BOTANICAL.—1. Used for mounting ferns, and made as follows: 5 parts gum Arabic; 3 parts white sugar; 2 parts starch; add very little water, and boil, stirring until thick and white. — 2. For moss work: Clarified glue, dissolved in water to the thickness of molasses; add a thickening of flour and water while the glue is boiling, until about as thick as clear starch; use hot. Put on the moss and the surface to which it is to be applied. The moss and lichen on old board fences or old shingled roofs is better, because it has a more even surface than that from walls and rocks. Peel it from the wood and remove all the bark, dirt and dust. The thinner it is, the better it will adhere. It works better damp, and if gathered before being used, should be kept in a cellar, and sprinkled occasionally.

DRAIPER'S.—3 parts glue in small pieces; cover with 8 parts water; let stand for several hours; then add ⅔ part hydrochloric acid and 1 part sulphate zinc, and expose the whole to a temperature of 178° to 192° Fahr., during 10 or 12 hours. The compound does not gelatinize; it only needs to be allowed to settle. A most useful agent for joining purposes.

EAST INDIAN, or PORTABLE. — Useful for many purposes, such as repairing book-binding, leather goods, bank bills, parchments, etc. For use, hold it over steam a moment, or wet it with the tongue and rub on the surfaces to be cemented. It is strong, and is prepared as follows: 2 lbs. white shell glue; boil and strain until clear; then boil 8 oz. Cooper's isinglass to a creamy consistency; mix the 2 substances while hot in a clean double glue pot; add 1 lb. good brown sugar to the mass, and boil, stirring until thick; pour off into shallow pans; when nearly cold, cut in pieces for the desk or pocket.

FIRE-PROOF.—Take the best glue; pour on an equal quantity of water; soak over night; melt it over a gentle heat, and add fine Paris white, or white lead; mix well, and add a little acetic acid, carbolic acid, or any ethereal oil, to prevent putrefaction. This cement is adapted for flexible objects, like leather. It will not withstand boiling water.

HAT MAKERS'.— This is prepared from the tendons of cattle. It is brown and soft; grows moist in damp weather, but it does not render felt brittle like other varieties.

LABELING ON METAL.—1. Take good yellow glue, break it into small pieces, and soak a few hours in cold water; pour off the supernatant water; place the glue in a wide-mouthed bottle; add sufficient glacial acetic acid to cover the glue, and facilitate solution by standing the bottle in warm water. This glue will stick anything. — 2. Add a little chloride of calcium to glue; this will prevent cracking and make it adhere to metal, glass, etc.

LIQUID.—1. The addition of a little nitric acid will prevent the glue from becoming solid. It is supposed that this is substantially the formula for making the well-known Spalding's glue, but this is doubtful. The addition of this substance injures the glue, however, as it is eventually decomposed.—2. 1 part refined glue broken, to 4 or 5 parts saccharate of lime; on warming the glue dissolves, and remains liquid when cold. It can be varied to make any thickness desired. The saccharate of lime is prepared by taking 1 part crushed sugar and dissolving in 3 parts water; adding to the sugar ¼ its weight slacked lime, and heating to 145° or 165°, and allowing it to macerate several days, with frequent shaking; then let it settle, and pour off the clear liquid for use. This is equal to the prepared glue sold for scrap book use. — 3. Best white glue, 16 oz.; white lead, dry, 4 oz.; rain-water, 2 pts.; alcohol, 4 oz. With constant stirring, dissolve the glue and lead in the water by means of a water bath. Add the alcohol, and continue the heat for a few minutes. Lastly, pour into bottles while hot. — 4. A bottle ⅔ full common glue; fill up with common whisky; cork, and set by for 3 or 4 days. — 5. Dissolve 1

lb. best glue in 1½ pts. water, and add 1 pt. vinegar. It is ready for use any time without warming.

MARINE.—This is probably the strongest cement known; when well made and properly applied, it will unite wood, metal, glass, leather, etc., with a strength that is astonishing. 1. Dissolve 3 parts shellac and 1 part india-rubber, in separate vessels, in ether free from alcohol, applying a gentle heat; when dissolved, mix the two solutions. Use rectified sulphuric ether and unvulcanized india-rubber. When the india-rubber has become softened, break into small pieces, and stir until a soft mass is obtained. It is well to cut the rubber into small pieces before pouring the ether on, but the mass must be frequently stirred. Pour the solution of shellac into the rubber, and incorporate by stirring. This is a modification of the famous marine glue, and resists water, both hot and cold, and most acids and alkalies. If thinned by admixture of ether, and applied as a varnish to leather, along the seams, it renders them water-tight and almost impossible to separate. — 2. India-rubber, 15 to 20 gr.; chloroform, 2 fl. oz.; dissolve, and add powdered mastic, ½ oz.; keep corked, and in a cool place. — 3. Finely divided india-rubber, 1 part, dissolved in crude naphtha, 40 parts. The solution is complete in 10 or 12 days, if repeatedly agitated. To it is then added gum lac, 2 parts by weight to 1 of solution. The compound is then placed in an iron vessel over the fire, and constantly thinned till homogeneous. It is then poured on a slab to cool, when it is broken up, and put by for use. India-rubber is sometimes omitted, in which case the proportions will be 1 part naphtha and 2 parts lac. For use, the cement is heated to 212° Fahr., in a vessel of copper or cast iron, and is brushed in thin layers on the surfaces to be joined; these are then brought into contact, and strongly pressed. If the surfaces are so wide that the cement becomes cool before the operation is finished, it is well to pass a hot iron, at about 140° Fahr., overit. It is valuable for repairing broken wood, cementing molds used in foundries, caulking ships, joining blocks of marble or granite, and for uniting wood and iron. It can be made as hard as desired by increasing the lac. — 3. Caoutchouc, 1 oz.; genuine asphaltum, 2 oz.; benzole or naphtha, q. s. The caoutchouc is first dissolved by digestion and occasional agitation, and the asphalt gradually added. The solution should have the consistence of molasses.

METAL.—Melt the glue as usual, and to every pt. add 2 spoonfuls, each, of powdered resin and powdered brickdust; incorporate together, and it will hold the metal much faster than plain glue.

MINERAL.—Starch, 2 dr.; white sugar, 1 oz.; gum arabic, 2 dr.; water to dissolve. Dissolve the gum, add the sugar, and boil until the starch is cooked. It is very adhesive, never becomes brittle or scales off from stones or other hard substances. In a geological cabinet it is simply invaluable.

MOUTH, or LIP.—(See *East Indian or Portable.*) 1. Soak 4 oz. best glue and 1 oz. isinglass in water until soft; pour off superfluous water, and add 1 oz. brown sugar; melt together with a gentle heat, until thick; pour into a flat-bottomed dish; if placed on ice, so much the better, as it will prevent the glue sticking to it. When solid cut into cakes.—2. Glue, 5 oz.; sugar, 1 oz.; dissolved in water, boiled down, poured into molds, and dried. — 3. Isinglass and parchment glue, each, 1 oz.; sugar candy and gum tragacanth, each, 2 dr.; add to them 1 oz. water; boil the whole to the consistence of glue; form into small rolls. This glue, wetted with the tongue and rubbed on the edges of paper, silk, etc., will, on their being laid together and suffered to dry, unite them as firmly as any other part of the surface.

PARCHMENT. — Parchment shavings, 1 lb.; water, 6 qts.; boil until dissolved; then strain and evaporate to proper consistence; use a water-bath if wanted light colored.

POTATO STARCH. — Pour upon 11 lbs. best potato starch a mixture of 7 oz. pure nitric acid and 4 lbs., 6 oz., soft water; stir together, and let stand 24 hours at the temperature of about 80° Fahr., stirring from time to time; then heat to 212° Fahr.; add gradually from 4 lbs., 6 oz., to 6½ lbs. more water, and boil till the mass begins to grow thick and transparent. Further add 1¾ oz. pure nitric acid, diluted with 2 lbs., 3 oz., water; boil till the liquid is clear, dilute with water if too thick, and strain through a woolen cloth; next, dissolve 11 lbs. gum Arabic and 2 lbs., 3 oz., sugar in 8¾ to 11 lbs. of soft water, warming slowly and adding a little more water if the whole is not dissolved; strain through a woolen cloth, and add to the filtered solution 1¾ oz. nitric acid, mixed with a little water; heat to 212° Fahr. for an hour, adding gradually the first-mentioned solution of starch, and allow the whole to stand at this temperature till perfectly clear. If it is at all turbid, dissolve at a boil 8¾ oz. isinglass in 6½ lbs. water and 2 lbs., 3 oz., alcohol, keeping up the heat till all the spirit has escaped; strain through a woolen cloth; add ¾ oz. pure nitric acid; heat once more, and add the solution gradually to the adhesive mixture. If any turbidity appears, filter again. The consistence can be regulated at pleasure by the addition of water.

RUBBER.—A most valuable glue for photographers, and extensively used by book-binders, is made from bottle india-rubber. This must be dissolved in highly rectified spirits turpentine.

SPALDING'S.—(See *Liquid.*)

TUNGSTIC. — This has been suggested as a substitute for hard india-rubber, as it can be used for all the purposes to which this latter is applied. Mixing together a thick solution of glue with tungstate of soda and hydrochloric acid, a compound of tungstic acid and glue is precipitated, which, at a temperature of 86° to 104° Fahr., is sufficiently elastic to be drawn out into thin sheets.

WATERPROOF.—1. Soak glue in water until it is soft, but still retains its form; then put it into raw linseed oil, and apply a gentle heat until it is dissolved by the oil. It is then used like ordinary glue. It dries soon, and water has no effect on it. — 2. A glue which will resist water to a considerable degree, is made by dissolving

common glue in skimmed milk. Fine levigated chalk added to the solution strengthens it, and renders it suitable for sign boards. — 3. A glue that will hold against fire and water, may be prepared by mixing a handful of quicklime with 4 oz. linseed oil. Thoroughly levigate the mixture; boil thick, and then spread it on thin plates in the shade; it will become hard, but may be dissolved like glue. — 4. Where glue is exposed to the weather, common glue, protected by a good coat of oil color, is superior to the one above. If both are combined (that is, the waterproof glue and the paint), a much greater advantage may be obtained. — 5. 1 oz., each, gum sandarach and mastic are to be dissolved in 1 pt. alcohol, to which 1 oz. white turpentine is to be added; at the same time a very thick glue is to be kept ready, mixed with a little isinglass. The solution of the resins is to be heated to boiling in a glue pot, and the glue added gradually with constant stirring. After the mixture is strained through a cloth it is ready, and is to be applied hot. It dries quickly, becomes hard, and surfaces of wood united by it do not separate when immersed in water. — 6. Glue, 12 parts; water, sufficient to dissolve; then add yellow resin, 3 parts; and, when melted, add turpentine, 4 parts. Mix together in a water bath. — 7. Ordinary glue can be rendered insoluble by adding to the water, with which it is mixed when required for use, a small quantity of bichromate of potash, or tannic acid, and exposing to light the articles to which it is applied.

MUCILAGES.

REMARKS. — The use of salicylic acid, corrosive sublimate, carbolic acid, boracic acid, cloves, or any essential oil, are recommended for preventing the decomposition of mucilage and paste, which, as generally prepared, become sour, ropy, and unfit for use.

CASEINE.—Take the curd of skim milk, carefully freed from cream or oil; wash thoroughly, and dissolve to saturation in a cold concentrated solution of borax. This mucilage keeps, and surpasses gum Arabic in adhesiveness.

DEXTRINE. — 1. Dissolve sufficient yellow dextrine in hot water to bring it to the consistency of honey. This forms a strong paste that will keep long unchanged if the water is not allowed to evaporate. Sheets of paper may be prepared for extempore labels by coating with the paste and allowing it to dry; to use slightly wet the gummed side. This paste is very useful in the office or laboratory, and is cheap. — 2. The following is said to be the formula for the mucilage used on United States postage stamps: Dextrine, 2 oz.; acetic acid, 1 oz.; water, 5 oz.; alcohol, 1 oz.; add the alcohol to the other ingredients when the dextrine is dissolved.

GUM ARABIC.—This is the principal material from which true mucilage is made. Put 3 oz. gum Arabic into ½ pt. cold water, and stir frequently till dissolved.

GUM TRAGACANTH.—1. Powdered tragacanth, 1 dr.; glycerine, 6 dr.; water, enough to make in all 10 oz. Rub the tragacanth in a mortar with the glycerine and then add the water. This will produce a mucilage of excellent quality. — 2. Dissolve equal parts gum Arabic and gum tragacanth in sufficient water. This will produce a stronger mucilage than either gum Arabic or gum tragacanth alone.

LABELING. — Ordinary mucilage from gum Arabic, does not fix paper to wood or pasteboard, or to metallic surfaces. These disadvantages are overcome by adding a solution of sulphate of aluminum, made up in 10 times its quantity of water. 10 grains aluminum sulphate are sufficient for 250 grains of mucilage. Prepared in this way it will not become moldy. Again, a few drops of strong sulphuric acid are added to the gum solution, and the precipitated sulphate of lime allowed to settle.

PEACH TREE.—Take the gum that exudes from the peach tree, put in a vial and add equal parts of water and alcohol, till of the right consistence. This is good and easily obtained by any one having peach trees.

PASTES.

REMARKS.—Except where paste is to be kept a long time, no additions are necessary. Carbolic acid may be used on the large scale. For small quantities, cloves are a good preservative, but a few drops of oil of cloves or any essential oil is more convenient. To prevent the attacks of insects, the addition of corrosive sublimate is a sure preservative; but this is a powerful poison and requires great care.

BOOKBINDERS'.—Place ½ gill flour in a saucepan, and as much cold water as will cover it. Break all the lumps while in state of dough; then pour on 2 qts. cold water and 1 oz. powdered alum. Set on the fire, and stir constantly while boiling, till thick.

CORN STARCH.—Corn starch makes a good paste for scrap-books. Dissolve a small quantity in cold water; then cook thoroughly; do not get it too thick. When cold it should be thin enough to apply with a brush. It is not so liable to mold and stain the paper as paste made from other kinds of starch.

FLOUR. — Mix good flour with cold water to a paste, then add boiling water, stirring up well until of a consistence capable of being spread with a brush. Add a little brown sugar, a little corrosive sublimate, and 6 drops oil lavender, and keep 2 days before using.

PERPETUAL. — Used for leather, paper, or cardboard. Let 4 parts by weight of glue soft-

en in 15 parts cold water, for 15 hours, then heat the mixture until clear. To this mixture 65 parts boiling water are added without stirring. In another vessel 30 parts starch paste are stirred with 20 parts cold water, so that a thin milky fluid is obtained without lumps. Into this the boiling solution is poured, with constant stirring, and the whole kept at boiling temperature. When cooled, 10 drops carbolic acid are to be added. It must be preserved in closed bottles, and will keep good for years.

PHOTOGRAPHIC.—Used for mounting photographs. 1. Mix thoroughly 630 grains finest Bermuda arrowroot with 375 gr. cold water in a capsule with a spoon or brush; then add 10½ oz. water and 60 gr. gelatine in shreds. Boil with stirring for 5 minutes, or until clear; when cold, stir in 375 gr. alcohol, and 5 or 6 drops pure carbolic acid. Keep in well-closed vessels, and before using it, work up a portion with a brush in a dish. — 2. 4 parts, by weight, of glue are allowed to soften in 15 parts cold water for some hours, and then moderately heated till the solution becomes clear; 65 parts boiling water are now added with stirring. In another vessel, 30 parts starch paste are stirred up with 20 parts cold water, so that a thin fluid is obtained without lumps; into this the boiling glue solution is poured, with stirring, and the whole kept at a boiling temperature. After cooling, 10 drops carbolic acid are added. This paste is of great adhesive power, and may be used for leather, paper, or cardboard with success. Preserve in closed bottles, and it will keep good for years.

SCRAP-BOOK.—1. Rice starch, 1 oz.; gelatine, 3 dr.; water, ½ pt.; heat with stirring, until the milky liquid becomes glassy. Keep in a tight bottle, with a few drops clove oil added. — 2. Dissolve in hot water a teaspoonful alum; when cold, stir in flour to make it like cream, stirring out all lumps. Stir in this as much powdered resin as will lay on a dime, and add 6 cloves. Put into another vessel a teacupful boiling water; set over the fire and pour the flour mixture into it, stirring well. It will soon be like mush. When cool, put into fruit jars, cover and keep in a cool place. For use, soften with warm water. It will keep a year, and does not blister the paper or stain through.

STARCH. — Prepared by triturating starch with cold water in a mortar until no lumps remain, and not too thick a mass is formed; pour into this boiling water slowly, with rapid stirring, until the paste begins to form, as indicated by increase of transparency, and then rapidly add the rest of the boiling water necessary. Boiling renders it less adhesive and liable to peel. Rye flour affords a more adhesive paste than starch, but of a gray color. A little alum, added to the water renders it more permanent, and the boiling lime water instead of pure water adds to its adhesiveness. An aqueous extract of decomposed gluten, affords the best paste with starch. By incorporating with the paste turpentine, equal in weight to the starch, and stirring well while hot, it will be rendered more impervious to moisture, and more adhesive.

Sealing Wax.

REMARKS.—All kinds of sealing wax, except that formed in round sticks, are molded in heavy iron molds. They are made in 2 pieces, each representing half the matrix. The wax is poured in from the top. The iron chills the stick and prevents it adhering. The sticks then go through an ironing process, which imparts the gloss. If the wax is not properly compounded and strained, the casts are likely to be imperfect. In forming round sticks, a portion of the mass should be weighed while ductile, divided into pieces, and then rolled out upon a warm slab by means of a wooden block like that used by apothecaries for pills. The variegated kinds are scented with essence of musk or ambergris, or any fragrant essential oil. The addition of a little camphor, or spirit of wine, makes sealing wax burn easier.

BLACK.—1. Shellac, 3 lbs.; Venice turpentine, 10 oz.; finest cinnabar, 2 lbs.; mix. —2. Resin, 4 lbs.; shellac, 2 lbs.; Venice turpentine and red lead, of each 1½ lbs. — 3. The following 3 receipts are for bottle corks, cask bungs, etc. Black resin, 6½ lbs.; beeswax, ½ lb.; finely powdered ivory black, 1½ lbs.; melt together. — 4. Black pitch, 6 lbs.; ivory black and whiting, each, 1 lb.; melted together.—5. Common resin, 20 lbs.; tallow, 5 lbs.; lampblack, 4 lbs.; mix, with heat.

BROWN. — 7½ oz. shellac; 4 oz. Venice turpentine; color with 1 oz. brown ochre and ½ oz. cinnabar. Mix thoroughly by a gentle heat, and mould as required.

GOLD.—Bleached shellac, 3 lbs.; Venice turpentine, 1 lb.; Dutch leaf, ground fine, 1 lb.; mix with a gentle heat, and pour into molds.

GREEN. — Shellac, 2 parts; yellow resin, 1 part; verdigris, 1 part; powder and mix by heating slowly.

MARBLED. — Mix 2 or 3 different colored kinds just as they begin to grow solid.

RED. — 1. Melt cautiously 4 oz. pale shellac in a copper vessel, at the lowest temperature; add 1½ oz. Venice turpentine, warmed, and stir in 3 oz. vermilion; pour into metallic molds to cool. — 2. Used for cans. Melt together yellow wax, 1 oz.; American vermilion, 3 oz.; gum shellac, 5 oz.; rosin, 16 oz.; run into molds.

WHITE. — Mix 3 parts resin, 1 part caustic soda, and 5 parts water; this is then to be mixed with ½ its weight of plaster Paris. The compound sets in ¾ hour, adheres strongly, is not permeable like plaster alone, and is affected but slightly by warm water. — 2. Soften glue in cold water; melt to a thick paste; add glycerine in quantity equal to the dry glue taken, and heat to expel the water. Cast on a marble slab to cool, and melt for use as required.

YELLOW. — Mix together 4 oz. pale shellac; 1½ oz. resin; 2 oz. Venice turpentine; ¾ oz. King's yellow (sulphuret of arsenic, or orpiment).

ARCHITECTURE IN THE EARLY AGES.

BUILDING.

ARCHITECTURE AND STYLES.—This department has been prepared under the supervision of Mr. Jerome B. Legg, of St. Louis, whose efforts have not been confined to that city and vicinity, but the monuments of whose architectural taste and mechanical skill loom up in widely scattered cities and dot the hillsides over a dozen states. His recent signal triumph in carrying off the honors in the hotly waged contest for the premium design for the great St. Louis Exposition Building, over competitors from the ranks of the most renowned architects of several of our largest cities, has placed him in the very front position, and stamps our selection of Mr. Legg with approval. His advice will be found fully abreast with all the latest modern requirements pertaining to home building.

To a close observer, the unwritten history of past nations may be followed, step by step, by the development or decay of their architectural cultural. No art allies itself so closely to the social condition of peoples; none follows with more fidelity their successes or reverses. Nowhere is found more information concerning bygone ages, than in the remains of their buildings; nations that have left none are the most unfathomable. Egypt, who built her pyramids and magnificent temples, which have withstood the elements, and stand as landmarks to explorers in ancient history, leads in the ranks of nations whom we are able to trace back for centuries where all authentic traces of their neighbors have disappeared. That they had such neighbors, is indisputable from references to them in Egyptian chronicles. With them architectural forms reached a higher standard than the earliest traces of contemporary nations, showing that they enjoyed superior knowledge and power and were rich and cultured. Babylonia, Syria, Persia, India and China, contain remains of the same nature, and their history is an open book so far as these ruins carry us, but sinks into oblivion as soon as their architectural traces are lost. In the following classification of architectural styles, it will be seen that it stops with the Renaissance. While the unlearned talk of "modern styles," there are no such styles. Since the Renaissance no architectural style has been developed with sufficient originality to claim classification. The 19th century sees an indiscriminate application of almost every preceding style. The so-called Elizabethan and Queen Anne styles are but mongrel varieties of Gothic and Renaissance, and, as applied in this country, seldom come up to the characteristics of their use in England. The results of the last 10 or 20 years' work here, show a gradual improvement in style, proportion and execution, the natural consequence of increasing wealth and cultivation. Where this movement may eventually lead, the future must decide; possibly to a new style, which will be national. The Colonial style arose from the necessities of our forefathers; and though sometimes attempts are made to harmonize it with the demands and conveniences of the present, it taxes the ingenuity of the architect, as the requirements are such as not to harmonize with the opportunities which that style of design offers. An attempt to describe these sub-types would end in a labyrinth. A passing notice only is taken of them in standard works on architecture. The difference in the many ways of applying old principles, heretofore explained, which often led to most curious combinations, is no greater than may be seen any day in a trip from the East to the West, in our own country, where each section is seen to have its peculiar style, regulated by the wants of the inhabitants and the materials which are at hand for satisfying them.

ARRANGEMENT.

REMARKS.—The first step, when intending to build, is to secure a good lot. Many important points are often overlooked in the desire to secure a bargain, or get into a particular neighborhood. For a dwelling house, the lot should be of natural ground, free from fill; for, unless the material used to grade up the lot is pure clay, or earth free from all vegetable or animal mat-

ter, serious consequences may follow, caused by the inevitable decomposition which follows any disturbance of such earth. Another point is, that a low piece of ground, which has served as drainage for the neighborhood, is certain to be impregnated with filth of all kinds, which is apt to form gases that will force their way to the surface. The purifying effect of the ground placed over them will reduce this result to an extent; but unless this fill is pure, it will fail even in this respect. Many cases of sickness could be traced back to some such source. Having selected a lot, the house should be placed at an elevation above the street from which it is to be viewed. Placing too low, will spoil the appearance of the best design. The height will vary with the style of the building and its surroundings, and no guide but good taste can be given. Another reason for placing the house on an elevation is to ventilate the cellar; or, in case there is none, more important still, the space under the house, so as to carry away all vapors and gases, which are constantly rising. The house should be so laid out as to get all the sun and air practicable in the living and sleeping rooms; for sunlight is as indispensable to healthy apartments as pure air is to breathe. No apartment is desirable where the sunlight has not the freest access. In the country, trouble about good building sites is seldom encountered, and the point to be looked after is that the ground slopes in all directions from the house sufficiently to drain the surface-water from it, and that natural drainage is handy for the discharge of the waste matter from the house. The next step is to consider the style. To do this, the number of and size of the rooms must be determined. The location of the house, as to the points of the compass, must be noticed. The location of the building, whether in city, village, or on a farm, must not be forgotten. The halls and stairways should be placed so that the distance between the rooms in connection be as short as possible; a few steps spared her housewife amount to considerable in the course of a year, and make a great difference in the convenience of a house.

Houses.

CITY DWELLINGS.—In erecting a city residence, the hints elsewhere, especially as to filled ground and arrangement of different rooms, must be carefully considered. The small space usually allotted demands the closest attention to its arrangements. A good, dry cellar, with as much light as possible; suitable location for a furnace; convenient coal and fresh air supply, and a good laundry, are conditions most commonly required. The cellar should not be less than 7 ft. to the underside of the first floor joist. The monotony of living apartments, where narrow lots will allow of no great projection, is sometimes nicely accomplished by the manner in which the closets are placed. Small projections in front relieve the stiffness of the elevation, and improve the parlor and front chamber. The height of stories should be 10½ ft. to 12 ft., in the first, and 10 ft. to 11½ ft., for the second story. The size of the rooms should be taken as a guide in determining the height of stories, as a small room, with too high a ceiling, is never pleasant and cosy. Within the above limits, there will always be sufficient height to thoroughly ventilate the apartments, and, unless very large, prevent any squatty appearance. Regarding the exterior of city houses, not much can be given as a guide; the three most common modes of handling being the stock-brick, brick and stone trimmings, and stone-fronts. Such matters depend on the owner's taste, and amount of money to be expended. As to brick fronts with stone or terra cotta trimmings, or stone fronts, it may be said, that in large cities, where the atmosphere is loaded with soot and dust particles, projections should be avoided, except in such places where provision can be made for a water drip to throw the wash from rains away from the walls; otherwise, the dirt and dust will be washed down the front, and produce a very bad effect. All stone, except granite (which is seldom used), disintegrates under the effects of the weather; it is, therefore, a good precaution, when used in combination with brick, to give the stone one coat of paint of the original stone color; it will effectually prevent the wearing of the stone, and stop the streaks, which appear soon after such work is completed, on the brick work below the stone. The space between the ceilings of the upper stories and the roof should always be ventilated, which will prevent the super-heating of the confined air, and keep the rooms cooler in summer.

COUNTRY TOWN DWELLINGS. — Houses built in country towns and in the suburbs of cities may be classed under one head, as the requirements are the same. More ground being available, the house assumes a broader shape, usually with a centre hall, making a double house. The hall should be made wide, with an easy stairway. The parlor, family room, and dining room should enter the hall with sliding doors. The family room, being used more frequently, should be roomy and have a pleasant exposure. The parlors, dining room and kitchen need the same conveniences as a city house. The bed rooms and general arrangement of the second story, should be according to directions elsewhere. The only point differing is the bath room, which requires some extra arrangments. City water not being usually available, parties desiring a bath room are compelled to provide a substitute. A tank is placed in the attic, or elevated in some room, so as to allow the water from the eave-gutters to flow in to it, and provided with a cut off, by which the supply can be thrown into the conductors leading to the cistern. This tank should be in connection with a force pump in the kitchen or laundry, which can draw the water from the cistern and throw it into the tank, so that in a dry season, when the water in the tank is low, a supply can be had from the cistern. The soil pipe (in case a closet is used), must empty into a cesspool, at least 40 ft. from any well or cistern, and inclosed with hard burnt brick laid in cement, to prevent seepage of the matter through the ground, which would follow any strata in the earth and

taint the contents of neighboring wells. Where a natural drainage can be had for cesspools, attention, in properly locating wells and cisterns, is especially necessary. Porches greatly increase comfort and should never be omitted. The front porch should shelter the entrance; and, if the exposure is south or west, could extend across the entire front and protect the parlor also. The kitchen porch ought to be large. The south and west fronts should have protection. If properly treated, porches will be a comfort to the inmates, and ornamental to the house. Good taste must be exercised, or, in trying to provide ample porch room, it may result in burying the house.

FARM HOUSES.—Their requirements differ from those of city and country towns. The parlors and library are omitted, and the kitchen, dining room and sitting room, are enlarged. In some cases the kitchen is made of a size sufficient to serve as kitchen and dining room. One or two bed rooms are usually provided on the ground floor. The general arrangement and disposition of the rooms have been thoroughly discussed elsewhere. This class of buildings is put up with small expenditure, and depends more on the skill of the architect than even the more elaborate ones. It is easy to procure fine effects when ample means are at hand; but, to produce a pleasing appearance, and convenient interior with small outlay, taxes the designer's skill to the utmost.

Rooms.

BATH ROOM.—This modern convenience, in order to be enjoyed, must be easy of access from all sleeping apartments; not located, when avoidable, on the north side of the building, and of sufficient size to be comfortable. It should never be connected directly with any bed room; for, although much improvement in sanitary devices has been made, we are still far from the point when we can guarantee safety from sewer gases.

BED ROOMS.—These should be placed where exposed to the sun sometime during the day. The furniture of the rooms must not be forgotten in the disposition of the doors and windows. It is not unusual to find houses in which no thought has been given to this point; where beds are placed across windows and before doors in the the most awkward position, simply because the designer of the room neglected to make it appropriate to the use intended. Bed, bureau and washstand, each demand a place. The bed should be located so as to avoid draughts, and still be where the air in summer can reach it; never between two openings, nor in such a manner as to project too far into the room, thus cutting it in two parts; neither must it come too close to fire places. The bureau requires good light, and is best provided for between the windows. The washstand is less important, and can be located in a corner of the room away from the door leading into the hall and the side where the principal windows are. Good ventilation is indispensable, and is gained by placing a transom over the door to the hall, and, where possible, the location of windows on two sides of the room.

CELLAR.—Complete drainage is an absolute requirement of all cellars; and, where this cannot be obtained, it is better to do without them, and merely ventilate the space beneath the first floor. The necessity for drainage will vary with the varieties of soil and the location of the house. With good clay and sufficient fall of grade in all directions, a cellar is not liable to be damp. If moisture should show itself, the cause may be sought in a careless ramming of the back filling around the walls. When there is a sandy soil, with a layer of clay underneath, cellars may be kept dry by sinking a trench around the walls at the level of the top of the clay bed, and filling with coarse gravel, rock, or, better still, laying ordinary clay drain tile. These trenches must have an outlet to some point low enough to drain the water from them. By catching all surface and subsoil water before it reaches the house, they keep the walls dry.

CLOSETS.—The convenience of closets is realized when one is unfortunate enough to occupy a house in which they have been omitted. A skilful designer can locate them so as to use corners and spaces which could not be utilized. Kitchen closets and pantries require considerable shelf room, and the lower shelf must not come nearer the floor than about 2 ft., 6 in., so as to allow a barrel to be placed underneath. In large pantries it is best to inclose the shelves with narrow, tight fitting doors. China closets need many shelves, placed with decreasing spaces as they go up. Clothes closets are fitted up with two shelves and a strip for clothes hooks.

DINING ROOM.—This room, in which the family gathers every day, and often used as a sitting room, should be pleasantly located; an eastern exposure is best, as the room is always cheerful in the morning. Its shape should have reference to the furniture. The table will be greatest in length; hence the room ought to correspond. If the fireplace is on the long side, width must be gained to prevent persons sitting on that side from being rendered uncomfortable. When the fireplace is at the small end, the sideboard should be placed at the opposite side of the room. The doors must be located to obviate passing close to parties seated at the table. The method of reaching this room, from main and rear portions of the house, should be as direct as the disposition of the rooms will admit.

HALLS AND STAIRWAYS.—The main hall of city houses is gradually assuming a more important place; the long, narrow passway, with its straight run of steps, will soon pass out of use. This is one of the most important steps of modern house building. The hall takes a prominent position among the several apartments; it is in constant use, and is seen by all guests. A pleasing effect here carries the feeling through the house. The vestibule and steps leading to it must not be cramped; the last step to the storm doors should be double width, so as to afford a good platform to rest on when the storm doors are closed. The stairs must not start too close to the front door, and must be constructed so as to show the newel, rail and balusters to the

best advantage. The doors of the rooms adjoining the hall, when well grouped, assist the general effect. Stained windows soften the light and are appropriate, and at a small cost add much to the general finish. Though any departure from the old fashioned hall is an improvement, the mistake of making the hall out of proportion is serious and must be avoided. In some cases, on narrow lots, no other style than a long hall can be applied; but where space will admit, a more pleasing arrangement can be obtained. The stairway, well proportioned, should measure 10½ in. to 12 in. on the treads and 6 in. to 7½ in. rise; a wider tread not being comfortable, and a higher tread making too great a step up. Where the story is high, platforms or landings make the ascent easier and beautify the stairs. Skylights of stained glass at the height of the ceilings produce pleasing effects. Open fire places are sometimes used with good results. Rear halls require good light, and stairs free from "winders;" or steps, which come in the turns, can be made with 8 in. rise and 10 in. treads. There are cases where "winders" have to be employed; but they should be used sparingly. More space than absolutely needed is a bad feature in rear halls, as they are cold passages in winter.

KITCHEN.—This should be conveniently isolated from the house, so as to prevent the odors of cooking from penetrating to the rooms. Nothing is more annoying to the housewife than this. A convenient connection of the kitchen with the front door is a good point, if attainable, and should not require passing through another room. The inside cellar stairs, to and from the kitchen, must be handy. Communication between kitchen and dining room must naturally be close, and where possible protected by double doors. A double pantry, with a slide, forms the best method of passing the eatables, though it should be used in connection with double doors. Sometimes the pantries can be made large enough to enable one to get necessary shelf room and a passage through the closets also. The exit to the yard must be protected by a porch or shed roof, so as to shelter the entrance from storms and sun. Sinks and flues should be carefully located with reference to light.

LAUNDRY.—This is not usually "finished," but the ceilings should be plastered in two coat work, which will prevent steam from penetrating to rooms above, and dirt from falling down on the clothes. The best form of floor is that finished in the best Portland cement. In some localities sand used for buildings contains iron, rendering it unfit for cement work below the ground; where this is the case, a top dressing of pure cement will obviate the difficulty. Concreting the cellar is excellent for excluding moisture and vermin, and, where the funds will allow it, should never be omitted. Cheaper floors are made by laying cedar sleepers and filling the space between with broken brick and stone, rammed solid, then covering with ordinary flooring. This filling should stop ½ in. below the sleepers, so as to leave an air chamber between the filling and bottom of the floor, which will prevent decay. Stationary tubs are not in general use for laundries. Though convenient, they become foul and afford a harbor for vermin; but if adopted, there should be as little wood work as possible surrounding them. Laundry sinks are set low, and should be placed on an open frame with turned legs.

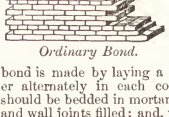
PARLOR.—This indispensable feature requires more symmetrical designs than any other part of the house. The fireplace and door to the hall should be on a line, in the centre of the room; the door between the parlors (or if there be but one, that leading to the library or dining room, as the case may be) also in the centre. The latter door is commonly a sliding door, and should not be less than 5 ft., 6 in. wide. Parlor furniture calls for some attention in the location of openings; and places for piano, sofa and corner stands are to be provided. The piano needs good light and a location where doors do not open against it. When the hall is wide, sliding doors connecting the parlor or parlors with it, and also between the parlors and dining room, make a fine suite of rooms, and, in giving entertainments, are fully appreciated.

SERVANTS' ROOM.—This, in a well-arranged building, is cut off from the rest of the house; where there are two stairways, this can be easily accomplished, and should never be overlooked.

CONSTRUCTION.

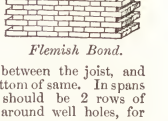
BRICK WORK.—This is of several grades. If the outer facings of the walls are of red brick, and the balance of salmon or soft, light, burnt brick, it is called a "merchantable job." If the facings are of dark red brick, and the balance of the walls of light red brick, it is called an "ordinary hard and red job;" and if the inner portions are of hard or red brick, it is a "strictly hard and red job." Extra fine, smooth brick, of even size and color, with square, full edges and corners, are called "stock brick," and are made larger than ordinary brick, to admit of neat joints in the outer facings and being laid in courses and bonded in with the common brick back of same. Stock brick are laid in fine, thin mortar, composed of white sand and Cape lime, but often made of a compound to produce a black or red mortar joint. If red or black joints are required, the brick is generally laid in white mortar; and, after the walls are up, the outer portions of the joints are scraped out, and the joints tuck-pointed. If the joints are cut back, and straightened with a steel, it is called "steel joints;" if worked with an oval convex face, with a concave rod, it is called a "rod joint." Stock brick work is laid with all stretchers on the face of the walls, that is, with the long edge of every brick showing outside; except on corners and angles the ends are alternately bonded in. The stock brick facings

are bonded to the common brick portion of the wall, by having the inner corners of the stock-brick clipped off, and extending the common brick clipped off, and extending the common brick work into this space. Walls are 2, 3, 4, 5, or more bricks thick, according to the height and strength required, and every course should be bonded together, every 5 or 7 brick in height, with heading courses; that is, with bricks laid lengthwise across the walls. The Flemish



Ordinary Bond.

Stock Brick Bond.

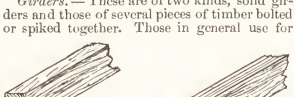


Flemish Bond.

bond is made by laying a stretcher and header alternately in each course. Every brick should be bedded in mortar, and all head joints and wall joints filled; and, where a good job is required, every course of headers should be slushed up with thin mortar, poured in to fill up every crevice in the walls. Brick, surrounding smoke flues, should be shoved up in mortar and the joints inside struck and pointed same as wall facings, where not of stock brick.

CARPENTER'S AND JOINER'S WORK.—There are two divisions of work under this head which are intrusted to the carpenter: 1. The carpenter's work proper, such as framing the joist, roofs and stud partitions; putting on roof sheathiny, and laying floors; he is required to furnish and cut all the wood blocks required, and, as the walls go up, for later use in securing stud partitions, finish wainscot, etc. 2. The joiner's work, is such as cornicing, doors, windows architraves and base finish, panel backs, shutters, etc., which are delivered to the building ready to go up, but fitted and put in place by the carpenter. (See *Joiner's Work.*) The carpenter has to fit and secure locks, bolts, hinges and other hardware. In rough framing the most important point is the quality of the wood, which should be dry and free from knots, which would be likely to impair the strength.

Girders.—These are of two kinds, solid girders and those of several pieces of timber bolted or spiked together. Those in general use for



Girders.

dwellings are usually made of 4 pieces of 2x10 or 12 in. joist, each spiked to the next, with the joints in long girders broken over the supports in such a manner as to let each piece lap over the joints in the next one. Where timber is strongly grained, have the grain lines reversed in adjoining pieces.

Joist.—The depth of a layer of joist varies with the length of the span, that is, the distance between supports, and the weight which they may be required to sustain. Joists should be sized to one depth at the ends, and rest on accurately leveled bearings, with the tops dressed in such a way as to leave them high in the in such a way as to leave them high in the centre, which is called crowning. Those coming above the first story in brick buildings should rest on a 3 in. x 4 in. piece of timber, laid even with the inner edge of the wall, with each joist spiked to same. Each tier of joists should be braced with small pieces (commonly 1 in. x 3 in.), so as to form a cross between the joist, and nailed to the top and bottom of same. In spans of over 14 ft. there should be 2 rows of bridging. In framing around well holes, for skylight, for stair openings and fireplaces, and from brick work of flues, the timbers should be doubled; the trimmers or long joists, which are placed at either end of the opening, or at sides of chimneys and flues, should be doubled and spiked, with mortises to receive the tenons of the header, or side pieces, which are also doubled and spiked together, and have mortises cut to receive in turn the tenons of such joist as come in the space and are supported by the header. When the studding for partitions come on the joist, they should be doubled for ordinary partitions; and, if more strength is necessary to sustain the weight, the number may be increased, thus forming a sort of girder in the floor. Under sliding door partitions there should be 3 joists, either blocked 2 in. apart by small pieces, spiked between, or trussed by cutting 2 in. x 4 in. or 2 in. x 6 in. pieces between them, so as to form an inverted V

Double Tenon.

Plan.

truss meeting in the centre at top line of the joist, and extended to lower edge at sides. It is of importance that spikes be not spared. The latter form of sliding door partitions is preferable.

Roof.—The rafters or timbers which support the inclined portions of a roof should rest at the base on a wall plate, a piece of timber commonly 2 in. thick, laid level on top of the wall; and where there are look-outs, or skeleton frames built in the wall to secure the cornice to, the plate should be spiked to them. Deck rafters or joist are those supporting the flat portions of a roof. The decks are supported, where there are no rooms underneath, by suitable posts placed under the deck plates, or plates on which the deck rafters rest; these posts should stand on sleepers, short pieces of

timber long enough to cover 4 or 5 of the joist below (ceiling joist). Valley rafters are those forming the line in the inner angle of a hipped roof. Hip rafters are those forming the line on the outer angle of a hipped roof. These latter (hip and valley rafters) should be heavier than the plain rafters, as they support the cripples or short pieces cut in to fill out the angles in the framing. The dimensions of roof timbers depend on the use to which they are put and the construction and size of the roof.

Partitions for separating the compartments of a building, are commonly made of timber, called "studding." For ordinary partitions, 2 in. x 4 in. stud are used, and for such as are required to carry a tier of joist, 2 in. x 6 in. They are placed 16 in. apart from the centre of one stud to the centre of the adjoining one. The correct construction of these partitions plays an important part in the stability of the plastering, and no point to secure that end should be slighted. In all cases where there is a partition or girder under a line of stud, the stud should continue on through the floor joist and rest on the girder or plate (a horizontal piece of timber placed over the top of a line of stud) of the partition underneath. The benefit to be gained by this, is the reduction of the amount of shrinkable timber in the height of the partitions, as wood in drying only contracts across the grain; and by not resting the studding on the joist, the shrinkage in them does not affect the plastering.

Sills.—It is not always practicable to have the upper partitions come over the lower ones; and, in such cases, the stud should be placed on a 2 in. piece of the same width as the stud, resting across the joist; this, of course, applies to partitions running in an opposite direction to the joist; when the direction is the same, the stud rests directly on the joists. (See *Joist.*)

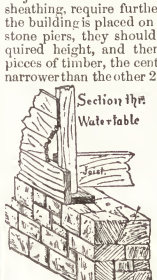
Plate. — Partitions should be capped with a plate 2 in. thick, of same width as the stud, with a couple of spikes through plates into the head of each stud. Where a partition supports a partition above, this plate should be doubled, with the joints of the upper half, so as to lap over those in the lower one, and securely spiked together.

Bridging. —All partitions should be bridged. There are two methods, the "block" and the "*zigzag*" bridging. The block bridging by cutting 2 in. stuff so as to fit in exactly between the stud, and then toe-nailing the pieces securely to the sides of stud. The zigzag bridging is formed by cutting the pieces about ½ larger than the distance between the stud, with the ends cut at such an angle as to fit exactly against the side of stud, and then toe-nailing ends to the studding, reversing the direction of slant of each piece, so that, when completed, the bridging will have a zigzag outline. This is to be preferred to the previous method, for unless the pieces in the block bridging are accurately fitted, they do not hold the stud in position and are of no practical service. This accuracy is difficult to obtain, as the spaces vary on account of difference in the width of studding; while in zigzag bridging, the pieces are wedged firmly between the stud in the process of nailing. Unless in very high partitions, one row of bridging will suffice. Sliding door partitions are formed by placing 2 lines of stud, 2 in. x 4 in., so far apart as to allow the door to slide back in the space between (called pocket). These partitions should be trussed over the opening for the doors, to prevent the weight of upper floor from sagging them down, which would impair the working of the doors. When the space at the sides of the opening is more than 4 or 5 ft., there should be a diagonal brace cut in on each side to prevent the ends of the truss over the door from moving sideways.

Door Jambs.—At all door jambs the stud of partitions should be double; and, if the finish is of such width as to require it, they should be blocked far enough apart to allow the nailing of the finish directly to the outer stud. Wall stud, or those coming against brick walls, should be spiked every 24 in. to wood blocks 3 in. x 4 in. x 8 in., which must be built in, as the walls go up, in the correct position. Care should be taken that the bricklayer does not neglect to build in the blocks; otherwise the partitions will invariably shrink from the brick wall, leaving an ugly crack in the plaster. Corner stud, or those forming the angles in partitions, must be well spiked, in such a manner as to leave good spaces for nailing the lath work. For these places, straight dry stud of even size, should be selected.

Floors.—These are generally made of ⅞ in. matched stuff, and from 3 in. to 5½ in. wide; the narrower widths preferable. In laying floors, the stuff should be selected to match in width, and nailed to every joist with a 10d nail.* Flooring should be absolutely dry, and never put in a building until the roof is on.

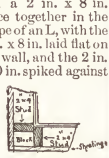
Balloon Frames.—The descriptions of girders, joist, studding, etc., is applicable to brick or frame structures, but in the latter, the bearing of joist on the outer walls, erecting of frame and sheathing, require further description. When the building is placed on wood posts, or brick or stone piers, they should be leveled at the required height, and then sills, composed of 3 pieces of timber, the centre one of which is 2 in. narrower than the other 2 (commonly two 2 in. x 10 in., and one 2 in. x 8 in.), all spiked together, with the joints broken, as described for girders, and the corners then carefully joined and spiked. The ends of the frame stud are then cut with a 2 in. mortise to fit in the channel between the 2 larger pieces of the sill, and carefully spiked to



Sections Through Water Table.

the same. If there is a brick or stone foundation, the sill is formed by spiking a 2 in. x 10 in. and a 2 in. x 8 in. piece together in the shape of an L, with the 2 in. x 8 in. laid flat on the wall, and the 2 in. x 10 in. spiked against the end of it. The frame stud are then notched out 1 in. for 8 in. of their height, so as to fit over the outer piece of the sill, and then spiked to each piece of the sill. The corner posts, if not solid, are made by spiking 2 pieces of stud together to fit the angle, with blocks inserted on those for outer angles, to stiffen them, about every 3 ft. Corner braces and pieces running from the bottom of the 2d tier of joist to the sills, as far from the corners as the window arrangements allow at the sills, and should always, be put in. For houses where studding used is 2 in. x 6 in., these braces should be 2 in. x 6 in. pieces; and where studding is 2 in. x 4 in. a 1 in. x 6 in. piece is preferable, as they (the braces) must be let in flush with the outer edge of the stud; if 2 in. braces were used in 4 in. studding, they would weaken it. The first tier of joist where there is a sill, should be sized by notching down on the sill, and then be spiked to the sill and also to the sides of the studding. Where the sill is of the second variety, the joist should be sized on the lower piece of sill and spiked to both pieces of the sill and to the stud. The second tier of joist, when the house is frame, rests on a 1 in. x 4 in. piece, let in flush with the inner edge of the stud, and the joist spiked to the sides of the stud. It is obvious how important a part spikes have in this construction, and a liberal use of them is necessary. Wherever possible, the stud should continue up the height of the walls, and must be doubled at the sides of all openings.

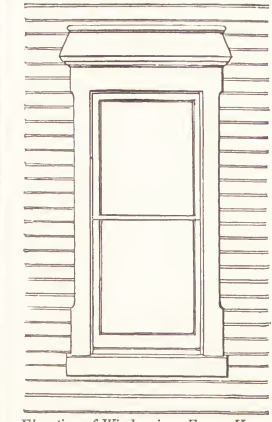
Gird Supporting 2d Floor Joist.



Construction of Corner.

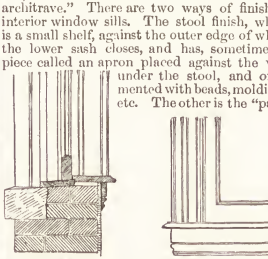
Sheathing.—In houses of good size, sheathing, or the covering of the frame with 1 in. boards, should never be omitted. In many cases these are, in turn, covered with felt paper, and the dressed siding or weather-boarding put over the felt. In houses of a cheaper class, in countries not exposed to severe climatic changes, the sheathing may be omitted; but this is not advisable, as it weakens the structure.

Joiner's Work.—The first portion of this work, is the door and window frames. Door frames are all plank except when paneled, and may be ornamented in various ways, with beads, flutes, etc.; those for outer doors should not be less than 1¾ in. thick; for inner frames, 1¼ in. They may be plain, single or double rabbetted (that is, reduced at the edges ½, to allow the door to fit in between the frame), giving the centre of the frame the appearance of a raised panel. The tops of sliding door frames should be made in one piece. Window frames are of 2 kinds, the box and plank. In plank frames, the sash are held up by catches, a great variety



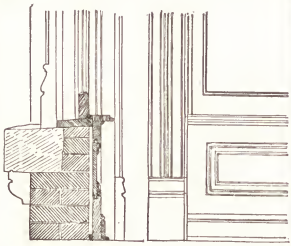
Elevation of Window in a Frame House.

of which are in the market. In box frames the sash are counter-balanced on cast iron weights, and hung by cords. Sash, in the better class of rooms, should be 1¾ in.; for those less important, 1⅜ in. Window sills, if wood, should be of cedar. The sub-sill placed on the sill. proper forms the bottom of the window frame. In frame buildings, exterior openings are ornamented by trimmings, called "outer architraves;" interior finish is called the "inner architrave." There are two ways of finishing interior window sills. The stool finish, which is a small shelf, against the outer edge of which the lower sash closes, and has, sometimes, a piece called an apron placed against the wall under the stool, and ornamented with beads, moldings, etc. The other is the "panel back," in which the entire space, from floor to sill, is covered with a wood panel; the inside architrave continuing to the base; while, with a stool



Section and Elevation of Window, with Stool and Apron Finish.

and apron finish, the architrave stops on the stool.



Section and Elevation of Window, with Panel Back.

Doors.—Ordinary doors are $1\frac{3}{8}$ in. thiek, 4 paneled; $1\frac{3}{4}$ in. thick are used for better elass interior doors, and should be used for exterior doors, except front and vestibule doors, which are made thicker and often of ornamental design. Sliding doors should never be less than $1\frac{3}{4}$ in. thick; the best elass $2\frac{1}{4}$ in.; doors of 2 thicknesses of $1\frac{1}{4}$ in. stuff glued. This prevents

Solid Molded.

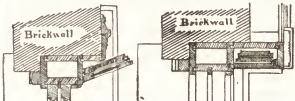
Flush Molded.

Lip Molded.

warping. Ordinary sliding doors are 6 paneled. Doors may be divided into the following styles: Those "molded on the solid" (such as have the panel molding worked on the stiles); "flush molded," or such as have a panel mold, which does not project beyond the face of the stile; "lip-molded," or with a projecting mold, which lips over the stile; or they may have raised panels in the main panel, or be plain. Doors are made with paneling of various kinds and styles.

Finish.—The interior trimmings of the openings of a building, the door and window finish, and the base boards. Plain finish consists of a simple casing, usually $\frac{7}{8}$ in. thick, of various widths; the top piece made $\frac{1}{4}$ in. thicker than the sides, and sometimes raised in the centre, called "pediment head." The base has the top edge beveled. Molded finish is of one or more members, which mitre around an opening with the outer mold in door casings, and when there are panel backs, made similar to the cap mold on the base, so as to mitre, making one continuous mold around the apartment. Plain pilaster finish has a molded or beaded easing in one piece, with a base, plain or molded, called "plinth," against which the base is stopped, and eorner blocks, in the upper angles, against which the side and top casing stop. Sometimes an ornamental top piece is added to the eorner block. Molded pilaster finish is designed to any degree of richness. The height of the base should be about 1-12 the height of an apartment, but varies with the style of the finish.

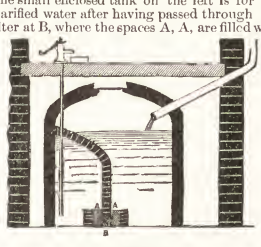
Blinds, omitting several patent varieties, are of 2 kinds, inside and outside. Inside are of $1\frac{1}{8}$ in. stuff, and, unless the width of opening is more than usual, in 4 folds. They are cut 2 sections in height, the division eoming at the meeting rail of the sash. The inner folds are



Sections Through Window Jamb, with Pocket for Inside Blinds.

made with movable slats, and the outer folds paneled and molded to match the finish in the apartment. There are 2 ways of disposing of the inside blinds when open, either to let them close against the window jamb and project in the room, or to prepare pockets in the jambs, into which they are pushed when open. The former is preferable. Outside blinds are made $1\frac{3}{8}$ in. thiek for ordinary dwellings. They are also sometimes made with a solid panel, when security is desired.

CISTERN. — The great importanee of pure drinking water is nowhere more appreeiated than in eountries where there are no wells; the illustration shows a form of filter eistern whieh will clear the most eloudy water. On the right is the receiving tank, where the diseharge from the down spouts from the house is received. The small enclosed tank on the left is for the clarified water after having passed through the filter at B, where the spaces A, A, are filled with



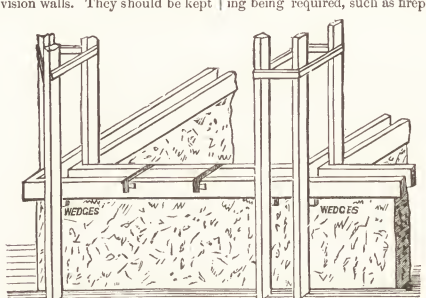
Filter Cistern.

gravel and fine charcoal. The supply is drawn from the second apartment, which fills as the

water is withdrawn. A more simple, and equally effective form of filter is made from an ordinary cistern, by building a partition wall in it, after the cementing of the outer surface has been completed; the pressure of water in the receiving side forces the water through the pores of the bricks and effectually clarifies it.

CONCRETE.—Made of broken stones, about 2½ in. in diameter, with the interstices filled with mortar, composed of 1 part cement and 2 parts sand; mixed together, dumped in position, leveled and rammed down solid with a maul, until the cement floats on top. This, 3 to 4 in. thick, makes a fine flooring for cellars; if used 10 in. to 15 in. thick, and 20 in. to 40 in. wide, it makes a fine footing or foundation for heavy walls, as good as stone, and cheaper.

CONCRETE HOUSES.—The method of building with concrete is shown in the illustration. Firmly fix stout wooden uprights, 3 x 9 in., at each angle of the building, and at the junction of cross or division walls. They should be kept



Manner of Constructing Concrete Houses.

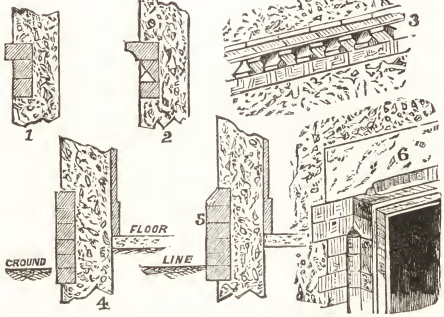
at a uniform width apart, with bolts or cross-pieces of wood; and stiffened with stays from the ground to keep them upright. Two 3 x 11 in. planks, one for each face of the wall (or four 3 x 7 in. deals, 2 for each face, each pair firmly secured with wedges), are required to form a trench the length and width of the intended wall. A piece of iron suited to the thickness of the wall, dropped over the plank at intermediate distances between the uprights and wedged up, will prevent the planks from bulging out by the pressure of the concrete; a few such pieces, to suit 6 or 9 in. walls, could be made by any blacksmith, of light bar iron. When the trench is filled with concrete up to the ground line, and above that to the top of the planks, they should be moved higher up, and secured with counter wedges. The lower edges of the planks should be allowed to cover the concrete about 1½ in., to securely confine the next layer of concrete and prevent oozing out. The trench being shallow, it may be filled in a day, allowing the concrete to set during the night, so that the trench may be ready for moving higher the next morning. The sides, being only a single plank, will be lighter to move up and down than if made up of 2 or 3 in depth; the shallowness of the trench will enable an unskilled laborer to fill it in better with concrete. It will also be open to supervision, although the progress will not be so fast as if the trench had been 18 in. deep; but where unskilled workmen are employed, the slower progress will be more sure. No scaffold poles will be required, as strong wood brackets can be secured to the wood uprights to carry the scaffold planks. Special provision will have to be made for fireplaces and for gables. Door and window frames should be built in, partially driving a few nails in at the backs of the frames, to take firm hold of the concrete. Joist should be fixed in place, and either wood fillet, hoops, iron, or nails driven in at the ends, so as to secure them to the concrete, and form a perfect tie from wall to wall. In the case of any opening being required, such as fireplaces or arches, wood cores or molds, made tapering, should be used so as to be easily withdrawn when the concrete has set; wood cores will be required for chimney flues, either round, square or oval, and by the same means air flues or other openings for ventilation can be formed as the work proceeds. The face of concrete being smooth, no parqueting will be required for flues; and one coat of plastering to walls will be saved. The floors of the kitchen, if formed with concrete, will be drier and warmer than either tiles or stone. Concrete (if made of Portland cement and fine broken material) is impervious to moisture, and will make a drier and warmer house than one built of brickwork. In the illustration, 1 2, 3, are details of a string to ½ in. scale; 4 and 5 are details of plinths; and 6 shows a window with stone head and chamfered red brick jambs.—*Making Concrete.* The position of the intended building being staked out, the trenches for the foundations dug, and the several materials required to make the concrete being arranged, 2 mixing boards are required, a useful size be-

ing 12 ft. x 7 ft.; but this will depend upon the nature and extent of the building. They should be made of 3 in. planks, firmly secured to cross sleepers, without sides, so as to form a good, firm and solid floor upon which to mix the concrete. The larger materials must be broken the size of a hen's egg and deposited in heaps around the mixing boards, within reach; a plank is laid from each heap to the board, and towards the building, to facilitate wheeling. The men should proceed to wheel on to the mixing board as much of the materials as can be conveniently turned by 4 men; 2 of the men wheel the stuff on, while the other 2 spread it evenly, depositing the whole in layers. The lime should be thoroughly slaked, the proportions being 1 part lime to 6 or 7 of broken material, large and small. These should be mixed in a dry state by turning the mass over twice. Commencing at the centre and throwing over towards the right and left, the mass will be divided into 2 heaps, which should be again thrown together, and form 1 heap. Water should now be sparingly added, and the whole thrown back in 2 heaps, and again back to 1, so that the various materials may be thoroughly incorporated. The mixture is now ready for use, and should be at once wheeled to the building and thrown into the trench or mold, as the case may be.—*Concrete Cement.* This is made in the same manner as for lime concrete. The only difference is that cement is used in the place of lime; as the building materials and the rough materials are reduced in size, the smaller the rough materials are broken up, the stronger will be the concrete. Concrete cement is used chiefly for walls above ground.

EXCAVATIONS.—Foundation walls for buildings must extend below frost line, and deep enough to reach solid ground. The earth should be removed from 4 in. to 6 in. from wall lines, to admit of the foundation walls being built and pointed; when the walls are up, this space should be filled with clay, puddled and rammed solid, to keep the water from the walls.

GAS.—The arrangement of gas fixtures depends on the use to which an apartment is to be put and must be governed thereby. Parlors, dining rooms and bed rooms should have centre lights; also front halls, where the gas is not on the newel posts. Bed rooms should have a bracket on each side of where the bureau would be placed. In first-class work there is a branch pipe leading from the supply of a story to where the centre drops come; and in no case should the joist be cut more than 24 in. from the points of support. Municipal gas companies have regulations governing the size of the pipe. There are various gas machines, each requiring their own sizes. All gas pipe should be tested after lathing is completed.

HARDWARE.—Consists of the hinges, locks, bolts, window locks and lifts, sash weights and cord, and the ornamental facings of the parts, called the "furniture. The most inexpensive is the Japanned finished, and the most expensive real bronze, more or less ornamental. The principal varieties are: Japanned, plated, Tucker and Berlin bronze, and real bronze. Knobs are mineral, porcelain, jet and bronze, Care should be taken to use none but the best brands and makes. Mortise locks should be used, as the old style rim lock is liable to become out of order and troublesome. Chamber doors and outer rear doors ought to have thumb-bolt attachments on the locks. No furniture should be put on any of the work before the varnish is thoroughly dry.



Details in Constructing Concrete Houses.

PAINTING AND GLAZING.—Painting should have special attention. The foundation of all durable work is good material. Pure lead and oil must be used, or all will be in vain. The wood-work must be smoothed before paint is applied, and knots covered with shellac; then the first coat can be applied. This coat ought to be composed principally of oil, with

just enough body added to fill pores. Using plenty of oil makes it penetrate the wood, and prepares it to receive following coats without drawing on them for oil, which would deaden and make the finish look spotty. The work must be sand papered before each coat is applied, dust or dirt removed, and each coat thoroughly dry before succeeding ones are applied. For common work 2 coats may suffice; but on all interior work, not less than 3 ought to be used. A good coat does not mean a heavy one, for, when heavy coats are applied, they are liable to blister. The coats should be medium, with sufficient body to cover well; and when well rubbed down, this will be found to produce satisfactory results. Graining, when put over good ground work, will have a proper foundation; but for fine panels, it is necessary to cover the panels with ground pumice stone and oil, and then rub down smooth with pumice stone and water. Good graining is a pleasing decoration; but poor work is a detriment, and plain painting in parti-colors is preferable. One of the most common mistakes in graining is to make the work too "loud," which here, as in every thing else, looks common. Oil color graining is more durable than when done in water colors. Varnish must be of good material and carefully applied, otherwise all defects present in the work will be magnified. It should never be applied when the temperature prevents it flowing freely, as then every hair in the brush will leave a ridge. As regards color, good taste must be the judge, and a selection of harmonious colors adds much to appearance. Glass may be classified into single strength, double strength and plate-glass. Single is used in less important sash, except in places where the size of the light prevents. Double is used for front sash. Good glass must be true, flat, and free from waves. To properly set glass, brads should be used without stint, as otherwise the movement of the glass will push back the putty before it hardens, leaving a space larger than the thickness of the glass; a rattling window will be the result. Even bedding of the glass against the sash is indispensable.

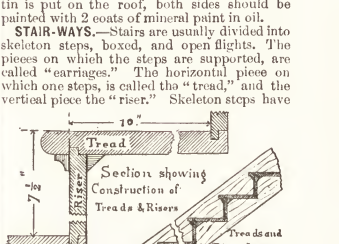
PLASTERING. — The foundation for plasterer's work must be looked after in that of the carpenter's, who must space his joist and studding accurately, 16 in. from the centres, so that the spaces will fit the length of the lath. Lath should be dry, carefully selected, and free from knots. Rafted lath are preferred to saw-mill lath. The spaces between the lath must be $\frac{3}{8}$ in. to $\frac{1}{2}$ in., for the plastering to be pushed between and run over on the back of the lath, forming the "key" of the plastering. The first or "scratch" coat, applied to the stud walls and ceilings only, must have plenty of long hair, mixed in when ready for use. This should be keyed to the lath work, and well cross-scratched to afford a good key to the second coat. When scratch coat is hardened, the second coat is applied, composed of clean, sharp sand and fresh strong lime, well tempered. In this coat all inequalities of surface should be overcome and the corners and angles be left sharp. This, like the first coat, must be dry before the white coat is applied. The white coat is composed of pure white lime and fine, sharp sand, washed to remove foreign matter, with sufficient plaster of Paris added to give it a smooth surface. This coat must be thoroughly "troweled" down, and washed with clean water and a brush. Troweling is important, otherwise the plaster will show cracks in all directions, which are hard to remove. While each coat of plaster must be dry before the next one is applied, too rapid drying must not take place; for that reason the blinds must be hung, and when there are no outside blinds, the sash put in place, so as to stop draughts. Cracks are annoying, as they do not show themselves, in some cases, until after the white coat is finished. Plaster cornices are measured by the length of the face measured around all the moldings. This can be ascertained by using a string and passing it over all and then taking the length of string used. The cornices and centres should be well keyed. Centres ought to follow the form of the room in shape. If there be any imperfect joints they should be discovered and fixed before plastering.

PLUMBING AND SEWERAGE. — This is a subject on which there is great diversity of opinion. Although much has been discovered, and many improvements made in the last 10 years, our advances have only taught us how much more there is about which our knowledge is insufficient. Too much attention cannot be paid to sewer pipes for the whole system of plumbing, which represent the main arteries; and any defect soon spreads through the whole structure. Where possible, the rain water from the roof ought to be taken through them, which will give them a wash out not to be attained in any other way. The pipe must be laid with a good fall to the outlet, not less than $\frac{1}{4}$ to 1 ft., and the more obtained within a limited extent, the better; more fall than 1 in. to 1 ft. being superfluous. They must rest on solid ground; and where such cannot be obtained, a prepared planking must be laid under them in the trenches. All joints should be thoroughly cemented. Between the house and the point of discharge, whether a sewer or vault, there must be a trap, with the neck ventilated by a stand pipe extended to the level of the yard. If the discharge is into a vault, connected with the sewer, a second trap ought to be placed between the vault and sewer (not ventilated), which will prevent gas from the main from penetrating to the vault. All sewer pipe inside of buildings, in good work, are made of socket joint iron soil pipe; those outside may be of glazed clay. Take the sewer out of the building or cellar as soon as practicable. No sewer pipe ought to be laid in the vicinity of cisterns or wells, as the effect of one imperfect joint would be disastrous to the health of those using the water. A few words are needful on the subject of traps and ventilation. A trap is the bent portion of a pipe, or a receptacle so formed as to retain a body of liquid large enough to completely fill the section of the pipe, thus shutting off the air from such portions of the works as lie beyond the trap, i. e., the branches leading to the plumbing.

To overcome the pressure of such air, which frequently becomes charged with sewer gas, ventilating pipes are provided which connect with the trap on the side of the discharge, thus affording a free outlet for such air. By supplying all branches with a constant volume of air all siphonage of traps is avoided. Some professional men advocate the use of a ventilation system only, and use no traps; but as our knowledge is limited, it would seem best to employ both safeguards. Water has great affinity for gases. This can be seen by the short time necessary to taint water placed in a bucket in a freshly painted apartment. If we did not use a system of ventilation, the great pressure exerted by accumulated sewer gas would charge the contents of the traps, and by evaporation it would be discharged into the apartments. By providing an outlet this danger is reduced. The more simple and condensed the plumbing of a structure, the better. Washstands in living apartments should be avoided, and a door connecting bed rooms with bath rooms is often a cause of disease. This is a matter where convenience should not be regarded, for severe and dangerous sickness may follow such indulgence. Laundry sinks are set low, so as to facilitate the emptying of large tubs, etc. Kitchen sinks are of many varieties, plain iron, enameled, soapstone, etc., and should have good drain boards. It is preferable to place sinks on open frames, to inclosing them, as such cupboards are likely to harbor vermin. Butler's sinks are made of copper, of a shape to suit space. All sinks should have a screw plug in the bottom of the trap, to facilitate cleansing. Strainers are needed in the sink to catch large particles and prevent choking the trap. Washstands should have plug chains and rubber plugs. Bath tubs are made of tinned copper, 12 to 14 oz. per sq. ft., and need plugs and chains the same as washstands. By using rubber plugs, they never batter the receptacles. The waste pipe and overflow of baths and washstands should be separately trapped. Water closets are made in endless styles, of which the "pan closet" is the worst; a side outlet hopper closet with flushing tank, is the most perfect. All plumbing above the first floor should be lined underneath with sheet lead, turned up not less than 3 in. on the edges, and connected with the soil pipe by a separate waste pipe and trap. Boilers ought not to be tested to less than 150 lbs. pressure. The supply pipes are of extra strong lead, usually $\frac{3}{4}$ to $\frac{5}{8}$ inch from the street main to the kitchen sink. The waste can be of medium lead pipe. Joinings must be carefully made, and air chambers provided over all cocks, to prevent hammering in the pipe. The supply pipe must be laid so as to enable one to drain them completely at some point in the cellar. Compression faucets are best. Keep all soil and waste pipe as short as possible, as every inch adds to the surface, gathering foul matter and discharging sewer gas into the house. Never try to economize in this part of the dwelling. The many new improvements made in this branch, render it difficult to select the best; a good adviser in this work is the most effectual safeguard.

ROOFING.—*Shingles.* These are made of different kinds of wood, cedar, cypress, and white pine, sawed or shaved. The best shingle is of shaved cedar. As a rule the shaved shingle is better than the sawed; $4\frac{1}{2}$ in. lap to the weather is usual to a 16 in. shingle; but $5\frac{1}{2}$ in. is sometimes allowed on buildings of minor importance. They should be carefully blind-nailed to the sheathing of roofs. For shingle roofs, less than $\frac{1}{4}$ pitch is not advisable.—*Slate.* The best quality of slate comes from Maine and Pennsylvania quarries. A simple test for the quality, is to take a dry piece, and, after weighing, immerse it in a bucket of water; then, after a soaking of 24 hours, re-weigh; the less water absorbed the better the slate. Slate roofs should be put on over felt paper, carefully lapped; none but galvanized iron nails are trustworthy.—*Tin.* Ordinary roofing is designated by I. C. Bright tin. The best quality used for the purpose is the I. X. Bright. For portions not liable to be walked over, the tin should be put on with standing grooves, with the seams carefully locked and soldered. For ordinary work, every other sheet of tin should have a tag soldered to the underside, to fasten it to the sheathing. In good work every sheet should be back-tacked. Before the tin is put on the roof, both sides should be painted with 2 coats of mineral paint in oil.

STAIR-WAYS.—Stairs are usually divided into skeleton steps, boxed, and open flights. The pieces on which the steps are supported, are called "carriages." The horizontal piece on which one steps, is called the "tread," and the vertical piece the "riser." Skeleton steps have no risers, and are only used for cellar stairs. Boxed stairs have walls, or partition on both sides, against which the outside carriages are placed, and are enclosed stairs; although, in some cases, there may be a rail on one side, with the space between that and the floor boarded with partition stuff. In such stairs the treads and risers are grooved and glued together with small blocks glued and screwed in the inner angle of joint, and then placed on the carriages. To prevent a squeaking the bearings of the treads on the carriages should be kept level so as to bring the weight on all the supports. Open flights are of 2 kinds: those of which the face string, or outer carriage is cut out for the treads and risers, and then the nosing with scotia and fillet returned on the string, or extended around



on the string. The other variety has a close or curb string which hides the treads and risers

Stair with Open Face String.

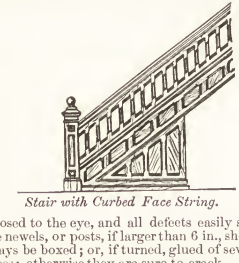
and continues in one width up with the slant of the stairs. Sometimes this string is ornamented. Rails are double-molded, and show the same shape on both sides. Balusters need no

Range Work.

Broken Ashler.

Tooled Margin.

description as they are of numberless forms, to suit taste and means. Great care should be taken in stair work, to secure accurate workmanship and dry material, as the entire work is



Stair with Curbed Face String.

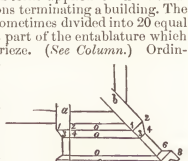
exposed to the eye, and all defects easily seen. The newels, or posts, if larger than 6 in., should always be boxed; or, if turned, glued of several pieces; otherwise they are sure to crack.

STONE WORK, Cut.—Is either drove, bush-hammered or tooled, and made to any degree of fineness. If the work required has to be fine, it is first cut to an even surface; then rubbed with a stone and fine sand and water. Stone fronts are generally built with thin stones, 4 in. or 5 in. thick, set on edges, and backed up with a brick wall, to which the stone is anchored with flat iron hooks with the outer end turned down and gained into the top edges of the stone; the other end turned up and built into the brick wall.

STONE WORK, Range.—A class of rough stone work facing the outer walls when exposed above grade, and consists of stones in even courses and regular height, and in rectangular blocks with the face left stone rough or with broken surface; the top, bottom and ends hammered off to admit of close, straight joints, which should be raise-pointed in best cement colored with lamp-black or bone-black, with straight oval joints. If the stories are of uneven height, and laid up without being kept in courses, the work is called "broken ashler;" if the face of the stones is worked off to an even surface with a pointed tool, it is called "pitch-faced work;" and, if dressed only on the margins, it is then "ashler" or "range work," with tool or drove margins.

STONE WORK, Rubble.—This means rough stone walls, built of promiscuous stones neatly fitted and bonded together, with the spaces filled with mortar. The stones should have flat bottoms and tops, and be selected and laid in the wall so as to break joints every time over each other on the space of the walls, and lap past each other, extending through the walls, and should be bonded every few feet with stones extending through the thickness of walls. All stones should be bedded in mortar, and spaces filled with mortar; where the spaces are large and stories irregular, such should be filled with spauls, or small stones, well bedded in mortar, so as to level up the walls to receive the stories above. These walls should be built 18 in. to 24 in. wide, to strength required; true and plumb to a line on both sides, with all joints and cracks neatly pointed.

CORNICE. — A term applied to horizontal molded projections terminating a building. The eaves cornice is sometimes divided into 20 equal parts, and is that part of the entablature which surmounts the frieze. (*See Column.*) Ordinarily it is composed of the fillet, cymatium, corona, ovolo and cavetto moldings and divided into 2 principal parts, the upper one of which projects beyond the lower, and is supported by modillions. The proportions of the cornice in rooms should be less than in halls, salons, etc. In rooms finished with a single cornice, it should not exceed 1-15 nor be less than 1-20 of the height of the room. The form of angle bracket for a cornice may be found as follows: Let *a* in the engraving be the common bracket; draw the parallel lines, *o o o*, to meet the mitre line, *c*; square up on each line at *c*, and set the distances, 1, 2, 3, 4, etc., on the



Angle Bracket.

common bracket, from the line, *d*, on the small lines from *c*; through these points, 2, 4, 6, etc., trace the form of the bracket.

DOME.—The concave covering of a building, and may be either a segment of a sphere, of a spheroid, or of any similar figure. When made of wood its strength depends on its construction. The usual form is that of the sphere. When the interior does not rise too high, a horizontal tie may be thrown across, by which any degree of strength may be obtained, and by means of which trusses may be formed on each side of the opening in the top. Upon these the whole frame-work is to depend for support, and their strength must be calculated accordingly. When the interior dome rises too high to admit of a level tie beam, the framing may be composed of a succession of ribs standing upon a continuous circular curb of timber. This must be well secured, as it serves to resist the lateral thrust of the ribs. In small domes the ribs may be cut from wide planks, but for large structures they must be built in 2 thicknesses, and placed 2 ft. apart at the base. The strength of the scantling varies with the size. For domes 24 ft. in diameter, 1x8 in. will be required, which will increase to 3x13 in. for one 108 ft. in diameter. The curve of equilibrium should pass through the middle of the depth of the framing. For an arched roof the curve of equilibrium is that of a parabola; for a dome having no tower or cupola above it, a cubic parabola; for one having a tower above it, an approach to a hyperbola, as great strength is required at its upper parts. The pressure of a circular dome is greatest at $\frac{1}{3}$ of its height; therefore an iron band should be placed around it at that height; also around or across the base. The boards may be applied either in the form of gores, or in portions of conic surfaces.—*To Find the Form of a Base or Covering for a Cone or Circular Dome.* Let *a*, *Fig. 1*, be the width of the base to the cone. Draw the line *b* through the centre of

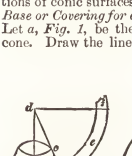


Fig. 1.

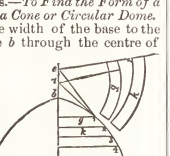

Fig. 2.

the cone; extend the line of the side *c*, till it meets the line *b* at *d*; on *d* for a centre, with 1 and 2 for a radius, describe *e*, which will be the shape of the base required; *f* will be the joint required for the same.—*To Find the Shape of Horizontal Covering for Circular Dome.* The principle which is employed is shown at *Fig. 2*, supposing the surface of the dome to be composed of many plane surfaces. The narrower the pieces the more accurately they will fit. Draw the line *a* through the centre of the dome, *Fig. 2*; divide the height from *b* to *c* into as many parts as there are to be courses of boards or tin. Through 1 and 2 draw a line meeting the centre line at *d*; that point will be the centre for sweeping the edges of the board *g*. Through 2 and 3 draw the line meeting the centre line at *e*; that will be the centre for sweeping the edges of the board *k*, and so on for the other courses.

DOORS.—Their construction should accord with the size and style of the building or apartment. The principal door of a public building should be 6 to 12 ft. wide, and proportionately high. The doors for a dwelling 2½ to 3½ ft. wide and a little more than twice their width in height. Closet doors 2 ft. wide, of even height with the other doors in the apartment. Folding doors should be used where greater width is required than 3½ ft.; the height about 1-10 greater than the adjacent single doors, and the width equal to 4-5 of the height, if the width of room allows. A 4 panel door is strongest. (See *Paneling.*) In doors having 2 panels, the stiles should be 1-7 of the width. Whatever the number of panels, the united widths of the stiles should equal 3-7 the width of the door. The bottom and lock rails should each be equal to 1-10 of the height of the door, and the top rail and all others of the same width as the stiles. The molding on the panel should be equal in width to ¼ the width of the stile. The lock rail is essential for strength and durability. Doors should be hung so as to open into rooms, and not into halls or passages. If it opens away to the right, it is a right-hand door; if to the left, it is a left hand-door. Doors are affected by an unequal temperature of adjoining rooms, causing the stiles to spring; this may be remedied by using three hanging butts. There is no rule as to the proper edge to which to affix the hinges.

DOVETAILING.—The dovetail joint shown in *Fig 1* consists of the pin, A, and the dove-tail B, the pins usually made first, and should be on the end or short side of the box. The marks, *e e e e*, show the size of the interior of the box when complete. Take the mitre bevel and set it about 60° or 70°, the angle is not important, and set off on the edge of each end of A the 2 outside pins, and any convenient number of pins between them, the bevel being reversed to mark the 2 sides of each pin. Produce the bevel round both faces of the board, with the square, as far as gauge lines *e e*. Now fix the board firmly on the bench, end up, and with the dovetail saw cut the gashes *c c c*. Lay the board flat on the bench, face down, and take a sharp chisel and a mallet, and give a cut exactly on the square line, *e*, between each pin. Turn the piece over, and cut from the other side gauge-line until the pieces between the pins are removed, taking care that the pins are not injured. Carefully square the spaces with the chisel, without using the mallet, and trim off the roughness left by the saw on the pins. Next take the front or back (2) of the box and lay on the bench inside uppermost, and place on it the end A on edge, with its inside edge touching the square mark *e*, and with its top and bottom edges flush with those of 2. Now, with the point of the striking-knife, mark off the bevels on the edges of each pin, and produce the lines with the square across the end of B and to the square mark on the other side, with the mitre bevel. Saw

lines *h h*, with the dovetail-saw, and remove spaces *i i* by chiseling out across the square

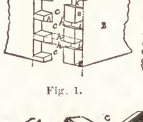

Fig. 1. Fig. 2.

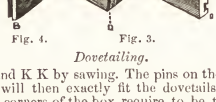

Fig. 4. Fig. 3.

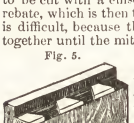
Dovetailing.

line, and K K by sawing. The pins on the ends of A will then exactly fit the dovetails in B. The 4 corners of the box require to be treated in the same way, the pins being worked on each end of the shortest side or end, and the dovetails on each end of the longest or side of the box. Glue in firmly, and after the work is dry plane off projecting ends. The appearance of the joint will then be as seen in *Fig. 2*, in which the end grain of the wood is shaded. *Fig. 3* represents the corner of a drawer as commonly made, on which, although the dovetails are seen on the side when the drawer is open, they are invisible in front. The latter having been planed up true, a line, C D, is made with the gauge on both ends of the same to mark the portion which is to be left uncut. Let the pieces be first rebated out, as A B, *Fig. 4*. The pins and dovetails are then to be cut with a chisel in both parts, below the rebate, which is then to be cut to a mitre. This is difficult, because the pieces cannot be fitted together until the mitreing is done. An easier method is the lap or secret dovetail, in which only one piece is rebated; but the dovetails in the other are not cut through. See *Fig. 5*. In this case no such difficulty occurs in marking and cutting the pins made in the rebated piece, and the pieces can be tried in their places with ease, as in common dovetailed work.

Fig. 5.

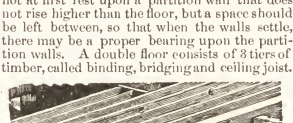


Secret Dovetail.

DURABILITY. — Certain timbers of great durability, when framed together produce mutual destruction. Experiments with cypress and walnut, and cypress and cedar, prove that they rot each other while joined together, but on separation the rot ceases, and the timbers remain sound for a long period.

ELASTICITY.—The quality of springing back, or toughness. The following is a comparison of the different woods: Ash is 1, fir .4, elm .54, pitch pine .57, teak .59, oak .63, spruce .64, yellow pine .64, cedar .66, chestnut .73, larch .84, beech .86.

FLOORS.— May be comprised in 3 following kinds: Single joisted floors, double floors, and framed floors. A single joisted floor consists of only one series of joist; sometimes every third or fourth joist is made deeper, with ceiling joist nailed across at right angles. This kind is used in ordinary buildings, where the span from wall to wall does not exceed 24 to 25 ft. Boards are laid transversely on the joist, and secured by long floor brads after having been pressed together by a screw attached to the joist like a vice during the process of laying and nailing. When a close floor is required, the planks must be jointed by a groove and tongue. After the planks have been nailed to the joist, the brads are countersunk, and the edges of the boards planed level. It is economy to have floors of narrow boards and good wood. Broad and poor boards shrink and leave cracks as vermin nests, and warp at the sides and ends and wear out carpets. Hemlock is probably the worst wood, and spruce or yellow pine the best. Oak is preferable. The combinations of walnut with chestnut, oak, and other lighter-colored woods, are durable, and save matting if carpets are removed in hot weather. The high temperature of the house, fire, hot-water pipes, etc., are severe; it is, therefore, necessary that the wood be well seasoned. What is called naked flooring are the joist which support the flooring boards and ceiling of a room. The wall plates or timbers which receive the ends of the girders or joist, should be sufficiently long and strong to throw the weight upon the piers. When the ends of girders lie over doors or windows, the strength of wall plates must be increased. Wall plates must be larger as their length and the weight of the floor increases; the scantlings will vary from 4½ by 3 in., to 7½ by 5 in. When the ends of joist are supported by outside walls whose height is great, the middle of such timbers should not at first rest upon a partition wall that does not rise higher than the floor, but a space should be left between, so that when the walls settle, there may be a proper bearing upon the partition walls. A double floor consists of 3 tiers of timber, called binding, bridging and ceiling joist.



Timbers Used in Flooring.

a a, girder; *b b*, binding-joist; *c c*, ceiling-joist; *d d*, wall-plates; *e e*, bridging-joist.

The binding joist is the principal support of the floor and run from wall to wall. The bridging joist lie transversely on the binders, and are attached to them by notching, or framed between with chased mortises. Ceiling joist are attached to the binders by notching, or pulley mortising. Framed floors differ from double floors in having the binding joist framed into

large pieces of timber, called girders. When the breadth of girders is considerable, it is an excellent method to saw them down the middle and bolt them together with the sawed sides outward. This gives an opportunity of examining the centre of the log, and reduces the timber to a smaller scantling and less liable to rot. The slips put between the halves or flitches should be thick enough to allow air to circulate freely. Single joisted floors, when the bearing exceeds 10 ft., should be cross-bridged between the joist, to prevent turning or twisting, and to stiffen the floor; when the bearing exceeds 15 ft., 2 rows will be necessary, and so on, adding another row for each increase of 5 ft. bearing. Single joisting may be used to any extent for which timber can be got deep enough; where it is desirable to have a perfect ceiling, the bearing should not exceed 18 ft., nor the distance from centre to centre be more than 16 in.; otherwise the bearing for the lath becomes too long to produce good work. Fire-proof floors may be made by filling a frame-work with concrete or cement, on which tiles may be laid to form the flooring, or joist of timber on which planks may be laid down and nailed in the ordinary way.

FRAMING. — The process of joining and fitting the timbers which comprise the skeleton of a building. A knowledge of the laws of pressure and strength of timber is imperative in determining the position and dimensions for the timbers which compose a roof, floor, partition, or bridge. Materials should be of good quality and in proper quantity, any superfluity being an injury. A heavy body exerts a pressure equal to its own weight in a vertical direction. When 2 supports are inclined at different angles, the pressure is proportionately unequal. The united pressures which are exerted by a weight upon 2 inclined supports will always exceed the weight. When the supports are not inclined equally, the strain will be greatest upon the support that has the greatest inclination to the horizon. The smaller the angle of horizontal inclination, the greater the pressure upon the supports. Correct ideas of comparative pressures can be formed by drawing designs of framing and estimating the strains according to the parallelogram of forces, always drawing the triangle so that the 3 lines shall be parallel with the 3 forces or pressures, respectively. If a scale cannot be had of equal proportions with the forces, the calculation is effected by making the line of the triangle that represents the known weight equal to the unity of a decimally divided scale, and measuring the other line in tenths and hundredths.

GLUING. — Carpenters use various forms of clamps to hold work until the glue is dry; but for those having no such convenience, the best plan is to bind the parts together with twine, and then set them aside for 12 hours. It is seldom that articles once united by glue and separated, will unite firmly a second time. (See GLUES in ADHESIVES.)

JOIST. — Narrow beams of timber about $2\frac{1}{2}$ in. thick, and varying in depth according to the extent of the span from wall to wall. As walls of successive stories are raised, the joist is laid across, 15 or 18 in. apart, and the ends imbedded in masonry. In building a row of houses, care should be taken to keep 7 in., at least, of masonry between the ends of the joist bridging the space from party wall to party wall, so as to prevent communication of the flames in case of fire. To steady the joist, cross struts are often nailed transversely to the joist and across each other like the letter *X*, at intervals of 2 or 3 ft. —*To Find the Depth of a Joist, the Length of Bearing and Thickness Being Given.* Divide the sq. of the length in ft. by the thickness in in., and the cube root of the quotient multiplied by 2.2 for pine, or 2.3 for oak, will be the depth in in.

TABLE OF SCANTLINGS OR JOIST FOR DIFFERENT BEARINGS, FROM 5 TO 20 FT.

Length of Bearing in Feet.	Thickness 2 in.	Thickness $2\frac{1}{2}$ in.	Thickness 3 in.	Thickness $3\frac{1}{2}$ in.	Thickness 4 in.
	Depth in In.	Depth in In.	Depth in In.	Depth in In.	Depth in In.

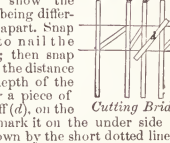
—*To Find the Depth of a Girder when the Length of Bearing and Thickness of the Girder are Given.* Divide the sq. of the length in ft. by the thickness in in., and the cube root of the quotient multiplied by 4.2. for pine, by 4.34 for oak, will give the depth required in in.—*To Find the Thickness when the Length of Bearing and Depth are Given.* Divide the square of the length in ft. by the cube of the depth in in., and the quotient multiplied by 74 for pine, or by 82 for oak, will give the thickness in in. In these rules the girders are supposed to be 10 ft. apart, and this distance should never be exceeded; but should the distance apart be more or less than 10 ft., the thickness should be proportionate.—*To Cut Bridging to Fit Exactly the First Time.* Let *a*, etc., show the floor beams, being different distances apart. Snap a line at *c* to nail the bridging by; then snap another at *d*, the distance from *c*, the depth of the timber. Lay a piece of bridging stuff (*d*), on the timber, and mark it on the under side by the timber as shown by the short dotted lines; saw correctly, and it will fit exactly when in place,



Cutting Bridging.

no matter what distance apart the timber is.

LADDERS. — The most desirable timber for the sides of ladders, is straight-grained white pine or basswood; these are light and tough. For a ladder 20 to 25 ft., have a plank sawed 2 in. thick, 8 in. wide, and length desired. It should be carefully laid away to season. When sawing, mark out so that the bottom of the side will be 5 in. wide and the top 3 in. In a 20 ft. ladder the sides at the top should be 13 in. apart, and 20 in. at the bottom. The rungs should not be less than 1 in. in diameter, of seasoned tough wood, pinned in position; the whole then painted and hung up under shelter. A ladder should be of length sufficient to reach the roof of the highest building in case of fire, or for repairs. A straight, second growth white pine, 6 in. in diameter at the butt, if peeled and split in 2, will make durable sides. Chestnut and other light woods may be used for the same purpose.

LATHING. — The process of nailing lath to the studding of a partition or joist of a ceiling. Lath is made in 3 and 4 ft. lengths, and is called single, lath and a half, and double, according to thickness. The first is the thinnest; the second about $\frac{1}{8}$ thicker, and the double twice as thick as single. Single lath is used for partitions, and the double for ceilings. Both lengths should be used for ceilings to enable the plasterer to break the joints, thereby improving the general key, and strengthening the ceiling. The ends of lath should never be lapped when they terminate upon a quarter or batten. Lath come in bundles of 100 each; 10 bundles, or 1,000 lath, will cover about 60 sq. yds., and will require about 7 lbs. of 3-penny nails.

LUMBER. — The best is that sawed from timber which has attained full maturity before being felled. The logs are cut from November to March; then hauled to the nearest stream and deposited to be rafted. When not rafted, or joined together, the logs are marked separately and floated. When ice breaks up and streams begin to swell, the process of guiding the lumber down the stream commences. When at its destination, it is taken to the saw-mill and cut into beams, posts, planks, seantlings, etc. — *Piling.* Lumber should not depreciate for lack of care in piling. Piles should be built so that the front cross-piece shall be higher than the back, and each in succession overlapped beyond the previous one. A pile 20 ft. high should incline outward from base to top 18 or 24 in., which will prevent storms from eating in, or snow from resting to melt and form ice. The sides should be carried up plumb, each cross-piece on top of another, so that the weight shall rest solidly on the foundation timber. If the courser be placed a little forward or back of the previous one, the weight above will warp and perhaps break the lumber. Piles should never be placed less than 3 ft. apart, and boards in the pile should be laid with 2 to 4 in. space between them. — *Rules for Measurement.* The unit of board measure is 1 sq. ft., 1 in. thick, when speaking of the contents of timber. The contents of a board, seantling or plank, can be ascertained by multiplying the length of the board in ft. by the width in in. and that by thickness, and dividing the product by 12; the result is the sq. ft. of the board. If the board or joist is broader at one end than another, multiply the length in ft. by the breadth of the middle in in. and divide by 12; or add together the width of the ends in in., and multiply the length by $\frac{1}{2}$ this sum, and divide by 12; the result is the number of sq. ft. in the board. Pine and spruce spars, 10 to 4½ in. in diameter are estimated by taking the diameter, minus the bark, at $\frac{1}{3}$ their length at the large end; they are bought and sold by the in. diameter, all under 4 in. called poles. Round timber is sold by the cu. ft., and when squared by hewing or sawing is estimated to lose 1-5; hence 1 ton of round timber is estimated to contain 40 cu. ft. The rule for measuring the contents of round logs, is to multiply the length by the sq. of $\frac{1}{4}$ the girt in in., taken about $\frac{1}{3}$ the distance from the larger end, and then divide the product by 144; the quotient is regarded as the contents in cu. ft. Square timber, hewn or sawn, is sold by the cu. ft., and rated at 60 cu. ft. to the ton, but, as usually surveyed, 1 ton of timber contains 50 and 92-100 cu. ft.

MITREING.—Joining 2 pieces of wood by gluing, the ends of which have previously been planed to an angle of 45°, and matching together, so as to form a right angle. Joints can be cut at once, without gauging and measuring to find the proper angle, with the aid of the mitre box; it has cuts in the sides at angles of 45°.

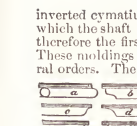
Mitre Box.

MORTISING AND TENONING. — Joining two pieces of wood at right angles, and generally adopted in heavy work, such as tables, doors and window sashes. A cavity, called a mortise, is cut into one piece of wood to receive the end of another piece shaped to fit, called a tenon. The mortise is marked on both sides of the wood by means of square and gauge, and cut equally from both sides by means of a chisel, care being taken to keep within the guide lines. The tenon is measured in the same manner as the mortise, and the cheeks cut away with a fine saw. If, instead of the outer cheeks, the piece between them is to be removed to make a double tenon, this must be done with a mallet and chisel, after sawing down the lines; the chisel used first on one side and then on the other, by which means the shoulder will be cut true to the guide lines. After joining, a small wedge is brushed with glue and driven in on each side of the tenon.

Mortising and Tenoning.

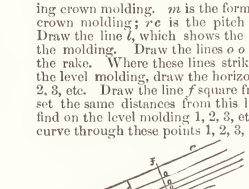
MOLDINGS. — The ornamental curved and plane projections used in cornices, arches, panels, wainscoting, etc. The regular moldings are 9 in number, as follows: Band or fillet, a low, flat, broad, but not deep circle; astragal, or bead, a narrow, curved ring; torus is large, semi-circular, and resembles a rope; scotia, sunken, or concave; ovolo, quarter round and egg-shaped; cavetto, cave, or hollow; cymatium, waved, upper part hollow, lower part swelling; ogee,

inverted cymatium; apophyge, the curve with which the shaft escapes into its base or capital, therefore the first molding in the entablature. These moldings are common to all architectural orders. The fillet, astragal and torus bind the parts; the ovolo and ogee support the projecting parts above them; the cymatium and cavetto core placed uppermost to cover and shelter the other parts; the scotia is introduced in the base of a column to separate the upper and lower torus, to give variety and relief. For beading and molding, the iron of the plane is filled into the shape of the molding it is meant to produce. That for a simple bead is made with a plane. The piece is first planed accurately to the width and substance required, and the plane is then applied, not perpendicularly, but on a slope, the edge and sole of the plane parallel to the surface to be cut, so that the strip may be planed to such inclination. The illustration shows how to find the form of raking crown molding. *m* is the form of the level crown molding; *r c* is the pitch of the roof. Draw the line *l*, which shows the thickness of the molding. Draw the lines *o o o* parallel to the rake. Where these lines strike the face of the level molding, draw the horizontal lines, 1, 2, 3, etc. Draw the line *f* square from the rake; set the same distances from this line that you find on the level molding 1, 2, 3, etc. Trace the curve through these points 1, 2, 3, etc., and you have the form of the raking molding. Hold the raking molding in the miter box, on the same pitch that it is on the roof, the box being level, and then cut the miter in that particular position.



Moldings.

a, astragal; *b*, ogee; *c*, cymatium; *d*, cavetto; *e*, scotia, or cassement; *f*, apophyges; *g*, ovolo, or quarter round; *h*, torus; *i*, reeding; *j*, band.



Finding Form of Crown Molding.

NAILS, Kinds and Sizes.—The following table gives the kinds of nails required:

3	penny, fine	1¼	in.	long,	720	in 1 lb.
3	" common	1¼	"	"	400	" " lb.
4	" "	1½	"	"	300	" " lb.
5	" "	1¾	"	"	200	" " lb.
6	" "	2	"	"	150	" " lb.
7	" "	2¼	"	"	110	" " lb.
8	" "	2½	"	"	85	" " lb.
9	" "	2¾	"	"	75	" " lb.
10	" "	3	"	"	60	" " lb.
12	" "	3¼	"	"	50	" " lb.
16	" "	3½	"	"	40	" " lb.
20	" "	4	"	"	22	" " lb.
30	" "	4½	"	"	16	" " lb.
40	" "	5	"	"	12	" " lb.
50	" "	5½	"	"	10	" " lb.
60	" "	6	"	"	8	" " lb.

CASING NAILS.

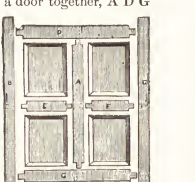
6	penny	2	in.	long,	220 in 1 lb.
8	"	2½	"	"	125 " " lb.
10	"	3	"	"	85 " " lb.
12	"	3¼	"	"	63 " " lb.

FENCE NAILS.

6	penny,	2	in.	long,	80 " " lb.
8	"	2½	"	"	50 " " lb.
10	"	3	"	"	30 " " lb.

From 4½ to 5 lbs. 4 penny nails, or 3 to 3½ lbs. 3 penny nails will lay 1,000 shingles. 5¾ lbs. 3 penny fine lath nails will put on 1,000 lath, joist being 16 in. to centres; 2½ lbs. 8 penny common nails will lay a square of flooring of 5½ in. matched boards, joist being 16 in. to centres; 2½ lbs. 7 penny nails will put on a square of lap siding, showing 4 in. to the weather.

PANELING.—The process of fitting thinner pieces of wood into frames, into the edges of which grooves have been cut to receive the panel. A B C in the illustration are the styles; D E F G the rails. The mortises and tenons are cut as usual. The inside edges of C B D G are then grooved with the plow, and both edges of the other pieces. The panels are squared up, and then beveled off at the edges to fit the grooves. To put such a door together, A D G E and F would be first arranged, then the panels slid in from the outside, and afterwards the stiles B and C put in place. The part beyond the outer mortises in the latter pieces, which are left for safety in cutting these mortises, and to prevent splitting when D and G are driven home, are not cut off until the glue is dry. The process is simple, but it requires care, both in setting out the measurements, and in squaring up the pieces. After the whole is dry, strips of molding, cut to miter-joints at the corners, are nailed on with brads round the panels to give a finished appearance.



Paneling.

PARTITIONS.—The settling of floors and cracking of ceilings and walls may be attributed to carelessness in constructing this part of the framework of a house. A partition should, if possible, be supported by the walls with which it is connected, in order that it may settle with the walls. The stud in a partition should be placed to throw the weight upon the points of support. All oblique pieces that do not tend to this, are better omitted. In partitions constructed for doors at the ends, the truss is formed above the door heads, and the lower parts suspended from it. The posts are halved and nailed to the tie and the sill. The braces in a trussed partition should be placed so as to form an angle of 45° with the horizon. The filling in pieces should be stiffened by short struts placed 3 ft. apart. The principal timbers should have the edge chamfered off, to allow the mortar to pass between and clinch the lath, thereby strengthening the plaster. When the

timbers require to be large for the purpose of greater strengtb, omit upright filling in pieces, and instead place a few horizontal pieces to sustain batten for lathing. Wbere practicable, the stud of a partition should extend down between the floor beams to the plate of tbe partition beneath.

PLANING.—The difficulty which amateurs experience in using the plane arises from its being badly set. If either corner projects beyond the level of the sole of the plane, this will score channels. Hence the extreme angle should be rounded off in sharpening tbe tool. The same effect will be produced if the plane iron is not ground square. The smaller, or break iron, whose office is to bend up the shaving somewhat sharply, should be placed to come within ⅛ in. of the extreme edge of the cutter for rough work, and within 1-20 for finer or finisbing work. The two should then be placed in position, so that the edge projects tbe smallest possible degree below the sole. The position can only be determined by looking along the bottom of the plane, with the point of the same next to the eye. The edge will, if correctly formed and placed, appear parallel with the sole. The same rule applies to small and large planes, except that in the jack plane the iron projects rather more, as it is used for roughing down. The longer the plane, the more accurately true will be the work. The jointer plane is longer than the trying plane. That used by the cooper for jointing staves of casks is longer still, so that it is leaned against a support, and the work taken in hand and moved to and fro along its sole. To plane long, thin slips, which would bend and break if set against the planing stop, tack them to the bench at the end next the right hand by running a brad-awl through and pinning them down; the action of the plane tends to stretch instead of doubling up tbe strip. Mitred edges or bevels are planed similar to those which are rectangular. For those which run lengthwise of the board, a long planing guide is needed, on which the plane sole, and its side, rest in positions according to the angle required. The drawback to such planing boards is the liability to cut the guide, and when it is of iron the tool is of course liable to injury. It will often be found best to place the plank edgewise in the bench vice, and with a gauge set the exact thickness; after it has been planed square, run a fine line on the flat side. (See *Plane* in *Carpenter's Tools.*)

POSTS.—Red cedar, cypress (see *Cypress* in Forestry) and yellow locust are the most durable for fence posts, the latter having been known to do good service for 20 years; the former is even more durable. White oak cut at the right time and well seasoned, is good; but chestnut is better; walnut is good for posts, and will stand for years free from rot. Experiments have proved that posts put in the ground in the same position as that in which they grew, rotted in 12 years, while their neighbors cut from the same tree, and placed top down, showed no signs of decay for years after. The theory is that the capillary tubes are so adjusted as to oppose the rising moisture when the wood is inverted.

PRESERVATION. — Wood is preserved by any agent which destroys the tendency to putrefaction, enables it to resist the attacks of insects and renders it unsuited to the growtb of fungi which produce dry rot. 1. The artificial preservation of timber is attained by injecting into the wood by hydrostatic pressure of a heavy liquid column, a solution of the acid tannate of iron. The principle is that the action of tannin upon the tissues is analogous to that which it exercises upon the animal tissues, effecting upon the former a kind of tanning, having for its result the formation of hard and imputrescible tannates, corresponding to the gelatinous tannates produced in the tanning of skins. The application fixes the putrescible matter in unalterable combinations, thus preventing decomposition.—2. The construction of air-drains around wood-work to be preserved is, where applicable, a great aid to the preservation of wood. — 3. Burnetizing lumber protects it from decay, and renders it almost as indestructible as stone from the ravages of fire. Experiments have demonstrated that wood thus treated will not burn with a blaze even in the most intense fire, but smoulders and wastes away. Burnetized shingles would not only endure the waste and wear of time, but they are as much a protection against fire as is slate. — 4. Wood carbonized by charring the surface prevents decay from exposure to air and moisture. Stakes and piles are thus treated before they are driven into the ground. Casks are charred on the inside when intended to hold water. In both cases the fire is commonly applied directly to the wood. — 5. Shingles are rendered more durable and less combustible by the following process: Water, 1 gal.; chloride of zinc, ½ lb.; digest the wood in this 48 hours; drain, and put into a solution of crude tungstate of soda, 1 lb., water, 1 gal. (hot) for 3 hours; then dry. — 6. Wood steeped in a solution of copperas becomes harder and more indestructible. — 7. Impregnation with creosote water or the "heavy oil" from coal tar distillation is an effectual preventive against the attacks of the teredo, an animal that destroys wood exposed to sea water. In using it care should be taken that the oil is of good quality, the impregnation thorough, and that woods be used that will absorb the oil readily, as fir and other resinous woods. — 8. Kyanizing is another method of preserving wood and cordage from decay. It consists in immersing the materials in a solution of corrosive sublimate, 1 part, and water, 50 or 60 parts, either under strong pressure or the contrary, as the urgency of the case or the dimensions of the articles may require. — 9. Preserving wood by the application of lime is found to work well. The plan is to pile the planks in a tank, and to put over all a layer of quicklime, which is gradually slaked with water. Timber for mines requires about 1 week to be impregnated, and other wood more or less time, according to its thickness. The material it is said acquires consistence and hardness and will never rot. Beech wood prepared in this way for bammers is found to acquire the hardness of oak, without parting with any of its elasticity or toughness, and lasts longer. — 10. Posts treated to 2 or 3 coats of boiled linseed oil and finely-powdered charcoal mixed to a paint will last as

long as iron in the ground and can be prepared for less than 2 cents a piece. They should be well seasoned before applying the mixture. — 11. A mixture of skim milk and brine is recommended as a wash for outbuildings, roofs, etc., being durable, cheap, impervious to water and rendering the wood uninflammable. — 12. Logs and planks split at the ends because the exposed surface dries faster than the inside. Saturate muriatic acid with lime, and apply like whitewash to the ends. The chloride of calcium formed attracts moisture from the air and prevents splitting. Tobacconists' signs have usually a hole bored through their centre from top to bottom; this prevents the outer surface from cracking, by allowing the wood to dry uniformly. — 13. A new method of carbonizing wood has been employed with apparent success. This consists in washing the wood with the strongest oil of vitriol. In this way the outer surface gets carbonized. It succeeds admirably with musty casks and vats. — 14. Wood impregnated with paraffine oil is preserved for years from rot, even under circumstances favorable to decay. Wooden taps, etc., are liable to crack. To prevent this, lay them in a bath of fused paraffine heated to 212° Fahr., and leave them as long as bubbles of air are given off. Then allow the paraffine to cool down to its point of congelation, remove the wood, and wipe off adhering wax; it may be used for inlaid woods and furniture. — 15. To prevent wood from shrinking or swelling, use the following: Paraffine, 1 lb.; benzole, 2 gals.; dissolve; digest the wood (dry) in this solution several days; dry in the air; then heat to about 250° Fahr., in an oven. — 16. Wood exposed to the weather is rendered durable by the application of crude petroleum. — 17. Pitch is a good preservative. — 18. Pillars of wood impregnated with salt last unimpaired for ages. Wooden piles driven into the mud of salt flats and marshes last an unlimited time, and are used for the foundation of brick and stone edifices; and the practice of docking timber by immersing it some time in sea-water, after it has been seasoned, is admitted to be promotive of durability. Experiments appear to show that even after dry rot has commenced, immersion in salt water checks its progress and preserves the remainder of the timber. Posts treated as follows, have been found sound at the end of 14 years: Bore a hole lengthwise into the post from the lower end, and somewhat deeper than the post is to set in the ground; 1½ in. is large enough for the diameter of the hole. Fill nearly full of dry salt, and plug tightly with a dry plug, being careful not to split the post. — 19. A process valuable for railway sleepers: Steam the timber and inject a solution of silicate of soda 8 hours; then soak the wood for the same period in lime water. — 20. Dry rot is prevented in new buildings and cured in old ones by filling up the spaces between the floor-joist with tank-waste from alkali works; it can also be applied to the ends of beams resting in walls. — 21. The following is a preventive against decay: Mix 40 parts chalk, 50 parts resin, and 4 parts linseed oil; melt together in an iron pot; add 1 part native oxide of copper, then 1 part sulphuric acid. Apply with a brush. When dry it is as hard as stone. — 22. Wood may be rendered indestructible as follows: The apparatus consists of a retort, in which resin, coal-tar, or other oleaginous substances, together with water, are placed to subject them to heat. Fire is applied beneath the retort, oleaginous vapor commences to rise, and passes out through a pipe into an iron tank containing the timber to be operated on. The heat acts on the wood, causing the sap to flow from every pore, which, rising in the form of steam, condenses on the body of the chamber and discharges through an escape pipe in the lower part. In this process a temperature of 212° to 250° Fahr. is sufficient to remove the moisture from the wood; but, after this, the temperature should be raised to 300° or more, in order to completely saturate the body of the wood with the antiseptic vapors and heavier products of the distillation. The hot vapor coagulates the albumen of the wood and opens the pores, so that a large portion of the oily product or creosote is admitted; the contraction resulting from the cooling process hermetically seals them, and decay seems impossible. There is a man-hole in the retort, used to change or clean out the contents; and the wood chamber is furnished with doors perfectly tight. The whole operation is completed in less than 1 hour, rendering the wood proof against rot, parasites, and the attacks of the naval worm.

RAFTERS. — The timbers that support the covering of a roof. The principal rafters are placed at intervals of 10 ft., or less, to which are attached the purlins or cross-pieces, forming the truss which supports the common rafters and the weight of the roof. The upper ends abut against the king-post, and the lower ends against the tie beam. The common rafters are usually notched down upon the purlins, their feet resting upon a piece of timber running longitudinally along the sides of the building, called the pole plate, and their summit abutting against the ridge-piece extending from one king-post to the other. When desirable that the common rafters should not stand above the principals, the purlins are framed by mortises and tenons into the principals. The longest rafters in a hip roof are those at the angles, called hip rafters, and the shorter ones jack rafters. — *To Find the Lengths and Bevels of Hip and Common Rafters.* Let *p p p* in *Fig. 1*, represent the face of the plates of the building; *d* the deck-frame; *a* is the seat of the hip-rafter; *b*, of the jack; and *c*, of the common rafter. Set the rise of the roof from the ends of the hip and common rafter towards *e e*, square from *a* and *c*; connect *f* and *e*, then the line from *f* to *e* will be the length of the hip and common rafter, and the angles at *e e* will be the down bevels of the same. — *To Find the Length and Bevel of the Jack Rafters.* *b* in *Fig. 1*, is the seat of a jack-rafter. Set the length of the hip from the corner, *g*, to the line on the face of the deck-frame, and join it to the point at *g*. Extend the jack, *b*, to meet this line at *h*; then from *i* to *h* will be the length of the jack-rafter, and the angle at *h* will be the top bevel of the same. The length of all the jacks is found in the same way, by extending them to

meet the line *h*. The down bevel of the jacks is the same as that of the common rafter at *e*. — *To Find the Backing of the Hip Rafter.* At any

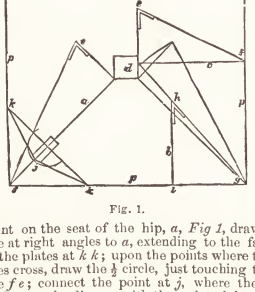


Fig. 1.

point on the seat of the hip, *a*, *Fig 1*, draw a line at right angles to *a*, extending to the face of the plates at *k k*; upon the points where the lines cross, draw the ½ circle, just touching the line *f e*; connect the point at *j*, where the ½ circle cuts the line *a* with the points *k k*; the angle formed at *j* will be the proper backing of the hip-rafter. It is not worth while to back the hip-rafter unless the roof is ½ pitch or more.

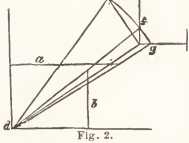

Fig. 2.

It is desirable to have the hip-rafters on a mitre line, so that the roof will all be the same pitch; but when this cannot be done the same rule is employed, but the jacks on each side of the hip are different lengths and bevels. The heavy line from *d*, *Fig. 2*, shows the seat of hip rafter; *a* and *b* the jacks. Set the rise of the roof at *e*; set the length of the hip, *d e*, from *d* to *f* on one side of the deck, and from *d* to *g* on the other side; extend the jack, *b*, and all the jacks on that side, to the line *d f* for the length and top bevels; extend jack, *a*, and all on that side, to the line *d g*, for the length and bevels on that side of the hip. The down bevels of the jacks will be the same as that of the common rafters on the same side of the roof. The lengths of hips, jacks, and valley rafters should be taken on the centre line, and the thickness or ½ thickness allowed for. (See *Fig. 3.*) Let *a b*, *Fig 4.* represent the valley-rafter; *j j* are corresponding jack-rafters. Set the rise of the roof from *a* to *c*; connect *b* and *c*; from *b* to *c* is the length of the valley-rafter, and the angle at *c* the bevel of the same; set the length, *b c*, on the line from *a*; extend the jack, *j*, to meet the line *b d* at *e*; then from *e* to *f* is the length of the jack, and the angle at *e* the top bevel of

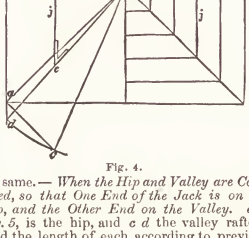

Fig. 4.

the same.— *When the Hip and Valley are Combined, so that One End of the Jack is on the Hip, and the Other End on the Valley. a b, Fig. 5,* is the hip, and *c d* the valley rafters. Find the length of each according to previous directions; find the lines *e* and *f*, as before. Extend the jacks, *j j*, to the line *e*, for the top bevel on the hip; extend the same on the other end to the line *f* for the top bevel on the valley; the whole length of the jacks is from the line *f* to the line *e*. If the hip and valley rafters lie parallel, the bevel will be the same on each end of the jack. In framing a hip-roof without a decking or observatory, a ridge-pole is used of such a length as to bring the hip on a mitre line; but this ridge-pole must be cut ½ its thickness longer at each end, or the hip will be thrown out of place. This is illustrated by the figure.

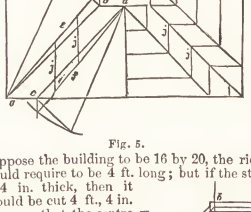

Fig. 5.

Suppose the building to be 16 by 20, the ridge would require to be 4 ft. long; but if the stick is 4 in. thick, then it should be cut 4 ft., 4 in. long, so that the centre line on the hip *a* will point to the centre of the end of the ridge pole *b* at 4 ft. long. — *To Find the Curve of the Hip.* Let *a*, *Fig. 7*, be the common

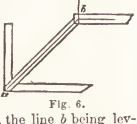

Fig. 6.

rafter in its true position, the line *b* being level. Draw the line *c c* on the angle the hip-rafter is to lie, generally a mitre line; draw the small lines *o o o* parallel to the plate *p*. The more of these lines the easier to trace the curve; continue the lines *o o o* where they strike the line *c c*, square from that line; set the distances

1, 2, 3, 4, etc. (on *a* from the line *b*), on the line *c c* towards *e*, at right angles from *c c*; through these points, **2**, **4**, 6, 8, etc., trace the curve,

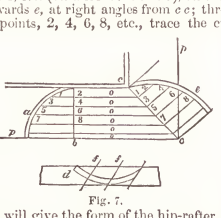

Fig. 7.

which will give the form of the hip-rafter. To get the joints of the jack-rafters, take a piece of plank, *d*, *Fig. 7*, the thickness required, wide enough to cut a common rafter; mark out the common rafter the full size; then get the lengths and bevels the same as a straight raftered roof, which this will be, looking down upon it from above; then lay out the joints from the top edge of the plank, as *f f*; cut joints first; saw out curves afterwards, and the jacks are ready to put up. Cut one jack of each length by this method, then use this for a pattern for the others. It will be seen that the down bevel is different on each jack, from the curve, but the same from a straight line, from point to point of a whole rafter. — *An Easy Way to Find the Lengths and Bevels of Common Rafters.* Suppose a building is 40 ft. wide, and the roof is to rise 7 ft., place the steel square on a board (*Fig. 8*),

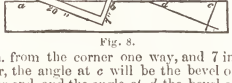

Fig. 8.

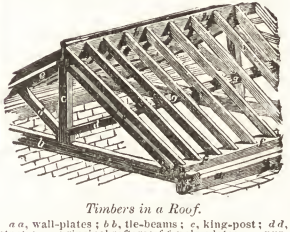
20 in. from the corner one way, and 7 in. the other, the angle at *c* will be the bevel of the upper end, and the angle at *d* the bevel of the lower end of the rafter. The length of the rafter will be from *a* to *b*, on the edge of the board. Always buy a square with the inches on one side divided into 12ths. The 20 in. shows the 20 ft., $\frac{1}{2}$ the width of the building; the 7 in. the 7 ft. rise. Now the distance from *a* to *b*, on the edge of the board, is 21 in., 2-12 and $\frac{1}{2}$-12; therefore this rafter will be 21 ft., $2\frac{1}{2}$ in. long.

RESONANCE. — The tone of musical instruments may be improved, and the wood rendered impermeable to temperature and moisture, by subjecting it to the action of pure oxygen ozonized by the passage of the electric current, and heated. The tone of the instrument is said to then improve with age rather than to deteriorate.

ROOFS. — In the construction of roofs, the climate is an important consideration, and they should be strengthened with reference to the weight of snow and force of wind. The weight of sliting per ft. on the inclined surface of a roof is about 7 lbs.; of roof plank, $1\frac{1}{4}$ in. thick, about 2.7 lbs.; of beams and jack-rafters, 2.3 lbs. The pressure per ft. on a horizontal roof is twice as great as that upon an inclined roof. The weight of trusses is nearly in proportion to their length and distance apart. The weight per ft. which the truss is to sustain, is found by dividing its weight by the span, and by the distance apart from centres at which trusses are placed. The weights of the ceiling beams and plaster upon the tie beams is 9 lbs. per ft. The force of wind may be reckoned as high as 50 lbs. per ft., and the weight of snow in proportion to the depth it acquires in a particular climate. Multiply the weight of the snow, 8 lbs. per cubic ft., by its depth. Next, allow for the strain by storage, dormitories, etc. Having found the weight per ft. of different pressure, the total weight is found by multiplying the weight by the area, which gives the weight supported by braces, suspension rods, rafters and tie-beams. To prevent walls from being pushed out of perpendicular by the weight of the roof and thrust of rafters, the latter are framed into a timber called a tie-beam, which is partially supported and prevented from sagging or bending in the middle, by securing it to the king-post by means of scantling, which combination is called a truss.



Timbers in a Roof.

a a, wall-plates; *b b*, tie-beams; *c*, king-post; *d d*, struts; *e e*, principal rafters; *f f*, pole-plate; *g g*, purlin; *h h*, ridge-piece; *i i*, common rafters.

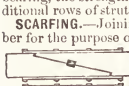
When the width of the span exceeds 30 ft., 2 upright posts called queen-posts are introduced, and a piece of timber called a collar inserted between, to prevent the posts from being drawn towards each other, and all trussed by scantling. When economy is desired, the king-post is omitted, and the rafters held by cross-pieces; this should never be done when the span exceeds 25 ft., nor where particular strains are to be provided against. When the span exceeds 45 ft. struts should be placed between the queen-posts, in addition to straining piece between them. For a span of 20 ft., tie-beams should be 9 by 4 in.; for 30 ft., 11 by 6 in.; for 40 ft., 12 by 5 in.; for 50 ft., 13 by 8 in.; for 60 ft., 15 by 10 in.; all other timbers proportionately increased in strength. When a span exceeds 35 ft., both king and queen-posts are used, and the distance between such supports should not exceed 13 ft. Tie-beams should never be omitted to accommodate an arch in the ceiling, as the powerful lateral strains exerted by the oblique position of

Queen-Post Roof.

a a, queen-posts; *b*, tie-beam; *c c*, struts or braces; *d d*, purlins; *e*, straining beam; *f f*, common rafters; *g g*, wall-plates; *h*, ridge-piece.

the supports tend to separate the walls. When the ends of joist cannot have a bearing upon the wall, a piece of timber, called a trimmer, is framed into 2 of the nearest joist. When the bearing of a joist exceeds 8 ft., a row of strutting pieces should be introduced to prevent horizontal twisting. For every increase of 4 ft. in the bearing, the strength should be increased by additional rows of strutting well fitted.

SCARFING.—Joining 2 or more pieces of timber for the purpose of lengthening, so that they may be equal in strength to a single piece of timber of the same length and strength. It is performed by indenting the joints, and passing bolts through the pieces within the lengths of the indents, and confining the bolts above and below by means of nuts and screws. Scarfing requires great accuracy, for if the indents do not bear equally, the greater part of the strength will be lost.



Various Modes of Scarfing.

SEASONING. — Green wood is seasoned by immersion in water a few weeks; this withdraws the sap rapidly, and subsequent exposure to the air thoroughly seasons it; in small pieces, the sap can be extracted in a few hours by boiling. Boards and all small timber liable to warp, are dried slowly in a kiln. Large timber is piled so as to allow ventilation; it is covered and allowed to dry 3 or 4 years. Its position should frequently be changed by repiling.

SHINGLING. —It is poor economy to use inferior shingles; it costs more to lay them, and they make a leaky roof. Spruce is used, but warps, twists and splits. Soft pine and cedar are cheapest in the end. Imperfect ones should be thrown out. A bundle of shingles has 25 courses on each end, and is 20 in. wide; or 22 courses on one end and 23 on the other, and 22 in. wide; 4 bundles contain 1,000. 1,000 shingles, laid 4 in. to the weather will cover 111 sq. ft.; laid $4\frac{1}{2}$ in., 125 ft.; laid 5 in., 139 ft.; 1,000 shingles require 5 lbs. 4-penny nails, or 3 to 4 lbs. 3-penny nails to lay them.

SHUTTERS, Inside. — Inside shutters, folding into boxes, require to have the box shutter 1 in. wider than the flap. The usual margin shown between the face of the shutter when folded into the box and the quirk of the stop-bead, or edge of the casing, is $\frac{1}{2}$ in.; and, in letting the whole of the thickness of the butt hinge into the edge of the box shutter, allowance must be made for the throw of the hinge; this may be estimated at $\frac{1}{4}$ in. at each hinging; which, being added to the margin, the entire width of the shutter will be $1\frac{1}{2}$ in. more than the width of the frame in the clear. To ascertain the width of the box shutter, add $1\frac{1}{2}$ in. to the width of the frame in the clear, between the pulley stiles; divide this product by 4 and add $\frac{1}{2}$ in. to the quotient, and the product will be the width.

STAIR BUILDING. — It is desirable to have stairs near the centre of the building. This position cannot always be accorded, because of insufficient light, unless a skylight is provided, which is desirable for ventilation. Landings should be introduced at intervals. The width of stair-case should accord with the importance of the building. From 3 to 5 ft. is sufficient for private dwellings and 8 to 12 for public halls, and should not occupy more than $\frac{1}{3}$ the width of the hall. The first step in the process of construction is to measure the height of the story from the top of one floor to the top of the next; also the run or distance horizontally from the landing to where the first riser is placed. The riser (see *Stairways* in BUILDING) varies in height. In first-class dwellings it is about 6 in. Upon the height of the rise depends the ease of ascent. The height of the rise will depend upon the number of steps. The greater the number of steps, the lower should be the rise. The number of risers is determined by dividing the number of in. in the height of the room, by the desired number of in. in the rise of the step. If there is plenty of room for the run, the step, or tread, should be made 10 in. wide, besides the nosing or projection; but if the run is limited, divide the number of in. in the run, by the number of steps, which is one less than the number of risers, because the upper floor forms a step for the last riser. The next step is the pitch-board. The hypothenuse of the pitch-board is the length from the top of one step to the top of another, and should be in proportion to the angle of ascent. If gradual, it should be longer; if steep, shorter. It is made as follows: Take a piece of thin, clear stuff and lay the square on the face edge, as shown in *Fig.* 1, and mark out the pitch board *p*. The string of a stair forms its ceiling or soffit. The space required for timber and plastering is 5 to 6 in. The stringer is laid out by taking the width of the step on the blade of the square, and the rise on the tongue of the square, or as follows: Nail a piece across the long edge of the pitch-board, as at *b*, so as to hold it up to the string. Then begin at the bottom, sliding the pitch-board along the upper edge of the string, and marking it out, as shown at *Fig.* 2. Winding stairs have the steps narrower at one end. In some stairs there are steps of parallel width, called flyers, combined with tapering steps called winders. Flights of stairs, broken at intervals by landings, are called platform stairs; they are preferable to those with winders, being simple in construction and convenient. *Fig.* 3 represents a flight of stairs with a wind at the top, and *Fig.* 4

Fig. 1.
Pitch Board.

Fig. 2.
String of Stair.

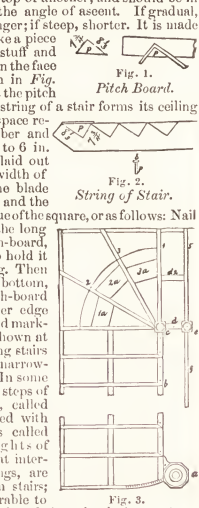


Fig. 3.

shows a more detailed plan of the wind. *Fig. 5* is an elevation of the winding posts showing the position of the mortises and risers. The lettering on these different cuts is the same for each part of the work: *b* is the face stringer, or carriage; *a* is the newel post; *c* is the winding post; *e* is the post at the upper landing, and is cut away so as to hook on to the upper post as seen in *Fig. 4*; *d* is a short piece of stringer, connecting the 2 posts *c* and *e*; *f* is the skirting board which is fastened to the trimmer, and makes a finish of the well-room. The risers 1 and 4 are tenoned into the post *c*, as shown in *Fig. 3*. Suppose that the rise is 7 in., then the top of riser 1 is 7 in. above the mortise, for the face-stringer *b*. (See *Fig. 5*.) The top of riser 4 is 21 in. above riser 1. The top of riser 4 and the piece of stringer *d* are even. The top of riser 5 is 7 in. above *d*, or riser 4. The width of the winding steps is alike, when measured on a circle struck from the winding post *c*, as shown in *Fig. 3*, at 1, 2, 3, 4. The face and centre stringers are usually made of 2 in. plank; the wall stringer of a stout in. board. The winding risers are 4 or 5 in. wider than the others; the extra width projecting below the preceding riser to afford a good nailing for the pieces of plank 1 *a*, 2 *a*, 3 *a*, called chocks, and the piece of stringer *d* 2. The steps are joined by mitering the risers into the face stringer (which should be allowed for in laying out the stringer), and are grooved to receive the tongue of the steps, as seen in *Fig. 6*. The ends of the steps are returned on the face stringer, and a scotia molding mitered beneath. The steps and risers are grooved to receive the base, which is tongued to fit. *Fig. 7* shows how to find the length of opening in the floor, to give sufficient head-room for the stairs. If the story is 9 ft. in the clear, and the upper flooring, lathing, and plastering, etc., 13 in., then the stairs must be 9 ft. + 13 in. = 10 ft., 1 in. from top to bottom, that is, 121 in. If we assume 7 in. for the rise, we have 17 2-7 risers. Since we must have a whole number of risers, we will adopt 17 as the number of risers; then the exact width of riser is 121 ÷ 17 = 7 2-17 in., practically, 7⅛ in. We will make the steps 9 in. on the stringer; but they will finish nearly 1 in. wider, owing to their projecting beyond the riser. Now the rise being 7⅛ in., we find when we have ascended 3 risers (that is, 21⅜ in.) we have 7 ft., 2⅜ in. head-room. Counting out from the top of the stairs, this point is width of 14 steps from the top, which is 14 × 9 in. = 126 in. = 10 ft., 6 in. So with an opening of 10 ft., 6 in., we have 7 ft., 2⅜ in. head-room. If we can do with less head-room, we ascend another riser, which takes us up 28½ in., leaving us still a head-room of 6 ft., 7½ in.; this is at a point the width of 13 steps from the top, which is 13 × 9 in. = 117 in. = 9 ft., 9 in.; so that, with an opening 9 ft., 9 in. in length, we still have 6 ft., 7½ in. head-room. The opening might be still further reduced by narrowing the steps 1 in. or so.

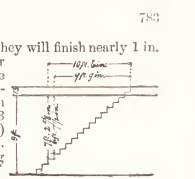

Fig. 7.

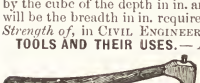
STRENGTH. — *Compression.* 1. To find the area of a post that will safely bear a given weight when the height of the post is less than 10 times its least thickness, divide the weight in lbs. by 1,000 for pine, or 1,400 for oak, and the quotient will be the least area of the post in in. This rule requires that the area of the abutting surface be equal to the result; should there be a tenon on the end of the post, this quotient will be too small. —2. To find the area of a rectangular post that will safely bear a given load, when its height is 10 times its least thickness or more, multiply the given weight or pressure in lbs. by the sq. of the length in ft.; and multiply this product by the decimal, .0015 for oak, .0021 for pitch pine, and .0016 for white pine; then divide this product by the breadth in in., and the cube root of the quotient will be the thickness in in. —3. To find the area of a round or cylindrical post, that will safely bear a given weight, when its height is 10 times its least diameter, or more, multiply the given weight or pressure in lbs. by 1.7, and the product by .0015 for oak, .0021 for pitch pine, and .0016 for white pine; then multiply the square root of this product by the height in ft., and the square root of the last product will be the required diameter in in. — *Tension.* To find the area of a piece of timber to resist a given strain in the direction of its length, divide the given weight to be sustained, by the weight that will tear asunder a bar 1 in. square of the same kind of wood as above, and the quotient will be the area in in. that will sustain the given weight; but, as a beam or post should never be strained or loaded to more than ⅓ its breaking weight, multiply the last area by 4. — *Cross Strain.* To find the scantling of a piece of timber to safely sustain a given weight, when such piece is supported at the ends in a horizontal position: 1. When the breadth is given, multiply the square of the length in ft., by the weight in lbs., and this product by the decimal, .009 for oak, .011 for white pine, and .016 for pitch pine; divide the product by the breadth in in. and the cube root of the quotient will be the depth required in in. — 2. When the depth

is given, multiply the square of the length in ft. by the weight in lbs., and multiply this product by the decimal, .009 for oak, .011 for white pine, and .016 for pitch pine; divide the last product by the cube of the depth in in. and the quotient will be the breadth in in. required. (See *Wood, Strength of*, in Civil Engineering.)

TOOLS AND THEIR USES. — *Adze.* This tool is the twin brother of the ax, and among ships' carpenters, wheelwrights and coopers, it is a tool of primary importance. When necessary to produce a flat surface with an ax, as when squaring logs of timber, the adze gives the work greater accuracy.



Adze.

Brace and Bits.—Fig 1. Represents a carpenter's brace, made of wood with brass mountings. It is in principle a simple crank handle. The top, A, which swivels loose, is rested against the chest; and in the bottom, B, there is a square hole into which the bit is inserted, and held by a spring catch, or a screw. There are varieties of this instrument, but the principle is the same. The brace is turned by the right hand, which grasps the part C; the handle, A, being kept in position on the chest by the left hand. *Fig. 2* is a centre bit, consisting of a central triangular point, A, which enters the wood first and guides the tool; an arm or knife, B, which regulates the diameter of the hole, cutting the edge clean, and a cutter or chisel, C, set obliquely, which follows and pares up the wood into shavings. Centre-bits are of various fixed sizes, but may be obtained with movable blades, so that by shifting this blade, holes of different diameters may be made with the same cutter. For small holes a gimlet-bit, pin and nose-bits are used. The pin-bit, *Fig. 3*, is a fluted wire, sharpened at the end like a gouge; the nose-bit is like a pin-bit with a small blade turned under, which cuts out the wood; *Fig. 4* is a countersink bit, used for enlarging holes, or to sink a depression to allow the heads of screws to be buried level.

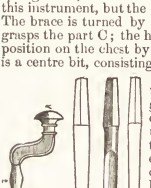


Fig. 1. 2. 3. 4.

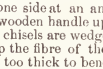
Brace and Bits.

Brad-Awls. — These are pieces of steel wire ground with 2 faces at the point. In use, this tool wedges the fibres of wood on either side. The upper end is sharpened and driven into a wooden handle which has a ring or ferrule to prevent splitting. Some awls are square wires sharpened to a point. Cooper's awls have curved blades. Sets of brad-awls which all fit into one socket, and store away in the handle, may be met with, but they are seldom satisfactory.

Carpenter's Rule.—Sometimes there is a brass slide to add to its length, and sometimes it is hinged to fold up. It is 2 ft. long, 1 ft. on each side of the central joint. Each in. is divided by short lines into 8 equal parts, called 8ths; at the second, the line is rather longer, this being $\frac{1}{4}$ in.; at the 4th, there is a longer line, the $\frac{1}{2}$ in.; then comes another $\frac{1}{8}$, then $\frac{3}{4}$, another $\frac{1}{8}$, and the in. is complete. One edge of the rule, or sometimes only 1 in. is divided into 16ths; sometimes divisions still smaller are used, which are $\frac{1}{2}$-16ths or 32ds, because 32 make the complete inch. Carpenters always reckon by the ft. and in., and by 8ths and 16ths of an in. The values of the numbers on those lines are governed by the value set upon the first figure, and, being reckoned decimally, advance 10-fold.

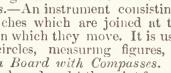
Chisels.—A common chisel is a flat blade of steel sharpened from one side at an angle of about 30°, driven into a wooden handle up to the shoulder. In principle chisels are wedges, and tend to split and tear up the fibre of the wood when the shaving cut is too thick to bend to the pressure of the edge of the tool. Paring chisels are thinner and wider, and are used for clearing out deep holes, such as mortises. — *Mortise Chisels* are much stronger and are sharpened in the same way, but with an angle less acute. Chisels are used either by the pressure of the hand or by blows, the flat side being kept in the intended path of the blade. A carpenter will need 3 or 4 of different sizes. The diagrams show the chisel blades seen on the edge and from the back.



Chisel.

Mortise Chisel.

Compasses.—An instrument consisting of 2 pointed branches which are joined at the top by a rivet on which they move. It is used for describing circles, measuring figures, etc. — *To Square a Board with Compasses.* Let *a*, *Fig. 1*, be the board, and *b* the point from which to square. Set the compasses from the point *b* any distance less than the middle of the board, in the direction of *c*. Upon *c* for a centre sweep the circle, as shown. Then draw a straight line from where the circle touches the lower edge of the board, through the centre, *c*, cutting the circle at *d*. Then a line from *b* through *d*, will be perfectly square from the lower edge of the board. This will be found valuable for laying out walks and foundations, by using a line or long rod in place of compasses. — *To Make a Perfect Square with a Pair of Compasses.* Let *a b*, *Fig. 2*, be length of a side of the proposed square; upon *a* and *b*, with the whole length for the radius, sweep the parts of circles *a d* and *b e*. Find $\frac{1}{4}$ the distance from *a* to *e* at *f*; then upon *e* for a centre sweep the circle cutting *f*. Draw the lines from *a* and *b*, through where the circles intersect at *c* and *d*; connect them at the top and it will form a perfect square.



Squaring Board with Compass.

Perfect Square.

Gauges.—The common marking gauge con-

sists of a rod which slides back and forth through a block, but can be fixed at any required place

Mortise Gauge.

by a screw; near one end is a hole through which a steel point is driven. In using this tool the right end is grasped by the right hand, the thumb and forefinger of which take hold round the block. In gauging, one edge, previously planed, is used as a guide, the left of the block being kept close up to it, the point marking a line parallel to the edge of the wood at any required distance. In cutting thin parallel laths, a knife is used instead of the point.

Gimlets and Augers.—The ordinary form of gimlet is a piece of steel wire fastened into a handle at right angles to it, the cutting part fluted so as to leave sharp edges. At the extreme end is a small screw, by which the tool forces its way into the wood, the edges of the flute cutting out the shavings. Twisted gimlets are best, the effect being the same, for as the flute is twisted round the barrel the wire is not much weakened, and the groove being in the form of a screw, the shavings are lifted out. Augers have two grooves wound round the rod; the bottom edges of the metal left by the 2 grooves are sharpened into a cutting edge, and their action is easy, smooth, and rapid. The largest augers are not fixed into handles, but have their tops expanded into rings, into which a movable handle is thrust.

Gimlet.

Gouges are semi-circular chisels, used to cut grooves, channels and holes, both in carpentry and turning, the difference being in the curved edge of the turner's tool.

Gouge.

Pincers and Pliers.—*Fig. 1.* represents the ordinary pincers, for obtaining a grasp on small objects, such as nails, pieces of wire, etc. Common pliers, *Fig. 2*, are used for the same purpose, but do not grasp so firmly; and *Fig. 3*, cutting-pliers, for small wire. The cutting edges are sometimes on the side, and sometimes on the top edges of the tool, serving the twofold purpose of cutting and holding.

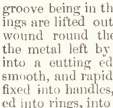


Fig. 1 Fig. 2. Fig. 3.

Planes.—The principle in a plane is the same as with a chisel, with greater steadiness on account of the increased power of guiding given by the sole. *Fig. 1* is a section showing the construction and arrangement of an ordinary plane. The body is of beech wood, the bottom of which is called the sole. The line B, on which the iron rests, is the bed, and is mostly inclined at an angle of 45°. The iron is fastened down to the bed by the wedge C, which fits into grooves on each side of the mouth D. The angle of the wedge is about 10°, cut away in the middle to leave room for the screw which holds the 2 irons together. The plane is pushed forward by the handle E, which is let into the top. *Fig. 2* shows the double iron found in most planes. A is the bottom iron, which is the cutting part, and B is the top iron or break to throw off the shavings. It is set with its edge about 1-20 in. from the cutting edge of the iron, to which it is held by the screw C. The adjustment is allowed by the long slot in the bottom iron in which the screw slides. The top iron is curved in the direction of its length, to keep its edge in contact with the lower iron so as to allow no shavings to pass. In setting a plane the 2 irons are screwed together, and placed on the bed with the wedge lightly pressed in its place; the edge will then be felt underneath by the hand, and can be adjusted. Should it be too far out, a tap with the hammer on the fore part of the plane will bring it up, or should it not project enough, a slight blow on the top of the iron will be necessary; when in its place a sharp blow on the wedge will fix it. *Fig. 1* shows the proportions of a jack plane, the length of which is 14 to 16 in. The smoothing plane is smaller, about 7 or 8 in. The trying plane is about 20 in., the length giving accuracy in the surface to be operated on. The following are kinds of planes used in wood working: 1. Compass planes have round soles according to the curve, they are required to cut, and are of great variety.—2. Jack plane for smoothing rough boards before marking and cutting.—3. Long planes, for long straight edges.—4. Match planes are in pairs. Their use is to cut, one a groove, *Fig. A*, the other a tenon, as in *Fig. B*, down the long sides of boards that are to be joined lengthwise.—5. Plow, with which grooves are cut in the sides of book-shelves, and for door panels, where boards are joined lengthwise, etc. —6. *Rebate.* A very narrow plane, fixed at

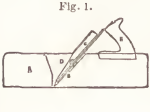

Fig. 1.

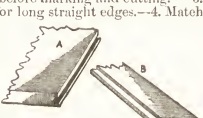
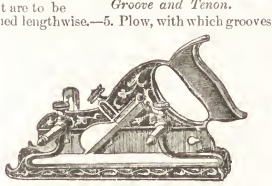
Fig. 2.



Groove and Tenon.



Plow and Match Plane.

an angle, and constructed so as to reach into recesses or to cut across the grain of the wood.

Rebates.

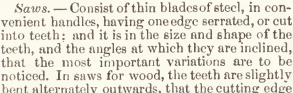
—7. Side or sash fillister, for cutting rebates. Has a wooden guide on 2 arms to regulate the width, and another of metal, moved by a screw, to regulate depth of cut. A rebate is a rectangular groove to receive glass in windows or glass in picture frames. — 8. Smoothing plane, used for finishing. It dips into hollows and rises over hills while seeming to plane true.

Sash Fillisters.

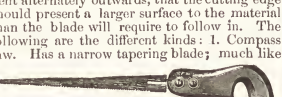
Rasps. — (See *Files*, in METAL WORKING.) The same in action as files, but being used for wood, the teeth are larger, being produced by the blows of a chisel, and always in lines ranged diagonally, or in curved rows across the blade.

Short or Smoothing Plane.

Saws. — Consist of thin blades of steel, in convenient handles, having one edge serrated, or cut into teeth: and it is in the size and shape of the teeth, and the angles at which they are inclined, that the most important variations are to be noticed. In saws for wood, the teeth are slightly bent alternately outwards, that the cutting edge should present a larger surface to the material than the blade will require to follow in. The following are the different kinds: 1. Compass saw. Has a narrow tapering blade; much like



Compass Saw.

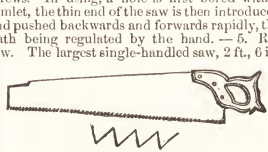


Cross Cut Saw.

the key hole saw, but is used for larger curves and coarser work. — 2. Cross cut saw. Used for cutting lumber across its grain. Worked singly, being of same general shape as rip saw, or by two men, backwards and forwards, cutting both ways; and for this reason the front and back angles of the teeth are equal, or about 60°. — 3. Dovetail saw. Resembles the tenon-saw, but is smaller and thinner in the blade and finer in the teeth. — 4. Keyhole saw. Has a long, thin, tapering blade, thicker on the teeth edge than at the back, to allow of the curve to be

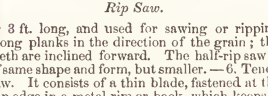
Keyhole Saw.

made. In order that the extreme end of the thin part may be used for small circles, the blade sometimes slides into a long hole right through the handle, and is fixed at any required place by screws. In using, a hole is first bored with a gimlet, the thin end of the saw is then introduced and pushed backwards and forwards rapidly, the path being regulated by the hand. — 5. Rip saw. The largest single-handled saw, 2 ft., 6 in.



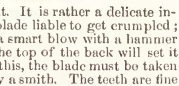
Rip Saw.

or 3 ft. long, and used for sawing or ripping along planks in the direction of the grain; the teeth are inclined forward. The half-rip saw is of same shape and form, but smaller. — 6. Tenon saw. It consists of a thin blade, fastened at the top edge in a metal rim or back, which keeps it



Tenon Saw.

firmly stretched out. It is rather a delicate instrument and the blade liable to get crumpled; if it is only slight, a smart blow with a hammer on the middle of the top of the back will set it right; but failing this, the blade must be taken out and re-fitted by a smith. The teeth are fine and the pitch is not very forward. — 7. Bracket scroll, or turning. It has a narrow blade, thinner on the back than in front. The blade is fixed by a rivet at each end to the handles, which are thrust through holes in the sides of the frame. A centre bar, D, keeps this frame distended,



Turning Saw.

and acts as a fulcrum, whereby the force generated by the twisting of the cord, is transmitted to the blade. The cord is twisted by the lever, F, and should consist of 5 or 6 turns of whipcord. The parts of the handles which go through the frame being cylindrical, they can be turned so as to

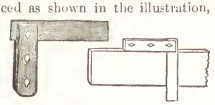
put the blade in any required position to keep the frame out of the way of the work. The handle behind the pitch of the teeth, which is the one taken hold of, is usually larger than the one at the other end. It may be used to cut out spaces, by first boring a hole, into which the blade, released from one of the handles by taking out the rivet, is inserted. The limit of distance from the edge of the work at which these saws can act, is equal to the space between the blade and the centre bar. (See *Saw Mills* in MECHANICAL ENGINEERING.)

Framing Square.—The *board rule* across one side of the blade is explained as follows: At 12 in. is laid down figures, commencing at the bottom: 8, 9, 10, 11, 12, 13, 14 and 15; these numbers represent the length in ft. of the board to be measured, and also the number of ft. in a board 12 in. wide. For any other width, as 8 in. and the length 15 ft. opposite 8 in. the space marked 15 is 10, the number of ft. in the board. If the board is shorter, or longer than is given on the square, take $\frac{1}{2}$ or double the numbers. On the tongue of the square, and on the same side that contains the board rule, is the *brace rule*. The figures are laid down as follows:

$$\begin{array}{cc} 24 & 27 \\ 24\ 33.9, & 27\ 38.19, \text{ etc.} \end{array}$$

The double numbers represent the 2 sides of a square, and the decimal numbers are lengths of diagonals. Thus, if the 2 sides of a square are 24 each, the length for a brace will be 33 and 9-10ths; if the sides are 27, the brace will be 38.19, and so on. The *diagonal scale* is laid down at the end of the brace rule near the corner of the square, which consists of 11 equidistant parallel lines, crossed by vertical ones, drawn obliquely, as follows: 1 in. is divided into 10 equal parts above and below, and a line drawn from the top of the first perpendicular to the first division below, and continued parallel, by which method the first division on the second line from the top becomes 100ths of an in., and each of the others on the parallel lines 1-10. The scale of hundredths reads downwards from the second parallel line where it intersects the first diagonal at the right-hand corner, this being 100ths of an in. The next space is 200ths, the next 300ths, and so on, the last being 10-100 or 1-10 in. On the *octagon rule*, on the other side of the square along the tongue, are a series of numbers: 10, 20, 30, 40, 50, and 60, which are 5-12ths of $\frac{1}{2}$ as many in., being the tangent of $22\frac{1}{2}°$ for circles whose diameters are 10, 20, 30, etc., in. These numbers are used as follows: We have a stick of timber 10 in. sq., and wish to make it 8 sq.; draw a centre line on each side of the stick; set the dividers from the beginning of the scale to 10, and set off this distance on each side of the line; this shows how much of the corner to take off. The octagon scale is on most of the pocket rules, given on 2 lines, marked M and E. The divisions on the line M will be found to correspond with those on the square, and are used in the same way. The line E gives the distance from the corner of the stick to the angle of the octagon. Suppose you have a stick 6 in. sq.; set a guage to 6, on the line E, and guage this quantity each way from all the corners. The lines M and E can also be used for a brace rule; the line E being a table of equal sides of a square, and M a table of diagonals, or braces.

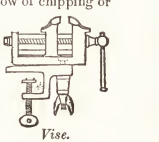
Try Square.—It is a handle and a blade, like a knife half-open, the one fixed exactly square, or at a right angles with the other. The blade is thinner than the handle, and when the latter is placed as shown in the illustration, a line



Try Square.

marked across the board against the edge of the blade will be square to the side, so that when cut off the piece will be like the end shown in the cut.

Vise. — A vise must supply the following qualifications: Strength to allow of chipping or filing the work without a possibility of the vise breaking; the inertia of the anvil should be sufficient to absorb the effect of the blows; the jaws should move parallel and freely, and should be arranged in such a manner as to get the whole power of the screw; all the parts should be durable, and lastly the tool furnished cheaply.



Vise.

TIMBER.—The best timber grows on high, dry, stony or sandy land, with the exception of the kinds indigenous to a low, swampy soil. Timber should be cut in midwinter or midsummer, when it contains the least amount of sap, and sawed as early as possible to prevent decomposition of the vegetable juices and fermentation of the albumen of the wood, which causes dry rot, and is indicated by yellow stains. Healthy timber is indicated by the dark green color of the leaves, which should be left on the tree felled in summer, as they rapidly exhaust the sap. In order to determine whether the heart of a tree is defective, without cutting, bore into the butt, 1 ft. from the surface of the ground, with a 2 in. auger, drawing out the chips for examination. In case the tree is of so large dimensions that the heart cannot be reached with an auger, an iron rod may be attached by welding, or by means of a socket made in the rod to fit the shank of the auger. An auger-hole near the ground will not injure a tree for timber, except it is to be employed for sleigh-runners or for ship building. After the timber is sawed into logs, the soundness may be tested by applying the ear to the middle of one of the ends, while another party strikes the other end. If the wood is sound, the ring of the blow will be distinct; but if decay has set in, it will be muffled. The best part of the tree is nearest to the ground, and the toughest on the north side of the tree.

TOOLS, Grinding and Setting. — Chisels, knives, axes, planes, and all tools with flat edges, are to be ground with the stone revolving towards you, by which means the filament of metal is driven back into the substance of the tool, instead of

drawn away from it. Gouges may be ground in the same way, but should be held across the stone in the same direction as their axis, and by rolling them over backwards and forwards you can give a very good shape to the edge, which should run slightly to a point. Turner's gouges should never be ground square across. The bevel of tools must be kept flat and even. Turner's chisels intended to cut soft wood, like deal, are ground to an angle of 20° to 30°, like C and D in the illustration. A tool for hard wood is given at E. The angle is now at least 40°, and ranges up to 80°, giving a stronger, thicker edge, but not so keen. I is the chisel (held edge-wise as before) ground as it ought to be for soft wood. In grinding plane irons, chisels, etc., they should be held firmly and squarely upon the stone at a point sufficiently near its upper part to allow the tool to be in a nearly horizontal position while its bevel lies flat upon it. If it is held too low, so that its handle points down, the tool cannot be firmly held, nor the work easily seen.

Cutting Edges of Tools. To sharpen and set a saw, first run a file along the edge of the teeth till they range in a line; then lay the blade on a smooth piece of lead, or on the end of a trying plane, and with a square punch give a gentle tap on it with a hammer; after placing it on one of the teeth, do the same with every alternate tooth. Reverse the saw and punch the teeth, on the other side, and look down the saw that the teeth are all equally set. Then begin with the file at that part of the saw nearest the handle. To sharpen or file the teeth to a good point, hold the file so that it makes an angle with the saw-blade of about 30°, or ⅔ that of a mitre angle, observing to shift the file for every alternate tooth in an opposite inclination, bringing each tooth to a sharp point, and keeping the upper edge of file nearly horizontal. Every tooth will then represent a sharp chisel, and cut as it goes without tearing. The illustrations show a "saw-set," the nicks of which

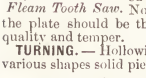
Saw Set.

are of different sizes, to suit the various thicknesses of blades; also the manner of filing the fleam, or lancet toothed saw; *a* the teeth, full size; and *b* the position of holding the saw. The saw is held flat on the bench, and one side is finished before it is turned over.

Fleam Tooth Saw.

No setting is needed, and the plate should be thin and of the very best quality and temper.

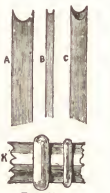
TURNING. — Hollowing out and forming into various shapes solid pieces of wood or metal by means of the lathe and suitable tools. The following are the principal tools:



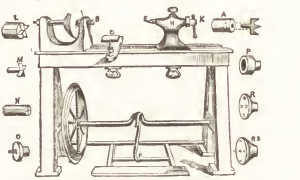
Broad.

Broad. Used for levelling the flat surface of lathe work, such as platters, etc., which are not easy to finish with the chisel and gouge. These are something like an arm-rest, being a broad bar of steel turned up at the extremity for a short distance and sharpened.

Beading. — A to C, in the figure, represent beading-tools. The bevel is on the under side, and it is better to interfere with it as little as possible, by always sharpening the flat face only. If necessary to touch the bevel, rub with a slip of oilstone, rounded on the edge. Conical grinders, revolving in the lathe, are used for small beading-tools, to be fixed in the slide-rest. K shows what are meant by beadings. If these are semicircular in section, they are finer in appearance than if of such curves as can be roughly cut by a chisel.



Beading Tools.



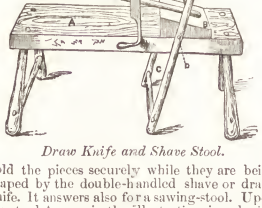
Turning Tools.

Chucks. — These hold in a firm position the work to be bored or turned, and which is fixed upon the screw of the mandrel, B, and held in a chuck suited to its particular form, but sometimes it is screwed directly upon the mandrel. The rest, C, is then fixed near it, and the tool is supported thereon and held firmly while the work revolves against it, remembering always to work down from right and left, into the various hollows; the fibres cannot be neatly cut by working up. The chucks are of wood and metal, according to the hardness of the wood to be operated on. First the prong-chuck, A, for soft wood. This is made to screw upon the mandrel. Its use is to hold one end of any piece of wood while the other is supported by the point, E, of the poppit, H, which poppit can be moved at pleasure along the lathe-bed, and fixed at any place by a hand-nut below. The point itself can be advanced or drawn back by turning the handle, K. A piece of wood thus mounted revolves with the mandrel, because, although it can turn round upon the point of the back poppit, it cannot do so upon the fork or prong, which enters and holds it securely. This chuck, or one of the same nature, is used for cylinders of soft wood, which can be supported at both ends, such as tool-handles, chair-legs, and other work not requiring to be hollowed out. The cross chuck, shown at L M, is preferable when the work is rough or turns upon the fork or prong. The centre of the little cross (which is of steel, and

fits into the same square or round hole in the socket which carries the prong, and which is also used to hold drills, pieces of iron rod to be turned, and other articles) is made to revolve in the precise axial line of the mandrel, or to run true with it, as it is called. The arms of the cross are to be imbedded in the work; which is effected by making in the latter 2 saw-cuts at right angles with each other. N, represents a piece ready for mounting. If you use the cross-chuck, take out the work to put on the ferrule, and replace exactly as before, and it will continue to run true. The next chuck O, is a taper screw of steel, fixed in a socket which can be attached to the mandrel. Two sizes of this would be useful for a large lathe. It is to hold pieces which only require to be supported at one end, so that a tool can be used to work upon the other, either to mold it into the required form, or to hollow it out. The cup-chuck is the last required. It is seen at P, and is sometimes of iron, but generally of brass. The flat plates, R R², can scarcely be called chucks, but they come in the list of such. The latter has 5 projecting points, which, sticking into a flat-board, hold it firm when the back centre is brought up against the other side of the piece, to allow of its being turned. The other is a flat plate with holes in it, through which screws can be passed from behind into any odd bit of wood of 2 or 3 in. in thickness, whereby a chuck can be quickly made to suit any required purpose; 2 or 3 of these would be convenient, 1 of which should be nearly as large as the lathe will carry; and in this one a great many holes and slots should be made. This is called a face-plate, and is fitted with clamps and bolts for the purpose of holding securely upon its face all kinds of flat work in wood or metal.

Chisels and Gouges. — With these alone you can do all the plain work in soft wood which does not require to be hollowed out.

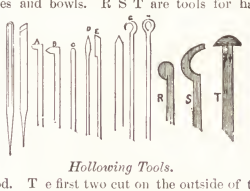
Draw-Knife and Shave Stool. — A useful apparatus for the preparation of long pieces is the shave-stool, used by coopers and chairmakers to



Draw Knife and Shave Stool.

hold the pieces securely while they are being shaped by the double-handled shave or draw-knife. It answers also for a sawing-stool. Upon the stool A, seen in the illustration, is a sloping block, B. A swinging frame C, is pivoted at D, so that if the lower part is pushed back from left to right, the upper cross-bar, E, will come forward and almost touch block, B, so that any piece of wood, such as F, will thereby be pinched and held tightly between the rail E, and the block. The workman sits astride of the stool at A, facing the block, and his feet are placed on the bar C. When he wishes to hold the wood to be shaved by the draw-knife C, he presses from the lower part of the frame, and he can instantly loosen the wood by drawing his feet towards him. The movement is made in a moment, and the wood shifted round as required, and alternately turned about and held tight, while the drawknife is used. A few minutes suffice to pare down a rough piece for the lathe. The cross-bar, E, should be strong, and is better if not rounded very nicely.

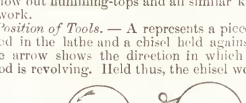
Hollowing Tools. — A to F, shown in the illustration, are for hollowing out hard woods. G and H are hook-tools for hollowing out soft wood boxes and bowls. R S T are tools for hard



Hollowing Tools.

wood. T e first two cut on the outside of the curved part all round. These would be used to hollow out humming-tops and all similar kinds of work.

Position of Tools. — A represents a piece of wood in the lathe and a chisel held against it. The arrow shows the direction in which the wood is revolving. Held thus, the chisel would

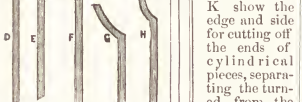


Position of Tools.

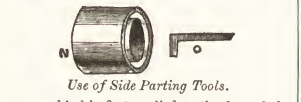
scrape; it could not possibly cut. But, held as at B, it would cut off a clean and continuous shaving, and this shaving would slide off along the upper face *b* of the tool. The tool acts like a thin, sharp wedge, which divides the material by pressure, which has to be great or slight according as the edge is sharp and thin, or the contrary. Between the two positions shown there are others at a greater or less angle; but the smallest possible angle it can make is the best, so long as the thickness of shaving removed will suffice. This rule holds good with all tools made with sharp cutting edges. Care must be taken that the lower face of the tool does not rub against the work. The chisel never lies flat on the rest or on the work, but always slightly raised to clear the upper point.

Side Parting Tools. — D, E and F represent side parting tools; it is usual to have several of these, the hooks increasing in length. The edge is on the extreme end. They are used to cut solid blocks of ivory and hard wood from the

inside of boxes, instead of cutting the material into a heap of useless shavings. Similar tools, G H, curved, serve to cut out a solid piece from the inside of a bowl. I and K show the edge and side for cutting off the ends of cylindrical pieces, separating the turned from the unturned, and for similar descriptions of work. A tenon-saw held still against a piece revolving in the lathe will often serve to cut it in two, but parting tools must also be had; a thick one should be kept for common woods, and a thin one for ivory and precious materials; sometimes one with a notched edge is used for cutting off soft wood. The use of the side parting tool is seen at L in the following illustration. A common straight parting-tool or

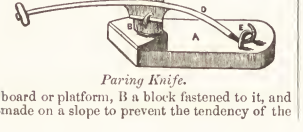


Side Parting Tools.



Use of Side Parting Tools.

narrow chisel is first applied to the face of the work to cut a deep circular groove or channel, as shown by the white space at N, and in section at L. This allows the narrowest of the hooked tools to be applied to under-cut the solid core *x*. This being withdrawn, a rather longer hook is applied, the hook being held downwards as at O, until it reaches the spot where it is to work, when it is gradually turned up (bevel below). Eventually, the solid core or centre block *x* will fall out entire, which may be used for other purposes. M shows how a similar but curved block can be removed from the inside of a cup or bowl. The paring-knife for short thick pieces is made like D. It consists of a long and curved handle, turned up at one end to fit under a staple E, with a cross-piece of wood for the hand at the other end, and a broad strong blade with one bevel in the middle. C is the piece of wood to be pared, A the bottom



Paring Knife.

board or platform, B a block fastened to it, and made on a slope to prevent the tendency of the wood to slip away from the knife. The whole of this may be screwed down to the bench. The hook and ferrule should not be made so large and loose as in the drawing, and a better joint is that of an ordinary hinge.

Ring Tools. — The illustrations P and Q show these tools. A recess is turned in the face of a piece of wood as if it was intended to hollow out a box. The ring-tool is applied bevel down and with the left cutting edge a bead is cut ½ through from the inside. The right edge is then applied to the outside, and when the cuts meet, the ring, neatly finished, will fall off; they require only a rub of sandpaper to finish them.

Ring Tools.

UTENSILS.—Wooden vessels for containing articles of food, wine and for culinary purposes, are hollowed out of various kinds of wood by the lathe. It is necessary that the wood be thoroughly seasoned to prevent its warping or splitting. To remove unpleasant extractive matters and fit the vessels for use, fill them with a solution of washing soda, and let stand 12 to 14 hours; then draw off the discolored liquid, rinse, and fill with pure water, and let remain a few hours more. Wooden vessels, especially in chemical works, should be well dried in hot air, then painted 2 or 3 times with a solution of paraffine in 6 parts petroleum benzine. Vessels in which boiling is affected with steam, should further be coated with linseed oil varnish, or with water glass; after drying, the water glass coating should be set by means of dilute muriatic acid. Paraffine is well adapted for packing stuffing boxes, especially in stirring apparatus exposed to vapors of fuming and English sulphuric acid.

VENEERING. — The art of covering a cheap and solid material with a layer of a more costly ornamental material, so as to convey the impression that the whole is formed of that which meets the eye. The veneer is sent to the cabinet-maker, rough upon both sides; nor does it assume the beautiful polish so ornamental to good furniture, until laying on the veneer is completed, which requires great skill, time, and care. The principal requisite to insure success is to select well seasoned wood for the ground, and to use the best and strongest glue. Be careful to exclude air in gluing, or a blister will arise and spoil the work. Keep thin-shaved veneers, such as ash and walnut burls, in rather a damp place until wanted; as they will curl and split if kept in a dry room. Select that piece of deal which is freest from knots; slit it down the middle, or take a piece out of the heart, and place the boards, when cut the required length, in a warm place for 2 or 3 days; then joint them up, placing a heart edge and an outside edge together; when dry, cut the top again between each joint, and joint afresh; you will then have a top glued up of pieces about 2 in. wide, and if you have been careful in making the joints good, the top will not be so liable to cast. Wainscot or other wood may be used instead of deal, but make the

joints in the same manner. It is also a good plan, after having veneered the top, to lay it on the ground with some shavings, with the veneer downwards; it then dries gradually and is much less likely to cast. In repairing furniture, workmen are sometimes at a loss to know how to get rid of those blisters which appear on the surface, in consequence of the glue under the veneer failing, or causing the veneer to separate from the ground. First, wash the surface with boiling water, and with a coarse cloth remove dirt or grease; then place it before the fire; oil its surface with common linseed oil; place it again to the fire, and the heat will make the oil penetrate through the veneer, and soften the glue underneath; then, while hot, raise the edge gently with a chisel, and it will separate completely from the ground; be careful not to use too great force. Again, if it should get cold during the operation, apply more oil, and heat it again. Repeat till you have separated the veneer, then wash off the old glue, and proceed to lay it again as a new veneer. Ordinary wood may be made to resemble expensive veneers by the following process: Soak the wood 24 hours, and boil ½ hour in a 10 per cent. solution of caustic soda. Then wash out the alkali; the wood will be elastic, leather-like, and ready to absorb the desired color. After immersion in the color bath, dry between paper under sufficient pressure.

WEIGHTS OF WOODS. —

	Lbs. in 1 cu. ft.		Lbs. in 1 cu. ft.
Beech	40	Lignum-vitæ	83
Ash	45	Pine, yellow	38
Birch	45	Cork	15
Cedar	28	Pine, white	25
Hickory	52	Birch charcoal	34
Ebony	83	Pine "	18

WHEELS. — If the felloes of a wagon-wheel are soaked in boiling linseed oil before the tire is put on, the tire will never become loose and the timbers will last longer. The oil is brought to a boiling heat, and the wheel placed on a stick, so as to hang in the oil, each felloe an hour. The timber should be dry. Care should be taken that the oil be not made hotter than a boiling heat, in order that the timber be not burnt. Timber filled with oil is not susceptible to water and is more durable. Wood-centred carwheels, which are used for passenger cars of railways, because of the decreased wear of axle and tire, are improved by making the bars with a number of arms extending to within a short distance of the tire, which do not prevent a close-fitting of the wooden segments. Another improvement consists in having the tire formed with a groove for the retaining ring.

WINDOWS. — An approximation of the necessary size may be obtained by multiplying together the length and breadth in ft. of the apartment to be lighted, and the product by the height in ft. The sq. root of this product will show the number of sq. ft. of glass. The dimensions of frames may be ascertained by adding 4½ in. to the width of the glass for their width, and 6½ in. to the height of the glass for their height, the measure being taken at the inside edge of the sill. In a brick wall, the width of the opening is 8 in. more than the width of the glass (4½ in. for the stiles of the sash, and 3½ for hanging stiles), and the height between the stone sill and lintel, or cross piece over the top, is about 10½ in. more than the height of the glass, it being buried according to the thickness of the sill of the frame. Windows should be placed as far as possible from the quoins of a building; they should be of different heights in different stories, but of the same width, and range perpendicularly over those of the first. The space above the head of a window should allow space between the window trimming and cornice of the room.

WOODS, Working Qualities of. — *Acacia.* An excellent, yellowish brown wood, tolerably hard, and takes a good polish. It is much used for turning. — *Apple Wood* is fine grained, hard and compact. Used when hardness and variegated color are objects. — *Ash.* Suited to all purposes requiring toughness and elasticity, as agricultural tools, wooden springs, frames of railway carriages, wheels, etc. Some specimens are beautifully marked, and are much prized for cabinet work. The wood takes a high polish, and may be cut to present a satin lustre. For the treads of stairs, floors of offices, mills and other buildings, it is regarded as superior to most woods thus employed. Its warm color makes it an effective finish when used with both lighter and darker woods. — *Beech.* A close, tough wood, used for framework of chairs, tables and bedsteads, handles for tools, etc. It is nearly of the color of birch, and may be known by the presence of peculiar little specks of a dark brown, seen in a carpenter's plane.—*Birch* is close grained, strong and easily worked, of a pale yellowish brown. If polished or varnished, it resembles satinwood, but is darker, and by staining is made to resemble Honduras mahogany. It is easy to work, and suitable for the purposes to which walnut is applied, and when properly stained it is almost impossible to distinguish the difference. It is susceptible of a beautiful polish, and its light weight, close grain and rich finish, make it suited for certain applications where fine finish and bright effects are desired. There is a species of bird's-eye birch, but it is very scarce. Most perforated chair-bottoms in use are manufactured from birch. — *Camwood.* A beautiful material when first cut; its rich red tint is diversified with brilliant yellow streaks, but these are not lasting; exposed to the air they become red. The wood has a fine, close grain, is hard, and much used for turning ornamental articles. — *Catalpa.* Being imperishable under or lying on the ground, it can be used for railroad ties, telegraph poles, fence posts, grape-vine posts, gate-posts, hop poles, timber for canoes, skiffs, shingles, weather-boarding, cooperage, water-tanks, framing timber for bridges, piles, the manufacture of railroad cars, lumber for sidewalks, pump-stocks, undertaker's stock, etc. — *Cedar.* Resembles mahogany, though more purplish. It has no curl, and is free from tendency to warp or cast. It is light, fine grained, compact, and is used for posts and shingles; it has been known to outlast a century. The

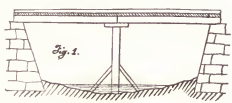
heart has a rich red color, and a pleasant odor, which renders it obnoxious to moths; hence it is highly valued for making drawers and chests for clothing.—*Cherry* is a very excellent wood; takes a fine polish; for light, elegant furniture it is scarcely equaled; dipped in lime water, it darkens,and by doing this here and there a mottled appearance is given; pipes and stems for pipes are made from it. This wood is not abundant, except in certain localities. It is pale and liable to sap-streaks, but answers very well for ebonizing.—*Chestnut.* (See *Chestnut* in FORESTRY.) Some of the best of the cheap furniture is made from it. It is of reddish-brown color, and looks so much like white oak as to be used in combination with it.—*Coral Wood* is bright red, hard and close in grain, well suited for chessmen, where that color is preferred. —*Ebony.* Highly prized for inlaying. It is exceedingly hard, heavy and durable, but expensive. Pear and other woods, dyed black, are substituted for it, but are not so permanent in color. The best comes from Africa, and is of a deep black color. Its colors are red, green and variegated brown in the East Indies, Mauritius and Ceylon.—*Larch.* The grain is large and coarse, and owing to the immense quantity of turpentine contained in it, it is well suited for out-door work, etc. (See *Larch* in FORESTRY.) —*Mahogany.* The most prized of the furniture woods; its size, soundness, almost perfect immunity from dry rot and shrinkage, and its beautiful appearance, render it most valuable for domestic purposes. It is of 2 kinds, Honduras and Spanish. The former has a coarse, loose, and straight grain, without much curl or wave; lighter in color and weight than Spanish and better for solid work. The latter is darker, with curl, by which in a great measure its price is regulated, and with a very fine, close texture. Spanish mahogany will bear great violence; it is also free from tendency to warp. When it is very much curled it is not nearly so strong or so free from twist; but this is of little consequence, as its value is so great that it is generally veneered on some less valuable wood. The heaviest is best. It is good for turning, and admits of a fine polish.—*Oak.* Takes long to season, and is worse than most woods if used green. It is from the numerous varieties of oak that timber for heavy building purposes and ship building is selected, being of immense strength, size, and peculiarly unsusceptible to the weather. It is hard, firm and of great tenacity; the best is of a light-brown color; darker kinds are softer and less durable, but being in most cases beautifully marked, are prized for church architecture and carving. Oak is difficult to work, owing to its hardness, but takes splendid polish. It improves with age. On account of its tendency to warp, a great deal of so-called oak is paneled with chestnut. The peculiar appearance of old oak is given to new wood by exposing it while very slightly damp to the fumes of ammonia.—*Partridge* is a hard, pretty wood, rather dark or gray; the fibres seem to run both ways, giving a mottled appearance when turned.—*Pear.* Is of a light brown or yellow color, but darkens by exposure; it has a fine, even grain, and is used for making the curved templates or patterns of curves for architects and engineers; a favorite for carving. It is often stained to imitate ebony.—*Pine.* There are 2 varieties used, white and yellow. When dry it is free from all tendency to warp; but in a half-seasoned state articles made of them fall to pieces. They are distinguished from each other by difference of color, and from deals by the absence of turpentine veins. When oiled and varnished it looks very well. This wood supplies the largest part of the timber for building purposes.—*Plum.* Veined like elm. It is the wild variety, and is excellent for small boxes. It looks well when turned and polished.—*Osage Orange.* Valuable for its durability; does not shrink and warp like other woods, and can, for some purposes, be used green.—*Osier.* A species of willow used in the construction of wicker work. The most highly cultivated yields the toughest and finest wood.—*Rattan.* A small sort of cane brought from China, Japan and Sumatra. Very pretty and durable summer chairs, lounges, tables, baskets, etc., are made wholly of rattan.—*Rosewood* is hard and dark, with some little curl, intermediate in this respect between Spanish and Honduras mahogany, and of a very open grain. Commonly used for furniture and turned work. Most articles of rosewood furniture are veneered, but the best are of solid wood. The color, which consists of large, elongated dark zones on a reddish brown ground, is permanent, unless exposed to the sun; it takes a fine polish, which is improved by waxing, or better by French polish, which brings out the color of the wood. The best comes from Brazil, and the grain is beautifully variegated.—*Bois de Rose.* An African wood, red, with yellow streaks; it seldom grows over 8 in. in diameter, and is cut into veneers and used bias for borders in inlaid or marquetry work.—*Satinwood.* Used for inlaying lining and veneers. It is of a full yellowish color, with a fine grain, little curl, and silky lustre. Its toughness fits it for furniture, but it is by no means hard; there is also a red satinwood.—*Sycamore* is white, and very soft until old, when it becomes harder. This is used for wooden bowls, backs of brushes, boxes, etc.

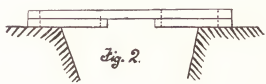
STONE, Improved Artificial.—By a new process artificial stone is manufactured free, it is claimed, from the usual liability to crack or fracture. The process is simple—that is, silicic acid, after being ground to powder, is cleansed from all impurities by ordinary means, and 5 to 10 per cent of it mixed up in warm river or rain water, which is either applied to slacked or well-burnt lime, or is added to hydraulic lime; the resulting product from this process, which is silicate of lime, is mixed with sand and small portions of fluor-spar. This mixture may be cast into molds, so as to give various shapes, as desired, and on being removed the castings are allowed to dry for from 12 to 24 hours, after which time they will be as dry as atmospheric air; they are then brought into a steam boiler and steam blown through so as to drive out all the air, after which the boiler is hermetically

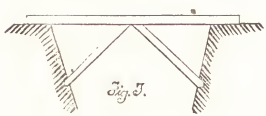
closed up and steam let in under a pressure of 10 atmospheres. In this high-pressure steam bath the stones remain for from 48 to 72 hours, afterward being submitted to a bath of boiling and saturated chloride of calcium during 6 to 12 hours, also under a pressure of about 10 atmospheres in the same boiler, and the condensed water may be used for the bath. These stones are allowed to dry in the open air, or, when desired to dry quickly, steam may be circulated inside of the boiler after the chloride of calcium has been withdrawn and before the stones are taken out of the drying boiler.

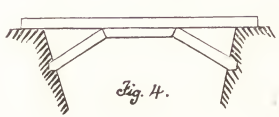
BRICKS.—These are formed by molding prepared clay into the required form and then burning the same in a kiln. The quality varies greatly according to the nature of the earth used, the care in their manufacture, and being more or less burnt. The weight required to crush 1 sq. in. of brick varies from 1,200 lbs. to 4,500 lbs.; but ½ the crushing weight will produce fracture in the brick. The weight of 1 cu. ft. of brickwork, set in mortar, is about 120 lbs. The tensile strength of bricks is somewhere about 275 lbs. for every sq. in.; but, in construction, they are seldom, if ever, exposed to a tensile strain. Great care should be taken in the selection of bricks for structures exposed to weather or the action of water; only the hardest burnt and best made bricks should be employed.

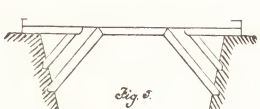
BRIDGES.—The most simple and natural form of a bridge consists of 2 timbers, laid across the stream, or opening, to be passed over, and covered with plank to form the roadway. Walls should be built to support each end of the timbers, and are named abutments; the width of the opening they cross is the span; the timbers themselves are the string-pieces; their number and size increase with the stretch. For a stretch of about 16 ft., they should be about 15 in. deep by 8 in. broad, and be placed at intervals of about 2 ft. This construction is only applicable to short stretches. For spaces of greater width, supports from the bottom of the opening may be placed at proper intervals, as in *Fig. 1.* They may be in the form of piers of masonry, or upright props or shores of timber, properly braced, and supported on piles,

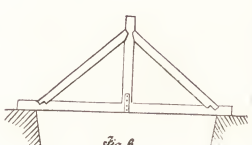


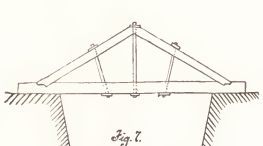


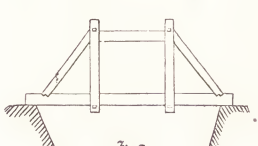












Forms of Bridges.

if the foundation be insecure. They will divide the long stretch into a number of shorter ones, and support the ends of the timbers by which each is spanned. But if the opening be deep, or occupied by a rapid stream, it is desirable to avoid the use of such obstructions. Means must be devised for strengthening the beams, to enable them to span larger openings. This may be effected by supports from below, or from above. Of supports from below, the simplest are shorter timbers (bolsters, or corbels), placed under the main ones, to which they are firmly bolted, and projecting about $\frac{1}{4}$ of the stretch as in *Fig. 2*. This will increase the stiffness. Still more effective are oblique braces or "struts," supporting the middle of the beam, and resting at their lower ends, in "shoulders" cut into the abutments as shown in *Figs. 3* and *4*. Similar braces may be applied to the bolsters of *Fig. 5*. The principle may be extended to very wide openings. But in many cases supports from below may be objectionable, as exerting too much thrust against the abutments, and being liable to be carried away by freshets, etc. The beams must in such cases be strengthened by supports from above. The simplest form of such is shown in *Fig. 6*, in which the horizontal beam is supported by an upright "king-post," being formed of 2 pieces, bolted together, and inclosing the beam between them. The king-post itself is supported by the oblique braces, or struts, which rest against notches in the horizontal beam. Since the king-post acts as a suspending tie, an iron rod may be advantageously substituted for it. The oblique braces may be also stiffened by iron ties, binding them to the main timbers, as in *Fig. 7*. For longer stretches, a straining beam may be introduced between the struts, as in *Fig. 8*, in which the posts are represented as enclosing the beam. For bridges of greater span, and more complicated structure, the assistance of a civil engineer should be secured. The subject is therefore not carried any further in this volume. For the same reason, bridges of stone and iron are omitted.

MASONRY, Strength of.—The strength of masonry is the strength of the cement or mortar used in construction. The adhesive strength of cement is directly as its age, and inversely as the magnitude of the joint. The relative strength of cement, cement and sand in equal portions, and pure lime mortar, are 1,092, 225 and 155. The resistance of the hydrates of the limes to a breaking or crushing weight, is inferior to that of the mortar of the limes. The following experiments show the method of determining the tensile strength of cements and mortars and their results. An arch of bricks, placed horizontally in the direction of their lengths, was built 15 ft., 4 in. in span and 9 in. rise. It bore a uniform load of 6,400 lbs., only deflecting $\frac{1}{4}$ in. It broke with 4 tons. A similar arch with mortar could not support itself. Two stones, each 39 in. x 29 in. x 26 in., weighing 2,662 lbs., were cemented together; they broke apart with a weight of 36,544 lbs.; they were cemented on the largest surfaces, having an area of 1,131 sq. in. The following table shows the strength or force which is required to tear asunder 1 square inch of the materials named therein:

Slate	12,000
Well-burned Brick	750
Inferior "	100 to 200
Portland Stone	857 to 1,000
Crown Glass	42,946
Limestone	670 to 2,800
Hydraulic Lime	140
" Cement	234
Portland "	6 mos. 414
Plaster of Paris	" 72

METALS.—Iron and steel are the only metals of importance for construction. Zinc is used somewhat for galvanizing iron. Cast-iron may be divided into white and gray. White iron has a white color, a crystalline structure, and is hard and brittle. Gray iron has a gray color, a more granular structure, and is softer and tougher than white. Cast-iron is peculiarly adapted for resisting compression, and is almost exclusively employed for this purpose, as pillars, columns, etc. Wrought iron is principally used for bolts, nuts, screws and nails, by which iron and timber are united, and for rods and stays exposed to a tensile or pulling strain. It rusts more easily than cast-iron. Of late years steel has successfully replaced, and in most cases been much superior to iron for many purposes.

METALS, Strength of. — The mean tensile strength of malleable iron is 25 tons per sq. in., but elasticity is destroyed by 10 tons, and iron ought not to be strained beyond its elastic power. In the following table the tensile strength of other metals besides iron are given for comparison. The figures show the force required to tear asunder 1 sq. in. by direct tension:

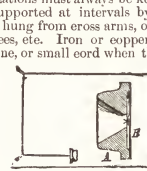
To find the tensile strength, multiply the area of the transverse section in inches by the weight given in the table, and the product will be the strength in lbs. A weight of 36,000 lbs. at-

tached to a bar of iron 1 in. sq. and 1,000 long, will draw it out 1 in.; 45,000 will stretch it 2 in.; 54,000, 4 in.; 63,000 8 in.; 72,000 16 in., where it breaks. Beams of maximum strength of cast iron, should be proportioned as follows: Sectional area of upper flange ¼ of lower, their thickness being as 1 to 2. Thickness of the web should equal that of the lower flange.

TELEPHONE.—The acoustic telephone, in its simpler forms, is easy to construct and operate. To make one, take a small sized box (an empty cigar box, for instance), and remove the lid and bottom. In place of the latter, tightly stretch and attach firmly a piece of parchment or dressed skin, in the manner that wire gauze is put in a sieve frame; that is, have a small frame that fits tightly on the open bottom of the box. A small hole is now made in the stretched skin through which the end of the line wire is passed from the outside. A small button is fixed to the end of the wire, which is then drawn tight, holding the button close against the stretched skin. At the other end of the line is an instrument similarly constructed. The wire between the stations must always be kept taut, and must be supported at intervals by a small cord or wire, hung from cross arms, on posts, the limbs of trees, etc. Iron or copper wire will do for the line, or small cord when the lines are short.



Acoustic Telephone.

To make the instrument work well, everything must be kept tight and snug. The wire, if possible, should be so placed that it will not be swayed by the wind. Another form of the acoustic telephone may be made by turning from wood a mouthpiece *A*, and attaching to it a disc *B* of ferrotype plate. The mouthpiece should be 2¼ in. in its largest diameter, and should have an annular surface ¾ in. wide for receiving the disc *B*, which is attached by means of sealing wax. The wax is first applied to the wood, and the disc is warmed and pressed against the mouth-piece. The disc is 2½ in. diameter. The portion left free to vibrate is 1⅜ in. diameter. The larger internal diameter of the mouth-piece is 1⅜ in., the smaller ½ in. There is a small hole in the center of the diaphragm for receiving the thread, which passes through a small piece of soft rubber and is knotted. The telephone thread must be supported on small elastic bands which must be put under tension. The string must also be taut. By means of this sound may be conducted at any desired angle, the elastic rubber supports being arranged as shown in the engraving. Whispers and even breathing may be heard over a long distance. When talking loud, the receiving instrument should be removed 2 in. from the ear.

