best gelatine, 1 part; glacial acetic acid, 1 part; soak the gelatine in cold water, until it has swollen up and become soft; throw away the water, and dissolve the gelatine in the acetic acid, applying gentle heat if necessary. — 3. Melt rosin, and stir in calcined plaster until reduced to a paste, to which add boiled oil until of the consistency of honey; apply warm. — 4. Melt rosin, 180 parts; stir in burnt umber, 30 parts; calcined plaster, 15 parts; and boiled oil, 8 parts. — 5. Mix thoroughly together 4 parts carpenter's glue and 1 part Venice turpentine.

METAL, To Glass.—1. Take 1 lb. shellac, dissolved in 1 pt. strong methylated spirit, to which is to be added .05 part of solution of india-rubber in carbon bisulphide. — 2. A mixture of 2 parts finely ground litharge and 1 part white lead; work to a paste with 3 parts boiled oil and 1 part copal varnish; add more litharge and white lead as required. — 3. 4 oz. thick solution glue; 2 oz. linseed oil varnish; 1 oz. turpentine; mix, and boil together in a close vessel. The metal and glass to be joined should be clamped for 48 hours, after being cemented. — 4. Copal varnish, 15 parts; drying oil, 5 parts; turpentine, 3 parts; melt in a water bath, and add 10 parts slaked lime.

METALLIC.—An alloy of copper, prepared as follows, is capable of attaching itself firmly to the surfaces of metal, glass and porcelain. From 20 to 30 parts finely divided copper (obtained by the reduction of oxide of copper with hydrogen, or by precipitation from solution of its sulphate with zinc) are made into a paste with oil vitriol; 70 parts mercury are then added, and the whole well triturated; when the amalgamation is complete, the acid is removed by washing with boiling water, and the compound is allowed to cool. In 10 or 12 hours it becomes sufficiently hard to receive a polish, and scratch tin or gold.

MICA.—Used for joining sheets of mica. Clear gelatine, softened by soaking it in a little cold water, and the excess of water pressed out by gently squeezing it in a cloth; then heated over a water bath until it begins to melt, and just enough hot proof spirit stirred in to make it fluid. To each pt. of this solution gradually add, while stirring, $\frac{1}{2}$ oz. sal ammoniac and $1\frac{1}{2}$ oz. gum mastic, previously dissolved in 4 oz. rectified spirit. It must be warmed to liquefy it for use, and kept in stoppered bottles when not required. This cement, when properly prepared, resists cold water and is colorless.

MICROSCOPIC.—Used for mounting opaque objects for the microscope. Put into a bottle 2 parts isinglass and 1 part gum Arabic; cover with proof spirit; cork the bottle loosely; place in water, and boil it till a solution is effected; strain for use.

MILK. — 1. Snugly tie together the different parts to be united, and lay in the pail while milking. After thoroughly drying, the pieces will be firmly united, and will remain together a long time if not soaked. — 2. Take fresh, warm milk, and turn it into a basin over the fire; into this lay the article to be mended, firmly tied together. Heat until scalding hot; then remove, and dry.

MILLSTONE.—1. Emery of the proper grain mixed with melted borax in slight excess. — 2. For a French burr millstone, a good cement can be made of alum and powdered burrstone; plaster Paris is generally used to cover the stone after making the joints with the cement.

OIL STONE.—Dissolve isinglass in the smallest quantity of proof spirit by the aid of gentle heat (over a water bath). In 2 oz. of this dissolve 10 gr. gum ammoniacum; triturate to effect solution; then add $\frac{1}{2}$ dr. gum mastic dissolved in 3 dr. rectified spirit. Stir well and keep stoppered. Liquefy by gentle heat when required for use. Clean the stone with hot lye, rinse thoroughly, and dry before cementing.