VELOCITY OF SOUNDS IN DIFFERENT MEDIUMS. — Sound travels through solids faster than through the air. This may be illustrated by placing the ear close to the horizontal bar at one end of an iron fence, and having a person at the other end strike the fence a smart blow. Two successive sounds will reach the ear; one through the metal, and afterwards another through the air.

MARBLE, Artificial.—Marble is now so closely imitated by chemical means that there is often great difficulty in telling the imitation from the natural stone.—1. By a new process limestones or chalk may be converted into the nature of marble of any tint or combination of shades, while the specific gravity is increased. On the surface of the water-bath used for the veining there is sprinkled a varnish composed of sesquioxide of iron, gum and turpentine, and water being unstable, a freedom of design is obtained, especially when the turpentine is broken up by the addition of soap. After the stone is dipped in turpentine, it is immersed in solutions of sulphate of iron, copper or zinc, separate or in combination. The difference in shades is obtained by varying the period of immersion, and the order of tanks used. Copper and iron sulphate give dark colors; zinc and iron alternately give light yellow, while the use of the 3 consecutively gives dark yellow and brown in variegated tints. After being treated in the sulphate baths, the stone is immersed in a warm water bath to fix the colors, all air being meanwhile expelled. The color is said to permeate the full thickness of the stone, which is afterwards dried in an oven. The next step is immersion in an indurating bath of solution of sulphate of zinc, which so closes up the pores and hardens the stone that it acquires nearly the density of natural marble, and is then ready for polishing in the ordinary way.—2. Very finely powdered marble or white limestone is mixed with milk of lime until a smooth paste is formed. Some powdered limestone may now be added, and the mixture used at once.—3. Reduce marble dust or white limestone to a very fine powder by grinding and sifting, mix with it intimately about $\frac{1}{4}$ its weight of zinc oxide (zinc white) and $\frac{1}{8}$ of its weight of Portland cement, and mix thoroughly into a thick paste with a sufficient quantity of a hot aqueous solution of waterglass, containing about 40 per cent of the glass. Mold the paste under pressure while warm, and expose the molded form for a week or 10 days to warm dry air before finishing.—4. A solution of alum is made by dissolving the alum in sufficient water, and then plaster of Paris is put right into the vessel containing the liquid. It is then so mixed that the solution reaches all portions of the plaster; next it is baked.—5. Good Portland cement and colors that take on that material are mixed dry and made into a paste with the least quantity of water added. One paste has to be made for each color. The different pastes are placed on top of one another in layers of different thickness. The mass is pressed from all sides and beaten so that the colors of the different parts impress themselves on each other without uniformity. The result is that more or less deep veins penetrate the mass; this is then sawed into plates, which are pressed in a mold for 12 days, during which time it is necessary to keep them moist as long as they are not entirely hardened. The plates are polished in the same way as marble.—6. This composition (marmorit) contains 2 parts of magnesia; 2 parts of lime and quicklime; 1 part of carbonic acid; $\frac{1}{4}$ part of silicic acid; $\frac{1}{4}$ part of argillaceous earth; and 1 part of magnesium chloride.

STONE SIDEWALKS, Artificial Cement for.—English Portland cement is generally preferred. Procure a sharp, light-colored sand, and wash it free from all particles of soft earth or soil; also some stone chips, gravel and large stone. Excavate the sidewalk about 18 in. deep, and fill in the large stone to within 6 in. of the surface; prepare a concrete made of the cement, 1 part; stone chips and gravel, about 6 parts; and bed it in upon the stone bottom to within 2 in. of the surface; then prepare a concrete of the cement, 1 part, and fine sand 2 parts, and lay it in up to the surface, floating the surface with cement at pleasure. Finish by lining off into very regular blocks. A more economical sidewalk can be made by omitting the stone bed, but it will require a good hard soil to lay it on, and then will not be so sure of being permanent.

MORTAR, Brick-Dust.—The use of brick-dust mortar, as a substitute for hydraulic cement where the latter cannot be obtained, is recommended on the best engineering authority. It is considered that the addition of even as small a proportion as 1-10 as much brick-dust as sand to ordinary mortars is preventive of the disintegration so often characterizing mortars used in the masonry of public works. The proportions used are 1 of brick-dust, 1 of lime, and 2 of sand, mixed together dry and tempered with water in the usual way. This mortar is superior in the construction of drains, culverts, etc.

ROADS.—Rapidity, safety and economy of carriage are the objects of roads. They should be so located and constructed as to enable goods and passengers to be transported in the least possible time, and with the least labor and expense. Every road (other things being equal) should be perfectly straight. Any unnecessary excess of length causes a three-fold waste. First, of the interest on capital; secondly, by continual expense of repairing; and, thirdly, of time and labor in traveling. A road should be slightly inclined in the direction of its length, that drainage water may be readily carried off by side ditches; for this a slope of at least 1 ft. in 125 should be employed. If the slope be too great, a large portion of the strength of horses will be expended in raising the load up ascents. If a road rises 1 ft. in every 20 of its length, a horse drawing 1 ton, is compelled to actually lift up 1-20 of the weight (100 lbs.) through the whole height of the ascent, besides overcoming the friction of the entire load. Calling the load which a horse can draw on a level, 100 lbs., then on a rise of 1 ft. in 100 he can draw only 90 lbs.; 1 ft. in 50, 81 lbs.; 1 ft. in 40, 72 lbs.; 1 ft. in 30, 64 lbs.; 1 ft. in 20, 40 lbs.; 1 ft. in 10, 25 lbs.; no slope on any road should be of a steeper grade than 1 in 30. In a flat country a road should be raised slightly above the surrounding country, and in cross sections it should not be flat, but must "crown," or be higher in the middle than at the sides, to allow water to run off readily. On each side of the road there should be inclined ditches to carry off the water which falls upon it. As the surfaces of newly

made roads are usually deficient in hardness and smoothness to make a good road, it is necessary to cover the earth, which forms the surface of the road, with some material such as stone, wood, etc. The benefits of this consist in substituting a hard and smooth surface for the soft and uneven earth and in protecting the ground beneath it from the action of rain water, which, by penetrating to it and remaining upon it, would impede the progress of vehicles and render the road too weak to bear weight. Gravel for road beds should be sharp and moderately clean, not contain too much earthy matter, nor yet be too clean, but should have sufficient earthy matter to bind the pebbles together somewhat. In making gravel road beds, about 3 layers of gravel, each 3 or 4 in. thick, are put down and each well rolled. Broken stone roads (which were largely introduced in England by Mr. McAdam, from whom they have taken their name) are much used in the United States. The harder and tougher the rock employed, the more suitable. On this account the basaltic and trap rocks are most suitable, but, not being as universally distributed as limestones, are not so largely employed. The stones should be broken by hand into angular fragments of about 2 in. These are then spread upon the road bed and in time become consolidated. The principal objection to limestone is that it is too soft, ruts soon wearing in the road bed and the rock being ground to powder. Telford roads (so called, from having been introduced in England by Mr. Telford) are made of broken stone and gravel resting on a prepared pavement. The pavement is made of cubical blocks of stone, about six in. deep, set close together on a proper road bed so as to form a close, firm pavement. On this about 4 in. of broken stones are put and rolled until compact. About 2 in. more of broken rock is then put on in the same way; and the whole covered with good clean gravel to a depth of about 2 in. Paved roads are best made of square blocks of stone resting on a stable foundation, made of small broken stones or gravel well rolled down. The cubes should be about 8 in. in every direction, slightly tapered towards their lower ends. These blocks are set so that the joints between them shall not exceed $\frac{1}{4}$ in. and the interstices are filled with clean, sharp sand, enough being put on to slightly cover the whole pavement.

ROPES, CABLES AND CHAINS. Strength of.—The strength of cords depends upon the fineness of the strands, and other conditions. Damp cordage is stronger than dry, and untarred ropes than tarred. Tarring ropes renders them impervious to water and less elastic. Silk cords are 3 times stronger than those of flax of equal circumference, and manilla is $\frac{1}{2}$ as strong as hemp. Ropes of iron wire are a little more than 3 times stronger than ropes of hemp, of equal circumference. White ropes are more durable than others. The qualities of hemp are to be determined in a measure by the color. The best hempen ropes are pearl gray; next greenish, then yellow; brown colored ropes have less strength. The breaking weight of a good hemp rope is 6,400 lbs. per sq. in., but no cordage may be counted on as capable of sustaining a weight or strain above $\frac{1}{3}$ that required to break it, and the weight of the rope should be included in the estimate. The reliable strength of a good hemp cable in lbs. is estimated as equal to the square of its circumference in inches $\times$ 120; that of rope $\times$ 200; thus, a cable of 9 in. in circumference may be relied on as having a sustaining power $= 9 \times 9 \times 120 = 9{,}720$ lbs. The weight, in lbs., of a cable laid rope, per linear ft. = the square of its circumference in inches $\times$ .036, very nearly. The weight, in lbs., of a linear ft. of manilla rope = the square of its circumference in inches $\times$ .03, very nearly. Thus, a manilla rope of 3 in. circumference weighs per linear ft. $3 \times 3 \times .03 = 27$-100 lbs., $= 3$ 7-10 ft. per lb. A good hemp rope stretches about $\frac{1}{5}$, and its diameter is diminished 1-5 before breaking. To find what weight a rope will lift when rove as a tackle, multiply the weight that the rope is capable of suspending by the number of parts at the movable block, and from this subtract $\frac{1}{4}$ for resistance. Thus: 8.9 tons, the strength of the rope, multiplied by 6, the number of parts at the movable block, minus the $\frac{1}{4}$, or 13.3, gives 40.1 tons as the weight required. To find what size rope is needed, when roven as a tackle, to lift a certain weight, divide the weight to be raised by the number of parts at the movable block, to obtain the strain on a single part. To this add $\frac{1}{3}$ for the increased strain brought by friction, and reeve the rope of corresponding strength; $\frac{1}{3}$ of 40 tons is $6\frac{2}{3}$ tons, which, with $\frac{1}{3}$ added, is 9 tons, nearly, for which reeve a 6 or $6\frac{1}{2}$ in. rope.

TABLE SHOWING WHAT WEIGHT A HEMP ROPE WILL BEAR WITH SAFETY.

Circumference.	Lbs.	Circumference.	Lbs	Circumference.	Lbs.

STONES.—The essential properties of rocks as building material are: Strength, or the resistance which is offered to rupture, caused either by compression, extension or a cross strain; hardness, or the capability of resisting shocks and attrition; and durability, or its unchangeable character when exposed to the extremes of temperature, to the atmosphere and to chemical agents. *Granite* consists of quartz, feldspar and mica, firmly united, forming one solid mass. The quality of the stone depends on the aggregation of the particles, their size, and the proportion of each; the best is usually that in which the particles are fine and uniformly distributed. —*Limestones.* These may be classed as granular and compact. The granular presents the appearance of an aggregation of grains of vari-

able size, from fine to coarse, apparently from irregular crystallization. The compact has a fine, uniform texture, without any appearance of grains, some of the varieties being loose and earthy in their texture. As a rule the compact and smooth varieties are much more durable and better suited for construction.—*Sandstone.* This consists of particles of quartz united by an argillaceous, calcareous or silicious cement. The objection to its use is that it absorbs a large quantity of moisture, which, when acted upon by frost, causes the surface of the stone to scale.

WOOD.—This may be classed as the most important material used for ordinary constructional purposes. The tree is felled after having matured, and before it begins to decline. The trunk and larger branches are cut into suitable dimensions, seasoned thoroughly, and are then known as timber. The best age to fell trees for timber, is from 50 to 100 years old, and when the sap is not in circulation. The best time of year is during December, January and February. The importance of this will be seen when it is stated that there are two kinds of decay, both caused by the fermentation and consequent putrefaction of the sap. Wet rot is caused by the wood being allowed to become alternately wet and dry; while dry rot is due to the want of a free circulation of air around the timber. If timber be not thoroughly seasoned, its durability will be affected, and, on account of shrinkage, will be apt to cause material injury to a structure. The common method of seasoning is to expose it, under cover, to the air for about 2 years. The most durable timber is procured from trees of a close texture; those which grow in moist and shady localities furnish weaker and less durable timber than that from trees grown in a dry and exposed place. Straight grained timber, free from knots, is superior in strength and quality to that which is reverse. The best methods of preserving timber is to procure a free circulation of air around it, to prevent moisture or the action of a warm, damp, stagnant atmosphere. Seasoned timber, when used for posts, can be preserved by slightly charring the end that is to be imbedded in the earth. White oak is well adapted for heavy timbers, but oak boards are subject to warping and cracking. Pine is considered second only to oak for durability, straightness of fibre and ease with which it can be worked. The other varieties occasionally used, are chestnut, cedar, ash, elm, walnut, etc.

WOOD, Strength of. — The following table shows the weight in lbs. required to separate 1 sq. in. of different woods:

Ash	16,000 lbs.	Mahogany	21,000 lbs.
Beach	11,500 "	Maple	10,500 "
Birch	15,000 "	Oak, American White	11,500 "
Box	20,000 "	Oak, seasoned	13,600 "
Cedar	11,400 "	Pine, Pitch	12,000 "
Chestnut	10,500 "	Poplar	7,000 "
Cypress	6,000 "	Sycamore	13,000 "
Elm	13,400 "	Walnut	7,000 "
Fir, strongest	12,000 "	Willow	13,000 "
" American	8,800 "		
Lig. Vitæ	11,800 "		
Locust	20,500 "		

To find the tensile strength of timber in lbs., multiply the area of the transverse section in inches by the weight given in the preceding table. Transverse strength is power to resist force in a perpendicular direction. The weight required to break a solid uniform bar of different materials, is given in the following table, the bar being 1 ft. long and 1 in. sq., fixed at one end, and the weight suspended from the other:

MATERIALS.	Breaking Weight. Lbs.	Greatest Deflection. In.	Weight Borne with Safety. Lbs.	Value for General Use. Lbs.
White Oak, seasoned,	240	9	196	40
Chestnut, "	170	1.8	115	65
Yellow Pine, seasoned,	150	1.7	100	62
White " "	135	1.4	95	64
Ash, "	175	2.4	105	77
Hickory,	270	8	200	50

The strength of a projecting beam is $\frac{1}{4}$ of what it would be if supported at both ends, and $\frac{1}{6}$ of what it would be if fixed at both ends. To find the transverse strength when the bar or beam is fixed at one end and the load applied at the other, multiply the value in the preceding table by the breadth and sq. of the depth in inches, and divide the product by the length in feet. The quotient will be the weight in lbs. When the beam is loaded uniformly throughout its length, the result must be doubled. When the bar or beam is fixed at both ends and the weight applied in the middle, multiply the value in the preceding table by 6 times the breadth and the sq. of the depth in inches, and divide the product by the length in feet. When the weight is equally distributed along its entire length, the above results must be doubled. When the bar is supported at both ends and the weight in the middle, multiply the value in the preceding table by the sq. of the depth and 4 times the breadth in inches, and divide by the length in feet.

TABLE SHOWING THE RESISTANCE OF WOOD TO CRUSHING WEIGHT PER SQ. INCH.

WOODS.	In Lbs.	In Tons of 2,000 Lbs.
Ash	8,083	4.3
Beech, well seasoned	19,363	9.6
Birch	11,663	5.8
Cedar	5,863	2.9
Elder	9,973	4.9
Elm, well seasoned	10,331	5.1
Fir (Spruce)	6,819	3.4
Mahogany	8,198	4.09
Oak	5,982	2.9
Pine, pitch	6,790	3.3
Pine, yellow	5,445	2.7
Poplar	5,124	2.5
Sycamore, highly seasoned	12,101	6.
Walnut	7,227	3.6
Willow	6,128	3.06

BOAT-MAKING. — *Scow.* Perhaps the cheapest and most easily made boat is the scow. Procure 8 or 9 boards of ¾ in. pine, 8 or 10 in. wide; 1 pine board 1 in. thick and medium width; 1 lb. 5-penny nails, and ½ lb. same sized wrought nails. Plane the boards on both the sides and edges. Select 2 of the clearest and best boards, 10 in. wide; saw them 10 ft. long, making square ends; then taper the ends down to 4 in. wide, making the shape shown by *A A*, *Fig. 1*. Round off the

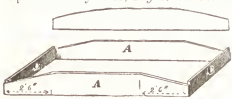

Fig. 1.

edges at the beginning of the tapering section. The curves should be gradual, and exactly the same on both boards. Saw out 2 other pieces, each 4½ in. wide, 1 in. thick, and 2 ft., 10½ in. long. These are the end pieces. Place the boards, *A A*, *Fig. 1*, parallel on their straight edges, and between their ends place the end pieces, *C C*. The ends of the side boards, *A A*, are to lap over the ends of the end pieces, *C C*, and the upper edges of the end pieces should project a little above the level of the side boards, as *Fig. 1* shows. Nail the side boards securely to the end pieces, making square corners. All the nails must be countersunk. Nail bottom boards, 3 ft. long, crosswise upon the edges of *A A*, *Fig. 2*. The edges of the bot-

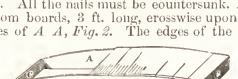

Fig. 2.

tom boards should fit closely; about 6 nails may be used in every board. After planing the edges of the end pieces, *C C*, *Fig. 2*, sufficiently to make a good joint, lap the bottom boards over them. After covering the whole bottom in this manner, cut 2 strips, each 10 ft. long, 1½ in. wide, and 1 in. thick; 4 ft., 5 in. from one end of each strip, cut a notch on the side ½ in. deep and 1½ in. long, and 3 in. from this notch, or 4 ft., 8 in., measuring from the same end, cut another same size. Turn the boat over and nail these strips on the upper edges of the side boards, *A A*, *Fig. 3*, on the outside of the same, with the notches inside. Use clinched wrought

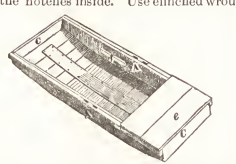

Fig. 3.

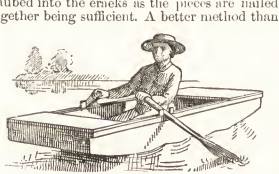
nails, 1 ft. apart. The mortices so formed are the rowlocks, hence those on one side must be opposite those on the other. Near the rowlocks the strips must be more securely fastened than elsewhere. The end of the scow nearer the rowlocks is the stern. Place a ¾ in. board in the middle of the bottom inside *Fig. 3*; bend it down against the bottom, and nail through the bottom boards into it, where the dots in the diagram indicate. 2 wrought nails in each bottom board, clinched in the side; this board to be known as the long bottom board. Place 2 boards crosswise, 3 ft., 2 in. long, at *e*, *Fig. 3*, and nail them to the edges of the side boards, *A A*. The opposite end of the boat is covered in the same manner. Nail a cleat about 1 ft. long on each side of the boat inside, at *f*, *Fig. 3*, with its aft end 5 ft., 4 in. from the stern, and its upper edge 6½ in. below the edge of the side board. These cleats should be fastened with clinched wrought nails; they are to support the seat board, which is 2 ft., 10½ in. long. Make 4 oak tholepins, *Fig. 5*, ½ in. thick, 4 in. long, 1½ in. wide, with a shoulder projecting over about 1 in.; fit them in the mortises, and thus complete the rowlocks. Pine or cedar will do for the oars, which should be 5 ft. long, 1¼ in. diameter at handle, and 2 in. diameter immediately below; blade, 18 in. long, 5 in. wide, and ¼ in. thick. Every part of the oar that will fall outside the rowlock when rowing should be as light as due regard for strength will permit. Bore a ¾ in. hole in the bow seat, through it run the end of a small rope and knot it inside *Fig. 4*. This rope is called the "painter," and should be about 9 ft. long. Wedge cotton evenly into all seams and cracks on the outside of the boat, except the end seats, leaving space above the cotton at least ½ in. deep; then fill the seams and cover the nail heads with putty. A good carpenter can fit the joints so that no caulking will be necessary; thick paint daubed into the cracks as the pieces are nailed together being sufficient. A better method than

Fig. 4. Fig. 5.



Scow.

caulking for this kind of boat, is to lay a strip of thick flannel, ¾ in. wide, saturated with paint, between the pieces as they are put together. This strip must be placed in every seam outside. 2 coats of paint will suffice. A neat color is a mixture of white lead and lampblack, forming a lead color. Use a lighter shade for inside. The seams leak at first, but a week's soaking closes them. Cost of all materials about $3.

Skiff. — The illustration represents a skiff costing about $5. 10 or 11 cedar boards ¾ in. thick, and not less than 7 in. wide, are required; also, 2 cedar boards ¼ in. thick, 14 in. wide, and

13 ft. long, free from knots. The latter will be called the side boards. They should both be of same quality, so that one will bend as easily as the other. Cedar is the wood used throughout, except where the name of the wood is given. A piece is cut, shaped like *Fig. 1*, with the entire length 4 ft., the width 12 in., and the distance *d* from the end to the dotted line 4 in. We will name this the cross-board. A piece of oak is cut of similar shape, but making the entire length 20 in., width 13 in., and distance *d* 6 in. This is the stern-piece. Both ends of each side-board are sawed off bevel, like the ends of the cross-board, and with same slant at both ends. The bevel at one end of the side-board should be the reverse of that at the other, making one edge 12 ft., 8 in. long, and the other 12 ft. The side-board has the appearance of *Fig. 1* elongated.

Fig. 1.

The tapering of the side-boards at the ends, which is necessary in the construction of the scow, is not required. The upward curve of the bottom is obtained by bending the side-boards. Set the side-boards, *B B*, *Fig. 2*, on edge parallel, with the longer edges uppermost, and at about the middle place

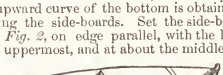


Fig. 2.

the cross-board, *t*, between, also with its longer edge uppermost. Nail the side-boards, *B B*, lightly to the cross-board, *t*. With the aid of ropes, draw two ends of the side-boards together; the other ends draw against the stern-piece, *R*, *Fig. 2*. In a piece of oak, about 16 in. long, cut grooves throughout its length, and make its cross section like *Fig. 3*. This "stem-piece," as it is called, is placed between the ends of the

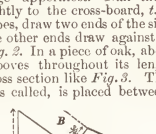

Fig. 3.

Fig. 6.

side-boards that were drawn together. After altering the shape of the stem-piece, if necessary, so that the ends of the side-boards, *B B*, *Fig. 3*, shall fit closely into the grooves, the side-boards are securely nailed to both stem-piece and stern-piece. The projecting upper end of the stem-piece is sawed off, and the boat inverted carefully. The convex edges of the side-boards are

Fig. 4.

planed down 1 in. or more at the middle, *c*, *Fig. 4*, so that the bottom (the boat is now bottom up) may be flat from *a* to *b*, making easy curves at *a* and *b*. This flattening of the bottom is not useless, the draft being thereby diminished, and the speed probably increased. Bottom boards $\frac{3}{4}$ in. thick are nailed on crosswise, *Fig. 5*, and the

Fig. 5.

projecting ends sawed off. A long bottom board is put in, as described for the scow, and the cross-board, which was only temporary, is knocked out. *Fig. 6* is the seat at the bow. The cross-piece *n* is secured by nails driven through the side-boards into its ends, as at *P*. In *Fig. 7*, which represents the seat at the stern, the cross-piece, *L*, is fastened in the same manner. There is a cleat at *K*. The seats in both bow and stern are about 3 in. below the edges of the side-boards, and the seat-boards are lengthwise. We are now ready for the "upper streaks," as they are called. Two strips are cut 12 ft., 8 in. long, 2 in. wide, and 1 in. thick; two notches, each $1\frac{1}{2}$ in. long, and nearly 2 in. deep, are cut in the upper edge of each side-board, *Fig. 8*. They are 3 in. apart, and the point midway between them is 5 ft., 1 in. from the stern, measuring on a straight line in the middle of the boat. All the longi-

Fig. 7.

Fig. 8.

Fig. 9.

tudinal measurements hereafter given are upon this line. The upper streaks are now nailed on the outside of the side-boards even with the upper edges of the latter, like the strips upon *A A*, *Fig. 3*, in scow. The joint made by the upper streaks at the bow is shown by *Fig. 9*, in which *A* is the stem-piece, *B B* are the side-boards, and *C C* are the upper streaks. The row-locks are now completed by a short strip, *y*, *Fig. 10*, strongly screwed on the inside, over the notches. Make thole-pins, of the shape shown by *Fig. 5* in scow, and fit them into these mortises. It is often quite convenient to have another pair of row-locks about 2 ft. nearer the bow, that when a person sits in the stern, the rower may shift forward to better distribute the weight, for a boat rows hard when the stern is weighted down. Make two cleats for the rower's seat, with their aft ends 6 ft. from the stern, and their upper edges $7\frac{1}{2}$ in. below the edges of the side-boards. Saw off a seat-board 3 ft. 10 in. long. Invert the boat and fit a piece of inch-board, *N*, *Fig. 11*, upon its edge, at the stern, upon and perpendicular to the bottom. It is fastened at *g* by a screw, between *g* and *M*, by nails driven into it through the bottom from the inside of the boat, and by the strip *M*, of the same thickness, nailed

Fig. 10.

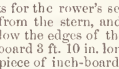

Fig. 11.

Fig. 12.

on the end of *N*, and crossing the stern-piece vertically, to which it is screwed. A $\frac{3}{4}$ in. hole is bored through the stem-piece at *l*. *Fig. 12*, through which the painter, 10 ft. long, is tied. An iron strap, shaped like the double line in the same figure, is screwed to the cutwater. The proper length for oars is about 7 ft. The boat is now to be caulked, unless rendered water-

Skiff.

tight by the methods described for the scow. Nail-heads are covered with putty, and 2 coats of paint applied.

Canoe Sail Boat.—The length is shown in the illustration is 13 ft., and is capable of carrying 2 persons, including guns, ammunition, etc.; designed for cruising on lakes, rivers and creeks, and on the sea-coast, in the latter ease carrying ballast. It is decked, quite stiff, rows easily, and carries 2 small sails made as safe and handy as possible. The masts are easily removed, and spars and sails stowed under deck. Dimensions are given for full sail, or for half sail, as desired. A centre-board is inadmissible, and a deep keel impossible, light draught being an object; good sailing qualities are obtained by using full-sized sails and a "lee-board." Without a deck, and fitted with thwarts, this craft would be an excellent row-boat for shallow waters. Estimated cost, $15. Draught, not over 3 in. with one person and baggage. The ribs are marked in *Fig. 1* as *A B C*, etc., ⊕ *1, 2, 3*, etc., which is a combination of cross sections, 1 at every rib. The canoe is a double-ender, that is, having bow and stern alike. The figure shows the series of ribs on only one side, and extending from ⊕ to only one end, those in the other section being precisely the same. The bottom is flat and coincides with line *0*, and the keel is a board 5 in. wide

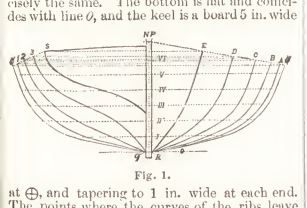

Fig. 1.

at ⊕, and tapering to 1 in. wide at each end. The points where the curves of the ribs leave line *0* are determined by the distances in column *0*, *Table 1*, measured from the dotted centre line *a a*, from which all horizontal measurements must be made. Lines *0*, *I*, *II*, *III*, are 1 in. apart; lines *III*, *IV*, *V*, 2 in. apart. The heights in *Table 2* are measured from line *0*. The ribs between ⊕ and the bow are designated by letters, and those between ⊕ and stern by figures. The bottom being flat, frames ⊕, *1, 2, A, B*, may each be of one piece, the mold-board being cut to represent the curves on both sides of the boat. In the table, the lengths of the ribs mentioned are doubled, and the "width at lower end" means the width of that section of each frame which crosses the flat portion of the bottom.

permit bailing. The deck is canvas, stretched on the framework shown in *Fig. 5*. *W* the gunwale, 1.8 in. deep and 1.3 in. thick. The ends of the deck-beams are let into it about .8 in., making beam-ends and gunwale flush with the up-

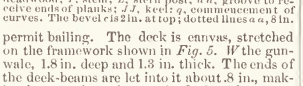

Fig. 4

per streak *N*. The slope of beams *4* and *5* is 4.5 in.; that on the others decreases toward bow and stern, so that if a board is set edgewise resting on the stem and the peak of beam *4*, it will also touch beams *1*, *2*, and *3*. The beams are cedar, .5 in. thick, 1.2 in. deep at ends, and 2.5 in. deep at peak.

Beam 1 is	6	in. abaft bow.	
" 2 "	.....1.5	" "	frame *D*.
" 3 "	2	" " "	*C*.
" 4 "	1	" forward frame	*B*.
" 5 "	1	" abaft "	*2*.
" 6 "	2	" forward "	*3*.
" 7 "	2	" abaft "	*4*.
" 8 "	6	" forward stern.	

D D, *Fig. 5*, are two ½ in. cedar boards, each 4 in. wide, running from beam *4* to the bow, and from beam *5* to the stern. They are nailed upon the tops of the aprons, and made flush with both gunwales and the stem and stern pieces. Beams *4* and *5* are made deeper than the others, and the ends of boards *D D* let into them. Boards *D D* need not be let into the others. The masts should be "stepped," before completing the deck. If full sail is spread, the foremast should be about 1 ft., 10 in. from bow, the mizzen mast 3 ft. abaft ⊕; if one sail is used, the mast should be 5 in. forward of frame *B*. The mast-holes are cut in boards *D D*, *Fig. 4*, ½ circle in each board. Sew breadths of duck together, making two roughly shaped pieces to cover the boat from bow to beam *4*, and from stern to beam *5*. Less material is consumed by placing the breadths across the boat. After securing the cloth by a few tacks on boards *D D*, stretch it tightly, fold the edges under, and tack it upon the outside of the upper streaks, the outer sides (not the edges) of beams *4* and *5*, and crossing boards *D D* near their ends. Copper tacks should be used. Next, boards *B B* (one is shown in *Fig. 5*), .6 in. thick, 4 in. wide, with a slope of 1 in 5, are laid with their ends on frames *4* and *5*, and their outer edges cover both gunwale and upper streak. They are nailed to the beams, and at intervals to the gunwales, and supported at frame ⊕ by a small iron brace (*Fig. 5*). Cut the mast holes through the canvas, and tack round them. Then, to bind together boards *D D*, screw a flat iron ring, bent to fit the slopes, round the aperture. (See *Fig. 4*). *Figs. 6* and *7* represent one of the outriggers. The iron rod *A* (*Fig. 7*) lies in a plane at right angles to the boat. It is screwed to the inner side of the gunwale, before the board *B* (*Fig. 5*) is put on, 2 in. forward of frame *1*; its lower end is bent toward the stern and screwed to frame *L*. The upper or outer end is bent back and made wide enough to drill a hole downward to admit the shank of the rowlock. The rowlock is secured at *d* by a peg or nut. To the extreme end *c* the rod *B* is welded, and screwed at its other extremity to the outside of the upper streak, near the top. Rod *A* should be quite stiff, as it bears the whole weight of the oar; rod *B* should be light. The section of rod *A* below the gunwale may be about 5 in. long; the length of rod *B* should be about 13 in. Sculls, 8 ft. long. In this boat, only one can row; but if designed for two, the rowlocks should be put further forward, about at frame ⊕. The rudder 14 in. wide for full sail, and fitted with a yoke. Dimensions for full sail: Foresail, height on mast, 9 ft.; length on boom, 6 ft. 8 in.; rise, 16 in. Mizzen sail: height on mast, 7 ft., 4 in.; length on boom, 5 ft., 4 in.; rise 14 in. Both are leg-o'-mutton sails, raised by halyards and attached to hoops

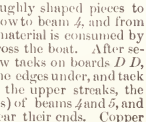

Fig. 6 Fig. 7.

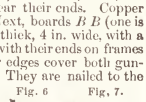

Fig. 8. Fig. 9.

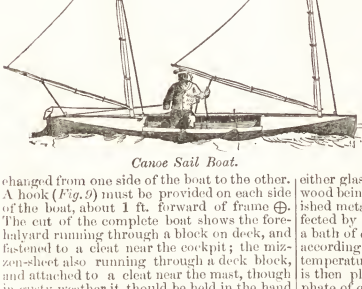
on the mast. Booms with jaws are best, and the sails bent upon them. Foremast, 10 ft. 7 in. long, 2 in. diameter at butt, 1 in. at top. Mizzenmast, 9 ft. long; diameter, 1.7 in. at butt, .9 in. at top. Dimensions for half sail: One foresail, size of either of the foregoing; must 5 in. forward of frame *B*. Beating to windward is impossible with this sail, and no leeboard is needed. Width of rudder, 12 in. To sail well the boat must be furnished with both sails and a leeboard. *Fig. 8* shows the leeboard in proper position, as it should float when partially submerged; but if the buoyancy of the wood causes it to rise, a lead or iron weight let into the board at its aft end will obviate the difficulty. The proper direction of the grain is indicated, and an iron strap on the forward edge. *Fig. 9* indicates the only manner of fastening. *I* is the board already described in *Fig. 5*. A bolt is run through the upper corner of the board, and furnished with rings at each end. This bolt should turn easily. Every time the boat "comes about" this leeboard must be



Canoe Sail Boat.

changed from one side of the boat to the other. A hook (*Fig. 9*) must be provided on each side of the boat, about 1 ft. forward of frame ⊕. The cut of the complete boat shows the forehalyard running through a block on deck, and fastened to a cleat near the cockpit; the mizzen-sheet also running through a deck block, and attached to a cleat near the mast, though in gusty weather it should be held in the hand with the other sheet. Diameter of cordage, $\frac{1}{4}$ in. The weight of anchor about 12 lbs. The cable of hemp, about 5 in. diameter, and length governed by waters in which used. The seam under board *B* (*Fig. 5*) should be caulked. If the canvas is stretched sufficiently, and painted, and the tacks placed $\frac{2}{4}$ in. apart, the deck will be tighter than if of wood. This boat, if submerged, will easily float with one person sitting in it. It is very desirable to galvanize all iron work used.

BOXES.—When made of wood, the pieces are accurately measured by the square; marked on both sides, and sawed through the line. The pieces are planed truly to the angle of the box to be made. Draw a pencil line across the 2 side pieces $\frac{1}{2}$ in. from the ends, by the help of the square, and with a brad-awl make holes along those lines. Do not make the first and last too near the edges, or they will split the wood. Now set up one of the short pieces, and place upon it the piece which you have bored holes in. Run the brad-awl a little way into the lower piece, through the holes made into the upper. Drive a brad through the middle hole first, then through the other holes. This corner should be square and neat. Do the same with the other short piece; then nail on the long side that is left. The frame of the box will now be complete. The following table gives the contents of boxes of different sizes:

Square		Depth.		Contents.
4 x 4	in.....	2½	in.....	1 pt.
4 x 4	"	4½	"	1 qt.

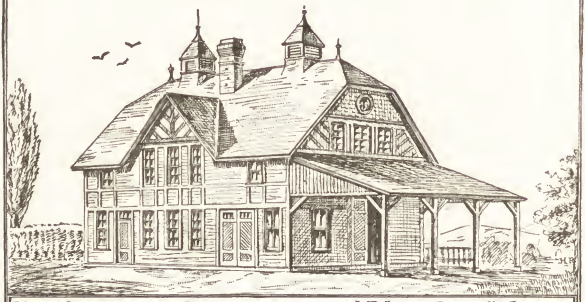
			or 8,467.20 cu. in.	

WOOD, To Make Look Like Metal.—The recently invented process, by which wood is made to take on some of the special characteristics of metal, has been turned to practical account. By this process the surface becomes so hard and smooth as to be susceptible of a high polish, and may be treated with a burnisher of either glass or porcelain, the appearance of the wood being then in every respect that of polished metal, with the difference that it is unaffected by moisture. The wood is steeped in a bath of caustic alkali for 2 or 3 days together, according to its degree of permeability, at a temperature of between 165° and 197° Fahr. It is then placed in a second bath of hydrosulphate of calcium, to which a concentrated solution of sulphur is added after 24 or 36 hours. The third bath is one of acetate of lead, at a temperature of from 95° to 120° Fahr.; and in this latter the wood is allowed to remain from 30 to 50 hours. After being thoroughly dried, it is in condition for being polished with lead, tin or zinc, as may be desired, finishing the process with a burnisher.

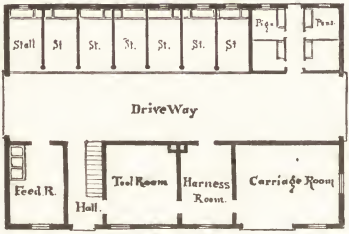
Examples of Buildings.

The cost of materials and labor varies so much in different parts of the U. S., that the estimates given for the cost of each building must be regarded as only approximate.

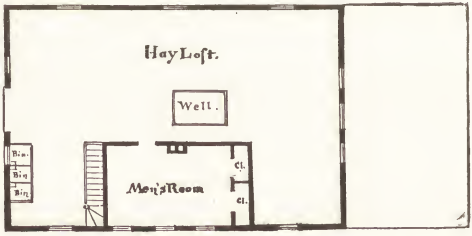
BARNS. — *Small.* In the country and suburbs a small barn, such as shown in the illustration, is sometimes desirable. The first floor has a carriage-house for 2 carriages; a covered open shed for a wagon; a large tool-room, with 3 stalls and a harness closet. The second floor has the grain bins and hay-loft. The loft is lighted by dormer windows, and the ventilating shaft



View of a mediumsize Barn. J.B.Legg Arch! St. Louis.

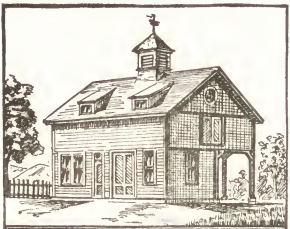


Ground Plan.

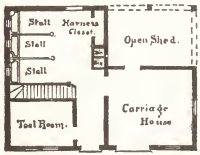


Loft Plan

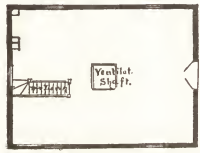
breaks the roof-line very effectively. Cost about $650.



A small Barn. J.B. Legg Arch't St. Louis.



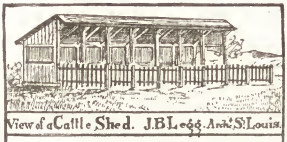
Ground Plan



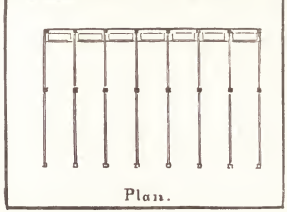
Plan of Hay Loft

Medium-Sized.—The importance of careful handling of farm stock is always kept in view by good farmers, and the accompanying plan may please many. The first floor has 7 large stalls and 4 pig-pens on one side of the drive-way; and the feed, tool, harness and carriage-rooms on the other; also the stairs leading to the second floor. The wagon-shed will accommodate about 4 wagons without encumbering the driveway to the stable. The second floor has a hay-loft with a well-hole to pass hay from the wagons up and also to haul grain through. Bins for oats, corn, and bran are provided. The men's room is large and has 2 closets. The hay-loft, owing to the high pitch of the roof, will hold a large supply of hay. Externally, the sides are weather-boarded with ornamental false framing to break the large surfaces of the sides. All the rooms are well lighted and ventilated. The cost is about $2,750.

CATTLE SHED.—To prevent the cattle from becoming reduced in condition during winter, some protection from the weather is necessary. When arranged in stalls, as shown in the



View of a Cattle Shed. J.B. Legg. Arch't St. Louis.

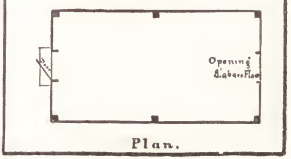


Plan.

illustration, they shelter when fattening for market or for milking. The closed side should be placed to the north. The small fences enable a separation of the stock. The cost per stall is about $350.

CORN-CRIB.—The corn-crib, shown in the il-

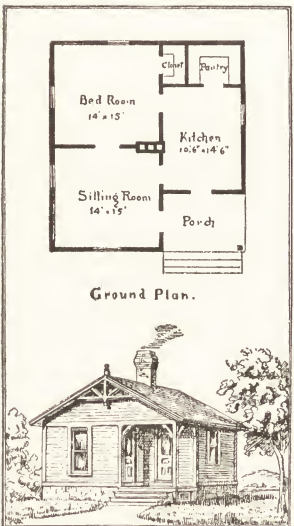
View of a Corn-crib. J.B. Legg Arch't St. Louis.



Plan.

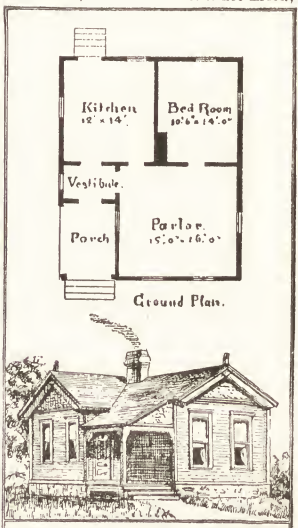
lustration, is elevated on 6 posts, and allows free circulation of air underneath, preventing dampness and keeping the grain dry. This also preserves the grain from attacks of vermin.

DWELLINGS.—*Plate 91, Design 111.* A building, no matter how small or unimportant, costs no more to erect if symmetrically arranged and designed in good proportions. The illustration shows how the most simple form of a house is improved by such treatment. This 3 room cottage, designed for a farm or small village, is compactly and economically arranged. The entrance is sheltered by the porch being drawn under the roof of the building; from it you can enter either the kitchen (intended to be used as a dining-room also), or the sitting-room. The kitchen has a good-sized pantry with ample shelf-room for all necessary utensils, and may serve as a store-room. The size of the kitchen is 10 ft., 6 in. by 14 ft., 6 in., large enough to serve the double purpose intended, for a small family.



The sitting-room, to the left of the porch, is 14 by 15 ft., having windows on 2 sides, and a door, with transom, entering the bedroom in the rear; it is well lighted and ventilated. The bedroom, the same size as the sitting-room and lighted in the same manner (windows on 2 sides), will make a pleasant sleeping room. A closet with shelves is attached to this room, and a door leads from it into the kitchen. This door should have no transom. One feature, and a very economical one, is the location of the chimney, so placed that it contains a flue for each room. Any one who has built in the country knows how expensive it is to build chimneys, and will appreciate this. Regarding the exterior, the perspective view shows plainly what the design is. The roof will take shingles about 33°, and has a hanging gutter on each side. The gables have small finials and simple frame work. The outer architraves are plain, and a belt rail extends on the level of their top from corner strip to corner strip. The cornice is a plain molded front railroad cornice. The cost of the building with a cellar under one room would be about $675.

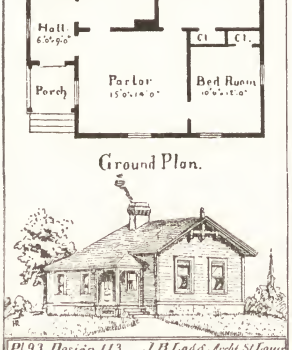
Plate 97, Design 117.— This cottage is a little more pretentious than the preceding one and has 3 rooms, but the entrance is not directly



into the rooms, a small vestibule being provided. The front is entered from the porch, which is covered by continuing the roof of main building over it. Passing into the vestibule, lighted by a window on the left side, you can go into the parlor, sitting-room, or kitchen. The parlor, on the right of the vestibule, is 15 by 16 ft.,

and has windows on 3 sides, 2 in front and 1 on the right and left. From this room doors enter the kitchen and bedroom. The bedroom, 10 ft., 6 in., by 14 ft., has windows on 2 sides, and is cut off from the kitchen. The kitchen is 12 by 14 ft., and has a window on 2 sides and a door leading to the yard in the rear. The rooms are well lighted, and having windows on 2 sides, will be cool in summer. The door from the vestibule into the parlor, and the one from parlor to bedroom, might have transoms, although not necessary. One chimney serves the 3 rooms. The exterior shows a broken roof, with a gable in front over the parlor and one over the kitchen, the roof in the rear at outer corner of the bedroom being hipped up. The outer architraves of the windows have molded caps. The porch roof is supported by square posts with small solid molded brackets in the angles. The weather-boarding only extends to the line of the eaves in the gables, and is capped by a molded belt rail, the space above which is shingled, as is also the spandrel formed by the roof in front of the porch. This shingling could be stained differently from the color of the siding and produce a pretty effect. The cornice is a plain molded railroad cornice with hanging gutter. The cost of the building with a cellar under the kitchen would be about $750.

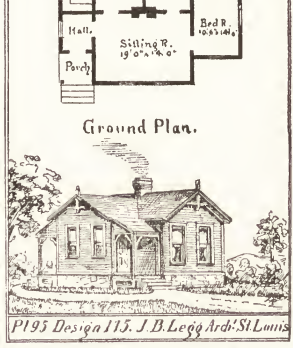
Plate 93, Design 113. — The plan of this 4



Pl.93. Design 113. J.B.Legg, Archt St Louis

room cottage is almost a perfect square, with rooms and porch under one roof. In front the house is entered from the porch into a vestibule, 6 by 9 ft., entering into the kitchen or parlor. The parlor, 14 by 15 ft., has windows on 2 sides, giving good ventilation, and doors to the kitchen and bedrooms. The front bedroom, 10 ft., 6 in., by 12 ft., and the rear bedroom, 15 by 12 ft., have each a closet, and windows on 2 sides of the rooms. The rear room has a stove flue, but the front room will require to be warmed from the parlor. The kitchen, 10 ft., 6 in., by 14 ft., has a door in the rear leading to the yard. On the left of the kitchen, and opening into same, is a large pantry or store-room, 6 by 9 ft., which is of sufficient size to contain the family stores. This plan has the same features described in previous examples as to the single chimney, style of architraves, cornice, etc., and needs no further explanation. Cost about $950.

Plate 95, Design 115. — This is a small 4 room cottage, adapted to farm or village, and by its economical construction suitable to persons of limited means. A small porch in front and rear covers the entrances and is roofed in with the building. Entering at the front is a small hall which leads into the sitting-room, 14 ft. wide and 19 ft. long, and designed to be a general family room. The side bedroom, 10 ft., 6 in., by 14 ft., and rear bedroom, 9 ft. 4 in. by 14 ft., are entered from this room. Each of these bedrooms is provided with a roomy closet. The rear bedroom has a flue-hole for a stovepipe in the chimney, which contains a fireplace for the sitting-room, and flues for the bedroom and

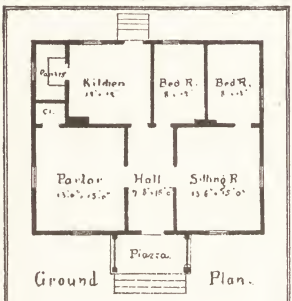


Pl.95 Design 115. J.B.Legg Archt St Louis

kitchen. The kitchen, 9 ft., 4 in., by 14 ft., is entered from the yard, or from the sitting-room. An extra large pantry opens into the kitchen, provided with shelving and roomy enough to be used to store flour, etc., in. A window gives the

pantry light and air. Though rather small, the kitchen is of a size to enable the family to use it as a dining-room; otherwise the sitting-room will be used. The exterior has been kept plain, and much of its good effect depends on the play of light and shade which the broken outline of plan and roof insure. The perspective represents the building with a stone foundation, though if posts or piers are used, the space below the water-table will have to be inclosed with matched boards placed upright and finished on the ground on a plain base. The water-table is simple, but enough to break the line between the foundation and superstructure. Molded top architraves are used on the front windows, the sides and rear being plain; it has a railroad cornice and the roof as flat as will work shingles. The corner boards are plain. One of the best features is the way in which the chimney comes through the ridge of the roof. The roof of side bedroom can be hipped into the main roof with good effect. The cost would be about $800.

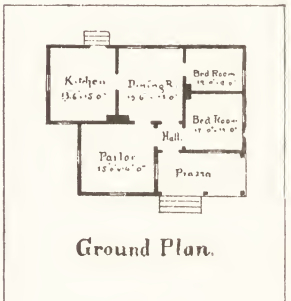
Plate 96, Design 116. — In plan nearly square, this house contains no waste spaces, and every portion of the floor space is utilized. In the



Pl.96 Design 116 J.B.Legg Arch.t St.Louis

front of the house is a roomy porch. The house is entered by square hall, 7 ft., 8 in., by 15 ft., which is a great assistance in making the house comfortable in summer, as it allows the ventilation of the rooms opening on it. To the left of the hall is the parlor, 13 ft., 6 in., by 15 ft., and on the right the sitting-room of same size. Both rooms have windows on 2 sides, and the parlor a good sized closet; both are provided with flues for stoves. The parlor has no connection with any other room, but from the sitting-room a door enters one of the bedrooms, 8 by 12 ft. The rear end of the hall opens into the kitchen, 12 ft. sq., or the second bedroom, 8 by 12 ft. Both of the bedrooms have flues for stoves. The kitchen has a pantry lighted by a window. The uses to which the rooms can be put may be varied to suit the needs of those living in it; for example, a door could be placed between the kitchen and parlor and the latter room used as a dining and family room, and the sitting-room and bedroom used as sleeping apartments. The building has a straight gable roof which extends across the building and broken into by the porch roof. This porch has neat, square, chamfered posts, molded corner brackets, and gable roof with ornamental gable and finial. Cost about $1,050.

Plate 94, Design 114. — A little better class of

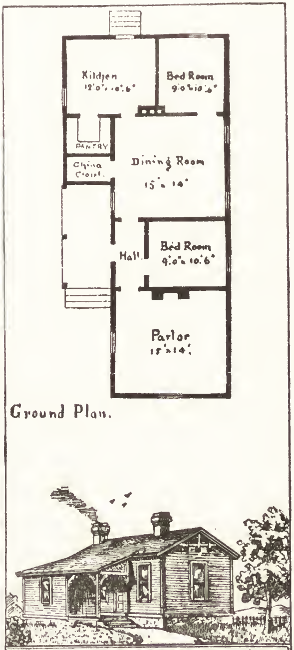


Pl.94 Design 114 J.B.Legg Arch.t St.Louis

cottage than the foregoing, requiring a wider lot, a corner being well adapted to it. A piazza in front, 16 ft. long, fills out the break made by

the projection of the parlor; from this you enter a small hall only large enough to prevent a direct entrance into the rooms, and thus obviate the tracking in of dirt in bad weather, and draughts when the front door is opened. To the right of the hall is the front bedroom, on the left the parlor, and directly to the rear the dining-room. The parlor, 14 by 15 ft., has windows on 3 sides and a door leading into the dining-room; one of the windows opens on the porch and might be made a bulk-head window, so that one could step directly on the porch without passing through the hall. The front bed room is 12 by 12 ft., and the rear one 12 by 9 ft., both containing flues for stoves; the rear bed room opening into the dining-room. The dining-room is 13 ft., 6 in., by 15 ft., and has 2 large windows in the rear. The kitchen to the left of the dining-room and of same size has windows to the front and side and a door leading to the yard. Two chimneys supply the rooms with flues. The windows have a plain architrave finish with molded sills. The front porch has a flat roof, to be covered with tin and a small modillion cornice. The porch columns are square with corner brackets. There is a gable over the front end of parlor and one on the right side over bedrooms, both finished plain with a drop and cross-bar and terminating on the top with finials. The broken outline of this roof is an effective feature of the design; the rear side is hipped up and the whole crowned by a small deck with neat cornice. This deck, like the porch, should be covered with tin. A good painter, and a little artistic feeling in the selection of colors, will repay, as an opportunity is offered for effective trimming. The porch, porch cornice, corner boards, gables and deck cornice and outer architraves allow of good contrasts. The cost of this building would be about $1,000.

Plate 92, Design 112. — A neat plain 5 room cottage is represented. Its long, narrow shape makes the rooms cool in summer and well ventilated, as it gives them windows on 2 sides. Though the arrangement may seem unhandy because of the distance between the rooms, an investigation will show that the rooms that will be used mostly in connection have been grouped. The house is entered by a porch into the hall, from which latter doors lead into the parlor, bedroom and dining-room. To the rear, adjoining the dining-room, is the kitchen, to the right of which, entered from the dining-room, is a second bedroom. The parlor, 15 by 14 ft., is in the front of the house and has windows on 2 sides and an open fireplace. The bedroom, between the parlor and diningroom, is 9 ft. by 10 ft., 6 in., and has a stove flue entering the parlor chimney. The dining-room extends across the width of the front of the house, and is 15 by 14 ft., and is provided with a closet large enough to contain all the dishes required, and has windows on either end. To the rear of the dining-room is the kitchen and a bedroom; the bedroom, 9 ft. by 10 ft., 6 in., and the kitchen, 10 ft., 6 in., by 12 ft. The kitchen has a pantry and store-room with ample shelf room. The kitchen, bedroom and dining-room are served by the same chimney, containing a flue for each. An entrance to the kitchen from the back yard is provided. The exterior follows the same style as in the preceding examples. The roof is low, and has as little pitch as would be safe to give a shingle roof. The gable in front has an ornamental drop composed of 3 posts and a cross-bar. The porch



Pl. 92 Design 112. J. B. Legg Arch't St. Louis

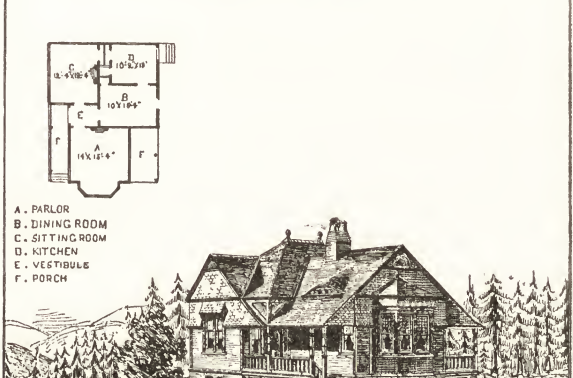
columns are square and without base or cap, running up to the eaves of roof with a spandrel in front intended to be shingled. Molded brackets are placed on the posts in the angles. The porch is large and will shade the sunny side of the house. The approximate cost of the building would be about $1,200.

Plate 89, Design 109. — A small 5 room cottage, somewhat out of the usual run of such buildings, but well adapted to a hilly situation. A large veranda extends across the front, and returns at the side as far as the vestibule, shading

the front part of the house. The steps to this porch on the right side of the house have the roof extended over them to form a shelter. A small vestibule with window, in which stained glass would be an ornamental feature, is entered from the porch and has doors opening into the parlor, A, and chamber, C. The parlor, 14 ft. by 15 ft., 4 in., has windows on 3 sides and also a door leading directly on the front porch. This room is only provided with a stove flue; but an open fireplace could be substituted, and would be a great improvement, though somewhat more expensive. A door leads from the parlor into the kitchen and dining-room, B, 12 ft., 4 in., by 15 ft., 4 in., having windows on 2 sides and a door leading to the yard. The chamber, C, can only be entered from the vestibule, and though adjoining the kitchen, will not be made uncomfortable thereby. This room is of the same size as the kitchen. Up stairs (the plan of which is not given), there are 2 bedrooms, comfortable and airy, though, from the shape of the roof, not high at the walls. Externally this cottage is picturesque, the effect of light and shade being quite apparent. The roof pitches upon a high gable over the rear part of the house, and the front portion, including porch, is then shedded up against it. These roof lines are broken by small dormers which run out through them. The sides of the house, instead of being weather-boarded, are covered with stained shingles. The porch posts are turned with square tops and bottoms. The cost would be about $1,000.

Plate 88, Design 108.— In general plan the house is nearly square, with the exception of the bay window in front, and is inexpensive from a constructional standpoint. The arrangements of porches on either side of the vestibule, E, open on it. The other porch, or balcony, as there is a balustrade inclosing it and no steps leading to yard, is entered from the parlor, A, or dining-room, B, by means of bulk-head windows reaching to the floor. The parlor is 14 ft. by 15 ft., 4 in., and further enlarged by the bay window, making a large-sized room, which would make a fine family room. The vestibule, E, 6 ft. wide, affords protection in winter to the rooms opening into it, and allows passing from either one of the 3 principal rooms to the outside without going through any of them. The dining-room, B, is 10 ft. by 15 ft., 4 in., and has a nice closet. The kitchen, D, 10 ft., 2 in., by 12 ft., has a closet and pantry in which there is a slide to the dining-room closet, allowing the passage of dishes. There is a door leading direct from the kitchen to the yard. The sitting-room, C, has a closet, and is 12 ft., 4 in., square. Good ventilation is secured by having transoms

over the doors entering the vestibule from the rooms. In the second floor plan (which is not shown), there are 3 bedrooms, well lighted and ventilated. In case less room is required, the dining-room and kitchen could be combined, and the sitting-room and dining-room used as bedrooms, leaving the parlor as a large family room. In this case the room could be simplified and the cost of the cottage reduced. The style of house shown in the perspective, is a good example of the prevailing "American Cottage style" and is picturesque. The effect can be heightened by use of a little coloring in painting, and would give the house a cosy, home-like appearance, with just ornamental features

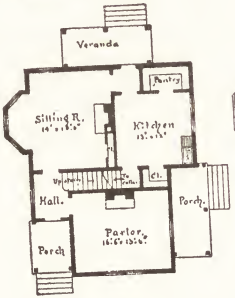


PL. 88. Design 106. J.B. Legg Architect. St. Louis.

leads on to the side porch to the right, which is of a large size. The dining or sitting-room has a bay window, adding to the size of the room and affording a view of the front yard. A small closet is provided at the side of the chimney breast. One of the best features is the small hall which separates the dining-room and kitchen, giving a double door connection and thus preventing odors from the kitchen being carried to the dining-room. The dining-room has a fireplace. The kitchen, 12 by 13 ft., has a pantry in the rear end and a closet on the side next to the parlor near the door leading to the cellar steps which go down under those to the second floor. On the second floor is a large hall, enough in the bay window, dormer windows and gables to make it attractive. Cost about $1,600.

Plate 86, Design 106. — An unusually complete house in its arrangement, for a small one. No detail for convenience has been forgotten. A small entrance hall has doors leading to the parlor, 15 ft., 6 in. by 13 ft., 6 in., occupying the front of the first floor and to the sitting and dining-room, 14 ft. 6 in. by 16 ft., 6 in. In this hall the stairs to the second floor ascend up between the parlor and rooms in the rear part of the house, and are 3 ft. wide. The parlor has an open fireplace and windows on 3 sides, that in front being a double-mullion window. A door at the end of which is the bath-room, located over the kitchen sink, thus simplifying the plumbing. The front chamber over the parlor and the one over the dining-room are of same size as the rooms below; and connect, through a large closet placed over the steps to the first floor. The front room has a fireplace, and the other 2 stove flues. The chamber over the kitchen is 12 by 13 ft., and a closet. All these rooms have connection with the main hall. The perspective elevation shows a cosy house, with an air of home-like comfort. The molded cornices, bay window, well proportioned and decorated gables, and steep pitched roof add to

Pl. 86. Design 106.



First Floor. Second Floor

Pl. 86. Design 106. *J. B. Legg, Architect. St Louis.*

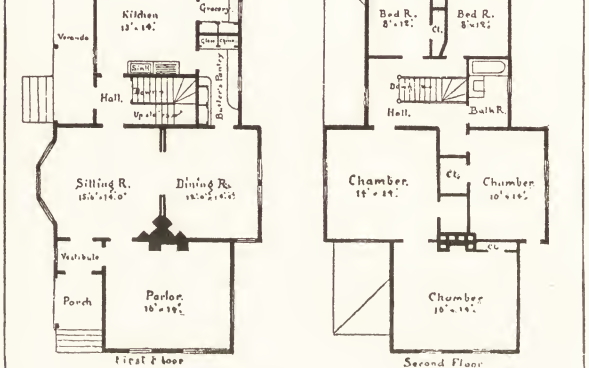
the attractiveness of the building, while the large porches, with balconies in the second story, convey the idea of ease. The small gable windows ventilate the space under the roof, and the upper rooms will be cool and agreeable in the warmest weather. Cost about $1,800.

Plate 82, Design 102.—Any one possessing a well situated lot in a hilly locality will find this design adapted to such a place. The house contains 7 good rooms and a large attic and bath room. The general plan is much after that of a city house. A large porch, with a balustrade, extends around the front and side of the hall, which is 9 ft. wide, and will show a nice stairway to advantage. To the left, on entering the hall, is the parlor, 15 by 16 ft., with a bay window in front and the fireplace located opposite into the kitchen. The bath-room is placed on the first floor so that a pump can be used to draw the water for the tub direct from the cistern. The hall (main) in the second story is of same width as on first. The front chamber is 14 ft., 6 in., by 16 ft., the one over family room 12 ft. 6 in., by 20 ft., and the small one, 13 by 16 ft., the same as the dining-room. The front chamber has a fireplace, the others flues. Large clothes closets connect with the large bedrooms. A nice feature is the balcony over the front door, entered from the hall by a bulk-head window. In the elevation, this house is only $1\frac{1}{2}$ stories high, cutting the corners of the second story rooms, but high enough at the eaves to allow 6 ft. in the clear. The gables are different in height and decoration, and the cornice has a heavy pro-

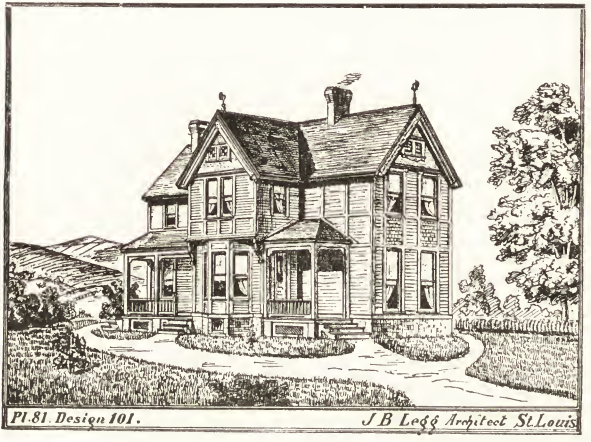


the centre of the door to the hall. This room is connected with the family room back of it by sliding doors. The family room is 16 by 16 ft., and has a large square bay window with windows on all sides, giving a view of the street. A door leads from this family room into the dining-room and also into the front hall. The family room and dining-room both have open fireplaces. In the rear of the back stairs is a closet, opening into the family room, for keeping articles desired under lock and key. The dining-room is 12 by 15 ft., and has a door leading on to the front porch. The closet and store-room, in the kitchen, are large. On the left of the kitchen, which is 13 by 16 ft., is the bath-room and a small porch with a door from the latter

jection throwing a good shade. The roof over the main body of the house is carried up very high and has an ornamental cresting in the ridge. Cost about $3,500.

Plate 81, Design 101.—A complete 9 room frame house, suited for a family of medium income, in the suburbs of a city or in a country town. It is compactly arranged and economically constructed. From a small front porch the vestibule is entered, from which the parlor and sitting-room can be gained. The parlor, occupying the front part of the house, is 16 by 14 ft., with 2 windows to the front and 1 on the side; it has an open fireplace, at the side of which is the door leading into the sitting-room. The sitting and dining-room are connected by

sliding doors, which when thrown open, make a fine apartment. The end of the sitting-room is bay-shaped, has 3 windows, and is 15 ft., 6 in., by 14 ft. The dining-room, 12 by 14 ft., has a double window in the end opposite the centre of the sliding doors and 1 to the front. These rooms have fireplaces placed in the angles of the sliding doors, making a unique finish. To the rear of the sitting-room, with a door leading into it from the sitting-room, is the hall with the stairway. This hall is 6 ft. wide on the first floor. From the end of the hall a door opens on a large veranda, extending the length of the rear wing. The steps to the second floor start on the right hand side of the hall, and on the left are those to the cellar. This is a boxed or inclosed stairway, a partition separating the upper from the room over **the sitting-room has not the bay** end of the latter, but is brought out square by means of brackets under the corners. This room has a stove flue and a large closet between it and the bedroom over the dining-room. The door leading into the hall is opposite the landing of the stairs, which end with double newels on second floor. The chamber over the dining-room is entered directly from the hall by a door placed alongside of that entering the bath-room. This room is 10 by 14 ft., and has a closet. The windows in these rooms come directly over those in the lower story. The bath-room contains a tub and water closet, but there is room for a washstand, if desired. The plumbing, if there is no public service, can be supplied by a tank, as described under *Country Town Dwell-*



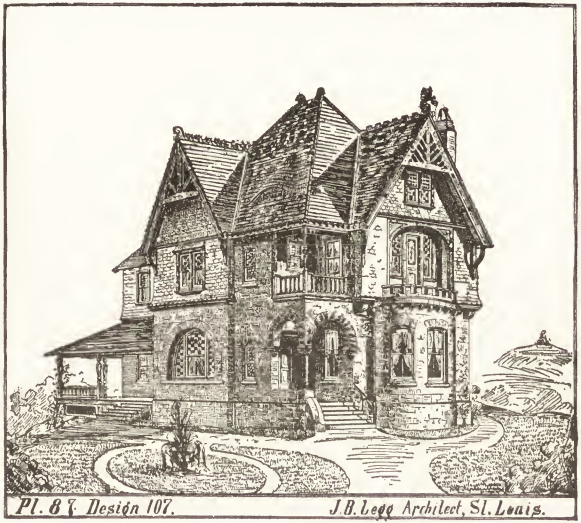
Pl. 81. Design 101. J B Legg Architect St Louis

lower flight. Passing from the dining-room to the kitchen, a large butler's pantry is entered, having a closed cupboard and inclosed closets in the rear end; on the right side is a long serving shelf. This pantry is lighted by a side window. The kitchen, 13 by 14 ft., has a door and window opening on the veranda, a door into the hall, and 2 windows in the rear end, being thus well supplied with air and light. A large pantry is on the right hand side, with long shelving and a good window. On the second floor, over the parlor and of the same size, is a chamber, intended for principal bedroom, and to be used in connection with chamber over sitting-room, 14 by 14 ft., which should serve as a children's room. The front chamber has a clothes closet and an open fireplace. The bed-

ings in HOUSES. In the rear wing, over the kitchen and pantries, are 2 small bedrooms, each 8 by 12 ft., with a closet for each, and stove flues. This is a complete, compact and comfortable house. The elevations have been designed in the "American style," if it may be so called, and have a pleasing appearance. The sheltered entrances, with porches and balustrades, throw effective shades on the building. The walls are broken by false framework panels, with those under the front windows shingled, making a contrast with the siding in the balance. The gables terminate in finials, and have small ornamental windows and shingled walls. The cornices are boxed railroad style, with paneled facine. The porch columns are plain, and the cornices correspond with those

of the building. The good result of corbeling-out the second story room over the sitting-room are evident from the perspective. Two chimneys give the rooms flues and fireplaces, and come through the roofs at the ridges. The building will cost about $3,350.

Plate 87, Design 107. — In the last few years many very fine examples of ancient and mediæval architectural designs, executed in a modern form, have been produced. This is a modern Gothic application, and shows what a careful adaptation of that style to our present wants may accomplish. The plan is of unusual compactness and groups those rooms used in connection successfully. A side entrance porch leads to dining-room. The kitchen is 14 by 16 ft., and has a good-sized pantry. A butler's pantry is located at the end of the hall leading from the dining-room to the kitchen. The rear side of the house is protected by a large porch with a smaller one at the kitchen door connected with it. Doors from the rear hall and kitchen open on these. The front chamber on second floor is 13 ft., 6 in., by 20 ft., has 2 large closets, dressing room and a balcony over the parlor bay. The bedroom over the sitting-room is 14 by 15 ft., 6 in., and has a closet. The one over the dining-room is squared over the bay of latter, and is 14 by 18 ft.; it connects with the front chamber and has a door leading into the private bath-room

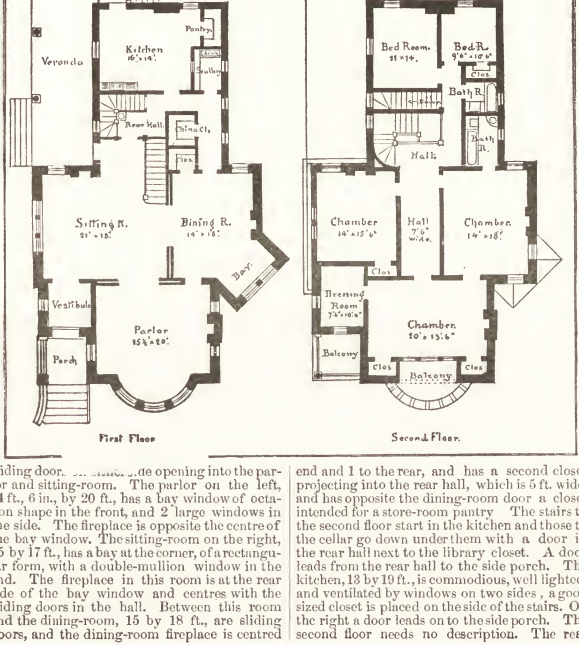


Pl. 87. Design 107. *J.B. Legg Architect, St. Louis.*

the vestibule of larger dimensions than usually found, opening directly into a hall used, at the same time, as a sitting-room; this is 10 by 21 ft., connected with the parlor, 15 ft., 6 in., by 20 ft., and the dining-room, 14 by 18 ft., by sliding doors. A small side door leads from the dining-room into the parlor. Each of these rooms has a bay window. The main stairs start in the sitting-room and land on a separate hall in the second story. The rear stairs start in the back hall in rear of the sitting-room, and there is a washstand in this hall. Between the dining-room and kitchen is a hall in which a large closet is located; a smaller one opens into the intended for this suite of rooms. A general bath-room is located back of the private one. Over the kitchen there are two bedrooms, 11 by 14 ft., and 9 ft., 6 in., by 10 ft., 6 in. All the bedrooms open directly into the halls. Noteworthy is the elevation of this plan. The first story is designed to be executed in rough ashler, and the second story faced with shingles. A heavy corner column supports the balcony over the portico from which massive arches are sprung to the walls on either side. The balcony over the parlor bay has a heavy stone balustrade. The grouping of the windows under the large arches is picturesque and adapted to emphasize the style. The high

pitched hip and gabled roof finishes the structure, and is appropriately finished with a heavy cresting. Good staining of the shingles is required to carry out the effect. The cost would be about $7,500.

Plate 83, Design 103. — This plan contains 1 more room than the preceding design, and is larger and more expensive; the many projections and angles combine to make it more costly; but for one with the means to erect such a building, it would make an excellent dwelling. It is a double house with a large 9 ft. hall; a veranda, with a balcony on the second floor, shades the front doors, which are double. The hall has with them, making, when all the sliding doors are thrown open, a grand suite of rooms. The dining-room has 2 windows in the end and 1 on the side. The hall, between the dining-room and the library, located behind the parlor, is widened to 10 ft., and here the stairway to the second floor starts. Under this stairway is the closet for the dining-room. A door from the latter room enters the rear hall at the side of the fireplace. The library, 15 ft., 6 in., by 16 ft., has a fireplace which backs up against that in the parlor, and a closet formed by filling up the recesses made by the depth of the 2 fireplaces. This room is well lighted by 2 windows in the



sliding door [illegible] opening into the parlor and sitting-room. The parlor on the left, 14 ft., 6 in., by 20 ft., has a bay window of octagon shape in the front, and 2 large windows in the side. The fireplace is opposite the centre of the bay window. The sitting-room on the right, 15 by 17 ft., has a bay at the corner, of a rectangular form, with a double-mullion window in the end. The fireplace in this room is at the rear side of the bay window and centres with the sliding doors in the hall. Between this room and the dining-room, 15 by 18 ft., are sliding doors, and the dining-room fireplace is centred end and 1 to the rear, and has a second closet projecting into the rear hall, which is 5 ft. wide, and has opposite the dining-room door a closet intended for a store-room pantry. The stairs to the second floor start in the kitchen and those to the cellar go down under them with a door in the rear hall next to the library closet. A door leads from the rear hall to the side porch. The kitchen, 13 by 19 ft., is commodious, well lighted, and ventilated by windows on two sides, a good sized closet is placed on the side of the stairs. On the right a door leads on to the side porch. The second floor needs no description. The rear

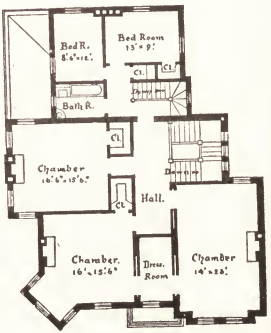
First Floor.



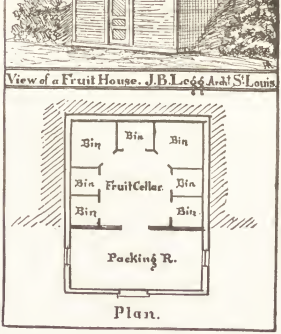
Second Floor.

Pl. 84. Design 104. J. B. Legg. Architect. St. Louis.

building, not being as high as the main one in the first story, has 3 steps rising from the platform where the rear stairs land to the level of the second floor of the main building. All the bedrooms are of the sizes of the rooms below and have closets. The window in the front of the hall should be a bulk-head window affording exit to the balcony over front porch. The design works up nicely in the elevations, the many breaks and projections in the ground plan affording opportunities for an artistic treatment of the roof. The outer architraves have molded caps and styles and the sills are also molded. The porch columns have small molded bases and caps, and large angle and face brackets extending to the frieze of the modillionod cornice. The bay window has a cornice to match. The roof has a large deck with a plain molded cornice. The main cornice is supported by brackets. Especially well treated are the gables, each slightly varying from the others. The chimneys are of ornamental brick work of effective design. The cost would be about $7,000.

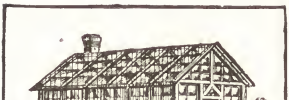
Plate 84, Design 104. — A large city or suburban residence well adapted to a corner lot. A stone portico with balcony on the second floor, supported on stone columns, covers the main entrance. The vestibule is made large enough to receive the storm doors. The front hall is 8 ft. wide in the clear and extends back to the stair hall back of the parlor. The parlor, 14 by 23 ft., is to the right on entering, and is connected with the hall by sliding doors; opposite the centre of these doors is the chimney; it is lighted from the front by a large triple window. On the left of the hall is the sitting-room, separated from the hall by an open archway to be closed by a curtain. The fireplace in the sitting-room is opposite the centre of the arch into the hall, and when the sliding doors of the parlor are open, the two fireplaces, sliding doors and arch all range. A feature of the sitting-room is the square angle bay which works up prettily and makes a pleasant corner, from the windows of which a fine view is commanded. This sitting-room is 13 by 15 ft. A single sliding door opens from the sitting-room into the dining-room, 15 by 18 ft., also connected with the stair hall by sliding doors. In the end of this room the fireplace is located, on either side of which are windows, and also one facing the street at the side. A door opens from the dining-room on the rear porch. The connection of dining-room and kitchen is through a closet of large dimensions. A window opening on the side veranda lights this closet, which on that side is shelved. The right hand side has closed cupboards. The main stair hall is finely designed. The stairs start on the rear side and wind up with platforms and drop newels, landing on the second floor on a line with the wall of right hand front chamber. Small stained glass windows furnish light for these stairs. The rear stairs start in the back building, back of the main stairs, and the cellar steps go down under them. The kitchen is 12 by 16 ft., 6 in., and has a pantry and grocery. The second floor contains bedrooms over all the rooms in main building and 2 in the rear over the kitchen, provided with large closets, and the front suite with a dressing room. The bath-room has a tub, water-closet and washstand. The third story may be finished and will give the same number of rooms as the second. The design of the exterior shows a stock-brick front with stone trimmings. The columns of the front portico are intended to be of polished granite. The base course, which is a heavy one, should be of limestone or other non-absorbent variety. The die course of pitch face ashler with tooled margins, the water-table, window-sills, skrewbacks and belt courses of some stone which will make a contrast with the color of the brick. The gables are of good design, and the high pitched mansard, with its heavy deck cornice, raises the house to a sufficient height to prevent a squatty appearance. The cost is about $6,500.

FRUIT AND VEGETABLE CELLAR. —The plan and perspective show the arrangement and construction. The site selected is a hill-side, where the cellar end of the building can be buried in the hill; a part of the roof is covered with 1 ft. or more of earth; this keeps the cellar cool and

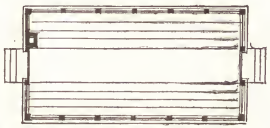


of an even temperature through the year. The projecting portion of the house is lighted by windows and used as a packing room. In constructing bins they must be arranged so as to allow the air to circulate freely, and for this purpose a ventilator should run out through the roof and a slide be made to open or close it. The portions of building coming in the hill ought to be of stone or brick; or, when wood has to be used, some variety that does not easily decay. Cost about $375.

GREENHOUSE. — The perspective and plan



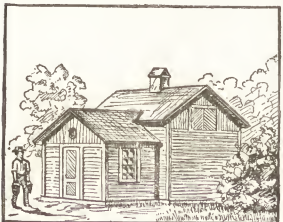
View of a Greenhouse. J.B. Legg Arch.t St Louis



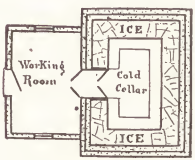
Plan.

of a greenhouse is here shown. The method of heating will be readily seen.

ICE AND DAIRY HOUSE. — Where butter is made, and ice inaccessible during warm weather, the farmer should have his dairy and ice-house; these can be combined as illustrated to good advantage. The walls of the ice-house are made by setting up 2 lines of studding, ceiling on both sides of each line, with matched flooring under which a layer of deodorized paper will be effective, then filled in between the stud with sawdust or cotton seed hulls, thus forming between the stud walls an air space. A third partition of stud with flooring on the one side separates the ice from the cold storage room or milk cellar. In front of these rooms is the working room for arranging the milk supply, churning and packing butter. This room prevents the warm outer air from entering the ice-room when opened. The ceiling of ice and cold storage rooms should be constructed the same as the walls, and the space between the ceiling and the roof ventilated. The cost of these houses depends upon the size required. It might be about $450.



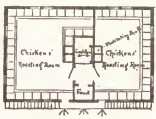
Combined Ice and Dairy House. J.B. Legg Arch.t St Louis



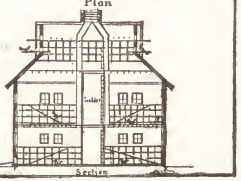
Plan.

POULTRY-HOUSE. — The illustration shows a large poultry-house, with 4 separate apartments for chickens, and a large loft for pigeons. To be used to advantage, the yard must be di-

View of a large Poultry House. J.B. Legg Arch.t St Louis

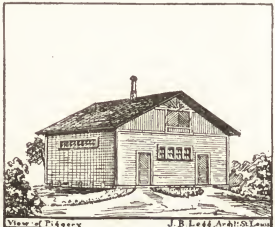


Plan



vided to match the apartments. The centre of the poultry rooms contains the roosts, and alongside the walls are nest boxes. The door shown leads to a ladder in the centre of the building, by which access to all the apartments is gained. Though neat in appearance this building would not be very expensive, the cost being about $600.

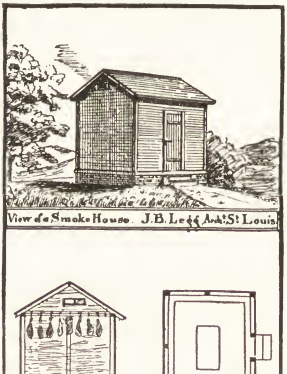
PIGGERY. — Successful pig raising requires attention to the comfort of the stock, and the cut shows a compact and economical way of arranging a piggery. 2 doors lead into their respective aisles, and the pens are arranged alongside the building. In the centre are the breeding



pens and feed bins, and at the front side the pump, boiler and mixing trough for the feed. The feeding troughs run along the sides of the bins and can be filled from the aisles. Cost about $500.

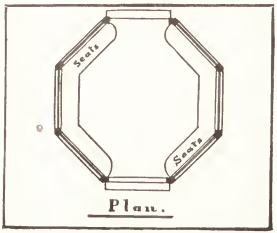
STABLE. —In cities, where room is small and valuable, the necessity of compact, small stables is keenly felt by all who are desirous of keeping their carriage at home. This plan embodies all the conveniences required and still does not cover much ground. The first floor contains a carriage-room sufficient for 3 vehicles, with a harness closet and grain chutes and stall room for 3 horses. The partition separating the stable from the carriage-house cuts off all gases from the former which would destroy in a short time the paint on the vehicles. The second floor has a large hay-loft and good-sized driver's room, with a closet. The elevation shows smooth press brick fronts and a high roof. A neat brick gable breaks the monotony of the front. Cost about $1,350.

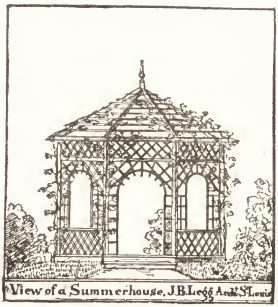
SMOKE-HOUSE. — In the accompanying illustration is shown a very desirable form of

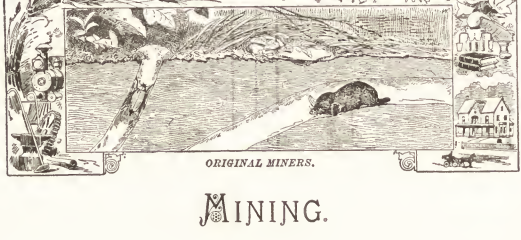


smoke-house, which is one of the most useful of the buildings connected with the farm. The plan and section of the same are here given.

SUMMER HOUSE. — In the illustration is shown the perspective and plan of a neat, cheap summer house, which will be an adornment to any landscape.







ORIGINAL MINERS.

MINING.

PROSPECTING.

REMARKS.—Before giving rules for searching for mineral substances, the way in which the more important ones generally occur will be noticed. The minerals useful to man form three categories: *1st.* The earthy, as gypsum, clay, marble; *2d.* The carbonaceous, as coal, lignite, petroleum; *3d.* Metallic, as iron, gold, silver. The metals occur rarely native, often as ores, that is combined with sulphur, silica, carbonic acid, etc. These form deposits differing from each other. They may be grouped into three classes: *1st.* Superficial deposits; *2d.* Stratified deposits; *3d.* Unstratified deposits. The first class includes gold, stream tin, platinum, gems, etc., obtained from the surface material; gravel, sand and clay, derived from the mechanical decomposition of rock masses through which metals or ores are sparsely distributed. Stratified deposits can be classed into two groups, which are, first, where the ore forms the whole strata, and second, where the ore forms only part of the strata. All stratified deposits are found in a horizontal position; hence, when looking for such deposits of iron ore, coal, lignite, etc., they are found in a nearly level position. Unstratified deposits include mineral veins, in which most of the silver, and part of the gold, lead, copper and zinc are found. Veins or fissures are cracks in the earth's crust, which have subsequently been filled with mineral more or less different from that in the surrounding rock, and are nearly always in a position more or less vertical. When the presence of any mineral is premised from the directions given, it must be proved by sinking shafts, digging trenches, or by some such means.

COAL.—One of the best means of determining the possibility of finding coal is by a study of the geology of the district. To those who do not understand geology, the following hints will be found valuable: First ascertain if coal is mined or known to exist in the neighborhood. Always expect to find coal in a more or less level bed. Examine the hillsides and the banks of creeks to see if the bed crops out. Although coal itself may not be seen, there are indications of its presence, the most important of which is a more or less thick and level smutty line in the creek bank or on the hillside; luxuriant vegetation on the hillside at about the same level; also, springs or wet places point to the possible presence of coal. But when the ground is level, the only sure way is to bore, or sink a small shaft.

DIAMONDS.—It is difficult to distinguish these from crystals of quartz or topaz. They are of various shades of yellowish brown, green, blue and rose-red, closely resembling the gravel by which they are surrounded. Often they are not unlike a lump of gum Arabic, neither brilliant nor transparent. The finest are colorless, and appear like rock crystals. In Brazil, the method of searching for them is to wash the sand of certain rivers in a manner similar to that employed in the gold fields, by prospecting pans. A shovelful of earth is thrown into the pan, which is then immersed in water, and gently moved about. As the washing goes on, the pebbles, dirt and sand are removed, and the pan then contains about 1 pt. of thin mud. Caution is now observed, and ultimately there remains only a small quantity of sand. The diamonds and particles of gold sink to the bottom, and are removed by practiced fingers. The stones suspected to be precious may be tried by attempting to cut with their sharp corners glass, crystal or quartz. When too minute the specimens may be pressed into the end of a stick of hard wood, and run along the surface of window glass. A diamond will make its mark and cause a fracture in the line over which it has traveled. It will easily scratch rock crystal as no other crystal will. But a more certain and peculiar characteristic is the form of its crystals. No mineral which will scratch quartz has the curved edges of the diamond. In small crys-

tals this peculiarity can be seen only by means of a magnifying glass, but it is invariably present. Interrupted, convex or rounded angles, are sure indications of genuineness. Quartz crystal is surrounded by 6 faces, the diamond by 4. The diamond breaks with difficulty, and a test sometimes used is to place the specimen between two hard bodies, as a couple of coins, and force them together with the hands; such a pressure will crush a particle of quartz, but the diamond will only indent the metal.

GOLD.—May occur, like diamonds, in the beds of rivers, creeks, etc., and is prospected for in the same manner that diamonds are (see *Diamonds*); or it may be found in mineral veins. In looking for veins expect to find them in mountainous regions, and at an elevation above the surrounding country. Examine the gravel and bowlders of the mountain streams, and note carefully the structure and character of the gravel wash. Try the sands at the head of the gravel bars for free gold, or for any crystallized minerals, etc. If fragments of ore are found on a mountain side, it is evident that the vein must have a higher location, for these fragments very probably came down the mountain. If the position of the vein is horizontal, and fragments of its minerals are found on the top of the mountain, there is no probability of finding the vein, for it is washed away. If fragments of mineral are found in a stream, the veins which supplied them must be higher up the stream; and the farther up, the lighter the material. Heavy minerals do not drift far, and, in consequence of their weight, are easily destroyed. Gold never drifts far in a stream; it is always found close to its source. If the current of water is strong enough to move grains of gold, it soon rubs them into such a fine dust that it can be carried off by the most gentle current. Therefore, gold is seldom found in the beds of rivers. Native metals, and sulphurets of metals, are always found near their source, because they cannot move far without destruction.

SILVER, LEAD AND COPPER.—Silver is to be searched for as directed in the case of mineral veins in *Remarks*. Lead, copper and zinc may also be found in the same way. They are also found in low, flat regions, and their presence in this case is only to be suspected when pieces of the ore are picked up on the surface. The ore body is then to be found by digging trenches or sinking small shafts.

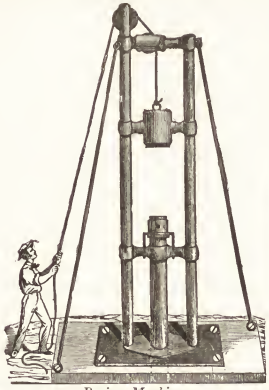
WATER.—In the early part of the year, if the grass assumes a brighter color and hardier growth in one particular part of a field; or, when the latter is plowed, if a part be darker than the rest, it may be suspected that water may be found. In summer, the gnats hover in a column, and remain always at a certain height, over the spot where springs are concealed. In all seasons of the year, denser vapors arise from the surface covering subterranean springs, especially in the morning and evening. The springs to which these rules apply, are those near the surface; when lower down, the only safe guide is boring; but to execute such operations successfully, a knowledge of elementary geology is necessary. Provided that the sources do not descend to any great depth, the principle that subterranean waters follow precisely similar laws to those upon the surface, holds good; but, when deep-seated, many disturbing causes modify their action. If, in a valley formed in a diluvial or alluvial deposit lying upon a more retentive stratum, the two sides are of the same height, the water must be sought in the middle; but if one side be steeper the stream would pass near the steeper side; in both cases, supposing that the materials of the upper stratum are equally permeable throughout, and that the depression of the lower stratum presents a basin-like depression. Springs are not often met with at the head of valleys; they are more frequently found at the intersection of secondary valleys with the principal one; and the most favorable point for finding water is that furthest from the intersection of these valleys, and in the lower parts of the plain, at those positions where there is the least water upon the surface. When the transverse valleys, giving forth streams to a river in the bottom of a longitudinal valley, are nearly at right angles to the direction of the latter, the quantity of water they yield is much less than when they form an angle with it. This law holds good equally with subterranean and surface waters, and it may be laid down as a maxim that the most favorable point for seeking a well would be at the mouth of long transverse valleys inclined to the principal one.

BORING.

REMARKS.—When it is wished to bore for any purpose, such as to get water or oil, or for prospecting purposes, the work may be done by the aid of steam or horse-power, or by 2 or 3 men without such aid.

HAND-BORING.—This should only be undertaken where the rock to be passed through is of moderate hardness. For hard, compact rocks, the diamond drill is the best for boring deep. The method here described is the simple hand boring. The simplest way to reach bed-rock is to drive down an iron pipe shod with a steel shoe. The pipe is made in sections, which are added on as the pipe is driven down. The driving may be done by means of a maul, but can be better done by using a machine as shown in the illustration. This machine holds the pipe firmly in its place, and guides it while being driven. As it is impossible for the pipe to get out of a direct line, and as the drop always hits a direct blow, it neither breaks the pipe nor bursts the sockets, saving labor and expense. It is so light and portable that it can be carried about in a light wagon and set up in a few minutes. Its whole weight is 125 lbs. The boring proper is done by means of a drill attached to a rope. This is raised, and the rope being then released, the drill drops, and this breaks up the rock beneath. The comminuted material is then removed by drawing up the drill and working a sand or sludge pump attached to a rope, up and down in the bottom of the hole. The pump consists of a cylinder with a valve in the bottom which opens upwards. The drill must

be heavy to do effective work; for this reason a proper height for an easy elevation of the feet of the operators, and the plunging motion of the excavator is imparted to the tools by the operators throwing sufficient weight upon their feet in the stirrup to flex or bend the spring, which allows the excavator or drill to fall of their own free weight, to be immediately picked up again by the reaction of the spring. As the tools have a direct connection with the windlass through means of the cable, they can be lowered by the ratchet as the work progresses, or withdrawn from the hole without loss of time in breaking or making other connections.



Boring Machine.

Machine for Raising Drill.

Tools for Drilling.

a heavy bar of iron, called the drill bar, is added to the drill. To keep the rope tight when the drill drops, a "jar" must be used. The construction of these tools and the means of attaching the rope will be understood by the illustration.

RAISING AND DROPPING DRILLS. — A machine such as represented in the illustration in the next column, should be used. It should be light and portable. Two men can set it up in a few minutes, and the same men can make a hole through earth from 6 to 12 in. in diameter, at the rate of 15 ft. per hour. It consists of a windlass, with ratchet wheel and pawl dog, light derrick, a strong hickory spring plank to raise the tools, and a hawser laid cable to which the tools are attached. The cable passes from the windlass through a pulley on the outer end of the spring, thence over a crown sheave at the top of the derrick and down to the tools. When in position to operate, the tools are suspended to the height of the stroke from the bottom, the stirrup is clamped to the drill bar or cable at

Developing and Working.

REMARKS.—Mining consists of two distinct descriptions of work—"dead work and extraction;" the first is necessary in opening a mine, making it advantageous for the extension of future operations. The preparatory work consists in sinking shafts or pits, driving drifts or in excavating drains. These remarks apply to the working of bed deposits, or irregular masses, as well as to veins.

SHAFTS.— These are usually made vertical and with greater or less degree of inclination. When steam or water power can be applied at a certain point, the transportation of which to another point would cost too much, an inclined shaft may be serviceable. There may be advantages in a sloping shaft under peculiar circumstances; but they should be well considered before the plan is adopted. The sectional dimensions of a shaft depend on the amount of ore to be raised in it; if the quantity is not so large as to require a double shaft, a single one may be sunk 4x4 or 4x5 ft. in the clear. Double shafts are made 4 to 6 ft. one way by 8 to 14 ft. the other. If merely intended for ventilation, any form or size will do. Shafts are made rectangular for convenience, as it makes the timbering easier. The timber is usually 6 to 8 in. sq., and framed rectangularly, the inside of the frame being the inside of the shaft. These frames are usually placed 1 to 1½ yds. apart, but when the lateral pressure is considerable and the timber cheap, but of inferior quality, they may be placed in contact. The timbers composing a frame are united at the corners by a half-check; the longer pieces extend 1 ft. or more beyond the frame and

rest in holes cut in the rock. When the frames do not touch each other, facing boards of strong planks or split rails are fastened behind the frames, to sustain the pressure of the ground. If the ground around the shaft is wet, puddle should, if possible, be put behind the planking.

TUNNELING.—If the tunnel or drift is only for drainage, it may be made narrow but high enough for the miner to stand upright. If the gallery is for transportation of materials, the height and width must be increased; a width of 4 ft. and a height of 6 ft. will generally be sufficient. If water is to be discharged by the drift, a drain should be cut in the floor and covered by cross timbers and planks; it should never be constructed upon a dead level, as the water always carries sediment, which requires a strong current to float it away; ¼ in. fall in 1 yd. may be sufficient. The drift must be timbered when the rock, mineral, or ground has not sufficient cohesion to sustain the pressure of the superincumbent mass. If only the roof of the level requires support, the upright timbers should be placed against the walls on both sides of the level and connected at the top by a cross-piece, which, while it keeps the uprights in position, rests firmly upon them and forms a support for the roof. The uprights should be slightly inclined towards each other at the top, so as to reduce the length of the cross-piece. When the drifts are narrow, the uprights should be set into the walls. When timber is scarce, uprights may be dispensed with and the ends of the cross-pieces let into the rock and rest upon it. When the strata is nearly, but not quite perpendicular, only the roof and one wall need support, and but one row of props be used, the other end of the cross-pieces resting in the rock. If the floor is not strong, a complete frame should be made, that is, with cross-ties at the top and bottom. If the ground is so loose that timber frames alone will not support it, facing boards should be used to keep the loose material behind the timbers.

WORKING BED DEPOSITS.—The principal mineral occurring in a bed deposit is coal; for this reason only the principles of coal mining will be given here. Coal seams about 7 or 8 ft. thick are the most economical to work. Only the general methods of working moderately thick beds of coal will be given, ignoring entirely the methods employed when the seams become very thin or when they are of great thickness. Before selecting the position for the shaft, it is desirable to know the dip of the bed (that is, the angle it makes with a level surface and whether it is basin shaped or has only one general slope). The shaft should be so situated that there will be room for surface buildings and railroad switches, etc., and placed so that it will reach the bed of coal at its lowest point. This is necessary, so that, in getting out the coal, the water will run to the bottom of the shaft and can be pumped from there to the surface. The shaft having been sunk to the bed of coal, two levels or tunnels are run in the coal, one on each side of the shaft, at right angles to the dip of the bed. These serve as the main roadways for conveying the coal, when mined, to the bottom of the shaft, whence it is hoisted to the surface. The two general systems followed in mining coal; viz., the post and stall, and the long wall systems. In the first method a set of excavations parallel to one another, and at certain intervals apart, are driven through the coal. These excavations are made as wide as possible, say 4 or 5 yds. or more. At right angles to these are run another set, farther apart and much narrower than the first set. These excavations leave rectangular blocks of coal. These are now generally taken out and the roof finally allowed to fall. In the second system the levels are run to the limits of the property and all the coal is then worked out in one long face, the roof being allowed to fall as the coal is removed. To protect the miners 2 or 3 lines of props must be kept behind the workmen to prevent the roof from falling. In this country mining is done almost entirely upon the post and stall system. To assist ventilation, a second shaft is sunk, and, to cause a draft up the shaft, a fire is built at its foot. This causes a current of fresh air to pass through the mine. In general it will not pay to work seams of coal below two feet in thickness.

WORKING VEINS.—Whether an ore is profitable depends upon the ease of separating it from the rock or "gangue" as it is called. Thus the minimum percentage of metal, below which the working of ore ceases to be profitable, is—

Of Iron	25	Per cent.
" Zinc	20	"
" Lead	20	"
" Antimony	20	"
" Copper	.02	"
" Tin	.01½	"
" Quicksilver	.01	"
" Silver	1–2000	"
" Platinum	1–10000	"
" Gold	1–100000	"

That is, an ore of iron which contains less than 25 per cent. of metal will not pay for working; for the reduction of iron in comparison with copper ore is difficult. Gold is easily extracted, hence quartz rocks which do not apparently contain a particle of gold, pay well, a bushel of rock often yielding ½ oz. Having discovered a paying vein, the next thing is to get it in a condition for the extraction of the ore. Select that point on the line of the outcrop where the best ore is found, then sink a shaft on the lode, following the angle of dip, keeping both foot wall and hanging wall exposed, if possible. If the lode is too wide for this, follow the best ore streak of the vein, and at every 50 ft. in depth make cross cuts to the walls of the vein. After 100 ft. deep has been reached, run levels each way from the shaft on the line of the vein, to determine the extent of the ore-chute or chimney on the horizontal line. When the limit of the ore body on the horizontal line has been ascertained, sink 100 ft. more, and drift right and left. If more than one chimney of ore is found on the line of the vein, a shaft should be sunk on it and drifts run, being careful to confine all the exploring work within the walls of the vein itself. The principal galleries must be connected at suitable points by small shafts, in order to secure good ventilation throughout the mine. In extracting the ore, the part of the vein between

two series of galleries is divided into terraces; one being 6 ft. in height, and a gang of men put to work on each terrace. In well managed mines preliminary explorations must be kept ahead of the ore extraction to show two years' output in sight. At least 1 ton of ore should be exposed in new ground for every ton extracted in the working parts. After a mine has been well opened and in good condition for output of ore, the success of the enterprise must depend upon the efficiency of the business management.

"THERE IS NOTHING LIKE LEATHER."

LEATHER AND SKINS.

CURING AND DRESSING.

REMARKS. — In curing skins and preparing leather, the skins are first taken from the animal (as directed in *Skinning*), and if not tanned immediately, are stretched and dried. Leather is either tanned or tawed, and it is afterwards curried to render it soft and pliable.

ALLIGATOR.—A large variety of pocket books, card cases, hand bags, and other articles are made from this leather. While the beauty of alligator leather is its chief characteristic, its durability is of hardly less importance. All sizes of alligators, from 2 to 18 ft. in length, are now killed. The choice skin is 6 ft. long. The skins are packed in lime 2 months, to remove the horny scales. The remaining process is much like that for any leather. It takes 4 months to prepare a skin.

BLADDERS. — Soak them 24 hours in water, to which a little chloride of lime or potash has been added; then remove extraneous membranes; wash them well in clean water, and dry them.

BUCKSKIN. — Take a skin, either green or well soaked, and flesh it with a dull knife; spread the skin on a smooth log, and grain it by scraping with a sharp instrument; rub nearly dry over the oval end of a board held upright. Take the brains of a deer or a calf; dry by the fire gently; put them into a cloth, and boil until soft; cool the liquid with water sufficient to soak the skin in, and soak until pliable; wring out dry; wash in strong soap suds, and rub dry; smoke well with wood smoke. Instead of brains, oil or lard may be used, and the skin soaked therein 6 hours.

BUFFALO. — The Indian process is as follows: Flesh and pare down the green hide with a bone, toothed something like a saw, and knives; cover it on the flesh side with the brains, blood, liver, grease, and the contents of the gall bladder of the buffalo or elk; thoroughly work it in near a fire or in the sun; after the hide is partially dried, work it over a cord and beam till the rope becomes soft and flexible.

CATGUT.—Take the entrails of sheep, or other animal, newly-killed, clean them from all impurities and fat, and wash well in clean water; soak in soft water 2 days, or in winter 3 days; then lay them on a table and scrape them with a small plate of copper, having a semicircular hole cut in it, the edges of which must be smooth and not capable of cutting; after washing, put them into fresh water, and let them remain till the next day, when they are again scraped, the larger ends cut off, and after washing, again steeped for a night in fresh water, and then for 2 or 3 hours in a weak lye of pearlash or potash (2 oz. to the gal.). They are lastly washed in clean water, and passed through a polished hole in a piece of brass to smooth and equalize their surface; after which they are twisted, and sorted, according to the uses intended. For many purposes the prepared gut is dyed or sulphured, and rubbed with olive oil. Catgut is used for strings of harps, violins, etc. Whipcord is made from it, being sewed together while soft with the filandre or scrapings, after which it is put into a frame and twisted. Bowstrings for hatmakers are made out of the largest intestines, 4 to 12 of which are twisted together, until the cord is extended 15 to 25 ft. It is then rubbed smooth, half dried, sulphured twice, again stretched and sulphured, and lastly dried in a state of tension. Clockmakers' cords are made of the smallest intestines. Coarse catgut, for turning lathes, etc., is made from the intestines of horses, cut into 4 or 5 strips, by forcing a ball with projecting knives placed crosswise along them. These strips are twisted, dried, and rubbed smooth with fish skin.

CHAMOIS. — It is not derived from the skin of the chamois, but from the flesh side of either doe or sheepskins split. The skins, having passed through the earlier processes of washing, etc., are soaked in lime-water, next in a mixture of bran and water, or in a weak solution of sulphuric acid; after which they are beaten in a mill till no moisture remains. Fish oil is then poured over the skins, which are again beaten till they are impregnated with it. This is done repeatedly until the skins can receive no more

oil, and then they are hung for a short time in a heated room. They are then washed in a solution of potash, which removes any oil that may still remain about the leather. Chamois skins are used for inside linings of gloves, etc., and for cleaning purposes in many departments.

COW HIDES. — Lay the hides flat, flesh side up, and form a nearly square bed 12 by 15 ft., folding in the edges so as to make them solid; split the ear in the cords that run up the ear in each one, so as to make them lie flat; sprinkle the hides with 2 or 3 shovelfuls coarse salt, covering the hides well, as it need not be wasted; let them lie in this 12 to 20 days, after which take them up, shake the salt out and use it again.

CURRYING. — Leather, after being tanned, is soaked in water, and beaten to render it supple; then scraped on the inside with a two-handled knife; the grain on the outer side is rubbed with pumice stone, the leather being frequently wetted; while wet it is smeared with oil or grease, called "dubbing," which penetrates the leather as the moisture evaporates. It next undergoes waxing; first rubbing it on the flesh side with a mixture of oil and lamp black; then black-sized with a brush or sponge, and, when dry, is tallowed with a proper cloth, and slicked upon the flesh side with a broad and polished lump of glass. Leather, curried on the hair or grain side, termed "black on the grain," is blackened by wetting it with iron liquor, and rubbing it with an iron slicker before applying the oil or grease. The grain is finally raised by the pommel or graining board, passed over it in various directions.

DEER SKINS, For Gloves. — For each skin take 1 bucket water and put it into 1 qt. lime; let the skin lie 3 to 4 days; then rinse in clean water, hair and grain; soak them in cold water to get out the glue; pound in good soap suds ½ hour; after which take white vitriol, alum and salt, 1 tablespoonful, each, to a skin; dissolve in sufficient water to cover the skin, and let it remain 24 hours; wring out, dry, and spread on with a brush ½ pt. currier's oil, and hang in the sun 2 days; after which scour out the oil with soap suds, and hang out again until dry; then pull and work until soft; and if time does not make them soft, scour out in suds again as before, until complete. The oil may be saved by pouring or taking it from the top of the suds, if left standing a short time. Buff color is given by spreading yellow ochre evenly over the surface of the skin when finished, and rubbing it well with a brush.

GLOVE-KID.—Lamb and kid skins are principally employed. For fine gloves the skins of young animals only can be used. The common style of manufacture is as follows: The dried skins are soaked in large wooden tubs, which occupies 3 to 4 days, according to the character of the soak water, size of skins, and time they have been stored. The skins, when thoroughly softened, are unhaired by painting the flesh side with a thin paste of lime, or in lime pits. In unhairing, by painting, the skins, after coating the flesh-side with lime, are folded together, so that the lime comes as little as possible into contact with the wool, and these bundles are placed in a tub and covered with water. After unhairing with a blunt knife, the skins must be limed some days that the leather may stretch; by this method the wool is preserved uninjured, but it is not suitable for finer sorts of leather. The unhairing in lime pits, is done with the so-called "poison lime," prepared by mixing red arsenic (arsenic sulphide) with lime, while it is being slaked, and is at its hottest. The calcic sulphydrate (and, perhaps, sulpharsenite) formed, hastens the unhairing, and gives the grain a higher gloss. The liming lasts 10 days, and is of great importance. It is essential that the interfibrillary substance shall be dissolved, that the leather may be stretched without springing back. It also depends upon the liming (and this is of special importance in the case of lamb skins) whether the tissue of the fat glands is well loosened, so that the fat may be readily worked out. Skins in which this is neglected, can never be properly dyed. When the hair or wool is loosened, the skins are rinsed in water, and then unhaired with a blunt knife. The water employed in washing should not be much colder than the limes. The skins are then put into water to which a little lime liquor has been added, to prevent precipitation of the lime in the skins by the free carbonic acid of the water, which would make them rough grained. Next, the loose cellular tissue on the flesh side is removed, with the head, ears and shanks, and the flanks trimmed. The skins are then thrown into water, softened with lime liquor as above described, and then into a bate of dog's dung, prepared by stirring up white and putrid dog's dung with boiling water, and straining it. The bate must be used tepid and not too strong. When the skins come out of the bate, they are stretched, and worked on the flesh with a sharp knife, and any extraneous tissue removed; then rinsed in warm water, and beaten with clubs in a tub, or worked in a tumbler drum, using but little water; and, finally, brought into a tank of water (not too cold) and kept in constant motion with a paddle-wheel. The skins are next cleansed on the grain side by working on the beam with plates of vulcanite with wooden handles, and are a second time washed in the paddle-tumbler, first in cold, and then in tepid water. After draining the water from them, they are transferred to the bran-drench, prepared by soaking wheaten bran in cold water, diluting with warm water, and straining through a hair sieve. Sufficient liquid must be employed to cover the skins, and the temperature range from 50° to 68° Fahr. The tawing mixture is composed of alum, salt, flour and egg yolks, in thin paste. The skins are either trodden in it, with the feet, or put into a tumbler drum with it. The tawed skins are dried by hanging on poles, grain inwards. Rapid drying in well ventilated, moderately heated, rooms is essential to a satisfactory product. The dry leather is rapidly passed through tepid water, and, after draining for a short time, is trodden tightly into chests, to remain for 12 hours. It is then trodden on hurdles, composed of square bars of wood, joined corner to corner, so as to make a floor of angular ridges. The next op-

eration is stretching over a circular knife, called the "stolmond;" then the leather is dried and slaked again.

IMITATION LEATHER. — 1. Mix 16 parts gelatine and 5 of glycerine; coloring is then added as required; caoutchouc to give elasticity, and boiled linseed oil to give flexibility. This is spread upon linen while hot, printed with any pattern desired. The surface is then treated with a solution of alum, sulphate of iron, copper or zinc. These solutions may also be mixed with the composition before it is spread on the linen. The surface is then varnished, and may be bronzed or gilt. — 2. Boil linseed oil with quicklime and borax; this, on cooling, becomes a thick paste; it is then mixed with rasped cork and more quicklime. — 3. Cork cut in sheets, or strips, and covered on either side with a skin of india-rubber, loses its friability, while keeping every advantage. Cork, thus treated, may be wrung out like a dish-cloth, doubled into any shape, and beaten with a mallet, but suffers no damage. It is water-proof and heat-proof.

KID. — The skins employed are those of the sheep, lamb and young goat. The skins are cleansed by immersion in running water for several hours (or for 2 days, if dry); then made flexible by rubbing them on the flesh side with the back of the flesh knife while spread over the beam. Next, they are hung singly, to dry as quickly as possible. The flesh side is then smeared with cold milk of lime, prepared by agitating 12 oz. good lime in 1 gal. water. The limed skins, placed back to back in pairs, are stacked in piles for several days, or until the hair gives readily; then well rinsed in running water and fleeced by plucking out the wool with spring tweezers and smoothing the hair side with a whetstone or rolling-pin. After fleecing, the skins are put into lime water for several hours, and then immersed in an old or weak lime water bath two weeks. While in this bath they are frequently taken out, drained and put back. They then undergo steeping for several days in the following mixture: Bran, 2 gals.; soft water, 1 gal. When the skins sink in the liquor they are sufficiently raised, and should be removed. The raising requires about 2 days in summer and 4 in winter. Next the skins go to the white bath, the composition for which for 100 skins may be alum, 10 lbs.; water, 12 gals.; salt, 2½ lbs. The salt increased to 3 lbs. in winter. In this bath, heated to boiling, the skins are passed separately and then transferred to it in bulk for 10 minutes; then removed and the bath allowed to cool. To this bath is then added 15 lbs. wheat flour, and afterwards the yolks of about 50 eggs, and then stirred to a smooth paste. The skins are passed singly through this paste, then transferred to it in bulk, and allowed to remain 24 hours or more. This makes them soft and white.— They are next stretched upon poles in a drying loft and left there about 10 days; then moistened with water, stretched and ironed; spread upon the beam with a clean undressed skin underneath, and worked over with the back of the fleshing knife. The finer skins are rubbed down with pumice stone powder and finished with a warm flat iron. In large factories the skins are put into a **churn with the alum bath and other** tanning materials. The skins, after dressing, are stretched on a zinc table and receive the color (if not to remain white) from a rubbing brush; the surface pumiced down, partly dried on a frame, and again stretched on the table to receive more color. These coloring, smoothing, stretching and drying operations are often repeated 3 times to insure full color. The skins are finally dried on hooks in lofts, where they can be suspended so as not to touch, and finally ironed.

LEATHER SCRAPS. To Utilize. — First clean the scraps; soak them in water containing 1 per cent. sulphuric acid until they are soft and plastic; then compress in blocks and dry by steam. In order to soften the blocks, 1 lb. glycerine is added to 100 lbs. material; then passed through rollers, and brought to proper thickness for inner soles of boots and shoes.

LEATHER, To Clean. — Mix well together 1 lb. French yellow ochre and 1 dessertspoonful sweet oil; then take 1 lb. pipeclay and ½ lb. starch; mix with boiling water, and, when cold, lay it on the leather; when dry, rub and brush it well.

LEATHER, To Gild. — Dampen the skin with a sponge and water, and strain it tight with tacks on a board; when dry, size with clear double size; then beat the white of eggs with a wisp to a foam, and let them settle; then take a book of leaf silver and blow out the leaves on a gilder's cushion; pass over the leather carefully with the egg size, and with a tip brush lay on the silver, closing any blister that may be left, with a bunch of cotton; when dry, varnish over the silvered surface with yellow lacquer, until it assumes a gold color. The skin gilded may be cut into suitable strips or patterns. Have the skin well dry before sizing it.

LEATHER, To Soften. — 1 pint boiled linseed oil; 2 oz. of beeswax; 1 oz. of Burgundy pitch; 2 oz. of turpentine; mix, and melt them over a slow fire. The mixture should be rubbed into the leather on both sides, but principally on the flesh side.

MOROCCO LEATHER.—Made of tanned goat skins. The skins are softened in water several days, treading them under the feet, and scraping on the fleshy side to produce evenness; then placed in lime pits (these preliminary operations require great care). The hair is easily detached after one month's soaking; then they are scraped on the beam, after which they are placed in a milk of lime, and fleshed with a scraping knife. The vatting of the unhaired skins is more important in making morocco than any other kind of leather, as a small quantity of lime will often destroy the action of the dye. To insure the skins being well washed after the vatting, they are placed in cylinders ½ filled with water, which revolve on a horizontal axis; afterwards frequently placed in a bath of lactic acid; in this manner the lime becomes soluble. Sumac, in nearly every case, is used for tanning. The skins are sewn together; the amount of tanning substance placed in the sack formed; then inflated with air, and sewn tightly to prevent its escape, and thrown into a vat contain-

ing a shallow depth of a weak solution of sumac; they are made to float 4 hours, being agitated occasionally in order to secure a uniform action of the sumach. They are then piled one on the other, the pressure produced by their weight being sufficient to force the tanning through the pores of the skin. This operation is repeated, after which the bags are unstitched, scraped on the beam, and placed in the drying-room, which has a direct communication with the open air. When dry, they are moistened, rubbed with a copper tool to make them smooth, and again hung to dry. The skins are now ready to be dyed. (See VEGETABLE DYES, IN DYEING.) The finest are dyed red. There are two kinds of morocco—the genuine and the imitation. The difference between the two is that the latter is obtained by the splitting of calf, sheep, and other skins, and is chiefly employed for book-binding. The preparation of these skins is the same as the above, except after being stripped of their wool they are submitted to a powerful hydrostatic pressure to get rid of oleaginous matter, which would interfere with tanning. Dyed skins are enhanced by dressing, and the grain given. They are first rubbed on the hair side with linseed oil, applied by flannel; then glazed by machinery. The peculiar appearance of the surface is given by rolling the skins on a table, under a weighted roller, having a grooved surface.

MOROCCO, To Restore.—Find some dyes the color required, and dilute for shade desired. When dry, finish with the white of eggs whipped and allowed to stand. The liquid is poured off, and this is the article required.

PATENT, JAPANNED, or ENAMELED LEATHER.—1. These are terms used to designate those leathers which are finished with a water-proof and varnished surface, similar to the lacquered wood-work of the Japanese. The term enameled is used when the leathers are finished with a roughened or grained surface; and patent, or japanned, when the finish is smooth. Though generally black, yet a small quantity is made in a variety of colors. The hides are generally tanned with hemlock, and require high liming and weak sour liquor to secure a soft grain. They are then run through splitting machines; the heavier hides passed through several times. The great essential in making superior patent leather consists in applying the polishing substance. The first coats of the Japan are made with linseed oil and Prussian blue, boiled together some hours; the last coat (or varnish), with linseed oil and lampblack, similarly boiled. Each coat is dried at 160° to 180° Fahr., and rubbed on the leather by hand, the skin nailed to the surface of a board. Any roughness found at any stage of the process is polished off with pumice stone, the dust being removed by a wet brush, followed by a dry one. The entire operation occupies 1 to 3 weeks. Enameled leather requires to be passed through a graining machine, with a heavy brass corrugated roller which presses upon the leather and performs a portion of the work of finishing; the balance being done by beating the leather with pine blocks. — 2. (*French.*) Work into the skin 3 or 4 successive coatings of drying varnish, made by boiling linseed oil with white lead and litharge (1 pound each of the latter to 1 gal. of the former), and adding chalk or ochre, each coat being dried before application of the next. Ivory-black is then substituted for the chalk or ochre, the varnish thinned with spirits turpentine, and 5 applications made in same manner as before, but put in on thin and not worked in. The leather is rubbed with pumice stone, in powder, and then placed in a room at 90°, out of dust. The last varnish is prepared by boiling ½ lb. asphaltum with 10 lbs. of the drying oil used in the first stage, stirring in 5 lbs. copal varnish and 10 lbs. turpentine. It must have 1 month's age before using it.

PATENT LEATHER, To Separate. — Patent and enameled leather will (if the glazed sides are placed together in warm weather) stick together, and unless carefully separated, the leather will be spoiled. To separate the sides place them in a drying room; when hot, they can be taken apart without injury to the surface. If a drying-room is not accessible, lay the sides on a tin roof on a hot day, and they will soon become heated to allow separation. Any attempt to separate without heating to a high degree will prove a failure.

RUSSIA. — Calf-skins being steeped in a weak bath of carbonate of potash and water, are cleaned and scraped, to remove hair and dirt; then immersed in a bath, containing dog and pigeons' dung in water; thus freed from alkali, they are thrown into a mixture of oatmeal and water, to slightly ferment. To tan these hides use birch instead of oak bark; and during the operation they should be handled or agitated. When tanned and dry, they are made pliable by oil and friction; then rubbed over gently with birch tar, which gives that agreeable odor peculiar to this leather, and which secures it against the attacks of moths and worms. This odor of the leather lasts for years and on account of it is much used in binding books. The marks or intersecting lines are given to it by passing over its grained surface a heavy iron cylinder, bound round by wires. To dye this leather of a black color, it is to be rubbed over, after tanning, with a solution of acetate, or pyrolignite of iron; to dye it red, alum and Brazil wood are used. — 2. Deer and goat skins after being cleaned and dressed are then put into a bath of bran in a state of fermentation with water for 3 days. Each skin is then put into a wooden tray, where, being spread out, it receives a portion of a liquor composed of honey and water. When the skin has combined with this liquor, it is immersed in salt brine a short time, and then dried. To dye red, it is to be made up in bags, and dipped in a bath of cochineal water and alkali; it is now to be immersed in a solution of alum, and then tanned with sumac. To give a brilliant and more lasting red, it is dipped in an infusion of galls, instead of sumac. To dye yellow, berries of buckthorn or the flowers of wild camomile are used. The graining is given by an iron instrument of great weight, having a number of blunt points.

SHAGREEN. — Prepared from the skins of the horse, wild ass, and camel, as follows: The skin,

freed from epidermis and hair by soaking in water, and, after dressing with the currier's fleshing knife, is sprinkled over, while still wet and stretched, with the seeds of a species of chenopodium, which are imbedded in it by strong pressure, and in this state it is dried; the seeds are then shaken off, and the surface rubbed down, nearly to the bottom of the seed-pits or indentations; it is next soaked in water, by which the skin swells, and the recently depressed surface rises into a number of minute prominences; it is, lastly, dyed and smoothed off. Black is given to it with galls and copperas; blue, with a solution of indigo; green, with copper filings and sal ammoniac; and red, with cochineal and alum. Shagreen was formerly very extensively used for covering the cases of watches, spectacles, surgical instruments, etc.

SKINNING. — As soon as possible after an animal is dead and dry, attend to skinning. For fur alone, small animals should be skinned by beginning at one of the hind feet; slitting the skin down to the anus; cutting around this and thence up to the other foot. To strip the skin from the tail, pull the skin back from 2 or 3 of the first joints; tie them firmly with a strong cord, and attach it to a strong hook in the wall; then introduce a cleft stick between the vertebræ and the skin; then force the stick to the extremity, and the tail bones will come out of the skin. Peel the skin off by drawing it wrong side out over the body; leave the fur side in. Larger animals are skinned by cutting from the front of the lower jaw to the anus, and peeling (without slitting) the legs, if possible; but if inconvenient, slit in a straight line on the inside of the leg from one foot to the other, making a double cross; chop off the feet, and remove the hide, as before. In removing the skin from the otter, and other wide-tailed animals, rip the skin along the under side of the tail, and open it out stretched flat on a board.

STRETCHING AND DRYING.—In drying skins it is important that they should be stretched tight, like a drum-head. There are 3 modes of stretching: The *Board Stretcher* is of light wood, and of various sizes. For a small one prepare a board 2 ft., 3 in. long, 3½ in. wide at one end, and 2½ in. at the other, and ⅜ in. thick; bevel it from centre to sides almost to an edge; round and bevel the small end 1 in. up on the sides; saw this board through the middle, and make a wedge of same length and thickness, 1 in. wide at the large end and ⅜ in. at the other, and drive it between the 2 pieces. This is suitable for a mink or marten. Two larger sizes, with similar proportions are required for the larger animals. The largest size, suitable for the full grown otter or wolf, should be 5½ ft. long, 7 in. wide at the large end when fully spread by the wedge, and 6 in. at the small end. For the fox, raccoon, fisher and some other animals, the board should be 3 ft., 7 in. long, 4½ in wide at widest part, 3⅜ in. at narrowest, and the wedge about the same width as given for a mink. These stretchers require that the skin of the animal should not be ripped through the belly, but stripped off whole. The skin should be drawn over the 2 pieces, stretched and tacked, the wedge driven in, and all made solid by a tack in the end of the tail; hang up to dry. For musk-rat and other small animals, take a thin board, 20 in. long, 6 in. wide at one end, tapering to 5½ in. at 6 in. from the small end, beveled and rounded as before; stretch the skin on tight and tack. The *Bow Stretcher*. Take a strip of any elastic wood, such as hickory, birch, elm, etc., bend it into the shape of an ox-bow, and shove it into the skin, which is drawn tight, and fastened by splitting down a sliver in the bow, and drawing the skin of the lip into it. For curing in this manner a musk-rat skin, for instance, the feet are first cut off; the skin is ripped with a knife from the centre of the under jaw down the middle of the belly, a little beyond the holes left by the forelegs; the skin is next cut loose around the lips, ears and eyes, and finally stripped backwards off the body. The *Hoop Stretcher*. The skins of large animals are best dried by spreading them at full size, in a hoop. Cut a stick of hickory, or other flexible wood, long enough to entirely surround the skin when bent, or splice together 2 small ones, place this in the skin, and lap and tie the ends. The skin of the legs must not be ripped in this method. This is the proper method of stretching the skin of the deer. When it is dry, it may be taken from the hoop, and is ready for packing and transportation. Skins stretched by these methods should not be dried in the sun nor by the fire, but in a cool place, and sheltered from rain. No salt or other preservative is used upon skins intended for the market.

TANNING. With the Hair on. — 1. First scrape off all the fat with a blunt knife so as not to cut holes into the hide; this should be done on a log, having a couple of legs in one end, like a trestle; the other end resting upon the ground. After the fat is cleaned off, take the brains of the animal, or of any other recently killed, and work them into the hide. This renders it pliable. Take 1 spoonful alum; 2 of saltpetre; pulverize, mix and sprinkle on the flesh side. If the hair side is greasy, a little weak lye will take it out. Yellow ochre, mixed with the brains, gives a fine color to the under side. The whites of several eggs, or the soaking of the skin ½ day in oil or lard is said to produce the same effect as brains. This process is good for deer skins, sheep-skin mats and saddle covers, and for tanning all small furs. — 2. If the skin has been already dried, soak it in clean running water 24 hours, working it with the hands until it becomes soft; remove any small pieces of flesh or fat, and in the case of full-sized tiger-skins, pare or scrape them down until reasonably thin. If the skin is fresh, and has not been dried, it need only be washed to remove any dust or dirt. Prepare the following mixture (the quantities given are sufficient for a small tiger-skin, and must be proportionately increased or diminished for different sized skins): Alum, finely powdered, 5 lbs.; salt, powdered, 2 lbs.; coarse wheat meal, 2 lbs. Mix in a large stoneware basin, and add gradually sufficient sour milk to bring it to the consistency of cream. After the skin has drained until the moisture has evaporated, lay it on a firm table, with the hair underneath, and rub some of the above mixture

into every part of the flesh side; the success of the operation depends upon giving the skin as much rubbing and handling as possible. When it will absorb no more, cover it with a layer of the composition about ½ in. thick; fold it up with the flesh surfaces together, and the hair outside, and lay it aside in a cool place. Next day open out the skin; add more of the mixture; rub thoroughly, and fold up as before. Repeat daily for 2 days more. Next wash the skin in clean water, removing all the composition; hang up to drain, and when half dry rub in a fresh supply of the mixture, and repeat the rubbing daily, adding more composition when necessary. In 5 days from the first washing, wash again; apply fresh mixture; and rub once daily for 7 or 8 days more, in all 17 days. This should be ample for a full-sized tiger-skin. For smaller skins 8 or 10 days will be sufficient, according to the amount of rubbing. When tanned, wash thoroughly in clean water repeatedly changed, or, in a running stream; take a strong solution of plain alum without salt, and after the skin has drained lay it out on a flat surface, exposed to the sun; apply the alum solution to the flesh side, and let it dry. The skin will now be found as hard as a board. Roll it up into a tight roll, fur outside; take a mallet and beat it thoroughly until it is less stiff; open it out, and stretch it as follows: Take a blunt instrument with a rounded edge, and laying the skin on the floor, work it from the centre to the sides with the blunt end of the tool, steadying the skin by placing the foot on it, using the tool with the right hand, and holding the skin with the left. When thoroughly worked all over, smooth with pumice-stone, and it is finished. The more it is worked the softer it will be.— *Without The Hair.* — 1. Flesh it with a dull knife and grain by scraping with a sharp instrument; then soak in pure water several days; afterwards in limewater till the hair pulls out easily; remove the hair by scraping backwards and replace the skin in fresh, weak limewater. Altogether, the skin should be in limewater 2 or 3 weeks, with a change of water every 4 or 5 days. Take out, scrape, trim, rinse in clean water and put in a mixture of wheat bran and water; after 2 weeks transfer to a mixture of alum, salt and water, stir well and replace for a day or two in the bran mixture; remove to a dry room, stretch for a while and then soak in warm water. While soaking prepare a paste in the following proportions (double the quantity, if necessary): ½ lb. salt, 1 lb., 3 oz. alum, 3 lbs. wheat flour, and the yolks of 16 eggs; mix with water, dissolving first the alum, then the salt. This is to be used in the next step when wanted—a little of the paste with a great deal of water. Change the soaking skin to a tub containing a proper quantity of the above preparation beaten to a froth; trump and work well; then remove, stretch, dry, and lastly run over it with a warm flat-iron. This process, though slow, makes a splendid leather, and is good for sheep, deer, dog, calf, and all smaller skins. — 2. Soak in lime water, remove the hair and cleanse the hide as above; then fill a boiler of copper, or any other metal that does not stain or color the liquor, half full with ground oak bark, and pour water upon it, up to the brim; the whole is then to be boiled for 3 hours, till the tanning principle is completely extracted; the liquor is then to run off by a cock into pits, where it stands to cool; the hides are put into the liquor, and handled frequently, by taking them out and putting them in again, because the liquor is too powerful for them to remain long at a time in the first stages of tanning; they are then to be removed to fresh liquors from time to time as the old is weakened, until the operation is complete. If leather is required with a lighter color or bloom, a small quantity of the dust of bark should be mixed with the liquor. Besides bark, oak chips and oak saw-dust may be used; and the barks of most trees that produce hard wood have a tanning principle in them. If, after being tanned, the leather is immersed in a bath of glycerine and left for several weeks, the pores will be impregnated with the greasy substance and the leather will be found more elastic. —3. For a 12-lb. calf-skin, take 3 lbs. terra japonica; common salt, 2 lbs.; alum, 1 lb.; put in a copper kettle with sufficient water to dissolve the whole without boiling. The skin will be limed, haired and treated every way as for the old process, then put into a vessel with water to cover it, and put in 1 pt. of the composition, stirring well, and adding the same night and morning for 3 days; then add the whole, handling 2 or 3 times daily, all the time tanning; continue to use the tanning liquid by adding ½ the quantity each time, by keeping these proportions for any amount. If it is desired to give a dark color to the leather, put in 1 lb. Sicily sumac; kip skins will require 20 days, light horse hides for harness 30 days, calf-skins from 6 to 10 days.— —4. After having removed the hair, scouring, soaking, and pounding in the suds, etc., take oil of vitriol (sulphuric acid) and water, equal parts, and wet the flesh side of the skin, with a cloth or sponge upon a stick; then, folding up the skin, let it stand for 20 minutes; have ready a solution of sal-soda and water (1 lb. to 1 bucket water), and soak the skin 2 hours; then wash in clean water, and apply a little salt; letting it lie in the salt over night; remove the flesh with a blunt knife, or by the regular beam and flesh knife; when dry, soften by pulling and rubbing with the hands, and with pumice stone. — 5. The raw hides are unhaired and swelled in the ordinary manner, and then placed in a solution of sour bichromate of potassa, or sour chromate of soda, or sour chromate of magnesia and alum, or sulphate of alumina and salt. They remain in this solution a few days, according to thickness and quality, and the concentration of the solution. Instead of placing the hides directly into one of the above solutions, they can be first submitted to the action of a solution containing about 10 per cent. alum and some small pieces of zinc. By the action of the alum and the zinc, amorphous alumina (clay) is deposited upon the fibres of the hide and prevents an injurious action of the strong solutions. If the hides have been in the above solutions of soda or alum for a certain time, a few per cent. of ferrocyanide or ferricyanide of potassa are added, which will prove to be very effective for leather to be used for uppers of shoes. They are then placed in a

solution of chloride of barium or acetate of lead, or soap, for a few days, to fix the tanning substances. They are then dried and treated with fat or paraffine, or naphtha dissolved in benzine and similar substances, to which a small quantity of thymol or carbolic acid should be added. This process requires but 3 to 5 days.

TAWING. — Soak and scrape the skins, and hang in a warm room until the odor of ammonia is given off, when the hair or wool may be readily removed. Soak several weeks in water and quicklime, changed several times; beam smooth, and trim the skins again; wash and soak in a vat containing bran and water, where they must gently ferment some weeks. Remove and place in a warm solution of alum and salt, and well work; again ferment in bran and water; then remove, drain, stretch on hooks, and hang to dry in a warm room. Place in water to soak again, and then work about in a mixture of the yolks of eggs beaten to a froth in water; stretch and hang to dry; smooth with a warm iron. To shorten this process, after the first soaking in bran and water, the skins may be soaked in part of the following mixture, largely diluted with water: Dissolve 8 lbs. alum and 3½ lbs. common salt in sufficient boiling water; add 21 lbs. wheat flour and yolks of 100 eggs; make into a paste.

POLISHES.

ENAMELED LEATHER SHOES. Polish For.— 1 pt. pure sweet cream; ½ pt. linseed oil; make them lukewarm separately, and mix them well together. Having cleaned the shoes, rub them over with a sponge dipped in the mixture; then rub with a soft, dry cloth, until a lustre is produced.

FRENCH POLISH.—To 1 pt. spirits wine, add ¼ oz. gum copal, ¼ oz. gum Arabic, and 1 oz. shellac; bruise the gums, and sift through muslin; put the spirits and gums together in a vessel closely corked; place near a warm stove, and frequently shake them; in 2 or 3 days they will be dissolved; strain through muslin, and keep it tightly corked for use.

GRAIN-SIDE BLACKING. — Take a barrel and into it quite a quantity of old iron; then fill nearly full of soft water, and add 1 pt. oil of vitriol; stir it up well, and in a month or two it will be ready for use.

HARNESS. — 1. Molasses, ½ lb.; lampblack, 1 oz.; yeast, 1 spoonful; sugar, olive oil, gum tragacanth and isinglass, each 1 oz.; and a cow's gall; mix with 2 pts. stale beer, and let stand before the fire for 1 hour. — 2. 4 oz. best glue; 1½ pts. best vinegar; 2 oz. gum Arabic; ½ pt. black ink; 2 dr. isinglass. Dissolve the gum in the ink, and melt the isinglass in another vessel in as much hot water as will cover it. Having first steeped the glue in the vinegar until soft, dissolve it by the aid of heat, stirring to prevent burning; add the ink to the gum and heat gently. Lastly, mix in the solution of isinglass and remove from the fire. When used, a small portion must be heated until fluid, then applied with a sponge and allowed to dry on. Dried in the sun or by the fire, it will have a better polish. — 3. Alcohol, 1 gal.; white turpentine, 1½ lbs.; gum shellac, 1½ lbs.; Venice turpentine, 1 gill; stand in a jug in the sun or by a stove, until dissolved; then add sweet oil, 1 gill, and lampblack, 2 oz. This will not crack when the harness is twisted. — 4. Shellac, 12 parts; white turpentine, 5 parts; gum sandarac, 2 parts; lampblack, 1 part; spirit turpentine, 4 parts; alcohol, 96 parts; stir, and digest in a covered vessel, until solution is complete. — 5. Isinglass or gelatine, ½ oz.; powdered indigo, ½ oz.; soft soap, 4 oz.; logwood, 4 oz.; glue, 5 oz. Boil together in 2 pts. vinegar till the glue is dissolved; then strain and bottle for use. — 6. Melt 8 oz. beeswax in an earthen pipkin; stir it into 2 oz. ivory black, 1 oz. Prussian blue ground in oil, 1 oz. oil turpentine, and ½ oz. copal varnish; make it into balls; apply with a brush, and polish with an old handkerchief.—7. Dissolve 3 sticks black sealing wax in ½ pt. alcohol, and then apply with a sponge. — 8. Dissolve lac in alcohol, and color with lampblack. This is a quick drying, hard varnish, liable to crack the leather, and should be put on as seldom as possible.

LEATHER, French Finish for. — Take a common pailful of scraps (the legs and pates of calf-skins are best), and put 1 handful, each, of salt and alum upon them, and let stand 3 days; then boil until they get a thick paste; in using warm it, and in the first application put a little tallow with it, and for a second time a little soft soap, and use it in the regular way of finishing, and the leather will be pliable, like French leather.

LEATHER SEATS, Polish for.—Beat well the yolks of 2 eggs and the white of 1; mix 1 tablespoonful of gin and 1 teaspoonful of sugar; thicken it with ivory black; add it to the eggs, and use as common blacking; the seats or cushions being left a day or two to harden.

LEATHER, Varnish for.—1. Spirits of wine, ¾ pt.; vinegar, 5 pts.; gum senegal, in powder, ½ lb.; loaf sugar, 6 oz.; powdered galls, 2 oz.; green copperas, 4 oz. Dissolve the gum and sugar in the water; strain and put on a slow fire, but don't boil; now put in the galls, copperas, and the alcohol; stir well 5 minutes; set off; when nearly cool, strain through flannel, and bottle for use. Apply with a pencil brush. — 2. 4 oz. shellac; ½ oz. lampblack; place in a stoneware vessel, into which pour 1¼ lbs. alcohol; cover it with a moist bladder; let them be frequently shaken for 24 hours; then puncture the bladder and add ½ oz. turpentine, and leave the whole 24 hours. Repeated applications of this will crack the leather, but for some purposes it is very useful. — 3. Durable leather varnish is composed of boiled linseed oil, in which a drier, such as litharge, has been boiled. It is colored with lampblack.

LIQUID BLACKING, For Boots and Shoes.—1. 4 oz. molasses; ½ oz. lampblack; 1 teaspoonful yeast; 1 teaspoonful oil of turpentine; mix well; apply with a sponge. — 2. Soft water, 4 gal.;

logwood extract, 6 oz.; dissolve by gentle heat; soft water, 1 gal.; borax, 6 oz.; shellac, 1½ oz.; boil until solution is effected; potassium dichromate, ⅜ oz.; water, ½ pt.; dissolve, and add all together; add to this before boiling, 3 oz. spirit of ammonia, or aqua ammonia. — 3. 3 oz. ivory black; 2 oz. molasses; ½ oz. sweet oil; mix to a paste; add gently ½ oz. vitriol; then add ½ pt. vinegar and 1¾ pts. water or sour beer. The oil of vitriol may be mixed with sweet oil. — 4. 1 dr. isinglass; ½ dr. indigo; ½ oz. soft soap; 2 oz. glue; small handful logwood raspings; boil all together slowly in 1 pt. vinegar until reduced ½; clean the shoes of all dirt and blacking with cold water; dry the shoes, and apply with a sponge. —5. Dissolve 18 oz. caoutchouc in 9 lbs. hot rape oil; add 60 lbs. fine ivory black, 45 lbs. molasses, and 1 lb. finely powdered gum Arabic, previously dissolved in 20 gals. vinegar; triturate all together in a paint mill till smooth; add 12 lbs. sulphuric acid in small successive quantities, with powerful stirring ½ hour; add 3 lbs. ground gum Arabic; stir ½ hour, repeating daily for 14 days; this gives a liquid form. For the paste, take same quantities of caoutchouc, oil, ivory black, molasses and gum Arabic, but dissolve the last in 5 qts. vinegar; grind to a paste; then add 12 lbs. oil of vitriol; stir daily 1 week, when it is ready for use. — 6. Gum Arabic, 4 oz.; molasses or coarse sugar, 1½ oz.; good black ink, ½ pt.; strong vinegar, 2 oz.; rectified spirit of wine and sweet oil, each, 1 oz.; dissolve the gum in the ink; add the oil, and rub them in a mortar, or shake them together till they are united; then add the vinegar, and lastly the spirit. Apply with a sponge, and dry out of the dust. — 7. Lamp-black, ¾ oz.; indigo (in powder), 1 dr.; put them in a mortar and rub with sufficient mucilage (made by dissolving 4 oz. gum in ½ pt. strong vinegar) to form a thin paste; add gradually sweet oil, 1 oz.; triturate until union is complete, adding toward the end the rest of the mucilage; further add of molasses, 1½ oz.; afterwards, successively, of strong vinegar, 2 oz.; rectified spirit, 1 oz.; bottle for use. Apply with the tip of the finger, or with a sponge. — 8. Mix the whites of 2 eggs with 1 tablespoonful spirit of wine, 2 lumps of sugar (crushed), and sufficient powdered ivory black to give the color and thickness, avoiding excess. Apply with a sponge or soft brush; when almost dry, polish with a brush or soft rubber. — 9. Boneblack (commercial ivory-black), 16 parts; molasses, 12 parts; oil of vitriol, 3 parts; sperm oil, 2 parts; gum Arabic, 1 part; strong vinegar, or sour beer, 48 to 50 parts (all by weight); place the boneblack in a capacious wooden, stoneware, or enameled iron vessel (avoid vessels of metal); add the oil, and rub well together; next gradually add the molasses, and grind or rub the mass, after each addition, until the oil is killed; then dilute the vitriol with about 3 times its bulk of water, and add it in separate portions to the former mixture, stirring together rapidly, on each addition of acid, and for some minutes after the whole is added, to render the mass homogeneous; let it stand, covered 2 or 8 days, stirring 15 or 20 minutes daily; lastly, having dissolved the gum in the vinegar, add the solution gradually to the rest, and stir together briskly and again daily for 3 or 4 days. It may be diluted with more vinegar or beer, or with water; but excessive dilution injures the richness of the blacking. If all the ingredients (except the vitriol) be made hot before admixture, the shining quality of the product will be improved, and the process shortened. — 10. Place 3 lbs. rainwater over the fire, and, when boiling, add 4 oz. white pulverized wax, 1 oz. clear, transparent glue in small pieces, 2 oz. pulverized gum Senegal, 2 oz. white soap scraped fine, and 2 oz. brown pulverized sugar; place the ingredients in one by one and stir up every time; take the pot from the fire every time a substance is added, to prevent boiling over; when all is added remove from the fire; when cool add 3 oz. alcohol, and finally 3 oz. fine Frankfort black, well mixed. Put on with a brush, and polish like shoe blacking.—11. Dissolve an equal quantity copperas and gum Arabic in a little boiling water; add a little extract of logwood; if it gums, dilute with hot water. Concentrated solution of shellac in hot aqueous solution of borax may be used in place of a portion of gum. — 12. Extract of logwood, 1 to 2 oz.; tincture of iron, 1 to 2 oz.; sweet oil, 1 to 2 dr.; diluted alcohol, 1 pt. — 13. Extract of logwood, 4 oz.; bichromate of potassa, 12 gr.; yellow prussiate of potassa, 12 gr.; rain water, 1 gal.; apply with a brush, and burnish with a hot iron.

MOROCCO SHOES. Polish For. — Pound black sealing wax and put it in a bottle with ½ pt. alcohol; shake frequently; when dissolved rub it on morocco shoes when sealed or defaced, and they will look like new. Dry in the sun.

PASTE BLACKING, For Boots and Shoes. — 1. 4 oz. oil of vitriol; 10 oz. tanners' oil; 2 lbs. ivory black; 10 oz. molasses; mix the vitriol and oil together, and let stand 24 hours; then add the ivory black and molasses, and mix into a thick paste. This will not injure the leather. —2. Mix 3 lbs. lampblack, ½ lb. bone-black, and 5 lbs. molasses and glycerine in equal parts; melt 2½ oz. gutta-percha in an iron saucepan; add 10 oz. olive oil and 1 oz. stearine, stirring; add this to the first mixture and stir thoroughly; dissolve 5 oz. gum Senegal in 1½ pts. water; and 1 oz., each, oils of rosemary and lavender; stir well into the double mixture. For use dilute the blacking with 3 to 4 parts water.

PATENT LEATHER, To Restore Enamel of. — When the enamel of the leather has chipped off, clean the parts well with fullers' earth and water, and then apply the following varnish: 2 oz. pure Prussian blue; 1 oz. vegetable black; 1 qt. drying oil; with a little copal or amber varnish. Stove at a heat not exceeding 160° Fahr.; but take care that the pigments are carefully ground in the drying-oil, and don't add the amber varnish till the third and last coat; polish with a piece of pumice stone.

WATER-PROOF BLACKING, For Boots and Shoes. — Take an old pair of india-rubber shoes, cut them up and pull off the cloth lining; put the rubber in about 1 pt. neat's foot oil, and set it on the stove until the rubber is melted, stirring once in a while, and don't let it boil or burn. It will take 2 days to melt. As soon as melted, stir in ½ lb. beef or mutton tallow, and ½ lb. bees-

wax. If it is not black enough, add lampblack. Wash the boots clean; when nearly dry, apply the water-proof; if the weather is cold, work near the stove, rubbing it in well with the hands.

SHOES, To Polish With a Banana.—Rub the shoe all over with the skin of a banana, and no blacking will be needed.

WATER-PROOF BLACKING, For Harness. — Melt in a glazed pipkin 2 oz. black resin; add 3 oz. beeswax; when melted, take it from the fire; add ½ oz. fine lampblack, and ½ dr. Prussian blue in fine powder; stir them so as to be perfectly mixed, then add spirits of turpentine to form a thin paste; when cool, apply with a linen rag evenly, and brush with a polishing brush.

WATER-PROOF BLACKING, For Leather. — 1. Shellac, ½ lb., broken small, in 1 qt. bottle; cover with methylated spirits; cork tight and set in a warm place, shaking several times each day; add camphor size of an egg; shake, and add 1 oz. lampblack. Pour a little into a saucer and apply with a brush, not drying it in. — 2. Neats-foot oil, ½ pt.; beeswax, 4 oz.; 4 tablespoonfuls lampblack; camphor size of a hen's egg; melt over a slow fire, stirring, never allowing it to boil; warm the leather and apply with a brush. Use little and often.

WATER-PROOFING. For Boots and Shoes.—1. Mutton tallow, 1 part; beeswax, 2 parts; melt together. Apply at night, and wipe off the boots next morning with a colored flannel. It will be more difficult to make the boots thus treated take a polish, but after a few times they will be as susceptible of polish as ever. — 2. Dissolve ½ oz. Burgundy pitch in ½ pt. drying oil, and mix with ½ oz. turpentine. Warm the boots and apply the mixture with a soft brush; dry thoroughly; then paint again. Put them in a warm, dry place 24 hours. — 3. 24 parts oleic acid; 18 parts ammonia soap; 24 parts water; 6 parts raw stearic acid; 3 parts tannin extract; melt the oleic acid with raw stearine; add the ammonia soap; afterwards the extract and water. The ammonia soap is obtained by treating oleic acid with ammonia until the smell of the latter does not appear after lengthy stirring. By adding to the mixture a solution of 2 parts copperas in 6 parts water, a deep black is obtained. — 4. A coat of gum copal varnish, applied to the soles of boots and shoes, and repeated as it dries, will make the soles waterproof. — 5. Put ½ lb. resin and 1 lb. tallow in an earthen pot; melt and mix over a slow fire. Warm the boots and apply the hot mixture with a brush until neither the sole nor the leather will absorb any more. With care the leather may be made hot through, so that the preparation may fill all the pores. For a polish, dissolve 1 oz. wax and 1 teaspoonful lampblack in a little turpentine. A day or two after the boots have been treated to the tallow and resin, apply the polish, but not before the fire. This gives the exterior a coat that will shine like a mirror. — 6. Mix 3 parts lard and 1 part rosin or black lead, and apply it. Shoes treated with it will soon take polish when blacked, and the soles may be saturated with it without danger of soiling the floor.

WATER-PROOFING, For Harness.—Beeswax, 2 lbs.; resin, ½ lb.; fish oil and neat's foot oil, each, ¾ pt.; spirits turpentine, 2½ pts.; glycerine, ½ oz.; lampblack, ½ lb.; melt the wax and resin; stir in the other ingredients, and it is ready. Apply with a brush, and polish with a wet brush. Excellent for boots, shoes and harness.

WATER-PROOFING, For Leather.—1. Mix 1 gal. nut and poppy oils with 3 gals. linseed oil; or, 1 gal. either nut or poppy oil may be added to 3 gals. of that expressed from linseed; or 2 gals. linseed oil may be combined with 1 pt., each, poppy and nut oil. These ingredients, either in the above proportions, or such others as may be required by the nature of the oils, being mixed in an iron pot, are placed over a gentle fire; to each gal. oil add 1 lb. white copperas, sugar of lead, colcothar, or other drying substance; when the whole has remained 6 or 7 hours over a degree of heat till sufficiently dry, it is taken off to cool; it is then ready for use.—2. Take 1 lb. gum resin, ½ lb. pitch, and ½ lb. each, tar and turpentine; mix these with 1 gal. of the oils prepared according to the first method, by gently heating the mass, then increasing the fire till the whole is incorporated. When the oils prepared according to the first method, or the gums according to the second, are cool, either is to be rubbed into the leather with a brush dipped in the respective composition; the impregnated leather stretched on a board, and the superfluous matter removed. Sole leather and other thick substances are first warmed, and after being fully saturated and properly dried in a warm place, they are ready for use.—3. First rub the leather with the following mixture: 1 oz. linseed mixed with 12½ lbs. concentrated sulphuric acid, neutralized with soda, water being added. This mass is heated; a solution of 4 lbs., 6 oz., of thick gum mucilage is added, to which either 3 oz. oxalic acid or 10 oz. salicylic acid have been added, in order to render the gum insoluble. Before using, fat or oil is added, or turpentine or tar oil; it can be made more fluid by the addition of alcohol or water. The leather is rubbed with this mixture, then dried and passed through the following bath: 5 lbs. gum or gelatine are dissolved in 100 gals. water; 3 lbs. oxalic or 10 lbs. salicylic acid are added, the whole being mixed with 50 lbs. of a solution of acetate of alumina. The leather is then dried, rubbed on both sides with the first mixture, tanned, dried and put in cold water, where the matter which has not been well absorbed by the leather can be removed. By this same process, textiles, wood, paper, etc., can be rendered water-proof and more durable.

TAXIDERMY.

REMARKS.—The preservation and stuffing of the skins of animals so as to preserve their natural appearance, requires skill and taste. It is more difficult with bird skins, as the preservation of the plumage is imperative. In killing birds, the feathers are often soiled with blood, which is difficult to remove. Be provided with some cotton wool, a dish to hold water, small sable brushes, and a piece of stiff wire rounded at one end. Get the bird as soon as possible after shooting; plug the shot holes with cotton by using the wire; also the mouth and throat. Clean the feathers with water and the brushes. If the blood is removed before it dries, it will leave no stain.

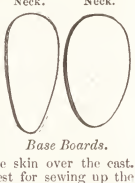
APPARATUS.—The following tools are required: The scalpel, which has a short, sharp blade; 2 pairs surgeons' scissors, one small and sharp pointed, the other of medium size; 2 or 3 spring forceps of various dimensions; a small

Implements of Taxidermy.

pair of pliers for clipping wire; some spools of cotton (Nos. 10, 30 and 100); a quantity of excelsior and tow; some cotton batting; prepared glue; a number of pieces of wire, about 15 in. long and straight (No. 20); a box of dry oatmeal and some arsenical soap.

DEER HEAD. To Mount.—Make a cut across the top of the head, from one horn to the other; run the knife from the middle of the head down the back of the neck to the shoulders; cut the skin around and a little below the neck, until free from the shoulders, and loosen the skin up to the ears; sever them at the base and skin to the bur of the horns; cut the pelt away around the horns and to the eyes; sever the skin carefully from the eyes, and flay down over the muzzle; skin the ears part way down; trim away most of the flesh on the under side of the lips, and rub the flesh side of the skin with arsenical soap. The head may be mounted on a cast or on the skull. *Mounting on a Cast.* Saw off the top of the skull from the top of the eye-holes, back to the upper part of the hole in the occipital bone. To have a perfect cast, take a mold of plaster from a shaved head, and make the mold in 4 pieces. To make the cast, grease the molds, tie tightly together, and run them full of thinly mixed plaster Paris. Take a piece of board of the shape shown in the illustration, with a wire through it to run down into the nose, and thrust it into the plaster until it bears against the front and rests on the top of the mold; place a heavy weight on the board to keep it in place until the plaster sets for 1 hour; then remove the cast; heat and dry it. Saw the cast off just above the eyes, to fit the portion of skull holding the horns; scoop out the eye-holes for glass eyes. If a head has a long neck, the neck-board can be pieced, screw an oval shaped base board on to the neck board, to fasten the skin to. If the head has a short piece of neck skin, the board in the cast will be long enough, and should have a long base board; if a long neck skin, it should have a short base board. Bore 2 holes into the top of the skull, 2 in. apart, directly over the wood in the cast; countersink the holes to receive the heads of the screws. Model with potters' clay where the skull bone joins the cast, to perfect the anatomy. Draw the skin over the cast. Waxed hemp twine is best for sewing up the skin. Gather the skin around each antler; draw it tightly about the base of the horns, and tie firmly; take a stitch through the 2 points of skin at the base of each antler, and tie fast; sew with 2 strings from each horn to the middle, by cross-stitching from the under side; then tie the strings tightly together; cut 1 string and continue the seam down the back of the neck; close the neck half way down; push clay under the skin about the horns until it looks natural. Fasten the eye-holes over the cavities in the cast by driving $\frac{3}{4}$ in. wire tacks through the skin at the inner corners of the eyes. Model about the eyes by inserting clay through the eye-holes. Tuck the skin about the mouth underneath. Finish the seam down the neck; draw the skin

Neck Board.



Base Boards.

The Taxidermist at Work.

tight, and nail it to the middle of the top of the base board; then draw the neck skin tight, and nail to base board. Stuff by forcing excelsior under the skin, between the nails, upon each side of the neck board, until the neck has the natural shape. Draw down the skin tight with pliers, and nail firmly to edge of base board. Put a large screw hook in the top of base board to hang up the head. Turn down the skin covering the under jaw; put a little clay under it around the edges, and nail with round nails. Pull down the nose skin; fill out the nostrils slightly with clay, also the lip, and turn in the dark skin of the lip over the clay; make a narrow fold at

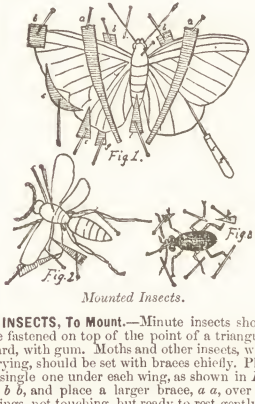
each corner of the mouth, that the skin may lie naturally, and secure it with wire tacks. Drive a small nail part way into the centre of the nose to hold the muzzle in position when drying. Model the nose, insert the eyes, and perfect the anatomy around them. Fill the ears full of clay at their bottoms, and sew pasteboard on their insides to hold them in position until dry. Make them stand in a pricked condition, and draw slightly together with thread; como the coat with a fine metal comb. Coat the hair with thin flour paste; hang up to dry; when dry, remove the pasteboard from the ears, and brush the hair clean. Draw the nail from the nose; perfect the nostrils and under parts of the eyelids with putty; paint them and also the muzzle with Cassel earth, and when dry, varnish. Clean the horns with a damp brush and cloth, and varnish. Fasten the head on a shield by running screws through it from the back into the base board of the neck. Remove the screw hook from the neck board to the shield.—*Mounting on the Skull.* Clean the skull and dry well; fill the brain cavity with plaster Paris, and insert an iron rod, bent double, inside the skull; when the plaster is set, perfect the anatomy by modelling with the same. Make a base neck-board, and run the iron rod through it, and clinch it in position in a groove with wire staples; bend the iron to the desired curve, and complete the head as above.

Cast Ready for Covering.

DRIED SKINS, To Prepare for Mounting. — When a skin is to be mounted, it must be soaked in alum water to soften it; ¼ lb. to 1 gal. water is about right. Soak till pliable. If the skull has been removed, replace it with a plaster of Paris one. The skin is then stuffed. Dried bird skins should have balls of wet cotton placed in the orbits of the eyes, and the legs and feet wrapped with wet cotton rags; a damp cloth thrown over the bird, and allowed to remain until next day. The neck and body are then filled with wet cotton, and in 4 or 5 hours it will be ready to stuff and mount.

FISH, to Mount.—Before skinning, the scales, as well as color, may be preserved by applying tissue paper, which will adhere firmly; this, being allowed to remain until the skin has dried, may be removed with a damp cloth. All small fish should be mounted in section, while larger varieties may be preserved entire. Supposing the fish to be of such a size as to be mounted in section, let it be as fresh as possible. Place the fish on one side, and cover the side uppermost with tissue paper; extend the fins by means of the same, and allow them to remain a few moments until dry. Spread a damp cloth upon the table, and place the fish upon it, papered side down. With the dissecting scissors, cut the skin along an oval line, following the contour of the body, a little below the extreme dorsal edge and a little above the ventral one, and remove the skin included within this line. The remaining skin must be detached from the flesh, beginning at the head down toward the tail. The spine must be severed close to the head, and also at the tail, and the entire body removed; the flesh having been taken from the skin, and the eyes removed, the inside must be wiped out and arsenical soap applied. The skin should now be filled with tow, evenly placed. When filled, it should be laid, open side down, upon a board, and fastened by small tacks, beginning at the head and fastening the edges down toward the tail; then set aside to dry. The paper is, after drying, removed, and eyes of wood (painted to the proper colors and not varnished) are inserted with putty. Finally the skin should receive a coat of colorless varnish.

INSECTS, to Preserve.—1. Saturated solution of alum, 100 grammes; saltpetre, 2 grammes. The article is to be immersed in the solution, when it becomes decolorized; in a few days the color returns, when it is taken out of the solution, and kept in a saturated solution of alum and water only.—2. Glycerine, 1 part; water, 2 parts.—3. Wood naphtha, 1 part; water, 8 parts.—4. Alum, 1 part; water, 16 parts.—5. Bay salt, 4 oz.; alum, 2 oz.; corrosive sublimate, 4 gr.; water, 2 gr.—6. Creosote, 25 drops; water, 1 wineglass.—7. A solution of arsenious acid.



Mounted Insects.

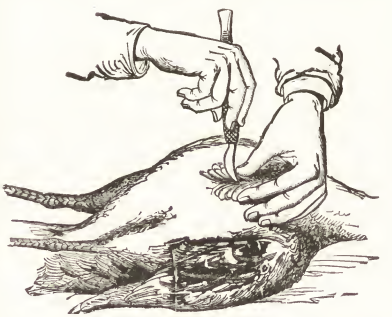
INSECTS, To Mount.—Minute insects should be fastened on top of the point of a triangular card, with gum. Moths and other insects, while drying, should be set with braces chiefly. Place a single one under each wing, as shown in *Fig. 1, b b*, and place a larger brace, *a a*, over the wings, not touching, but ready to rest gently on them when required. Raise the wings to the proper position with the setting needle, and use the other braces, *b, c, g, l, t.* The feet and other parts are kept in position by pins. Bodies of insects of the cricket and locust kind, shrivel in drying, and the intestines should be extracted and the body filled with cotton. They are set as shown in *Figs. 2* and *3*.

SKELETON. To Mount. — There are 2 ways: one in which the bones are connected with wire; the other, in which they are connected by the natural ligaments. 1. To make wired skeletons, study the manner in which the bones are naturally connected. Boil the flesh off; then strip off the ligaments; they will look better by afterwards boiling them in a weak alum solution. Connect the bones with brass wire. To do this study the skeletons in museums. — 2. Remove all muscles; dry the ligaments left in the desired position; then varnish. — 3. To obtain skeletons of mice, rats, squirrels, etc., place the dead animal (cleaned) near a nest of ants, and cover with a tin pan; they will take all the flesh and leave the ligaments and cartilages, so that the skeleton, when clean, will not want wiring.

SKINNING ANIMALS.—An accurate measurement should be taken of birds and animals before skinning to prevent stretching; the neck is liable to be unduly stretched; the natural length should be preserved. Skinning should be done as soon as possible, for when decomposition sets in the hair will come out. Lay the animal on its back; plug the nostrils, mouth and wounds with cotton. Make a longitudinal incision in the lower part of the belly, in a straight line from the root of the tail ¼ the length of the body; sometimes as high as the collar bone. Do not cut the abdominal muscles; separate the hair, right and left, to prevent cutting; loosen the skin as far as possible; sever the legs from the body at the hip joints; cut off the intestinal canal a little above the anus; separate the tail close to the body; pull the back part of the body out of the skin; remove the forelegs from the body at the shoulder joint; when the joint of one shoulder has been separated, put the leg again into the skin, and repeat the process with the other, returning the limb; draw the skin carefully over the head and neck and loosen it as far as the nose, so as not to injure the eyelids; avoid cutting the lips too close; cut the ears off close; separate head from the body by disjointing the neck at the upper joint of the vertebræ; remove the muscles of the head and face and leave the bones clean; open the occipital bones with a sharp knife, and remove the brains with a scoop; cover the parts well with arsenic, and return the head to the skin. Pull the forelegs out of the skin by drawing the legs one way and the skin the other; clean the bones, preserving the ligaments and tendons; return the bones into the skin; treat the hind legs in the same way. To remove the skin from the tail, see *Skinning* in CURING AND DRESSING. After removing all muscles and particles, cover the inside of the skin with arsenical soap, rubbing it in by hand.

SKINNING BIRDS.—In cool weather let the bird lay 24 hours before skinning, previously inclosing it in a cone of paper that the feathers may be kept smooth. Before skinning place fresh plugs in the holes, mouth and nostrils. In commencing, the left hand is used to part the feathers, exposing the skin from the apex of the breast bone to the tail. With the scalpel, held like a pen, make a free incision between these points; divide the skin without cutting the flesh; press apart the skin and dust oatmeal into the cut, to absorb any fluids; carefully lift the skin clear of the flesh until the leg is reached; then use the scalpel to separate the thigh joints; push back the skin the whole length of the thigh; remove the flesh; replace the bone, and treat the other thigh in the same manner. Cut the wings from the body at the joint next the same, and scrape the bones. Divide the neck so that the skin, with the head attached, can be peeled to the root of the tail; bend the tail toward the back with the left hand, keeping down the detached parts of the skin on each side of the vent; make a deep cut across the vent and sever the back bone at the joint, leaving enough bone at the root of the tail, so that it will not come out. Pull the skin of the neck over the flesh till the skull is exposed; remove the ears; carefully separate the lids from the eye-balls. Scrape out the eye cavities. Cut away the flesh of the neck, removing at the same time a small portion of the base of the skull; through this cavity extract the tongue and brains; clean away all fleshy matters; paint the eye orbits with arsenical soap. Care should be taken not to detach the skin from the bill. Fill the interior of the skull with tow, after it has been

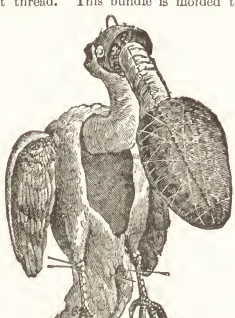
Paper Cone.



First Incision in Skinning.

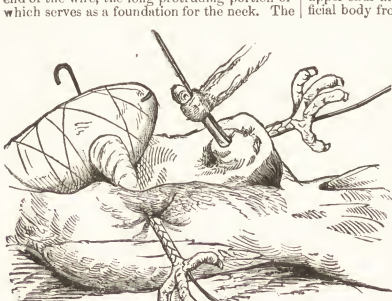
coated internally with the prepared soap.

STUFFING AND MOUNTING BIRDS.—1. Before skinning, measure girth and length. From these data an artificial body is constructed as follows: On a piece of straight wire, a bunch of excelsior is secured by repeated winding with stout thread. This bundle is molded to re-



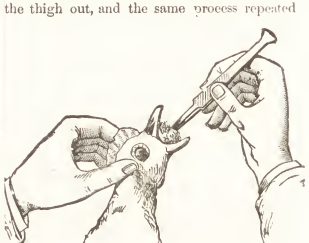
Attaching the False Body.

semble the bird's body. It is attached at the end of the wire, the long protruding portion of which serves as a foundation for the neck. The



Stuffing the Legs.

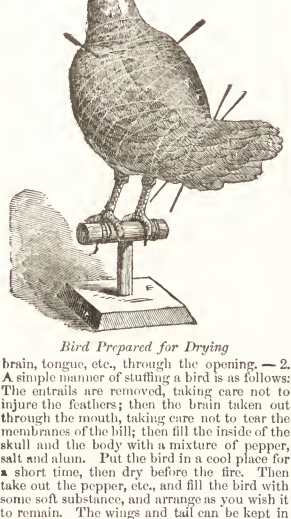
extremity of the wire is clipped to a point, and forced diagonally upward through the skull, on top of which it is clinched flat. Cotton batting is wound about the wire between the skull and body, sufficient to fill the skin of the neck. Paint the inside of the skin with arsenical soap; then draw the skin back to envelop the false body; a needle and thread are thrust through the nostrils to make a loop for convenience in handling. The finest pair of forceps is employed to pull the eyelid skin into place, arrange the feathers, and pull up the cotton in the orbits. More cotton is pushed down the throat until filled; 2 pieces of wire are then sharpened at one extremity; taking the wire in one hand and guiding it with the other, shove it into the leg from the ball of the foot up alongside the thigh bone, the skin being turned back; cotton is then wound about both wire and bone to fill the thigh out, and the same process repeated



Filling the Throat.

for the other side, the ends of the wire below protruding to support the bird on a perch; the upper ends are pushed clean through the artificial body from below, and clinched on the upper side; this secures the legs, which are afterwards bent in natural position. The bird can now be set up. For small birds, the cut in the breast need not be sewn up; a chicken or larger fowl will require a few stitches. If the tail feathers are to be spread, a wire is thrust across the body and through each feather; the wings are then gathered closely into the body, and 2 wires, one from each side, are pushed in diagonally from up, down and through the skin of the second joint. (See illustration, *Bird Prepared for Drying.*) The wings are thus held, and the wires, as well as that through the tail, are left protruding. A touch of glue within the eye-lids prepares for the eyes, which may be purchased from taxidermists; for smaller birds, black beads will answer. If plain glass beads can be readily obtained, by the aid of a little paint they can be made to imitate the eye of a chicken. After the eyes are inserted, a needle is used to pull the lids around them and into place; then, with a fine pair of forceps, adjust the feathers, smoothing them with a large camel's hair brush. Thread must then be wound over the body loosely, beginning at the head, and continuing

until all the feathers are bound. The bird is left to dry for a day or two, when the thread is removed, the ends of the wire cut off close to the body, and the work is complete. In ducks, hens, etc., the neck is so long and narrow that the skin cannot be drawn over the head with these birds; therefore, skin the neck high and cut it off; make a cut through the skin from the angle of the jaw to the bottom of the piece of neck attached to the head, and remove the neck,



Bird Prepared for Drying

brain, tongue, etc., through the opening. — 2. A simple manner of stuffing a bird is as follows: The entrails are removed, taking care not to injure the feathers; then the brain taken out through the mouth, taking care not to tear the membranes of the bill; then fill the inside of the skull and the body with a mixture of pepper, salt and alum. Put the bird in a cool place for a short time, then dry before the fire. Then take out the pepper, etc., and fill the bird with some soft substance, and arrange as you wish it to remain. The wings and tail can be kept in position with fine wire.

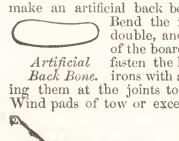
STUFFING AND MOUNTING SMALL ANIMALS.—Select a piece of wire of such thickness that 4 pieces, introduced into the legs, will support the animal. A thinner piece, 2 ft. long, is next taken and bent ½ its length into an oval shape smaller than the hand; the 2 ends twisted together, leaving 1 end shorter than the other; then the wire must be cut the same length as the tail, independent of the oval. Wrap the wire in flax, constantly increasing towards the oval; rub the whole with paste to preserve the shape. With a small brush put a little of the preparation into the tail, and coat the towed wire with the same, and put it into the skin of the tail; place the oval end within the body; this serves to fix the tail to the iron backbone. Take 5 pieces of iron wire, the diameter of a straw; 1 a foot longer than the body of the animal, the 4 others the length of the legs they are to support; the points must be sharp at one extremity in a triangular form. Form a ring at the unpointed end of the long wire, large enough to pass the little finger through, bending the wire back on itself 1½ turns with round pincers; form a similar ring on the same wire, by 1 turn, in the part that will come between the animal's shoulders. The rest of the wire must be straight and pointed triangularly. Having anointed the skin with preservative, fill the hollows of the head with chopped flax; insert one end of the long piece of wire into the middle of the skull, and restore the head to its place; stuff the skin of the neck with the same, preserving dimensions. The second ring of the wire must correspond with the pelvis. Next take one of the foot wires and pass it behind the bone of the front leg, placing the point which comes out at the sole under the highest ball of the foot; then draw the bones of the leg up within the skin, and tie the wire to the bone of the arm and forearm with packthread; anoint the parts and twist them with chopped flax. To fix the forelegs, pass their wires in the little ring of the middle or back wire, and twist the ends together with pincers. For an animal the size of a fox the pieces left to twist should be 5 to 6 in. long. Bind the wires on the under side against the back wire, and fasten with packthread; replace the 2 legs, and bend them according to the attitude intended. The skin of the shoulders and belly are next stuffed, putting sufficient flax under the back wire. Sew the anterior part of the opening, preserving the appearance of the scapulæ, and that thickness which appears at the junction of the shoulder and bone of the forefoot. The wires for the hind legs should be longer than for fore legs, and be inserted into the paw, loosely fastened to the thigh and leg bone, and the flax applied. If the whole is bound round with thread, it will prevent slipping up when the leg is placed within the skin. Pass the extremities of the wires of the hind legs through the second ring of the back wire, which ring should be at the pelvis; bend the ends and twist them in opposite directions round the ring. To give strength, pass a piece of packthread several times round these 3 wires and tie it. Replace the body by chopped flax, laying it under the wires, preserving the circumference and imitating irregularities caused by the muscles; then, with a triangular pointed needle and strong silk, sew up the incision down the belly; pass the needle from the inner surface, dividing the hairs to prevent their being drawn in with the edge of the skin. When the skin is sewed up turn the subject in all directions, and press it into a correct shape, and restore the appearance of the muscles. Next take a board and drill 4 holes same circumference as the foot wires, at a distance to suit attitude; insert the wires of the feet through the holes, and with pincers draw them close to the board, so that the soles rest firm; bend the wires on the underside of the board, and clinch with short nails.

The specimen being erect, give proper attitude to the head, imitating muscles by stuffing in cotton at the orifices. Put the artificial eyes in while the eyelids are still fresh. Place cotton inside the lips and secure by pins; distend the nostrils with cotton closely pressed, and the flesh saturated with the preservative. If the ears are to be erect, pass a connecting thread through the base of each, tightening it until sufficiently near to each other. If the ears are large, pasteboard of the same form may be placed within and fastened round the edges with small pins. Anoint the ears, nose, lips and paws with a brush dipped in spirits of turpentine, and afterwards wipe the hair with cotton. Repeat this 7 or 8 times at intervals of some days. When quite dry, the wire which passes from beyond the head may be cut.

STUFFING AND MOUNTING LARGE ANIMALS.—Pour the skull full of plaster; bend double an iron rod and insert inside the skull; make an artificial back bone of 1½ in. plank.

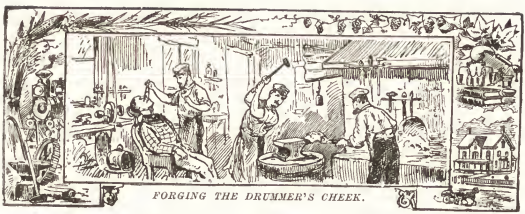
Artificial Back Bone.

Bend the iron for the neck double, and fasten to the side of the board with wire staples; fasten the leg bones to the leg irons with annealed wire, bending them at the joints to the desired shape. Wind pads of tow or excelsior with string, to form the legs and quarters; substitute the main cords of the hind legs, running from the hocks, with wires covered with tow. Drill holes into the projecting bones of the hocks, and fasten the wires by inserting the ends; give them the right curve, and lash the other ends to the legs. Coat with thin glue to give an even surface. When the legs are formed, bend the projecting irons like *a*, in the illustration; fasten them on the board, in position, with wire staples, 1 set of staples holding both irons. Reverse the bending of the irons to the hind legs, and fasten as before. Take a piece of wire longer than the tail of the animal; bend at one end and fasten it on the board with wires, as shown in the illustration. The whole anatomy of the body is made by binding on pads of tow. The dummy is fastened on a stand by bending the irons under, plugging the holes tightly around them, and clinching them with wires. Having coated the skin with arsenical soap, lay it on the body; and if a good fit is made, commence sewing up the legs, cross-stitching from the inside; correct any imperfections in the anatomy by cramming stuffing under the skin. Model the feet in cement and nail them in position. The lower parts of the legs may be modeled in clay over the excelsior. When the last seam has been closed the coat should be combed out with a fine metal comb. The anatomy of the head should be first roughed out over the skull with plaster or cement; then the skin should be tacked in position, with the eyes straight. Model the under jaw first, holding the skin in position by stitching across the inside of the mouth. Fill the nose with clay or cement. Turn the skin of the lips in under; then form the upper lip into shape and work down to a natural position. The features are gradually worked out, the eyes set, the ears erected by sewing on pieces of pasteboard, and the hair combed smooth. The eyes, lips and claws should be painted naturally and varnished.



Position of Irons.

STUFFING. Preparations for. — Camphor, 1 oz.; corrosive sublimate, 1 oz.; alum, ½ oz.; sulphur, 1 oz.; all powdered and mixed. — 2. Tanners' bark, dried and powdered, 2 oz.; burnt alum, 1 oz.; snuff, 1 oz.; mix, and add arsenic, ¼ oz.; camphor, ¼ oz.; sulphur, 1 dr. — 3. Arsenic, 4 oz.; tanners' bark, 8 oz.; mix and reduce to powder; sift fine; add camphor (reduced to powder with spirits of wine), 2 oz.; musk, 30 gr.; keep in a closed jar. — 4. (*Arsenical Soap.*) Camphor, 5 dr.; arsenic, 4 oz.; white soap, 4 oz.; carbonate of potash, 12 oz.; air-slaked lime, 4 oz.; make a stiff paste with a little water.



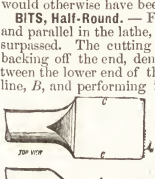
FORGING THE DRUMMER'S CHEEK.

METAL WORKING.

ALL METALS.

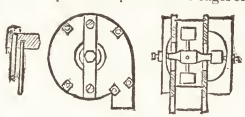
THE method herein adopted for treating of metal working is to divide it according to the metal operated upon. Certain operations are common to all the metals, namely, polishing, grinding, etc.; there are, also, certain machines and tools employed in working all the metals, such as the lathe, file, scraper, etc.; for these reasons the subject of ALL METALS is adopted. On account of the importance of BRASS it will be classed as one of the metals and passed unnoticed among ALLOYS, under which head it would otherwise have been treated.

BITS, Half-Round. — For drilling holes true and parallel in the lathe, the ½ round bit is unsurpassed. The cutting edge, *A*, is made by backing off the end, denoted by the space between the lower end of the tool and the dotted line, *B*, and performing its duty along the radius, denoted by the dotted line in the end and top views. It is only necessary to start the ½ round bit true, to insure its boring a hole of any depth true. To start it, the face of the work should be made true; this is not positively necessary. A recess, true and of the same diameter as the bit, must be turned in the work, the bit placed in position, and the dead centre employed to feed it to its duty, which (if the end of the bit is square, if a flat place be filed upon it, or any other method of holding it sufficiently tight be employed) may be made as heavy as the belt will drive. This is simple, positive and effective.



Half Round Bits.

BLOWER. — A simple method suitable for the sand blast: Make 2 wooden side pieces, of the form shown in the side elevation. Cut a groove in each to receive the sheet iron strip which forms the curved sides. Turn a wooden shaft. Insert metal bearing pieces in its ends. Bore 4 holes in the hub, and insert 4 arms with fans attached. Support the shaft on pointed screws inserted in the cross pieces attached to the side pieces. Clamp the side pieces to the edges of the



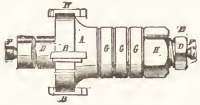
Blower.

sheet iron by small bolts. The dimensions are: Diameter of case, 6 in.; thickness of case inside, 2½ in.; size of opening in sides, 2½ in.; size of fans, 1½ x 2 in.; discharge opening, 1½ x 2½. The size and proportions may be varied. A fan of this sort will answer for the sand blast or for a small forge, but if it is to be used continuously, the shaft should be iron or steel, and it should be run in well made boxes.

BORING ARBOR AND TOOL THAT WILL NOT CHATTER. — Boring tools, when used in small arbors, are always liable to chatter and make a rough hole. To best prevent this, the tool should be turned in a lathe, while in its position in the arbor, upon the circle of the size of the hole to be bored, and the bearing lengthwise of the arbor, only as wide as the feed of the lathe; for if the bearing of a tool is on the face, the more it will chatter.

BORING-BAR, For Lathe-Work. — In boring work chucked and revolved in the lathe, as axle boxes for locomotives, the boring bar is an excellent tool. *A* represents a cutter head, which slides along, at a close working fit, upon the bar, *D D*, and is provided with the cutters, *B B*, fastened into slots provided in the head, *A*, by keys. The bar, *D D*, has a thread upon part of its length, the remainder plain, to fit the sliding head. One end is squared to receive a wrench, which prevents the bar from revolving upon the lathe centre, *F F*, by which the bar is held in the lathe. *G G G* are plain washers, provided to make up the distance between the thread and

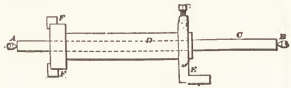
plain part of the bar where the sliding head, *A*, requires considerable lateral movement, there



Boring Bar.

being more or fewer washers employed according to the distance along which the sliding head is required to move. The edges of these washers are chamfered off to prevent them from burring easily. To feed the cutters, the nut, *H*, is screwed up with a wrench. The cutter head, *A*, is provided in its bore with 2 feathers, which slide in grooves provided in the bar, *D D*, preventing the head from revolving upon the bar. It is obvious that this bar will take out a much heavier cut than any boring tool; and there being 4 cutters, they can be fed up 4 times as fast as would be possible with a single tool or cutter.

BORING-BAR, For Tapering Holes.—In the illustration one end of the work is secured in the chuck with the other end running in the steady rest. The turned bar, *C*, mounted on the centres, *A B*, serves as a guide for the cutter head, *D*, and its long sleeve, the hind end of the sleeve being secured to the tool-post by means of the

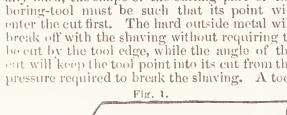


Boring-Bar for Tapering Holes.

dog, *E*, so as to effect a feed. By setting the tail stock over, as in taper turning, a hole of any desired taper may be bored. The main feature of this bar is that the work revolving may be trued by outside or other parts. Any degree of taper that can be turned may be bored by using this bar. One or two cutters, *F F*, may be used.

BORING TOOL, For Metal Having a Hard Skin.—When the skin of a metal to be cut is unusually hard, the shape of the cutting part of the boring-tool must be such that its point will enter the cut first. The hard outside metal will break off with the shaving without requiring to be cut by the tool edge, while the angle of the cut will keep the tool point into its cut from the pressure required to break the shaving. A tool

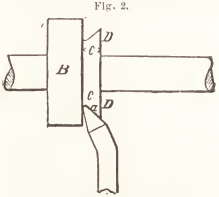
Fig. 1.



Tool for Cast Iron.

of this description is represented in the illustration, *Fig. 1*. *a* is the point of the tool, and from *a* to *B* is the cutting edge; the dotted lines, *c* and *D*, represent depth of cut, *c* being the inside skin of the metal. The angle at which the cutting edge stands causes the pressure to be in the direction of *c*, which keeps the tool point into its cut; while the resistance of the tool point to this force, reacting upon the cut, from *a* to *B*, causes the hard skin to break away. But for use on wrought iron, the tool presented below will work better. In the event of a side face being hard, it possesses the advantage that the point of the tool may be made to enter the cut first, and, cutting beneath the hard skin, fracture it off without cutting it, the pressure of the shaving on the tool keeping the latter to its cut, as shown in *Fig. 2*. *a* is the cutting part of the tool; *B* is

Fig. 2.



Tool for Wrought Iron.

a shaft with a collar on it; *c* is the side cut being taken off the collar, and *D* is the face, supposed to be hard. The cut is here shown as being commenced from the largest diameter of the collar, and fed inward so that the point of the tool may cut well beneath the hard face, *D*, and the pressure of the cut on the tool keep it to its cut. The tool will cut equally well if the cut is commenced at the smallest diameter of the collar and fed outward, if the skin, *D*, is not unusually hard.

BORING TOOLS, Shapes of.—The pressure on the cutting edge of a tool acts in 2 directions, 1 vertical, the other lateral. The downward pressure remains the same; the lateral pressure varies according to the direction of the plane of the cutting edge of the tool to the line or direction in which the tool travels; the general direction of pressure being at a right angle to the general direction of the plane of the cutting edge. For example, the lateral pressure, and hence the spring of the various tools, shown in the illustration, will be in the direction denoted by the dotted lines. *D* is a section of a piece of metal requiring the 3 inside collars to be cut out; *A B* and *C* are variously shaped boring tools, from which it will be seen that *A* would leave the cut in proportion as it suffered from

Lateral Pressure of Tool.

spring, which would increase as the tool edge became dull, and that the cut forms a wedge, tending to force the tool toward the centre of the work. *B* would neither spring into nor away

from the cut, but simply require more power to feed it as the edge became dulled, while *C* would have a tendency to run into the cut in proportion as it springs; and as the tool edge became dull, it would force the tool point deeper into the cut until something gave way. In addition to this consideration of spring, is the keenness of the tools, it being obvious that (independent of any top rake or lip) *C* is the keenest and A the least keen tool; since wrought iron requires the keenest, cast iron a medium, and brass the least keen tool, it follows that we may accept, as a rule, *C* for wrought iron, *B* for cast iron, and *A* for brass work. In the illustration of boring tool for brass, *B* represents a section of the work; the first represents a boring tool with top rake, for wrought iron, and the second a tool without top rake, for brass work, which may be used for cast iron when or clamp. **A tool for use on wrought iron should** have the same amount of top rake, no matter how far it stands out from the tool post; whereas one for use on cast iron or brass requires to be the less keen the further it stands out from the tool post. To take a smooth cut on brass work, the top face of the tool, shown at 2 in the second cut, must be ground off, as denoted by dotted line. A positively sharp corner, unless for a special purpose, is undesirable, because the extreme point wears away, leaving the cutting qualification of the tool almost destroyed, and the work rough, and can only be employed with a very fine feed. As a rule, for roughing cuts, the corner should be sufficiently rounded to give strength to the tool point; in finishing cuts, the point may be made as round as possible without causing the tool to jar or chatter. Since the tendency of the tool to chatter depends upon 4 points, the distance it stands out from the tool post, the amount of top rake, the acuteness or keenness of the general outline of the tool, and the shape of the cutting corner, it will be seen that judgment is required to determine the most desirable form for particular conditions, and that it is only by understanding the principles governing the conditions that a tool to suit them may be at once formed. The illustrations show the forms of boring tools in ordinary use.