OPTICIAN'S.—1. Shellac softened with rectified spirit or wood naphtha. For fine work. — 2. Beeswax, 1 oz.; resin, 15 oz.; melt and add whiting (previously made red hot and still warm), 4 oz. — 3. Resin, 1 lb.; melt, and add plaster Paris, dry, 4 oz. — 4. Pitch, 5 parts; wood ashes, 1 part; tallow, 1 part, less or more, according to the temperature of the season. — 5. A useful cement for many purposes. It is employed by opticians for uniting the lenses of achromatic objectives. For this purpose it must be pure and colorless. It is bleached by exposure to sunlight. If too thick, it may be thinned by benzole. In cementing the 2 parts of an achromatic lens together, the surfaces should be well cleaned, and the glasses, previously warmed, laid on some surface that will not scratch them. By means of a rod of glass or metal, place a drop of balsam on the centre of one lens, and gently lower the other down upon it. Now apply a slight pressure, and the dark disc in the centre, indicative of optical contact, will rapidly increase in size, until the balsam reaches the margin and begins to ooze out. By means of a piece of soft string, if the lenses are large, or a spring clip, if they are small, the lenses should be held firmly together, and exposed to a gentle heat in an oven that is cooling, or before a fire, until the balsam at the edges has become hard and dry. The string or clip may then be removed, and all traces of balsam, first by scraping, and afterwards with a little benzole or ether. The above directions, modified to suit circumstances, apply to the cementing of glasses for transparencies or opal pictures; also to the varnishing of magic lantern slides, and the protection of any transparent surfaces from the air.

PARIS, or SEA SHELL.—Used for mending shells and other specimens of natural history. 1. It is composed of gum Arabic, 5 parts; sugar candy, 2 parts; and white lead enough to color. — 2. A bit of isinglass boiled in spirits of wine.

PEASLEY.—Prepare a solution of 200 parts white glue in water; another, of 50 parts isinglass, 3 parts gum Arabic, and 3 parts tragacanth; and

finally, another of 1 part shellac in alcohol. Then pour these 3 solutions together; mix them with 24 parts white lead, and add 12 parts best glycerine, and 200 parts alcohol. The mastic obtained should be immediately put up in bottles, and well corked.

PLUMBERS'.—Used to fix the pieces of metal while cutting, and also to secure seals and tools in their handles. Black resin melted with about an equal weight of brick dust. Sometimes a little pitch or tallow is added. It grows harder and improves every time it is melted.

PORCELAIN.—1. 2 parts isinglass are soaked in water until swollen; the water is then poured off, and the isinglass is dissolved in alcohol by heat. 1 part mastic is then dissolved in 3 parts alcohol, and added to the above solution; then 1 part gum ammoniacum. The solution is well shaken, and evaporated to the consistency of strong glue, when it solidifies on cooling. For use, the cement and the articles themselves must be warmed. — 2. Used to unite glass, metal, porcelain, etc., quite firmly. Add plaster Paris to a strong solution alum, till of the consistency of cream. It is probably suited for large rather than small surfaces.

RUBBER.—1. Pieces of india-rubber may be united by means of the pasty mass obtained by acting upon pure rubber by its appropriate solvents. These are sulphuric ether, coal-tar, naphtha, bisulphide of carbon, caoutchoucin, and oil of turpentine. As it is difficult to dissolve rubber on the small scale, and, as the cement may be bought ready made, it is hardly worth while to enlarge upon its preparation. Those who wish to try it, will probably succeed best by cutting pure rubber (not that which has been vulcanized) into thin slices, boiling it in water so as to soften and expand it, and then digesting it in hot coal tar, naphtha, or oil of turpentine. Several days are required to effect the solution. When used for uniting rubber, the surfaces to be joined must be fresh; the surfaces should be either pared with a knife or rasped with a file. They may then be coated with the cement, pressed firmly together, and exposed to a gentle heat for a few days. — 2. For mending india-rubber shoes, boots, and apparatus, when the regular rubber cement cannot be obtained, the following directions are given: Cut 2 lbs. caoutchouc into thin, small slices; put them in a vessel of tinned sheet iron, and pour over 12 to 14 lbs. sulphide carbon. For the promotion of solution, place the vessel in another containing water, previously heated to about 86° Fahr. The solution will take place, but the fluid will thicken soon, and thus render the application difficult. To prevent this thickening, a solution of caoutchouc and resin in spirits of turpentine must be added to the solution of caoutchouc in sulphide of carbon, and in such quantity that the mixture obtains the consistency of a thin paste. The solution of caoutchouc and resin in spirit of turpentine should be prepared as follows: Cut 1 lb. caoutchouc into thin, small slices; heat over a moderate coal fire until the caoutchouc becomes fluid; then add ½ lb. powdered resin, and melt both materials at a moderate heat; when these materials are fluid, gradually add 3 or 4 lbs. spirit turpentine in small portions, and stir well; by the addition of the last solution rapid hardening will be prevented, and a mixture obtained which fully answers the purpose of gluing rubber surfaces, etc. — 3. Used for uniting leather or rubber that has not been vulcanized. 16 parts gutta-percha; 4 parts india-rubber; 2 parts common caulker's pitch; 1 part linseed oil; melt together, and use hot.

RUBBER, To Wood, Metal or Glass.—Used to fasten gum covering on iron rollers. Melt together over a gentle fire equal parts black pitch and gutta-percha. If this is required to set very hard, 1 part powdered shellac may be added. The addition of 1-10 part caoutchoue clippings makes it more adhesive, but prevents, in a measure, its final hardening. This cement should be used hot.

SAFETY ENVELOPE. — To be used in 2 portions, neither being of any value till moistened and joined to the other. One portion is composed of a preparation of chromium, and is made by dissolving crystallized chromic acid in water, in the proportion of 2.5 grams of acid to 15 grams of water; 15 grams of ammonia are added to this, and then about 10 drops sulphuric acid are added, with finally 30 grains sulphate of ammonia and 4 grams white paper. The 2d preparation is made by dissolving isinglass in dilute acetic acid (1 part acid to 7 parts water). This cement is designed chiefly for envelopes, and in using it the chromium preparation is applied to the back of the envelope, and the isinglass to the flap. On wetting the flap and pressing it down, the two preparations meet and form a firm and insoluble cement, binding the paper against every effort to open it. The materials may be applied in the same manner to other uses.

SAND SLAG.—A good hydraulic cement from blast furnace slag is made by selecting such portions of it as are readily dissolved in dilute hydrochloric acid. On subjecting it to the action of the acid, silica is thrown down, which is afterward to be washed, dried, and pulverized; 1 part of this is to be mixed with 9 parts powdered slag and the necessary quantity slacked lime. This matter soon hardens, and rivals Portland cement in its durability.

SEAL ENGRAVERS'.—Common brick dust and resin melted together in an earthen pipkin; with this the handles of loose knives and forks may also be fastened.

SECTIONS OF CAST-IRON WHEELS.—Used for fastening stone to stone, or iron to iron. Make a paste of pure oxide lead, litharge, and concentrated glycerine.

STEAM BOILER.—Used to stop cracks and leaks in iron boilers, stoves, etc. 1. Dried clay, in powder, 6 lbs.; iron filings, 1 lb. Make into a paste with boiled linseed oil. — 2. Powdered litharge, 2 parts; very fine sand, 2 parts; slaked quicklime, 1 part. Mix all together. To use, mix the proper quantity with boiled linseed oil, and apply quick. It gets hard very soon. — 3. This cement offers great impermeability and strength. It is prepared by an intimate mixture of 6 parts graphite finely ground; 3 parts slaked lime; 8 parts sulphate baryta, and 7 parts linseed oil varnish.