CASTING.—To reproduce from a broken casting, without the original pattern, put the pieces together, and mold them, and cast from this mold. When the casting is drawn from the sand, place it in a charcoal fire and anneal it. It will expand to the original size of the pattern, and remain in that state.

CASTINGS, Sands and Facings for.—For castings, such as pipes or small cylinders, fine sand, termed No. 1, is used, the facing being plumbago. A good facing for loam castings is made of 1 part Whitehead sand to 3 parts fire sand. For very fine faced castings, Albany or Waterford sand is unsurpassed. Another facing for fine castings is 1 part of sea coal to 8 or 10 of Albany sand; for heavy castings, 1 to 5 will answer.

CASTINGS, Shrinkage of.—Shrinkage sideways and endwise, on castings of 3 in. and less size, is compensated for by the shake in the sand given by the molder to the pattern in order to extract it from the mold.

Iron, small cylinders	= 1-16 in.	per foot.
" Pipes	= $\frac{1}{8}$ "	"
" Girders, Beams, etc.	= $\frac{1}{8}$ "	in 15 in.
" Large Cylinders, the contraction of the diameter at top	= 1-16 in.	per ft.
Ditto at bottom	= 1-12 "	"
" in length	= $\frac{1}{8}$ in	16 in.
Brass, thin	= $\frac{1}{8}$ "	9 "
" thick	= $\frac{1}{8}$ "	10 "
Zinc	= 5-16 in.	in 1 ft.
Lead	= 5-16 "	1 "
Copper	= 3-16 "	1 "
Bismuth	= 5-32 "	1 "

CASTINGS, Small.—In small castings requiring to be of correct size, allowance should be

made in the pattern for the shake of the pattern in the sand. A pattern of an in. cube will require to be made 1-22 in. less endwise and sideways, and the usual allowance above an in. must be made on the top face of the pattern, which should have "top" marked on it; thus the shake endwise and sideways given to the pattern, to extract it without lifting the sand, will be allowed for in the size of the pattern. The effect of this shake in the sand is appreciable in patterns up to about 4 in. diameter. It is a common practice to cool brass castings to loosen or remove the sand. The effect is to place conflicting strains and tensions upon the whole skin of the metal, which will alter its shape when the outer skin of such faces is removed; so that, supposing the casting to be a cube, no one face will be true when planed, no matter how true the surfacing.

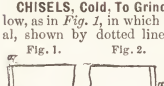
CASTINGS, Smooth. — A means recommended for obtaining smooth castings, is mixing with the green foundry sand forming the mold about 1-20 part of tar without the addition of any other substance.

CASTINGS, Weight of. —

A Pattern Weighing 1 lb., and Made of	Will Weigh When Cast in				
	Cast Iron.	Zinc.	Cop.	Yel. Brass	Gun Metal
Mahogany	8	8	10	9.8	10
" (St. Domingo)	10	9.5	12	11.5	12
Maple	10	9.8	12.5	12	12.4
Beech	11	11	14	13.4	13.8
Cedar	11.5	11.4	14.5	14	14.5
Yellow Pine	13	12.6	16	15.5	16
White Pine	14	14.5	18	17.5	17.8

CHISELS, Cold, To Grind.—Chisels made hollow, as in *Fig. 1*, in which are 2 sections of metal, shown by dotted lines, *a a*, are liable to break from weakness and the strain outward placed upon them by the cut, which endeavors at each blow to drive them outward instead of inward, as would be the case in a properly shaped chisel, as shown in *Fig. 2*, *a* being the cutting edge. When using, hold it firmly against the cut, and it will do work smoother and quicker. The cape, or cross cut chisel, is used to cut furrows across the work to be chipped, which being cut at a distance from each other less in width than the breadth of the flat chisel, relieve the flat chisel and prevent its corners from "digging in" and breaking. If a large body of metal requires to be chipped off cast iron or brass, the use of the cape chisel becomes advantageous, for the metal, weakened by the furrows, will break away in pieces from the force of the blow, without requiring to be cut by the chisel; care must be taken to leave sufficient metal to take a clean finishing cut; when the metal is broken away, by the force of the blow, it is apt to break out below the level of the cut. It is necessary to nick deeply with a chisel the outside edges of the work at the line representing the depth of the metal to be chipped off, so that the metal shall not break away at the edges deeper than the cut is intended to be. The chisels should weigh about 1¾ lbs., and have handles 15 in. long.

Fig. 1. Fig. 2.



Cold Chisel.

CHISELS, Cold, To Harden.—Heat the chisel to a distance about equal to its width; immerse it about ½ that distance in the water; hold it still about 4 seconds; suddenly dip it a little deeper, and then withdraw. Brighten one flat surface with a piece of grindstone or an emery block; then brush the hand or a piece of waste over the brightened surface to remove the false color, and finally cool out in the water, when the clear blue color appears.

CHISELS, Cold, Use of.—Hold a cold chisel firmly to its cut, without removing it at every blow. This increases effectiveness, and decreases liability to break. Rest the head upon a block of iron, and strike the burrs from the under side and they will break readily and easily off. Chisels should be kept thin at the cutting end, which saves time and labor.

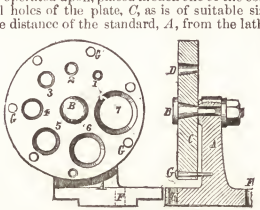
CLOUDING.—Metal work may be clouded by putting a piece of fine emery paper under the thumb or finger and working it over a surface of the metal with a spiral motion.

COCKS, To Grind Plugs in.—The best material for this purpose is the red, well burnt sand from the core of a brass-casting, the sand being sifted before using. It will cut more truly and smoothly than any other material; use with water. After the cock is ground, wash it and barrel with clean water; after wiping (but not quite dry), revolve the plug backward and forward in its place under a slight pressure, and the surface will assume a rich brown color, showing very distinctly the precise nature of the fit and leaving a smooth surface. Valves may be ground to their seats in a similar manner.

COLORING.—1. Metal can be dyed any color by dissolving any of the aniline dyes in methylated spirit and adding shellac. This solution must be painted on until the desired shade is obtained. If the iron has been previously painted white so much the better. — 2. Take hyposulphite of soda, 4 oz., dissolved in 1½ pts. water; add a solution of 1 oz. acetete of lead in same quantity of water. Articles to be colored are placed in the mixture, which is then gradually heated to boiling. The effect of the solution is to make iron resemble blue steel; zinc becomes bronze, and copper or brass becomes successively yellowish-red, scarlet, deep blue, bluish white, and finally white with a tinge of rose. The solution has no effect on lead or tin. By replacing the acetate of lead in the solution with sulphate of copper, brass becomes of a fine rosy tint, then green, and finally of an iridescent brown color. Zinc does not cover in this solution; but if boiled in a solution containing both lead and copper, it becomes covered with a black crust, which may be improved by a thin coat of wax.

CONE-PLATE, For Boring in the Lathe. — For chucking shafts and similar work in the lathe (to bore holes in the ends of the shafts, etc.), the cone plate shown in the illustration is the best appliance known. *A* is a standard, fitting in the shears of the lathe at *E*, and holding the circular plate, *C*, by means of the bolt, *B*, made to clamp

the plate, *C*, tightly when the nut is screwed. The plate contains conical holes, 1, 2, 3, etc. (shown in section at *D*). The object of coning the pin, *B*, where it carries the plate, *C*, is that the latter shall be made to a good working fit. The operation is to place the shaft in the lathe, one end provided with a driver, placed on the running centre of the lathe; the other end, to be operated upon, placed in such one of the conical holes of the plate, *C*, as is of suitable size, the distance of the standard, *A*, from the lathe-



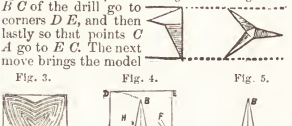
Cone-Plate for Boring in the Lathe.

centre is to be adjusted so that the work will revolve in the coned hole with about as much friction as it would have were it placed between both the lathe centres. The conical hole will take the place of the dead centre of the lathe, leaving the end of the shaft free to be operated on. *F F* are holes to bolt the standard, *A*, to the lathe shears or bed; and *G G*, etc., are taper holes to receive the pin, *G*. These holes and pin are to adjust the conical holes so that they will stand true with the lathe centres. Hole No. 7 is shown in position to operate the pin, *G*, locking the plate, *C*, in that position. In setting the work, the nut on the pin, *B*, should be eased back to allow the plate, *C*, to revolve by hand; the work then put in position, the pin, *G*, put in place, the standard, *A*, adjusted to its distance from the live lathe centre, and bolted to the lathe bed; finally, the nut on the pin, *B*, is screwed up tight, when the work will be held true, and the cone-plate prevented from springing. Care must be taken to supply the conical holes with oil, otherwise they will abrade.

CONES IN HOLES, Fitting. — Rub the cone with red marking or else chalk; a narrow strip running from the end of the cone will do. Put the cone into its place, press it forward and revolve it back and forth, and the marks will show where it binds.

COTTON-WASTE, To Clean Greasy. — Boil in a strong solution of common soda in water, and save the resultant soapy liquid to keep drills and reamers wet when boring iron.

DRILLING SQUARE HOLES. — The tool is the form shown in *Figs. 1* and *2*. Clamp or chuck this drill in its holder so that "it will wobble." Instead of making a round hole, if tightly grasped, when loosely held it produces a square one. The tool mark, enlarged, is represented in *Fig. 3*. Evidently the boundaries of the figure inclosed in the square are arcs of circles having for their centres the corners. To see how this is produced, make a card-board model of any size, representing a section of the drill, as in *Fig. 4*, bearing in mind that the points, *A B*, and *C* are equidistant. Now draw a square having sides equal to the distance between two points of the drill, as *A C*. Place the model upon this square, as in *Fig. 5*. The points *A* and *C* will plainly enter corresponding corners of the square, but there will be a space between the point *B* and the side *D E*. Now, retaining the point *A* in its corner, swing the model to the left, so that the point *B* will enter corner *D* (dotted-line arc). The point *C* will then pass to *F*, and the centre of the model *G* to *H*. The points *A* and *B* of the model then correspond with *A* and *D* of the square. Swing the model again, so that the points *B C* of the drill go to corners *D E*, and then lastly so that points *C A* go to *E C*. The next move brings the model



Tools for Drilling Square Holes.

back to its first position, and it will have made an entire revolution. Now if we have marked the arcs described by the points, the outline of a figure similar to that represented in *Fig. 3* will be found, and it will be clear that this may approximate closely to the square. The material in the re-entering angles on the sides of the figure is probably cut away by abrasion of the chips after the drill has penetrated a short distance. The amount of "wobble" to give to the drill is measured by the distance of point *B*, *Fig. 5*, from side *D E*. It will be seen that this principle can be extended; for example, to the boring of a hexagonal hole by a 5 pointed or varied drill, easily tried with a card-board model. Begin by swinging the side *A B* on *A* as a centre to *A F*. The distance *B F* represents the "wobble." From this position swing the point *C* a distance equal to *B F* from this point *D*, and so on around the pentagon. The figure described by the sides will be found to be a hexagon.

DRILLING HOLES WITHOUT A REAMER. — It is sometimes necessary to drill a hole to fit a certain shaft, and have it smooth without reaming. This may be done by first drilling a hole 1-100 in. smaller than the size desired, and then making a drill the exact size and running it through to finish with. This last drill should have the corners of its lips rounded, like a reamer, and the hole finished without holding the drill with a rest.

DRILL SOCKETS, or COLLETS. — The best collets for correct work on drill lathes are formed to screw on to the spindle, and constructed with a tapering hole for the retention of the drill, and a key-way to secure the end of the drill from turning. Sockets for ordinary job form should be shaped with a set-screw to retain the drills, and the aperture for the drills drilled circu-

lar, adapted for the reception of round drill steel about 7-16 in. in diameter. For collets to screw on the drill lathe, bore out the end and shape the screw to conform to the spindle, and attach it by screwing it on to the lathe where it is required for use. Next, bore a hole for the drill shank 1¼ in. deep, straight and true, ream it tapering, and cut a key-way through the metal, below the lower part of, and running into the aperture bored for the shank. This key-way is intended to secure the drill and ought to be ¼ in. long and ¼ wide. A collet for upright drills should be made by drilling the centres and turning up the ends to be drilled for the shank to adapt it for running in a back rest; then insert the end to be drilled into the back rest and the other end on the lathe centre and proceed to drill out the hole for the shank; then remove it from the back rest, and, making use of the hole for a centre, turn it to fit the drill, insert a set screw in it, and all is finished.

DRILLS, To Temper. — Select the finest and best steel for drills. Never heat higher than a cherry red, and hammer till nearly cold. Do the hammering in one way; for if, after having flattened the piece out, you attempt to hammer to a square or a round it will spoil it. When the drill is in shape heat it to a cherry red, and thrust it into a piece of resin or quicksilver. Some use a solution of cyanuret potassa and rain water for tempering drills, but resin or quicksilver seems to work better.

EMERY, To Prepare Fine. — When no fine emery is at hand, place coarse emery upon an iron block or plate, and hammer it with the face end of the hammer; after which grind it with the hammer face.

EMERY WHEELS.—1. These can be made with shellac powdered fine, a piece of rosin size of a walnut to 1 oz. shellac, and a piece of old vulcanized india-rubber same size, which gives it toughness.—2. Shellac, 1 oz. to 1 lb. emery; melt, and stir in a frying pan; well mix the powders before applying heat. Be careful not to burn it, or get grease in it; have a ring of iron and a piece of plate iron prepared with black lead and beer pretty thick; place the ring upon the plate and make a mold; turn the stuff into it, and ram down evenly; when cold, turn out and chuck in lathe, and with a piece of red-hot iron bore a hole for spindle; after spindled put between centres and trice up with hot iron.—3. Good grindstones may be made with silver sand mixed with powdered glass; it is necessary to have some body besides shellac for coarse emery to form a body to bed the grains in. Emery dust from grinding glass, and Turkey stone slips and slate, may be used as a substitute for the flour. —4. The best emery wheels are formed of clean emery with sufficient of boiled linseed oil, the mixture being agitated under exposure to a considerable temperature and a free access of atmospheric air; it assumes the necessary degree of tenacity, and while warm, being exposed to hydraulic pressure in a suitable mold, and subsequent drying in a stove, the emery wheel is complete. Emery wheels may be trued by means of a diamond tool, a red hot iron, or a file applied to the wet periphery of the wheel. In using emery paper or cloth for nnishing, the paper, although the easiest to destroy, imparts the smoothest polish to the metal.

PROPER SIZE, SPEED, ETC., OF EMERY WHEELS.

26.....	450		
30.....	400		
36.....	325		

ENAMEL. — Mix 100 parts pure lead with 20 to 25 best tin, and bring them to a low red heat in an open vessel. The mixture then burns nearly as rapidly as charcoal, and oxidizes fast; skim off the crusts of oxide successively formed, till the whole is calcined; then mix the skimmings, and heat until no flame arises and the whole is of a gray color. Take 100 parts of this oxide 100 parts white sand, and 25 or 30 of common salt; melt the whole by a moderate heat. This gives a grayish mass, often porous and apparently imperfect, but which runs to a good enamel when afterwards heated.

ENAMEL, To Remove. — To remove enamel from work without annealing it, take fluor-spar; pound it fine; use enough of the powder to cover well the article; then take a lead cup and pour vitriol on sufficient to make a thin liquid; boil the article in this and the enamel will be removed. Be careful to let the fumes pass up chimney, as they are injurious.

EXPANSION. —

LINEAR, PRODUCED BY RAISING THE TEMPERATURE FROM 32° TO 212° FAHR.

	1 Part In		1 Part In
Zinc	.322	Gold	.682
Platinum	.351	Bismuth	.719
Tin (pure)	.403	Iron	.812
Tin (impure)	.500	Antimony	.923
Silver	.524	Palladium	1000
Copper	.581	Platinum	1100
Brass	.584	Flint Glass	1248

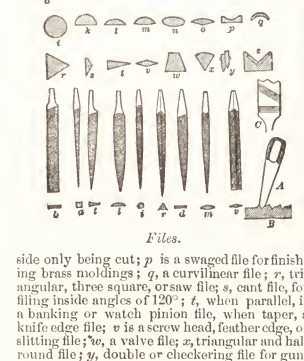
Brass Wire	.517	Reflector Metal	.517
Blistered Steel	.870	Refined Silver	.528

FILES. —Files are graded by shape, size, and fineness of cut; and also are known by their purpose. The series given in the illustration will be readily understood: *a, b, c, d, e, f, g, h* are sections derived from the square; *i, k, l, m, n, o, p, q* are derived from the circle, and *r, s, t, v, w, x, y, z*, from the triangle. The files are known as follows :*a* is a square file, parallel or taper, sometimes with a safe side; *b*, when large, is a cotter file, when small, a verge or pivot file; *c* is a flat file; when small, a pottance file; when narrow, a pillar file; *d*, when parallel, is an equaling, clock pinion, or endless screw file; when taper, a slitting, entering, warding, or barrel hole file; *e f* is a French pivot or shouldering file; when parallel, a V file; *g* is a nail file for the finger nails; *h*,

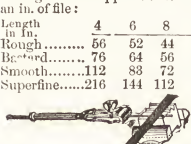
a pointing mill saw and round edge file; *i*, round, gulleting, or rat edge file; *k*, frame saw file; *l*, half round, nicking, piercing, or round off file; *m*, cross file, double half round file; *n*, oval file; *o*, balance wheel or swing wheel file, the convex



Files.

side only being cut; *p* is a swaged file for finishing brass moldings; *q*, a curvilinear file; *r*, triangular, three square, or saw file; *s*, cant file, for filing inside angles of 120°; *t*, when parallel, is a banking or watch pinion file, when taper, a knife edge file; *v* is a screw head, feather edge, or slitting file; *w*, a valve file; *x*, triangular and half round file; *y*, double or checkering file for gunsmiths; *z*, double or pencil sharpening file. As to teeth, the classes are: Double cut, having 2 sets of teeth crossing obliquely; single cut or float, having but 1 row of teeth; rasp, having detached teeth made by a punch instead of a chisel. At *A* is shown the position and action of the file chisel on the blank. *C* shows the appearance of the rows of teeth. The following table gives the approximate number of cuts in an in. of file:

Length in In.	4	6	8	12	16	20
Rough.....	56	52	44	40	28	21
Bastard.....	76	64	56	48	44	34
Smooth.....	112	83	72	72	64	56
Superfine.....	216	144	112	88	76	64

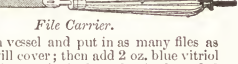


Filing Block.

The first of the annexed illustrations is a tool holder, and used to mount a file in a similar manner. The file block is of wood, gripped in a vise. It has grooves of varying depth, in which small rods, bars, or wires may be laid, to be filed conveniently.

FILE, Choosing.—To select a flat file, turn its edge upward, and look along, selecting those that have an even sweep from end to end, and having no hollows. To choose a ½ round file, turn the edge upward, look along it, and select that which has an even sweep, and no hollow places on the half round side

FILES, Resharpening. — The files must be cleansed in warm water containing potash, which readily removes all dirt; then washed with warm water and dried. Next place 1 pt. warm water



File Carrier.

in a wooden vessel and put in as many files as the water will cover; then add 2 oz. blue vitriol (sulphate of copper), finely pulverized, and 2 oz. borax, well mixed, taking care to turn the files over so that each may come in contact with the mixture. To the mixture add 7 oz. sulphuric acid and ½ oz. cider vinegar, which will cause the files to assume a red appearance at first, but they will in a short time resume their natural color. Then remove, wash in cold water, and dry. When dry, sponge with olive oil, wrap in porous paper, and lay aside for use.

FILING. — In draw filing, take short, quick strokes, which will prevent the file from pinning and scratching. To prevent files from pinning and scratching, properly clean them, and then chalk them well. Long strokes are useless save to make scratches. Remember that it is less the number of strokes you give the file than the weight you place upon it that is effective; therefore, when using a rough file, stand sufficiently away from the vise to bring the weight of the body upon the forward stroke. To file a surface true, on commencing squeeze the file tightly between the third and fourth fingers and palm of the hand until used to it. The position in filing should be half left face to work, with the middle of the right foot 15 in. behind the left heel; to file work true or square, reverse the work often so as to see the whole surface you are filing and whether you are filing true. When work is heavy file first to the right and then to the left, as by this means you can see the file marks, and this assists you in filing true. New files should be used at first upon broad surfaces, since narrow edges are apt to break the teeth. For brass work, use the file on a broad surface until its teeth are dulled, then make 2 or 3 strokes of the file under a heavy pressure upon the edge of a piece of sheet iron, which will break off the dulled edges of the teeth, and leave a new fibrous edge for the brass work. Use bastard cut files to take off a quantity of metal of ordinary hardness; second cut, in fitting, and also to file unusually hard metal; smoothing, to finish in final adjustment, or preparatory to applying emery cloth; dead smooth, to finish very fine work; float-file on lathe work.

FILING SQUARE HOLES. — To file a hole square, reverse the work often; a square file should first be used, and the holes finished with a diamond shaped file, or a half round.

GRAVERS, Grinding. — Gravers should be ground on the end only, and not on the sides of the square, except when applied to brass work.

GRAVERS, To Temper.—Gravers and other instruments larger than drills, may be tempered in quicksilver, or you may use lead instead of quicksilver. Cut down into the lead, say ½ in.; then, having heated your instrument to a light

cherry red, press it firmly into the cut. The lead will melt around it and an excellent temper will be imparted.

GRINDSTONE, Artificial. — Washed silicious sand, 3 or 4 parts; shellac, 1 part; melt together, and form the mass into the proper shape while warm, with strong pressure. The fineness of the sand must depend on the work the stone is intended for. The same composition is formed upon pieces of wood, as corn rubbers, and for the purpose of sharpening knives, and cutting stones, shells, etc.

GRINDSTONES. Care of,—These should never be left in the sunlight, or with one side standing in water, since heat evaporates the water in the stone, leaving it harsh and hard, while saturation softens it. The grindstone is a self sharpening tool; and after being turned in one direction for some time, if a hard stone, the motion should be reversed. Sand of the right grit applied occasionally to a hard stone will improve it.

GRINDSTONE-SPINDLES.—Common spindles are open to the objection that the stone will never keep round, because every person is inclined to follow the motion of his foot with his hand, which causes the pressure on the stone to be unequal. The harder pressure being applied to the same part of the stone, will soon make it uneven. To avoid this put in place of the crank a small cog-wheel to the spindle, say with 12 cogs; have another short spindle with a crank and a cog-wheel of 13 cogs, to work into the former. The stone will make about .07 of a revolution more than the crank, and the harder pressure of the tool on the stone will change to another place at every turn, and the stone keep perfectly round.

HARDENING.—Iron, 60 parts, chrome, 40 parts, form a composition as hard as the diamond. A high degree of hardness may also be imparted to iron or steel by adding ½ part of silver. Copper may be externally hardened by the fumes of zinc and tin. The specula of Lord Ross' telescope is 1 part tin and 1 part copper; this is hard as steel, and takes a high polish; if more than this be added it will scarcely cohere.

KEYS AND KEY-WAYS. — Keys should in all cases be made to fit the key-ways for which they are intended at a good easy fit on all sides, without being tight, the locking being performed by the taper of the top and bottom, the amount of which should be about ¼ in. per ft. of length. When it is not convenient to take locks apart in the event of keys being lost, stolen, or missing, and you wish to fit a new key, take a lighted match or candle and smoke the new key in the flame; introduce it carefully into the key-hole and then press it firmly against the opposing wards of the lock, withdraw it, and the indentations in the smoked part of the key will show you exactly at what place the key ought to be filed.

LATHE. — The lathe in its improved form as shown in the illustration, is simple in design, heavy and has back gears, screw cutting apparatus, compound rest, power cross feed, adjustable journal head boxes, etc. The cones are for belts as wide as 3½ in., and the screw is cut 4 threads to the in. The feed gearing is connected to rack on the bed and driven from a slot in the screw. Pulleys on counter shaft are 16 in. in diameter by 9 in. in face, and should make 85 revolutions per minute.

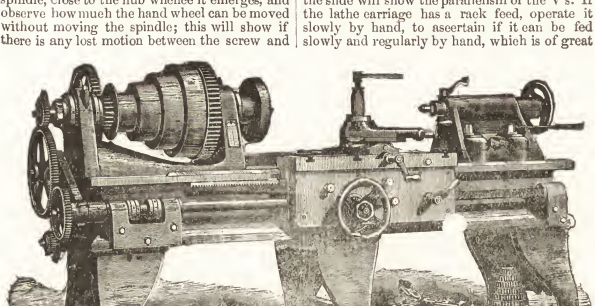
LATHES. Care of. — To utilize lathes, etc., for nice, fine work, and keep the ways, arbors, and centres in order, keep them clean by brushing away all the rubbish from the working parts; clean well by frequent rubbing with cotton waste, and keep them in easy working order by regular oiling.

LATHES. Deadening Noise of. —Two methods are here given: 1. Rubber cushions under the legs of the work bench. 2. Kegs of sand or sawdust applied in the same way. A few in. of sand or sawdust is first poured into each keg; on this is laid a board or block upon which the leg rests, and around the leg and block is poured fine dry sand or sawdust. All noise, vibration and shock are prevented; an ordinary anvil, so mounted, may be used in a dwelling house without annoying the inhabitants.

LATHES, Face Plates of. — To set work on the face plate of a lathe, let the work be set out and first lightly prick-punched; then clamp to place lightly as near as possible, but never set the "dead-centre" against the work, for that will not bring it true; now with a scratch awl or sharp pointed centre, with the point resting in the prick-mark, and the other end held against or on the dead centre, revolve the work. If the point marked is out of true, the scratch awl will vibrate. Put into the lathe rest a tool, without fastening it, and push it up to the scratch as the work is revolved, and the extent of the vibration can be seen. The work can be driven as thus indicated when there is no vibration of the scratch or centre, the work is perfectly set, and may be securely fastened.

LATHES, Testing. — To test if the cone spindle is parallel with the ways or shears, bore a long hole in cast iron, using a stout tool holder and a short, stiff tool, taking a fine cut, with a tool having its cutting edge slightly rounded, with a feed of 16 to an in., at a speed of 25 ft. per minute. Let the tool feed through the hole and back again, so that the tool does not spring from the work. Then, without moving the tool, wind the tool to the entrance of the hole, and let it stand there while the lathe runs 40 or 50 revolutions. Traverse the tool to the other end of the hole; let it stand while the lathe runs; then stop the lathe, and traverse the tool (without taking it from the cut) along the hole; if it marks a line stronger at one end of the hole than at the other, the tool has sprung, and another fine cut must be taken; but if not, and the hole is parallel, the spindle is true. To avoid wear, the tool is made hard. If the cut was started at the front, and the hole bored is smallest at the back, another cut should be taken, commencing at the back and feeding toward the front. If the hole is still smallest at the back, the lathe cone spindle is not parallel with the ways. To determine whether the cross slide is at a right angle with the ways or shears, take a fine cut over a radial face, and test the finished plate with a straight edge. If the plate runs true and shows true with a straight edge, grind a piece of steel a little rounding on its

end, and fasten it in the tool post or clamp, with the rounded end next to the face plate. Let the rounded end be about ¼ in. from the face plate; put the feed motion into gear, and with the steel near the periphery of the face plate, let the carriage feed up until the rounded steel end will grip a piece of thin paper against the face plate tight enough to cause a strain in pulling the paper out; wind the tool in toward the lathe centre, and try the friction of the paper there; if equal, the cross slide is true. In taking a cut down a radial face, to test the truth of the cross slide of the rest, start from the periphery, as by beginning the cut at the outer diameter, the strain will get less, while the tool edge becomes duller. To test the workmanship of the back head or tailstock, place the forefinger on the spindle, close to the hub whence it emerges, and observe how much the hand wheel can be moved without moving the spindle; this will show if there is any lost motion between the screw and the nut in the spindle. Next wind the back spindle as far as it will go, take hold of the dead centre and pull it back and forth; an imperfect fit between the spindle and the hole in which it slides will be shown by the lateral motion of the dead centre. Wind the dead centre in again, and tighten and loosen the spindle clamp, and see if doing so moves the spindle in the socket. Wind the dead centre out again, and slide the tailstock up the lathe bed until the dead centre nearly touches the live one, and after bolting the tailstock to the lathe bed, bring the centre points together, and see if they coincide. If the tailstock sets over, for turning tapers, the setting screws may be operated to adjust the centres. The lathe centres should be of equal height. It is as well to turn the back centre partly in its socket while making this test, so as not to be deceived by any want of truth in the back or dead centre.



Lathe.

To examine the slide rest, move the screw handles back and forth, to find how much they may be moved without giving motion to the slides; this will determine the amount of lost motion between the collars of the screws, and between the screws themselves and the nuts in which they operate. To try the fit of the movable slides in the stationary sliding ways, or V's, remove the screws, and move the slide so that only about ½ in. is in contact with the V's, then move the slide back and forth laterally, to see if there is any play. Move the slide to the other end of the V's, and make a similar test, adjusting the slide to take up any play at either end. Then clean the bearing surfaces, and move the slide back and forth on the V's, and the marks will show the fit, while the power required to move the slide will show the parallelism of the V's. If the lathe carriage has a rack feed, operate it slowly by hand, to ascertain if it can be fed slowly and regularly by hand, which is of great importance. Then put the automatic feed in gear, and operate the feed gear back and forth, to determine how much it can be moved without moving the slide rest. To test the fit of the feed screw to the feed nut, put the latter in gear, and operate the rack motion back and forth. It has been assumed, in this method of testing, that means of adjustment are provided, whereby any play in the cone spindle bearings may be taken up.

LATHES, Turning Shafting on. — See that the centres are true, adjust correctly if they are not, using a square end tool, keeping them true to a three-square gauge. Now set your puppet head so that it will turn the shaft true and straight, and if without a straight mark upon it, turn one end of the shaft for about 1 in.; next, without stirring your tools, take the shaft from the lathe, run the carriage down to the main head, and if

the tool comes in contact with the spot you have turned, the machine is straight; if not, screw over the puppet head, and keep adjusting it until the tool touches the place turned at both ends of the lathe.

LATHES, Turning Tapering on. — Calculate a certain amount of taper to the foot or the extension of the piece to be turned; for instance with a shaft 1 ft. long with a thickness of 1 in. at one end larger than the other, set the puppet head over $\frac{1}{2}$ in. and you will obtain the desired taper of 1 in. per ft. With a shaft 20 in. long you will obtain a taper of 2 in. over its whole length, by setting your lathe over 1 in. The following table shows the angle to set a compound rest to bore a given taper:

Taper in In. to 1 Ft. in Length.	Angle to Set Rest. Deg.	Min.	Taper in In. to 1 Ft. in Length.	Angle to Set Rest. Deg.	Min.
$\frac{1}{8}$	0	18	$2\frac{3}{4}$	6	32
$\frac{1}{4}$	0	36	3	7	8
$\frac{3}{8}$	0	54	$3\frac{1}{4}$	7	47
$\frac{1}{2}$	1	12	$3\frac{1}{2}$	8	18
$\frac{5}{8}$	1	30	$3\frac{3}{4}$	8	53
$\frac{3}{4}$	1	47	4	9	28
$\frac{7}{8}$	2	5	$4\frac{1}{4}$	10	2
1	2	23	$4\frac{1}{2}$	10	37
$1\frac{1}{4}$	2	59	$4\frac{3}{4}$	11	12
$1\frac{1}{2}$	3	35	5	1	46
$1\frac{3}{4}$	4	10	$5\frac{1}{4}$	12	20
2	4	46	$5\frac{1}{2}$	12	54
$2\frac{1}{4}$	5	21	$5\frac{3}{4}$	13	28
$2\frac{1}{2}$	5	57	6	14	2

LINERS, Thickness of. — To ascertain the proper thickness of a liner, necessary to go between a pair of brasses so that (when the faces do not meet), the liner may be placed between them and the brasses, when bolted up tight, without jamming the journal, place a piece of lead wire between the brasses, and then screw the cap down tight, and the lead wire will compress, denoting the necessary thickness of liner. The latter should be made a shade thicker than the distance the wire was compressed, so that the brasses may fit without binding the journal.

MOLD JOINTS, Asbestos for.—Asbestos can be employed for making the joints of molds for casting steel and other metals under pressure. The method is to use strips or rings of asbestos, millboard, or asbestos fibre made into a gaskin between the bottom of the ingot mold and the bottom upon which it stands, and the lid and the top of the mold, and if the mold is made into more than one piece, between the joints of the pieces.

NUTS, Tight, To Ease.—To ease a nut upon a bolt, place it upon the bolt, and resting it upon an iron anvil or block, strike the upper side with a hammer, turning the nut so that not more than two blows will fall upon the same face. The smaller the nut the lighter the blows, and *vice versa*.

NUTS, Tight, To Unscrew.—To start a nut that is corroded so that the wrench fails to move it, strike a few blows upon its end face; then holding a dull chisel across the chamfer of the nut, strike the chisel-head several sharp blows, which will, in a majority of cases, effect the object.

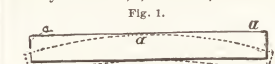
OIL STONES, To Face.—Take a piece of planed iron; scatter emery or fine sand on the iron plate; add a little water on the face of the stone, renewing the emery or sand and water as requisite, and finishing with water without sand. This makes the stone perfectly straight in 5 to 10 minutes.

PATTERNS.—These should never be left in the foundry. To get a pattern to fit closely over an irregular casting having angles or crooks (such as a casting with which to patch cylinders or junctions of pipes), take sheet lead, and hammer it lightly with a round pene hammer, closing it round the casting until it will, by stretching, conform to the shape of the surface. The molder can then cast a patch from the sheet lead, making it of any required thickness.

PENING, Setting Work by. — The operation termed "pening," is stretching the skin on one side of work to alter its shape, the principle of which is that, by striking the face of the metal with a hammer, the face of the metal struck stretches, and tends to force the work in a circular form, of which the part receiving the effect of the hammer, is the outside circle or diameter. *Fig. 1* represents a piece of flat iron, which would, if well hammered on the face, *a a a*, with the pene of a hammer, alter its form to that denoted by the dotted lines. Or, let the rod, *a*, be attached to a double eye at one end, the other end requiring to come fair with the double eye, *b*, at the other end; then, if it is pened perpendicularly on the face, *c*, of the rod, the stretched

Fig. 1.

Fig. 2.



Pening.

skin will throw the end around so that it will come fair with the eye, *b*. Connecting rod straps a little too wide for the rod ends, may be closed so as to fit by pening the outside of the crown end; or if too narrow, opened by pening the inside of the crown end; in either case the ends of the strap alter most in consequence of their lengths, and the strap will require refitting between its jaws.

PIPE, Connecting Lead and Iron. — A safe method of connecting lead and iron waste-pipes is with tinned brass ferrule, the taper end of which is slipped into the lead pipe and soldered fast; the other end, provided with a flange, drops into the soil-pipe branch and is secured in place by a well-caulked lead joint.

PITH FOR CLEANING. — The stalk of common mullen affords the best pith for cleaning pinions. Gather it when the stalk is dry. Some use cork, but it is inferior.

PLANING.—The first operation is to oil the planer and find out if the bed is smooth; if not, file off rough places; change the dogs to see if they work well, and find out the movements of

the planer; then bolt the work on the bed, and if it is a long, thin piece, plane off a chip; turn it over and finish the other side, taking 2 chips, the last of which should be light. Care should be taken in bolting it to the bed, not to spring it. After finishing this side turn it to the other side, and take off a light cut to finish it. In planing perpendicularly, swivel the bottom of the small head around, so that it will stand $\frac{3}{8}$ in. inside of square towards the piece to be planed; this prevents breaking the tool when the bed runs back.

POLISHING.—The polishing of metals differs according to kind, but there are general principles common to all. All polishing is begun by rubbing down the surface with some hard substance that will produce scratches in all directions, the level of which is the same, so as to obliterate the marks of the file, scraper or turning tool that has been used. For this, coarse emery, pumice stone and water, or sand and water, is applied upon a piece of felt or similar material. When the first marks have been removed, proceed to remove those left by the pumice stone, by finely powdered pumice stone ground with olive oil, or fine emery and oil. In some cases polishing stones are employed, as a kind of hard slate used with water. To proceed, still finer powders are used, as tripoli and rotten stone. Putty of tin and crocus martis are also used for high polishing. But the whole process consists in removing scratches by substituting those which are finer, until no longer visible to the eye; and even after that, if the surface is examined with a microscope, it will be seen covered over with an infinity of them. Care must be taken to have the last polishing material very fine, for a single grain of coarse substance will produce a scratched instead of a polished surface.

POLISHING MATERIALS.—*Rouge.* The rouge used by artisans is a mineral. In its preparation crystals of sulphate of iron, known as copperas, are heated in iron pots, by which the sulphuric acid is expelled and the oxide of iron remains. Those portions least calcined, when ground, are used for polishing gold and silver, and are of a crimson color. The darker and more calcined portions are known as crocus, and are used for brass and steel. For the finishing process of the specula of telescopes, crocus gives a splendid polish. Others prefer the peroxide of iron precipitated by ammonia from a dilute solution of sulphate of iron, washed, compressed until dry, then exposed to a low red heat and ground to powder. — *Crocus.* Put pure tin into a glass vessel and pour in sufficient nitric acid to cover it. Great heat is evolved, and care must be taken not to inhale the poisonous fumes. When there is nothing left but a white powder, heat in a Hessian crucible to drive off the nitric acid. Crocus, mixed with a little linseed oil, makes a hard and useful cement. — *Powders for Cleaning Plate.* 1. Take equal parts precipitated subcarbonate of iron, and prepared chalk. — 2. An impalpable rouge may be prepared by calcinating oxalate of iron. (See *Silver, Powders for Polishing* in HOUSEHOLD.) — *Jewelers' Rouge.* For fine work decompose a solution of sulphate of iron with oxalic acid in solution; a precipitate of oxalate of iron falls, which must be washed and dried; when gently heated, the salt takes fire, leaving an impalpable powder of oxide of iron. — *Putty Powder,* or *Oxide of Tin.* Metallic tin is dissolved in nitro-muriatic acid, and precipitated from the filtered solution by liquid ammonia, both fluids being largely diluted with water. The peroxide of tin is then washed in abundance of water. Collect in a cloth filter, and squeeze dry in a piece of new linen. The mass is now subjected to pressure in a screw press, or between 2 lever boards, to make it quite dry. When the lump thus produced has been broken, it is placed in a crucible, and closely covered up to prevent jets from entering, then exposed and heated to a white heat, and ground for use in the usual way. This is used for cements and polishing astronomical object glasses for astro-telescopes. The putty powder of commerce, if of good quality, is alloyed with equal parts of tin and lead, which answers for ordinary purposes, but not for polishing lenses, in which good work is dependent on the quality of the powder. — *Specula Powder.* Precipitate a dilute solution of sulphate of iron by ammonia in excess; wash the precipitate; press it in a screw press till nearly dry; then expose to heat until of a dull red color in the dark.

PROPERTIES. — The following table shows the ductility, malleability, heat conducting power and power of conducting electricity of metals, beginning with the highest:

Ductility.	Malleability.	Power of Conducting Heat.	Power of Conducting Electricity.
Gold.	Gold.	Silver.	Silver.
Silver.	Silver.	Copper.	Copper.
Platinum.	Copper.	Gold.	Gold.
Iron.	Tin.	Tin.	Zinc.
Nickel.	Platinum.	Iron.	Iron.
Copper.	Lead.	Lead.	Tin.
Zinc.	Zinc.	Bismuth.	Lead.
Tin.	Iron.		Antimony.
Lead.	Nickel.		Bismuth.

PUNCHING.—The same elements of resistance enter into the operation of punching as in that of shearing. A punch and die may be considered as shears with circular blades. The coefficient of pressure in punching, for any given area of section, will be exactly that for shearing the same area of section, without reference to thickness of material. The measure of force necessary to effect the various punchings, gives the value of the resistance to shearing in cases of ordinary metals. This resistance per sq. ft. is determined to be in lbs.: For lead, 392.548; block tin, 450,784; alloy of lead and tin, 731,176; zinc, 1,843,136; copper, 4,082,941; iron, 103,333.

REAMERS.—Fluted Reamers should be turned to a 32nd of an in. of the finished size, then heated and allowed to cool in a perpendicular position, previous to finishing. The treatment removes the strains and the occasional hardness made by the hammering, so that they will not spring in heating for tempering. The lips of a reamer should be uneven; otherwise, when it chatters, it leaps from one lip to the other. In reamers from 1 in. to $1\frac{1}{4}$ in. in diameter, the channels should be 9 in number, and 11 in

reamers of from $1\frac{1}{2}$ to $1\frac{7}{8}$ in. in diameter. Reamers from $\frac{1}{4}$ to $\frac{5}{8}$ in. in diameter, should have 5 flutes, and reamers from $\frac{5}{8}$ to 1 in. should have 7. After cooling, turn the part intended for the lips a 100th of an in. larger than the finished size; afterwards turn a spot in the middle of it $\frac{5}{8}$ long, and 1-12 the size of the reamer smaller than the reamer. After hardening, this is the place to pene straight. When the turning of all but the upper part is finished, put it on the centres, and prepare to flute it, deferring turning of the upper part until after the hardening and straightening. Place it on the centres; if on a planer, then flute with a round end tool, 1-10 in. thick, and plane down to the face of each lip, to the bottom of the spot intended for the pening, and

Fluted Reamer.

Sq. Thread Tap.

Single Lipped Drill.

Single Lipped Reamer.

Counter Boring Tool.

Reamers, Taps and Drills.

plane them so that the space between every other of the 2 lips will be shorter than the 2 just before them. The next step is to plane off the back side of the lips with a square end tool to within a 32nd of an in. from the face. The faces of the lips should be placed even with the centre, the lips dressed smooth with the file, hardened again, and then pened straight. Finish by turning the upper part to the desired size, and polish; grind the lips to a sharp edge and to the proper size. To flute taps, adjust the work on the centres, and plane the faces of all the teeth with a cutter or planing tool, made circular at the end, the thickness at the end being $\frac{1}{4}$ the diameter of the tap. Taps should be fluted with the teeth slightly hooking on the face. Dress the faces of all the teeth with the planer $\frac{1}{2}$ the depth of the thread deeper than the bottom of the thread; this done, plane off the back parts of the teeth, giving them $1\frac{1}{2}$ the breadth of their pitch, leaving them, if the pitch is 10, a 10th and a 20th. Trim the back parts of the teeth with a planing tool equal in thickness to the size of the tap. Two taps should be used for each thread; with the 1st, remove $\frac{3}{4}$ of the thread, and finish off with the other. No taper is required on taps for 5 threads; if they are fabricated by this plan they are not liable to break. Extra large mongrel-thread taps should be of 2 or more sizes, owing to the coarse thread and the mass of metal to be removed by them, which would be crushed and torn. Single lipped reamers should be made from a piece of steel, with head forged square to adapt it to a proper wrench; turn it tapering and exactly round, and, after placing it on the centres, plane a groove through its length, one side of which will form the lips of the reamer. From this

End View of Counter Boring Tool.

End View of Fluted Reamer.

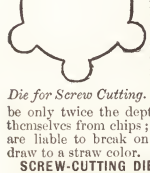
groove dress off the 64th of an in. half the distance round. Finish by filing up the face of the the lips on a line through the middle on the end; next harden and temper. Rose reamers should be made with square ends, with the corners removed, lips cut about 9 to the in. on the end, and a little hooking, with a temper like other reamers.

SANDIRONS, Finishing. — The buff wheels should be well balanced after covered. Let the wheel be covered with thick leather before covering with emery. Get a good surface on the article from a wheel covered with No. 70 emery. Mix flour of emery with melted beeswax, and stir in till it is thick. When the mass is cool, rub it on a newly covered wheel with No. 80 emery. Then set the wheel running, and hold on a flint to smooth it until the surface is sufficiently fine.

SCRAPERS. — All work should be fitted as true as possible before being scraped with the flat scraper, which is intended for flat surfaces only. For hollow work, curves, etc., the $\frac{1}{4}$ round scraper is the best, the 3 cornered being least efficient. Part of the blade of a broken saw makes a good scraper; but it is difficult to cut it into the required form. The best way is to mark it

out to the size wanted; then place the blade or steel plate in a vise whose chaps shut close, placing the mark even with the face of the vise, and the part to be cut off to waste, above the vise; then, with a cold chisel, holding it close to the vise, and rather inclined upwards, begin at one end of the steel plate, and with a sharp blow of the hammer it will cut it. Keep going on, and you will cut it to the shape required; grind the edges of the scraper level, and finish by rubbing it on Turkey stone.

SCREW-CUTTING DIES. — In making dies for screw cutting, they should be lapped with a taper tap, as they cut more easily and wear longer than when cut straight, and then tapered off to make the screw "take." Very fine threaded screws cut well with straight dies. Small dies should only have 3 lips in them. Dies from $\frac{1}{4}$ to $\frac{1}{2}$ in. should have 4 lips in them. Dies from $\frac{3}{4}$ to 1 in. should have 6 lips in them; and dies from 1 in. to $1\frac{1}{2}$ in. should have 7 lips in them. The cuts through dies should be only twice the depth of the thread to free themselves from chips; when cut too deep they are liable to break on the face. Harden and draw to a straw color.



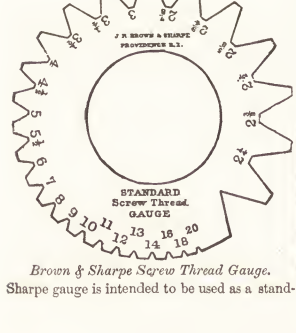
Die for Screw Cutting.

SCREW-CUTTING DIES, To Ease when Tight. —Supply them with fine emery and oil, and work them backward and forward in their place along the travel.

SCREW-CUTTING DIES, To Fit to Quadrants. —When the dies or quadrants are to be hardened, make them a shade too small to allow for swelling during the process of hardening.

SCREW-CUTTING DIES, To Renew Worn-out. — Slightly close the holes by swaging; fill the clearance-holes with Babbitt-metal, and recut them with the hub.

SCREW-CUTTING GAUGE. — The Brown & Sharpe gauge is intended to be used as a standard for grinding tools to cut threads according to the system recommended for adoption by the Franklin Institute of Philadelphia. The angles are 60°, and the flat surfaces at top and bottom of threads are equal to $\frac{1}{8}$ of the pitch.



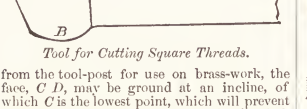
Brown & Sharpe Screw Thread Gauge.

SCREW-CUTTING. Gearing Lathe for. — Every screw-cutting lathe contains a long screw called the lead screw, which feeds the carriage of the lathe while cutting screws; upon the end of this screw is placed a gear to which is transmitted motion from another gear placed on the end of the spindle; these gears contain a different number of teeth for the purpose of cutting different threads, and the threads are cut a certain number to the in. from 1 to 50. To find the proper gears to cut a certain number of threads to the in., first multiply the number of threads to cut to the in., by any small number (4 for instance); this will give the proper gear to put on the lead screw; with the same number, 4, multiply the number of threads to the in. in the lead screw, and this will give the proper gear to put on the spindle. Always multiply the number of threads to be cut first. Most small lathes are made with a stud geared in the spindle, which runs $\frac{1}{2}$ as fast as the spindle, and in finding the gears for these lathes, first multiply the number of threads to be cut, and then multiply the number of threads on the lead screw, as double the number it is.

SCREW-CUTTING HAND-STOCK DIES. — Dies for use in hand-stocks are cut from hubs of a larger diameter than the size of bolt the dies are intended to cut; this being done to cause the dies to cut at the cutting edges of the teeth which are at or near the centre of each die, so that the threads on each side of each die act as guides to steady the dies and prevent them from wobbling; the result is that the angle of the thread in the dies is not the correct angle for the thread of the bolt, even when the dies are the closest together; and hence taking the finishing cuts on the thread, although the dies are nearer the correct angle when in that position than in any other. A little practice at cutting threads with stocks and dies demonstrates that the tops of the threads on a bolt cut by them are larger than was the diameter of the bolt before the thread was commenced to be cut, from the pressure placed on the sides of the thread of the bolt by the sides of the thread on the dies, in consequence of the difference in their angles; which pressure compresses the sides of the bolt thread and causes an increase in diameter. The variation of angle in adjustable dies prevents a square thread being cut by them, and they do not cut a good V-thread. In the case of a solid die, the teeth or threads are cut by a hub the correct size, and stand at the proper angle; each diameter in the depth of the teeth of the die cuts the corresponding diameter on the bolt, and there is no strain upon the sides of the thread save that due to the force necessary to cut the metal of the bolt thread.

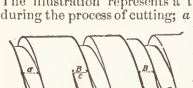
SCREW-CUTTING SQUARE THREADS. — For cutting square threads, the tool here represented is used. The point at *C* is made thicker than the width at *D* to give the sides clearance from the sides of the thread. At *B* it is made thin-

ner to give the tool clearance, and deeper to compensate for lack of substance in thickness. The top face may, for wrought-iron or steel, be ground hollow, *C* being the highest point, to make it cut cleaner; while, when held far out



Tool for Cutting Square Threads.

from the tool-post for use on brass-work, the face, *C D*, may be ground at an incline, of which *C* is the lowest point, which will prevent the tool springing into the work. If the pitch of the screw to be cut is coarse, a tool nearly $\frac{1}{2}$ width of space between one thread and the next should be employed, to avoid the spring which a tool of full width would undergo. After several cuts the tool must be moved laterally to the amount of its width, and cuts taken off as before until the tool has cut deeper than before being moved, when it must be placed back into its first position, and the process repeated until the required depth of thread is attained. The illustration represents a thread or screw during the process of cutting; *a a a* is the groove taken out by the cuts before the tool was moved; *B B* the first cut taken after it was moved; *c* the point to which the cut, *B*, is supposed to have traveled. The tool used having been a little less than $\frac{1}{2}$ the proper width of the space of the thread, the thread will be left with more than its proper thickness, which is done to allow finishing cuts to be taken upon its sides, for which purpose the knife tool is used, and placed true, so as to cut both sides of the thread of an equal angle to centre line of screw. Adjustable dies, which take more than one cut to make a full thread, should never be used in cases where a solid die will answer, because adjustable dies take every cut at a different angle to the centre line of bolt.



Screw During Cutting.

SCREW THREADS.—Screw threads are employed for 2 principal purposes, for securing and for transmitting motion. There are in use in machine shop practice 4 forms of screw threads: 1. The sharp V-thread shown in *Fig. 1*, in common use in the United States. 2. The U. S. standard thread, the Sellers' thread, or the Franklin Institute thread, as it is sometimes called, all 3 designations signifying the same form of thread. This thread was originally proposed by Wm. Sellers, and afterward recommended by the Franklin Institute. It was finally adopted as a standard by the U. S. Navy Department. This form is shown in *Fig. 2*. 3. The Whitworth or English standard thread shown in *Fig. 3*, sometimes termed the round top and bottom thread. To a small extent it is used in the U. S. 4. The square thread shown in *Fig. 4*, used in all countries for coarse pitches and for transmission of motion.

Fig. 1. Fig. 2.

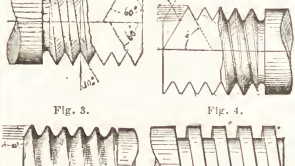


Fig. 3. Fig. 4.

Screw Threads.

The sharp V-thread, *Fig. 1*, has its sides at an angle of 60° one to the other, or each side of the thread is at an angle of 60° to the axial line of the bolt. The U. S. Standard, *Fig. 2*, is formed by dividing the depth of the sharp V-thread into 8 equal divisions and taking off one of the divisions at the top and filling in another at the bottom, so as to leave a flat place at the top and bottom. The Whitworth thread, *Fig. 3*, has its sides at an angle of 55° to each other, or to the axial line of the bolt. In this the depth of the thread is divided into 6 equal parts, and the sides of the thread joined by arcs of circles that cut off one of these parts at the top and another at the bottom of the thread. The centres from which these arcs are struck, are located on the second lines of division, as denoted by the dots. Screw threads are designated by their pitch or the distance between the threads. Mougrel, or $\frac{1}{4}$ V, $\frac{1}{8}$ square threads, are made for great wear, and should be cut the depth of their pitch, and for extraordinary wear may be cut $1\frac{1}{2}$ the depth of the pitch. The point and the bottom of the grooves should be in width $\frac{1}{4}$ the depth of their pitch. What is meant here by the point of the thread, is the outside surface; the bottom of the groove is the groove between the threads. In cutting these threads use a tool about the shape of the thread, and in thickness about 1-5 less than the thread is when finished. As it is impossible to cut the whole surface at once, cut it in depth about 1-16 at a time; then chip off the sides of the thread, and continue in this way alternately until at the depth required. Make a gauge of the size required between the threads, and finish by scraping with water. It is best to leave such screws as these a little large until after they are cut, then turn off a light chip to size them; this leaves them true and nice.

SOLDERING. — Soldering, or uniting the surfaces of metals by means of a more fusible metal or alloy, is one of the indispensable arts, and one which, once thoroughly understood, is invaluable to every mechanician, whatever his branch of mechanics may be. It is the purpose of this article to describe such of the processes for sol-

dering as may be of the most general application. A few solders, the metal to which they

Fig. 1.

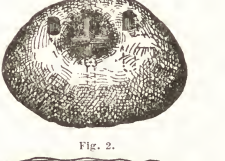

Fig. 2.

Soldering.

are applied, and their appropriate fluxes are tabulated below.

NAME.	COMPOSITION.
Soft, coarse	Tin, 1; Lead, 2.
" fine	" 2 " 1.
" fusible	" 2 " 1; Bis. 1.
Pewterer's	" 3 " 4; " 2.
Spelter, soft	Copper, 1; Zinc, 1.
" hard	" 2; " 1.
Silver, fine	Silver, 66.6; Copper, 23.4; Zinc, 10
" common	Silver, 66.6; Copper, 30; Zinc, 3.4
" for Brass and Iron	Silver 1; Brass 1.
" more fusible	" 1; " 1; Zinc, 1.
Gold; for 18 Carat Gold	Gold, 18 Carats fine, 66.6. Silver, 16.7; Copper, 16.7.
" more fusible	Same as above with a trace of Zinc.
Platinum	Fine Gold.

MATERIAL TO BE SOLDERED.	SOLDER.	FLUX.
Tin	Soft, coarse or Fine.	Rosin or Zinc, Chl.
Lead	Soft, coarse.	Rosin.
Brass, Copper, Iron and Zinc	Soft, coarse.	Zinc, Chl.
Pewter	Pewterer's or fusible.	Rosin or Zinc, Chl.
Brass	Spelter, soft	Borax.
Copper and Iron	" " or hard.	" "
Brass, Copper, Iron, Steel	Any Silver S.	"
Gold	Gold, S.	"
Platinum	Fine Gold	"

The chloride of zinc solution is prepared by cutting zinc in muriatic acid to repletion, and diluting with an equal quantity of water. For iron, a small quantity of sal ammoniac may be added. For large work, where spelter is used, it is powdered and mixed with pulverized borax, the mixture made into a paste with water and applied with a brush. Soft solders are fused with a copper, or blowpipe after the application of the flux. While the work is hot and the solder fluid, surplus may be removed with a moist brush. A mat joint may be made between closely-fitting surfaces by placing a piece of tin foil between the parts, and fusing in a blowpipe flame. For small work spelter and silver solders are fused by means of the blowpipe; the work being laid upon a charcoal or piece of pumice stone. It is often desirable to flank the work with an additional piece of charcoal, to economize the flame, as well as that resulting from coal. If the work is inconvenient to clasp or rivet together, or to wire it, it may be kept in place upon the coal by tacks forced in at points where they will be effectual. When tacks are unavailable, parts may be held by wire loops and stays. (See *Fig. 1.*) If part of the work has been already done, and it is desired to unite pieces having parts previously soldered, in close proximity, these may be held in any position, and the joints already soldered prevented from melting by encasing the work in the following manner (see *Fig. 2*): Take equal parts plaster Paris and fine, sharp sand; add sufficient water to make a batter, and imbed the work in it, leaving the entire joint to be soldered and the adjacent parts exposed. Do not get the plaster into the joint, as it will prevent the solder flowing. It is difficult to hold the various parts to be united so as to apply the plaster; these may be put into position and fastened temporarily by means of a drop of wax, which, when the work is encased and the plaster sets, may be melted out and the flux and solder applied. In every case the flux should be brushed into the joints before placing the work on its support. A convenient way of preparing flux for small work is to rub a piece of borax with a few drops of water on a slab until it appears like paste; this should be applied to the work with a camel's hair pencil. Small pieces of solder are dipped into the borax paste and put on the joints of the work. A pair of tweezers will be convenient for this. When the job is encased, as in *Fig. 2*, it may be placed in a common fire until it has nearly attained a red heat, when, on applying the blowpipe, the solder will flow with little expenditure of time and breath. Work too large to be readily soldered by the means noticed, may be done in a charcoal fire with a blast; even a common fire may be made to answer the purpose. Brazing or hard soldering must not be tried in a fire, or with coals or tools which have the least trace of soft solder or lead about them; neither must the brazing of work previously soft soldered be attempted. A neglect of these cautions insures failure. A wash of clay applied to surfaces not to be joined, prevents the flow of solder. The vitrified flux may be removed by boiling the articles a few moments in dilute sulphuric acid; this is best done in a copper vessel.

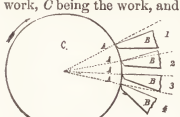
SOLDERING WITHOUT HEAT. — Brass filings, 2 oz.; steel filings, 2 oz; fluoric acid, ½ oz; put the filings in the acid, and apply the solution to the parts to be soldered, after cleaning the parts in contact; then dress together. Keep the fluoric acid in lead or earthen vessels.

SOLDER, To Remove Zinc and Iron from. — Digest the metal in grains in diluted sulphuric acid. The acid will dissolve the zinc first, the

iron next, and all traces of these metals by subsequent washing.

SURFACES, To Protect from Moisture. — Inclose them in tight compartments containing lumps of quicklime.

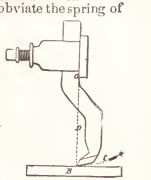
TOOLS, Cutting versus Scraping. —A tool will either cut or scrape, according to the position in which it is held, as, for instance, below the line *A* in the illustration. Line *A* is in each case one drawn from the centre of the work to the point of contact between the tool edge and the work, *C* being the work, and *B* the tool. The angle of the top face of the tool varies in each case with the line *A*. In position *1*, the tool is a cutting one; in *2*, it is a scraper; in *3*, it is a tool which is a cutter and scraper combined, since it will perform both functions at



Cutting and Scraping.

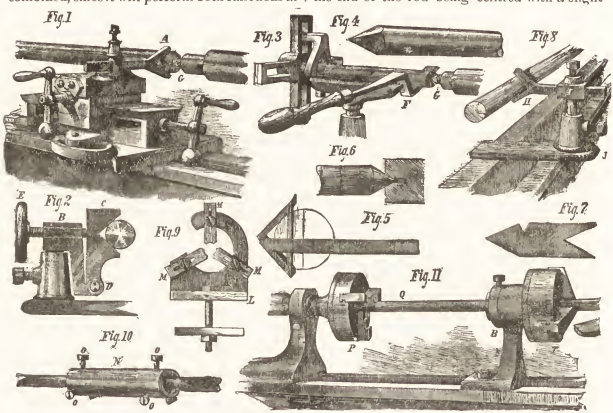
off clean, if desired, as from a knife blade; or it may be thinned with coal oil or benzine.

TOOLS, Spring of. — To obviate the spring of tools which must, of necessity, be held out a long way from the tool post, the fulcrum off which the tool springs must be adjusted so as not to stand in advance of the tool's cutting edge.



Spring Tool.
a, fulcrum; *B*, work to be cut; *C*, line in which the point of the tool would spring; *D*, line perpendicular to the line of the back

TOOLS, Steadying and Centreing.—The method of centreing in *Fig. 1* is most common where the lathe is fitted with an engine rest. A forked tool, *A*, is clamped in the tool-post so that a line drawn from the point of the tail centre will bisect the angle of the fork. A square-pointed centre, *G*, part of the tool, is inserted in the tail spindle and moved against the end of the rod being centred with a slight



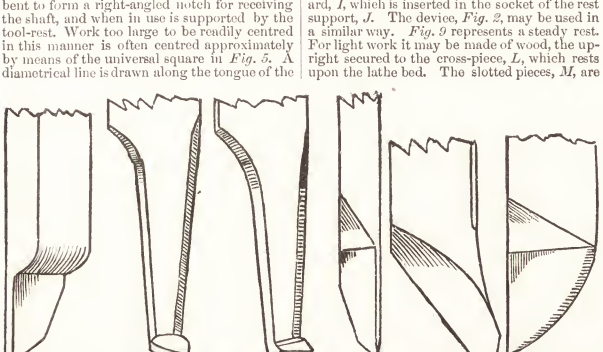
Steadying and Centreing Tools.

one and the same time; and in *4* it is a good cutting tool, the shapes and angles of the tools being the same in each case.

TOOLS, Keeping. — When tools are clean and bright, they may be kept so by wiping, before putting them away, with a cloth dipped in melted paraffine. The following is a simple preparation to prevent tools from rusting: Slowly melt together 6 or 8 parts lard to 1 of rosin, stirring till cool. This remains semi-fluid, always ready for use, the resin preventing rancidity and supplying an air-tight film. Rubbed on a bright surface thinly it protects and preserves the polish effectually, and it can be wiped

pressure, the tool, *A*, at the same time moved forward by the screw of the engine rest until the rod turns smoothly in the fork and the square-pointed centre has found the centre of the rod; the tail spindle is then moved forward until the cavity is sufficiently deep to permit of starting the centre drill. The angle of square centre, *G*, for hard material, should be a little more obtuse than in *Fig. 4*. In any case it should be of good material and well tempered. In *Fig. 2* a centreing tool takes the place of the engine rest and fork in *Fig. 1*. The part *B* is fitted in the place of the ordinary tool-rest, and the jaw, *C*, which has in it a V-shaped notch, is hinged to

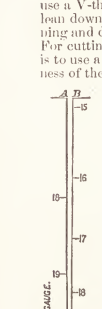
the part *B* at *D*. A screw, *E*, passes through the upper end of the part *B* and bears against the jaw *C*. After what has been said in connection with the engine rest, the manner of using this contrivance will be understood. In *Fig. 3* the hand tool, *F*, is employed for steadying the shaft and bringing it to a centre. This tool is bent to form a right-angled notch for receiving the shaft, and when in use is supported by the tool-rest. Work too large to be readily centred in this manner is often centred approximately by means of the universal square in *Fig. 5*. A diametrical line is drawn along the tongue of the uniformity in everything, the centre gauge, *Fig. 7*, should be used for getting the required angle on the lathe centres and on the drills used in centreing. The matter of steadying long, slender rods being turned in the lathe is often perplexing; it may be done tolerably well as in *Fig. 8*. The fork, *H*, is supported by the standard, *I*, which is inserted in the socket of the rest support, *J*. The device, *Fig. 2*, may be used in a similar way. *Fig. 9* represents a steady rest. For light work it may be made of wood, the upright secured to the cross-piece, *L*, which rests upon the lathe bed. The slotted pieces, *M*, are



Turning Tools.

square, the work is then turned through of a $\frac{1}{4}$ revolution, and another line drawn. The intersection of these lines will be the centre approximately. This point may now be marked with a centre punch, and the work may be tested in a lathe. If found to revolve truly on the centres it may be drilled, otherwise the centre must be corrected with the centre punch and the work tested in the lathe. After centreing by any of these methods, the centre must be drilled and countersunk with a suitable tool so that it will fit the lathe centre as in *Fig. 6*. The angle of the lathe centres should be 60°. To insure adjustable lengthwise to accommodate size and position of shaft. When required to support a bar not round, the sleeve, *N*, *Fig. 10*, is used. It slips over the shaft and revolves in the steady rest. The bar is centred by the screws *O*. The device, *Fig. 11*, is used where a hollow mandrel lathe is not at hand. A piece of gas-pipe, *Q*, is held by the chuck, *P*, and secured by a set screw in the sleeve, *B*, which is journaled in the standard, *S*, and carries the chuck, *T*. This arrangement may be employed by turning the ends of long rods where not desirable to put them ularly on the centres of the lathe.

TOOLS, Turning.—For turning balance wheels, or squaring up large surfaces, use a round end tool constructed well tapering to cut from the side. The best tool for turning small shafting is a diamond point tool; for heavy shafting use a round end tool, shaped to stand high like a diamond point and to cut full and free from the side. For cutting off a shaft, use a tool shaped thin and having the tapering down the reverse of turning tools. For cutting a V-thread screw use a V-thread tool, with the points ground to lean down when finished, so as to prevent running and destroying both the tool and the work. For cutting a square thread screw, the best way is to use a square point tool about $\frac{3}{4}$ the thickness of the thread you intend to cut, and finish with another the exact size of the thread. In cutting a thread within a hole apply the same method. For boring out a hole use a lathe boring tool with the end turned on a right angle to the left, and the point turned up hooking. The side for wrought iron, should, for light work, be hardened right out; temper to a straw color for heavy work. For heavy work on a slotting machine, temper to a brownish purple, and grind so that the cutting edge first strikes the cut near the body of the tool, and not at the point ends; use at a speed of about 10 ft. per minute. (See *Side Tools* in Iron.) Milling tools or cutters ought to be chucked to fit loosely on the arbor, so that they may not prove to be too small for after hardening. Now turn them to within a 32nd of an in. of the required thickness, and again heat previous to finishing. (See illustrations on page before this.)



Wire Gauges.

WIRE GAUGES. — The want of uniformity in common wire gauges is well known; but if they all agreed with published tables of sizes, there would still exist objections to their use, as the variations between different numbers are irregular. This will be seen by reference to the diagram. The 2 lines *A C* and *B C* meeting at *C*, represent the opening of an angular gauge. The divisions on the line *A C* show the size of wire by the Birmingham gauge, those on the line *B C* by the new standard American gauge. Wire to be measured by such a gauge, is passed into the angular opening till it touches on both sides, the division at the point of contact indicating the number. Thus, No. 26, old gauge, would be No. 25 by the new. The angular principle is used in the cut. It is proposed to make gauges to correspond with the new standard. The divisions on the line *A C* are irregular, while those on *B C* increase by a regular geometrical progression. This principle is thought to be the true one for the construction of a gauge. The annexed table gives the dimensions of each size of several of the gauges in ordinary use, and show the necessity of the adoption of a common standard by which the confusion now exis-ting may be avoided.

DIMENSIONS OF SIZES IN DECIMAL PARTS OF AN INCH.

WHETSTONES. — For oil on whetstones, a mixture of glycerine and alcohol may be used. The proportions vary according to the instrument operated on. An article with a large surface sharpens best with a limpid liquid, as 3 parts of glycerine to 1 part of alcohol. For a graving tool, it is necessary to employ glycerine pure, with but 2 or 3 drops of alcohol.

ALLOYS.

REMARKS. — Alloys of metals differing in fusibility, are made by adding the more fusible, either in a melted state or in small portions at a time, to the other melted or heated to the lowest temperature at which union will take place between them. The mixture is usually effected under a flux, or some material that will promote liquefaction, and prevent unnecessary

exposure to the air. Thus, in melting lead and tin together for solder, resin or tallow is thrown upon the surface; in tinning copper the surface is rubbed with sal ammoniac; and in combining some metals, powdered charcoal is used. Quicksilver combines with many metals in the cold, forming amalgams.

AMALGAM. — Mercury unites with many of the metals by contact, and with some, as gold, silver, tin and lead, in certain proportions without losing fluidity. In a few cases, as with potassium, this union is attended with violence and the production of light and heat. Most of these compounds may be formed by agitating or rubbing the mercury with the other metal in the state of filings or small fragments, either with or without heat; or with the easily fusible metals, by adding it to them in the melted state, care being taken in both cases that the heat be not sufficient to volatilize the mercury. Some amalgams are solid and crystalline; others are fluid. Of the latter, several crystallize after a time, being probably merely solutions of the solid amalgams in excess of mercury. The amalgams of gold, silver, tin, zinc, etc., are employed in gilding, silvering, dentistry, etc.

AMALGAMATING SALT.—This is a mercury salt with 3 acids, and is composed of the sulphate, nitrate and bichloride of this metal. It is liquid, colored, dense, and gives in water a yellow precipitate which is dissolved by an excess of acid. It produces a violet stain on the skin, and amalgamates copper and its alloys rapidly. It is used for amalgamating the zincs of batteries and dispenses with metallic mercury; it is easily applied, and prevents much trouble in gilding works. It is prepared by boiling the nitrate of binoxide of mercury upon an excess of a powder composed of equal parts of bisulphate and bichloride of mercury; the liquor only, remaining after cooling, is used.

AMALGAM, Electrical. — Used to cover cushions of electrical machines. A little of the powder is poured on paper, crushed smooth with a flat knife, and spread thinly on the surface of the cushion, previously slightly smeared with tallow; or, the powder may be rubbed down with a little tallow, prior to the application of it. — 1. Take zinc and grain tin, each, 1 oz.; melt in an iron ladle; remove it from the fire, and add of mercury, hot, 3 oz.; stir the whole together with an iron rod; pour it into a well-chalked box, and agitate it violently until cold; or, instead of this, it may be stirred until cold, and then powdered. Preserve in a corked glass bottle. — 2. Zinc, 2 oz.; grain tin, 1 oz.; beeswax, ½ oz.; melt; add of mercury, 6 oz.; proceed as before. — 3. Zinc, 2 oz.; mercury, 5 oz.

AMALGAM, Gilding. — Grain gold, 1 part; mercury, 8 parts; put them into a ladle, and apply a gentle heat, using a smooth piece of iron as a stirrer; when solution is complete pour it out on a smooth slab. Used to gild brass, copper, etc., in the common process of wash or fire gilding. A less proportion of gold is used when a cheap gilding is required; as by increasing the quantity of the mercury the same weight of the metal may be extended over a larger surface.

AMALGAM, Silvering Globes. —Pure lead and grain tin, each, 1 oz.; melt in a clean ladle and add 1 oz. bismuth; skim off the dross, remove the ladle from the fire, and before the metal sets add 1 oz. quicksilver; stir well, avoiding the fumes.

ANTI-FRICTION METALS.—1. (*Babbitt's well-known Anti-Attrition Metal.*) Copper, 4 lbs.; regulus of antimony, 8 lbs.; Banca tin, 96 lbs.— 2. Grain zinc, 7½ lbs.; purified zinc, 7½ lbs.; antimony, 1 lb. —3. Zinc, 17 parts; copper, 1 part; antimony, 1½ parts. This possesses unsurpassable anti-friction qualities, and does not require the protection of outer casings of harder metal. —4. Block tin, 8 lbs.; antimony, 2 lbs.; copper, 1 lb. If the metal be too hard, soften by adding lead. — 5. Melt in a crucible 1½ lbs. copper, and, while the copper is melting, melt in a ladle 25 lbs. tin and 3 of antimony, nearly red hot; pour the 2 together, and stir until nearly cool. This makes the finest kind of lining metal.—6. Lead, 100 lbs.; antimony, 15 lbs.—7. (*For Bearings to Sustain Great Weights.*) Copper, 1 lb.; zinc, ½ oz.; tin, 2½ oz. — 8. (*Hard Bearings for Machinery.*) Copper, 1 lb., tin. 2 oz. — 9. (*Lining Metal for Boxes of Railway Cars.*) Mix tin, 24 lbs.; copper, 4 lbs.; antimony, 8 lbs.; then add tin, 72 lbs. — 10. (*Lining Metal for Locomotive Axle Trees.*) Copper, 86.03; tin, 13.97.

ANTI-FRICTION METAL, Lining Boxes with.— The article to be lined, having been cast with a recess for the lining, is to be nicely fitted to a former, which is made of the same shape as the bearing. Drill a hole for the reception of the metal ½ to ¾ in. Coat over the part not to be tinned with a clay wash, wet the part to be tinned with alcohol, and sprinkle on it powdered sal ammoniac; heat it till a fume arises from the sal ammoniac, and then immerse in melted Banca tin, taking care not to heat it so that it will oxidize. After the article is tinned, should it have a dark color, sprinkle sal ammoniac on it, which will make it a bright silver color. Cool gradually in water; then take the former, to which the article has been fitted, and coat it with a thin clay wash and warm it till dry; heat the article until the tin begins to melt, lay it on the former and pour in the metal, which should not be so hot as to oxidize, through the drilled hole, giving it a head, so that as it shrinks it will fill up. After it has sufficiently cooled remove the former. A shorter method may be adopted when the work is light enough to handle quickly; namely, when the article is prepared for tinning, immerse in the lining metal instead of the tin, brush lightly in order to remove the sal ammoniac from the surface, place immediately on the former and line at the same heating.

BELL METAL. — Castings in bell metal are more or less brittle; and, when recent, are of a dark ash gray to grayish white, which is darkest in the more cupreous varieties, in which it turns somewhat on the yellowish red or bluish red. The larger the proportion of copper the deeper the tone. The addition of tin, iron, or zinc, causes them to give out their tones sharper. Bismuth and lead are added to modify the tone, which each metal affects differently. The addition of antimony and bismuth is frequently made to

give a crystalline grain to the alloy. All these additions are prejudicial to the sonorousness of bells, and of doubtful utility. Rapid refrigeration increases the sonorousness of all these alloys. Where the quality of tone is the chief object care should be taken to use commercially pure copper. The presence of a lead or any similar metal lessens sonorousness, while that of silver increases it. The specific gravity of a large bell is seldom uniform; nor can the sp. gr. from any given proportion of its constituent metals be exactly calculated, owing to many interfering circumstances. The nearer this uniformity is approached, or chemical combination is complete, the more durable and finer toned will be the bell. In general it is necessary to take about 1-10th more metal than the weight of the intended bell in order to allow for waste and scorification during the operations of fusing and casting. A cracked bell which gives a jarring sound may be improved by sawing or filing the ruptured edges so that they are not brought together by the vibration of the blow. The following are some of the formulæ used for bell metal: 1. Copper, 72 parts; tin, 26½ parts; iron, 1½ parts. Used for bells of small clocks or pendules. — 2. Copper, 72 parts; tin, 26 parts; zinc 2 parts. Used for small bells. — 3. Copper, 70 parts; tin, 26 parts; zinc, 2 parts. Used for bells of repeating watches. — 4. Melt together copper, 100 parts; tin, 25 parts. After being cast into the required object, it should be made red hot, and then plunged into cold water to impart the requisite degree of sonorousness. For cymbals and gongs. — 5. Melt together copper, 80 parts; tin, 20 parts. When cold it has to be hammered out with frequent annealing. — 6. Copper, 78 parts; tin, 22 parts. This is superior to the former, as it can be rolled out. For tom-toms and gongs. —7. Melt together copper, 72 parts; tin, 26 to 56 parts; iron, 1.44 part. Used in making the bells of pendules or ornamental clocks.

BRITANNIA METAL, or PEWTER. — 1. Plate brass, bismuth, antimony, and tin, equal parts, melted together, and the resulting alloy added at discretion to melted tin, until it acquires the proper color and hardness. — 2. To the alloy, prepared as in 1, add 1-5 of its weight of metallic arsenic, before mixing it with the melted tin. — 3. Antimony, 1 part; brass, 4 parts; tin, 5 or 6 parts; melted together.—4. Tin, 150 parts, copper, 3 parts; antimony, 10 parts. — 5. Tin, 46½ parts; copper, 1 part; antimony, 3 parts.— 6. (*For Casting.*) Tin, 100 parts; hardening (tin, 105 parts; copper, 2 parts; antimony, 12 parts), 5 parts; antimony, 5 parts. —7. (*For Handles.*) Tin, 140 parts; copper, 2 parts; antimony, 5 parts. — 8. (*For Lamps, Pillars and Spouts.*) Tin, 75 parts; copper, 1 part; antimony, 3¾ parts. — 9. (*For Registers.*) Tin, 25 parts; antimony, 2 parts; hardening, 2 parts. — 10. (*For Spinning.*) Tin, 25 parts; antimony, 1 part; hardening, 1 part. — 11. (*For Spoons.*) Tin, 20 parts; antimony, 2 parts; hardening, 1 part.—12. (*For Spouts.*) Tin, 46½ parts; copper, 1 part; antimony, 2 parts.

BRITANNIA METAL, Hardening for. — Tin, 1 part; copper, 2 parts.

BRONZE. — On the small scale this alloy is prepared in crucibles; but for statues and large works on reverberatory hearths. The fusion of the mixed metals is conducted rapidly under pounded charcoal, and the melted mass frequently stirred to produce a perfect mixture before casting.

BRONZE, Aluminium.—1. 100 parts copper and 10 aluminium, measured by weighing, when combined, is a durable alloy, which may be forged and worked in the same manner as copper, and is the same color as pale gold. — 2. 80 parts copper, 19 zinc, and 1 aluminium, form a good durable alloy.

BRONZE, Antique. — Copper, 100 parts; Tin, 7 parts; Lead, 7 parts.

BRONZE, Blue. — The blue bronzes are produced in the wet way by coloring white bronze with aniline blue. A white bronze made of pure English tin is boiled for 5 hours in a solution of 20 grammes alum in 4½ litres water; then washed clean and put into a porcelain dish, and covered with a solution of 15 grammes aniline blue in 1½ litres alcohol, and stirred until dry; this manipulation repeated 6 or 8 times until the desired blue is obtained. When the bronze is dark enough it is washed in warm water, and before it is quite dry a large spoonful of petroleum is poured upon each kilo of bronze, mixed, and the odor allowed to escape into the air for a few days.

BRONZE, Brownish Gold. —This is made from fine clean iron filings by moistening repeatedly with a little water and exposing them to the air, then boiling several times and drying. It forms a deep rust-brown powder, which becomes intensely red if nitric acid is added in the last boiling. It is elutriated to separate any metallic particles, and dried. By mixing this with imitation gold bronze, mosaic gold, copper bronze, and greenish bronze, separately or together, the most varied and different shades can be obtained.

BRONZE, For Door Knobs. — The alloy used in bronze busts, door knobs and similar articles, is made of copper, 89 parts; tin, 8 parts; zinc, 3 parts.

BRONZE, For Edge-Tools.—Copper, 100 parts; tin, 14 parts. When skilfully hardened and tempered this alloy is capable of receiving an edge nearly equal to that of steel.

BRONZE, For Small Castings. — Copper, 95 parts; tin, 4 parts; melt together.

BRONZE, Gilding.—1. Copper, 82 parts; zinc, 18 parts; tin, 3 parts; lead, 2 parts. — 2. Copper, 83 parts; zinc, 17 parts; tin, 2 parts; lead, 1 part.

BRONZE, Imitation Silver. — Bismuth and tin, of each 2 lbs.; melt together and add 1 lb. of quicksilver; pound all into a powder. This is used as an imitation of silver bronze for plaster figures and other common purposes, in the same way as the *aurum musivum* is for gold colored articles. It may be used as spangles in sealing-wax; it must then be mixed when the resinous part of the wax is getting cold.

BRONZE, Platinum. — Nickel, 100 parts, tin 10 parts, platinum 1 part. It is unoxidizable, and especially adapted for cooking utensils.

BRONZE, Red. — Made by using the follow-

ing: 86 parts copper; 11 parts zinc; 3 parts tin.

BRONZE, Statuary. — 1. Copper, 88 parts; tin, 9 parts; zinc, 2 parts; lead, 1 part.—2. Copper, 82½ parts; zinc, 10½ parts; tin, 5 parts; lead, 2 parts. — 3. Copper, 90 parts; tin, 9 parts; lead, 1 part. — 4. Copper, 91 parts; tin, 9 parts.

BRONZING BRASS BLACK. — 1. Dip the article bright in aquafortis; rinse the acid off with clean water, and place it in the following mixture until it turns black: Hydrochloric acid, 12 lbs.; sulphate of iron, 1 lb.; and pure white arsenic, 1 lb.; then take out, rinse in clean water, dry in sawdust, polish with black lead, and then lacquer with green lacquer.

BRONZING COPPER. — Dissolve in vinegar 2 parts verdigris and 1 part sal ammoniac; boil, skim, and dilute with water, until white precipitate ceases to fall; set in a pan the articles to be bronzed, made clean and free from grease; boil the solution briskly and pour over the articles in the pan and boil them briskly. A bright reddish brown color is acquired; but the articles should be frequently inspected, and removed as quickly as the desired shade is obtained; then repeatedly washed and dried. The solution must not be too strong, for then the bronze will come off by friction, or turn green on exposure to air.

BRONZING COPPER ANTIQUE. — Dissolve in 20 parts by weight of strong vinegar 3 parts carbonate or hydrochlorate of ammonia, and 1, each, common salt, cream of tartar, and acetate of copper, and add some water. When an intimate mixture has been obtained, smear the copper object with it, and let it dry at the ordinary temperature for nearly 48 hours. After that time the object is covered with verdigris of various tinges. Then brush the whole, especially the reliefs, with the waxed brush. If necessary, the raised parts are set off with chrome yellow, or other suitable colors. Light touches with ammonia give a blue shade to the green portions, and carbonate of ammonia deepens the color of the parts on which it is laid.

BRONZING ELECTROTYPES GREEN. — Steep the figure in a strong solution of salt or sugar or sal ammoniac, a few days; wash in water and allow to dry slowly; or suspend over a vessel containing a small quantity of bleaching powder, and cover over; the length of time it is allowed to remain will determine the depth of the color.

BRONZING GAS FIXTURES.—1. Boil the work in strong lye, and scour it from all grease or old lacquer; pickle it in diluted nitric acid till clean (not bright); then dip in strong acid, and rinse through 4 or 5 waters; repeat the dip, till it is bright; next bind it very loose with some thin iron wire, and lay it in the strongest of the waters you have used for rinsing. This will deposit a coat of copper over it if the water or pickle be not too strong; if such is the case the copper will only be deposited round where the wire touches. When the copper is of sufficient thickness wash it again through the waters, and dry it with a brush in some hot sawdust; boxdust is best, but if not at hand, oak, ash, or beech will do. It is now ready for bronzing. The bronze is a mixture of black lead and red bronze, varied according to shade required, mixed with boiling water. The work is to be painted over with this and dried, then brushed until it polishes. If there are black spots or rings on the work, another coat of the bronze will remove them. Lacquer the work with pale lacquer, or but very slightly colored, for if it is too deep it will soon chip off. — 2. Mix vinegar or dilute sulphuric acid (1 part acid, 12 water) with powdered black lead in a saucer or open vessel; apply this to the brass with a soft plate brush by gentle brushing. This will soon assume a polish, and is fit for lacquering. The brass must be made slightly warmer than for lacquering only. The color, black or green, varies with the thickness of black lead.

BRONZING GREEN. — 1. (See *Bronzing Gas Fixtures, 2.*) — 2. Repeated applications to copper or brass of alternate washes of dilute acetic acid and exposure to the fumes of ammonia will give a very antique-looking green bronze; but a quick mode of producing a similar appearance is often desirable. To this end the articles may be immersed in a solution of 1 part perchloride of iron in 2 parts water. The tone assumes darkness with the length of immersion. Or the articles may be boiled in a strong solution of nitrate of copper. Or they may be immersed in a solution of 2 oz. nitrate of iron, and 2 oz. hyposulphite of soda in 1 pt. water. Washing, drying, and burnishing complete the process.

BRONZING GUN BARRELS. — 1. Chloride of antimony has been used for bronzing gun barrels, and called, in consequence, bronzing salt. It is used for bronzing, mixed to a creamy consistence with olive oil; the iron is slightly heated, dressed upon its surface with this mixture, and left until browning is produced. The sharpening of the chloride of antimony can be effected by adding a little nitric acid to the paste of olive oil and chloride of antimony, so as to hasten the operation. — 2. Aquafortis, ½ oz.; sweet spirit of nitre, ½ oz.; spirit of wine, 1 oz.; blue vitrol, 2 oz.; tincture of chloride of iron, 1 oz.; water, 40 oz.; dissolve the blue vitriol in the water; then add the other materials, and the water is warmed to dissolve the blue vitriol; let it get cold before adding the other materials. The burnishing and marking can be effected with the burnisher and scratch brush. The polishing is effected by rubbing with a piece of smooth, hard wood, called polishing wood; then varnished with shellac varnish, and polished with the hard wood polisher. Some prefer the brown produced by blue vitriol, 1 oz.; sweet spirit of nitre, 1 oz.; water, 20 oz. In any case, the surface of the iron must be cleaned, and rendered bright; it is then freed from grease by rubbing with whiting and water, or with powdered quicklime and water. The browning composition is then placed on, and allowed to remain 24 hours; it is then rubbed off with a stiff brush. If not sufficiently browned, repeat the last process after browning. Clean the surface with hot water containing soda or potash, and, lastly, with boiling water, and dry it. The surface can be burnished and polished. Varnish with tinsmith's lacquer, or with gum shellac, 2 oz.; dragon's blood, 3 dr.; methylated spirits of wine, 4 pts. The metal should be made hot

before applying this varnish, and will present an excellent appearance. If the varnish is not required to color, but to preserve the actual tint produced by the browning fluid, leave out the dragon's blood.

BRONZING HARDWARE. — Brown bronze dip, for coating hat hooks and similar hardware articles, is made of iron scales, 1 lb.; arsenic, 1 oz.; muriatic acid, 1 lb.; zinc, solid, 10 oz. The zinc should be kept in only when the bath is used. The castings must be free from sand and grease.

BRONZING LIQUID. — 1. (*Acid.*) Cobalt, 4 lbs., pulverize; sift through a fine sieve; put in a stone pot; add ½ gal. nitric acid, a little at a time, stirring frequently for 24 hours; add about 5 gals. muriatic acid, or until the work comes out dark brown. — (*Alkali.*) Dissolve 5 lbs. nitrate of copper in 3 gals. water and 5 lbs. pearlash; add 1 or 2 pts. potash water; then add from 2 to 3 lbs. sal ammoniac or until the work comes out the required color.

BRONZING MEDALS AND COINS, — This gives to new metallic objects the appearance of old ones, especially to copper and its alloys. 1. The most simple bronze is obtained by applying upon the cleansed object a thin paste of water with equal parts of plumbago and peroxide of iron, with a certain proportion of clay. Then heat, and when the object is cold, brush in every direction for a long time with a middling stiff brush, which is frequently rubbed upon a block of yello. wax, and afterwards upon the mixture of plumbago and peroxide of iron. This gives a very bright red bronze, suitable for medals kept in a show case. — 2. Dip the article into a mixture of equal parts perchloride and nitrate of sesquioxide of iron, heating until these salts are dry; then rub with the waxed brush as described. — 3. Cleanse the article, and cover it with hydrosulphate of ammonia, which allow to dry, then brush with peroxide of iron and plumbago, and afterwards with the waxed brush. If the piece impregnated with hydrosulphate of ammonia is gently heated, a black bronze is obtained, which being uncovered at certain places produces a good effect. — 4. Clean and dip in a strong aqueous solution of cupric chloride.

BRONZING TIN. — Sulphate of iron and sulphate of copper, each, 1 oz.; water, 1 pt.; dissolve; wash the surface of the articles with it; let them dry; then apply a solution of verdigris, 2 oz., dissolved in strong vinegar, ½ pt; when dry, polish with a soft brush, and either some plumbago or colcothar. Used for tin castings.

BRONZING ZINC. — The zinc to be bronzed must receive an electro-deposit of brass, which is then dipped into a weak solution of sulphate of copper for a red tinge. When dry, wet with a rag dipped into hydrosulphate of ammonia, or a solution of polysulphide of potassium, or protochloride of copper dissolved in hydrochloric acid. After another drying, the surface is brushed over with a mixture of peroxide of iron and plumbago, according to tint desired. The brush may be wetted with essence of turpentine, which aids the adhesion of the powders. The raised parts are rubbed to uncover the brass. Afterwards give a coat of colorless varnish.

BULLET METAL. — 38 parts lead to 2 parts arsenic. **For round** shot the fused metal is dropped from a high elevation in a shot tower into a basin of water; or thrown down a stack of limited height, in which a strong draught of air is produced by a blast machine.

CANNON METAL. — Tin, 10 parts; copper, 90 parts; melt.

CASTINGS, Alloy for Defects in. — Lead, 9 parts; antimony, 2 parts; bismuth, 1 part. This expands on cooling.

CYLINDERS OF LOCOMOTIVES. Alloy for. — Copper, 88.63 parts; tin, 2.38 parts; zinc, 6.99 parts.

CYMBALS, Alloy for. — 100 parts of copper with about 25 of tin. To give this compound the sonorous property in the highest degree, the piece should be ignited after it is cast, and plunged immediately into cold water.

FUSIBLE ALLOY. — 1. An alloy of 7½ parts bismuth, 4 of lead, 1½ of tin, and 2 of cadmium, melts at a temperature of 151° Fahr. There are several alloys of bismuth, lead and tin, which melt below the boiling point of water. The one which is simplest in composition, consists of 2 parts bismuth, 1 of lead and 1 of tin. A bit of it dropped into boiling water becomes at once a melted globule. — 2. Tin, 8 parts; lead, 4 parts; bismuth, 3 parts; melt together, removing the scum. Used as a metal bath. — 3. Bismuth, 8 parts; lead 5 parts; tin 3 parts. Used as a metal bath. — 4. Lead 3 parts, tin 2 parts, bismuth 5 parts. This melts at 197° Fahr. — 5. (*For Anatomical Injections.*) Melt together with a gentle heat 174 parts tin, 312 of lead, 514 of bismuth, with a little charcoal; remove from the fire, and add 100 parts of mercury, previously heated. It is fluid at 173°; solid at 140° Fahrenheit.

GERMAN SILVER. — A well known alloy; the finer varieties nearly equal silver in whiteness and susceptibility of receiving a high polish, while they surpass it in durability. The following formulæ give the composition of German silver for various purposes: 1. Copper, 50 lbs.; zinc, 25 lbs.; nickel, 25 lbs.—2. (*Second Quality, for Casting.*) Copper, 50 lbs.; zinc, 20 lbs.; best pulverized nickel, 10 lbs. — 3. (*For Rolling.*) Copper, 60 lbs.; zinc, 20 lbs.; nickel, 25 lbs. — 4. (*For Bells and other Castings.*) Copper, 60 lbs.; zinc, 20 lbs.; nickel, 20 lbs.; lead, 3 lbs.; iron (that of tin plate is the best), 2 lbs. — 5. (*For Castings.*) Lead, 3 parts; nickel, 20 parts; zinc, 20 parts; copper, 60 parts; mix. — 6. (*For Rolling.*) Nickel, 5 parts; zinc, 4 parts; copper, 12 parts; mix. — 7. Copper, 40.62 parts; zinc, 43.76 parts; nickel, 15.62 parts. — 8. Copper, 41.47 parts; zinc, 26.08 parts; nickel, 32.35 parts. — 9. Copper, 55.55 parts; zinc, 5.55 parts; nickel, 38.90 parts. — 10. Copper, 53.40 parts; zinc, 29.10 parts; nickel, 17.50 parts. — 11. (*Alfenide.*) A trace of iron; copper, 59.60 parts; zinc, 30.30 parts; nickel, 10.10 parts. —12. (*Genuine German Silver*). Iron, 2½ parts; nickel, 31½ parts; zinc, 25½ parts; copper, 40½ parts; melt.

GERMAN SILVER, To Melt.—Use a black lead crucible, cover with charcoal, and give a good white heat in a small crucible or melting furnace.

GERMAN SILVER, To Polish.—Take 1 lb. peroxide of iron, pure, and put ½ into a wash basin,

pouring on water, and keeping it stirred until the basin is nearly full. While the water and crocus is in motion, pour off, leaving grit at the bottom. Repeat this a second time, pouring off with another basin. Cleanse out grit, and do the same with the other $\frac{1}{2}$. When the second lot is poured off, the crocus in the first will have settled to the bottom; pour off the water gently, take out the powder, and dry it, and put both when clear of grit and dried, into a box into which dust cannot get. If the silver work is dirty, rub the mixture of powder and oil on with the fingers, and then it will be known if any grit is on the work. If the work is not black, take a piece of chamois leather, and rub some dry crocus on, and when well rubbed, shake out the leather, and let the powder fall off that is not used, or rub it off with a brush. Do not put down the leather in the dust.

GERMAN SILVER, Soldering. —To solder German silver, rub a lump of borax with a drop or so of water on a slab, until a paste is produced. Clean the surfaces to be soldered and paint on the borax paste; dip the silver solder in the borax paste and place it in position on the work. Pin the work on a charcoal or piece of pumice stone, with common tacks, not tinned; direct the reducing flame of a blowpipe upon the work until it becomes red hot, then project it on the solder. The small silver 3 cent pieces make excellent solder for German silver, brass, copper, iron and steel.

GILDING METAL. — The metal employed as a base for gilding is usually brass, or a mixture of brass and copper. The following proportions have been recommended: 1. Copper, 6 parts; brass, 1 part.—2. Copper, 4 parts; Bristol brass, 1 part. — 3. Copper, 13 parts; old Bristol brass, 3 parts; tin, 14 parts.

GOLD MOSAIC.—Melt 1 lb. tin in a crucible; add $\frac{1}{2}$ lb. purified quicksilver to it; when cold, reduce to powder and grind with $\frac{1}{4}$ lb. sal ammoniac and 7 oz. flour of sulphur, till thoroughly mixed; they are then calcined in a matrass, and the sublimation of the other ingredients leaves the tin converted into the mosaic gold powder found at the bottom of the glass; remove any black or discolored particles. The sal ammoniac must be white and clear, and the mercury of the utmost purity. When a deeper red is required, grind a small quantity of red lead with the above materials.

GUN METAL.—An alloy containing 90.5 per cent. copper, and 9.5 per cent. of tin, used for casting pieces of ordnance (sometimes erroneously termed "brass guns"), also those parts of machinery which may be subjected to considerable friction.

JOURNAL BOXES, Alloy for.—Copper, 24 lbs.; tin, 24 lbs.; antimony, 8 lbs.; melt the copper first, then add the tin, and lastly the antimony. It should be first run into ingots, then melted and cast in the form required for the boxes.

KUSTITIEN'S METAL. — Take of malleable iron, 3 parts; beat it to whiteness and add of antimony, 1 part; Molucca tin, 72 parts; mix under charcoal, and cool. Used to coat iron and other metals with a surface of tin; it polishes without a blue tint, is hard, and has the advantage of being free from lead and arsenic.

MUNTZ METAL, For Ships. — Best selected copper, 60 parts; best zinc, 40 parts. Melt together in the usual manner, and roll into sheets of suitable thickness. This resists oxidation from exposure to sea water, and prevents adhesion of barnacles.

NIELLO SILVER.—9 parts silver, 1 part copper, 1 part lead, and 1 part bismuth, melted together and saturated with sulphur. This produces the gorgeous blue erroneously spoken of as steel blue.

NUTS OF COARSE THREADS AND BEARINGS, Metal for. — Copper, 1 lb.; brass, $1\frac{1}{2}$ oz.; tin, $2\frac{1}{2}$ oz.

PIPE METAL FOR ORGANS.—Melt equal parts of tin and lead. This alloy is cast in the form of sheets, in order to obtain a crystallized metal, which produces a finer tone. The sheets are formed by casting the metal on a horizontal table, the thickness regulated by the height of a rib or bridge at one end, over which the superfluous metal flows off. The sheets are planed with a carpenter's plane, bent up, and soldered.

POT METAL. — Copper, 40 lbs.; lead, 16 lbs.; tin, $1\frac{1}{2}$ lbs.

RIVET METAL. — 1. Copper, 32 oz.; tin, 2 oz.; zinc, 1 oz. — 2. (*For Hose.*) Copper, 64 lbs.; tin, 1 lb.

SILVER MOSAIC. — An amalgam of equal parts tin, bismuth, and mercury; $12\frac{1}{2}$ dr. good tin is fused in a crucible, and as soon as melted $12\frac{1}{2}$ dr. bismuth are stirred in with an iron wire until it is all liquid, the crucible then removed from the fire, stirred as long as liquid, and $6\frac{1}{4}$ dr. mercury added, and all mixed until stiff enough to be ground upon a stone.

SILVER WHITE. — Melt together 1 oz., each, bismuth and tin; add to this mixture 1 oz. of

MELTING. —

FLUXES.

A. Borax.
B. Salam. or Mur. of Amm.
C. Muriate or Chlor. of Zinc.
D. Common Resin.
E. Venice Turpentine.
F. Tallow.
G Gallipoli Oil, or common Sweet Oil.

MODES OF APPLYING HEAT.

a. Naked fire.
b. Hollow furnace or muffle.
c. Immersion in melted solder.
d. Melted solder or metal poured on.
e. Heated iron not tinned.
f. Heated copper tool, tinned.
g. Blowpipe flame.
h. Flame alone, generally Alcohol.
i. Stream of heated air.

mercury; afterwards cool, and then powder.

SLIDING LEVERS OF LOCOMOTIVES, Metal for. — Copper, 85.25 parts; tin, 12.75 parts; zinc, 2 parts.

SPECULUM METAL. — 1. Take copper, 64 parts; pure tin, 69 parts; melt them separately under a little black flux; next incorporate thoroughly by stirring with a wooden spatula, and run the metal into the molds, so that the face of the intended mirror may be downwards; lastly, allow the whole to cool very slowly. — 2. Pure copper, 2 parts; pure tin, 1 part. Used to make mirrors of reflecting telescopes. The addition of a little metallic arsenic renders it whiter.

STATUARY METAL. — 91.4 parts copper; 5.53 parts zinc; 1.7 parts tin; 1.37 parts lead.

STERRO METAL. — Copper, 55 to 60 parts; zinc, 34 to 44 parts; iron, 2 to 4 parts; tin, 2 to 4 parts. Sterro metal is used for the pumps of hydraulic presses, etc. It is capable of withstanding a pressure of from 43,000 to 85,000 lbs. per sq. in.

TINNING, Hard Compound for. —The proportions of nickel and iron mixed with tin, to produce the best tinning, are 10 oz. best nickel and 7 oz. sheet iron, to 10 lbs. tin. These metals are mixed in a crucible to prevent oxidation of the tin by high temperature necessary for fusion of nickel; the metals are covered with 1 oz. borax and 3 oz. pounded glass. The fusion is complete in ½ hour, when the composition is run off through a hole made in the flux. In tinning metals with this composition proceed in the ordinary manner.

TINNING METAL. —Malleable iron, 1 lb.; heat to whiteness; add 5 oz. regulus of antimony, and Molucca tin, 24 lbs.

TYPE METAL.—An alloy formed of antimony, 1 part; lead, 3 parts; melted together. Small types are usually made of a harder composition than large ones. A good stereotype metal is made of lead, 9 parts; antimony, 2 parts; bismuth, 1 part. This alloy expands as it cools, and brings out a fine impression.

WETTERSTEDT'S PATENT SHEATHING FOR SHIPS.—Lead with from 2 to 8 per cent. of antimony; about 3 per cent. is the usual quantity. The alloy is rolled into sheets.

WHITE METAL.—1. Melt together 20 oz. lead; 10 oz. bismuth, and 8 dr. regulus of antimony. — 2. Melt together 4 lbs. regulus of antimony, 1 lb. brass, and 20 oz. tin.

ALUMINUM.

REMARKS.—A cubic inch of pure aluminum weighs approximately 1-10 of a pound avoirdupois, being about ⅜ the weight of an equal bulk of pure silver. Pure aluminum can be rolled, drawn, spun, stamped, engraved, burnished, polished, and soldered, almost to the same extent and by the same processes as used on brass.

ALLOYS.—1. (*Aluminum and Tin.*) Aluminum, 100 parts; tin, 10 parts.—2. Aluminum, 90 per cent; tin, 10 per cent.—3. Aluminum and tin, equal parts. This alloy solders easily. —4. (*Aluminum and Zinc.*) Aluminum, 8 parts; zinc, 92 parts.—5. Aluminum, 12 parts; zinc, 88 parts.—6. Aluminum, 15 parts; zinc, 85 parts.—7. Aluminum, 20 parts; zinc, 80 parts. The aluminum is first melted, the zinc added gradually, finally some fat is added, and the whole is stirred with an iron rod and poured into molds. For flux use copaiba balsam, 3 parts; Venice turpentine, 1 part; and a few drops of lemon juice. Dip the soldering iron into the same flux.—8. (*Aluminum Bronze.*) 100 parts copper and 10 parts aluminum, measured by weighing, when combined, is a durable alloy, which may be forged and worked in the same manner as copper, and is the same color as pale gold. 80 parts copper, 19 zinc, and 1 aluminum form a good durable alloy.—9. (*Aluminum Silver.*) The following alloy takes a high silver polish, and exhibits a beautiful silvery color: Copper, 70 parts; nickel, 23 parts; aluminum, 7 parts.

ANNEALING. — A very low and even temperature should be maintained in the muffle. Aluminum melts at about 1,300 degrees Fahrenheit—a very dark red. The inexperienced therefore cannot judge the proper annealing temperature by the eye alone, without danger of fusing the metal. When the metal has been heated enough to char the end of a pine stick, thus leaving a black mark in the wake of the stick as it is drawn across the metal, it is sufficiently annealed. The metal should then be withdrawn from the furnace and allowed to cool slowly in the air. For some work, such as stamping and drawing, it is sometimes better not to heat the metal so hot as to leave a dead black mark with the stick, but just enough to show a dark brown mark instead. Very thin sheets or wire can be annealed sufficiently for some purposes in boiling water.

BRAZING.—Aluminum bronze will braze as well as any other metal by using ½ brass solder (copper, 50 per cent; zinc, 50 per cent), and ¾ borax.

BURNISHING. — Use a bloodstone or steel burnisher. For hand burnishing use either kerosene or a solution composed of 2 tablespoonfuls of ground borax, dissolved in about 1 qt. of hot water, with a few drops of ammonia added. For lathe work the burnisher should wear upon the finger of his left hand a piece of Canton flannel, keeping it soaked with kerosene, and bringing it in contact with the metal, supplying a constant lubricant. Very fine effects can be produced by first burnishing or polishing the metal, and then stamping it in polished dies, showing unpolished figures in relief.

DIPPING AND PICKLING.—Remove the grease and dirt by dipping in benzine, to whiten aluminum, leaving on the surface a beautiful white mat; dip first in a strong hot solution of pot-

ash, then rinse in water and dip in undiluted nitric acid, 42°. Then wash in water and dry as usual in hot sawdust.

ELECTRO-PLATING.—1. Aluminum may be deposited on copper from a dilute solution of the double chloride of aluminum and ammonia. —2. Aluminum is one of the most difficult and uncertain of metals to deposit electrolytically. Following is said to furnish excellent results: 50 parts by weight of alum are dissolved in 300 of water, and to this is added 10 parts of aluminum chloride. The solution is heated by 200° F., and when cold 30 parts of cyanide of potassium are added. A feeble current should be used. The object to be plated has to be cleaned, and to be absolutely free from grease in any form, whereupon it is suspended in the bath over the electro-positive electrode, the plate of metallic aluminum to be suspended on the negative pole. The electric current ought to be weak.—3. Dissolve in distilled water the required quantity of aluminum, either the sulphate, muriate, nitrate, acetate or cyanide. Concentrate this solution to 20° Baume. Use 3 pairs Bunsen's zinco-carbon cells, connected for intensity. Attach an anode of aluminum to the negative wire. Acidulate the solution slightly with the appropriate acid heated to 140° F. Keep this solution at this temperature during the operation.

MILLING, PLANING AND TURNING. — Use plenty of oil to prevent the clogging of the tool and to make it cut smooth.

POLISHING.—Use fine white polishing composition or rouge, and a rag buff.

SAND CASTINGS.—Use open, but very fine, sand, and bake the mold. Large feeding gates should be provided, and the mold should be well vented. Pour the metal quickly, at a temperature but little above the melting point. Use either Taylor's or Dixon's plumbago crucibles.

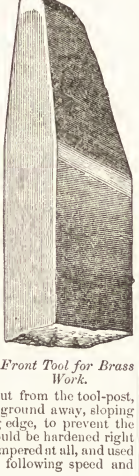
SOLDERING.—The inventors claim that surfaces of aluminum may be soldered to each other, and to other metallic surfaces by using silver chloride as a flux in conjunction with ordinary solder. After the pieces of metal are placed in the required position, finely powdered fused silver chloride spread along the line of junction, and solder melted on with a blow-pipe or other device. The joints are thus easily and rapidly made, and neither crack, flake nor check.

Brass.

REMARKS.—Brass is generally manufactured by plunging copper, in slips, into zinc melted in the usual manner. The former metal combines with the fluid mass, and the addition is continued until an alloy somewhat difficult of fusion is formed, when the remainder of the copper is added. The brass obtained is broken into pieces, and remelted under charcoal, and a proper addition of zinc or copper made, to bring it to the color and quality desired, then poured into molds of granite. Before being submitted to the rolling-press for reduction to thin plates, it undergoes annealing. The proportions of metals forming this alloy are varied according to desired color and the purposes to which it is to be applied. The following formulæ give the compositions of brass best suited for the purposes named: 1. (*Yellow, for Turning.*) Copper, 20 lbs.; zinc, 10 lbs.; lead, 4 oz. —2. (*Best Red, for Fine Castings.*) Copper, 24 lbs.; zinc, 5 lbs.; bismuth, 1 oz. — 3. *Red Tombac.*) Copper, 10 lbs.; zinc, 1 lb. — 4. (*Tombac.*) Copper, 16 lbs.; tin, 1 lb.; zinc, 1 lb. — 5. (*Heavy Castings.*) Copper, 6 to 7 parts; tin, 1 part; zinc, 1 part. — 6. (*Malleable.*) Copper, 70.1 parts; zinc, 29.9 parts. — 7. (*German.*) Copper, 1 lb.; zinc, 1 lb. — 8. (*Watchmakers'.*) Copper, 1 part; zinc, 2 parts. — 9. (*Wire.*) Copper, 72 parts; zinc, 28 parts. — 10. (*English Wire.*) Copper, 70.3 parts; zinc, 29.3 parts; lead, 3 parts; tin, 2 parts. — 11. (*Heavy Work.*) Copper, 100 parts; tin, 15 parts; zinc, 15 parts. —12. (*Fine Buttonmakers'.*) Copper, 8 parts; zinc, 5 parts. — 13. (*Common Buttonmakers'.*) Button brass, 6 parts; tin, 1 part; lead, 1 part; mix. —14. (*Mallet's.*) Copper, 25.4; zinc, 74.6; used to preserve iron from oxidizing.—15. (*Best for Clocks.*) Rose copper, 85 parts; zinc, 14 parts; lead, 1 part. The following formulæ, especially intended as brass for machinery work, are also added: 1. Copper, 2 lbs.; tin, 2½ oz.; zinc, ½ oz. — 2. (*Tough.*) Copper, 10 oz.; tin, 1½ oz.; zinc, 1½ oz. — 3. (*Wheels and Valves.*) Copper, 90 lbs.; tin, 10 lbs. — 4. (*Tenacious.*) Copper, 88.9 parts; tin, 8.3 parts; zinc, 2.8 parts. — 5. (*Lathe Bushes.*) Copper, 80 parts; tin, 20 parts. — 6. (*Machinery Bearings.*) Copper, 88 parts; tin, 12 parts. — 7. (*Boxes for Engines Running at High Speed.*) Copper, 7 lbs.; tin, 1 lb.; add spelter, 1 lb. to every 40 lbs. of the mixture. Use steel piston rods for high speed, and lignum vitæ or apple tree wood for shoes or gibbs on the cross-heads.

BEDDING-DOWN.—In bedding down brasses or journal boxes of any description, the following plan should be employed to gauge as much as requires to be chipped or filed away from any part of the bed of the brass to enable it to bed to its seat all over: Take ordinary red marking, composed of Venetian red and common oil, mixed to a thick paint, and paint over the bed into which brass is to be fitted; then take putty, mixed stiffly; roll into pellets, the size of a large pea; place them here and there upon the painted surface; then drive the brass home and drive it out again, when it will be found that the thickness to which the pellets have been smashed by the bottom of the brass registers, to the greatest possible exactitude, how near the bottom of the brass comes to the bed of the bottom of the bearing, indicating the amount to be taken off the bottom of the brass to bed it. Be careful not to take too much off at first, and repeat the process with the pellets. Carefully replace the old pellets with new ones at each trial, otherwise you will be misled. Painting with red marking before placing the pellets, causes them to stick to the box and not to the brass, and pre-

FITTING.—In doing this, a piece of wood must be used to hammer on in driving them in and out; driving them with the hammer, a piece of metal, or a mandrel, stretches the skin and enlarges the diameter across the bore; then when the brasses are bored and the stretched skin is removed, the brass resumes its original shape, and becomes loose in the strap or box. In fitting brasses leave them a little too tight; all brasses contract across the bore in the process of boring. This rule applies to journal boxes of cast iron or any other metal.



Front Tool for Brass Work.

FRONT TOOL. — As shown in the engraving, this tool is ground to suit either roughing out or finishing. For slight work limble to spring, it may be ground more keen on the side faces, the top face not requiring under any circumstances to be ground keener than is shown. When held far out from the tool-post, the top face should be ground away, sloping down toward the cutting edge, to prevent the tool from jarring. It should be hardened right out, and not lowered or tempered at all, and used for roughing out at the following speed and feeds:

Size of Work, in Inches.	Revolutions of Lathe.	Feed.
1 and less	350	.25
2 to 5	250	.25
5 " 12	200	.25
12 " 20	150	.30

For finishing cuts, the cutting speed may be increased about 1-5, which rule will apply to its use upon yellow brass for roughing out as well as finishing purposes.

FROSTING.—Scour the brass with strong ley, and hold the work against a circular scratch brush of fine brass wire, secured in a lathe and driven at a high speed.

LACQUERING.—For flat work, cleanse by boiling the articles in strong potash water. Place the work on an iron plate, at a low heat, and pass the lacquer regularly and rapidly over the surface with a good sized fine camel's hair brush, keeping the iron plate warm until the work is dry. Small circular work, after being cleansed, and burnished if need be, and slightly heated in a stove or over a charcoal fire, should have the lacquer thinly and evenly applied while in motion in the lathe, holding a charcoal brazier under the work for a short time, to avoid cooling too soon.

MELTING.—Place the article in a sand crucible with a little borax. A coal fire with a good draught is necessary to melt it. When ready, place the crucible well down in the fire.

ORMOLU.—The ormolu of the brass founder, known as an imitation of red gold, is used by the French workmen in metals. It is found in combination with grate and stove work. It is composed of a greater portion of copper and less zinc than ordinary brass, is cleaned readily by acid, and burnishes with facility. To give this material the rich appearance, it is not unfrequently brightened up after cleaning in acid by means of a scratch brush, the action of which helps to produce a brilliant gold-like surface. It is protected from tarnish by the application of lacquer.

PARTING TOOL.—The parting tool for brass is governed by the same principle as that for iron, save that its top face must be ground level, except where the cutting edge stands far out from the tool-post, in which event the top face must

Parting Tool for Brass.

be ground away at an angle of which the cutting edge is the lowest part. It is rarely necessary for brass work to grind the cutting edge much below the level of the top face of the body of the tool, as is shown for use on wrought iron. The degree of hardness of the tool should be the same for brass as that given for wrought iron.

PATTERNS.—In making a pattern for a brass to fit in a semi-octagonal bed such as is employed in pillar-blocks, and sometimes in the small ends of connecting rods and axle boxes; after having made the bed of the brass to the same shape as the seat into which it beds, take off 1-16 in. in brasses below 3 in. bore, or $\frac{1}{8}$ in. in brasses above that size, from the crown face of the brass pattern, for the following reasons: The casting of iron or of brass contracts, in cooling, most at the sides, and the above is to compensate for this. It will require only 1-16 in. to be cut off the angles to let a brass (having bed angles at 40°), down $\frac{1}{8}$ in. on the crown; whereas it will require $\frac{1}{8}$ in. taken off the crown face to let the bed angles down 1-16 in. A strict observance of this rule will save half the time required to fit such brasses to their places. In brasses whose bed angles are more acute, a greater allowance must be made.

PINCHBECK. — Put into a crucible 5 oz. pure copper; when it is in a state of fusion, add 1 oz. zinc. These combine, forming an alloy not unlike jewelers' gold; pour it into a mold of any shape. This alloy is used for inferior jewelry. Some use only half this quantity of zinc, in which proportion the alloy is more easily worked, especially in the making of jewelry.

POLISHING.—Rub the metal with rotten stone and sweet oil; then rub off with cotton flannel, and polish with soft leather. A solution of oxalic acid rubbed over tarnishhd brass soon removes the tarnish. The acid must be washed off with

water, and the brass rubbed with whiting and soft leather. A mixture of muriatic acid and alum dissolved in water imparts a golden color to brass articles that are steeped in it for a few seconds. The following may be used for polishing brass work: 1. Seed lac, dragon's blood, annatto and gamboge, each 4 oz.; saffron, 1 oz.; spirit of wine, 10 pts. — 2. Alcohol, 1 pt.; turmeric, 1 oz. (powder); annatto, 2 drs.; saffron, 2 drs.; agitate occasionally for a week; filter, and add seed lac, 3 oz., and let stand 2 weeks with occasional agitation. Keep well stoppered.

SCALE. — To remove the scale from brass castings to give a surface on which solder may be flowed with a hot copper, dissolve 6 oz. bichromate of potash in 3 pts. warm water; when cool, add 6 fluid oz. sulphuric acid. Rinse the castings well after pickling in this solution.

SCRAP.—To utilize scrap brass melt it in with new brass, putting it in with the zinc after the copper is melted.

SETTING. — In setting brasses or any other journal boxes to be bored, place a piece of sheet tin between the joint of the brasses, and bore the brasses or boxes the thickness of the tin too large, which thickness may be gauged by placing a small piece of the same tin under the leg of the inside calipers when trying the bore. Practice demonstrates it to be an invariable rule that a $\frac{1}{2}$ circle or $\frac{1}{2}$ hole, whether in a movable brass or in a solid box, will never fit down upon its journal, but will bind upon the edges across the diameter, and must be scraped or filed on the sides to let the crown down. This defect is obviated by the employment of the sheet tin, which will save $\frac{3}{4}$ the time required to fit such work to a good bearing. This plan is advantageous in boring eccentric straps and large brasses; and the larger the size, the thicker the tin may be.

SIDE TOOL. — This tool fills the same place with reference to brass that the side tool and knife tool do to iron work; it has no superior for taking out corners, for cutting out holes or recesses which do not pass entirely through the metal. In conjunction with the front tool for brass it will perform any duty upon either inside or outside brass work, except cutting out narrow grooves. Its cross section is somewhat diamond shaped; and it is made right and left by bending in opposite directions. It is a better tool than those bent round at the end after the manner of a boring tool; and being more rigid, it is easier to forge and grind, and less liable to jar. It is applicable as a roughing out or a finishing tool. It should be hardened right out, and used at the speeds and feeds given for the front tool for brass.

Side Tool for Brass.

SOFTENING.—Heat it to a low red and plunge in water. It cannot be hardened except by rolling or hammering.

TEMPERING. — Brass is rendered hard by hammering or rolling. When making anything of brass necessary to be in temper, prepare the material before shaping the article. Temper may be drawn from brass by heating it to a cherry red, and then simply plunging it into water the same as when tempering steel.

TUBES.—Brass or other tubes are made of rolled metal, cut to desired width by revolving discs; in the large sizes, the metal is partially curved in its length by a pair of rolls; when in this condition, it is passed through a steel hole or a die, a plug being held in such a position as allows the metal to pass between it and the interior of the hole. Oil is used to lubricate the metal; the motion is communicated by power, the drawing apparatus being a pair of huge nippers, which holds the brass and is attached to a chain and revolves round a windlass or cylinder. The tube in its unsoldered state is annealed, bound round at intervals of a few in. with iron wire, and solder and borax applied along the seam. The operation of soldering is completed by passing the tubes through an air-stove heated with "cokes" or "breezes," which melts the solder and unites the 2 eyes of the metal and forms a perfect tube; it is then immersed in a solution of sulphuric acid to remove scaly deposits, the wire and extra solder having been previously removed; drawn through a "finishing hole plate," and the tube is complete. Mandrel drawn tubes are drawn upon an accurately turned steel mandrel, by this means the internal diameter being rendered smooth. The tubes drawn by this process are adapted for telescopes, syringes, small pump cylinders, etc. The brass tubes for the boilers of locomotive engines are made by casting and drawing without being soldered, and some of them are drawn taper in their thickness. Tubes 1-10 in. internal diameter and 8 or 10 in. long, up to those of 2 or 3 in. diameter and 4 or 5 ft. long, are drawn vertically by means of a strong chain wound on a barrel by wheels and pinions, as in a crane. In Donkin's tube drawing machine, which is applicable to making tubes, or rather cylinders, for paper making and other machinery as large as $26\frac{1}{2}$ in. diameter and $6\frac{1}{2}$ ft. long, a vertical screw is used, the nut of which is turned round by toothed wheels driven by a windlass. The fluted tubes of pencil cases are drawn through ornamental plates with elevations and depressions corresponding to the impressions left on the tube.

TUBES, BENDING.—Run melted lead or resin into the pipe till full; then bend it gradually into any desired shape; the pipe may then be heated and the lead or resin melted and run out.

UNITING WITHOUT SOLDER.—The brass rims of the large mural circles for observatories are sometimes cast in 6 or more segments, and attached by burning. The ends of the segments are filed clean, 2 pieces are fixed vertically in a sand mold in their relative positions, a shallow

space is left around the joint, and the entire charge of the crucible, say 30 to 40 lbs. of the melted brass, a little hotter than usual, poured on the joint to heat it to the melting point. The metal overflows the shallow chamber or hole, and runs into a pit prepared for it in the sand; but the last quantity of metal that remains solidifies with the ends of the segments, and forms a joint as perfect as the general substance of the metal; the process is repeated for each joint of the circle.

WATERED.—1. To put on a watered or mottled appearance to brass articles, the brass is first polished, and if it is a fine surface the mottled appearance is imparted by rubbing over it with a gyratory motion a Scotch gray stone moistened with water. If the work is not fine, a piece of fine emery paper may be used in the same way. If it is coarse, a dead smooth file may be used. — 2. Secure emery cloth or paper to the end of a small round stick, placing the stick in the universal chuck of a lathe, holding the work against it with a light pressure, and moving it along while the lathe revolves.

COPPER.

CASTING. — Cast in green sand and not in dried molds, using 1½ lbs. zinc as a flux, as pure copper will not run sufficiently free to prevent honeycombing.

CLEANING.—1. (*Coins.*) Boil in a strong aqueous solution of caustic soda; rinse in soft water, and dip bright in nitric acid, and quickly rinse again. Polish with a little putty powder, rouge or tripoli. — 2. (*Specimens.*) Use a strong solution of cyanide of potassium and a stiff brush; rinse in cold, then in hot water; as soon as dry, coat with colorless shellac varnish thinned with alcohol, otherwise the metals will soon tarnish again. — 3. (*Buttons.*) To remove tin, solder and dirt, cleanse first in a boiling solution of 3 parts caustic soda, 1 part nitre and 5 parts water, and then in dilute sulphuric acid; or dip momentarily in warm nitric acid, sp. gr. 1.2, and wash immediately in running water.

COATING CASTINGS.—1. The article should be rendered free from rust by rubbing with an emery cloth, or by dipping it into a pickle composed of sulphuric acid, 2 oz.; hydrochloric acid, 1 oz.; water, 1 gal. After remaining some time in this pickle it should be taken out, and the rust removed by a brush and wet sand; if the oxide cannot easily be cleaned off it must be returned to the pickle. As soon as the article is bright it is washed in a warm solution of soda or potash to remove grease; lastly, it is rinsed in hot water, and placed in a concentrated solution of sulphate of copper, to which a little sulphuric acid has been added. In a short time it will be coated with metallic copper. — 2. Have the article clean; then wash with the following solution, and it presents at once a coppered surface: Rain water, 8 lbs.; sulphate of copper, 1 lb.

COATING WITH IRON.—10 parts ferrocyanide of potassium and 20 parts tartrate of soda are dissolved in 220 parts distilled water, adding a solution of 3 parts sulphate of iron in 50 parts water. Caustic soda solution is poured into the mixture until the Prussian blue formed is redissolved.

COPPER DIP. — The solution used by fixture manufacturers on their iron castings is copper sulphate, 3½ oz.; sulphuric acid, 3½ oz.; water, about 1 gal.; place the clean casting in a tumbling barrel with sawdust, bran, or sand moistened with this solution, and revolve a few minutes; a longer exposure will spoil the film of copper deposited. In place of tumbling the articles, they may be rubbed with this mixture.

ENAMELING.—1. Flint glass, 6 parts; borax, 3 parts; red lead, 1 part; oxide of tin, 1 part; mix all together, frit, grind into powder, make into a thin paste with water, apply with a brush to the surface of the vessels, after sealing by heat and cleaning them; repeat with a second or even a third coat; then dry, and fuse on by heat of an enameled kiln. — 2. Pulverize finely 12 parts fluor spar, 12 parts unground gypsum, and 1 part borax, and fuse together in a crucible; when cold, mix with water to a paste, and apply to the interior with a paint brush; when dry the vessel should be baked in a muffle or furnace.

LUSTER.—Obtained by dissolving a piece of zinc with muriatic acid, and mixing the solution with spirit of tar, and applying it to the surface of the iron.

PLATINIZING.— In order to obtain a platinizing fluid capable of platinizing copper, yellow metal and brass, add to a moderately concentrated solution of chloride of platinum, finely powdered carbonate of soda until effervescence ceases; next some glucose, and afterwards as much common salt as will cause a whitish-colored precipitate. When desired to apply this mixture for platinizing, the objects to be treated are placed in a vessel made of zinc, perforated with holes; the vessel then placed, with its contents, for a few seconds in the mixture, which, previous to using, should be beaten to 60° C. On being removed from the zinc vessel, the objects are to be washed with water and dried in sawdust.

PURIFYING. — Black oxide of manganese, 1 part; copperas and common salt, 4 parts each; dissolve in soft water, and boil till dry; when cool, pulverize, and mix freely with nice welding sand. When you have poor iron, heat it, and roll it in this mixture; working for a time, reheating, etc., will soon free it from impurities; by this process you can make good horse nails out of common iron.

REFINING. — Copper may be separated, in a state of purity, from antimony, arsenic, bismuth, lead, iron, tin, zinc, etc., as it exists in bell-metal, brass, bronze, gun-metal, mosaic gold, and other commercial alloys, by fusing it in a crucible for ½ hour, along with copper scales (black oxide) and ground bottle-glass, or other like flux. The

pure metal is found at the bottom of the crucible, whilst the impurities are volatilized or dissolved in the flux. The proportions for refining commercial copper are, metal, 10 parts; copper scales and bottle-glass, each 1 part.

TIN. To Remove.—Immerse the article in a solution of blue vitriol. To remove tin from plates without acid, boil the scrap tin with soda lye in presence of litharge.

WELDING.—Boracic acid, 2 parts; phosphate of soda, 1 part; mix. This powder should be strewn over the surface of copper at a red heat; the pieces then heated up to a full cherry red, or yellow heat and brought under the hammer. Heat the copper at a flame, or gas jet, where it will not touch charcoal or solid carbon.

WIRE DRAWING.—To draw copper wire, which is too large, down to a smaller size, take a well annealed piece of good tool steel ¼ in. thick, drill in it several holes of the size of the smallest wire to be drawn, make them all tapering, and enlarge with a reamer so that the holes will vary regularly down to that of the smallest wire to be drawn. Harden the plate, polish the holes, reduce the size of the end of the wire, and draw it through the several holes in succession, greasing it before each drawing, and annealing it whenever it becomes stiff.

IRON.

BEVEL GEARS. — These are turned a certain bevel to correspond with each other, according to the angle upon which the shafts driven by them are set. If 2 shafts are set upon an angle of 90°, the surfaces of the faces of these gears will stand at an angle of 45°. To get the surface of these gears, in turning them, put a straight edge across the face. Then set the level on an angle of 45°, and try the face of the teeth by placing the level on the straight edge. After turning the face of the teeth, square the outer diameter by the face of the teeth; and to get the size to which you wish to cut, measure from the centre of the face of the teeth.

BLUING WIRE.—1. To blue small wire articles, such as hair pins, fish-hooks, etc., dip them in a lacquer composed of a good quality of alcoholic shellac varnish to which has been added a little aniline blue. — 2. Demar varnish, ½ gal.; fine ground Prussian blue, ½ oz.; mix; makes a splendid appearance. Excellent for bluing watch-hands.

BRASSING WIRE. — To give iron wire a permanent brassing, place the wire, cleaned, in a solution of sulphate of copper, when it immediately becomes covered with a thin film of copper; now cover with a paste of pure oxide of tin, and heat hot enough to fuse the copper.

BRAZING CAST IRON. — There are 2 ways of joining cast iron: 1. Fit the broken pieces exactly together in molding sand and pour melted iron over the parts to be joined. When cold, chip off the superfluous metal and the joint will scarcely be detected. — 2. Well tin the parts to be joined, fit together in sand as above, and pour melted brass over them,

BREAKING OLD CASTINGS. — 1. Old cannon and massive castings may be cut in two by a continuous stream of hot molten iron, which wears away the iron as a stream of hot water would eat into a mass of ice.—2. The gun may be rolled on a frame to the mouth of a furnace, and the muzzle end shoved in as far as possible among other iron, the opening filled up and luted around the gun, the end of which is melted off. At the next charge shove it in another length, and so on until the breech is disposed of. — 3. Large masses of cast iron may be broken up by drilling a hole in the most solid part, filling it up with water, fitting a steel plug accurately into the hole, and letting the drop of a pile driver descend on the plug with its irresistible force.

BRIGHTENING.—When taken from the forge or rolls, articles may be placed in dilute sulphuric acid (1 to 20) for an hour; then washed clean in water, dried with sawdust, dipped for a second or so in nitrous acid, washed and dried as before, and finally rubbed clean.

BURNT IRON, Restoring.— Give a smart heat, protected from the air; if injured by cold hammering, anneal slowly and moderately; if hard or steely, give one or more smart heats, to extract the carbon.

CASE-HARDENING.—The operation of giving a surface of steel to pieces of iron, by which they are rendered capable of receiving great external hardness, while the interior portion retains the toughness of good wrought iron. Iron tools, fire-irons, fenders, keys, etc., are usually case-hardened. — 1. The goods, finished except polishing, are put into an iron box, and covered with charcoal, and cemented at a red heat, for a period varying with the size and description of the articles operated on.—2. Cow's horn or hoof is to be baked or thoroughly dried and pulverized. To this add an equal quantity of bay salt; mix them with stale chamber-lye, or white wine vinegar; cover the iron with this mixture, and bed it in the same in loam, or inclose it in an iron box; lay it then on the hearth of the forge to dry and harden; then put it into the fire; then blow till the lump has a blood-red heat, and no higher, lest the mixture be burnt too much. Take the iron out, and immerse it in water to harden.—3. The iron, previously polished, is to be heated to a bright-red and rubbed or sprinkled over with prussiate of potash. As soon as the prussiate appears to be decomposed and dissipated, plunge the article into cold water.—4. Make a paste with a concentrated solution of prussiate of potash and loam, and coat the iron; then expose it to a strong red heat; and when it has fallen to a dull red, plunge the whole into cold water.—5. To harden to any considerable depth, put the article into a crucible with cyanide of potash; cover over and heat altogether, then plunge into water. This process will harden to the depth of 1 or 2 in. (See *Tempering*, in STEEL.)

CASTINGS, Holes in. — To prevent holes in castings when casting on iron or steel spindles, the molds are cast endwise, letting the cast metal

covering the spindle be an in. longer on the uppermost side than is necessary when the job is finished; the air-holes, if any, will form in the extra in. of length, and may be cut off in the lathe.

COATING WITH EMERY. — Give the iron a good coat of oil and white lead; when this gets hard and dry, apply a mixture of glue and emery.

COATING WITH QUICKSILVER.—Clean the iron first with hydrochloric acid; then immerse it in a dilute solution of sulphate of copper mixed with a little hydrochloric acid, when it will become covered with a layer of copper. It is then to be brought into a diluted solution of mercurial sublimate mixed with a few drops of hydrochloric acid. The article will become covered with a layer of mercury, which cannot be removed even by rubbing. This is a protection from rust.

CUTTERS FOR BOILER-PLATES AND SIMILAR WORK.—Cutters are steel bits, held in either a stock or bar, fitted and keyed to the same; by this means, cutters of various shapes and sizes may be made to fit one stock or bar, obviating the necessity of having a multiplicity of these tools. Of cutter-stocks, which are usually employed to cut out holes of comparatively large diameter, as in the case of tube-plates for boilers, there are two kinds, the easiest to be made being that shown in *Fig. 1*. *A* is the stock, through which runs a slot or key-way into which the cutter, B, fits, being locked by the key, *C*. *D* is

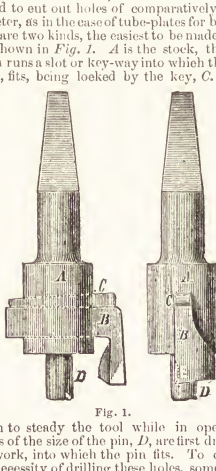


Fig. 1.

a pin to steady the tool while in operation. Holes of the size of the pin, *D*, are first drilled in the work, into which the pin fits. To obviate the necessity of drilling these holes, some modern drill-stocks have, in place of the pin, *D*, a conical-ended pin which acts as a centre, and which fits into a centre punch mark made in the centre of the hole to be cut in the work. Most of these devices are patented, and the principle upon which they act will be understood from *Fig. 2*. *A* being the stock to which the cutters *B B*, are bolted with 1 or more screws. *C* is a spiral spring working in a hole in the stock to receive it. Into the outer end of this hole fits, at a working

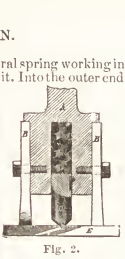

Fig. 2.

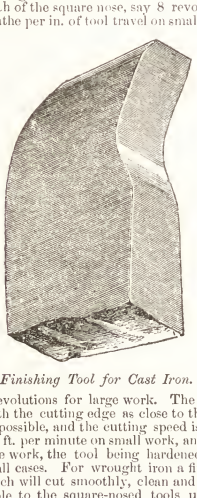
fit, the centre, *D*, which is prevented from being forced out (from the pressure of the spring, *C*), by the pin working in the recess. *E* is the plate to be cut out, from which the centre, *D*, is forced into the centre-punch mark in the plate by the spring, *C*, and serves as a guide to steady the cutters and cause them to revolve in a true circle, so that first drilling a hole, as required in the ene-employment of the form of stock shown in the first figure, is obviated.

ENAMELING CAST IRON. — To enamel cast iron and hollow-ware, use one of the following compositions: 1. Calcined flints, 6 parts; Cornish stone or composition, 2 parts; litharge, 9 parts; borax, 6 parts; argillaceous earth, 1 part; nitre, 1 part; calx of tin, 6 parts; purified potash, 1 part. — 2. Calcined flints, 8 parts; red lead, 8 parts; borax, 6 parts; calx of tin, 5 parts; nitre, 1 part. — 3. Potter's composition, 12 parts; borax, 8 parts; white lead, 10 parts; nitre, 2 parts; white marble, calcined, 1 part; purified potash, 2 parts; calx of tin, 5 parts.— 4. Calcined flints, 4 parts; potter's composition, 1 part; nitre, 2 parts; borax, 8 parts; white marble, calcined, 1 part; argillaceous earth, ½ part; calx of tin, 2 parts. Any one of the above which may be used, must be powdered, mixed and fused. The vitreous mass is to be ground when cold, sifted, and levigated with water; it is then made into a pap with water or gum water. This is brushed over the interior of the vessel, dried and fused with heat in a muffle. Clean the vessels before applying. — 5. Take powdered glass, 1 lb.; feldspar, 8 oz.; borax, 12 oz.; saltpetre, 4 oz.; oxide of zinc, 1 oz.; mix, and fuse in a crucible; then pour out on a slab to form thin cakes. When cold, the material is powdered and ground with water by millstones, when it is ready for use. The iron ware prepared to receive the composition, is covered with the enamel in a moist condition, and allowed to dry; then heated to dull redness in a muffle; the result is a vitrified, brilliant enamel, which adheres strongly to the metal. To obtain various colors the following chemicals may be added to the enamel body before the first melting: For blue, oxide of cobalt; green, carbonate of potassa and sulphur, a fine shade; red, ammoniated copper; black, peroxide of manganese; brown, oxide of iron; yellow, oxide of uranium; gray, 2 parts oxide of tin to 1 of manganese; and white, oxide of tin alone.

FACING CAST IRON.—For squaring or facing up cast iron surfaces, a round end tool is best. A rough chip should first be taken off, over the entire surface to be faced; then speed the lathe up, and, taking a light chip, enough to take out the first tool mark, run over the entire surface again. In turning up surfaces it is best to begin at the centre and feed out, as the tool cuts freer and will wear twice as long.

FACINGS FOR CASTINGS.—1. As a facing for loam castings use fire-sand, 3 parts; Whitehead sand, 1 part; mix.—2. For pipes and small cylinders, use No. 1, or fine sand, facing with plumbago. Albany or Waterford sand is excellent for fine castings; or, use 1 part sea coal to 8 or 10 Albany sand; 1 part to 5 will do for heavy castings.—3. To insure smooth castings, mix with the green foundry sand 1-20 part tar.

FINISHING TOOLS.—Cast iron may be finished true and smoothly by a tool having a broader cutting and scraping surface than is applicable to any other metal; the tool shown in the illustration is therefore used, setting it so that its square nose is placed parallel with the work, and feeding it with a feed almost as coarse as the width of the square nose, say 8 revolutions of the lathe per in. of tool travel on small work,



Finishing Tool for Cast Iron.

and 3 revolutions for large work. The tool is held with the cutting edge as close to the tool-post as possible, and the cutting speed is about 25 to 30 ft. per minute on small work, and 18 ft. on large work, the tool being hardened right out in all cases. For wrought iron a finishing tool which will cut smoothly, clean and true is preferable to the square-nosed tools used for finishing iron, since such tools do not turn wrought iron true, but follow the texture of the metal, cutting deepest in the softer parts, especially when their edges become in the least dull. This tool should be held with the cutting edge as close in to the tool-post or clamp as it can be with a quick speed and fine feed, soapy water being applied to the work. It may be used for taking light roughing cuts on small work, and is an excellent tool upon work so slight as to be liable to spring, for which the cutting point should not be much rounded. Ground keen, it will answer for copper work, the cutting speed being great; at least fourfold that given below, which is for finishing cuts on wrought or cast iron.

Size of Work, Inches Diameter.	Cutting Speed, Feet per Minute.	Feed.
1 and less	38	30
1 to 2	30	25
2 " 5	25	20
5 " 12	23	20
12 " 20	20	16
20 and over	18	14

Finishing Tool for Wrought Iron or Steel.

This tool should be hardened right out; and if used upon cast iron, it should have less keenness upon the top face; the plane of the top face should be ground more nearly to the same plane as the top face of the body of the tool. For use upon steel, the top face must be ground more nearly horizontal, a rule which applies to all tools used upon wrought iron. It should be placed in the lathe so that its cutting edge stands above the horizontal centre line of work.

GALVANIZING.—Cleanse the articles in a chaffing mill, which consists of a barrel revolving on its axis, containing sand; when the sand is removed, take them out and heat one by one, plunging while hot in a liquid composed as follows: 10 lbs. hydrochloric acid and sufficient sheet zinc to make a saturated solution. In making this solution, when the evolution of gas has ceased, add muriate or sulphate of ammonia, 1 lb., and let it stand till dissolved. The castings should be so hot that when dipped in this solution and removed they will quickly dry, leaving the surface crystallized like frost-work. Next plunge them while hot, but dry, in a bath of melted zinc, previously skimming the oxide on the surface away, and throwing thereon a small amount of powdered sal ammoniac. If the articles are small, inclose them in a wrought iron basket on a pole, and lower them into the metal. When this is done, shake off the superfluous metal, and cast them into a vessel of water to prevent them adhering when the zinc solidifies.

HARDENING CAST IRON.—1. Salt, 2 lbs.; saltpetre, ½ lb.; roche alum, ½ lb.; ammonia, 4 oz.; salts of tartar, 4 oz. Pulverize all together, and incorporate thoroughly. Use by powdering all over the iron while hot, then plunging in cold water. — 2. To 1 pk. salt add 1 pt. oil of vitriol, and ½ lb. saltpetre, dissolved in 10 gals. water; mix well. Heat the iron to a cherry red and dip it therein; this will harden cast iron to an unusual degree.

JAPANNING CASTINGS. — Clean them well from the sand; then dip them in or paint them over with good boiled linseed oil; when moderately dry heat them in an oven to a temperature that will turn the oil black without burning. The stove should not be too hot, but the heat gradually raised to avoid blistering; the slower the change in the oil is effected the better the result. The castings, if smooth at first, will receive a fine black and polished surface.

KEYS AND KEY-WAYS. — To insure an easy entrance, apply oil to the key-way and enter the key, marking where it binds, avoiding extreme tightness at the sides, and securing the lock by a proper taper at the rate of about ⅛ in. to the ft. of length. To ease hardened key-ways and slots, use a strip of copper as a file on the surface of the metal, together with emery and oil. To plane a key way in a shaft, drill a hole the size of the way the depth you wish to plane; then plane the key-way narrower than the intended size; this is done with a square point tool; afterwards finish with a tool of desired size; this insures a neater finish, than the use of one tool only. To insure true cutting in adjusting a tool for cutting a key-way, test each side of it by a square set on the planer bed, to see that it is perpendicular. To plane a T shaped slot or way, plane to desired depth with a square point tool, then plane the upper part of the way to proper width. Now plane the bottom part of the way with 2 tools, each being bent to a different angle, one to the right and the other to the left. Shallow ways may be cut out, the upper width and proper depth, then finished with one tool shaped the desired form of the way. Powerful tools should be used in planing large ways in order to avoid breaking, and should cut easily on each of the 3 sides. Use a sheet iron gauge and plane the way to conform to it. To plane a gibe rest or slide, plane it all over, omitting the slide, on both sides; then set the planer head at an angle of 30°, and finish the slide with a taper point tool. In planing thin cast iron surfaces, it is necessary, in order to prevent springing owing to the expansion of the scale, to plane over a cut on each side previous to finishing either. To close a quadrant or link that has sprung or opened in hardening, clamp with bolts and plates, placing the die in the slot to support any part which does not require to be closed. To open the slot of a quadrant or link that has closed in being hardened, take 2 keys having an equal amount of taper upon them, and place them together so that their outside edges are parallel. Insert them in that part of the slot requiring to be opened, and holding a hammer against the head of one key on one side of the link, drive in the other key with a hammer on the other side of the link. After the key is driven as far in as the judgment suggests, measure the width of the slot, so that, if the operation was not performed to a sufficient extent on the first attempt, the operator may judge how much to essay at the second, and so on. To prevent a slot link or quadrant from altering its shape in the process of hardening, fit into the slot, at various parts along its length, pieces of iron of the same diameter as the die intended to work in the slot, and in quenching the quadrant, immerse it endwise and vertically.

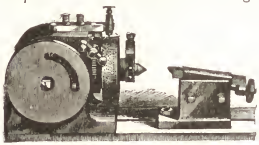
MALLEABLE IRON CASTINGS.—2 oz. fluoric acid, 1 oz. nitric acid, 1 oz. saltpetre, to 10 lbs. metal. When the metal is melted, add the solution. It can be made in a crucible in a brass furnace. When the patterns are cast off, the castings want keeping at red heat for 3 or 4 days in iron boxes in a furnace. For the purpose of casting, pig of a fine quality is needed, and great care is used in preparing the molds, so that there may be no imperfection in casting. The latter, after cooling, is hard and brittle, and it is to remove this and give it the character of malleable iron that the special process is required. The casting is now placed in hermetically sealed pots or boxes, surrounded by powdered ore, and subjected for several days to intense heat, which, by cementation, gradually softens it and renders it malleable to the core, when it may be bent into any shape. The annealing process takes about 10 days. Thus a pot made up on Tuesday is got up to a white heat about Friday, and this heat is maintained for some 24 hours or more, according to the size or thickness of the article annealed. The fire is then allowed to die down, and when the mass is cool the castings are found to be thoroughly annealed and malleable.

MENDING BROKEN IRON.—Zinc dissolved in mercury; mix well; then take the pieces of iron to be joined and sprinkle; stick the 2 pieces together, and keep it pressed close till dry.

MENDING CRACKED VESSELS.—Drill a hole at each extreme end of the crack, to prevent its further extension; plug rivet the holes with copper, and with fine iron filings saturated with urine caulk the crack; 4 parts pulverized clay and 1 part iron filings made into a paste with boiling linseed oil, and applied hot, is a good cement for the same purpose.

MILLING MACHINE. — A milling machine bears the same relation to iron working machines that a molding machine does to wood working machines. In both the work is reduced to shape by rotary cutters, so that the most complex shapes can be made, and even the tools to accomplish this purpose made by the machine itself. These machines can be operated by a cheaper class of labor than any other producing the same work. For finishing nuts and heads of bolts and set screws, the saving of files would, in many shops, more than pay the interest on the cost of a machine. The mills for plain work are cheaply made and extremely durable. By using a proper grinding machine, the mills are ground as readily as a lathe or planer tool. For fluting taps or reamers its superiority over a planer is obvious; the milling tool, if of prop-

er shape, removes all the metal at one cut, and accomplishes the result without disturbing the



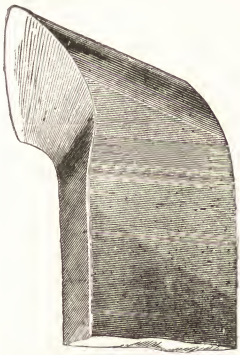
Universal Head.

grain of the steel at the cutting edges of the tap or reamer; while the planer jumps from thread to thread, tearing the corners and straining the steel, so that much filing has to be done in finishing. For cutting key-seats there can be no substitute for the milling machine; the metal is removed at one cut, and of exactly the right width and depth; and 100 to 1,000 may be cut with one cutter, and each one be a duplicate. The illustration represents the "universal head." By the aid of this valuable adjunct, spurs and bevel gears can be cut, and work milled at any angle or position. It takes in work 18 inches long.

PATTERNS, For Cast Iron.—These should be made smooth, then slightly warmed and waxed over with best beeswax.

POLISHING.—1. To polish bar iron and steel, take an ordinary bar of malleable iron; remove the oxide from its surface with diluted sulphuric acid, after which wash the bar in an alkaline solution, then cover it entirely with oil or petroleum. The bar is then ready for the process. A muffle furnace is so prepared that a nearly uniform heat can be maintained within it, and in this the bar is placed. Care must be taken that too great a heat is not imparted to it. When the bar approaches a red heat just perceptible, the proper degree has been attained. The bar is then removed and passed through the finishing rolls 5 or 6 times, when it will be found to have a dark polished surface and the appearance of Russian sheet iron. — 2. A good polish for iron or steel rotating in the lathe, is made of fine emery and oil, which is applied by lead or wood grinders screwed together. 3 good oils for lubrication are olive, sperm and neat's foot. — 3. To make iron take a bright polish like steel, pulverize and dissolve in 1 qt. hot water the following: Blue vitriol, 1 oz.; borax, 1 oz.; prussiate of potash, 1 oz.; charcoal, 1 oz.; salt, ½ pt.; then add 1 gal. linseed oil; mix well; bring iron or steel to the proper heat, and cool in the solution.

ROUGHING TOOL.—The illustration represents the best form of tool for roughing out wrought iron, or for removing a large mass of that metal in the lathe or planing machine. When used on large work it should be tempered to a light straw color, which will leave it strong enough to stand without breaking the heavy strain due to the cut. It must be held firmly and with the cutting edge as close to the tool-post as it can be. The following are its rates of cutting speed and feed; the speed meaning the length of shaving it cuts off, and the feed implying the revolutions of the lathe to feed the tool an in. along its cut.



Roughing Tool for Wrought Iron.

Size of Work, Inches Diameter.	Cutting Speed, Feet per Minute.	Feed.
1 and less	35	.25
1 to 2	25	.20
2 " 5	20	.20
5 " 12	18	.15
12 " 20	16	.12
20 and over	15	.12

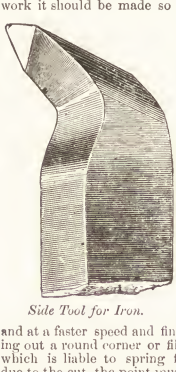
For work of 5 in. diameter and all sizes below, the tool should be made as hard as fire and water will make it, and not tempered. For work of a larger size it should be tempered to a light straw color. This tool, with the top face ground more nearly horizontal, is excellent for steel, and the harder the metal to be cut, the more nearly horizontal the top face must be. It should be placed, for lathe work, so that the cutting edge stands a little above the horizontal centre line of the work.

SCALING CAST IRON. — Vitriol, 1 part; water, 2 parts; mix, and lay on the diluted vitriol with a cloth in the form of a brush, enough to wet the surface well; after 8 or 10 hours wash off the water, when the scaly surface will be removed.

SIDE TOOLS.—The illustration represents a side tool for wrought iron, employed for squaring the ends of work held between the lathe centres, and in other cases where there is not sufficient room to admit a stouter tool. The cutting edge should be made more keen for wrought than for cast iron. In forging it, the hammering edgewise should be performed first, nor should any hammering be done to it edgewise after the steel has lost its redness. It should, for light duty and for all finishing purposes be hardened right out, and for heavy duty be tempered to a straw color. If this tool is employed

for heavy duty on a slotting machine, taking a cut, say, 2½ in. deep and ⅛ in. thick, it must be lowered to a brownish purple, and used at a cutting speed of about 10 ft. per minute, and be ground so that the cutting edge first strikes the cut near the body of the tool, and not at the point end. For ordinary work, it is best used with a comparatively fine feed and quick speed, since it is not sufficiently strong when made very hard to stand heavy duty.—*Side Tool for Wrought Iron, Cast Iron or Steel.* The illustration below represents the most superior side tool for use on wrought or cast iron or steel, the only difference being that it requires to be less keen for the latter than the former. It is used to cut side-faces and to take out round or square corners. For small work it should be made so that it will cut at the point, and not on both edges at one time when used in a square corner. For heavy work it may be made more round-nosed, and allowed to cut all round the curve; it will, in either shape, work well as a roughing out or finishing tool, only requiring to be ground keener to fit it for finishing purposes (which should be, on wrought iron, performed with soapy water applied to the work), and at a faster speed and finer feed. For taking out a round corner or fillet in slight work, which is liable to spring from the pressure due to the cut, the point must be rounded very little, the curve being made by operating both the straight and cross feeds of the lathe. This tool is made right or left-handed by bending it in the required direction, the illustration showing a left-hand tool. It should be made as hard as fire and water will make it, and used at the following speeds and feeds:

Side Tool for Squaring Ends of Wrought Iron Work.



Side Tool for Iron.

Diameter of Work, in Inches.	Speed, in Feet, per Minute.	Feed.
1 and less	30	.30
1 to 2	25	.25
2 " 5	22	.20
5 " 12	20	.20

When it is employed for roughing-out purposes, these speeds may be slightly diminished and the feeds increased.

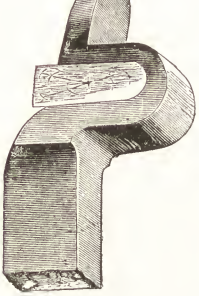
SLEIGH BELLS.—In making sleigh bells, the iron ball is put inside a sand core just the shape of the inside of the bell. Then a mold is made of the shape of the outside of the bell. This sand core, with the jingle inside, is placed in the mold of the outside, and the melted metal poured in, which fills up the space between the core and the mold. The hot metal burns the core so that it can be all shaken out, leaving the ball within the shell. Ball valves, swivel joints, and many other articles are cast in the same manner.

SOFTENING.—Either of the following methods will make iron or steel soft: 1. Anoint it all over with tallow, temper it in a gentle charcoal fire, and let it cool. — 2. Take a little clay, cover the iron with it, temper it in a charcoal fire. — 3. When the iron or steel is red hot, strew hellebore on it. — 4. Quench the iron or steel in the juice or water of common beans. — 5. To soften bright work without damaging the finish, place the pieces in an iron box, and fill in the interstices with iron turnings; close the box, lute the cracks with fire-clay, and heat to a red, allowing the box to cool slowly. It is a good plan to let the furnace fires go out and leave the box in the furnace to cool. — 6. To soften for drilling, heat cast iron to a cherry red; let it lie level in the fire; then, with a pair of cold tongs, put on a small piece of brimstone (the same to be smaller than the hole you wish to drill); this softens the iron entirely through. Let it lie in the furnace until it is somewhat cool, when it is ready to drill.

SOLDERING IRON PIPES TO LEAD. — File the end of the iron pipe bright; see that the soldering iron is well tinned; have the iron ready, and as hot as it will bear; wet the part to be tinned with spirits of salt that has had as much zinc chippings put in it as it will dissolve, then apply the solder with the iron. The pipe will have to be very hot with the iron before it will tin; it would be well to tin the iron pipe with a little block tin or pewter. If any difficulty is found in tinning the iron pipe, sprinkle a little powdered sal ammoniac over it when hot; this done, the lead pipe must be widened out so as to form a lip all round the iron pipe, and soldered, round with fine solder, keeping the heat of the iron on the iron pipe rather than the lead; or a plumber's joint may be made by pouring on a quantity of plumbers' solder from a ladle, and wiping off superfluous solder with a greased cloth.

SPRING TOOL.—The spring-tool is adapted to finishing sweeps, curves, or round or other corners, and answers for any metal. The face is given an upward incline to make it keen for wrought iron or steel. For brass work, this face should be made horizontally level; or, if the cutting stands with its cutting edge far out from the tool-post, it may be inclined downward to make it cut smoothly. The piece of wood driven in the bend is to correct any tendency of the tool to spring away from the hard parts of the metal. The spring-tool does not turn as true

as is desirable; still the smoothness of its finish makes it a desirable tool. It should have its face filed smoothly before being hardened, and should



Spring Tool.

not be ground on that face. The application of the oilstone improves it for finishing. It should be tempered to a brown color on the face and left soft around the bend.

STRAIGHTENING WIRE.—The most simple straightener is 3 steel pins driven into a plank. If the pins are properly arranged and the wire drawn over the first, under the second, and over the third, it may be straightened enough for some purposes.

TUBE MANUFACTURE.—In the present method of manufacturing the patent welded tube, the end of the skelp is bent to the circular form; its entire length raised to the welding heat in an appropriate furnace, and as it leaves the furnace at the point of fusion, it is dragged by the chain of a draw-bench, after the manner of wire, though a pair of tongs with 2 bell-shaped jaws opened at the time of introducing the end of a skelp, which is welded without the agency of a mandrel. By this arrangement wrought iron tubes may be made from the diameter of 6 in. internally and about $\frac{1}{8}$ to $\frac{3}{8}$ in. thick, to as small as $\frac{1}{4}$ in. diameter and 1-10 bore. Sometimes the tubes are made one upon the other when great thickness is required; but those stout pipes, and those larger than 3 in. are seldom required.

WEIGHTS OF BAR-IRON.—If a bar of iron be thicker than contained in the table, add together the weight of two numbers, or treble the weight of one number, Wanted, the weight of 1 ft. of bar iron, 4 in. broad and $2\frac{1}{2}$ in. thick. Opposite 4 and under 1 is 13.364, which, doubled, is 26.728; add the weight of $\frac{1}{4}$ (3.341), and it equals 30.069 lbs.

WELDING. — To obtain a good weld, the following points should be observed: The scarf should be larger than the finished side to permit the weld to be well drawn out after welding. The joint surface of the scarf should be rounding, so that, when the 2 pieces are placed together to weld, there will be no air inclosed between them. They should be heated in a clear fire of bright coal. Thick pieces should not be heated too quick, or the interior metal will not be brought to the required temperature. They should be frequently turned in the fire and made as hot as possible without burning them. They should be withdrawn occasionally and sprinkled with sand to exclude air, prevent oxidation and cool the outer surface and thin edges, so that the interior metal and thicker parts will have time to heat through. When the pieces are placed upon the anvil to weld they should be cleaned with a wire brush or a piece of wood made ragged; the scarfs placed to overlap each other, and receive light and quick blows at first, and heavier ones afterward. As soon as the pieces are joined, the blows should be directed so as to close the edges of the scarf, so that the joint of the weld shall not show. It requires precision and quickness to do a nice job. The metal must be handled while hot enough to join well under the hammer's blows and the work finished during that time.

WELDING POWDERS.—1. Mix borax with 1-10 of sal ammoniac; fuse, and pour it on an iron plate. When cold, pulverize and mix it with an equal weight of quicklime; sprinkle it on iron heated to redness, and replace it in the fire. It may be welded below the usual heat.—2. To 1 lb. borax add red oxide of iron, $1\frac{1}{2}$ oz.; melt together in a crucible; let the mixture become cool and then pulverize it, after which it is ready for use.—3. 4 parts iron turnings; 3 parts borax; 2 parts borate of iron; 1 part water.—4. For welding iron and steel a composition has been patented in Europe, of iron fillings, 40 parts, borax, 20 parts, balsam of copaiba or some other resinous oil, 2 parts, and sal-ammoniac, 3 parts; mixed, heated and pulverized. The process of welding proceeds as usual, the surfaces being powdered with the composition and then brought to a cherry red heat, at which the powder melts, when the portions to be united are taken from the fire and joined.

LEAD.

BURNING.—There is required a cast-iron furnace, 2 or 3 ladles, and some molding sand. Burning is resorted to where soldering will not stand, such as retorts in bleaching works where acid destroys soldering. Cast a sheet of lead of the proper thickness, and cut the proper size, turn it up round like a hoop, bringing the ends together to form a joint on the outside, and firmly tack them together on the inside; roll it over to see that the joint is close on the outside, and paste stout brown paper 4 in. wide over the length of the joint. The sand must be tempered and have no wet lumps in it; make a level bed with the sand 5 or 6 in. thick; roll the hoop on the sand so that the joint will come under; be careful not to shift it backwards or forwards, but ram up under both sides. Have a strip of wood longer than the joint, $\frac{3}{4}$ in. thick, to form the runner with; place it along on edge on the top of the joint; now place on sand on both sides and ram it together until there is a good bank on the top of the work; smooth off with a trowel; cut it down towards the strip, so as to form a funnel, leaving 2 in. of the strip buried; draw out the strip endways; be careful not to break the sand, leaving one end stopped up; the other end stop up about 1 in. high. At this end make a pond for the overflow to run into. Have the metal red hot, be careful that the runner is free from loose sand; shake a little pounded rosin along in the runner; have a trying stick that can be drawn easily along the runner. Now begin to pour the metal, holding the ladle 1 ft. above the runner to give weight and force to the burning metal. When the joint is burnt through, try

it by drawing the trying stick along in the runner; if it feels smooth along the bottom it is burned; if not, pour some more until it is; stop up the end where the metal has been running off, and fill up about 2 in. high, and watch for shrinkage; have some hot metal ready to fill up as it shrinks in cooling, or else the joint will not be round. When set, remove it from the sand, and cut off the runner with a mallet and chisel, finishing off with a piece of cardwire; the paper on the outside will strip off, leaving it clean. Proceed with burning in the bottom, having a hole or pit in the floor deep enough for the hoop to go down level with the floor; place it in level. Fill up with sand inside and out rather slack. When filled within 4 or 5 in. from the top, ram it down for the other part quite hard on the outside, leaving the sand rather higher than the edge; then with a straight-edge scrape off level with the edge of the lead. Now with a scribe take out the sand the thickness of the required bottom; plane the sand off with a trowel, and the work will turn out clean. The sand on the outside being up level with the edge, smooth off and cut a bay all round to take the overflow; shake pounded rosin round the edge; having the metal red hot, begin to pour quickly the hot metal along the edge until it is properly burned down; when burned deep enough, pour a few ladlefuls over the bottom, to get it in a fluid state; then with the edge of the trowel clean off the dross, leaving a bright surface; let it remain to set. If well burned it will be perfectly solid.

CORROSION, To Prevent.—Pass a strong solution of sulphide of potassium and sodium through the inside of the pipe at a temperature of 212°, and allow it to remain 10 or 15 minutes. It converts the inside of the pipe into an insoluble sulphide of lead and prevents corrosion.

DETECTING IN TIN.—To determine the presence of lead in tin, touch with nitric acid and heat, when the acid evaporates. If lead be contained, stannic acid and nitrate of lead remain. Iodide of potassium is then applied, forming yellow iodide of lead; while the stannic acid is white. The yellow stain indicates lead, the white tin.

EXPLOSIONS, To Prevent.—A piece of resin, the size of the end of a man's thumb, dissolved in the ladle of melted lead designed to be poured around a wet joint, will prevent explosion.

MIXING WITH ZINC.— When working a mixture of lead and zinc for casting, mix the fused metals together; stir until cooled nearly to solidification; then cast. If the casting is large, so that the alloy does not chill at once, the metals are apt to separate somewhat unless the mold can be reversed or moved about.

PLATES, To Join. — The joints of lead plates may be made as follows: The edges are brought together, hammered down into a channel cut out of wood, and secured with tacks. The hollow is then scraped clean, rubbed over with candle-grease, and a stream of hot lead poured into it, and the surface afterwards smoothed with a red hot plumbers' iron.

PIPE. — Lead pipe is made by forcing lead, while heated to a plastic state, over an annular mandrel or die to form the core, by means of the use of powerful hydraulic pressure.

PIPES, To Join. — Widen out the end of one pipe with a taper wood rift, and scrape clean inside; scrape the end of the other pipe outside a little tapered, and insert it in the former; then solder it with common lead solder; or, if it requires to be strong, rub a little tallow over, and cover the joint with a ball of melted lead, holding a cloth (2 or 3 plies of greased bedtick) on the under side; and smoothing over with it and the plumber's iron.

PIPES, To Repair.—It frequently happens that lead pipes get cut or damaged when the water is running at a high pressure, causing trouble to make repairs, especially if the water cannot be turned off. In this case plug both ends of the pipeat the break and place a small pile of broken ice and salt around them. In a few minutes the water in the pipe will freeze; next, withdraw the plugs and insert a new piece of pipe; solder perfectly, thaw the ice, and it will be all right.

SHOT.—The following is a short outline of the manufacture of shot in the ordinary shot tower: The lead is mixed with a certain proportion of a combination of mineral substances called "temper." The "temper" is fused with the lead, and gives the metal consistency to make it drop. If it were not for the "temper," the lead would be molded by the sieve, and form little pencils instead of round shot. When shot are to be made, the lead is poured into a pan perforated with holes corresponding to that size. The pellets come pouring down in a shower, and fall into a tank filled with water on the ground floor. In their descent of 200 ft. they become spheres, firm and dense. The shot must fall in water, for if they should strike any firm substance they would be knocked out of shape. To get the pellets dry after they have been in the "well," is most difficult. An elevator, with small buckets, carries the shot up as fast as they reach the bottom of the "well," and deposits them in a box 60 ft. above the first floor. The water drips from the buckets as they go up, and not much is poured into the receiver above, although it is intended to be a sort of dripping machine. From this receiver the shot run down a spout into a drying pan of sheet iron. The pan rests at an angle which permits the wet shot to roll slowly down to the chamber below, and the pellets become dry as they pass over the warm sheet iron.

SULPHIDE OF LEAD, To Remove. — Allow a not concentrated solution of sulphide of sodium to flow through the pipes for 10 or 15 minutes. The inside of the pipes will then appear as if coated with a gray glaze, and water may then be passed through them free of lead.

UNITING TO IRON.—For uniting thin sheet lead to cast iron the sulphur sulphide composition, called Spence metal, is said to answer very well. In a capacious iron vessel with a loose cover melt by heat 2 lbs. sulphur. Heat to bright redness in a sand crucible 3 lbs. coarsely powdered sulphide of iron. Remove the crucible and melted sulphur out of doors; quickly, but cautiously, transfer the contents of the former to the latter; cover, and smother the flames by covering the pot with moist earth or sand. When cold remelt the contents of the pot at a

gentle heat, and after having packed the base of the joint, lead on the outside, with oakum, pour in the previously melted composition.

NICKEL.

CLEANING.—To clean nickel-plated brass or iron which has become coated with burned grease and dirt, without injuring the surface, boil in strong solution of potash or soda; rinse in water, and rub first with moistened and then with dry rouge or chalk.

PLATING.—To deposite nickel without the aid of a battery, proceed as follows: To a solution of from 5 to 10 per cent. chloride of zinc, pure as possible, add enough sulphate of nickel to produce a strong green color, and bring to a boil in a porcelain vessel. The piece to be plated, must be bright and free from grease, then introduced so that it touches the vessel as little as possible. Boiling is continued 30 to 60 minutes, water being added to replace that evaporated. During ebullition nickel is precipitated in the form of a white coating. The boiling may be continued for hours without increasing the thickness of the coating. As soon as the object appears to be plated, it is washed in water containing a little chalk in suspension, and dried. The chloride of zinc and sulphate of nickel must be free from metals precipitable by iron. If, during precipitation, the liquid becomes colorless, sulphate of nickel should be added. The spent liquid may be used again by exposing it to the air until the iron is precipitated, filtering and adding the zinc and nickel salts as above. Cobalt also may be deposited the same way.

PLATING, Imitation.—Coarse rasped granulated zinc is boiled for some time in a mixture of 3 parts by weight of sal ammoniac, and 10 of water, the object immersed and stirred with a zinc rod. The deposit is silvery, and resists mechanical action as well as a coating of nickel. The process can be recommended for goods meant for a second coating of some other metal, since any other is easily deposited on zinc.

—o—

STEEL.

REMARKS.—In working steel for tools, care should be taken to hammer all sides alike; for if one side is hammered more than another, it will cause it to spring in hardening. When being hammered, steel should be heated as hot as it will stand, until finishing, and then be hammered until almost black hot, as it sets the grain finer, and gives the tool a better edge. Heating the steel so hot while hammering makes the steel tougher when hardened, and softer when annealed; while, if it were worked at a low red heat, the continued percussive shocks of the hammer would so harden it as to make it impossible to anneal it, and at the same time render it brittle when hardened. A good, soft heat is safe to use, if steel be immediately worked. Good steel will endure more pounding than iron. If steel be left long in the fire it will lose its nature and grain, and assume that of cast iron. Steel should never be kept hot longer than necessary for the work to be done. It is entirely mercurial under the action of heat, and an injurious internal strain is created whenever two or more parts of the same piece are subjected to different temperatures. When steel has been subjected to heat not absolutely uniform over the whole mass, careful annealing should be resorted to. As the change of volume, due to a varied degree of heat, increases rapidly with the quantity of carbon present, high steel is more liable to dangerous internal strains than low steel, and great care should be exercised. Hot steel should be put in a dry place of even temperature while cooling. A wet place in the floor might cause serious injury.

ANNEALING.—1. For a small quantity, heat the steel to a cherry red in a charcoal fire; then bury the steel in sawdust, in an iron box, covering the sawdust with the ashes, and let it remain till cold. For a larger quantity, and when it requires to be soft, pack the steel with cast iron (lathe or planer) chips in an iron box as follows: In the bottom of the box have a layer of ¾ in. in depth of chips; put in a layer of steel, then more chips to fill spaces between the steel, and also the ½ or ¾ in. space between the

sides of the box and the steel, then more steel; and lastly, from 1 to 2 in. chips in depth, well rammed down, on top of steel. Heat to and keep at a red heat for from 2 to 4 hours. Let the box remain quietly in its place till cold. —2. Heat the steel to a red heat, and let it lie a few minutes, until nearly black hot; then throw it into soap-suds; steel in this way may be annealed softer than by putting it into the ashes of the forge.

BLUE BLACK COATING.—To produce a blue black coating on polished steel, dip it into melted nitrate of potash. The bloom improves its appearance and seems to wear well.

BLUING.—To blue small articles, put in a box or on an iron plate a small quantity of charcoal ashes; place over the fire and heat slowly. Place the articles in the ashes, and as the same get heated, take them out occasionally to see how the color is. When the articles become blue, let them remain until they become white again, then remove them, and let them cool. Then return the articles to the ashes again to become reheated, and you will have the second blue. The second blue will wear a length of time; to get a good color, polish the article free from grease of any kind; and in no case must you dip the article in oil or water before or after the bluing, as it injures the color. Give the articles a fine polish, after which lay them in a sheet-iron pan, with some slaked lime. Place the pan over any place where the heat can be regulated and pay attention until you have obtained the right color. If the steel be a good article, they will take on a vivid blue.

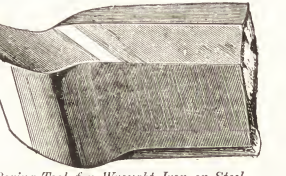
BLUING SCREWS. — To blue screws evenly, take an old watch barrel and drill as many holes into the head of it as you desire to blue screws. Fill it ¼ full of brass or iron-filings; put in the head, and fit a wire, long enough to bend over for a handle, into the arbor holes, head of the barrel up. Brighten the heads of the screws; set them, point down, into the holes drilled, and expose the bottom of the barrel to the lamp till the screws assume the color wished.

BLUING, To Remove. — Immerse in a pickle composed of equal parts muriatic acid and elixir vitriol. Rinse in pure water and dry in tissue paper.

BLUING WITHOUT HEAT. — Mix finely powdered Prussian blue with rather thin shellac varnish; gently heat the steel, and apply the varnish.

BORING GUN BARRELS.—Take a piece of rod, cast steel, ¼ in. smaller than the interior of the barrel, and a few in. longer; beat one end up something larger than the size of the bore; then turn or file it in the shape of an egg, leaving the swell or centreing part 1-20 in. larger than the bore. With a saw file cut longitudinal cuts, ⅛ in. apart, laying them the same angle as a rose bit countersink, taking care not to injure the periphery of the tools; harden and temper to straw color.

BORING-TOOL, For Wrought Iron or Steel. — The cutting end of this tool must not be bent, in forging, any further round than shown in the illustration; the strain placed upon the tool by the cut will be in a direction tending to revolve the tool in the tool-post, giving a tendency to spring away from its cut; and so stout a tool could not be got into the same size of hole. The degree of bend or angle of the centre-line of the bent end to the centre-line of the length of the body of the tool, causes the strain of the cut to be placed endwise of the tool, endeavoring to force it back into the tool-post, and thus places the strain in the direction in which the tool is best capable of withstanding it. The keenness and shape given to the top face of the tool make the cutting edge perform its duty on the front edge, which tends to place the strain endwise



Boring-Tool for Wrought Iron or Steel.

on the tool, operating by the strain on the top face of the tool (caused by its bending the shaving), to keep the tool to its cut by giving it an inclination to feed itself forward, relieving the feed-screw and nut of the slide-rest of a part of the duty of feeding. The cutting edge should not, even when the tool is newly forged, stand much above the horizontal plane of the top of body of the tool, otherwise so stout a tool cannot be got into a given size of hole. Boring-tools are apt to spring away as the cutting proceeds toward the back end of the hole, making the latter a taper, of which the back end has the smallest diameter, necessitating fine finishing cuts in order to make a parallel hole. If every means is taken to use as stout a tool as the size of the hole will admit, the boring-tool will bore a true and smooth hole. To prevent chattering or jarring when extending far out from the tool-post, or when it is very slight in body, it should have the top face depressed toward the cutting edge. When this tool is a stout one, the point may be ground more round, which will make it cut to finer finish.

BURNT, To Restore. — 1. 2 parts horn filings; 10 parts tallow; 1 part sal-ammoniac; 1 part pulverized charcoal; 1 part soda; pulverize the hard ingredients separately; mix all with the tallow; bring the burnt steel to a cherry red, and dip it in the mixture; when it gets cold it may be hardened in the usual manner. — 2. Burnt steel may be instantaneously restored by plunging it while hot in cold water, and hammering it with light strokes on the anvil, turning it so as to hammer all over it; again dipping in the cold water, and repeating the hammering as before.—3. Borax, 3 oz.; sal ammoniac, 8 oz.; prussiate of potash, 3 oz.; blue clay, 2 oz.; resin, ½ lb.; water, 1 gill; alcohol, 1 gill; put all on the fire, and simmer till it dries to a powder. The steel is to be heated, dipped in this powder, and afterwards hammered.—4. 1 oz.

bicarbonate potassa; ½ oz. copperas; fine salt, 3 oz.; and 3 lbs. sand; mix well, and sprinkle over the steel when hot.—5. To 4 lbs. fine white sand pulverized, add ½ lbs. sal ammoniac, ¼ lb. copperas, and ½ lb. resin, all pulverized; mix well. When the steel is hot, sprinkle, and let cool. This process will restore any burnt steel.

CLEANING. — 1. Unslaked lime is a capital thing to clean steel articles. If steel ear-rings, brooches, etc., are kept in powdered quick-lime they suffer little from rust. They should be cleaned when put away, to remove moisture that may have collected on them by handling. To clean swords, etc., rub them with powdered brick-dust and oil, rub dry with brick-dust, polish with crocus and leather.— 2. Cocoanut husks are better than waste and turpentine.

COLORING WIRE.—To color bright wire black or blue and perfectly smooth for use, take asphaltum, 3 oz.; boiled oil, 4 qts.; burnt umber, 8 oz.; mix by heat, and thin with turpentine (oil) before the mixture becomes cool; dip the wire in this (not too thick) and harden in a Japanner's oven at as high a heat as will bear without blistering.

CUTLERY. — There are 3 kinds of steel employed in manufacturing cutlery, common, shear and cast steel. All edge tools which require to be tenacious without being very hard, are made of shear steel. The best scissors, razors, penknives, etc., are made from cast steel, which takes a fine polish; common steel is only used in making cheap articles. In making good table-knives, shear steel and cast steel are preferred. In the ordinary method of making knives, the blades are cut out of a sheet of steel, and the backs, shoulders and tangs of wrought iron, are attached to the steel blades by welding. The knife is then ground to proper shape, and the blade polished and hardened. Fork manufacture is a distinct branch, and manufacturers of knives buy their forks from the fork makers ready to be put into handles. In making table knives, 2 men are employed; maker and striker. Penknives were forged by a single hand, with hammer and anvil. The grinding and polishing of cutlery are performed by machinery; the business of the grinders is divided into grinding, glazing and polishing. Those articles which require temper are ground on wet stones. Glazing gives a lustre to cutlery; it is performed with a glazier, consisting of a circular piece of wood, covered with leather, or an alloy of lead and tin; it is fixed on an axis like a grindstone. Polishing is last, and is performed on a similar piece of wood covered with buff leather. Only articles of cast steel which have been hardened and tempered are subjected to this operation. Butcher knives are forged out until near the proper thickness, care being taken not to heat too high. To temper they are heated to a cherry red; it is plunged plumb into water, and when taken out it is straight; taken from the water and passed through flame until it is a little hot; then rubbed on both sides with a candle; passed again through the flames until the tallow disappears, as though it soaked into the steel; then taken out and the operation of rubbing the candle repeated as before; again placed in the flames, and there kept until it starts into a blaze with a snap; an even heat over the entire length and width of the tool is necessary; then the operation three times of rubbing the tallow and placing it in the flames is repeated; lastly the tallow is rubbed over it again, pushed into the dust of the forge, and let remain until cold.

CUTTERS AND REAMERS, To Prevent Cracking when Hardening. — Drill a small hole from the side to meet the large one at its enclosed termination.

CUTTING. — It is known that soft iron discs running at a circumferential speed of 12,000 ft. per minute will cut hard steel; but 5,000 ft. per minute will not cut iron—a fact which is taken advantage of in rolling mills to cut large bars and beams exact lengths. To fit up the periphery of a disc of soft iron to cut steel, cut it with heavy shears as nearly round as practicable, after which hold a piece of grindstone or sandstone so that the edge of the disc will strike it when in motion, Use a stone and file, and then attempt to cut steel a little, thus working off the periphery until it is as smooth and true as it can be made. Then the cold and soft iron when in high motion will literally melt the hard and cold steel and drive the melted metal from the bar in a stream of white-hot sissing and burning steel dust.

DIES, To Temper.—In using dies for cutting sheet metal, both dies should be tempered. To temper large curved dies for cutting iron and steel plate, fill the holes with fire-clay and wire to keep it in place. Heat evenly and slowly in a furnace. Lift the dies from the furnace with the face vertical and plunge vertically into water heated to about 50° and containing about ½ lb. salt per gal. Hold them still at the bottom of the water until cooled.

DRILLING.—1. Make the drill oval in form, instead of in the usual shape, and temper as hard as it will bear without crumbling. Roughen the surface of the object into which you desire to drill with a little diluted nitric acid. Start the drill, and, to prevent it from becoming heated, use spirits turpentine instead of oil. Some use kerosene with gum camphor dissolved in it instead. When the drill begins to run smooth in consequence of the bottom of the holes becoming burnished, clean out the turpentine or kerosene and roughen with acid; then proceed. —2. Cover the steel with melted beeswax; when cooled and cold, make a hole in the wax with a fine-pointed needle the size you require; put a drop of nitric acid upon it; after an hour rinse off, and apply again; it will gradually eat through.

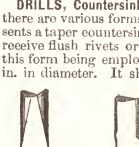
DRILLING, Spiral Tool For.—These are annealed, and turned to 1-50 of an in. larger than the finished size; then heated again, and annealed in a vertical position, among lime, ashes, or soap-suds; the shank is then turned to fit a proper collet socket, and afterwards the point may be turned to desired dimensions and shaped. The spiral grooves are cut on a machine containing a spindle, which imparts the double movement of sliding and revolving slowly while the spirals are being cut. The spindle contains a screw, on which a chuck to hold the drill is

adjusted. The drill being inserted in the chuck, proceed to elevate the sliding block beneath the

Spiral Drill.

drill, so that it will touch it, adjusting it so as not to raise it too high; then insert a cutter, which should be ½ the diameter of drill, and groove your drills, which should, for a drill 1 in. in dianeter, be cut 1 to the in., and down to within a 32nd of the centre; for ½ in. drills, cut the grooves 1½ to the in., down to within a 64th of the centre; for ¼ in. drills, cut the grooves 2 to the in., down to within a 100th of the centre, computing as you would in cutting a screw in a lathe, the index plate giving you the two starting points at which to commence the work.

DRILLS, Countersink-Pin. — Of these tools there are various forms. The illustration represents a taper countersink employed for holes to receive flush rivets or countersunk head-bolts, this form being employed for holes above 5-16 in. in diameter. It should be made, tempered and used as pin-drills. In tempering these tools, or any others having a pin or projection to serve as a guide in a hole, the tool must be hardened right out from the end of the pin to about ⅜ in. above the cutting edges. Then lower the temper of the metal (most at and near the cutting edges), leaving the pin of a light straw color.



Countersink-Pin Drill.

DRILLS, Slot, For Key-ways. — For drilling out oblong holes, such as key-ways, or for cutting out recesses required to receive short feathers in shafts, the drill known as the slotting-drill is brought into requisition. No. 1 is the form in which this tool was employed in the early days of its introduction; it is the stronger form of the two, and will make the heaviest cut. The objection to it is that, in cutting out deep slots, it is apt to drill out of true, the hole gradually running to one side. The method of using these drills is to move the work back and forth, in a chuck provided for the purpose, the drill remaining stationary. If these tools were used as common drills, they would cut holes of the form shown in No. 2.

Slot Drills.

EXPANSION.—It is important to remember that if a piece of cast steel be made red hot and quenched in cold water it will become longer, but if the same operation be performed upon a piece of wrought iron it will become shorter.

FILES, To Soften.—Cover them with oil and hold them over the fire until the oil blazes; as soon as the flame runs all over the file, plunge it into the water; or put them in a moderate hot oven for ½ hour if large files, but if small the first plan is the best.