STEAM-PIPE JOINTS.—1. Sal ammoniac, 2 oz.; sublimed sulphur, 1 oz.; fine cast-iron turnings, 1 lb.; mix in a mortar, and keep dry; when to be used, mix with 20 times its quantity of clean iron filings, and triturate the whole in a mortar; then wet with water until of proper consistence. — 2. Used for iron steam pipes. 2 parts litharge; 1 part dry slaked lime, and 1 part fine dry sand. Combine thoroughly, and add sufficient hot linseed oil varnish to form a paste. It sets hard quickly, and must be freshly prepared every time it is required. Apply only when the cement is hot. — 3. Good linseed oil varnish ground with equal weights white lead, oxide of manganese and pipe clay. — 4. White lead, ground in oil, 10 parts; black oxide of manganese, 3 parts; litharge, 1 part. Reduce to the proper consistency with boiled linseed oil, and apply. — 5. Mix finely ground soapstone with a little plumbago and mica in it, into a paste, with an equal weight plaster Paris, and the proper quantity of water, and cast in flat bricks or in semi-cylindrical, well-oiled molds, to fit the pipes, etc.

SULPHUR.—Roll sulphur is frequently used alone as a cement for fastening iron bars in holes drilled in stone. The addition of brick dust, sand or resin, lessens its liability to crack. When the yellow color of brimstone is an objection, a little plumbago may be mixed with it.

TURNERS'.—1. Melt 1 lb. resin in a pan over the fire; when melted add ½ lb. pitch; when these are boiling add brick dust until, by dropping a little on a cold stone, it is hard enough. In winter it may be necessary to add a little tallow. By means of this cement a piece of wood may be fastened to the chuck, which will hold when cool, and when the work is finished it may be removed by a smart stroke with the tool. Any traces of the cement may be removed from the work by means of benzine. — 2. 16 parts whiting are finely powdered and heated to redness; when cold, this is mixed with 16 parts black resin and 1 part beeswax, the latter having been previously melted together, and the whole stirred till of uniform consistence.

UNIVERSAL. — 1. Used for cementing wood, iron, leather, glass, paper, and almost all kinds of household materials. Best isinglass, ½ oz.; rub it between the hands until it breaks into a powder; put in a bottle, and put as much common acetic acid to it as will wet the mass through; stand the bottle in some boiling water, and the paste will dissolve and be fit to use at once; it will be solid when cold, but is easily warmed up the same as before. Leave the cork out when warming, or there is danger of bursting the bottle. — 2. Used for repairing fractured bodies of all kinds. White lead ground upon a slab with linseed oil varnish, and kept from contact with air. It requires a few weeks to harden. — 3. When stone or iron are to be cemented together, a compound of equal parts sulphur with pitch answers very well.

VARLEY'S.—Black resin, 16 parts; beeswax, 1 part; melt; add whiting (sifted, dried by a a dull red heat, and allowed to cool), 16 parts; and stir until cold.

WATERGLASS. or SILICATE OF SODA. —Also called "soluble glass," and when mixed with the following forms a good cement for mending ornaments and vessels of zinc, sticking alike well to metals, stone and wood. — 1. Finely pulverized or levigated stibnite (gray antimony, or black sulphide of antimony) will produce a dark cement, which, after burnishing with an agate, will present a metallic appearance. — 2. Pulverized cast iron; a gray cement.—3. Zinc dust (so-called zinc gray). An exceedingly hard, gray cement, which, after burnishing, will exhibit the white and brilliant appearance of metallic zinc. —4. Used for glass, earthenware, and porcelain. Rub together 1 part fine pulverized glass, and 2 parts pulverized fluorspar, and add enough waterglass solution to give it consistency. — 5. Used for edges and joints of stone and marble slabs. Waterglass mixed with hydraulic cement to a thick dough. It is well to mix but a little at a time, as it hardens very quickly.