FINISHING.—For hollow finishing the following wheels are required: A mahogany wheel for rough glazing; a mahogany wheel for smooth glazing; a lead wheel, or lap. For flat finishing: A buff wheel, each, for rough, for smooth, and for finishing; lastly, a polisher. To make glaze wheels: Get spindles, and point them on each end; then get a block of beech and wedge it on the steel at one end with iron wedges, and turn it for the pulley for the band to run on. Take 2 pieces of flat mahogany and glue and screw them together, so that the grain of one piece crosses the other, to prevent warping. Let it get dry, and wedge on the spindle and turn true. The lead wheel is made the same way, but wider, and a groove turned in the edge. Then the wheel is put into sand, and a ring of lead run round the edge; it is then turned true. To make buff wheels, proceed as with the glaze; but pine or deal will do as well as mahogany, only leave it about double the width of the glaze, which is about ½ in. wide by 12 or 14 in. across. The buff wheels are covered with glue, and then the leather is tacked on with tacks driven in about ½ way, so that they may be easily drawn out again. The leather is then turned true. The polisher is made the same way, but the size of the polisher must be a little less than that of the other wheels, say about 1 in. The buff wheels are dressed by laying on a fine, thin coat of clear glue, and rolling them round—No. 1, in superfine corn emery; No. 2, in smooth emery; No. 3, by making a cake of equal parts of mutton suet, beeswax, and washed emery; then it is held on the wheel while it goes round. The glaze wheels are dressed while using, by mixing a little of the emery with oil, and putting it on the wheel with a stick or the finger. The leather of the polisher is not covered with glue, but dressed with a mixture of crocus and water, not oil. Care must be taken to keep each wheel and substance to themselves, and the work carefully wiped after each operation. Cleanliness must be studied in using the polisher, as the slightest grease getting on it stops the polishing.

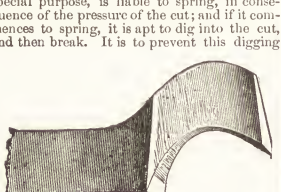
HARDENING AXLETREES.—The method used in the manufacture of axletrees is to use wrought iron and weld 2 pieces of steel into the lower side, where they rest upon the wheels and sustain the load. The work is heated in an open forge fire, in the ordinary way, and when it is removed, a mixture, principally prussiate of potash, is laid upon the steel; the axletree is immediately immersed in water, and additional water allowed to fall upon it from a cistern. The steel is considered to be materially hardened and the iron around the same is partially hard-

ened. One good way to chill axletree boxes is to mold from wooden patterns on sand, and cast them upon an iron core, which has the effect of making them hard. To form the annular recess for oil, a ring of sand, made in appropriate core-box, is slipped upon the iron mandrel, and is left behind when the latter is driven out of the casting.

HARDENING TAPS.—In hardening a tap, use a clear, bright fire; a fire of charcoal is best; heat to a cherry red, and holding it by the upper end immerse the entire thread-part first, keeping it stationary until the smooth part attains a dark red color; then gradually dip the whole tool, holding it stationary until cold. Brighten the fluted parts and proceed to temper the tool by heating a piece of iron pipe to a bright red; remove it from the fire, place it in a vertical position, and insert the tap in the centre of the tube (not touching any part of it) with the threaded part outside. The interior of the tube should be twice the diameter of the tool, and the length but ½. Revolve the tap in the hot pipe until the smooth part is warm enough to slightly pain the hand, keeping it in motion endways, back and forth through the pipe and turning it until the thread is tinted to a deep brown, and the rest of the tool to a brown purple; modify irregularity in the color by holding the light colored parts longer in the tube, or if any parts color too deep, cool off with a little oil. The squares of taps should be tempered to a deep blue color.

MARKING TOOLS. — To mark tools, warm them slightly, and rub the steel with wax, or hard tallow, till a film gathers. Scratch your name on the wax, cutting through to the steel. A little nitric acid poured on the marking will quickly eat out the letters. Wipe acid and wax off with a hot, soft rag, and the letters will be found etched.

PARTING TOOL.—The parting tool is applicable to cutting grooves or for parting. The cutting point is made thicker than the metal, vertically and horizontally, behind it, so that the latter shall clear and not grind against the sides of the groove. This tool, if made thin to suit a special purpose, is liable to spring, in consequence of the pressure of the cut; and if it commences to spring, it is apt to dig into the cut, and then break. It is to prevent this digging



Parting Tool for Iron or Steel.

in that the top face of the cutting part of the tool is placed below the top face of the body of the tool, which may be dispensed with when the cutting edge is held close in to the tool-post, and the grooving is not required to be deep. When these requirements exist, the form illustrated is indispensable to rapid and reliable duty, whether the tool be used in a lathe or a planing-machine, the cutting edge of the tool being kept at about the horizontal centre of lathe-work, by packing-pieces placed beneath the body of the tool. If the width of the tool is not less than 3-16 in., and does not require to cut a groove deeper than ⅜ in. it should be hardened right out; if these conditions are reversed, it should be tempered to a dark straw, and for weak tools even to a purple color, as lowering the temper increases the strength of tools. If the groove to be cut is sufficiently broad to cause the tool to spring, it is best to use a narrower one and cut it out in two separate cuts, moving the tool.

POLISHING.—Use bell-metal polishers for arbors, having first brought up the surface with oilstone dust and oil and soft steel polishers; for flat pieces use a piece of glass for the oil-stone dust, and a bell-metal block for the sharp red stuff, and a white metal block for the fine red stuff. The polishing stuff must be well mixed up and kept clean; the polishers and blocks must be filed to clean off the old stuff, and then rubbed with soft bread; put only a little red stuff on the block and keep working it until it is quite dry; the piece will then leave the block clean; use bread to clean off surplus red stuff before using the brush. If the piece is scratched, put on some more red stuff, which must not be too wet, and try again.

RAZOR PASTE.—1. Mix fine emery with fat and wax until of proper consistency, and then rub it well into the leather strap. Prepare the emery by pounding in a mortar the coarse kind, throwing it into a large jug of water and stirring well. When the large particles have sunk, pour off into a shallow plate, and let the water evaporate. This emery is better for engraving and other purposes than that prepared at the emery mills. — 2. The grit from a fine grindstone is efficient for a razor paste. — 3. Levigated oxide of tin, prepared putty powder, 1 oz.; powdered oxalic acid, ¼ oz.; powdered gum, 20 gr.; make into a stiff paste with water, and spread it thinly over the strap. This gives a fine edge to the razor, and its efficiency is increased by moistening it. — 4. Emery reduced to impalpable powder, 2 parts; spermaceti ointment, 1 part; mix and rub over the strap. — 5. Jewelers' rouge, black lead and suet, equal parts; mix.

SPIRAL SPRINGS.—Unless the circumstances of the case necessitate that the spring be put to its utmost tension, brass will do as well as steel, and better, providing the strain or the spring is well within its capacity. If the length or diameter of the spring is of no consequence, a brass spring will serve as well as a steel one, if the situation in which the spring is to be used renders a steel one liable to corrosion, thus destroying its temper. If the space in which the spring is to operate is confined so that the spring is made as small as possible, it is imperative that it be made of either spring or double-shear steel. For electrical purposes, brass-springs may be used, except where from derangement of the insulation the spring may be liable to become

heated and softened, and a brass-spring that has lost any of its temper thus is worthless. Cold rolled or drawn iron wire may be used to make springs in which their sizes are large in proportion to the duty required. The iron wire must have been cold rolled or drawn without being annealed to produce upon it a close-grained and clean surface, having a dull polish. Cast steel may be used for springs, but it is apt to break in cold weather. If the spring is to be of brass select a mandrel to run between the lathe centres, having upon it a spiral groove of the requisite pitch, but smaller than the diameter of the required finished spring, because the spring unwinds a little as soon as it is released from tension around the mandrel. The mandrel must be longer than the required length of spring to admit of the application of a lathe dog to drive it, allowing clearance between the end of the spiral groove and the dog. Near one end of the mandrel a small hole is drilled, there being sufficient space between the hole and the end of the mandrel to admit of a loose washer being placed thereon; the bore of this washer requires to be larger in diameter than the outside diameter of the spring, when wound upon the mandrel, and requires to be provided with a key-way and key. Now wind the spring as shown in *Fig. 1*, in which *A* represents the man-

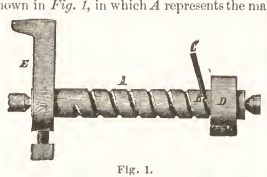


Fig. 1.

drel, *B* the small hole with the wire inserted, *C* the wire, *D* the loose washer and *E* the driver. While keeping a stiff tension on the wire by pulling it against the mandrel, start the lathe and wind the spring, closing it around the mandrel, if it does not wind closely, by tapping it with a hammer. When the spring is wound to the requisite distance slip the washer up and drive the key home, as shown in *Fig. 2*, and

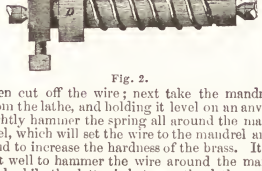

Fig. 2.

then cut off the wire; next take the mandrel from the lathe, and holding it level on an anvil, lightly hammer the spring all around the mandrel, which will set the wire to the mandrel and tend to increase the hardness of the brass. It is not well to hammer the wire around the mandrel while the latter is between the lathe centres, which would damage the centres and bend the mandrel. If the wire is too stiff to be held by the hand against the mandrel with sufficient force to cause it to bend closely round the mandrel, while the lathe is slowly revolving, and if the lathe is a self-acting one, put on the gearing necessary to cut a thread of the same pitch as the spring requires to be, and then fasten in the tool-post of the lathe a grooved piece of metal as shown in *Fig. 3*, *A* representing the mandrel,

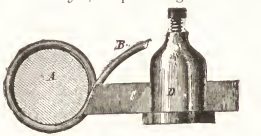

Fig. 3.

B the spring wire, *C* the piece of metal acting as a guide and also to bend the wire close to the tool-post of the lathe in which *C* is fastened. If the lathe is not a self-acting one and has a hand-slide rest, take the screw out from the straight feed of the rest and use the metal guide, allowing the groove to carry the wire along, the groove being as deep as $\frac{3}{8}$ of the diameter of the wire. Having wound the spring, place the washer in position, as shown in *Fig. 2*, and cut off the wire. If the wire is of iron or brass take it to an anvil and hammer it all over its circumference, beginning at one end and following along the wire with blows delivered not more than $\frac{1}{4}$ in. apart. If the wire is of steel take the mandrel with the spring wound on it and fastened by the washer as shown in *Fig. 2*, and heat to a low red heat so as to set the spring to the mandrel; the hammering process only tends to close the grain of the metal and add to its elasticity without having much effect towards closing the spring around the mandrel except the spring be made of small wire. To harden spiral springs made of light wire, or those long in proportion to their diameter, they should be placed on a mandrel fitting easily to their bore, and should be heated while on the mandrel, otherwise they are apt to become bent and the coils disarranged during heating. The fire should be clear. A good plan is to make a clear fire around a piece of gas-pipe, and insert the spring in the gas-pipe, which will facilitate getting an even heat. The spring being heated to a cherry red must be plunged endways into clear water having the chill taken off, and held until cold. If on taking the spring from the water its surface is found to be black and not mottled, it is not sufficiently hardened, which may arise from the poor quality of the steel, or because it was not sufficiently heated. Steel of good quality is sufficiently heated when hot enough to just form scales when taken from the fire. If it is found difficult to harden the steel (known from the fact that well-hardened steel is white when taken from the water), the water should have sufficient salt dissolved in it to make a strong brine, and the hardening process repeated. The whiteness of the surface is a better test of the degree of hard-

ness of the metal than testing the metal with a file. The most reliable method of tempering an ordinary spring is to fry it in oil, heated sufficiently to cause it to blaze. The spring should be occasionally (before being finally removed from the oil) taken from and re-dipped in the blazing oil 2 or 3 times; after the blazing takes place freely all over the spring, and has on the last remove from the tank burned out at any one part of the spring, the latter should be dipped in lukewarm water and left to cool off. This diminishes the danger of any one part of the spring being lowered more than another, and the heating takes place sufficiently slow so that the metal gets heated through. The thicker the spring the longer it should blaze, it being dipped frequently and removed; to insure that every part of the spring shall be heated, and to give the steel time to get heated equally inside and out. It is well in blazing a spring to reverse it in the pan, and to revolve it so that the blazing oil shall not run down along one side of the spring. A good oil composition for blazing is made in the following proportions: 1 gallon spermaceti oil; 1 lb. rendered beef-suet; 1 gill neat's foot oil; ½ lb. resin. The pan or tank in which this composition is used should have a closely-fitting cover, so that the blaze may be put out when the tempering is finished.

SPIRAL SPRINGS, To Repair. — Take a piece of flat metal, about 1-16 in. in thickness, and cut it in the shape of a parallelogram, the length ½ in. greater than the diameter of the broken spring, the width equal to 4 of its coils; bore 2 holes on each side exactly the diameter of the spring apart, and sufficiently large to admit the spring wire; make, with a round file, a slight groove opposite each hole. Screw the broken ends of the spring into these holes from opposite sides, and the job will be complete, and at as trifling a cost.

SPRINGS, Reducing Elasticity of. — A well-tempered bar-spring will lose much of its elastic strength by filing off a very thin scale from the surface.

TAPS. — In making taps, have immediately under the square head, a place the accurate size of the outside of the thread, so that there will be no trouble in getting dimensions of the thread wherever an odd number of flutes exist. Every tap should be the accurate size of the bottom of the thread to within about ½ in. of the square head; shaping it this way, when a strain comes in the work, it will twist instead of breaking. The threads on V taps ought to be cut with a tool exactly three square (unless the thread is rounded on the top), and then finished with a sharp tool without polishing, as this produces a glaze on the metal while being tapped. In making a tap for common machine screws or for bolts, measure with calipers the lower part of the thread of one of the screws, and proceed to cut your tap at the bottom of the thread the size of the measurement. Strong taps for square thread screws ought to be cut ½ the depth of their pitch; so if the thread is 5 to the in. cut 1-10 in. deep. The threads being 5 to the in. leaves a space between the threads of 1-10 in., and the thread being 1-10 in depth and 1-10 wide, would make the thread square. In square threads required for wear, the cut should be ⅔ the depth of their pitch. In finishing taps and reamers, the forgings are got out in the usual way, left to anneal, centred, and turned sufficient to remove the scale. Then anneal again, and turn down to within 1-32 in., or less, of finishing size. Anneal once more, and finish in the lathe. If not sprung in turning, the tap or reamer will come out all right when hardened. This has been tested successfully with taps from ½ in. in diameter and 3 in. long up to those of 1 in. in diameter and 2 ft. long.

TEMPERING or HARDENING.—When cast steel, heated to redness, is plunged into water until its temperature is reduced to that of water, it is hardened. The degree of hardness will depend upon the quality of steel, the temperature to which it was heated, and upon the temperature of the water in which it was cooled. Reheat the steel and a softening process will accompany the increasing temperature, until upon becoming red-hot it will assume its normal softness, and if allowed to cool in the atmosphere the effects of the first hardening will be removed. If after the steel is hardened, it is polished on one of its surfaces and slowly reheated, that surface will assume various colors, beginning with a pale yellow and ending in a blue with a green tinge, each color appearing when the steel has attained a definite degree of temperature; by the appearance of the colors the temperature of the steel is known, as also to what extent the re-softening has progressed. This fact is taken advantage of to obtain in steel any required degree of hardness less than that of the absolute hardness obtained by hardening, and is termed tempering. The temperatures at which these respective colors appear are as follows:

Very pale yellow	430° Fahr.
Straw yellow	460° "
Brown yellow	500° "
Light purple	530° "
Dark purple	550° "
Clear blue	570° "
Pale blue	610° "
Blue tinged with green	630° "

As the steel becomes heated it expands; if one part becomes hotter than another, it expands more, and the form of the steel undergoes the change necessary to accommodate this local expansion, and this alteration of shape becomes permanent. In work finished and fitted, this is of great consideration, and, in the case of tools, it assumes sufficient importance to entirely destroy their value. If an article has a thin side, it requires to be so manipulated in the fire that such side shall not become heated in advance of the rest of the body of the metal, or it will become locally distorted; though there exists little difference in the temperature of the various parts, the more solid parts are too strong to give way to permit the expansion; hence the latter is accommodated at the expense of form of the weakest part of the article. It does not follow that the part having the smallest sectional area is the weakest when in the fire, unless it is as hot as the rest of the body. It is well to consider

the size of an article in heating it, because by heating steel in the open fire it becomes decarbonized; and the smaller the article in sectional area the more rapidly this takes place. In large bodies the decarbonization due to a single heating is not sufficient to have much significance; but if a tool requires frequent renewal by forging, the constant reheating will impair its value; and in any event it is an advantage to maintain the quality of the steel at its maximum. To prevent decarbonization, for ordinary work charcoal instead of coal is used; and where hardening is not done continuously it is a good practice. Charcoal should be used for forging as well as for hardening. Green coal should never be used for heating the steel for hardening; because, while the steel is being well forged its quality is maintained, but afterward the deterioration due to heating is more rapid. A coke suitable for heating to harden should be made and kept on hand. The whole value of the temper will be destroyed if the steel is made too hot and becomes what is known as burned. Steel may have its quality impaired by over-heating without giving evidence of being burned. If a piece of hardened tool steel shows a crystalline formation under fracture, it has most probably been burned; but if the fracture appears dull and even, it has not. When a tool requires to be tempered at and near the cutting edge only, and it is desirable to leave the other parts soft, the tempering is performed by heating the steel for some little distance back from the cutting edge, and immersing the cutting edge ½ of the rest of the steel, which is heated to as high a degree as a red-heat in the water until it is cold; then withdraw the tool and brighten the surface which has been immersed, by rubbing it with soft stone or a piece of coarse emery cloth, the object being to cause the colors to show themselves so as to indicate the state of the steel. The instant this operation has been performed the brightened surface should be brushed by switching the finger rapidly over it; for unless this is done the colors appearing will be false, in which case the steel after quenching will be of one color, and, if then wiped, will appear of a different hue. A piece of waste or other material may be used in place of the hand. The heat of that part of the tool which has not been immersed will become imparted to that part which was hardened, and by the deepening of the colors denote the point of time at which it is necessary to again immerse the tool and quench it altogether cold. The cooling requires as much skill as the heating, to prevent warping and cracking and to straighten the article as much as possible during the cooling process, and should be performed with a view to prevent the contraction of the metal from warping the weaker parts; to aid this, those parts are made a little hotter than the more solid parts, the extra heat required to be extracted compensating for the diminution of sectional area from which the heat must be extracted. The distance a tool requires to be heated and dipped at the first dipping, and the distance to which the transient dipping should be performed, vary with the substance of the metal; no rule can be given more than to say that the heating should be to a red-heat for a distance of about 3 times the diameter of the steel. A great deal of the cracking occurring during hardening arises from improper dipping. Cylindrical or square bar pieces should be dipped endwise. Blades should be dipped vertically and edgewise, with the length of the blade horizontal. The steel should be lowered vertically in the water, and for hardening should be held quite still near the bottom of the tank. The thick side should enter the water first. The water should be heated to prevent liability to crack; a difference of 40° or 50° makes no practical difference in the effectiveness of the quenching water, providing its temperature is at least 20° above the freezing point. Soft water is better for tempering than hard water, and the water improves by age, providing it is kept clean. Water at 200° will harden, and reduce the liability of the work to crack, but it should contain 1 lb. salt per gal. in solution.

TEMPERING ANVIL FACES. — Fill a vessel with water; place bricks or other support for the anvil, so that the top of the anvil will be about 1 in. below the top of the vessel; have a hogshead or tank filled with water and elevated 5 to 10 ft. above, with a pipe from it arranged to discharge water on the face of the anvil. When the anvil is properly heated lower it into the first tank face up, then open the pipe from the higher tank to discharge the water on the face of the anvil till it is cooled. When you open this pipe, keep away from the anvil, for if any portion of the steel is not welded, it may crack and fly off.

TEMPERING LIQUIDS. — 1. Water, 3 gals.; soda, 2 oz.; saltpetre, 2 oz.; prussic acid, 1 oz., or oil vitriol, 2 oz.—2 Water, 6 gals.; saltpetre, sal ammoniac and alum, of each, 4 oz., and draw no temper.—3. Water, 4 gals.; saltpetre and alum, of each, 4 oz.; sal ammoniac, pulverized, 1 oz.; salt, 3 lbs.; heat to a cherry red and plunge in, drawing no temper.—4. Water, 4 gals.; saltpetre, 1 oz.; pulverized borax, 1 oz.; pulverized sal ammoniac, 1 oz.; white vitriol, 2 oz.; salt, 3 pts.; do not hammer too cold nor heat too high. —5. Water, 4 gals.; salt, 2 teacupfuls; saltpetre, 2 oz.; pulverized alum, 4 teaspoonfuls; never heat over a cherry red, nor draw any temper.—6. Water, 2 gals.; add corrosive sublimate, 1½ oz.; common salt, 2 handfuls; when dissolved it is ready for use. The first gives toughness to the steel, while the latter gives the hardness, causing the water to adhere to the steel, which otherwise would be repelled by the heat.—7. (*For Mill Picks.*) Water, 3 gals.; spts. of nitre, 3 oz.; hartshorn, 3 oz.; white vitriol, 3 oz.; alum, 3 oz.; sal ammoniac, 3 oz.; salt, 6 oz., with 2 handfuls parings of horses' hoofs. Heat the steel to a cherry red. A large jug of this preparation should be kept corked tight, in order to retain its strength. Use soft water in all these tempering liquids.—8. Resin, 2 lbs.; tallow, 2 lbs.; black pitch, 1 lb.; melt together, and dip in the steel when hot. — 9. Wheat, flour, salt and water, using, say, 2 teaspoonfuls water, ½ teaspoonful flour, and 1 of salt. Heat the steel to be hardened enough to coat it with the paste by im-

mersing it in the composition, after which heat to a cherry red and plunge into soft water. If properly done, the steel will come out a beautiful white.

TEMPERING, Metallic Bath for.— Use a black lead or cast iron crucible and place the same, filled with lead, on a fire made of coal or charcoal, and surrounded by a metallic or brick wall, level with the top of the crucible, but at a sufficient distance (5 or 6 in.) from it, to receive the fuel to maintain the fire, to keep the lead in a melted state. Let the crucible rest on iron bars, and leave apertures to admit air to the fire. The articles, slightly greased, are immersed in the melted lead (kept at a red heat) by means of tongs, 2 or 3 pairs being generally used, in order that 1 or 2 pieces may be heated while the other is undergoing manipulation by hardening. Keep the lead covered with charcoal dust or cinders. This plan is used by cutlers and file manufacturers for giving the proper degree of heat in tempering their wares, and the process is highly valued.

TEMPERING RAZORS AND CUTLERY.—Razors and penknives are frequently hardened without the removal of the scale arising from the foregoing; this practice cannot be too much deprecated. The blades are heated in a coke or charcoal fire, and dipped in the water obliquely. In tempering razors, they are laid on their backs upon a clean fire, about ½ doz. together, and removed one at a time when the edges come down to a pale straw color. Should the backs accidentally get heated beyond the straw color, the blades are cooled in water. Pen blades are tempered 1 or 2 doz. at a time, on a plate of iron or copper, 12 in. long, 3 or 4 in. wide, and ⅛ in. thick. The blades are arranged close together on their backs and lean at an angle against each other. As they come down to the temper, they are picked out with small pliers and thrown into water if necessary; other blades are then thrust forward from the cooler parts of the plate to take their place. Axes, adzes, cold chisels, and other edge-tools, in which the total bulk is considerable compared with the part to be hardened, are partially dipped; afterwards let down by the heat of the remainder of the tool; and when the color indicative of the temper is attained, entirely quenched. With the view of removing the loose scales, some rub the objects hastily in dry salt before plunging them in the water, in order to give them a cleaner and brighter face.

TEMPERING SAWS. — A late improvement consists in tempering and straightening the saws at one operation. This is done by heating the saws to the proper degree, and then pressing them with a sudden and powerful stroke between two surfaces of cold iron. A drop press is employed for the purpose. The mechanism is quite simple and inexpensive. Its use effects an important economy in the manufacture of nearly all kinds of saws, and also improves their quality.

TEMPERING STEEL SPRINGS.—1. The steel should be that called "spring" for the large work; for small work, "double shear." After hardening in water as usual, or, as some prefer, in oil, dry the spring over the fire to get rid of its moisture, then smear it over with tallow or oil, hold it over the flame of the smith's forge, passing it to and fro, so that the whole of it will be equally heated, holding it there until the oil or tallow takes fire. Take the article out of the fire and let it burn a short time, then blow it out. The process may be repeated 2 or 3 times if the operator fancies that any portion of the spring has not been raised to the proper temperature. — 2. For tempering cast steel trap springs, all that is necessary is to heat them in the dark, just so that you can see that they are red; then cool them in lukewarm water. You can observe a lower degree of heat in the dark than by daylight, and the low heat and warm water give the desired temper.

TEMPERING VERY HARD.—Heat to a cherry red and plunge in mercury. As the vapor of mercury is deleterious it should be used with great care.

TESTING.—Good steel, with a white heat, will fall to pieces; with bright red heat will crumble under the hammer; with middling heat may be drawn to a needle point. To test hardening qualities, draw under a low heat to a gradually tapered square point and plunge into cold water; if the broken point will scratch glass, the quality is good. To test tenacity, a hardened piece will be driven into cast iron by a hardened hammer; if poor, will crumble; excellence will be in proportion to tenacity in a hard state. Soft steel of good quality gives a curved line fracture and uniform gray texture. Tool steel should be a dull silver color, uniform, and free from sparkling qualities. Aquafortis applied to the surface of steel, produces a black spot; on iron, the metal remains clean. The slightest vein of iron or steel can be detected this way.

TWIST DRILLS, To Forge. — It is necessary to forge a flat blade similar to a flat drill, and then twist this blade into the resemblance required; then, with a light hammer and careful blows, hammer the twisted edges so that they will be thicker than the central line of the tool. This will give greater strength and a better drill, and, to cut well, the central line or cutting point must be made quite thin. Be careful to get the same twist at the point of the drill as upon the body of the drill. The inexperienced often leave the point straight like a flat drill.

WEIGHT. — The following table gives the weight of 1 ft. in length of flat steel:

Size.	Thick ¼ In.	Thick ⅜ In.	Thick ½ In.	Thick ⅝ In.	Size.	Thick ¼ In.	Thick ⅜ In.	Thick ½ In.	Thick ⅝ In.
In.	Lbs.	Lbs.	Lbs.	Lbs.	In.	Lbs.	Lbs.	Lbs.	Lbs.
1	.852	1.27	1.70	2.13	2½	2.13	3.20	4.26	5.32
1⅛	.958	1.43	1.91	2.39	2⅝	2.34	3.51	4.98	5.85
1¼	1.06	1.59	2.13	2.66	3	2.55	3.83	5.11	6.39
1⅜	1.17	1.75	2.34	2.92	3½	2.77	4.15	5.53	6.92
1½	1.27	1.91	2.55	3.19	3½	2.98	4.47	5.98	7.45
1⅝	1.49	2.23	2.98	3.72	3⅝	3.19	4.79	6.38	7.98
2	1.70	2.55	3.40	4.26	4	3.40	5.10	6.80	8.52
2⅛	1.91	2.87	3.83	4.79					

WELDING CAST STEEL. — 1. Heat the steel,

carefully watching it, in a gentle fire, kept free from dirt, and use the following composition: 10 parts borax and 1 sal ammoniac; grind them together roughly and then fuse them in a metal pot over a clear fire; continue the heat until all spume has disappeared from the surface. When the liquid appears clear, pour out to cool and concrete; then grind to fine powder. This may be done by running it into a strong iron vessel; or, if in a smith's shop, into a hole in the swage; put in a piston, and use the sledge-hammer. Care should be exercised in hammering the splice. To use this composition, the steel to be welded is raised to a heat of a bright yellow; then dipped into the welding powder and again placed in the fire until it attains the same heat as before; it is then ready to be placed under the hammer. — 2. Borax, 10 parts; sal ammoniac, 2 parts; flour of sulphur, 1 part; grind or pound them roughly together; fuse them in a metal pot over a clear fire, continuing the heat until all scum has disappeared. Use as No. 1. — 3. Rock saltpetre, ¼ lb.; dissolve in ¼ lb. oil vitriol, and add it to 1 gal. water. After scarfing the steel, get it hot, and quench in the preparation. Then weld the same as a piece of iron, hammering it very quick with light blows. It answers the purpose better than borax; cork it in a bottle and it will keep for years. — 4. Borax, 15 parts; sal ammoniac, 2 parts; cyanide of potassium, 2 parts; dissolve all in water, and evaporate the water at a low temperature. — 5. Copperas, 2 oz.; saltpetre, 1 oz.; common salt, 6 oz.; black oxide of manganese, 1 oz.; prussiate of potash, 1 oz.; all pulverized and mixed with 3 lbs. nice welding sand, and use the same as sand. High-tempered steel can be welded with this at a lower heat than is required for borax. — 6. Pulverized borax, any quantity; slightly cover it with dragon's blood; heat the steel red hot; shake the borax over it; place it again in the fire till the borax smokes on the steel, which will be much below the ordinary welding heat, and then hammer it.

WELDING POWDERS. — Iron filings, 1,000 parts; borax, 500 parts; balsam of copaiva or other resinous oil, 50 parts; sal ammoniac, 75 parts; mix together, heat and pulverize. Weld at cherry red. — 2. Borax, 15 parts; sal ammoniac, 2 parts; cyanide of potassium, 2 parts; dissolved in water, and the water afterward evaporated at a low temperature. — 3. Borax, 1½ lbs.; sal ammoniac, ¾ lb.; prussiate of potassa, ¼ lb.; rosin, 1 oz.; alcohol and water, each 4 oz.; pulverize the borax, etc., fine, and slowly boil all the ingredients together in an iron kettle until the mass becomes a thick paste. Use as borax.

—o—

TIN.

CLEANING.—Acids should never be employed to clean tinware; they attack the metal and remove it from the iron. Rub first with rottenstone and sweet oil; then finish with whitening and a piece of soft leather. Pure tin should be cleaned in the same manner. In a dry atmosphere, tinware will remain bright for a long period, but is soon tarnished in moist air.

CRYSTALLINE SURFACE FOR FOIL.—Chloride tin, 2 parts; hot water, 4 parts; muriatic acid, 2 parts; nitric acid, 1 part; mix. The tin foil is dipped in this mixture and left until crystals appear. Small crystals are obtained when the solution is applied cold—large when used hot. The most beautiful specimens of this kind are produced with varnishes colored with the aniline dyes.

CRYSTALLIZATION. — A platinum capsule is covered with an outer coating of paraffine or wax, leaving the bottom uncovered. This capsule is set upon a plate of amalgamated zinc in a porcelain capsule. The platinum is then filled completely full of a dilute and not too acid solution of chloride of tin, while the porcelain is filled with water acidulated with 1-20 of hydrochloric acid, so that its surface comes in contact with the surface of the liquid in the platinum. A feeble electric current is set up, which reduces the salt of tin. The crystals after a few days are well developed; they are washed with water and dried quickly.

CRYSTALLIZED PLATE.—A variegated primrose appearance, produced upon the surface of tin-plate, by applying to it in a heated state some dilute nitro-muriatic acid for a few seconds, then washing it with water, drying, and coating it with lacquer. The figures are more or less diversified, according to the degree of heat, and relative dilution of the acid. Place the tin-plate, slightly heated, over a tub of water, and rub its surface with a sponge dipped in a liquor composed of 4 parts aquafortis, and 2 parts distilled water, holding 1 part of common salt or sal-ammoniac in solution. When the crystalline spangles are thoroughly brought out, the plate must be immersed in water, washed with a feather or a little cotton, taking care not to rub off the film of tin that forms the feathering, then dried with a low heat, and coated with a lacquer varnish; otherwise it loses its lustre. If the whole surface is not plunged at once in cold water, but is partially cooled by sprinkling water on it, the crystallization will be finely variegated with large and small figures. Similar results will be obtained by blowing cold air through a pipe on the tinned surface, while it is just passing from the fused to the solid state. In the above recipe, the aquafortis can be replaced by sulphuric acid.

CUTTINGS. — Cuttings of tin are roasted until the surface is covered with a brittle brownish crust, of which the upper surface is oxide of tin and the lower one magnetic oxide of iron. The scrap is then agitated in rubbing cylinders until the oxide is deposited as dust. The tin is easily obtained from the combined oxide, and has the advantage of being free from sulphur and arsenic; or the oxide of iron may be obtained by simply treating with sulphuric acid. The iron scrap can be made into good wrought

iron, or melted, but, having regard to its state of subdivision, its most advantageous use is for depositing copper.

DROSS.—Work necessitating the melting of large quantities of pig tin, causes much dross. This consists of a mixture of tin oxide and finely divided metal, usually calcined and sold in this condition as putty powder. The metal can be recovered from the dross by mixing the latter with $\frac{1}{3}$ its weight of fine coke or charcoal, and heating in large luted crucibles gradually to redness. The reduced metal remaining with the unconsumed carbon may be separated by pounding the mass and sifting out the carbonaceous matters, and remelting the granular metal at a low heat.

MENDING.—Take a small bottle, and fill it full of muriatic acid, after which put in all the chippings of zinc it will dissolve; then put in this mixture about the size of a pea of sal ammoniac, and fill up the bottle with water. Wet the place to be mended with this mixture; place a piece of zinc over the hole, and then apply the flame of a lamp or candle below it, which melts the solder on the tin, and causes the zinc to fasten.

RECOVERING.—Melt the metal, and while hot sprinkle sulphur over it; stir it up for a short time; this burns the other metals out of the tin, which may then be used for any purpose desired.

REMOVING FROM COPPER.—Immerse the articles in a solution of blue vitriol.

REMOVING FROM PLATES.—Boil the scraptin with soda lye in presence of litharge.

SEPARATING FROM LEAD.—If the lead and tin are in solution, precipitate the former by sulphuric acid, and the latter with sulphureted hydrogen gas. In an alloy the lead will dissolve in nitric acid, leaving the tin as an oxide.

SHEET METAL WORK, To Cut Out.—The illustrations given under this head show the shapes that dies should be made in order to stamp out plate to form the articles named. The table in the next column gives the sizes of tinware of different kinds.

Right-Angle Elbow.—Strike out the length and depth of the elbow, as shown in the illustration, drawing semicircles at the end. Then draw 7 horizontal lines as shown extending along the small figures. Divide the circumference or length into 16 equal parts by drawing 15 vertical lines as shown. Now draw a line from h to k and d; directly opposite draw another line along the letters $v\ r\ p$; for the top sweep set the

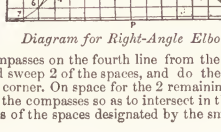

Diagram for Right-Angle Elbow.

compasses on the fourth line from the bottom, and sweep 2 of the spaces, and do the same at the corner. On space for the 2 remaining sweeps set the compasses so as to intersect in the 3 corners of the spaces designated by the small cross marks. The drawing does not include seams or laps; these must be added.

10 " 20 " 42 "	100 " 40 " 98 "
15 " 30 " 42 "	

This includes all the laps, seams, etc., which will be found sufficiently correct for all practical purposes.

Elbows for Gutters for Eaves of Roofs.—Eave-troughs possess a form resembling the undivided $\frac{1}{2}$ of a pipe divided lengthwise; therefore, by describing $\frac{1}{2}$ of one end of the elbow of a pipe whose size is equal to the size of the gutter at the top, you have the requisite pattern; extra allowance to be made for bead.

Common Flaring Vessels.—Form a right-angled parallelogram, H K D V, H K; H K, equal to the circumference of the wide end of the diagram, and N P equal to its circumference at the indicated points, K D being the elevation; draw the right lines H N R and K P R; from R as a basis lay out arcs from H to K and N P, calculating proper allowance for backs. For a cone form a parallelogram as in the diagram;

the space from H to K equivalent to the diameter of the cone; K to D equal to the elevation; next draw lines from H and K to the centre of the line D V, and from this as a base or centre, describe a segment of a circle from H to K.

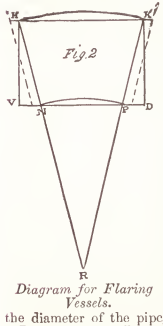

Diagram for Flaring Vessels.

Circular Elbow.—Lay out 2 curved lines, F I and G D, to suit the length of elbow; the space from F to G equivalent to the intended diameter of the pipe; lay off the circles, F D, G I, into as many divisions as desired; construct the parallelogram, *Fig. 4*, the length equivalent to the diameter of the pipe, the width equal to C B in *Fig. 3*; lay off a segment of a circle equal in diameter to the pipe, touching the point H; divide the segment into any desired number of equal divisions; draw lines across the dots parallel to V V; open the compasses $1\frac{1}{4}$ times the diameter of the pipe, and describe the line from V to the intersection of the lines, P P and R R; draw curvilinear lines to the crossings of the

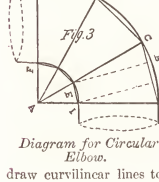

Diagram for Circular Elbow.

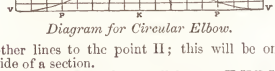

Diagram for Circular Elbow.

other lines to the point H; this will be one side of a section.

Ovals. — Make the parallelogram H K D V; H K equal to the long and K D to the short diameter; divide it into 4 equal parts by drawing the lines, P R and N N; mark the point L $\frac{1}{4}$ the distance from N to O; then describe the arcs, I S I, I S I, and from the line N N describe the segment I N I. To describe an egg-shaped oval with ends of unequal magnitude, construct the frustrum of a cone that will embrace the oval and proceed as in *Fig.*

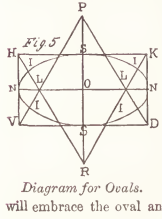

Diagram for Ovals.

5. For an oval flaring vessel in 4 sub-divisions, find the circumference of the arcs I S I and I N I for the bottom of the pieces; form a parallelogram the length of which shall be equal to the circumference of the top of either division, and operate as in *Fig. 2*. The same allowance must be accorded for flare on the side parts as on the ends, allowing for burrs and locks.

Heart.—Draw a straight line, H D K, equal to the breadth of the heart; lay off the segments H D and D K; then with the dividers extended from H to K, describe the arcs H to K and K V.

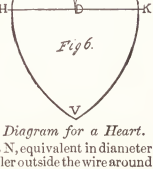

Diagram for a Heart.

Oval Wash Boiler Covers.—Describe the line V R equal in extension to half the length of the boiler; from the central point D, lay off the circle M R N, equivalent in diameter to the breadth of the boiler outside the wire around the rim; describe the line, H K, so as to cross the line V R, as shown in illustration; make V S $\frac{3}{8}$ in. high, more or less, as desired for the pitch of the cover; place the corner of the measuring square on the line H K, laying the flat part touching the point S; then describe the lines H N, H S, S K and K M; this, with the allowances for locks and edges, completes the cover.

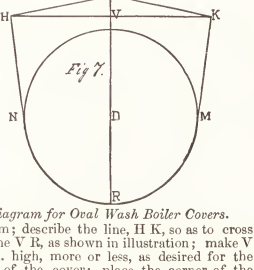

Diagram for Oval Wash Boiler Covers.

Can Tops and Bevel Covers. — Describe the circle K K K for the size of the can or cover; allow the space between K K K and D D D for edges to the same, and the distance between V V V and D D D for the flare; span the dividers from R to K and divide the curvilinear line V V V into 6 equal divisions; cut out the pieces, H H H, D D D, leaving edges

for locks parallel to H V. For the opening in the can head or top, describe the curvilinear line H H H, equal in magnitude to the circumference of the opening.

Patterns for the Envelope of a Cone. — Lay off the lines H N and K N; the space from H to K corresponding to the circumference of the cone at the largest end; H N equal to the sloping height; from N as a basis describe the segments H K, D D, V V, R R and P P; each of the parts between these segments will compose a section of the covering if allowance be made for the laps. To lay off the frustrum of a cone, see *Fig. 2.*

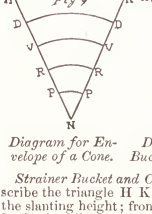

Diagram for Envelope of a Cone.

Diagram for Strainer Bucket and Coffee Pot Lips.

Strainer Bucket and Coffee Pot Lips. — Describe the triangle H K D, H K, equivalent to the slanting height; from D lay out the section, H K; describe the sections of the circles from K to D and H to D according to the dimensions of the vessel. In coffee pots, the section extending from H to K should be regulated according to the style in which it is to be constructed. In describing tea-kettle and tea-pot spouts proceed as in *Figs. 1* and *4.*

Lips for Measures. — Lay out a circle the dimensions of the top of the vessel; describe a line through the centre of the circle and divide it into 4 equal sections; span the compasses on the line ¼ the distance from the end, and describe a semi-circle touching the opposite end of the line; pass the compass the breadth of the lips desired, and lay out an arc until it approaches the semi-circle, which will allow the desired lip.

TINNING BRASS WIRE. — Have 2 baths, one containing the molten tin, kept at a proper temperature, the other a saturated solution of chloride of zinc. Immerse the coil of brass wire in a boiling solution of caustic potash, and remove it to a bobbin, having a fixed spindle and one movable end. Pass the wire by means of hard wood or brass deeply-grooved pulleys, so that it shall pass through the chloride of zinc bath into the molten tin; after immersion pass between the grooves of two pulleys, revolving in contact with each other, so that the grooves form a hole equal in size to the tinned wire; these will squeeze off superfluous metal; carry forward the end and attach to it a fresh bobbin, and wind off at a speed regulated by experience. The wire must be raised in temperature before it will take the tin, and properly cooled before it reaches the final bobbin, which can be effected by placing it at a proper distance from the tin bath.

TINNING, Cold. — Block tin dissolved in muriatic acid with a little mercury forms a good amalgam for cold tinning; or, 1 part of tin, 2 of zinc, 6 of quicksilver; mix tin and mercury together until they form a soft paste. Clean the metal to be tinned; rub it with a piece of cloth moistened with muriatic acid, and immediately apply a little of the amalgam to the surface, rubbing it in with the rag. The amalgam will adhere to the surface and tin it. Cast iron, wrought iron, steel, and copper may be tinned this way. Those who find it difficult to make soft solder adhere to iron with sal ammoniac, will find no difficulty if they first tin the surfaces in this manner, and then proceed as with ordinary tin plate.

TINNING COPPER. — 1. Wash the surface of the article to be tinned with sulphuric acid, and rub the surface well, so as to have it smooth and free of blackness caused by the acid; then sprinkle calcined and pulverized sal ammoniac upon the surface, holding it over a fire, when it will be sufficiently hot to melt a bar of solder which is to be rubbed over the surface. Any copper dish or vessel may be tinned in this way. —2. Boil 4½ lbs. cream of tartar, 3 gal. water, and 2½ lbs. grain-tin or tin shavings. After boiling a sufficient time, the article to be tinned is put therein, and the boiling continued, when the tin is precipitated in metallic form.

TINNING IRON ARTICLES. — 1. Articles of cast iron may be tinned by wrapping them loosely with zine wire and immersing in a solution of perchloride of tin in 10 parts soft water for 15 minutes. The castings must be well cleaned by pickling them in dilute sulphuric acid and scouring with sand and water or scratch brushing. Use the bath at ordinary temperatures and polish the goods with whiting and the brush. — 2. Clean the iron thoroughly by rubbing and dipping it in a bath of diluted sulphuric acid; after which dip the iron in a solution of 1 part sal ammoniac in 7 parts water. The tin used is alloyed with 6 oz. copper to every 200 lbs. tin. Experience teaches at what temperature the melted tin will attach itself to the cleaned cast iron. When too hot the tin will not adhere well. The articles to be tinned must be smooth, or the tinning will not succeed. To make the alloy with copper, it is best to melt the copper first with a few lbs. of the tin, so that experience will teach what temperature will be required to succeed with the balance. — 3. Cleanse the metal to be tinned, and rub with a coarse cloth, dipped in hydrochloric acid, and then rub on French putty with the same cloth. French putty is made by mixing tin filings with mercury.

TINNING INTERIOR OF LEAD PIPES. — Apply a flux of grease or muriate of zinc, or any other flux that will protect the lead from oxidation, and insure a perfect coating of tin, when the tin is poured through the pipe or the pipe dipped into the bath of tin. After the lead pipe has been made, place the same in a nearly vertical position, and pass down through the same a strong cord, to which a weight is attached to draw the cord through the pipe; and at or near the other end of the cord, a sponge or other

porous or elastic material is attached of a size to fill the pipe, 6 in. more or less. The sponge or porous wad being saturated with the flux, is drawn through the pipe, and by its length insures the covering of the entire inside surface of the inside of the pipe with the flux, so that the melted tin, subsequently applied, will adhere to all parts with uniformity and firmness.

TINNING SMALL ARTICLES. — The goods are to be cleaned; then an earthen pot is to be prepared. First a thin sheet of block tin is to be placed at the bottom, then a steam pipe is to be introduced nearly down to the same; next put in a layer of the goods, then a sheet of tin as before, next more goods, and so till it is filled. Then fill up with water till all are covered. Throw in some cream of tartar and turn on the steam just enough to keep boiling. After whitening, rinse in clear water, and pass through sawdust. In a small way, ordinary tinners' ware has been whitened by covering with tin foil, and boiling over the fire, filling up the water as it evaporates.

TIN PLATE. — Pure tin melts at 424° Fah., and when iron, cleansed from oxide and other impurities, and heated somewhat above this temperature, is plunged into the melted metal and allowed to remain there for a time it receives a coating of the white metal. The chief difficulty in this plating process is to get the surface clean. Clean the metal by boiling in strong potash water, rinsing, pickling in dilute sulphuric acid, and scouring with a stiff brush and fine sand. Pass through strong aqueous sal ammoniac solution, then plunge in hot oil (palm or tallow). When heated remove and dip in a pot of fused tin (grain tin) covered with tallow. When tinned, drain in oil pot and rub with a bunch of hemp. Clean and polish in hot sawdust. The plate may then be sorted and boxed; each box of I. C. plate containing 112 lbs. or 112 plates, the plates having a gauge of No. 30, and weighing 1 lb. each. I.X. brand weighs 140 lbs. to 112 sheets. In the trade the grade, weights, and sizes of the plates are indicated by certain marks, as shown in the following table:

NUMBER, WEIGHT, SIZE, LENGTH AND BREADTH OF TIN PLATES.

ZINC.

AMALGAMATING. — Put a little mercury on the zinc plate, and pour on it dilute sulphuric acid; then rub the mercury over the surface by means of a piece of linen.

BLACK COLORING. — Zinc may be given a fine black color by first cleaning it with sand and sulphuric acid and afterward immersing a moment in a solution composed of 4 parts each of sulphate of nickel and ammonia, and 40 parts water, acidulated with 1 part sulphuric acid; washing and drying it. The black coating adheres, and becomes a bronze color under the burnisher.

COATING WITH IRON. — The objects should first be plunged into a hot solution of 160 grammes ferrous sulphate and 90 grammes sal ammoniac in 2,500 cubic centimeters boiling water. After 2 minutes' exposure remove and brush off in water. This cleanses the surface. They are then again placed in the bath and heated, without brushing or washing, until the sal ammoniac fumes are gone; then washed, and this operation repeated 3 or 4 times, when a coating of iron will be formed on the zinc, which takes a fine polish under the brush.

COLORING. — The metal must be pure, also the materials of which the following bath is composed: Tartrate of copper, 30 parts; caustic potassa, 40 parts; distilled water, 400 parts. After being submitted 2 minutes to the action of this bath, the zinc takes a violet tint; after 3 minutes' immersion, it becomes a deep blue; in 4½ minutes, green; in 6½ minutes, golden yellow; and in 8½ minutes, purple.

DEPOSITING. — 1. Zinc is deposited by the wet way and by the battery. The dead lustre

color is a gray bluish-white. Precipitate a soluble zinc salt by ammonia; this precipitate redissolved in an excess of alkali gives a satisfactory bath; any kind of zinc salt may also be dissolved in cyanide of potassium or a soluble sulphite. These deposits are different as regards durability, from the so-called galvanizing, when cleansed iron is plunged into a bath of molten zinc, and is thus protected against oxidization for a long time, which is not the case with electro-deposited zinc. For depositing upon copper or brass, in the wet way, prepare finely-divided zinc, by pouring the molten metal into a previously strongly heated iron mortar, and stirring until nearly cold. The powdered zinc obtained is placed in a porcelain vessel, and to it is added a concentrated solution of sal ammoniac. This mixture is heated to boiling; and the copper or brass objects to be coated with zinc, previously cleansed, even with an acid, are then placed in a liquid where they obtain a brilliantly white adhering layer of zinc. — 2. Vessels of copper and brass may be covered with a firmly adherent layer of pure zinc, by boiling them in a solution of chloride of zinc, pure zinc turnings being at the same time present in considerable excess. The same object may be effected by means of zinc and a solution of chloride of ammonium or hydrate of potassium.

GRANULATING. — Fuse commercial zinc in a crucible; pour it in a thin stream into a bucket of cold water, and afterwards dry the zinc.

PAINTING. — A difficulty is often experienced in causing oil colors to adhere to sheet zinc. Their adhesion is insured by the employment of a mordant compounded as follows: 1 part chloride of copper, 1 part nitrate of copper, and 1 part sal ammoniac, are to be dissolved in 64 parts of water, to which add 1 part commercial hydrochloric acid. The sheets of zinc are brushed over with this liquid, which gives them a deep black color. In 12 to 24 hours they become dry, and to their then dirty gray surface a coat of any oil color will firmly affix itself. Sheets of zinc prepared in this way, and afterward painted, have been found to withstand all atmospheric changes.

PURIFICATION. — 1. Granulate zinc by melting it, and pouring it while hot into a deep vessel filled with water; place the granulated zinc in a Hessian crucible, in alternate layers, with ¼ its weight of nitre, with an excess of nitre at the top. Cover the crucible, and secure the lid; then apply heat. When deflagration takes place, remove from the fire, separate the dross, and run the zinc into an ingot mold. It is quite free from arsenic. — 2. Pure zinc may be obtained by precipitating its sulphate by an alkali, mixing the oxide produced with charcoal powdered, and exposing the mixture to a bright red heat in a covered crucible in which the pure metal will be found as a button at the bottom when cold.

REDUCING OXIDE OF ZINC. — The oxide may be put in quantities of 500 or 600 lbs. weight into a large pot over the fire; pour a sufficient quantity of muriatic acid over the top, to act as a flux, and the action of the fire will melt the dross, when the pure metal will be found at the bottom of the pot.

REMOVING ZINC COATINGS.—To remove the zinc coating from galvanized articles scour them with silicious sand well moistened with muriatic acid diluted with 3 volumes of soft water.

RIGIDITY OF PLATES. — It is now found practicable to relieve zinc plates or sheets of their rigidity, and facilitate the working of the same into the various forms desired. In the treatment of sheet zinc, with this in view, a bath of linseed oil is prepared, and into this the plates are plunged, these being subjected to the action of oil while in a state of ebullition for some 30 minutes according to thickness of the metal; the plates are then removed, and after the oil is drained from their surfaces they are cleaned and ready for the market. Plates which have passed through this process are represented to possess great ductility, and to be capable of receiving high polish; on this account they may be employed as a substitute for lead or pewter, at a great reduction of cost, in a variety of cases as the linings of sinks and cisterns, and the covering of counter and other surfaces requiring a metallic protection.

SOLDERING. —The parts to be soldered must be cleaned and bright; tin the copper soldering iron by rubbing it while hot in dry hydrochlorate of ammonia with a globule of solder. First wet the parts to be soldered with a solution of chloride of zinc. For zinc plates use the acid alone; next apply the solder, rubbing it with the iron till it unites with the metal. The solder for zinc is composed of 2 parts tin and 1 part lead.

WATCHMAKING AND JEWELRY.

GEMS.

REMARKS. — Gems must be cut and polished by an artisan called the lapidary. His work is performed by the friction of small metal or wooden wheels, which revolve with great rapidity, being frequently driven by the means of a small steam engine. For cutting all kinds of gems and stones, the wheels are made of iron and have a sharp edge, to which diamond or emery powder, moistened with water, is applied during the operation; but for polishing the same, wheels made of softer metal, or wood, are used, the edge of the wooden wheels being sometimes coated with buff-leather; but when the wheels are without a coating of leather, the gem is frequently held against the side instead of the edge. Gems and precious stones differ greatly in hardness and require a different mode of treatment accordingly, although the means used for cutting and polishing are the same in all cases. The softest substances to be cut are alabaster, moth-

er-of pearl, coral, malachite and glass; the emerald, agate, garnet, amethyst, opal, topaz, carbuncle, and many kinds of ornamental stones, are harder than those mentioned, but not so difficult to cut as the diamond, sapphire and ruby.

AGATE. To Convert into Onyx. — Place polished agates 1 week in a solution of iron in nitric acid one millimeter deep; treat those portions to be white with a solution of equal parts of carbonate and hydrate of potash; dry, and burn in an earthen pot until the color is obtained.

AMBER. — A well-known yellowish, semi-transparent, fossil resin; found in pieces on the sea coast, and dug up in diluvial soils; hard, brittle, tasteless, glossy; color yellowish; negatively electric by friction; smells agreeably if rubbed or heated; soluble in pure alkalies, and, without decomposition, in oil of vitriol, which then becomes purple; insoluble in essential and fixed oils without long digestion and heat; soluble in chloroform; melts at about 550° Fahr.; burns with a yellow flame, emitting a fragrant odor, and leaving a light and shiny coal. Amber may be known from mellite and copal, both of which are occasionally substituted for it, by the following characteristics: 1. Mellite is infusible by heat, and burns white; 2. A piece of copal, heated on the point of a knife, catches fire and runs into drops, which flatten as they fall; 3. Amber burns with spitting and frothing, and when its liquefied particles drop, they rebound from the plane on which they fall; 4. Neither mellite nor copal yields succinic acid by distillation; nor the agreeable odor of amber when burnt; nor do they become so readily electric by friction.

AMBER, To Mend. — Smear the parts to be united with linseed oil; hold the oiled part carefully over a small charcoal fire, a hot cinder, or a gas-light, being careful to cover up all the rest of the object loosely with paper; when the oiled parts have begun to be sticky, pinch or press them together, and hold them so till nearly cold. Only that part where the edges are to be united must be warmed, and with care, lest the form or polish of the other parts be disturbed; the part joined requires a little re-polishing.

AMBER, To Work. — Amber in the rough is first split and cut rudely into the shape required by a leaden wheel worked with emery powder, or by a bow-saw having a wire for the blade, tripoli or emery powder being used with it. The pieces are then smoothed with a piece of whetstone and water. The polishing is effected by friction with whiting and water, and, finally, with a little olive oil laid on and well rubbed with a piece of flannel, until the polish is complete. In this process the amber becomes highly electrical; as soon as this happens it must be laid aside to recover itself before the polishing is continued, otherwise the article will be apt to fly into pieces.

AMETHYST. — This precious stone is a variety of vitreous quartz, the color ranging from white to a deep purple. It is found in many parts of the world, and often in pieces of considerable size. The value of the pieces varies considerably, according to color and size. It is best set with diamonds or pearls, but by candle-light it becomes less lustrous, and often of a blackish hue. The use of it is chiefly in jewelry. The Oriental amethyst is more costly, and quite a different stone, being a ruby or sapphire of an amethyst color, harder, and more brilliant.

AMETHYST, Artificial. — 1. Paste or strass, 500 gr.; oxide of manganese, 3 gr.; oxide of cobalt, 24 gr. — 2. Strass, 4608 gr.; oxide of manganese, 36 gr.; oxide of cobalt, 2 gr. — 3. Strass, 9216 gr.; oxide of manganese, 15 to 24 gr.; oxide of cobalt, 1 gr.

AQUAMARINE. — The aquamarine and the beryl are by some treated as identical, because chemically similar; they are distinguished in commerce. The jewelers give the name of aquamarine to the green and blue varieties, while the yellow variety is called beryl. This stone has one admirable quality, which is, that it retains its brilliancy in artificial light. Brazil is the country from which most aquamarines are derived, ready cut. Three sorts of aquamarine are recognized: Aquamarine, pure light blue; Siberian aquamarine, light greenish blue, bright lustre, and faintly colored; aquamarine chrysolite, greenish yellow, sometimes yellowish green, with bright lustre.

AQUAMARINE, Artificial. — Strass, 4800 gr.; glass of antimony, 30 gr.; oxide of cobalt, 1½ gr.

AVENTURINE.—A vitreous variety of quartz, of a pearly-grey, brown, or reddish-brown color, and contains minute particles of mica, which give it a sparkling appearance; not very transparent, and not much used for jewelry; found in Europe and in Asia, and makes pretty cane-handles, snuff-boxes, and such like. One sort is more valuable, and owes its glittering appearance not to mica, but to small quartz crystals scattered through it, the color being a greenish-white, sometimes reddish-brown. Other substances are sold under the name, but while the effect is similar the composition is different, some being feldspar, and of little worth. The sunstone is a variety of aventurine; it is yellow, rare and beautiful.

AVENTURINE, Artificial. — 1. Strass, 500 gr.; scales of iron, 100 gr.; black oxide of copper, 50 gr.; fuse until the black oxide of copper is reduced to the reguline form, then allow the mass to cool slowly, so that the crystals of metal may be equally diffused through it. Has a golden iridescence. — 2. As the last, but substituting oxide of chromium for the protoxide of copper. Appears brown, filled with countless gold spangles; or, when mixed with white paste, of a greenish grey, filled with green spangles.

BERYL. — A beautiful mineral, which, in its richer forms, is classed with the gems; usually of a green color of various shades, passing into honey-yellow and sky-blue; allied in composition to the emerald; but occurs in larger crystals than that gem, and owes its color to oxide of iron instead of oxide of chromium.

BERYL, Artificial. — Strass, 3456 gr.; glass of antimony, 24 gr.; oxide of cobalt, 1½ gr.

CARBUNCLE. — Really a *Garnet*, which see.

CARNELIAN. — A variety of chalcedony; colors, red, yellow, and white, and one of the quartz group of precious stones; capable of a fine polish,

and specially adapted for seals, as it easily detaches itself from wax, and leaves a perfect impression. It is found in various countries, is engraved with facility, and is cheap.

CARNELIAN, Artificial. — *Red.* Strass, 7,000 gr.; glass of antimony, 3,500 gr.; calcined peroxide or iron, 875 gr.; binoxide of manganese, 75 gr. — *White.* Strass, 7,200 gr.; calcined bones, 250 gr.; washed yellow ochre, 65 gr.

CARNELIAN, To Cut. — Some specimens may be cut by means of a thin rotating iron disc with emery and water. Extremely hard specimens require diamond dust. It should be mixed with a little olive oil and applied sparingly to the edge of the disc. To cut plane surfaces and facets use a flat lead lap-wheel with emery and water. Polish with rotten stone and water applied to a pewter lap.

CAT'S-EYE. —A semi-transparent gem, a variety of chrysoberyl, and usually cut with a rounded top. The ray across the stone is often definite; color greenish yellow to black. Set in rings or pins they are handsome, and fine specimens bring a high price. The same name is given to a chalcedonic variety of quartz, of a yellowish-green, yellowish-brown, blackish, and hyacinth-red color. It has an opalescent lustre, usually translucent, and easily broken. The chrysoberyl cat's-eye is more beautiful and valuable, but the two are often confounded, as they are cut alike, and resemble each other.

CHALCEDONY. — One of the quartz group of precious stones, usually of a grayish color, but occurs of a pinkish, bluish, or milky-white tinge. The blue shade is called sapphirine. Some specimens are nearly opaque; others semi-transparent. It is found in various countries, and is suitable for seals. White chalcedony, with small red specks, is called St. Stephen's stone. With alternate stripes of white and gray it is called chalcedonyx. Another variety is the plasma, which is greenish, with minute spots of yellow and white, and is translucent.

CHRYSOBERYL. — A brilliant gem of various shades of yellow or white. One kind is known as the *Cat's-eye*, which see. The transparent yellow stones are cut as brilliants, and are almost as bright as diamonds.

CHRYSOLITE. — Transparent, lustrous, and of a greenish-gold color; when of a deep olive-green, it is called a peridot, and olivine when the green is somewhat in excess of the yellow; can be scratched by quartz; is not much used for fine jewelry, therefore cheap. No particular style is adhered to in the cutting.

CHRYSOLITE, Artificial. — Strass, 7,000 gr.; pure calcined sesquioxide of iron, 65 gr.

COLORING. — The coloring substances are the following oxides: Gold, for purple; silver, for yellowish green; copper, for bright green; iron, for pale red; cobalt, for blue; tin, for white; manganese, in small quantity to make the glass devoid of color; in a larger, to give it an amethyst color; in great quantity, to make it black and opaque; antimony, for reddish hyacinth color.

CORAL. — A calcareous deposit or secretion of several kinds of zoophytes, which assumes beautiful forms. In many parts of the ocean, especially in the Pacific, huge coral reefs testify to the work that is done by these little sea-builders. The carbonate of lime, of which the coral consists, is partly derived from calcareous springs at the bottom of the sea, and partly from the sea itself. The common red coral is obtained principally in the Mediterranean, where there are extensive coral fisheries. Black coral is highly prized.

CORAL, Artificial. — To 2 dr. vermilion add 1 oz. resin; melt together; have ready twigs peeled and dried, and paint them with this mixture while hot; then hold them over a gentle fire, turning them round till perfectly smooth. White coral may be made with white lead, and black with lampblack mixed with resin.

CORAL, To Bleach. — Immerse in a mixture composed of 1 part hydrochloric acid, and 30 parts water; and keep it in this liquid until it becomes white. It should then be taken out, washed well in cold water, and allowed to dry.

CORAL, To Close Cracks in. — Warm carefully, and with a pencil brush cover the crack with watch oil: when cool the seam will not show.

DIAMOND. — This gem derives its name from adamant, of which it is a corruption, and is so called on account of its hardness, for which, combined with its brilliancy, it surpasses all other precious stones. It consists of pure crystallized carbon, with an average specific gravity of 3.5. The primitive form of the crystal, and that into which it may be converted by cleavage, is the regular octahedron. The diamond is found of all colors—white, yellow, orange, red, pink, brown, green, blue, black, and opalescent. Of all the diamonds the white translucent stone that is free from flaw and perfectly cut is most valuable. Pink diamonds are rare, but bright yellow, brown and jet black may be easily found in the market. While a dull tint injures a white diamond, a marked color of red or green adds to its value. 9-10 of the blue diamonds are milky, while all the fine white stones have just a suggestion of blue in their composition.

DIAMOND, Artificial. — 1. Rock crystal, 1,600 gr.; borax, 560 gr.; carbonate of lead, 3,200 gr.; oxide of manganese, ½ to 1 gr.; powder each separately; mix together; fuse in a clean crucible; pour the melted mass into water; separate any reduced lead; again powder and remelt the mass. — 2. Pure silica, 150 gr.; pure litharge, 250 gr.; borax and nitre, each, 50 gr.; arsenious acid, 21 gr. — 3. Rock crystal, 4,056 gr.; minium, 6,300 gr.; potash, 2,154 gr.; borax, 276 gr.; arsenic, 12 gr. — 4. Rock crystal, 3,600 gr.; pure carbonate of lead, 8,508 gr.; potash, 1,260 gr.; borax, 360 gr. — 5. (*Yellow.*) Strass, 500 gr.; glass of antimony, 10 gr.

DIAMOND DUST. — Place a few small pieces of cheap diamond on a block of hard polished steel, in a suitable vessel and cover it with water to prevent it scattering; then place a flat steel punch on each piece, and strike the punch with a mallet with sufficient force to crush the diamond. When reduced fine the dust may be collected and dried for use; after drying, graduate for different purposes by mixing it with a little watch oil; when agitated, the finest par-

ticles float near the surface, whilst the coarse sink to the bottom; thus by decanting the oil in which the dust floats, as many grades of fineness as desired may be obtained. The dust may be separated from the oil by pouring on a piece of smooth clean paper; the paper will absorb the oil while the dust will remain on the surface; to prevent waste, leave it in the oil and use directly therefrom as required, or the oil may be washed out of the dust with alcohol.

DIAMOND FILES. — Shape your file of brass, and charge with diamond dust, as in case of the mill given below. Grade the dust in accordance with the coarse or fine character of the file desired.

DIAMOND MILL. — Make a brass chuck or wheel, suitable for use on a foot-lathe, with a flat even surface, or face of about 1½ or 2 in. in diameter; place a number of the coarsest pieces of diamond dust on different parts of its face, and with a smooth-faced steel hammer drive the pieces of dust all evenly into the brass nearly or quite level with the surface. The mill, thus prepared, is used for making pallet jewels or for grinding stone and glass of any kind. For polishing, use a bone or box-wood chuck or wheel, of similar form to the mill, and coat it slightly with the finest grade of diamond-dust and oil; with this a beautiful polish may be given to the hardest stone.

DIAMOND, To Cut. — Diamonds are cut in 4 shapes: Brilliant, rose, table and brilliolet. It is unnecessary to describe the two latter, as they have gone out of fashion and are now rarely seen. The rose diamond is flat on the under surface, and is cut into innumerable facets on the upper. It is the best form in which to cut diamonds of small depth. Rose diamonds give a larger display of surface brilliancy in proportion to their cost than brilliants. Brilliants have a top called a table; from this the jewel expands on innumerable facets, to an edge called the girdle; from thence it recedes again to a blunted point called the culet. Fixed laws govern the proportions of brilliants. A one-carat stone with a diameter on the girdle of ¼ in., should have a depth of rather over ⅛ in.; a two-carat stone, with a diameter on the girdle of nearly 5-16 in., should have a depth of nearly 3-16. Nothing but the diamond will cut the diamond. In order to cut a rough diamond into a brilliant it is set and soldered firmly into the end of a stick, and held against a wheel which revolves with great velocity and is armed with diamond dust. It may be split by a sharp blow from a chisel along the line of cleavage. But workmen are so apt, in performing this delicate operation, to ruin the gem, that it is seldom risked, and the slow but surer agency of the diamond-dust wheel is employed.

DIAMOND, To Test. — 1. Apply a file to the top or table, and to the bottom or culet. If the stone be genuine, the file may be applied for a month without leaving a mark. — 2. The true diamond will scratch the sapphire; nothing else will. — 3. The specific gravity of the diamond is 3°4′ to 3°6′.—4. If a person looks through a transparent stone at any small object, such as the point of a needle, or a little hole in a card, and sees two small points or two small holes, the stone is not a diamond. All white colorless gems, with the exception of the diamond, make the object examined appear double; double refraction, whenever exhibited by a stone, is conclusive proof that it is not a diamond.

EMERALD. — A stone of a bright, rich, deep-green color, occurring in hexagonal prisms, in granite, gneiss and mica rocks. It ranks next to the diamond and is a little less hard than beryl. The finest are brought from Peru, but fair varieties are found in Bavaria, Siberia, and India.

EMERALD, Artificial. — 1. Strass, 7000 gr.; carbonate of copper, 65 gr.; glass of antimony, 7 gr. — 2. Paste, 960 gr.; glass of antimony, 42 gr.; oxide of cobalt, 3½ gr. — 3. Paste, 4,608 gr.; green oxide of copper, 42 gr.; oxide of chrome, 2 gr. — 4. Paste, 9,612 gr.; acetate of copper, 72 gr.; peroxide of iron, 1½ gr.

FOILS. — These are thin leaves of polished metal, placed under precious stones and pastes, to heighten their brilliancy, or to vary the effect. Foils were formerly made of copper, tinned copper, tin, and silvered copper, but the last is the one wholly used for superior work. Foils are of two descriptions: White, for diamonds and mock diamonds, and colored for the colored gems. The latter are prepared by varnishing or lacquering the former. By their judicious use the color of a stone may often be modified and improved. Thus, by placing a yellow foil under a green stone that turns too much on the blue, or a red one under a stone turning too much on the crimson, the hues will be brightened and enriched. — *Amethyst.* Lake and Prussian blue, finely ground in pale drying oil. — *Blue.* Prussian blue ground with pale, quick-drying oil. Used to deepen the colorof sapphires. — *Crystal.* Made by coating a plate of copper with a layer of silver, and then rolling it into sheets in the flatting mill. The foil is then polished or covered with crystal varnish. The inside of the socket in which the stone or paste is to be set is covered with tin foil, with a little stiff gum or size; when dry, the surface is polished and the socket heated, and, while it is warm, filled with quicksilver; after repose 2 or 3 minutes the fluid metal is poured out, and the stone gently fitted in its place; lastly, the work is well fitted round the stone, to prevent the alloy being shaken out. The bottom of the stone is coated with a film of real silver, by precipitating it from a solution of the nitrate in spirit of ammonia, by means of the oils of cassia and cloves. This method increases the brilliancy of real and factitious gems, and the work is permanent. — *Garnet.* Dragon's blood dissolved in rectified spirit of wine. — *Green.* 1. Pale shellac, dissolved in alcohol (lacquer), and tinged green by dissolving verdigris or acetate of copper in it. — 2. From sesquiferrocyanide of iron and bichromate of potassa, each, ½ oz.; ground to an impalpable powder, first alone, and then with gum mastic (clean and also in fine powder), 2 oz.; a little pyroxilic spirit is next added, gradually, and the whole ground until the mass becomes homogeneous and of a fine transparent green. The beauty increases with grinding. The predominance of the bichromate turns it on the yellowish green;

that of the salt of iron on the bluish green. For use it is to be thinned with pyroxilic spirit. Used for emeralds. — *Red.* Carmine, dissolved in spirit of hartshorn, or in a weak solution of salt of tartar; and a little gum (dissolved) added. — *Ruby.* 1. Lake or carmine, ground in isinglass. — 2. Lake ground in shellac varnish. Both are used when the color turns on the purple. — 3. From bright lake ground in oil. Used when the color turns on the scarlet or orange. — *Yellow.* 1. Various shades of yellow may be produced by tinging a weak alcoholic solution of shellac or mastic, by digesting turmeric, annatto, saffron, or socotrine aloes in it. The former is the brightest and is used for topazes. — 2. Hay saffron digested in 5 or 6 times its weight of boiling water until the latter becomes sufficiently colored, and a little solution of gum or isinglass added to the filtered liquor. When dry, a coating of spirit varnish is applied.

GARNET. — This stone is of various kinds, which are extensively used in jewelry. They occur in many colors, black, brown, green, red, white and yellow, and may have a white streak. All are brilliant when cut and polished, but vary in transparency. The more important varieties are the almandine, cinnamon-stone or essonite, and the red garnets styled pyrope, Bohemian, and Syrian or Oriental. Carbuncles are garnets of a red color, and owe their name to their color, though it is only used of such as are cut with a rounded top and a flat or hollow base. Garnets are found in all quarters of the globe, and are cheap. Of the inferior varieties the following deserve to be named: The grossularite, greenish or black; the succinite, yellow; the colophonite, brown; the melanite, black; the leucite, white; the spessartine, brown; the uwarowite, with a bright green shade. Some of these are softer than the better kinds, but not so beautiful.

GARNET, Artificial.—1. Paste or strass, 1,200 gr.; glass of antimony, 580 gr.; purple of cassius and binoxide of manganese, each, 3 gr. — 2. Paste, 513 gr.; glass of antimony, 256 gr.; purple of cassius and oxide of manganese, each, 2 gr. — 3. Paste, 7,000 gr.; glass of antimony, 3,460 gr.; calcined peroxide of iron, 56 gr.

LAPIS LAZULI.—A beautiful stone of a rich blue color, often showing white or golden specks; found in Persia, China, etc., and of an inferior quality in Chili. When cut and polished, it is used for brooches, rings and studs, and for mosaic and costly articles of furniture. Ground to powder it makes ultramarine; for this it is now but little, if at all, employed, chemistry having provided a cheaper substitute. It occurs in masses and small crystals. It is opaque, and not being hard loses its polish when worn much.

LAPIS LAZULI, Artificial. — Paste, 7,000 gr.; calcined horn or bones, 570 gr.; oxides of cobalt and manganese, each, 24 gr. The golden veins are produced by painting them on the pieces with a mixture of gold powder, borax and gum water, and then gently heating them until the borax fluxes.

MOONSTONE.—A variety of feldspar with a reflection like that of the cat's-eye, and usually of a pearly white color. The best come chiefly from Ceylon, and are often cut into the form of heads and polished, or mounted in cheap jewelry with a rounded top. The moonstone is sometimes called selenite, Ceylon opal, or water opal. An opaque green variety from Siberia has the name of Amazon stone. Though once popular, the moonstone is now of trifling value.

OPAL.—One of the most beautiful of precious stones, and yet is nothing but quartz with an addition of 5 to 10 or even 13 per cent. of water. Its varieties include the "noble" or precious opal, the "fire," or reddish opal, the common opal, the semi-opal, the hydrophane or Mexican opal, cachoelong, opal jasper, wood opal, etc. These differ and are of unequal value and beauty. The precious opal is highly prized for its exquisite play of colors, a peculiarity scarcely perceptible in some sorts. Opals are easily broken; they are cut and polished for jewelry, and in that state have at various times been in demand. The hydrophane loses its beauty when exposed to water. Opals for jewelry are cut with a rounded top, and usually are oval in form.

OPAL, Artificial.—1. Strass, 960 gr.; calcined bones, 48 gr. — 2. Paste, 1 oz.; horn silver, 10 gr.; calcined magnetic ore, 2 gr.; absorbent earth (calcined bones), 26 gr.

PEARL. — The most beautiful and costly are obtained from the pearl oyster of the Indian Seas. The principal fisheries are on the coast of Ceylon, and at Olmutz in the Persian Gulf. An inferior description of pearl is procured from fresh water shell fish. Pearls are composed of membrane and carbonate of calcium, or substances similar to bladder and chalk in alternate layers. The cause of the production of pearls is curious and interesting. When any foreign body gains a permanent lodgment within the shells of any of the mollusca which are lined with pearly matter, or nacre, the pearly secretion of the animal, instead of being spread in layers on the inside of its habitation, is accumulated around the offending particles in concentric films of extreme tenuity, and more or less spherical, forming a pearl.

PEARL, Artificial. — Hollow globes of glass, coated internally with a substance which resembles the peculiar lustre of the native pearl. They are lighter and more brittle than real pearls, but sometimes the resemblance is exact. One sort of artificial pearl is solid, made of fish scales, and is more costly and less easily broken than false pearls of glass. The imitation of pearls is effected in other ways, but the above are said to be the most common.

PEARLS, To Clean. — Soak in hot water in which bran has been boiled with a little salts of tartar and alum, rubbing gently between the hands when the heat will admit of it. When the water is cold renew the application till any discoloration is removed; rinse in lukewarm water, and then lay on white paper in a dark place to cool.

RUBY.—The ruby is a gem of the class styled corundums. It is one of the most beautiful, and when of large size, good color and free from defects, is the most valuable of precious stones;

so that, weight for weight, a ruby may be worth more than a diamond. It and the sapphire are next in hardness to the diamond. The chief sources of it are Siam, Burmah and Ceylon. The color varies from light rose tint to deep carmine. The most prized are of the shade called "pigeon's blood," a pure, deep, rich red, without any admixture of blue or yellow. One variety with a peculiar reflection is called the star ruby. The form in which rubies are mostly cut is called half-brilliant, though stones of less value are often cut with a rounded top. Real rubies of small size have been produced by artificial means, but not large enough for jewelry.

RUBY, Artificial.—1. Paste, 45 parts; binoxide of manganese, 1 part. — 2. Paste, 1 lb.; purple of cassius, 3 dr. — 3. Paste, 2,880 parts; oxide of manganese, 72 parts. — 4. Topaz paste that has turned out opaque, 1 part; strass, 8 parts; fuse together for 30 hours; cool, and again fuse it in small pieces before the blowpipe. Very fine. — 5. Strass, 16 oz.; precipitate of cassius, peroxide of iron, golden sulphide of antimony, and manganese calcined with nitre, each, 168 gr.; rock crystal, 2 oz. or more. — 6. Paste and glass of antimony, each, 8 oz.; rock crystal, 1 oz.; purple of cassius, 1½ dr.; turns on the orange.

SAPPHIRE. — A gem of same nature and composition as the ruby, but different in color, and oftener found of a large size. Though usually blue its tint varies from white to black; the quality varies exceedingly. One variety is called the star sapphire from the peculiar radiation it exhibits. It would be difficult to give hints for the guidance of purchasers, who, in this case, must rely mainly upon the honor and experience of the dealer. Ordinary sapphires are cut with a flat top more or less resembling a brilliant, but star sapphires are rounded at the top. This gem is often imitated, or other and inferior stones are substituted for it.

SAPPHIRE, Artificial. — 1. Strass, 3,600 gr.; oxide of cobalt, 50 gr.; oxide of manganese, 11 gr. — 2. Paste, 4,608 gr.; oxide of cobalt, 68 gr.; fuse in a Hessian crucible for 30 hours. — 3. Paste, 8 oz.; oxide of cobalt, 49 gr.

TESTS. — The only tests applicable to gems and precious stones are the determination of their relative hardness and specific gravity. By the first test, pastes or factitious gems are readily detected, but owing to the difficulty of applying it ceases to be useful to persons unconnected with the trade. The determination of specific gravity is of more general application, as gems are dismounted when offered for sale, or are so set that they may be removed from their mountings without injury. To obtain the sp. gr. of a gem, weigh it first in air, then in water, and divide the weight in air by the difference between the two. The relative hardness of the different substances is measured by the power which they possess of cutting or scratching the other substances having a smaller number attached to them in the table. Thus, no gem but the diamond will scratch the ruby or the sapphire; and for the same reason a blue stone that will cut emerald or topaz, can be no other than the sapphire. The sp. gr. is ascertained in the usual manner, and will be found sufficiently indicative of the true nature of the stone when considered in connection with its other characteristics. The index of refraction is a key to the quality of the stone in the hands of those who are capable of determining it, and may be applied to either mounted or unmounted gems.

HARDNESS, SPECIFIC GRAVITY AND REFRACTIVE POWER OF PRINCIPAL GEMS AND PRECIOUS STONES, AND SOME MINERALS.

Name.	Relative Hardness.	Specific Gravity.	Index of Refraction.
Agate	12	2.6	
Amethyst (occidental)	11	2.7	
Calcareous spar	6	2.7	
Chalk	3	2.7	
Chrysolite	10	3.7	
Carnelian	11	2.7	
Crystal	11	2.6

" (whitish)	14	3.5	
Tourmaline	10	3.0	
Zeolite	8	2.1	
Zircon	—	—	1.961

TOPAZ.—A name commonly given to a hard and beautiful gem of various shades of yellow, but found of several colors. In Australia the green and yellow crystals are found; in Saxony the pale violet, and in Bohemia the sea-green variety. Brazil supplies red and other varieties, and large numbers are collected from Siberia, Ceylon, Peru, Asia Minor, Great Britain, Ireland, etc. Some are colorless. Topaz occurs occasionally in large masses. Pink specimens bring a good price, and like some other tints may be taken for different stones. The cairngorm is often sold for topaz, though inferior every way. It has been frequently imitated, and when genuine the color, if pink, is probably due to the skillful application of heat. The Oriental topaz, or yellow sapphire, is a variety of corundum. It is frequently mistaken for a yellow diamond, and is of little value in commerce; even jewelers frequently confound it with the ordinary topaz.

TOPAZ, Artificial.—1. Strass, 1,050 gr.; glass of antimony, 44 gr.; purple of cassius, 1 gr. — 2. Paste, 3,456 gr.; calcined peroxide of iron, 36 gr.

TURQUOISE.—This stone is extensively imitated, and the genuine is of different degrees of merit and value. The fine blue stones alone are of much worth. They are not found in crystals, but in small lumps of various sizes, and for jewelry are cut and polished with a rounded top. Persia is the source of the best, but inferior sorts occur in China, Thibet, Silesia, Saxony and near Mt. Sinai; these last are darker than the Persian, but are apt to lose color; they may be readily distinguished from real turquoise by the stratum, in most cases apparent at the back, being of a pale yellowish-red color instead of dark brown. The Persian turquoise may also change color, but if not brought into contact with acids, musk, camphor, or other scents, it retains its hue for years, turning at last to a green or a white.

TURQUOISE, Artificial. — Blue paste, 20 to 24 parts; calcined bones, 1 part. The substances employed should be free from impurities, especially of a mineral kind. The litharge, oxide of lead and carbonate of lead, must be free from oxide of tin, as the smallest part of that substance may impart a "milkiness" to the paste. All the ingredients must be separately reduced to powder, and, after being mixed, sifted through lawn. The fusion must be carefully conducted and continuous, and the melted mass allowed to cool slowly after having been left in the fire 24 to 30 hours. Hessian crucibles are preferred, and the heat of an ordinary pottery or porcelain kiln is sufficient in most cases; but a small wind furnace devoted to the purpose is more convenient. It is found that the more tranquil, continuous and uniform the fusion, the denser and clearer is the paste, and the greater its refractive power and beauty.

GOLD.

REMARKS. — Pure gold is too soft for practical purposes, therefore it is usually alloyed with copper or silver; the first alloy producing a reddish color, and the second pale yellow. Our gold coin contains 1-10 copper and silver, mostly copper. For jewelry, the alloy differs with the quantity, and it is estimated by carats. A carat is the 24th part of any given quantity. When gold is called 24 carats, it means that it is all gold; when 20 carats, that of every 24 parts, 20 are gold; 18 carats is the most common alloy used by jewelers, and keeps as well as pure gold; 12 carats is ½ gold, and is a low alloy, apt to tarnish easily, and lose lustre, requiring frequent cleaning. To find the number of carats of gold in an object, first weigh the gold and mix with 7 times its weight in silver. This alloy is beaten into thin leaves, and nitric acid added; this dissolves the silver and copper. The remainder (gold) is fused and weighed; by comparing the first and last weights the number of carats is found. This operation is repeated several times, and if any difference occurs in the result, all is done over again.

ALLOYS. — *Pale 18 k.* Fine gold, 1 oz., 12 gr.; fine silver, 3 dwt., 8 gr.; fine copper, 3 dwt., 8 gr. — *18 k. for Rings.* Gold coin, 19½ gr.; pure copper, 3 gr.; pure silver, 1½ gr. — *16 k.* 64 parts gold; 15 parts silver; 17 parts copper. — *14 k.* 140 parts gold; 40 parts silver; 60 parts copper. — *12 k* Gold coin, 25 gr.; pure copper 13½ gr.; pure silver; 7½ gr. — *10 k.* 100 parts gold, 60 parts silver, 80 parts copper. — *10 k.* Red gold: 100 parts gold, 50 parts silver, 90 parts copper. — *4 k.* Copper, 18 parts; gold 4 parts; silver, 2 parts. *Pale.* 1. Gold, 1 oz.; silver, 8 dwt.; copper, 3 dwt. — 2. Gold, 1 oz.; silver, 1 dwt., 20 grs.; copper, 1 dwt., 4 gr. — 3. *18 k.* Pale gold, 1 oz.; silver, 4 dwt.; copper, 2 dwt., 15 gr. — 4. *18 k.* Gold, 1 oz., 12 gr.; silver, 3 dwt., 8 gr.; copper, 3 dwt., 8 gr. — *Deeper Color.* 1. Gold, 1 oz.; silver, 1 dwt., 12 gr.; copper, 2 dwt., 12 gr. — 2. Gold, 1 oz.; silver, 9 dwt., 12 gr.; copper, 7 dwt., 12 gr. —3. Gold, 1 oz.; silver, 14 dwt.; copper, 8 dwt. — 4. Gold, 2 oz., 5 dwt.; silver, 1 oz., 6 dwt.; copper, 5 dwt.; pinbrass, 5 dwt. — 5. BRITTLE, To Make Strong. — Gold is sometimes brittle, probably due to phosphorus, not detected in the assay. The remedy is to pass chlorine gas through the molten gold, by which treatment gold otherwise unfit for certain kinds of work can be redeemed.

CLEANING. — 1. Wash with warm water, Castile soap, and 1 teaspoonful spirits of ammonia to 1 pt. water; rinse in alcohol, and dry in boxwood sawdust. — 2. To clean gold ornaments, mix jewelers' rouge with a little salad oil, and with a toothbrush rub the ornament till clean; then wash in warm soap and water with a brush and dry with wash leather. — 3. Dissolve sal ammoniac in urine; put the jewelry in it for a short time; then take out, and rub with chamois leather. — 4. Mix eau de Cologne and whiting to the consistency of cream; apply it to the article; brush it well in, and leave it to harden. Finally brush it off. — 5. To clean old work that is tarnished, heat the articles gently with a blowpipe, and then boil out in rather strong pickle of muriatic acid; it may be removed by boiling in chloride of lime and water in a pipkin, and touching the work at a lathe with a scratch-brush.

COLORING.—(*Dry Process.*) Polish the work well and for every 2 oz., take saltpetre, 8 oz.; alum, 4 oz.; salt, 4 oz.; melt together in a black lead pot, stirring with a thin iron bar. Use the fire on a forge and urge it well with the bellows. The polished work being well cleaned with soda, soap, and hot water, is dried in box sawdust, and afterwards covered with a thin layer of borax; annealed and boiled out, and again dried in box sawdust, and finally hung on platinum or silver wire. When the "color" in the pot assumes a brown yellow flame, the work is dipped in for 2 or 3 seconds, and quenched with hot water, diluted with muriatic acid. This ought to produce the desired color, but if it does not, repeat the process, previously drying the work before re-immersion. The color-pot must be emptied immediately upon the forge, so that it may be ready for future use. —2. (*Wet Process.*) For 5 oz. of work take saltpetre, 16 oz.; alum, 8 oz.; salt, 8 oz.; all pulverized, and muriatic acid, 2 oz.; dissolve the ingredients gradually in a black lead pot. When it boils up, add the acid, and stir the whole with a wooden spoon. Having annealed the work and made it clean, tie in small parcels with platinum or fine silver wire, and when the color boils up immerse it therein 4 minutes, moving it about; then take it out and rinse in boiling water; then immerse in the color 1½ minutes and rinse in fresh hot water. Now add 2 oz. fresh hot water to the color in the pot, which will cause it to sink. When it rises put in your work for 1 minute; rinsing in fresh hot water again, when it will begin to brighten. Now immerse ½ minute longer, and rinse for the last time in clean hot water, when it will appear of a beautiful color.

ENAMELING. — The basis of all enamels is a transparent and fusible glass called *frit*, *flux*, or *paste*, which readily receives a color on the addition of the metallic oxides. It is made as follows: Red lead, 16 parts; calcined borax, 3 parts; pounded flint glass, 12 parts; flints, 4 parts. Fuse in a Hessian crucible 12 hours, then pour it out into water, and reduce to powder in a biscuit-ware mortar. The following directions will show how the coloring preparations are made: *Black* enamels are made with peroxide of manganese, or protoxide of iron, to which more depth of color is given with a little cobalt.— *Violet* of a fine hue is made from peroxide of manganese, in small quantity, with saline or alkaline fluxes. — *Red.* Protoxide of copper; boil a solution of equal parts of sugar and acetate of copper in 4 parts water. The sugar takes possession of a portion of the cupreous oxide, and reduces it to the protoxide; when it may be precipitated in the form of a granular powder of a brilliant red. After about 2 hours moderate boiling, the liquid is set aside to settle, and decanted off the precipitate, which is washed and dried. By this pure oxide any tint may be obtained from red to orange by adding more or less peroxide of iron. The oxide and purple of Cassius are likewise employed to color red enamel. This composition resists a strong fire well. — *Green.* A mixture of yellow and blue, generally obtained direct from the oxide of copper, or with the oxide of chrome, which last will resist a strong heat. — *Yellow.* 1 part white oxide of antimony with from 1 to 3 parts white lead, 1 part alum, and 1 part sal ammoniac; each pulverized, then all exactly mixed, and exposed to a heat adequate to decompose the sal ammoniac. This operation is finished when the yellow color is well brought out. — *Blue.* Obtained from the oxide of cobalt, or some of its combinations, and it produces it with such intensity that only a very little can be used lest the shade should pass into black. — *White.* Prepared with a calcine formed of 2 parts tin and 1 part lead, calcined together; of this combined oxide, 1 part is melted with 2 parts fine crystal and a little manganese, all previously ground together. When fusion is complete, the vitreous matter is to be poured into clear water, and the frit dried and melted anew. Repeat pouring into water 3 or 4 times, to insure a combination. Screen the crucible from smoke and flame. The smallest portions of oxide of iron or copper admitted into this enamel will destroy its value. The artist prepares his enamel colors by pounding them in an agate mortar, with an agate pestle, and grinding them on an agate slab, with oil of lavender rendered viscid by exposure to the sun, in a shallow vessel, loosely covered with gauze or glass. He should have a stove, in which a moderate fire is kept up, for drying his work whenever the figures are finished; then passed through the muffle.

FUSING GOLD DUST. — Use a crucible as for melting brass; heat hot; add gold dust mixed with powdered borax; a scum or slag will arise on the top, which may be thickened by adding a little lime or bone ash. If the dust contains any of the more oxidizable metals, add a little nitre; skim off scum carefully; when melted, grasp the crucible with strong tongs and pour into cast iron molds, slightly greased. The slag and crucibles may be afterwards pulverized, and the auriferous matter recovered through cupellation by means of lead.

GILDING, By Dipping. — The composition and preparation of the bath are as follows: Distilled water, 17 pts.; pyrophosphate of potash, or soda, 28 oz.; hydrocyanic acid or ⅛ prussic acid, ¾ oz.; crystallized perchloride of gold, ⅔ oz. Put 17

pts. of distilled water in a porcelain vessel and add, by small portions and stirring with a glass rod, the pyrophosphate; heat, filter, and let it cool. The chloride of gold is prepared by introducing into a small glass flask pure gold finely laminated, ½ oz.; hydrochloric acid, pure, nearly 1 oz.; nitric acid, pure, ½ oz. The flask is slightly heated, effervescence and abundant nitrous vapors result, and in a few minutes the gold has disappeared, leaving a reddish-yellow liquor. The flask is then put upon a sheet of iron, with a hole in its centre, and supported by a tripod. The whole is heated by a spirit lamp to evaporate excess of acids, which may cause great irregularities in the working of the bath, and even prevent its action. The evaporation is finished when vapors escape from the flask, and when the liquid becomes oily and of a deep red. The flask is then removed from the fire by wooden pincers, and set to cool upon a ring of plaited straw. Well-prepared chloride of gold, when cold, forms a saffron-yellow crystalline mass; if red, it has been too much evaporated, and must be heated again after a small addition of the two acids. If it has passed to insoluble protochloride or metallic gold, the treatment must be begun again with the indicated mixture of pure nitric and hydrochloric acids. When cold and crystallized, dissolve it in the flask with a little distilled water, and filter into a clean bottle. Rinse the flask and filter with the unemployed water, so as to get all the gold. Pour the filtered solution of chloride of gold into the cooled one of pyrophosphate, and stir with a glass rod. Lastly, add the hydrocyanic acid, and heat the bath nearly to the boiling point for use. If the solution of pyrophosphate is still tepid, add the hydrocyanic acid before the chloride of gold. When the solutions are mixed in the cold, the liquor is yellow or greenish-yellow, but becomes colorless by the increase of temperature. If the liquor becomes currant-red or wine-lees violet, it is an indication that there is too little hydrocyanic acid; add it, drop by drop, until the liquor becomes colorless. Add prussic acid gradually to baths too rich in gold; correct excess of prussic acid with a small proportion of chloride of gold, until the gilding is of the proper shade. Thus prepared the bath will produce fine gilding upon clean articles, having passed through a very diluted solution of nitrate of binoxide of mercury, without which the deposit of gold is irregular, and will not cover the soldered portions. The articles are supported by a hook and agitated while in the bath. Gilders employ 3 baths in close proximity to each other, and heated upon the same furnace; the first bath is deprived of gold by a previous operation, and used for removing excess of acid; the second retains some gold, but not enough to give a rich gilding. The pieces passed through it begin to receive the deposit, which will be finished in thickness and shade in the third bath. A gas furnace is desirable for heating the baths, as the temperature can thereby be controlled. This method produces more gilding with a given quantity of gold, than one bath alone. The gilding is done in a few seconds; the finishing operations consist in rinsing in fresh water, drying in dry and warm saw-dust, and burnishing.

GILDING, By Diluted Bath. — Employed as a complement to the cleansing process, before a more resisting gilding, as its results have little durability. Water, 2 gals.; bicarbonate of potash, 7 oz.; caustic potash, 63 oz.; cyanide of potassium, 3 oz.; metallic gold to be transformed into chloride, ½ oz. Bring to the boiling point, maintain it at the proper strength by additions of gold and salts in the proportion of ½ oz. This bath will gild about 140 oz. of small jewelry with 1-30 oz. of gold, whereas a pyrophosphate bath gilds about 35 oz. of small articles with the 1-30 oz. of gold extracted from the liquor.

GILDING, By Stirring and Amalgam. — In the centre of a charcoal stove put a crucible holding a given quantity of pure and dry mercury; when the temperature has reached 212° Fahr. add ½ the weight of gold. Stir until it has acquired the consistency of butter; throw it into cold water, and keep it there for use. Cleanse the articles in aquafortis; put in a stoneware pan, and pour over them a diluted solution of nitrate of binoxide of mercury, moving the articles about. Add the amalgam; on stirring the articles this is spread all over them; then rinse in cold water, place in a large and deep copper ladle, perforated with numerous small holes, and having a long handle. Hold the ladle over a charcoal fire, and constantly stir to have the heat equal. The mercury of the amalgam is soon volatilized, and the gold remains adherent to the articles. If instead of a yellow gilding a red one be desired, pour upon the pieces, kept in the ladle and upon the fire, in a well mixed and fluid state, oil, 25 parts; yellow wax 25 parts; acetate of copper, 10 parts; red ochre, 40 parts; constantly agitated and allowed to burn out, then thrown into a diluted solution of sulphuric acid. This waxing is to be done after the complete volatilization of the mercury. When removed from the pickle, the gilding has a dull ochre appearance, and must be scratch-brushed. Small articles are brightened in a long narrow bag, where they are put with copper pearls, or the waste from these pearls, and wet with vinegar water; a to-and-fro motion is imparted to the bag, and the gilt articles and the copper granules polish each other. Rinse and dry in sawdust, and burnish if required.

GILDING, Cold, with the Rag.—Dissolve finely laminated pure gold in aqua regia made of nitric acid, 5 parts, sal ammoniac, 2 parts, and saltpetre, ½ part; heat upon a gentle fire; when the gold has disappeared, pour the cooled contents of the flask into a flat-bottomed stoneware pan; into this liquor place, one upon the other, in sufficient quantity, squares of linen cloth; strike them with a glass rod, that they may absorb the chloride of gold. Each square of cloth is taken out with wooden pincers; drained and spread for drying in a dark chamber. When nearly dry, each piece, supported upon glass rods, is placed on top of a charcoal fire, and soon takes fire. The combustion is aided by the saltpetre, and finished upon a marble slab. Grind the ashes with a muller and keep them between the folds of a parchment leaf, around which a

wet cloth has been folded; it is then ready. Mix it upon a slab with a few drops of water, and rub on the previously cleaned silver. The smooth surfaces are rubbed with the thumb, the fillets with a cork cut to the proper shape, and the corners or angles with a stick of soft wood, such as linden or poplar; then burnish; if a red shade be desired, add a little pure copper to the gold to be dissolved in aqua regia.

GILDING, Coloring.—If the gilding is dull and irregular in color, melt together in their water of crystallization, at about 212° Fahr., equal parts sulphate of iron, sulphate of zinc, sulphate of alumina and potash, and saltpetre. Cover the articles with the mixture and put them into a cylindrical and vertical grate. This is placed in the centre of a furnace, where the charcoal burns between the sides and the grate which holds the articles. When the moistened finger is presented to one piece, and a slight hissing sound is heard, the heat is sufficient. Put the articles rapidly into a very diluted solution of sulphuric acid, where the coating of salts is quickly dissolved; the articles present a uniform color. If the copper articles are not entirely gilt by the first operation, the portions ungilt will show red, and the articles must then be deprived of gold, cleansed and regilt. Sometimes, instead of this, the articles are placed for a few moments in the electro bath.

GILDING, Green and White.—For these shades add, drop by drop, until the desired shade is obtained, to the bath of double pyrophosphate of soda and gold, a solution of nitrate of silver, for which dissolve in 5 oz. distilled water, ½ oz. nitrate silver crystallized. Before gilding green or white, yellow gild the objects in the ordinary bath; then pass rapidly through the mercurial solution; lastly dip them into the gold bath holding the nitrate of silver. To maintain the constancy of the shade add a few drops of the silver solution when required.

GILDING SILVER, By Dipping.—The articles, previously cleansed and scratch-brushed, are boiled ½ hour in the gold bath of pyrophosphate, to which add a few drops of sulphurous acid, or preferably hydrocyanic acid, in excess of the quantity needed by the primitive bath. This is very fine, but without firmness. The deposit is rapid when the silver articles are stirred with a rod of copper, zinc or brass.

GILDING, With Bicarbonates.—The bicarbonate bath is prepared in a cast-iron kettle turned smooth inside, on the lathe, and gilt by the protracted ebullition of nearly spent gold baths. Water, 3½ gals.; bicarbonate of potash or soda, ½ oz.; pure metallic gold transformed into chloride, 4¼ oz.; the whole boiled 2 hours and fresh water added to replace that evaporated. A part of the gold in violet-black powder precipitates, requiring the cooling and decanting of the liquor; this is boiled, and the gilding proceeded with as in *Gilding by Dipping* (which see), except that the mercurial solution should be more diluted than for the baths of pyrophosphates. The operation is finished when about ½ the gold in the liquor is deposited.

GRAIN.—Cupelled gold, 1 part; silver, 3 parts; melted together, and poured in a small stream into water; the silver afterwards dissolved out by digestion in boiling nitric acid, and the grains, after being well washed in water, heated to redness in a crucible or cupel. Used to make preparations of gold.

IMITATION.—1. (*French or Oreide.*) 100 parts, by weight pure copper, 14 parts zinc or tin, 6 parts magnesia, 3 6-10 parts sal ammoniac, limestone and cream of tartar. The copper is melted, then the magnesia, sal ammoniac, limestone and cream of tartar in powder added separately and gradually; the mass stirred ½ hour; the zinc or tin dropped in piece by piece, and the stirring kept up till they melt; finally, the crucible is covered, the mass kept in fusion 35 minutes, the scum removed, and the metal poured into molds, when it is ready for use. The alloy is said to be fine grained and malleable, takes a high polish, and does not easily oxidize. — 2. Fuse together with saltpetre, sal ammoniac and powdered charcoal, 4 parts platina, 2½ parts pure copper, 1 part pure zinc, 2 parts block tin, and 1½ parts pure lead. — 3. 2 parts platina, 1 part silver, and 3 parts copper.

LACE.—The refiner first prepares a solid rod of silver 1 in. thick; then beats this rod, applies upon the surface a sheet of gold leaf, burnishes this down, and so on, till the gold is about a 100th part as thick as the silver; the rod is then made into fine wire, when it is passed through holes in a steel plate lessening step by step in diameter. The gold never deserts the silver, and maintains the same ratio. It has been calculated that the gold actually placed on the finest silver wire for gold lace is not more than ½ of 1,000,000th of an in. in thickness.

LEAF.—According to color, gold leaf is termed deep, medium, fine, red, pale red, deep orange, lemon, pale white, etc. Deep gold admits very little alloy, usually about 2½ parts silver and 2½ parts copper, making 5 in all. A medium kind is made of 42 parts pure gold, 12 parts silver, and 6 parts copper. The gold is first made into ingots, 1½x¾ in. and 3-16 in. thick; then passed between 2 polished steel rollers, until it becomes a long ribbon 1-800 in. thick; the ribbon being cut into in. sq. pieces, 150 of these are interleaved with thick paper and inclosed in a parchment case called a "kutch," which is subjected to a continued series of blows with a 16 lb. hammer. When each piece has been stretched out to 4 in. sq., the kutch is opened, the pieces are cut into 4 of 2 in. sq. each, and interleaved in a book of gold-beater's skin, called a "shoder," the 150 pieces being now 600. Another beating with a 9 lb. hammer spreads out these, and another cutting augments the number from 600 to 2,400. These are separated into 3 packets of 800 each, and each beaten in a book of gold-beater's skin, called a mold; this beating, lasting 4 hours, is done with a 7 lb. hammer. The leaves are then cut into 3¼ in. sq., which are interleaved in books and made up in packs. Leaf gold is the thinnest substance produced, being 1-280,000 of an in., a single grain covering 56 sq. in. Dentists' gold is thicker than ordinary leaf gold.

MELTING. — Prepare a good fire; heat the ingot in which you wish to cast the gold, a lit-

tle hotter than boiling water; next put the alloy in the crucible, add a small quantity pulverized borax, and leave on the fire until melted. Cast this in a clean ingot; after breaking the bar into fragments, return to the pot and remelt, not adding borax this time, but when the gold looks clear and smooth on the top, add for every 6 oz. a piece of saltpetre size of a pea; and in about a minute pour the gold. Keep up the heat after adding the saltpetre, and, previous to pouring the gold, pour a few drops of oil into the iron ingot. If the stock was clean the gold will roll well. Much depends on the first rolling of the stock; 18 carat should be subjected to a heavy strain; the first and second draughts, which imparts a grain to the stock; light draughts stretch the gold on the surface, and the middle portion remaining as cast, causes the gold to crack; many good bars having been condemned, when the trouble was in the rolling. After the 18 carat has been rolled to twice its original length, it must be annealed, then rolled to the size required. Proceed with melting 14 carat as described for 18 carat, giving it as heavy strains in the rolls, but not rolling so much before annealing as the 18 carat. The other carats do not require saltpetre to toughen; instead use a little sal ammoniac, and proceed as above. When annealing red gold, do not quench when red hot, but allow the gold to blacken before quenching, otherwise it will slit. Melt new alloys twice; treat solder the same way, to insure thorough admixture of the copper with the gold.

PLATING.—Cast the bar of gold to be plated the width desired and roll to $\frac{1}{8}$ in. in thickness. If silver, cast the bar same width as the gold and roll a little longer. Usually lower grade metal is 2 or 3 times the thickness of the better, therefore use as much as will make the proportion desired. Planish as nearly flat and straight as possible; then file one face of silver and one face of gold until bright. Previous to this roll a piece of plate solder thin, say 36 in. round size plate, and cut a strip a little wider and a little longer than the gold. Emery paper can be used to clean each side from dirt. Cover the surface with ground borax on each side; do the same on the bright faces of the gold and silver; place the solder between them, as meat in a sandwich. Have a piece of iron wire $\frac{3}{8}$ in. thick and 3 ft. long, place lengthwise on the gold and squeeze the whole tightly in a vice. Now bind with heavy binding wire every in. or so together. Make a charcoal fire in the forge, and build it so as to be like an oven and then solder; when the solder melts on each side the whole length, the thing is done; then roll as other stock. If you are making gold plating, 18 k. or 16 k. on 14 k. and 12 k., you must use gold solder, about 5 or 6 kts. less than the inferior gold. If gold on silver or composition, use one of the solders given in this department.

POLISHING POWDERS.—1. Rock alum burnt and finely powdered, 5 parts; levigated chalk, 1 part; mix; apply with a dry brush.—2. Sesquioxide of iron (iron rust), 70 per cent., and sal ammoniac, 20 per cent. To prepare it, protochloride of iron, obtained by dissolving iron in hydrochloric acid, is treated with liquid ammonia until a precipitate is no longer formed. The precipitate is collected in a filter, and dried at such a temperature that the adhering sal ammoniac shall not be volatilized. The protoxide of iron precipitate at first becomes charged with sesquioxide.

RECOVERING FROM GILT METAL.—Take a solution of borax water, apply to the gilt surface and sprinkle over it some finely powdered sulphur; make the article red hot, and quench it in water; then scrape off the gold, and recover it by means of lend.

RECOVERING GOLD LOST IN COLORING. — Dissolve a handful of sulphate of iron in boiling water; add this to the "color" water; it precipitates the small particles of gold; draw off the water, being careful not to disturb the sediment; now proceed to wash the sediment from all trace of acid with plenty of boiling water; it will require 3 or 4 separate washings, with sufficient time between each to allow the water to cool and the sediment to settle before pouring the water off; then dry in an iron vessel by the fire, and finally fuse in a covered skittle pot with a flux.

REFINING. — 1. Melt in a small black lead crucible with about an equal weight of silver (or copper); pour in a thin stream into cold water (to granulate), and boil in pure nitric acid until action ceases. The gold will be found at the bottom. Decant the liquid, wash the residue, and fuse in a crucible. Precipitate the silver from the liquid by addition of hydrochloric acid; gather it on a filter; wash with hot water; mix with a quantity of dilute sulphuric acid (acid 1, water 5), and add a few strips of zinc. The zinc will dissolve, and the silver be reduced to metallic form. Wash, dry, and fuse the silver sponge. The copper may be obtained from the liquid by adding zinc. As the zinc dissolves the copper is deposited. — 2. To remove tin from the stock, previous to pouring the gold throw a small piece corrosive sublimate in the pot; stir with a long piece of pointed charcoal, and allow the pot to remain on the fire $\frac{1}{2}$ minute. This will take tin from the alloy; while the tin is in, the gold will not roll without cracking. To remove emery or steel filings from gold, add a small piece of glass gall, while melting; it will collect them in the flux.

— 3. To separate gold from silver; the alloy is to be melted and poured from a height into a vessel of cold water, to which rotary motion is communicated, reducing to a finely granulated condition. The metallic substance is then treated with nitric acid and gently heated. Nitrate of silver is produced, which can be reduced by any of the ordinary methods; while metallic gold remains as a black mud, which must be washed and melted.

SOLDERING. — 1. Use solder adapted to the work on hand; never soft solder on an article when it can be avoided, provided there is any great strain on the part broken, or it may require to be hard soldered; and there is scarcely any worse job than to hard solder work once soft soldered. Before commencing, remove the set; if it can not be done, bury the set and ring in a raw potato; if very delicate, cut a thin slice of the potato, and push the ring through far enough to allow the set enough projection to be covered by water (which is in a glass and the potato bound on top). Place a small piece of charcoal under the joint, if there is room enough; use plenty of borax, and heat gradually until pretty well forged; then place a brass pin across the joint to attract the solder; place enough solder on to make a firm joint, and fuse quickly. To prepare an article to be soldered make the broken parts bright and even so as to press against each other firmly, or hold in place by binding wire. In soldering rings, beware of the low carat gold or those filled with base metal fusible at a low temperature. The best way to mend the latter class is to place a thin band the size of the ring, to extend $\frac{1}{4}$ way on the inside of the ring, and fasten in with a liberal supply of soft solder, which may be dressed out so as not to show, and make a very respectable job. — 2. To hard solder solid gold set rings such as amethyst, cameo and garnet, use jewelers' solder with gold of a somewhat lower title than the article to be soldered, using borax, flux, and blowpipe, enveloping the other parts with tissue paper and whiteningor plaster Paris.

SOLDERS.—1. (*Easy Running.*)3 dwt. silver solder; 1 dwt. 12 k. gold; as much arsenic as can be held on a silver 5 cent piece.— 2. (*Soft.*) 4 parts gold, 1 part silver, and 1 part copper. It can be made softer by adding brass, but the solder is liable to oxidize.—3. (*Enameled Work.*) Gold, 1 oz.; silver, 1 oz.; copper, 10 dwt.; silver solder, 8 dwt., 8 gr.—4. (*For 22 k.*) Gold for 22 carats, 1 dwt.; silver, 2 gr.; copper, 1 gr.— 5. (*For 18 k.*) 14 gr. gold; 6 gr. silver; 4 gr. copper. — 6. (*For 18 k.*) Red gold to color; 14 gr. gold; 5 gr. silver; 5 gr. copper. — 7. (*For 16 k.*) 12 gr. gold; 7 gr. silver; 5 gr. copper. — 8. (*For 16 k.*) Red gold to color; 12 gr. gold; 7 gr. silver; 5 gr. copper. — 9. (*For 14 k.*) 10 gr. gold; 8 gr. silver; 6 gr. copper. — 10. (*For 14 k.*) Red gold to color; 10 gr. gold; 8 gr. silver; 6 gr. copper. — 11. (*For 7½ k.*) 7½ dwt. gold; 9$\frac{3}{4}$ dwt. silver; 6$\frac{3}{4}$ dwt. copper. To make this flow easily, add 15 gr. brass (second melting.) — 12. (*For 5 k.*) 5 dwt. gold; 13 dwt. silver; 6 dwt. copper; add 15 gr. brass (second melting.) — 13. (*For 3½ k.*) 1 dwt. gold; 1 dwt. copper; 1 dwt. brass; 4 dwt. silver coin; add the brass when it is melted a second time.

SOLDER, Soft, Removing.—1. Place the articles in a vessel containing muriatic acid, and allow them to remain in 2 hours; the acid should be warmed, say 90°. The articles require to be recolored or gilt afterward. — 2. Nitric acid dissolves solder without affecting the gold unless of inferior quality.

SOLVENT.—Mix equal quantities nitric and muriatic acids.

TESTING. — 1. A liquid for testing gold may be made with 2 oz. nitric acid, 4 dr. water, and 1 sc. muriatic acid, mixed together and kept for use in a stoppered glass bottle; the stopper should have a glass prong dipping into the mixture, so that when it is taken out the article to be tested may be touched by this prong with some of the liquid upon it. But before touching with the acid, a file should be drawn over some part of the article to make certain that it is not plated, and the liquid applied to the file marks; if the metal is base, the fact will be detected; the acid has no effect on gold. Qualities above 9 carat will stand this test. The acid would boil more or less green in inferior qualities; if alloyed with an extra quantity of silver, they will only partially stand this test, and the color of the gold would then be paler. — 2. A good test for gold is a piece of lunar caustic, fixed to a pointed piece of wood. Lightly wet the metal to be tested, and rub gently with the caustic. If gold the mark will be faint, but if an inferior metal, it will be black.

SILVER.

ALLOYS. — Copper is the only less precious metal that alloys well with silver. Its addition is an improvement, rendering the silver finer in

appearance and more sonorous; it is astonishing to note the quantity that may be added without changing the appearance of the metal. An alloy of silver and copper in the proportion of 4-5 silver to 1-5 copper, is fully as white as silver pure. When the proportion of copper rises above 1-5 it has an influence on the color. American coin silver is 1-10 copper. The baser white metals cannot be alloyed with silver to any extent, as they impart too great brittleness. A small proportion of block tin converts it into bell metal. The following are some of the alloys of silver: 1. Silver, 11 oz., 2 dwt.; copper, 18 dwt. — 2. Silver, 1 oz.; copper, 1 dwt., 12 gr. — 3. Silver, 1 oz.; copper, 5 dwt. — 4. Pure silver, 1 oz.; copper, ½ oz.; brass, ⅜ oz.; bismuth, ½ oz.; clean salt, ⅜ oz.; white arsenic, ⅛ oz.; potash, ½ oz. Melt the silver, copper and brass first, then add the other articles in the order named. Sprinkle a little borax in the crucible while melting. — 5. (*For Plating.*) Silver. 1 oz.; copper, 10 dwt.—6. (*Common, for Chains.*) Silver, 6 oz.; copper, 4 oz. — 7. (*French Alloy.*) Silver, 20 parts; purified nickel, 28 parts; copper, 52 parts. Melt the copper and nickel in the granular state; then introduce the silver. The flux employed is charcoal and borax, in powder, and the ingots obtained are rendered malleable by annealing for a considerable time in powdered charcoal.

BURNISHING. — Polishing by removing the roughness upon the surface. This mode of polishing is expeditious, and gives great lustre. The form and construction of the burnisher is variable and must be adapted to the various kinds of work. In general it is only intended to efface inequalities. Whatever substance the burnisher is made of, is of little consequence provided it is a harder substance than the article operated on. To burnish silver, clean off any kind of dirt contracted while making, as that would spoil the burnishing. Take very fine pumice-stone powder, and with a brush, made wet in strong soapsuds, rub the work, even those parts which are to remain dull, which will receive a beautiful white appearance; wipe with an old linen cloth, and proceed to burnishing. The burnishers are of 2 kinds (steel and hard stone, curved or straight, rounded or pointed), and made to suit projecting parts or hollows. Stone burnishers are made of blood-stone, cut and rounded with the grindstone, or rubbed so that they present at the bottom a blunt edge or a rounded surface. These are polished with emery like steel burnishers, and are finished by rubbing upon leather covered with crocus martis. The stone is mounted in a wooden handle. The best bloodstones contain the most iron, and when polished present a steel color. Take hold of the tool near the stone, and lean hard with it on parts to be burnished, causing it to glide by a backward and forward movement without taking it off the piece. When requisite that the hand pass over a large surface at once without losing its point of support on the work-bench, in taking hold of the burnisher place it just underneath the little finger. During the process, moisten the tool with black soapsuds. The water causes it to glide easily, prevents heating and facilitates action. The black soap, containing more alkali than the common, acts with greater strength in cleansing away greasiness; it also detaches spots which spoil the beauty of the burnishing. In consequence of friction, the burnisher loses its bite, and slips over the surface as if it were oily; to restore its action, rub from time to time on the leather. The leather is fixed on a piece of hard wood, with shallow furrows along it. There are generally two leathers—one of sole leather, the other of buff leather. The first impregnated with oil and crocus martis, and used for blood-stone burnishers; the other has a little putty of tin in the furrows for rubbing steel burnishers. Bloodstone being hard, is used in preference to the steel burnisher. It is only on small articles and in difficult places, that steel burnishers are used. When the articles, on account of their minuteness, or from any cause, cannot be held in the hand, fix them in a frame on the bench; but manage the burnisher so as to leave untouched those parts of the work intended to remain dull. When, in burnishing plated or silver lined articles, there is any place where the precious metal is removed, restore it by silvering the places. The burnishing finished, remove the soapsuds which adhere to the work, by rubbing with old linen cloth. When there are a great number of small pieces to finish, throw them into soapsuds and dry afterwards with sawdust.

CLEANING.—When silver becomes tarnished from soldering, either of the following may be used: 1. Expose to a uniform heat, and boil in strong alum water. — 2. Immerse in a liquid made of ½ oz. cyanuret of potassa to 1 pt. rain water; then brush off with prepared chalk. (See receipts in HOUSEHOLD.)

COATING FOR SILVERWARE. — 1. The loss of silver from the action of sulphur compounds in the air, especially where gas is burned, is great. As a protection apply a coat of collodion as follows: Warm the articles and apply a thin coat diluted with alcohol, using a soft brush. — 2. Spirits wine, 1 pt., divided into 3 parts; mix 1 part with gum mastic in a bottle; 1 part spirits and ½ oz. sandarae in another bottle; and 1 part spirits and ½ oz. whitest gum Benjamin in another bottle; mix and temper to suit. If too thin, add mastic; if too soft, add sandarae or Benjamin. When used, warm the silver before the fire, and, with a flat camel's hair pencil stroke it over till no white streaks appear; this will preserve the silvering for years. (See *Metals, Polished, Varnish for*, in VARNISHES, JAPANS AND LACQUERS.)

FROSTING. — 1. Put 1 dr. sulphuric acid into 4 oz. rain water. Heat the solution and sink the silver in it till frosted, then wash clean and dry in sawdust. — 2. To frost polished silver, cyanide of potassium, 1 oz., dissolved in ½ pt. water. Do not hold the silver in the hand, but use pliers of lancewood or boxwood, and apply the mixture (violent poison) with a brush to the surface.

IMITATION. — 1. Combine by fusion 1 part pure copper, 24 parts block tin, 1½ parts pure antimony, ½ part pure bismuth and 2 parts clear glass. The glass may be omitted save in cases

where it is an object to have the metal sonorous. — 2. Pure copper, 750 parts; nickel, 140 parts; black oxide of cobalt, 20 parts; tin, in stick, 18 parts; zinc, 72 parts. — 3. (*Byzant.*) Melt 4 lbs. pure copper with 3 oz. tin. This closely resembles and rings like sterling silver, and is valuable for mountings, etc., where pure silver would be too expensive.

NIELLED. — A kind of inlaid enamel obtained by sulphuration of parts of a silver object. Instead of being direct, it is produced by inlaying the silver surface with a sulphide of the same metal prepared beforehand. For preparing the niel, heat a certain proportion of sulphur in a deep crucible; heat a certain quantity of silver, copper, and lead in another crucible, and when melted pour into the fused sulphur, which transforms these metals into sulphides; then add a little sal ammoniac; remove from the crucible and pulverize for use. First crucible—flowers of sulphur, 27 oz.; sal ammoniac, 2¾ oz. Second crucible, which after fusion is poured into the first—silver, ½ oz.; copper, 1½ oz.; lead, 2¾ oz. 1. After having reduced the niel to a fine powder, mix with a small proportion of a solution of sal ammoniac; hollow out the engraving upon a silver surface and cover the whole with the composition; then heat in a muffle until the composition solders to the metal. Uncover the pattern by a level polish, when the silver will appear as over a black ground. — 2. Engrave in relief a steel plate, and press it against the silver plate between two hard bodies. The copy is hollow and ready to receive the niel. A great many copies may be obtained from the same matrix.

OLD SILVERING, To Imitate. — To imitate silver productions, the ground work and hollow portions are covered with a blackish red earthy coat; the parts in relief remain with a bright lead lustre. Mix a thin paste of finely-powdered plumbago with essence of turpentine, to which add a small proportion of red ochre, to imitate the copper tinge of old silverware; smear over the articles. After drying, gently rub with a soft brush, and the reliefs are set off by cleaning with a rag dipped in spirits of wine. Old silver is easily removed and the brightness of the metal restored by a hot solution of caustic potash, cyanide of potassium, or benzole. To give old silver tinge to small articles such as buttons and rings, throw them into the above paste and rub in a bag with a large quantity of dry firwood sawdust until the desired shade is obtained.

ORNAMENTAL DESIGNS ON SILVER. — Select a smooth part of the silver and sketch on it the design with a sharp lead pencil; place the article in a gold solution with the battery in working order, and in a short time all the parts not sketched will be covered with gold. After cleansing the article, the black lead is easily removed by the fingers, and the silver ornament disclosed. A gold ornament may be produced by reversing the process.

OXIDIZED. — Ornaments to which this name is given have a surface of silver acted on by some chemical liquid. A solution of sal ammoniac will give a brownish tint; a better one is obtained by using equal parts sulphate of copper and sal ammoniac, dissolved in vinegar. A fine black tint may be produced by a slightly warm solution of sulphide of potassium. Solutions of the chlorides of platinum and gold are sometimes adopted.

PLATING. — File the parts to receive the plate smooth; apply over the surface muriate of zinc; hold this part over a dish containing hot soft solder, and with a swab apply the solder to the part to which it will adhere; brush off superfluous solder that the surface may be smooth; now take No. 2 fair silver plate, of the right size to cover the surface, and lay the plate upon it, and rub down smooth with a cloth moistened with oil; then, with a tinned soldering iron, pass slowly over the surface of the plate, which melts the solder underneath it, causing the plate to adhere firmly; then polish the surface and finish with buckskin.

REFINING. — 1. The impure metal is dissolved by nitric acid, and the solution being largely diluted with water, add to it an excess of a filtered solution of common salt. A white precipitate of chloride of silver is produced, which settles to the bottom of the vessel. All the silver salt is decomposed when the clear liquid is not rendered turbid by a further addition of common salt. The chloride of silver is collected and washed several times until the liquors are no longer colored brown by yellow prussiate of potassa; this is proof that the copper has been washed out. The washed chloride of silver is mixed with 2 or 3 times its weight of carbonate of soda; dried, and melted in a crucible; after cooling the metal is found at the bottom of the crucible. To granulate, the molten silver is poured from a height of about 3 ft. into water. — 2. The alloy of copper and silver is dissolved in nitric acid and the solution evaporated until the salts fuse. After cooling, the fused mass is gradually thrown into a red-hot crucible, when the nitric acid escapes, leaving the silver in a metallic state and the copper as oxide. The separation of the two is aided by adding dry borax. Silver is easily dissolved in pure nitric acid, but not so rapidly in one contaminated by chlorine or hydrochloric acid, which produces a coat of chloride of silver around the metal, and retards solution. Sulphuric acid combines with silver, and resulting salt is slightly soluble. Pure silver is employed for the preparation of the nitrate and other silver salts, and for soluble anode in silver baths.

SILVERING. — 1. Dissolve 2 oz. silver with 3 gr. corrosive sublimate; add tartaric acid, 4 lbs.; salt, 8 qts. — 2. Dissolve 1 oz. nitrate of silver in crystals in 12 oz. soft water; then dissolve in the water 2 oz. cyanuret of potash; shake together, and let stand till clear. Have ready ½ oz. vials; fill ⅓ full Paris white, or fine whiting; then fill the bottles with the liquor, and it is ready for use. The whiting helps to clean the articles and save the silver fluid. — 3. Dissolve 1 oz. silver in nitric acid; add a small quantity of salt; wash it and add sal ammoniac, or 6 oz. salt and white vitriol; also ½ oz. corrosive sublimate; rub together to a paste; rub the piece to be silvered with the paste; heat till the silver runs,

after which dip it in a weak vitriol pickle to clean it. — 4. Chloride of silver, 3 oz.; salt of tartar, 6 oz.; prepared chalk, 2 oz.; common salt, 3 oz.; mix well; dip a moist cork into this powder and rub the article to be silvered.

SOLDERS. — Silver solders are used for soldering silver work, gold, steel, and gun-metal. A neater seam is produced with the hard silver solders than with soft solders. — *Hard.* 1. 2 or 3 parts of good silver and 1 of ordinary brass pins or wire well melted, is a good jewelers' hard solder; but it must not be melted more than once. — 2. Hard silver solder composed of 4 parts fine silver and 1 of copper, made into an alloy and rolled into sheets, is difficult of fusion. These alloys are run into convenient bars or strips for use. — 3. (*White.*) Silver, 1 oz.; tin, 1 oz.—4. 16 dwt. silver coin; 3 dwt. brass; 1 dwt. copper. — *Soft.* A strong, easy-flowing white solder is composed of lead, 1 part; tin, 2 parts. When the lead is melted put in the tin; then throw in a small piece of rosin as a flux. In soldering fine work wet the parts with muriatic acid in which as much zinc has been dissolved as the acid will take up. It is cleaner than using Venice turpentine or rosin. (See *Soldering* in ALL METALS.)

TESTS. — 1. 12 grains nitrate silver, crystal; 7 drops nitric acid, pure; ½ oz. distilled water. A drop of the fluid on gold or silver will turn black on counterfeit; on genuine remain clear. — 2. Place a genuine coin in the mouth partly under the tongue, then place the suspected coin on the tongue permitting the outer edges of the two pieces to come in contact. If a counterfeit, a peculiar stinging sensation and a disagreeable taste is experienced, which does not occur if both pieces are genuine.

WHITENING. — 1. Adapted to treating silver filagree ornaments, rendering them dead white. If pewter is found in the articles, it should not be attempted. Pound together charcoal, 3 parts; nitre, 1 part; add water to form a paste. With a camel's hair brush give the article a thin coat of mixture; put it in a small annealing-pan, and submit to fire until red-hot; then withdraw it, let it stand a minute, and turn it out into a weak solution of sulphuric acid (1 part acid, 10 parts water) in the boiling-pan. Boil; pour off the acid; rinse; wash with warm water and soap, using a soft brush; dip in spirits of wine, and dry in boxwood sawdust. If spots remain, anneal without the mixture; boil out and wash as before. Burnish parts intended to be bright. Do not use the common American saltpetre; English nitre goes further and does the work more effectually. — 2. ½ dr. sulphuric acid to 4 oz. water makes a good solution for whitening silver articles.

SPECTACLES.

REMARKS. — The important parts of perfect spectacles are the sides, the nose-piece, and the lenses. The sides should be elastic and yet firm enough to hold the lenses correctly to their position before the eyes. The nose-piece should be of proper length and its curve of right depth, so that the centre of each lens shall be opposite the pupil of the eye. For reading-spectacles, the curve of the bridge should be deep, and the bridge at the curve bent out from the line of the lenses. For distant-sight, the curve of the bridge should be shallow and not bent forward from line of lenses. In order to bring the surface of the lenses at right angles to the axis of the eyes when the spectacles are on, set the sides at an angle with the line of the lenses. Cheap spectacles wear the eye and injure the optic nerve; the glasses are only pressed in a convex form, therefore not the same power all over the glass, and are full of bubbles. The important parts of an eye-glass are the form of the eye, the spring and the lens. The oval form is the best, as it is impossible with any other shape to have the centres of the lenses opposite the pupils of the eyes. Spectacle lenses are double convex or concave, periscopic-convex or concave, plano-cylindrical and sphero-cylindrical. They are made of crystal Brazilian quartz, commonly called pebbles, and flint glass. Pebble-lenses are extremely hard, do not scratch or break readily and bear a higher polish than glass; are more refractive and not so thick. Next to pebbles, fine white flint is a good material.

DEFECTIVE VISION. — The 5 most common causes of weak eyes and defective vision susceptible of relief and improvement by spectacles, are as follows: *Astigmatism.* A defect of vision arising from a want of conformity in the outer curve of the cornea, or front portion of the eyeball opposite the pupil, the cornea having form of a cylindrical curve. This defect exists at birth if discovered afterward, and is overcome by the use of a lens having a cylindrical form.—*Diplopia*, or *Double-Sight.* Caused by weakness of the muscles which move the eye from side to side. This can often be relieved by prismatic spectacles. — *Cataract.* A term used to denote gradual loss of sight, arising from the lens of the eye becoming turbid. At the proper time the lens is removed by an oculist, after which strong convex lenses will restore the vision. — *Hypermetropia.* This arises from a defectively constructed eye-ball; it is the reverse of myopia, being too short from the lens to the retina; consequently the rays of light from the distant objects are not sufficiently bent to come to a focus on the retina. The impression of the object formed on the retina is confused. Hypermetropia is a birth inheritance where it is found to exist in after years; old-sighted people are apt to become hypermetropic after 60. Hypermetropic eyes are generally small and deep sunken. Convex glasses are required for correcting the defect.—*Myopia*, or *Near-Sightedness.* A difficulty to see distant objects distinctly. It arises from a defectively constructed eye-ball; the distance from the lens to the retina at the back part of the eye being too great, the rays of light coming from a distant object are bent to a focus before reaching the retina, and form confused pictures. Myopia may exist at birth, or be contracted in youth, by long application to reading, writing, or sewing, particularly where the light is poor. Near-sighted eyes are generally prominent, and require concave lenses. — *Presbyopia.* "Old-sight" or

"far-sight;" a physiological defect depending upon the hardening of the lens of the eye, so that it can no longer change its shape to the same extent as formerly. This begins early and gradually increases, but in natural eyes causes no inconvenience until from the 40th to 45th year, when it will be found difficult in ordinary light to read diamond type nearer than 8 in. For comfortable use of the eyes by gas-light, a weak convex glass to assist the lenses of the eyes is necessary.

FOCAL DISTANCE OF LENSES, To Ascertain. — Place the end of a measure of 30 or 40 in. in length against a smooth wall in plain view of some well-defined object a few rods distant. Then place the edge of the lens on the measure, and move it backwards or forwards until a clear and distinct outline is produced on the ground against which your measure rests. This point will represent sufficiently near the exact focal distance of the lens, and correspond in in. with the number on all properly marked convex spectacles.

LENSES, To Polish when Scratched. — If the scratches are not deep, stretch a piece of silk over the face of the lens, and apply to it a ball of sealing wax warm enough to take the form of the lens when it is pressed on the silk. When the wax is cool, remove it and the silk together from the lens, and coat the silk with a paste of putty powder. Rub the face of the lens with the instrument thus made, giving it a gyratory motion. Keep the putty powder moist.

TIME-KEEPERS.

REMARKS. — When buying a watch, while adhering to taste and elegance, choose one thick enough. In a watch that is too thin or too little, the parts are feeble and have not space to work well. Avoid those that point the days of the month, and so forth. These pieces necessitate additional parts which encumber the limited space, though complicated watches, such as chronographs, repeaters, etc., are now brought to a high state of perfection at a correspondingly high cost. Do not be attracted by the supposed advantages of new escapements. In watches for ordinary purposes, the lever and the horizontal escapements generally give the best results. A watch bought for utility ought to be as plain as possible, which is a distinguishing characteristic of good quality. Having obtained a serviceable article, wind it up every day at the same hour. Avoid putting a watch on a marble slab or near anything cold. The sudden transition contracts the metal, and may cause the mainspring to break. The cold, also, coagulates the oil, and the wheel-work and the pivots working less freely affect the regularity of the time-keeper. When laying aside slope it on a watch-case so as to keep it in nearly the same position as it has in the pocket. Be sure that it rests on its case, as by suspending it free the action of the balance may cause oscillation, which may interfere with its running. To keep clean, see that the case fits firmly, and never put it in any pocket but one made of leather; pockets lined with cloth, cotton or calico, give off fluff, which enters most watches, even in the cases of those which shut firmly. The key should be small, in order that the resistance of the stop-work may be felt, so as to stop in time. The square of the key should correspond with that of the watch. If it be too large, it may cause the wind-up square to suffer from undue wear and tear, the rectifying of which is expensive. It is always better to move the hands forward to adjust the watch to correct time.

GLOSSARY OF TIME-KEEPER TERMS. —

ARBOR.—An axle which turns upon itself by means of its pivots. Some watchmakers apply the term only to the post on which the key is placed to wind the watch, and to the rod passing through the cannon.

ANCHOR. — A piece of the escapement used in clocks and lever watches.

ANCHOR ESCAPEMENT WATCH. — A detached lever.

BARREL. — That piece of the watch which contains the main spring.

BRIDGE. — A piece secured to the plate, in which a pivot works, as in the case of skeleton levers.

BALANCE. — A wheel which moves back and forth in obedience to the adverse action of the lever and hair spring.

BEAT. — Each "tick" of the watch.

CLICK. — A small lever which works into a ratchet and prevents the sudden recoil of the mainspring when the watch is wound up.

CENTRE WHEEL. — The large wheel immediately in the centre.

CHICK. — A small pin; usually those which hold the bridges in position.

CYLINDER. — The hollow piece which checks the onward motion of the scape-wheel in cylinder escapement watches.

CANNON. — The steel piece which comes up through the dial, and around which the hour wheel revolves. In English and American levers the minute hand is fastened upon it.

COMMON PINION. — The pinion at the lower end of the cannon, which moves the minute wheel.

COCK. — Bridge over the balance.

COLLET. — A small ring fitting on the balance staff or arbor, and holding the inside end of the hair-spring. The rings into which jewels are sometimes set are called collets.

DIAL. — The face of the watch or clock.

DIAL WHEELS. — Those working between the dial and pillar plate.

DEPTHING TOOL. — An instrument used for finding the proper location of pivot holes.

ESCAPEMENT. — Those pieces which work together and regulate the velocity of the time train.

FUSEE. — The cone-shaped wheel upon which the chain works.

FOURTH WHEEL. — The wheel which works into the scape-wheel.

FOURTH WHEEL SECOND. — A watch carrying a second hand on the pivot of its fourth wheel.

FORK. — That part of the lever into which the ruby pin plays.

FLY. — An arbor carrying two wings for the purpose of meeting with atmospheric resistance, thus regulating the motion of striking trains in clocks.

GUARD POINT. — The wedge-shaped elevation back of the fork in detached levers.

GEARING. — The action of the teeth of one wheel upon those of another wheel or pinion.

HOUR WHEEL. — The wheel working around the cannon, and upon which the hour hand is fastened.

INDEX. — Hand.

JEWEL. — The stone or glass settings against which the pivots work; also the settings in the pallets and the roller.

LEAVES. — Teeth or cogs of a pinion.

LEVER. — A horizontal bar upon which the pallets are secured, and which conducts the effect of the motive power from the train to the balance.

MINUTE WHEEL. — A name given to that dial wheel which is driven by the cannon pinion.

MOVEMENT. — The interior works of the clock or watch.

PALLETS. — The jeweled piece of the lever watch which works into the teeth of the scape-wheel.

PIVOT. — The end of an arbor turned very small to avoid friction.

PINION. — A small leaved wheel.

PILLARS. — Posts which in plate watches hold the plates the proper distance apart for the working of the train or trains between them.

PILLAR PLATE. — Usually the bottom plate of a watch; but European watchmakers call both pillar plates, distinguishing them as the upper and lower.

TIME-KEEPER TERMS, *Continued.*

PUTTING UP. — Setting the different parts of a clock or watch into their proper places.

PIVOT WOOD. — A tough wood employed in cleaning out pivot holes; sometimes called peg wood. A scape-wheel is sometimes called a ratchet in Europe.

RATCHET. — A steel wheel into which the click works.

RUBY-PIN. — A small glass or stone pin which works in connection with the lever.

ROLLER. — The circular plate into which the ruby-pin is set; often called the ruby-pin table.

STOP WORKS. — A mechanism to prevent the watch from being wound up too far.

STAFF. — A name applied to the balance arbor of lever watches as solo the arbor passing through the pallets.

SCAPE-WHEEL. — The last wheel of the train.

SECOND WATCHES. — Watch with a second hand.

SCRATCH BRUSH. — A brush made of fine brass wire.

TEETH. — Cogs by which the motion of one wheel is communicated to another.

TRAIN. — A collection of wheels so arranged that the moving power applied to the first wheel is communicated to them all.

THIRD WHEEL. — The wheel into whose pinion the centre wheel works.

TAKING DOWN. — Taking apart the different pieces of a clock or watch.

WHEEL BED. — A bed turned out in the plate of a watch to receive a wheel.

BEAT, To Put Watches in.—If a cylinder escapement or a detached lever, put the balance into a position; then turn the regulator to point directly to the pivot-hole of the pallet staff, if a lever, or of the scape-wheel, if a cylinder. Then lift out the balance with its bridge or clock; turn it over, and set the ruby-pin directly in line with the regulator, or the square cut of the cylinder at right angles with it; the watch will then be in perfect beat. If an American or an English lever, when the regulator is fixed upon the plate, proceed differently. Fix the balance into its place, cut off the connection of the train, if the mainspring is not entirely down, by slipping a fine broach into one of the wheels; look between the plates and ascertain how the lever stands. If the end farthest from the balance is equidistant between the 2 brass pins, it is all right; if not, change the hair-spring till it becomes so. If a duplex watch, see that the roller notch, when the balance is at rest, is exactly between the locking tooth and the line of centre; that is, a line drawn from the centre of the roller to the centre of the scape-wheel. The balance must start from its rest and move through an are of 10° before bringing the locking tooth into action.

BRUSHES, Cleaning.—Wash them in strong soda water; when the backs are wood, avoid that part as much as possible, for, being glued, the water will injure them.

BURNISHERS. — Burnishers which have become too smooth, may be improved with flour of emery. Melt a little beeswax on the face of the burnisher; its effect on brass or fine metals will equal the best buff. A small burnisher prepared in this way is the very thing to polish watch wheels; resting them on a piece of pith while polishing.

BUSHING. — The holes through which the great arbors, or winding axles, work, are the only ones that require bushing. When too much worn, the great wheel on the axle strikes too deeply into the pinions above it, and stops the clock. To remedy this, drive a steel punch into the plate above the axle hole, forcing the brass downward until the hole is reduced to its original size. Or solder a piece of brass upon the plate in a position to hold the axle down to its proper place.

CLEANING CLOCKS.—Take the clock to pieces; brush the wheels and pinions with a stiff brush; also the plates which the trains work; clean the pivots by turning in a piece of cotton cloth held tightly between the thumb and finger. The pivot holes in the plates are cleansed by turning a piece of wood in them, but a strip of cloth or a soft cord drawn tightly through them acts best. If 2 cords are used, the first slightly oiled, and the next dry, all the better. Do not use salt or acid; boiling the movement in water is foolishness.

CLEANING WATCHES. — Great care is necessary in taking the watch down, and separating its parts. First remove the hands carefully; next the movement from the case, and take off the dial and dial wheels; let down the mainspring by placing the bench-key upon the arbor or winding-post, and turn as if to wind until the click rests lightly on the ratchet; with screwdriver press the point of the click away from the teeth and ease down the springs; draw the pins and remove the bridges of the train, or the upper plate, as the ease may be; remove the balance with care to avoid injuring the hair-spring. The small post into which the hair-spring is fastened may be removed from the plate of most watches without unkeying the spring, by slipping a thin instrument, like the edge of a blade knife, under the corner of it and prying up; this will save trouble in not having the hair-spring to adjust when the balance is reset. If the watch has an upper plate, loosen the lever before entirely separating the plates; or it will hang and probably be broken; brush dust from the parts, and carefully examine with the eye-glass. The teeth of the wheels and leaves of the pinions should be perfect and smooth; the pivots all straight, round and polished; the holes through which they are to work not too large and not oval in shape; every jewel smooth and sound, and not loose. See that the escapement is not too deep or too shallow; that the lever or cylinder is perfect; that the wheels have play to avoid friction; that none of them work against the pillar plate; that the balance turns horizontally and does not rub; that the hair-spring is not bent or wrongly set so that the coils rub on each other or on the plate or on the balance; in short that everything is just as it should be. If otherwise, repair in accordance with judgment, after which clean as follows: Simply blow upon the plate or bridge to be cleaned, then use the brush with a little prepared chalk. The wheels and bridges should be held between the thumb and finger in a piece of soft paper, otherwise the oil from the skin will prevent their becoming clean. The pinions may be cleaned by sinking them several times into a piece of pith, and the holes by turning a nicely shaped piece of pivot wood into them, first dry and afterwards oiled a little with watch oil. When the holes pass through jewels work gently. Some employ the "chemical process" to clean, as follows: Remove the screws and steel parts; then dampen with a solution of oxalic acid and water; let it remain a few minutes, then immerse in a solution made

of ½ lb. cyanuret potassa to 1 gal. rain water; let remain about 5 minutes; then rinse well with clean water, after which dry in sawdust or with a brush and prepared chalk. This gives the work an excellent appearance.

DEMAGNETIZING. — A watch is formed of a case of gold or silver, and glass inclosing brass or nickel plates, between which are a number of steel arbors forming the axles and pinions of the brass wheels; also the spring of steel which uncoils itself; older watches have in addition a steel chain which uncoils from the fusee on to a brass barrel inclosing the mainspring; the hair-spring, parts of the balance wheel escapement, stem winding apparatus, etc., are also of steel; thus there is abundant material for magnetization. These are only moderately hard and easy to demagnetize. Some have their lengths at right angles to the plane of the watch, like the arbors; others, like the main and balance wheel springs and the nickel (nickel takes a magnetic charge, only feebler) plates inclosing the movements, have their greatest dimension in the plane of the watch. The position determines to a great extent the directions of their magnetic axes (imaginary lines joining the two poles of a magnet). The arbors have their magnetic axes in the direction of their lengths; plates are most likely to have theirs in the direction of one of their diameters. No matter in what direction, all these bodies may be demagnetized by properly oscillating the watch before the pole of a magnet. The watch is placed close to the magnetometer and with the centre of the thickness of the watch about on a level with the centre of the needle of the magnetometer, and with the line, connecting the centre of the watch, *C*, *Fig. 1*, and the centre of the needle, at right angles to the magnetic meridian, it is turned slowly around on its centre as an axis, and each hour on its dial is, in succession, brought opposite to the center, *C*, of the magnetic needle of the magnetometer. The following results of experiments will ensue: *N* and *S* indicate the kind of magnetic polarity at each hour, and the angles show the effect in angular deflection on bringing that hour of the dial opposite the centre of the magnetometer needle:

Hour.	Ang. of Deflection of Magnetometer.	Kind of Magnetism.
XII	20°	N.
I	5°	N.
II	18°	S.
III	72°	S.
IV	56°	S.
V	22°	S.
VI	5°	N.
VII	17°	N.
VIII	16°	N.
IX	16°	N.
X	20°	N.
XI	24°	N.

When the hour III is brought opposite the magnetometer needle the fusee axle and the centre of the semicircular steel catch of the inner cover of the works are presented to the magnetometer. The strong south magnetism of III is due to the magnetization of these bodies, which deflects the needle of the magnetometer 72°. The strong north magnetic action of XI is due to the magnetized main spring. We may now regard the watch as a magnet, having the form of a disc,

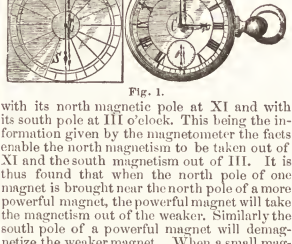

Fig. 1.

with its north magnetic pole at XI and with its south pole at III o'clock. This being the information given by the magnetometer the facts enable the north magnetism to be taken out of XI and the south magnetism out of III. It is thus found that when the north pole of one magnet is brought near the north pole of a more powerful magnet, the powerful magnet will take the magnetism out of the weaker. Similarly the south pole of a powerful magnet will demagnetize the weaker magnet. When a small magnet, made of steel not too hard, is vibrated around its centre in front of the pole of a powerful magnet, the small magnet is demagnetized. These facts show how to demagnetize the watch. XI is of the strongest north magnetism of any on the dial; therefore place this hour opposite the north pole of the rat-tail file magnet shown in *Fig.* 2. The centre of the watch, *C*, is placed so that the prolongation of the axes of the magnet (shown by the dotted line X X′) passes through it. The watch is now vibrated around an axis passing through *C* and at right angles to *X X*′. By this operation the watch is successively brought into the positions *A* and *B* of *Fig. 2*. After several vibrations of the watch before the north pole of the magnet, turn the hour III, of strong south polarity, opposite the south pole of the magnet, and vibrate the watch as in the previous experiment. By these vibrations the watch cuts across the lines of magnetic force, and any magnetism in it is thus taken out. After these operations performed on the hours XI and III, the watch is again examined before the magnetometer, and the following table gives the effect of the vibrations before the magnet:

Hour.	Ang. of Deflection of Magnetometer.	Kind of Magnetism.
XII	2°	N.
I	5°	N.
II	4°	N
III	0°	
IV	5°	S.
V	8°	S.
VI	2°	S.
VII	4°	N.
VIII	4°	N.
IX	2°	N.
X	1°	N.
XI	0°	

There is a great difference between the magnetometer deflections of the first table and those of the second. It is observed that the hours III and XI, which were respectively of strong south

and north magnetism in the first table, are in the second table marked 0°. This result being attained after a series of vibrations before the pole of the demagnetizing magnet, the magnetic condition of hours III and XI are tested. Sometimes the magnetism almost disappears, then changes, or rather is inverted, so that hour III has north instead of south polarity, and hour XI has south instead of north magnetism. When this happens present hour III before the north pole of the magnet and the hour XI before the south pole. After repeated trials hours III and XI can be demagnetized so that they produce no action whatever, or 0° on the needle of the magnetometer. The watch is again brought before the magnet, and its V o'clock vibrated before the south pole till this south magnetism disappears; in other words, produces no deflection on the needle of the magnetometer. An examination of the magnetism of the watch before the magnetometer gives the following results:

Hour.	Ang. of Deflection of Magnetometer.	Kind of Magnetism.
XII	1°	
I	0°	
II	0°	
III	0°	
IV	2½°	S.
V	2°	S.
VI	2°	N.
VII	6°	N.
VIII	5°	N.
IX	2°	N.
X	1°	S.
XI	2½°	S.

The hour VII was demagnetized of its 6° of north magnetism by vibrating this hour opposite the north pole of the demagnetizing magnet.

DIALS, Figures on Gold and Silver. — Hold a small piece of copper over a gas flame a few minutes till coated with soot; clear this off on to a piece of finely ground glass; add fat oil and a small quantity of oil of spike lavender, and grind up; then paint with a small camel's hair pencil.

DIALS, To Restore. — If the dial be painted, clean the figure with spirits of wine; heat to a bright red, and plunge into a strong solution of cyanide of potassium; then wash in soap and water and dry in box dust. Repeat if not a good color. India ink, ground with gum water, will do for the figures.

FROSTING WATCH MOVEMENTS. — Sink the part to be frosted for a short time in a compound of nitric acid, muriatic acid and table salt, 1 oz. each. On removing from the acid, place it in a shallow vessel containing sour beer sufficient to cover it; with a scratch brush scour, letting it remain under the beer during the operation; then wash off, first in pure water and then in alcohol. Gild or silver.

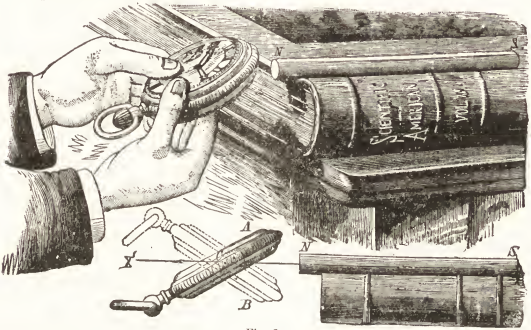

Fig. 2.

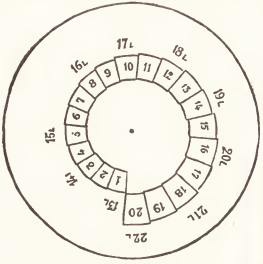
GAUGE. — As there is no recognized standard for length of watch hands, the accompanying gauge is given to supply this deficiency. It consists of a disc with graduated scale numbered from 1 to 20, in two snails from the centre, the inner snail for the hour, and the outer for the minute hand. The even numbers correspond with the hour and minute circles of dials of English movements of the sizes which those numbers indicate. The odd numbers are for intermediate sizes, dials with wide margins, such as crystal case or chonograph watches, or others in which the dial painter has not adopted the usual distances for the hour and minute circles. In such cases there cannot be exact correspondence between the numbers of the movements and those on the gauge. But these numbers may still be accepted, as well as many others, in the presence of these irregularities, being sufficient to meet all requirements. The figures 14L, 15L, etc., signify "lignes," showing where the signs are coincident with the dials of Swiss watches. This gauge enables watchmakers to have hands such lengths as they require, by the mention of the number on the gauge, without sending the dial, or marking off the lengths. It should be retained by dial painters to avoid deviation, not

only in the size of the minute circles, but the length of the hour figures. As movements are



Watch Gauge.

made to a recognized standard, the painting of dials should follow the same regularity, and if so, this gauge will supply a standard.

HAIR-SPRING, To Reduce. — 1. Effected by grinding the spring down. Remove the spring from the collet, and place it upon a piece of pivot wood cut to fit the centre coil. A piece of soft steel wire, flattened to pass between the coils and armed with pulverized oil-stone and oil, will serve as a grinder, and with it the strength of the spring will be reduced. The operations will be confined to the centre coil, for no other part of the spring will rest against the wood to enable you to grind it. — 2. Another and later process is to fit the collet (without removing the spring) upon a stick of pivot wood, and, with a little diluted nitric acid in a watch-glass, plunge the centre coils into it, keeping the other parts of the spring from contact by holding it in the shape of an inverted hoop-skirt, with tweezers. Expose a few seconds, governing the time by the degree of effect desired; then rinse, first with clean water, afterwards with alcohol. Dry in the sun, or with tissue paper.

HANDS, To Redden.—Mix to a paste over a lamp, 1 oz. carmine, 1 oz. chloride of silver, and ½ oz. tinners' Japan. Put some of the paste on the hands, and lay them face up on a sheet of copper, holding it over a spirit lamp till the color appears.

HANDS, To Reblack.—Use asphaltum varnish. One coat will make old rusty hands look as good as new.

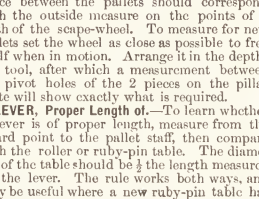
JEWELING. — The diamond broach, used in jeweling, is made as follows: Prepare a number of brass pins of size and form desired; stir the point of each separately into a medium grade of diamond dust (see *Diamond Dust* in GEMS) and oil until evenly covered; then place on a smooth stake or anvil, and with a light hammer go over the surface, driving the dust into the brass. In using broaches, press but lightly into the jewel hole, and turn the broach rapidly with the fingers. For polishing use a bone or ivory point, lightly coated with diamond dust and oil, and while using it with one hand accompany it with a slight oscillating motion of the other hand in which the jewel is held. This insures a more even polish, with less liability to press the jewel out of its place. (See *Diamond Files*, and *Diamond Mill*, in GEMS.)

LEVER ESCAPEMENT, To Change Depth of.— If operating on a fine watch, put a new staff into the lever, cutting its pivots a little to one side, just as far as is desired to change the escapement. The usual process with common watches is to knock out the staff and with a small file cut the hole oblong in a direction opposite to that in which you desire to move the pallets; then replace the staff, wedge it up to the required position, and secure by soft soldering. Where the staff is put in with a screw, take out the staff, pry the pallets from the lever, file the pinholes to slant in the direction you would move the pallets, without changing their size on the other side of the lever. Connect the pieces as they were before, and, with the lever resting on some solid substance, strike lightly with the hammer until the bending of the pins allows the pallets to pass into position.

LEVER PALLETS, Proper Size of.—The clear space between the pallets should correspond with the outside measure on the points of 3 teeth of the scape-wheel. To measure for new pallets set the wheel as close as possible to free itself when in motion. Arrange it in the depthing tool, after which a measurement between the pivot holes of the 2 pieces on the pillar plate will show exactly what is required.

LEVER, Proper Length of.—To learn whether a lever is of proper length, measure from the guard point to the pallet staff, then compare with the roller or ruby-pin table. The diameter of the table should be ½ the length measured on the lever. The rule works both ways, and may be useful where a new ruby-pin table has to be supplied.

MERIDIAN, To Find. — Set up a stick, *A B*,



Finding the Meridian.

and on its end fasten a piece of tin perforated with a hole. Let the string of a plumb bob hang through the centre of this hole, and thus get a point in the vertical marked *V* in the dia-

gram. About 9 A. M. mark the centre of the image of the hole at D, then with the line $A\,D$, as a radius, describe an arc of a circle; and when, in the afternoon, the image of the hole falls on this line, as at E mark, then the line $N\,S$, which bisects the angle $D\,A\,E$, is the true meridian.

MAIN SPRINGS. — When a main spring is cleaned, inexperienced workmen take hold of one end and pull the spring $\frac{1}{2}$ its length straight out; this will ultimately break the spring. If old oil is used, or of an inferior quality, the acid will eat into the spring and destroy it. The coil nearest the centre breaks first, and as it recoils it breaks every coil in the barrel, and sometimes each coil is broken twice.

OILING CLOCKS. — Only the pallets of the verge, the steel pin upon which the verge works, and the point where the loop of the verge wire works over the pendulum wire, should be oiled, and that lightly. Use the best watch oil.

OIL, Watchmakers'.—1. Take neat's-foot oil, and put into it some lead shavings in order to neutralize the acid in the oil; let this stand, the longer the better. Oil thus prepared never corrodes. — 2. Best olive oil; stir for some time with water kept at a boil; then, after separation, shake up in a bottle with a little fresh lime, and let it stand some weeks exposed to the sunlight and air, but protected from wet and dirt; when filtered it will be limpid. — 3. 1 qt. olive oil; put it into a cast-iron vessel capable of holding 2 qts.; place over a slow fire, keeping a thermometer suspended in it, and when the temperature rises to 220° check the heat so as not to exceed 230° nor descend below 212,° until the water and acetic acid are evaporated; the oil is then exposed to a temperature of 30° to 36° for 2 or 3 days; then filtered; lastly, the fluid portion must be filtered once or more through newly prepared animal charcoal, coarsely powdered, and placed on bibulous paper in a wire frame within a funnel, by which the oil is rendered colorless.

PENDULUM, Defect in.—Examine the pendulum wire at the point where the loop of the verge wire works over it; generally a small notch or rough place is found worn. Dress it out smooth, or the clock will not work well; this defect stops numbers of clocks.

PHOSPHORESCENT DIALS. — These are made of paper, or thin card-board covered with adhesive varnish or white wax mixed with turpentine, upon which is dusted powdered sulphide of barium. The sulphides of strontium and calcium possess the same property, but lose it more quickly. After the dial has remained in darkness some days it loses its phosphoreseence; this may be restored by exposure for an hour to sunlight, or by burning near the dial a few in. of magnesium wire.

PINIONS OR BEARINGS, To Preserve from Rust. — In ease of the lower centre bearing under the eannon pinion corroding, take the central wheel off; clean it thoroughly; if the pivot is scratched, polish, then make a little hollow in the top hole, put good fresh oil on it, and the pivot will not corrode for 2 or 3 years. The other pivots should be cleaned; if no dust gets in and no accident happens, the watch will run for years.

PINIONS, Rules for Finding Diameter, by Measuring Teeth of the Wheel that Match into it.—The term full, as used below, indicates full measure from outside to outside of the teeth named, and the term centre, the measure from centre of one tooth to centre of the other tooth named, inclusive. For diameter of a pinion of 15 leaves measure, with calipers, a shade less than 6 teeth of the wheel, full; for diameter of a pinion of 14 leaves measure, with calipers, a shade less than 6 teeth of the wheel, centre; for diameter of a pinion of 12 leaves measure, with calipers, 5 teeth of the wheel, centre; for diameter of a pinion of 10 leaves measure, with calipers, 4 teeth of the wheel, full; for diameter of a pinion of 9 leaves measure, with calipers, a little less than 4 teeth of the wheel, full; for diameter of a pinion of 8 leaves measure, with calipers, a little less than 4 teeth of the wheel, centre; for diametcr of a pinion of 7 leaves measure, with calipers, a little less than 3 teeth of the wheel, full; for diameter of a pinion of 6 leaves measure, with calipers, 3 teeth of the wheel, centre; for diameter of a pinion of 5 leaves measure, with calipers, 3 teeth of the wheel, centre. As a general rule, pinions that lead, as in the hour wheel, should be larger than those that drive, and pinions of clocks should be somewhat larger proportionally than those of watches. For diameter of a pinion of 4 leaves measure, with calipers, $\frac{1}{2}$ of one space over 2 teeth of the wheel, full.

PINIONS, Worn, to Remedy.—Turn the leaves or rollers so the worn places will be towards the arbor, and fasten them in that position. If they are rolling pinions, and cannot be secured otherwise, do it with a little soft solder.

PIVOT, Broken. — Drill into the end of the pinion or staff and having inserted a new pivot, turn it down to the proper proportions. This is not difficult when the piece to be drilled is not too hard, or when the temper may be slightly drawn without injury to other parts.

PIVOT FILES. — Dress up a piece of wood file-fashion 1 in. broad, and glue a piece of fine emery paper upon it. Shape the file then as you wish it, of the best cast steel, and before tempering pass emery paper heavily across it several times, diagonally. Temper by heating to a cherry red, and plunging into linseed oil. Old worn pivot files may be made new by this process. They dress a pivot more rapidly than any other file.

POISING WATCH BALANCE. — This may be done very accurately by scraping one arm of the calipers with a file when the balance is set in motion. This will cause the heaviest part to settle down with certainty, observing always that the pivots are nicely rounded and formed at the ends. In some cases it is necessary to put a balance out of poise to make the watch go equally in various positions. To make the watch gain, the balance should be heaviest on the lower side when hanging up; to make it lose, the reverse.

POLISHING BROACHES. — These are usually made of ivory, and used with diamond dust, loose, instead of having been driven in. Oil the broach lightly, dip it into the finest diamond dust, and proceed to work it into the jewel the same as you do the brass broach. Too many fail to attaeh sufficient importanee to the polishing

broach. The sluggish motion of watches is often attributable to rough jewels.

REGULATING. — Ascertain how many vibrations the watch beats in one minute, by counting every other vibration and comparing with a regulator. In general, Swiss watches beat 18,000 in 1 hour, or 300 in 1 minute; American watches, 16,200, or 270 per minute; English levers, 14,400, or 240 per minute. If there is any doubt count up leaves and teeth, and ascertain the number; but cases are scarce where watches beat odd numbers. Having found the number, examine the balance for 1 or 2 minutes, counting every vibration from right to left, and in the meantime examining the regulator to see when one minute is up. If the watch is well regulated, the number of vibrations must be exactly $\frac{1}{5}$ of the regular first number, viz., 150, 135, or 120, as only every other vibration has been recorded to facilitate observation. If not so, move the regulator, right or left, until a perfect coincidence comes. To pick up a new hair-spring, after having recorded the right number of beats—either by the old hair-spring or by the numbers of the train—lay first the spring with its centre well in the centre of the cock jewel, and having ascertained where the coil will enter between the pins of the regulator, note the place. Stick to the pivot of the balance a small round piece of beeswax; then stick it to the centre of the spring, to establish a temporary connection of the two pieces, and having pinched with the tweezers the hair-spring to the place indicated by the regulator pins, cause it to vibrate gently; then count the vibrations for one minute, and when you have a spring that will produce nearly the required number of beats, pin it to the collet, and cause it to vibrate, moving the tweezers forward and backward, until the right number of beats is produced; with another pair of tweezers, pinch the hair-spring $\frac{1}{8}$ in. back of the regulating point, to counterbalance the gain produced by the regulator pins, and bend slightly the wire, which is the place where the hair-spring must be pinned to the stud. Having trued up the spring, proceed to put the regulator to the right place. The balance must be made to vibrate on some hard and well polished substance to keep up the vibration to the standard of regular running. A little practice enables the watchmaker to change a hair-spring quick and without any trouble.

RUSTED SCREWS. To Remove. — When the screws have become rusty, they can only be removed by mechanical means, such as scouring with fine powder or with fine emery paper.

STRIKE, Correcting. — In putting up a clock be careful to get none of the striking train wheels in wrong. If this happen, pry the plates apart on the striking side, slip the pivots of the upper wheels out, and having disconnected them from the train, turn them part around and put them back. If still not right, repeat the experiment. A few efforts will get them working properly. The sound in cuckoo clocks is caused by a wire acting on a small bellows connected with 2 small pipes like organ pipes.

TIGHTENING A COMMON PINION ON CENTRE ARBOR.—Grasp the arbor lightly with a pair of cutting nippers, and by a single turn around the arbor cut or raise a small thread thereon.

TEETH, To Put in Wheels without Dovetailing or Soldering.—Drill a hole wider than the tooth, square through the plate below the base of the tooth; cut from the edge of the wheel square down to the hole drilled; flatten a piece of wire to fit snugly into the cut of the saw, and with a light hammer form a head on it like a pin; then press the pin into position in the wheel, the head filling the hole drilled through the plate and the end projecting out to form the tooth; then, with a sharp-pointed graver cut a small groove each side of the pin from the edge of the wheel down to the hole, and with a blow of the hammer spread the face of the pin to fill the grooves cut. Repeat the operation on the other side of the wheel, and finish in the usual way. The tooth will be found riveted and as strong as the original one, while in appearance it will be equal to the best dovetailing.

TEMPERING CASE SPRINGS.—Having fitted the spring into the case, temper hard by heating and plunging into water; polish the small end so as to see when the color changes; lay it on a piece of copper or brass plate, and hold the plate over a lamp with the blaze under the largest part of the spring. Watch the polished part of the steel, and when it turns blue remove the plate, letting all cool gradually. When cool, polish the end of the spring, place it on the plate and hold over the lamp. The third bluing of the polished end will leave the spring in temper.

TEMPERING CLICKS, RATCHETS, Etc. — Clicks, ratchets or other steel articles, requiring a similar hardness, should be tempered by heating to a cherry red and plunging into mercurial ointment. No other mode will combine such toughness and hardness.

TEMPERING STAFFS, CYLINDERS OR PINIONS. Without Springing.—Prepare the articles as in the preceding process, using a steel plug. Having heated the key-pipe to a cherry red, plunge into water; polish the end of the steel plug, place the key upon a plate of brass or copper, and hold it over the lamp with the blaze under the pipe till the polished part becomes blue; cool gradually, then polish again. Blue and cool a second time, and the work is done.

TEMPER. To Draw from Small Articles.—Hold the part with a pair of tweezers, and with your blowpipe direct the flame till sufficient heat is communicated to the article to produce the desired effect.

TIME, To Prevent Losing.—Pin the pendulum spring into the stud, so that the part of the eye immediately emerging from the collet and the centre of the collet are in a line, pinned in, in equal terms, as it is called. Bring the watch to time by adding to or taking from the balance, and poise it; try the watch with the 12 up for 2 hours, then with the 6 up for 2 hours, then lying down for the same time; the trials described will be sufficient if the watch has seconds; keep the curb pin close to allow the spring only a little play; the vibration of the balance should be $1\frac{3}{4}$ turn or $1\frac{1}{2}$ lying.

INVASION OF THE GOTHS AND VANDALS.

PAINTING AND PAPER-HANGING.

BRONZING AND GILDING.

REMARKS.—Bronzing, in the narrower sense, includes only those manipulations whereby the appearance of bronze is imparted to the surface of an article of metal, wood, plaster, etc., by covering it with a metal. But the meaning of the word has been extended to include every process whereby a metallic appearance is imparted to any non-metallic object, or the bright surface of a metal is covered with a thin, dull coating of brown, reddish, or even black color, to protect it from change. In the former kind of bronzing, finely divided metal is dusted upon the object after it has been painted with oil varnish and is almost dry, the surface being then burnished with hard tools; in the latter kind, several methods are employed. For the first kind of bronzing, different metallic or dust bronzes are employed; these are pulverized metallic alloys, much used to cover wooden, plaster, and metallic articles, on account of their beautiful color and lustre. They are made from the scraps and waste of real or imitation gold or silver leaf and other alloys, beaten thin, mixed with honey or gum solution, and rubbed upon marble slabs. On a large scale metal foil, greased with olive oil, is rubbed through wire sieves by means of wire brushes, and pulverized in steel mortars, then polished with revolving brushes. In some cases a bronze appearance is produced by the use of chemicals applied to the surface; receipts of this kind will be found in METAL WORKING. The commonest bronze colors are real gold leaf, mosaic gold, real silver leaf, imitation silver leaf, mosaic silver, steel, copper bronze, bronze colored bronze or bronze powder, the greenish copper bronze, brownish gold bronze, gold colored copper bronze, blue bronze, and some alloys of bronze metal. Gilding is usually performed by applying size to the object to be gilded, then laying gold leaf on this. The necessary materials to be used are a cushion, knife, and tip, a large, short and thick camel's hair brush, cotton-wool, and oil and japanners' size. There are 13 varieties of tint, ranging from a deep orange red down to a white approximating silver. The cushion is a piece of wood about 8 in. by 5, covered first with baize, and then with buff leather tightly stitched. At one end there is a raised edge of parchment, which turns partly round the sides, to prevent the leaves being blown away. Underneath, the cushion has 2, and sometimes 3 small loops of leather, one for inserting the thumb to hold it by, the other for sticking the knife and camel's hair brush in. The knife for cutting the leaf has a long flexible blade, set in a light handle like a palette-knife. The knife must be kept bright. The tip is a large flat brush for taking up and placing the gold leaf.

BRASS, Bronze for. — *Black.* Lampblack, a thimbleful; put it on flat stone; add 4 or 5 spots of gold size; mix with a palette-knife; make it as thick as putty; well mix. The less gold size the better, so that the lampblack sticks together; if too much be added, the effect will be a bright black and not a dead black; now add turpentine, twice its own volume, to the whole; mix with a camel's hair brush, and apply to the brass.

BRIGHTENING GILDING.—Alum and common salt, of each, 1 oz.; purified nitre, 2 oz.; water, ¼ pt. Used to impart a rich color to gold surfaces, principally trinkets. It should not be too long continued, as it dissolves a small portion of the gold. For common use, dilute with water.

GOLD COLORED BRONZE.—1. Verdigris, 8 oz.; tutty powder, 4 oz.; borax and nitre, of each, 2 oz.; bichloride of mercury, ½ oz.; make into a paste with oil and fuse together. — 2. Gold bronze for furniture is a mixture of copal varnish, made with gold colored bronze powder (bisulphate of tin). — 3. Gold bronze is used on carriage parts for striping and ornamenting, using the same size as that used for gold leaf. For taking up and applying the bronze, take a piece of plush or velvet and make a pounce bag by tying up a wad of cotton, rubbing the bronze gently over the size. To vary the appearance, a mixture of copper, gold, and silver bronze may be applied. For fancy work in bronze, cut out any desired pattern on thin sheet brass, pasteboard, or paper; and apply it to any nearly dry varnished surface; rub the bronze on through the apertures in the pattern.

GRECIAN GILDING.—In this variety sal ammoniac and corrosive sublimate, equal parts, are dissolved in nitric acid, and a solution of gold made with this menstruum; after slight concentration the liquid is applied to the surface of silver, which becomes black, but on being heated exhibits a rich gilded surface.

GREEN BRONZE.—Bluish-green bronze for ornamental articles is made of any metal, first covered with a varnish made of ground tin or bronze powder, rubbed up with honey in gum water; then wash with a mixture composed of sal ammoniac, ½ oz., common salt, ½ oz., and 1 oz. spirits hartshorn in 1 pt. vinegar. After applying the mixture, leave for a day or two in the sun, and, if necessary, add a second coat. This is a good way to renovate old gas fixtures.

IRON BRONZE.—Ivory black, 1 oz.; chrome yellow, 1 oz.; chrome green, 2 lbs.; mix with raw linseed oil; add a little japan to it, and you have a very nice bronze green. Gold bronze may be put on prominent parts, as on tips or edges of iron railings, where the paint is not quite dry. Use a piece of velvet to rub on the bronze.

JAPANNERS' GILDING.—The surface is covered with oil size, thinned with spirits turpentine, and gold, in powder, is gently dabbed on with a puff of wash leather; this gives the appearance of frosted gold. A coating of varnish is next given, followed by exposure to a gentle heat in the stove.

PAINT, Gilding on.—The paint must first be dry. The letters must be written on the paint with gold size, and allowed to get a little dry. Now press the gold leaf on the size, and rub it down with a piece of cotton-wool. If by accident there is more than one thickness of gold it will appear dull.

PICTURE FRAMES, To Gild.—The ornaments being adjusted and allowed time to harden on the frame, the first step taken by the gilder is to wash them, together with the frame, from the adherent oil and dust; when dry, apply a uniform coat of thin white to the frame, and, after drying, fill all holes and defective parts with the stopping; when this becomes hard, go over every part of the work and bring it to smoothness with fine glass paper. Now dust off the work and apply the clay; allow it to dry, and rub smooth with fine glass paper. A coat of clear cole is now applied, consisting of parchment size diluted to a thin consistency with water. Apply 2 coats of this size in a warm condition. It prevents absorption of the succeeding coat of oil size. The gilder prepares the oil size (boiled linseed oil and ochre well ground together) by bringing it to a creamy consistency, and purifies it by straining through a clean rag held under pressure, squeezing out the size. This preparation is spread evenly over the prepared surface, and allowed to stand until it becomes tacky, when the knife, cushion and gold leaf are brought into requisition, and the leaf applied with the tip to the entire surface covered with size. This process requires care; the gilder blows the gold leaf out on the cushion with his breath, and divides it with his knife to cover the different parts of the work. The leaf is dabbed down with a dabber of cotton-wool, and finished with a badger. The frame, being now covered, is brushed off to clear it from the gold particles adhering, and is finished by applying the finish-size evenly with a hog's-hair brush over the work. The finish consists of a somewhat weak, clear size, which may be tempered with a little ormolu to impart a finer color to the gold. (See *Varnish for Gilding.*)

PLASTER OF PARIS, To Bronze.—Lay the figure over with isinglass size, until it holds out, or without any part of its surface becoming dry; then, with a brush, termed by painters a sash tool, go over the whole, to remove any of the size that may lodge on the delicate parts. When dry, take a little thin oil gold size, and with as much as just damps the brush, go over the figure, allowing no more to remain than causes it to shine. Set in a dry place free from smoke, and in 48 hours the figure is prepared to receive the bronze. After having touched over the whole figure with the bronze powder, let it stand another day, and then with a soft, dry brush rub off all the loose powder, particularly from the points, or more prominent parts of the figure.

POWDERS, For Bronzing and Gilding.—1. Pure gold, 5 dr.; pure copper, 1 dr.; aqua regia, 10 oz.; dissolve; moisten clean linen rags with the solution; dry them, and burn them to ashes. The latter contain the gold in a state of minute division, and must then be carefully collected.—2. Put into an earthen mortar some gold leaf, with a little honey or thick gum water, and grind the mixture till the leaf is reduced to minute particles. When done, a little warm water will wash out the honey or gum, leaving the gold behind in a powdered state.—3. Dissolve the pure gold, or the leaf, in nitro-muriatic acid; then precipitate it by a piece of copper, or by a solution of sulphate of iron. The precipitate, if by copper, must be digested in distilled vinegar, and then washed by pouring water over it repeatedly, and dried. This precipitate will be in the form of fine powder; it works better and is more easily burnished than leaf ground with honey.—4. (*Brownish Gold.*) This is made from clean iron filings, by moistening repeatedly with a little water and exposing them to the air, then boiling several times and drying in the sun or on a stove. It forms a rust brown powder, which becomes more intensely red if some nitric acid is added in the last boiling; it is elutriated to separate any metallic particles, and dried. By mixing this powder with imitation gold bronze, mosaic gold, copper bronze, and greenish bronze, separately or together, the most varied and different shades of bronze color can be obtained.—5. (*Gold Imitation.*) Made, like the real gold bronze, from the waste of beating of the so-called Dutch leaf, by triturating with a solution of gum, washing in water, and drying quickly, then rubbing again to increase the lustre. The color depends upon the proportion of copper to zinc; if the former predominates, it is redder; if the latter, yellower; so that the deepest red consists of pure copper; the bright yellow of 83 parts copper and 17 of zinc; the orange red of 99 parts copper and 1 of zinc. The violet and green shades are obtained by heating with a greasy substance (oil, wax,

or paraffine), which produces a sort of patina.

SIGNS. To Gild.—The following method is for working in the open air, when the process with the cushion is rendered difficult if there is much wind to blow. Take a sheet of tissue paper and rub it over on one side only with a piece of white wax. This should be rubbed briskly over the surface of the paper, which should be placed on something flat, so that the wax is spread evenly. The paper thus rubbed will possess a sticky quality, scarcely perceptible to the touch, but sufficient to cause the leaf to adhere. After a whole sheet of paper has been waxed, it should be cut into squares a little larger than the leaves of the book of gold. The gold-leaf book must be opened and the waxed side of the tissue paper gently pressed upon the gold leaf with the hand. On removing the paper the gold leaf will be found attached to it. The tissue paper may be used over and over again. It is supposed that the letters to be gilded have been written in the most suitable material, and that they are ready to receive the gold leaf. Take up the tissue paper and place it with the gilded side to the letters, and, having rubbed the back lightly with the hand, the gold will come off the paper and adhere firmly to the mordant with which the lettering has been written. By this method little gold is wasted, as, the tissue paper being semi-transparent, the gold leaf shows through it, and the operator can see where any portion adheres to the paper, and can place it on such portions of the work as it will best fit without an undue number of joinings; though by this process, if the gold leaf is good, not the slightest trace of joining is discernible. The gold leaf should be gently dabbed over with a pad of cotton-wool, which will smooth the gilt, and remove superfluous pieces of leaf. As a newly-painted surface is sticky, if the gold leaf were to be applied to it, it would adhere to parts of the ground color where the size had not touched and where the golu was not required; it is needful, before letters or parts to be gilded are marked out, that the painted surface should be dabbed lightly with dry whiting; but care should be taken that loose particles are dusted off by the application of a silk handkerchief. If the ground is a dark one, this pouncing will so far lighten it, that the gilder will be able to distinguish any lines he may make with size, as the size will restore the ground to its original color. But if the ground is a light one, the pouncing will not have this effect, and it is necessary to mix some kind of color with the size to enable the gilder to make certain that he has covered the portion to be gilded. For pouncing, put some powdered whiting in a linen bag, tied tightly, and gently dab the parts to be pounced. The whiting is removed from the ground after the gold leaf is applied, by means of a damp chamois. The sizes used for gilding are of different kinds. Picture-frame gilders use gilders' size, made of fat oil, in which yellow ochre has been ground. This is a good material for the sign-writer, but is too thick for general adoption, especially in cold weather. In hot weather, it is not so thick, and may be used with advantage. The gold leaf must not be applied to this size for at least 24 hours after its application, and it will remain tacky for 2 or 3 days. When gilding has to be finished rapidly, japanners' gold size is employed. The gold leaf may be laid on this in ½ hour after its application. Sometimes the gilder is compelled to prepare his work and put on the leaf a few minutes afterwards; in this case, gold size is used. But if an interval of a few hours is no object, it is customary to add oil varnish to the gold size, regulating quantity according to time at disposal. Linseed oil should not be mixed with gold size to retard its drying properties, because it is apt to destroy the adhesiveness of the size, and to sweat and discolor the leaf. A few drops boiled oil may be added to the size occasionally, but varnish is preferable to oils. (See *Gilding on Glass*, in SIGNS.)

SIZING.—1. Put 12 gals. linseed oil into the iron set-pot; boil 2 hours; then gradually introduce 12 lbs. litharge; continue the boiling moderately for 6 hours; let it remain until next morning, then bring to a simmer, and run in 10 lbs. gum animeand 2 gals. oil. When these 2 runs of gum are poured into the iron pot, put in 7 lbs. Burgundy pitch, which soon melts; continue the boiling, and keep ladling it down; boil it moderately, and, when right, mix it with 30 gals. turpentine, or more if needed; this should be left a little thicker than japanners' gold size, as it is used for paper-stainers to lay their flock on, and ought to dry slowly in 1 hour. — 2. (*Birmingham.*) Good drying oil, 1 lb.; pure gum anime, powdered, 4 oz.; bring the oil almost to the boiling point in a covered metal pot; add gum cautiously to the oil, stirring to dissolve completely; boil to a tarry consistency and strain through silk into a warm bottle with a wide mouth; keep corked; use as required, thinning with turpentine. — 3. Yellow ochre, 1 part; copal varnish, 2 parts; linseed oil, 3 parts; turpentine, 4 parts; boiled oil, 5 parts; mix. The ochre must be in the state of the finest powder, and ground with a little of the oil before mixing. — 4. Heat raw linseed oil in a pan till it emits a black smoke; set it on fire, and, after burning a few minutes, cover the pan to put out the blaze; pour the oil while warm into a bottle in which pulverized red lead and litharge have been introduced; stand the bottle in a warm place for 2 weeks, shaking often. It will then be ready to decant and bottle. — 5. To ½ lb. parchment shavings or cuttings white leather, add 3 qts. water; boil till reduced to ½ the quantity; then take it off the fire, and strain it through a sieve; be careful in the boiling to keep it stirred, and do not let it burn. — 6. (*Japanners' Gold.*) Gum ammoniac, 1 lb.; boiled oil, 8 oz.; spirits turpentine, 12 oz.; melt the gum; then add the oil, and lastly the spirits turpentine.

SOLUTIONS FOR GILDING.—1. (*Elkington's Liquid Gilding.*) Fine gold, 5 oz. (troy); nitro-muriatic acid, 52 oz. (avoirdupois); dissolve by heat, and continue the heat until red or yellow vapors cease to be evolved; decant the clear liquid into a suitable vessel; add distilled water, 4 gals., pure bicarbonate of potassa, 20 lbs., and boil for 2 hours. The nitro-muriatic acid is made with pure nitric acid, 21 oz.; pure muriatic acid,

17 oz., and distilled water, 14 oz.—2. Silks, satins, woolens, ivory, bone, etc., may be readily gilded by immersing them in a solution of neutral terchloride of gold (1 of the salt, and 3 to 6 of water), and then exposing them to the action of hydrogen gas. The latter part of the process may readily be performed by pouring some dilute sulphuric acid on zinc or iron filings, in a wide-mouthed bottle, and placing it under a jar or similar vessel, inverted, at the top of which the articles to be gilded are suspended. Flowers, or other ornamental designs, may be produced by painting them on the surface with a camel's hair pencil dipped in the solution. The design, after a few minutes' exposure to the hydrogen, shines with all the splendor of the purest gold, and will not tarnish on exposure to the air, or in washing. — 3. (See *Gold Colored Bronze*, 2.)

STEEL, Polished, Bronze for. — To 1 pt. methylated spirits add 4 oz. gum-shellac and ½ oz. gum benzoin; put the bottle in a warm place, shaking it occasionally. When dissolved, decant the liquid and keep for fine work. Strain the residue through a fine cloth. Take ½ lb. powdered bronze green, varying to suit the taste with lampblack, red ochre, or yellow ochre. Take as much varnish and bronze powder as required, and lay it on the article, which must be thoroughly clean and slightly warm. Add another coat, if necessary. Touch up with gold powder according to taste, and varnish over all.

VARNISH, For Gilding.—Cheap bronzes and gilding with alloys may be kept from tarnishing by covering with either of the following: 1. Beeswax, 4 oz.; verdigris and sulphate of copper, of each, 1 oz. — 2. Beeswax, 4 oz.; verdigris, red ochre and alum, of each, 1 oz.; mix. Used to give a red color to water gilding.

WATER GILDING.—Will not bear being wetted, and is only fit for work kept in-doors. The wood is first covered with 4 or 5 coats whiting and size; and, that the gilding be perfect, it is necessary there should be a sufficient body of whiting. When these are dry, they are laid over with a coat of gold size, made of Armenian bole, a little wax, and some parchment size. When the size is dry, a portion of the surface is wetted with clear water and a soft brush, and a leaf of gold is applied, so as to almost float on the water, when it instantly settles down and adheres to the size; great care must be taken not to suffer any of the water to come over the gold, or a stain will be produced. When the whole is covered with gold leaf, the effect is what is called matt, or dead gold, and is the natural color of gold not burnished. Parts required to be burnished are rubbed with a burnishing tool of agate. Ornaments executed partly matt and partly burnished, have a very rich effect, which is seen in most picture frames. Frames executed in water gilding are sometimes required to be regilt; this cannot be done without taking off the whole of the whiting, and commencing the process again, which is expensive. When this is done, the frames may be either regilt in the water or in the oil manner; and as the last is much the cheapest, it is sometimes preferred, although it cannot be burnished.