WATERPROOF, or HYDRAULIC. — 1. Shellac, 4 oz.; borax, 1 oz.; boil in a little water until dissolved, and heat to a paste. — 2. 10 parts carbon disulphide and 1 part oil turpentine are mixed, and as much gutta-percha added as will readily dissolve. — 3. Melt together equal parts pitch and gutta percha; apply warm, and press the parts firmly together until cold. — 4. Used for glass, porcelain, etc. Simple shellac, made up into sticks, is commonly sold for such cement. The articles to be cemented are warmed sufficiently to melt the shellac brought into contact with them. It is not adapted for flexible objects, as it cracks, and will not withstand heat or alcohol. — 5. Take alcohol, 1 pt.; sandarac, 1 oz.; mastic, 1 oz.; common white turpentine, 1 oz.; glue, isinglass, and water sufficient. Dissolve the sandarac and mastic in the spirit, then add the turpentine to the solution. Make some strong glue, and add to it a good pinch of isinglass. Heat the alcoholic varnish until the liquid begins to boil; then stir in the warm glue; the amount of liquid glue to be added is determined by noting the point at which, after thorough mixture, a magma or thin paste is formed capable of being strained through a cloth. When required for use, the strained mixture is to be warmed and applied like glue. A junction is effected which is not destroyed by cold water, and only after a time by hot water or ordinary saline solutions. — 6. 2 gills litharge; 2 gills plaster Paris; 2 gills fine, dry white sand; ⅔ gill finely powdered rosin; sift, and keep them for use, when they should be made into putty by mixing them with boiled linseed oil, to which a little dryer has been added. Use within 12 hours after being mixed.

WHITE.—Beeswax, 1 oz.; resin 4 oz.; powdered plaster Paris, 5 oz.; melt together; to use, warm the edges, and use the cement warm.

WOOD, To Metal, Glass, etc. — Dissolve isinglass in acetic acid, in such quantites that it becomes solid when cold. When applied let it be heated. It resists moisture well.

ZEIODELITE. — Used for uniting stones or bricks and for cementing iron rods into holes cut in stone. 19 parts sulphur and 42 parts powdered glass or earthenware, mixed together by heating the sulphur.

ZINC.—(*Sorel's.*) The following composition

forms an excellent material for molding or for uniting stone, etc. Mix commercial zinc white with ½ its bulk fine sand, adding a solution chloride of zinc of 1.26 specific gravity, and rub the whole together in a mortar. The mixture must be applied at once, as it hardens quickly.

GLUES.

REMARKS.—Common glue is generally prepared from waste pieces of hides and skins, the refuse of tanneries and offal of slaughter houses. They should be kept dry to prevent decomposition. Before conversion into glue they are steeped in weak milk of lime, well worked in water, and exposed to air for 24 hours; then placed in a copper boiler, ⅔ filled with water, and furnished with a perforated false bottom to prevent burning, and as much is piled on as will fill the vessel. Heat is applied, and gentle boiling continued until the liquor, on cooling, becomes a gelatinous mass. The clear portion is then run off into another vessel, kept hot by a water bath, and allowed to repose some hours to deposit, when it is run into the congealing boxes and placed in a cool situation. The next morning the gelatinous mass is turned out upon boards wetted with water, and cut horizontally into thin cakes with a stretched piece of brass wire, and into smaller cakes with a moistened flat knife. These cakes are placed upon nettings to dry, after which they are dipped one by one in hot water, and slightly rubbed with a brush wetted with boiling water, to give them a gloss; they are lastly stove dried for sale. The undissolved skins left in the copper are treated with water, and the operation repeated again and again. The first runnings produce the best glue. Refuse matter from the tanners and leather dressers yields, on an average, when dried, 50 per cent. of its weight in glue. To bleach common glue, soak in moderately strong acetic acid for 2 days; drain, place on a sieve, and wash well with cold water; dry on a warm plate.

BANK-NOTE.—(See *East Indian, or Portable.*)