WOOD, To Bronze.—1. Pipeclay, 2 oz.; Prussian blue, patent yellow, raw umber, lampblack, of each, 1 oz.; grind separately with water on a stone, and as much of them as will make a good color put into a small vessel ⅔ full of size. The wood, having been previously cleaned and smoothed, and coated with a mixture of clean size and lampblack, receives a new coating twice successively with the above compound, having allowed the first to dry. Afterwards the bronze powder is to be laid on with a pencil, and the whole burnished, observing to repair the parts which may be injured by this operation; next, the work must be coated over with a thin layer of Castile soap (which will take the glare off the burnishing), and afterwards carefully rubbed with a woolen cloth. The superfluous powder may be rubbed off when dry. — 2. The wood is first covered with a uniform coating of glue or drying oil, and, when nearly dry, the bronze powder, contained in a small bag, is dusted over it. The surface of the objects is afterwards rubbed with a piece of moist rag. Or the bronze powder may be previously mixed with drying oil, and applied with a brush.

YELLOW AND LIGHT RED BRONZE.—Copper bronze powder, 1 oz.; mix with japanners' gold size, adding turpentine during its use to keep it the consistency of cream; mix with a palette-knife on glass; if made too thin, it is liable to be removed by the brush as fast as put on. Apply with a soft brush.

CALCIMINING AND WHITENING.

REMARKS.—All processes under this class may be regarded as water colors, as distinguished from the usual oil-mixed colors of painting proper. *Whitewashing* is the first and crudest process, in which only quick lime slaked in water, with perhaps the addition of a little salt, are used. *Whitening*, depending on whiting as a covering agent, with glue or other sizing to increase adhesion, is a finer process, and usually the last finishing coat over whitewash, with a little ultramarine added to give it a blue cast; this color disappears in drying, leaving a perfect white. *Calcimining* is, simply stated, colors of any desired hue added to whitening. If the ceiling and walls are new, there will be nothing further required than a coat of good Paris white, with sufficient glue-size added to bind it, provided the finishing plaster was good; but if inferior and porous, it will require a preparation of strong size, soft soap, and a handful of plaster Paris. For old ceilings and walls, all the previous whiting, etc., must be washed off with an old whitewash brush and hot water, and allowed to dry before re-whitening. When this is done, if they are porous and soak in the moisture very quickly, they must be prepared with

a mixture of lime, 1 handful; whiting, the same; glue, ½ lb.; soft-soap, ½ lb.; and if smoky or damp, about 2 oz. alum, to make a pail ¾ full. When this is dry, they are ready for the finish. Use the preparation thin. Before putting on the whiting, shut doors and windows; take a sweep right across the room, and continue till finished. When finished, the doors and windows can be opened, as the sooner they dry the more even it will look.

CEILINGS AND WALLS.—1. Take 4 oz. glue; soak the same in 1 qt. warm water from 15 to 24 hours; add 1 pt. water; then place the vessel, either tin or thin metal, containing the glue, in a kettle of hot water over the fire, the glue being stirred until melted and quite clear; then put 5 or 6 lbs. powdered Paris white into a large pail, and add hot water sufficient to make the mixture of the consisteney of cream. Then mix the glue water with the same, stirring constantly, after which paint the walls with the mixture with a whitewash brush. — 2. Take clean lumps of well-burnt lime; slake in hot water in a small tub, and cover to keep in steam. Then pass through a fine sieve in fluid form, to obtain the flour of lime; add ¼ lb. whiting or burnt alum, 2 lbs. sugar, and 3 pts. rice flour made into a thin and well boiled paste, and 1 lb. glue dissolved over a slow fire. It is more brilliant than plaster Paris, and will last a long time. It should be put on warm with a paint brush. — 3. 10 lbs. whiting, dissolved in hot or boiling water; ¼ lb. glue put to soak over night in 1 pt. water; it may now be melted on a stove, stirring it frequently. 2 oz. ultramarine blue; 1 oz. Venetian red; mix separately with cold or soft water, and strain each in separate vessels. The whiting may now be stirred well; if too thick, add more hot water, and strain through a sieve into a good sized pot. — 4. 1 dozen balls of good whiting, 2 lbs. size, and 1 oz. celestial or ultramarine blue; this will cover 12 sq. yds. Mixing: Take the whiting and break up in just enough water that you can work it about in a bucket with a stout stick. Next, take a saucepan, about 3 qts., and put a pt. water in and boil; take off the fire, and drop the size into it, and let it stand upon the stove until melted. When warm, pour into the whiting, and keep stirring it. Mix the blue with a flat stick upon a slate or board, and add until it becomes of the shade required. Lime that will produce a fast lime wash is burnt in the bottom of brick kilns, the bricks upon the top, and fired with heath, fir loppings, coal, wood, ferns, and gorse. The sand from the bricks, the chalk and the potash from the wood combined, cover the chalk or lime with a silicate soluble in water. To use this, get it fresh burnt, break it up, and pour boiling water upon it; it subsides into a beautiful cream-like consistence. This, owing to the soluble silicate in it, must be used and made fresh. It is fast, and frequently presents a glazed surface, and, if not put on too thick, is very durable. A pk. of lime will do about 20 sq. yds.; this is merely lime—the fresher the better. Slake it. Make it of the proper consistence, and add to every bucket 1 gill turps and linseed oil, mixed. Some use tallow; some size. — 5. Take 12 lbs. whiting (in large balls), break them up in a pail, and cover with water to soak. During this time melt over a slow fire 4 lbs. common size, and, at the same time, with a palette-knife, rub up fine a dessertspoonful of blue-black with water to a fine paste; then pour the water off the top of the whiting, and with a stick stir in the black; when mixed, stir in the melted size and strain. When cold, it is fit for use. If the jelly is too stiff for use, beat it and add a little cold water. Commence whitewashing over the window, and so work from the light; lay off the work into that done, and not all in one direction, as in painting.

CELLARS AND OUT-BUILDINGS. — 1. Put ½ bush. lime into a clean water-tight barrel, and pour over it boiling water to cover it 4 to 5 in. deep, stirring briskly until the lime is slaked; after slaking, add water gradually, stirring until thin enough to use; then add 1 lb. salt and 2 lbs. sulphate of zinc; this will cause the wash to harden, and prevent cracking or rubbing off. — 2. Water lime, 1 pk.; freshly slaked lime, 1 pk.; yellow ochre, in powder, 4 lbs.; burnt umber, 4 lbs.; dissolve in hot water, and apply with brush. —3. Take 1 bush. lime, and slake it with cold water; when slaked, add to it 20 lbs. Spanish whiting, 17 lbs. salt, and 12 lbs. sugar. Strain through a wire sieve, and it will be fit for use after reducing with cold water. This is intended for the outside of buildings, or where it is exposed to the weather. To give a good color, 3 coats are necessary on brick, and 2 on wood. It may be laid on similar to whitewash. Each coat must have time to dry, before the next is applied. — 4. Skim-milk, 2 qts.; fresh slaked lime, 8 oz.; linseed oil 6, oz.; white Burgundy pitch, 2 oz.; Spanish white, 3 lbs. The lime to be slaked in water, exposed to the air, mixed in ¼ the milk; the oil, in which the pitch is previously dissolved, to be added a little at a time; then the rest of the milk, and afterwards the Spanish white. This is sufficient for 27 sq. yds., 2 coats. — 5. Take 11 lbs. unslaked lime and 1 gal. boiling water, and stir into a thick pudding; then add 2 gals. boiled linseed oil and ½ lb. white potash, dissolved in 1 pt. boiling water; mix thoroughly, and if the oil and potash do not unite, add a little more potash-water; there must be enough to cut the oil, but no more. It will look thicker than paint, but will spread easily, and wear well, and has all the appearance of a superior paint, while its cost is less than ½. For barns, out-houses, fences, etc., it is unequaled.— 6. Well burned quicklime, ½ bush.; salt, 1 qt.; rice flour, and glue, ½ lb. each; water-glass (syrupy solution), 1½ pts.; water, q.s. Soften the glue over night in cold water, then dissolve it in a small quantity of boiling water. Make the flour into a paste with a little hot water, and add it to the glue solution; dilute the water-glass with boiling water, and add the salt; slake the lime with boiling water; then stir in the other materials with enough hot water to reduce to a consistence for use; stir together, cover, and let it stand several hours before using. When wanted for use make hot. — 7. Take ½ bush. nice unslaked lime; slake with boiling water; cover during the process; strain through a sieve or strainer, and add to it 1 pk. salt previously dissolved in warm water; 3 lbs. ground rice, boiled to a thin paste;

½ lb. powdered Spanish whiting, and 1 lb. clean glue, previously dissolved by soaking, and then hang it over a slow fire in a small kettle within a larger one filled with water; add 5 gals. hot water to the mixture; stir well and let stand for a few days covered from dust. It should be put on hot, and for this purpose it can be kept in a kettle on a portable furnace. Fine or coarse brushes may be used, according to the neatness of the job required. It answers as well as oil paint for wood, brick or stone, and is cheaper. It retains its brilliancy for years. Buildings or fences covered with it will take a much longer time to burn than if they were painted with oil paint. Coloring matter may be put in and made of any shade desired.

COLORINGS FOR WALLS.—Distemper color of any tint may be made by using ochre, chrome, Dutch pink, raw sienna for yellows and buff; Venetian red, burnt sienna, Indian red, or purple brown, for reds; celestial blue, ultramarine or indigo, for blues; red and blue for purple, gray or lavender; red lead and chrome, for orange; Brunswick green for greens. *Blue.* Boil slowly for 3 hours 1 lb. blue vitriol and ½ lb. best whiting in 3 qts. water; stir frequently while boiling, and also on taking it off the fire. When quite cold, pour off the blue liquid; mix the cake of color with good size, and use in the same manner as whitewash, for walls or ceilings. — *Lavender.* Make a light blue, and tint it slightly with vermilion. — *Lilac.* Add to the calcimine, 2 parts Prussian blue and 1 part vermilion, stirring thoroughly, and taking care to avoid too high a color. — *Pink.* 1. Take 1 lb. madder, and soak over night in a brass or copper kettle; set it on the fire and let it come to a boil. — 2. 2 oz. cochineal; steep in warm water 2 hours; add to it ½ oz. cream tartar. Put as much or as little of this decoction in whitewash as will make the desired shade. — *Rose.* 3 parts vermilion and 1 part red lead, added in small quantities until a delicate shade is produced. —*Straw.* Chrome yellow, with a touch of Spanish brown.

RED WASH, For Bricks. — Red ochre, 5 lbs.; water-glass, ½ lb.; dissolve the latter in boiling water and add the ochre to form a thin wash. Apply with a stiff brush while hot. — 2. To remove the green that gathers on bricks, pour over them boiling water in which any vegetables, not greasy, have been boiled; repeat for a few days, and the green will disappear. For the red wash, melt 1 oz. glue in 1 gal. water; while hot, add a piece of alum the size of an egg, ½ lb. Venetian red, and 1 lb. Spanish brown; if too light, add more red and brown; if too dark, water.

FIRE-PROOFING.

REMARKS.—The woods least inflammable are beech, oak, American elm, plane tree, and other non-resinous woods. Nothing has yet been discovered which will render wood or any vegetable fibre entirely fire-proof. There are washes and solutions that will render them uninflammable, but when exposed to great heat, the fibre will be consumed.

FENCES, Wash for. — 1 qt. fine sand, 1 part sifted wood ashes, and 3 parts lime ground with oil; mix together. Apply the first coat thin, the other thick. This adheres to planks so strongly as to resist an iron tool or fire, and is impenetrable by water.

SHINGLE ROOFS, Wash for.—Lime, salt, and fine sand or wood-ashes, put on like whitewash, renders a shingle roof 50-fold more safe against fire from falling cinders. It has a preserving influence against the weather; the older the shingles, the more benefit derived. The application of the wash restores their original form, closing the space between the shingles, and the lime and sand, and, by filling up the cracks, prevents warping. By adding lampblack, the wash may be made the color of old shingles, and thus the glare of a whitewashed roof is removed.

WOOD WORK. — 1. Apply hot glue water as long as it is absorbed into the pores of the wood; then apply a thick coat of boiled glue, and, while fresh, dust over with a powder composed of 1 part sulphur, 1 part ochre of clay, and 6 parts ferrous sulphate. — 2. A wash made of skim milk and water brine will render wood uninflammable. — 3. Paint twice with a hot saturated solution of 1 part green vitriol and 3 parts alum. When dry, paint with a weak solution of green vitriol in which pipe clay has been mixed to the consistence of paint. — 4. Boards become almost incombustible when painted with a diluted solution of silicate of soda, which is usually sold as a thick fluid, like honey. This may be thinned with water, 6 to 7 times its own bulk. The water must be soft. Apply the solution warm; in about 24 hours apply a second coat, and perhaps a third. Use a new brush, and wash in clean water after using or it will get too soft; avoid grease on the boards before painting them. This is for inside work only. — 5. Soak the wood in a strong solution of alum and sulphate of copper; about 1 lb. alum and 1 lb. sulphate of copper for 100 gals. water. These substances are dissolved in a small quantity hot water; then mixed with the water in the vessel in which the wood is to be steeped. The timber can be kept under the liquor by stones. All that is required is a water-tight vessel, sufficient to hold enough liquor to cover the timber, which should steep 4 or 5 days; then take out and let it dry before using — 6. 5 parts alum, 7 parts rye meal paste and 3 parts finely divided clay. — 7. 2½ parts sal ammoniac, 1 part sulphate of zinc, 2 parts joiner's glue, 20 parts zinc white, and 30 parts water. This will prevent wood from bursting into a flame when ignited, and delay its destruction when a fire is raging. — 8. The following may be used as a fire-proof wash for inside work: 20 lbs. pulverized glass, 20 lbs. pulverized porcelain, 20 lbs. stone in powder, 10 lbs. calcined lime, and 30 lbs. silicate of soda. The solid elements, having been powdered fine and sifted, are moistened and mixed with the silicate of soda. This yields a syrupy mass for painting either

alone or mixed with color. The lime gives unctuosity to the mass for whitewashing, and its combination with the silicate of soda serves to bind the materials together. The proportions of the different elements may be changed, save that of the silicate; these elements may even be replaced one by another; but always preserve the lime. Instead of the silicate of soda, soluble glass of potash may be used, but the former is less expensive. The coating is applied as other paints, uniformly over the surface. The first coat hardens immediately, and a second one may be applied 6 hours afterwards; two are sufficient.— 9. Asbestos paint makes a fire-proof wash for inside work. It is prepared by grinding and regrinding asbestos in water, potash, or soda aluminate, and potash or soda silicate. When it is to be exposed to the weather, it must be combined with oil, driers and gummy matters, and in some cases with zinc oxide or baryte.—10. Wood can be rendered fire-proof by first drying it, and then coating it with common whitewash. If the wood is not thoroughly dry, the whitewash shells off. It is a difficult matter to burn wood plastered over with whiting or lime wash. — 11. Commercial tungstate of soda, 1 lb.; phosphate of soda, ½ lb.; water, 2 gals.; dissolve. Apply boiling hot.

GRAINING.

BIRD'S-EYE MAPLE. — 1. Graining color: Equal parts of raw sienna and burnt umber mixed in ale, of two thicknesses. First lay on a coat of the thin mixture; then, with a smaller brush, put in the darker shades; mottle and soften with a badger-hair brush. The eye is imitated by dabbing the color, while still wet, with the fingers. When dry, put on the top grain in prominent places, and shade the eyes with a little burnt sienna. Some grainers use brushes called maple eye-dotters, instead of the fingers, for the eyes. Various forms of brushes are used for mottling; some consist of short camel's hair closely set, while, to give the wavy appearance, hog's hair mottlers are used, with long hairs, against which the fingers are pressed as the brush is drawn over the work, causing a variety of curves. The lines to imitate the heart of the wood are put in with a small brush, and the outer lines parallel to the heart are formed with the overgraining brush. Overgraining brushes for maple consist of small sable brushes mounted a little distance from each other in a frame.—2. Grind equal parts of raw and burnt sienna in water and ale. Coat the work with this color; then rub down with a long piece of buff leather, cut straight at the edge and pressed against the work. Proceed for the imitation of the eyes and heart of the wood as before directed.—3. For outside work grind the raw and burnt sienna with a little of the patent driers, and then with boiled oil; lay on an even coat, and rub down with buff leather; soften, and when dry put on a top grain of burnt umber and raw sienna ground in ale.

BLACK AND GOLD MARBLE.—1. Ground, deep ivory black. Put on veins of white lead, yellow ochre, and burnt and raw sienna, with a camel's hair brush. The spaces between the veins must be glazed with a thin coat of grey or white, over which p ss a few white veins. The veins may also be put on with gold leaf. —2. Have a yellow ground, streaked with broad ribbons of black, in which fine veins are obtained by drawing a sharp piece of wood along them while wet, so as to expose the yellow beneath.

BLACK AND WHITE MARBLE.—White ground, and with dark veins, put on with a marbling crayon, and softened while the ground is wet. Or, when the ground is dry, cover it with a thin coat of white lead, and put the veins in with a camel's hair pencil; blend while wet.

BLACK WALNUT.—The ground should be of drab, made of lead, yellow ochre, Venetian red and black. The grain color is burnt umber. Dampen the work with the grain color. Spread on the grain color with a brush; blend crosswise. Wipe out the light parts with a cloth. Blend till soft. Put in the blazes up through the centre with the blaze stick. Blend down the crude roughness of this lengthwise. When dry, rub off with a soft cloth the rough particles.

BLUE AND GOLD MARBLE.—Ground, a light blue; when dry, take blue with a small piece of white lead and some Prussian blue, and dab on in patches, leaving portions of the ground to show between; blend together with a softener; next put on white veins in every direction, leaving large spaces to be filled up with a pale yellow or gold paint; finish with fine, white, irregular threads.

DOVE-COLORED MARBLE. — Ground, lead color, of which give 2 or 3 coats. If the work is new, let it dry hard; rub smooth with fine glass paper after each coat, and do not rub the paint off the sharp edges of the wood. For marbling, take lead color, such as used for the ground; thin it with turpentine, and rub a light coat over a small part of the work; and with a whitish color form the small specks or fossil remains. Proceed, piece by piece, till the whole surface is covered, being careful to paint but a small part of the ground at once, so that the colors may have time to blend while wet, otherwise the work will appear harsh; then, with a small sash tool, put in faint, broad veins, of the thin ground color, and numerous fine veins over the whole surface of the work, crossing in every direction; then make the color lighter, by adding white lead, and, with a feather, pass over the broad veins in the same direction, forming streams of threads. With thin white, and with a camel's hair pencil, go partly over the same vein with short, thick touches, then with a fine striping pencil. When the work is hard, it should be smoothed with very fine glass paper before being varnished. The first layer of veins should be faint; for, as the lighter shades are put on, the former veins will appear sunk, which will give a good effect.

GRANITE.—1. Gray ground, with white and

black spots. — 2. Venetian and white for the ground, with white, black and vermilion spots. The spots are put on in several ways: A sponge may be charged with the marbling color and dabbed on the work, or a common brush may be struck against a stick held at a little distance from the work, so as to throw off blots and spots of color.

HAIR WOOD. — For ground color, take white lead and thin it with turpentine, and slightly stain it with equal quantities Prussian blue and lampblack. For graining color, grind in ale a mixture of Prussian blue and raw sienna; when the ground is dry spread a transparent coat of the graining color on the surface of the work, and soften; then, with the cork, mottle by rubbing it to and fro across the work, to form the fine long grain or mottle; when this is done, soften and top grain in wavy but perpendicular directions; varnish when dry.

ITALIAN MARBLE.—Ground, a light buff. For marbling, mix stiff in boiled oil, white lead, ochre and a little vermilion; grind burnt sienna very fine in boiled oil, and put it into another vessel; mix pure white stiff in oil, and keep this separate. Thin these colors with turpentine, and have a brush for each. Take the buff brush moderately full of color, and dab it on in patches, varying as much as possible; take another brush and fill in the spaces between with sienna. With a softener blend the edges, making them as soft as possible; draw a few thin, white veins over the work with a hair pencil; run in a few thin lines of sienna, and soften.

JASPER. — Mix the ground the same as for mahogony, with red lead, Venetian red and a little chrome yellow, thinned with equal parts oil and turpentine; lake or vermilion may be substituted for Venetian red, if a brilliant tint is desired. While the ground is wet, dab on spots of white; soften with a softening brush. Other colors may be applied in the same manner. When dry, put on the veins with a camel's hair brush.

MAHOGANY.—1. Vandyke brown and a little crimson lake, ground in ale, laid on, allowed to dry, and then smoothed, forms the ground. Then lay on a second thicker coat; soften with a badger brush; take out the lights while it is wet, and imitate the feathery appearance of mahogany heart; soften, and top grain with Vandyke brown, laid on with an overgraining brush of flat hog's hair, combed into detached tufts. In softening be careful not to disturb the under color.— 2. Grind burnt sienna and Vandyke brown in ale; lay on a coat; mottle with a camel's hair mottler, and soften; when dry, overgrain as above. — 3. (*Mottled.*) The ground is prepared with the best Venetian red, red lead, and a small portion of white lead. The graining colors are burnt sienna, ground in ale, with a small portion of Vandyke brown, sufficient to take away the fiery appearance of the sienna. Cover the surface to be grained; soften with the badger hair brush, and, while wet, take a mottling roller and go over the lights a second time, in order to give a variety of shade; then blend the whole of the work with the badger softener; put the top grain on with the same color; when the work has become thoroughly dry, varnish.

OAK. — *Dark.* 1. Raw sienna, burnt umber, white lead, and Venetian red. — 2. Yellow ochre, Venetian red, and white-lead. — 3. (*Pollard.*) The ground color is prepared with a mixture of chrome yellow, vermilion, and white lead, to a rich light buff. The graining colors are Vandyke brown and small portions of raw and burnt sienna and lake ground in ale or beer; fill a large tool with color, spread over the surface to be grained, and soften with badger-hair brush; take a moistened sponge between the thumb and finger, and dapple round and round in kind of knots; soften lightly; then draw a softener from one set of knots to the other while wet, to form a multiplicity of grains, and finish the knots with a hair pencil, in some places in thicker clusters than others; when dry, put the top grain on in a variety of directions, and varnish with turps and gold size; then glaze up with Vandyke and strong ale. To finish, varnish with copal.

PORPHYRY.—1. Ground, purple-brown and rose-pink. Grind vermilion and white lead separately in turpentine, and add a little gold size to each color to bind it; more turpentine must be added before the color is applied; when the ground is dry, fill a large brush with vermilion, squeeze out nearly all the color by scraping the brush on the edge of the palette-knife; hold a rod in the left hand, strike the handle of the brush against it, so as to throw small red spots on to the work till the surface is covered; make the color lighter by adding white lead, and use as before; then with clear, thin white throw on very fine spots, and when dry put in a few white veins across the work. This marble may be imitated in distemper in precisely the same manner as in oil. — 2. The ground in Venetian red, with a little vermilion and white. For marbling, add a little more white to the ground color, and sprinkle over the first coat. When dry, repeat the splashing with a mixture of Venetian red and vermilion, and then with white in very fine spots; form opaque white veins across the work, and transparent threads in various directions. This must be done when the work is dry, with a sable pencil, and the threads drawn with a feather. For each separate color use a different brush.

RED MARBLE. — For the ground, put on a white, tinged with lake or vermilion; then apply deep rich reds in patches, filling up the intermediate spaces with brown and white, mixed in oil; then blend; if in quick drying colors, use about ½ turps and gold size. When dry, varnish, and while the varnish is wet, put in a multitude of the fine white threads, crossing the work in all directions, as the wet varnish brings the pencil to a fine point.

ROSEWOOD. — 1. Mix vermilion and a small quantity of white lead for the ground; take rose pink, tinged with lampblack or Vandyke brown, and grind fine in oil; then take a flat graining brush, with the hairs cut away at unequal distances, and cut down the grain as if wending round a knot. When nearly dry, take a graining comb that is used for oak and draw down the grain; this will give it the appearance of na-

ture. When dry, varnish. — 2. The ground color is prepared with vermilion and small quantities of white lead and crimson lake. When the ground is dry and made smooth, take Vandyke brown, ground in oil, and with a small tool spread the color over the surface, forming knots. Before the work is dry, take a piece of leather and strike out the light veins, having previously prepared the darkest tint of Vandyke brown, or gum asphaltum; immediately take the flat graining brush with few hairs in it, draw the grain over the work and soften. When varnished, the imitation will be excellent. — 3. Mix Venetian red, white lead powder, vermilion and common size, which, when cold, must be like a trembling jelly. With this paint the work twice over. When the ground is dry, take lampblack, finely ground in beer, and beat the white of an egg into it; take the flat graining brush, dip in the black, and put on the grain. When dry, stain the first coat of varnish with rose pink, ground in turpentine, and finish the work by giving it a coat of clear varnish.

SATINWOOD.—This ground is prepared with white lead, stone ochre, and small quantities chrome yellow and burnt sienna. The graining color is $\frac{1}{4}$ raw sienna and whiting, ground in pale ale, very thin. Spread the color over the surface to be grained. While wet, soften and have ready a mottling brush, in order to take out the lights; blend the whole with a badger's hair brush. When the work is dry, take the flat brush, and with the same color put on the top again. When dry, varnish.

SIENNA MARBLE. — 1. Ground ochre and white lead. Use burnt and raw sienna, white, black, and a little lake for marbling. These colors should be laid on as a transparent glaze, and marked and softened while wet. The colors should be properly softened with a badger brush. — 2. Ground raw sienna or yellow ochre. When dry, mix raw sienna with white lead; have ready also some white paint; put in broad transparent tints of white and yellow, and while wet blend with a softener. Mix Venetian red and a little black, and put in some broad veins in the same direction as the patchy tints run; for the darker veins, take a mixture of Venetian red, lake and black, and draw them over the first layer of veins with a feather in fine threads, running to a centre, and in transparent veins in different directions. Mix some Prussian blue and lake, and put in the darkest and finest veins over those before laid on. Put in a few touches of burnt sienna between the fine veins which are formed into small masses. All the colors should be ground in spirits turpentine, and mixed with sufficient gold size to bind them.

VERDE ANTIQUE MARBLE.—If the work is new lay on a coat of dark lead oil color; when dry, smooth with glass paper, and lay on a coat of black paint; when this is dry, mix white lead with water and a little beer; lay this on in large streaks; fill up the spaces left with veins of lampblack, finely ground in beer, thus covering the surface of the work. While wet, soften with a badger hair brush, to cause the veins to run into one another. On the darkest parts lay dabs of white, carelessly applied, to imitate fossils, and dab the light parts of the work with the black color for the same purpose. With a thin, flat graining brush, dipped in the white, form small veins over the black; a few dark blue wavy veins may also be put on. When dry, glaze with a thin coat of raw sienna and Prussian blue ground in spirits turpentine and mixed in copal varnish. A little emerald green added here and there heightens the effect.

YEW.—The ground is a reddish buff. For the graining color grind in ale equal portions Vandyke brown and burnt sienna, with a small quantity raw sienna. When the ground is dry, spread the surface even with the color, and soften; then with a piece of cork with a sharp edge, rub the work cross and cross to form the fine grain. When dry, dip the tip of the fingers in the graining color to form the eyes or knots, and put in the small touches with a camel's hair pencil. When dry, put on the top grain, and when this is dry, varnish.

PAINTS.

PIGMENTS.

THE term pigments is applied to coloring matters which are mixed in a powdery form with oil or other vehicle for the purposes of painting.

GRINDING.—When a color mill is not used, a marble, or other smooth slab, and a muller are necessary. The purity of colors sold ready ground are not always to be depended upon. Some colors, as lakes and Prussian blue, will not keep long after grinding. The slab for grinding on is of porphyry, marble or granite, about 2 ft. sq., hard and close grained. The muller is a hard stone, in shape like a sugar loaf, and in size not larger than to be well grasped by both hands; it should be perfectly flat and smooth on the face. A large palette-knife is used to gather the color when ground. All substances used for painting in oil must be ground with a portion of the oil, previous to mixing them with the whole quantity. They must first be pounded in a mortar, passed through a sieve, and then mixed with linseed oil sufficient to just saturate them only; a quantity of this mixture, of the size of an egg, is then taken on the end of the knife and deposited on the centre of the slab; the muller is then placed upon it, moved round about and to and fro in all directions, bearing a little weight on it; this process is continued until the mass is ground to the smoothness of butter. Occasionally gather the color from the outer parts of the slab and from the edges of the muller with the knife, and put in the centre of the stone to regrind. When sufficiently ground, remove the color, and proceed with a fresh quantity. It is not well to have much color on the stone at one time; it makes

it laborious, and will take a longer time to grind.

LAKES.—1. (*Carthamine, or Safflower.*) Wash safflower till the water comes off colorless; mix it with water holding 15 per cent. carbonate of soda in solution, so as to form a thick paste; leave it for several hours; then press out the red liquid, and nearly neutralize it with acetic acid; then put cotton into it, and add successive small portions of acetic acid, to prevent the liquid becoming alkaline. In 24 hours take out the cotton, wash it, and digest ½ hour in water holding 5 per cent. crystallized carbonate of soda in solution. On removing the cotton, supersaturate the liquid with citric acid, and collect the precipitate, which must be repeatedly washed in cold water. For pink saucers the liquor is allowed to deposit in the saucers. Mixed with scrapings of French chalk it constitutes rouge.—2. (*Orange.*) Take of the best Spanish annatto, 4 oz.; pearlash, ¾ lb.; water, 1 gal.; boil ½ hour; strain; precipitate with alum, 1 lb., dissolved in water, 1 gal.; observing not to add the latter solution when it ceases to produce an effervescence or a precipitate; strain, and dry the sediment in small squares, lozenges, or drops.—3. (*Red.*) Take pearlash, 1 lb.; clean shreds scarlet cloth, 3½ lbs.; water, 5 gals.; boil till the cloth is discolored; filter the decoction, and precipitate with a solution of alum, as before.—*Yellow.* 1. Boil French berries, quercitron bark, or turmeric, 1 lb., and salt of tartar, 1 oz., in water, 1 gal., until reduced ½; then strain the decoction and precipitate with a solution of alum.—2. Boil 1 lb. of the dye-stuff with alum, ½ lb.; water, 1 gal.; as before, and precipitate the decoction with a solution of carbonate of potash. *Madder.* 1. Crop madder, 2 oz.; tie in a cloth; beat well in 1 pt. water in a stone mortar, and repeat the process with about 5 pts. fresh water until it ceases to yield color; boil the mixed liquor in an earthen vessel; pour it into a large basin, and add 1 oz. alum, previously dissolved in 1 pt. boiling water; stir well, pouring in gradually a strong solution of carbonate of potassa or oil of tartar, 1½ oz.; let stand until cold, then pour off the yellow liquor from the top; drain; agitate the residuum with boiling water in separate quantities, 1 qt.; decant, drain, and dry; product, ½ oz.—2. Add a little solution of acetate of lead to a decoction of madder, to throw down the brown coloring matter; filter; add a solution of tin or alum; precipitate with a solution of carbonate of soda or of potassa; proceed as before.—3. Ground madder, 2 lbs.; water, 1 gal.; macerate with agitation for 10 minutes; strain off the water, and press the remainder dry; repeat the process a second and third time; then add to the mixed liquors, alum, ½ lb., dissolved in water, 3 qts.; and heat in a water bath for 3 or 4 hours, adding water as it evaporates; next filter, first through flannel, and, when cold, through paper; then add a solution of carbonate of potassa as long as a precipitate falls, which must be washed until the water comes off colorless; and lastly dried. If the alkali be added in 3 successive doses, 3 different lakes will be obtained, successively diminishing in beauty.

MIXING COLORS.—The following is a good table for mixing different colors to produce a variety of the most common and useful shades:

Brown,	mix together	Venetian red and lamp black.
Buff,	"	white, yellow ochre, red.
Chestnut,	"	red, black, yellow.
Chocolate,	"	raw umber, red, black.
Claret,	"	red, umber, black.
Copper,	"	red, yellow, black.
Cream,	"	same as buff, with more white.
Dove,	"	white, vermilion, blue, yellow.
Drab,	"	white, yel. ochre, red, black.
Fawn,	"	white, yellow, red.
Flesh,	"	white, yel. ochre, vermillion.
Freestone,	"	red, black, yel. ochre, vermil.
French Gray,	"	white, Prussian blue, lake.
Gray,	"	white lead, black.
Green, dark,	"	lamp black, chrome green.
Green, pea,	"	white lead, yellow, red.
Gold,	"	white, stone ochre, red.
Green bronze,	"	chrome green, black, yellow.
Lead,	"	white lead, black.
Lemon,	"	white, chrome yellow.
Limestone,	"	white, yel. ochre, black, red.
Olive,	"	yellow, blue, black, white.
Orange,	"	yellow, red.
Peach,	"	white, vermilion.
Pearl,	"	white, black, blue.
Purple,	"	violet, more red and white.
Red,	"	white lead, vermilion, scarlet lake, Venetian red, red lead, or burnt ochre.
Rose,	"	white, madder lake.
Salmon,	"	wht. lead, blue, yellow, red.
Sandstone,	"	white, yel. ochre, black, red.
Snuff,	"	yellow, Vandyke brown.
Stone,	"	white lead, spruce ochre.
Straw,	"	white lead, yellow.
Violet,	"	red, blue, white.

OILS.

BLEACHING.—Pour linseed oil 1 in. deep into a shallow earthen vessel; then pour in 6 in. water; cover with a fine cloth, and let stand in the sun for a few weeks, until thick, when it should be poured into a vial and submitted to a gentle heat; after which the clear is to be poured off and strained through a flannel cloth.

BOILED AND DRYING.—1. Linseed oil is mixed with powdered litharge and heated until thick. A pale drying oil is obtained by mixing with linseed oil sufficient dry sulphate of lead to form a milky liquid, and shaking it repeatedly for some days, letting it stand exposed to the light; when clear, pour off from the dregs. The sulphate of lead, when washed from the mucilage, may be used again. Or it may be prepared as follows: 1 lb. acetate of lead dissolved in ½ gal. rain water, and 1 lb. powdered litharge added; the mixture is exposed to a moderate heat and stirred till no particles of litharge can be seen. A white deposit is formed, which may be left in the liquid or separated by filtration; 20 lbs. linseed oil, in which 1 lb. levigated litharge has been diffused, are gradually added to the lead solution, previously diluted with an equal bulk of water; the mixture frequently stirred, and left to clear itself in a warm place. To obtain it bright, filter through coarse paper; and bleach by exposure to the sun. The lead solution which subsides from the mixture, may be filtered and used again, after dissolving it in 1 lb. litharge as before. The oxide of lead contained in the oil may be removed from it by agitating it with diluted sulphuric acid, and letting it settle.—2. (*Fet.*) 8 lbs. nut oil or linseed oil; 1 oz. white lead, slightly calcined; 1 oz. yellow acetate of lead, also calcined; 1 oz. sulphate of zinc; 12 oz. litharge, and a head of garlic, or a small onion. When dry substances

are pulverized, mix them with the garlic and oil over a fire sufficient to cause a slight ebullition; continue it till the oil assumes a reddish color and the garlic becomes brown. A pellicle will soon form on the oil indicating that the operation is complete. Take from the fire, and the pellicle, being precipitated by rest, will carry with it all the unctuous parts of the oil. When the oil becomes clear, separate it from the deposit, and put it into wide-mouthed bottles, where it will clarify and improve in quality. — 3. (*Fat.*) 1½ oz. litharge, ⅜ oz. sulphate of zinc, and 16 oz. linseed or nut oil. The operation must be conducted as in the preceding case. The choice of the oil is not a matter of indifference. If it be destined for painting articles exposed to the external air, or for delicate painting, nut oil or poppy oil will be requisite. Linseed oil is used for coarse painting, and that sheltered from the rain and sun.—4. (*Fat.*) A drying quality may be communicated to oil by treating, in a heat capable of maintaining a slight ebullition, linseed or nut oil, to each lb. of which is added 3 oz. litharge, reduced to powder. — 5. 2 lbs. nut oil, 3 lbs. water, and 2 oz. sulphate of zinc. Mix, and subject to a slight ebullition till little water remains. Decant the oil and separate the water by means of a funnel. The oil remains nebulous for some time; after which it becomes clear and seems to be very little colored. — 6. (*Poppy.*) Into 3 lbs. pure water, put 1 oz. sulphate of zinc; and mix the whole with 2 lbs. oil of pinks, or poppy oil. Expose this mixture in an earthen vessel capable of standing fire sufficient to maintain a slight ebullition. When ⅓ or ⅜ of the water has evaporated, pour the whole into a jar, and leave it at rest till the oil becomes clear; decant the clear part by means of a glass funnel, the beak of which is stopped with cork. When the separation of the oil from the water is effected, remove the stopper and supply its place with the forefinger, applied so as to suffer the water to escape, and to retain the oil. Poppy oil, prepared in this manner, becomes limpid and colorless. — 7. (*Resinous.*) Take 10 lbs. drying nut oil, if the paint is for external use, or 10 lbs. drying linseed oil, if for internal articles; 3 lbs. resin, and 6 oz. turpentine. Cause the resin to dissolve in the oil by means of gentle heat. When dissolved and incorporated with the oil, add the turpentine; leave the varnish at rest to deposit resin and other impurities; then preserve it in wide-mouthed bottles. It must be used fresh. If this resinous oil assumes too much consistence, dilute it with essence, if for articles sheltered from the sun, or with oil of poppies.

LINSEED OIL, To Clarify.—1. Heat in a copper boiler 50 gals. linseed oil to 280° Fahr.; add 2½ lbs. calcined white vitriol, and keep the oil at the above temperature ½ hour; remove it from the fire, and in 24 hours decant the clear oil. It should stand a few weeks before it is used. — 2. In 236 gals. oil pour 6 lbs. oil of vitriol; stir together for 3 hours; then add 6 lbs. fullers' earth, well mixed with 14 lbs. hot lime, and stir for 3 hours; put the oil into a copper boiler, with an equal quantity of water, and boil for 3 hours; then extinguish the fire; when the materials are cold draw off the water, and let the oil stand for a few weeks before using.

Mixed Colors.

ANTI-CORROSIVE PAINT.—Take equal parts by weight of whiting and white lead, with ½ the quantity fine sand, gravel or road-dust, and sufficient coloring matter. This mixture is made in water, and can be used as a water color; but it is more durable to dry it in cakes after mixing, and then use it as an oil paint by grinding in linseed oil. The preparation of oil for this purpose is 12 parts by weight of linseed oil, 1 part boiled linseed oil, and 3 parts sulphate of lime, mixed; 1 gal. of this oil to 7 lbs. powder.

BLUE.—Blue black, ½ cwt.; whiting, 1 cwt.; road-dust, 2 cwt.; blue, ½ cwt.; lime water, 12 gals.; factitious linseed oil to grind.

BROWN.—Venetian red, or Spanish brown, 1 cwt.; road-dust, 3 cwt.; common soot, 28 lbs.; limewater, 15 gals.; factitious linseed oil to grind.

COVERING, Quantities Required for.—

1 gal. priming color will cover 50 square yards.

"	white zine	"	50 "
"	white paint	"	44 "
"	lead color	"	50 "
"	black paint	"	50 "
"	stone color	"	44 "
"	yellow paint	"	44 "
"	blue color	"	45 "
"	green paint	"	45 "
"	bright emer. green	"	25 "
"	bronze green	"	45 "

CREAM.—*1st Coat:* White lead, in oil, 66.66 parts; French yellow, 3.33 parts; Japan varnish, 1.33 parts; raw oil, 28 parts; spirits turpentine, 2.25 parts. *2d Coat:* White lead, in oil, 70 parts; French yellow, 3.33 parts; Japan varnish, 1.33 parts; raw oil, 24.5 parts; spirits turpentine, 2.25 parts. 1 sq. yd. of new brick work requires for 1st coat .75 lb.; 2d coat, .3 lb.

DRAB.—1. White lead with a little Prussian blue and French yellow, linseed oil and turps. — 2. White lead with a little Prussian blue and lampblack, linseed oil and turps.

FLEXIBLE.—Cut soap into slices, and to every ¾ lb. add 2 qts. boiling water; and while hot mix with 62 lbs. oil paint. Excellent for canvas.

GREEN.—1. Lime water, 6 gals.; whiting and road-dust, of each, 1 cwt.; blue black, 30 lbs.; yellow ochre, 28 lbs.; wet blue (previously ground in prepared residue oil), 20 lbs.; grind together. For use, thin with equal parts prepared residue oil and linseed oil. — 2. Yellow ochre and wet blue, of each, 1 cwt.; road-dust, 1½ cwt.; blue black, 10 lbs.; lime water, 6 gals.; prepared fish oil, 4 gals.; prepared residue and linseed oils, of each, 7½ gals. — 3. (*Pea.*) Take 1 lb. genuine mineral green, 1 lb. precipitate of copper, 1½ lbs. blue verditer, 3 lbs. white lead, 3 oz. sugar of lead, and 3 oz. burnt white vitriol; mix these in linseed oil; grind fine. It will produce a bright mineral pea green paint, preserve a blue tint and keep any length of time in any climate, by putting water over it. To use for house or ship painting, take 1 lb. of the green paint with some pale boiled oil; mix together;

this will produce a strong pea green paint. The tint may be altered by adding a proportionate quantity of white lead to the green, ground in linseed oil, and thinned with spirits turpentine for use. It may also be used for Venetian window blinds, by adding white lead and mixing the color with boiled oil. For all the aforesaid preparations it will retain a blue tint.

LEAD COLOR.—Whiting, 1 cwt.; blue black, 7 lbs.; white lead, ground in oil, 28 lbs.; road-dust, 56 lbs.; lime water, 5 gals.; prepared residue oil, 2½ gals.

METALLIC PAINT.—Break common resin into dust or small pieces, and then dissolve in benzoline or turpentine until the solution acquires the consistency of syrup; or equal parts of each of the above spirits or hydrocarbons, and any other hydrocarbon that will dry and combine with drying oils, can be used instead of benzoline or turpentine. When the solution is complete, it is gradually added to oxide of zinc, which has previously been made into a paste with boiled linseed oil, until the whole mixture acquires the consistency of paint suitable for use; a white paint is thus produced of a durable and glossy character. Other pigments, such as sulphate of barytes, oxide of iron, Brunswick green, or red lead, can be added to make any desired color of paint. One great advantage of its use, it is said, is its effectual resistance to heat and moisture. It never blisters or cracks even under the hottest sun or in the most inclement weather.

MILK. — For painting in rooms, where the smell of oil or turpentine would be objectionable, a preparation may be made as follows: Take 8 oz. freshly slaked lime and mix it in an earthen vessel with 3 qts. skimmed sweet milk; in another vessel mix 3¾ lbs. Paris white with 3 pts. milk; when these mixtures are well stirred up put them together, and add 6 oz. linseed oil; mix these well, and it will be ready for use. This preparation is equal to oil paint, and is excellent for walls and ceilings. Any shade may be made by the addition of dry pigments thoroughly mixed.

MIXING.—Before the colors which have been ground can be applied to the work they must be rendered fluid by linseed oil or spirits of turpentine, or certain proportions of both. When a tinted color is required to be mixed, a small quantity of the proper tint should be first mixed on the palette to serve as a guide to mix the whole. With the ground white lead there should first be mixed a portion of oil, and then the tinting color added as ascertained by the pattern on the palette. When these are mixed and matched to the proper tint, the remaining portion of the oil or turpentine is to be added; this is better than putting in all the oil at once; it should then be strained through fine canvas, and be of the consistence of cream. If too thick, the work will have a cloudy appearance; if too thin, it will run, or will require a greater number of coats to cover the ground, and to render the work solid. The straining ought not to be neglected when the appearance of the work is studied. The following table gives the proportions, by weight, used in mixing pigments:

100 parts	white lead.....	require	12 parts oil.
"	zinc white	"	14 "
"	green chrome.....	"	15 "
"	chrome yellow...	"	19 "
"	vermilion.....	"	25 "
"	light red	"	31 "
"	madder lake.....	"	62 "
"	yellow ochre.....	"	66 "
"	light ochre	"	72 "
"	camel's brown.....	"	75 "
"	brown manganese	"	87 "
"	terre verte	"	100 "
"	Parisian blue	"	106 "
"	burnt terre verte	"	112 "
"	Berlin blue.....	"	112 "
"	ivory black	"	112 "
"	cobalt.....	"	125 "
"	Florentine brown	"	150 "
"	burnt terre sienna	"	181 "
"	raw	"	140 "

OUTSIDE WORK, Durable Paint for.—1. Take some charcoal, and pulverize it fine, add sufficient litharge as a drier, and levigate with linseed oil; a good black paint is produced, to which, if yellow ochre is added, an excellent green will ensue, which is preferable to the bright green used by painters for garden work, and does not fade in the sun. — 2. For weather-worn weather-boarding, take ½ common whiting and ½ white lead; throw in small portions red lead and chrome yellow to overcome the blackness of the wood, or add umber for a drab color. Fresh paint is always best. Where persons wish to do their own painting, it is sometimes best to buy the paint dry. Take a board with a smooth surface, find a muller 3 in. in diameter at one end, and conveniently shaped to hold with both hands, and you can mix up the paint readily. Use flaxseed oil; a little turpentine will make the paint flow freely from the brush. Small portions of Venetian red and lampblack will do for a dark color.

PAINTS WITHOUT OIL. — Any color desired may be added to the following: 1. 1 oz. borax; 2 oz. shellac; 1 pt. water; boil a few minutes, and stir with a piece of wood. — 2. 1 oz. liquid ammonia; 2 oz. shellac; 1 pt. water; add more or less shellac, as may be required. — 3. Break an egg into a dish and beat slightly; use the white only, if for white paint; then stir in coloring matter to suit. Red lead makes a good red paint. To thin it, use skim milk. Eggs that are a little old will do. — 4. Slake stone lime with boiling water in a tub, to keep in the steam; then pass 6 qts. through a sieve; to this add 1 qt. coarse salt and 1 gal. water; boil the mixture and skim it clear. To every 5 gals. add 1 lb. alum and ½ lb. copperas, and by slow degrees ¾ lb. potash and 4 qts. sifted ashes or fine sand. — 5. (*Pink.*) Take Brazil wood, 1 lb.; boil 2 hours, having 1 gal. water at the end; strain it, and boil alum, 1 lb., in the water until dissolved; when cool, add muriate of tin, ¾ oz. Now take Paris white, 12½ lbs.; moisten up to a salvy consistence, and, when the first is cool, stir them together; let stand 24 hours. — 6. (*Reddish Brown.*) The wood is first washed with a solution of 1 lb. cupric sulphate in 1 gal. water, and then with ½ lb. potassium ferrocyanide, dis-

solved in 1 gal. water; the resulting brown cupric ferrocyanide withstands the weather, and is not attacked by insects. It may be covered, if desired, with a coat of linseed oil varnish.

PHOSPHORESCENT. — 1. Heat strontium theo-sulphate 15 minutes over a Bunsen lamp, and then 5 minutes over a blast lamp. — 2. Heat equal parts of strontium carbonate and lac sulphuris gently 5 minutes, then strongly 25 minutes over a Bunsen lamp; then over a blast lamp, 5 minutes. — 3. Precipitate strong aqueous solution of strontium chloride by means of sulphuric acid; dry the precipitate, and heat it to redness for some time in a current of hydrogen; then over a Bunsen lamp for 10 minutes, and 20 minutes over a blast lamp. Mix any of the above with pure melted paraffin for use as a paint, and expose for a time to sunlight. The 2 former yield a greenish phosphorescence in the dark, the latter a bluish light. — 4. Take oyster shells, and clean them with warm water; put them into the fire ½ hour, then take them out; when cold, pound fine and take away any gray parts; put the powder into a crucible, in alternate layers with flowers of sulphur; put on the lid, and cement with sand, made into a stiff paste with beer; when dry, put into the fire, and bake 1 hour; wait until cold before opening the lid. The product ought to be white. Separate all gray parts. Make a sifter in the following manner: Take a jam pot; put a piece of fine muslin loosely across it; tie round with string; put the powder into the top, and rake about with a bit of stick until only the coarse remains. Open the pot, and you will find a very fine powder. Mix into a thin paint with gum water. Two thin applications are better than one thick one.

REDDISH-BROWN.—1. (*Dark.*) For common purposes. Mix Venetian red in boiled oil, with a little red lead and litharge, to give a drying quality. — 2. (*Lighter.*) Mix equal parts Venetian red and red lead in boiled oil and turps.— 3. (*Imitation Vermilion.*) Grind together in oil red lead and rose pink. — 4. (*Deep Red.*) Mix in oil, vermilion, with a dust of Venetian red or red lead.

STEEL.—Mix ceruse, Prussian blue, fine lac and vermilion, with oil and turps.

STONE.—Lime water, 4 gals.; whiting, 1 cwt.; white lead, ground in oil, 28 lbs.; road-dust, 56 lbs.; prepared fish, linseed, and prepared residue oils, of each, 3 gals.

STRAW.—A mixture of chrome yellow, white lead, oil and turps.

WHITE. — 1. The white destined for varnish or oil, requires a metallic oxide, which gives a body to the color. Take ceruse; reduce to powder; grind it with oil of pinks, and ¾ oz. sulphate of zinc for each lb. oil. Apply the second coat without the sulphate of zinc, and let dry; cover the whole with a stratum of sandarac varnish. This color is durable and brilliant. Boiled linseed oil may be employed instead of oil of pinks, but the color will injure the purity of white.— 2. Pure white oxide of lead, ground with a little essence, added to oil of pinks, and mixed with gallipot varnish. The color may be mixed with essence diluted with oil, and without varnish, which is reserved for the two last coatings. If for a lively white, heighten with a little Prussian blue or indigo, or prepared black; the latter gives it a gray cast. Pure white lead is reserved for valuable articles. If a durable white is required, grind with a little essence, and mix it with sandarac varnish.

YELLOW. For Floors. — White lead and linseed oil, mixed with some French yellow and a little chrome yellow to brighten it, and some red lead, burnt white vitriol and litharge added, to give it a drying quality. Mix with equal parts boiled oil and turpentine, and use thin.

PAINTING.

CARRIAGE.

CARRIAGE painting should be conducted in a room where dust can be entirely excluded, and where ready means of ventilation are always at hand.

COATS.—For the priming coat use white lead mixed in prepared raw oil and ⅛ part turpentine, with a shade of lampblack if the carriage is to be a dark color. The less paint used in priming the better, taking care not to leave it thick upon the edges or mouldings, but going well over cracks, cheeks and screw heads, so that they have at least one coat over the surface which is to be puttied up. After the priming has been 4 days drying, and then sand papered, give another coat of the same paint used for priming with a little drier, and ¼ as much turpentine as oil. Be careful with the second coat, to lay it equally over every part, and, when dry, rub down with finer sand paper than the last, being careful to make the surface smooth. Now give the third coat (after dusting off), putting on the paint not too lavishly, but rub it out well. The next step, after the coat dries, is to rub it down with pumice stone, first rubbing the pumice flat upon a stone before using it. In rubbing down, use plenty of water, supplied from a sponge in the left hand. Be cautious to avoid cutting through, and feel the parts frequently to ascertain when smooth, then with a sponge wash off, and with wash leather dry it off clean.

COLORS.—*Blue* (*Ultramarine*). For ground color grind Prussian blue in oil, and add to white lead as much of the blue as will make it sufficiently dark to form a ground for the ultramarine blue; 2 coats will be required. When dry, grind some best ultramarine with varnish; add enough to body flowing varnish to impart the right color; 2 coats will be necessary; use sugar of lead as a drier. Before giving the second coat rub down with ground pumice and water, using a cloth; the next coat will flow better for this treatment. After a few days rub again; wash, and dry with chamois skin, when the work

will be ready for picking out and striping. — *Brown* (*Oxford*). A little chrome yellow, India red b st ochre, white lead, burnt umber, just white enough to be seen; yellow is the leading color; red to warm it, and umber to impart the brown shade. — *Carmine.* For fire engines. For a ground use the best vermilion, then add pure carmine, ground in a little drying oil. to the body flowing varnish, and apply 2 coats carefully. This extends the color, so that 1 oz. will suffice for a carriage or machine.—*Drab.* White and raw umber form a cool drab, which may be varied with chrome or red. — *Fawn.* Use yellow, red, a little black, a little terre de sienna or burnt umber may be added to obtain the right shade. — *Green* (*Chrome*). Grind greens in Japan, or use greens composed of chrome yellow and Prussian blue. In laying the finishing coat of any compound green on coach bodies, it is necessary that the color be worked full, and laid off smooth and light, by working the brush from top to bottom; otherwise compound green colors will appear shaded, and if highly varnished the shades will be conspicuous. Several greens, from the nature of their parts, will cause the varnish, however good and old, to ferment and fall into pin-holes. — *Lakes.* Vermilion and rose pink, in oil, for first coat. When dry, give another light coat, previously rubbing down with ground pumice and water. For a rich, light claret, be sparing of rose pink in the ground color; for dark claret, use more. For darker shades use more rose pink in the ground color, then use best crimson lake, same way as for light claret; 2 coats will do. For a purple shade of claret use vermilion, rose pink, and a spice of ultramarine blue for a ground color; then add proper quantity of ground purple lake to body flowing varnish, and apply 2 coats. — *Olive Shades.* Take deep chrome yellow and powdered drop black; mix in a pot with drying Japan and a little turpentine; grind together; be sure that the color is right; if wished lighter, add more chrome yellow; if darker, more drop black; grade the color to a proper thickness, and apply at once; 2 coats required. — *Plum.* Drop black and vermilion makes a good color at a cheap rate. — *Yellow.* When a coach is to be painted pale yellow, take 3 lbs. dry white lead, 1 lb. whiting, ½ lb. litharge, ½ lb. pale spruce oehre; all dried; grind with 3 parts raw oil and 1 part turpentine; add gold size, to make it dry, firm and hard; as soon as dry, sand paper and putty up the work with hard putty; then prepare a sufficient quantity of the above colors; apply 3 coats, rubbing down with care; after these apply a fourth, and, if necessary, a fifth coat, made of 3 lbs. dry white lead, ½ lb. dry spruce ochre, ½ lb. pumice stone, ground with 3 parts raw oil and 2 parts turpentine, adding a little pale gold size to dry it firm. When dry and rubbed down, apply the finishing coat, pale patent yellow, ground in 4 parts prepared oil and 1 part turpentine. 1 coat looks more clear and bright than 2. The above being a mineral metallic color, is compact and durable, and will dry harder as well as support varnishing and polishing better than other colors.

HEARSE BODY, To Paint White. —To paint white, oil should be discarded after priming, and in the priming it is not advisable to use all oil in the lead; ½ oil and ½ turpentine, with a small quantity of driers, is preferable. Litharge is safest for under coats. After the body is primed, allow it to stand the usual time, and second coat with the same color. When dry, putty with white lead putty, made with rubbing varnish; glaze or sheet all over as smooth as possible, and if necessary putty all screw holes and other bad places the second time. To make filling for white work, mix same as ordinarily, using all dry lead; apply this rather stouter than English or other powdered material. Rub carefully with pumice, which will give you a white ground; when rubbing, keep pumice stone clean, to avoid scratches; also, wash clean, particularly in corners. The job is now ready for color. Mix the color from best grade of white, hard drying body varnish into a thick paste and reduce with turpentine. Half elastic brushes are best, as the color would be apt to curl under camel's hair blenders. Apply 2 coats, and add more drying varnish to whatever color is left. Let this stand until dry; then rub down with pumice, and apply second coat with more hard drying added. Each coat of rubbing should have some of the white added. Place 4 coats on, and on the last coat, instead of using fine finishing varnish, use same as under coats and polish on it. Polishing a body is tedious, and a large number of painters know little about it. When the last rubbing coat is on, let it stand for 2 weeks, and rub with fine pumice, being careful not to rub through; wash clean, and chamois dry. Next rub with rotten stone and sweet oil, with a piece of clean chamois, leaning very heavy, but be careful not to heat the varnish; should the varnish become warm under the rag, stop until cooled. When the rubbing is finished, sprinkle flour over, and it will remove any oil or moisture; the flour can be taken off by using a camel's hair duster. After dusting, take a silk handkerchief and rub lightly. If properly cared for, this body will outwear some of the best oil-coated jobs, with no risk of it turning yellow; and it seldom cracks, unless sufficient time is not allowed between the coats.

IRON WORK. — The iron work of a carriage should have 2 coats of oil lead color; sand paper well; give 1 coat more; after which give 1 coat best oil black, 2 coats black Japan, a slight rubbing, and a flowing coat of varnish.

PICKING OUT, or STRIPING.—Care is required to carry a steady hand, so that the lines may be drawn equidistant and neat. For fine lines grind the color in drying oil. Japan color will do for broad or coarse lines on a blue ground. If with heavy wheels, draw lines with Frankfort black, Japan mixed color, from ¾ in. to 1 in. broad, on all parts of wheels, springs, spokes, hubs, etc.; then draw fine lines of light orange or light primrose color about ⅜ or ¼ in. from the broad black line, with 1 fine line around the edges of the black nuts and bolt heads. On superior work, pure white, gold or deep orange lines may be drawn down the middle of the black lines, producing a fine effect. On greens pick out with black; if a light green,

black lines will be sufficient; if desired better, run up the centre of the black lines with white; on dark green pick out with black, running fine lines on each side of the black ⅜ in. off the black; this also sets off a bright green to advantage. On clarets pick out with black, with vermilion, or rich orange fine side lines, or light orange side lines with vermilion line run up the centre of the black; or light gold line up the centre of 1 large black line. On Oxford brown pick out with black, and fine line with vermilion or medium tint of chrome yellow with a slight tint of red in it; or part the black line with white down the centre. On fawn colors pick out with broad black, fine line with white on each edge, or brown drab shade. On Japan or plum browns, vermilion line has the best appearance. On olives or Quaker greens pick out with black, with white for fine lines, or orange or light green. On drabs pick out with black, fine line with vermilion or high colored orange, or white centre line for extra finish. On purple pick out with black, and fine line with a bright tint of orange or vermilion.

POLISHING AND VARNISHING.—Good coach bodies are seldom polished with less than 5 or 6 coats of varnish. Decorations, heraldic devices, and so on, should have 2 coats of varnish. Work to be finished with 1 coat of varnish ought to be laid on full and flowing; but if 2 coats are intended, the first coat should be laid on sparingly; the second applied the third day after; and, where a third is applied, the second coat ought previously to be rubbed down to nearly a dead flat with ground pumice dust and water. If it is to be afterwards polished, let it stand 14 days; then take fine pumice dust, sifted through fine silk or muslin; wet the work with a brush and clean water; have ready some pieces white woolen cloth folded; dip a piece into water and then in the pumice dust; rub down the work from top to bottom, bearing steadily, but lightly, rubbing all alike, because on that depends the beauty of the polishing; wash off with a sponge and water during the polishing, until, with the palm of the hand rubbed 2 or 3 times in the same place, the work shows polish; then, with a bit of flannel dipped in refined linseed oil, rub the work over, and afterwards clean it off with a piece of fine leather dipped in fine dried flour. When cleared of oil, a piece of flannel, dipped in dry flour and rubbed over it, will give it lustre. Varnishing must be conducted in a warm atmosphere of equable temperature; it is a good plan to have a stove in the room. Coach painters are aware that some copal varnishes answer very well upon one coach body, but when applied upon another sink in dead, fall into pinholes, and are at a loss how to account for such failures. When any piece of work is painted with a hard, heavy, compact, metallic or mineral color, such as white lead, patent yellow, etc., the grounds appear firm, close and solid; and almost any copal varnish will look well, stand polishing well and sooner than on other grounds; it will last, however, but a short time, for if the varnish is deficient in gumminess, the metallic color will imbibe the virtue of the varnish and cause it to decay. The same varnish applied upon green grounds will sink in sleepy or dead, not having a sufficient oily and gumimy body. For hard, compact, solid grounds a strong, gummy, tough, but flowing varnish should be used; and for soft, absorbent grounds, such as compound greens, lakes, browns, drabs, a soft, strong, oily, free flowing varnish. Copal varnishes, abounding with oil and gum, are fittest for coach work, as they possess toughness and durability; yet they are slower in drying, and must stand some time before polishing; brittle varnishes dry firm and hard, bear polishing soon, but afterwards crack and fade. Coach painters ought to use the best polishing body copal for bodies, and even for carriage work, where the colors are pale and delicate, or at least lay the last coat with body varnish. Where the work is dark, there is no occasion to fear using a middling dark carriage varnish. Amber varnish is used for varnishing black grounds, or black Japan; it is easy to lay on.

REPAINTING.—Previous to repainting or re-varnishing old coach work, first wash the work clean; rub down the surface with a wet cloth and ground pumice powder, until it appears quite dead, or without gloss. The work should then be washed and dried with wash leather, after which it is fit to receive paint or varnish. Should the surface be clear from grease, no paint or varnish will adhere on the old surface without its having been first rubbed down with pumice powder and water. Paint or varnish will then adhere to the old ground, and can be worked and extended with the brush, without the color "cissing," as it is termed. Varnish is apt to ciss on old work, if the second coat is not applied as soon as ever the first coat is hard enough to bear varnishing.

House.

REMARKS. — The best time for painting the exterior of buildings, is late in autumn, or during winter. Paint then employed, will endure twice as long, as it dries slowly, becomes hard, and is not easily affected by weather or beating storms. Before commencing, the surface must be perfectly dry. Use paints containing oil and turpentine. The gloss will be less as the proportion of oil is lessened. Paints require more driers in cold than in hot weather. Successive coats should have a day intervene between them. Dark colors should have a glossy finish. The paint must be well mixed, both before and during the work; if neglected, the ingredients settle, leaving oil and turpentine on the surface. Before painting inside, clean the work, removing all projections or spots with the stopping knife and duster; then cover over the knots with red lead knotting. If the knots are very bad they must be cut out. After knotting comes priming or first coat. This should preferably be of some soft pigment, yellow ochre being most highly valued. The priming establishes a good foundation for subsequent coats, and its color is immaterial, except for white, for which all coats should be white. When the priming is dry, all nail-holes and defects are to be puttied; then

proceed to the next coat; when dry, those places are to be stopped which were omitted in the last coat; and proceed according to the number of coats to be given. The second color for new work is made up chiefly with oil, as it best stops the suction of the wood; but second color for old work is made up chiefly with turpentine, because oil color would not dry or adhere so well. The color should be spread evenly; and, to effect this, as soon as a convenient quantity is covered, the brush should be passed over it in a direction contrary to that in which it is finally to be laid off; this is called crossing. After crossing, lay off carefully in a direction contrary to the crossing, but with the grain of the wood, taking care that none of the cross marks be left visible. The criterion of good work is that the paint be laid on evenly, and the brush marks be not observed. In laying off, the brush should be laid into work already done, that joining may not be perceived. Every coat should be allowed to dry, and all dust removed. Priming for new work is made of white lead, with driers, and a little red lead to harden. It is thinned well with oil, as new wood and plaster suck it in fast. It is a practice to save the oil coats by giving the new work a coat of size, called clear cole; but where durability is consulted this should not be done. The size stops the suction of wood or plaster, but prevents the oil paint from adhering, causing it to peel off. Clear cole is sometimes used on old greasy work on which oil paint would not dry.

HOUSE, Old, Paint for.—Take 3 gals. water and 1 pt. flaxseed; boil ½ hour; take it off, and add water to make 4 gals.; let it settle; pour off the water into a pail, and put in enough Spanish white to make it as thick as whitewash; then add ½ pt. linsced oil; stir well, and apply with a brush. If the whiting does not mix readily, add more water. Flaxseed, having the nature of oil, is better than glue, and will not wash off as readily.

KNOTS, To Kill.—1. Take a hot iron and press it against the knot, by which means the pitch may be extracted; after which use glue size and red lead. — 2. Gum shellac, mixed with red lead, or gutta-percha dissolved in ether. But, if the work is a fine one, after removing the iron, scrape the pitch off with a knife, after which size the knot with oil size, and then lay on it a leaf of gold or silver, and give it 2 coats.

LAPS.—Laps are the joining of 2 applications, or the edges of the stretch coming together and forming 2 coats wherever the lap is made. This should be avoided, because it presents disfigurement, and will remain a long time. It is best to prime but a few boards, or a narrow space across the building at a time, or, if working on ladders, and it is not easy to move often, the lap may be avoided by rubbing out properly at the edges.

PAINT, Old, To Remove. — 1. Moisten the paint well with naphtha, repenting as often as necessary. As soon as the paint becomes soft, remove by means of a rag, aided by a scratch knife and stiff brush, moistened with naphtha. — 2. Slake 3 lbs. stone quicklime in water, and add 1 lb. pearlash, making the whole the consistence of paint. Lay over the old work with a brush, and let it remain 12 to 14 hours, when the paint can be easily scraped off. — 3. Dissolve 1 lb. potash in 3 pts. water over the fire; then add yellow ochre or some common dry paint, until it is as thick as rough stuff; spread this over the old paint, and after a little it will come off easily; then wash the wood with soap and water to remove all the potash; dry off and sand paper; then give a coat of clean, raw oil. — 4. Use the special gasoline lamp to soften the old coats, which are then easily scraped off. So much heat must not be applied as will burn the wood.

PLASTER, To Paint. — If there should be cracks in the plastering, and the wash be sound around the cracks, plaster Paris is best to fill them with, as it hardens quickly, and leaves the surface level. If the plaster Paris sets before it can be worked, wet with vinegar. If cracks be filled with putty, and the walls be painted in gloss color, the streaks of putty are apt to be flat (no gloss), and if painted in flat color, the streaks will have a gloss. These streaks spoil the beauty of the work, but do not affect its durability. When filled with plaster Paris the reversion of gloss never appears. If the cracks be only in the wash, it is loosening, and will soon scale, and all attempts to fasten it will be total loss. If it be loose enough, scrape the wall, taking care not to injure the original wall. If not loose enough, let it alone until it is. If the wash be thin, solid and even, it can be painted to look and wear well. When the surface is lumpy, rub off with sandstone. After a wall has been prepared, as in either of the above cases, size with 2 coats glue size (3 oz. glue to 1 gal. water). Be sure the glue is dissolved before using. Let the first coat dry before the second is put on. 5 coats will be requisite to paint plaster well; but where it is not of a very absorbent nature 4 will answer. The first is white lead, diluted with linseed oil to a thin consistency, so that the plaster may be saturated; and into this is put a small quantity of litharge to insure drying. In painting quick plaster, the oil in this coat is absorbed, hardening it to the extent of about ½ in. inwards. When this is the case, the second coat should be thin, that the plaster may be saturated; after this give 3 coats. The second coat will be found to be partially absorbed, and it is therefore requisite to make the third coat thicker, adding a little spirits turpentine, and such coloring pigments as may bring it near to the tint of which the apartment is to be when finished. The fourth coat should be as thick as can be used, and diluted with equal parts oil and spirits turpentine. The color ought to be several shades darker than that intended for finishing, and the dry ingredient sugar of lead instead of litharge. These coats ought to be laid on with care, and each lightly rubbed with sand paper before the application of the other. The finishing coat is next applied. It ought to be of pure white lead, ground as already described, and diluted entirely with spirits turpentine, and should appear, when mixed, a few shades lighter than the pattern chosen for the wall, as it darkens in drying. The drying ingredient

should be a small portion of japanner's gold size. This coat must be applied with care and dispatch, as the spirits of turpentine evaporate rapidly, and, if touched with the brush after that takes place, which is in little more than 1 minute, an indelible glossy mark will be left. The time that each of the coats will take to dry sufficiently to receive the next, depends upon the weather, the quantity of driers used, and the atmosphere in the apartment. The first coat ought to stand a few days before applying the second; the second a little longer; and the third (unless in 4 coat work) should have still longer time. But the coat immediately before the finishing coat ought not to stand above 2 days, as the beauty of the work will depend on the latter dying into and uniting with the former.

ROOFS. — 1. There is no better paint for tin roofs than common Spanish brown, Venetian red, and yellow ochre, mixed with equal parts pure raw linseed oil and good fish oil. — 2. 10 lbs. red oxide iron ; ½ gal. raw linseed oil ; ¼ pt. Japan. This is the best known reliable red roof paint for tin and iron. For shingle roofs the color can be shaded down by a little black or other suitable pigment.

OTHER OBJECTS.

BANNERS. — Lay out the letters accurately with a crayon, then saturate the cloth with water to render the painting easy. On large work a stencil may be found useful. Take a piece of tin, lay the straight edge to the mark, brush over with a sash tool, and by this means a very clean edged letter will be made. Use stiff bristle pencils in painting on canvas.

BLACKBOARDS.—1. Place ½ lb. lampblack on a flat piece of tin or iron on a fire until it becomes red; take it off, and leave it until cool, when it must be crushed with the blade of a knife on a flat board quite fine; then take ½ pt. spirits turpentine; mix both together, and apply with a size brush. If the board is new, give it 1 or 2 coats lampblack (not burnt, but mixed with boiled oil), adding ½ lb. patent driers. After the board is dry, apply the burnt lampblack and turpentine. The preparation must be laid on quickly. — 2. Take ½ lb. logwood and sufficient boiling water to cover it; allow it to stand 24 hours; strain, and apply the solution boiling, if possible twice, allowing the board to dry in the interval; then dissolve ½ lb. copperas in 1 pt. boiling water, and apply it boiling, once or twice, according to the degree of blackness obtained. Before using it, rub it over well with rushes, straw, ferns, or shoemakers' heel ball. It may be a little difficult to rub the chalk off at first, but after a fortnight's use that will disappear. Use prepared chalk, which writes well.

GLASS.—Take some good, clear rosin; melt it in an iron pot; when melted let it cool, and before it begins to harden pour in oil of turpentine sufficient to keep it liquid when cold. In order to paint with it, use with colors ground with oil.

GLASS, Ground, To Imitate. — 1. Grind and mix white lead in ¾ boiled oil and ¼ spirits turpentine, and to give the mixture a drying quality, add sufficient burnt white vitriol and sugar of lead. The color must be thin, and put on the glass with a large size paint brush evenly. When a number of panes are painted, take a dry duster, quite new, and dab the ends of the bristles on the glass in quick succession, till it has a uniform appearance. Repeat till the work appears soft, and it will look like ground glass. When the glass requires fresh painting, get the old coat off first by using strong pearlash water. — 2. Spirits of salts, 2 oz.; oil of vitriol, 2 oz.; sulphate of copper, 1 oz.; gum Arabic, 1 oz.; mix all well, and dab on the glass with a brush. — 3. Dab the squares regularly over with putty; when dry, go over them again; the imitation will be complete. — 4. After applying a coat of white paint to the surface, take a bunch of cotton; wrap it in a piece of muslin cloth, and with this dab the paint evenly.

IRON.—1. Take sufficient quantity common litharge, and place it over a fire in a shovel; when warm, scatter over it a little flour of brimstone, which will convert it into a blackish color, and which, when ground in oil, makes a good dark lead color. It dries quickly, gets hard, and resists the weather better than any lead color. — 2. Good varnish, ½ gal.; boiled linseed oil, ½ gal.; add red lead sufficient to bring it to the consistency of paint. Apply with a brush. Applicable to any kind of iron exposed to weather.

METALS IN SALT WATER. — Red lead, 55 parts; quicksilver, 30 parts; thick turpentine, 7 parts; mix with boiled linseed oil to a proper consistency. The quicksilver must be thoroughly amalgamated with the turpentine by grinding, and this mixture must be ground with red lead and more boiled oil. As little oil as is necessary to make the paint lay well must be used. To make the paint adhere more firmly, a previous coat of oxide of iron paint may be used.

TOOLS.—White lead, ground in oil, mingled with Prussian blue, similarly prepared to give the proper shade, and finally mixed with a little carriage varnish, is an excellent and durable paint for farm machinery and tools.

WATERPROOFING, Hot, for Metals.—Prepare the metal by cleaning it with turpentine or benzine; then apply 2 thin coats of a mixture of white lead, spirits of turpentine and carriage varnish, and follow at once with a thick coat of carriage varnish and white lead.

WINDOW SHADES, Transparent Painting on. —The muslin is spread on a frame and secured with tacks; then sized with a mixture of fine flour paste, white glue and white bar soap; the soap renders the muslin pliable. A thin coat is applied, which is nearly invisible when dry. A coat of pure linseed oil, diluted with spirits turpentine, is then applied to the whole or part; lay it on quickly and smoothly to insure a transparent surface. The colors used are ivory black, ultramarine, Paris green, sienna, umber, verdigris, asphaltum, etc. The design is drawn with a small pencil with black or umber, after which the colors may be applied, more or less diluted, as more or less transparency is desired. In general, the brightest colors should be applied first, and the darker shades over them. The colors must be laid evenly, with soft brushes, and if any

part be made too dark, scrape off with a stick before the color gets too dry. The best designs consist of landscape views. Stencils will be useful in this work, in making corners of stripes for borders.

WIRE WORK. — Boil good linseed oil with as much litharge as will make it of the consistency to be laid on with a brush; add lampblack at the rate of 1 part to every 10 by weight of the litharge; boil 3 hours over a gentle fire. The first coat should be thinner than the following coats.

Putty.

GLAZIER'S.—Glaziers' putty is made of whiting and oil. The whiting should be in the form of a very dry fine powder; it should be specially dried for the purpose, and passed through a sieve of 45 holes to the in., and then be mixed with as much raw linseed oil as will form it into stiff paste; this, after being well kneaded, should be left for 12 hours, and worked up in small pieces till quite smooth. It should be kept in a glazed pan and covered with a wet cloth. If putty should become hard and dry, it can be restored by heating it and then working it up again while hot.

INDESTRUCTIBLE, or FRENCH.—Boil 4 lbs. brown umber in 7 lbs. linseed oil for 2 hours; stir in 2 oz. of wax; take from the fire and mix in 5½ lbs. chalk and 11 lbs. white lead, incorporate thoroughly. The latter operation is essential.

POLISHER'S.—1. A crude peroxide of tin, obtained by exposing metallic tin in a reverberatory furnace, and raking off the dross as it forms; this is afterwards calcined until it becomes whitish, and is then reduced to powder.— 2. Another method is to melt tin with rather more than an equal weight of lead, and then to rapidly raise the heat so as to render the mixed metal red hot, when the tin will be immediately flung out in the state of putty or peroxide. The products of both the above processes are very hard, and are used for polishing glass and Japan work, and to color opaque white enamel. — 3. For use on carriages, mix dry white lead with Japan and rubbing varnish, equal parts, to the proper consistency, beating it with a small mallet to bruise the lumps. Keep it, when not in use, in water, to prevent it drying.

REMOVING. — 1. Take 1 lb. American pearlash and 3 lbs. quicklime. After slaking the lime in water add the pearlash, and let the mixture be made of a consistence about the same as that of paint. When required for use apply it to both sides of the glass, and let it remain in contact with the putty for 12 hours; after which the putty will have become so softened that the glass may be removed from the frame without any difficulty. — 2. Run a red hot iron over it, and it will peel off easily. — 3. To remove old putty from broken windows, dip a small brush in nitric or muriatic acid, and with it anoint or paint over the dry putty that adheres to the broken glass and frames of your windows; after an hour's interval the putty will become so soft that it can be removed without any difficulty.

WOOD-WORKER'S.—1. Glue, 14 lbs.; resin, 7 lbs.; linseed oil, 2½ pts.; water, 5 pts. (more or less); whiting, q. s.; ½ lb. pitch is sometimes added; melt the resin; add the oil (hot); soften the glue in cold water; then dissolve it in hot water; add the glue to the oil and resin; beat together; add enough warm whiting to make a stiff dough. Oil the mold with sweet oil, and mold by pressure. The dough will not keep; it soon hardens, so that it should be prepared only as required. — 2. Put any quantity of fine sawdust of the same kind of wood into an earthen pan, and pour on it boiling water; stir it well, and let it remain for a week or 10 days, occasionally stirring it; then boil it for some time, and it will be of the consistence of pulp or paste; put it into a coarse cloth, and squeeze all the moisture from it. Keep for use, and, when wanted, mix a sufficient quantity of thin glue to make it into a paste; rub it well into the cracks, or fill up the holes in the work with it. When quite hard and dry, clean the work off, and, if carefully done, you will scarcely discern the imperfection. —3. Slaked lime, 1 part; rye meal, 2 parts; made into a paste with a sufficient quantity of linseed oil. — 4. Glue, 1 part, dissolved in water, 16 parts; when almost cold, sawdust and prepared chalk may be stirred in to the required consistence. — 5. Oil varnish thickened with a mixture of equal parts white lead, red lead, litharge and chalk.

Signs.

REMARKS.—Introduce into the sign a curved line or two, or section of a circle; it is pleasing, and relieves the stiffness of straight lines. The space between each letter in the same line must be equal. Each line of letters must begin and end at an equal distance from the side of the board. Never begin or end a line of letters with such words as *and, to, for, with,* etc., but let them come in between the lines of large letters. Always make important words, such as the name, business, etc., the largest, most distinct, and easily read. Never make any 2 main lines, that are near to each other in the sign, of the same length.

CHANGEABLE. — Make a wooden sign in the usual manner, having a projecting molding around it. Now cut thin grooves into the molding 1 in. apart, allowing each cut to reach the surface of the sign. In each of those grooves insert strips of tin 1 in. wide, and long enough to reach quite across the sign board. When all are fitted, take out the tin strips, and placing them edge to edge on a level table, paint any desired words on their united surface; when dry, reverse them and paint other words on the opposite side. Now finish your lettering as usual on the wooden sign board, and when dry, insert the painted tin strips in correct order in the grooves. This will present 3 signs in one, as viewed from different positions.

COLORS FOR GROUND AND LETTERS.—Mix the colors for writing in boiled oil, and use for a drier gold size. 1. On an oak ground, ornamental letters, in ultamarine blue, filled in with

gold and silver leaf, blocked up and shaded with burnt sienna. — 2. Gold letters on a white marble ground, blocked up and shaded with a transparent brown and burnt sienna. — 3. On glass, gold letters, shaded with burnt sienna. — 4. On glass, gold letters, shaded black, on scarlet or chocolate ground. — 5. On rich, blue ground, gold letters, double shaded, black and white.— 6. White letters on a blue ground, shaded with black, look very well.—7. On a purple ground, pink letters shaded with white. —8. Mix ultramarine and vermilion for a ground color; letters, white shaded with a light gray. — 9. Vermilion ground, chrome yellow, stained with vermilion and lake, for the letters, shaded black.

GILDING ON GLASS. — The gold used is the ordinary gold leaf. Procure some fine isinglass, and place about as much in a tea-cup as will cover a dime piece, and then pour on it about ½ a cupful of boiling water; before the water is cold add about as much spirits of wine as there is water in the cup; then strain through a clean silk handkerchief, and the mordant is ready for use. The design must first be set out on a sheet of white paper, and painted with Brunswick black, so that it can be seen on the reverse side. This paper, with the writing reversed, should be fixed at the edges or corners to the glass, the writing appearing backwards. The glass having been thoroughly cleansed and rubbed with a silk handkerchief, the gilding may be commenced, the gold leaf being laid on the reverse side to that to which the paper is attached. The mordant is put on with a large soft camel's hair pencil, and the gold leaf is lifted from the cushion and placed on the mordant with a tip, after having been cut to the required dimensions. If the line of writing is less than 3 in. in height, it is advisable to gild the whole line, without paying any regard to the shapes of the letters, so that when the line is finished it will be a solid piece of gilding about the same height and length as the letters. The first piece of gold leaf should be placed at the beginning of the line, which is the top of the glass, and each succeeding piece below it, the different pieces just overlapping each other. If the pieces of gold do not meet, the interstices will probably show when the work is completed, and will prevent the uniformity of burnish. For letters larger than 3 in. in height, the gilding may be made to cover each letter, leaving the spaces between untouched. As soon as this part of the gilding has been completed it should be left to dry in a warm room, or placed before the fire, in which case it will be dry in a few minutes. When the gilding is perfectly dry and bright, it should be rubbed over gently with a piece of cotton wool. After the gilding has been treated as described, a flat soft camel's-hair brush charged with the isinglass size should be passed lightly over the work. To complete the burnish of the gold hot water is poured over the gilding, and this washes out any little specks which may appear on the front of the gold, enhancing its brilliancy considerably. The hotter the water poured over the work, the brighter the gilding becomes, but care must be taken. A second layer of gold leaf over the first is necessary to insure a satisfactory result. The second coat of gold is put on with the isinglass sized as the first; and as it dries, the gilding viewed from the front of the glass will present a rich and finished appearance; the loose pieces of gold should be removed as after the first coat, by means of cotton wool gently rubbed over the work; another coat of size made hot may now be applied, and the gilding is ready to be written upon. Leave the gilding on for a day or two before writing upon it, because the isinglass does not get thoroughly hard, though to all appearance it is perfectly dry in an hour or two. There are several ways of transferring the outline of the writing to the gold. The most expeditious method is to rub some dry whiting over the front side of the writing, on the paper, place this over the gilding, face downwards, then go over the outline of the letters with a pointed stick or hard pencil. On removing the paper, it will be found that where the letters have been traced, the whiting has marked the gold. Having an outline of the writing or design, paint the letters with a sable writing pencil, and the ordinary Japan black used by coach painters. If on turning the glass round it should be seen that the Japan black deadens the gilding, or is perceptible in any way on the front of the glass, another coat of size should be passed over the gold to prevent the black from coming through the gold leaf. When the Japan black is hard, the superfluous gold must be washed off with a sponge and warm water. When the Japan is dry, the edges of the letters may be cut sharp and true by passing a small chisel along a straight edge, so as to trim the writing and make the tops and bottoms perfectly regular. All the straight lines of the letters may be thus trimmed, but the curved ones must be perfected with a writing pencil. The softened colored thicknesses added to the letters are painted with the ordinary oil colors thinned with boiled oil and turpentine, the latter being used sparingly. Three or more tints are generally mixed on the palette, with a separate pencil to each, and these are softened with a larger sable pencil, and the outer edges are cut up with a pointed stick guided by a straight edge, while the color is wet, and the superfluous color is wiped off with a piece of rag. By this means a sharpness of outline is obtained which the most skilful writer would fail to get by the mere use of the pencil. The shadow is put on as soon as the thickness is dry, and not being softened down, quick drying colors may be employed. (See *Signs, To Gild*, in BRONZING AND GILDING.)

ORNAMENTAL DESIGNS ON GLASS. — In making scrolls, eagles, etc., on glass, some painters put on the outlines and shades first, and then the gold leaf over all; another good way is to scratch the shades on the gold leaf after it is dry, and put the colors on the back of the gold. Silver leaf may be used in the same manner as gold, but it will not wear as well. A very pretty letter may be made by incorporating silver with gold; take paper and cut any fancy design to fit the parts of the letter; stick it on the size before laying the leaf, allowing it to dry and wash off as before; then with a penknife raise

the paper figure, and the exact shape of the figure will be found cut out of the gold letter; clean off; apply more size and lay silver leaf to cover the vacant spots; wash off when dry.

SMALTS, To Use.—For a gold lettered sign, lay out on a lead color or white surface the line of letters, and roughly size the shape of each letter with fat oil size. This must be allowed 12 hours to get tacky and ready for gilding. After the gold leaf is laid and perfectly dry, mix up (for blue smalts) Prussian blue and keg lead with oil, adding a little drier. Outline carefully around the letters, and fill up all the outside with blue paint; then with a small sieve sift on the smalts, allowing the sign to lay horizontally. Cover every part with plenty of smalts, and allow it to remain unmolested until the paint is dry. Then shake off all the surplus smalts and the work is done.

TINSELED LETTERS ON GLASS. — Paint ground work, on the glass, any desired color, but be careful to leave the lettering or design naked; after it is dry, take any of the fancy colored copper or tin foils, crumple them in the hand and apply over the black lettering, etc., after partially straightening them out.

PAPER-HANGING.

COLORS.—Paper having a variety of colors should be rejected. Have regard to the uses of each apartment. The drawing-room should be light and cheerful; the parlor warm and comfortable; and the bed-rooms cool and quiet, with neat patterns. The creamy, olive and fulvous tints, are suitable for the latter. Brilliant green, containing arsenic, and some kinds of glossy white, oxide of lead, should be avoided, as they have a pernicious influence on health. It is well, in selecting papers, to take into consideration what adornments in the shape of pictures, etc., are to be disposed on the walls; gilt frames show best on a dark ground, and dark frames, such as black walnut, etc., on a light ground. Pale tints will be found best. Rooms hung with scarlet are dismal and oppressive; they require also to be illuminated at an earlier hour in the evening than lighter colors.

DADOS, FRIEZES, ETC. — A dado, or frieze, tends to shorten the height of a room, and should not be used when the ceiling is low. In spacious rooms, with high ceilings, they may sometimes be used with elegant effect. A narrow molding of wood can be fixed along the upper edge of the dado, 3 or 4 ft. from the floor, and stained, painted or gilded; or a border of some decided pattern looks well, especially in gold on a dark ground. The dado should be of a plain color, without decoration, and darker than the space above it. The frieze may be ornamented with patterns, arabesques, or figures. In some of the higher priced, the ground of the frieze is of gold, and figures employed in various avocations are placed upon it. Below the frieze, and separating it from the general surface of the wall, it is not unusual to have a narrow band, bearing mottoes or maxims.

DESIGNS. — Large, showy figures are not in good taste; no furniture will show to advantage with such patterns, and the size of the room is diminished thereby. Nothing should be chosen that appears extravagant or unnatural; choose simple designs, never such as are capable of distortion into unpleasant things. Diaper patterns are to be recommended. The division of the diaper should not be too large, especially for bedrooms. Strong figures have the effect of killing pictures or any ornament placed on the wall. In proportion to the absence of pictures, walls require a strong and elaborated treatment. Where large figures are adopted, they should be interlaced, and the colors blended so as to soften the design.

LINING.—Lining paper is to be recommended as a ground for delicate paper hangings; it adds a soft effect, an evenness, to a wall, and absorbs paste quicker. It is to be had in large rolls. Hang without lapping.

MEASURING PAPER. — English papers are printed in pieces of 12 yds. in length, and 1 ft. 8 in. wide; hence 1 yd. in length contains 5 ft. superficial; therefore, any number of superficial ft. divided by 60 (the length 36 ft. $\times$ 1 ft., 8 in.) will give the number of pieces wanted. American papers are 8 yds. long, and 1 ft., 6 in. wide; therefore, if the number of ft. contained in a room be divided by 4.6, it will show the number of yds., or by 36, it will show the number of pieces of paper required. French papers are 1 ft., 6 in. wide, and contain 9 yds.; therefore, if the number of ft. required to be covered be known, divide by 4.6 for the number of yds., and by 41.6 for the number of pieces.

PAPER, Old, To Remove.—Take a whitewash brush and a pail of water; wash the wall all over, and the paper can be torn off in sheets. Care must be taken not to break the surface of the ground, lest there be a ridge that will show badly if the new paper has a light ground; if it is dark and the pattern is in arabesque, it will not show.

PASTING.—Lay the breadths carefully on the table, and bring the first piece just to the edge; have the paste pail and brush at the right hand, and take a brush full of paste, and begin from left to right; double over the paper and pass to the left and finish, and double the balance; fold the longest part to commence with at the right top, to have the breadth plumb and match the pattern. With borders it is well to paste double and cut after pasting.

REPAPERING. — When repapering, the old paper should be torn or scraped from the walls, as it has absorbed exhalations and gathered smoke and dust till it is very foul. If the paper around the bottom of a room has become soiled, it can be fixed so as to look nicely, as well as form a fashionable dado, by getting a striped paper which harmonizes; if of a panel design, all the prettier. Cut it out in points around the top of the panels, and fit it as high as the back of an ordinary chair. When buying wall paper, get an extra roll to repair damages at any time.

POLISHING.

CARVINGS.—Dissolve 2 oz. seed-lac and 2 oz. white resin, in 1 pt. spirits wine. This varnish must be laid on warm, and if the work is warmed also, so much the better; moisture and dampness must be avoided. The carved parts of cabinet work are polished thus: Varnish with common wood varnish, and having dressed them off where necessary with emery paper, apply the polish used for the other parts of the work.

CLOCK CASES. — Copal varnish, 2 lbs.; linseed oil varnish, ½ oz.; mix well, shake often, and place in a warm spot. The wood is prepared with a thin coat of glue water, and rubbed with fine pumice stone. In light colored wood, a light pigment, such as chalk, is added to the glue water; in dark wood, a dark pigment. The articles are varnished with the mixture, and, after drying, rubbed with a solution of wax in ether, thereby receiving a high polish.

COPAL. — Melt with gentle heat finely-powdered gum copal, 4 parts; gum camphor, 1 part; with ether to form a semi-fluid mass, and then digest with a sufficient quantity of alcohol.

DINING-TABLE.—1 pt. linseed oil; 2 oz. black resin; 2 oz. spirits nitre; 4 oz. distilled vinegar; 1 oz. spirits salts; and 2 oz. butter of antimony. The tables are to be washed on alternate days; first day with boiling water; second day with the polishing liquid; third day with cold vinegar. The tables assume a lustrous appearance; hot dishes placed upon them without a mat will have no effect upon them, and any liquid spilt, will, if wiped dry, leave no mark.

FRENCH POLISH. — Shellac, 3 parts; gum mastic, 1 part; gum sandarac, 1 part; spirits wine, 40 parts; the mastic and sandarac must first be dissolved in spirits wine, and then the shellac; to do this put them into a bottle loosely corked, and place it in a vessel of water, heated to a little below 173° Fahr., until solution is effected; the clear solution may be poured off into another bottle for use.

HORN AND TORTOISE-SHELL.—A very perfect surface is given by scraping; the scraper may be made of a razor blade, the edge of which should be rubbed upon an oil-stone, holding the blade nearly upright, so as to form an edge like a currier's knife, and which may be sharpened by burnishing. When scraped, polish. To effect this, first rub with a buff, made of woolen cloth, perfectly free from grease; the cloth may be fixed upon a stick, to use by hand.

ITALIAN.—To produce the Italian polish, first saturate the surface well with olive oil, and then apply a solution of gum Arabic dissolved in spirits wine; the length of time for saturation will depend upon the state and kind of wood; so with the proportions of gum and spirits wine. Gum will not dissolve in alcohol or spirits wine; therefore pound it small and add as little boiling water as possible to dissolve it. When the gum is dissolved and cold, add to it spirits wine; but, as the polish should be applied hot, put the solution in a bottle corked loosely, and immerse the bottle in a pot or saucepan, placed over the fire, till it is hot; be careful that the bottle be placed upon a plate, or on a wisp of hay in the water, or it will burst. This way of warming is much the same as that practiced by carpenters to warm glue, and prevents the spirit evaporating. Let this application and the subsequent friction take place in a warm room; the proportions of the gum and alcohol being adapted to the climate and the height of the polish required.

IVORY OR BONE. — These admit of being turned very smooth, or, when filed, may afterwards be scraped, so as to present a good surface. Rub first with fine sand paper, and then with a piece of wet linen cloth dipped in powdered pumice stone; this will give a fine surface, and the polish may be produced by fine whiting, applied by a piece of cloth wetted in soap suds. Care must be taken in this, and in every instance where articles of different fineness are successively used, that previous to applying a finer, every particle of the coarser material be removed, and that the rags be clean and free from grit.

PLASTER CASTS. — 1. Put into 4 lbs. clear water 1 oz. pure curd soap, grated and dissolved in a well-glazed earthen vessel; then add 1 oz. white beeswax, cut into thin slices; when the whole is incorporated, it is fit for use. Having dried the figure before the fire, suspend it by a twine and dip it once in the varnish; upon taking it out, the moisture will appear to have been absorbed in 2 minutes; stir the mixture and dip a second time; this generally suffices. Cover from the dust 1 week; then with soft muslin rag or cotton wool, rub the figure gently, when a brilliant gloss will be produced. — 2. Take skimmed milk, and with a camel's hair pencil lay over the model till it will imbibe no more. Shake or blow off any that remains, and lay the figure in a place free from dust; when dry, it will look like polished marble. If the milk is not carefully skimmed, it will not answer. — 3. Fuse ½ oz. tin with the same quantity bismuth, in a crucible; when melted, add ½ oz. mercury; when combined, take from the fire and cool; this substance, mixed with white of egg, forms a beautiful varnish for plaster casts. — 4. Stearine and Venetian soap, each 2 parts; pearlash, 1 part; the stearine and soap cut small, and mixed with 30 parts solution caustic potash; boil ½ hour, stirring; add the pearlash dissolved in a little rain water, and boil a few minutes; stir until cold, and mix with more lye until it is quite liquid; keep covered up; remove all dust and stains from the plaster, and apply the wash as long as it is absorbed; when dry, rub with a soft leather. Should the surface not shine, apply another coat. This composition may be preserved for years. — 5. Coat with melted white wax, and place them before a fire till the wax is absorbed; polish by friction. — 6. First make smooth and free from grit with sand paper; oil with linseed oil; when dry, French polish in the usual way. If a bust, or anything similar, is required to be white, make smooth size with white size, and varnish with white hard varnish.

RUBBER, Hard. — Remove scratches with a

smooth wet water of Ayr stone, and then polish in the lathe with fine pumice and a stiff brush; after washing the pumice off, polish it with whiting and a soft brush.

WAINSCOT. — Take as much beeswax as required; place it in a glazed earthen pan; add as much spirits wine as will cover it, and let it dissolve without heat; add either one ingredient as is required, to reduce it to the consistence of butter; when this mixture is well rubbed into the grain of the wood, and cleaned off with clean linen, it gives a good gloss to the work.

WALNUT, Dark. — To produce a dark, dead, smooth surface, pulverize asphaltum; place it in a jar; pour over it twice its bulk of turpentine or benzole; put in a warm place, and shake from time to time; when dissolved, strain it, and apply it to the wood with a cloth or stiff brush. If it should make too dark a stain, thin it with turpentine or benzole. This will dry in a few hours. To bring out the grain more, apply a mixture of boiled oil and turpentine; this is better than oil alone; put no oil with the asphaltum mixture. When the oil is dry, the wood can be polished with the following: Shellac varnish, of the usual consistency, 2 parts; boiled oil, 1 part; shake well before using; apply it to the wood by putting a few drops on a cloth and rubbing for a few moments. This polish works well on old varnished furniture.

WHITE.—To make this splendid polish, grind dry zinc white with white varnish, which affords a glossy finish, to be laid on after the second coat. A more perfect surface may be obtained by covering the second coat with several other coats of hard drying paint, mixed with turpentine, Japan and litharge; then rubbing with pumice stone, followed by a coat of polish white, and finished with a flow coat of white varnish, containing a little zinc white. Although this requires more time and trouble, the result will compensate. When the last coat is to be glossy the previous coat must be flat or dead, and a flat coat for finishing should be preceded by a somewhat glossy coat.

WOODS.—1. The wood is first well smoothed with fine sand-paper, then covered with a thin coating of size from transparent glue, or thin shellac, to prevent the varnish from sinking into the wood. When dry, pour some varnish into a saucer; take a fine camel's hair brush, and commence to varnish at one corner, gradually spreading over the whole surface. Take care that there is not too much varnish on the brush, otherwise an even surface cannot be obtained. The first coating must be allowed to dry, which will take 2 or 3 hours; then sand-paper the surface smooth. This done, with great care spread the next coat of varnish, always using sand-paper when the surface does not turn out smooth. The whole, when dry, may be rubbed well with a piece of worn woolen till bright and smooth. —2. To French polish, make the wood smooth; then pour some prepared polish into a saucer, and some linseed oil into another; take some pieces of woolen rag, and roll them up into a ball, covering them with a piece of linen drawn tightly over; the rags inside should first be saturated with the polish, and the whole should be taken in the fingers of the right hand in such a way that the linen may be drawn tightly over, and may present to the wood a smooth, rounded surface. Polish with free, circular strokes, and gradually traverse the whole surface; apply now and then a drop of polish and a drop of oil to the surface of the rubber. When the grain of the wood disappears, allow it to stand 1 hour, or until hard, and then sand-paper the whole; repeat the polishing until smooth. If dull patches appear, they may be removed by a few drops of spirits wine on a new rubber. — 3. Dissolve, by heat, so much beeswax in spirits turpentine, that when cold it shall be thick as honey. This may be applied to furniture or to work running in the lathe, by means of a piece of clean cloth, and as much as possible should then be rubbed off by means of a clean flannel. Beeswax alone is often used; upon furniture it must be melted by means of a warm flat-iron; but it may be applied to work in the lathe, by holding the wax against it until a portion of it adheres; a piece of woolen cloth should then be held upon it, and the lathe turned quickly, so as to melt the wax; the superfluous portion may be removed by a small piece of wood, when a light touch with a clean part of the cloth will give it a gloss. A good polish may be given to mahogany by rubbing it with linseed oil, and then holding against it a cloth dipped in fine brick dust. — 4. (*Dark.*) Seed-lac, 1 oz.; gum guaiacum, dragon's blood, and gum mastic, of each, 2 dr.; put in a bottle with 1 pt. spirits wine; cork close; expose to a moderate heat till dissolved; strain into a bottle for use, with ¼ gill linseed oil; shake together. — 5. Take a piece of smooth pumice stone and water and pass repeatedly over the work till the rising of the grain is cut down; then take powdered tripoli and boiled linseed oil, and polish bright.

STAINING.

REMARKS.—In making the preparations for staining, it is of importance to powder all the dry stuffs previous to dissolving or maccrating, and to purify all the liquids by filtration before use. Their coloring powers should be carefully tested before using, and the absorbent properties of the materials to be stained should be also tested. It will be better to coat twice or three times with a weak stain, than only once with a very strong one; by adopting the first mode, a particular tint may be effected, but, by pursuing the latter course, an irremediable discolorization may result. Coarse pieces of carving, spongy end and cross-grained woods, should be prepared for the stain by putting on a thin layer of varnish, letting it dry, and then sand-papering it completely off. Fine work requires to be oiled and slightly rubbed with the finest sand-

paper. Thus prepared, the fibre will take the stain regularly and retain smoothness. When stain is put on with a flat hog's hair tool, it is softened by a moderate application of a badger hair softener; the steel comb is used for streaking artificial oak, and the mottler is used for variegating and uniting the shades and tints of mahogany. Flannels and sponges are often worked with instead of brushes, but the implements most serviceable for veining or ingraining purposes, are small badger sash tools and sable pencils.

BILLIARD BALLS. — *Black.* 1. Use nitrate of silver, dissolved in water, and expose the pieces to strong sunlight. — 2. Steep for several days in a decoction of 2 lbs. logwood, 1 lb. galls, and then for a few hours in acetate of iron. — *Blue.* 1. Stain them green, and then immerse in a hot solution of pearlash. — 2. Boil in logwood decoction and then in an aqueous solution of copper sulphate. — 3. Steep them in a weak solution of sulphate of indigo, to which a little tartaric acid has been added. The coal tar colors, though brilliant, are apt to fade. — *Green.* Steep in a solution of verdigris, to which a little nitric acid has been added, or in a solution of distilled verdigris in acetic acid. Sal ammoniac is sometimes added to this solution. Do not use metallic vessels.—*Purple.* Steep in a weak aqueous solution of terchloride of gold, or boil for some time in a strong aqueous solution of logwood extract, and then add 4 oz. alum to the gal. of solution, and continue boiling until the ivory is sufficiently colored. — *Red.* Soak the pieces for a few minutes in weak nitric acid, and then in a strong decoction of cochineal in ammonia water.— *Yellow.* 1. Steep 24 hours in a solution of lead acetate, and, after drying, in a solution of potassium bichromate. —2. Steep the pieces in a saturated solution of orpiment (sulphide of arsenic) in strong ammonia, and dry. The depth of color depends upon the degree of concentration of the solution.

BLACK.—1. Boil ½ lb. chip logwood in 2 qts. water; add 1 oz. pearlash, and apply it hot to the work with a brush; then take ½ lb. logwood, boil it as before in 2 qts. water, and add ½ oz. verdigris and ½ oz. copperas; strain; put in ½ lb. rusty steel filings; with this go over the work a second time. — 2. (*Ebony Imitation.*) Mix up a strong stain of copperas and logwood; to this add powdered nut-gall; stain with this solution; dry rub down well; oil; then use French polish, made tolerably dark with indigo, or finely powdered stone blue.

BLACK WALNUT. — 1. ¼ lb. asphaltum, ½ lb. common beeswax, and 1 gal. turpentine; if the mixture is found too thin, add more beeswax; if too light in color, add more asphaltum; a very little will make a great difference in the shade; varnishing is not necessary. A good stain for pine. — 2. Take 1 gal. very thin sized shellac; add 1 lb. dry burnt umber; 1 lb. dry burnt sienna; ¼ lb. lampblack; put these into a jug, and shake frequently till mixed; apply 1 coat with a brush; when dry, sand-paper with fine paper, and apply 1 coat shellac varnish. A good imitation of solid walnut; it may be used on pine and white wood.

BLUE.—1. Into a clean glass bottle put 1 lb. oil vitriol and 4 oz. best indigo, pounded in a mortar; take care to set the bottle in a basin or earthen glazed pan, as it will ferment; put the veneers into a copper or stone trough; fill it with rather more than ½ water, and add as much of the vitriol and indigo as will make a fine blue; let the veneers remain till the dye has struck through. The color will be improved if the solution of indigo in vitriol be kept a few weeks before using. The color strikes better if the veneers are boiled in plain water, remaining a few hours thereafter to dry, previous to immersing in the dye. — 2. Dissolve copper filings in aquafortis; brush the wood with it, and then go over the work with a hot solution of pearlash (2 oz. to 1 pt. water) till it assumes a blue color. — 3. Boil 2 oz. indigo, 2 lbs. wood, and 1 oz. alum, in 1 gal. water; brush well till thoroughly stained. — 4. Throw pieces of quicklime into soft water; stir well; when settled, strain; then to every gal. add 10 to 12 oz. best turnsole; put the whole into a copper with the veneers, which should be of white holly, prepared by boiling in water; then let them simmer gently in the color, but not boil, as that would injure the color.

BROWN.—1. Boil ½ lb. Vandyke brown and 2 oz. carbonate soda in 12 oz. water, and add ½ oz. bichromate of potassa; or use a weak aqueous solution of permanganate of potassa in water. Remove the varnish first with sand-paper, and varnish after staining. — 2. (*Light Reddish.*) Boil ½ lb. madder and ¼ lb. fustic to 1 gal. water; brush the work, when boiling hot, until properly stained. — 3. Hold the work to the fire, to receive gentle warmth; then take aquafortis, and, with a feather, pass it over the work till it changes to a fine brown (keeping it near the fire); it may then be varnished or polished. — 4. Paint the wood with a solution, made by boiling 1 pt. catechu with 30 pts. water and a little soda; dry, and then paint with a solution of bichromate of potash, 1 pt.; water, 30 pts. By a little difference in the treatment and by varying the strength of the solutions, various shades may be given to these materials. The colors will be permanent and will tend to preserve the wood.

FLOORS.—1. The cheapest stain of any color is made with aniline colors, dissolved in hot water; some of these will fade, but yellow, red and brown, especially when covered with a coat of linseed oil, will last a long time. Any shade can be obtained by mixing. — 2. Put 1 oz. Vandyke brown in oil; 3 oz. pearlash and 2 dr. dragon's blood into an earthenware pan; pour on the mixture 1 qt. boiling water, and stir with a piece of wood; use hot or cold; smooth the boards with a plane, and sand-paper; fill the cracks with plaster Paris, and use the brush, not across the boards, but lengthwise, and coat only a small space at a time; when quite dry, size the floor with glue size, made by boiling glue in water, and brushing it into the boards hot. When dry, sand-paper smooth and varnish with brown, hard varnish. — 3. To strong lye of wood ashes, add enough copperas for the required oak shade; put on with a mop, and varnish. — 4. A kitchen floor may be stained of an

agreeable color by coating it with a mixture of 5 lbs. French ochre, ¼ lb. glue, and 1 gal. hot water; put on hot; when dry, cover with 2 coats boiled linseed oil. The floor should be made smooth before colored. For colors not given here, see other receipts in this department for staining in imitation of different woods.

GREEN.—Dissolve 4 oz. best verdigris, and ½ oz. each sap green and indigo, in 3 pts. best vinegar; put in the veneers and gently boil till the color has penetrated. The hue of the green may be varied by altering the proportion of the ingredients; unless wanted for a particular purpose, leave out the sap green, as it is a vegetable color, and apt to change when exposed to the air.

HORN.—(See same in VEGETABLE DYES.)

IVORY.—(See same in VEGETABLE DYES.)

MAHOGANY. — 1. Break 2 oz. dragon's blood in pieces, and put in 1 qt. rectified spirits wine; let the bottle stand in a warm place, and shake it frequently; use when dissolved; applied to common wood it will be an excellent imitation of mahogany. — 2. Take nitric acid, dilute with 10 parts water, and wash the wood with it. — 3. (*On Beech.*) Pulverized dragon's blood, 2 oz.; rectified spirits wine, 1 qt. — 4. (*On Maple.*) Dragon's blood, ½ oz.; alkanet, ½ oz.; aloes, 1 dr.; spirits wine, 16 oz.; apply it with a sponge or a brush. — 5. Boil ½ lb. madder and 2 oz. logwood chips in 1 gal. water; brush over while hot; when dry, go over the whole with pearlash solution, 2 dr. to the qt.

MUSICAL INSTRUMENTS.—*Black.* In general, when black is required in musical instruments, it is produced by japanning; the work is well prepared with size and lampblack; apply black Japan; after which varnish and polish. A black stain is sometimes required for finger-boards, bridges and flutes. The wood ought to be either pear, apple or boxwood; the latter is preferable; and if it be rubbed over, when dry, with a rag or flannel, dipped in hot oil, it will give it a gloss equal to ebony.—*Blue.* Into 1 lb. oil vitriol, in a clean glass vial, put 4 oz. indigo, and proceed as directed in dyeing purple. — *Crimson.* Boil 1 lb. good Brazil dust in 3 qts. water, 1 hour; strain, and add ½ oz. cochineal; boil it again gently ½ hour, and it will be fit for use. If more of a scarlet tint is desired, boil ½ oz. saffron in 1 qt. water 1 hour, and pass over the work previous to the red stain. — *Green.* 3 pts. strong vinegar; 4 oz. verdigris, pounded fine; ½ oz., each, sap green and indigo. *Purple.* 1 lb. good chip logwood; 3 qts. water; boil well 1 hour; then add 4 oz. pearlash and 2 oz. indigo, pounded. — *Yellow.* A small piece of aloes, put into the varnish, will have all the desired effect.

OAK.—1. Wash the wood carefully in a solution of copperas, dissolved in strong lye, in the proportion of 1 lb. copperas to 1 gal. lye. When the wood is dry after saturation, oil it, and it will look fresh for a year or two, when it can be re-stained and again oiled. When not subjected to hard usage, the color may remain undimmed for years by oiling occasionally. The color may be put on with a short bristle brush, or the hands, being protected with thick buckskin gloves, the wash may be applied with a cloth, which will saturate the wood evenly. It will blister the hands if not protected. — 2. Prepare the wood with a solution of 1 oz. catechu, boiled in 1½ pts. water; when dry, brush over a solution of bichromate of potash, 1 oz. to 1½ pts. water. By varying the proportions, different shades may be had. — 3. Grind Vandyke and whiting in turpentine; add a bit of common soap to make it stand the comb, and thin with boiled oil.

PURPLE.—To 2 lbs. chip logwood and ½ lb. Brazil dust, add 4 gals. water, and after putting in the veneers boil 3 hours; then add 6 oz. pearlash and 2 oz. alum; let them boil 2 or 3 hours every day till the color has struck through. The Brazil dust makes the purple of a redder cast; it may be omitted if a bluish purple is required. — 2. Boil 2 lbs. logwood chips or powder, in 4 gals. water, with the veneers; after the color has well struck in, add by degrees, vitriolated indigo, till the purple is of the shade required, which may be known by trying it with a piece of paper; then boil 1 hour, and keep the liquid in a milkwarm state till the color has penetrated the veneer. This will produce a brilliant purple, not so likely to fade as the foregoing. — 3. Chipped logwood, 1 lb.; water, 3 qts.; pearlash, 4 oz.; powdered indigo, 2 oz.; boil the logwood in the water, ½ hour; add the pearlash and indigo, and when dissolved, it will give a beautiful purple.

RED.—1. Put 1 oz. potash in 1 qt. water, with red sanders, 1½ oz.; extract the color from the wood and strain; then add gum shellac, ½ lb.; dissolve it by a brisk fire. Used upon logwood stain for rosewood imitation. — 2. (*Bright.*) To 2 lbs. genuine Brazil dust, add 4 gals. water; put in as many veneers as the liquor will cover; boil 3 hours; then add 2 oz., each, alum and aquafortis, and keep it lukewarm till it has struck through. — 3. Take 1 lb. Brazil wood to 1 gal. water; boil 3 hours with 1 oz. pearlash; brush it hot on the wood, and while hot brush the wood with a solution made with 2 oz. alum in 1 qt. water. — 4. An infusion of Brazil wood in stale urine, in the proportion of 1 lb. to 1 gal. for wood; to be laid on when boiling hot, and laid over with alum water before it dries. — 5. Archil will produce a good stain, when used cold; if, after 1 or 2 coats, and when they are almost dry, it is brushed over with a hot solution of pearlash in water, it will improve the color. — 6. (*Cherry.*) Rain water, 2 qts.; annatto, 4 oz.; boil in a copper kettle till the annatto is dissolved; then put in a piece of potash size of a walnut; keep it on the fire ½ hour longer, and then bottle for use.

ROSEWOOD. — 1. 1 gal. alcohol; 1 lb., each, red sanders, dragon's blood, and extract logwood; ½ lb. shellac; put the mixture into a jug; steep it till it obtains full strength; strain, and it will be ready for use; apply with a brush, giving 1, 2 or more coats, according to depth of color desired; then give 1 or more coats varnish. This stain is suitable for cane, willow or reed work, and produces a good imitation of rosewood. — 2. Take alcohol, 1 gal.; camwood, 2 oz.; set them in a warm place 24 hours; then add extract logwood, 3 oz., and aquafortis, 1 oz.;

when dissolved it is ready; it makes a bright ground like the most beautiful rosewood. Give 1 or 2 more coats, as desired.

SATINWOOD. — 1. Take white for the first coating, light blue for the second, and dark blue or dark green for the third. — 2. Alcohol, 2 pts.; powdered gamboge, 3 oz.; ground turmeric, 6 oz.; steep to obtain full strength, and strain through muslin; apply 2 coats with a fine sponge; sand-paper, when dry, and varnish or French polish.

YELLOW.—To every gal. water necessary to cover the veneers, add 1 lb. French berries; boil till the color has penetrated; add to the infusion of French berries the following liquid, and let the veneers remain for 2 or 3 hours, and the color will be very bright: Reduce 4 lbs. barberry root to dust, by sawing; put into a copper or brass trough; add 4 oz. turmeric and 4 gals. water; then put in as many white holly veneers as the liquor will cover; boil 3 hours, often turning them; when cool, add 2 oz. aquafortis, and the dye will strike through sooner.

VARNISHES, JAPANS AND LACQUERS.

REMARKS.—*Japanning* is the art of covering paper, wood, or metal, with a coating of hard, brilliant and durable varnish. The surface is colored or painted with devices, etc., as desired; next, covered with a highly transparent varnish (amber or copal); then dried at a high temperature (135° to 165° Fahr.), and, lastly, polished. Wood and paper are first sized, polished and varnished. For plain surfaces, asphaltum varnish, or Japan is used. *Lacquering* is by a solution of shellac in alcohol, tinged with saffron, annatto, aloes, or other coloring substances. It is sometimes applied to wood, but usually to metals to impart a golden color. This is done in 2 ways, called cold lacquering and hot lacquering. By the former, a little lacquer is taken on a camel's hair varnish brush, and laid evenly over the work, which is then placed in an oven or on a hot stove; the heat continued a minute or two to set the lacquer, and the work is finished. Care must be taken not to have the work too hot nor yet too cold, or the lacquer will not thoroughly set. By the second method, the work is heated, first, to about the heat of a flat iron as used by a laundress, and the lacquer quickly brushed over it in this state; the work then subjected to the oven for a minute afterwards, or not, as the operator sees fit. The article, if small, requires this, having parted with most of its heat during lacquering; if heavy, it retains sufficient heat to perfect the process. The greatest difficulty is to know the exact degree of heat, which cannot be attained except by experience, so different is the nature of the materials, the quality of different lacquers, and the effect to be produced. *Varnish* is a solution of a resin in oil of turpentine, wood-naphtha, spirits of wine, or some other solvent, which, on evaporating, leaves the resin behind in a thin, transparent, highly polished film. The resins most employed in making varnishes, are copal, mastic, demar, sandarac, cowrie, lac, amber, and occasionally elemi and anime. The solvents used are oil of turpentine, spirits of wine, wood-spirit, methylated spirit, and lighter portions of the coal and petroleum oils. In manufacturing varnishes, if too much spirit is used, they crack in drying. To remedy this, oil of turpentine and linseed or poppy oil are added, to prevent hasty evaporation.

AMBER VARNISH, Pale.—1 Amber, pale and transparent, 6 lbs.; fuse; add hot clarified linseed oil, 2 gals.; boil till it strings strongly; cool a little, and add oil turpentine, 4 gals. Pale as copal varnish; soon becomes hard, and is the most durable of oil varnishes, but requires time before fit for polishing. When wanted to dry quickly, drying oil may be substituted for linseed, or driers may be added during the boiling. — 2. Amber, 1 lb.; melt; add Scio turpentine, ½ lb.; transparent white resin, 2 oz.; hot linseed oil, 1 pt.; and afterwards oil turpentine sufficient, as above. Very tough. — 3. Very pale, transparent amber, 4 oz.; clarified linseed oil and oil of turpentine, of each, 1 pt.. — 4. Fuse 6 lb. very pale clear amber, and add 2 gals. hot clarified oil; boil until it strings strong; remove from the fire and stir in 4 gals. oil of turpentine; allow plenty of time before polishing. Amber varnish is suited for all purposes where a hard and durable varnish is required. The pale is superior to copal, and is often mixed with the latter to increase its hardness and durability.

ANTI-RUST VARNISH, For Iron and Steel.—Resin, 120 parts; sandarac, 180 parts; gum lac, 60 parts; essence of turpentine, 120 parts; rectified alcohol, 180 parts. Pound the first 3 ingredients; digest them by regular heat until melted; add the turpentine gradually; after solution has taken place, add the alcohol, and filter through fine cloth; keep in well-stoppered bottles.

ASPHALT VARNISH.—Boil coal tar until it shows a disposition to harden on cooling; this can be ascertained by rubbing a little on a piece of metal; then add 20 per cent. of lump asphalt, stirring it with the boiling tar until the lumps are melted; then let it cool, and keep for use. A very bright varnish for sheet metals, and is cheap and durable.

BALLOON VARNISH.—Take india-rubber and dissolve it in 5 times its weight of spirits turpentine, keeping them some time together; then boil 1 part of this solution with 8 parts boiled linseed oil a few minutes; strain. Apply warm.

BASKET VARNISH.—Take sealing wax, of the color desired; to every 2 oz. add 1 oz. spirit of wine; pound the wax fine; sift till fine; put it into a vial with spirits wine; shake; let it stand near the fire 48 hours, shaking often; then, with a little brush, rub the baskets all over with it; let them dry, and do them over a second time.

BESSEMER'S VARNISH. — 8 lbs. copal; 2½ gals. drying oil; 25 gals. oil of turpentine. They are made into a varnish nearly as directed for

Cabinet Varnish (which see), and afterwards mixed with 1 gal. slaked lime; then left 3 days to settle. The clear portion is then drawn off, and 5 parts varnish mixed with 4 parts bronze powder.

BLACK JAPAN.—1. Amber, 12 oz.; asphaltum, purified, 2 oz.; boiled oil, ½ pt.; resin, 2 oz.; oil of turpentine, 16 oz. Fuse the gum, resin and asphaltum; add the hot oil; stir well, and when cooling add the turpentine. — 2. Asphaltum, 1 lb.; balsam of capivi, 1 lb.; oil of turpentine, q. s. The asphaltum is melted over a fire, and the balsam, previously heated, is mixed in with it; the mixture is then removed from the fire and mixed with the turpentine. — 3. Moisten good lampblack with oil of turpentine, and grind it very fine; then add sufficient ordinary copal varnish, and rub well together.

BLACK ROSEWOOD JAPAN.—The work must be grounded black, after which grind some red lead, mixed up as before directed, which lay on with a flat, stiff brush in imitation of the streaks in the wood; then take a small quantity of lake, ground fine, and mix it with brown spirit varnish, observing to have no more color than will tinge the varnish; if too red, add a little umber ground fine, and pass over the whole of the work intended to imitate black rosewood. If well done, when it is varnished and polished, it will scarcely be known from rosewood. Instead of umber, Vandyke brown may be used; it is more transparent than umber.

BLACK VARNISH.—1. (*For Iron.*) Mix with a small quantity of oil of turpentine, drop by drop, oil of vitriol, until it forms a syrupy precipitate which no longer increases in bulk; the mass is then poured over with water, stirred well, the water removed, and repeated as often as it shows a trace of acid on litmus paper; the remaining precipitate is then strained dry, and when required for use, a portion of it is placed on the iron (stove, etc.), and the stove heated and the powder burned; if too thick a layer, it must be thinned, and spread out with more turpentine, so as to give a uniform coating to the metallic surface; the residue left after burning, is then rubbed in with a rag dipped in flaxseed oil until the proper polish is acquired. — 2. (*Aniline.*) Dissolve 6¾ dr., avoirdupois, of aniline blue, 1¾ dr. fuchsine, and 4½ dr. naphthaline yellow, in 1 qt. alcohol; the whole is then dissolved by agitation in less than 12 hours; 1 application renders an object ebony black; the varnish can be filtered, and will never deposit afterwards. — 3. (*For Coal Buckets.*) Asphaltum, 1 lb.; lampblack, ¾ lb.; resin, ½ lb.; spirits turpentine, 1 qt. Dissolve the asphaltum and resin in the turpentine; then rub up the lampblack with linseed oil to a paste, and mix with the others. Apply with a brush.

BLUE JAPAN.—Blue Japan grounds may be formed of bright Prussian blue. Mix with shellac varnish, and bring to a polish with 5 or 6 coats of varnish of seed-lac. The varnish is apt to give a greenish tinge to the blue; when a light blue is desired, use the purest varnish.

BRASS, Lacquer for. — 1. Turmeric, 1 oz.; saffron and annatto, each, ½ oz.; rectified spirits, 1 pt. Digest at a gentle heat for several days; strain through coarse linen; bottle and add 3 oz. coarsely pulverized seed-lac; place in a moderate heat, and shake occasionally till dissolved. — 2. Alcohol, 12 gal.; seed-lac, 9 lbs.; turmeric, 1 lb. to 1 gal. of the above mixture; Spanish saffron, 4 oz.; the saffron is to be added for bronze work. — 3. (*Gold Colored.*) Alcohol, 36 oz.; seed-lac, 6 oz.; amber, 2 oz.; gum gutta, 2 oz.; red sandal wood, 24 gr.; dragon's blood, 60 gr.; oriental saffron, 36 gr.; pulverized glass, 4 oz. — 4. (*Red.*) Alcohol, 8 gals.; dragon's blood, 4 lbs.; Spanish annatto, 12 lbs.; gum sandarac, 13 lbs.; turpentine, 1 gal.

BROWN LACQUER, For Copper Bronze.—2½ oz. shellac; 2 qts. wine spirit; 2 oz. gum sandarac; ½ oz. gum elimi; mix, and keep warm until solution is effected; then strain, and color with dragon's blood and aniline brown to suit.

BRUSHES, Varnish, Care of.—Suspend them by the handles in a tightly covered can, keeping the points ½ in. from the bottom and apart from each other. The can should be filled with slowly drying varnish up to 1-16 in. above the bristles; and the can kept in a close cupboard. As wiping a brush on a sharp edge will ruin it, the top of the can should have a wire soldered along the edge of the tin, and turned over. Finishing brushes should not be cleansed in turpentine. When taken from the can prepare them for use by working them out in varnish, and before replacing, clean the handles and binding with turpentine.

CABINET VARNISH.—Fuse 7 lbs. fine African gum copal; when it runs freely, pour into it ½ gal. clarified linseed oil; when clear, remove from the fire, and mix 3 gals. spirits turpentine with it, and strain. If properly boiled, it will dry in 10 minutes; if boiled too much, it will not mix with the turpentine. Used by japanners, cabinet and coach makers.

CANADA VARNISH.—Clear balsam of Canada, 4 oz.; camphene, 8 oz.; warm gently, and shake together till dissolved. For maps, drawings, etc., they are first sized over with a solution of isinglass, taking care that every part is covered; when dry, the varnish is brushed over it.

CARRIAGE JAPAN.—40 gals. raw linseed oil; 40 lbs. litharge; 20 lbs. red lead; 10 lbs. black oxide manganese; 2 lbs. white gum shellac; set the oil over the fire, and bring to the boiling point; add by degrees litharge and red lead alternately and slowly; add the gum, and when melted put in the manganese, and keep the whole in rapid motion from the time the oil is at 200° Fahr. until the making is finished; when cool enough to bear the finger in a moment, add from 20 to 30 gals. spirits turpentine.

CARRIAGE VARNISH.—1. 8 lbs. second sorted African copal; 2½ gals. clarified oil; boil till very stringy. ¼ lb. dried copperas; ¼ lb. litharge; 5½ gals. turpentine; strained. 8 lbs. second sorted gum anime; 2½ gals. clarified oil; ¼ lb. dried sugar of lead; ¼ lb. litharge; 5½ gals. turpentine; mix with the first while hot. This varnish will dry hard if well boiled, in 4 hours in summer and 6 in winter. It is used for wheels, springs, and carriage parts of coaches, chaises, etc.; it is used by house painters and decorators, because of its drying quality and strong gloss.

— 2. 8 lbs. second sorted gum anime; 2¾ gals. fine clarified oil; 5½ gals. turpentine; ½ lb. litharge; ¼ lb. dried sugar of lead; ½ lb. dried copperas; boiled and mixed as before. When three runs are poured into the boiling pot, the driers put in, and well boiled, this varnish will dry hard in 4 hours in winter, and in 2 in summer. Used for varnishing dark carriage work or black Japan, and by house painters for dark work.

CHINESE LACQUER.—Chinese lacquer work is done over tin-foil, and consists of a mixture of 2 parts of copal and 1 of shellac, melted together; when fluid, add 2 parts boiled linseed oil, and, when taken from the fire, add gradually 10 parts oil of turpentine. If color is required, gum gutta (or gamboge), dissolved in oil of turpentine, yields yellow; and dragon's blood, dissolved in the same liquid, yields red.

CHINESE VARNISH. — 1. Mix 3 parts fresh blood, deprived of its fibrin by beating with twigs or broom straws, 4 parts slaked lime, and a little alum. Use at once. It is said that baskets coated with it are rendered water and oil tight, and that pasteboard to which it has been applied, becomes as hard as wood. — 2 Mastic and sandarac, of each, 2 oz.; rectified spirit, 1 pt. Close the matrass with bladder, with a pin hole for the escape of vapor; heat to boiling in a sand or water bath, and when dissolved strain through linen.

COLORLESS VARNISH. — 1. Dissolve 2½ oz. shellac in 1 pt. rectified spirits wine; boil for a few minutes with 5 oz. well-burnt and recently heated animal charcoal; filter a small portion, and if not colorless add more charcoal. When all color is removed, press the liquor through a piece of silk, and filter through blotting paper. This varnish should be used in a temperature of at least 60° Fahr., perfectly free from dust. It dries in a few minutes, and is not liable afterward to chill or bloom. It is particularly applicable to drawings and prints that have been sized, and may be advantageously used upon oil paintings that are thoroughly hard and dry, as it brings out the colors with the purest effect. This quality prevents it from obscuring gilding, and renders it valuable for all kinds of leather, as it does not yield to the warmth of the hand, and resists damp. Its useful applications are numerous, indeed to all the purposes of the best hard spirit varnishes. — 2. A common lac varnish may be made by digesting 4 oz. clear grained lac in 1 pt. spirits wine in a wide mouthed bottle, keeping in a warm place for 2 or 3 days, and occasionally shaking it. When dissolved, strain through flannel into another bottle for use.

COLORINGS.—*Blue.* Indigo, Prussian blue, blue verditer, or ultramarine. All these must be powdered fine. — *Green.* Verdigris, crystallized verdigris, compound green (a mixture of yellow and blue). The first 2 require a mixture of white in proper proportions, from ½ to ⅔, according to tint. The white used is ceruse, or the white oxide of lead, or Spanish white. — *Pearl Gray.* White and black; white and blue; for example, ceruse and lampblack, ceruse and indigo; mix with the varnish, according to tint required. — *Red.* 1. Vermilion, red oxide of lead (minium), red ochre, or Prussian red, etc. — 2. Dragon's blood, brick red, or Venetian red, etc. — *Violet.* Vermilion, blue, white, in proportion as required to color the varnish. — *White.* 4 oz. copal; ½ oz. camphor; 3 oz. white drying oil; 2 oz. essential oil of turpentine. Reduce the copal to powder; mix the camphor and drying oil; then heat it on a slow fire; add the turpentine, and strain.—*Yellow.* Yellow oxide of lead of Naples and Montpellier, reduced to impalpable powder. These yellows are hurt by the contact of iron and steel; in mixing them up, a horn spatula, with a glass mortar and pestle must be used. Gum gutta, yellow ochre, or Dutch pink, is used, according to the nature and tone of the color to be imitated.

COPAL JAPAN. — Copal varnish is one of the finest for japanning purposes. It can be dissolved by linseed oil, rendered dry by adding quicklime at a heat less than will boil the oil by it. This solution, with a little turpentine added, forms a transparent varnish, which, properly applied and dried, is hard and durable. Used for snuff-boxes, tea boards, etc. It preserves paintings, reflecting light more uniformly. It is good for metals. Each coat of varnish must be dried in the oven. It can be colored; alcohol varnish will mix with any coloring matter. For white japans or varnishes, fine chalk or white lead is used as a basis, and the varnish coated over it.

COPAL VARNISH. — 1. Gum copal, 8 lbs.; linseed oil, 2 gals.; sugar of lead, ½ lb.; turpentine, 3½ gals. Boil till stringy. — 2. Gum copal, 8 lbs.; oil, 2½ gals.; sulphate of iron, ¼ lb.; turpentine, 5½ gals. Good for house and sign painting. In making the above, melt the gum in a small quantity of boiling oil, and pour gradually into the kettle containing the other oil, while boiling. When done, and cool enough not to ignite the turpentine, add it. — 3. Fuse 8 parts fine African copal, and add 2 gals. clarified oil. Boil slowly 4 or 5 hours, until stringy; then mix with 3½ gals. turpentine. — 4. (*Transparent Green.*) A transparent green varnish is made by taking a small quantity of Chinese blue, with about twice the amount finely powdered chromate of potash; stir these in copal varnish, thinned with turpentine; thoroughly grind this mixture, intimately incorporating the ingredients; otherwise it will not be transparent. A preponderance of chromate of potash gives a yellowish shade, and a deficiency increases the amount of blue. Thus colored, it produces a striking effect in japanned goods, paper hangings, etc., and can be made very cheaply.

DEMAR VARNISH. — Gum demar, 10 parts; gum sandarac, 5 parts; gum mastic, 1 part; digest at a low heat, occasionally shaking with spirits turpentine, 20 parts; finally, add more spirits turpentine, to give the consistency of syrup.

FLEXIBLE VARNISH. — This is used for balloons, gas bags, etc. 1. India-rubber (cut small), 1½ oz.; chloroform, ether (washed), or bisulphuret of carbon, 1 pt. Digest in the cold until solution is complete. Dries soon as laid on. Pure gutta percha may be substituted for india-rubber.—2. India-rubber, 1 oz.; drying oil, 1 qt. Dissolve by heat. Very tough; dries in 48

hours. — 3. Linseed oil, 1 gal.; dried white copperas and sugar of lead, of each, 3 oz.; litharge, 8 oz. Boil with constant agitation, until it strings; then cool slowly and decant the clear portion. If too thick, thin with quick-drying linseed oil.

FURNITURE VARNISH. — 1. Shellac, 1½ lbs.; naphtha, 1 gal. Dissolve, and it is ready without filtering. — 2. Shellac, 12 oz.; copal, 3 oz. Dissolve in 1 gal. naphtha. — 3. Shellac, 1½ lbs.; seed-lac and sandarac, of each, 4 oz.; mastic, 2 oz.; rectified spirit, 1 gal.; dissolve. — 4. Shellac, 2 lbs.; benzoin, 4 oz.; spirit, 1 gal. — 5. Shellac, 10 oz.; seed-lac, sandarac and copal varnish, of each, 6 oz.; benzoin, 3 oz.; naphtha, 1 gal. To darken, use benzoin and dragon's blood; turmeric and other coloring matters are also added; to make it lighter, use bleached lac, though some add oxalic acid to the ingredients. It is insoluble in spirit or naphtha. For ordinary purposes the first form is best, while its appearance is equal to any other.

GILT ARTICLES. Varnish for.—Gum lac, gamboge, dragon's blood and annatto, of each, 125 parts; saffron, 32 parts. Dissolve each resin in 1,000 parts, by measure, of absolute alcohol; 2 separate mixtures must be made with the dragon's blood and annatto, in 1,000 parts such alcohol; and a proper proportion of each added with the gamboge to the varnish, according to the shade required.

GLASS VARNISH. — Fuse together 15 parts powdered quartz or of fine sand, 10 parts potash, and 1 of charcoal; pulverize the mass and expose it for some days to the air; treat the whole with cold water, which removes the foreign salts, etc.; boil the residue in 5 parts water until it dissolves. It is permanent in the air, and not dissolved by cold water. Used to protect wood, etc., from fire.

GLASS, Varnish for.—1. Wax, 1 oz.; mastic, ½ oz.; asphaltum, ¼ oz.; turpentine, ½ dr. — 2. Mastic, 15 parts; turpentine, 7 parts; oil of spike, 4 parts.

GOLD LACQUER. — 1. Put into a clean, 4 gal. tin, 1 lb. ground turmeric, 1½ oz. gamboge, 3½ lbs. powdered gum sandarac, ¾ lb. shellac, and 2 gals. spirits wine. When shaken, dissolved and strained, add 1 pt. turpentine varnish, well mixed. — 2. 3 parts seed-lac; ½ part old varnish; 10 parts oil turpentine. This lacquer would require no coloring; but the precautions to a successful working would be those that have to be observed with all solid lac varnishes. — 3. (*Deep Colored.*) Best alcohol, 40 oz.; Spanish annatto, 8 gr.; turmeric, 2 dr.; shellac, ½ oz.; red sanders, 12 gr.; when dissolved, add spirits turpentine, 30 drops.

GOLD VARNISH. — 1. Turmeric, 1 dr.; gamboge, 1 dr.; oil turpentine, 2 pts.; shellac, 5 oz.; sandarac, 5 oz.; dragon's blood, 7 dr.; thin mastic varnish, 8 oz. Digest with agitation 14 days in a warm place; then set aside to fine, and pour off the clear. —2. Dutch leaf, 1 part; gamboge, 4 parts; gum dragon, 4 parts; proof spirit, 18 parts. Macerate 12 hours; then grind.

GRATES, Varnish for.—Melt 4 lbs. common asphaltum; add 2 pts. linseed oil and 1 gal. oil turpentine. If too thick, add more turpentine.

GRECIAN VARNISH.—3 oz. balsam fir; 2 oz. alcohol; 1 oz. spirits turpentine. Mix together.

GREEN LACQUER. — Add to pale lacquer, when mixing, 6 oz. turmeric and 1 oz. gum gamboge.

GUN-BARREL VARNISH. — Shellac, 1½ oz.; dragon's blood, 3 dr.; rectified spirit, 1 qt. Applied after the barrels are browned.

INDIA-RUBBER VARNISH. — 1. 2 oz. india-rubber, finely divided; phee in a vial, and digest in a sand-bath with ¼ lb. camphene and ½ oz. naphtha. When dissolved, add 1 oz. copal varnish, which renders it more durable. — 2. Digest in a wide mouthed glass bottle, 2 oz. india-rubber, in shavings, with 1 lb. oil turpentine, during 2 days, without shaking; then stir with a wooden spatula. Add another lb. oil turpentine, and digest with agitation until dissolved. Mix 1½ lbs. of this solution with 2 lbs. white copal oil varnish, and 1½ lbs. boiled linseed oil. Shake and digest in a sand-bath until united into a good varnish. — 3. 4 oz. india-rubber, in shavings; dissolve in a covered jar, by means of a sand-bath, in 2 lbs. crude benzole; and then mix with 4 lbs. hot linseed oil varnish and ½ lb. oil turpentine. Dries well.

IRON, Varnish for.—1. Take oil of turpentine and drop into it, drop by drop, commercial oil of vitriol; the acid will cause a dark, syrupy precipitate in the oil of turpentine. Keep adding drops of vitriol until the precipitate ceases; then pour out the liquid and wash the syrupy mass with water, and it is ready. Heat the iron to be varnished to a gentle heat; apply the syrupy product, and allow it to dry. — 2. Asphaltum, 8 lbs.; melt in an iron kettle, slowly adding boiled linseed oil, 5 gals., litharge, 1 lb., and sulphate of zinc, ½ lb., continuing to boil 3 hours; then add dark gum amber, 1½ lbs.; boil 2 hours longer; when cool, reduce to a proper consistence to apply with a brush, with spirits turpentine. — 3. Dissolve in about 2 lbs. tar oil, ½ lb. asphaltum and a like quantity pounded resin; mix hot in an iron kettle, care being taken to prevent any contact with the flame. When cold it is ready. Used for out-door wood and iron work.

LINSEED OIL VARNISH.—Pour 25 lbs. pure linseed oil into an enameled iron pot which holds about 40 lbs. weight; then place on a moderately strong charcoal fire, and heat the oil ½ hour to boiling point; in the mean time rub 4 oz. pure oxide of manganese in linseed oil; put this mass into a small vessel provided with a spout, and pour in drops into the boiling linseed oil, while being gently stirred with a wooden spatula. During effervescenee of the oil, the dropping in of the manganese must stop. As soon as the oil has settled, the dropping in is continued to the last. The vessel is washed out with linseed oil, which is poured into the boiling oil. The varnish is now boiled slowly 1 hour; but if stronger varnish is desired, boil ½ hour, or 1 hour longer. When removed from the fire, cover with a clean plate, and let rest 24 hours; then carefully pour off into clean vessels; the sediment and other residue are used for the preparation of ordinary ground colors. The varnish, when poured into glass bottles, can then be

bleached by exposure to the sun and moon. Moonlight bleaches quicker than sunlight. The bleached is used only for the finest white oil and lac colors, and for dissolving fine copal lacs, as well as a drying medium for fine oil colors.

MAHOGANY VARNISH. — Gum anime, 8 lbs.; clarified oil, 3 gals.; litharge and powdered dry sugar of lead, of each, ½ lb. Proceed as for body varnish, and thin with oil turpentine, 5 gals., or a sufficient quantity.

MASTIC VARNISH.—1. Pale and picked gum mastic, 5 lbs.; glass (pounded small, washed and dried), 3 lbs.; finest newly rectified oil turpentine (lukewarm), 2 gals.; put them into a clean 4 gal. tin bottle or can, bung down, and keep rolling it backwards and forwards smartly on a counter or other solid place, 4 hours; when the gum is dissolved, the varnish may be decanted, strained through muslin into another bottle, and allowed to settle; if the solution is still incomplete, the agitation must be continued longer, or gentle warmth applied. Very fine. — 2. Mastic, 4 lbs.; oil turpentine, 2 gals.; dissolve with heat. Used for pictures, etc.; when good, it is tough, brilliant and colorless; it improves by age, and should never be used before 12 mos. old. Should it get "chilled," add 1 lb. well-washed silicious sand, made moderately hot, to each gal.; agitate 5 minutes and let it settle.

METAL, Polished, Varnish for. — 1. Bleached shellac, pounded; place in a bottle of alcohol until some shellac remains undissolved; agitate often, and let it stand; pour off the clear. This forms the varnish. Warm the metal surface and coat with a camel's hair brush. If not transparent, warm the varnished surface before a fire until it becomes clear. Common orange shellac answers, and for large surfaces even better, as it is more soluble than bleached, and coats more perfectly, but care must be taken not to use the varnish insufficiently diluted. — 2. Digest 1 part bruised copal in 2 parts absolute alcohol; but, as this varnish dries too quickly, it is preferable to take 1 part copal, 1 part oil rosemary, and 2 or 3 parts absolute alcohol. This gives a varnish limpid as water. It should be applied hot, and when dry it will be found hard and durable. — 3. Mix equal quantities Canada balsam with clear spirits turpentine, until of the consistency of varnish, which can be determined by constantly shaking and allowing to settle. This may be applied without warming varnish or metal.

OAK VARNISH. — 1. Clear pale resin, 3½ lbs.; oil of turpentine, 1 gal.; dissolve. — 2. Clear Venice turpentine, 4 lbs.; oil of turpentine, 5 lbs.; mix. Both are good common varnishes.

PAINTINGS, METAL, ETC., Lacquer for. — 1. Seed-lac, 8 oz.; alcohol, 1 qt. Digest in a close vessel, in a warm situation, 3 or 4 days; decant and strain. — 2. Substitute lac bleached by chlorine for seed-lac. Both are tough, hard and durable; the last almost colorless.

PURPLE GROUND JAPAN.—Made by a mixture of lake and Prussian blue or carmine, or, for an inferior color, vermilion. When the ground is laid on and dried, a fine coat of pure boiled nut oil, laid on and dried, is a good method to have the Japan not liable to crack; a better plan is to use this oil in the varnish given, the first coat, after the ground is laid on, and which should contain considerable pure turpentine. Where oil is used for any purpose for varnish, it is the better if turpentine is mixed with it. Turpentine enables oils to mix with either alcohol or water. Alkalies have this property, also.

RAISED FIGURES, On Japan Work.—Prepare a mixture of whiting and size (some prefer the whites of eggs), to the consistency to flow freely from a pencil, the hairs of which must be rather long. Begin with a figure, or other part; do not do too much at a time; trace the outline with a free hand; then take a stick pointed at the end, dip it in the composition, and fill up the inside outline; continue to put more of the mixture on till it is raised sufficiently above the surface; let it get dry; then polish with a small camel's hair pencil and clean water, so as to make it smooth and level. Care must be taken that the composition is not too thin, or it will spread beyond the bounds of the outline, but just so thick as to drop from the stick. Some mix with the whiting flake white or dry white lead. This is an improvement for particular work.

RED GROUND JAPAN. — The base of this ground must be made with madder lake, ground with oil of turpentine; this forms the first ground; when dry, a second coat must be applied, composed of lake and white copal varnish; and the last with a coat of a mixture of copal and turpentine varnish mixed with lake. Vermilion or carmine can be used for red Japan instead of lake.

SCARLET JAPAN.—Ground vermilion may be used, but, being glaring, it must be covered with rose pink or lake, which have a good effect. For a bright crimson ground, safflower or Indian lake should be used, dissolved in the alcohol of which the varnish is made. In place of this lake, carmine may be used. The top coat of varnish must be made of white seed-lac, and as many coats given as may be thought proper.

SHELLAC VARNISH. — 1 part gum shellac, dissolved in 3 to 4 parts alcohol of 92 per cent., mixed with 1 part water; filtered, pressed, and the solution distilled until the alcohol is evaporated. The gum precipitated from this solution is dried on a water bath and dissolved in double its weight of alcohol of 96 to 98 per cent.

SILVER VARNISH. — Gum elemi, 30 parts; white amber, 45 parts; charcoal, 30 parts; spirits turpentine, 375 parts. Used in a heated state, the metal to which it is applied being heated.

STOVE VARNISH.—Melt ½ lb. asphaltum, and add to it ½ pt. linseed oil, and 1 pt. turpentine; this will be enough for 4 grates. If too thick as it gets to the bottom, add more turpentine. It is for black stoves, which must be washed clean of dirt and black lead, and when dry apply the varnish with a brush.

TAR VARNISH.—1. (*For Iron.*) Place a convenient quantity coal tar in small retorts, and heat until the oil commences to distil over; then let the retorts cool somewhat; when they are opened and a proportionate quantity of heavy oil of tar added, and the mixture well stirred; then pour the mixture out, and the operation is

complete. Made in this way it is preferable to tar, and dries in from 24 to 48 hours. By incorporating naphtha of the lowest quality (to do which the mass must be warm) with the material made with light oil instead of heavy oil, a varnish may be obtained which will dry in 1 hour or less. — 2. Tar, 2 gals.; tallow, 1 lb.; melt; then add ground ochre, 7 lbs.; spirits of turpentine, 6 lbs.; mix well. By regulating the quantity of ochre, a very excellent chocolate paint for rough out-door work will be produced.

TEA-TRAYS, Japan for.—First clean them with soap and water and rotten stone; dry by wiping and exposure to the fire; then get good copal varnish; mix it with bronze powder, and apply with a brush to the denuded parts; then set the tray in an oven at a heat of 212° to 300° till the varnish is dry; 2 coats will make it like new.

TIN, Japan for.—Draw letters on paper to suit the piece of tin, having first cleaned it with diluted alcohol and a piece of cotton. Take whiting and rub it over the back of the paper upon which your design is made, and lay it upon the japanned tin; next place a weight upon the 4 corners of the paper; then, with a pointed piece of hard wood, trace the design, bearing upon the paper with the point hard enough to cause the whiting on the under side of the paper to adhere to the tin; after going over the whole you will have transferred the design in fine outline to the tin. Size with oil size, and when dry enough for gilding lay on the gold leaf and dab it down; brush off the loose gold with a flat camel's hair brush.

TIN, Lacquer for. — Put 3 oz. seed-lac, 2 dr. dragon's blood, and 1 oz. turmeric powder, into 1 pt. well rectified spirits; let the whole remain 14 days, but agitate once a day; when combined, strain through muslin. It is brushed over tinware intended to imitate brass.

TORTOISE-SHELL JAPAN.—Prepared by taking good linseed oil, 1 gal. and umber ½ lb; boil together until the oil becomes brown and thick; strain through a cloth, and boil again until of the consistence of pitch, when it is fit for use. Clean the copper or iron plate or vessel that is to be japanned, and lay vermilion, mixed with shellac varnish or with drying oil diluted with turpentine, thinly on the places intended to imitate the clean parts of the tortoise-shell. When the vermilion is dry, brush over the whole with the above varnish diluted with turpentine; and when set, put into a stove to undergo a strong heat for a long time; even 2 weeks will not hurt it. This is the ground for snuff-boxes and tea boards, and the grounds can be decorated with all kinds of paintings that fancy may suggest; and finish in an annealing oven.

TURPENTINE VARNISH.—Put 1 pt. turpentine into a bottle, with ½ lb. white rosin in powder; dissolve in a gentle heat, by placing the bottle in an iron pot surrounded by dry sand, over a moderate fire.

TRANSPARENT JAPAN.—1. Oil turpentine, 4 oz.; oil lavender, 3 oz.; camphor, ½ dr.; copal, 1 oz.; dissolve. Used to Japan tin, but quick copal varnish is mostly used instead. — 2. Copal varnish, 35 parts; camphor, 1 part; boiled oil, 2 parts; mix.

VIOLIN VARNISH.—1. Rectified spirits wine, ½ gal.; add 6 oz. gum sandarac, 3 oz. gum mastic, and ½ pt. turpentine varnish; put the above in a tin can by the stove, frequently shaking till dissolved; strain, and keep for use. If you find it harder than you wish, thin with turpentine varnish.—2. Heat together at a low temperature, 2 qts. alcohol, ½ pt. turpentine varnish, and 1 lb. clean gum mastic; when the latter is dissolved, strain through a cloth. — 3. Coarsely powdered copal and glass, of each, 4 oz.; alcohol, 64 per cent., 1 pt.; camphor, ½ oz. Heat the mixture with frequent stirring in a water bath, until solution is complete; when cold decant the clear portion.

WAINSCOT VARNISH. — 8 lbs. second sorted gum anime; 3 gals. clarified oil; ¼ lb., each, litharge, dried copperas, and dried sugar of lead; 6½ gals. turpentine. Boil until it strings; then mix and strain. Where large quantities are required, boil off the 3 runs in the boiling pot. Used by house painters, grainers, builders and japanners; it will dry in 2 hours in summer and in 4 in winter.

WAX VARNISH.—1. Take of pure white wax, 1 lb.; melt with gentle heat; add of warm rectified spirit, sp. gr. .83, 1 pt.; mix, and pour the liquid out upon a cold slab; grind to a smooth paste, adding more spirit as required; put the paste into a marble mortar, make an emulsion with water, 3½ pts., gradually added, and strain through muslin. Used as a varnish for paintings; when dry, a hot iron is passed over it, so as to fuse it and render it transparent; when cold, it is polished with a clean linen cloth. The most protective of all varnishes. — 2. Wax, 5 oz.; oil of turpentine, 1 qt.; dissolve. Used for furniture.

WHITE GROUND JAPAN. — Flake white, or white lead, washed and ground up with ½ of its weight of starch, and dried; temper properly for spreading with mastic varnish. Lay on the body to be japanned; then varnish with 5 or 6 coats of the following: Seed-lac, 2 oz.; gum anime, 3 oz.; reduce the gums to a coarse powder; dissolve in 1 qt. spirits wine; strain off the clear. The seed-lac will give a slight tinge to this composition, but it cannot be omitted where the varnish is wanted to be hard, though where a softer will answer the end the proportion may be diminished, and a little crude turpentine added to the gum anime to take off the brittleness.

WHITE VARNISH.—1. Gum sandarac, 3 oz.; mastic, in drops, 1 oz.; gum elemi, ½ oz.; oil of spike lavender, ½ oz. Put into 1 pt. vial, and fill up with best spirits wine; let it stand in a rather warm place till the gums are dissolved; then pour off into a clean vial, and it is ready. — 2. (*Imitation Ivory.*) Take ½ oz. isinglass, boiled gently in ½ pt. water till dissolved; then strain, and add flake white powder till it becomes as white as cream. Give the box or carved wood 3 or 4 coats, letting each dry before the other is put on; then smooth it with a damp rag. It has the appearance of ivory. If, when mixed, it looks too white, a few grains of carmine will give it a pink look, or use chrome yellow; either of these colors improve it.

WATER-PROOFING.

AWNINGS.—Awnings can be rendered water-proof by plunging the fabric into a solution containing 20 per cent. of soap, and afterwards into another solution containing the same percentage of sulphate of copper. Wash, and the operation is finished.

CANVAS.—1. The oiled water-proof is usually prepared by saturating the dry fabric with a varnish prepared as follows: Boiled linseed oil, 100 parts; wax, 15 parts; litharge, 3 parts; oil of turpentine, q. s. The oil is heated so as to melt the wax, which, with the litharge, is then incorporated with it, and the mixture thinned with turpentine. — 2. 3 baths are prepared in separate vats, standing side by side. The first is made by dissolving simple sulphate of alumina (the commercial concentrated alum cake), in 10 times its weight of cold water. For the second, make a solution of equal parts of resin and palm soaps, in 30 times their weight of boiling water. The third bath consists of water only. Soak the fabric thoroughly in the alum bath; next pass through the soap bath, still hot, and finally rinse in the water bath. — 3. Saturate the fibres with soap, by boiling in strong soapsuds of Castile or curd soap; press out the excess of liquid, and steep 24 hours in a strong aqueous solution of alum; rinse in water, and repeat, if necessary. — 4. 9½ gals. linseed oil; 1 lb. litharge; 1 lb. umber; boil together 24 hours; may be colored with any paint; lay on with a brush.

PACKING PAPER.—Cover the paper with a resinous liquid; then paint with a solution of glue and soot, as, without this, the paper will later show blotches; when this has dried, the water-proof coat is applied. Put 2½ oz. powdered shellac in 2 pts. water; bring to a boil gradually, and add ½ oz. powdered borax; while hot, any mineral color may be added, such as lump-black, yellow ochre, red ochre, iron blue, or burnt umber. The liquid is now left to cool, when it is ready for use. The operation is performed with a brush.

TEXTILE FABRICS.—1. Soap, 2 oz.; glue, 4 oz.; water, 1 gal. Soften the glue in cold water, and dissolve it with the soap in the water by aid of heat and agitation. The cloth is filled with this solution by boiling it in the liquid several hours, depending on the kind of fibre and thickness of the cloth. When saturated, the excess of liquid is wrung out and the cloth exposed to the air until nearly dry; then digested 5 to 12 hours in the following solution: Alum, 13 oz.; salt, 15 oz.; water, 1 gal. It is finally wrung out, rinsed in clean water, and dried at a temperature of about 80° Fahr. — 2. Moisten the cloth on the wrong side with a weak solution of isinglass; when dry, apply an infusion of nut-galls. — 3. Apply a solution of india-rubber, dissolved in oil of turpentine; then lay on a coat of another india-rubber varnish, made drying by the addition of driers. — 4. 1 lb. sugar of lead; 1 lb. alum; pound separately, and mix in a basin; pour 2 qts. boiling water on the mixture; let it stand 6 hours, and then bottle for use. Apply to the cloth with a sponge or soft brush on a table till well saturated; then iron it and hang up to dry. — 5. Take 3 lbs. alum, and dissolve it in water, and to it add 1 lb. acetate of lead, previously dissolved; let this stand till clear; then pour off the solution on to 1 lb. glue, previously dissolved in water; heat up to 185°, and place the cloth in for ½ hour; take it out and place in running water; afterwards dry. — 6. Boil together 2 lbs. turpentine, 1 lb. litharge in powder, and 2 to 3 lbs. linseed oil; put on the cloth with a brush and dry in the sun. — 7. The following is for linen, hemp, and cotton fabrics: 1 lb. white soap is dissolved in 13 gals. water, which must be heated without raising it to a boil; 2½ lbs. alum are dissolved in a similar quantity of water; to this solution 2½ oz. gelatine are added, previously dissolved in water; lastly, the solution of soap is mixed with that of alum. Enter the goods and distribute them in the warm (but not boiling) liquid; when impregnated, hang them up by one end, and allow the water to drain off. — 8. Cloth coated with linseed oil, to which a little wax and litharge have been added, will be water-proof.

UMBRELLAS. — Dry first in a warm place; then apply a coat or two of a solution of 100 parts paraffine and 5 to 10 parts beeswax in 500 parts benzine.

WALLS, Concrete.—Boil linseed oil 2 or more hours, until it forms, on cooling, a tough, viscid mass. If, while hot, or thinned a little with benzine, this is painted over walls, the composition will form a water-proof coating. In boiling the oil, take care that the fumes do not take fire; but if they do, put a sheet iron, or tin, or a thick wet mat, or piece of carpet over the pot, to shut out the air and extinguish the flames; on no account throw in water; be provided and ready for the emergency.

WALL DECORATION.

DISTEMPER.—Colors are said to be in distemper when mixed with size or gum and not with oil. Painting in distemper is sometimes identified with fresco painting, but there is a difference. Fresco painting is executed upon a damp surface and distemper on a dry one. Since colors prepared with size soon dry or set, the work requires rapid execution; and since they may be seriously injured by damp and other causes, varnish the work if its durability is important. Distemper colors are applied to plaster, and, to a large extent, to wood and other

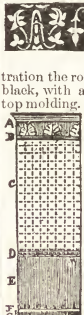
materials. It is cheaper than oil, looks well, and, if protected, lasts long. The process for a wall or ceiling coated with plaster is this: Put some whiting into water, and when well saturated pour the clear water off. Grind separately in water a little indigo or ivory black, and mix it with the whiting. Then stir in strong warm size; strain while warm and put in a cool place; when it becomes a jelly it will be fit for use. If too much size is employed the color may peel off; for a first coat the mixture must be moderately strong. The plaster must be clean before covered. A second coat must be applied to finish the operation. The colors, previously ground in water, should be cautiously mixed, and the shade tested by drying a little on a shingle or white paper; if too dark, add more whiting; if too light, more color. Now add enough melted glue to fix the color hard, so as not to rise or wash up with your second coat, and test on paper or wood also. For *Yellow*, chrome yellow or different tints may be used. *Buff* or *Drab* can be got by a mixture of yellow ochre, red, blue, or black, and sometimes umber. Buff or drab colors may be produced by yellow ochre, chrome yellow, or raw sienna, intermixed with Turkey umber. For *Green*, mineral or Paris green are first class. Any good chrome green will suit. For *Blue*, use cobalt ultramarine blue, Prussian blue and verditer. For *Gray*, a composition of white, blue, red and black. For *Red*, vermilion, Indian red, Venetian red, lake, carmine. For *Pink* or *Rose* tints, a mixture of red with white; if not wanted bright, use Indian red; if a rich color is desired, use carmine, lake, Venetian red, or vermilion. For *Black*, blue black and the Frankfort, or pure ivory black. For *Browns for shading, etc.*, burnt sienna, burnt ochre, purple brown, colcother, burnt umber, Vandyke brown. *French size, for Gilding Ornaments, Ceilings, etc.*: Mix thick glue to the proper consistence with a little pure honey; this imparts a beautiful color to the gold, and gives a splendid effect to the work. Previous to using the distemper colors, give the walls and ceilings, if new and clean, a good coat of paint, which should be mixed about $\frac{2}{3}$ turpentine and $\frac{1}{3}$ linseed oil, using as much Japan dryer as will dry it hard; be careful of adding too much oil, as it will spoil the subsequent work. When distemper is applied to wood, it will bear almost any of the common varnishes; and when quite dry, a coat of linseed oil will render it almost equal to ordinary oil paint.

FRESCO.—This method of painting is confined to decorating walls of buildings, and is executed by incorporating the colors with the still moist plaster, or gesso. The pigments are mineral or vitreous. While the ground is being prepared, a drawing on paper is made of the subject, executed with a correct outline and with the wished-for effect properly shown. When the finished drawing is made the size of the painting, it is executed in black and white with ink or crayons; but it is necessary to have a study of the subject is colors, and this is done on a small scale. The pigments used are mostly minerals, ground and applied with pure water. With the surface of the wall still wet, but firm and smooth, the tracing is laid over the portion prepared, and the lines of the drawing slightly indented on the plaster with a blunt point; or the lines have small holes in them pierced at intervals, and the design, thus pricked, is laid upon the ground and dusted with a pounce-bag containing fine dry powder, and the outline repeated on the ground by the dots of powder. When the intonaco has become firm enough to bear the pressure of the finger the first washes of color may be put on. If the painting is to be large, only sufficient plaster is put on to serve for the part which can be accomplished in the time at the disposal of the painter, and this portion should end at the edges of some bold outline, as flowing drapery, a pillar, etc. A difficulty with fresco painting is that the colors become lighter after the plaster dries. This can be avoided by putting a touch of color upon a piece of umber, which instantly dries and shows the color as it will be after the intonaco dries.

STENCILING.—This is produced by applying color with a brush over a plate of zinc or piece of stout card-board on which the design has been cut out. When the ground color is judiciously chosen, and the patterns for "wall powderings," as they are termed, are of satisfactory design, an excellent effect can be gained, and a clearer surface than wall-paper can yield may be obtained. Great attention should be given to obtaining harmony in colors. The color for the patterns should be "flatted" oil color. The patterns should be of a diaper character, of which examples are here given. In the illus-

Stencil Patterns.

tration the room has a shirting-board, painted black, with a narrow gold line run along the top molding. The dado, 4 ft. high from the floor, is dark olive or sage color, with a border of small gold bead at the top; above, to within 18 in. of the ceiling, the wall is stained with a dull orange yellow, powdered with rosettes of olive. The frieze may consist of some conventional figure or floral pattern in sea green, white and deep red, with a few black lines; and if there is any cornice above, it may be lightly picked out in the primary colors or heightened with gold. Here *A* is the cornice; *B*, frieze; *C*, represents the filling in; *D*, shows the border; *E*, is the dado; *F*, gold molding; *G H*, skirting-board. A purple design on a citrine ground, or russet figures on an apple green, would also be in harmony.



Wall Decoration.

Stencil Corner.

PROF. SLICK DISCOVERS A STRONG SOAP.

SOAP AND CANDLES.

CANDLES.

CANDLES are either dipped, molded or rolled. The cheaper sorts of tallow candles are formed by the first process, and wax candles by the last; all the other kinds are molded.

ADAMANTINE, From Tallow.—Melt together 10 oz. mutton tallow; camphor, ¼ oz.; beeswax, 4 oz.; alum, 2 oz.

BLEACHING WAX.—Stakes or posts are driven into the ground, and 2 ft. from the ground bagclothes are stretched over them, or table-like frames are made from strips of cloth stretched over the frames in the same manner as a sacking-bottom is stretched over a bedstead, care being taken to fasten the ends of the cords to the posts sufficiently firm to prevent loosening. The wax ribbons are spread upon the cloth in a thin layer. It is important that the sun's rays may have full play upon the exposed wax, but at the same time protected from winds. The ribboned wax is daily turned over, in order that fresh portions may be affected by the sun; and should it not be sufficiently moistened by the dew or rain, soft water is poured over it. When not gradually becoming whiter, but continuing yellow upon the fracture, it is remelted, ribboned, and again bleached. The continuence of the bleaching varies, depending upon the weather; often one exposure to the sun and air suffices to bleach it. Four weeks are generally sufficient. The bleached wax is finally fused into cakes or blocks, previously moistening the molds. As fast as the wax congeals, the cakes are thrown into a tub of clean, cold water, and then taken out and spread upon a packthread sieve for draining. Eventually, they are dried and packed in boxes for the market, the loss being from 2 to 8 per cent.

BLEACHING AND CLEARING TALLOW.—Dissolve alum, 5 lbs., in water, 10 gals., by boiling; and when dissolved, add tallow, 20 lbs.; continue boiling for an hour, stirring and skimming; when cool, strain through thick muslin; then set aside to harden; when taken from the water, lay it by for a short time to drip.

BOUGIES.—Melt slowly over a moderate fire, in a well-tinned copper kettle, 70 lbs. pure spermaceti; then add piecemeal and during constant stirring, 30 lbs. best white wax. By increasing the wax to 50 lbs., the resulting product is much more diaphanous; however, the bougies molded of this mixture are not as durable as candles made exclusively of wax. They are tinted in different colors. For red, carmine or Brazil wood, together with alum, are used. Yellow is given with gamboge, blue with indigo, and green with a mixture of yellow and blue. Sometimes the bougies are perfumed with essences, so that in burning they may give an agreeable odor.

COMPOSITE.—Melt together, over a water bath, 100 parts stearic acid, and 10 to 11 parts bleached beeswax; to insure success, the mixture must remain over the bath 20 to 30 minutes, without being stirred. At the end of that time the fire is to be extinguished, and the fluid allowed to cool until a pellicle is formed on the surface, when it is cast direct into the molds, heated to the same temperature, with the precaution of avoiding stirring the mixture, which would cause opaqueness.

DIPPED CANDLES.—These candles are made by stringing a number of wicks upon a rod, and dipping them in melted tallow repeatedly. The clarified and remelted tallow is poured into a tightly joined walnut or cherry trough, 3 ft. long, by 2 ft. wide, and 10 to 12 in wide at the top, gradually diminishing to 3 or 4 in. at the bottom. A handle is fixed on each end for easy removal, and when not in use closed with a cover. The operator commences by stringing 16 to 18 wicks at equal intervals on a thin wooden rod, 2½ ft. long, and sharpened at the ends; then takes 10 or 12 such rods and dips the wicks rapidly into the fluid tallow in a vertical direction. This tallow should be liquid, so that the wicks may be soaked uniformly, after which the rods are rested on the ledges of the trough, when, if any wicks be matted together, they are separated, and the rods so placed on a frame, having several cross-pieces, that the uncongealed tallow from the wicks may drop down; while this is going on, which continues until the tallow is solidified, the operator is preparing another

batch of rods. The fat in the trough, meanwhile, is so far cooled that in immersing the first dip again, a thicker layer will adhere to the wicks. When the tallow solidifies at the sides of the vessel, the temperature is the most convenient for the object in view. It is sometimes necessary to stir the ingredients to produce a uniform admixture, and in such cases much care should be taken, so that no settlings be mingled with the mass, while, by the addition of hot tallow, any desired temperature may be obtained. The tallow on the wicks between each dipping becomes so gradually hardened that, at the third or fourth immersion, new layers solidify; as a natural consequence of dipping, the lower ends of the wicks become thicker than the upper, to remedy which the lower ends are again put into the melted fat for a few minutes, when the heat diminishes their dimensions. The dipping is continued until the candles acquire the requisite thickness. The conical spire at the upper end is formed by immersing deeper at the last dip, and if, eventually, the candles are too thick at the lower end, they are held over a slightly heated folded copper sheet, so that the fat may melt, but not be wasted.

HARDENING TALLOW.—To 1 lb. tallow, take ½ lb. common rosin; melt them together, and mold the usual way. This will give a candle of superior lighting power, and as hard as a wax candle; a vast improvement on the common tallow candle in all respects, except color.

IMITATION WAX. — 1. Throw quicklime into melted mutton suet; the lime will fall to the bottom, and carry along with it all the dirt of the suet, so as to leave it as pure and fine as wax itself. — 2. One lb. alum dissolved in warm water to each 5 lbs. tallow; melt the tallow; add the alum water; let the water pass off in steam; run into molds. This will make the candles hard and look like wax.

LARD.—Dissolve ½ lb. alum and ½ lb. saltpetre in ½ pt. water on a slow fire; then take 3 lbs. lard, cut into small pieces, and put into the pot with this solution, stirring constantly over a moderate fire, until the lard is dissolved; then let it simmer until all steam ceases, and remove at once from the fire. If you leave it too long it will get discolored. These candles are harder and better than tallow.

MOLDED CANDLES. — For molding, besides the common metal molds (a mixture of tin and lead), molds of glass are sometimes used. The former are slightly tapering tubes, varying in length and dimensions according to the size of the candle to be manufactured, and, when required, are arranged in regularly perforated wooden frames or stands, with the smaller end downwards, forming the upper or pointed part of the candle. At this smaller end, the wick, previously saturated in melted fat, is inserted, filling the aperture, and, passing up the centre, is fastened perpendicularly at the upper end of the tube, to which is attached a movable cover. The melted fat is then poured in, generally with a small can, but a tinned iron syphon is better. It is requisite that the tallow should completely fill the mold, remain uncracked on cooling, and be easily removable from the molds. This can only be obtained when the fat at the sides cools more quickly than that in the interior, and when the whole candle is rapidly cooled. A cool season is far better; but a certain condition of the tallow, namely, that which it possesses at a temperature very near its melting point, is absolutely necessary. Candle-makers recognize the proper consistence of the tallow for molding by the appearance of a scum upon the surface, which forms in hot weather between 111° and 119° Fahr., in mild weather at 108°, and in cold about 104°. The tallow is usually melted by itself; sometimes, however, over a solution of alum. The candles are easily removed from the mold the day after casting, to be cut and trimmed at the base. Molding by hand is a tedious operation, and only practiced in the small factories; in extensive establisments, where economy of time and labor is a consideration, machinery is employed.

ROLLED, or WAX CANDLES.—Made either by pouring melted wax over the wicks, or by applying the wax in a soft state with the hands, and afterwards rolling it smooth with a roller of polished boxwood, upon a table formed of polished walnut. They are then cut and trimmed. The first part of this process is conducted over cisterns of melted wax, and the wicks are strung upon an iron hoop suspended from the ceiling.

SPERMACETI.—This is usually mixed with 3 per cent. wax or paraffine, to destroy its crystalline structure; it is molded in the usual way with plaited wicks that require no snuffing.

STEARINE. — Made of the stearine of stearic acid, obtained from tallow, in the same way as other mold candles. They furnish a superior light, and burn a long time.

TALLOW.—First, the fat is chopped; cutting machines are often used similar to the straw-cutting table; sometimes a thin, sharp-edged mince hatchet is employed, about 2½ ft. long, held with both hands, and the fat, spread on a beech block, is chopped into pieces in all directions. A third instrument is a kind of stamp trough, with a muller, having a sharp blade in the form of an *S*. A more desirable instrument is the ordinary rotary sausage cutter. The fat is then placed in caldrons, made of cast iron and heated by open fire. These caldrons are covered with movable tin plate hoods, so adjusted that, by means of pulleys, ropes and counter weights, they can be raised or lowered, while, at the same time, they serve to carry off offensive vapors. Water is sometimes mixed with the fat in the caldrons, and is beneficial when the fat has been long kept during summer, and thereby lost moisture by evaporation. By gradually raising the temperature in the pan, the fat runs from the cells, and the whole is kept boiling 1 to 1½ hours. During the operation of melting and boiling, the ingredients must be stirred, in order to keep the fat and cracklings in agitation; otherwise pieces of unmelted suet, coming in contact with the sides or bottom, would scorch and acquire a brownish tint, of which the whole melting would necessarily partake. Scorched tallow is not readily whitened. For separating the melted fat from the cracklings, it is ladled off from the caldron into a willow basket, or a copper box, perforated

at the bottom with small holes, set over large copper coolers, and allowed to remain undisturbed till all foreign matters have settled. Before it congeals, it should be transferred into wooden pails. This operation is continued as long as the cracklings yield fat; and during the process the heat maintained at a moderate temperature, to avoid scorching. When the cracklings begin to harden, they acquire a darkish tint, and hence are said to be browning. They are then pressed, and the fat thus obtained possesses somewhat of the brown color of the cracklings, but not so much as to render it unfit for use as soap stock; it may be mixed with that which has spontaneously separated while heating.

TALLOW, To Deodorize.—Mix 14½ lbs. freshly melted fat with 5 dr. table salt and 15 gr. powdered alum; heat until a scum forms, which is to be separated; when the fat has cooled, it is washed with water to remove the salt, and then heated gently until the water is evaporated.

TAPERS. — These are of various degrees of thickness, not made of pure wax, but of wax (usually vegetable wax) and tallow, the latter being added to give flexibility. When required to be colored, resin and turpentine are added to the tallow.

WICKS. — The wicks of tallow candles are made of the rovings of Turkey skein cotton, 4 or more of which, according to the intended thickness of the wick, are wound on a reel, from which they are again run off and cut into proper lengths. Latterly, wicks of best candles have been made so that they do not require snuffing. This is effected by causing the wick to bend over, and its end to fall outside the flame, where it is exposed to the oxygen of the air. This bending over is variously brought about, by twisting the wick with one strand shorter than the rest, which, being slightly stretched during molding, contracts again and bends the wick when the fat melts; and by plaiting the cotton into a flat wick, which naturally takes the required curve; such a wick is generally dipped in a solution of borax, which preserves it from being acted upon by the flame except at its extreme point at the edge of the flame. A very fine wire is sometimes included in the plaited wick. The wicks of candles should be free from inequalities, as well as from adhering particles of cotton, the presence of all of which are the cause of guttering. The finer the thread of which wick is composed, the more complete will be the combustion. Unless the above precautions are attended to, in selecting the wick, it will not be entirely consumed.

SOAP.

REMARKS.—All soap is a compound in definite proportions of some oil, fat or resin, with a saponifying base, which must be alkaline if intended for cleansing purposes. Fats are composed of a solid substance, called *stearine*, and a liquid one called *oleine*. When either of these is boiled with a strong solution of caustic potash or soda, a remarkable change takes place, called *saponification*. The product is a viscid, homogeneous and transparent mass, soluble in warm water, and partially so in cold, but insoluble in saline solutions. The basis of scented or toilet soaps is good soap of the ordinary kinds, either soft or hard, which is remelted and perfumed. The soaps are first reduced to shavings; these are put in a copper pan with a water bath; if the soaps are new they will melt on application of heat; but, if they are old, a little water is added; when the fusion is complete, some perfume, and, if required, some coloring matter, are added, and the soap is then poured into molds. Cheap scented soaps contain a very large proportion of yellow soap or of common curd.

INGREDIENTS.

BEEF TALLOW.—This is mostly used; it has a yellow tint, due to coloring matter, separable by several washings in hot water; firm, brittle, but not so white as mutton suet. That rendered by steam is generally the whitest.

BONE FAT.—Bones contain about 5 per cent. of fat, brownish white in color, and of an oily consistency. Only fresh bones are adapted for the extraction of fat. They are generally split up lengthwise by a hatchet, boiled in water, by means of which the fat is extracted, decanted, and filtered. For purifying bone fat, melt the fat and a small quantity of saltpetre together, and afterwards add sufficient sulphuric acid to decompose the latter. The mass scums much, becomes of a light yellow color, loses its noxious smell, and furnishes a fat well adapted for soaps.

COCOANUT OIL. — Six fatty acids have been discovered in the cocoa butter; most of which being solids accounts for the great firmness of the soaps it forms. This fat is also remarkable as uniting with soda lyes in any proportion, without separating from them. Owing to this property, this fat is used in large quantities for the making of filled soaps. It is very slow to unite with lye by itself; it is, therefore, usually applied in combination with tallow or palm oil, increasing their emollient properties, and also giving to the tallow soaps a brilliant whiteness.

FISH OIL.—Fish oil is used as a burning fluid, for making soft soaps, and for adulterating other oils.

GREASE, To Preserve. — Boil all the scraps, rinds, and bones, in a weak lye, and the purer grease in clear water; let the mixture cool, take off the cake of grease, and strain it; it is well to do this occasionally, as you save it; for when kept a long time, impure grease becomes offensive. Dry off all the water before laying away.

HORSE FAT.—The soap made from horse fat, after several successive boilings, is white and firm; but, owing to its peculiar odor, it can only be employed in the preparation of palm and rosin soaps.

LARD.—Lard is an excellent material for soap

manufacturers; it forms a white, sweet, and pure soap. For the purpose of rendering it more frothing, it is saponified either with tallow or cocoanut oil.

LYE. — 1. The potash lye is used for making soft soap, and in domestic practice is generally obtained by filtering water through a mixture of 19 parts hard wood ashes and 1 of freshly slaked lime. — 2. When wood ashes cannot conveniently be had, it is usual for soap manufacturers to use equal quantities of freshly slaked lime, and sal soda, soda ash or caustic soda, using water enough to give the lye sufficient strength to support a fresh egg. It must be strong. The solution can be effected by heat, or stirring, finally drawing off, or baling out the liquid clear of sediment, previously throwing in salt and giving time for sediment to settle. 1 ton of yellow soap will require about 1,000 lbs. tallow and 350 lbs. resin, with lye sufficient. The same quantity of white soap will require nearly 1,300 lbs. tallow, boiling in every case with the proper quantity of lye, until it forms a perfectly homogeneous mass by a perfect blending of the component parts; when it is poured out into suitable frames to harden. It is afterwards cut up into bars by means of wires to which handles are attached, and then piled to dry.

MUTTON TALLOW.—This, saponified with soda lye, yields a beautiful white soap, but being rich in stearine it is liable to become too hard. In order to obtain a more unctuous product, it is mixed with 20 per cent. of lard or cocoanut oil, whereby a superior soap is obtained.

OLIVE OIL. — There are 3 kinds, namely, the virgin oil, obtained by a gentle pressure of the fruit; a second kind, gained by submitting them to the action of hot water and pressing them between metallic plates previously heated; and the third, an inferior kind, is the product of this residuum when boiled in water. Only the two latter serve in the manufacture of soaps; they yield an excellent soap, esteemed for its agreeable odor. It is extensively used by soap manufacturers in Marseilles and for Windsor soap.

PALM OIL.—This is of an orange color, and when not rancid, of a violet odor. Palm oil is employed both in the bleached and in the natural state. Bleached, it produces a soap of beautiful whiteness, and rich with the characteristic odor of the oil.

POPPY OIL. — Is whitish yellow, of an almond taste, and is especially used for the manufacture of soft soaps; in France it is employed with tallow for the manufacture of an imitation Marseilles soap.

SODA. — Soda is of more importance to the manufacturer of soap than potash, because he could not make hard soap without it. The amount of native soda is decreasing and inadequate to supply the demand. A small quantity is produced by the incineration of certain plants, but the largest portion now used is acquired from the transformation of salt. The best quality of native soda is generally imported from Spain and the Levant, and known as barilla. It contains from 15 to 30 per cent. of carbonate with a little sulphuret, and is mixed with sulphate and muriate of soda. It is considered superior to the artificial, as the hard soap made with it is found to be less brittle and more plastic.

SODA ASH.—The method of manufacturing soda ash is based upon the preparation of sulphate of soda from salt, its transformation into crude carbonate of soda, designated black ash, and the purification of the crude soda by lixiviation, evaporation, and calcination. The product obtained is white ash, or soda ash.

SODA, Caustic.—This can be purchased either as a solid or a liquid. In the latter state it is called concentrated lye, and soapmakers find it a convenient commodity, as it saves the trouble of preparing it. A certain weight of caustic soda represents a larger amount of soda combining with the fats than the ordinary soda. Both red and white are of equal value, for when the red caustic soda is dissolved, the coloring matter generally settles at the bottom, and liquid becomes clear.

SPERM OIL.—Found in commerce bleached and unbleached, the latter having a brownish appearance and disagreeable odor. It is easily saponified, and the resulting soap is readily soluble in water.

Laundry Soaps.

CALIFORNIA.—For large bars of yellow soap. 2 lbs. sal soda; 3 oz. borax; 1 oz. liquid ammonia; shave the soap in thin slices; put into 8 qts. rain-water; when the soap is nearly dissolved, add the borax and sal soda; stir till all is melted; pour it into a large tub or shallow pan; when nearly cool add the ammonia slowly, mixing it well; let stand a day or two; then cut into bars, and dry in a warm place. Excellent for all household purposes.

CHEMICAL.—1. Pour 12 qts. soft boiling water on 5 lbs. unslacked lime, then dissolve 5 lbs. washing soda in 12 qts. soft boiling water; mix the two together and let them remain so 12 to 24 hours, for chemicalizing; now pour off the clear liquid, being careful not to disturb the sediment; add to the liquid 3 lbs. clarified grease and 4 oz. rosin; boil together 1 hour; pour out to cool, and cut in bars. — 2. Powdered Fuller's earth, ½ oz.; just moisten with spirits turpentine; add salts tartar, ½ oz.; best potash, ½ oz.; work the whole into a paste with a little soap. Excellent for removing grease spots.

ENGLISH BAR.—6 gals. soft water; 6 lbs. good stone lime; 20 lbs. sal soda; 4 oz. borax; 15 lbs. fat (tallow is best); 10 lbs. pulverized rosin, and 4 oz. beeswax; put the water in a kettle on the fire; when nearly boiling add the lime and soda; when these are dissolved, add the borax; boil gently; stir until dissolved, then add the fat, rosin, and beeswax; boil gently until it shows flaky on the stick, then pour into molds.

ERASIVE.—1. A genuine erasive soap that will remove grease and stains from clothing, is made as follows: 2 lbs. good Castile soap; ½ lb. carbonate of potash, dissolved in ½ pt. hot water; cut the soap in thin slices; boil with potash until it is thick enough to mold in cakes; add alcohol, ½ oz.; camphor, ½ oz.; hartshorn, ½ oz.; color with ½ oz. pulverized charcoal. — 2. Take 6

lbs. good white soap, 1 ox-gall, and the whites of 4 eggs; put them into a mortar with 2 lbs. calcined and powdered alum; grind together thoroughly, and put the mortar in a damp place for 24 hours. By that time the mixture should be a thick paste, which must be worked into cakes. If at the end of 24 hours it is not a thick paste, put it in a dry place until it has hardened; then cut anew and grind again in the mortar.

EXCELLENT HOUSEHOLD.—1. When the boiling lye will strip a feather clean, put in 2 gals. lye, 1½ lbs. clean grease; boil it (trying whether it has enough of grease with a feather), until it becomes thick; then throw in 1 pt. salt and 5 lbs. borax, to 4 gals. soap; boil it awhile longer; and set it off to cool; when hard, cut in bars, scrape off the sediment from the bottom, and put it on a shelf to drain. The lye, etc., at the bottom of the kettle answers for rough scouring, but it is more useful on the garden. — 2. Take 3 lbs. unslacked lime, 6 lbs. washing soda, 4 pailfuls soft water, boiling hot, turned over the soda and lime; let it stand over night. In the morning pour it off; then put in 6 lbs. tallow and boil 1½ hours, stirring occasionally; then put in 1 pailful cold water and boil ½ hour; then put in two handfuls salt, and let it stand until cold; cut into bars and dry. — 3. Take 5 lbs. Castile soap, cut fine; 1 pt. alcohol; 1 pt. soft water; 2 oz. aquafortis; 1½ oz. lampblack; 2 oz. saltpeter; 3 oz. potash; 1 oz. camphor, and 4 oz. cinnamon, in powder; first dissolve the soap, potash, and salpeter by boiling; then add the other articles, and continue to stir until it cools; then pour into a box and let it stand 24 hours and cut into cakes. — 4. Dissolve ½ pt. washing soda; put in 2 lbs. good hard soap; cut in slices, and boil until a mass is formed; then add ½ oz. each alcohol, camphor, ether and liquid ammonia, and mold into cakes. — 5. For 4 lbs. tallow, oil, or lard, take 2 lbs. soda, 1 lb. unslaked lime, ½ oz. beeswax, ½ oz. rosin, ½ teaspoonful borax; put the lime and soda in a vessel with 6 qts. water; stir well, and allow the liquid to settle till clear; then pour off and strain the clear lye, and pour into the lime and soda 1 gal. water; when clear, strain into another vessel; melt the grease, and when it is boiling, pour in the weak lye, a cupful at a time, till the whole is saponified; continue to boil, and add the strong lye till the whole is in; keep boiling and stirring till so thick that the spoon will stand without holding; now add the rosin and borax pulverized; stir them in well and pour the soap into a mold, cut to suit when cold. — 6. To make matchless soap, take 1 gal. soft soap, to which add 1 gill common salt, and boil 1 hour; when cold, separate the lye from the crude; add to the crude 2 lbs. sal soda, and boil in 2 gals. soft water till dissolved. — 7. Take 3½ lbs. good soft soap; 2 lbs. sal soda; 1 oz. borax; ½ ounce hartshorn, and ½ lb. rosin; dissolve in 11 qts. water, and boil 20 minutes.

GALL.—Gall soap, excellent for washing silks and ribbons, may be made by heating 1 lb. cocoanut oil at 60° F., into which ½ lb. caustic soda is gradually stirred; then add ½ lb. Venice turpentine, previously warmed in another vessel. The kettle is allowed to stand 4 hours, subject to a gentle heat, after which the fire is increased until the contents are clear. 1 lb. ox gall, followed by 2 lbs. Castile soap, is then mixed in, and the whole allowed to cool, when it may be cut into cakes.

LARD.—Sal soda and lard, each, 6 lbs.; stone lime, 3 lbs.; soft water, 4 gals. Dissolve the lime and soda in the water by boiling and stirring; settle and pour off; then return to the kettle (brass or copper) and add the lard; boil till it becomes soap; then pour into a dish or molds; and when cold, cut into bars.

TURPENTINE. — Cut up 1½ lbs. brown soap, and melt it in 3½ qts. water; then put it in a stone pot, and add 1½ tablespoonfuls spirits turpentine and 3 of alcohol.

YELLOW.—Common yellow soap consists of soda, with oil or fat, and resin. Resin is a feeble acid, capable of combining with alkali, but neutralizing it less completely than oil, so that the soap formed is too powerfully alkaline. But when resin is worked with an equal proportion of oil, it makes an excellent soap for many purposes. The following is a good receipt: Tallow and sal soda, of each, 112 lbs.; resin, 56 lbs.; stone lime, 28 lbs.; palm oil, 8 oz.; soft water, 28 gals. Pour soda, lime and water into a kettle and boil, stirring well; then let it settle, and pour off the lye. In another kettle melt the tallow, resin and palm oil, having it hot, the lye being also boiling hot; mix all together, stirring well, and the work is done.

Soft Soaps.

BROWN COUNTRY.—10 lbs. potash of a gray or dark chocolate color; pure rendered tallow or grease, 12 lbs.; dark resin, 12 lbs.; place the potash in an iron kettle, add 4 or 5 gals. boiling water, and boil till the potash is dissolved; if it should attempt to boil over, add a little cold water; let it stand a few hours to settle; then drain off the clear lye and add more cold water to the sediment, and drain off as before; repeat, if necessary, to obtain all the strength. Now add the lye, tallow, and resin together, and boil gently till the tallow is saponified, which is known when the soap becomes clear like honey; now add 12 to 15 gals. water, and set aside for use.

COLD. — Take from 20 to 30 lbs. strained grease to 1 bbl.; the lye or potash must be strong enough to bear up an egg, so as to leave a spot as big as a dime piece clear. Heat the grease very hot, turn it into the barrel, and fill up gradually with strong lye. If only 20 lbs. of grease are used, it must not all bear up an egg; but if made strong, it must be reduced when you use it, by adding an equal quantity boiling water, when it will be as thick as before.

EXCELLENT HOUSEHOLD. — 1. Put 1½ pails lye, that will bear up an egg, in the soap barrel, and add 8 lbs. melted grease, free from sediment; thin with weak lye as it is obtained from the leach; stir occasionally. It should thicken and be ready for use in 2 or 3 days, providing the weather is warm, or the barrel stands in a warm place. — 2. ¾ lb. washing soda and 1 lb. brown soap (cut in small pieces); put into a large stone

jar on the back of the range, when not very hot, and pour over it 1 pailful cold water; stir once in a while, and when dissolved put it away to cool. It forms a sort of jelly, and is excellent to remove grease on floors or shelves. — 3. To 20 lbs. clear grease, take 17 lbs. pure white potash in fine lumps, and place it in the bottom of the soap barrel, which must be water tight and well hooped. Boil the grease and pour it hot on the potash; then add 2 pailfuls boiling hot water; dissolve 1 lb. borax in 2 qts. boiling hot water, and stir well. Next morning add 2 pails cold water, and stir ½ hour; continue this, till a barrel containing 36 gals. is filled. In 1 week it will be fit for use. The borax can be turned into the grease while boiling, and also 1 lb. resin. Soap made in this manner always comes, and will last twice as long as that bought. Grease must be free from scraps, ham rinds, bones, etc. The soap will be like jelly. — 4. Dissolve 1 lb. concentrated lye in 8 gals. water; boil it with 4 lbs. clear soap fat, and when the grease is all cut set it away to cool; add 1 gal. hot water to this and stir well; in the course of a few hours put in another gal., and continue adding water until the soap is of the desired consistency. To make hard soap of this, stir in common salt; but an easier way would be to substitute washing soda for a portion of the potash, and use some lime with it. — 5. Take 6 gals. soft water; add 3 lbs. best hard soap (cut fine); 1 lb. sal soda; 4 tablespoonfuls hartshorn; boil till dissolved; pour into vessels, and when cold it is fit for use. This makes 50 lbs. fine jelly soap.

LARD.—Potash, 6 lbs.; lard, 4 lbs.; resin, ¼ lb. Beat up the resin; mix all together, and set aside for 5 days; then put the whole into a 10 gal. cask of water, and stir twice a day, for 10 days, when it is ready for use.

Toilet Soaps.

ALMOND. — Oil of almonds, 7 lbs.; soda, 1½ lbs.; water sufficient. The soda must be rendered caustic before adding it to the oil, and heat then applied. An easy way of preparing the soda is to treat it in solution with powdered quicklime.

ANTIMONIAL.—Prepared by dissolving 1 part golden sulphuret of antimony in 2 parts of a saturated solution of caustic potash, to this add of Castile soap, in powder, 4 parts; triturate till the whole assumes a proper consistency.

BOUQUET. — 1. White curd soap, finest, 17½ lbs.; olive oil soap, 2½ lbs.; oil of bergamot, 1 oz.; oils of cassia, cloves, sassafras and thyme, of each, 1½ dr.; oil of neroli, 1 dr.; brown ochre, levigated, 2 oz. Proceed as for almond soap. It may be varied by substituting oil of lavender for the neroli. — 2. White curd soap, 20 lbs.; oil of bergamot, 2½ oz.; oil of cloves, ½ dr.; oil of neroli, ½ dr.; oil of sassafras, ½ dr.; oil of thyme, ½ dr. Colored with 2½ oz. brown ochre. — 3. Good tallow soap, 30 lbs.; essence of bergamot, 4 oz.; oils of cloves, sassafras and thyme, each, 1 oz.; color, brown ochre, 7 oz. — 4. (*Palmer's.*) White Castile soap, 10 lbs.; oil of lavender (English), 2 dr.; oil of citronella, 2½ dr.; oils of lemon and bergamot, of each, 4 dr.; palm oil, 2 lbs. Melt the soap and palm oil together by a gentle heat, and, when nearly cold, add the perfumes, previously dissolved in sufficient alcohol.

CAMPHOR.—Curd soap, 28 lbs.; otto of rosemary, 1½ lbs.; reduce the camphor to powder; add 1 oz. almond oil; then sift it; when the soap is melted and ready to turn out, add the camphor and rosemary.

CAMPHOR SAVONETTE. — Spermaceti, 2 oz.; camphor, powdered, with the addition of a little spirits, 1 oz.; white curd soap, melted with a little water, 24 oz.; amalgamate with a gentle heat, and mold into balls.

CARBOLIC ACID.—Take freshly prepared cocoanut oil soap, 75 parts, and fuse; then add a solution of alcohol, 5 parts; carbolic acid, 3 parts; caustic potassa, 1 part; oil of lemon, 1 part; mix with stirring; to be poured into molds.

CASTILE. — 1. Made like almond soap, only using olive oil. It is mottled by adding a solution of sulphate of iron while in the liquid state. — 2. Boil common soft soap in lamp oil, 3½ hours.

CINNAMON. — Tallow soap, 14 lbs.; palm oil soap, 7 lbs.; oil of cinnamon (cassia), 3 oz.; oil of sassafras and essence of bergamot, of each, ½ oz.; levigated yellow ochre, ½ lb.

COCOANUT OIL. — Put 50 lbs. cocoanut oil and 50 lbs. caustic soda lye, of 27° Baume, into a soap kettle; boil and mix for 1 or 2 hours until the paste thickens; then diminish the heat, but continue stirring till the cooling paste assumes a white, half solid mass; then transfer quickly to the frames.

COLORING. — For coloring ordinary fancy soaps, mineral colors are employed; for superior toilet and transparent soaps, organic pigments are used. Generally, the red coloring matter is derived from vermillion or chrome red, the violet from fuchsine solved in glycerine, the red-brown and brown from cumarel and the various kinds of umber. For green, chrome green is used; a beautiful vegetable green is obtained by stirring in the soap, saponified with 7 to 10 per cent. of palm oil, some smalts or ultramarine. For blue, smalts or ultramarine. Yellow is obtained by mixing palm butter with the fat to be saponified. For black, common lampblack is used. Fine toilet soaps and transparent soaps may be colored as follows: For red color, tincture of dragon's blood or liquid carmine. Rose, tincture of carthamine or of archil. Yellow and orange, tincture of annatto or saffron. Blue and violet, tincture of litmus, or of alkanet-root, or soluble Prussian blue, basic, or a very little indigo in impalpable powder. Green, a mixture of blue and yellow.

CREAM WASH BALLS. — White curd soap, 7 lbs.; powdered starch, 1 lb.; water, or rose water, q.s. Beat the whole together, and form into balls.

ENGLISH BATH. — Tallow oil, 4 lbs.; palm oil, 4 lbs.; cocoanut oil, 2 lbs.; alcohol, 4 pts.; soda lye, at 36°, 5 lbs.; oil of sassafras, ½ oz.; oil of peppermint, ½ oz.; oil of lemon, ½ oz.; oil of cinnamon, ½ oz.; oil of lavender, ½ oz.; mix, and proceed as in the directions for *Transparent Soap*, omitting the glycerine.

FLOATING.—Fine soda oil soap (in shavings), 9 parts; water, 1 part; put them in a clean copper; place it in a water bath; melt; then agitate the mixture until its volume is doubled, or until it becomes wholly composed of froth; then pour it out to cool, and cut into cakes.

GLYCERINE.—1. Take toilet soap; slice and melt with gentle heat, and add to 1 lb. soap 1 oz. pure glycerine; when sufficiently cool make into balls. — 2. Take 100 parts oleine of commerce (winter strained lard oil will answer), and add 314 parts heavy glycerine; heat to 50°, and then add 56 parts aqueous solution of caustic potassa, sp. gr. 1.34, and stir the mixture well. This soap exhibits the consistency of honey, in which state it remains.

GLYCERINE BALLS.—To any recently made toilet soap, sliced, and melted by a gentle heat, without water, if possible, add glycerine, 1 oz. to the lb.; thoroughly incorporate by stirring until the mass has cooled considerably, when it should be made into balls.

HONEY. — Cut 2 lbs. common bar soap into shavings, and put in a tin pail, with barely hot water enough to cover. Place the pail in a kettle of boiling water, and when its contents are melted, stir thoroughly, and add ½ lb., each, of honey, almond oil and powdered borax; mix together, by stirring, for 10 minutes; then add oil of cinnamon or bergamot, a few drops, or any scent preferred. Mix well, and turn the soap into a deep dish to cool; then cut into squares. It can be made into sand soap balls by adding equal quantities of white sand and Indian meal, until it is so stiff that you can roll it in the hands. There is no soap that will whiten the hands like this. — 2. Some of the finer kinds are made of olive oil soap and palm oil soap, of each, 1 part; white curd soap, 3 parts; deepened in color, while in a liquid state, with a little palm oil or annatto, and scented with 1 to 1½ oz. essential oils to each ½ lb., or 1 to 1½ lbs. to each cwt.

IODINE. — Make a solution of 1 part iodine of potassium in 3 parts water; to this add of pounded Castile soap, 16 parts; melt in a porcelain vessel, by the aid of a water bath.

LAVENDER. — The basis of Windsor soap, scented with oil of lavender, 1 to 1½ fl. oz. per 7 lbs., supported with a little oil of bergamot and the essences of musk and ambergris. It is often colored with a little tincture of litmus, or corresponding mineral pigments.

LEMON WASH BALLS.—Cut 6 lbs. soap into small pieces; melt in 1 pt. water in which 6 lemons have been boiled. When melted, withdraw the soap from the fire, and add 3 lbs. powdered starch, and a little essence of lemon; knead into a paste and form into balls.

MARBLED BALLS. — 1. Take 10 lbs. white oil soap and 10 lbs. Joppa soap; cut into small square pieces, which set to dry for 3 days; the oil soap, particularly, must be thus dried. — 2. Scrape, very fine, 5 lbs. oil soap, which dry for 1 day in the open air; mix it well in the shaving box with 5 lbs. powder, and add 1½ oz. best vermilion; in mixing, place pieces of soap and colored powder in layers in the box; making in all 5 alternate layers of each. When a layer of each has been laid in the box, sprinkle 1 pt. rose water over the cut soap; for, if it be much combined with the powder, it will become lumpy and hard, and consequently spoil the wash balls. The same quantity of water is to be used for moistening each of the other soap layers. Next, mix 1 pt. thin starch, which has been well boiled in ½ pt. rain water, with ½ pt. rose water, and distribute it, equally well mixed, among the mass, by turning it over repeatedly, and then press it down close with the hands. If a piece be now cut from the mass, the operator will perceive whether the marbling is sufficiently good; and, if so, he may proceed immediately to form his wash balls.

MARINE.—This is made by substituting cocoanut oil for fats and oils used in the manufacture of common soap. It has the advantage of forming a lather with salt water.

MERCURIAL.—Beat into a homogeneous mass in a Wedgewood mortar, Castile soap, 1 lb.; protochloride of mercury, ½ oz., dissolved in 4 oz. alcohol.

MUSK. — Take of good tallow soap, 15 lbs.; palm oil soap, 10 lbs.; powder of cloves, pale roses and gilliflower, of each 2½ oz.; essence of bergamot and essence of musk, each, 1½ oz.; brown ochre, or Spanish brown, 4 oz.

MYRTLE.—Dissolve 4½ lbs. white potash in 10 qts. water; then mix with it 20 lbs. myrtle wax, or bayberry tallow; boil over a slow fire till it becomes soap; then add 1 teacupful cold water, and let it boil 10 minutes; at the end of that time turn it into tin molds or pans, and let it remain 8 or 10 days to dry; then turn the cakes out of the molds. If the soap is to be scented, stir in just before pouring. This kind of soap is an excellent one for shaving with, and also for chapped hands. It will be fit for use in 20 to 30 days after made; becomes better with age.

OATMEAL.—Make a saturated solution of borax (the pulverized is best); cut into it bits of fancy, Castile or glycerine soaps; let the mixture boil until the soap is dissolved; make it as thick as cream, by boiling, or by adding more, if too thick; then stir into the mass oatmeal enough to make a soft paste. Stir until it cools and hardens. A little sulphur, also pulverized camphor of sulphur, may be mingled with the meal. While warm and soft place in a box, so that, when hard, it may be turned out and cut into squares. This soap softens the skin.

OPODELDOC.—1. Rectified spirit, 1 qt.; Castile soap, 5 oz.; camphor, 2½ oz.; oil of rosemary, 2½ dr.; oil of origanum, 5 dr.; solution of weak ammonia, 4 oz.; digest till dissolved, and pour while warm into wide mouthed bottles.—2. Rectified spirit, 8 pts.; white soap, 20 oz.; camphor, 8 oz.; water of ammonia, 4 oz.; oil of rosemary, 1 oz.; oil of horsemint, 1 oz.. Dissolve the soap in the spirit by a gentle heat, and add the other ingredients; bottle while warm.

ORANGE-FLOWER. — 1. Like rose soap, but using pure neroli, supported with a dash of the essences of ambergris and Portugal, instead of otto of roses, as scent. The French orange flower soap is scented with equal parts of neroli and geranium. — 2. Tallow and palm oil soap, to which add essence of orange flowers, 7½ oz.;

ambergris, 7½ oz.; color, chrome yellow, 8 oz.; red lead, 2 oz.

PALM OIL.—Palm oil is seldom used alone as a saponaceous fat, but is employed in conjunction with other fats and with resin; this latter being saponified separately and mixed afterwards.—1. 15 lbs. palm oil, 10 lbs. tallow, and 1 lb. resin. —2. 15 lbs. palm oil, 25 lbs. tallow, and 10 lbs. resin. — 3. 45 lbs. palm oil, and 5 lbs. cocoanut oil. — 4. 3 lbs. palm oil, 11 lbs. lard, 1 lb. cocoanut oil, and 1 lb. clarified resin.

PERFUMING.—Perfuming is generally done when the paste is in the frame, as, if added in the pan when the soap is hot, most of the essential oils would be volatilized. It is best to mix the colors and the perfumes together with some alcohol or glycerine, and stir in well.

PRIMROSE.—This has usually a similar basis to honey soap, faintly scented with mixed oils, similar to those used as cowslip perfume, and colored pale yellow, or greenish yellow.

ROSE.—1. Palm oil soap, in shavings, 3 lbs.; finest white curd soap, in shavings, 2 lbs.; soft water, ½ pt.; melt together in a bright copper pan, set in a water bath; add levigated vermilion, ¼ oz.; and when the mixture has cooled a little, stir in finest otto of roses, 2 dr.; oil of bergamot, 1½ dr.; oil of cinnamon, oil of cloves, of each, ¾ dr.; oil of rose geranium, ½ dr.; mix well, and pour the mass into an open bottomed wooden frame, set on a polished marble slab. Sometimes it is colored with tincture of dragon's blood, or of archil, instead of with vermilion. —2. White curd soap, 20 lbs.; essence of rose, 1½ oz.; oil of cloves, ½ dr.; oil of cinnamon, ½ dr.; oil of bergamot, 1 dr.; oil of neroli, ½ dr.; colored with 2 oz. vermilion.

SAND.—Prepared soap, 8 lbs.; marine soap, 7 lbs.; sifted silver sand, 25 lbs.; oils of French lavender, thyme, caraway and cassia, of each, 2 oz. Mix the usual way.

SHAVING.—1. Take 4 lbs. white bar soap, 1 qt. rain water, ½ pt. beef gall, and 1 gill spirits turpentine; put the whole over the fire, and boil until dissolved, stirring meanwhile. — 2. A nice soap for shaving may be made by mixing ¼ lb. Castile soap, 1 cake old Windsor soap, 1 gill each of lavender and Cologne waters, and a little alcohol; boil all together until mixed. — 3. Good white soap (in thin shavings), 3 lbs.; palm soap, 1 lb.; soft water, ¾ lb.; soda, 1 oz. Melt carefully over a slow fire in an earthen vessel, then add oil of lavender, 60 drops; oil of lemon, 40 drops; bergamot, 50 drops. Mix well, and make it into forms.—4. Take 3 lbs. white bar soap, 1 lb. Castile soap, 1 qt. rain water, ½ pt. beef's gall, 1 gill spirits turpentine. Cut the soap into thin slices, and boil 5 minutes after the soap is dissolved, stir while boiling; scent with oil of rose or almonds. To color it, use ½ oz. vermilion.

SULPHUR.—White Castile soap, ½ lb.; flowers of sulphur, 1 oz.; alcohol, 1 oz.; oil of cloves, ½ dr.; oil of lavender, 1 dr. Mix; beat the whole to a smooth mass in a mortar.

TRANSPARENT.—Slice 6 lbs. nice yellow bar soap into shavings; put into a brass, tin or copper kettle, with alcohol, ½ gal., heating gradually over a slow fire, stirring till dissolved; then add 1 oz. sassafras essence, and stir until mixed; now pour into pans about 1½ in. deep, and when cold cut into square bars.

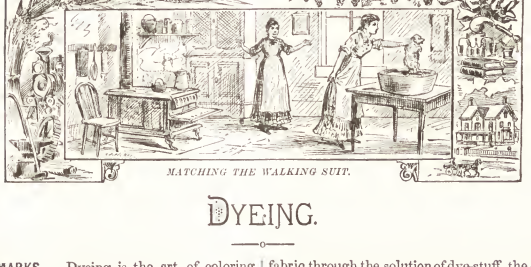
VARIEGATED.—Soft water, 3 qts.; nice white bar soap, 3 lbs.; sal soda, 2 oz.; Chinese vermilion and Chinese blue, of each, about 7 gr.; oil sassafras, ½ oz. Shave the soap in thin slices and add it to the water as it begins to boil; when dissolved, set it off the fire; take out 1 cup soap and stir in the vermilion; take out another cup soap and stir in the blue; then pour in the contents of the first cup, giving 2 or 3 turns only with a stirring stick; then add the other cupful in the same way; then pour into molds, or into a proper box, and, when cold, cut into bars; it will present a beautiful streaked appearance.

VIOLET.—1. Any white toilet soap, strongly scented with essence of orris root, either colored, or not, with tincture of litmus, or a little levigated smalts, ultramarine or indigo. — 2. White curd soap, 3 lbs.; olive oil soap, 1 lb.; palm oil soap, 3 lbs.; melted together, and further scented with a little essence of orris root, which is best added cold; and colored, or not, at will. Very fragrant, but does not take color very well.

WHALE OIL. — Render common lye caustic, by boiling it at full strength with quicklime; then take the caustic lye and boil it with as much whale oil foot as it will saponify; pour into molds, and when cold it will become tolerably hard. Whale oil foot is the sediment produced in refining whale oil. This soap is especially valuable for the destruction of small vermin, insects, etc. A solution of it in water may be applied to plants afflicted with lice, etc.

WHITE.—1. 10 lbs. soap grease (refined tallow is best), boiled in lye made of 5 lbs. soda; ½ as much fresh lime, boiled ½ hour in 7 gals. water. When the lye is cold, it is drained from the soda and lime and boiled with the grease 1 hour, until clear, then poured into a tub to cool. The soap floats on the top, and may be cut into bars. — 2. To 15 lbs. lard or tallow, made hot, add slowly 6 gals. hot lye, or solution of potash that will bear up an egg high enough to leave a piece as large as a dime bare. Take out a little and cool it. If no grease rises, it is done. If any grease appears, add lye, and boil till no grease rises. Add 3 qts. fine salt, and boil again. If this does not harden on cooling, add more salt. If it is to be perfumed, melt it next day; add the perfume, and run it in molds, or cut into cakes. — 3. Fresh slaked lime, sal soda, and tallow, of each 2 lbs.; dissolve the soda in 1 gal. boiling soft water; now mix in the lime; stir occasionally for a few hours; let it settle; pour off the clear liquor, and boil the tallow therein until dissolved; cool in a flat box; then cut into bars or cakes. Stir in the perfume when cool.

WINDSOR.—*Brown.* Prepared soap, 40 lbs.; burnt umber, 4 oz.; English vermilion, 1 oz.; lampblack, ½ oz.; oils of cinnamon and bergamot, each, 2 oz.; oils of thyme, peppermint, caraway and cloves, each, 1½ oz.; lavender, 2 oz. Mix according to the usual way. — *White.* Curd soap, 50 lbs.; marine soap, 10 lbs.; oil soap, 14 lbs.; oils of cassia and cloves, each, 2 oz.; oil of caraway, 4 oz.; oil of thyme, 3½ oz.; rosemary, 4 oz. Mix in the usual way.



MATCHING THE WALKING SUIT.

DYEING.

REMARKS. — Dyeing is the art of coloring articles, generally textile fabrics, with solutions of coloring matters or dye-stuffs. Those which impart their tints without the intervention of other substances, are called "substantive colors;" while those which require such aid are called "adjective colors." The different materials take dyes in different proportions; thus silk and wool take the coal-tar dyes perfectly, but cotton requires the intervention of a mineral or animal mordant. Wool takes the coloring matters of most dye-stuffs so that the deepest tints can be produced. Silk and cotton are dyed with greater difficulty, while linen shows still less disposition to take dyes. The operations which take place in dyeing are "mordanting," "ageing," "dunging," "dyeing," and "clearing." Some of these processes, however, are not needed with aniline dyes, on wool and silk goods, as this class of dye-stuffs acts more directly on the fibre than do those of vegetable extraction. But, before them, all grease and oil must be removed from the goods. Woolen and silk garments, before dyeing, should be washed in soap and water, and rinsed in clean rain water. Grease spots must be removed. (For other hints see RENOVATING in HOUSEHOLD.) Usually then the first thing to be done is to mordant, or subject the fabric to the action of a substance which, having a twofold attraction for organic fibres and coloring matter, serves as a bond of union, and gives fixity to dyes. After the fabric has been mordanted, it is hung up in a room through which steam and air pass, by which the union between the fibre and the mordant is quickened. This exposure to moist air is the step to which the term ageing is applied. The cloth is then dunged, to remove superfluous mordant not absorbed. This was formerly effected by passing the fibre through a mixture of cow-dung and water; but this has been superseded in a measure by dung substitutes, the principal of which are arsenic, arseniate and silicate of soda, phosphate of lime and caustic soda. Dunging is one of the most important processes in dyeing, care being taken to keep the dunging-liquor at a proper strength and temperature. The next process, dyeing, is effected by running the fabric through the solution of dye-stuff, the color being modified by the mordant used. When the fabric has received the color, it is washed in a solution of soap to which a little alkali has been added; then boiled in water with or without the addition of a solution of tin or other brightening substance. It is then said to be "fast." The water in which fabrics are worked and the dye-stuff dissolved, is called a "bath." The amount of water used should simply be enough to cover the goods, and should be clean and soft. All the dye will go to the goods if they are left in long enough. Ordinary water may be improved by the following process: To 4 pails water add 1 qt. wheat bran. Tie the bran loosely in a thin, coarse bag. Before the water heats, squeeze the bran until the water is white, and when it boils take off the scum. Do not use too much water, or the dye will be wasted. Keep the goods in a large enough kettle and with water sufficient to cover them. Earthen or enameled vessels are much the best for most of the dyes, as copper, iron and brass affect some colors. Whatever is used must be perfectly clean. It is always best to rip apart old garments, and iron out flat all the folds at the old seams; but heavy garments can be dyed whole, if preferred. It is well to wet the goods with hot water before entering the bath. After stirring the bath well and being sure the color has been dissolved, enter the goods, with a clean stick in each hand, slowly and as open as possible; lift and stir frequently. To know when the right shade has been reached, try first some small pieces of similar fabric, and test according to directions before proceeding. The shade can be told approximately by floating a corner of the goods on the top of cold water. It will appear under water of the same shade as it will when dry. It is important to remember that a color to be dyed over must be lighter than the color wanted. It is impossible to dye a dark garment light. And the original color may be expected to affect the new so much that such dyes must be selected as will combine with the shade to produce the color wanted. Thus, violet over rusty black will produce "seal brown." Woolens, to avoid shrinking, after dyeing, should be rinsed out in water

of the same temperature as the bath, and dried in the shade, occasionally stretching in all directions. After dyeing, silk should be dried by pressing between two cloths. After hanging in the shade, and while still damp, press by placing a fine cloth over them, and iron dry with a moderately warm flat iron. Silk ribbons can be dried by firmly winding around a bottle of hot water and leaving in a warm place. Silks and fine goods should be tenderly handled, to avoid injury. If silks are limpsy, and need stiffening, rinse in water, containing a little dissolved white glue, ½ oz. to 1 gal. After dyeing velvets, press between 2 cloths, to remove all water; make ready a hot flat iron, fixed firmly, face upward; press the back of the velvet on the iron, and, as the steam comes through, raise the pile with a soft brush, and lay it in the right direction. An easier way is to similarly use a hot stove pipe, after cleaning it thoroughly. Rumpled, creased and fretted velvets can thus be made even. Feathers should be cleaned by soaking in soap suds 15 minutes; then, after drawing between the thumb and forefinger a few times, rinse in warm water. After dyeing, rinse in cold water, and press between 2 cloths to remove water. Hold before a fire, shaking lightly, until nearly dry, and curl by drawing 3 or 4 sprigs at a time between the thumb and back of the scissors. Be cautious with other colors than black, not to get too much dye into the bath. The best colors are produced by adding the color slowly. If too deep, a portion may be discharged by washing in hot suds. When goods are of mixed materials, dye by the receipt for each fabric, to be sure of a fast color. But only ½ the amount of dye need be used for each material in the goods. Dye the wool or silk first; then dye for cotton; the water should never rise above lukewarm in the bath for cotton; and let the goods stay in the cold dye over night with all colors except black. In accommodation to the requirements of dyers, many of the following receipts are calculated for large quantities of goods, but to make them adapted for the use of private families they are given in even quantities, so that it is easy to ascertain the quantity of materials required for dyeing, when once the weight of the goods is known; the quantity of materials used being reduced in proportion to the smaller quantity of goods. Calico printing is allied to the art of dyeing, but as it is done in great factories, and never at home or on a small scale, it will not be included in this work. The process is as follows: The pieces, before printing, are perfectly bleached. After the "colors" have been printed on, the next step is ageing; the goods are laid in bundles upon sparred floors. The temperature is 80° Fahr. Ageing may last 2 to 3 days; its object is decomposition of the acetates of alumina and iron in the mordants, so that either the bases or hydrated subsalts are left attached to the fibre. The next step is dunging, which is the removal of the thickeners. The process was formerly performed with cow dung, but now superseded by double phosphate of soda and lime, arsenite and arseniate of soda, and silicate of soda. The pieces are passed through warm solutions of these substances. This is often performed twice, the first being called fly-dunging, and the next second dunging. When silicate of soda is used, the goods pass through 2 cisterns, heated to 122° Fahr., or higher, containing 738 gals. water and 19 gals. silicate of soda at 14° Tw., if the goods have been mordanted for brown and red, black and red, brown only, red only, and rose on a white ground. But if mordanted for black only, purple only, or purple and black, the proportion of silicate of soda is reduced to 13½ gal. at the same strength. The next step is dyeing with artificial alizarine, or anthrapurpurine. The color is now permanently attached to the mordanted portions; but the whites are stained or soiled, and the pieces are therefore submitted to the clearing process, consisting of successive treatments with soap lye. A common treatment is 2 soapings at a boil, each time for ½ hour, with ¼ to ½ lb. soap. The pieces are washed in clean water after soaping. The quality of the soap is of importance; it should be neutral, and is made from palm oil. Freedom from akalinity is important for madder purples. Grass-bleaching is used in the clearing process for chintzes, cretonnes, etc., to render the shades more transparent. By a discharge, is understood a mixture which, if printed upon cloth previously dyed some uniform color, such as Turkey red, vat blue, aniline black, etc., destroys such ground color, leaving a design which may be white, black, yellow green, etc. The term "discharge style," is more especially applied to patterns of this nature obtained upon a Turkey-red. The new coal-tar dyes will be treated of separately, under the head of ANILINE DYES, while the older processes will be found under VEGETABLE DYES.

ANILINE DYES.

REMARKS.—No mordant is usually necessary for these colors when used on silk or woolen; the proper quantity of clear liquid is mixed with slightly warm water, the scum skimmed off, and the goods entered and worked until the shade is obtained. For dyeing on cotton, the cloth is steeped in sumac or tannic acid dyed in the color, and fixed by tin; or the cloth may be sumaced and mordanted as usual with tin, and then dyed. *Directions for Solutions:* Fuchsine, violet, soluble blue, alkali blue, dissolve in considerable water; 1 lb. to 200 or 300 lbs. water. Methyl and malachite green are first made into a paste by mixing with cold water; then gradually add hot water, 1 lb. to 100 lbs. Eosine, erythrosine, phloxin, rose bengale, 1 lb. to 25 lbs. water. Orange, claret red, fast scarlets for wool, 1 lb. to 15 lbs. boiling water.

BLACK.—SILK OR COTTON. 1. Water 20 to 30 parts; chlorate of potassa, sal ammoniac, chloride of copper, aniline, and hydrochloric acid, of each, 1 part, previously mixed together. The

fabric is dried in ageing rooms at a low temperature for 24 hours, and washed afterwards. — — 2. (*Vanadium.*) Water, 35 fl. oz.; muriate of aniline, 2⅜ oz.; chlorate of potash, 1¼ to 1⅜ oz.; chloride of vanadium, 1½ gr. Steep the fabric, freed from fatty matter, uniformly in the mixture, and hang in well-aired oxidizing chambers, kept at 59° to 68° Fahr.; then raise to 95° until the goods are dry. If the black has the desired tone, they are taken through a beck of bichromate of potash, 150 gr. to 35 fl. oz. water; dried again, and washed with soap and water. If the black is not intense enough, the goods, after drying and washing, but before the chroming, may be steeped once or twice more in the beck, ageing after each immersion. The chrome counteracts the greenish tint of aniline black. For cotton, the quantity of the salt of aniline may be diminished, and for wool may be doubled.

BLUE.—Wool. 1. Prepare bath with ½ lb. soda ash, and add solution of 3½ oz. alkaline blue; boil, refreshen, enter wool, and dye 1 hour without allowing to boil; lift, and rinse carefully; put in fresh bath containing 1¼ lbs. sulphuric acid; rinse and dry. — 2. For 100 lbs. Dissolve 1¼ lbs. aniline blue in 3 qts. hot alcohol; filter, and add it to a bath of 130° Fahr.; also, 10 lbs. Glauber salts, and 5 lbs. acetic acid. Enter goods and handle well for 20 minutes; next, heat slowly to 200° Fahr.; add 5 lbs. sulphuric acid, diluted with water; boil 20 minutes longer; then rinse and dry. If the aniline be added in 2 or 3 proportions during the process, it will facilitate evenness of color. — 3. (*Navy.*) 1st bath, for 100 lbs.: 3 lbs. Guernsey blue; 5 lbs. borax. Enter wool at 120° Fahr.; raise to boiling, while turning, for about 40 minutes; take out; let cool, and wash. 2d bath, containing oil vitriol: Enter wool to raise the color. As the first bath cannot be exhausted, retain the liquor; and for further operations 2 lbs. Guernsey blue, instead of 3 lbs., are sufficient for navy blue. — 4. For 100 lbs. 1st operation: Bath containing 2 to 5 lbs. sal soda, or 1½ to 2 lbs. borax; 1 lb. Nicholson blue, less or more, according to shade. Enter goods at 100° Fahr.; time, 45 to 60 minutes; take out, let cool, and wash well. 2d operation: Raise color in a bath acidulated with oil vitriol; temperature, 100° to 150° Fahr. — Silk. For 11 lbs., add to a water bath 17½ oz. sulphuric acid and 3½ oz. solution white soap; stir well, and dye at 158° Fahr. with 1¾ oz. aniline blue, added in 4 portions; wash, brighten with vitriol sours, and rinse. — Cotton. 1. For pure blue, prepare the goods for fuelsine, and dye like violets. For a greenish and dark blue, dye in a bath of prussiate of potash and sulphuric acid, as mentioned in the receipt for dyeing cotton with blue violet. For very dark shades, place the goods subsequently into a new tepid bath, containing 4 oz. perchloride of tin for every 20 lbs. goods. — 2. 5 lbs. alum; 2½ lbs. Glauber salt; dissolved color. Enter yarn at 100° Fahr.; give 4 turns; raise temperature to 180°, and turn to shade.

BROWN. — 1. Dissolve 1 lb. brown in 2 gals. spirit specific gravity .82; add sufficient to the bath, and immerse fabric. No mordant is required. — (*Bismarck.*) Mix 1 lb. Bismarck dye, 5 lbs. water, and 12 oz. sulphuric acid. This dissolves in hot water, and may be used directly for dyeing. For wool, acidulate bath with sulphuric acid, add sulphate of soda, immerse the fabric, and add color by small portions, keeping temperature below 212° Fahr. Various shades may be produced by combining the color with indigo paste or picric acid. Cotton must first be mordanted with sumac and acetate of alumina, and the bath be below 100° Fahr.

CRIMSON. — 1. Obtained by use of aniline yellow and magenta; dip first in aniline yellow; then pass through a bath of magenta till desired shade is obtained. — 2. Dissolve crimson aniline, and dye same as with aniline red.

FEATHERS.—May be dyed by immersion for 2 or 3 minutes in a bath of any aniline color.

GREEN.—Wool. 1. 2 lbs. alum; ¼ lb. tartar; 5 lbs. Glauber salt; 3 oz. picric acid; 12 lbs. indigo extract; dissolve. Enter yarn at 190° Fahr.; give 3 turns; boil up; after ½ hour, raise and add ½ oz. acid green aniline; re-enter and give 5 turns. — 2. For 100 lbs. 8 oz. or more (according to shade) of malachite green are dissolved as directed under solution in *Remarks.* The dissolved dye is added to a bath containing 8 oz. bicarbonate soda, or sal soda. Enter goods at 100° Fahr.; put on steam; turn to boiling; give 7 turns after 1 hour's boiling; take out, let cool, wash in cold water, and raise with 2 turns in a bath containing 2 to 3 lbs. oil of vitriol. — Silk. Dissolve 1 lb. iodine or night green in 1 gal. alcohol; then mix with 2 gal. water, containing 1 oz. sulphuric acid. — Cotton. 1. Methyl green, 11 lbs. Dissolve in boiling water 7 1-10 oz. tanning lay the cotton over night in the hot solution; wring out; dye in cold water with solution of color according to shade; wring out, and dry in the dark without washing. — 2. For 22 lbs. For lighter shades, bleach and work in warm soap beck, to remove chlorine. Enter into a boiling lye of curd soap, and wash out in cold water. Make a cold dye beck with 3 parts color to 100 parts cotton; give 5 to 6 turns, and let steep over night; dry the next morning; if the shade is not enough, take through tanning beck, and dye again.

HORN. — This may be dyed any color, in a hot or spirituous solution of the aniline dyes.

ORANGE.—Wool. Wash the wool well; bring bath to near boiling point; add dissolved dye gradually, and it will readily go on the fibre. — Silk. Add to the water bath (100° Fahr.), a solution of Castile soap; take the silk through it, raise temperature to 130°; then add dissolved orange to bath, heating gradually; when silk has taken color, add to bath a little sulphuric acid, which sets it; then handle quick, heating the bath to 170°. Wash well after dyeing. —Cotton. For 60 lbs. Boil 3 lbs. tannic acid, and add to warm water; work the yarns 5 turns and wring; add 3 qts. nitro-muriate of tin to enough cold water, and mordant in the mixture; wash well in cold water, with a little soap in the last water; dissolve 12 oz. aniline orange, and add the solution to warm water; give 5 turns, wash and stove dry.

PANSY.—Old Mixed Silks. Boil out 25 dr. sumac in water; strain, and steep goods overnight in the clear, hot liquid; take out next

morning, squeeze, and dye in solution of methyl violet.

PINK.—Cotton Yarn. Dissolve 5 lbs. Glauber salt; 5 oz. erythrosine. Enter yarn at 120° Fahr.; raise to 140°, and turn to shade. It is advisable to use the required aniline in 2 portions—½ to begin, and balance when finishing.

PURPLE.—Acidulate bath by sulphuric acid, or use sulphate of soda; both these render the shade bluish; dye at 212° Fahr. To give a fair middle shade to 10 lbs. wool, a quantity of solution equal to ½ to ¾ oz. solid dye will be required. The color of the dyed fabric is improved by washing in soap and water, and then passing through a bath soured by sulphuric acid.—Silk or Cotton. Prepare the goods for fuchsine as directed for wool under *Red*, and turn them over a few times in a tepid solution of 2½ oz. crystallized perchloride of tin for every 10 lbs. goods; remove the latter; add violet solution as the shade requires; dye for ½ hour; wring well, and dry. Washing in a solution of alum and starch will render the color more solid.

RED.—Wool. (*Fuchsine* or *Magenta.*) Place fuchsine crystals in a stone jar; pour upon each part 100 parts boiling water, and stir until dissolved; set aside to cool and filter. For 100 lbs. woolen goods (flannels, yarns, etc.), 5 oz. fuchsine will give a fair middle shade. For use, a quantity of water, which more than covers the goods, is heated to 170° Fahr., and as much of dissolved dye added as will produce the shade. Place the goods in the bath; stir well, and remove in ½ hour; then free from water by an ordinary clothes wringer. The same bath may be used a whole day by adding more fuchsine solution; but do not keep it over night. — Silk. Prepare the silk by washing it in a solution of Castile soap; dye in a lukewarm bath, adding the dissolved fuchsine gradually; silk will take the color readily. To intensify the brilliancy, wash the silk in a bath slightly soured by sulphuric acid, or, better, tartaric acid, after dyeing. If goods or ribbons require stiffening, put them through a bath containing a little gelatine or gum Arabic. — Cotton. 1. For 10 lbs. Make a decoction of 1 lb. sumac in sufficient water, in which the goods are left 2 hours, turned a few times, then wrung out, and dyed in a tepid fuchsine bath, like woolen goods; time for dyeing, ½ hour. — 2. A bright red may be produced on cotton goods by the following process: For every 5 lbs. goods, dissolve ½ oz. soap in hot water; let solution down to 90° Fahr., then add 2½ oz. olive oil. Stir this mixture, and put into tepid water, in which the goods should remain 5 minutes, turned 5 or 6 times, then removed and wrung out. Next, for every 5 lbs. goods, a bath of ¼ lb. sumac should be prepared, in which the goods are turned 5 or 6 times, then removed, and 1 oz. tin crystals added. The goods are returned, turned a few times, wrung out, and finished in a tepid water bath, in which fuchsine is dissolved to give the desired shade.

SCARLET.—For 40 lbs. Dissolve 5 lbs. white vitriol at 180° Fahr.; place goods in this bath for 10 minutes; then add color, prepared by boiling for few a minutes 1 lb. aniline scarlet in 3 gals. water, stirring continually; filter the solution before added to bath; the goods remain in the latter 15 minutes, then boiled another ½ hour in the same bath after the addition of sal ammoniac. The more added, the deeper the shade.

VIOLET.—Same as for *Purple.*

YELLOW.—This is slightly soluble in water, and may be used directly for preparation of bath dye; but it is best to dissolve 1 lb. of dye in 2 gals, alcohol. Temperature of bath under 200° Fahr. The color is improved by a trace of sulphuric acid. — 2. Dissolve, by boiling in water. For dyeing silk, add to bath acetic or sulphuric acid in small quantity, and dye at 170° Fahr. For wool dye same way, but add oxalic or sulphuric acid. If aniline yellow is shaded off with fuchsine, every shade from orange to scarlet may be obtained.

Vegetable Dyes.

ARTIFICIAL FLOWERS. — In dyeing artificial flowers the color is usually applied with the fingers, muslin, or paper; but the flowers may be simply dipped in the solution. *Blue.* Sulphate of indigo in solution. — *Green.* Solution of distilled verdigris.—*Lilac.* Liquid archil.—*Red.* —Carmine dissolved in carbonate of potash, or in spirits of hartshorn. — *Violet.* Liquid archil mixed with a little salt of tartar. — *Yellow.* Tincture of turmeric.

BLACK.—Wool. 1. For 50 lbs. 20 lbs. logwood; 7 lbs. yellow wood; 6 lbs. sumac; 2½ lbs. tartar. Boil in this bath for 2 hours; re-place the evaporated water, and wet the wool, continually shaking it, with a solution of 2½ lbs. sulphate of iron and 1½ lbs. sulphate of copper; boil 1 hour. For bluish black, wet the wool as above, soon as lukewarm, with 2 lbs. sal ammoniac, and then rinse and dry well. For deep black, substitute for ammoniac 1½ lbs. bichromate of potash; dissolve it in boiling water, and boil for ½ hour. — 2. For 5 lbs. Take 6 oz. blue vitriol and boil a few minutes; dip the goods ¾ hour, airing often; take out the goods and make a dye with 3 lbs. logwood; boil ½ hour; dip ¾ hour; air the goods, and dip ¾ hour more; wash in strong suds. This will neither crock nor fade. — 3. For 10 lbs. Bichromate of potash, 4 oz.; ground argal, 3 oz.; boil together, and put in the wool; stir well, and let it remain in dye 4 hours. Then take out and rinse slightly in clear water; then make a new dye, into which put logwood, 3½ lbs. Boil 1 hour, and add chamber-lye, 1 pt., and let the wool lie in all night. Wash in clear water. — Silk. 1. A bath of nut-galls is given for 12 to 36 hours, occasionally working the goods therein; next take out, rinse and air; then pass for a few minutes through a bath containing sulphate of iron; drain, rinse, and air. The steep in the nut-gall bath may be

repeated, if necessary, followed as before, by the iron bath, previously replenished with a little fresh copperas. The quantity of galls for 1 lb. silk varies from ½ to ¾ lb.; that of the copperas (for the first bath), from 3 to 4 oz.—2. For 5 lbs. Turn the goods for an hour through a mordant formed of 1 lb. copperas and 2 oz. nitrate of iron, with sufficient water; after rinsing in cold water and airing, work them for 1 hour in a decoction of 5 lbs. logwood and 1 lb. fustic; then lift from the bath, add 2 oz. copperas, reimmerse, and work 10 to 15 minutes longer; lastly, rinse, air and finish. A full deep black. —Cotton. 1. For 40 lbs. Sumac, 30 lbs.; boil ¾ hour; let goods steep over night; immerse them in lime water 40 minutes; remove and allow them to drip ¾ hour; now add coppers, 4 lbs., to the sumac liquor, and dip one hour more; next work them through lime water for 20 minutes; make a new dye of logwood, 20 lbs; boil 2½ hours; enter goods 3 hours; then add bichromate of potash, 1 lb., to the new dye, and dip one hour more; work in clean cold water and dry out of the sun. — 2. To each lb. of cloth, 1 oz. extract logwood and ½ oz. blue vitriol; put the cloth in an iron kettle, with enough soft water to prevent the cloth being crowded; bring water to a scalding heat; take it out and let drain; add blue vitriol, and when dissolved put in the cloth again, and let it remain ½ hour at scalding heat; then take out and rinse in soft water. Empty the vitriol water into another vessel and dissolve the extract of logwood in sufficient water; scald, skim and put in the cloth, still keeping the dye hot; let it remain ½ hour; air frequently; then take it out and drain it; add the vitriol water to the dye, put it in again, occasionally airing it; cleanse in soft water and dry. — 3. For 110 lbs. 8¾ lbs. solid extract logwood; 5 lbs., 10 oz., catechu; boil together; boil the yarn in the decoction for 1 hour; steep in the cold liquid 24 hours; raise to a boil again; lift and air over night. Dissolve in sufficient fresh water, 2¼ oz. chromate of potash and 2¼ oz. blue vitriol, and work the cotton in this for ½ hour. Lift, drain, and dissolve 2¾ lbs. soda ash in the cold logwood liquor; heat to 139° Fahr. Re-enter the cotton; work 15 minutes, and rinse. This color bears washing and milling, and does not smear whites.

BLUE.—Commonly produced from indigo either in the form of sulphate or in aqueous solution. The most permanent blue is given by indigo, and particularly by what is called the "indigo vat." A variety of shades of beauty and permanence may be given by the Prussian blue process. With a persalt of iron or tin as a mordant, Prussian blue gives a splendid dark blue. Cheaper blues are commonly dyed with logwood and woad, sometimes aided by sulphate of indigo. There are two methods of preparing solutions of indigo for dyeing: by deoxidizing it, and then dissolving it in alkaline menstruum; and by dissolving it in sulphuric acid. The former method is used in preparing the ordinary indigo vat of the dyers. Wool, silk, linen and cotton, may be dyed blue in the indigo vat. The goods, after being passed through a weak alkaline solution, are subjected to the action of the vat for 15 minutes; then exposed to the air; the immersion in the vat and the exposure are repeated until the color becomes deep. Woad and madder improve the richness of the dye. Other deoxidizing substances besides those below mentioned, may be used to effect the solution of the indigo; thus, a mixture of caustic soda, grape sugar, indigo and water, is often employed in Europe for this purpose; and orpiment, lime and pearlash, are also used. When properly prepared, the indigo vat may be kept in action for months by the addition of one or another of its constituents as required. An excess of copperas or lime should be avoided. The cold vat is the one generally used for cotton, and is prepared as follows: Indigo, in powder, 1 lb.; green copperas, 2½ to 3 lbs.; newly slaked lime, 3½ to 4 lbs.; triturate the indigo with a little water or alkaline lye; then mix with some hot water; add the lime, and again mix; then stir in the solution of copperas, and agitate the whole at intervals for 24 hours. A little caustic potash or soda is frequently added, and a corresponding portion of lime omitted. For use, a portion of this vat is ladled into the dyeing vat, as wanted. After being employed for some time, the vat must be refreshed with a little copperas and fresh slaked lime, the sediment stirred up and the whole mixed together. The potash vat is best adapted to woolens; it is prepared with indigo, in powder, 12 lbs.; madder, 8 lbs.; bran, 9 lbs.; potash, 24 lbs.; water at 125° Fahr., 120 cu. ft.; mix well. At the end of 36 hours add 14 lbs. more potash; after 10 or 12 hours longer, add 10 lbs. potash, and rouse the whole up well; as soon as the fermentation and reduction of the indigo are developed, which takes place in about 72 hours, add a little fresh slaked lime. This vat dyes quickly, and the goods lose less color in alkaline and soapy solutions than when dyed in the common vat. The woad vat is prepared like the potash vat, except that woad is used instead of madder. The vat is set at 160° Fahr., and kept so until deoxidation and solution of the indigo has commenced. The woad and potash vat are sometimes called the warm vat. — Wool. 1. For 100 lbs. 4 lbs. Guatemala or 3 lbs. Bengal indigo, in the soda or woad vat; then boil in a kettle a few minutes, 5 lbs. cudbear or 8 lbs. orchil paste; add 1 lb. soda, or better 1 pail of urine; then cool the dye to about 170° Fahr., and enter the wool. Handle well for 20 minutes; take out, cool, rinse and dry. It is all the same if the cudbear is put in before or after the indigo. 3 oz. aniline purple, dissolved in alcohol, ½ pt., can be used instead of the cudbear. It produces a very pretty shade, but should never be used on mixed goods which have to be bleached.— 2. (*Purple Blue.*) For 100 lbs. Dip in the blue vat to a light shade; then boil in a solution of 15 lbs. alum, and 3 lbs. half refined tartar, for 1½ hours; then the wool taken out, cooled, and let stand 24 hours. Then boil in fresh water 8 lbs. powdered cochineal for a few minutes; cool the kettle to 170° Fahr.; handle the prepared wool in this for 1 hour, when it is ready to cool, rinse and dry. By coloring first with cochineal, and finishing in the blue vat, the fast purple or dahlia will be

produced. Tin acids must not be used in this color. — 3. For 2 lbs. Alum, 5 oz.; cream tartar, 3 oz. Boil goods in this 1 hour; then put into warm water which has more or less extract of indigo in it, according to depth of color desired, and boil again until it suits, adding more blue if needed. — 4. (*Saxony.*) For 100 lbs. Thibet or comb yarn. Alum, 20 lbs.; cream tartar, 3 lbs.; mordant, 2 lbs.; extract indigo, 3 lbs., or carmine, 1 lb., makes a better color. When all is dissolved, cool the kettle to 180° Fahr. Enter goods, and handle quickly; let it boil 1 hour, or until even. Long boiling dims the color. Zephyr worsted yarn ought to be prepared, first, by boiling it in a solution of alum and sulphuric acid, then the indigo added afterwards. — 5. (*Sky.*) Water, 1 gal.; sulphuric acid, a wineglassful; Glauber salts, in crystals, 2 tablespoonfuls; liquid extract of indigo, 1 teaspoonful. Boil the goods 15 minutes; rinse in cold water. —6. For 40 lbs. Bichromate of potash, 8 oz.; alum, 1 lb.; dissolve all and bring the water to a boil; put in the goods; boil 1 hour; then empty the dye, and make a new dye with logwood, 8 lbs; or extract of logwood, 1 lb., 4 oz.; boil in this 1 hour longer; grade the color by using more or less logwood, as you wish it dark or light in the color. This may also be used for silk. — 7. For 100 lbs. Color the cloth first by 1 or 2 dips in the vat of indigo blue, and rinse it well; then boil it in a solution of 20 lbs. alum, 2 lbs. half refined tartar and 5 lbs. mordant, for 2 hours; then take it out and cool. In fresh water boil 10 lbs. good logwood ½ hour in a bag or otherwise; cool off to 170° F., before entering; handle well over a reel; let it boil ½ hour; then take it out, cool, and rinse. This is a firm blue. — 8. For 3 lbs. Dissolve 1 oz. copperas in 4 gals. rain water; wet the goods in warm suds; then put into copperas water and let it remain 10 minutes; dissolve in another vessel 2 oz. prussiate of potash in 4 gals. rain water; now wring goods and put them into the solution and let them remain 5 minutes; then wring out again; now add 1 oz. oil vitriol to the potash water; stir well, then put the goods in again and bring to a boil, letting the goods remain in until the desired shade is obtained. — Silk. 1. (*Light.*) For cold water, 1 gal.; dissolve alum, ½ tablespoonful, in hot water, 1 teacupful, and add to it; then add the chemic blue, 1 teaspoonful at a time, to obtain the desired color; the more chemic the darker the color. — 2. To 45 or 50 gals. water, heated to 122° Fahr., add 12 oz. indigo, 8 oz. madder, 8 oz. bran, and 24 oz. potash; in 36 hours introduce 12 oz. more potash, and the same in 12 hours after; in 72 hours, add a little lime to check fermentation. Wool, silk, linen and cotton may be dyed in this bath. — Cotton. 1. Triturate 1 lb. of indigo with water and a little caustic potash; then add 3 lbs. lime, and afterwards 2½ lbs. sulphate of iron in solution, stirring together. The solution contains refined indigo, soluble in lime and alkalies. The cotton, linen, etc., to be dyed, is repeatedly dipped in the solution, and afterwards rinsed in water soured with hydrochloric acid. — 2. For 5 lbs. 6 oz. copperas; 1½ oz. prussiate of potash; ½ oz. sulphuric acid; dissolve the copperas in enough hot water to cover goods; put in the goods and let them remain 1 hour; then rinse and put them in the solution of prussiate of potash and sulphuric acid, previously prepared; simmer 1 hour, or until color suits; then hang out to dry. Prepare the solution of prussiate of potash and sulphuric acid by first dissolving the potash in sufficient hot water to cover goods, then add the acid, stirring constantly.

BROWN. — Wool. 1. (*Snuff.*) For 50 lbs. Camwood, 10 lbs.; boil for 20 minutes; dip the goods for ¾ hour; then take them out and add to the dye, fustic, 25 lbs.; boil 12 minutes, and dip the goods ¾ hour; then add blue vitriol, 10 oz., copperas, 2 lbs., 8 oz.; dip 40 minutes; add more copperas, if the shade is required darker. — 2. (*Olive.*) For 10 yards. Boil fustic, 1 lb.; logwood, 3½ oz.; cudbear, 2½ oz.; cool to 200° Fahr.; enter, and winch for 20 minutes; air out; repeat; sadden to pattern with 4 oz. copperas; wash and dry. — 3. Water. 3 gals.; bichromate of potash, ¾ oz.; boil the goods in this 40 minutes; wash out in cold water; then take 3 gals. water, 6 oz. peachwood, and 2 oz. turmeric; boil the goods in this 40 minutes; wash out.— 4. (*French.*) For 50 lbs. Preparation, 1½ lbs. chrome. Dyeing, 6 lbs. fustic; 1 lb. ground madder; ½ lb. cudbear; 1 lb. tartar; if not dark enough, add 8 oz. logwood; boil ½ hour.—Silk. Annatto, 4 oz.; pearlash, 1 lb.; dissolve in boiling water, q. s. The silk is passed through it for 2 hours, then taken out, and squeezed dry; it is next passed through a mordant of alum, and then through a bath of Brazil wood, followed by another of logwood, to which a little green copperas has been added. — Cotton. Give the goods as much color, from a solution of blue vitriol, 2 oz., to water, 1 gal., as it will take up in dipping 15 minutes; then rub it through lime water; this will make a beautiful sky blue of durability; then run through a solution of prussiate of potash, 1 oz., to water, 1 gal.

BUFF.—1. (*Dark.*) Boil 6 lbs. turmeric with 3 lbs. alum in 6 gals. water; add this to hot water. Work yarns 5 turns, and lift. Add 6 gills nitrate of iron; 3 turns more. Wash in cold water, and stove. — 2. (*Light.*) Bleach; add a clear lime water. Work yarns 5 turns, and wring. Boil 2 oz. Bismarck brown; add this to a cold water bath. Work yarns 5 turns; wash in cold water, and stove.

CLARET.—Cotton. 11 lbs. yarns. Make up a beck with 17½ oz. prepared catechu, and work the yarns in it for 1 hour. Wring and steep for ½ hour in a hot beck of 6¼ oz. chromate of potash; take through cold water, and wash for ½ hour in a beck of 8 lbs. sumac at 190° Fahr. Dye in a cold beck with 1¾ oz. magenta; lift; add to the beck 8¾ oz. alum and the decoction of 2½ lbs. logwood. Enter again; work in the cold beck; lift, and add, according to the shade, ½ to 1¾ oz. chromate of potash; re-enter, and work to shade.

CRIMSON.—Wool. 1. 1½ lbs. lac dye; 5 oz. muriate of tin. Put the lac dye into a brass kettle and add sufficient water to cover goods; let it stand 12 hours; then add the muriate of tin; stir well together; put in the goods, and bring slowly to a scalding heat; retain this temperature for ½ hour for light crimson, or 2 hours

for deep crimson. — 2. For 10 yards. Bottoming, cudbear, 1½ oz.; preparation, tartar, 1½ oz.; scarlet spirits, 3½ oz.; dyeing, cochineal, 2 oz. Boil or scald the cudbear; winch in this 30 minutes; then prepare and dye as before. — 3. For 50 lbs. Prepare with 2 lbs. alum and ½ lb. tartar. Boil ½ hour; wash in 3 warm waters. Boil in 11 lbs. limawood, and add ½ lb. eudbear; boil in this ½ hour, and blue with warm water. — SILK. For 1 lb. Alum, 3 oz.; dip at hand heat 1 hour; take out and drain, while making a new dye, by boiling 10 minutes, cochineal, 3 oz.; bruised nutgalls, 2 oz.; and cream tartar, ½ oz., in 1 pail water; when a little cool, begin to dip, raising the heat to a boil, continuing to dip 1 hour; wash and dry.

DAHLIA.—This is produced by combining a blue or purple with red when a compound color is used. Upon wool and silk it can be obtained directly by means of archil or cudbear, either alone or blued by a small quantity of sulphate of indigo. Upon cotton indifferent shades of dahlia are obtained by macerating in sumac liquor, working in tin solution, and dyeing in logwood, mixed with red wood.

DRAB.—WOOL. For 50 lbs. 7 lbs. fustic; 8 oz. madder; 4 oz. cudbear; 2 lbs. alum; 8 oz. tartar. Enter between the cold and 160° Fahr. After heating up, boil from 10 to 30 minutes; wash in 2 waters. Dark shades may be slightly impaired with chrome; wash in 2 waters. — 2. (*Light.*) For 56 lbs. 4 lbs. fustic; 1⅞ lbs. alum; 4 oz. madder; 4 oz. tartar; 3½ oz. cudbear. Work as for dark drab. — 3. For 50 lbs. Logwood and alum, of each, ½ lb.; boil well. Enter the goods, and dip for 1 hour. Grade the color to any desired shade by using equal parts logwood and alum. — SILK. 1. For 100 yards. Boil 4 lbs. fustic and 6 oz. logwood; 2½ oz. eudbear; 1½ oz. copperas; cool to 200° Fahr. Enter; winch 20 minutes; air out; repeat; then take a little liquor out of the boiler; dissolve the copperas, reduce it to handling heat with water, and give 1 or 2 shots through it, as the pattern requires; 1 water out of the saddening; then give a warm but weak sour to clear the color; wash in 2 waters and dry. — 2. (*Fawn.*) Take hot water, 1 gal.; annatto liquor, 1 wineglassful; 2 oz., each, sumac and fustic; add copperas liquor according to shade required; wash out. It is best to use the copperas liquor in another vessel, diluted according to shade desired. — COTTON. For 40 lbs. Boil 6 lbs. fustic; scald 2½ lbs. limawood and 2 lbs. sumac; decant into a wooden vessel capable of containing 100 gals.; reduce with cold water to handling heat. Enter; 6 turns; wring out; sadden with 8 oz. copperas; 4 turns; wring out again, and give 4 oz. bluestone.

FEATHERS.—The same preparation as would dye silk of the same color will dye feathers. In dyeing silks the water is used hot, or on the simmer, for most colors; but feathers must be dyed in cold liquors, except for black, the dyeing materials being first boiled and then left to cool; the feathers must then be put in, and when this liquid is exhausted, add a fresh one, pouring off the old liquid.

FURS.—Any dye that will color wool will also color furs. — *Black.* 1. The best black is obtained by first dyeing the skin a blue. Then boil ¼ lb. powdered gall nuts, and 1½ oz. logwood, in 3 gals. water. If the flesh side is to be blue, while the fur or wool is another, this decoction must be sponged on. Get the wool or hair thoroughly impregnated with this, and then add ¼ lb. copperas to the dye, and go over the fur or wool many times with the sponge. The process above given will answer without previous blueing, but the black is not so brilliant.— 2. Make a bath of 8 oz. bichromate of potash, 6 oz. alum, and 4 oz. fustic; boil in water enough to cover a single skin. Make another bath of 4 lbs. logwood; 4 oz., each, barwood and fustic; or 8 oz. fustic; and same amount boiling water as last. Stir the skin well around in the 1st bath, keeping the water hot for 1 hour; then work it in the 2d bath the same length of time; take out and wring; then add ¼ lb. copperas, to the last bath, and give it a good stirring.— *Blue.* Furs are never dyed blue for sale, but sheep-skins are. The skin should be dipped several times in a bath of hot alum water, allowed to drain, and then dipped into a solution of sulphate of indigo and water, with a few drops sulphuric acid added. This gives a pale blue. — *Green.* Dye first blue, as explained above; then pass through a yellow dye till you get the shade required. An alum bath, cream of tartar, or spirits of tin, as below, must be used before the blue is given. — *Yellow.* Sheep-skins may be dyed yellow with black oak bark (quercitron bark), old fustic, annatto, and Persian (also called French) berries. The skin should be previously dipped into a hot bath of alum, cream of tartar, or spirit of tin, about 2 oz. to the gal. About ½ lb. of annatto, or 1 lb. of the other articles, are enough for a single skin.

GLOVES, Kid.—If not greasy, they may be dyed with any of the ordinary dyes by brushing the latter over the gloves stretched out smooth. The surface alone should be wetted, and a 2d or 3d coat may be given after the former one has become dry. When the last coat has become dry, the superfluous color should be rubbed out, a smooth surface given by rubbing them with a polished stick or piece of ivory, and the whole gone over with a sponge dipped in white of egg.

GRAY.—WOOL. 1. (*Ash.*) For 20 lbs. Dissolve 1 lb. tartar in 4 gals. water; turn the stuff through the liquor for ½ hour; add a decoction of galls, ¼ lb., and sumac 1½ lbs; put in the stuff and boil ½ hour; then take out the stuff; add sulphate of iron, 1 lb., when dissolved again, put it in, and work well ½ hour longer. — 2. (*Iron.*) Give the stuff a pale blue tint in the indigo bath; pass it through a weak decoction of galls and sumac; take it out; add a little iron liquor to the bath, and work the stuff well. In this way every shade of iron gray, slate gray, and the other shades that turn upon the blue, may be given. — 3. (*Pearl.*) Sumac, 2 lbs.; logwood, 1 lb.; make a decoction with water; pass the stuff through it; afterwards through a weak iron water; lastly, add a little iron liquor to the decoction, and again turn the stuff through it. — 4. (*Yellowish.*) Pass the stuff through a weak fustic bath, and next through a weak decoction

of galls, to which a little alum has been added. Remove the goods; refresh the bath with a little logwood; boil ½ hour; add some blue and green vitriol, and when dissolved finish. — HALF WOOL. Prepare for 3 hours with 2 lbs., 12 oz., sumac; wring out, and boil ¾ hour with 4½ oz. logwood and 1 oz. fustic. Sadden in the same beck with 1¾ oz. copperas at 200° Fahr. — COTTON. For 2 lbs. Take ¼ lb. cheapest black tea to be found; steep in an iron kettle, with the tea in a bag, and then boil, squeezing the leaves dry; add 1 teaspoonful copperas. Put in the goods. For light gray or drab, leave the goods in a short time; for darker colors, leave longer. Rinse in clear warm water. Wool long boiled and aired often, becomes brown in this dye.

GREEN.—WOOL. 1. For 1 lb. Fustic, 1 lb., with alum, 3½ oz. Steep until strength is out, and soak goods therein until a good yellow is obtained; then remove the chips and add extract of indigo or chemic, 1 tablespoonful at a time, until color suits.—2. (*French.*) For 50 lbs. Boil 7 lbs. fustic and 12 oz. cudbear; add 6 oz. extract of indigo and 1 pt. sulphuric acid; cool to 180° Fahr. Enter, and boil 20 minutes. — 3. (*Grass.*) For 10 yards. Fustic, 12 oz.; extract of indigo, 3 oz., 3 dr.; alum, 3 oz., 3 dr.; sulphuric acid, 1½ oz. Boil the fustic first; then add the extract of indigo, alum and acid; put off the boil. Enter and winch to shade required. If not blue enough, give more extract of indigo; if not yellow enough, more fustic. — 4. (*Myrtle.*) For 10 yards. Fustic, 1 lb.; logwood, 3 oz., 3 dr.; extract of indigo, 3 oz., 3 dr.; bluestone, ½ oz. Boil the logwood and fustic together; put off the boil. Enter; winch 20 minutes; air out and repeat; raise with 3 oz. bluestone dissolved in the boiler; then give the extract of indigo 1 water; rinse in the remaining 2 oz. bluestone; harden in a solution of alum, and dry. — 5. (*Olive.*) For 100 yards. 10 lbs. fustic; 2 lbs. logwood; 10 oz. camwood. Boil together 30 minutes; put off the boil. Enter, and winch 20 minutes; air out and repeat; sadden with 3 or 4 oz. copperas in the same liquor, or with a little of the liquor in another dish; when the required shade is obtained, wash and dry. — SILK. For 1 lb. Yellow oak bark, 8 oz. Boil ½ hour; turn off liquor from bark, and add alum, 6 oz.; let stand until cold. While making this, color goods in blue dye tub a light blue; dry and wash; dip in the alum and bark dye. If it does not take well, warm the dye a little. — COTTON. 1. For 40 lbs. Fustic, 10 lbs.; blue vitriol, 10 oz.; soft soap, 2½ qts.; logwood chips, 1 lb., 4 oz. Soak the logwood over night in a brass vessel; put it on the fire in the morning, adding the other ingredients; when quite hot it is ready for dyeing. Enter the goods, and handle well. Different shades may be obtained by letting part of the goods remain longer in the dye.—2. For 7 lbs. 2 lbs. fustic and 1 oz. extract logwood. Boil 2 hours; then add 1 oz. blue vitriol; color in brass. After it is colored dry it, and then wash it in strong suds.

HORN. — *Black.* 1. 5.5 lbs. burned lime are slaked in a little water, so that a powder-like hydrate of lime is obtained; this is mixed with 2.2 lbs. minium, and this mixture is formed into a thick paste with such lye as soap-boilers use, having a specific weight of 1.036. The articles of horn are placed in this solution for 24 hours; they are then taken out, rinsed off with water, dried with a cloth, brushed over with rape-seed oil, and then again rubbed dry. — 2. .14 oz. silver are dissolved in 2.1 oz. nitric acid (aquafortis), and this solution is applied several times to the article to be stained; the first coat should be entirely dry before another is applied. The articles are then burnished. — *Green.* 1. .52 oz. fine indigo-carmine are dissolved in 2.1 oz. rain-water; then .175 oz. pure picric acid are dissolved in 2.1 oz. boiling hot rain-water, and both solutions are mixed together. A beautiful, durable green color will be obtained, and can be used for the various manipulations. —2. 4.2 oz. copper cut up fine and gradually dissolved in 13 oz. nitric acid, and the articles to be stained boiled in this solution until they assume a fine green color. — *Purple.* 17.5 oz. logwood are boiled in 4.4 lb. milk of lime, and the same method is observed in the following. — *Red.* 17.5 oz. red Brazil-wood are boiled 1 hour in 4.4 lb. milk of lime, and filtered through a cloth. The articles of horn, ivory, or bone to be stained are boiled for 1 hour in a solution of 1.05 oz. alum in 17.5 oz. water. They are then placed in the above stain, and allowed to remain until the desired color has been produced. Articles stained in this manner will acquire a beautiful purple color by dipping in alum water. — *Bright Red.* 8.75 oz. logwood and 8.75 oz. red Brazil-wood are boiled in 4.4 lb. milk of lime. It is applied in the same manner as the one before. — *Tortoise-shell.* A rough dough is prepared from 17.5 oz. white litharge, 2.2 lbs. finely powdered unslaked lime, and 3.3 lbs. soap-boilers' lye having a specific weight of 1.036. The places of the horn which are to become dark are covered with this dough, and the horn allowed to remain in contact with the dough for 24 hours, until the latter has become dry. The horn is then cleansed with a brush. — *Yellow.* 17.5 oz. alum, free from iron, are dissolved in 4.4 lbs. rain-water. The articles are allowed to lie in this for 1 or 2 hours. In the meanwhile 7 oz. yellow berries are boiled with 4.2 oz. carbonate of potash in 2.2 lbs. water for 1 hour, and then strained. The articles stained with alum are placed in this decoction, and allowed to lie in it for 1 hour. They are then taken out and dried.

IVORY.—The pieces are first polished with whiting and water, and when washed clean from the whiting are then prepared for the stain by an immersion of from 3 to 5 minutes in acidulated cold water, in proportion of 1 part of muriatic acid, the ordinary acid of commerce, to 40 or 50 of water, or in an equally weak solution of nitric acid. This cleansing fluid extracts the gelatine from the surface of the ivory, and is essential to the attainment of a perfect color. Extreme cleanliness is necessary, with which view the work in process of staining is at no time touched by the fingers, but removed from one vessel to another by flat pieces of wood, attached to each other by a flat metal spring after the form of a pair of sugar-tongs, separate pairs being kept for different colors. Subsequently to

its treatment with the acid, the ivory is again placed in cold water that has been boiled, before it is transferred to the stain. — *Black.* 1. Lay for several hours in a strong solution of silver nitrate, remove and expose in a strong light. — 2. Place a handful of logwood in about 1½ pts. water in a saucepan, and let simmer till reduced to ¾ pt.; put the ivory into the boiling liquid, and let remain for 10 minutes; remove and lay before a fire or in an oven till well dried; afterwards polish with chamois leather. — 3. Make a decoction of 2 oz. logwood dust in 1 qt. water, and stain; dissolve 1 oz. iron sulphate in 1 qt. water; then heat the two stains in separate vessels to 100° Fahr., and immerse the ivory in the logwood 15 minutes; well wash, and put it into the iron sulphate for 5 minutes. — *Blue.* 1. Immerse for some time in a dilute solution of indigo sulphate containing potash. — 2. Elder berries and alum. — 3. Steep in a solution of verdigris and sal-ammoniac in weak nitric acid, in the proportion of 2 parts of the former to 1 of the latter, being careful to observe the same precautions as in staining red; then dip in strong solution of pearlash and water. — *Brown.* Alkanet root. — *Green.* Boil in a solution of verdigris in vinegar till the desired shade is produced. — *Red.* 1. Make an infusion of cochineal in liquor ammoniæ, and immerse pieces therein, having previously soaked them for a few minutes in water slightly soured with nitric acid. — 2. Dip in a solution of nitro-muriate of tin, and then in lac, to produce scarlet; by then plunging into a solution of potash it will become cherry red. — 3. Boil cuttings of scarlet cloth in water, and add pearlash by degrees till the color is extracted; add a little rock-alum to clear the color, then strain. Steep the ivory in nitric acid diluted with twice the bulk of water; take out and plunge into the dye till sufficiently deep. The acid bath must not be too strong, and the ivory should be taken out as soon as the surface becomes rough; the dye bath must be warm, but not hot. A variegated appearance may be produced by covering portions with white wax, these retaining their natural whiteness. — *Yellow.* 1. Immerse in a solution of ¼ lb. alum per pt.; then boil in decoction of turmeric in lime water. — 2. .175 oz. picric acid are dissolved in 1.05 oz. hot water. On the other hand, .07 oz. concentrated sulphuric acid are diluted with .35 oz. hot water, and the freshly-smoothed articles are laid in the fluid, and frequently turned. They are then taken out, dried off, and placed in a solution of picric acid while this is still hot, where they remain until uniformly yellow. A lustre is given by polishing with soap and water and fine whiting. This is a very good method for coloring billiard balls yellow. — *Vegetable Ivory.* Objects of this material may be stained by boiling a long time in a clear solution of the desired coloring matter. Picric acid, or potassium bichromate, iodine green, sumac, aniline dyes, etc., may be used conveniently. The ivory must be clean. It may be bleached by immersion several hours in a solution of permanganate, and then in sulphurous acid.

LAVENDER.—WOOL. For 50 lbs. Boil 5½ lbs. logwood with 2 lbs. alum; then add 10 oz. extract of indigo. When cold, put in the goods, and gradually raise to boiling point. — SILK. In a vessel of warm water as hot as the hand can bear, dissolve white soap enough to raise a lather; then add 1 gill archil liquor, and work the goods in this for 15 minutes; wring out and dry. Boil 1 oz. cudbear, and add the solution to the soap and water instead of archil, which will give a lavender having a redder tint than with the archil. If a still redder shade be required, the soap may be dispensed with. — COTTON. For 100 yards. Take 1 lb. logwood and 2 lbs. sumac; scald them separately; then decant into a proper sized tub; let them cool to 150° Fahr., and add 2 gills vitriol. Winch the goods in this 20 minutes; lift, and run them slightly through acetate of iron; wash in 2 waters; then give 1 lb. logwood as before; raise with 1 pt. chloride of tin. Wash in 2 waters; then, in a tub of cold water, put 4 oz. extract of indigo. Enter, and winch in this 15 minutes; lift, give 1 water, and dry.

LEATHER. — *Black.* Put the skin on a clean board, and sponge it over with gall and sumac liquors, made strong; then take a strong logwood liquor, and sponge it over 3 or 4 times; next take a little copperas, mix it in the logwood liquor, sponge over the skin, and finish as follows: Take the white of an egg, and a little gum dragon, and mix the 2 together in ¼ gill water; sponge over the skin, and when dry polish with a bottle, or a piece of glass prepared for the purpose. — *Blue.* 1. Steep the leather for a day in urine and indigo; then boil it with alum; or it may be given by tempering the indigo with red wine, and washing the skins therewith. — 2. Boil elder berries, or dwarf elder; then smear and wash the skins therewith, and wring them out; then boil the berries as before in a solution of alum water, and wet the skins in the same manner once or twice; dry them, and they will be very blue. — 3. (*Sky Blue.*) This is given with indigo steeped in boiling water, and the next morning warmed and smeared over the skin. — *Green.* Smear the skin with sap green and alum water, boiled. — *Dark Green.* Steel filings and sal ammoniac, steeped in urine till soft, then smeared over the skin, which is to be dried in the shade. — *Light Orange.* Smear with fustic berries, boiled in alum water; or, for a deep orange, with turmeric. — *Purple.* Wet the skins with a solution of roche alum in warm water, and, when dry, again rub them with the hand with a decoction of logwood in cold water. — *Red.* Wash the skins, and lay them 2 hours in galls; then wring them out, and dip them in a liquor made with privet berries, alum and verdigris, in water; and lastly in a dye made of Brazil wood boiled with lye. — *Yellow.* 1. Smear the skin over with aloes and linseed oil, dissolved and strained; or infuse it in weld. — 2. Picric acid gives a good yellow without any mordant; it must be used in very dilute solution, and not warmer than 70° Fahr., so as not to penetrate the leather.

MAROON.—WOOL. To a clear solution of 10 lbs. catechu, add 2 lbs. logwood and 2½ lbs. tartar. Boil the wool for 2 hours in this bath;

rinse, and add to the above bath 2 lbs. bichromate of potash and 1 lb. sulphate of copper. Put the wool in, and boil for ½ to 1 hour, according to shade required, and then rinse. — SILK. Take the silk through a catechu beck, weight for weight, if a good yield is desired. If a smaller yield is wished, less catechu is taken. Dye at a boil; lift, wring, and pass into a chrome beck at 6½° to 8½° Tw., and 77° Fahr. If the shade desired is very dark, the heat may be raised a little more. Wash well. Make up a beck of fustic, extract of indigo and orchil; add a little alum to draw on the fustic, and acidulate slightly with sulphuric acid for the blue. Dye at a boil, adding more of any of the colors as the shade may require.

NANKEEN.—Boil annatto with an equal weight of pearlash, in sufficient water.

OLIVE.—WOOL. 1. For 50 lbs. 10 lbs. bark; 2 lbs. logwood; 8 oz. bluestone. Boil the bark in a bag; put off the boil, and enter; winch 20 minutes. Lift, and put in the bluestone; return for 10 minutes; lift, and wash in 2 waters, and top; give the logwood in another dish; when dark enough, wash and dry. — 2. For 10 lbs. yarn. Boil with 96 dr. prepared tartar, 20 dr. blue vitriol, 375 dr. orchil, 50 dr. turmeric, and 40 dr. indigo sulphate. Cerise as required. — COTTON. For 11 lbs. Extract 8¾ oz. sumac in boiling water. Enter the yarn into the clear liquid; let steep, and make up a fresh beck with the same weight of copperas. Wring out the yarn, and enter into this second beck, working for ½ hour. Wring, and enter into a fresh beck of red liquor at 1½° Tw.; give 12 hours; heat to 144° Fahr. Wring out; and work for ½ hour in a decoction of quercitron bark.

ORANGE.—WOOL. 1. For 50 lbs. Boil 10 lbs. bark and 1½ lbs. cochineal; add 2 lbs. tartar and 2½ qts. yellow spirits. Enter at 200° Fahr.; boil 30 minutes. — 2. For 5 lbs. Muriate of tin, 6 tablespoonfuls; argal, 4 oz. Boil, and dip 1 hour, and add again 1 teacupful madder. Dip again ½ hour. Cochineal, about 2 oz., in place of madder, makes a brighter color. — SILK. For 10 yards. Annatto, 1¾ oz.; bark, 1½ oz.; chloride of tin, 1½ oz. Give a good body of annatto at 212° Fahr.; wash in 1 water, then top with the bark and chloride of tin. — COTTON. Boil 12 lbs. sugar of lead in 12 gals. clear limewater till dissolved; add this to enough cold water. Work yarn 5 turns, and wring. Repeat this process twice in the cold liquors, wringing after each time. Get a clear lime water up to the boil, and give the yarns 5 turns in it, working very quickly. It is important that the lime water should be boiling, to keep the yarns level. Wash off in warm water with a little soap and dry. This color, like all others in which lead is an ingredient, will be darkened and spoiled if exposed to fumes of sulphuretted hydrogen.

PEACH.—For 50 lbs. Drench 8½ lbs. cudbear with a little hot water; boil or scald it in 3 or 4 gals.; decant the clear liquor into a boiler containing 100 gals. water. Enter cold; bring to the boil; lift, and put in 1 lb. soda, or 2 gals. urine; return, and boil 10 minutes.

PINK.—WOOL. 1. Washed safflower, 2 oz.; salt of tartar, ½ oz.; cold water, 1 qt.; digest 3 hours; express the liquor and strain. Used to dye silk stockings rose color. The color is brought out afterwards by passing the articles through water soured with lemon juice.—2. For every 3 lbs. material, take 3½ qts. water, 2 oz. cochineal, and ½ oz. cream tartar; steep the cochineal in warm water 2 hours, or until the strength is extracted, and add the cream tartar; then wet the garment in clean water; wring dry; put it into the dye; bring it to a scalding heat, and let it remain a few minutes, stirring all the time, when it will be finished. If a lighter color is needed, use less cochineal; if darker, more. A cheaper dye may be obtained by using madder for cochineal. — 3. (*Purple.*) For 5 lbs. Boil 1 lb. cudbear in sufficient water; put in 1 oz. alum; when dissolved, put in the goods and let them simmer for ½ hour, stirring frequently; rinse in warm water. A tin pan is best for this color; iron will brown it. — COTTON. For 40 lbs. Redwood, 20 lbs.; muriate of tin, 2½ lbs.; boil the redwood 1 hour; turn off into a large vessel; add the muriate of tin, and put in goods; let it stand 5 or 10 minutes, and a nice pink will be produced.

PRIMROSE.—For 50 lbs. Boil 2½ lbs. bark; add 2 lbs. tartar; 2 qts. muriate of tin. Enter at 150° Fahr.; boil 30 minutes.

PURPLE.—WOOL. For 1 lb. Rinse goods well in soap suds; then dissolve 2 oz. cudbear in hot suds, and soak goods until of the required color. The color is brightened by rinsing in alum water. — SILK. 1. For 40 lbs. Bichromate of potash, 8 oz.; alum, 1 lb.; dissolve all, and bring the water to a boil, and put in the goods; boil 1 hour; empty the dye, and make a new dye with logwood, 8 lbs., or extract of logwood, 1 lb., 4 oz., and boil in this 1 hour. Use more or less logwood as you wish dark or light color. — 2. For 10 lbs. Enter goods in blue dye-bath, and secure a light blue color; dry, and dip in a warm solution, containing alum, 2½ lbs. Should a deeper color be required, add a little extract of indigo.

RED.—WOOL. 1. (*Rose.*) For 40 lbs. 1 lb. cochineal; 3 gills double muriate of tin; 1 lb. tartaric acid. Enter at 100° Fahr.; heat up; boil 15 minutes; lift, and cool to 120°, by throwing out part of the liquor, and filling up with water; add 1 gill ammonia paste, 12 oz. tartaric acid, and 6 oz. oxalic acid. Bring up to the boil. When the desired shade is obtained, wash well, and dry. — 2. The goods are first steeped or boiled in a weak mordant of alum and tartar, for 1 hour, and then allowed to lie in the cold liquor for 2 or 3 days, with frequent moving about; they are lastly boiled in the Brazil-wood bath for about ½ hour. — 3. For 40 lbs. Make a tolerably thick paste of lac dye and sulphuric acid; allow it to stand for a day; now take tartar, 4 lbs; tin liquor, 2 lbs., 8 oz., and 3 lbs. of the above paste; make a hot bath with sufficient water. Enter the goods for ¾ hour; afterwards carefully rinse and dry. — SILK. 1. The goods, after being alumed in the same way as wool, but at a lower temperature, are rinsed, and passed through the Brazil wood bath lukewarm.— 2. The most lively tints of cherry, flame, flesh, orange-red, poppy and rose color, are imparted to silk by the following process, modified to suit

the particular shade required: The safflower (previously deprived of its yellow coloring matter by water) is exhausted with water containing either carbonate of soda or of potash, in the proportion of about 5 per cent. of the weight of the prepared dye-stuff acted on; the resulting liquid is next treated with pure lemon juice until it acquires a distinct and rich red color; the silk is then introduced and turned about as long as it is perceived to take up color, a little more lemon juice being added as may appear necessary; for deep shades this is repeated with one or more fresh baths, the silk being dried and rinsed between each immersion; it is lastly brightened by turning it for a few minutes through a bath of warm water, to which a little lemon juice has been added. For flame color the silk should receive a slight shade with annatto, before putting it into the safflower bath. For the deeper shades, when expense is an object, a little archil is commonly added to the first and second bath. — Cotton. 1. (*Bright.*) The most permanent is Turkey red, which is made from madder, but the process is too complicated for family use. The following is easier and gives fair results: First steep the yarn or cloth several hours in a decoction of sumac with a little sulphuric acid; after the sumac has had time to form an intimate combination with the cotton, the yarn is worked in a solution of bichloride of tin of sp. gr. 1.015, and transferred to a boiler, in which about its own weight of barwood, finely rasped, is added, the water being nearly boiling, and the goods worked about until the required shade is obtained. — 2. Clean the goods by alkaline baths, after which they are steeped in oily liquors, brought to a creamy state by a little carbonate of soda; a bath of sheep's dung is next used as a secondary steep; the oleaginous bath, and the operation of removing loosely adhering oil with an alkaline bath, is repeated 2 or 3 times, care being taken to dry the goods after each process; then follow the distinct operations of galling, aluming, maddering, and brightening, the last for removing the dun-colored principle, by boiling at an elevated temperature with alkaline liquids and soap; the whole is generally concluded with treatment by spirit of tin. In this way are given the most brilliant reds on cotton. — 3. The goods are first boiled in a bath of sumac; next worked through a weak mordant of solution of tin, and then run through the Brazil bath lukewarm. This gives a bright red.

SALMON. — 1. For each lb., ¾ lb. annatto; ½ lb. soap; rinse goods in warm water; put them into the mixture, and boil ½ hour; shade will be according to amount of annatto. — 2. For 10 yards. Annatto, 1½ oz.; cudbear, 4 dr. Boil the annatto; then add the cudbear; put off the boil. Enter and winch 30 minutes; wash in 2 waters; then dry.

SCARLET.—Wool. 1. Take soft water sufficient to cover the cloth you wish to color; bring it to a boiling heat in a brass kettle; then add 1½ oz. cream tartar for every lb. cloth. Boil a minute or two; then add 1 oz. powdered cochineal and 3 oz. muriate of tin; boil 5 minutes; wet the goods in warm water; then wring and put in the dye; boil the whole nearly 1 hour; take the cloth out and rinse well in clear cold water.—2. Dissolve in boiling water, liquid extract of quercitron, 3 lbs., 8 oz.; oxalic acid, 3 lbs., 8 oz.; tin crystals, 1 lb., 12 oz.; tartar, 4 lbs.; eochineal, 4 lbs.; chloride of tin solution, 8 lbs.; mix well when dissolved; add cold water. Enter wool, and boil from 1 to 1½ hours. — Silk. 1. Boil for ½ hour 11 lbs. ground eochineal; filter, and set to clear liquor at 4° Tw.; add to the beck about 24 fl. oz. tin solution, and dye. It requires 24 hours to produce the scarlet. After dyeing, the silks are left wrapped up for 12 hours, rinsed slightly, brightened with citric acid, and dried. The solution of tin is made of 4 lbs. muriatic acid, 2 lbs. nitric acid, 5 lbs. feathered tin, dissolved gradually in the course of a day. — 2. Prepare in stannate of soda at 4° Tw. in the cold; take through weak vitriol sours, and wash well. Give a second mordant of red liquor at 8½° Tw., thickened with calcined starch at the rate of 3½ oz. per 35 fl. oz. of the mordant. Dry without rinsing for at least 24 hours; then rinse and dye with decoction of cochineal. When the color is as deep as is required, add nitrate of tin to the same beck. This process gives scarlets as fine as *1*, and with less loss of coloring matter. The object of the addition of calcined starch is to give the silk more body. In many dyeworks scarlets for silks are grounded with annatto.

SLATE. — Wool. Boil sugar-loaf paper with vinegar, in an iron utensil; put in alum to set the color. To produce a light slate color, boil white maple bark in clear water, with a little alum; the bark should be boiled in a brass utensil. The dye for slate color should be strained before the goods are put into it. They should be boiled in it, and then hung where they will drain and dry. — Silk. For a small quantity, take a pan of warm water, and about a teacupful of logwood liquor, pretty strong, and a piece of pearlash about the size of a nut; take gray colored goods and handle a little in this liquid, and it is finished. If too much logwood is used, the color will be too dark.

STONE.—For 50 lbs. 1 lb. logwood; 4 oz. fustic; 8 oz. extract of indigo; 3 lbs. alum; 1½ lbs. tartar. Work as for drab.

STRAW. — Bleach; mordant in either tin or red liquor; boil 1½ lbs. fustic extract in 3 gals. water; add this to warm water. Work yarn 5 turns; wash in cold water, and stove.

STRAW HATS. — *Black.* To obtain a level color, a solution of gluten is added to a lye of soda, which is allowed to stand for 24 hours and filtered. The hats are then steeped for 12 hours in the clear liquid. The straw is thus freed from grease, and the mordants of nitrate, sulphate or acetate of iron, as well as the decoction of logwood mixed with sumac or galls, is evenly taken up by the fibre. A slight addition of bichromate of potash improves the dye, and the goods are then finished by the use of gum or gelatine. — *Blue.* With 1 lb. litmus or lacmus, ground, and a sufficiency of potash lye, make a decoction; put in the straw and boil it. *Chestnut Brown.* For 25 hats. Use ground sanders, 1½ lbs.; ground curcuma, 2 lbs.; powdered gall nuts or sumac, ¾ lb.; rasped logwood, 1-10 lb.; boil all together with the hats in a large

kettle for 2 hours; then withdraw the hats; rinse, and let them remain over night in a bath of nitrate, of 4° Baume, when they are washed. A darker brown may be obtained by increasing the quantity of sanders. To give the hats lustre, they are brushed with a brush of dog's grass when dry. *Red.* Boil ground Brazil wood in a lye of potash, and boil the straw hats, etc., in it. *Silver Gray.* For 25 hats. Select the whitest hats, and soften them in a bath of crystallized soda, to which some clean lime water has been added. Boil 2 hours in a large vessel, using for a bath a decoction of the following: Alum, 4 lbs.; tartaric acid, ⅜ lb.; some ammoniacal cochineal and carmine of indigo; a little sulphuric acid may be necessary to neutralize the alkali of the cochineal dye. If the last mentioned ingredients are used, let the hats remain an hour longer in the boiling bath; then rinse in slightly acidulated water. — *Slate.* Soak the bonnet in strong, warm suds, for 15 minutes, to remove sizing; rinse in warm water; now scald cudbear, 1 oz., in sufficient water to cover the hat or bonnet; work in this dye at 180° until you get a light purple. Now have a bucket cold water, blued with extract of indigo, ½ oz.; work in this until the tint pleases; dry, then rinse with cold water, and dry again in the shade. If you get the purple too deep, the final slate will be too dark. — *Violet.* Alum, 4 lbs.; tartaric acid, 1 lb.; chloride of tin, 1 lb.; dissolve and boil. Allow the hats to remain in the boiling solution 2 hours; then add as much of a decoction of logwood and carmine of indigo as is requisite to induce the desired shade; rinse in water in which some alum has been dissolved.

VIOLET. — Wool. Prepare a bath of 10 oz. of bichrome; 5 oz. sulphuric acid; 6 oz. oxalic acid. Work 1 hour in this, and then put in fresh bath with 15 lbs. logwood; 8 lbs. archil; boil 1 hour. — Silk. A good violet may be given to silk or wool by passing it first through a solution of verdigris, then through a decoction of logwood, and lastly through alum water. A fast violet may be given by first dying goods a crimson with cochineal, without alum or tartar; then rinse, and pass through the indigo vat. — Cotton. Linens and cottons are first galled with about 18 per cent. of gall nuts; next passed through a mordant of alum, iron liquor and sulphate of copper, working well; then through a madder bath, made with an equal weight of root; and, lastly, brightened with soap or soda. Another method is to pass cloth, previously dyed Turkey red, through the blue vat. Wool, silk, cotton, or linen, mordanted with alum and dyed in a logwood bath, or a mixed bath of archil and Brazil, takes a pretty, but false violet.

YELLOW. — Wool. To dye a buff, boil equal parts annatto and common potash, in soft, clear water; when dissolved, take it from the fire; when cool, put in the goods, previously washed free from spots and color; set them on a moderate fire till the goods are of the shade wished. — Silk. The silk must not be washed. A red shade is first given with annatto in a soap beck, not too strong; then washed and rinsed in the cold with sulphuric acid. The yellow shade is then given with picric acid, and the silk dried without washing. For a heavier shade the process is the same, but turmeric is used instead of picric acid. The solution of annatto is made by boiling together for ½ hour equal weights of potash and annatto. — Cotton. For 40 lbs. Sugar of lead, 3 lbs., 8 oz.; dip goods 2 hours. Make a new dye with bichromate of potash, 2 lbs.; dip until color suits. Wring, and dry. If not yellow enough, repeat the operation.

THE PURSUIT OF PLEASURE.

ATHLETICS.

GYMNASTICS.

REMARKS ON TRAINING.— Gymnastic exercises may be begun at 8 years old, or earlier; but they must begin gently and proceed gradually, and never immediately after meals. The pupil should be careful, after exercise, of draughts or cold, and refrain from lying on the ground, or standing without coat or other garments. Rigidly guard against drinking cold water, which, in many instances, has been known to produce immediate death. A proper practice of gymnastics will develope the muscles for the performance of all athletic sports and exercises. But, as it is dry exercise for one alone, it will be best to get several to join him and form a club, and thus increase his interest in this recreation.

Baths.—An essential requisite and preparation for athletic feats, is the daily use of the cold bath. Dry and rub down the body with a towel until a healthy glow suffuses the skin; then put the towel aside and use the palms of the hands until obliged to cease from sheer weariness.

Costume. — The dress should be of little weight; and small, thin men should be observant of this, heavy clothing operating against them. Short-sleeved merino or gauze jerseys, and loose drawers reaching to the knee, are most useful.

Diet.—Articles of food, nutritious to some, act in the opposite manner on others; consequently each person must exercise judgment with regard to articles of consumption. No rule can be implicitly relied on. The following regulations will be found generally successful: *Breakfast* should be taken at 8 or 8:30, and consist of chops, chicken, beef or mutton, new-laid eggs, bacon and ham, oatmeal, toast or stale bread, tea or ale. Coffee should be avoided, unless felt to be beneficial. *Lunch* at 11 A. M. This should be light, consisting of biscuits or sandwiches. *Dinner* should be taken at 1:30 P. M. Roast mutton is very nutritious, but beef and game may be taken occasionally. Avoid fat as much as possible. Vegetables in moderation are good. Potatoes are least beneficial. Light puddings may occasionally be indulged in. Strawberries, oranges and figs can be eaten; but nuts, plums, etc., must be avoided. In a dinner of courses, eat little of each, and choose the simplest viands. This moderation is a great secret of training. *Supper* should be taken at 7 P. M., consisting of oatmeal, 2 fresh eggs, fresh berries or stewed gooseberries; with bread, toast and tea. Regular hours must be observed.

Disease.—It is an error to suppose that athletics induce heart-disease, though it may be developed where the seeds exist. It is advisable to be examined by a good physician before attempting to excel in athletics.

Drink.—A glass of wine now and then, of good quality, assists the system; but spirits should be totally shunned, except largely diluted with water. If a man has not been in the habit of taking them, he should abstain altogether. In the case of one accustomed to spirits, a wineglassful mixed with water should be the limit, and only taken at meal times. If fatigued from exercise, it is beneficial to take a glass of sherry before eating.

Exercise.—An essential to success in any test of skill, is regular exercise of the muscles to be exerted. Nothing is so beneficial and strengthening to the body as a walk. It is advisable to walk every morning before breakfast 3 to 6 miles, if weather permits and a reduction in weight is necessary. Before going out in the morning, if convenient, take an egg beaten up in sherry, or suck a raw egg and eat a biscuit. A crust of bread and ½ glass fresh milk are often handy, and answer the purpose as well. Regular exercise in the special branch in which a trainer is to appear, should be practiced daily, from 10.30 A. M. until noon, and from 3.30 P. M. until 5 P. M. Never do your best at any exercise until warmed up.

Sleep.—To attain the best physical and mental condition, 8 hours of sound, undisturbed sleep must be had. The trainer should retire at 9.30 P. M. regularly, and rise at 6 A. M., and rest from 12 M. to 1 P. M.

Smoking.—Those accustomed to smoke large-

ly should lessen the quantity until the practice is almost given up. The staying powers of the smoker are to a degree impaired, the wind is affected, and the languor occasioned by it induces a man to remain inactive when he ought to be taking his exercise.

CALISTHENICS.

A PRELIMINARY course to regular gymnastics consists in simple movements without implements, called CALISTHENICS.

ARM MOVEMENTS.—*Exercise 1.* Place the heels together and toes turned out; keep the body upright, shoulders well back, and arms stretched out on a level with the shoulders (*Fig. 1*); then bring the tips of the fingers quickly together in front of the chest (*Fig. 2*), having the

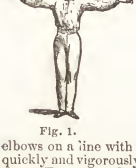

Fig. 1.

Fig. 2.

elbows on a line with the shoulders; then strike quickly and vigorously back to the original position.—*Exercise 2.* Close the hands tightly, bring them up to the chest, with the elbows close to the body; then strike forward vigorously (*Fig. 3*), backwards (*Fig. 4*), upwards (*Fig. 5*), downwards (*Fig. 6*), and sideways (*Fig. 7*), with the

Fig. 3.

Fig. 4.

Fig. 5.

Fig. 6.

hands closed. The elbows should be close to the body in the forwards, upwards and sideways movements; but brought up, away from the body, previous to backwards and downwards movements.—*Exercise 3.* Stretch the arms sideways and keep them straight, and the body erect; then describe quickly a circle from the shoulders, keeping the palms of the hands facing all the time (*Fig. 7*). The circle should become larger as the exercise proceeds.—*Exercise 4.* Stretch the arms forward, with the tips of the fingers touching. Strike back from the position, keeping the arms on a level with the shoulders.

Fig. 7.

BODY MOVEMENTS.—*Exercise 1.* Stretch the arms up, the palms of the hands facing each other; and keep the legs stiff; then bend forward, and, with the knees still firm, touch the ground with the tips of the fingers (*Fig. 8*). From this position, swing backwards to the back bend, keeping the legs straight.—*Exercise 2.* Stretch the arms up, the palms of the hands facing each other; heels together and toes pointing out. Bend to the right from the hips from this position, and then to the left (*Fig. 9*).

Fig. 8.

Fig. 9.

Fig. 10.

—*Exercise 3.* Advance the right leg 18 in., and stretch the arms up. Bend from this position to touch the ground with the tips of the fingers. (*Fig. 10*); then bend back (*Fig. 11*). The same

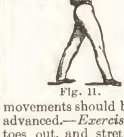

Fig. 11.

Fig. 12.

movements should be repeated with the left leg advanced.—*Exercise 4.* Place the heels together, toes out, and stretch the arms up, with the palms of the hands facing each other; then hollow the back, bend down from the hips, keeping the head back, and looking up to the ceiling. The legs should be kept straight (*Fig. 12*) while exercising.—*Exercise 5.* Place the heels together, toes out, hands on the hips; then turn the body from the hips, first to right, then to

Fig. 13.

Fig. 15.

Fig. 14.

left (*Fig. 13.*)—*Exercise 6.* Place the heels together, toes out; put the hands on the hips, and keep the shoulders well back. Rise from the toes (*Fig. 14*); then sink down, separating the knees (*Fig. 15*); again raise the body from this position on the toes, and return to first position. Repeat the exercise several times quickly.

LEG MOVEMENTS.—*Exercise 1.* Place the heels close together, with toes pointed sideways; the hands on the hips, and shoulders kept well back (*Fig. 16*); then bend the legs as much as possible. — *Exercise 2.* Stand with the hands on the hips, body upright, toes together, and heels pointing sideways (*Fig. 17*); straighten the legs. —*Exercise 3.* Place the right heel to the left toe, and bring the feet close (*Fig. 18*); then bend the legs, keeping the body erect and the head back.

Fig. 16.

Fig. 17.

Fig. 18.

Fig. 19

—*Exercise 4.* Body upright and hands on the hips. Raise the right knee high up (*Fig. 19*); strike out forwards, letting the toe point well down (*Fig. 20*); then bring the heels together again. This should be gone through quickly, the legs, after a little time, being reversed. — *Exercise 5.* Raise the left leg from the ground slightly, point the toe down; then bend down on the right leg, without allowing the left to touch the ground (*Fig. 21*), almost sitting on the heel. From this position the body must be raised again, heels together. Do this with the right leg stiff.

Fig. 20.

Fig. 21

DUMB BELLS.

FOR preliminary practice, dumb bells should not exceed 6 lbs. weight. For lads, 4 lbs. will be sufficient.

BELLS. Taking Up.—Stoop, as shown in *Fig. 1*; seize both bells, recover upright position, and raise them above the head. Repeat, lowering the bells to the ground, bending the knees, and rising on the upright position (*Fig. 1*).

Fig. 1.

Fig. 2.

CIRCULAR MOVEMENTS.—First with one and then with the other, and finally with both at once, will be understood by an examination of *Fig. 2*. These are succeeded by various elbow exercises—the forearm thrown out or raised, and brought slowly back, the other arm swerving in like manner, and then both arms together.

HORIZONTAL AND SLANTING PLANES.—Stand with arms extended over the head, bend gradually down, keeping the arms extended; then slowly resume upright position, and bend to the other side. (See *Fig. 3*).

MANTLET.—From the position shown in *Fig. 4*, swing the arms and meet the bells behind the back. After practice you will be able so to

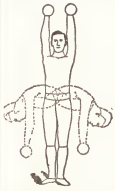

Fig. 3.

Fig. 4.

swing arms and clap palms of hands together behind the back without dumb bells.

SHOULDER FEATS.—Stand erect, holding the bells at the chest. Step out to the side, extending the arms horizontally. Regain first position, and repeat the movement on the opposite side. Vary the movement by stepping to the front and to the rear. (See *Fig. 5*).

Fig. 5.

SPREAD ARMS AND HEAD SWING. — These movements are shown in the illustration. Move the arms in graceful sweeps and curves, so as to avoid collision. The elbows should be close to the sides at the starting of each movement. (See *Fig. 6*).

Fig. 6.

Fig. 7.

THRUSTING OR STRIKING MOTION. — At

starting keep the elbows close to the sides; bend the right arm, and hold the bell to the chest; at the same instant raise the left high above the head. Reverse the arms, and repeat the motion as shown. Repeat the exercise again and again, till perfect. (See *Fig. 7.*)

Indian Clubs.

The beginner should use light clubs at first. In using them, the chest is expanded, greater freedom given to the arms, the muscles of the whole body brought into use, the wrist strengthened, the grasp of the hand made firmer, the circulation of blood regulated, and health greatly improved. The clubs should be grasped on the outside, palms turned in; position upright, heels together, arms down, head erect; clubs held an in. or two from the ground (*Fig. 1*).

Fig. 1.

From this position the clubs are raised horizontally, sideways, first right and then left, and then together; moving them to the left and right until about 6 in. apart.

BENT ARM EXERCISE. — Start from the first position—*To Order*—one or both clubs; and on the words, "To shoulder up!" bring the left hand club as seen in *Fig. 2* and keep it perpendicular. Perform the same movement with the other hand, and so alternate the motions. From this position you can thrust out, forward or

Fig. 2.

Fig. 3.

sideways; always with club straight. After the clubs have been raised forwards or sideways, before and behind, shifting the feet as needed, you can bring them to the front, and repeat the performance. In thrusting forward, the tops of the handles should nearly meet in front of the chest. Having brought the clubs above the head, drop them backwards (*Fig. 3*). This, when efficiently performed, is an elegant exercise.

CIRCLING THE CLUBS.—This mode is attractive, especially in public exhibitions. *Fig 4* is one of the most effective methods. Hold the clubs *To Order*, and then circle them forwards, sideways and backwards, and to left and right in front of the body, the arms remaining straight, and steady; they can also be circled in contrary directions in front of the body, one to right and

Fig. 4.

the other to left. Beginning from *To Order*, the right club is moved first, and the left follows when the right is upright. Inside and outside circles are described by holding the clubs horizontally or sideways (*Fig. 5*). They are done first with one arm, then with both in the same direction, and lastly in contrary directions. An outside circle backwards by the right club is made by

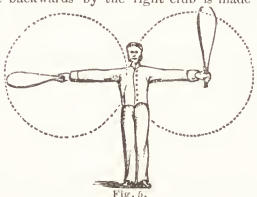

Fig. 5.

holding out the arms sideways, while the left describes an inside circle. The outside circles, with swinging forward, are shown at *Fig. 6*. At one, the clubs are raised to *A*; at two, circle backwards; at three, swing the clubs back to *B*; at one, again to *A*, and so on. The outside circles backwards, with swinging sideways, are shown in *Fig. 7*. At one, both clubs should be raised, twisting the body and bending the left knee; at two, circle backwards back; at three

Fig. 6.

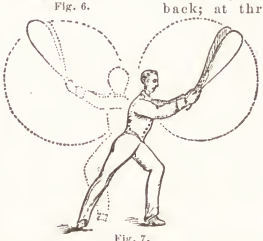

Fig. 7.

swing the clubs close in front of the body, twisting

the body in same direction, bending right knee; at four, circle backwards. Less attractive are the circles round the head. Starting from *To Order*, bring the left club, as shown in *Fig. 8*, and, without stopping, pass it by the back to its original position, as indicated by the dotted line. A similar performance is done with the right club, then both clubs alternately, and lastly both together. The body is bent forward. The circles in rear are done from the club above the shoulder. The club dropped to right or left describes a circle, passing close to the rear in a vertical plane. The back is hollow and the hand stationary. This circle should be practiced in rear, first with right club, then with left, and then with both simultaneously. When the latter exercise is done in the same direction (to the left or right) both clubs start together; but when the circles are made in a contrary direction, the second club only starts when the first has completed $\frac{1}{2}$ circle. Great regularity must be observed in describing circles, and no stoppages or jerks made. *Fig. 9* shows the circle in front, starting from the position with clubs above shoulder. In describing the circle the arm is stretched nearly to its full extent; but as the clubs swing round the arm bends by degrees until again in position above the shoulder from which it started, on the completion of the circle. This circle in front is done to left and right, alternately and simultaneously in the same manner as the circle in the rear. The above circles mastered, they should be

Fig. 8.

Fig. 9.

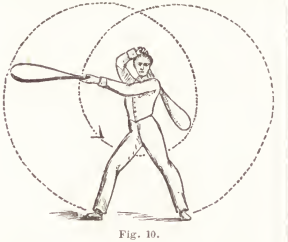

Fig. 10.

practiced in combination. Bring the right club up to the shoulder, describe a circle in rear, and follow up, without stopping, by a circle in front. When this is accomplished easily with the left and right clubs, raise both clubs to the shoulder, and while describing a circle in rear with the right, describe a circle in front with the left club (*Fig. 10.*) Circles above the head are done with an ordinary motion, and reversed. The clubs are raised above the shoulders, rather higher than for the circles in rear; the clubs are then swung round in an analogous manner to the circles already described. The back is hollow, and the performer looks up (*Fig. 11*).

Fig. 11.

HEAVY CLUBS. For Both Hands. — The men fall in at arms' length from each other, the club standing on the right side. On the words *clubs in front*, the clubs are placed in front between the two, and they are then ready to begin. The club is raised forwards horizontally above the head, and can be dropped behind the head. Of more value are the exercises which are struck with club. The club is raised above the head and struck downwards. The alternate bendings and stretchings of the legs are shown in *A B*, (*Fig. 12*). A variation of the above is the

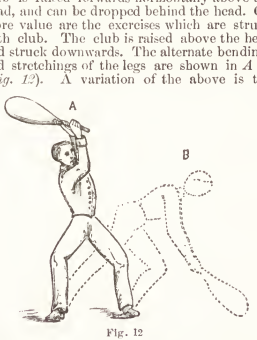

Fig. 12

sledge-hammer exercise. Instead of raising the club above the head, bring it over one of the shoulders, and deliver the stroke in the opposite direction, obliquely downward. Swinging the club in a circle over the head, and other exercises, can be practiced.

Fig. 13.

STRAIGHT ARM EXERCISE. — Raise the clubs horizontally in all directions. Forwards, diagonally forwards to the left and to the right, sideways,

and backwards. Both clubs can be raised to the side diagonally forwards or sideways, the body moving in the direction of the implements. Bring the clubs parallel to each other. Change from one side to the other by swinging the club down and up close by the legs; the arms kept straight (*Fig. 13.*) Next raise the clubs above the head, forwards, sideways, and to right and left alternately. (*Fig. 14.*) Having raised the clubs, swing them forward and backward, rising on tiptoe with every backward swing (*Fig. 15.*) Then move them horizontally, as directed. For the

Fig. 14.

Fig. 15.

circular motions (*Fig. 16*) form arms and clubs in one straight line. Then swing the right club

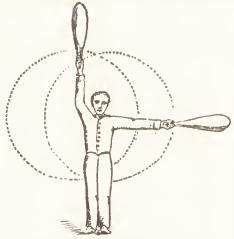

Fig. 16.

down, and round up. Follow it with the left hand club as soon as the right has completed 3 parts of the circle. Once in motion, swing the clubs in regular cadence. Many variations will suggest themselves. Both clubs may be swung in the same direction, or both in contrary lines, or each in a line of its own, taking care they do not clash; keep them parallel to each other, with both arms at their full stretch. Practice these, till you find you can perform them with ease and dexterity.

WRIST EXERCISE.—The arms are kept stationary, and the clubs moved by a turn of the wrist. Raise the clubs horizontally forward, and then drop them, in 2 motions, to the shoulders. At one they are to be raised perpendicularly; at two, they are to be dropped upon the shoulders. The same exercise may be performed with the clubs raised sideways (*Fig. 17.*) Variations of the wrist movements will suggest themselves, as grasping them in the front, swinging them to and fro, sideways, and so on (*Figs. 18* and *19*). The hands may be dropped, raised, again lowered, and reversed, according to the will of the performer, always keeping the clubs from contact with each other.

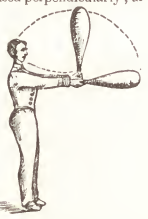

Fig. 17.

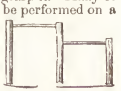
Fig. 18.

Fig. 19.

HORIZONTAL BAR.

Fix 3 posts, 1 lower than the other 2, in the ground, about 6 feet apart, and fix a bar between either 2 of them. One of the posts should be filled with notches to reach the top easily, or to descend. The bar at first should be placed just out of reach of the hands, so that a small spring is necessary to grasp it. Many of the feats here described may be performed on a swinging bar as proficiency is attained. At first the bar should be firm, and grasped with the hand, not with thumb and fingers. The thumb should rest by the side of the fingers, which should assume a hook-like form.



Horizontal Bars.

BREASTING THE BAR.—The first position is by taking hold with both hands (*Fig. 1*) of the side of the bar towards you, and raising yourself until you can look over it. Lower yourself gradually, and continue the exercise until it is easy and familiar. When it can be done easily, the body may be raised to the full extent of the arm (*Fig. 2*). This exerts the muscles and requires a strong effort. Raise the body as high as it is possible, throw the arms over the bar, holding firmly

Fig. 1.

by them (*Fig. 3*). This relieves pressure on the wrists, and is a useful exercise, particularly when

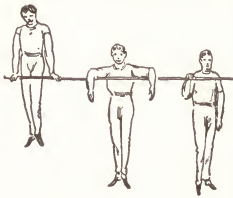


Fig. 2. Fig. 3. Fig. 4.

the body is raised from the ground, and is held up by one arm. To do this, the arm must be passed underneath the bar, which must be pressed firmly between the hand and shoulder (*Fig. 4*). Each arm should be tried alternately.

BRINGING THE BODY THROUGH.—1. Hang on the bar (*Fig. 5*), and gradually bring the legs up towards the bar; bend the knees, and pass them between the arms, under the bar, and allow the legs to pass through together with the body, which should fall as low as the arms will allow. Return through the arms again, without allowing the hands to loose their hold, or the feet to touch ground.

Fig. 5.

CIRCLING. — Pull the body up with the arms, and a slight motion of the wrist; carry the legs completely over the bar, and in going over they will act (*Figs. 6* and *7*)

Fig. 6.

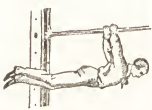

Fig. 7.

as a sort of balance to the body, and with the assistance of the arms, the body will be brought into the required position. For a young gymnast, fix the bar only about as high as his chin.

EVERLASTING TWIST.—Proceed as above, but in lieu of bringing the body again through the arms, let go one hand, when the body will swerve round; grasp the bar again, and repeat the exercise as often as convenient. If it be done 6 times without stopping, and always letting go the same hand, it will appear as if the arm was being twisted completely round.

HANGING BY THE LEGS.—Bring the legs through, and throw the legs over the bar instead of allowing them to fall toward the ground. Rest them, as shown in *Fig. 8*, bending them over the bar as far and as firm as possible; let go the hands, and allow them to hang loosely. After remaining in that position as long as convenient, bring the arms up, and by drawing the body up a little, grasp the bar again, and allow the body, after having unhitched the legs, to fall and drop to the ground, taking care to alight on the toes.

KICKING THE BAR.—Hang by the hands and draw up the feet slowly until the instep touches the pole. This is difficult, but is soon learned; do not kick or jerk violently.

Fig. 8.

LEVER.—This requires strength in the muscles of the arms, and is only to be achieved by practice. Go through the arms, keep the legs straight with the body, and gradually lower them until level with the ground. After remaining in that position a short time, drop to the ground, or carry the body back again through the arms; the latter preferred.

PANCAKE.—The bar should be placed about 2 ft. above the head of the gymnast, when standing on the ground. When the body has swung nearly as high as the bar, let go the hands (*Fig. 9*), and after bringing them smartly together renew the hold on the bar, and continue to swing.

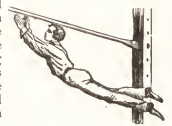

Fig. 9.

PANCAKE, To Turn.—Proceed as above, and when the body is in the forward swing (with the back toward the ground), give a smart turn, letting go the bar and grasping it again quickly, before the body has time to descend. After a little practice the body should be turned every time, thereby preventing it from descending in the backward swing; thus the gymnast has the opportunity of seeing which way he goes.

SITTING ON THE BAR.—When hanging on the bar, hitch one leg over the bar, the other leg hanging as low as possible (*Fig. 12*). Give a swing backwards and come up right on the bar. The other leg can be brought over so as to sit on the bar. The same attitude is assumed by passing both feet under the bar and stretching them straight into the air (*Fig. 10*) until the head points to the ground, and the heels to the air. Draw yourself up until the weight of the legs and feet brings you upon the bar seated (*Fig. 11*).

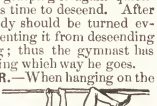

Fig. 12.

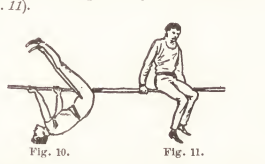

Fig. 10. Fig. 11.

SPINNING.—Assume the position shown in

Fig. 13, and try to turn round the bar. When you can do this easily, try the reverse way: bring the legs backward over the bar and spring in the Indian Cradle position (*Fig. 14*).

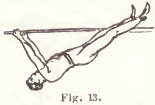

Fig. 13.

Fig. 14.

SUSPENDER.—Stand under the bar and grasp it with both hands, one on either side, and with a sudden spring throw the right leg over the bar towards the left; then place the toes of the left foot under the bar; then let go the hands, and allow the body to lower itself as much as possible, remaining in that position as long as convenient. Repeat the exercise by reversing the position of the legs. Keep the legs under the bar straight.

SWINGING. — Hang by the hands about the middle of the bar, move the legs and body to and fro as if on a common swing (*Fig. 15*); after a little practice the body will rise level with the bar. Swing to and fro about a dozen times, and in leaving the bar do so in the forward swing and alight on the toes. The farther the gymnast can alight on his feet from the bar, the greater his after success, and the more graceful his performance. Avoid jerking the legs in swinging.

Fig. 15.

WALKING.—Spring up from the floor and grasp the bar, fingers and thumbs on outside (*Fig. 16*). Keep arms straight and let the body depend from them in an easy and unconstrained manner, with the legs stiff and the toes pointing outward and downward. Now move, or, as it is called, "walk," along from one end of the bar to the other, one hand at a time. In this exercise you slip or press the hands forward. In dropping from the bar, take care to alight on the toes.

Fig. 16.

PARALLEL BARS.

THE bars should be about 7 or 8 feet long, and 4 feet high; smooth, rounded and strong. By their use the muscles are admirably developed. Ease and dexterity in their use, all come with practice.

BARS, To Get On.—Grasp the bar round the end, fingers outside and thumbs inside, and arms slightly bent (*Fig. 1*). Then spring up from the ground, keeping the arms perfectly straight. Practice till it can be done with ease.

BARBER'S CURL.—Stand between the bars, and sink down until the head is below the bars. Grasp the bars with the hands, and straighten the knees into a sitting posture, forming the letter L; then bring the legs gradually over between the arms (*Fig. 2*) till they form a circle, or come nearly down to the ground (*Fig. 3*); after staying thus for a short time, bring them back again slowly. The knees must be kept straight during this exercise, and the feet off the ground.

Fig. 1.

FORWARD SOMERSAULTS. —Generally performed at the end of any other exercise which brings you to the end of the bars. When the end of the bars is reached, with the hands firmly grasping the ends, lean a little forward and bring the body into an upright position, with legs bent over the head (*Fig. 4*), and in so doing bend the arms, causing the shoulders to come between the bars; bring the legs over; when nearly overbalanced, give a light spring with the wrists, and let go the hold of the bars, and alight on the feet; a slight swing will carry over the legs better, but the swing must not be too strong, or the head will go farther than is required.

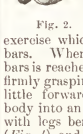

Fig. 2.

Fig. 3.

Fig. 4.

HOPPING. — Jump along from one end of the bars to the other, springing up, and taking rather short leaps (*Fig. 5*).

JANUS.—Mount between the bars in the middle, and throw a leg over each in front of the hands. Grasp the bars firmly, and, with a spring, bring the legs between the bars, and carry them behind; but cross the legs (*Fig. 6*), and in giving the body a slight twist, allow them to rest on the bars, when the right leg will be on the left-hand bar, and the left leg on the right-hand bar (*Fig. 7*). Do not always turn your body the same way, or let the same leg be always uppermost in crossing them. Repeat 5 or 6 times successively.

Fig. 5.

Fig. 6.

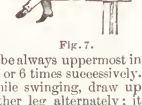

Fig. 7.

KICK OR SPUR.—While swinging, draw up both legs at once, or either leg alternately; it should be done in the back swing, and when the

legs are high above the bars. The sudden motion of the legs is likely to throw the body a little out of balance, but grasping the bars firmly will prevent it.

LEGS, To Bring Over.—Grasp the bars firmly, swing between the bars, and with a gradual motion throw both legs over the right-hand bar. (*Fig. 8*). With a sudden spring bring the legs

Fig. 8.

Fig. 9.

between the bars again, and throw them over the left bar.

LONG LEAP.—This exercise requires great strength. Swing the body at one end of the bars (*Fig. 9*), and, with a spring, jump to the other end, which must be done in the forward swing.

LONG RUN.—Get at one end of the bars with bent arms; let go the bar with the right hand, and balance the body with the left. Bring the right arm straight down by the side, and then grasp the other bar about 18 inches forward (*Fig. 10*). Now, raise the body into position; sink down with the arms in this stretched position, and bring the body close to the right side;

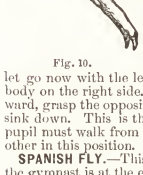

Fig. 10.

let go now with the left hand, and balance the body on the right side. Bring the left arm forward, grasp the opposite bar, raise the body, and sink down. This is the "long stride," and the pupil must walk from one end of the bars to the other in this position.

SPANISH FLY.—This is a brilliant finish when the gymnast is at the end of the bars. When at the end of the bars, place the hands over the ends, swing to and fro twice, making the back swing last, which must be made much higher than the bars; then open the legs, carry them over both bars, and by letting go your hold, alight on the ground. In flying over the ends of the bars, let the body lean forward, assisted with a spring of the hands, giving courage to let go, and a better method of bringing the legs together again. The greater the impetus used in swinging, the greater will be the success.

STANDING ON THE BARS.—Place your hands on either bar, spring with your toes, and throw the right leg over. Bring the other leg up, and hitch the toe under the bar; lean the body forward, with the arms extended in front to balance yourself, then bring the other (right) foot on the bar, as close as possible to the body, and by means of the toe under the bar, raise your body up so as to stand on the right leg. Do not unhitch the toe until you are firmly standing on the bent leg. Now lower yourself again, taking care how you slide the toe along under the bar, and to maintain a good balance.

SWINGING.—To get freedom in the arms and wrists, while suspended between the bars, swing the legs and body to and fro; little at first, for safety (*Fig. 11*). The legs must be kept close together, and straight. In

Fig. 11.

increasing the swing, the legs must be made to do their utmost in the forward and backward swing, and the feet carried as high as the head (*Fig. 12*). In the backward swing the body will be parallel with the bars (*Fig. 13*).

Fig. 12.

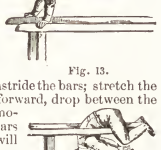

Fig. 13.

TURN-OVER.—Sit astride the bars; stretch the hands in front, fall forward, drop between the bars with a quick motion, and grasp the bars behind you, which will cause you to release your hold with your legs (*Fig. 14*), and by bringing them together directly they are free of the bars, they will drop between them, when you may alight on the ground. Try it slowly at first, and do not attempt to let go the bars with your legs until your hands have a firm hold, or when sure of not making a false aim at them. Gradually increase the quickness of the motion until you can achieve it without any pause.

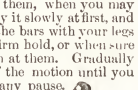

Fig. 14.

WALKING.—Bend the arms slightly, and incline the body forward, keeping the head back and the toes pointing down (*Fig. 15*); in this position jump along from one end of the bars to the other, raising both hands from the bars at the same time. Do not try at first to swing forward so much as in an upward direction. Spring well up.

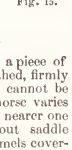

Fig. 15.

WOODEN HORSE.

FOR this exercise it only requires a piece of the trunk of a tree, barked and smoothed, firmly fixed on 4 posts, or legs, so that it cannot be pushed over. The height of the horse varies from the waist to the nose. A little nearer one end than the other, a rough, stout saddle should be placed, with wooden pommels covered with leather; the hind pommel higher than the other. On the off side of the horse a sawdust bed, 4 ft. sq., should be made, on which to alight. On the near side a spring board. A slight covering of sand on the near side is absolutely necessary to avoid slips in taking the leaps.

EXERCISE 1. — Grasp each of the pommels, thumbs inside and fingers outside (*Fig. 1*); spring up from the toes, and vault the horse over the right side, then over the left side.

EXERCISE 2. — Grasp the pommels. Now spring up and vault, allowing the left leg (bent) to go between the hands, and carrying the right leg (straight) over the head of the horse (*Fig. 2*). Proceed as above, but bring the right leg up and straighten the left, alighting on the opposite side of the horse.

Fig. 2.

Fig. 1.

EXERCISE 3. — Grasp the pommels. Now spring up to position *Fig. 3*, and carry the legs between the hands (*Fig. 4*), keeping the toes down, and alighting on the toes on the opposite side (*Fig. 5*).

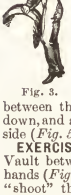

Fig. 3.

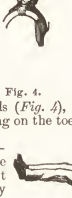

Fig. 4.

Fig. 5.

EXERCISE 4. — Vault between the hands (*Fig. 4*), but "shoot" the body well off from the horse as in *Fig. 6*. Hollow the back.

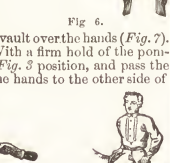

Fig 6.

EXERCISE 5. — Lay hold of the pommels, spring up, part the legs and vault over the hands (*Fig. 7*).

EXERCISE 6.—With a firm hold of the pommels, spring up to *Fig. 3* position, and pass the right leg between the hands to the other side of the horse. Sink down into bent arms (*Fig. 8*), rise to straight arms, and bring the legs up together to *Fig. 4* position, carrying the left leg in front and the right behind. This should be done quickly.

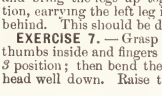

Fig. 7.

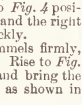

Fig. 8.

EXERCISE 7. — Grasp the pommels firmly, thumbs inside and fingers outside. Rise to *Fig. 3* position; then bend the arms and bring the head well down. Raise the legs as shown in *Fig. 9*; hollow the back, and do the somersault backward. Straighten arms, and alight on feet.

EXERCISE 8. — Sit on the horse at one side of the pommels (*Fig. 10*). Grasp the pommels and carry the legs over the end of the horse behind, and come into the same position on the other side of the pommels, then back again. This should be done quick.

Fig. 10.

EXERCISE 9. — For this exercise take the pommels off. Take a good run and jump the full length of the horse, grasping the horse a little above ¾ the length, and parting the legs as in *Fig. 11*.

Fig. 9.

EXERCISE 10.—Take a good run, but instead of jumping the full length of the horse, spring from the ground and let the hands be brought nearer to the end than as in *Fig. 11*; quickly hollow the back, bring the head well down, and carry the legs over the head (*Fig. 9*), throwing a somersault over the full length of the horse.

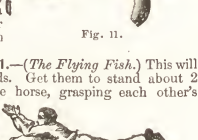

Fig. 11.

EXERCISE 11.—(*The Flying Fish.*) This will require 2 friends. Get them to stand about 2 yards from the horse, grasping each other's shoulders as in *Fig. 12*. Now take a run and jump over the horse without touching, head first, throwing the arms well up, and alighting in the arms of your friends.

Fig. 12.

Flying Rings.

The best rings are of wrought iron, covered with leather, 1¼ in. in diameter, and securely attached to the ropes by which they depend from the roof or a platform. Avoid home-made articles, and look especially well to the ropes.

EXERCISE 1.—Take each ring into the hands, thumbs inside. Hang by the rings and rise up to the position shown in *Fig. 1*. Hold well by the left hand, and carry the right out sideways (*Fig. 2*); remain thus a while. Bring the right hand back, and the same with the left. Repeat.

EXERCISE 2.—Grasp the rings with the wrists well up. Rise slowly to position *Fig. 3*; straight-

en the arms and come into *Fig. 4* position. Sink again into original position and repeat.

Fig. 1.

Fig. 2.

Fig. 3.

Fig. 4.

EXERCISE 3.—Hold the rings with stretched arms. Carry the legs up, drawing the body well together to *Fig. 5* position. Let the legs fall down backwards; hollow the back, and straighten the arms; keep the head well back; then fall into *Fig. 6* position. Raise the legs up to the back horizontal position and carry them between the rings again down to the first position. Keep the legs straight.

Fig. 6.

Fig. 5.

EXERCISE 4.—Carry the legs up to *Fig. 5* position. Place 1 foot in each ring, bring the head back, and twist the body coming into position (*Fig. 7*) with back bent. From this come back into *5*, or the feet can be loosed from the rings while in *Fig. 7* position, and the legs lowered as in *Fig. 6*, and then drop on the feet.

EXERCISE 5.—Swing well, keep the legs nearly straight, and when the body is at the forward position (*Fig. 2*) jerk above the rings (*Fig. 8*), keeping the head well back, back hollow, and toes pointing down. From *Fig. 8* position swing back; then lower and up forwards.

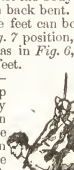

Fig. 7.

Fig. 8.

EXERCISE 6. — Swing well, rise above the rings forward (*Fig. 2*), swing back and lower, swing to the front again, and when at the back-swing rise above the rings again; swing up forward and backward alternately.

EXERCISE 7. — Hold each ring loosely, and stand under them. Quickly carry the legs up to *Fig. 5* position, and quickly part the legs, carry them over the hands (*Fig. 9*); let go the rings with the hands, alighting on your feet. Unless done quickly, the learner will fall unpleasantly. When this can be well done, try instead of alighting on the ground on the feet, to catch the rings with the hands. Repeat.

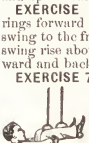

Fig. 9.

EXERCISE 8. — Stand under and grasp the rings loosely; bring the legs together, spring off the ground, carry the legs up, and separate them at same time (*Fig. 10*). As soon as the body gets in this position, nearly touching the rings, let go with the hands, throw the head back, and hollow the back, when you will alight on your feet. If not done quickly you will come down on all fours.

Fig. 10.

EXERCISE 9. — Grasp the rings firmly and carry the legs up as in *Fig. 5*. From this position let the head be brought back, back hollow, legs straight, and toes up. Now balance the body (*Fig. 11*). This may be done swinging, keeping the body and legs on a line with the ropes. From position *11* rise, bending the arms and keeping the legs up.

Fig. 11.

EXERCISE 10. — Swing well. Carry the legs up at the forward swing (*Fig. 2*) to position *5*. When at the back position with the legs up, raise the arms a little, hollow the back, and shoot the legs out backward (*Fig. 12*). Continue the swing to forward position, then raise the legs and repeat.

Fig. 12.

EXERCISE 11. — Hold each ring, carry the legs up (*Fig. 5.*) and hitch 1 foot in the ring; at the same time loose hold with the hand, and twist the body round in *12* position. Sink down into the straight arm, hollowing the back and keeping the leg straight. Rise with one hand to *13* position, and from here rise above the ring into the straight arms.

EXERCISE 12.—*Fig. 13* position, but grasping the rings with both hands, come down below the rings to stretched arms, keeping the foot in the ring. Twist round, coming again into original position.

EXERCISE 13. — Spring up and grasp the ropes above the rings, pull the body up and place the feet in the rings (*Fig. 14*). Grasp the ropes firmly, bring the legs up above the head, and carry them down backwards; dislocate; and come into first position (*Fig. 14*).

Fig. 13.

Fig. 14.

EXERCISE 14. — Grasp the rings and carry the legs up as in *Fig. 5*. Place the feet in the rings, toes pointing down, straighten the legs, lower the body, and hang by the toes. Then do

this exercise swinging. Raise the body, lay hold of the rings with the hands, and loose the feet.

EXERCISE 15.—Lay hold of the rings, bring the legs up (*Fig. 5*) and place the right leg over the right arm, left leg hanging down (*Fig. 16*).

Fig. 16.

Straighten the left arm, hollow the back, bring the body forward, and twist the body round, throwing the left leg backward over the right arm and leg, coming into the same position again (*Fig. 16*).

EXERCISE 16. — Stand under the rings and grasp them firmly. Keep the head back, and hollow the back, allowing the legs to fall gracefully down, toes pointing down. Raise the body from the ground (*Fig. 17*), and turn slowly round, head first, raising the legs and keeping the back hollow to position *18* down to position *6*. Slowly raise

Fig. 17.

Fig. 18.

the feet in the same manner round to the forward horizontal position. This requires great strength.

EXERCISE 17.—Position as in *Fig. 5*; carry the body a little further backward, and twist the body on to the right arm; hollow the back, and keep the legs straight; bring the head well back, and let go the ring with the left hand,

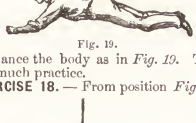

Fig. 19.

and balance the body as in *Fig. 19*. This requires much practice.

EXERCISE 18. — From position *Fig. 19*, al-

Fig. 20.

low the body to fall slowly forward (*Fig. 20.*)

EXERCISE 19. — Grasp the rings with the wrists high, muscle up, to *Fig. 3* position, and swing the legs up into the ropes backwards, head down, legs slightly bent, and feet touching the ropes (*Fig. 21*). Lower down to bent arms upon the rings, and raise again to stretched arms in first position.

EXERCISE 20.—From position *13* above the rings, which must be quite still, thumbs inside,

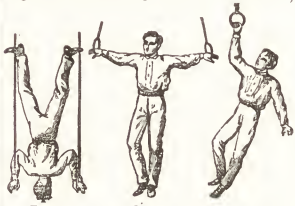

Fig. 21. Fig. 22. Fig. 23.

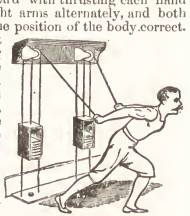
lower slowly down, stretching the arms out sideways (*Fig. 22*).

EXERCISE 21.—Grasp one of the rings firmly and hang at the full length of the arm (*Fig. 23*); now endeavor to rise up so as to touch the ring with the chest.

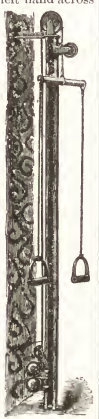
PULLEY EXERCISES.

CHEST WEIGHTS.—1. Grasp the handles, and stand away sufficient to clear the boxes from the rubber buffers. Keep the ropes straight, pull steadily, and do not allow the boxes to strike at top or bottom. The pulleys are placed shoulder-high for a variety of movements. If one foot is placed before or behind the other for a brace, change frequently, or the development will be one-sided. If the boxes strike at the top, step forward; if at the bottom, backward. Stand with feet together in executing forward and backward movements. — 2. Stand face out, handle in each hand, elbows close to the sides, knuckles of hand on line with chest, head thrown back; lean forward and backward with thrusting each hand forward to straight arms alternately, and both together; keep the position of the body correct. Now turn about face, standing with feet a little apart, braced; pull alternately, with the knuckles up, and bringing the handle to the shoulder at each time. — 3. Grasp the handles, and stand about 3 ft. from the apparatus, with feet together, holding the handles vertical; draw them back alternately to the sides of the body. — 4. Position as above,



Chest Weight Apparatus.

handles held horizontally; draw them alternately over shoulders with bent-arm movement.—5. Stand with back to the apparatus, and 2 ft. from it. Grasp the handles, thumbs out; bring the hands forward in a direct line, with bent-arm movement. —6. Position as above, with back to apparatus; bring handles to shoulders in a vertical position; then strike up and forward at an angle of 45°, keeping back and legs straight. —7. Face the apparatus, standing 3 ft. from it. Grasp the handles, hold them in a vertical position, thumbs up, and draw them alternately back to the sides of the body. — 8. Grasp both handles, and turn right side to apparatus; brace with the right leg, and draw the left hand across the body. — 9. Reverse of the above, with left side to apparatus.—10. Take a position facing the apparatus, in a bracing attitude; alternately pull handles to shoulders, with elbows pointing out.



Apparatus for Developing Muscles.

PULLING MUSCLES, Apparatus for Developing.—1. Grasp the handle with both hands, facing apparatus, arms straight, standing 30 in. from apparatus, feet together; bend trunk well forward, legs straight. Raise up, step back with right and left foot alternately, bend trunk backward, with an overthrow backwards without bending elbows, head bent back; hold in this position a moment; return to starting-point, bringing up the foot, and repeat. Use the apparatus suited to the strength of the performer. — 2. Stand with back to apparatus, heels touching foot-piece, arms raised overhead, grasping the handles; pull down without bending elbows, till the handle touches the body; return to starting position, and repeat.

ROWING MACHINE.—1. Body straight, facing apparatus; resist any tendency to bend forward; palms down, handles horizontal. Right and left alternately; begin with left; bring arm straight down at side, handle just passing the thigh. — 2. Sit on sliding seat, and place feet in the straps; knees bent till the seat is as far forward as possible; grasp the handle, throw back head and shoulders until handle nearly touches legs; straighten knees, and bring handle with straight arms over the knees; then, with bent arms, bring the handle nearly to the pit of the stomach, keeping the body, after first throwing back head and shoulders, a little back of perpendicular. Sit on the sliding seat, with toes in straps; slide forward and grasp handle, and pull it nearly to pit of stomach; then keep legs straight; lean forward until handle just passes the toes; then bring handle back, with straight arms, to pit of stomach, leaning back until the body is nearly horizontal. — 3. Sit on sliding seat, with toes in straps, hands on hips; lean backward at an angle of 45°; then come to perpendicular. After practicing, lean back till

Rowing Machine.

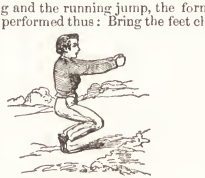
head touches the floor, with hands clasped behind neck.

JUMPING.

OF all corporeal exercises, jumping is most useful. To jump with ease and confidence, always fall on the toes, taking care to bend the knees and hips; the upper part of the body inclined forwards, and the arms extended towards the ground. In jumping, hold the breath, and be very careful that you never alight on the heels.

DOWNWARD LEAP.—Having mounted to the height from which you are to leap down, stand with feet together, toes pointing forward, not outward. Close the fists at the sides, and raise yourself gradually on tiptoe, bending the knees and raising the hands; on bending the third time, drop gently off the elevation, avoiding a spring, and, as you descend through the air, straighten the body, throwing the arms upward as much as possible. Directly the points of the toes touch the ground, bend the knees forward, to break the impetus of your fall. Take care to increase the height from which you leap gradually, and never attempt a deeper jump till quite perfect in the previous one. Another plan is to hang from the edge of the wall or bank, by the hands, which will lessen the distance of the leap.

HORIZONTAL LEAP. — This is divided into the standing and the running jump, the former of which is performed thus: Bring the feet close



Horizontal Leap.

together, bend the legs slightly, throw the arms forward, with the hands closed, at the height

of the shoulders. The bending of the knees should be repeated 2 or 3 times. When the right impulse is obtained, press the soles of the feet hard against the ground, and by a sudden and vigorous spring, extend the legs and arms at once; launch forward, alighting as far as possible on the toes. Care must be taken to bend the legs the moment the feet touch the ground after the leap, as this deadens the shock caused by the weight of the body on the feet. Begin with short distances; leap gracefully, gradually extending the distance.

RUNNING LEAP.—Start at a brisk pace, increasing as the point is neared; in reaching the point, jump without hesitation. On rising to leap, press the balls of the feet strongly against the ground, throwing the fists forward horizontally in the direction of the leap. On touching ground after the leap, the knees must be bent and the body thrown back. Two points are to be observed in jumping with a run: 1st, bound from the ground with as much force, and 2d, alight upon it with as little force as possible. Come down upon the ball of the foot, with toes and heels raised, then bring down the heels as the legs are straightened after the jump. In a horizontal leap, the jumper sometimes finds himself thrown unpleasantly forward, because he has not leaped high enough off the ground.

UPWARD LEAP. — Bring the feet close; close the fists, raising them above the head, and bend the knees 2 or 3 times to get an impulse. Jump suddenly from the ball of the foot (the heel not touching the ground), and as you rise, bring the hands rapidly down to your sides to give an additional impulse upward. Here the distance of the leaps must be increased gradually, as missing your tip, as it is called, may be unpleasant.

POLE-LEAPING.—The pole should be of hard, tough wood, and adapted to the strength of the person. The beginner may practice with a short pole, and without running. Hold the pole with the right hand above the head, thumb upward, and with the left hand at the height of the thigh, thumb downward; then start with a run, keeping the lower end of the pole in front of you. On reaching the edge of the ditch, or space you wish to jump, stick the end of the pole into the earth, and by a powerful spring raise the body, leaning the weight on the arms as you rise, making a half turn as you clear the space, and alight on the balls of the feet, on the other side, bending the knees to break the force of the descent. The longer the distance to leap, the nearer the top you grasp the pole, the distance between the hands and the lower end of the pole being the radius of $\frac{1}{4}$ circle, of which the feet in leaping describe the circumference. Low walls and fences may be jumped. It is necessary to lift the feet high, so as to clear the wall, and as you descend bring the upper hand smartly down, so as to jerk the lower end of the leaping pole upward, that it may clear the wall.

WRESTLING.

THE art of forcing an antagonist to the ground without resorting to blows, kicks, or any unmanly or unfair proceeding. The *Græco-Roman* style is much taught. In it the antagonists are not permitted to hold each other below the waistband, to throw by tripping, nor to turn back in the struggle. A distinction is made between full-hold and half-hold. In the former, both arms pass below those of the opponent; in the latter, one arm is passed above and the other below. The full hold is most advantageous, but in the half-hold both are on an equality. Sometimes they start with one and sometimes the other, facing each other, and endeavoring to obtain the full-hold; both are allowed to improve the hold, and the first full fall, when both shoulders touch the ground, gives the upper wrestler the victory. Another mode of wrestling is called *Catch as catch can*, in which all modes of attack or defence are fair except the following: The wrestler must not kick, strike or lay hold by the hair, flesh or clothes; he must not twist finger or arms, or make use of painful or dangerous grasps, nor get out of temper. If any of these be resorted to, the umpire must interfere, and the bout end. Whoever declines these restrictions is disqualified. In wrestling, either man going to ground so that both shoulders touch the floor, is declared thrown. This is the professional rule; the more usual one considers a wrestler thrown when he touches the ground with any part of his body, except hands, feet and knees. The wrestling position is, legs astride sideways, knees bent, hands on or in front of knees, with the thumbs outside, or held in front with the backs towards the body. Eye fixed on antagonist. The following instructions apply generally to both "Catch as catch can," and the *Græco-Roman* styles, with this exception, however: in the latter style no hold is allowed below the waist, nor tripping, nor using the legs in any manner.

Græco-Roman Style.

Wrestling Position.

HOLDS. — 1. Approach your opponent without getting into an erect position; place your right hand on his neck, looking over his right shoulder; then grasp his hand with your disengaged hand (*Fig. 1*). You are then on an equality. Close and wrestle. A common way to close is that adopted by boys; each taking the other by the collar of his coat, and endeavoring to throw him by tripping with the foot. The first fall completes the bout. —

Fig. 1.

2. (*Full-Hold.*) If it can be secured, the full-hold is advantageous (*Fig. 2*). The wrestler who keeps his back well bent is not exposed to risk

from this mode of attack. If such a hold be attempted, at the instant your opponent's hands are close to your loins, lower both arms, grasp the wrist of your left hand (the back of which is turned inwards) with your right hand, straighten arms and lean forward; you can press upon your antagonist's arms, and make him soon withdraw them. Allow him to do this to a certain extent, but as soon as you have space to turn in, give up the pressure suddenly, and catch your antagonist's right wrist with your left hand; turn to the left about, put your right arm round his neck or back, and throw him, as seen in illustration of *Head in Chancery*. Should he succeed in getting a full hold, so as to hug you close, you are almost certain to be thrown. But you may still save yourself by turning round during the fall. This is a favorite expedient to prevent coming down on the back. You may defeat his intention by keeping a firm hold of him till he is fairly aground. — 3. Place the right arm against the opponent's left arm; hook fingers, and press the back of left hand against his right loin; legs astride; left foot 24 in. in front, and weight of body resting principally on right leg. The shoulders must be squared, and the collar bones of both on same level (*Fig. 3*). To improve the hold, shrink the right breast under that of the opponent; tighten your arms round his loins, or pinion his right arm by pressing upon it with your left; then wrestle for the fall.

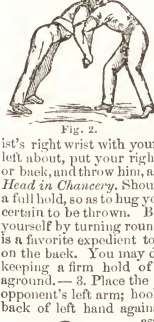


Fig. 2.

Fig. 3.

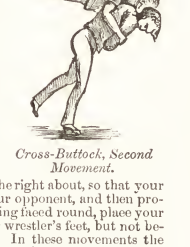
BACK-HANK. — The wrestler on one side makes a movement as if to give the buttock, and stands on the left of opponent; then raises his left leg backward, and passes it from the inside round his opponent's right leg to bring his instep in front of his shin. While effecting this he keeps nearly upright to prevent the other throwing him forward. Having attained this position, he turns suddenly to the left and forces his antagonist back and bears him to earth.

Back-Hank.

BACK-HEEL. — Pull your opponent towards you and put your left heel behind his right heel; then throw your whole weight upon him, at the same time forcing his foot up forward; then throw him backward. To counteract this the wrestler puts back his foot, or, if caught, tries to face while coming to the ground. The hank can be met with the right leg hipe. As soon as your antagonist advances his left leg to hank you, hipe him with the right thigh. *Hamming* is done similar to the back heel. Instead of passing your leg behind your opponent's heel, pass it behind his knee; this generally succeeds. To avoid it, get your leg out of the way; or, if your antagonist should raise his left leg, you can swing him round to the right.

Stopping; *Hamming*.

BUTTOCK AND CROSS-BUTTOCK.—These are similar, and succeed best with a slack hold. They are generally done facing to the right—the buttock; or to the right about—the cross-buttock. The wrestler suddenly turns or hoists to the right, so as to place the left hip against his opponent's middle. Then he pulls him close towards himself, stoops forward, and lifts him off ground. If he continue to turn round he will fall on his back. In the cross-buttock you face to the right about, so that your back is turned to your opponent, and then proceed as before. Having faced round, place your feet in front of your wrestler's feet, but not between them; tussle. In these movements the hands remain locked round the adversary's body, and shifted round according to circumstances. To save yourself from being thrown, hold firmly round the middle, crouch down and withdraw your head. On the other hand, if you fail in the buttock, you should try the look or back-hank. As soon as familiar with this, the technical terms will seem plain.



Cross-Buttock, Second Movement.

CROSS-BUTTOCK. — Starting from position, *Fig. 1*, shown in *Holds*, *A* places his right hand on *B*'s neck, and *B* puts his left hand on *A*'s neck, so as to leave *A*'s arm inside. *A* grasps with his left hand *B*'s right wrist. *A* now faces to the left about, letting go with the right hand, which he puts on *B*'s back, passing his arm beneath *B*'s left arm. Having a firm hold on his antagonist's right shoulder, or near his hip, he lifts him off the ground by stooping forward, and throws him. Having faced about, *A* must keep his legs astride in front of *B*. There are 2 ways of stopping the fall. As soon as *A* begins to turn, *B* places the knuckles of his left hand on his adversary's chest. If *B* is sufficiently nimble, he may throw *A*; all he has to do is to turn a little to the right, and place his left arm around *A*'s neck. The second way of stopping the fall is by putting your left leg over the left leg of opponent after he has turned round; this is a certain stop. To wrestle with advantage, practice con-

tinually, and without violence. *A* and *B* have the hold; *A* grasps with his left hand *B*'s right wrist; faces to left about, turning his back to-

Cross-Buttock; Arm Around Body.

Cross-Buttock; Arm Around Neck.

wards *B*'s chest, his legs standing in front of those of *B*, at the same time bringing his right hand round *B*'s neck. *B*'s right arm must be kept to the front; if *A* stoop forward *B*'s feet will leave the ground; and, with a swing and twist to the left, *A* throws him on his back. If done with energy, *B* will turn a somersault in the air; the cross-buttock will be completed. To stop this fall, as soon as *A* has faced about, *B* holds him firmly round the body with both arms; having thus insured himself against being thrown, it is advisable to let go, for there is little chance for *B* getting a throw.

Head in Chancery.

HEAD IN CHANCERY AND CROSS-BUTTOCK.—*A* and *B* place their right hands on each other's neck; *A* suddenly pulls *B*'s head towards him, and then brings it below his left arm-pit; then passes his left arm around his opponent's neck, and puts his right arm on his back. In this position *B* is helpless, for *A* presses upon him heavily, and prevents his freeing his head. Having kept his adversary for some time in chancery, the uppermost wrestler relaxes the hold of his left arm. The other withdraws his head; but on the instant *A* grasps his right wrist with the left hand, puts his right hand further round *B*'s back, faces left about, and throws him cross-buttock. To stop this, *A* disengages or twines his disengaged leg round that of his antagonist, so as to procure a double fall. Professionals make a sort of half turn in this fall, and occasionally succeed in getting the opponent beneath.

Withdrawing the Head.

LEFT-LEG HIPE.—Hug your opponent close; lift him off the ground and swing him round to the right, and turn in the same direction; then suddenly push or strike the inside part of his right thigh with the outside of your left thigh, and thus throw him off his balance; if the swing be strong, down he must go, with you on top. When the hipe does not succeed, change tactics, and try back-hank or buttock.

— *To Stop the Left-Hand Hipe.* As your opponent is about to insert his left leg, cross it with your right knee (shin), and when he attempts to lift you off ground, shrink your chest under him and get away. Previous to attempting to hipe you, he will slip in with his right leg; at that instant give him the back-heel with your right leg. Hiping is rough and dangerous, till you get used to the modes of attack and defence. The right-leg hipe exposes the wrestler to less risk than the left. There are other modes, as the right-leg stroke, right-leg hipe, etc.; but these are met by counter movements, as pushing with your left leg, putting it quickly down again, facing to the left, throwing him over the right buttock, etc.

Left-Leg Hipe.

LEFT-LEG STROKE. — Chip your opponent's right knee with your left leg, so that your knee is outside and your instep inside; then swing him round to the left. To stop this stroke, ham your opponent with your left leg. Some make this stroke outside the leg, instead of in and out.

Left-Leg Stroke.

LEG-HOLD.—If you maintain position shown in *Holds*, your opponent will not find it difficult to lay hold of your legs. *A* and *B* place their left hands on each other's neck; *A* grasps *B*'s right wrist with his right hand, and pulls him towards him. If *B* is induced to step forward with his left leg, *A* lays hold of it near the knee, pulls it up to the left, pulling *B*'s left arm to the right, or pressing upon the chest, he throws him on his back. Again, *A* and *B* place their right hands on each other's neck. Each endeavors to lay hold of his opponent's disengaged arm. Let us suppose *B* to have succeeded in grasping *A*'s left wrist; *A* lets go quickly with his right hand; with a push he releases his left, places it from the outside on *B*'s right shoulder-blade, and then takes hold of his elbow with his right hand. *A* now leans heavily on *B*'s right side, and to relieve himself, the latter grasps his assailant's fore-arm with his left hand; then *A* lays hold of *B*'s right knee with his left hand, lifts it up, and pressing his right fore-arm on *B*'s chest forces him down backwards. Once more *A* and *B* hold

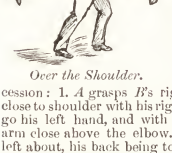
Leg-Hold.

each other by the upper arms. *A* pulls *B* towards him, and lets go suddenly; he instantly drops on his left knee, puts his head between *B*'s legs, which he grasps firmly; *A* lifts him off the ground, and throws him back. If done quick, it is often successful. To save himself, *B* leans forward, and seizes *A* round the body. There is great art in falling gracefully.

LOCK. — Put the left leg inside antagonist's right, or *vice versa*, and then bring him down.

RUSH. — *A* and *B* place left hands on each other's neck; *A* puts his disengaged right hand back, to induce *B* to catch it. In order to do this *B* leans to the left. At this instant *A* grasps with both hands *B*'s left upper arm; pulls him to the right, and simultaneously, his left shoulder in advance, he rushes upon *B*'s left shoulder, and forces him to the ground. To save himself, *B* places the back of his right hand upon *A*'s chest; he may then lay hold of his assailant's left leg with his right hand; the other secures himself by springing back. In this, all depends on quickness of eye.

THROWS OVER THE SHOULDER.—Only accomplished when players are about the same weight. From the hold *A* and *B* place their right hands on each other's necks. *A* grasps *B*'s right wrist with his left hand, pulls his arm down from the neck, and makes the four following movements in succession: 1. *A* grasps *B*'s right uppermost arm close to shoulder with his right. 2. He then lets go his left hand, and with it grasps *B*'s right arm close above the elbow. 3. *A* turns to the left about, his back being toward *B*, and places *B*'s arm on his right shoulder, as in illustration *Over the Shoulder*. Then *A* stoops forward and throws *B* on his back. This exercise should be thoroughly learned before being attempted in earnest. The defence to this is the same as that against the cross-buttock. Again, *A* and *B* take each other's neck as before. *A* grasps *B*'s left wrist further inside with his right hand, pulls down *B*'s left arm from his shoulder, rapidly raises it again, and grasps *B*'s upper arm from below. *A* now steps forward, left foot first, passes *B*'s left arm over his head, faces about at the same instant, and puts *B*'s arm on his right shoulder; *A* is then able to throw his antagonist.



Over the Shoulder.

TRIPPING-UP. — Place one leg behind your opponent's leg, and suddenly trip him forward, and force him down backward. When wrestlers face each other, the one who steps forward sideways to the left can put his right leg behind that of his antagonist; to avoid this, step back or meet with a counter-trip (*Fig. 1*). Another way is this: Suppose *A* places his right hand on *B*'s neck, grasping his left wrist with his own left hand. *A* pulls *B* obliquely to the left, taking a step with his right foot diagonally to the right, his right hand holding his adversary's right shoulder, the left grasping his left wrist, and his right leg behind the other's right leg; from this position the best man can force the other down backward (*Fig. 2*). Or *A* and *B*, standing as before, each with right hand on the other's neck; *A* grasping *B*'s right wrist with his left hand, and *B* doing the same to *A*. Both turn to the left about, and put themselves in the position shown in *Fig. 1*, in which case either has it in his power to throw the other. By putting your hip well under your opponent, you have the advantage (*Fig. 3*). In the struggle each man seems to have an equal chance; but one steps forward, puts his right foot behind that of his opponent, and by sudden movement of foot and arm, throws him.

Fig. 2.

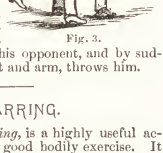

Fig. 3.

SPARRING.

SPARRING, or *Boxing*, is a highly useful accomplishment, and a good bodily exercise. It teaches to be on the alert with eyes, limbs and hands, and gives confidence.

Rules, etc. — Blows from the belt up, are fair, all others are foul; if a person is struck upon or below the waistband, his adversary loses the battle. Blows are of 4 descriptions; round, straight and chopping blows. The first are given by those not skilled in the art; the second belong to boxers, and form the surest mode, because a straight line will reach an object sooner than one that is circular. Neither of these ought to be constantly followed; aim those blows to which the adversary appears most exposed, and which the circumstances appear likely to render successful. The parts of the body and face which are subject to suffer by round blows, are the temporal arteries, the jaw bone, the glands of the ears, the ribs and the loins; those subject to straight ones, the eyes, nose, mouth, and pit of the stomach. In hitting, drive home by the full weight of the body, the hands tightly closed. In the left hand lead off at the head, the blow should be given with the upper knuckles. In leading off with the left hand at the head, the arm should be straight, with elbow turned under and palm up. For other blows the arm should

be slightly bent, the elbow pointing outwards and the palm turned half down and inwards. There are 4 hits: The left hand at the head; the left hand at the body; the right hand at the head; the right hand at the body. The best gloves for boxing are of soft leather and ventilated in the palms; backs of dressed sheep-skin, stuffed with hair. Should dirt get on these gloves, it is easily washed off with a sponge and some soap and water.

Left Hand Lead Off at Head.

Left Hand Body Blow.

Right Hand Cross Counter.

Right Hand Body Blow.

ATTITUDE, or GUARD. — Stand astride with the left foot about 20 in. in advance of the right; the toe of the left foot points toward the antagonist, and the right forms a nearly right angle with the left. The legs are slightly bent, and the weight of the body rests on both. The body must be kept erect and head thrown back. Both arms are then brought to the front. The left arm in advance, and its fist higher than the right. The elbows turned in, and close to the sides. The arms are moved to and fro in anticipation of a blow from the adversary. The fingers are tightly clenched, with the thumb doubled down over them outside. When striking, the muscles of the hand, arm, and entire body, must be braced up. At other times the fist remains clenched, but not tightly, to avoid fatigue. To bar a blow place your arm on the part at which it is aimed.

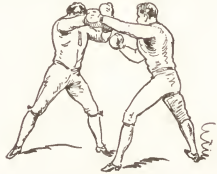
Both Men on Guard.

ADVANCING.—Move the left foot about 10 in. forward, placing it upon the ground, heel first. Let the right foot follow it in the same distance. The space between the feet should vary as little as possible.

BREAKING GROUND.—This term is applied to the usual method of retreat. In leading off at the head the right foot will be raised from the ground. As it is set down again and the weight of the body transferred to it from the left leg, spring backwards, letting the left foot touch the ground first, and alighting on the same spot upon which you formerly placed the right, which then assumes its natural position in the rear. It is necessary, if the opponent follows up very quickly, to double the step, that is, to make two consecutive springs backwards. For other blows, although the right foot is not raised from the ground at the moment of striking, the movements in breaking ground are precisely the same, for the moment the weight falls on the right leg, spring back as described above.

Breaking Ground.

CHOPPING BLOW.—A blow given downwards or sideways, on the face with the back of the hand. The power of striking this blow with dexterity often enables one to return with the same hand with which the hit of the adversary was parried. Thus, if struck at either side of the face,



Chopping Blow.

raise up your elbow, catch the blow on it, quickly bring round your arm, and give the chop. Whenever the elbow is pointed a little upwards it is a more favorable situation for striking the chopper than when your fist is raised up for it.

CLOSING, or GRAPPLING. — At the moment of grasping, throw your left foot behind your adversary's right, and attempt to fling his body over your foot. To prevent this he should remove his left leg from before his opponent's and place it behind, by which you stand in the dangerous situation from which he has just extricated himself. Remove your leg from before his, and put him in the same state he was at first. Then lose no time in throwing him, lest he should alter your respective situations again and throw you. Let one of your arms, instead of clinging round his neck, be against it in front, which, by pushing him from you, will contribute to pitch him over your leg more effectually.

COUNTER-HITTING.—Giving blow for blow, or anticipating a blow and paying it back. If your opponent is addicted to counter-hitting, your best plan is to draw him out by a feint, to parry, and plant a good hard blow in return.

DISTANCING.—Sometimes done by your having longer arms than your adversary, and thus keeping him off, sometimes by throwing your body on the hind leg when he strikes, and sometimes by retreating. Either of these methods is fair.

DRIVING.—A man is driven when he finds he cannot stand against his opponent, and is driven before him.

DROPPING.—Falling on your breech, knee or back, when your adversary strikes, or when you have struck at him and wish to avoid the return.

DUCKING.—Throwing the head on one side and slightly lowering the body, so as to allow

the blow intended for the head to pass harmlessly over the shoulder. Never duck without at the same time hitting. When opposed to a bigger man, fight at his body. There are five ducks: The duck to the right, as practiced when countering with the left hand on the head; the duck to the right, when intended to deliver a left hand body blow; the duck to the left while delivering a right hand cross-counter; the duck to the left, giving at the same time a right-hand body blow; the duck to right, which is sometimes used when leading off at the head with the left hand, in order to avoid a counter.

Lead-off with Right Hand at Head, and Duck.

FACE BLOWS. — Keep your fists near each other at some little distance from your body, as in the guard, except that your elbows are more inclined towards your side and that the flat part of your fingers is opposite your adversary. Then throw your arms one after the other in a direct line towards the centre of your adversary's face, first with your right hand, which is instantly to return to its former situation, and afterwards with the left, which is to return there likewise. Thus keep successively striking with each hand and recovering your guard, aiming your blows in a straight forward direction at his face, while he secures himself from being struck, by holding his head and stomach back, just far enough to prevent your blows from reaching him.

FEINTING.—A false attack made to divert attention from the real danger which follows. Its object is to induce the opponent to deliver a certain blow which it is your intention to counter; you do this either by feinting and enticing him to follow you up, or by laying yourself open with apparent carelessness to the attack which you wish him to make. When your opponent feints or attempts to draw you, either get back or guard both head and body.

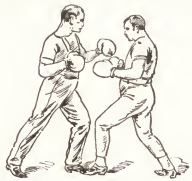
HEAD IN CHANCERY. — When in close quarters be on a look out to get your adversary's head in chancery. If it occurs, grasp him firmly round the neck with the left arm, and use the right to punish him.

Head in Chancery.

HEAD IN CHANCERY, To Get Out.—Push your opponent back, and at the same time fight with both hands. If the danger is discovered before the grasp has tightened, place one hand under his forearm near the elbow, the other under the shoulder, and push the arm up, ducking at the same time, and dragging the head away.

HITTING, To Prevent.—Bend the elbow quickly; place your fore-arm against his throat, and thrust his head back. Grasp left shoulder with left hand and seize left elbow with right hand.

IN-FIGHTING. — Half-arm hitting with both arms, when close to antagonist. Rely upon quickness in hitting, and do not pay much attention to guarding. Bring right foot forward until nearly in line with left; drop the chin and lean forward to receive the blows on forehead. Keep your eyes fixed on the antagonist. Use both hands and hit rapidly, bringing the shoulder well forward at each blow. The arms should not be drawn too far back; a great deal of the force of the blow is obtained by turning the body to right or left. Keep the hands close together, to have them inside those of the antagonist. Aim the left hand at the eyes and nose, the right at the chin or angle of jaw. Never fight at the body in in-fighting; make the head your mark.



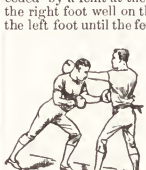
Getting Out of Chancery.

Avoiding Blow, Having Led Off and Passed Over Antagonist's Shoulder.

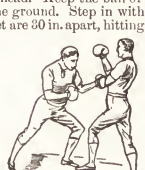
In-Fighting.

LEAD OFF AT THE BODY. To Avoid.—When attacked, retire a step, to take you out of distance; then, as your opponent is recovering guard, deliver a left hand hit at his face.

LEFT-HAND BODY BLOW.—Never attempt this without plenty of room behind you. Direct the blow at the pit of the stomach, and it may be preceded by a feint at the head. Keep the ball of the right foot well on the ground. Step in with the left foot until the feet are 30 in. apart, hitting out and ducking to the right. If the adversary try to counter you with



Left-Hand Body Blow.



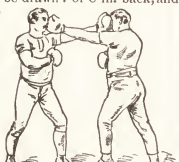
Guard for Left-Hand Body Blow, and Double Lead-Off at Body and Head.

the left, your head will be outside his arm, which will then pass harmlessly over your left shoulder. For this blow the arm should be bent, the elbow turned out, and the palm of the hand turned in and partly down. The right arm should be drawn back 7 or 8 in., and the glove held close to the side. To get away, turn the left heel out and spring back, taking care not to raise the head until out of distance.

LEFT-HAND BODY BLOW. Guard Against. — To guard the left-hand body blow, throw the left arm across the mark, and put up the right-hand guard, so that, should the adversary make the double lead off at the body and head, you are guarded. Hold the left arm firmly against the body. Step back 6 in. with the right foot, to be able to resist a rush.

LEFT-HAND FACE BLOW. — Having foreseen your adversary's intention, hit him full in the face with your left hand before he can get his head down. Keep your right arm in its original position across the mark.

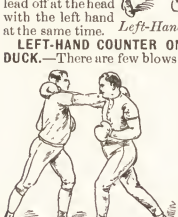
LEFT-HAND COUNTER ON THE BODY. — Delivered when adversary is leading off at your head with his left hand. Duck to the right, step in 12 in., and aim at the pit of his stomach. The right hand should be drawn 7 or 8 in. back, and held close to the side. To get away, turn the left heel out and spring back; do not raise the head until out of distance.



Left-Hand Counter on Head.

LEFT-HAND COUNTER ON THE HEAD. — This happens when 2 men lean off at the head with the left hand at the same time.

LEFT-HAND COUNTER ON THE HEAD AND DUCK. — There are few blows more startling than a good left-hand counter which meets you full-face. As your adversary leads off at your head with his left hand, duck to the right to allow his blow to pass over your left shoulder; step in about 12 in., and strike at his face. The right foot must not move.



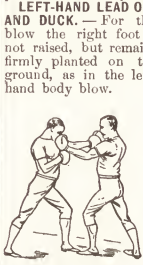
Left-Hand Counter on Head and Duck.

LEFT-HAND COUNTER ON THE HEAD AND GUARD. — The difference between this and the preceding counter consists simply in guarding your opponent's lead off, instead of ducking. You step in, and hit out as before.

LEFT-HAND FEINT AND LEAD OFF. — Feint a lead off with left-hand, to induce adversary to throw up his right-hand guard; should he do so, hit at the pit of the stomach. Should he not raise his right hand, follow the feint with a lead off at the head. Particular attention should be paid to the feet. Make a short step with the left foot (about 6 inches), as though going to lead off, then withdraw it, and suddenly deliver the blow. This movement requires practice, as it should be performed with rapidity.

LEFT-HAND LEAD OFF AND DUCK. — For this blow the right foot is not raised, but remains firmly planted on the ground, as in the left-hand body blow.

Left-Hand Lead-Off and Duck.

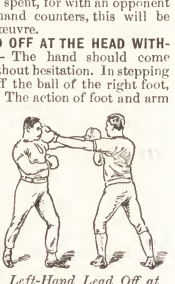


Left-Hand Lead Off.

Left-Hand Lead Off at Head and Guard.

LEFT-HAND LEAD OFF AT HEAD AND GUARD. — It requires practice to do this without detracting from the rapidity of your lead off; your trouble will be well spent, for with an opponent who attempts left-hand counters, this will be found a useful manœuvre.

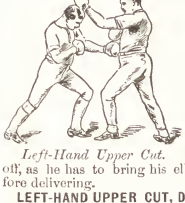
LEFT-HAND LEAD OFF AT THE HEAD WITHOUT GUARDING. — The hand should come straight out, and without hesitation. In stepping in push yourself off the ball of the right foot, and spring in 18 in. The action of foot and arm should be simultaneous. The lead off at the head with the left hand is the only blow delivered while the right foot is raised from ground. As you step in, the right foot should follow, and at the moment of striking hang over the spot formerly occupied by the left. When you step in, place the left foot upon the ground, heel first. If the toe touches the ground first, and your adversary gets back instead of guarding or receiving your blow, you do not meet with the expected resistance, and are apt to overbalance; and, until you can recover, you are at his mercy.



Left-Hand Lead Off at Head Without Guarding.

LEFT-HAND UPPER CUT. — This blow should be given when a man is leading off at your head while his left hand holds his head down. Guard your face with the right arm, step in 12 in., and hit up with the left. The arm should be bent, and elbow turned down. The force of the blow must come from the body. It is necessary to

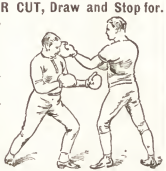
keep the elbows close to the sides, as by doing so the body is better covered when on guard; you are readier for hitting, and can hit straighter, quicker and with more force. A man who spars with his elbows stuck out makes two motions instead of one, in leading off, as he has to bring his elbow into line before delivering.



Left-Hand Upper Cut.

LEFT-HAND UPPER CUT, Draw and Stop for. — Feint a lead off at opponent's face with head down, then duck to the right, and give the left-hand body blow.

OUT-FIGHTING. — Out-fighting means long-arm hitting and guarding, and includes manœuvering for a hit with a readiness to guard.



Stop for Left-Hand Body Blow.

RIGHT-HAND BODY BLOW. — Aim a little below the heart; deliver under the same circumstances and in the same manner as the left-hand body blow, with these exceptions: Duck to the left instead of right, and the feet, when you have stepped in, should be 20 in. apart instead of 30. Have room behind for retreat. Should he attempt to put his left arm round your neck while

Right-Hand Body Blow.

Guard for Right-Hand Body Blow.

delivering this blow, duck to your right under his arm, and get away. This should be done when a man attempts to seize your head. When opposed to a man who stands with the right leg in front, duck to your left.

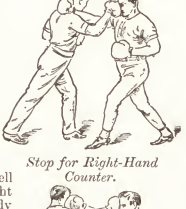
RIGHT-HAND BODY BLOW, Guard for.—Bring the left side forward and drop the left arm slightly bent so as to cover the side and front of the thigh. Press the arm close to the body, to prevent the jar of the blow.

RIGHT-HAND BODY BLOW, Stop for.—This is the same as that recommended for the left hand body blow.

RIGHT-HAND COUNTER, Stop for.—Duck your head to the left as you lead off.

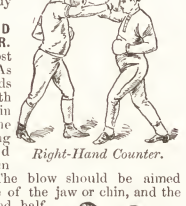
RIGHT-HAND COUNTER.—This occurs when both men lead off together with the right hand.

RIGHT-HAND COUNTER ON THE BODY. — Duck to the left to avoid opponent's lead off, and strike out with the right hand at a point a little below the heart. Draw the left hand back. In other particulars this blow represents the preceding. For this and the left hand counter it would be well to study the right and left hand body blows.



Stop for Right-Hand Counter.

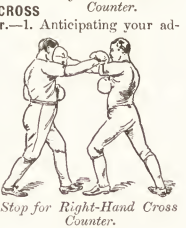
RIGHT-HAND CROSS COUNTER. —This is the most severe blow. As your opponent leads off at your head with his left hand, step in 12 in. ducking to the left, and shooting the right hand across his left arm and shoulder. The blow should be aimed either at the angle of the jaw or chin, and the palm of the hand half turned down. Let both feet be turned slightly to the left; as by this means the right side is brought forward, and greater force given to the blow. As the counter is delivered, draw the left hand back to position; then, should a second blow be necessary, deliver it.



Right-Hand Counter.

Right-Hand Cross Counter.

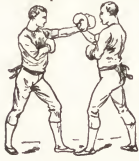
RIGHT-HAND CROSS COUNTER. Stop for.—1. Anticipating your adversary's purpose, hit him full in the face with the left hand before he ducks; or deliver the blow on the right side of his chest near to the shoulder, and his right hand will be stopped. — 2. As you lead off with your left, drop the head well forward, so that at the end of the movement your left ear will be touching the inside of your upper arm when the angle of your jaw and chin will be covered by your shoulder.



Stop for Right-Hand Cross Counter.

RIGHT-HAND GUARD FOR HEAD.—To guard the head from your opponent's left hand, raise

the right hand to a level and in front of the left temple. Let the fore-arm cross the face, and be thrown forward so as to turn the weight of the blow. Keep the elbow down. Close the hand firmly to brace the sinews, and turn the palm partly out, or the blow will fall on the bone of the arm; bend the head forward and to the right; thus, the face is well out of danger and you can see your opponent over the fore-arm.



Right-Hand Guard for Head.

RIGHT LEAD OFF AT THE HEAD.—Feint with the left, hitting opponent on right arm. Do not withdraw your hand, but as he raises his guard rest upon it with your left, and pin it to his chest; then bring in the right hand, aiming at the chin or angle of the jaw.

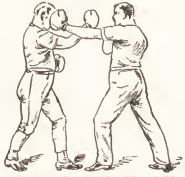
Right-Hand Lead Off at Head and Guard.

Right-Hand Upper Cut.

RIGHT LEAD OFF, AND GUARD FOR IT, AT THE HEAD.—Feint with the left, then bring in the hand, aiming it at the chin or angle of the right jaw.

RIGHT-HAND UPPER CUT.—With this exception that you do not guard, this blow is similar to and delivered under the same circumstances as the left hand upper cut, and the head slightly bent to the left.

Fig. 1.



Draw and Stop for Right-Hand Upper Cut.

RIGHT-HAND UPPER CUT, Draw and Stop for. — 1. Feint with the head as if it were your intention to lead off with it down, then throw the head back and lead off at your adversary's face with the left hand. — 2. Feint a lead off at your opponent's face with the left hand; then duck to the left and put in the right hand body blow. The position of the hand not absolutely in use should be noticed. Never drop your hands until out of distance.

Fig. 2.

Draw and Stop for Right-Hand Upper Cut.

RIGHT LEG AND ARM IN FRONT, Guard For. —Lead off with the right hand and duck to the left. When your adversary leads off with the right hand, duck to the left and counter either upon the face or body.

SHIFTING. — Resorted to, to get beyond reach of opponent. Standing on guard with left foot in advance as usual, place your right 20 in. behind it, changing guard at the same instant. Then put the right foot a step back, again changing guard; and so on continuously. Practice this in advancing.

Duck and Counter for Lead Off at Head, Right Leg in Front.

SIDE STEP.—Useful in avoiding a rush or in getting away when you are driven back against the ropes. Suppose you are in position facing the adversary; by a sudden movement of the feet half spring, half step, turn the body to the right, change the relative position of the legs, and assume the attitude of a fencer on the lunge, the right instead of the left leg in front, as is usual in boxing. The left should now be turned towards your adversary, the line of your feet being at right angles to the line in which they formerly stood. The left foot should be upon almost the same spot formerly occupied by your right foot. If the adversary advances hastily and without due caution, he is apt to trip over your left leg. Bring the left foot into position before the right and you will then stand a pace to the right of your original station. If executed rapidly you elude your opponent, and can easily get away from the ropes. A combination of the side step and breaking ground should also be practiced. Spring back as if breaking ground, and alight in the posture above described as that of a fencer on the lunge, with the body turned to the right, bring the left foot into position before the

Side Step.

right, and thus get back and work to the right of yourself at the same time.

SLIPPING.—This is a useful manœuver, which enables you to avoid a rush or get out of a corner. Feint a lead off, tapping your adversary lightly on the chest or right arm; do not retire, but as he comes at you duck to the right, make another step forward and pass under his left arm. To face him, again turn to the left.

Slipping.

FENCING.

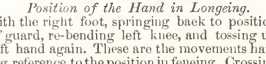
FENCING has become almost obsolete in America, except in a few circles, and it is not deemed advisable to give much space to it. Still, it is an admirable exercise, bringing into play most of the muscles of the whole body and limbs, and training to quickness of the eye and hand.

ATTITUDE.—Place your right breast opposite adversary, eyes fixed on his, right foot pointing to the front, the left to the left, at right angles; right heel in front of left ankle; body upright; hips drawn back without constraint; head erect; hands hanging easily, the left holding the foil as if a sword in its scabbard, convex side of handle up. Raise the right hand in front of body as high as the face, palm up, and bring it across to the hilt of the foil, which grasp lightly. Raise both hands above the head, separating them, so that the left hand holds the point of the foil. Bring down right arm with foil, until elbow is on a level with waist, and 8 in. in front of it; the thumb along the surface of the hilt; the fore-finger under the thumb; the point of foil as high as chin; and forearm and foil in a straight line. The left arm must remain in the position in which it held the point above the head, except that the palm of the hand is to be turned to the front. Then, without moving the body or neck, bend both knees as low as you can, and advance the right foot 12 or 14 in., so that the leg, from knee to ground, is perpendicular. You are on guard, the position from which attacks are made and parried. Short men should have the guard as high as their necks; men of middle height a little above the middle of chest; tall men the middle exactly. Regulate height of guard by that of adversary. Upon the hold of the hilt depends freedom of the wrist. The arm and hand may be turned and twisted, but no finger stir from the position. The foil must be held firmly; the thumb advanced along the upper side of the hilt, and nearly touching the shell; the fore-finger exactly underneath it; the others close up to fore-finger, not separated.

How to Hold the Foil.

ADVANCE AND RETREAT.—Take a short, quick pace to the front with right foot, not raised too high, but so as just to skim the ground. As the right foot touches, bring up the left the same distance, keeping the feet in their relative positions, *i. e.*, at right angles, and the right heel on a line with the left ankle. In the *retreat*, take a short, quick pace to the rear with left foot, and as it touches ground bring back right foot, planting it firmly on the ground.

LONGE.—Straighten right arm, raising the hand and depressing the point of the foil, until arm and foil form one horizontal line; and as you do this, turn the nails up. Then step forward 15 to 18 in. with right foot, and straighten left leg by pressing back the knee; not moving the left foot, but keeping it flat and firmly planted; then let the left hand fall to within a few in. of the thigh. Have a mark on the adversary's plastron to aim at; or, for self-practice, make a mark on a wall at the height of the centre of a man's breast. The lowering of the left arm is useful to preserve balance. To recover from the extended position, press the ground



Position of the Hand in Longeing.

with the right foot, springing back to position of guard, re-bending left knee, and tossing up left hand again. These are the movements having reference to the position in feneing. Crossing swords is termed the engagement. When your opponent shifts his blade into a new line, as from the inside to the outside, or *vice versa*, he disengages. In the engagement the sword should be held securely, without strain; but at the moment of parrying, the hold tightened. Simple parries are when, on the adversery's disengagement, your point is passed in direct course either from tierce to quarte, or quarte to tierce (high lines); septime to seconde, seconde to septime (low lines); or when the point is raised and lowered from high to low, or from low to high lines on the same side, *e. g.*, from quarte to septime, septime to quarte. Thus the simple parries always throw off the attack in the line it is directed. Counter-parries are when the sword-hand (in parrying a disengagement) describes with the point a circular course round adversary's blade, till it meets it in the line of the original engagement, throwing off the attack in an opposite line. This movement commences under the adversary's blade in the high lines, and over his blade in the low; from the engagement of quarte (the foils joined on the inside), on the adversary's disengagement the circle is described by lowering the point, passing it under his blade, towards the right, returning up, and resuming position of quarte. From the engagement in the other lines, the disengagements are parried on the same principle, as seen in diagram, where the arrow-heads denote the course taken by the foil. The counter-parry may be used to meet a direct thrust, without disengagement; in quarte, by dropping the point under adversary's blade and circling up, throwing off attack in the opposite line of tierce; in tierce, by throwing it off in quarte. Parries are termed semi-counters when, by a half-circular action, the attack is thrown off from a high line into the opposite low (quarte to seconde) or brought up from a low line into

the opposite high (as septime to tierce). As a general parry, a circular movement of the point in front of the body, from right to left or left to right (the hilt maintained at the centre), may be adopted. Two or more parries are often combined in continuous action, so that if the adversary's blade should be missed in one line it may be met in another. A simple parry is performed after a counter, or a round parry after a simple. All these parries are not of equal importance. Tierce, with its counter (or outer circle), and quarte, with its counter (or inner circle), should be principally employed. In parrying during the action of recovering from the longe, the outer circle is preferable to the inner. Other parries are variations of quarte and tierce in lowering or raising the point. The half of the foil nearest the handle is called the *forte*, the other half the *faible*. To constantly oppose the forte of your blade to the faible of your adversary is one of the secrets of fencing. Keep your wrist raised a little above your adversary's, so as to dominate his in the upper lines; in the lower lines, keep your wrist a little lower. The *Line* is the direction the foil should take for attack or defence, pointing to opponent's body, not extremities.

DEFENCE. — Pupil and instructor are on guard, opposite to one another at longeing distance; the blades of their foils joined on the inner line, touching but not pressing. The clearest description of the lines of defence is afforded by the diagram. A swordsman presenting his point to the front, defensively or offensively, may be attacked in one of the following lines of defence:

On the left of his sword-hand, beneath the hilt, the low inside line.
On the right of his sword-hand, beneath the hilt, the low outside line.
On the right of his sword-hand, above the hilt, the high outside line.
On the left of his sword-hand, above the hilt, the high inside line.

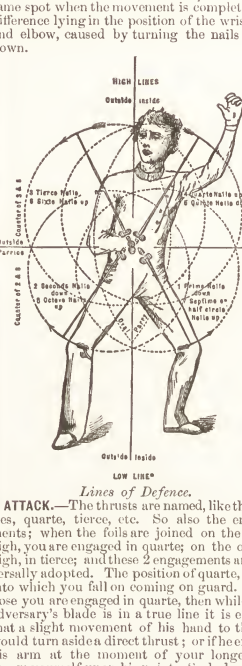
It will be seen that, with a sword of ordinary length, I only of these lines can be defended at a time, and the 3 other lines remain open to attack. For the defence of each line there are 2 parries; the sword being placed in a similar direction, the parries differing only in position of sword's edge, the sword-hand being held in the one case in supination (the nails turned up), and in the other in pronation (the nails turned down). These 8 parries are called:

Prime.	Quarte.	Septime (or half circle).
Seconde.	Quinte.	Octave.
Tierce.	Sixte.	

The allotment of these parries to the lines of defence is thus: From the centre of the breast, and with the elbow moderately bent:

1. Prime and 7. Septime (or half-circle).	The hand tending to the left, the point lowered and inclined to the left, the nails turned down. The same, but with the nails turned up and the arm elongated.
2. Seconde and 8. Octave.	The hand tending to the right, the arm straightened, the point lowered and inclined to the right, the nails turned down. The same, but with the nails turned up.
3. Tierce and 6. Sixte.	The hand tending to the right, the point raised and inclined to the right, the finger nails turned down. The same, but with the nails turned up.
4. Quarte and 5. Quinte.	The hand tending to the left, the point raised and inclined to the left, the nails turned up (slightly). The same, but with the nails turned down.

These parries are effected with the forte of the blade upon the adversary's faible, by a sharp bent or a simple pressure. In each of the 2 parries to meet the same attack, the foil blade follows the same line, so that the point is in the same spot when the movement is completed, the difference lying in the position of the wrist, arm and elbow, caused by turning the nails up or down.



Lines of Defence.

ATTACK.—The thrusts are named, like the parries, quarte, tierce, etc. So also the engagements; when the foils are joined on the inside high, you are engaged in quarte; on the outside high, in tierce; and these 2 engagements are universally adopted. The position of quarte, is that into which you fall on coming on guard. Suppose you are engaged in quarte, then while your adversary's blade is in a true line it is evident that a slight movement of his hand to the left would turn aside a direct thrust; or if he extends his arm at the moment of your longe, you throw yourself upon his point. Seek, by pressing with the forte of your sword upon the faible of his, to force it out of line. If he allow you to do this, his breast is exposed to attack, and a direct thrust will hit it without risk to yourself.

If your adversary obtains advantage in the engagement, and his sword commands yours, the direct thrust becomes impossible, and you must disengage to get an opening. The more completely his inside line is guarded (in quarte) the more exposed must he be on the outside line. Lower your point under his hilt, straightening your arm as you shift to the outside line, and longe like lightning. Rapid as you are, your adversary is as quick; his eye is fixed on your wrist; his foil touching yours, aids him to divine your intentions, and when you disengage he is ready with his parry in tierce or seconde before you longe. In this case you seek your opening for a second engagement, and hit him in quarte after all. This double disengagement is called the *one, two*, and is difficult to defeat with two consecutive parries; for the formation of the first leaves the breast so much exposed, that it is barely possible to form the second in time.

Binding.—In a counter-disengagement, your foil follows and avoids adversary's. When your blade clings to his, as it turns with it, in conjunction with the delivery of your thrust, it is termed *binding* his blade. The favorite attack on this principle is termed *falconade*, and the following directions will explain the principle: Draw your wrist sufficiently in towards you to oppose the forte of your blade to antagonist's feible; then suddenly bind your sword over his, and without quitting it bring your point in a line with his body under his arm, and immediately longe, strictly in opposition, which will here be in octave; the opposition being that of one blade against the other. If the swords are not in opposition, you cannot presage an attack, and are unable to insure against mutual hits. The change of engagement differs from a disengagement, as it is a shifting of your foil from one side of your adversary's to the other without straightening the arm; it is an attack upon his blade only. In the high lines it is performed by a circular movement which carries the point of your sword under that of adversary; in the low lines, by passing over the forte of his blade into the opposite line. When an adversary changes his engagement follow him, so as to prevent his gaining command of your blade; if he beat, do not change engagement, but disengage. During a succession of changes of engagement, be on the alert to parry. Feints are used to bring an adversary, who seeks an advantage by refusing his blade, to an engagement, or to draw him from his line of defence. They may be either offers of direct thrusts or disengagements without longeing. A beat is a sharp blow on the opponent's blade to confuse him, or throw his weapon off the line preparatory to a feint or attack. Frequent extension of the right arm without longeing is to be avoided.

Cut-over Point. — The attacks hitherto mentioned are directed either below the adversary's hilt, or to the side of his blade; there is another in which you seek to reach the adversary's breast by a whip over his weapon; raising your point, clearing his, extending your arm as your point descends, and longeing when it is extended, these motions being simultaneous, when you have learned to perform them. The action may be exemplified by taking a cricket stump, and fixing it in the ground by a downward throw. The action is that of striking, but the result is to fix the point in the spot aimed at. Never attempt the cut over in loose play until you are perfect at it, or you will slash your opponent over the arms and shoulders. The most dangerous moment for a fencer is that following an unsuccessful attack.

Ripost.—This is the return thrust, and more hits can be made by it than by any other form of an attack. Commence by paying attention to the formation of the parry, so that the attacking blade may be thrown out of line, and then, from the position of the parry, without longeing (the adversary's body being brought within distance by his longe), without movement but that of the sword-arm, thrust in return. As you acquire precision, make the ripost more rapidly, until that and the preceding parry appears almost one movement to a bystander. The ripost is generally delivered with the hand in supination, but when executed from a parry in which the nails are turned down, as from prime or seconde, there is advantage in keeping the hand in pronation during return thrusts. The ripost with a mere extension of the arm is not always feasible; the adversary, feeling his thrust parried early, may recover in time, and yet leave an opening; then the ripost must be accompanied by the longe. These ripostes, so deadly from their rapidity, are called direct; but if you are quick enough to seize the opening afforded by the adversary's attack, and find the line of direct return closed, make your ripost by disengaging, cutting over the point, or passing under the hilt, either with or without the longe.

Hand in Supination.

Hand in Pronation.

Remise.—When the original attack is yours and the adversary delays the ripost after having parried, you may repeat your attack while on the longe, without springing up to the guard again in the ordinary way.

Reprise. — A doubling of the attack while on the longe, but made without reference to opponent's play.

Time Thrusts.—Success depends upon their being timed exactly as your adversary is planning or executing an attack. You thrust in forestalling it, instead of turning it with a parry. Time thrusts are made in opposition (with the blades crossing) or out of opposition (with the blades not meeting). Those in opposition are least exposed to the danger of an exchange of hits, and of these there are 2, the time over the arm, and the time in octave. Time over the arm is applicable to all thrusts when the longe is made on the outside. Time in octave when the longe is directed to the inside of the body or under the arm. Time thrusts out of opposition are only employed where the adversary exposes himself, by exceeding wildness in attack, drawing back his arm to thrust, or longeing without straightening it. Even the legitimate time thrust, made

with the swords in opposition, is to be avoided unless you are sure of what you are about; for if you make a mistake a mutual hit is hardly to be avoided.

FIELD SPORTS.

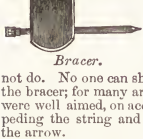
ARCHERY.

IMPLEMENTS.

ARROWS. — As much depends upon the arrow as the bow in making a successful shot. They are made of lancewood, pine, linden, ash and poplar; those without feathers will not fly true. For a bow 5 ft., 10 in., the arrows should be 27 in. in length. Ladies' arrows are generally 2 ft. long. The notches for the string in the tips are called hocks. The *Quiver* is a case generally of green tin, for keeping arrows in. The *Belt* is worn round the waist, and carries the arrows in use, a pot of grease, composed of beeswax and suet, and a tassel to wipe the dirt away from the arrows.

BOWS.—Bows are made from yew, lancewood and hickory. Those made of yew are unequalled in elasticity of pull, and freedom from tendency to kick. For beginners the best bows are self-bows, that is bows made from a single stick. Of this class the majority are of lemon wood and lancewood. The strength must be in proportion to that of the archer. An ordinary man will commence with a 50 lb. bow, and continue until he can draw a 75 lb. bow. A youth's or lady's bow should be from 25 to 40 lbs. in strength. Every bow has over the handle the number of lbs. it takes to draw the bow down to the length of an arrow, and is ascertained thus: The bow being strung is placed horizontally on a ledge; a scale is hooked on the string, in which weights are put, and that quantity which bears the string down till it is the length of an arrow from the bow, is its weight. The bow-string should be of flax or hemp; the latter preferred. The distance between the bow and string should be 6 in. at the widest part.

BRACER, or ARM GUARD.—A piece of heavy hard leather, 7 in. long and curved laterally to fit on the inside of the left arm from the wrist toward the elbow, and is fastened by 2 elastic bands, having rings and hooks. This is to prevent the blow of the sharp cord from injuring the arm or sleeve, and to allow the string to slide forward when it is struck, which the sleeve will not do. No one can shoot in comfort without the bracer; for many arrows will fall short that were well aimed, on account of the sleeve impeding the string and retarding the flight of the arrow.

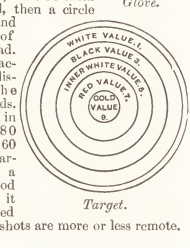


Bracer.

SHOOTING GLOVE.—Composed of 3 finger ends of thin leather, kept in place by strips branching from a broader part, strapped round the right wrist, for the protection of the fingers. The archer will also shoot with greater regularity and more accuracy who accustoms himself to shoot with it.

Shooting Glove.

TARGET.—The modern target is a flat circle of straw covered with painted canvas, the centre a circular patch of gilt, 7 in. across, then a circle of red and another of white, each of them 3½ inches broad, then a circle of black, 1½ in., and an outer one of white, 1 in. broad. It varies in size according to its distance from the archer. At 100 yds. it should be 4 ft. in diameter; at 80 yds., 3 ft.; at 60 yds., 2 ft. The target is fixed on a triangle of wood or iron, so that it may be elevated or depressed, as shots are more or less remote.



Target.

SHOOTING.

AIMING.—The first principle is to have the arrow, in drawing, directly under the right eye, and lying directly in the line of vision, as it looks at the point of aim. The bow being strung, take your stand in front of the target. Take an arrow from your quiver with the right hand (bow being held in the left). Grasp the arrow between the forefinger and middle finger, 6 in. below the feather. Holding the bow with the left hand horizontally across the body, with the upper limb to the right, pass the point of the arrow under the string and over the bow, until it projects 6 in. beyond the bow. Hold it there with the forefinger of the left hand, while you shift the right hand past the feathers to the nock. With the right hand turn the arrow till the cock-feather comes uppermost; then pass the arrow down the bow, and fix it upon the nocking-point of the string, exactly opposite that portion of the upper limb of the bow that joins the plush handle. The upper limb of the bow is made longer than the lower, that the arrow may slide on the upper limb, just above the plush handle. The archer should test the matter, and discover

that point of the string coinciding with this point of the bow, and then mark it with a little wrapping of fine red silk-thread; thus he will know the proper point for the arrow nock. The strings come wrapped for about 6 in. at the centre with black thread, to prevent the wear of the string. When this wrapping becomes loosened or worn, remove it, and take a silk thread rubbed with bees-wax; string the bow so as to hold the cord tight, and wrap the cord anew. Put the wrapping on in the direction of the twist of the bow-string. The ends of the thread should be drawn under the wrapping neatly. If the string becomes frayed, rub it with bees-wax. Every arrow describes in flight a regular parabola, and if the mark is 50 or more yards distant, allowance must be made for the falling of the arrow. No rule can be formulated to guide in this matter, for the elevation given to the arrow does not altogether depend upon distance. The strength of

Drawing the Bow.

the bow, the quickness of its cast, the weight of the shaft, the width of the feather, and many other things, affect the range of an arrow. The wind will increase the elevation of the bow-hand, if blowing hard along the range in the face of the arrow, and diminish the elevation for a shot in the opposite direction. Continual practice will enable the archer to raise his bow-hand instinctively to the proper elevation at any distance within the range of his bow. There are several causes for the wabbling of the arrow. One is the placing of the arrow-nock too low or too high on the string. If your arrow wabbles, place the next higher; if it continues to do so, place it lower. If, after many shiftings of the nock, the uneven flight continues, see if one of the eyes of the string is not awry in the nock. If the string is even, you are holding the string too high upon your fingers. Draw with the cord a little nearer the tips, and see if the flight is not true. Continue your examination into the causes of poor flight until you get at the truth. If the arrow does not fly perfectly steady, something is wrong. Although the feathers appear straight, yet they are not so, but are put on in a slightly spiral course, so that they turn as they fly, and this motion tends to keep them in a direct course.

ATTITUDE.—Never shoot with the right hand below the top of the right ear. It is easier for the novice to shoot with the right hand low, but he can never be a good archer shooting thus. Do not look at the arrow-head at the moment of loosing, to see if drawn too far, but depend upon your sense of touch. Keep your eyes upon the centre of the mark, and lose sight of all other objects. Do not attempt to take sight, but when the mind thinks that the arrow is properly directed, let drive. When the arrow is drawn to the head, loose at once. Fix your mind upon the matter in hand, so that the instant the right hand stops at the ear, the direction is found and the arrow gone. A second's hesitation will destroy the shot.

STRINGING THE BOW.—Hold the handle in the right hand, with the back of the bow towards you. Place the bottom horn against the hollow

Stringing the Bow.

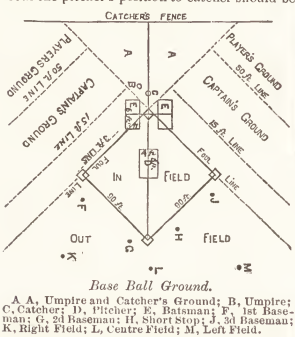
of the right foot, turning the latter so as to secure it, the left foot being advanced. Place the palm of your left hand on the upper end of the bow, taking the eye of the string between the finger and thumb, and slide it up towards the notch as you push with the left hand, and pull with the right till the string is in the notch. Make sure that it is firmly there, and not awry. Some use the left hand to pull at the handle with, and push the top of the bow with the right. Unstring in a similar manner. If the weather is cold, warm the bow before bracing it. If a powerful bow, you may not be able to put it in practice; then you may use your knee as a fulcrum, placing the bow across it with the lower horn in the ground, and the rounded inner side toward you, and pulling the top down with the left hand, while you nock the string with the right. Do not keep your bow strung; when not using, unstring it at once, even if only a few minutes are likely to elapse before you use it again. A bow kept braced too long will acquire a bend; this detracts from its strength. Rub the bow frequently with an oiled rag; the better the care, the better will be the results.

TARGET SHOOTING.—Target shooting is best

practiced by small parties of 4 to 8; 2 targets are needed, placed from 40 to 120 yds. apart. Each stand, properly placed, is called "an end." The proper number of arrows, as fixed by agreement, are then shot from one "end" to the other by each archer, when all walk to the other "end." Extract such arrows as are fixed in the target, gather up those that have missed, and then shoot back at the opposite target. This is continued until the whole number of "ends" agreed upon have been shot. Targets are made of plaited straw faced with canvas, and having a target face of muslin or linen upon the outside, painted with a gold centre, or bull's eye, and with 4 concentric rings from the bull's eye, in the following order: Red, white, black, white. In scoring, the gold counts 9; red, 7; the inner white, 5; the black, 3; the outer white, 1. Targets are of several sizes; but those 4 feet in diameter are generally used. When 4 ft. targets are used, the general distance for shooting is 60 yds., though many ranges are shot at 100 and 120 yds. If the archer is determined to become a good shot, the longer ranges he shoots the better. Target shooting is preferable to any other form of practice for the beginner, because he can keep his scores, and by comparison can discover just the extent of his daily improvement. A target card is carried at archery meetings—the ladies wearing it suspended from the waist, the men from a button-hole. On it the scores of the competitors are marked with pin-pricks, the columns being colored in correspondence with the target. When the number of arrows agreed upon are shot, the score is thus easily cast up. In target practice none but the best-footed, full-nocked arrows, with parallel points, should be used.

BALL GAMES.

BASE BALL. — A base ball field should be at least 500 ft. in length and 350 in breadth; the in-field level and covered with rolled turf of small grass and clover; the grass frequently cut so as to become velvety and close. The ground from the pitcher's position to catcher should be



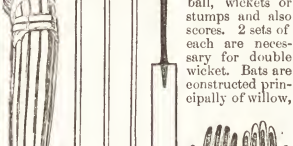
Base Ball Ground.

A A, Umpire and Catcher's Ground; B, Umpire; C, Catcher; D, Pitcher; E, Batsman; F, 1st Baseman; G, 2d Baseman; H, Short Stop; I, 3d Baseman; K, Right Field; L, Centre Field; M, Left Field.

bare, 8 ft. wide and laid with hard, dry soil, so as to throw off water, and the edge level with the turf border. The paths on the lines from base to base, 3 ft. in width, laid with hard soil, and a circle around each base. The in-field is marked off in the shape of a diamond, with equal sides, each measuring 90 ft.; bases are placed at 4 corners, so as to be distinctly seen by the umpire. The 1st, 2d and 3d bases should cover a space equal to 15 in. sq., and the home base 1 sq. ft. of surface. The 1st, 2d, and 3d bases should be canvas bags, painted white, and filled with soft material; the home base, white, of marble or stone, fixed in the ground even with the surface, and within the diamond. One corner of said base faces the pitcher's position, and 2 sides form part of the foul lines. The foul-ball posts are placed on a line with the home and 1st base, and home and 3d, and should be at least 100 ft. from the bases. On a line between home and 2d base, 50 ft. from the centre of the home base, is the pitcher's 1st point; the 2d point being 6 ft. farther on the same line. The following are the terms used in the game: A *fair ball* is a ball delivered by the pitcher wholly within the lines of his position and facing the batsman, and the ball passing over the home base at the height called for by the batsman. An *unfair ball* is a ball delivered by the pitcher as before, except that the ball does not pass over the home base, or does not pass over the home base at the height called for by the batsman. A *balk* is a motion made by the pitcher to deliver the ball to the bat without delivering it, except the ball be accidentally dropped; or, the ball be held by the pitcher so long as to delay the game; or, delivered to the bat by the pitcher when any part of his person is upon ground outside the lines of his position. A *dead ball* is a ball delivered to the bat by the pitcher, that touches the batsman's bat without being struck at, or any part of the batsman's person while standing in his position, without being struck at, or any part of the umpire's person, without first passing the catcher. A *block* is a batted or thrown ball that is stopped or handled by any person not engaged in the game. A *fair hit* is a ball batted by the batsman, standing in his position, that first touches the ground, the 1st base, the 3d base, the part of the person of a player, or any other object in front of, or on either of the foul lines, or (exception) batted directly to the ground by the batsman, standing in his position, that (whether it first touches foul or fair ground). bounds or rolls within the foul lines, between home and 1st, or home and 3d bases, without first touching the person of a player. A *foul hit* is a ball batted by the batsman, standing in his position, that first touches the ground, the part of the person of a player, or any other object that is behind either of the foul lines, or that strikes the person

of such batsman, while standing in his position, or (exception) batted directly to the ground by the batsman, standing in his position, that (whether it first touches foul or fair ground) bounds or rolls outside the foul lines, between home and 1st, or home and 3d bases, without first touching the person of a player. When a batted ball passes outside the grounds, the umpire shall decide it fair should it disappear within, or foul should it disappear outside the range of the foul lines. A *strike* is a ball struck at by the batsman without its touching his bat; or, a ball legally delivered by the pitcher at the height called for by the batsman, and over the home base, but not struck at by the batsman. A *foul strike* is a ball batted by the batsman when any part of his person is upon ground outside the lines of the batsman's position. *Play* is the order of the umpire to begin the game, or to resume play after its suspension. *Time* is the order of the umpire to suspend play. Such suspension must not extend beyond the day of game. *Game* is the announcement by the umpire that the game is terminated. An *inning* is the turn at bat of the 9 players representing a club in a game, and is completed when 3 have been put out. A *time at bat* is the term at bat of a batsman. It begins when he takes his position, and continues until he is put out, or becomes a base-runner. *Legal*, or *legally* signifies, as required by the rules of the playing clubs. The contestants include 9 on each side, one side taking the field, and the other side going to the bat. Their different positions are shown in the diagram. When the fielders have taken their positions, the pitcher delivers the ball in any manner the batsman demands—a high ball which is higher than the belt, but not higher than the shoulder, or a low ball which is not higher than the shoulder nor lower than the knee. If the batsman hits the ball and it is not declared foul by the umpire, he drops the bat and starts on a run to reach the 1st base, and, as he sees opportunity, the 2d, 3d and home bases. If he succeeds, without being put out, he scores a run, and the side scoring the greatest number of runs during the 9 innings, wins the game. If, before the batsman can reach a base, a fielder holding the ball touches that base or the person of the runner; or, if the ball, hit by the bat, is caught before touching the ground; or, if a foul ball be caught after touching the ground but once; or, if after the batsman has struck at the ball 3 times in vain, he fails to touch the 1st base before the ball is legally held there, he is declared out by the umpire. Each batsman is followed in rotation by the other batsmen of his side, until 3 are put out, when the field side takes the bat. A batsman becomes a base runner when 6, 7 or 8 balls, as required by the rules of his particular club, have been called by the umpire, and after 3 strikes have been declared. He is entitled to hold a base until he has legally touched the next base, or until he has been forced to vacate for a succeeding base runner. The 1st, 2d and 3d basemen must be sure catchers, swift and accurate throwers, and good judges of which base to send the ball to in order to put an opponent out, and must exert themselves to touch the person of the player while off base. The umpire is the arbiter of every point of the play, whether pitching, catching, fielding, striking or running. The catcher's duty is, when the striker has made the 1st base, to close up behind the bat to take the ball from the pitcher quick enough to send it to second base and prevent the 1st base from making 2d base. The pitcher must deliver the ball to the batsman, by toss, jerk, or over-hand throw, according to the demand of the batsman. His tactics should be to deceive the eye of the batsman as to where the ball is coming; and he should squarely meet and catch all balls hit straight at him. The short-stop is required to back up all the positions of the in-field and to catch over-thrown, or wide-thrown balls, to occupy any base player's position, while he (the base player) goes after the ball, and to intercept a ball thrown by the pitcher, and prevent the basemen reaching home. The out-fielders, right, left and centre, are to catch balls and return them to the pitcher or the basemen; and they should never hold a ball longer than necessary to handle it. Upon their good running, judgment, and quick returns of the ball depend much of the success of the game. The captain of each 9 is spokesman, and stations and directs the players. As each club or association has its rules, it is not advisable to give any one set, especially as the game is a modern one, with changing regulations from year to year.

CRICKET.—There are 2 forms of cricket, known as single and double wicket. Single wicket may be played by 2 or more players, but for double wicket 2 sides should be formed, each consisting of 11 players. The game should be played on smooth ground. The implements for single wicket are, a bat, a ball, wickets or stumps and also scores. 2 sets of each are necessary for double wicket. Bats are constructed principally of willow,

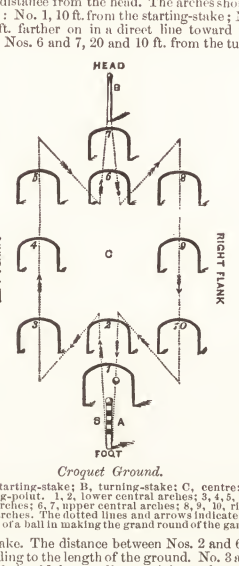


Leg Guard. Stumps. Bat. Gloves.

the handles being generally made of cane, or of willow spliced with cane or whalebone. Each wicket consists of 3 stumps, made of lancewood or ash, pointed at one end for insertion in the ground, and tipped with brass and grooved at the top. In the grooves at the tops of the stumps, are set, when fixed, 2 small pieces of wood, termed bails, their length being fixed at 8 in. For double wicket, the wickets are pitched opposite each other and 22 yds. apart. A line 6 ft., 8 in., in length is drawn at each wicket, the stump standing in its centre; this line is termed the *bowling-crease*. At each end of this line, short lines are drawn at right angles

behind the wicket, known as the *return-crease*. Within the spaces marked out by these lines, the bowler stands to deliver the ball. 4 ft. in front of the wicket and parallel to it and the bowling-crease, is another line of unlimited length, but not shorter than the bowling-crease, known as the *popping-crease*. Having chosen sides and tossed for innings, the players on the side which is out take their places, the bowler behind the wicket from which he intends to bowl, and the wicket-keeper behind the wicket opposite him. All the other men on the outside are called *fielders*, and consist of the long-stop point, cover-point, short-slip, long-slip, middle-wicket, long-field-off, long-field-on, and leg. When all are in their places, the players on the inside send out 2 batsmen, who take up their posts before each wicket respectively. One of the umpires calls "play," and the bowler delivers the ball towards the opposite batsman, so as to either hit the wicket, or that the batsman may play a catch; if either case happens, the striker is out. If the batsman hits the ball to such a distance that he is able to exchange places with the opposite batsman, he scores 1 run to his side. Every time an exchange occurs, a run is scored to the side which has the innings. The delivery of every 4 balls constitutes an "over," the bowling is transferred to the opposite wicket, and all the fielders change their positions accordingly. When a batsman is put out, another of the players on his side takes his place, and so on, till all but one are put out, when those who have had their innings field out, and those who have been fielding out take their innings. Each side has 2 innings, and that making the largest score wins. If the bowler sends a ball on the outside of the popping-crease at the opposite wicket, it is called a wide ball, and scores 1 to the inside. The bowler must also deliver the ball within 1 foot behind the bowling-crease; the ball must be bowled, not thrown or jerked, and the bowler must not raise his hand above his shoulder in delivering the ball. An infraction of these rules constitutes a "no ball," which scores 1 to the inside.

CROQUET.—This can be played only on level ground with an area of about 60 by 90 ft., provided with a shallow ditch around it to prevent the balls from straying. The lower part is the base, the opposite end the head, and the sides the right and left flanks. In the centre of the foot from whence the play begins, the starting-stake is set; and in the centre of the head is the turning-stake. There are 10 bridges, with a span of 12 in., made of iron wire, and stuck in the ground, leaving 6 to 8 in. above ground. The stakes are of wood, 2 ft. in length, and having 8 rings of different colors running down in this way—black, yellow, red, white, blue, orange, brown, green. It is from the starting-stake, through the bridges, touching the turning-stake, and from the other flank back to the spot, that the balls are driven by a mallet in the hands of the player. The balls are of wood, and painted to correspond to the rings on the starting-stake. This allows 1 to each player, though when 4 play they can use 4, or play 2 each. The distance from the starting-stake should be about 10 ft. from the base, and the turning-stake should have the same distance from the head. The arches should be set: No. 1, 10 ft. from the starting-stake; No. 2, 10 ft. farther on in a direct line toward the head; Nos. 6 and 7, 20 and 10 ft. from the turning-stake. The distance between Nos. 2 and 6 is according to the length of the ground. No. 3 and No. 10 should be on a line at right angles with Nos. 1, 2, 6 and 7, and in line with 2; and No. 5 and No. 8 in a like position with No. 6. Midway between 3 and 5, and 8 and 10, the two remaining arches are set. The precise place of the spot is one mallet's length behind arch No. 1. Another mode of setting the arches is the same as that shown in the diagram, except that the arches 4 and 9 are set at right angles, so as to have their edges presented to the arches immediately above and below them. The object of each player is to make the grand round, and strike out against the starting-stake. The course of the ball is, first from the spot, through arches 1 and 2, upward; then to the left flank in front of 3; through 3, 4, and 5; back to the line of the centre in front of 6; through 6 and 7, making the half-round. The stake is next struck; after which the ball runs back through 7 and 6, downward, or contrary to its previous course. Having re-run 7 and 6, it crosses over to front of the right flank arches, their front being the reverse to that of those on the left. It then runs 8, 9, and 10 downward; crosses again to the centre line above 2, and re-runs 2 and 1 toward the starting-stake. It has thus completed the grand-round; and being once



Croquet Ground.

more placed upon the spot, has the option either of striking out or continuing the play, with the privileges of the rover. As victory is not declared till all the friends of a side are struck out, striking out is delayed by each until the last of that side has completed the round. The striking out of a ball, while any of its friends are back in the game, is a serious loss to the side to which it belongs; especially since the rover is endowed with privileges which render him a valuable friend or a formidable enemy. 2 of the party, usually best players, are chosen chiefs, one for each side; these determine the first choice of players by a trial of skill. Each chief in turn plays a ball from the starting-point, and he who, with one blow of the mallet, drives his ball nearest the turning-stake, wins, and opens the game, and is followed by the chief of the opposing side, and the players on each side play alternately, in accordance with the colors marked upon the starting-stake. Each player continues to play so long as he drives his ball through the next arch in order, strikes the

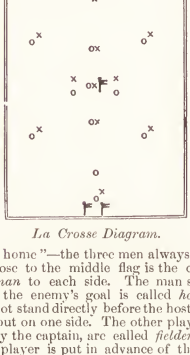
turning-stake in order, or achieves either roquet, croquet, or roquet-croquet, or a combination of 2 or more of these. Failing to accomplish either, he relinquishes his turn. Each player, at starting, places his ball a mallet's length in front of the starting-stake, opposite the centre of the first arch, and, holding the mallet with one hand, strikes.

FOOT-BALL. — There are two styles, one known as the *Rugby* game, and the other as the *Association* game; the former uses an oval ball, and the latter a round one. They are made of India rubber bladder covered with strong leather. In all games of foot-ball, the object is to drive the ball towards the opponent's goal, and score a "goal." The ground from goal to goal should not be less than 100 yds. in length, nor more than 200 yds. Its width from touch line to touch line should vary from 50 to 100 yds., according to length. The lines of touch are marked out by 4 flags for each line. The goal is formed of 2 upright posts, which, in the Rugby game, are joined by a cross-bar at a height of 10 ft., and in the Association game by a tape at the height of 8 ft. The aim in the Rugby is to drive the ball between the posts and over the cross-bar of the enemy's goal; in the Association, to drive it through the posts below the tape. 2 side-lines, called goal-lines, are drawn from each of the goals, and the boundary of the ground on each side is marked by a line called *touch-line*. The opposing players take position opposite each other at different ends of the field. The game is decided by the number of goals won in a certain time, which is divided into equal parts, after each of which the players change ends. The Rugby commences by a *place-kick* (kicking the ball when placed on the ground) from the middle of the field. A goal may be won by a *drop-kick* (letting the ball fall from the hands and kicking it the instant it rises) over the adversary's goal, or by a place-kick resulting from a *touch-down* (putting the hand upon the ball to make it dead) or a drop-kick over the adversary's goal, or by a place-kick, resulting from a touch-down or *fair-catch* (a catch direct from a kick, or a throw forward, or a knock on, by the opposite side). The touch-down is as follows: Any player who catches the ball before it has touched ground or on the bound, may run with it till he gets behind the adversary's line of goal, where he will touch it down as near as he can to the goal, if possible between the posts. This is called *running-in*, and secures the right of a place-kick at the goal, from any spot outside the goal-line in a straight line from where the touch-down was made. When the ball is touched down behind the goal line, but not near the goal, a different mode, called the *punt-out*, is adopted. When the ball crosses the touch-line at the side of the field, it is lifted and thrown out in a straight line, to be secured by either side. In the Association rules, holding or carrying the ball is prohibited, and no one is allowed to use his hands, except the goal-keepers, to protect the goal. Tripping and hacking is not allowed, and the game is milder than the Rugby.

LA CROSSE. — In this game the ball is not thrown by hand, but hooked up from the ground by a long stick of hickory, bent at the top, and across the hooked portion of which a net-work is formed of raw hide or dock strings. The ball is of India rubber sponge, 8 to 9 in. in circumference. 2 poles, surmounted by flags of different colors, are set up at each end of the field, and are called goals. The object is to drive the ball through the goal of the adversary. The players are distributed into pairs (a friend and foeman)

through the field; and it is better for the contestants to dress in contrasting colors, and to have their flags similar. 12 players constitute a full side, but fewer can play. No two of a side should be close together, except goal-keeper and point. The diagram shows the positions of the players, the marks O and × representing players of the respective sides: Goal-keeper, point, and

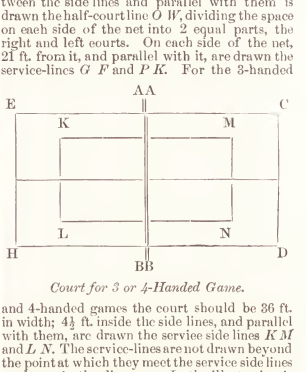


La Crosse Diagram.

hostile "home"—the three men always close to goal. Close to the middle flag is the centre or *facing-man* to each side. The man stationed next to the enemy's goal is called *home*; he should not stand directly before the hostile goal-keeper, but on one side. The other players, disposed by the captain, are called *fielders*. One forward player is put in advance of the centre flag, close to the enemy's cover-point. Each side has a man standing behind each facing-man, or behind its own facing-man, to take the ball from him if he succeeds in getting it away from his opponent. The players are supposed to keep to their stations, especially goal-keeper and point. Beginning near the centre of the field, the players struggle for mastery over the ball, and to convey it to the opponent's goal. When scooped up from the ground, it is carried horizontally on the crosse, the player running towards one of the goals. If possible, he pitches the ball off his crosse towards a colleague, in a better position to convey it towards the goal. The ball is not touched by the hand, except under special circumstances. If the ball be accidentally driven through the goal of the same side, the other side wins the game. The player must not strike, trip up, grasp another, nor lay hold of his crosse. Two on the same side may fling or carry the ball consecutively.

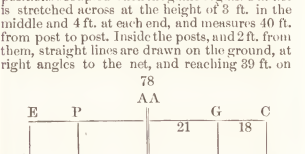
The Crosse, or La Crosse Stick.

LAWN TENNIS. — This may be played on a lawn of moderate dimensions by 2, 3, or 4 persons. For the single game, the court is 78 ft. long and 27 ft. wide. It is divided across the middle by a net, the ends of which are attached to 2 posts, *A A* and *B B*, standing 3 ft. outside the court on either side. The height of the net is 3 ft. 6 in. at the posts and 3 ft. in the middle. At each end of the court parallel with the net and 39 ft. from it, are drawn the base lines *C D* and *E H*, the ends of which are connected by the side lines *D H* and *C E*. Half way between the side lines and parallel with them is drawn the half-court line *O W*, dividing the space on each side of the net into 2 equal parts, the right and left courts. On each side of the net, 21 ft. from it, and parallel with it, are drawn the service-lines *G F* and *P K*. For the 3-handed



Court for 3 or 4-Handed Game.

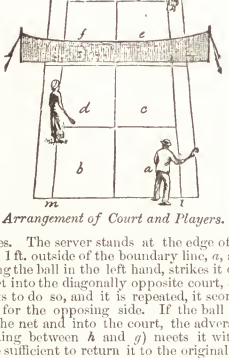
and 4-handed games the court should be 36 ft. in width; 4½ ft. inside the side lines, and parallel with them, are drawn the service side lines *K M* and *L N*. The service-lines are not drawn beyond the point at which they meet the service side lines as shown in the diagram. In the illustration is shown a lawn-tennis court, with 4 players in the positions occupied when the game begins. The net is stretched across at the height of 3 ft. in the middle and 4 ft. at each end, and measures 40 ft. from post to post. Inside the posts, and 2 ft. from them, straight lines are drawn on the ground, at right angles to the net, and reaching 39 ft. on



Court for Single-Handed Game.

each side of it. The ends of these lines are joined by 2 other straight lines, parallel with the net, the whole court forming a parallelogram, 78 ft. long and 36 ft. broad, divided into 2 equal parts by a line running lengthwise down it, so that there is a right hand court (*c a l*) and (*f k h*) and a left hand court (*d b m* and *e g i*), intersected by a cross line, 21 ft. from the net, called the *service-line*, which separates the ground on each side of the net into 4 courts. To make strokes more easy an inner line on each side of the ground is run across it parallel with the side lines, 4½ ft. from them, and at right angles to the net shown at *k m l i*. In a 4-handed game they cut off from the 4 inner courts, into which the ball is served from

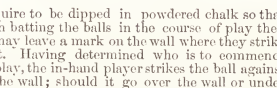
time to time, a part of the extreme portion, where it is easy to place difficult services. Unless the ball falls into the central part, it is a fault. In a single game, the lines reduce the size of court by cutting off the outer portion between them and what is in a 4-handed game the boundary. The choice by sides and right of serving during the 1st game is decided by toss; provided that, if the winner of the toss choose the right to serve, the other player has choice



Arrangement of Court and Players.

of sides. The server stands at the edge of the court, 1 ft. outside of the boundary line, *a*, and, holding the ball in the left hand, strikes it over the net into the diagonally opposite court, *b*. If he fails to do so, and it is repeated, it scores a point for the opposing side. If the ball falls over the net and into the court, the adversary (standing between *h* and *g*) meets it with a stroke sufficient to return it to the original server, who returns it at the first bound. The ball is thus returned alternately, until one makes a failure, either striking the net or sending the ball outside the opposite court, when it scores a point for the adversary. The person who begins to serve continues through the game. If the ball, in passing, strikes the net, it is not a failure, provided it falls in the proper court. The players change sides at the end of every set of games. When a series of sets is played, the player who was server in the last game of one set is the striker-out in the first game of the next. In the 2-handed game, the single player serves in every alternate game. In the 4-handed game, the pair who has the right to serve in the 1st game may decide which partner shall do so, and the opposing pair may decide similarly for the 2d game. The partner of the player who served in the 1st game serves in the 3d, and the partner of the player who served in the 2d game serves in the 4th; and so on the same order in subsequent games of a set or series of sets. The players take the service alternately throughout each game; no player receives or returns a service delivered to his partner.

RACKETS.—Usually played out of doors on an open space of ground bounded at one end by a high wall. The ground is marked out into 4 compartments or courts, so that there may be 2 courts adjoining the wall and 2 beyond. A broad white line is marked on the wall about 42 in. above the ground, and in play every ball struck against the wall should hit it above this line. The game is played by 2 or 4 players; in the latter case they form sides, 2 on each side. When only 2, each guards 2 courts; when 4, they each occupy a court, those nearest the wall being the in-hand, and those farthest from the wall the out-hand players. To strike the ball a light bat or *racket* is used. This consists of a frame-work of wood or cane, with a strong network of catgut, and provided with a handle. The balls are tennis balls, and should not weigh more than 1 oz. each. A large number are required; after being struck one or twice they re-



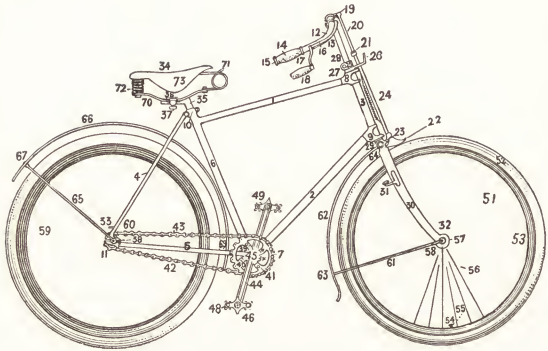
Racket for Throwing Ball.

quire to be dipped in powdered chalk so that in batting the balls in the course of play they may leave a mark on the wall where they strike it. Having determined who is to commence play, the in-hand player strikes the ball against the wall; should it go over the wall or under the white line, or rebound anywhere but in one of the outer courts, the striker is out, and the out-hand player takes his place. Should it rebound into one of the outer courts, the out-hand player must strike it against the wall above the line in such a way that it may rebound into one of the inner courts. Should he fail to do this, the in-hand player scores 1 point, and serves the ball again, and so on. Should the out-hand player succeed, the in-hand player must take the ball as it rebounds and strike it so that it may in turn rebound in one of the outer courts. The great object of the game is to strike the ball so that on its rebound in the legitimate court the opposing player may fail to strike it correctly.

GOLF.—A Scottish game, played with ball and club. The players number one or more on each side, and each is provided with a separate ball. The most skillful player is he who can land his ball in a given series of holes with the fewest strokes of his club. To place the ball in a proper position for striking off is called "teeing," and the plot in which the game is played is termed the "putting ground." The balls now used are generally made of gutta-percha. Golf may be practiced on any good stretch of meadow-land, where the grass is not too rank. Small holes, of about 4 in. diameter, are punched in the turf at distances indefinitely variable, but ranging from about 100 to 400 or 500 yds.; and from one of these holes into the next in order, a ball of about $1\frac{3}{4}$ oz. weight has to be driven with implements (clubs) of some variety devised for the purpose. These clubs may generally be shafts of wood with so-called *heads* of wood or iron attached.—1. *Mode and Order of*

Playing. The game is played by 2 persons, or by 4 (2 of a side), playing alternately. It may also be played by 3 or more persons, each playing his own ball. The game commences by each party playing off a ball from a place called the *tee*, near the 1st hole. In a match of 4, those who are opposed to each other, and to play off, shall be named at starting, and shall continue so during the match. The person entitled to play off first shall be named by the parties themselves; and, although the courtesy of starting is generally granted to old captains of the club, or members, it may be settled by lot or toss of a coin. The hole is won by the party holing at the fewest strokes, and the reckoning of the game is made by the terms *odds* and *like, one more, two more*, etc. The party gaining the hole is to lead, unless his opponent has won the previous match, in which the latter leads off, and is entitled to claim his privilege, and to recall his opponent's stroke should he play out of order. One round of the links, or 18 holes, is reckoned a match, unless otherwise stipulated. If, in a double match, 1 person shall play twice in succession, he loses the hole.—2. *Place of Teeing.* The ball must be teed not nearer the hole than 8, nor further than 12 club lengths, except where special ground has been marked by the conservator of the links, which shall be considered the "teeing ground," and the balls shall be teed with and not in advance of such marks. After the balls are struck off, the ball farthest from the hole to which the parties are playing must be played first. When 2 parties meet on the putting green, the party first there may claim the privilege of holing out, and any party coming up must wait till the other party has played out the hole, and on no account play their balls up lest they should annoy the parties who are putting. No player may play his teed ball till the party in front have played their 2d strokes. —3. *Changing the Balls.* The balls struck off from the tee must not be changed, touched or moved before the hole is played out (except in striking, and the case provided for by Rule 9), and if the parties are at a loss to know the one ball from the other, neither shall be lifted till both parties agree.—4. *Rubs of the Green.* Whatever happens to a ball by accident, such as striking any person, or being touched with the foot by a third party, or by the fore cady, must be reckoned a rub of the opponent, or his opponent's cady or clubs, the opponent loses the hole; or if he strikes himself or his partner, or their cadies or clubs, or if he strikes the ball a 2d time while in the act of playing, the player loses the hole. If the player touch the ball with his foot, or any part of his body, or with anything except his club, or if he with his club displace the ball in preparing to strike, he loses a stroke, and if one party strike his opponent's ball with his club, foot, or otherwise, that party loses the hole. But if he plays it inadvertently, thinking it his own, and the opponent also plays the wrong ball, it is then too late to claim the penalty, and the hole must be played out with the balls thus changed. If, however, the mistake occurs from wrong information given by one party to the other, the penalty cannot be claimed; and the mistake, if discovered before the other party has played, must be rectified by replacing the ball as nearly as possible where it lay. If the player's ball be played away by mistake, or lifted by a third party, then the player must drop a ball as near the spot as possible, without any penalty. Whatever happens to a ball on a medal day, such as a player striking his cady or himself, or his clubs, or moving his ball with his foot or club, or his cady doing so, or the player's striking it twice before it stops rolling motion, the player in such cases shall lose one stroke only as the penalty.—5. *Lifting Balls.* When, on any part of the course, or off it, or in a bunker, the balls lie within 6 inches of each other, the ball nearest the hole must be lifted till the other is played, and then played as nearly as possible in its original position—the 6 in. to be measured from the surfaces of the balls. In a 3-ball match, the ball in any degree interposing between the player and the hole on the putting green, must be played out.—6. *Ball Lost.* If a ball is lost, the player (or his partner, in a double match), returns to the spot, as near as possible, where the ball was struck, tees another ball, and loses both the distance and the stroke. If the original ball is found before the party has struck the other ball, the first ball shall continue the one to be played.—7. *Holing Out the Ball.* In holing no mark shall be placed, or line drawn, to direct the ball to the hole; the ball must be played fairly and honestly for the hole, and not on your opponent's ball not being in the way to the hole; nor, although lying in the way to the hole, is the player entitled to play with any strength upon it that might injure his opponent's position, or greater than is necessary honestly to send your own ball the distance of the hole. Either party may smooth sand lying around the hole, but this must be done lightly and without pressure, or beating down with the feet, club, or otherwise. If, in holing out, the ball rests upon the flag-stick in the hole, the player shall be entitled to have the stick removed, and if the ball falls in, it shall be considered as holed out; but either party is entitled to have the flag-stick removed when approaching the hole.—8. *Unplaying Balls.* In *Match* playing, every ball must be played, wherever it lies, or the hole given up, excepting when it lies on clothes, in water, or in the bed of the burn, or in any of the holes, or short holes, made for golfing, in which latter case it may with propriety be lifted, dropped behind the hazard, and played without losing a stroke. In *Medal* playing a ball may, under a penalty of 2 strokes, be lifted out of a difficulty of any description, and teed behind the hazard, and if in any of the golfing holes, it may be lifted, dropped, and played, without a penalty. In all cases where a ball is to be dropped, the party doing so shall front the hole to which he is playing, standing close on the hazard, and drop the ball behind him from his head.—9. *Breach of Rules.* Where penalty for infringement of a rule is specially mentioned, the loss of it shall be understood to be the penalty.

BICYCLING.



The Parts of a Bicycle.

This description applies to an ordinary diamond-frame wheel. There are many extra attachments, and different makers have different ways of putting a wheel together, so that they may differ in one or two minor details. The description given, however, is in the main correct. It includes mud-guards and their parts—which are used but little here, but are on all wheels made in England. They are used generally on drop-frame wheels in this country.

1 Upper main tube.
2 Lower main tube
3 Front frame tube
4 Rack stays.
5 Back forks.
6 Center stay.
7 Crank brackets, containing cones at outer ends; crank axle with ball bearings and adjustment clip bolt
8 Upper ball head race, or cup
9 Lower ball head race, or cup
10 Saddle post adjustment clip.
11 Back fork end.
12 Handle-bar
13 Handle-bar stem
14 Handle.
15 Ferrule, or nickel tip.
16 Brake lever.
17 Brake lever crank.
18 Brake lever handle.
19 Brake plunger connecting bolt.
20 Brake plunger.
21 Brake plunger adjustment nut.
22 Brake shoe.
23 Brake shackles, bolts and nuts.
24 Brake spring.
25 Handle-bar clip and ball head cone.
26 Lamp bracket.
27 Lock nut for handle-bar clip.
28 Ball head adjusting nut
29 Front fork crown, with brake lug in front.
30 Fork sides, right and left.
31 Coasters
32 Fork ends.
33 Step.
34 Saddle.
35 Saddle post.
36 Saddle clip.
37 Set screw
38 Chain adjustment bolt
39 Crank axle.
40 Detachable sprocket wheel.
41 Sprocket bolts
42 Chain.
43 Detachable link in chain.
44 Crank.
45 Cotter pin nut and washer for detachable crank on other side of machine.
46 Pedal.
48 Pedal pin
49 Nut and washer.
51 Steering wheel.
52 Tire.
53 Rim.
54 Air valve.
55 Valve cap.
56 Spokes.
57 Hub, which comprises outside shell, with ball bearings, bushes and axle.
58 Washers for fixing to forks.
59 Driving wheel.
60 Driving wheel hub.
61 Front mud-guard stays
62 Front mud-guard
63 Front mud-guard screws.
64 Back mud-guard.
65 Back mud-guard screws
66 Back mud-guard screws
67 Back mud-guard screws
70 Saddle frame.
71 Front saddle spring.
72 Rear saddle spring.
73 Leather top, with tension adjustment screw in front, underneath.

LEARNING TO RIDE.—Any person who has the use of his limbs can learn to ride. The beginner should have the assistance of a cycling friend. He should steady the machine by means of the handle-bar while you mount, and then should hold the bar firmly with one hand, while with the other he grasps the saddle spring or lower part of the saddle. This avoids a fall and gives complete control of the wheel. He should then walk by your side, holding the machine as described, and assist you in your efforts to steer it. The bicycle is maintained in its upright position through balancing it by means of steering wheel. When you find yourself about to fall to the right, turn the wheel towards the right; if about to fall to the left, turn the wheel towards the left; in short, turn the wheel towards the side to which the machine is falling. This action will restore the equilibrium of the rider. Should a violent and unexpected swerve occur so that the machine actually falls, simply hold out your foot on the side you are falling, and you will save yourself and wheel. When you find you can steer well enough to keep the machine erect and able to use the pedals, you can dispense with friend and try it alone. Hold the bars firmly and steer steadily, and, should you fall, it is very easy to put out your foot

and save yourself. A little practice of this sort will soon enable you to become accustomed to the wheel. The next thing is to learn to balance the wheel from the step preparatory to mounting. Stand behind the machine, leaning forward and grasping both handle-bars; then place your left foot on the step and put the wheel in motion by hopping 2 or 3 times with your right foot. Keep your wheel erect and straight by turning the steering wheel very gently from side to side. After a few hops rise carefully on your left foot, thus carrying your weight on the step, and see how far you can maintain the balance of the wheel, always remembering to turn towards the side you are falling. When you can preserve your balance on the step, and ride a short distance standing on it, move your right leg along until it rests partly over the saddle, then slide gently forward into it. Do not give a spring or jump, but take it easy and gently. The easier the mount you make the less is the steering affected. A jump or lurch into place will make the machine wabble. Feel quickly for your pedals, in order to keep the wheel in motion. At first you will experience trouble, but practice will soon give you confidence and final control of the wheel. A woman may learn to ride just as easy as a man, and often more quickly. The method is the same as with a man regarding the assistance of a friend, only the care and attention should be a little greater. The assistant should place the machine in position, with the right pedal a little forward of the vertical. Then he should hold the handle-bar firmly while she grasps the handles from the left side, places her foot on the right pedal and rises to the saddle. After she is properly seated he should grasp the handle-bar and frame and walk along on the left side of the wheel, steadying it with his right hand and assisting in steering with his left. The rider must pedal slowly, in order to enable her assistant to keep pace with her and keep the wheel steady. Frequent rests should be taken, as it is tiresome work at the start, and the first lessons should be short ones. To mount and dismount alone is the next thing to learn. The simplest way to get off the machine is to slow up until you are just moving, then apply the brake, and as the wheel inclines to one side reach for the ground with the foot on that side. As the foot touches the ground, draw the other foot through after it, taking care to hold the handles steadily and prevent the pedal from striking the ground. Although this is not a very graceful dismount, yet it is practically unavoidable at the start. The becoming and regular dismount is to ride very slowly, apply the brake as the left pedal reaches the lowest point, bear all your weight upon the left foot as you stop, carrying the right foot through to the left side, and so stepping off upon the ground on the right foot. A little practice is required to do this well, but it can be learned with patience. To mount alone, the novice can go to a curb or large stone, stand close to the left side of the wheel, holding the handles firmly, with the right pedal just a little forward, beginning to descend. Put the right foot upon the pedal, adjust your dress to hang evenly, and then rise to the saddle by bearing your weight upon the right pedal. This action enables you to reach the saddle and also put the wheel in motion. It should be done quickly, but evenly and without a jerk or a jump. You will find the machine begin to move forward as you rise, and you must pay attention to the steering. The proper position for a bicycle rider is, in the first place, an upright one. He should push nearly straight downward with his legs—not backward, as one must do who bears far forward. His arms should not be rigid and extended to their full length, but a little bent, and the handles can be easily adjusted to bring this about.

CLEANING AND OILING.—A wheel should be cleaned and oiled at least once a week. To clean the wheel, place the wheel upside down, resting on the saddle and the handle-bar, which should rest on a cloth or piece of old carpet to prevent its being marred. The dust should be removed from the wheel with a dry brush. If the rims and frames are muddy, use a wet cloth; a small brush will be found useful in cleaning the sand or mud from the hub or sprocket wheel. If the enamel of the frame appears streaked after washing off the mud, it should be rubbed with a dry piece of cloth or chamois skin. Oily rags should not be used on the enameled parts. The spokes should be cleaned with a cloth.

PUNCTURES.—A simple manner in which to repair a puncture of a single-tube tire, if it is not a difficult one, is to insert a nozzle to which a tube of cement can be attached in the puncture. Then turn the wheel until the puncture is at the lowest point, when a drop or two must be injected. Immediately withdraw the nozzle while the cement is still running, so that all sides of the puncture will be coated with the cement. Wind on ½ doz. turns of tire tape and inflate, still having the puncture down, in order to keep the cement over the puncture. The tire should be blown up very hard, and then ridden for about ½ hour. The tape can be removed in 24 hours, and the tire will be found intact. It takes only about 3 minutes to fix a tire by this method, and it's always successful.

—o—

HUNTING.

DOGS.

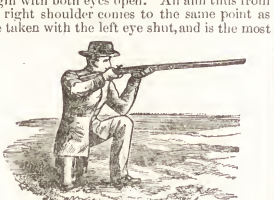
A WELL-TRAINED dog is indispensable to success in gunning. The highest place among shooting-dogs is awarded to the *setter*, the hairy protection of his feet enabling him to go through an amount of work without injury. The *pointer* is more nearly allied to the hound than any other. It will, with little breaking, stand at game of any kind. To select a pointer choose one

whose head is broad at the tip, long and tapering, the poll rising to a point; nose open and large; ears tolerably long, slightly erect and falling between the neck and jawbone, slightly pointed at the top; eyes bright and clear; neck and head set on straight; chest broad and deep; legs strong, muscular and straight; feet small and hard; body not too long and well ribbed up; loins broad at the top, but thin downwards; hind quarters broad; hind legs strong and large; tail long, fine and tapering; hair short, sleek and close. If these points are found in a dog, he is a good pointer, and will give satisfaction. The *water spaniel* and the *Newfoundland* are of great use to a sportsman when bent on shooting water birds. The water spaniel rivals every other breed in docility. The retriever's value consists in his fearlessness and perseverance in penetrating the thickest bushes. (See DOGS in PET STOCK.)

GUNS.

REMARKS.—The barrel, lock and mounting are of metal; the stock of wood. The interior of the barrel is called the bore, the front end the muzzle and the back end the breech. The following explains the parts of a muzzle-loading gun: Butt of stock, extremity of stock, placed on the shoulder in taking aim; chain or swivel, a small chain connected with tumbler and mainspring; chamber, a cavity in the breech to receive the powder; cock, the striker; guard, bar to protect the trigger; heel-plate, plate which guards the butt of stock; lock-plate, supports the principal works of the lock; mainspring, which governs the tumbler and the cock; scear, which catches the tumbler for ½ or whole cock; tumbler, movable centre piece of trigger; worm, screw at end of ramrod.

AIMING.—The manner of holding the gun is shown in the illustration; many first-rate shots prefer holding the left hand close against the trigger guard. Practice bringing the piece to shoulder with breech and sight on a level, and pulling the trigger the moment the gun is brought up to the centre of the object; as the first sight is best. Begin with both eyes open. An aim thus from the right shoulder comes to the same point as one taken with the left eye shut, and is the most



Rifle Shooting at Long Range.

ready method of shooting quickly. Time must be allowed for the movement of the game as well as for the attraction of gravitation and reflection of the charge caused by the wind. When on the wing, aim well forward and higher, as game, particularly wild fowl, is always further off than it seems.

CHOICE.—A good gun is necessary to success in hunting. Barrel should not exceed 30 in. and be of medium gauge; a twisted barrel is best. To ascertain whether the shape of the stock is best adapted, the shooter should frequently raise the gun to his shoulder, and take aim at a distant point with both eyes open; then, closing the left eye, he will perceive whether or not he has taken correct aim. If, with the left eye closed, he does not see the object, the stock is too crooked; if he sees all the rib, it is too straight; and if his line of aim is not along the centre of the breech, but from the left corner of it, the stock is not properly cast off. Should the line of aim be along the right side of the breech, the stock is too much thrown off. With a gun properly fitting, the aim is instantaneous. In looking along the rib, ⅓ of the whole length of the stock next the muzzle should be visible, as well as the sight. This gives the shot elevation and increases the range. The wood should be hard and tough; the mounting and locks carefully fitted; in shape the stock should be thin and suited to the grasp; the fore-end of stock broad, full and wide at the end of the lock plates; the lock simple, but finished in all its parts to perfection; the mainspring of good metal and elastic. A good lock should not grate harshly when the striker is raised. Draw the trigger, retaining the thumb upon the striker, and observe that it goes down freely, with increasing force as it approaches the nipple. The trigger should be long and well curved, affording a good hold for the finger; the edges rounded so as not to cut the finger and set well separate. The guard of the trigger, termed the bow, should be rounded and somewhat thick at the edges, and have no improper projection likely to injure the middle finger.

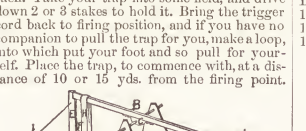
BREECH-LOADERS.—The advantages of breech-loaders are the facility, quickness, and additional safety in loading; the increased rapidity of shooting; absence of foulness, recoil, and liability to be affected by damp. In using this gun, place the stock under the arm, and with the right hand pull the lever back, and ease down the barrels with the left hand. Take out the exploded cartridges with the thumb; or, should they be rather tight, tap the pin with a loaded cartridge, or draw them out with the small instrument made for the purpose. When loading, pour the powder and shot into a basin. Use the small brass measures, and first put in a measure of powder, then 2 felt waddings, next the shot, and then 1 card wadding, and turn the end of the paper over to secure the wadding, with a screw-press socket. To clean, wipe out the barrels with dry tow; grease them slightly with an oiled rag. The barrels need not be taken off the stock in cleaning.

LOADING.—(*Muzzle-Loaders*). Rules on the subject must be laid down with several reservations. Hold the gun upright, and in that position pour in the powder, striking the butt-end of the piece against the ground, to carry down such grains of powder as may be lodged against the

sides of the barrel, and also to settle the mass. Next, pass the powder-wad down until it reaches the powder, on which press tightly; then pour down the shot, and give a shake or two to settle them in their bed. Place over them wadding of sufficient substance and elasticity to maintain the shot in position, by giving a pressure to the wad, but do not ram it hard. The first charge may be pressed harder than subsequent ones. When the powder is wadded, observe whether it makes its way to the nipple. It does not always follow, that if the powder is not seen on the pivot, it will not explode; but it is more satisfactory to see it there; and when it cannot be seen, the breech should be slightly tipped to introduce the powder up the touch-hole. Lastly, put on a cap, letting the cock down gently. When a gun has been discharged, it is a good practice to load it while the barrel is still warm.

POWDER.—The quality of gunpowder is estimated by actual trial of its power and cleanliness in use. It should be dry, hard and free from any dust; the grains of uniform size, glossy, and of a dark gray, or brownish gray, not perfectly black. A very little placed on a piece of paper and fired, should instantly explode with a flash, and neither leave a residue on the paper nor burn it. Dried by the heat of boiling water, it should not lose more than ½ to 1 per cent. of its weight. When gunpowder has been exposed to the air, it should be dried before using, especially when the atmosphere is moist. The common tin case is not sufficient for keeping it, unless it be rendered water-proof, and closed either by a soft velvet cork, or a fine-threaded screw. An excellent plan is to divide large quantities into smaller ones, and put them into bottles, each containing 4 oz.; which, being corked and sealed, prevents exposing more than is wanted for use.

PRACTICING.—It is better to practice at glass balls thrown into the air by means of a spring, until proficiency in aiming is acquired. The illustration shows a trap, or spring, for the purpose, which can be made at home at no expense for material except for 2 rubber springs, at 25 cts. each. Take your trap into some field, and drive down 2 or 3 stakes to hold it. Bring the trigger cord back to firing position, and if you have no companion to pull the trap for you, make a loop, into which put your foot and so pull for yourself. Place the trap, to commence with, at a distance of 10 or 15 yds. from the firing point.



Trap or Spring.

A, Platform of 1¼ in. boards; B, lever of hard wood, 1¼ in. square, and 36 in. long; C, cleat, nailed on lever to receive D, a rod of iron, placed about 12 in. from one end of the lever, serving as a pivot, and passing through holes at the top of CC, the standards, in length about 12 in. above the platform to the pin D; E, a trigger, held at foot by a hinge, and drawn forward by a rubber spring, F; G, a block of wood to check trigger at desired point, with arms on either side to direct the trigger in line with the lever; H, a heavy rubber door spring, which can be purchased of every dealer in rubber goods, and at most of the hardware stores. It is secured to the foundation, and passes under G; I, cup to receive object to be thrown; K, check cord of stout clothes-line or strap, which regulates the direction ball is thrown by being lengthened or shortened; L, trigger cord, for releasing the lever. A guiding ring (O) should be fastened to platform, through which to pass pulling cord. From trigger E to axle D, 12 in.; from D to cup I, 24 inches.

Glass balls are not large enough for the first lessons; old oyster or fruit cans are better, and even after they have been shot full of holes you can tell when struck again, as they will be driven onward. If glass balls are considered expensive, pine blocks may be substituted.

RUST, To Prevent.—To those who shoot along the seashore, the following mixture will prove invaluable: Take any quantity of olive oil, with ¼ its bulk of camphor, and a few shavings of lead, and it will be found superior vaseline jelly.

RUST, To Remove.—Have an ashen rod turned a few in. longer than the barrel, and nearly the size of the bore. Let one end of the rod be cut lengthwise, so as to make a slit of 6 in. long; into which insert as much fine emery paper as will completely fill up the bore of the barrel, taking care in folding the paper tightly round the wood, that the emery surface is outward. Force it into the barrel by screwing it downwards from the top to the bottom; repeat this process until the barrels show a perfectly clean and polished surface. Sand and other coarse materials should never be used.

SHOT. — Use as large shot as consistent with even, regular and close distribution at ordinary range, and vary the size according to the size of the bird hunted, and the season. As fall comes on, birds are stronger and more wary, and a larger size will be necessary. For quail, plover, woodcock, wild pigeon and birds of similar size, use Nos. 7, 8, or 9 shot. For larger birds use from 1 to 7; for smaller, 8 to 10. For geese, and other heavy birds at long range, shells loaded with B B shot, or B shot, are desirable.

SHOT, No. of to the Ounce.

SHOT GUN. — The gun principally used in hunting, since the disappearance of large game from the older sections of the country, and is exclusively used for fowl shooting. Its first essential of good quality should be the force with which it throws the shot; second, the evenness with which it disperses them. Heavier charges

of shot require heavier charges of powder. For a No 12 gun of $7\frac{1}{2}$ to $8\frac{1}{4}$ lb. weight, use 3 to $3\frac{1}{4}$ dr. powder, and $\frac{7}{8}$ to 1 oz. shot. Increase the quantity of powder and shot for a heavier gun, until the charge reaches 4 dr. powder and 1 oz. or more for a gun of 10 to 11 lb. weight. The proper charge once learned, do not vary it.

SHOT, Scattering, To Remedy.—The only remedy known to gunsmiths is *choke-boring*; that is, boring from the breech of the gun, so as to have a gradual taper towards the muzzle. This improves the shooting qualities of the gun, as the charge concentrates at the muzzle. Large shot are more apt to scatter than fine, but this depends on the bore. A large bored gun does not shoot fine shot so well as medium. A small bored gun throws fine shot with greater force than a large bored one. As a general thing, a small bored gun is not adapted to large shot, as it does not chamber them well. The length of gun also depends on the size of bore—28 or 30 in. for a gun of from 10 to 14 gauge; 30 to 34, of guns from 8 to 10; 26 to 28, of guns 15 to 18 gauge.

GAME.

BARKING SQUIRREL.—Strike the bullet under the point of the limb where the animal is stretched out, so that the blow will shiver the bark, kill the squirrel by the concussion, and send it whirling to the ground. The skin will not be injured nor the flesh torn.

BUFFALO. — Buffalo hunting is not without danger. When the head of the herd is disturbed, they flock together in a mass, and rush through all obstacles; they should only be approached on the outskirts. The usual way of hunting them is on horseback, as a person on foot cannot approach them without screening himself. An 8 in. navy revolver is best, but a breech-loading carbine or rifle is good. Hunt up a drove feeding; approach them from the leeward side, or they will scent you and move off. Lie down on the horse and let him gradually work towards them; select a cow, and approach her on the left side if you have a pistol, and right side if you have a rifle. Shoot for the heart; aiming just back of the fore leg, a few inches above the brisket.

DEER.—In hunting deer, approach from the leeward. When ascending a hill, keep the body below the level of the top. When a sight of game is obtained, it is generally necessary to make a *detour* to get within range without causing alarm. In mountainous sections, a light is affixed to the hunter's hat. In winter deer are followed by their trail in the snow, or paths in the forest. Dogs are seldom used, except where 2 men work together, one with the dogs driving out the deer, while the other awaits them at their *runs*. Sometimes the game is driven in this way to the water, the hunter being in a boat. In *still hunting*, the trail is followed up till in sight of the deer. The hunter should provide himself with a good rifle, and a pair of deer-skin moccasins. When finding the trail, he should walk carefully, and keep a good look out, as deer are always looking back on their trail. When routed, they almost always stop on hills. In order to get within gunshot, circle round, and come up toward in front or at the side. When early snow comes, deer usually feed till about 10 o'clock A. M., when they lie down till 3 o'clock P. M., then start on a rambling excursion till near the next morning. They almost always return to the place from whence they started, or near to it. In still hunting, when the buck, doe and fawns are found together, shoot the doe first; the buck will not leave till you get another shot. A favorite method is night hunting in a boat, a lighted torch being placed in the bow of the boat, shining on the forward gun-sight, leaving the hunter concealed. The deer are fascinated, and not only permit the silent boat to approach, but swim toward the light. The animal's position is shown by the eyes, and at these the aim is directed. It is in summer and early autumn that they frequent the neighborhood of rivers and lakes, in winter returning to more elevated regions. 1 person, equipped with fire-pan and gun, can hunt in this way; but commonly 2 go, one carrying the gun and the other the pan. The party with the gun walks in front, a few paces in advance of the light, as noiselessly as possible, and watchful for the "eyes." The man with the torch follows. On his shoulder he supports a long-handled pan containing the light, made from pine-knots or cotton balls saturated with tar or spirits of turpentine. The wildest and shyest animals pause and gaze intently. The animal's bright orbs, reflected by the strong light cast upon the barrel of the gunner's weapon, allow him to see the sights clearly, and draw accurate aim at the motionless game. Allowing for the elevated position of its head, aim 1 ft. or more below the eyes.

GRIZZLY BEAR.—On sighting the hunter, the bear will make for his enemy, and has a habit, when 60 or 70 yards distant, of sitting up erect, and will repeat this at intervals of nearly 20 yds. as he approaches. The hunter will do well to reserve his fire until the bear comes within a few yards, when, if he suddenly extends his arms, the animal will come to a full stop and erect himself. This is the time to take aim at close quarters, and make sure work. On the Pacific coast he is often hunted in mounted companies of 5; 4 use the lasso, which they throw over the bear at opposite angles from each other, and while he is thus held from 4 opposite directions, it is possible for the fifth man to approach and finish him. It is dangerous work; for if one or more of the ropes should slip, unless it is immediately secured by another successful throw, there is danger of instant death to the nearest man, if his horse is not smart enough to carry him off.

QUAIL. — The best time for quail shooting is in the morning early, or late in the afternoon. Cross-shots may be effected by walking across or heading your dog when pointing. If you go straight from him to the birds, they will generally go straight away. Birds, when flying across you, present an easier shot. Wheat stubbles and turnips are the best spots for holding quail. In storms and fogs quail lie close, and in fine days which follow storms. Heavy rains cause them to lie extremely close in turnips.

RABBITS.—These are the best for the first ef-

forts of the young sportsman. In approaching, never advance in a straight line, or look directly towards them; walk leisurely along in the face of the wind; stoop and pick up a bough or piece of turf, or examine any matter before you; such conduct will often throw them off their guard. If a dog is with you, keep him close; your clothes, also, should be dark. When you have ventured as near as they will allow, then stoop. When storms arise, the intervals between are often favorable for getting near rabbits, particularly when the wind blows from them to you. When a number are come upon suddenly at the edge of a wood, it often happens that the old ones will immediately take the covert; but the young ones will prick up their ears and perhaps raise themselves up to examine you; now take your shot.

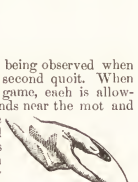
SNIPE, or WOODCOCK.—Found in low, marshy grounds, but in spring they disperse to higher situations. The first sight is the best. Not a moment should be lost after you have drawn a sight; pull the trigger at once. In cross-shots, fire well before your bird. Differing from the usual practice, you should walk down wind; the cause for this is, that the snipe always rises against it. The difficulty of hitting them when on the wing is surmounted if they are allowed to reach a certain distance, when their flight becomes easy to traverse with the gun, and they will fall to the ground if struck with the smallest shot. In severe weather they visit warm springs. Snipe lie better in windy weather than any other, and as they usually make a momentary halt or hanging on, that is the time to fire. A regular snipe locality should be tried not only every day, but twice a day, so uncertain are they in fixing themselves even for a day. Avoid hurry and keep cool.

WATER FOWL. — Do not fire too soon; many good aims are worthless through miscalculated distance. Experience and practice enable the sportsman to judge correctly. The scent of the fowl is keen, and to get within range keep to the leeward of them. All moving about in the boat should be avoided, and the body kept from view by the sails. The lower the position when firing, if a number of birds are together, the better; a larger family shot may be made in this position than when standing, as the aim is not so likely to be distracted by the motion of the boat. When firing at a large number on the water, aim at the birds farthest from you. In shooting select for your aim those that are sitting with their heads away from you, particularly when using a small gun, in order that the shot may pass under the feathers; for every bird you will kill in this position you would fail to hurt 2 or 3, though you struck them sitting facing you. Never take the eyes off the birds till they have gone right away, for it nearly always happens that there are several birds in a flock mortally wounded, which fly possibly 100 or 200 yds., and then fall dead.

WILD TURKEYS.—The best hour for their pursuit is early in the morning, before leaving their roosts, when they can often be approached within range. When discovered in the woods, stand still until the bird has moved position so that you are no longer in view. Then move to leeward, and advance as rapidly as consistent with caution, looking well to likely roosting trees to which they often fly when frightened. When within shot, aim at the head. Well-trained dogs are invaluable in wild turkey hunting, as they drive them to the trees, and the birds are so absorbed with them, that they are easily approached. A successful method of hunting them is to climb into a small tree having a dense top, first having placed a tame gobbler near by with a string to his leg. By pulling at the string, it will give voice, and decoy any bird within sound. A call is sometimes made from a turkey bone. They may also be hunted sucessfully by moonlight.

QUOITS.

THE common game of quoits is played with iron rings, nearly flat, the inner edge higher and thicker than the outer edge, which is sufficiently thin to stick in the ground where thrown; these are made and distinctively marked in pairs, each 2 of a similar size, mark and weight, to suit the player; the points, or spots, at which the quoits are aimed, are marked by iron pins, called *mots*, sufficiently long to allow of being driven firmly in the ground, and project exactly 1 in. above. The object is to throw the quoits as near as possible to the mot. The method of playing is as follows: 2, usually the best players, are selected as chiefs, who decide for choice of players by tossing a quoit, the winner having the first choice, and then alternately till the sides are arranged. Each player having furnished himself with a pair of quoits, the game is commenced by the chief who won the toss, by throwing one of his quoits, followed by the chief of the other side, and the other players of each side alternately, the same routine being observed when the players throw their second quoit. When 2 players engage in the game, each is allowed a director, who stands near the mot and furnishes him with the necessary information and directions for placing his quoit. When more than two play, the chief, or any other player on the same side, acts as director. In match games, each side chooses a non-participant as umpire, and the umpires select a third party to act as referee, whose decision is final in case of disagreement between the umpires. The points are made in the following manner: The quoit nearest to the mot scores 1 point to the side to which the thrower



Holding the Quoits.

belongs. Then such other quoits as belong to the same side which has not been beaten by a quoit which belongs to the other side, also will score one point each.

—o—

RIDING.

DRIVING.

HOLDING THE REINS. — In driving, the fore-finger is first placed between the reins, then both reins are grasped by the other fingers, and the near side rein held firmly against the fore-finger by the thumb. In this way, on emergency, the left rein may be pulled by holding it firmly with the thumb, and suffering the other to slip through the fingers, or *vice versa*. While turning, or when driving a high-spirited horse, and in critical situations, the right hand must be called to the assistance of the left; thus, the reins being grasped as before stated, you pass the 2d and 3d fingers between them, and loosening your hold on the off-rein a little, let the right hand have command, still firmly holding both reins in your left; this position gives great power over the horse.

STARTING. — Holding the reins with both hands, start the horse either by voice or by reins, gently feeling his mouth, but neither pulling at it nor jerking. If a young horse's mouth is hurt by the driver checking him every time he starts he is sure to incur some vice. If he refuses to start, let the groom lead him off, caress him, and encourage him to proceed, and if he presses on one side, as if he wanted to go round, turn him round, if there be room, and as soon as he has his head the right way, give him his liberty, and by voice or whip urge him to proceed.

TRAVELING.—Look well ahead, to avoid carriages and impediments, such as loose stones, by which the horse might be thrown down, or any object which might frighten him. Keep your horse well in hand; be prepared, if he stumbles, to help him; if he starts, draw the reins gently, so that he can feel them. This is called driving with a light hand, and is the perfection of driving; but drivers, in attempting this, frequently allow their horses to run from one side of the road to the other, which must be avoided, as nothing is so ungraceful. Holding in hand sometimes produces another bad practice, particularly if the horse's mouth is not delicate; it gets him into the habit of hanging in your arms, and bearing continually upon the bit, until his mouth becomes so callous that if he stumbles he must come down, unless you can hold him up by main strength. This may be avoided sometimes by keeping the bit moving in his mouth, but more frequently by not unnecessarily pulling at the rein. If the reins are held with both hands, you will have more command, and a little attention will prevent these inconveniences. Continual whipping dispirits, and does not remedy the evil. If kept well in hand, you will generally be able to keep him from coming down. You will naturally put more force to your pull upon his making the stumble, and this jerk, if succeeded by a strong, continuous aid, generally keeps him on his legs, a smart stroke with the whip should follow, to remind him that his carelessness is not to be repeated. If a horse slips, a sudden jerk will probably throw him down; in such a case, the horse must be aided by a strong, steady hold.

HORSEBACK RIDING.

MOUNTING AND DISMOUNTING.—If there is a groom, he should hold the rein with his right hand, standing by the off shoulder of the horse, so as with his left hand to hold the stirrup iron for the rider's right foot, as he throws it over the horse's back. The rider stands at the shoulder of the horse, with his left side toward that part; then lays hold of the reins with his left hand, drawing them up so short as to feel the mouth, and at the same time twisting a lock of the mane in his fingers, so as to steady the hand; next, the left foot is placed in the stirrup; at this moment a spring is given from the right foot, the right hand reaches the cantle of the saddle, and the body is raised till the right leg is brought up to the level of the left, when the slightest pause is made, and then the right leg is thrown over the back of the horse, keeping the toe down and heel elevated, while the right hand leaves its hold, and the body falls into its position in the centre of the saddle; after which, the right foot has only to be placed in the stirrup. Dismounting is exactly the reverse of mounting, and requires, first, the reins to be shortened and held in the left hand, with a lock of the mane; secondly, the right leg is taken out of the stirrup, and thrown over the back of the horse, until it is brought down to the level of the other leg. After this, if the horse is of a size suitable to the rider, the body is gently lowered to the ground, and the left leg liberated from the stirrup; but if the horse is too high, the foot is taken out of the stirrup by raising the body by means of the hands on the pommel and cantle of the saddle, and then the body lowered to the ground by their assistance.

POSITION IN SADDLE.—Should be square to the front, without either shoulder being in advance; the loins arched inward without stiffness; the elbows close to the side, held easily; the knees placed upon the padded part of the flat in front of the stirrup-leathers; toes turned slightly out, and the foot resting on the stirrup, the inside of which should be opposite the ball of the great toe, and the outside corresponding with the little toe. In hunting, it may be placed with the stirrup close to the instep. The heel should be lowered as far as possible beneath the level of the toe, which gives a firm seat. The great point is to obtain a good grasp of the saddle by the knees, without tiring the muscles by such an effort. The left hand is now to be held slightly above the pommel, and the right easily by the side of it, with the whip held in a slanting position.

Lady's Position.—The lady should sit so that her weight falls perpendicularly to the back of the horse; her face directly to the front, shoulders drawn back, and elbows held to her sides. She will permit her body, from the hips upward, to bend with the motions of the horse, in order that she may preserve her balance. The reins are held in the manner prescribed for men, the hand in front of the body, and in a line with the elbow. The whip is carried in the right hand, with the point toward the ground. The horse should never be struck upon the head, neck or shoulder. The horns of the saddle, the superfluous one at the right side being dispensed with, should be of length and curvature to suit the rider. The right leg holds the upright horn close in the bend of the knee, by such a pressure as the action of the horse or other circumstances dictate, the left foot thrust into the stirrup to the ball of the foot, and the heel, as a rule, carried down; but when the heel is elevated, the upper part of the left knee should find support in the side horn, and for that end the stirrup-leather given such a length as will permit this. By the grasp given by the elevation of the left knee from the stirrup, and the embrace upon the upright horn by the right leg, the rider will have as strong a seat as her strength can afford, and, with a proper balance, she will not be likely to find a horse that will unseat her.

REINS. Management of.—When the single rein is used, the best position is to place the middle, ring, and little fingers between the two reins; then to turn both over the fore-finger, where they are tightly held by the thumb. In all cases the thumb ought to point toward the horse's ears. If a double rein, let the snaffle (*S*) be first taken

Single-Rein Grip. *Double-Rein Grip.*

up on the middle finger, and then let the curb (*C*) reins pass in a similar way on each side of the third finger; let the loop of the reins come out below the thumb, so that the rider can discover which of the two to tighten when required, by drawing them through his left hand by means of the right; then, with the reins in the grasp, it is safe to mount (or take a hand up, if the rider is too small to reach the stirrup).

TROT. CANTER AND GALLOP.—To cause the horse to *trot*, the reins are taken rather short in the hand, and the mouth held firmly, but taking great care not to jerk it. The animal is then slightly stimulated by the voice, and the body if necessary rises from the saddle, so as to indicate what is wanted. This seldom fails, and the horse at once breaks into a trot; or, if very irritable, he may be compelled to do so by laying hold of an ear and twisting it, to avoid which he drops his head, and trots. The *canter* is an acquired pace, and for its performance a curb-bridle is required. In order to make the horse begin, the left rein is pulled, and the rider's left leg pressed against the side, by which the horse's right leg is made to lead off, this being the usual and most comfortable "lead" for the rider. The hands must make a gentle and steady pull on the curb-rein, and the body be very quiet in the saddle, while, at the same time, a gentle stimulus is given by the voice, repeated at short intervals, or the canter will be changed to a trot or walk, both of which gaits are preferred by most horses. Young riders should avoid cantering long upon one leg, as it leads to inflammation of the joints; and they should either change the lead or alter the pace to a trot or walk. In the *gallop*, the

The Gallop.

seat is close to the saddle, with the body inclining backwards, or standing in the stirrups, in which position the knees and calves only touch the saddle, and the body is bent over the withers. It should be the endeavor of the rider, while he bends his shoulders forward, to throw his loins well back, to avoid straining the horse's forequarters, by bearing too much weight. This is done by the hold of the knees on the saddle, and by keeping the feet back; also, by rounding the loins backwards, and thus throwing the centre of gravity as far as possible behind the stirrup-leathers. The object of standing in the stirrups is to save the horse when at full gallop. This attitude allows the horse to exert himself without feeling the weight of the rider to impede his movements.

LEAPING.—This requires only an extra exertion, added to the ordinary spring of the gallop, the attitude being the same. It is best learnt by beginning with small ditches, which the rider is soon able to clear. In riding at a bar, lay hold of a snaffle-rein in each hand, taking care to keep them close together by the right rein being held also in the left hand. The horse is then urged to a canter or hand gallop, and held straight to the bar in this way, so that he is obliged to leap; or if disliking the act, being urged by the whip down the shoulder, or spur, or the groom's voice and whip behind. Young riders should never be put upon a bad or reluctant leaper, but should be taught upon one which is fond of the amusement. At the moment of rising into the air for the leap, the reins are relaxed, but should not be left quite loose; while the horse is in the air the

body becomes upright, and as he descends it leans well back, until, after a high leap, it almost touches the croup. During this period the reins should be suffered to remain nearly loose, the hand barely feeling the mouth; but, as the horse reaches the ground a stronger hold is taken, to guard against a mistake, which might require the aid of the rider to prevent a fall. There are various kinds of leaping; as the flying leap, the standing leap, the leap in hand, etc. The flying leap is one taken at a fast pace, and when the rider can maintain a good seat in the gallop. The standing leap is effected from a state of quiescence, and is more difficult to sit, because the horse rises and falls more suddenly. Between the two is the slow or steady leap, which is only effected safely by the hunter or well-broken horse; but, when perfect, it is almost as smooth as a rocking-horse. This is the mode in which the young rider should be taught to leap. Leaping in hand is necessary for horses in the hunting field, which would otherwise never be able to compete with full-sized hunters in the way they do. The young hunter, when he meets with a gate or other strong fence, which he knows is too much for the powers of his horse, at once gets off and leads him over by the rein.

RUNNING.

CORRECT METHOD.—Good running must be accomplished on the ball of the foot, with the heel elevated; the arms kept well up to the sides, but not too high. When you can work the arms and legs together, you will be able to take a good stride with ease.

RACING.—Stand on the balls of the feet, with one foot toeing the mark, and the other 12 in. behind. The forward leg and foot will bear the weight of the body until the body is drawn back to get a final impetus. A vigorous dash when the signal is given puts the body in motion, and in a few yds. you are running at full speed. In every description of race, even when awaiting one is contemplated, obtain a good start. It does no harm to dash off the first 50 yards at the highest speed, and then settle down to a steadier pace. It frequently so surprises an opponent as to paralyze his efforts, so that he is unable to regain his lost ground. The inside position should be immediately taken, and no deviation made from it during the whole race, except to pass an adversary. This rule may not be observed when a waiting race is to be made with an obstinate and tough opponent, whom it is advisable to intimidate as soon as possible, or when the running path is cut up so that it is desirable to obtain a better footing on a part of the course less used. When the former tactics are necessary, the right shoulder (supposing the race be run to the right) should be kept close in the rear of the other competitor and the position maintained until the proper moment arrives for passing. This movement should be done with celerity, when the antagonist exhibits a tendency to hang back and shows signs of weariness. The greater speed with which he is passed, induces him to believe his opponent capable of winning the race. No relaxation in efforts should take place at such a moment, and though the opponent seems to have the race in his hands, there is every probability of another change in their places before long. It frequently happens that a runner who has seemingly gone by in the grandest style decreases his speed considerably before reaching the post, although using his best exertions. This is because the spurt has been made too soon, or is the result of certain circumstances of condition. Although the decrease of speed is perceptible to the body of spectators, it may not be so apparent to those running immediately behind him. The efforts of the latter should never cease for a moment, for it is impossible to calculate upon the leading man not tiring or giving way. In the straight run home, or in the last lap, this watching is of infinite importance. During a final struggle, avoid every chance of a collision, and with every sinew and muscle braced together, run to the tape at top speed.

TRAPPING.

REMARKS.—The skins of animals trapped are far more valuable than those shot. To get the highest price for skins, they must be taken care of, cleaned and properly prepared. Visit the traps frequently so as to obtain the skins free from taint. Winter is the best season, as the skins of fur-bearing animals are then in the best condition, but trapping may be profitably done from Oct. 1st to April 1st. Under the head of traps are included all contrivances for the capture of birds and animals, either by inclosing them, seizing and holding them, or by killing them. 1st, set the trap so that the animal will go to it; 2d, so it will catch him; 3d, so it will hold him when caught. A cautious animal should be invited several times before the trap is set; arrange a place with saw-dust, hay seed, chaff, and chicken feathers, several inches deep; scatter through it food adapted to the animal to be caught; offal of chickens, bones, meat, fish-heads, etc., if for fox; nubbins of corn, etc., for coons; set your trap (free from the iron smell) and cover with the material you have used; scatter bits of food therein. Strong smelling substances are the best baits; and if the smell of the kind of animal to be caught can be given to the bait, it will be sure to lure the animal. If a fox skin be dragged along the ground in the direction of the trap, every fox striking the trail will follow it up; so it is with other animals. The baits for

steel traps consist of some substance which forms the food of the animal to be captured, or for which they have a liking. The muskrat will take carrots, potatoes or apples, or any similar food. The mink, sable, fisher, skunk, ordinary weasel, etc., will take fish fresh or salt; it should be toasted, so as to emit more smell. Beavers will take any fresh root or sapling for bait. Castoreum, called bark-stone by the fur traders, is a fatty substance of an intensely strong odor contained in similar sacs in the back parts of the beaver. It forms a more attractive scent for that animal than any other. It is pressed from the bladder-like bag which contains it into a vial with a wide mouth. 5 or 6 of these stones are taken, and a powered nutmeg, a dozen or more cloves, a teaspoonful of ground cinnamon, all mixed with alcohol or whisky until it is about as thick as good syrup; cork the bottle and keep 3 or 4 days. It should be used for attracting the beaver toward the trap, but not be put in it. Fish oil is prepared by cutting up eels, trout or other small fish, into small pieces; these are placed in a bottle loosely corked, and hung for 2 or 3 weeks exposed to the heat of the sun; a kind of oil results, possessing a penetrating odor, which can be detected by these animals from a great distance, and allures them to the spot where it has been sprinkled. Another secret of old hunters is to take the parts peculiar to the sex of the female wolf, fox or dog, and preserve it in alcohol or whisky for use. A small piece of this is used in drawing either fox or wolf to the traps, and proves irresistible to the male, and no matter from which species it is taken, it proves alike attractive to the fox or wolf. It is not used as a bait, but to bring the animal toward the trap. The trap may be baited as usual, or the substance may be suspended over the trap; in trying to reach it to smell at it the animal steps into the trap.

BADGER.—The badger is a cunning animal, and not easy to catch without considerable caution. Set the traps at the mouth of their holes, carefully covered, or in the paths which they make in corn-fields. Early in the spring they may be caught by pouring water in their holes; for the ground being frozen at that period, the water does not escape through the sand, but soon fills the hole, and its tenant is obliged to come out. They may also be caught in deadfalls (which see); the bait may be a mouse or a piece of meat, as anything in the shape of flesh is food for the badger. The most appropriate size of steel trap is that known as the Newhouse, No. 3.

BEAR, Black. — It requires a large steel trap for the bear; the Newhouse Nos. 5 and 6 are best. It must have a short chain attached to a clog, the weight of which must be according to the kind of bear found in the locality. Select a spot for the trap between logs, trees, or hills, close to the suspected haunts, and secure it with a a short, stout chain. Bait the trap with pork, mutton or beef, and if the bait is scented with honey it will prove a powerful attraction. The following stratagem has proved successful in destroying the bear: Take a portion of some domestic animal (or other bait of which he is fond) to the woods and place it in such a position, near some fallen trees, so that the bear will be compelled to go between two logs in order to reach the carcass. At right angles with this passage way, but back from it, secure a rifle (loaded with slugs) in a firm position so as to sweep the passage, and arrange a small cord extending across the narrow avenue, with one end fastened to the trigger of the rifle, and the other to the timbers opposite its muzzle. A dead bear shot through the heart behind the fore-legs, within a few feet of the rifle, will be the result.

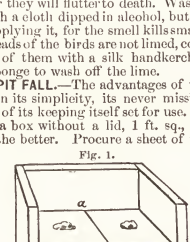
BEAVER.—In its prime about October 1st, and continues to improve till about May, when it deteriorates. They have numbers of holes in the banks of the streams, as places of retreat when injury is offered to their houses, and it is in those holes that they are taken. To find these places each man is furnished with an ice-chisel, which he lashes to the end of a small staff about 4 or 5 ft. long; he then walks along the edge of the banks, and keeps knocking his chisel against the ice. When the hole is thus indicated by sound, a portion is cut through the ice large enough to admit a full-grown beaver; this is continued till as many as possible of their bodies are found. While thus employed, others are busy breaking open their houses. When the beavers find their habitations are being invaded, they fly to their holes in the banks for shelter; the entrances of the holes are then blocked up with stakes of wood, and the beavers are hauled out by hand, or by a long stick with a large hook at the end, if the hole be deep. Beavers are occasionally caught by spearing through the ice, when thin, as they come up to the surface of the water under the ice to breathe. The experienced trapper readily detects any sign of proximity to a beaver lodge, and proceeds to plant his trap upon the shore below the surface of the water, and secures it by a chain to a pole set deep in the mud. A small twig is then stripped of bark, and one end dipped in the bait. This end of the stick rises 4 in. above the surface of the water; the other end is planted between the jaws of the trap. The beaver is attracted by the odor of the bait, and as he raises his nose to it, his foot is caught in the trap. In his fright he throws a somerset into the deep water. The trap resists all his efforts, the chain by which it is fastened defies his teeth, he struggles, at length sinks, and is drowned. Upon rocky bottoms, where it is not possible to plant the pole, it is thrown into the stream. In case several members of a household have been trapped, and the others become shy, the trapper gives up the use of the bait, and conceals the traps in their usual paths and crossing-places.

BIRDS. — These may be caught in traps (see *Brick, Coop, Fowling Net, Sieve, Snare,* and *Spring Trap*), and with bird-lime. It may be made from the holly, slippery elm, mistletoe berries, and the young shoots of the elder. It should be boiled with water in a pipkin till the green bark is separated from the gray; the green bark should then be laid upon the stone of some outhouse and covered with rushes; in about 14 days it will turn into a kind of slime; beat this up in a mortar with a few grains of wheat, after which it may be put into an earthen vessel and kept: when required to be used, it should be

melted over the fire with a little goose-grease, in a dry pipkin; the twigs should then be smeared with it. When the bough is well limed it must be fixed on a low dead hedge near a rickyard, hemp or flax field, or in some other resort for small birds, and the sportsman having concealed himself as near to the bough as he can, must imitate, with his mouth or with a bird-call, the notes which birds make when they attack or call one another; but if he should not be expert at this, there is another mode called a *stale*. A hawk of any species, or a bat, make very good stales, but an owl makes the best of any. If an owl be fastened in some conspicuous place at a short distance from the limed bough, the birds will collect around it in great numbers, and will settle on the bough and be taken. When one bird is thus enticed and stuck fast, it must not be disengaged, but suffered to remain and attract others by its fluttering, so that many may be taken at once. A stuffed owl will do nearly as well as a live one. Sometimes the representation of an owl carved in wood is used, and being painted in the natural colors of the bird, is found to succeed. As soon as the birds are caught relieve them, or they will flutter to death. Wash off the lime with a cloth dipped in alcohol, but be careful in applying it, for the smell kills small birds. If the heads of the birds are not limed, cover that portion of them with a silk handkerchief, and use a sponge to wash off the lime.

BOX PIT FALL.—The advantages of this trap consist in its simplicity, its never missing, and the fact of its keeping itself set for use. It consists of a box without a lid, 1 ft. sq., and the deeper the better. Procure a sheet of tin large

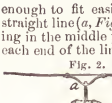
Fig. 1.



Box Pit Fall Trap.

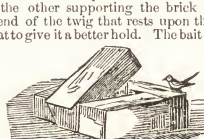
enough to fit easily inside the box; scratch a straight line (*a*, *Fig. 1*) across the centre, and ending in the middle points of 2 opposite sides; at each end of the line solder a loop of tin (*b*, *Fig. 2*); over the middle of the line, and at right angles across it, rivet a strip of tin in the form of a loop, extending 1½ in. on each side of the line, and bagging out about 2 in. In the centre of the loop bore a hole, through which pass a string with a weight attached, to hang down 3 or 4 in. (*a*, *Fig. 2*). The weight must be enough to serve as a counterpoise to keep the tin in a horizontal position. The tin is then fastened inside the box, to form a platform 3 in. below the top edge of the box, done by driving 2 pieces of stout wire, one through each side of the box, so as to pass through the small loops soldered on the edges of the tin; these pivots form the only support of the tin platform, which swings freely on them; the weight of a small mouse jumping on it will tilt up the platform, and let the mouse drop down into the box. As soon as the tin is relieved of the weight of the mouse it returns to a level position. The bait is placed on each side of the tin, and fastened by a string passing through holes in the tin; without this the bait would fall off the first time it was disturbed. The box should be sunk into the ground with its upper edges level with the surface.

Fig. 2.



Box Pit Fall.

BRICK.—Bricks are arranged, 2 lengthwise, upon their narrow sides, 1 in front, and the 4th between the 2 side bricks; this is so placed that it will fall easily upon the front brick. Within the trap a stout peg is driven into the ground, upon which a forked twig is placed horizontally; above this a stick is placed, one end on the twig and the other supporting the brick slanting. The end of the twig that rests upon the peg is cut flat to give it a better hold. The bait is strewn

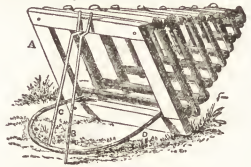


Brick Trap.

upon the ground inside of the trap. When the bird flies to the trap he generally perches for a moment on the forked twig and causes it to give way; the brick that has been propped up falls upon the front brick, securing the bird. In preparing the trap proper caution should be used in setting the upper brick, so that it does not fall between the 2 side bricks unsupported by the front brick, as in such a case the bird would be crushed.

COOP.—Construct a coop with strips of wood, in the manner shown in the illustration. Procure a thin strip of rattan, or a thin piece of willow; its length such that, when bent into a semi-circular arch, the height of the arch will be a little more than ½ the diameter of the coop. Through each end of the rattan, burn a hole with a piece of hot wire; nail the ends to the inner edge of one side of the coop, in such position that all parts of the curved rattan are well inside the opening of the coop; also using nails that fit loosely through the holes, and allow the rattan some freedom of motion. Next get a straight stick *B*, with a fork at one end, and long enough (exclusive of the fork) to support one side of the coop when tilted up at an angle of about 30°; another stick is needed, having a crook 2 in. long at one end, as shown at *C*; the straight part of this stick should be 1 in. less than the straight part of the forked stick *B*. To set the trap, raise up one side of the coop to the height of the fork of the stick *B*; insert the crook of *C* through the fork and underneath the edge of the

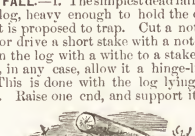
coop, forming a catch on which the side of the coop rests; press the lower end of *C* back inside the rattan hoop, and lift the latter from the



Coop Trap.

ground high enough to catch and hold the end of the stick *C*. Lastly, strew appropriate bait on the ground inside the hoop. When a bird hops on the rattan, the suspended hoop will fall to the ground, releasing the end of the stick *C*; the coop will fall, and enclose the bird.

DEAD FALL.—1. The simplest dead fall is made with a log, heavy enough to hold the creature which it is proposed to trap. Cut a notch in a stump, or drive a short stake with a notch in it, or fasten the log with a withe to a stake or sapling, or, in any case, allow it a hinge-like motion. This is done with the log lying on the ground. Raise one end, and support it upon a



Dead Fall Trap.

figure four (which see), baited. The bait stick of the figure four must be at right angles with the log, and inclosed with stakes, to allow the animal to approach only from one side, and obliging it to stand to cross the line in which the log would fall. Another way is to arrange 2 logs, one to fall on the other in the same way. Stakes may be driven at the side, if necessary, to insure one log falling on top of the other.

FIGURE 4.—For rabbits, squirrels, opossums, wood chuck, etc., use an ordinary box trap, with a figure 4 to support the lid.

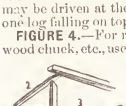


Fig. 4 Trap in Position.

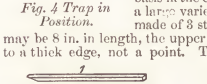
But if for any animal but a rabbit, line with tin or sheet iron, to prevent them gnawing their way out. The *figure four*, which forms the basis in the construction of a large variety of traps, is made of 3 sticks; the first may be 8 in. in length, the upper end whittled to a thick edge, not a point. The horizontal



Pieces of Fig. 4 Trap.

piece or trigger, 10 in. long and square, has a notch on one side, 7 in. from one end. On the upper face of the trigger, 6½ in. from the side notch, is another notch. The diagonal has both ends beveled or brought to a wide edge, and a notch cut near one end. In setting up the figure, hold the perpendicular up, fit the trigger to its side, then adjust the notch in the diagonal to the perpendicular, and insert the other end of the diagonal in the notch near the end of the trigger. Let the lid of the trap, or the fall, rest on the end of the diagonal immediately over the trap: this makes the figure four stand firm, yet ready to fall at a slight pull upon the trigger, to which the bait is fastened, the trigger extending 3 in. from the perpendicular. Directly under the fall dig a hole, 4 to 6 in. in depth; the size regulated by the board; over the hole place a bridge of sticks, or fill it up with straw. When the trap springs, and the board falls, it will strike the bird or animal sufficiently hard to kill it, but the straw under it will keep it from being crushed.

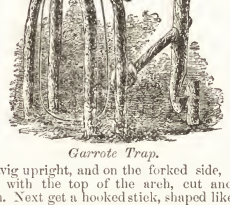
FOWLING NET.—A contrivance for catching birds at night, and is constructed as follows: 2 poles of light flexible wood, 8 ft. long, bent at one end, each kept in a bent position by a cord (*C*), one end of which is tied to the top of the pole, the other end secured half way down. The 2 bent ends are hinged by a strip of leather at *E*. A fine net (*A A A*), 7 ft. long and 4 ft. wide, is fastened between poles, the bottom end of it turned up 8 in., forming a bag or pocket (*B*). There must be 3 persons engaged, one to hold the net, another to carry a lantern, and a third to beat the bushes. The darkest nights should be chosen; and if a stiff breeze is blowing, so much the better, for the birds then roost low, and are not able to hear well. The net should be held 1 ft. from the bush, etc., and the lantern held so that the light is thrown evenly over the back of the net. The bush should be slightly beaten, and the birds, on being disturbed, will fly against the net, which should be instantly closed and brought to the ground, and the birds secured.

Fowling Net.

FOX.—The trap should be a Newhouse No. 2, and free from human scent. In order to avoid this, the trap must be thoroughly washed in weak lye, and when dry, greased and smoked over burning feathers. The fox has a keen scent; it is therefore necessary to employ clean buckskin gloves in handling the trap. The trap should be concealed in a bed of ashes, leaves, chaff, or buckwheat, well smeared with blood or beeswax. Fasten to a clog, so that he can move about. To make the allurement sure, obtain from the female of the dog, fox or wolf, the matrix, in the season of coition, and preserve it in alcohol, tightly corked. Leave a small portion of it on something near the trap; and, when visiting the trap, put some on your boots. Make a trail round the trap; a piece of raw flesh may also be dragged about; and leave everything around the trap as natural as possible. Another good plan is to get some earth from a kennel where a tame fox is kept. Set the trap in it. Bait the beds several times before setting the trap, until a degree of

confidence appears to have been established, then put the trap in its place, and catch him.

GARROTE.—Provide 2 stout switches 30 in. long, sharpen both ends, bend one into the form of an arch and plant it firmly in the ground; bend the other into the same form, and plant it by the side of the first, leaving one in. clear between them. Cut a number of stakes and plant them in the ground so as to make a circular fence of which the second arch forms a part, inclosing a space 1 foot in diameter, to which the only entrance is through the arches. Drive a notched peg into the ground at the back of the inclosure, opposite the centre of the arch; cut a piece of twig a little longer than the height of the arch (it should have a short fork sloping away from its side, to which the bait is fastened); at the lower end of the twig and on the side opposite to the fork, cut a notch to fit into the notch in the peg driven in the ground; hold



Garrote Trap.

the twig upright, and on the forked side, at a level with the top of the arch, cut another notch. Next get a hooked stick, shaped like the one in the illustration, long enough to reach from the outer arch back to the upright twig. On a line with the arches, and 3 ft. distant, drive into the ground a crotched stick, so that the crotch is level with the top of the arches. Get a stiff pole, 6 ft. long, weighted at one end with a heavy stone tied to it; at the other end fasten a loop of cord or fine wire in the shape of a U, the same width and height as the entrance under the arch. To set this trap, lay the pole across the crotch, adjusting it so that the loop hangs exactly between the arches; place the hook of the stick, under the top of the front arch, the remainder of the stick extending over the pole and back into the inclosure; catch the end of it in the upper notch of the upright twig, and secure this last by its lower notch to the notch in the peg which has been driven in the ground; let the fork which holds the bait point a little sideways from, rather than towards the entrance of the arch, as it will make the springing of the trap more certain. The animal must first pass partly through the arches; as soon as it seizes the bait the upright twig is displaced, the hooked stick set free, and the loop hoists the animal up by his hind-quarters, and holds it firmly caught against the top of the arches. This is an excellent snare for rabbits, raccoons, etc.

GOPHER.—Hillocks of earth serve to show the track of the burrow beneath, and by digging down in the line between the hills of earth which the animal deposits at intervals of 5 and 6 yds., the burrow will be found, and a No. 1 steel trap may be set on a level with the bottom of the passage, laying a piece of board over the opening, and re-arranging the earth above it; the gopher will be caught in the trap the first time it passes through.

HAWK AND OWL.—To catch hawks or owls, take a pole 20 ft. long, to be set a short distance from the house or barn, or on the poultry house. Split the top to admit the base of a common steel trap, which should be made fast. These birds naturally light on high objects, such as dead branches of trees, or tops of stacks, and one should use judgment about the place to put the traps; an open field near the chicken-yard is probably the best.

MARTEN.—The *Pine-Marten*, or *American Sable*, lives in the trees and preys on partridges, mice, squirrels, hares, etc. A piece of either of these may be used as bait, or the head of a fish, pheasant, or a piece of meat, and the trap (Newhouse No. 3) may be placed in a hollow tree, in any inclosure, or in the track of a deer; in each case let it be well covered with light grass, moss, or rotten wood, to present a natural appearance. The *Fisher-Marten* is attached to low, swampy ground; is partially web-footed, and subsists on fish, mice, rabbits, etc. Be careful to scent the trap and conceal it properly; also attach it to a spring-pole, so that when caught it will be elevated out of the way of becoming a prey to larger animals, and prevented from dismembering itself to get clear of the trap. The pine-marten and the fisher live and breed in hollow trees; they are not difficult to trap, but are furious when caught. Draw a trail composed of oil of anise, assafœtida, and the musk of the muskrat, mixed with fish oil, and placed in a deer-skin bag about the size of a mitten, pierced full of holes with a small awl. If drawn along the line of traps, the scent is sure to attract the fisher's attention; and when an animal once finds it, he will follow the trail till he comes to the trap.

MINK.—Minks should not be taken for the fur earlier than October nor later than March. They can be taken on land or water; the land is preferred by trappers. The trap is set near the bank of a stream. If one of their holes cannot be found, make one. Three sides of the cavity should be barricaded with stone, bark, or wood, and the trap set in the entrance. For bait, use fish, bird, or muskrat, cut in small pieces, and placed in the hole beyond the trap. Cover the trap with leaves, grass, or feathers. In the coldest weather, smoke the bait. The best scent for attracting mink is fish oil. The chain of the trap should be fastened to a spring-pole, to lift the animal out of the reach of depredators; or, if the trap is set near water, it should be attached to the sliding-pole, so as to drown it at once. Another plan is to form a triangular inclosure, by driving short stakes into the ground. One side is left open for an entrance, and for a cover a few evergreen boughs are used. The bait is pinned by a forked stick to the ground in the point of this inclosure, and the trap set in front, so that the game must pass over

it in order that it may be able to reach the bait.

MOLE TRAP.—1. In *Fig 1*, the plank, *P*, 8 to 12 ft. long, has a hole in the lower end which passes over a pin driven into the ground, to hold it in place; 3 or more stout wires, very sharp, are inserted 1 inch apart on each side of the end of the plank. The pairs of wires should be 9 in. apart. A stone or other weight, *S*, is added to bring it down forcibly. A common fig. 4, *T*, is placed under the plank, with the trigger lying across the mole track. When setting it, the track is flattened with the foot where the trigger is to rest upon it. The plank should have a fall of 12 to 15 in. The mole in passing lifts the trodden ground and the trigger resting upon it, and is instantly pierced by

Fig. 1.

Mole Trap on Fig. 4 Principle.

the descending points. — 2. Mark every new mole hill by a slight pressure of the foot, and observe on the following day whether a mole has passed over it and destroyed such mark; this operation should be repeated 2 or 3 mornings without making the pressure so deep as to alarm the animal. A trap should be then employed, as shown in *Figs. 2* and *3*, made of wood, and thus constructed: Take a piece of wood, 4 in. long, 2 in. wide, and ½ in. thick. In one side of this insert 2 half circles of wood, *A A*, *Fig. 3*. Bore a hole through the centre, and one at each end. Make 2 loops of wire by bending and pinching it through the holes at each end, so as to leave the ends standing up a little way out of the holes, above the surface of the wood, where they are to be tied to a string. In the half circle of wood cut small grooves, and open the wire loops so that the wire may lie in these grooves; then plaster them over with mold. To set the trap, select a tough, green stick to act as a springle, and tie a piece of strong cord to the end of it. Pass the other end of this cord through the hole in the middle of the trap, and tie a knot in it. This hole must be large enough to allow the knot to pass through easily. A little wedge of wood (*B*, *Fig. 3*) is pushed up between the knot and the wood beneath, to keep the knot from slipping through, and 2 pieces of wood are placed across the trap to keep it down to the ground. The springle, fixed in the ground, is driven down and tied to the string to which the wires are attached. The trap is then set in the

Fig. 2.

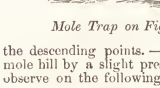


Fig. 3.

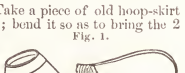
Mole Trap.

places marked, and when the mole attempts to pass it is compelled to go through one of the half circles of the trap, and in doing so it moves the wedge which holds the knot of the string tied to the springle. This done the springle flies up, draws the wire loops tight, and the mole and the trap are by this means both suspended in the air.

MOUSE. — 1. Take a piece of old hoop-skirt spring 14 in. long; bend it so as to bring the 2 ends together to make an irregular oval (*Fig. 1*). Tie the bait, strong-smelling bacon or toasted cheese, or anything of the sort, to the place where the spring is brought together. Turn a wash-bowl upside down, put the spring as arranged on its edge, under one edge of the bowl, bait inside, and your trap is set. This trap springs readily; but there is a difficulty in securing your game. A flexible piece of wood will answer instead of the spring. — 2. This is made of a common brick with 2 pieces of wood inserted into the ground (*Fig. 2*); a bit of sewing-thread is tied to each stick, and a loop is formed in the thread in the centre, into which a bean is put. To form this loop, take the 2 ends of the string and cross them, in the same manner as when tying a common knot; then draw the ends, and the loop will become smaller; insert the bean, and draw the thread tight, until it slightly penetrates the bean. Poise the bean half way between the 2 sticks, and let the brick rest upon the string, which should be tied tightly. When the mouse nibbles at the bean it will gnaw the thread, the brick will fall, and the mouse will be killed. — 3. Procure a tolerably tight barrel; bore a hole near the bottom for entrance; set in the place where mice gather; throw into it an armful of ears of corn and a handful of rags or waste paper, to make a nest; cover it, and let it stand a few days to give the mice time to colonize, then plug up the entrance. As mice are lively little animals, dash in a few gallons of water to moderate their friskiness.

Fig. 1.



Mouse Trap.

Fig. 2.

Mouse Trap.

MUSK-RAT. — Allied to the beaver, and may be caught in the same way (see *Beaver*); they may also be taken as follows: 1. Sinking an old barrel with its top on a level with the ground, on the edge of a stream near their haunts; half fill it with water; put in a couple of shingles or light strips of board to float on the water; on these place small bits of sliced apples, potatoes or carrots, and some in the runs, so as to lead them towards the barrel. The rats will leap into the barrel after their food, and cannot get out.— 2. Find a muddy spot near the rat's hole; make a pen of sticks driven down close together, leaving an opening in front just wide enough for the trap. Put sweet apples in the pen far enough so that the animal will have to step over the trap

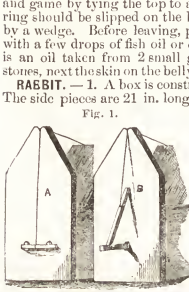
in order that he may be able to get at them.

OPOSSUM.—They may be caught by setting traps in their haunts, baited with corn, mice, etc. They visit hen-roosts, and can be caught at the entrance by traps. A Newhouse No. 2 or 3 will answer for an ordinary-sized opossum.

OTTER.—The fur is valuable. In summer it is short, and almost black; in winter, a rich reddish brown. Look along a stream for the deepest holes where the fish ily when pursued. On close observation tracks where the otter comes out up the bank will be seen, and often you will find a tuft of grass greener than the rest; open this, and you will find the dung of the otter, full of scales and bones of fish. Having found out his favorite landing-place, make a run, shunting from the water up the bank, with a trapping-paddle; dig out a place the form of the trap; set the trap shunting, so that the otter should not tread on the spring, and cover it over with fine mold. When done, go back as far as you can, and with your hand throw water on the place where the trap is set and all around, to take away the scent of your hand and the fresh mold. Fasten the trap as follows: Cut a small tree, the size of the chain ring, and set it upright near enough to the path to help the animal into the trap, supporting it in that position, and securing the trap and game by tying the top to another tree. The ring should be slipped on the butt and fastened by a wedge. Before leaving, perfume the trap with a few drops of fish oil or otter-musk. This is an oil taken from 2 small glands called oil stones, next the skin on the belly of both sexes.

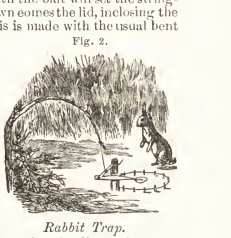
RABBIT.—1. A box is constructed as follows: The side pieces are 21 in. long and 9 wide; the bottom the same length as the side-pieces, and 7 in. wide; the piece for the back 18 in. high and 7 wide. Nail the side-pieces against the edges of the bottom; set the back-piece upright in the end and nail it fast through the sides and bottom. The movable lid consists of 2 parts; the lid itself 20 in. long and 7 in. wide, and the end-piece 8½ in. long and 7 wide; nail the end of the lid on to the top edge of the end-piece, and plane off the edges of the lid and flap, to allow the whole to work freely inside the box. Bore a hole through each of the side-pieces, 4 in. from the tall end, and ⅜ in. from the upper edge. Through each of these holes drive a piece of stout wire (2 in. long, pointed at one end), one into each edge of the lid; these serve for hinges. Bore a hole through the tall end-piece, *B*, 4 inches above the bottom, and 2½ in. from the right side of the box, making the hole admit freely a round stick of wood, the thickness of an ordinary lead pencil, and 4 in. long, for a bait-stick; provide another strip of wood for a string-piece, 6 in. long, and thicker than the bait-stick; fasten the end of a piece of strong cord to the middle point of the extreme edge of the lid; cut a nick in the top point of the tall end-piece, pass the string over the nick, and down the back of the end-piece, as seen at *A*; tie this end of the cord to the string-piece, 2 in. from its end, adjusting length of string so that, when the lid of the box is down, the string-piece to which the cord is attached will hang down on the back of the end-piece 10 in. above the bottom of the box. At a point on the back, 2 in. distant from the left side, and 4 in. above the bottom, drive in a nail, so that the head will project ½ in. To set the trap, put the bait on the end of the bait-stick, insert the other end of the bait-stick from inside the box, into the hole, allowing it to project outside the back ½ in.; pull the string-piece down, slip the shorter end under the nail, and let the other longer end catch slightly but securely underneath the projecting end of the bait-stick. The lid of the trap will be found to have been raised 6 in., affording free ingress to any animals passing by; the first one that ventures to meddle with the bait will set the string-piece free, and down comes the lid, inclosing the prisoner. — 2. This is made with the usual bent sapling and string.

Fig. 1.



Rabbit Trap.

Fig. 2.



Rabbit Trap.

A circle of stakes acts as the spreader. The string comes down from the spring, is tied to the diagonal of a figure four, passes thence around the ring or stakes, but not enclosing the upright of the figure four. The noteh in the horizontal bar must be sharp and oblique, so that the diagonal cannot draw out. The noteh in the upright should be square and deep, for it is here the leverage comes. Although the notch in the upright is square and deep, a little pushing on the part of the rabbit at a bit of apple easily throws ont the trigger, when he will be found caught, if he does not sit entirely in the ring. If he does the string is likely to pass over him; but if, like most wild animals, he nibbles a bit before he crosses the line, he is almost certain to be caught.

RACCOON.—Set a steel trap on the edge of a swamp, 1½ in. below the surface of the water, and secure by a chain to a stake. Suspend the bait, a piece of chicken, fish, or frog, 2 ft. above the pan of the trap. The raccoon will leap for it, and when he comes down he springs the trap, and is held a prisoner.

RAT.—1. Take a circular piece of wood, smaller in circumference than the barrel in which it is to be placed; saw it straight through the middle. Hinge each piece, like a table leaf, to a bar fitted across the middle of the open end of the barrel. Pass a cord through a small hole in each leaf, and make a knot underneath to prevent it from pulling through. Fasten a weight to the loose end of each cord, and pass them over the bar, crossing them, and hang them down

into the barrel, to keep each leaf extended in a horizontal position. The bait is fastened to the top of each leaf, to prevent it from falling off. The weight of the rat turns the leaf, and precipitates it into the barrel, which should contain sufficient water to drown a number. To be self-adjusting, the hinges and cords must work freely.—2. Procure a barrel which is water-tight; place a stone or rock in the bottom, and pour in water to nearly cover the rock, leaving only enough of it bare to allow of a resting-place for a single rat. Instead of the head, stretch a piece of thick paper, or other durable material, over the top of the barrel, and fasten it securely by means of a cord passed around the outside of the barrel; damp the paper slightly with a sponge, and it will become tight when dry. On the paper strew cheese parings, etc., several days in succession. As soon as the rats appear to have sufficient confidence to come regularly to supper, cut a cross in the middle of the paper, and spread the feast as before. The first rat that drops through will establish himself on the rock; the next rat falls, and tries to gain a footing on the rock; the first rat resents the aggression, and the 2 argue the point with such determination, that all the rats in the vicinity hasten to the disturbance, and meet the fate of their predecessors.

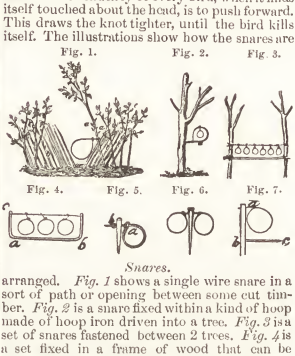
SIEVE. — For taking all birds that gather upon the ground. It is most effective when snow lies upon the ground, for then the birds are less shy in the pursuit of food. The trap consists of an iron or wooden hoop covered with a net formed of meshes of about 1 in.; the lighter the net the better. The hoop is put to stand at an angle, and is propped up by a piece of stick 2 feet in length. At the bottom of the net, and lying upon that part of the hoop which rests upon the ground, is placed a heavy stone, so that when the stick is withdrawn, the net drops down upon the

Sieve Trap.

birds. A long string is tied to the stick, and is held by the person, who keeps as far away as is compatible with his being able to see when the birds are under it. It is better not to drop the trap when a single bird enters, as it will serve as a decoy, and a little patience will be rewarded by the capture of a number of birds instead of one.

SKUNK.—Place an old barrel on the side of a triangular stick of wood 6 in. high, fastening the bait on the bottom of the barrel. When the skunk goes for the bait, as soon as he passes the centre, the barrel turns up with the skunk, without any scent. Then take it by the tail, and do with it as you please. Great care must be taken in placing the barrel, that it will not be too high, as it might throw over, and not remain upright. The more skunks you catch in the same barrel, the better the trap.

SNARES. — Snares are not very certain, but they are little trouble to make. They must be set in the paths or runs of the birds. They are of horse-hair or thin copper wire, tied in a running knot. The tendency of every bird, when it finds itself touched about the head, is to push forward. This draws the knot tighter, until the bird kills itself. The illustrations show how the snares are



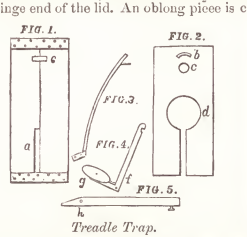
Snares.

arranged. *Fig. 1* shows a single wire snare in a sort of path or opening between some cut timber. *Fig. 2* is a snare fixed within a kind of hoop made of hoop iron driven into a tree. *Fig. 3* is a set of snares fastened between 2 trees. *Fig. 4* is a set fixed in a frame of wood that can be taken up and set down anywhere. Care must be taken that the frame be heavy enough not to topple over, or it should be sustained by small sticks. *Fig. 5* is made of stiff string or thin cat-gut, fixed to a stake driven into the ground, and *Fig. 6* is a double wire snare, in which the wire is passed through the stake. This is also driven into the ground. *Fig. 7* shows a snare arranged as it would be in an ordinary post. In *Figs. 3, 4* and *7* the parts of the arrangement immediately below the snare, which serves for the bird to perch upon, should be wide enough to contain small grain.

SQUIRREL. — Place a steel trap on the upper rail of a fence where they frequent; set a pole with an ear of corn, or other squirrel food, fastened on the end, up against the fence, leaving it so as to spring the bait over the trap at a height of 6 or 8 in.; when the squirrel reaches to get the bait he will get into the trap.

TREADLE, For Small Animals.—It should be made of common outside boards of pine, and stained (not painted). *Fig. 1* is the floor of the trap, 22 in. long, 14 in. wide, and $\frac{3}{4}$ in. thick. It must be made in 2 pieces to admit of the treadle or trigger being screwed on the edge of one of the boards, which must then be nailed together with 2 battens, 2 in. wide and $\frac{1}{2}$ in. thick. A strip is cut out 6 in. long and $\frac{3}{4}$ in. wide, at *a*, and the heel of the trigger works in this opening, and is screwed through the hole at *f*. *Fig. 4*, on the edge at *a*, *Fig. 1*. *Fig. 2* is the lid, made solid, or in 2 pieces, like *Fig. 1*, but 2 in. shorter; *b* is a staple to receive the end of the

lever; *c* is a hole to allow the iron stanchion, *Fig. 3*, to pass through without grazing; *d* is a hole, 3 in. in diameter, with its centre 4½ in. from the hinge end of the lid. An oblong piece is cut



Treadle Trap.

out from this hole to the hinge end ½ in. wide, so as to allow the neck of the trigger to work freely. The hinges may be made of old stirrup leather. *Fig. 3* is an iron stanchion of ½ in. round iron, flattened at the foot, having 2 holes for screws; it must be bent to a radius of 15 in.; ½ in. from the other end it must have a pin riveted in, about the thickness of a quill, standing out at right angles, and ¾ in. long. The stan-

Fig. 6.

Treadle Trap.

chion is screwed on to the floor at *e*. *Fig. 4* is the trigger and plate. From notch to *f* is 4½ in.; from *f* to *g*, 3 in. The plate is a piece of round sheet iron, 3½ in. in diameter, with a hole in it to be riveted to the trigger. *Fig. 5* is a wooden lever, ¾ in. wide and ½ in. thick, to reach from the top of the trigger, when set, to the staple *b*, *Fig. 2*. 2 in. from the end, as at *h*, is a hole to receive the pin in the top of the stanchion, and at the other end a lath-nail to catch the notch in *Fig. 4*. *Fig. 6* is the trap when set. *Fig. 7* is a round piece of sheet iron, 4 in. in diameter, with 4 holes punched in to tie the bait on. To set the trap, put the lever on the iron stanchion, raise the lid till the end of the lever catches under the staple; press the other end down, and let the nail catch the notch in the top of the trigger, and weight the lid with stones. Having tied the bait on *Fig. 7*, merely place it on the hole *d*, with the bait downwards, but not too low. The animal, reaching up to smell at it, lets the trap off by setting its feet on the trigger.

STEEL.—These are about the best traps used; are made of every style, and are best bought. The Newhouse are much used, and we give the following directions for them:

SIZES OF NEWHOUSE TRAPS ADAPTED TO THE CAPTURE OF DIFFERENT KINDS OF GAME.

Kind of Animal.	No. of Trap.	Bait Required.
Squirrel	0	Grain, nuts, or ear of corn.
Gopher	1	Grain, nuts, or ear of corn.
Muskrat	1	Carrots, potatoes, apples, etc.
Woodchuck	1 or 1½	Roots, fruit, corn, or bread.
Mink	1½	Fowl, flesh, or roasted fish.
Fisher-Marten	1½	Meat, muskrat, or deer flesh, fish.
Skunk	1½ or 2	Mice, meat, piece of a fowl.
Fox	2	Fowl, flesh, fish, toasted cheese.
Opossum	2 or 3	Nuts, corn, mice, piece of fowl.
Raccoon	2 or 3	Chicken, fish or frog.
Badger	3	Mice or flesh of any kind.
Otter	3	Fish, piece of a bird, or otter musk.
Marten	3	Head of a fish, piece of meat or fowl.
Beaver	4	Fresh roots, eastoreum on the end of a stick.
Wolf	4	Waste parts of tame or wild fowl.
Com. Black Bear	5	Pork, beef, ear of corn, honey.
Grizzly Bear	6	Pork, beef, ear of corn, honey.

The numbers 0, 1, and 1½, respectively, are single spring traps; No. 0 is the smallest size; all the others are double spring traps, No. 6 being the largest trap made. The above baits should be scented where necessary by a proper selection from the preparations previously described.

WILD TURKEY.—A trap is made by digging a ditch; then over one end is built a rude structure of logs, covered at the top. The structure should not be tight, but sufficiently close not to let the birds through. Indian corn is scattered about, and in the ditch and inside the pen. The turkeys follow up corn in the ditch, and emerge from it on the inside. Once there, the birds never think of descending into the ditch, but walk round and round the pen, looking through the chinks of the logs for escape that way. To make all sure, the ditch should end about the centre of the pen, and a bridge of sticks, grass and earth built over the ditch, just inside of the pen, and close to the logs; otherwise, in going around, the bird might step inside the ditch.

WOLF.—The wolf may be caught in various ways. An attractive bait will allure them into any fair sized dead-fall, or they may be secured in a steel trap of medium size, attached to a clog. The trap may be placed at the entrance to an inclosure. The wolf is very shy, and almost as quick-scented as the fox. Use a trap well cleaned with weak lye; after drying, oil or grease it well, and smoke it over burning hair or feathers. In handling it, use clean buckskin gloves, to avoid imparting the least human odor. Make the bed for the trap 3½ ft. in diam., so that the jaws, when set, will be on a level with the ground. Cover with fine dried grass, wheat, oat or buckwheat chaff; secure it well with a chain; level all neatly to a natural appearance, and bait with fresh meat or roasted cheese. Wolves are strongly attracted by the odor of sweet-fennel, which may be sprinkled in a powdered state around the traps, to overcome human traces; the oil of rhodium is successful in luring the wolves to any spot where placed; and some trappers use this

oil on the soles of their boots, in order to cause the wolves to follow their tracks leading to the traps. A small quantity of strychnine, mixed with lard, smeared on slices of meat, and the meat rolled up so as to conceal the poison, will kill a wolf in a few moments. The poisoned baits may be laid around in places where they prowl; or the animals may be attracted from a distance by the smell of blood taken from any fresh killed beast or bird, and judiciously exposed in the neighborhood of traps and baits. Poisoning is often resorted to when wolves make havoc among sheep or in the farm-yard; but the use of it is detrimental to the fur, when the animals are trapped for their skins.

WATER SPORTS.

FISHING.

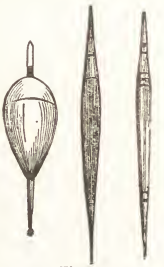
REMARKS. — The art of angling is varied by circumstances, and must be based on a knowledge of the habits of fish. The regular season for fishing is from April to November. The best time of the day during summer is from sunrise to 2 or 3 hours after, and from 2 hours preceding sunset until 1 hour after; in the colder months, from 12 to 3. The south wind, and after that the west, is considered best by experienced anglers; a cloudy, though not cold day, is favorable. Fish are whimsical; one may have fine fishing on a cold day, with an east wind; and then again when the sun is beaming down scorchingly, and not a cloud in the sky. Be cautious. Fish are shy. Never show yourself near where the fish lie, if you can help it. Never let your shadow fall on the water; and if you cannot fish with your face to the sun, take shelter behind a tree, bush, or rock. A disgorger will be necessary to aid in getting out the hook when swallowed very far; and also a little leather case containing extra hooks, a pair of pliers, scissors, some shoemaker's wax in a piece of soft leather, and a piece of stout cord, to be waxed and wrapped around the rod, in case it should break; and lastly, a fish-basket.

TACKLE.

CARE OF.—Every line, after use, should be run off from the reel and laid out freely, or stretched on pegs to dry. Should they have been lying by for any length of time, they should be examined and tried in every part before using. Lines will chafe and fray out by constant wear, and many large fish are often thus lost. When the season is over, the rod should be cleaned, oiled, and put away in a cool place. The best rod, if exposed a length of time to a dry atmosphere, will shrink, causing the ferrules and guides to become loose. A moist atmosphere is preferable to a dry one. When rods have not the ends covered where the joints are put together, and become by a day's service swelled, hold the ferrule over a candle or lighted paper, to dry out the moisture, and the parts can be easily separated. To prevent this, oil the wooden part that is let into the socket.

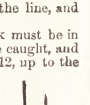
CLEARING-RING.—A ring weighing ½ lb. to 6 oz., tied to a stout cord, and when the line is caught in some obstacle under the water, is placed around the line, and sent down to clear the way.

FLOATS.—Floats can be procured of all sizes and shapes. For small fish and slow streams, quill floats are best; and in strong rivers, or for larger fish, cork floats can be employed. If the angler prefers to make his floats, procure a piece of fine-grained, sound cork, and bore a hole through it with a small red hot iron; then put in a quill which will exactly fit the aperture, and cut the cork into the shape of a pear. When this is finished, grind it smooth with pumice stone, and paint and varnish it. The cork float should swim perpendicularly in the water, so that it may betray the slightest nibble, and must be poised by fastening a few shot on the line; the proper sizes of shot are from swan shot down to No. 4; they should be split ½ way through with a small chisel, so as to make a gap sufficiently wide to admit the line, and the gap closed with pliers.



Floats.

HOOKS. — The size of the hook must be in proportion to the kind of fish to be caught, and vary from the little fly hook, No. 12, up to the salmon, No. 0. As to style, the Limerick, *A*, *B*, is decidedly a favorite; although, for some fishing, the Kirby, *C*, is excellent. The sizes of both kinds are the same. There is also the Virginia hook, which is popular with Southern fishermen. It is shaped like the Kirby with a Limerick barb, and is longer in the shank than either. After getting the hook to suit, test each and see that it has a good temper, and that the point is sharp and perfect. When fastening the hooks on the lines, use strong but fine silk near the color of the bait; wax the silk thoroughly with shoemaker's wax, and wrap it 4 or 5 times round the body of the hook, then place the gut or hair



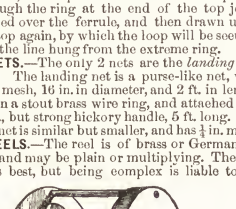
Fish-Hooks.

on the inside of the hook, and continue winding the silk tightly round till wrapped about 3 parts down the hook. Whipping is finished off by slipping the end of the silk through the last circle, and drawing it tight; knotting by laying 2 pieces of gut or hair together, one overlapping the other 3 in. or so, then holding one end in the left hand, while forming a simple slip-knot on it; then turning the other end to the right and doing the same; after that drawing the two together, which makes the knot complete. No direct pull will ever unloosen this, though it can be undone easily.

LINES.—Different lines are required. For catching shiners, a stout piece of homespun thread will answer, and with this and a No. 11 hook, you can capture a ½ lb. sunfish or perch. Sea grass is good for a short line. For the main line, plaited silk or well-twisted hemp is best, measuring 50 yds. It should be boiled in linseed oil before use, which will render it less liable to kink. To catch large pike, where you troll for them, a stout cotton or hemp line is best. The most serviceable lines are pure horse-hair. Good lines should be perfectly twisted; round, and without irregularities, and those of a light gray, brown or white are most useful; some prefer a light sorrel tint. The bottom or casting line for fly fishing, which is affixed to the line on the reel, must be of gut, and of about the same length as the rod; the gut should be strong at the top, and very fine at the dropper or bottom, and before any flies are made upon it, it should be picked to see that it is of uniform thickness. When fastening the line on the rod, the loop of the line should be passed through the ring at the end of the top joint, carried over the ferrule, and then drawn up to the top again, by which the loop will be secured and the line hung from the extreme ring.

NETS.—The only 2 nets are the *landing* and *bait*. The landing net is a purse-like net, with ⅜ in. mesh, 16 in. in diameter, and 2 ft. in length set on a stout brass wire ring, and attached to a light, but strong hickory handle, 5 ft. long. The bait net is similar but smaller, and has ¼ in. mesh.

REELS.—The reel is of brass or German silver, and may be plain or multiplying. The latter is best, but being complex is liable to get



Reel.

out of order. The plain imported reel is very good. The reel is used for the purpose of carrying the line safely, and to allow of rapid extension or drawing in of the line.

RODS.—Fishing rods are made of vine, bamboo, hazel and hickory, of various lengths and fashion. The butts are frequently made of maple, with bored bottom. Rods for travelers are made in joints. A perfect rod should taper from end to end, be tight in its joints, and uniformly pliable, not bending in one place more than another. Have a rod for each kind of fishing. The rods should be ringed to guide the line from the reel; and when screwing the joints together attention should be paid to the rings to see that they run regularly on the under side of the rod, so that the line will not get twisted. If the joints of the rod shrink in dry weather, moisten a little to make them adhere better. Varnish the rods once in 2 or 3 years with copal varnish, or else with india rubber dissolved over a slow fire in linseed oil; either preparation preserves the rods. When re-varnishing, scrape off the old surface before putting on the new. A single-handed fly rod ought to be 12 to 15 ft. long, and as light and elastic as possible; a trout rod, for trolling with minnow, about the same length, but stronger; a rod for worm fishing, the same; while a pike rod ought to be strong, stiff, and as straight as a dart, and 14 ft. long; the rings through which the line passes ought also to be of good size and strong, and the fewer of them on the rod the better.

SINKERS AND SWIVELS.—The ordinary plain sinker is of lead, round, like a pipe-stem, and swelling out in the middle, with loops of brass wire on either end to attach the line. The weight is from ¼ oz. for trout, to 2 lbs. or more for sea-bass and porgies. The swivel-sinker is similar to the plain one, except that instead of loops, there are swivels on each end to attach the line. This prevents the line from twisting and tangling. In trolling, swivel-sinkers are indispensable. The slide-sinker, for bottom-fishing, is a leaden tube, which allows the line to slip through it when the fish bites. This is an excellent arrangement, as one can feel the smallest bite, whereas, in the other case, the fish must first move the sinker before you feel him. Split shot are sometimes put on trout lines in place of a sinker. Independent swivels are useful in some kinds of fishing, to prevent the entanglement of the line.

Baits.

REMARKS.—Fish take such bait as the changing seasons produce, and will not at one time of the year bite at the same bait which they will at another; in spring and autumn, worms may be used all day long, and night too; but in summer, worms must only be used early and late, morning and evening. An earth-worm is the first bait the angler looks out for, and may be used for certain kinds of fish, with the certainty of hooking something. When baiting with a worm, the hook should be put in close to the top of the worm's head, and then passed carefully down, gently working the worm up the hook at the same time. Not more than ¼ in. of the worm should be left hanging over the hook. To scour or starve these worms, and get rid of the earthy matter they contain, they must be placed in damp moss, not soddened with water, but only damp. In creeping through the fibres of the moss, they compress and empty themselves. They grow

almost everywhere except in sandy soils. The common white grub is used in trout fishing. They are found in fresh-plowed earth, and under old stumps, decaying foliage, etc. The grasshopper is good for trout in his season. The trout or salmon spawn will attract trout quicker than any other bait, but it is not always to be had. Caterpillars, flies, locusts, beetles, etc., are good for trout.

FLY, Natural. — Fishing with living flies, grasshoppers, etc., which are found on the banks. It is practiced with a long rod, running tackle, and fine line. When learning this system of angling, begin by fishing close under the banks, gradually increasing the distance until you can throw your live bait across the stream, screening yourself behind a tree. In rivers where weeds grow so as almost to check the current, fish where the stream runs most rapidly; in throwing your line into these parts, do not entangle it among the weeds. Draw out only as much line as will let the fly touch the surface; and if the wind is at your back, it will be of no material service to you in carrying the fly lightly over the water. In such places the water is still, and the bait must be dropped with no more noise than a living fly would make if it fell into the water. Keep the top of the rod a little elevated, and frequently raise and depress it and move it to and fro gently, that the fly by its shifting about may deceive the fish. The instant the bait is taken, strike smartly, and if the fish is not so large as to overstrain and snap the tackle, haul it out immediately, as you may scare away many while trying to secure one. Wasps, hornets, and bumble-bees are good baits for dace, eels, roach, bream and chub; they should be dried in an oven over the fire, and if not overdone, they will keep a long while.

FLY, Artificial.— These should be made to resemble, in form and color, the natural fly; but for hiding the counterfeit, and also to hide the hook, add to it an unnatural quantity of legs (hackles), which move with the movements of the fly; these make it impossible for the fish to discriminate between the natural and the artificial fly. The points to keep in view are size, shape and color. Flies are made of green, brown, or yellow silk, and should be coated with a colorless, waterproof wax, made as follows: Burgundy pitch, 120 gr.; white resin, 60 gr.; tallow, 20 gr.; reduce the rosin and pitch to a mixed powder and put them into an oven, and when quite melted add the tallow, stirring thoroughly for several minutes; then cool, and it is ready for use in 12 hours. The following table will be useful in making artificial flies:

COLOR.	HACKLE FOR LEGS AND WHISKERS.	BODY.
Green ..	Very dark green...	Dark green sewing silk, lightly waxed with colorless wax.
Brown.	"Fiery," or cinnamon (not claret) brown	Dark orange sewing silk, well waxed with cobbler's wax, and then drawn tightly between the finger and thumb.
Yellow	Darkish golden olive	Golden yellow sewing silk, lightly waxed with colorless wax.

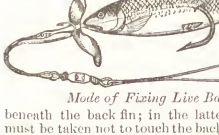
The single rod for artificial fly fishing should be 11 to 13 ft. long, light and flexible, and one easily wielded. Swing the rod back without effort, so as almost to describe a circle round the head, and when the line has reached its full extent behind you, throw it forward, taking great care in the movement. In order to acquire a good style of throwing, and a correct eye for measuring distances, practice at first at a short length only, without a fly on the line, and when you can throw to a moderate range one fly may be put on and practiced with; and as expertness is gained, 2 or 3 may be employed. It is a good plan to fish in rapid streams, until dextrous in casting the fly. When casting, drop the fly lightly on the water. On perceiving a rise, throw the fly above the spot, and let it drop down the stream, and directly the bait is taken strike quickly. When you have hooked a fish, run him down the stream, play him cautiously, keep his head up, and draw him by gentle force toward you. Keep the back to the wind, and if the sun is shining stand with your face to it, that your shadow may not be cast upon the water. If the day is calm, keep away from the brink. The best time for fly fishing is when the day is overcast and gloomy after a beautiful clear night, or when a light breeze agitates the stream; and if the wind is from the south or west and the water turbid from recent heavy rains, it is all the better. Keep your fly in motion that it may appear to be a natural one.

GROUND BAIT, Natural.—Ground baiting is an essential part of angling, as success in bottom or float fishing cannot be expected unless proper means for drawing the fish together are resorted to. The object of throwing bait into the water, is to collect the fish to one spot, and then use a superior bait on the hook. When going to use earth worms, throw in for ground bait those that are unscoured, and fish with those well scoured. For small creek fish, mix bran and clay together into lumps the size of an apple; place grubs in the middle and close the clay over them. It is useful in a still pond, hole, or slight eddy. Or take the crumb of white bread, soak it in water, and squeeze it almost dry; add bran, and work them up together until like clay. Brewer's grains are serviceable, but must be fresh. Grubs, worms, the toughest parts of crabs, lobsters or clams, may be thrown in without taking the trouble of working them into balls or clay, if the water is still; but if fishing in a stream, such a system is injurious, as they are carried away and draw the fish from the spot.

GROUND BAIT, Artificial.—1. Salmon roe is an excellent bait for trout. The roe of large trout or salmon trout is just as good. These are tempting baits for many fresh water fish. Fishermen preserve it as follows: 1st, put it in warm water, not hot to scald; then separate the membraneous films; rinse it well in cold water, and hang it up to dry. The next day salt it with 2 oz. salt and ½ oz. saltpetre to 1 lb. roe. Let it stand another day and then spread it to dry. When it becomes stiff, put it in small pots, pouring over each some melted mutton tallow. —2. The English are famous for paste baits, some of which are made as follows: Shrimp paste is made from shrimps, being prepared as

the salmon roe. Wheat, rye, barley and other grains, soaked in water and then boiled in milk, are good baits for small fish in still water. Soft bread and honey, kneaded together, is a good bait. Grated cheese, worked into paste with soft bread, honey and saffron, are frequently used. Tallow chandler's scraps, fresh scalded to separate the slimy particles, the particles then mixed with clay and bran, are a good ground bait. It is only good when fresh made.

LIVE.—The live bait must have a No. 3 or 4 hook passed either through its lips or the flesh



Mode of Fixing Live Bait.

beneath the back fin; in the latter plan care must be taken not to touch the backbone, or the bait will die. If the live bait seeks the weeds, it must be stopped, and should it become sluggish a good shake of the rod will stir it up. Use a float with live bait, as the length of the line renders it difficult to heave the bait in mid-water at a proper depth without.

SECRET. — The following secret arts are inserted to gratify curiosity, but are not recommended, and some of them are prohibited by statutory law: 1. Put oil of rhodium on the bait.— 2. (*Chinese Method.*) Take *Coccubus Indicus* or Indian hemp; pulverize; mix with dough, and scatter it over the water. The fish will seize it with avidity, and turn belly up on top of the water, and may be easily gathered, and if put into fresh water will be as lively as ever. — 3. Take for bait a handful of swamp apple blossoms; put them in a glass jar or bottle, with 1 gill rum; cork the bottle tight, and stand in the sun for 3 or 4 hours; then take ½ pt. water from a place where fly-trap grows, in quag-moss, around a fresh water pond; saturate the bait with the liquid several hours before using. — 4. Take the juice of a smallage or lovage and saturate any kind of bait. — 5. Get over the water at night with a light and a dead fish that has been smeared with the juice of the stinking gladwyn. The fish will gather around in great numbers and may be easily scooped up.

TROLLING. — Generally practiced at mid-water, and includes spinning with a live, a dead, or an artificial bait. When neither fly fishing nor bottom fishing can be practiced, trolling can be resorted to. The fish taken by any sort of trolling in rivers are pike, perch and trout. Trolling is divided into 3 parts: Sinking and roving, trolling with gauge and snap-hooks, and spinning. Sinking and roving is practiced with a live bait: a minnow or a loach for the common trout or perch; bleak, gudgeon, dace, or roach for pike or large trout. The best bait for all sorts of trolling is the gudgeon. The rod should be a long bottom one, with a good winch, and prepared plaited silk trolling-line. For footline, 1½ yds. best gut. The link to which the hook is tied should be of fine gimp, if pike are sought for; but gut, or three-twisted hairs, will do for trout and perch. The bait must be lively, and placed on the hooks carefully. Allow the bait to swim here and there, generally at mid-water; but in deep places, deeper, drawing it up gently to the surface now and then, letting it sink again, and guiding it to the best looking spots. Snap-baits are used when pike do not feed with voracity. The rod used must be short and stiff; the pant-barbel rod is the best. Snap-baits are two-fold, one which does not spring when you strike the fish, and the other which does. The first named consists of 3 hooks, 2 large ones, tied back to back, with their barbs pointing different ways; and one smaller, tied on at the top of the shanks of the others, and pointing straight out from them. The spring-snap is used with dead bait; it requires deep insertion in the bait to allow the spring to act, which it will not do without some resistance. Spinning is a dashing, killing method, and requires muscular exertion. The best spinning rod is of East India mottled cane, 14 or 16 ft. long, well ringed, with a screw winch, requiring no winch fittings. With this, salmon and large trout can be trolled for in deep and wide waters. In narrow streams, spin with a small portion of line out, and avoid casting, the length of the rod allowing the bait to be dropped noiselessly where wished, and to spin accordingly. The baits should be of the brightest minnows and gudgeons; the hooks of bright steel color, and whipped on with light-colored silk, waxed with white wax. Artificial spinning bait kill fish more or less successfully; but they are inferior to the natural bait. A small sail boat is used, with an attendant to manage the boat. Live, or an artificial bait may be used. A stiff rod and reel, with the same tackle as before described, and no sinker, is requisite. The boat should move gently, and the line drag far in the rear. With artificial bait the fish is hooked instantly. If you use live bait, be careful in determining when the fish has gorged it; give him several minutes after he has seized it. On seeing the bait, a pickered will generally run off with it, and will then stop to gorge it; the sign that he has swallowed it is a peculiar slackening of the line, which experienced anglers understand. But if he has gorged the bait, he will soon start off a second time, and sometimes will stop and start off the third time. In these cases, never be in a hurry. When convinced that he has taken down the bait, draw a tight line, and strike. If he is large, play with him until he is exhausted, or you may lose him. The difficulty of taking a pickered from the hook may be obviated, in a measure, by gagging. For this purpose anglers provide themselves with prepared sticks of various lengths. If the hook is swallowed, open the stomach in the middle, cut away the hook, and unslipping the knot that holds the gimp, draw it out that way rather than through the mouth.

WINTER CATCHING. — 1. On the clear ponds in the North, when frozen over, fish are caught as follows: The fisherman, armed with a hatchet, or ax, or mallet and hatchet, goes upon the ice when the sun is shining, and the fish, lying close up to the ice, sunning themselves; when a

smart blow of the mallet stuns them so that a hole can be cut in the ice, and the fish taken out. If put in fresh water again they recover. — 2. A plan practiced on the Western lakes in winter consists in having a small house, built on runners like those of a sled, in which is placed a stove, while in the floor a small aperture is left, through which to drop the lines. Holes are cut in the ice, the houses are moved over them, and the fishermen sit by a warm stove while drawing in the fish.

Varieties of Fish.

BLACK BASS. — This fish is peculiar to the Western lakes and streams running into the great rivers of the West. It resembles the sea-bass, but is not black. There are several varieties—some bottle green on top and some with broad stripes around them. They harbor in deep holes in summer, shooting out into shallows at times, after small fish. The best bait is the minnow or chub, to be caught in their vicinity; and if for big fish, use tolerably large bait. The black bass is prized by the angler on account of his gamy qualities and excellence as food. The following are the ways of fishing: *Still fishing*, so

Black Bass.

called because the fisherman remains stationary, either in an anchored boat or upon the shore, is the most common way. A moderately stiff rod is used, 12 feet long. The further the bait from the boat, the better. A strong line and reel are used. The hook should be tied on single gut snell. If fishing with cork and bobber on the line, measure the depth of water, and place the bobber so that the bait will be 1 ft. from the bottom. A light sinker is necessary, placed 1 ft. above the bait. When the bass sees the minnow he darts for it, takes it in his mouth, and carries it 5 or 6 ft. before he overcomes the force of the rush. When he stops, he shifts the minnow about in his mouth until he gets it head foremost, and then proceeds to swallow it. As soon as he gets the minnow swallowed, he will start to swim off. When the angler sees that a fish has struck his bait, give him line until he stops, and when you see he has stopped nibbling and is moving off, make a quick strike, which can be done so that if you don't hook the fish the bait will not move more than a foot, and if you miss the fish the first time the chances are that he will take it again. If fishing without a bobber, after you see that the fish is not hooked, let the bait settle to the bottom, and the fish will think he has killed the minnow, and nine times out of ten he will go for him again. — *By Artificial Flies.* Fishing for black bass with artificial flies, by trolling or casting, is considered the most scientific way, as the tackle is finer and more skill is required to handle and land the fish. The act of casting requires practice and skill. In trolling with flies use the same rod, line and reel as for still fishing. Use a single gut leader. The gut should be one size finer than salmon gut, and the leader should be in length 1 ft. shorter than the length of your rod down to the reel. A small brass swivel should be used to connect the leader with the line to keep the leader from twisting, and 2 B shot split and placed on the leader about 1 ft. from each end. The body of the fly should be nearly as large round in the thickest part as an ordinary lead pencil. The brightest flies should be placed at the upper end of the leader, for bright flies attract the bass, and your lower lines, following in quick succession, are the ones on which the fish are usually caught. When hooking a fish, take time in getting him in, for, in doing so, you save the fish, and, if there is another fish near, the chances are that he will take one of the remaining flies. Keep the fish on the spring of the rod, and do not let the line slack.

BLACKFISH.—Found in the bays from Cape May to Cape Cod. Striped bass tackle and soft shell clam bait, are used; but he will often bite at the large salt beach worm. Look for him on rocky bottoms; he will not bite well during a thunder storm, nor in dull weather.

BLUE-FISH.—Abound in the waters of Massachusetts, Rhode Island and Connecticut. The tackle consists of a large hook, attached to an ivory or bone imitation of a small fish. In the absence of this gear a common cod line, with a piece of red flannel wound round the cord close to the heel of the hook, so as to form a cylinder ½ in. in diameter, will answer. A quick working boat is necessary, and at least a 5-knot breeze, for the fish are taken by trolling. Throw the line overboard, and make fast at the stern

Blue-Fish.

of the boat while under full headway. The hook will drag near or on the surface of the water, and the blue-fish will snap at the bait. When he gets on, pull in, and be sure you keep a taut line all the time. If you succeed in getting him into the boat, hit him over the head with a club, for he has teeth, and has been known to bite.

CARP, or TENCH. — Requires strong tackle; a light quill float, a short leader of gut, and a light-colored worm, a brandling being better than an angle-worm. Fish on the bottom, or near it. He is a very shy fish; bait the spots the day before fishing, by throwing in bread-crumbs, chicken-entrails, or lumps of dough.

CAT-FISH.—A fresh water bottom fish, found

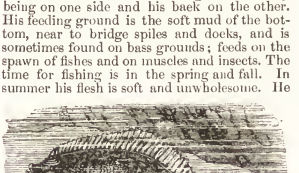
in streams and ponds; easy to catch. Procure tackle strong enough, using a hook according to the size of your game. A single or double gut leader is necessary. Minnows, pieces of fish, shad-roe, worms, toasted cheese, insects, pieces of meat or liver, chicken's offal, attract the catfish. The proper hook is the Limerick salmon, from No. 1 to 5, according to the size of fish. They do not bite vigorously, but perform a series of nibbles. They are plentiful in mud bottoms, above mill-dams, and in coves of the river. The large ones are often taken by trolling with artificial squid or fly. The time for fishing catfish begins in April, and lasts until cold weather.

COD AND HADDOCK. — Bait each hook, of which there should be 2 on the line, with a whole clam, and let the line run out till the sinker strikes the bottom; then haul in about 3 feet, and hold the line between the thumb and forefinger. When you feel a sharp pull, jerk the line up and haul in. Keep the fish bearing upon the line all the time. May and June are the best months; and the later in the season the farther out to sea you must go. — *Rock Cod.* If you do not succeed in deep water, run in near the rocks; anchor, or make fast the painter of the boat to some buoy which marks a sunken ledge, and you may catch rock cod. They are fine fish for the pan or chowder-pot.—*Cod Net.* The cod keeps near the bottom of the sea, and the net is made about 3 fathoms wide; ordinary seine twine is used. One edge of the net is weighted to keep it on the bottom, the other edge buoyed by hollow balls of glass; the net is set with anchors at each end, left out over night, the same as a trawl, and hauled in at the first opportunity. The mesh used being large, the small and unmarketable fish will not be taken at all, and the expense of procuring bait and the disagreeable job of baiting trawls avoided.

DRUMFISH.—A very large fish, and is sometimes caught when fishing for blue-fish or bass, and unless you are expert and he is very small, he will teach the necessity of taking extra hooks and leaders when fishing.

EELS.—*Bobbing.*—There is good sport sometimes in bobbing; but the eel is not much liked on a hook, from his habit of twining the line, and the slime he leaves on the fingers when handled. He is found especially in muddy bottoms. Bobbing for eels is very amusing night sport. String worms on threads, by running a blunt-pointed long needle through them from head to tail. When enough strings are threaded, tie the ends together, and then fold them into a regular hank, like a hank of yarn, and double and treble, until 3 in. long. Through the middle tie a stout cord, to the bottom of which is a round dipsy. Over this last the two ends of the bunch (which should be about the size of a boy's fist) hang. Anchor the boat on the muddy flats of a river, at high tide, or lean over the bank of a creek or river at a muddy bottom, and drop in the bob and sinker. Presently a sharp pull is felt. Draw up into the boat, or on the bank. The eel has his teeth entangled in the thread, and cannot let go until he is in the boat, or on the bank. To grasp an eel on the hook, place the second finger on one side of him, and the first and third on the other, 1½ in. from his neck; then, by pressing the fingers together he cannot move, and you may take the hook from his mouth, and throw him in your basket. — *Potting.* Eels are caught in rivers, in baskets or pots, to which access is easy, but retreat difficult, wherein have been placed small fish, or some flowers of the elder tree, and in bucks, which are large baskets made on the same principle, fitted to a frame-work, and at suitable periods and convenient states of the water, lowered therein, when the eels run into them on their downward passage to the sea, or when seeking a new locality. —*Spearing.* Eels are taken by spearing them while they are lying singly on the bottom, or in clusters imbeded in the mud. The instrument used is called an eel-spear, consisting of 6 or 8 prongs of flattened iron, the edges of each prong notched and fastened to a long pole. It is then plunged into the mud and quickly withdrawn, and the eels retained between the prongs.—*Sniggling.* The line must be of plaited silk or whipcord, and instead of a hook a stout worsted needle should be fastened by its middle to the line. A large worm, tough and well scoured, is the best bait. When baiting the needle thrust its point into the worm's head, and draw it through the body of the worm until the latter completely enshrouds it. When sniggling carry the line on a winder in hand, and search for the fish near flood-gates, wharves, bridges, piles, holes in the banks of rivers, ponds and canals, in ditches, and among osiers and willows. Put the bait into the lurking holes with a stick having a forked head, and when the bait is taken give the fish a few seconds to gorge, and then strike smartly, which will cause the hook to fall across his stomach; then hold the line fast and pull it toward you.

FLOUNDER.—An odd-looking fish, his belly being on one side and his back on the other. His feeding ground is the soft mud of the bottom, near to bridge spiles and docks, and is sometimes found on bass grounds; feeds on the spawn of fishes and on muscles and insects. The time for fishing is in the spring and fall. In summer his flesh is soft and unwholesome. He



Flounder.

will bite at almost any thing used in salt water for bait. Use any kind of tackle. A small hook is necessary, No. 8 being the usual size.

GARFISH.—Called often the garpike, having a long bony snout armed with teeth. No hook

will enter his snout. The best thing when they are around, is to go somewhere else. To catch him, prepare a bunch of thread and horsehair, which dispose of around the live bait, loosely but firmly. Pull out suddenly on the bite, and the chances are that the gar's teeth will be so entangled that he will drop on the bank.

HALIBUT.—A deep sea fish, taken by fishing schooners, principally on George's Banks and off the coast of Nova Scotia, with hook and line.

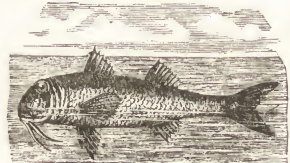
Halibut.

MACKEREL.—If so fortunate as to fall in with a school of mackerel, abandon all thoughts of cod, haddock and perch. If you strike the school, occasionally heave over refuse fish or

Mackerel.

clams, cut up fine, to keep them near the boat. Bait the jig with salt pork, and sink it only 2 or 3 ft. They bite quick and snarp. Haul them in, swing them over the fish tub with a jerk, and they drop from the line without further assistance. Catch them as fast as you can, or you will not catch them at all.

MULLET. — Always fish on the bottom for these, with a small hook and any moderately



Red Mullet.

strong line. They require no skill, and the coarsest and cheapest tackle will answer.

PERCH.—The white, yellow, black and red perch belong to this family. Perch fishing is pretty sport. A strong line and a stout pole are not required, and you will rarely, unless with a big fellow, have occasion to use the reel. He is a quick biter. The bait may be small minnows, shrimps or worms. Great numbers are taken in rivers from the first hour before the flood of tide to the hour after, just outside of the channel grass, with a bow line made with a whalebone, which is kept near the bottom by a dipsy. Each end of the bow is furnished with 2 or 3 hooks, set on 4 or 5 in. of gut, and baited with worms. From May to July is their best season, and the hook is a Limerick trout, from 2 to 5 in size. Perch are gregarious, and in the winter, when frosts and floods have destroyed the beds of weeds, they congregate in pools and eddies, and are then to be angled for with great success from 10 to 4 o'clock, at the edge of the streams forming such eddies.

PIKE AND PICKEREL.—The varieties of this fish are numerous. Besides the true pike, there is the pickerel, and in the West and Southwest the muskallonge. Then there is a fish known

Pike.

on the Ohio and its waters as the salmon, but properly called the pickerel. The pike and pickerel are fond of shady places, and in summer frequent parts of the stream near where the pickerel weed grows. In winter they get under rocks or stumps, or convenient holes, and can be taken then with small live fish for bait. Pickerel are caught near the mouth of some small stream emptying into the river. The fall is the best time. In the hot summer months they seldom bite except on a very windy day. Pickerel fishing in the spring is sometimes successful, though the fish are not so good. In more Northern waters they are sometimes taken as early as August in good condition. The tackle used is a 10 ft. rod, with a reel, and some 50 or 60 yds. of flax line, protected by the hook with gimp or wire. The Limerick or Kirby salmon hook is used; the size is 0 to 5. In a running stream the sinker and float will be necessary. The bait should be a small live fish or frog, or the hind leg of a frog, skinned. In using live bait do not draw the line too quick. The bait, if properly impaled, will be lively. Inexperienced anglers may take this movement for a bite; but when the bite comes there is no mistaking it. When using live frog bait, pass the hook through the skin of the back or belly, or the back muscle of the hind legs. The live frog is generally used on the top of the water; if not, let him rise occasionally to take air. When the pickerel has seized the bait, give him time to swallow it, and

plenty of line. Sometimes he will hold it in his mouth and play with it before gorging. On bringing him to land be careful of his teeth.

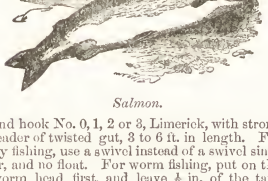
RED EYE. — A Western fish, looking like a cross between the striped bass and sunfish, with a red spot in his eye. He is taken after the manner of perch (which see); he is good at all seasons; his haunts are under banks and beneath overhanging bushes.

REDFISH. — Found southward of Cape Hatteras, as far as Pascagoula, and occasionally in Delaware Bay and on the New Jersey coast; length from 1 to 4 ft. He is like silver in color but becomes darker when out of the water. Just in front of his tail fin is a black or brown spot, bordered with white, which has given him the name of the "Branded Drum." His time of biting is from March until January, except far south, where he is taken all the year. He is caught with a stout hand line and cod hook, with shrimp bait or pieces of fish, and may also be taken with rod and reel.

RED-HORSE. — A species of soft-fleshed fish, sought after in spring, when he swarms in the Western waters. He will not bite well at that time, and is taken by spearing. He may be caught with a worm, by ground fishing, in the autumn months, but is bony and not prized.

ROACH.—A silver-sided, handsome fish, small, and considered poor eating; taken in most of the rivers in the eastern part of the Northern States, in the same manner as sunfish. He will bite well at small lumps of dough.

SALMON.—Confined to Maine, California and Oregon, and some of the Western lakes. The time of taking is from April to July, and they are treated either to the fly, worms or minnows. A heavy rod and a large reel are needed, and from 300 to 600 ft. of line. A swivel sinker and cedar float are used, when fishing with live bait,



Salmon.

and hook No. 0, 1, 2 or 3, Limerick, with strong leader of twisted gut, 3 to 6 ft. in length. For fly fishing, use a swivel instead of a swivel sinker, and no float. For worm fishing, put on the worm head first, and leave ½ in. of the tail; throw it gently in the current, draw it up quietly after it has floated down, keeping the bait in motion. Keep a tight line when he bites, but do not strike too soon; allow him to gorge, then strike sharply. If the bite should be only a sudden jerk, pay no attention to it; wait, and he will call again; if he does, look sharp. Let him have line enough as he goes from you, but as he returns reel up. Keep him clear of stumps and rocks; draw him gently to shore; and then put the hook of the gaff in his gills and land him.

SEA BASS.—Well known to all. Take about 80 ft. stout hemp line, with 2 or 3 No. 1 Kirby

Sea Bass.

hooks, and a dipsy weighing 1 lb. This, with hard clams, well salted for bait, and a pair of old gloves, to keep the hands from being chafed by hauling on the line so much, completes the outfit.

SHEEPSHEAD. — Has a smutty face, banded sides, and a queer mouth, not unlike a sheep's. To capture him, requires a strong cord ¾ in. in diameter, 20 to 50 yds. long, a heavy sinker, a stout blackfish hook, and either soft shell clam, with the shell on, or small rock crab, and fish near the bottom. There is a fresh-water sheepshead, caught at times in the lakes, but he is worthless.

STRIPED BASS, or ROCKFISH.—They delight in rocky shoals. When the sea is agitated cast-

Striped Bass.

ing for them from the rocks with rod and reel, and menhaden bait, is more exciting than angling for any other fish. The rod and tackle required is the same as for salmon, with a hook from No. 0 to 3. The bait is minnow, shiner or shad-roe, and when in the bays or mouths of rivers, shedder crabs, shrimp and shad-roe in their season. In boat-fishing in still water, use a cedar or large cork float, but in fishing at the bottom of dams or in swift currents, have no float and no other sinker than a plain swivel. Manage them, in striking and taking, like the salmon. They can be caught by trolling, with either squid or spoon bait or minnow.

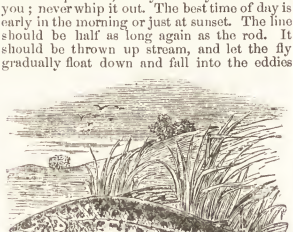
SUCKERS.—There are many different species, and some of them will not bite at any bait. The kind that does not bite, is sometimes taken with a wire slip noose. The regular trout tackle and hooks are used, and worms for bait, though he will bite at shad-roe in the spring. They suck in the bait, and thus nibble at the hook. They are not lively when pulled up, and unless they

are cooked immediately their flesh grows soft.

SUNFISH.—Several varieties. An extemporized rod, of length according to the place, a light line, a No. 7, 8, or 9 hook, and a lively worm or a grasshopper, are all that is necessary. He lies in holes under banks, and in tolerably deep water. His spines protect him from larger fish, and he is quite fearless and handsome.

Sunfish.

TROUT. — Caught in the numerous running streams of the United States, and varies in color and size. Black trout are found in sluggish, muddy streams, and do not belong to the species. The time for taking trout is in the spring and summer. The finest are taken in May and June. They bite best in March and April. Fly fishing is the most interesting mode in summer. The rod should be light, and the line made of hair, or silk and grass. The fly should be placed on a length of gut, or a single light hair. Fish with the face to the sun; stand as far from the stream as possible; always throw your line from you; never whip it out. The best time of day is early in the morning or just at sunset. The line should be half as long again as the rod. It should be thrown up stream, and let the fly gradually float down and fall into the eddies



Trout.

where the fish are apt to retreat. Let your line fall into the stream naturally and lightly, and raise it gently and by degrees. Only a part of the line should be in the water. If bushes intervene do not rustle them, or make a noise. The usual length of a rod is 14 ft. The bottom of the line, unless light hair, should be strong silkworm gut. The size of the hook will depend upon the flies. Nos. 4 and 5 are used for worms and beetles, and 7 to 9 for small flies. If the flies are too small, put two on the hook. The largest and best trout lie in shallow water, faced up stream, or else near the surface. They are found on the shady side of the stream. Grasshoppers and other small field insects are used with success when worms fail. Worm fishing for trout is practiced with caution. After a rain, when the water of the brook is a little riley, trout can be caught very rapidly. A single split shot will generally be enough to sink the line, unless the stream is rapid. The rod should be of bamboo, 16 to 20 ft. long, and the line shorter than the rod. Keep the point of the rod above bait, steadily following it, as the bait drags along the bottom. When the fish takes the bait, do not let him run with it, but keep a steady hand. Do not jerk, but play gradually with him. If the day be clear, and the stream shallow, wade up the stream, throwing your line far up, and letting it come gradually towards you. Bottom fishing with blue-bottle flies is practiced as follows: Use a silk or fine hair line, with gut leader, and a small quill float. Hook No. 10 is about the proper size. You will want one or two split shot on the line. Fill a glass bottle with the common blue-bottle fly found on fresh horse or cow dung. Bait the hook with two of these flies, and let it sink nearly to the bottom. This kind of fishing is practiced in July and August. When the fish has taken the bait, play him towards the top of the water. Do not let him tangle your line in weeds. The fin of a trout, or rather small fish, is sometimes used as a bait for trout with success. It is dropped and roved, as with a minnow or fly. The following are the different varieties of trout:—*Brook.* Too well known to need description.—*Black.* This seems to be the same as the brook trout, modified by its dwelling-place, which is muddy streams and ponds. Then there is the *Salmon.* It has a finer flavor than the lake trout. For all of these fish you want a heavy rod, and spoon-bait or revolver. You troll for him, or you can use the large minnow. The line must be stout. Manage the fish as in taking any other salmon, for a member of the salmon family he is.—*Lake.* Found in a few lakes in the Middle and Northern States, and differs from the Mackinaw trout. It is blackish, with gray spots, body comparatively short; its back fin has a sinuous margin, and its length is 2 to 4 ft. *Mackinaw.*—Dark-gray above, of a light ashgray or cream-color on chin, throat and belly; back and sides having many lighter gray, brown, or dirty white spots; breast and belly-fins yellowish; teeth, gums, and mouth of a purplish tinge; length 2 to 5 feet.—*Hulbo.* Has a forked tail, dusky back, yellowish belly-fin; all the other lines palish purple, and grows from 2 to 4 ft. long. It is to be taken after the fashion of the lake trout. The best time for taking the common trout is from April to August; or, if it be mild weather, as early as March.

WEAKFISH.—Sometimes called wheatfish, and sometimes squeteague; has an even tail, speckled back and sides, one or more sharp, long front

teeth in the lower jaw, and yellowish ventral fins; found in salt or brackish waters, in New York, Connecticut and Massachusetts; bites at shrimp and shedder crab, and is to be caught with the same tackle and in the same manner as the striped bass. They will be found in rather deeper water, farther from shore, and more in the eddies.

BOATING.

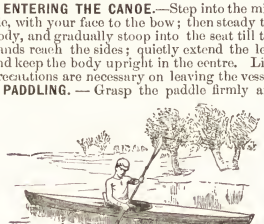
REMARKS. — Until within a few years, the English custom of having a *coxswain* in every boat propelled by several oarsmen, was not adopted in America. Instead, the oarsman who had the best "head,"—who was the coolest leader and commander—was denominated the "captain;" while the most powerful and capable oarsman, giving time to the rest, was called "stroke-oar." Frequently, but not always, these two positions were combined in the same man, and the fashion still largely prevails, except in eight-oar practice and regular races, where the English coxswain has become firmly established. This result simply exhibits the influence of the superior English method and style, after several international contests had occurred. Our instructions, therefore, will be found to largely follow English authorities, which will account for the frequent allusion to the coxswain.

CANOEING.

CAPSIZING, To Prevent.—Take a strip of linen drill, duck, or strong calico, 12 or 14 in. wide, and the length of the gunwale; sew the edges close, forming a bag; fill with cork shavings; sew the ends up, and give 2 or 3 coats of oil paint (white). Lash one on each side of the canoe, on the outside, below the gunwale, and above the water line.

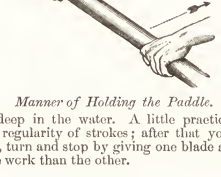
ENTERING THE CANOE.—Step into the middle, with your face to the bow; then steady the body, and gradually stoop into the seat till the hands reach the sides; quietly extend the legs and keep the body upright in the centre. Like precautions are necessary on leaving the vessel.

PADDLING. — Grasp the paddle firmly and



Paddling.

decisively. The hands should be at an easy distance from each other, with backs uppermost. The blade should enter the water close to the side of the canoe, and be drawn back as far as the length of the arm will allow. The canoe then shoots forward in a straight course. A slow, steady stroke is the one by which the best work can be achieved. Hurry and fuss are to be avoided. In a cruise, greater progress is made by taking things quietly, than by exerting too much at the beginning. 20 miles is a fair day's work. In propelling the blades of the paddle must take a circular direction, not going

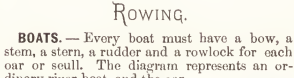


Manner of Holding the Paddle.

too deep in the water. A little practice will give regularity of strokes; after that you will steer, turn and stop by giving one blade a little more work than the other.

ROWING.

BOATS. — Every boat must have a bow, a stem, a stern, a rudder and a rowlock for each oar or scull. The diagram represents an ordinary river boat, and the oar.



Boat.

1, Cutwater, or stem; 2, the bows; 3, the midships; 4, the stern; 5, the rudder; 6, the rowlocks; 7, the seats, or thwarts; 8, stern-sheets; 9, fore-sheets.

Oar, or Scull.

ENTERING THE BOAT. — Step in with your face to the stern; place yourself nearly in the centre, and take your seat quietly on the thwart, which should be firmly fixed. Thus you will sit square, and swing back and fore in the line of the boat's progress. Have the stretcher adjusted to allow the oar to clear the knees. Keep the button inside the thole. Grasp the oar with the thumb above the handle, the inside hand grasping the loom just where the rounded part joins the square or wider part, with the thumb beneath. You are now ready for the stroke—body upright, shoulders square, elbows to the sides, arms straight, and head bent slightly forward.

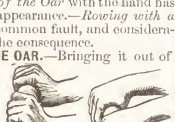
FAULTS.—*Catching Crabs.* Falling back from the seat, through not taking hold of the water

in the attempt to pull.—*Doubling the Body over the Oar at the End of the Stroke.* Prevents

Catching Crabs.

shooting of the arms and body simultaneously forward.—*Jerking.* A fault to which men who are powerful in the arms are liable; instead of throwing the body gradually back, and thus partially pulling by their weight, they depend upon the muscles.—*Not Keeping Time.* Not putting your oar into the water at the same time as the stroke-oar; an effectual bar to rowing in concert. —*Not Keeping Stroke.* It is not doing work at the same time as the stroke-oar. It is the most destructive fault that can be committed; for the speed of the boat must depend upon the simultaneous effort of its crew. The pull should commence the moment the blade is properly immersed in the water.—*Rowing Round.* This arises from not entering the water deep enough at the first. The rower feels that he has not sufficient resistance, and consequently deepens water with an oar, forming a portion of a circle, and brings the flat part of the blade perpendicularly to the water, tending to drag the boat down.—*Slacking Arms Too Soon.* Decreases the power of the stroke, and causes an impediment to rapid progress; this habit is generally accompanied by feathering the scull before it is out of the water, or allowing the boat to carry it along. In the former you add to your labor; in the latter you, to a certain extent, stop the boat. Light boats are apt to cause these faults. The remedy is, to dip the scull deeper at the commencement of the stroke; but the same faults are also committed in ordinary boats.—*Throwing Up Water.* This must be avoided, as it is excessively annoying.—*Capping the End of the Oar* with the hand has a very awkward appearance.—*Rowing with a Round Back.* A common fault, and considerable loss of power is the consequence.

FEATHERING THE OAR.—Bringing it out of the water in a flat or horizontal position, by dropping the wrists smartly at the end of each stroke.



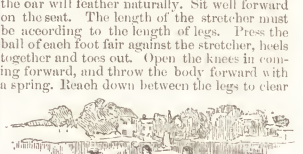
Feathering Positions.

LANDING. — If the tide favors, bring the boat in a rather slanting direction toward the landing. In landing on the sea-shore where there is a swell, more care must be used. Watch for a smooth sea, then give way to the shore. The bowman should jump ashore with the painter and then pull the boat well up out of the reach of the surf.

LAUNCHING.—When there is a swell, and the boat is large, 2 should get into the boat with their oars; the others, equally divided, lay hold of each side of her gunwale, entering the water with her and forcing her head to the sea. They must not all jump in until fairly afloat, for if she were to ground and ship a sea, the probability is that her head would be turned, and the next sea capsize her.

MEETING AND PASSING. — In meeting, the boat going with the tide or stream must get out of the way. If the boats are close to each other the sculls are usually unshipped and laid flat on the water (shifted out of the rowlocks and allowed to drift on one side) till the boats have passed. In going in the same direction, or passing a boat in the water, the sculler who passes the other boat must take the side farthest from shore and nearest to the middle of the stream. If the other boat is a distance from shore, this is not necessary. Whatever way a boat is going, avoid a collision, and keep clear of the sculls of other boats. When one boat is crossing the water, and another is going with the tide, the one crossing should be allowed to pass, and the boat which has the assistance of the tide should hold astern.

PULLING. — Catch hold of the oar as it is—hands about 4 in. apart, one being at the extremity, and train both thumbs under the handle. Hold the oar tight, and when getting forward do not shift the hands, but let the knuckles and back of the hand turn with the handle, so that when you are forward as far as you can, a person sitting and looking straight at you would only see the back of your hand on the handle. When you have pulled the oar through the water, and your hands are well home to your body, the oar will feather naturally. Sit well forward on the seat. The length of the stretcher must be according to the length of legs. Press the ball of each foot fair against the stretcher, heels together and toes out. Open the knees in coming forward, and throw the body forward with a spring. Reach down between the legs to clear



Rowing Pair-Oar Outrigger.

the top of the stretcher. Take care, when reaching forward, to put the oar into the water where you reach to, and not bring the oar back before you put it in. Dash the oar in lively, and pull as hard at the beginning as at the end of the stroke. Pull the oar well through the water from beginning to end. The blade of the oar should be the same depth in the water all through the stroke, and the hands kept the same height. Do not shirk at any part of the stroke. One man rowing mild, and leaving an unfair

quantity of work for the rest, brings them into a bad state. Row the oar home close to the body, by throwing the shoulders back and bringing the elbows straight behind you. The handle of the oar should be at last a little below the chest, close to the navel. Feather the oar low in coming out of the water, and bring it out clean without throwing up water on the next oar. Bring the outer hand and handle a little to the side; by this means the oar is longer in the water, and more work is done at the last part of the stroke. It is a bad thing to go too far back. A crew may be strong, and each man pull well, but if they do not keep time, it is one pulling against the other.

SEA ROWING.—The oar must be held firmly. The whole art consists in the crew moving backward and forward (called "swinging"), and laying hold of the water, avoiding pulling in the air with force when there is a trough or interval between two waves, and avoiding a heavy wave, which has a tendency to dash the oar out of the hand. This requires practice, and the steersman or coxswain should watch for the high waves and warn his men. He should take care to cross the roll of the sea as much as possible, so as to avoid being struck on the side of the boat called "the counter," which would swamp her or knock the oars out of the rowlocks. In this kind of rowing the feathering of the oar is not attempted, but merely pulled steadily, strongly backward, and then pushed forward in the rowlocks. To pull up sharp, the order is, "Hold water," or "Hold up all!" If passing close to the piers of a bridge, a vessel at anchor, or any obstruction, the command to prevent the oars touching it is, "Mind your oars, bow side," or "stroke side." With these words the crew is conducted, adding the number of the man when giving personal orders.

STEERING.—Every 8-oared boat usually has a coxswain or steersman, who is of lighter build than the average oarsman. Take your seat on the aftermost thwart, in the middle. Sit upright and easy, with the body prepared to swing forward with the motion of the stroke. Cross the legs and bring them close under, so that the feet will rest on their outer edges, and the knees be well apart. Take the yoke lines, one in each hand—a turn of the lines round the hands, and pulled taut. There are loops made in the yoke lines for the thumbs, which can be used; but always tie the lines together in front, so that in case of a lurch, the yoke lines will not slip overboard and tow astern. The hands may rest on the gunwale, with the fingers outside and thumbs inside; this will help steady the boat, and a turn of your wrist will slacken or tighten the yoke lines; or the hands may be held in the lap. At every stroke ease slightly forward with the lift of the boat, but do not bob backwards and forwards. The coxswain pulls the line on the side he wants the boat to go. If steering a straight course, take as a mark an object, such as a tree or chimney; if there is a turn in the river, keep the course straight for the point in the water where the boat will turn, keeping wide of the corner. Do not jam the rudder hard up suddenly; the boat's head should be brought round gently. The coxswain has the direction of the crew, and the few words of command must be remembered. When the men are in their places he asks, "Are you all ready?" and then says, "Row on all." To decrease speed, he says, "Row easy, or "bow side." At the order, "Easy all," every one stops. This order should be given as the crew are coming to the end of a stroke.

Sculling.

REMARKS.—Sculling, is using both sculls at once, one by each hand. There is no difference in the action of sculling from rowing, except that in the latter the oarsman pulls one oar with both hands, and in the former he pulls a pair

Sculling.

of shorter oars one in each hand. But there is a marked distinction in some minor points. The oarsman does not sit in the centre of the boat, while the sculler sits exactly in the middle of the thwart. The sculler should sit low in the boat, with his stretcher perpendicular to give his feet a purchase. His speed when in good form is from 30 to 40 strokes a minute; the average is about 32 or 33; except in sudden spurts, it is impossible to keep up the higher rate. In a match the great difficulty is to keep the course and avoid obstructions. Familiarity with the boat and the sculls comes with practice.

ENTERING THE BOAT.—The boat is placed in the water sideways, and not end on, with its head against the stream or tide. Get in and sit in the middle of the thwart, and get the outside scull in position by placing the handle through the rowlock from the outside, and drawing it inboard till the button is within the thole pins; next, do the same with the inside scull. The attendant will then take hold of the end of the blade of the inside scull, and, holding it close to the water, gently push off.

FAULTS.—A bad sculler may be known when he does not straighten his arms before him, and keeps two convex, instead of the outside wrists bent; when, after the shoulders have attained full reach, he puts his hands forward by a subsequent motion, thus getting the body forward without the arms. The opposite error is, when he extends the arms without a simultaneous bend on the part of the shoulders, which is getting the arms forward without the body. An imperfect sculler catches the water with unstraightened arms, and slackens the tension of the pull, and weakens uniformity of work; hangs, before dip-

ping downwards to begin the stroke, and in dipping does not cover the blade up to the shoulder; rows round and deep in the middle, with hands high, and blades still sunken after first contact, and curves his back forward or aft; rocks when he should be steady, and holds one shoulder higher than the other; prematurely slackens the arms, and cuts short the end of the stroke; doubles forward, bending over the oar at the "feather," and brings the body up to the handle of the oar, instead of pulling the oar to the body; the feather is consequently shivered out while work may yet be done; he has an ungainly and exhausted look when he holds the head between the shoulders, instead of erect; rolls backwards with an inclination toward the inside of the boat; turns the elbows at the feather, instead of bringing them sharp past the flanks; looks out of the boat instead of straight before him, causing a roll of the boat; and, finally, throws up the water, instead of throwing it well aft at the lower angle of the blade.

LANDING.—In landing, bring the boat alongside by holding water with the inside and pulling with the outside sculi; always have the boat with its head against the stream or tide.

PASSING.—If not using the sculls, let them lie flat on the water. In cases of meeting or passing other boats, if you are sculling with the stream or tide, get out of the way; or take the outside, unless there is plenty of room between the boat passing and the shore; if the boats are close, lift the sculls out of the rowlocks and let them lie alongside in the water.

PULLING.—Seated well in the centre of the boat, the stretcher fixed, the legs extended, the sculls shipped and lying flat on the water, the boatman grasps the sculls and prepares for business, as follows: Bend the body so that the head is well on the knees; extend the arms straight and well forward, with the sculls a corresponding distance behind; dip them well and pull; let the dip of both sculls be of equal depth. The young sculler's first difficulty is that the sculls seem longer than they need be, and the body is not perfectly straight. One sculi is apt to go higher than the other, which can be remedied by moving the seat a few inches to right or left without shifting the feet from centre of stretcher. A slightly oblique position is obtained, and the hands worked clear of each other. The end of the pull does not take place till the elbows are brought to the top of the hips and the hands towards the chest. The body is thrown back by pulling; the sculls as they leave the water, feather, and prepare for the return of the sculls for the following stroke; done by bending up the wrists, while the backs of the hands are turned toward the forearms, which offers the least resistance to the water and brings you again into position. Stroke after stroke the same series of actions proceeds, till it becomes as easy to row as to walk.

TURNING.—In turning a boat much art is required. When the inexperienced tries for the first time to turn round, he will find both hands have a tendency to go the same way. The difficulty is overcome by practice. In turning a boat in the water, pull with one sculi and back with the other. One sculi must be reversed, its rounded face towards the sculler while he pushes it from him, at the same time that he pulls sharply with the other until the boat's head is turned round in the direction intended. When the boat is righted, both sculls should be pulled together, a little extra pressure being given to the side which has been backing water.

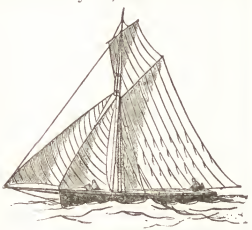
RULES.—1. Take the whole reach forward, and fall back gradually a little past the perpendicular, preserving the shoulders square and the chest developed at the end. 2. Catch the water and begin the stroke with a full tension on the arms at the instant of contact. 3. A horizontal and dashing pull through the water immediately the blade is covered, without deepening in the space subsequently covered. 4. Rapid recovery, after feathering, by an elastic motion of the body from the hips, the arms being thrown forward straight simultaneously with the body, and the forward motion of each ceasing at the same time. 5. Equability in all the actions, preserving full strength, without jerking, isolated movements.

—o—

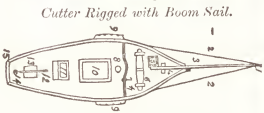
SAILING.

REMARKS.—Local prejudices rule in all parts of the world; and the rig, size and model of a yacht, are defined by the custom of the waters in which it is to be sailed. Iron yachts are most lasting, and have more accommodation than wooden ones of the same tonnage; but they are more affected by temperature, being extremely chilly in cold, and uncomfortably hot in warm weather. Their compasses are liable to error, and their bottoms require constant cleaning. The combination system of wood and iron affords nearly equal advantages with regard to space and accommodation with those possessed by iron yachts, and presents none of the drawbacks enumerated. For bays, sounds, harbors, and inland tidal waters, the yacht should be of a shoal model and centre-board principle, and usually the sloop or cat-boat rig. For ponds and small lakes it should be of good beam, light draught and small sail, on account of the frequency of puffs of winds from unexpected quarters. For outside work, or in places where the tidal currents are strong, or the wind sweeps across the water for miles, the deep keel model, with schooner or cutter rig, will be the better boat. But even on this question there are disagreements. The following are the different kinds of yachts in use: The *Cutter* has 1 mast and 4 sails, viz.: Mainsail, maintopsail, foresail and jib. Some smaller crafts have larger jibs and no foresail. — *Dandy-Rigged Yacht, or Yawl.* Differs from a cutter in having no boom for the mainsail, which can be hauled up by a rope passing round it. She has a mizzen-mast

standing in the stern, which sets a sail called a mizzen, and which is stretched on a horizontal spar projecting over the stern. This style is more safe for a yacht, as the boom in ordinary



Cutter Rigged with Boom Sail.



Deck Plan of Cutter.

1, bowsprit; 2, bowsprit shrouds; 3, stem; 4, bowsprit bitts; 5, fore-hatchway; 6, windlass, with bitts; 7, foresheet-horse (an iron bar passing from side to side); 8, mast; 9, channels; 10, main-hatchway; 11, companion and binnacle; 12, tiller for rudder; 13, cabin skylight; 14, rudder-head and case; 15, taffrail.

cutters is liable to sweep persons overboard, and the sail can be taken in quicker by brailing it up. — *Hatteener.* Has 2 sails, a foresail and mainsail, of a triangular shape. Each has a spar standing from deck to peak of the sail, and

Yawl, or Dandy-Rigged Cutter.

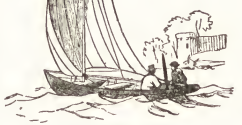
a boom at the bottom like a cutter. This rig is adapted for narrow waters. — *Lugger.* Used by fishermen and smugglers, and is a handy vessel when managed with skill; but luggers are difficult to maneuver by the ordinary means. — *Mainsail and Foresail.* This rig is adopted in open boats which are broad in the beam and roomy. It is an easily managed boat. — *Schooner Rig.* It has a mainsail, mainguff, topsail, foresail (or fore-spenser) and jib. Occasionally it

Mainsail and Foresail Rig.

has a third sail, called a jigger, raised on a light spar at the stern. A schooner has 2 masts, a standing bowsprit and jib-boom, and occasionally a running bowsprit. Schooners are fore-and-aft or square top-sail. The former have a mainsail, main-gaff-topsail, foresail (or fore-spenser) and

Schooner Rig, with Sprit Sail.

fore-gaff-topsail, fore-staysail and jib, while the latter carry a square-topsail and top-gallant-sail on the fore-topmast. The square-topsail schooner carries a square-topsail and top-gallant on the foremast. It is the perfection of a sailing yacht of large tonnage; but requires a competent captain and crew. — *Lugsail. Spritsail, etc.* For small



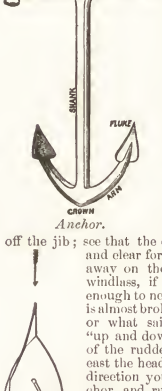
Lug Sail.

open-decked yachts, the lugsail and spritsail, the spritsail-and-foresail, and the balloon-foresail are the general styles of rig. All are intended for experienced handling, and are much in use at watering-places. A single sail in an open boat is usually a lugsail, and is controlled with com-

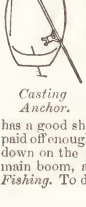
parative ease. The lugsail brings the boat well round in tacking, because that a portion of the sail is before the mast in sailing close-hauled, while the boat rigged with a spritsail only has its canvas abaft, and needs to be aided by putting out an oar to leeward in bringing her round. For a small crew or a single man the lugsail is preferred.

BALLAST. — Broad, shallow yachts need less ballast than deep, narrow ones. Large pieces of iron and tanks of water are used as ballast. For bay and harbor sailing and short cruises, there is nothing better than canvas bags of sand. As a rule, sailing boats and small yachts are "trimmed by the stern;" that is, the bow is slightly elevated from the water, the boat being pressed by the position of its ballast, deeper into the water at the stern than at the bow.

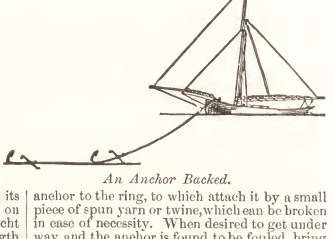
CASTING ANCHOR.—On the anchor and its appurtenances rests the safety, often, of all on board. Every yacht over 25 ft. in length should be fitted with 3 anchors, or at the very least, 2. If 3 in number, 2 of them should be nearly of same size, and one small, called the "kedge anchor." Iron cables are used in large ships, and manilla hawsers in small yachts. There are advantages in favor of a chain-cable for small yachts; but, as a rule, pliable but strong manilla rope is the favorite. To cast the anchor, hoist the mainsail, and take the gaskets off the jib; see that the downhaul is cast off and clear for hoisting; then heave away on the cable, by hand or windlass, if the yacht be large enough to need one, till the anchor is almost broken out of the ground, or what sailors call, the cable, "up and down;" then, by means of the rudder, if in a tide-way, cast the head of the yacht in the direction you wish; trip the anchor, and run up the jib as soon as it will draw. If there is no tide-way to act upon the rudder, then, before breaking out the anchor, hoist the jib; if desired to cast the boat upon the port tack, trim the jib to port, and shove the main boom well out over the starboard quarter; and, when the boat has a good sheer, trip the anchor; when she has paid off enough, let go the port jib-sheet, and trim down on the starboard-sheet, and haul aft the main boom, and proceed on the way. — *For Fishing.* To drop anchor, to hold the yacht stationary for a short time in some known place, make it fast with a clove hitch around both arms at the crown, and lead it along the shank of the



Anchor.



Casting Anchor.



An Anchor Backed.

anchor to the ring, to which attach it by a small piece of spun yarn or twine, which can be broken in case of necessity. When desired to get under way, and the anchor is found to be fouled, bring enough strain upon the cable to part the twine at the ring. — *Grounding and Floating.* If the yacht takes the ground on any shoal, and is left by the tide, get out an anchor in the direction of the wind before the tide returns.—*In a Gale.* When caught in a gale, anchor before the yacht has been driven too near the shore or breakers. When everything is ready, bring the yacht to the wind, and let the sails shake in the wind's eye; as she gets stem-way, let go the best bower anchor, taking care not to snub her too quickly, but let considerable of the cable run out before checking her; then take a turn or two round the knight-heads, long before there is any strain, and be ready to give her cable as she needs it; get this turn round the knight-heads before there is any strain, for, if it has been neglected, it will be too late, and the whole cable go overboard, unless the yacht be brought up by its being fastened below. The first anchor bites, and the yacht seems to come head to wind, and hold, let go the second anchor, and pay out plenty of cable on both, keeping the strain equal on each.

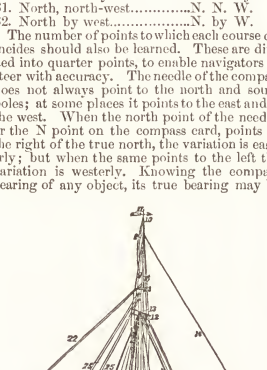
CHART, Use of.— Care should be taken to see whether the courses laid down to be sailed are magnetic ones; that is, with the variation of the compass allowed. There are charts where the variation of the compass must be allowed to make the courses true. Read all the notes upon the margins of a chart. Nearly all the charts of harbors and the coast-line will be found with two scales of miles upon them; one marked statute miles, and the other nautical miles. A scale that marked statute miles means a mile of 320 rods of 16½ ft. each, or 1,760 yds. of 3 ft. each, or 5,280 ft.; while a nautical mile means the 60th part of a degree of the earth's surface measured at the equator, which is about 6,086.4 ft. in length.

COMPASS. — Familiarity with the compass is essential, and all beginners should learn to box it; that is, to commit to memory the names of the points. The following are the 32 points, each representing 11° 15′, or in all 360°.

1. NORTH.....N.
2. North by east.....N. by E.

3. North, north-east.....N. N. E.
4. North-east by north.....N. E. by N.
5. NORTH-EAST.....N. E.
6. North-east by east..... .....N. E. by E.
7. East, north-east .....E. N. E.
8. East by north.....E. by N.
9. EAST.....E.
10. East by south.....E. by S.
11. East, south-east .....E. S. E.
12. South-east by east.....S. E. by E.
13. SOUTH-EAST.....S. E.
14. South-east by south.....S. E. by S.
15. South, south-east.....S. S. E.
16. South by east.....S. by E.
17. SOUTH .....S.
18. South by west.....S. by W.
19. South, south-west .....S. S. W.
20. South-west by south.....S. W. by S.
21. SOUTH-WEST.....S. W.
22. South-west by west.....S. W. by W.
23. West, south-west.....W. S. W.
24. West by south..... .....W. by S.
25. WEST.....W.
26. West by north.....W. by N.
27. West, north-west..... .....W. N. W.
28. North-west by west.....N. W. by W.
29. NORTH-WEST .....N. W.
30. North-west by north.....N. W. by N.
31. North, north-west.....N. N. W.
32. North by west.....N. by W.

The number of points to which each course coincides should also be learned. These are divided into quarter points, to enable navigators to steer with accuracy. The needle of the compass does not always point to the north and south poles; at some places it points to the east and to the west. When the north point of the needle, or the N point on the compass card, points to the right of the true north, the variation is easterly; but when the same points to the left the variation is westerly. Knowing the compass bearing of any object, its true bearing may be



Cutter at Anchor.

determined by applying the variation when easterly to the right hand, when westerly to the left hand, the observer supposed to be placed in the centre of the compass, and looking towards the points from which the navigation is to be allowed. The influence of iron disturbs the direction of the magnetic needle, according to the extent and position of that metal.

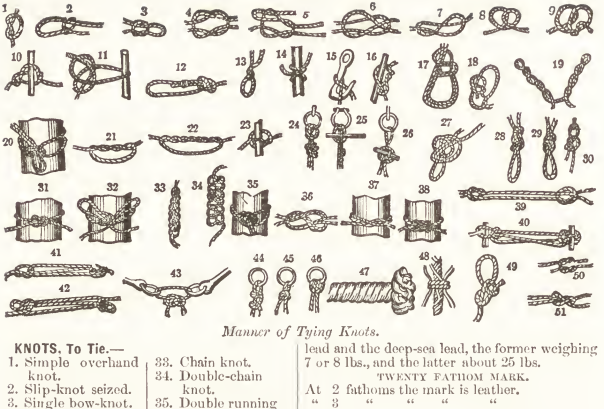
COMPASS, To Steer by.—The periphery of the circular casing in which the card revolves should be marked plainly with a perpendicular black line; this line should, by moving the compass-box, be brought to bear in a direct line with the keel of the yacht, and the box secured in that position. Move the helm to bring the point on the compass-card opposite to this black mark on the compass-box, and, having brought the point needed to this position, keep it there by moving the helm; this is called "keeping the vessel on her course."

HULL, MASTS AND SPARS.—

1. Stem.
2. Stern.
3. Tiller.
4. Anchor.
5. Cable.
6. Bowsprit.
7. Bobstay.
8. Mast.
9. Topmast.
10. Truck.
11. Vane and Spindle.
12. Cross-trees.
13. Trussle-trees.
14. Gaff.
15. Boom.
16. Topmast-shroud.
17. Topmast-backstay.
18. Topmost-stay.
19. Runner and Tackle.
20. Traveler for Jib.
21. Forestay.
22. Topping Lift.
23. Lift Blocks.
24. Mainsheet.
25. Peak Halliards.
28. Foresheet.
29. Signal Halliards.
30. Companion.
31. Forecastle.
32. Rudder.

JIB, To Reef.—If fitted with a bonnet instead of reef-points, bring the yacht to the wind, lower away on the jib-halliards, and bowse on the down-haul, and lower the jib enough so as to bring the reef cringle down to the bowsprit; then, if a bonnet, unlace and cast off, and if reef points, tie up the sail with them, and lash the outer clew to the bowsprit, and cast off the jib-sheet blocks, and hook the sister-hooks into the reef-cringle; hoist up the sail, and trim it.

JIB, To Take in.—First bring to by the wind; but the jib can be taken in and furled, with the yacht in different positions. Stand by the jib-halliards, and have the down-haul well manned, also the lee jib-sheet; then, at the command, "Down jib!" or, "Let go the jib-halliards!" or, "Take in the jib!" the halliards are cast off, the lee jib-sheet eased off, and the down-haul bowsed upon, till the head of the jib is snug down to the boom, when it should be carefully belayed, and the lee-sheet again made fast, leaving a little slack for furling. Then lay out upon the bowsprit, on the weather-side, and pick up the sail from out to leeward, and furl it to the bowsprit by stops, or in any way arranged for, being careful, if the yacht is pitching much, not to be thrown over the bowsprit to leeward, if submerged in a sea; for the person is suddenly lifted by a sea that may reach only to the middle, and, if care is not taken, pitched over the bowsprit to leeward. Having made everything fast, lay in, and set taut the jib-halliards, and belay them, and bring the after-clew of the jib amidships, by setting taut on the starboard and port jib-sheets, and belaying them, and coiling down everything snug.



Manner of Tying Knots.

KNOTS. To Tie.—

1. Simple overhand knot.
2. Slip-knot seized.
3. Single bow-knot.
4. Square or ruf-knot
5. Square bow-knot.
6. Weaver's knot.
7. German, or figure 8 knot.
8. Two half hitches, or artificer's knot.
9. Double artificer's knot.
10. Simple galley knot
11. Capstan or prolonged knot.
12. Bowline knot.
13. Rolling hitch.
14. Clove hitch.
15. Blackwall hitch.
16. Timber hitch.
17. Bowline on a bight.
18. Running bowline.
19. Catspaw.
20. Double running-knot.
21. Double knot.
22. Six-fold knot.
23. Boat knot.
24. Lark's head.
25. Lark's head.
26. Simple boat knot.
27. Loop-knot.
28. Double Flemish knot.
29. Running knot checked.
30. Crossed running knot.
31. Lashing knot.
32. Rosette.
33. Chain knot.
34. Double-chain knot.
35. Double running knot, with cheek knot.
36. Double twist knot.
37. Builder's knot.
38. Double Flemish knot.
39. English knot.
40. Shortening knot.
41. Shortening knot.
42. Sheep shank.
43. Dog shank.
44. Mooring knot.
45. Mooring knot.
46. Mooring knot.
47. Pigtail worked on the end of a rope.
48. Shroud knot.
49. A bend or knot used by sailors in making fast to a spar or a bucket handle before casting overboard; it will not run. Also used by horsemen for a loop around the jaw of a colt in breaking; the running end, after passing over the head of the animal and through the loop, will not jam therein.
50. A granny's knot.
51. A weaver's knot.

LEAD LINE.— For the purpose of sounding, vessels are supplied with 2 lead lines, the hand-lead and the deep-sea lead, the former weighing 7 or 8 lbs., and the latter about 25 lbs.

TWENTY FATHOM MARK.

At	2	fathoms	the mark is	leather.
"	3	"	"	"
"	5	"	"	white rag.
"	7	"	"	red rag.
"	10	"	"	leather with round hole.
"	13	"	"	blue rag.
"	15	"	"	white rag.
"	17	"	"	red rag.
"	20	"	"	piece of cord with 2 holes.

The deep-sea line is marked in a similar manner to the 20 fathom mark, after which an additional knot to every 10 fathoms is fixed in the line, and between the 10's a piece of leather; both leads have a hole in the end filled with soap, so that when it strikes the bottom it may bring up a sample of it, which adheres to the soap.

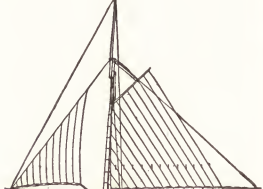
LEAKS, To Stop. — Never neglect a leak, but have it repaired at once. The pump should be kept in order, and ready for use. To stop a leak pass a light sail over the bows, and bring it aft over the leak by means of ropes on both sides of the yacht. Leaks are more easily stopped on the outside, the pressure of the water forcing the canvas into the damaged part. When a leak is discovered the yacht should be put before the wind till it is secured.

MAINSAIL, To Take in and Furl.—Bring the yacht close to the wind, and haul the main-sheet flat aft, and belay it carefully. Then stand by the throat and peak halliards, and, at the word "Lower away," ease away on each, taking care not to let the peak drop too fast, which causes the hoops to jam and the sail to stick, till the peak halliards are hoisted upon again to clear things. When the sail is down, make fast the halliards, and get along on the weather-side of the main-boom, and pick up the sail by what is called "skinning it," repeatedly taking the canvas, and shaking it towards one, it is finally rolled up so

as to lay snugly on the boom, to which it should be fastened by gaskets. The main boom should then be lifted into a crotch, and the throat and peak halliards hauled taut, and the main sheet again belayed, as it will have to be slacked to get the crotch under the boom, and every thing coiled up snug and belayed.

REEF, To Put in a Mainsail.—Haul down the jib, bring the yacht to the wind, haul the main-boom chock aft, and belay the sheet carefully; lower away on the throat and peak-halliards till the reef-band is down lower than the main boom; then, by the reef pennant rove through the reef-cringle on the outer leach of the sail, bowse the foot out on the boom, and lash it fast by passing an earing through the cringle and around the boom by several turns, till the clew of the sail is fastened; then pass an earing from the reef cringle in the luff of the sail around the main boom in the same manner, and commence fastening the reef-points, either around the main-boom, or to an iron jackstay, fastened to the boom, or around the foot of the sail, according as the yacht may be arranged, making each knot a square knot. When the sail is half lowered, so as to get at the reef-band, etc., the yacht is kept head to sea and "hove to," by placing the tiller towards the lee-side of the yacht, or what is called "hard-a-lee," where it is secured till the vessel is reefed, and started on her way. In reefing, haul out on the reef pennant first, and stretch the foot of the sail, and then lash the luff next, and fasten the reef-points last. When the points are tied, hoist away on the throat and peak halliards, and set sail. Take in a second reef in the same manner as the first, except in first commencing to reef, two reefs can be taken in one by lowering the sail to the second reef band, and proceeding the same as in the first reef, except that the two extremities of the sail are lashed at the second reef-band cringles; and in tying the reef-points no notice is taken of the first reef points, but they are stowed with the rest of the sail to the boom, and are not tied.

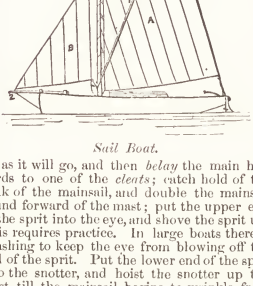
REEF, To Shake Out.—Bring the yacht to the wind as for reefing, and unknot all the reef-points; then cast off the lashing at the luff,



Reefed Sails.

and, lastly, the earing at the end of the boom.

RIGGING.—The sail-boat is sloop-rigged, with or without a jib, but has no main boom nor gaff, the sail being kept up by a *sprit*. Her rig is as follows: One mast, with a *mainsail*, *A*, and a *foresail*, *B*; one mast, a *sprit*, *1*, and a short *bowsprit*, *2*. The mast has one *shroud* on each side, and a *forestay* to the stem, each set up by *lanyards*. The mainsail is hoisted by a *main halliard* passing through a hole, or over a *sheave* in the mast; have this hole or sheave *above* the shrouds, as also the hole for the fore-halliards, one hole above the other. The *sprit* fits into an *eye* at the peak of the mainsail, and into a *becket* or *snotter* round the mast; large boats have a rope to hoist and keep up the snotter. In small boats, the snotter, when wetted, sticks tight enough to the mast. The *mainsheet* works on a *horse* at the stern. The *fore-halliards* pass through a hole in the mast-head, and the foresail is *laced* to the forestay. The *foresheets* lead through holes in the knees. To set the sails, hoist the mainsail by the main-halliards *chock up*, or as



Sail Boat.

far as it will go, and then *belay* the main halliards to one of the *cleats*; catch hold of the peak of the mainsail, and double the mainsail round forward of the mast; put the upper end of the sprit into the eye, and shove the sprit up. This requires practice. In large boats there is a lashing to keep the eye from blowing off the end of the sprit. Put the lower end of the sprit into the snotter, and hoist the snotter up the mast till the mainsail begins to wrinkle from tack to peak; then haul the mainsheet taut and belay it till ready to start. The foresail is wrapped around the forestay; *untoggle* the sheets and unwrap the foresail, then toggle on the sheets, ship the *tiller*, and the boat will be ready. The usual small sail boat is rigged without a foresail or jib, and the mast, to balance it, is set forward of the spot where it stands in the cut. It has no shroud or forestay, being shipped into a thwart running across the boat, and secured in a step below. It is set with more of a *rake* or pitch backward than is shown in the illustration. The beginner will soon learn the principles on which a boat *tacks*, how to *jibe* safely, *reef* the mainsail and the foresail, fit a *reefed snotter*, *stow the sail* and *moor the boat*, *pick up moorings* and *come alongside*. Sailing boats are usually fastened by a chain to a stone under water; when the boat gets *under way*, the chain is let go and

is then picked up again by a rope, one end of which is made fast to the chain, the other to a piece of wood, called a *buoy*. To pick up this buoy the sails are lowered, and the boat runs at it; but usually the boat is taken to leeward, and at the proper distance is *luffed up*, so as to come head to wind, and stop as nearly as may be over the buoy. The beginner should go where he has plenty of room, taking out a buoy or piece of wood, and practice picking that up till he can measure his distance accurately.

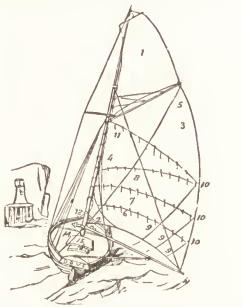
ROPES. — The ropes to hoist and lower sails are called halliards; there are other ropes, called sheets, to haul in sails and make them stand to wind. In a yacht the mainsail has sometimes a sheet on each side; and sometimes only 1 sheet reeved through double blocks, which travel on an iron rod, called a "horse," from side to side.

Topmast and Fore-topmast Stay.

The jib has 2 sheets, the starboard and port. The foresail has the same, except when it has but 1 sheet working on a traveler, like the mainsail. The topsail has 1 rove through a sheave at the end of the gaff, and a block at the throat of the gaff, and then down to a cleat on deck. Signal halliards pass through a small sheave in the truck at the end of the topmast. Ensign halliards are reeved through a small block at the peak end, and lead down to the boom. The other ropes, for support of spars, are called "standing rigging," while those for sails are called "running rigging."

RUDDER AND TILLER.—The rudder is a flat board, with a pole rising up on the side, fastened to the vessel, on the top of which is fixed the tiller. In large vessels there are 2 ropes fastened to the tiller, carried through blocks on each side of the vessel, then brought back through blocks fastened on the mizzen mast, and passed round a wheel. The tiller passes through the rudder head, and is moved to right or left, termed moving the helm. When the tiller is moved to right (starboard) the rudder is forced in the water to the left (port).

SAILS. — It is necessary to fully understand the sails to become a thorough yachtsman. The illustration represents a yacht in full sail, running before a light breeze. The sails are governed and managed by certain ropes, spars, etc., known as rigging. The quantity of sail carried by a yacht must vary with wind and weather, the build of the vessel, position of mast, number of persons aboard, and other circumstances. The following directions are good for a cutter yacht: *Nice working breeze.* Whole mainsail, large working topsail, whole foresail and No. 1 jib. — *Stiff breeze.* Whole mainsail, topmast housed, whole foresail, and No. 2 jib. — *Strong Breeze.* Single-reefed mainsail, single-reefed foresail, and No. 3 jib set on a reefed bowsprit. — *Strong squally winds and sea rising.* Double-reefed mainsail, double or single-reefed foresail, and No. 4 jib on a double-reefed bowsprit. — *Gale with moderate sea.* Three-reefed mainsail, close-reefed foresail, and No. 5 jib on close-reefed bowsprit.—*Strong gale with heavy sea.* Trysail and storm jib, and bowsprit slung in. These gradations of wind must be judged by the yachtsman; experience is the only guide, and even that must give place sometimes to foresight and mother wit.



Sails, Etc., of a Cutter.

1, gaff topsail; 2, foresail; 3, mainsail; 4, tack bracing line; 5, peak line, or signal-halliards; 6, 7, 8, first, second, and third reefs; 9, reef ear-rings; 10, cringles; 11, balance reef; 12, anchor stock; 13, windlass; 14, foresheet horse; 16, main hatch; 10, companion and binnacle.

SCUDDING. — The most difficult steering of any; in rough water it is hard to keep the yacht upon her course; the seas will lift the stern out of the water, neutralize the use of the rudder for a moment, and cause the yacht to yaw; the speed changes and affects the rudder. When on the top of a sea, and all the sails full, the yacht will go fast; when she attempts to bury her head and kick up her heels, and beclams the jib and lower part of the mainsail, she will go slower. In running before the wind, guard against "jibing" of the main boom. If the sea is bad and the yacht steers wild, tack down to leeward by hauling up the yacht a little toward the wind on either tack, to bring it over the quarter, and then run before it for a distance, and by careful jibing bring the wind over the other quarter, and then proceed on.

SIGNAL LIGHTS.—The lights mentioned in the following articles, and no others, shall be carried in all weathers between sunset and sunrise:

Steamships. — All steam vessels, under way, shall carry: 1. At the foremast head a bright white light, fixed to show an unbroken light over an arc of the horizon of 20 points of the compass; fixed to throw the light 10 points on each side of the ship, from right ahead to 2 points abaft the beam on either side, and of such a character as to be visible on a dark night, with a clear atmosphere, at a distance of 5 miles. 2. On the starboard side a green light, to throw a uniform and unbroken light over an arc of the horizon

of 10 points of the compass ; fixed to throw the light from right ahead to 2 points abaft the beam on the starboard side, and of such a character as to be visible on a dark night, with a clear atmosphere, at a distance of 2 miles. 3. On the port side a red light, to show a uniform, unbroken light over an arc of the horizon of 10 points of the compass ; fixed to throw the light from right ahead to 2 points abaft the beam on the port side, and of such a character as to be visible on a dark night, with a clear atmosphere, at a distance of 2 miles. 4. The said green and red side lights fitted with inboard screens, projecting at least 3 feet forward from the light, to prevent these lights from being seen across the bow.

Steam-Tugs.—Steamships, towing other ships, shall carry 2 bright white masthead lights vertically, in addition to their side-lights, to distinguish them from other steamships.

Sailing Vessels.—Sailing vessels, under way, or being towed, shall carry the same lights as steam-ships under way, with the exception of the white masthead lights, which they shall never carry.

Exceptional Lights for Small Sailing Vessels.—Whenever, as in the case of small vessels during bad weather, the green and red lights cannot be fixed, these lights shall be kept on deck, on their respective sides of the vessel, ready for exhibition; and shall, on the approach of or to other vessels, be exhibited on their respective sides in time to prevent collision, in such a manner as to make them most visible, and so that the green light shall not be seen on the port side, nor the red light on the starboad side. To make the use of these portable lights certain and easy, they shall each be painted outside with the color of the light they respectively contain, and be provided with suitable screens.

Ships at Anchor.—Ships, whether steamships or sailing ships, at anchor in roadsteads or fairways, shall, between sunset and sunrise, exhibit where it can best be seen, but at a height not exceeding 20 ft. above the hull, a white light in a globular lantern of 8 in. diameter, so constructed as to show a clear, uniform and unbroken light visible all around the horizon, and at a distance of 1 mile.

Pilot-Vessels.—Sailing pilot vessels shall not carry the lights required for other sailing vessels, but shall carry a white light at the mast-head, visible all around the horizon; and also exhibit a flare-up light every 15 minutes.

Fishing Vessels.—Open fishing boats and other open boats, shall not be required to carry side-lights required for other vessels, but shall, if they do not carry such lights, carry a lantern having a green slide on the one side, and a red slide on the other side; and, on the approach of or to other vessels, such lantern shall be exhibited in time to prevent collision; so that the green light shall not be seen on the port side, nor the red light on the starboard side. Fishing vessels and open boats at anchor, or attached to their nets, and stationary, shall exhibit a bright white light. Fishing vessels and open boats shall not be prevented from using a flare-up light in addition, if considered expedient.

SIGNALS. Fog.—Whenever there is a fog, by day or night, the fog-signals described below shall be carried and used, and shall be sounded at least every 5 minutes. Steamships under way shall use a steam whistle placed before the funnel, and not less than 8 ft. from the deck. Sailing vessels under way shall use a fog-horn. Steamships and sailing vessels when not under way, shall use a bell.

SPEED, To Ascertain. — The rate of a ship's sailing is measured by a log-line and half-minute glass. The line is marked with a knot for each mile. The real distance between each knot being the 1-120 of a mile, since ½ minute is the 1-120 of an hour, and the number of knots carried out while the glass is running out, will show the number of miles the vessel goes in 1 hour.

SQUALLS.—If the sail is loose, and the boom, or lower leach of the sail, can move in a direction parallel to the wind, the boat cannot be upset by a gust of wind. It is the flaws of wind caught by the sail that capsize a boat; and, if the wind that has force enough to do this could be "spilled" out of the sail, the boat would be relieved. To insure safety, the person steering a boat should never belay the sheet, but keep it in hand, so as to be able to slack it off gradually, or cast it off at a moment's notice. To do this, one turn should be taken round the cleat; so that the sheet will slip under the force of a gust of wind, when the hand retaining it in place slackens it. If the whole sail points towards the wind's eye, it no longer has any effect upon the boat. The sail then shakes in the wind exactly as a flag does from the top of a flag-staff. Should the sheet be hauled aft, the sail would be filled with wind upon one side; and, if the wind had strength to overcome the gravity of the boat, capsize her. With boatmen who are practiced, the slacking of the sheet is seldom done; they obtain the same result with the rudder by bringing the boat into the wind until the sail shakes, with the sheet still fast. The best thing in a sudden squall is to use a modification of both methods; slack off the sheet a foot or two, so that the sail, before it can fill with wind, will be at such an angle with the hull, that the shock upon the latter cannot be great. This gives command of the boat, and insures quicker movement of the hull and obedience to the helm, should a sudden change occur. Slacking of the sheet prevents the boat from going about on the other tack, should she be brought too suddenly to the wind. If the boat is well under command when the squall is advancing, the method of steering into the wind's eye may be adopted. In small sail boats, on ponds or arms of the sea, when a thunder shower is coming up, take the boat as quickly as possible toward the nearest land, unless inaccessible; in which case furl all sail and let go an anchor, paying out such scope of cable that the boat will ride easily; the thunder gust can then do no harm. With an oar head the boat towards the coming blast, so that she will feel little of its force, and prevent dragging the anchor. Boats are often capsized by those on board scrambling to windward when a squall buries the lee gunwale in water. Should the boat at this moment be taken

aback by a counter squall or flaw, she will capsize. The safest position is for all, except the helmsman, to sit down in the bottom of the boat near the centre, which increases the steadiness of the boat.

STEERING. — The yachtsman should never neglect an opportunity of making himself a good steersman, which requires the eye of a hawk. He must thoroughly know his vessel. Different yachts demand different handling. He should always stand to windward of the tiller, to see the canvas and the direction of his course, so as to have more command over the vessel. A short, bluff-bowed, beamy yacht requires different steering from a long, sharp, narrow clipper; the former will quickly answer to the motion of the helm, while the latter will be longer. It is understood that when the rudder is placed at an angle of 35° to 40° with the line of the keel, it is in position to produce the greatest effect with the least diminution of speed. The nearer it is to a right angle, the more it tends to diminish speed, and the less effective it is in turning the vessel. If the desired effect upon a vessel's course is produced, the less helm given her the better. A yacht in perfect trim ought not to require much helm. If she does, something is defective in the balance of sails, adjustment of ballast, or form of the hull as regards draught of water forward. In beating to windward the sails should be kept full, and yet the vessel sailed as near the wind as she can go. Every stronger puff than usual should be taken advantage of, to eat as far into the wind as practicable; and in coming about the yacht should be given the full benefit of her run up into the wind's eye in stays, and no time lost in getting life into her on the other tack. A cutter-yacht is difficult to steer when she has the wind well abaft the beam or dead aft, especially if there is a heavy quarterly or following sea. This demands skill and judgment. The yacht will have a tendency to yaw wildly, alternately coming up in the wind and then falling off again. It is of the utmost importance that the steersman concentrate his attention, watching every variation in the yacht's course and every change in the wind. The following are the rules for steering:

Meeting. — If 2 sailing ships are meeting end on, or nearly end on, so as to involve risk of collision, the helms of both shall be put to port, so that each may pass on the port side of the other.

Crossing. — When 2 sailing ships are crossing so as to involve risk of collision, if they have the wind on different sides, the ship with the wind on the port side shall keep out of the way of the ship with the wind on the starboard side, except in the case in which the ship with the wind on the port side is close hauled and the other ship free, in which case the latter ship shall keep out of the way. But if they have the wind on the same side, or if one of them has the wind aft, the ship which is to windward shall keep out of the way of the ship to leeward.

Sailing Ships and Ships Under Steam. — If 2 ships, one of which is a sailing ship and the other a steamship, are proceeding in such directions as to involve risk of collision, the steamship shall keep out of the way of the sailing ship.

Ships Under Steam to Slack Speed.—Every steamship when approaching another ship so as to involve risk of collision, shall slacken her speed, or, if necessary, stop and reverse; and every steamship shall, in a fog, go at a moderate speed.

Vessels Overtaking Other Vessels. — Every vessel overtaking any other vessel shall keep out of the way of said vessel.

WIND, Sailing Against.—Only good boats sail with the wind on the bow or before the beam, and then not when the wind is more than 4 points before the beam, reckoning by the 32 points of the compass, and to do that the sails must be well set. Suppose a boat with her head pointing to the wind; her sails will then flap about and tend to drive her astern. Now suppose her bow gradually turned from the wind: if the sails are hauled pretty flat, after a time, when her bow is 4 points or the 8th of a circle off from the wind, the sails will fill and she will move ahead. Having gone some distance she may be put about and go at a similar angle to the wind in the other direction, and will thus advance against the wind; this is called tacking or turning to windward. In sailing to windward, the sails are hauled aft to an angle which varies for each boat, and is found by experience. They should be kept properly full of wind; if empty, they are doing no good; if too full, the boat is off her course. A rule is to keep the flag or vane just over the mainsail. Boats ought to carry a weather helm; that is to say, the bow should have a tendency to turn toward the wind. Putting weight in the bow makes the weather-helm stronger, putting it in the stern or increasing the head sails has the reverse effect. When the wind is on the starboard side of the vessel, she is on the starboard tack; when the wind is on the larboard, she is on the port tack; and when vessels meet, that which is on the starboard tack either keeps straight or luffs; that on the port tack gives way and passes to leeward. To sail with the wind on the bows, the boat must have a keel. In a sail boat this is made movable, sliding up and down within a well in the centre, and is called the sliding-keel or centre-board. A skiff may be made to tack by holding the flat blade of a scull deep in the water against the side of the boat on the leeward side.

SKATING.

REMARKS.—The dress should fit closely and yet insure freedom of motion. Neither skirts to coats nor full trousers should be worn. The wood of the skate should be hollowed, to adapt it to the ball of the foot. There are many varieties of skates; some are made with high

irons and some with low; some with narrow and some with broad; some with the bottoms of the irons at right angles with the sides, and some with a groove running lengthways through the bottom of the iron. For beginners, a low iron is best, and squarely ground.

BEGINNING.—The first attempt is to walk, which becomes a sliding gait, done entirely on the inside edge of the skate. The first impulse is to be gained by pressing the inside edge of one skate against the ice and advancing with the opposite foot. To do this, bring the feet nearly together, turn the left somewhat out, place the right a little in advance and at right angles with it, lean forward with the right shoulder, and move the right foot onwards, and strike the ice with the inside edge of the left skate, throwing the weight on the left foot. While thus in motion, bring up the left foot nearly to a level with the other, and proceed a short way on both feet. Next, place the left foot in advance in its turn, bring the left shoulder forward, incline to that side, strike from the inside edge of the right skate, and proceed as before. Repeat this motion on each foot alternately. Some use a stick, but it is best to have the support of a companion.

Inside Edge.

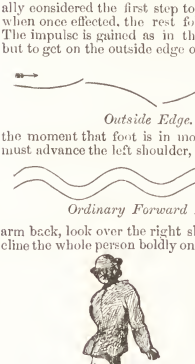
FORWARD ROLL. or OUTSIDE EDGE.—Usually considered the first step to figure skating; when once effected, the rest follows with ease. The impulse is gained as in the ordinary run; but to get on the outside edge of the right foot,

Outside Edge.

the moment that foot is in motion, the skater must advance the left shoulder, throw the right

Ordinary Forward Roll.

arm back, look over the right shoulder, and incline the whole person boldly on that side, keeping the foot suspended behind. On proceeding, bring the left foot past the inside of the right, with a jerk, which produces an opposing balance of the body; the right foot must then quickly press, first on the outside of the heel, then on the inside; the left foot is placed down in front,



Outside Edge Forward.

before it is removed more than 8 or 10 in. from the other foot; and, by striking outside to the left, giving a strong push with the inside of the right toe, the skater passes from right to left, inclining to the left side, in the same manner as he did to the right; then continues to change from left to right, and from right to left in the same manner.—*The Cross Roll*, or *Figure 8*, is done on the outside edge forward. This is only the completion of the circle on the outside edge, performed by crossing the legs and striking from the outside instead of the inside edge. To do this, as the skater draws to the close of the stroke on his right leg, he throws his left quite across it, causing him to press hard on the outside of the right skate, from which he immediately strikes, throwing back the left arm and looking over the left shoulder, to bring him well upon the outside of that skate. By completing the circle on each leg the 8 is formed. — *The Mercury Figure* is merely the outside and inside forward succeeding each other on the same leg alternately, by which a serpentine line is described, and is done with the force and rapidity gained by a run. When the run is complete and the skater on the outside edge, his person assumes the attitude of Mercury, having the right arm advanced and raised, the face turned over the right shoulder, and the left foot off the ice, a short distance behind the other, turned out and pointed.

Fig. 8.

INSIDE EDGE BACKWARDS, or FIGURE 3.—This is formed by turning from the outside edge forward to the inside edge backward on the same foot. The head of the 3 is formed like the half circle, on the heel of the outside edge, but when the half circle is complete, the skater leans suddenly forward, and rests on the same toe inside, and a backward motion, making the tail of the 3, is the consequence. At first, he should not throw himself quite so hard on the outside forward, in order that he may the more easily change to the inside back. When the skater is able to join the ends of the 3, so as to form one side of a circle, then, by striking off in the same manner, and completing another 3, with the left leg, the combination of the two 3's will form an 8. In the first attempts, the 3 should not be made above 2 ft. long, which is acquired imperceptibly.

Fig. 3.

OUTSIDE EDGE BACKWARDS.—The backward curve constitutes the base of all retrograde or backward figures. The position of arms and head is not the same as for the ordinary curve on the outside edge. When executing the outward retrograde curve the face must be turned toward the left shoulder. Having completed the 3, and being carried on by the first impulse, he continues his progress in the same direction, but on the other foot, putting it down on its outside edge, and continuing to go backwards slowly. To accomplish this, after making the 3, and placing the outside edge of the left foot on the ice, he should at once turn his face over the right shoulder, raise the right foot from the ice,

and throw back the right arm and shoulder. If unable readily to raise that foot which has made the 3, and leave him on the outside of the other skate, he may keep both down, putting himself in the attitude of being on the outside only of one skate, and gradually raising the other off the ice. When finishing any figure, the use of both feet backward has great convenience and beauty. In the *Double 3* the skates are brought from the inside back of the first 3, to the outside forward of the second. Having completed one 3, and being on the inside back, he must bring the whole of the left side forward, particularly the leg, till it is thrown almost across the right, on which he is skating. This action brings him once more to the outside forward, from which he again turns to the inside back. While still in motion on the second inside back of the right leg, he must strike on the left, and repeat the same on that. The *Back Roll* is a means of moving from one foot to another. Suppose the skater to have put himself on the outside edge back of the left leg, with considerable impulse, by means of the 3 performed on the right (not bearing hard on the edge, for the object is to change it, and take up the motion on the right foot); this is effected by throwing the left arm and shoulder back, and turning the face to look over them; when, having brought the inside of his left skate to bear on the ice, he must immediately strike from it to the outside back of the other, by pressing it into the ice as forcibly at the toe. Having been brought to the backward roll on the right foot, he repeats the same with it.—The *Back Cross Roll* is done by changing the balance of the body, to move from one foot to the other as for the back roll. The stroke is from the outside instead of the inside edge of the skate; the edge on which the person is skating not being changed, but the right foot, which is off the ice, being crossed at the back of the left, and put down, and the stroke taken at the same moment, from the outside edge of the left skate, at the toe. The outside backward roll is attained by a run, when the skater strikes on the outside forward of the right leg, turns the 3, and immediately puts down the 3 on the outside back. He then flies rapidly over the ice, the left arm being raised, the head turned over the right shoulder, and the right foot turned out and pointed.

Outside Edge Backward.

SALUTES. — The salute in a right line is not easy. Having struck out, place the feet in a horizontal line, elevating and rounding the arms. Continue the movement as long as you can. The salute in a curved line is easier. Having started, put your feet in the position you would adopt to describe the salute in a right line, only less horizontally. The head and body must be upright, the arms rounded, and the hands placed on the haunches; in this position describe a circle; then draw yourself up, the knees having become slightly bent, and, raising the right or left foot, prepare for another evolution, striking out straight forward, or toward one side.

Salute.

STOPPING.—Bring the second foot down on the ice, then glide forward, with both feet pointed in front of you, and parallel to each other, like the irons of a sledge; bend the body forward and throw the weight upon the heels. Those who wear skates with rounded heels cannot stop in this way, as the rounded irons, instead of sticking into the ice, would trip; he puts the second foot to the ground at right angles with the other, pointed entirely sideways, which stops his career.

SWIMMING.

REMARKS. — In the essential part of swimming (keeping the head above water) there is no skill; confidence in the sustaining power of the water is the secret; and if the novice will remember 3 simple rules, he cannot sink: 1. Keep the hands and feet well below the surface, and immerse the whole body up to the chin. 2. Hollow the spine and throw the back of the head upon the shoulders. 3. Move the limbs quietly. A good swimmer is distinguished by the ease of his movements. The arms and legs are flung out to their full extent, sweep round in the water equably, and are drawn up for another stroke without hurry. The bad swimmer never waits long enough to make a full stroke, but gives short jerks with his arms and legs, never extending them more than half their length. The best time of the day for swimming is before breakfast, between 6 and 8 in the summer, or 11 and 12 in the forenoon. Never enter the water on a full stomach, or after dinner; and never when over-heated or exhausted. Avoid entering when cold or with a headache. It is bad to walk until you get hot, then to sit down and cool, and afterwards to enter the water. It is wrong to enter during rain, as the clothes are often wet or damp, which gives cold.

AIDS. — Cork is sometimes used as an aid. It may be strapped on the back, as shown in the illustration. Boards are preferable. They should be over 4 ft. long, over 1 ft. wide, and 2 in. thick, and made of soft white pine or cedar. Wade into the water up to the shoulders, then take hold of the end of the board; push it be-

fore you; spring forward with the feet, and throw yourself flat upon the water. This car-

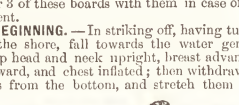
Swimming with Cork as an Aid.

ries you along a few feet; then draw up both legs at the same time; keep the knees as far apart as possible, and strike out with both feet

Swimming with a Board as an Aid.

sideways, like a frog. The stroke is made slowly and is repeated again, drawing up the legs slowly. The board keeps the head above water. When the leg stroke has been learned, one hand is taken from the board and the stroke learned, or the chin may be rested on the board while the stroke is taken with both hands; this compels the swimmer to keep his hand under the water. By-and-by the board may be pushed ahead, and the swimmer may swim after it. When a number go to swim, they should have 2 or 3 of these boards with them in case of accident.

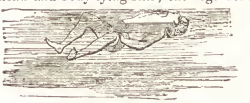
BEGINNING.—In striking off, having turned to the shore, fall towards the water gently; keep head and neck upright, breast advancing forward, and chest inflated; then withdraw the legs from the bottom, and stretch them out;



Striking Off and Swimming.

strike the arms forward in unison with the legs. The back can scarcely be too much hollowed, or the head too much thrown back; those who do otherwise will swim too near the surface, instead of allowing their feet to be 1½ ft. deep in the water. The hands should be placed in front of the breast, fingers pointing forward and kept close together with thumbs to the edge of the forefingers; the hands must be made concave on the inside, though not so much as to diminish the size. In the stroke of the hands, they should be carried forward to the utmost extent, taking care that they do not touch the surface of the water; they should next be swept to the side, at a distance from, but as low as the hips; then drawn up again, by bringing the arms towards the sides, bending the elbows up and the wrists down, so as to let the hands hang down while the arms are raising them to the first attitude.

BACK, Swimming on.—Place the hands on the sides of the body near the hips; lay the head and body easily on the water, the knees and elbows turned out so that they keep under; the head and body lying still; the legs drawn



Swimming on the Back.

up and used the same as in *Chest Swimming* (which see), not forgetting to use the ankle joint.

BACK, Swimming on, without Employing the Feet.—1. (*In the direction of the feet.*) The body is placed in a horizontal position, feet stretched out stiffly, heels and toes kept in contact, body somewhat curved at the seat, hands stretched flatly forward over the body, and slowly striking in small circles, the loins somewhat drawn up at each stroke.—2. (*In the direction of the head.*) The body is placed horizontally, but somewhat curved in the seat, head in its natural position, arms close to the body, elbows inclined inward, and hands describing small circles from the back to the front at about 1½ ft. from the hips. This strengthens the arms without fatiguing the breast.

BALANCING.—To perform this, when out of depth, fall gently back with the chin elevated to a line passing exactly through the centre of the body, from the chin to the toes, then fold the arms and remain motionless; the person may then suspend himself perpendicularly; but if he should extend his arms back and pass them gradually beyond his head, his toes, tips of his knees, abdomen and part of his chest, with the whole of his face will appear, and he will float horizontally without motion.

Balancing.

CHEST, Swimming on.—The great difficulty will be found in the management of the legs. The movement of the arms is natural, but that of the legs unnatural. The secret is to kick out the legs wide. The propelling power is caused by the legs being suddenly brought from a position in which they are wide apart into one in which they close together like the blades of a pair of scissors. In bringing the legs suddenly together, a wedge of water is forced backwards, and the resistance propels the body forward in an opposite direction. When this is considered, the importance of drawing the legs well up will be manifest. The beginner having practiced to move his legs properly by catching hold of

some object with the hands, should then try a few strokes in which he uses hands as well as

Chest Swimming.

legs. He will here experience a check. The moment he tries to move his hands, he will find that his legs refuse to obey. Were the hands placed sideways, the water would offer little resistance. By keeping the hands in the position named, the resistance offered by the water, in case of sinking, would be considerable. In drawing up the legs, the toes should be pointed. By this means the resistance of the water against the insteps of the feet is avoided. The movement of the arms is never one in which great difficulty will be found. The two hands shall be kept flat, the palms resting on the water; and, at the same time, as the swimmer strikes out with his legs, each hand should be brought slowly round, one to the right and the other to the left.

CRAMP. — Cramp proceeds from acidity of the bowels, or from the effects of cold water on the system. Some are subject to it, and will do well never to go out of their depth. But should a swimmer be seized with cramp, he should not be frightened, but the moment it is felt in in the foot or leg, strike out that foot or leg with the heel elongated, and the toes drawn upwards toward the shin-bone, never minding any pain it may occasion. Should this not succeed, he should, throw himself on his back, float quietly and paddle to the shore. He may also swim with his hand like a dog, and practice any motion of the upper part of the body for keeping his head above water till assistance arrives.

FLING.—The swimmer lays himself flat upon his waist, draws his feet close under the body, stretches his hands forward, and, with the feet and hands beating the water violently, raises himself out of the water. In this manner one may succeed in throwing one's self out of the water as high as the hips. This exercise is useful for saving one's self by catching a rope or other object that hangs from above the surface of the water, or from a perpendicular height.

FLOATING.—Floating is set down as the first requisite. Even an expert swimmer is liable to have his powers put to a test, so that the art of resting on the water without effort may be vital to him; while to him who knows nothing of swimming, to float securely is his only hope of safety in case of accident. Floating in a walking position, called "treading water," is easy to learn, but it presupposes deep water. Having learned to rest at ease on shallow water, the bather can float into deeper water without losing confidence, and thus pass by easy stages to swimming on the back, or through the practice of treading water to swimming in the usual way. The quantity of air in the lungs and buoyant portions of the viscera, but little more than suffices to float the body. With the arms extended the body is balanced as upon a fulcrum; the natural tendency of the feet to sink is counteracted, and the body floats, with the

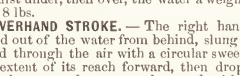
Floating.

mouth and nose out of water. With the arms at the sides, the preponderance of weight is below the centre of buoyancy, the feet drop, and considerable effort is required to keep the nose and mouth from being submerged, either by throwing the head back or paddling with the hands. It is true that a slight movement of the hands by a practiced floater suffices to keep the feet from dropping and the body horizontal; but that little effort is fatiguing, and is sure to be unskillfully made by a novice. Unless one is lean or deficient in lung capacity, floating can be easily learned; and in case of emergency the non-swimmer will find it a certain way of sustaining himself on water.

MILL. — The swimmer lays himself on his back, and contracts himself so that the knees are brought almost to the chin, and while one of the hands keeps the equilibrium by describing circles, the other continues working; thus the body is kept turning round more or less rapidly.

ONE HAND, To Swim with.—The learner, to do this, swims on one side, keeps his feet deeply sunk, while the arm which ought to work is kept quiet, and might be even taken out of the water. It is a good practice of strength to carry, first under, then over, the water a weight of 4 to 8 lbs.

OVERHAND STROKE. — The right hand is lifted out of the water from behind, slung forward through the air with a circular sweep to the extent of its reach forward, then dropped into the water edgeways, and turned, with the palm a little hollowed, downward, the body be-

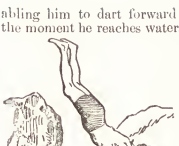


Overhand Stroke.

ing thrown a little on one side, and the right leg struck out backward to its full extent. The hand descends toward the thigh and then passes upward through the water in a curve toward the surface. The left hand and leg perform a similar movement alternately with the right, and the measure of progression attained by these combined movements is considerable.

PLUNGING AND DIVING. — In diving from a height, say 6 ft., the heels must be thrown well up, the legs kept straight and well together, and the hands brought forward in front of the head. The hands act as a breakwater, and should be turned up the moment the water is reached, preventing the diver going down deep, and en-

abling him to dart forward along the surface the moment he reaches water. A good diver can dive from a height of 40 to 50 ft., and yet never go a yard below the surface. If necessary to take a dive from a high place, you must not give the same movement to your body as if going off from the height of a few feet, otherwise you will turn over in the air and come down on your back.



Plunging and Diving.

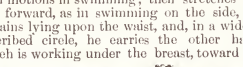
SAVING LIFE. — The swimmer must avoid approaching the drowning person in the front, in order that he may not be grasped by him. He should seize him from behind, and let go of him if the other turns toward him. His best way is to impel him before him to the shore, or to draw him behind: if the space to be passed be too great, he should seize him by the foot and drag him, turning him on his back. If the drowning person should seize him, there is no alternative for the swimmer than to drop with him at once to the bottom of the water, and to wrestle with his antagonist; the drowning man, by instinct to regain the surface, usually quits his prey, particularly if the diver attacks him with all his power. For 2 swimmers the labor is easier, as they can relieve each other. If the drowning person has presence of mind, they will seize him, one under *one arm, and the other under the other*, and without any great effort in treading water, bring him along, with his head above water, while they enjoin him to keep himself stretched out and as much as possible without motion.

SIDE, Swimming on. — The body is turned either on the left or right side, while the feet perform their usual motions. The arm from under the shoulder stretches out quickly at the same time that the feet are striking. The other arm strikes at the same time with the impelling of the feet. The hand of the latter arm begins its stroke on a level with the head. While the

Side Swimming.

hand is again brought forward in a flat position and the feet are contracted, the stretched-out hand is, while working, drawn back toward the breast, but not so much impelling as sustaining. As swimming on the side presents to the water a smaller surface than on the waist, when rapidity is required this way is often preferable.

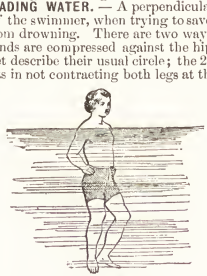
THRUSTING.—In the thrust the swimmer lies horizontally on his waist, and makes the common motions in swimming; then stretches one arm forward, as in swimming on the side, but remains lying upon the waist, and, in a widely-described circle, he carries the other hand, which is working under the breast, toward the



Thrusting.

hip. As soon as the arm has completed this motion, it is lifted from the water in a stretched position, and thrown forward in the greatest horizontal level, then sunk, with the hand flat, into the water; while the swimmer stretches forth the arm with the other hand stretched as wide as possible, he describes a small circle to sustain the body; then brings his hand in a largely described circle rapidly to the hip, lifts the arm out of the water, and thrusts it forward. During the describing of the larger circle, the feet make their movements. To make the thrust beautifully, practice is required. This mode of swimming is useful where rapidity is required.—*Double.* In the performance of this, the arm is thrust forward, backward, and again forward, without dipping into the water; in the mean time the stretched forth arm describes two circles before it begins the larger one.

TREADING WATER. — A perpendicular position of the swimmer, when trying to save a person from drowning. There are two ways: 1st, the hands are compressed against the hips, and the feet describe their usual circle; the 2d mode consists in not contracting both legs at the same



Treading Water.

time, but one after the other, so that while the one remains contracted the other describes a circle. In this mode the legs must not be stretched out, but the thighs are placed in a distended position, and curved as if in a half-sitting posture.

UNDER WATER. — When under water, the swimmer may move in the usual way, or keep his hands stretched before him, to enable him to cut the water and relieve his chest. If he approaches too near the surface of the water, he must press the palms of his hands up. If he wishes to dive to the bottom, he must turn the

palms of his hands up, striking with them rapidly while the feet are reposing; and when he has obtained a perpendicular position, he should then stretch out his hands like feelers, and make the usual movement with his feet, then he will descend with rapidity to the bottom. It is well to accustom the eyes to open while under the water, as it will enable the swimmer to ascertain its depth.

WHEEL BACKWARDS AND FORWARDS.—In the forward wheel the hands are put as far back as possible, and so pressed against the water that the head is impelled under the surface, and the feet, by a pressure of the hands in a contrary direction, are rapidly flung above the head, which in this manner is rapidly brought again to the surface. In the backward wheel the swimmer lies upon his back; he contracts himself; the hands, stretched forward as far as possible, describe small circles; the feet rise, and as the point of equilibrium has been brought as near as possible to the feet, the head sinks, and the feet are thrown over.

WALL FLOWERS.

DANCING.

REMARKS.—In dancing, to relieve the mind and prevent confusion, some person (not one of the dancers) should call out the details of each figure for the direction of the dancers, and the person must have experience in order to fulfill his duties creditably. The caller should ascertain what pitch of voice is most audible with the least noise; every word be clearly enunciated; not a word used beyond what is necessary to make the call plain, which should be so timed that the last word of the command is finished at the moment the corresponding movement is to begin, and not made an instant sooner than necessary. If the command is given in a short and distinct manner, the time occupied by the musical bar preceding the movement is ample. To simplify verbal instruction, there are 5 fixed positions for placing the feet, as follows: *1st Position.* The feet must be placed with both heels touching and toes pointing out, so as to form an angle of 60° or the 6th part of a circle. For precision it is supposed that the learner is standing with his face looking due north, body erect, without stiffness, and this maintained under all circumstances, the movements being made by the feet alone. The 1st position is the same for both feet.—*2d; Right Foot.* The weight of the body is thrown on the left foot, the right foot extended due east, with the toe on the ground and instep well arched, as far as it will reach without causing the body to deviate from its perpendicular position.—*3d; Right Foot.* The right heel is brought down against the middle of the left foot at an angle of 60°.—*4th; Right Foot.* The right foot is extended with the toe touching the ground as far due northeast as it will go without disturbing the equilibrium of the body, now resting on the left foot.—*5th; Right Foot.* The heel of the right foot is brought down touching the toe of the left foot, and forming an angle of 60° with it.—*2d; Left Foot.* The feet are supposed to be in the 1st position. The left foot is extended, with the toe on the ground, due west.—*3d; Left Foot.* The left heel is brought to touch the middle of the right foot at an angle of 60°.—*4th; Left Foot.* The left foot is extended with the toe on the ground, as far due northwest as the perpendicular position of the body will allow.—*5th; Left Foot.* The heel of the left foot is brought touching the right toe at an angle of 60°. In the 2d and 4th positions of the right foot the weight of the body rests perpendicularly on the left foot, and *vice versa.* In the 1st, 3d and 5th positions the weight is on both feet. These positions are indispensable, and should be carefully practiced, so that when referred to they will be comprehended. The 1st position is an absolute necessity, as it gives the key to the direction of the feet under all circumstances. Nothing is more ungainly for a dancer than attempting to execute any step, or even to walk with his toes straight in front of his feet; and there is a constant risk of treading on his partner's toes.

CONTRA DANCES.

REMARKS. — This is a class of dances which derives its name from the manner in which the dancers are arranged. In the quadrille, partners stand side by side, each couple forming the side of a quadrilateral figure or square. In the contra dances the partners of each couple stand opposite to and facing each other, the couples collectively forming two parallel lines.

VIRGINIA REEL.— The couples form in 2 lines down the middle of the room, gentlemen on one side and ladies on the other, partners facing, the gentleman and lady of the head couple standing at the head of their respective lines at the top of the room. The couples may be designated *first, second, third,* etc. (in their order as they stand), to the *last* couple; the top or bottom couple being that which happens during the dance to occupy the position at the top or bottom of the lines. Each couple in turn becomes top couple and bottom couple at least once during the dance. The step used is an easy swing trot, in exact time, commencing with the music. *First gentleman and opposite lady forward and back.* At the commencement the first and last couples are top and bottom. The first gentleman and last lady take 4 steps towards each other and back, without turning; count 8.— *First lady and last gentleman.* The same; count 8.—*First gentleman and last lady swing right hands.* Dance up to meet one another, join right hands, swing

half round and straight back to places; count 8.—*First lady and opposite gentleman.* The same; count 8.—*First gentleman and last lady swing left hands.* Same movement as last reversed; count 8. The other opposites do the same; count 8.—*First gentleman and last lady swing both hands.* Meet in middle as before, and swing half round to left, holding both hands, and back to places; count 8. The other opposites do the same; count 8.—*First gentleman and last lady dos à dos.* Advance to middle, pass each other on right hands, round each other to the right, back to back, without turning, and back, passing to left of each other to places; count 8. The other opposites do the same If the set consists of a large number of couples, and is long, each pair may find difficulty in traversing half way up and back in only 8 counts. If this should be the case, the other pair of opposites must commence to move *on time*, avoiding collision with the dancers who are behind time on their way back to their places.—*First couple turn right hands.* The first gentleman and partner join right hands across the head of lines, turn fully once round, and drop right hands; count 4.—*Separate and turn second couple, left hands.* The gentleman joins left hands with second lady, and swings her half round; at the same time the first lady joins left hands with second gentleman, and swings half round; the first gentleman and his partner meet face to face; count 4. The first couple repeat these 2 movements with each other and each succeeding couple, until they reach the bottom. There the first couple join hands and dance up the middle to their former places at top. The gentlemen march to the left in line; the ladies to the right, and come up the middle again to places. The top couple dance down the middle to bottom, and become the bottom couple, the second couple at top. This left them at the bottom of the lines. Top and bottom couples begin the figure over again, the dance continuing until the first couple have got back to the top.

MARCH OR POLONAISE.

REMARKS. — It is usual to inaugurate the dances of the evening at a ball by a preliminary march. It should be led off by a gentleman and lady who understand the necessary evolutions, assisted, in case of necessity, by one or more of the floor commitee, to preserve uniformity of action through the march. All marching should be done in straight lines, following the direction of the walls of the room, the change of direction being made at each corner. The leader and his partner should lead the march; moving slowly once or twice round the room, to give couples time to fall in and follow. To insure success no gentleman can act as cavalier to two ladies, as the movements require all to march in couples. The leader should regulate his pace to suit circumstances, keeping the line of march unbroken, and the couples at uniform distances. The couples must follow exactly in the track of those before them and the leader, keeping correct time with the music, and conforming in every particular with the leader's movements.

ARBOR MARCH. — All the couples march round the room in order. The first couple join right hands, stop, and raise hands, forming an arch. The second couple pass underneath the arch, the gentleman first, and form another arch; the third couple pass under both, and form an arch; each couple passing through the arches ahead of them in turn, until one continuous arch has been formed. The first couple (now in the rear) passes through and out at the front end of the arbor, followed by each rear couple, until the arches have disappeared. If the number of couples is large, the first couple can follow the last couple at once under the arches, and repeat the arbor as long as desired. The plain march in couples is then resumed, until the line of march is in order again.

MARCH IN COLUMN.—The first couple lead round the room, until the leader reaches the bottom left hand corner. There, instead of turning upwards at right angles up the side of the room, the first couple file to the right and march in a line parallel with the advancing couples, but in an opposite direction across the room; as each couple arrives at the same corner, they file to the right and follow the leader. When the leader has got across the room, the first couple file to the left, and march straight across back again, and so on, forming a serpentine line of march backwards and forwards across the room until the top of the room is reached. To make this effective it requires a number of couples, so that there will be at least four lines, constantly passing each other in opposite directions. When the first couple reach the top of the room, they lead the march round the room, until all the couples are following in regular column.

MARCH IN FILE.—As soon as all are in order the leader heads the line of march up the middle of the room; when he has reached the top, he turns to the left, and his partner to the right; the gentlemen follow in single file, the ladies following the leading lady in the same manner; when the leaders of the 2 lines arrive at the bottom, they pass to the left of each other, the gentlemen marching round the room on the outside, and ladies inside them, and in the opposite direction. When the first gentleman meets his partner at the top of the room, they march together round the room to the right; followed by the other couples in order. The leader should introduce sufficient plain marching between each figure to get all the couples following him in column before commencing a new evolution.

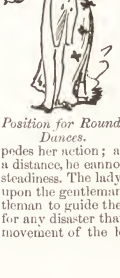
MARCH IN PLATOONS.—The first couple lead the march up the centre of the room. As they reach the top, the first couple passes to the right; the second couple to the left; the remaining odd couples in their order to the right, and the even couples following to the left. All march down their side of the room, until they meet in the middle at the bottom; then turn up the centre again 4 abreast. Arriving at the top, the first 4 wheel around by the right; the second 4 wheel round by the left, and so on alternately, each division marching down its side of the room. When they meet at the bottom, they advance up the centre again, 8 abreast. On reaching

the top of the room the first and the third 8 wheel to right, and the second and fourth wheel to left, each succeeding 8 wheeling right and left alternately down the sides of the room, meeting at bottom, and marching up the centre 16 abreast, thus forming full lines. At the top of the room all halt, the first, third, etc. (odd) lines face all to right; the second, fourth, etc. (even) lines all to left, the gentlemen step up by the side of their lady partners, and the front line marches off in couples to the right, the other lines following in their track, in the same manner as the *March in Column* (which see), and finishing the same.

SERPENTINE MARCH.—The couples march once round the room. The leader steps in front of his lady and leads the way up the centre of the room; as each couple turns to go up the centre, each gentleman steps into single line ahead of his lady, forming the couples into single file. When the first gentleman reaches the top of the room, he leads the way to the right entirely round and round the room, each successive round passing inside the former, describing a spiral track towards the centre of the room. As soon as the inner coil becomes small, the leader turns sharp round to the left and retraces his steps between the coils, until he marches between the coils entirely out of them. He continues his march until all the coils are unwound; then each gentleman retires a step to the left of his lady partner, and the march is continued in column until all the couples have fallen into order. At the conclusion of the march the leader stops, gives a signal for the music to change into a waltz, and leads off with his partner, followed by the other couples until the dancing becomes general.

Round Dances.

REMARKS. — In all couple dances, before commencing, the gentleman places his right hand to the lady's waist, so as to form a perfect support, and the lady then places her right hand in the gentleman's left. Both should turn their heads slightly to the left, the gentleman looking over the lady's right shoulder, and the lady over the gentleman's right shoulder, which position is maintained all through the dance without appearance of constraint. The gentleman should also preserve a proper distance between himself and partner. If he draw the lady too close, he necessarily impedes her action; and if he maintains too great a distance, he cannot support her with sufficient steadiness. The lady should not lean too heavily upon the gentleman. It is the duty of the gentleman to guide the lady, and he is responsible for any disaster that may occur. The slightest movement of the left hand indicates a change of direction. The lady should abandon herself to the guidance of her partner, and obey the slightest motion; for success depends upon the partners moving in concert. With fine dancers this seems like intuition. The gentleman should vary the direction of the dance, going forward and backward, turning to the right and reversing to the left in unceasing succession. The lightness and elasticity of successful waltzers can only be acquired by practice; and by shunning the appearance of laborious effort, the student will rapidly attain proficiency. One of the leading qualifications of a good dancer is not only to execute every step with precision, but adapt his steps and movements to conform with a partner who may not be absolutely correct.



Position for Round Dances.

ESMERALDA.—Music in 2-4 time. The gentleman slides 2 steps forward with left foot; then executes 1 polka step with the left foot (count 2), and continues 2 more polka steps with the right and left (count 2), recommencing the slide with the right foot, changing the feet alternately every time the sliding is commenced. The lady same as the gentleman, except the feet are reversed, she starting with right foot instead of left.

GALOP.—Although the time of this dance is different from the waltz, the portion of it used in turning is the same. In going straight down the room 1 foot is continually in front (left foot, gentleman; right foot, lady). Slide the front foot forward, bring the other foot up quickly behind, and slide the front again. Continue this movement till you wish to turn, then use the waltz step.

POLKA.—In this dance a hopping or jumping movement is ungraceful; so is the habit of kicking out the heels. The feet should scarcely be lifted from the ground, the dancers sliding and

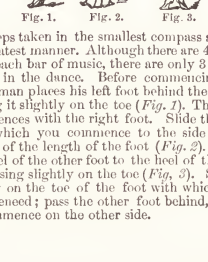


Fig. 1. Fig. 2. Fig. 3.

the steps taken in the smallest compass and in the neatest manner. Although there are 4 quavers in each bar of music, there are only 3 movements in the dance. Before commencing, the gentleman places his left foot behind the other, resting it slightly on the toe (*Fig. 1*). The lady commences with the right foot. Slide the foot with which you commence to the side to the extent of the length of the foot (*Fig. 2*). Bring the heel of the other foot to the heel of the first one, rising slightly on the toe (*Fig. 3*). Spring lightly on the toe of the foot with which you commenced; pass the other foot behind, ready to commence on the other side.

RACQUET.—The lady slides forward 3 steps with right foot; kick with right; count 1; kick with left; count one; kick with right; recommence the 3 slides with left foot, and so on. Do not kick high, but simply slide the foot outward slightly. A pretty way is to draw the foot slightly backward; the same for gentleman, except the feet are reversed.

REDOWA. — The most graceful of all couple dances; to execute it well avoid stiffness in the movements. The music is in $\frac{3}{4}$ time. The position in which the feet should be placed before commencing is the 3d, made by placing the heel of the right foot to the hollow of the left, the feet sufficiently turned so as not to make the dancers uncomfortable.—1. Spring lightly to the side with the right foot, point the toe of left to 2d position.—2. Slide left foot forward, pointing the toe of right foot behind.—3. Bring right foot up behind left to 3d position; then commence the step with left foot. Before attempting the backward step, with which the gentleman always commences, practice the forward step. To make the backward step, spring upon left foot, pass right foot behind, then bring left foot up to 3d position, in front of the right. The dance should be practiced up and down the room before attempting to turn.

SCHOTTISCHE.—Danced in 2-4 time, the first and third beat in each bar slightly marked. The slower the time played, in moderation, the more pleasing the effect. The gentleman starts off with the design of moving in circles; he slides forward the left foot, and as it stops, brings the right up to it smartly; slides the left forward again, and gives a spring on it, while he raises the right foot, and points it ready to start off with that, and repeat these movements. They may be continued without variation, the dancers revolving as in a waltz, if it is agreeable to the lady. When the first step has been performed 8 times, that is, 4 starting with the left foot and 4 with the right, alternately, the second part of the figure commences. This consists of 4 double hops. Take 2 on the left foot, half turning at the same time, then 2 on the right, completing the round. Repeat this; resume the first step for 2 bars; and so on throughout. But the *valse à deux temps* step is now substituted for the hops, and when a Schottische is played, good dancers often use that step throughout.

WALTZ, Boston Dip.—An exaggeration of the *Glide Waltz*, each glide accompanied by a considerable bend of the knee, which causes the body to sink down or dip at constantly recurring intervals. 1st. The gentleman should glide left foot forward; count 1. 2d. Bring up the right foot to 3d position, springing on it, and at the same time raising the left, pointing the toe to the floor; count 2. 3d. Spring again on the right, bring the left back close to and behind the right, heel raised, toe pointing to the floor; count 3. 4th. Glide left foot diagonally forward towards your partner, turning slightly to the right; count 4. 5th. Glide the left again, and bring the right in front of the left foot in the 3d position, and at the same time turn half round; count 5. The gentleman then commences with right foot, continuing with 5 more counts, making another half turn, thus completing the circle or turn. In taking the fourth step with right foot, the dancer (lady or gentleman) steps between his partner's feet, and not forward as directed for the left foot. The lady same as the gentleman, except the feet are reversed, she starting with right, instead of left foot.

WALTZ, Glide.—Music in $\frac{3}{4}$ time. 1st. The gentleman should glide backward with the left foot 1 step, bending both knees; count 1. 2d. Draw right foot back about 6 in. beyond the left, straighten the knees by slightly rising on the toes, and turn nearly half round to right, by throwing right shoulder back; count 2. 3d. Complete the half turn by bringing left heel up to right, settling down on both; count 3. 4th. Glide right foot directly forward, bending both knees; count 4. 5th. Advance left foot directly in front of right (4th position), straighten both knees by slightly rising on the toes, at the same time turn half round; count 5. 6th. Complete the half turn by bringing right heel up to left, and settling down on both. The lady commences at 4th position, right foot forward, continuing thus: 4th, 5th, 6th, 1st, 2d, 3d, and so on through all the waltz. While the gentleman executes 1st, 2d, 3d, the lady executes 4th, 5th, 6th, and while the gentleman executes 4th, 5th, 6th, the lady executes 1st, 2d, 3d. This continues all through the waltz without variation. The reverse is similar to the corresponding movement in the waltz. the change being made by gliding the left foot forward at 4th, instead of the right: 1st. Glide the left foot directly forward; count 1. 2d. Advance the right foot beyond the left, at the same time turning toward the left; count 2. 3d. Complete the half turn by bringing the left heel up to the right in 3d position; count 3. 4th. Glide backward with the right foot, bending the knees; count 4. 5th. Draw the left foot back 6 in. beyond the right, at the same time turning toward the left; count 5. 6th. Complete the half turn by bringing the right heel up to the left in 3d position. The lady executes 4th, 5th, 6th, while the gentleman executes 1st, 2d, 3d, and so on alternately.

WALTZ, Hop.—Music in $\frac{3}{4}$ time. 1st. The gentleman should spring from the right foot upon the ball of left, passing left foot behind right in 4th position; count 1. 2d. Pass right foot 2 or 3 in. behind left heel, turning on the ball of each foot; count 2. 3d. Complete the turn, bringing right foot front in 3d position; count 3. 4th. Spring from left foot upon ball of right foot, advancing right foot directly forward in 4th position; count 4. 5th. Advance left foot in front of right, turning on the ball of each foot; count 5. 6th. Complete the turn, bringing right foot front in 3d position; count 6. The reverse is executed the same as the plain waltz. The lady commences at 4th, continuing 4th, 5th, 6th, 1st, 2d, 3d, without changing.

WALTZ, Modern Plain. — This is the 3 step waltz, and the time is $\frac{3}{4}$. The gentleman takes his partner around the waist, same as for polka and other round dances. Pass left foot backward in direction of left. Pass right foot past left in same direction care being taken to keep right foot in rear of left (third beat), and then bring left up behind right; count 1. 1. Pass right

foot forward toward right. 2. Pass left foot forward still toward right. 3. Bring right foot up to right, turning at same time on both feet, and completing the turn; count 2. Always conclude with right foot in front to be ready to commence with the left. The above description is intended for the gentleman, who invariably commences on left foot; if, for a lady, *right* is substituted for *left*, it will be equally applicable. The usual progression of all waltzes is from the gentleman's left to right; but a good dancer should waltz equally well in the reverse direction.

WALTZ, Two Step.—Music in $\frac{2}{4}$ time, *i. e.*, 3 crochets in a bar. Commence from same position as in *Redowa*. Slide right foot forward (*Fig. 1*). Bring left foot up to 3d position, close behind right (*Fig. 2*). Slide right foot again forward (*Fig. 3*). Having completed the step with right foot, commence with left. In the backward step commence by sliding left foot back (*Fig. 4*). In practicing the step up and down

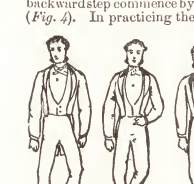

Fig. 1. Fig. 2. Fig. 3. Fig. 4.

the room, the gentleman commences with the left foot, and makes the step backward.

Square Dances.

REMARKS.—Square dances should be danced by four couples, each couple occupying one side of the square. The gentleman stands on the left of his lady partner. In a ball-room the location of the first couple in each quadrille is usually on the side of the square nearest to the head of the room. The second couple stands opposite to and facing the first. The 3d couple is on the right hand of the first, and the fourth couple stands on the left of the first and opposite the third. The first and second are designated *head couples*, and the third and fourth the *sides*. It is not advisable to introduce more than 4 couples in a set, although occasionally done where space is limited, or when there are not couples enough to form 2 sets. A quadrille must consist of 5 parts. As soon as a gentleman has engaged his partner for the quadrille, he should endeavor to procure as his *vis-à-vis* some friend or acquaintance; and should then lead his partner to the top of the quadrille, provided that post of honor be still vacant. The music is divided into 8 bars for each part of the figure; 2 steps should be taken in every bar; every movement consists of 8 or 4 steps. When all the couples and sets are in order, the signal is given for the music to commence; the first 8 bars are preparatory, during which the partners of each couple salute one another; each gentleman bows first to his own partner, then to the lady of the couple on his left; each lady curtsies, first to her partner, and then to the gentleman of the couple on her right. People now generally walk through a quadrille. A perfect knowledge of the figure, a graceful demeanor, and a correct ear for the time of the music are required. The various figures of square dances are made up by combining certain elementary movements, each known by a distinctive name as follows:

TERMS USED IN DANCING.

SWING CORNERS.—Each gentleman takes 4 steps towards lady of right hand couple, who advances to meet him, count 4; he swings her half round, right hands joined, count 4; he then advances 4 steps towards his partner, who comes to meet him, count 4; and swings her with left hands joined to places, count 4.

ALL CHASSEZ ACROSS AND TURN CORNERS.—The gentlemen make 4 steps to right; the ladies 4 to left, and turn corners with right hands once round; count 8; all make 4 steps back to partners and turn them with left hands to places.

ALL FORWARD TO CENTRE.—All the couples join hands, forming a circle; advance 4 steps towards the centre, and retire; count 8.

ALL FORWARD AND TURN PARTNERS.—All, still with hands joined, advance 4 steps, and then turn partners to places; count 8. The entire figure is repeated by head couples, except that the second time, in crossing over, the second couple pass inside in going, and outside in returning. The side couples perform the same figure twice, in the same manner.

ALL POLKA TO THE RIGHT.—Each couple turns with 2 polka steps to right, and they occupy the former positions of their next right hand couples; count 4.

ALL PROMENADE.—The partners of each couple cross hands, right hands uppermost; all promenade to the right around the space of the quadrille, reaching their places at the end of the 8 bars of music; count 16.

BALANCE.—This term, strictly applied, is the movement made by a lady and gentleman as described under the head of *Balance in Place*; but by some old, but generally accepted perversion of terms, the second and fourth movements of the first figure in the plain quadrille are called balance, whereas they are really a promenade movement. In that instance, the term balance means promenade; but, under other contingencies, it is the same as *Balance in Place*.

BALANCE IN PLACE.—Slide right foot to the right, bring left foot in front of the right in 3d position, count 2; slide left foot to the left, bring right foot in front of left in 3d position, count 2; repeat the whole, count 4.

BALANCE TO CORNERS.—Each gentleman turns towards the lady of the couple on his left, makes 3 short steps or glides to the right, and stops; count 4; then 3 to the left, and stops; count 4; turns her with both hands, and returns to places; count 8. Ladies advance 4 steps to the right, 4 steps to the left, counting 8; turn gentleman to the right, and return to places; count 8.

BALANCE TO PARTNERS.—The partners of each couple face each other; each takes 4 steps to the right, and 4 back again to the left; count 8. Turn partners, holding both hands; count 4.

CHASSEZ.—This is properly the name of a step, but from being generally employed to execute certain movements, these movements have been identified with, and known by the same name. The step is very simple, and may be done by either foot. Slide the foot sideways (the right foot to the right, or the left foot to the left), and bring the other foot close up to it, repeating the same successively once to each beat or count of the music, as many times as circumstances may require.

CHASSEZ ACROSS.—This movement is generally executed when all the couples of a quadrille are standing in column, as in the last figure of the *Lancers*. Each lady makes 4 steps to the left, passing across in front of her partner, at the same time each gentleman makes 3 steps to the right; bring left foot up, count 4. All make a short step forward and back in half time, count 4. All make 3 steps sideways, back again to first positions, count 4; and two short steps again to fill up 4 counts.

CHASSEZ ALL.—Ladies chassez 4 steps to the left and back; at the same time the gentlemen chassez 4 steps to right and back, behind their partners; count 8.

Turn partners with both hands to places; count 8.

CHASSEZ TO PARTNERS.—Partners face each other; each takes 3 steps forward, passing one another on right side; count 4; then 3 steps backward again; count 4; turn partner in place with both hands; count 8.

CROSS OVER.—When a couple cross over, each partner proceeds in a straight line across, and faces round, occupying the place opposite that from which he or she started, so that the gentleman who was on the left of his lady when he started, finds himself on her right after they have crossed over.

CROSS RIGHT HANDS.—This requires 4 persons. The 2 opposite join right hands, and the 2 other opposites join right hands at right angles across the hands of the first 2. In this position all make 4 steps to left; stop; drop right hands, turn round and cross left hands; in this position all make 4 steps to right; back again to former positions; count 8.

DOS-A-DOS.—Usually danced by a gentleman and opposite lady. They advance, pass on each other's right side, step across to right, back to back, without turning round, and pass each other's left hands to places; count 8.

FIRST COUPLE SEPARATE, CROSS RIGHT HANDS WITH SIDE COUPLE, AND TURN TO LEFT.—First gentleman goes to left, and crosses right hands with the side couple on his side; the lady goes to right and crosses right hands with the side couple on her side; these 2 triangles turn once round to the left; count 8.

FORWARD AND BACK.—Begin with right foot, take 3 steps forwards, and bring left foot behind right; count 4; commence with left foot, take 3 steps backwards, and bring right foot in front of left; count 4.

FORWARD AND DOS-A-DOS.—Forward again, each gentleman going to left of opposite lady, passing round behind her, back to back, from left to right, and return to place; count 8. Sometimes each gentleman turns opposite lady with both hands, instead of dos-a-dos.

FORWARD FOUR.—Each gentleman of the head couples joins right hands with his partner, advances 4 steps, and retires; count 8. Again advances 4 steps; first gentleman leaves his partner, who joins left hands with opposite gentleman, who retires with both ladies, first gentleman retiring to his place alone; 8 counts.

FORWARD AND LADIES TO THE CENTRE.—Partners join right hands, advance 4 steps; count 4; retire 4 steps to places; count 4; again advance 4 steps towards centre; count 4; each gentleman swings his partner half round, so as to face him; she remains in centre, and he retires to his place; count 4.

FORWARD AND STOP.—Commence with right foot, take 3 steps forwards, and bring left foot up behind right; count 4. Remain so until further orders.

FORWARD THREE.—Second gentleman and 2 ladies advance 4 steps, and retire; he again advances and hands the 2 ladies to first gentleman (who advances to receive them), and retires, the 3 retiring at same time; 8 counts; first gentleman and 2 ladies advance 4 steps and retire; advance again and meet second gentleman, all joining hands in a circle; count 8.

GENTLEMAN TO THE RIGHT.—Each gentleman takes 4 steps to right, in front of his right hand couple; count 4; dances 4 steps in front of the lady on his right; count 4; then turns her once round with both hands, and so on around the set.

HALF PROMENADE.—Head partners join hands and cross over to other side, head couples passing on the right; count 8.

HALF PROMENADE AND TURN PARTNERS.—Partners join hands and promenade to places; count 8; then turn partners in places; count 8.

HALF RIGHT AND LEFT.—Head couples cross over, each lady passing between opposite couple, and touching right hands in passing; partners join left hands and turn half round to places; count 8. The whole figure is repeated by the head couples, and then performed twice by the sides, making 4 times altogether.

HANDS ALL ROUND.—All the couples join hands, forming a ring, and swing entirely round in a circle back to places; or, swing 8 steps to left, stop, and 8 steps to right back again to places; count 16. Either of these 8 steps, alone, constitute *hands all half round.*

HANDS AROUND.—Performed by 3 or more persons joining hands in a ring, and swinging round in a circle one revolution.

HEAD COUPLES CROSS RIGHT HANDS.—Head couples advance and cross right hands, the 2 gentlemen joining right hands above, and the 2 ladies below; all make 8 steps to left, half round; count 8; reverse by crossing left hands, and make 8 steps, returning to places; count 8.

HEAD COUPLES FORWARD.—Advance 4 steps and retire; count 8. Advance again, salute and retire; count 8.

HEAD COUPLES RIGHT AND LEFT.—Cross over, touching right hands in passing, and partners swinging half round with left hands; count 8. Back again in same manner to places; count 8.

LADIES BALANCE TO THE RIGHT.—Each lady advances to the gentleman on her right, taking 4 steps to right and 4 to left; he then turns her round and places her at his right side, in the place his partner has left. In this manner each gentleman gets an exchange of partner.

LADIES CHAIN.—Danced by 2 opposite couples at same time. The opposite ladies cross over, giving each other right hands in passing; count 4; each lady joins left hands with opposite gentleman, and swings half round; count 4. Repeat, swinging partners with left hand to places; count 8. When not repeated, this is called *Half Ladies' Chain*, leaving each lady standing to the right of opposite gentleman.

LADIES FORWARD AND BACK.—The 4 ladies advance to centre 4 steps and retire; count 8

LADIES' GRAND CHAIN.—This movement is similar to the *Ladies' Chain*, but performed by all 4 ladies at the same time. The 4 ladies cross right hands in centre, making a half turn; count 4; drop right hands, and each lady joins left hands with opposite gentleman, swinging him half round in place; count 4. Repeat the movement back to places; count 8.

LADIES TO THE RIGHT.—Each lady takes 4 steps to right, in front of her right hand couple; count 4; she then dances 4 steps in front of the gentleman on her right; count 4; she turns him once round with both hands, and remains standing on his right side, taking the place of his partner; count 8.

PROMENADE.—Each gentleman crosses hands with his partner, right hands uppermost, and crosses over, passing to the right of the opposite advancing couple, to opposite couple's place; count 8. Executed by a simple walking step, or the chassez step. The same repeated, in the same manner, back to places; count 8. When it is not repeated, it is called *Half Promenade*, and leaves the couple in opposite places.

PROMENADE ALL.—Partners cross hands, right hands uppermost, and all the couples glide or chassez 7 steps to right to opposite places, and stop; repeat to places. When this is not repeated, it is called *Half Promenade All.*

RIGHT AND LEFT.—Performed by 2 opposite couples. The 2 couples cross over, each gentleman touching right hands with opposite lady in passing; count 4. As he drops the passing lady's right hand, he joins left hands with his partner, both turning half round into opposite couple's place; count 4. The same is repeated, bringing the couples back to their original positions; count 8. When not repeated it is called *Half Right and Left*, and leaves the couple in the places opposite to those from which they started.

RIGHT AND LEFT ALL ROUND.—The partners of each couple turn facing one another and join right hands; the gentlemen all go round to right, the ladies to left. Each gentleman in starting passes his partner on her right hand, and drops her hand; count 4; joins left hand with next lady (advancing to meet him), and passes her on her left, and drops her hand; count 4; joins right hands with next advancing lady, passes her on her right, and drops her hand; count 4; and so on, alternately, right hand and left hand with each succeeding lady, until he meets his partner just half way round the quadrille; there he salutes her, and joining right hands with her repeats the whole again back to places, filling up 6 bars of music, or 32 counts.

RIGHT AND LEFT HALF ROUND.—The gentlemen each holds his partner's right hand, passing to right; the ladies passing outside to left; the gentlemen giving alternately left and right hands to ladies in passing, until they meet their original partners half way round. They can stop, take their partners by the right hand and swing once round; count 16.

RIGHT HAND ACROSS AND LEFT HAND BACK AGAIN.—Opposite couples cross straight over, ladies inside, each lady touching right hands with opposite gentleman in passing; count 8. All face round and return, each lady joining left hands with opposite gentleman, whose hand she retains; she then crosses her right hand over her left, and joins right hands with her partner; count 8.

TAKE SIDE LADIES AND GO OPPOSITE.—First gentleman holds his partner's right hand with his right; with his left he takes third lady by her right hand, and leads the 2 ladies to second couple's place; the second gentleman does the same in regard to his partner and the fourth lady, and leads them to first couple's place; count 8.

TURN PARTNERS.—The gentleman takes his partner with both hands, and they turn once round to the left. When *Turn Partners* is called, it means that both hands are to be used, unless the right or left hand is specified.

LANCERS.—1ST FIG. Top lady and opposite gentleman advance and retire; then advance and swing round; top lady and gentleman change places with opposite couples, passing in the centre and return to places, passing outside;

set to corners and turn. The other 6 do same. —2D FIG. *Head Couples.* Forward and back, count 4; forward and leave ladies in centre, count 4; chassez to right and left, count 4; turn partners to places, count 4. *Side Couples:* Divide, all forward in 2 lines, count 4; forward again, and turn partners to places, count 4. *Repeat. Side Couples:* Same twice. — 3D. FIG. Top lady advances alone, then the opposite gentleman does same; lady courtseys, gentleman bows, both retire. The 4 ladies give right hands across, and dance round to left; then change hands and dance round to right; gentlemen dance round singly, the reverse way to the ladies, changing as they change. — 4TH FIG. *Head Couples:* To the right, count 4; to the left, count 4; turn partners to places, count 4; right and left, count 8. *Repeat. Side Couples:* Same twice. — 5TH FIG. Grand chain, giving right and left hands all round, till all in places. Top lady and gentleman advance to top, standing with backs to bottom couple; the second lady and gentleman on their right place themselves behind them, the couple on their left behind the second couple; and, finally, the bottom couple place themselves behind the other 3 couples, advance and retire, across and back; the gentlemen turn off to the left and the ladies to the right, gentlemen following first gentleman and ladies following first lady; when all are returned to the former situation they form 2 lines, each gentleman facing his partner, and chassée forward and back; gentleman turns his partner into her own place; the other 6 do the same.

PARISIENNE.—This variety of quadrilles does not confine itself to the waltz alone, but introduces also the polka and redowa, affording a pleasing contrast. The change in the time of the music will prepare for the waltz or polka movement at the proper moment. 1ST FIG. *First Couple:* Advance and salute right side couples, count 2; back to places, count 2; advance and salute left side couple, count 2; back to places, count 2. *Head Couples:* Right and left across and back, count 8. *All:* Waltz, count 16. Danced 4 times, each couple leading off in rotation. —2D FIG. *First Gentleman and Opposite Lady:* Forward, count 2; swing half round with left hands, facing partners, count 2; chassez to right, count 2; half turn with left hands, count 2; the above repeated, count 8. *All:* Polka to right, count 2; polka step to centre and back, count 2; the last 4 bars danced 4 times in all, requiring additional 12 counts. The whole figure is performed 4 times, commenced by each gentleman in succession.—3D FIG. *First Gentleman:* Leads lady on his left to centre, count 2; leads opposite lady to centre, count 2; leads lady on his right to centre, count 2; lastly his own partner to centre, count 2. *Four Ladies:* Join hands around gentleman, swing to left, count 4. *Four Gentlemen:* Turn partners to places, count 4. *Four Couples:* To the centre, count 4. *All:* Waltz to places, count 4. *Four Couples:* To centre, count 4. *All:* Waltz to places, count 4. — 4TH FIG. *First Couple:* To centre and swing half round, count 4; separate, cross right hands with side couples, turn to left, count 4. *First Gentleman:* And lady forward and back, count 4; turn left hands to places, count 4. *Head Couples:* Cross over and turn in opposite places, count 4. *Side Couples:* The same, count 4. *Head Couples:* The same to places, count 4. *Side Couples:* The same, count 4. Performed 4 times, each couple taking the lead successively. — 5TH FIG. *First Gentleman and Opposite Lady:* Forward and back, count 4. *Head Couple:* Salute and separate to sides, count 4. *All:* Forward and back, count 4; forward and form a star, count 2; balance, count 2. *Gentleman:* Forward to next ladies and balance, count 4; forward to next ladies and balance, count 4; repeat twice, count 8. *All:* Waltz round, count 16. Performed 4 times, each gentleman and opposite lady leading off in rotation.

PLAIN QUADRILLE. — 1ST FIG. *Head Couples:* Right and left, count 8; balance, count 8; ladies' chain, count 8; balance, count 8. *Repeat. Side Couples:* Same twice. —2D FIG. *Head Couples:* Forward 2; forward and back, count 4; cross over, ladies inside, count 4; chassez to partners, count 4; cross over to places, ladies inside, count 4; balance, count 8. *Repeat. Side Couples:* Same twice. —3D FIG. *Head Couples:* Right hands across, count 4; left hands back, count 4; balance in centre, count 4; half promenade to opposite places, count 4; 2 ladies forward and back, count 4; 2 gentlemen forward and back, count 4; forward 4 and back, count 4; half right and left. count 4. *Repeat. Side Couples:* Same twice.—4TH FIG. *Head Couples:* Forward 4 and back, count 4; forward 4, first lady cross over, count 4; forward 3 and back, count 4; forward again, ladies cross over, count 4: forward 3, count 4; forward again, count 4; 4 hands half round, count 4; half right and left, count 4. *Repeat. Side Couples:* Same twice. — 5TH FIG. *All:* Promenade, count 8. *Head Couples:* Forward 2, same as in *2d Fig.*, count 16; balance, same as in *2d Fig.*, count 8. *Repeat. Side Couples:* Same twice. *All:* Chassez.

PRINCE IMPERIAL. — As usual in all quadrilles, the first 8 bars of music are employed by the gentlemen saluting first their own partners, then the lady on their left. 1ST FIG. *Head Couples:* To the right and salute, count 4; take side ladies and go opposite, count 4; ladies' grand chain, without gentlemen, count 8. *All:* Chassez to right and left, count 4; turn partners, head couples at opposite places, count 4. *Head Couples:* Repeat as they stand. *Side Couples:* Entire figure once. — 2D FIG. *First Gentleman and Second Lady:* Forward, count 2; turn both hands, and both face first lady, count 2; cross over and turn with left hands, count 4. *Head Couples:* Forward and back, count 4; half ladies' chain, count 4. *All:* Chassez and turn corners, right hands, count 4; turn partners, left hands, to places, count 4. This figure is danced 4 times, each gentleman and opposite lady commencing in turn.—3D FIG. *First Couple:* Forward, count 2; gentleman back to place, leaving lady facing him in centre, count 2. *Second Couple:* Same, count 4. *Third Couple:* Same, count 4. *Fourth Couple:* Same, count 4. *Four Ladies:* Join hands back to back, 1

turn to left, count 4. *Four Gentlemen:* Complete the ring and salute, count 4. *All:* Balance as they are, count 4; turn partners to places, count 4. Perform 4 times, each partner leading off in turn. — 4TH FIG. *Head Couples.* Forward and back, count 4. *First Lady and Second Gentleman:* To sides, count 4; forward 6 and back, twice, count 4; foward 2 and back, count 4; forward 2, salute, and face partners, count 4; 4 hands, half round, with sides, count 4; half right and left to places, count 4. *Head Couples:* Repeat. *Side Couples:* Same twice. —5TH FIG. *Four Ladies:* To the right, 4 times, count 16. *First Gentleman:* And opposite lady. forward and back, count 4; forward and swing to face partners, count 4. *Head Couples:* Chassez to right and left, count 4; turn partners to places, count 4. *Head Couples:* Repeat the whole figure with second gentleman and opposite lady. *Side Couples:* Same twice.

SARATOGA LANCERS.—This set is similar to the regular *Lancers*; the difference lies in the modification of the figures to allow as many as possible to join in the dancing. 1ST FIG. *Head Couples:* Forward and back, count 4; balance and turn opposite partners, count 4. *All:* Allemand, count 4. *Repeat. Side Couples:* Same twice. — 2D FIG. *All:* Forward 4 and back, count 4; forward and ladies to centre, count 4; chassez and turn partners to places, count 4. This figure is performed 4 times.—3D FIG. *All:* Forward and back, count 4; forward and salute, count 4; ladies' grand chain, count 8. The whole figure 4 times. — 4TH FIG. *Head Couples:* To the right, salute, count 4; to the left, salute, count 4; 4 hands round, count 2; to opposite places, count 2; half right and left to places, count 2. *Repeat.* Head couples first to left, then to right. *Side Couples:* Same twice. —5TH FIG. *All:* Right and left half round, count 8; swing partners half round with right hands, and right and left back to places, count 8. *First Couple:* Promenade, count 8. *All:* Fall in and march, count 4. *Gentlemen and Ladies:* In opposite lines forward and back, count 4; forward and turn partners to places, count 4. Performed 4 times, each couple leading off in turn. *All:* Half right and left and back, count 8.

WALTZ LANCERS. — The *Glide* or *Waltz Lancers* consist of the corresponding figures of the original set, curtailed to allow of the introduction, at intervals, of the waltz movement. 1ST FIG. *Head Couples:* Forward and back, count 4; forward and turn opposite partners, count 4; waltz, count 16. *Side Couples:* The same. — 2D FIG. *Head Couples:* Forward and back, count 4; forward, ladies face partners, count 4; chassez and turn partners to places, count 8. *All:* Waltz, count 16. *Repeat. Side Couples:* Same twice. — 3D FIG. *Head Couples:* Forward and back, count 4; forward and salute, count 4; waltz, count 16. *Repeat. Side Couples:* Same twice. — 4TH FIG. *Head Couples:* To the right, salute, count 4; to the left, salute, count 4; waltz, count 16. *Repeat. Side Couples:* Same twice. — 5TH FIG. *All. First Couple:* Waltz, count 8. *All:* Chassez across, count 8. *First Couple:* Promenade, count 8. *All:* Forward and back, count 4; forward again, turn partners to places, count 4. *Repeat. Side Couples:* The same twice, ending with right and left all round. At the close of the waltz movements all form in 2 lines; ladies in one line, gentlemen in the other, as in the *Fig. 5* of the *Lancers.*

THE GERMAN.

REMARKS. — It is of importance to have a leader or conductor who is familiar with and able to impart the details of each figure with precision, and to insure success he must be obeyed promptly. He alone gives the signal to the orchestra, designates what figure must be performed, and when it shall be commenced and ended, and prompts those who are at fault. He is for the time an autocrat; but he should exercise his power with judgment, avoid all appearance of pretension, and should seem to indicate rather than direct. The ladies and gentlemen composing the German should lighten the duties of the leader as much as possible; they should give attention and preserve silence while he explains the figures, and during the performance of a figure, none, except those participating in it, should dance or promenade in any portion of the room. The leader, with his partner, is seated on the right, and the other couples on his left. He, with his partner, is the head. Each gentleman places his partner on his right. To preserve regularity, the same place or seat should be maintained by each throughout. At the beginning of each figure the leading couple make the *Tour de Valse*, and may be followed by as many couples as the leader indicates. He signals for dancing to cease by clapping his hands or sounding a whistle, and the couples stop as soon as they can reach their seats. The leader designates each figure, and it is danced by all the couples successively from right to left. The German may be composed of any number of couples, but in a large party the leader should seat himself in the centre, and select dancers from each end of the circle alternately; this shortens the dance and prevents it becoming tedious. In case the ladies should be in the minority, the gentlemen who have not been fortunate enough to secure a partner, are permitted to engage any of the ladies for a single figure without any formal introduction. Ladies who have no cavaliers are in the special care of the leader, who either dances with them or presents to them some of the gentlemen for casual figures. People invited to assist at a German are such as would form a social party, and ceremonious deportment is unnecessary. In the choice of figures the leader must be governed by the number of couples and their ability. Some of the figures are exceedingly amusing, and if entered into with a proper spirit of co-operation, may be made the means of a great deal of well-bred hilarity. In any of the following figures, the term waltz refers to any of the round dances that may have been selected as appropriate for the figure.

ALTERNATE MOULINET. — The first 4 or 6

couples make the *Tour de Valse*. The gentlemen who retain the left hand of their partners, form a *moulinet* by crossing left hands, and make a complete turn. At a signal (still retaining the left hands of their partners), they make an exchange of places, gentlemen turning behind and placing ladies in front, and the ladies form the moulinet, by crossing their right hands in the centre; in this position they make a complete turn in the opposite direction. At a signal they change, this time turning in front, and again describe a circle in moulinet. The figure terminates in a general waltz.

ARBOR.—4 or more couples perform a *Tour de Valse*, and afterwards form a circle with joined hands, all facing outwards. An equal number of couples join hands in another circle outside the first one and facing inwards. The gentlemen of both circles join hands above, and the ladies join hands below, the gentlemen raising their arms high enough to allow the ladies to pass beneath them. The ladies all pass around hand in hand in the passage way between the two rows of gentlemen. When the signal is given, the gentlemen lower their arms and each dances with the lady he has entrapped.

ARCADES.—All the couples waltz for a short time, then join hands, raising the arms as much as possible, so as to form a sort of arch; the end couple then separate and waltz round the room, stopping when they reach the end of the line, and joining hands to form another arch. This figure is animated and graceful when rapidly executed.

BASKET OF EIGHT. — 4 couples perform an introductory *Tour de Valse*, ending in the centre of the room; the 4 gentlemen join hands back to back, and the 4 ladies join hands in a ring, inclosing the gentlemen and facing them. All dance round, the gentlemen to the right and the ladies to the left; at a signal, the ladies raise their arms, and allow 1 gentleman to pass under each pair of uplifted arms, still retaining hold of hands and forming a basket. In this position they dance in a ring once round; all let go of hands and execute a grand chain once round, closing with a waltz by the couples as they find themselves.

BASKET OF VEGETABLES. — An immense basket, filled with vegetables, cut out of cardboard, and made to represent leeks, carrots, potatoes, etc., is placed in the centre of the room, and similar vegetables are given to the ladies, who pin them as trophies to their bodices. The gentlemen are supplied with card-board forks, covered with silver paper, which they plunge into the basket and hook out some vegetable. Each dancer then seeks the lady who wears the corresponding vegetable, and waltzes with her, holding the fork in his hand.

BASKET, RING AND FLOWER. — The first couple perform the *Tour de Valse*. The gentleman then presents to his partner a basket containing a ring and a flower, and retires to his place The lady gives the ring to one gentleman, the flower to another, and the basket to a third. The gentleman who receives the basket must dance alone, holding it in his hand; the one who has the ring may choose a lady to dance with him, and the one who has the flower is to dance with the lady who presented it to him. When they have danced several times round the room they resume their seats and the next couples continue.

CORNET BOUQUET.—The cornet bouquet is attached to a cornet, and is composed of little bunches of flowers. The leader puts his mouth to the instrument and sings some popular air, and when he has finished singing a gentleman rises and detaches one of the little bouquets, which he gives to a lady; she immediately opens the paper which is wrapped round the stock, and which always contains some comical head-dress, with which she adorns her partner's head, after having fastened the bouquet of flowers to her bodice.

CROZIER.—A gentleman stands in the middle of the room, holding a crozier of silver paper, and to which are attached ribbons of different colors, which are held by six dancers. The leader then takes six ladies, who form a circle round the six cavaliers, who turn very quickly in one direction, while the ladies turn in another. At a signal they stop, and each gentleman dances with the lady opposite to him, still holding the ribbon and waltzing around the crozier. The same figure is repeated, the ladies holding the ribbons.

DOUBLE VIS-A-VIS.—The first 4 couples perform a *Tour de Valse*, afterwards arranging themselves in two lines, facing one another, the first and third couples forming one line, and the second and fourth couples the opposite. Then the first and third couples half right and left with opposite couples, and balance back to places. The couples then quarter face round so that the first and second couples will be opposite the third and fourth. Again half right and left with opposite couples, and balance to places.

FIGURE OF EIGHT.—Two chairs are placed in the centre of the room, 5 ft. apart. The first couple lead off and pass behind a chair, and then repass behind the other chair, so as to describe the figure eight. This is done without retarding the waltz; each couple in turn repeat the same figure.

FLAGS.—The leader provides himself with 10 pairs of flags of different patterns; he hands a set of exact duplicates to his partner, and they make a *Tour de Valse*. He then presents his flags to different ladies, and his lady hands her duplicates to as many gentlemen. Each gentleman seeks for, and makes a *Tour de Valse* with the possessor of the flag similar to the one presented to him. Having waltzed once around the room, each gentleman hands his flag to another lady, and his partner hands her flag to another gentleman, and the search for partners and valse are repeated, until all have danced.

LABYRINTH.—All the couples form a ring, and turn to the left. At a signal the leader quits the hand of the lady to his left, and continuing to turn to the left, enters the circle, forming a *colimacon* (snail), while the lady moves to the right, outside the others. A circular space must be maintained, to waltz within it. In this position the leading couple set out by waltzing, following the windings of the labyrinth formed

by the general chain coiled upon itself, until they arrive at the last couple, and then take a place in the chain. As a new couple arrives, it takes its place next to the last arrival. When all in turn have arrived, finish with a *Tour de Valse*.

LITTLE ROUNDS. — The first 3 or 4 couples lead off with a *Tour de Valse*. Each gentleman selects a gentleman, and each lady a lady. The gentlemen place themselves 2 by 2, one couple behind the other, leaving a space of 4 ft. between the couples. The ladies form in the same manner, but face in the opposite direction, so that the first 2 gentlemen and first 2 ladies of each column face each other. The first 2 gentlemen and first 2 ladies join hands and turn to the left, making a complete circle, and, without stopping, the 2 gentlemen raise their arms so as to permit the 2 ladies to pass under. The 2 first gentlemen are now face to face with the next 2 ladies, and the first 2 ladies with the next 2 gentlemen, and the figure is repeated until the ends of the column are reached. After passing out of the end of the column, the gentlemen form a line at right angles with the column on one side, and the ladies form directly opposite and facing them, thus: When the two lines are completed as above, all forward and back during 8 bars; then forward again, and each gentleman takes the opposite lady and makes a *Tour de Valse*. The remaining couples perform the same figure, 3 or 4 couples at a time.

MAZE.—4 couples perform a *Tour de Valse*, and then form a quadrille. 4 other couples take up positions, so that a new couple stands behind each one of the couples that form the quadrille. The figure commences by the 4 inside ladies crossing right hands; they move entirely round, giving left hands to partners, and swinging round to places. While the inner couples are thus engaged, the 4 outer couples waltz half round, outside the quadrille, to opposite places. Then the inner couples waltz entirely round, resuming their places, but facing outwards. All chassez at places; turn at corners with right hands and turn partners with left hands to places. All the gentlemen then waltz to seats with the ladies standing opposite them.

INVERTED COLUMNS.—3 couples commence by a *Tour de Valse*. At a signal from the leader each gentleman selects another gentleman, and each lady chooses another lady. The first, second and third gentlemen arrange themselves in line, the 3 newly chosen ladies forming in the same line to the right of the gentlemen. The first, second and third ladies form in line opposite to and facing their respective partners, the 3 chosen gentlemen continuing the line to the left of the ladies, and each facing one of the chosen ladies. The figure is commenced by the gentleman next to the third lady in the ladies' line, giving his right hand to the third gentleman, his left hand to the second gentleman, his right hand to the first gentleman, whose place he takes at the head of the gentlemen's line. The third gentleman performs a similar chain with the 2 other chosen gentlemen, taking his position at the bottom of the line. The third lady and the first chosen lady next perform a similar figure, bringing the partners facing each other again; then all forward once and waltz.

MILITARY FLAGS.—10 pairs of flags, say 2 of each nation, are distributed by the leader and his partner. 4 lines of 4 each, alternately gentlemen and ladies, are formed with an officer in front of each. These lines march once round the room in regular file, and then march a second time round, coming last up the centre of the room. As each file reaches the head of the room, the gentlemen march to the left in single file; the ladies in the same manner to the right; halting on opposite sides of the room, and facing half round, gentlemen facing ladies. The corresponding pairs of flags then become partners for a dance.

NINE PINS. — An extra gentleman takes a position inside of the circle, and is known as the "Nine Pin." Opens with hands all around; Nine Pin then turns each lady in succession; ladies and gentlemen circle alternately around Nine Pin; back to places, and grand chain, Nine Pin joining in. At the sound of the cornet or stoppage of music, whoever is unfortunate enough to be without a partner (right hand to ladies in every instance), is considered Nine Pin, and must take his position inside of circle.

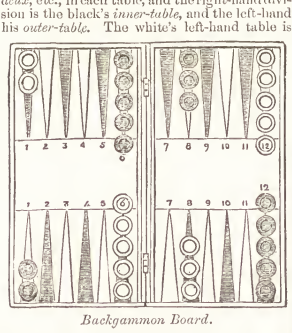
PYRAMID.—The first 3 couples begin with a *Tour de Valse*. The 3 ladies choose 3 other ladies. The 3 gentlemen then select 3 other gentlemen, who join hands in a line, the leader on the right. The line of gentlemen is conducted entirely around the first lady, then round the next 2, and then round the next 3. The movement is then repeated in reverse order until the leader arrives in front of the first lady, with whom he waltzes, and each of the other gentlemen takes the nearest lady.

THE GAME OF ALL GAMES.

GAMES.

SKILLED.

BACKGAMMON.—Played by two persons with dice, upon a board or table divided into 2 parts, upon which there are 12 points of one color and 12 of another; usually blue and red. Each player has 15 men, black and white, placed as in the diagram. The left-hand division is named the inner table, or home, and the right-hand division the outer table. The points are called by their French names, *ace* (one), *deux* (two), *trois* (three), *quatre* (four), *cinque* (five), *six* (six). That division in which are placed 5 white men and 2 black, is called the table of the *white*, and *vice versa*. That division between the boards is called the bar, and the 1st point on the other side of the bar is called the bar point. If the black be placed into the right-hand table, 2 men are placed upon the ace-point in the adversary's table, 5 upon the sixth point in his outer table, 3 upon the fifth point in your outer table, and 5 upon the sixth point in your inner table. The points are named alike, *ace, deux*, etc., in each table, and the right-hand division is the black's *inner-table*, and the left-hand his *outer-table*. The white's left-hand table is



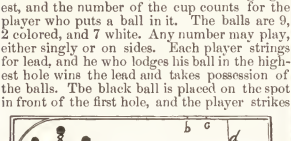
Backgammon Board.

his inner, and the right-hand his outer-table. The object of the game is to bring your men round into your own inner-table; and this is accomplished by throws of the dice. The game is determined by the chances of the dice, 2 of which are thrown by each player alternately. According to the numbers thereon are the points to which the men are moved in "measured motion" always toward the ace corner. Such man or men can only be placed on points not in possession of your adversary; 2 or more men on any point have possession of that particular point. But though you may not place your men on any of these points, you may pass over them. One man left alone on a point is called a blot, and may be taken up by opponent, if the throw of his dice calls for that point. It is placed on the division bar of the table until the owner can enter it again, by throwing a number on the dice which is not covered, or is merely blotted on the enemy's table. As only single men can be captured, 2 or more men being unassailable, the player should endeavor to secure as many points as possible by 2 or more men, thus preventing the adversary from entering any more. No man on the side of the player who has a man to enter can move until it is entered, and even if both parties have men to enter, they must go on throwing the dice until a number is turned up corresponding with a vacant or blotted point, the game remaining in *statu quo* until the men are entered. If 2 numbers are thrown, only one of which enables a man to enter, the other goes for naught, and if there be more than 1 man to enter, and only 1 number giving the privilege of entry appears on the dice, the game remains in *statu quo* till a proper number be thrown. When doublets (2 dice with the same number upwards) are thrown the player has 4 moves instead of 2. The route of each of the player's men is through the adverse inner table over the bar, through the opponent's outer table, round into their own outer table and over the bar home. Having brought the men home, the player for every number thrown removes a man from the corresponding point. Should the adversary be waiting to enter any of his men which have been hit, care should be taken to leave no blots or uncovered points. If a low number is thrown, and the cor-

responding point holds no men, they must be played up from a higher point. If one player has not borne off his first man before the other has borne off his last, he loses a "gammon," which is equivalent to 2 games. If each player has borne off, it is reduced to a hit, or game of 1. If the winner has borne off all his men before the loser has carried his men out of the adversary's table, it is "backgammon," and usually held equivalent to 3 games. A knowledge of the game can be acquired by playing, or studying these instructions, with a board before the learner. The rigbt of first play is determined by each one throwing dice, the highest number leading.

BAGATELLE.—Played on a table smaller than that for billiards, cushioned and semicircular at one end, and with cups instead of pockets, set flush with the table, into which the ivory balls are driven with the cue. These pockets are 9 in number in the small table, which is about 10 ft. long, and are set equidistant from each other, 1 in the centre and the others arranged around it, at the semicircular end of the table. Playing is done from the other end in the larger table, 12 to 14 ft. long; the cups are 15 in number, each numbered, the centre being highest, and the number of the cup counts for the player who puts a ball in it. The balls are 9, 2 colored, and 7 white. Any number may play, either singly or on sides. Each player strings for lead, and he who lodges his ball in the highest hole wins the lead and takes possession of the balls. The black ball is placed on the spot in front of the first hole, and the player strikes

Smaller Bagatelle.



Larger Bagatelle.

from the balk at the black ball, and endeavors to put it, his own, or both balls, into a hole or holes. The black ball counts double. The striker's ball must be placed within the balk line, and is struck with the cue at the black ball. The remainder of the balls are then driven in the same manner, and the sum total of the holes made is the player's score. Any number of rounds may be played previously agreed upon. The side obtaining the highest score wins. Any ball rebounding beyond the balk line, or forced over the board, is not played again during that game.

French Game.—The game is usually 100 up, and may be played by 2 or more players; 2 or 4 usually. The score is taken, as in *La Bagatelle*, from the figures marked within the cups. The red ball is placed on the spot, and he who has the break strikes at it with the other colored ball. If he succeeds in holing a ball he goes on till he fails; his adversary then plays, and so on alternately till the number determined on is obtained. He who first gets that number wins. While either of the colored balls remains out of a hole it must be played at, and he who fails to strike it, forfeits 5 to his adversary. If both reds are holed, the nearest white ball, if any, must be played on. Missing a white ball counts 1 to the adversary. Knocking a ball off the table is a forfeit of 5, though in some rooms no penalty is inforced. If a ball lies over a hole and does not immediately fall into it, the adversary may say; "I challenge that ball;" when, if it drops into the cup (from the vibration of the room or table, etc.), it must be replaced.

Mississippi.—Played by means of a bridge placed across the board, and a couple of cushions against the side. Each player strikes his ball against one of the cushions, to make it rebound on to the bridge, each arch of which bears a number. When the ball passes through the bridge, the player reckons the number of the arch to his score; and he who gains the highest number in 2 or more rounds wins.

Trou Madame.—Played the same as Mississippi, except that the balls are played direct at the bridge from the string, without the small cushions.

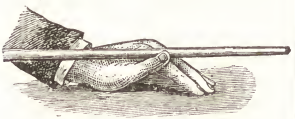
Carom Game. —Consists entirely of caroms, and may be played any number up. It is played with 3 balls. There is not much art in making caroms on a bagatelle board.

Irish Game.—Consists of caroms and winning hazards only. It is played with 3 balls, the carom counting 2, and the hazard as many as is marked on the cup. If the player's own ball falls into a hole, it counts to his adversary.

There are 2 or 3 other games on the bagatelle board, but they are too simple to need explanation.

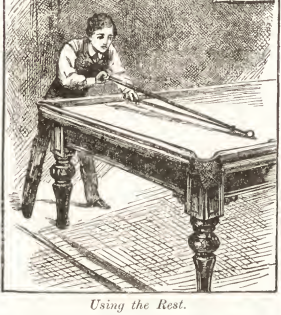
BILLIARDS. — Played upon a rectangular table. The size for match games is 5 ft. in width by 10 long, but smaller sizes are sometimes preferred. The proportion of length to breadth is as 2 to 1. The "pocket" table is seldom used, except in 15-ball pool. The preference in this country is for the carom table. The game is played with ivory or composition balls, propelled by a cue or mace. The standard size of the balls is $2\frac{3}{8}$ in. in diameter. The cue is a tapering maple or ash stick, 4 ft. 6 in. to 5 ft. in length, measuring 1 to $1\frac{1}{2}$ in. at the butt, and $\frac{1}{2}$ to $\frac{5}{8}$ in. at the tip; its weight, 12 to 21 oz. The mace (seldom used) has a boxwood head, flat, and is $1\frac{1}{2}$ in. sq., with smooth under surface, which slides over the cloth in pushing the ball. Inserted in this head is a light rod, 5 ft. in length. In using the cue, the thin end is allowed to rest between the thumb and forefinger of the left hand. The butt-end of the cue is grasped with the right hand 2 in. from the extremity. When the cue-ball is beyond reach, the player may use an instrument called the "bridge" or "rest," a slender ash rod affixed to a cross-head of bridge shape, with notches in its upper side, in which the cue rests for use. The following are the most popular games of billiards in the U. S.:

American 4-ball carom game, French carom or 3-ball game, 15-ball pool, pin pool, and the following 3 variations of the French carom game:



Position of the Hand in Playing.

Cushion caroms, balk-line, champions.' The last 2 are seldom played except by professional players, and for that reason a description is not here given.



Using the Rest.

American Four-Ball Game.—4 balls are used; 1 dark red, 1 light red, 1 white, and 1 white with a black point, from which it is called the spot ball. At the beginning of the game the red balls are placed at the spots marked *A* and *B* in diagram. One player takes the white, the other the spot-ball, and the question of the first play is decided as follows: The players place their

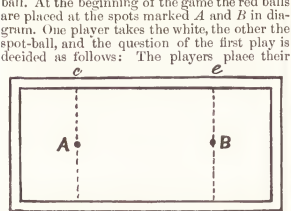


Diagram of Billiard Table.

balls as they choose at the head of the table, both being inside of an imaginary line, *c d*, drawn through the point *A*, called the string; they play against the cushion at the other end; he who succeeds in making his ball on rebounding from it approach the nearer to the head cushion from the vicinity of which he played, leads. The loser in stringing for the lead places his ball near the foot of the table, and inside on an imaginary line *e f*, drawn through the point *B*; and the play begins by the leader's playing from within the string on the ball of his antagonist. After the first shot no regard is paid to the string, to its corresponding limit at the foot of the table, or to the spots, unless one of the balls is accidentally knocked off the table, when, if it be a player's ball, its owner must play next time from within the string, and if it be a red ball, it must be placed on its appropriate spot. A carom, striking in a single play (either directly or by rebounding from the cushions, more than 1 ball) on a red and white ball, counts 2 in the regular rules of the game; the 2 reds counts 3, and on all the balls 6. These methods of counting are frequently varied; it being common to count every carom 3, or, more often, to count each carom 1. The game is won by the player who first makes a certain number of points; 100, 50, 34, 21, or whatever number of points may have been previously agreed upon.

French Game.— Played in all tournaments and public exhibitions, and of late years is the only game recognized by experts. It is played with 3 balls, 2 white and 1 red. The red is placed on the spot assigned to the deep-red in the American 4-ball game. At the commencement 1 of the white balls is placed on the light-red spot, connected with which is a described radius of 6 in. The other white ball, being in hand, may be played from any part of the semicircle, which answers for what in the 4-ball game is known as "the string." And whenever this cue-ball is in hand, the player has the right of playing it. The number of points to constitute a game is left to the option of the players. The game is begun by stringing for the lead, as in the American game. Should the play fail to count, his opponent then makes the next play, aiming at will at either ball on the table. A carom will count 1 for the player. A penalty of 1 is counted against the player for every miss. A ball forced off the table is put back on its proper spot. Should the player's ball jump off the table after counting, the count is good; the ball is spotted, and the player plays from the spot. If, in playing a shot, the cue is not withdrawn from the cue-ball before the cue-ball comes in contact with the object-ball, the shot is foul; the player loses his count, and his hand is out. If balls are disturbed through the medium of any agency other than the player, they must be replaced and the player allowed to proceed. If, in the act of playing, the player disturbs any other ball than his own, he cannot make a counting stroke, but may play for safety. Should he disturb a ball after having played successfully, he loses his count on that shot; his hand is out, and the ball so disturbed is placed back as near as possible in the position which it formerly occupied, the other balls remaining where they stop. Should a player touch his own ball with the cue or otherwise previous to playing, it is foul; the player

loses one, and cannot play for safety. If the player, after having touched his ball, gives a second stroke, then the balls remain where they stop, or are replaced in their former position at the option of his opponent. When the cue-ball is near another, the player shall not play without warning his adversary that they do not touch, and giving him time to satisfy himself. When the cue-ball is in contact with another, the balls are spotted, and the player plays with his ball in hand. Playing with the wrong ball is foul. However, should the player using the wrong ball play more than one shot with it, he shall be entitled to his score just the same as if he had played with his own; as soon as his hand is out, the white balls must change places, and the game proceed. The object-balls shall be considered crotched, whenever the centres of both lie within a 4½ in. square at either corner of the table. When the object-balls are so within said square, the 3 counts are allowed, except one of the object-balls or both be forced out of it. In case of failure by the player, his hand is out, and the next player goes on to play with the balls in position as left by last player.

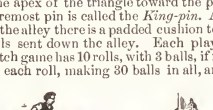
Fifteen-Ball Pool.—Played on a table with 6 pockets, one at each corner, and 1 on each side midway between the head and foot of the table. It is played with balls numbered from 1 to 15, and 1 white ball not numbered; the latter the cue-ball, and the player plays with it from within the string at the head of the table, at the opening of the game, at any of the numbered balls, and afterwards as he finds it on the table, his object being to pocket as many of the numbered balls as he can. Before commencing, the 15 numbered balls are placed in the form of a triangle; the ball numbered 15 is placed at the apex, pointing up to the head of the table, resting as nearly as possible on the spot known as the deep-red spot in the 3 or 4 ball carom games. The other balls are placed in the triangle so that the highest numbers are nearest the apex, the lowest numbers forming the base. The string line occupies the same place on the table as it does in the 4-ball carom game. The numbers on the balls count for the players who pocket them fairly.

Pin Pool (*New York Game*).—Played by 2 or more persons in the following manner: There are 5 small wooden pins set up in the centre of the table, diamond-like; the one at the apex next the head of the table is No. 1, the one to the right No. 2, the one to the left No. 3, the one next the foot No. 4, and the one in the centre No. 5; and they are placed about 2½ in. apart. The usual way of designating them is, by marking the numbers on the cloth next to the spot which each pin occupies, and the rotation of the players is determined by the small numbered balls. After this is determined, each player has another small ball, with a number on it, dealt to him by the game-keeper. The red ball is then placed on its appropriate spot, 5 in. from the lower cushion, midway between the two corner pockets; and he who has ball No. 1 plays from the string; No. 2 then plays from the string with the other white ball; No. 3 succeeds No. 2, and can play with, or at, any ball on the table. The player must first strike a ball with his own ball, before he knocks down the pins, otherwise it is no count. There are 3 balls used, 1 red and 2 white. The object is to knock down as many pins as will count 31, by adding the pins so knocked down, and the number on the private ball together, and he who first makes this 31 wins the pool. For example, if the number on the private ball be 10, it will then be necessary for the player to make the number count 21 by the pins. In many other parts of the United States 4 balls are used, and the game varies in many respects from the New York game. The number on the private ball is kept secret from the other players, although a skillful player may form a pretty correct idea of the number of the player's private ball, by the strokes and angles played by the striker.

Cushion Caroms. — Played with 3 balls (2 white and 1 red). The billiard table has 3 spots in a line, dividing the table lengthwise, running from the centre of the head cushion to the centre of the foot cushion; one of those spots, cutting the line in 2 equal parts, is called the centre spot, and the other 2 are situated half way between the centre spot and the head and foot cushions. The spot at the head is called the white spot, and the one at the foot the red spot. The centre spot is only used when a ball forced off the table finds both white and red occupied. In beginning, the red ball and one white are placed on their respective spots; the other white remains in hand and is placed near the white spot previous to the opening stroke in the game. The player can take any position within a radius of 6 in. of the white spot on or within a line parallel with the head cushion; but he must strike the red ball first before a count can be effected. The game is begun by stringing for the lead as in the *American Game*. If the player fails to count, his opponent then makes the next play, aiming at either ball on the table. Each cushion carom counts 1, and a penalty of 1 is counted against the player for every miss. A ball forced off the table is put back on its proper spot. If the ball jump off the table after counting, the count is good, and the ball is spotted. If the player disturbs any ball but his own, he cannot make a count. If he disturbs a ball after playing successfully, he loses his count, his hand is out, and ball disturbed is placed in its former position. When the cue-ball is in contact with either or both of the object-balls, it is optional with the player to spot the balls and play as at the opening of the game, or to play away from the balls, and count from a cushion. When the player's ball is in contact with a cushion, it may be played to rebound from the cushion, and if it comes in contact with the 2 object-balls, before or after striking another cushion, the stroke is a valid cushion carom; but if the player aim directly at the object-balls when his ball is in contact with a cushion, without making the cue-ball rebound from the cushion or take another cushion before effecting the carom, it is no count. The following are considered foul strokes: 1. Strokes made except with the point of the cue. 2. When the cue is not withdrawn from the cue-ball be-

fore the latter comes in contact with an object-ball. 3. Playing at a ball inside or on the string line, or when in hand playing from any position not within the 6 in. radius. 4. If, in striking, 1 foot does not touch the floor. 5. Striking while a ball is in motion. 6. Touching the cue-ball more than once. 7. Playing directly at any ball in fixed contact. 8. Marking the cloth as a guide to playing. 9. Playing with the wrong ball; but if the player use the wrong ball more than once, he is entitled to his score, but as soon as his hand is out, the white balls must change places, and the game proceed.

BOWLING, or TEN PINS.—Played on smooth platforms, 60 ft. in length and 4 in width, called "alleys," at the end of which the pins, 10 in number, are set up in a triangular arrangement, with the apex of the triangle toward the player. The foremost pin is called the *King-pin*. At the end of the alley there is a padded cushion to stop the balls sent down the alley. Each player in the match game has 10 rolls, with 3 balls, if requisite, to each roll, making 30 balls in all, and the



Bowling Alley.

game is kept on a slate or black-board, with 10 divisions for each player, each division representing the aggregate number of pins knocked down with the balls of that division. If a player knock down all the pins with one ball, it is called a 10-strike, and entitles him to a *double-spare*, or two spare balls, and he may score what he makes with the 2 first balls of the next division, in addition to the 10 already obtained; thus, if he make 9 with the next 2 balls, he scores 19 in his first division, and then counts in the second division what he may make with the 3 balls. If a player knock down the 10 pins with 2 balls, it is called a spare, and he counts, in addition to those 10, the pins knocked down by the first ball of the following division.

CARDS.—The terms made use of in playing cards are as follows; *Shuffling*. Mixing the cards, as is proper before every new deal. Each player has a right to one shuffle; the dealer has the last, and then the player to his right is to cut. He cannot substitute a shuffle for the cut, and require the dealer to deal from the shuffle. —*Cutting*. Lifting from the top of the pack a portion of the cards, which must be more than a trick, generally from $\frac{1}{4}$ to $\frac{3}{4}$ of the pack, and placing that portion under the remainder.—*Cutting for the Deal*. Each person lifts a few cards from the pack, and shows the undermost card of the parcel lifted; and whoever shews the lowest card (which is an ace in this case) is entitled to deal. If 2 have cards equally low they each drop 2 or 3, and the person showing the lowest deals. It is usual in large companies, instead of cutting, to deal 1 card to each, and the person getting the lowest is dealer. The exceptions to the above are in the games of All-Fours and Sixty-Six, in which the highest cut has the deal.—*Dealing*. Distributing the cards, by giving to each player in succession, from the top of the pack, 1, 2, or 3 cards at a time, according to the game played, the dealer beginning with the person on his left hand, and going round.—*Faced Card*. A card lying in the pack face up, so as to be seen in dealing, and in most games renders a fresh deal necessary. — *The hand* of cards is the portion which is given to each player. — *Elder Hand*. The person who *leads* or plays the first card; and the suit to which the card he plays belongs is called the *suit led* in that trick. —*Trick*. The cards played in a round, which consists of as many cards as there are individuals playing. The card which ranks highest of those played takes the trick, provided it be of the suit led; but the cards rank differently in value at different games.—*Trump*. The card turned up after the players have got their portions, and in games where all the cards are dealt out it belongs to the dealer. The cards of the suit to which the trump card belongs are called trumps, and the smallest card of that suit ranks higher in value than the best of any other suit. The *suits* in a pack of cards are 4 in number. Spades and clubs (black), and hearts and diamonds (red), each consisting of 13 cards: Ace, king, queen, knave, ten, nine, and so on, down to two. —*Renouncing*. Playing a card of a different suit from that led. If a trump card is played, it is called *trumping suit*. Severe penalties are annexed to renouncing or trumping suit, if a player holds a card of the suit led, and it is in this case termed *revoking*.

All-Fours, or *Seven-Up*.—Two persons play with a complete pack of cards. 6 cards are dealt out, and the 13th is turned up for the trump. There are 4 chances of scoring points; 1 is scored for each chance. Should the 4 fall into the hands of one player, he has *All-Fours*. He who can score 10 points first wins. The 4 chances are, high, low, jack and game. High signifies the best trump out; low the smallest trump dealt (this is always scored by the person to whom it is dealt); jack is the knave of trumps (when he is turned up as the trump card, the dealer scores). Game is scored by the player who can count the greatest number from the following cards in his tricks: 4 for ace, 3 for king, 2 for queen, 1 for knave, and 10 for ten. It is the object of each player to keep his own court cards and tens, and get those of his opponent. The player who lays down high or low trumps may ask if it be high or low. Also, if a player is not satisfied with his cards, he may say, "I beg," and the dealer is obliged to give him a point, or else deal out 3 more cards to each player, the 7th card being trump. But should this prove to be of the same suit, 3 more must be dealt till the suit is changed. This request can only be made once.

Cassino.—Played by 2, 3 or 4 persons. The dealer and partners are determined by cutting. The dealer gives 4 cards, 1 at a time, to each; either regularly as he deals, or by 1, 2, 3 or 4 at a time; lays 4 more face up on the board, and after the first cards are played, 4 others are dealt to each, until the pack be concluded; but

it is only in the first deal that any cards are to be turned up. The deal is lost, if, in the first round, before any of the cards are turned upon the table, a card is faced by the dealer; but if a card happen to be faced in the pack before any of the said 4 be turned up, then the deal must be begun again. Each plays 1 card at a time, with which he may not only take every card of the same denomination upon the table, but also all that will combine. A 10 takes not only every 10, but also 9 and ace, etc.; and if the player clear the board before the end of the game, he scores a point. Whenever a player cannot pair or combine, he puts down a card. The number of tricks must not be examined or counted before all the cards are played; nor may any trick but the last won be looked at, as every mistake must be challenged immediately. After the pack is dealt out, the player who obtains the last trick sweeps all the cards remaining unmatched on the table. It sometimes happens that the points are not set up, and that neither player gains anything in the deal; but the smaller number is subtracted from the larger, both in cards and points, and if they both prove equal the game is recommenced, the deal being taken in rotation. When 3 play, the 2 lowest add their points together and subtract from the highest; but if their 2 numbers added together amount to or exceed that of the third player, then neither scores. The following terms are used in the game: "Great cassino," the 10 of diamonds (containing 2 points); "little cassino," the 2 of spades (reckoning 1 point); the "cards," when a person has a greater share than his adversary, which counts 3 points; the "spades," when one has a majority of that suit, which counts 1 point; the "aces," each one of which stands for 1 point; and the "lurched," when a player's opponent has won the game before he has gained 6 points.

Cribbage.—There are several varieties of the game, such as "five-card," "six-card," and "eight-card" cribbage, the first and second being more common. Court cards and tens count as 10 each, and all the rest count for the number of spots upon them. The players may be 2, 3, or 4. The board is oblong, but for a 3-hand game is triangular, pierced with rows of holes, in which pegs are inserted to mark the points each player makes. The score is 61. The deal determined, the cards are shuffled by the dealer, who then lays them on the table on his opponent's side of the cribbage-board, which is usually placed on the table between two players. The non-dealer then cuts the pack into 2 parts, and with the undermost half the dealer distributes 5 cards each, beginning with his adversary. The dealer then places the remaining cards on the other heap, and the pack remains undisturbed till the crib cards are discarded. Each player looks at his hand and throws out 2 cards, it being imperative that the non-dealer throws first. The elder hand (the non-dealer) puts the cards on the table by taking up any number, not fewer than 3, without exposing the faces; the dealer lifts the topmost card of the lot left on the table; the non-dealer replaces the cards he cut, and the dealer puts the top card face up on the whole. The discarded and the exposed cut card (the turn-up) form the *crib*. The number scored in the crib belongs to the dealer; the deal being taken alternately. If a knave happens to be the turn up, the dealer takes "two for his heels." The turn-up is reckoned in making up the score of each player's hand, as well as of the crib. When the cards are played out, the non-dealer proceeds to count and take for his hand, reckoning the cards every way they can be varied, and including the turned-up card. For every 15, as queen and 5, 9 and 6, 8, 3 and 4, etc., 2 points; pair, 2 points; pair royal, 6 points; double pair royal, 12 points; sequence, or flush, or both, according to the number; knave of the same suit as the turn-up, 1 point. The dealer proceeds to reckon first his hand, and then his crib in the same way, and each marks the number of points gained. The main difference is to get 31, and then abandon the remaining cards; at the 6 card game the whole are played out. There are more points made in the play, while, at 5 cards, the game is often decided by the loss or gain of 1 point.

Euchre.—Played with 32 cards; all below 7 spot being rejected, except the ace. The cards rank in value as in most other games: Ace, king, queen, jack, ten, etc., excepting that jack of trumps, called the *right bower*, is the highest card of the hand; and the other knave of the same color, called the *left bower*, is the card of second importance. The other 2 jacks are inferior in value to the ace, king and queen. 4 persons constitute the complement, and partners are determined by dealing and turning up 1 card to each; those receiving the 2 lowest, and *vice versa*, being associated. Players usually cut for deal, and he who cuts the lowest card is entitled to the deal. The dealer deals 2 cards to each at the first round, beginning at the left, and then dealing an additional 3 cards in the same order. After 5 cards have been dealt, the dealer turns up the top card on the pack, called the trump. After the first hand, the deal passes to each player in rotation. When the trump is turned, the first person to the left of the dealer looks at his cards. If he thinks he can secure 3 tricks, he will say, "I order it up," and the dealer then takes the card turned up, and discards one from his hand; and the card taken up becomes the trump. If the eldest hand has not enough strength to order it up, he will say, "I pass," and then the partner of the dealer has to determine whether he will "pass" or "assist." If he has enough, with the help of the card his partner has turned, to make 3 tricks, he will say, "I assist," and the card is taken up. If he passes, it goes to the third hand, who proceeds as the eldest hand. Should all the players pass, the dealer announces what he will do, and if he thinks he can take 3 tricks, he says, "I take it up," and immediately discards his weakest card, placing it under the remainder of the pack, and instead of the card thus rejected he takes that turned up, which remains the trump. It is not considered *en regle* for the dealer to remove the trump card until after the first trick has been taken, unless he needs it to play. It is let lay, that every one may see what the trump is. It is always the

dealer's privilege to discard any one card in his hand, and take up the trump card; and this holds good whether he is assisted by his partner, is ordered up by his adversaries, or takes it up himself. This gives the parties having the deal an advantage equal to one trick. Should the dealer not be confident of winning 3 tricks, he says, "I turn it down," and at the same time places the turn-up card face down on the pack. Should all the players decline to play at the suit turned up, and the dealer turn it down, the eldest hand is entitled to make trump what he chooses (excepting the suit turned down.) If the eldest hand is not strong enough in any suit, and does not wish to make the trump, he can pass again, and so it will go in rotation, each having an opportunity to make the trump in his regular turn, to the dealer. If players and dealer should decline making the trump, the deal is then forfeited to the eldest hand. The eldest hand, after the dealer has discarded, opens the game, and leads any card. The person playing the highest card takes the trick, and he in his turn is obliged to lead. In this manner the game proceeds, until the 5 cards in each hand are exhausted. Players are required, under penalty of the loss of 2 points, to follow suit. If they cannot, they may then throw away a small card or trump. The game consists of 5 points, the parties getting that number first being winners, and the points are indicated by the number of tricks taken by the players. If all the tricks are taken by one side, it constitutes what is termed a *march*, and entitles the parties to a count of 2. It is necessary to take 3 tricks to count 1 or make a point. Taking 4 tricks counts no more than 3. If the elder hand order up the trump and fail in securing 3 tricks, it is called being *euchred*, and entitles the opponents to a count of 2; or if he make the trump after the original one has been turned down, and does not secure 3 tricks, he is also euchred, and it counts as before. Any 2 cards are used for counters that will, when combined, make 5 or more, such as the deuce and tray, or 4 and tray.—*With the Joker.* Played exactly as 4 hand euchre, with the addition of the odd card contained in every euchre pack, called the *joker* or *white face*, and which takes rank above right bower. If this happens to be turned for trump, the dealer turns the next card for trump. — *Set Back Euchre.* Differs from the regular game in the manner of counting. The players start at 5 points, and count only the score lost as a point, each winning point reducing the score, and the one first reaching zero being accounted winner. Other games can be played in the same way, taking as the starting point the number of points considered game in each.

Poker.—Draw poker is played with 52 cards and by any number of persons from 2 to 6. Before the dealer deals, the player next to his left, called the *ante-man* or *age*, must deposit in the pool an *ante* not exceeding ¼ the limit agreed upon, called a *blind.* The deal is performed by giving 5 cards to each, 1 at a time, beginning with the player to the left. After the cards have been dealt, the players look at their hands, and each in rotation, beginning with the player to the left of the age, determines whether he will go in or not. Any player who decides to play for the pool, must put into the pool double the amount of the ante, except the player holding the age, who contributes the same amount as his original ante. This makes the blind good, and all interested in that hand will have contributed alike. Those who decline to play throw their cards face down in front of the next dealer. Any player, when his turn, and after making the ante good, may increase the ante any amount within the limit of the game; the next player, after making good the ante and raise, may then raise it any amount within the limit, and so on. Each player as he makes good and equals the other players who are in before him, may increase the ante, if he chooses, compelling the others to equal that increase, or abandon their share of the pool. Each player who raises the ante, must do so in rotation, going round to the left, and any player who remains in to play, must put in the pool as much as will make his stake equal to such increase, or abandon all he contributed. Another feature introduced when betting upon the original hand, is the *straddle.* The straddle is nothing more than a double blind. For example: A, B, C, D and E play, A deals. B, the player holding the age, antes 1 chip. C can straddle B's ante by putting in the pool 2 chips, provided he does so before the cards are cut for the deal. D may double the straddle, that is to say, straddle C, and so on up to the age, provided the bets do not exceed the limit. In the above instance, supposing C only to straddle, it would cost D, E and A each 4 chips to go in, and B 3 and C 2 chips. Each straddle costs double that of the preceding one. The straddle does not give the player the age, it only gives him first opportunity to be last in before the draw; that is, the player to the left of the last straddler, after looking at his hand, and before the draw, must be the first to declare whether he will make good the straddle, and so on, in rotation, up to the player who made the last straddle. After the draw, the player to the left of the age must make the first bet, provided he remains in. A good player rarely straddles. When all are in who intend to play, each player has the right to draw any number of cards, from 1 to 5, or he can retain his cards as dealt to him. If a player draws cards, he must discard a like number from his hand previous to drawing, and the rejected cards must be placed face down near the next dealer. The dealer asks each in rotation, beginning with the holder of the age, how many cards he wants, and when the player has discarded, he gives the number requested from the top of the pack. When the other hands have been helped, the dealer, if he has gone in and wants cards, helps himself. When all hands are filled, the player to the left of the age has first say, and he must either bet or retire from the game, forfeiting what he has already staked. The same with the other players, in rotation, up to the age. When a player makes a bet, the next player must *see him, i. e.,* put in the pool an equal amount, or *go better, i. e.,* make the previous bet good, and raise it any amount not exceeding the limit, or he must pass out. This

continues until some one player drives the others out of the game, and takes the pool without showing his hand, or until the other players who remain in see the last raise (no one going better), and *call* the player who made the last raise. When a *call* is made, the players remaining in show hands, and the strongest hand takes the pool. The following is an example illustrating the mode of betting before and after the draw: The limit is 30 chips, and A, B, C, D and E are the players. A deals. B, holding the age, antes 1 chip; C goes in and puts up 2 chips; D makes good and raises 10 chips, putting in 12 chips; E passes out of the game: A makes good, and sees D's raise, putting in 12 chips; B makes good, sees D's raise, and goes 5 chips better; this costs him 16 chips; C passes out and abandons the 2 chips already put in; D sees B's raise, and bets the limit better, contributing 35 chips; A sees D, and deposits 35 chips; B also sees D, and puts 30 chips in the pool. A, B and D now each have 47 chips in the pool, which, together with the 2 abandoned by C, make a total of 143 chips. After the hands are filled, B holding the age, and C having passed out, it becomes D's say, *i.e.*, D's turn to declare what he will do. D determines to stake 5 chips; A sees D's bet and goes 30 chips better, and puts up 35 chips; B sees A, and deposits 35 chips; D makes good, putting up 30 chips, and calls A. Each of the players now have 82 chips in the pool, which, including the 2 chips which C forfeited, make a total of 248 chips. They show hands, and A having the best hand, captures the pool. If all the players pass up to the age, the latter takes the pool, and the deal ends. The value of the hands is as follows, commencing with lowest: *One Pair.* (Accompanied by 3 cards of different denominations.) If two players each hold a pair, the highest pair wins; if the two are similar, the highest remaining card wins. *Two Pair.* (Accompanied by a card of another denomination.) If two each hold 2 pairs, the highest pair wins; if the 2 pairs are similar, the player whose remaining card is the highest wins. *Triplets* (three cards of the same denomination, not accompanied by a pair.) The highest triplets win. Triplets beat two pair. *A Straight* (a sequence of five cards not all of the same suit.) An ace may either begin or end a straight. For example: Ace (highest), king, queen, knave, ten, is a straight, and the highest straight. Five, four, three, two, ace (lowest), is a straight, and the lowest straight. An ace cannot occupy an intermediate position, thus: King, queen, ace, two, three, is not a straight. If more than one player holds a straight, the straight headed by the highest card wins. A straight will beat triplets. Straights are not always played; it should be determined whether they are to be admitted at the commencement. If agreed that straights are to be counted, a straight flush outranks 4 cards of the same denomination, 4 aces for instance. *A Flush* (5 cards of the same suit not in sequence). If more than 1 player holds a flush, the flush containing the highest card wins; if the highest cards tie, the next highest in these two hands wins, and so on. A flush will beat a straight and triplets. *A Full* (3 cards of the same denomination and a pair). If more than one player holds a full, the highest triplet wins. A full will beat a flush. *Fours* (4 cards of the same denomination accompanied by any other card). If more than one player holds fours, the highest fours win. When straights are not played, fours beat a straight flush. *A Straight Flush* (a sequence of 5 cards all of the same suit). If more than one player holds a straight flush, the winning hand is determined in the same manner as the straight. When straights are not played, the straight flush does not rank higher than a common flush; but when straights are played, it is the highest hand that can be held, and beats 4 of a kind. When none of the foregoing hands are shown, the highest card wins; if these tie, the next highest in these two hands, and so on. If, upon a call for a show of hands, two or more parties interested in the call hold hands identical in value, and those hands are the best out, the parties thus tied must divide the pool, share and share alike. — *Old-Fashioned Game.* The foregoing is a description of modern draw poker, now almost universally played in this country; but some players, who object to a compulsory blind, which the ante of the player holding the age really is, prefer the old game of draw poker, which differs from the modern game in the following particulars: The dealer opens the hand by putting up a fixed ante before dealing, which is not, in strict sense, a bet or a blind. The age alone has the privilege of going a blind, provided he does so before the cards are cut for the deal, but this is optional. Previous to the draw any player may pass and come in again, provided no bet or blind has been made before he passes. If, previous to the draw, the players, including dealer, pass without making a bet, the hand is ended, and the eldest hand puts up an ante and deals. This contingency is not likely to occur often.

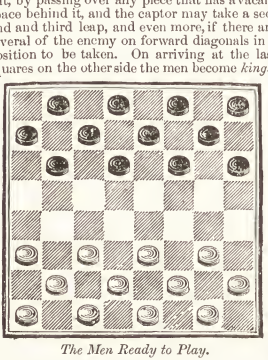
Sixty-Six.—Played with 24 cards: Ace, ten, king, queen, knave, and 9 of each suit, the cards ranking in value in order named above, trumps being the superior suit. When played by two, commence by cutting for deal, which belongs to the player who cuts the highest card, valued in accordance with their rank in the game, ace being highest and the ten next. The cards are cut by the eldest hand, after having been shuffled by the dealer, who then gives each 6 cards, 3 at a time, commencing with the eldest hand, turning up the next or 13th card for trump, which is laid on the table. A misdeal must be dealt over by the same dealer. The player having 9 of trumps may exchange it for the trump card turned up at any time after he has won a trick; this is called discarding. The eldest hand leads first, after which the lead belongs to the winner of the previous trick. After each trick each player draws a card from the top of the talon (cards remaining in the pack); the winner of the previous trick first, and the loser next; continuing this until the talon is exhausted or one of the players closes. The game consists of 7 points, and the player who first scores that number wins. The points are made in the following manner: The player who counts 66 first scores 1 point towards game; if he makes 66

before his opponent counts 33, he scores 2 points; or before his opponent wins a trick, 3 points. The cards count as follows to the winner of the trick containing them: Ace counts 11, ten 10, king 4, queen 3, knave 2, nine has no value. When a player has in his hand a king and queen of the same suit, he may, when it is his turn to lead, play the one, and, showing the other, announce 20 points, which are good, although he may lose the trick. He may not count these 20 points unless he has taken, or until he takes, a trick. The king and queen of trumps count 40. In the 3 handed game the deal passes in rotation to the left, the dealer giving the other two players their 6 cards, commencing with the eldest hand, but none to himself; and, when the round is finished, counts to his score the same number of points made by the winner of that round; but he cannot count his seventh point with the hand he dealt.—*Four-Handed Sixty-Six.* A modification of Sixty-Six for 4 players, and is the most popular 4 handed game played by the Germans, who call it *Kreutz Mariage.* The seven and eight of each suit are added to the 24 cards used in Sixty-Six, making 32 in all. The game is commenced by any one of the 4 persons proposing to play, dealing the cards round, face up, until an ace falls to one of them; the dealing is then continued to the 3 others, until another ace falls; the holders of the 2 aces are to be partners in the game, and play against the other two. The player to whom the first ace falls becomes dealer for the first round, the deal afterwards passing in rotation to the left. The deal is conducted as in whist; the last card turned up for trump, which is the property of the dealer, who takes it up in his hand after the first trick. The play follows in the same manner as at whist, except that a player, unable to follow suit, must trump if he can. The last trick counts 10 points to the winners of it. There is no announcing or discarding as in Sixty-Six. The score of the game is 7 points, as follows, the value of the cards counting the same to the winners of the tricks containing them as in Sixty-Six. If, at the end of the round, the winning partners count 66 or more, but not over 100, they score 1 point towards game; if over 100, but less than 130, 2; if they take every trick, 3. Whichever party captures the ten of trumps, scores a point and wins the game, if they have already scored 6 points. If, at the end of a round, both parties count 65, neither score, but the winners of the next round add 1 point to whatever they then make. When trumps are led, a player must play to take the trick, if he can.

Whist.—The players are 4, 2 of whom are partners against the other 2, the choice being decided by cutting the cards; the 2 who cut the highest are partners, and the 2 who cut the lowest are partners. The latter may choose their seats, and the lowest has the deal. Partners sit opposite each other. In cutting, the ace is lowest. Each player has a right to shuffle once before each deal, the dealer having the final shuffle; but it is not necessary for more than one partner on each side to shuffle. The pack is cut by the person on the right hand of the dealer, who puts the pack together again, and deals the cards round one at a time, beginning with his left-hand opponent. The last card is turned up and called a trump. The players then sort their hands, and the first card played is by the person at the dealer's left, called an elder or leader, and the others proceed and follow suit if they can. This completes the first trick, and the cards are taken by the side that wins and placed face down. A player who cannot follow suit may play any card. The player of the highest trump card wins the trick when he cannot follow suit. The winner of a trick is the leader for the next, and so on till the 13 tricks are played. The cards rank in value as follows: Ace, king, queen, knave, ten, and so on, down to two, the lowest in each suit; but any card of the trump suit is better than any card of another suit, and takes the trick in which it has been played. No intimations of any kind between partners during the playing of the cards are admitted, except in the case of a revoke, the partner is allowed to ask him whether he is sure he has none of that suit in his hand. Every trick above 6 which each party takes in the course of playing reckons one point towards game. The ace, king, queen, and knave of trumps are called honors, and each reckon on 1 point towards the game of the party to whom they are dealt. But one party having 3 of them counts only 2, and the other party none. If each party has 2, the honors are divided, and neither party reckons any. 10 is game; and if one party has made 9 points towards game they are not allowed to count honors, though they hold all the 4. If they have 8 points, and one of the partners holds 2 honors, he may ask his partner, at any time before he plays in the first round, but not afterwards, "Can you one?" meaning, have you an honor? If he has, he says, "Yes," or "I can;" and on both showing that they have 3 honors between them, the game is terminated in their favor without playing that hand. The points are marked or scored at the end of each hand, either by the holes in a cribbage-board, or with 4 counters. When one party is out, or has 10, before the other has made 5 points, it is called a double game; if before they can reckon 1, it is called a triple game; and the losing party is said, in either of these cases, to be *lurched. A Rubber* is the best of 3, or 2 out of 3 games; and the points of the rubber are, a single game, 1 point; a double game, 2 points, and the rub 2 points; so that 6 points may be gained in one rubber, namely, 2 doubles and the rub. When triple games are admitted, they reckon for 3 points each, thus allowing the possibility of 8 points being gained in one rubber.

CHECKERS, or DRAUGHTS.—Played by two persons. The pieces, or men, are 24 in number, 12 of each color. The board is placed between the players, each having an upper white corner on his right hand. On beginning, the men are placed in 3 rows on the white squares at the opposite ends of the board. The men can only be moved forward one square at a time, and from one white square to another. They must move diagonally, and never cross a black square. The aim of each is to reach the farthest squares

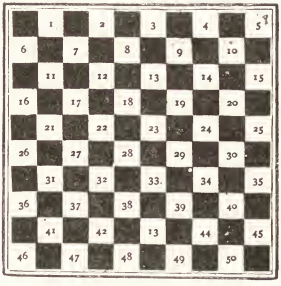
on the opposite side, and to take as many of the antagonist's pieces as possible. The men take in the direction in which they move, right or left, by passing over any piece that has a vacant space behind it, and the captor may take a second and third leap, and even more, if there are several of the enemy on forward diagonals in a position to be taken. On arriving at the last squares on the other side the men become *kings*,



The Men Ready to Play.

and can then move backwards or forwards. To get a man crowned is of the first importance, as the more pieces a player has thus invested with the privilege of forward and backward movement, the greater are his chances of winning.

Polish Game.— Played upon a board of 100 squares, with 40 men, 20 black and 20 white. When played upon the ordinary board, 24 men are used, 12 white and 12 black. As in the common game the men move forward one square at a time, except in taking a piece, when they move forwards and backwards. The kings (sometimes called queens) may move several squares at a time, and, if the passage be free, the whole length of the board. The men are generally placed on the white squares, though it is immaterial whether they are placed on black or white. The board should so stand that each player has a double corner on the right hand: The black squares, 41 and 46, and the white, 45 and 50. In this way the board is divided into 2 parts, the black men occupying 20 squares from No. 1 to 20, and the white men an equal number, from 31 to 50, leaving between the men of the two players two rows of vacant squares on which the front men are played. As a rule, between players of equal strength, the game is drawn when one of the players is reduced to a king and the other to 3 common men, as there is no stroke by which the latter can win. When one at the end of a game has a king and a man against 3 kings, the best way is to sacrifice the man as soon as possible, because the game is more easily defended with the king. If the game is embarrassed, open it by giving man for man or 2 for 2; if a dangerous stroke is in preparation, avoid it by exchanging man for man; if it is requisite to strengthen the weak side of your game, it may be managed by exchanging; if you wish to acquire an advantageous position, a well managed exchange will produce it; it is by exchanges that one man keeps many confined,

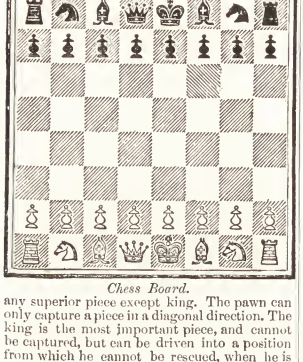


Polish Draughts.

and that the game is won. When 2 men of a color are so placed that there is an empty square behind each, and a vacant square between them where his adversary can place himself, it is called a *lunette*, and is much more likely to occur in the Polish than in the common game. In this position one of the men must be taken, because they cannot both be played nor escape at the same time. The lunette frequently offers several men to be taken on both sides, as it is most frequently a snare laid by a skillful player; for it is not to be supposed that the adversary, if a practiced player, would expose himself to lose. Before entering the lunette, look at your adversary's position, and calculate what you would do in a similar game.

CHESS.—The board resembles an ordinary draught board, so placed that each player has a white square at his right hand. Each has 16 pieces, arranged as in the illustration. The rooks occupy the corner squares; next to them, on each side, is placed a knight; then a bishop. The king and queen occupy the two centre squares of the first row; and the 8 pawns are placed in front on the second row. The queen stands always on a square of her own color. The rook moves in straight lines, backwards or forwards, right or left. The rook, bishop and queen may move one or more squares in their proper direction. The bishop moves diagonally to right or left, backwards or forwards, but cannot move to another color from that on which it was first placed. The queen moves in any direction, and may move more than one square. The knight is required to move two squares (one backwards, forwards or sideways, the other diagonally), but may pass over and past friend or foe to gain his position. The pawn can only move one square straight forward, except the first move, which may embrace two squares. When a pawn attempts to make this move of two squares, if it passes over a square commanded diagonally by an opposing pawn,

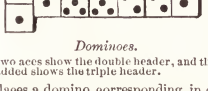
this opposing pawn may take it *en passant*, and move to the commanded square. When a pawn reaches the 8th square he may be exchanged for



Chess Board.

any superior piece except king. The pawn can only capture a piece in a diagonal direction. The king is the most important piece, and cannot be captured, but can be driven into a position from which he cannot be rescued, when he is said to be *checkmated*, which is the object of the game. He can move only one square at a time, but in any direction, and the player who succeeds in bringing him within the line of the movement of, or upon a square commanded by, any one of his pieces, puts the king in check, from which he can only free himself by moving out of the range of the adversary, or by interposing one of his pieces, or by capturing the piece giving check. Castling the king is a combined movement of king and rook, and can be made only when neither of these pieces has been moved and no piece intervenes between their positions; provided also that the king be not in check at the time of castling; and that no square over which the king may have to pass, be commanded by an adverse piece or pawn. The king may then castle in the manner following: On castling with king's rook, move king to knight's square and rook to king's bishop's square. To castle with queen's rook, move king to queen's bishop's square, and rook to queen's square; that is to say, in each case you move king two squares towards the rook with which you propose to castle, and place rook on that square over which the king may pass. In this game the captured piece is removed, and the opponent's piece substituted instead of jumping over. When a king, though not in check, is required to move, and cannot move without being placed in check, he is said to be stale-mated, and the game is considered drawn.

DOMINOES.—The dominoes are placed on the table, face down, and each player takes up one at hazard, to settle which is to have the *pose* or right of playing first; the highest number of points decides this; they are then put back among the rest, and are well shuffled. The two players choose 7 dominoes each, ranging them upright in a line on the table, with faces toward them, so that each may see his own. Thus the players will have taken up 14 out of 28 dominoes. The other 14 remain on the table, face down, to form a reserve. The winner of the pose puts down on the table, face up, the domino that suits him best. The adversary places a domino corresponding in one of its numbers with that placed by his adversary; the single numbers being placed lengthways, the doubles transversely; and so the game proceeds, till the player who won the pose has expended all his dominoes, his adversary having one left, say six-three. In this case the first player will count 9 toward the game, that being the number of points in his adversary's hand. The game is won by the player who first scores 100. The dominoes are shuffled again, the second player has the pose, and the game continues with a fresh deal. After two or three dominoes have been placed by the two players, one of them is unable to match any of those in his hand with the numbers at each end of the row on the table. In that case he passes, and his adversary plays instead of him, and continues to do so until the first player can again make use of one of his dominoes. If both players are compelled to pass, neither of them having a domino that will suit, they turn their hands face up, and the one who has the smallest number of points counts all his adversary's points toward his own game. This is called the block game. The rule for the player who has the pose is to play out the number which occurs most frequently in your game. For instance, if the number 4 occurs four times in your hand, the chances are that your adversary will have only one, or, perhaps, none at all of the same number, and he will thus be compelled to pass, and you will gain a turn. It is good to get rid of the higher numbers as soon as possible, for in case of a block, he who has the lowest number of points wins. Get rid of the doubles, also, for they are the hardest to place. The game of dominoes is one of mingled skill and chance. Nothing can avail against a lucky hand; but the combinations of the game give scope for a good deal of ingenuity. Sometimes, with two players, "drawing" is resorted to; that is to say, when one of the players cannot follow suit, he takes a domino at hazard, from the reserve; and if this will not do, a second, and so on, till his purpose is answered; this is called the draw game. Generally the game is confined to two; but four, five, or even six may join it, each playing on his own account, or divided into sides. In the latter case, the partners sit opposite to each other, the players having first drawn for partners, in the same way that they would for the pose, and the two high-



Dominoes.

The two aces show the double header, and the double ace added shows the triple header.

est playing against the two lowest. The play is from left to right, and the side of the first player who is out wins, counting to its score the number of points still held by the opposite party. In this game there may be drawing or not, according to agreement. If the players don't draw, and, on a block occurring, and the dominoes being turned up, both sides are found to have the same number, the deal counts for nothing.

Bergen. — Each player draws 6 pieces from the pool. The lowest double leads at the beginning, and is called a double-header. After that the parties lead alternately right to left. If no one has a double when his turn comes to lead, he plays his lowest piece. When a player sets down a piece, which makes the extremities of the line the same, it is called a double-header. If one of the extremities be a double, and the next player can lay a piece that will make the other extremity of the same value, or if a double can be added to one end of a double-header, it makes a triple-header. If a player is not able to match, he draws one piece from the pool and plays. If he is still not able to play, the next plays or draws, and so on, alternately. If domino is made, the one who makes it wins the hand. If it be blocked, they count, and the lowest wins; but if the lowest holds a double and his opponent none, the opponent wins. Or, if there be 2 with doubles, and 1 with none, the last wins. If there be a double in each hand, the lowest double wins. If there be more than one double in any one's hand, and all have doubles, the one with the least number of doubles wins, without reference to the size of the doubles he holds. Thus, if a player holds 2 doubles, though they be the double-blank and double-ace, and his adversary hold but one double, though it be the double-six, the latter wins. The game is 10 when 3 or 4 play, and 15 when 2. A hand won by either domino or counting, scores 1. A double-header led or made, counts 2; a triple header, 3. When either party is within 2 of being out, a double-header or a triple-header will count him but 1; and if he be within 3 of being out, a triple header will count 2. A prudent player will retain the doubles as long as possible to make triple-headers.

Bingo. — Played similarly to the card game of Sixty-Six. The rank of the pieces is the same as in other domino games, except that blanks count as 7 spots. The double blank, called *Bingo*, counts for 14 spots, is highest, and will take the double of trumps. The game is played by 2, and is commenced by drawing for the lead, and he who draws the lowest has the lead. Each player draws 7 pieces, after which the eldest hand turns up another piece, the highest spot on which is trumps. The eldest hand leads, and the play is conducted as Sixty-Six at cards. The game consists of 7 points, made in the following manner: The player who first counts 70 scores 1 point towards game; if he makes 70 before his opponent has counted 30, he scores 2 points; if before his adversary has won a trick, 3 points. If bingo capture the double of trumps, it adds 1 point to the winner of the trick. The pieces count as follows to the winner of the trick containing them: Double trumps, 28; the other doubles, and all the other trumps according to their spots; the six-four and three-blank are good for 10 each, whether trumps or not; the other pieces have no value. If a player have 2 doubles in his hand, he can, when it is his turn to lead, play 1, show the other, and announce 20 points, which are added to his count as soon as he has won a trick. If he hold 3 doubles, he counts 40; for 4 doubles, 50; for 5 doubles, 60; for 6 doubles, 70. If bingo be among the doubles held, it adds 10 more to the count.

Euchre.—Usually played by 4. The pieces rank as follows: The double of the trump-suit is the right bower, and the next lower double is the left bower. There is an exception to this rule, for when blank is the trump, it being impossible to have a lower double than the double-blank, the double-six is adopted, and becomes left bower. In this instance the lowest double is right bower, and the highest double is left bower. After the right and left bower, the value of the dominoes is governed by the number of spots following the trump. For instance, if six is trump, the double-six is right bower, and the double-five is left bower, followed by six-five, six-four, six-tray, and so on down to six-blank. If ace be the trump, the double-ace is right bower, and the double-blank is left bower; the ace-six is next in value, the ace-five is next, and so on down to the ace-blank. When the blank is trump, the double-blank is right bower, and the double-six left bower; the next trump in importance being blank-six, the next blank-five, and so on down to blank-ace, the lowest trump. When a suit is not trump, the value of the pieces take rank from the double of the suit in regular order, downward. At the beginning of the game the players draw to decide who shall turn up trumps; he who draws lowest is termed dealer. When the dominoes have again been shuffled, each player draws five pieces, beginning with the eldest hand; the dealer then turns up one of the remaining pieces for trump. That portion of the domino which has the highest number of spots determines the suit of trump. If six-ace be turned, six is trump suit. After the first hand the privilege of turning trump passes to each in succession. The eldest hand does not have the lead unless he exercises the privilege of ordering up, or making the trump. Only the player who takes the responsibility of the trump, that is, he who takes up, orders up, assists, or makes the trump, has the right to lead; with this exception, domino euchre is like the card game.

Matador.—Differs from all other games. Each player, instead of matching the pieces, must make up the complement of 7. For instance, a five requires a two to be played to it, because 2 added to 5 make 7. On a six, an ace must be played; on a four, a three-spot, and *vice versa*. There is no piece capable of making a seven of a blank; to obviate this there are 4 matadors, the double-blank, and the 3 natural seven-spots, namely, six-ace, five-two, and four-three. These 4 matadors can be played anywhere, at any time, and are the only ones which can be played on a

blank. Each player, at the commencement, draws 3 pieces; the one who has the highest doublet commences; or, if neither have a doublet, then the highest piece. If double-four lead, the player, whose turn it is next, must play a three to it; or, failing to have a three in his hand, must draw till he gets one. Supposing it to be a three-five, the end spots will be a four and a five; the next player must then either play a three on the four, or a two on the five, and so on. This game may be played by 2, 3, or 4. When 2 play, there must be 3 pieces left undrawn, to prevent each from knowing his opponent's hand. When more than 2 engage, all the dominoes may be drawn. The player who makes domino first, counts the spots on the other hand, or hands, and scores them towards game, which is 100 or more, as agreed on. If domino be not made before the drawing is ended, and a player cannot play in his turn, he must pass, and await his turn, but he must play if he can; failure to do so, deprives him of any count he may make with that hand. In playing, a doublet counts only as a single piece; for instance, double-six is a six, and can only be played on an ace-spot, or on double-ace; but, if left in hand after domino is called, it counts 12 points to the winner. If the game be blocked, and neither player can make domino, then the one whose hand contains the least number of spots wins, but his own hand does not count. Blanks are valuable; the double-blank being the most valuable of all the matadors. As it is impossible to make a seven against a blank, if you hold blanks you may easily block the game and count. When you have the worst of the game, and at other times, guard against your adversary's blanks, and prevent him from making them, which you may do by playing only those dominoes which fit with the blanks already down. Never play a blank at the lead, unless you have a matador or a corresponding blank. Keep back your double-blank till your opponent makes it blanks all; you can then force him to play a matador, or compel him to draw till he obtains one.

Muggins.—Each draws 5 pieces. The highest double leads; after that they lead alternately. The count is made by fives. If the one who leads can put down any domino containing spots that amount to 5 or 10, as the double-five, six-four, five-blank, tray-deuce, etc., he counts that number to his score. In matching, if a piece can be put down, to make 5, 10, 15 or 20, by adding the spots contained on both ends of the row, it counts to the score of the one setting it. Thus a trey being at one end and a five at the other, the next player in order putting down a deuce-five would score 5; or, if double-tray was at one end, and a player was successful in playing so as to get double-deuce at the other end, it would score 10 for him. The player who makes a count must instantly announce it when he plays his piece, and if he fails to do so, or if he announces the count wrongly, and any of his opponents call "Muggins," he is debarred from scoring. If a player cannot match, he draws from the pool the same as in the draw game, until he gets the piece required to match either end, or exhausts the pool. As in the Draw or Block game, the first one who plays his last piece adds to his count the spots his opponents have; and the same if he gains them when the game is blocked, by having the lowest count. But the sum thus added to the score is some multiple of 5 nearest the actual amount. The number of the game is 200, if 2 play; but 150 if there be 3 or more players.

Tiddle-a-Wink.—If 6 or more play, each takes 3 dominoes. The double-six is then called for, and the person holding it leads. If it is not out, the next highest double is called, and so on downwards until a start is made. In this game, he who plays a double, either at the lead or at any other part of the game, is entitled to play again if he can, thus obtaining 2 turns instead of one. The game then proceeds in the ordinary way, and he who plays out first, cries out "Tiddle-a-wink," having won. In the event of the game being blocked, he who holds the lowest number of pips wins.

MINOR GAMES.

ADVICE GRATIS. — Each player is provided with a slip of paper, on which he is to write a piece of advice, either original or a proverb. The papers are then folded and shaken up in a hat. Each person draws 1, and reads it aloud, first declaring, without seeing it, whether the advice is good, uncalled for, or mistaken.

BLINDMAN'S BUFF.— A person has a handkerchief bound over his eyes to blind him, and he tries to chase the other players, either by the sound of their footsteps or their subdued merriment, as they scramble away endeavoring to avoid being caught by him; when he can manage to catch one, and guesses who he is, the player caught must in turn be blinded, and the game be repeated. A modified way of play it is as follows: The party take hands and form a circle. In the midst stands Mr. Buff, blindfolded, and with a short, thin stick in his hand. The players keep running round in a circle, singing, while Buff approaches gradually, guided by their voices, till he manages to touch one of the circle with his stick. Then the dancers stop and become silent. The player who has been touched must take the end of the stick in her hand, while Buff holds the other, and she must distinctly repeat 3 times after him, any word he chooses to name; "Good morning," or "Good night," for instance, disguising the voice as much as possible. The blind man tries to guess the name of his captor. If he succeeds, the person caught becomes blind man; if not, Buff must try again.

BOUTS RIMES.—A number of slips of paper are distributed, and each person writes 2 words that rhyme. The slips are then collected and

read aloud, and each is then required to write a stanza introducing all the rhymes. Sometimes the whole of the rhymes are supplied by the leader.

CONSEQUENCES.—A round game, to play at which the company must be seated at a table. Each player has before him a long, narrow piece of writing paper, and a pencil. At the top of the paper each writes the quality of a gentleman. "The fickle," for instance, "the insinuating," "the handsome," "the ugly," or any epithet that may occur to the mind; but no one must see what their neighbors right or left have written. The top of each paper is folded down to hide what has been written, and each passes his paper to his neighbor on his right. On this he writes a gentleman's name; if that of one of the company, so much the better. Again the papers are passed to the right, after being folded over; the beauty of the game being that no one may write 2 consecutive sentences on the same paper. The quality of a lady is now written. Fold and pass the paper; the lady's name; then where they met; what he said to her; what she said to him; the consequence; and what the world said. The papers are now unfolded in succession and the contents read.

COPENHAGEN.—Procure a long piece of tape or twine, sufficient to go round the company, who stand in a circle, holding in each of their hands a part of the string; the last takes hold of the 2 ends. One remains standing in the centre of the circle, who is called "the Dane," who must endeavor to slap the hands of one of those holding the string before they can be withdrawn. Whoever is not sufficiently alert, and allows the hands to be slapped, must take the place in the centre, and, in his turn, try to slap the hands of some one else. Kissing the person caught is also frequently a part of the game.

DICE.—In all dice games, unless different arrangements be previously made, the highest throw wins. Each player throws the dice 3 times, and the sums of the spots uppermost at each throw are added together and placed to the score of that player. Ties are thrown over again, if it be necessary to establish any result.

Draw Poker.—Played with 5 dice; each player having 1 throw, with the privilege of a second if he desires it. In the first throw all 5 dice must be thrown; the player can leave all, or as many as he pleases, on the table, then gather up such as do not satisfy him, and throw them again. The throws rank as in the card game, beginning with the lowest; 1 pair, 2 pairs, triplets, a full hand, four of the same. The highest throw is 5 alike, ranking in the order of their denomination, from 6 down to 1; so that 5 sixes make an invincible hand; this can only occur in the dice game, while a flush occurs only in the card game. It should be understood that six is the highest and ace the lowest, the intermediate numbers ranking accordingly.

Going to Boston.—Played with 3 dice, which are thrown precisely as in *Multiplication.* The difference is in the counting; the result of the last throw being added to, instead of serving for a multiplier of the sum of the 2 remaining on the table.

Help Your Neighbor.—Played with 3 dice, and may be played by 6 persons, as follows: The players throw in regular rotation. The first player, or number one, throws 2, 4, 6, and as he has not thrown one, the number corresponding to his own, he scores nothing; but 6 being highest thrown, number six scores 6 points. The second player throws 2, 3, 5; he counts 2, and helps his neighbor five to 5 points. The third throws fours, so he gets nothing, while his neighbor four, scores 4 points; the raffles counting 4 instead of 12. Number four throws 1, 3, 3, making nothing for himself, but 3 for number three, or the third player. Number five throws 3 fives, which counts him 5 points. Number six throws 3 aces, which count him nothing, but enables number one to score 1 point. In this way the game proceeds, until some one wins by making the number of points agreed upon. When the game is played for a pool made up by the joint contributions of the players, the first out wins; but if for refreshments, the last player out loses.

Multiplication.—Played with 3 dice and 3 throws, as follows: The first throw is with 3 dice; the highest one is left on the table, and the other two taken up and thrown again; the higher one is left, and the lower one taken up and thrown again. The spots on the 2 left on the table are added together, and their sum multiplied by the spots on the third, or last die thrown; and this total placed to the score of the thrower. Thus we will suppose the player to throw as follows: First throw, three, two, and five; the five will be left on the table, and the three and two returned into the dice-box for the second throw, four and six; the six will remain on the table, and the four replaced in the dice-box. Third throw: Three. This will count 33; thus, the sum of five and six, the dice remaining on the table after the first and second throws, is 11; this sum multiplied by 3, the result of the third throw, makes 33.

Raffles.—3 dice are used, thrown by each player until he succeeds in throwing 2 alike; the first throw made containing a pair, counts its number of spots to the thrower's score. Triplets, or 3 alike, take precedence of pairs, so that 3 aces (the lowest triplet) will beat 2 sixes and a five. This is sometimes played differently, triplets counting only as pairs; thus, 3 fives would be reckoned as 15 points, and would be beaten by 2 fives and a six.

Round the Spot.—Played with 3 dice, thrown 3 times, the sum of the spot being thus reckoned, those spots only count which lay around a central spot, viz.: the three and five, the three spot counting for 2, and the five-spot for 4; thus it will be seen that six, four, two and ace do not count, and a player may throw 3 times and count nothing.

Vingt-un.—Played with a single die, each throwing it as many times as is necessary to get the sum of the spots equal to, or as near as possible, but not over 21. Throwing 22 or more bursts the player, depriving him of further participation for that round. The thrower of 21, or

failing that, the nearest to it, wins the game; but where a forfeit is played for, the player who fails the most in approaching the 21 loses the game. We will suppose B playing at Vingt-un, and throws as follows, viz.: Six, four, ace, and five; he now has 16, and should his next throw be a five, he will be just 21; but if his last throw, instead of five, had been six, it would have burst him, as he would be 22.

EARTH, AIR AND WATER.—One of the players is furnished with a handkerchief, which he throws suddenly and unexpectedly at another, crying out the name of "earth," "air," or "water," whichever he likes, and then counting 10 as rapidly as he can. Before he has come to 10, the person at whom the handkerchief is thrown must name a creature that inhabits the element thus mentioned, or, failing to do this, pays a forfeit. If the question is put very abruptly, and the number quickly counted, the players will often be unable to get out their reply quickly enough, and the forfeits come in merrily. The best way is to look at one person, and then unexpectedly throw the handkerchief at another.

EMPEROR OF MOROCCO. — One of those games in which the art consists in preserving gravity under every provocation to laugh. Two of the players, generally one of each sex, advance with measured steps into the middle of the room, and ceremoniously salute each other, and the following dialogue takes place, the speakers being compelled to look one another full in the face: *First player:* The emperor of Morocco is dead. *Second player:* I'm very sorry for it. *First player:* He died of the gout in his left great toe. *Second player:* I'm very sorry for it. *First player:* And all the court are to go into mourning and wear black rings through their noses. *Second Player:* I'm very sorry for it. They then bow again and retire to their places, while another pair comes forward to go through the same impressive dialogue; and so on, till the game has gone all round the circle, a forfeit being the penalty for the slightest approach to a giggle.

EYE-PEEPING. — Two holes are made in a screen. The performers stand behind it and place their eyes in the holes, while the persons in front guess to whom they belong.

THE FAMILY COACH. — Each in a company represents something connected with a family coach. One begins to relate an anecdote, and each time he mentions the family coach, all the players rise from their seats and turn round. When he mentions harness, wheels, pole, or any other part of the equipage, the persons representing those parts rise, each, at the mention of his name and turn round; failing to do this, they pay a forfeit.

FORFEITS.—*To act the dumb servant.* Performed by acting out the answers to the questions put by the master of the ceremonies; as, "How do you make bread?" "How do you make soup?" etc. — *Bite 3 in. off the poker.* Take the poker, hold it 3 in. from your mouth, and bite. — *Count 60 without saying 7.* Done by counting 6, the number next to 7, etc. But it is difficult to avoid mistakes. — *Hold the candle, and beg some one to kiss the candlestick.* The owner of the forfeit is herself the candlestick. — *Compliments under difficulties.* Pay 6 compliments to 6 different persons, avoiding the use of the letter *l* in every one. — *Kiss the one you like best in the room without hurting any one's feelings.* Do this by kissing every one. — *To sit upon the fire.* Do this by writing "the fire" upon a piece of paper and sitting on it. — *Kiss a book inside, outside and in the middle, without opening it.* Done by kissing the book in the room, outside the room, and in the middle of the room. — *Kiss one another rabbit-wise.* Done by each little girl taking an end of the same piece of string into her mouth and nibbling it until their lips meet, without either one dropping the string. — *To perform the egotist.* The victim is required to propose his own health in a flowery speech, and to sing the musical honors as a solo. — *To perform a Grecian statue.* A boy's forfeit, done by mounting on a chair or table, when each one of the company advances in turn and puts him in a different attitude, in which he remains until changed by the next person. — *To go out of the room with 2 legs and come in with 6.* Done by leaving the room and bringing in a chair on the return. — *To shake a dime off the forehead.* The owner of the forfeit is told that he will have to shake a dime off his forehead. The dime is inclosed in a damp handkerchief, and pressed hard against his forehead, but he is not allowed to put his hands up to his head. Feeling the impression of the dime, he will have no doubt that it has been fastened on, and not suspecting its removal in the handkerchief, he will begin shaking his head from side to side, and even rubbing it against pieces of furniture to get rid of what is not there.—*To push a chair through a finger ring.* This is done by putting the ring on the finger and pushing the chair (any other object will do as well) with the finger. —*To put a newspaper upon the floor in such a way that 2 persons can stand upon it and not be able to touch each other with their hands.* By putting the paper in the door-way, one half inside and the other half outside of the room, and closing the door over it, the two persons can easily stand upon it, and still be beyond each other's reach.—*To place a straw (or other small article) on the floor so that one cannot jump over it.* May be done by putting it close to the wall of the room.—*To pinch your own arm below the elbow.* This is a catch, and may be done by pinching the wrist of the right arm with the left hand.—*To put yourself through a keyhole.* Write the word "yourself" upon a piece of paper, and push it through the keyhole.—*To ask a question that cannot be answered in the negative.* Ask "What does *yes* spell?" *To play the judge.* Consists in sitting on a chair in a conspicuous part of the room, and listening with gravity to the complaints brought by the rest of the company, who try, by all kinds of ridiculous reports and artifices, to upset the stolidity of the learned gentleman on the bench.— *To put one hand where the other cannot touch it.* Grasp the right elbow with the left hand.—*The knight of the rueful countenance.* The knight whose forfeit is to be redeemed is marched

slowly round the circle of company by his squire, who kisses the hand of every young lady (and the cheeks of all under a certain age), wiping the mouth of the knight after each salute. If the knight's countenance relaxes from a rueful expression into a smile, his forfeit is not returned until he has gone through some other task. — *To blow a candle out blindfold.* The victim having been shown the position of the candle, is securely blindfolded, and after having been turned round once or twice, is requested to go and blow it out. — *Prison diet.* A glass of water and a teaspoon are brought into the room, the person who has to undergo "prison diet" is blindfolded, and a teaspoonful of cold water administered to him by any of the others, until he guesses who is feeding him. — *Pay each person in the company a compliment, and then spoil it.* This exercises the wit of the performer, and enables him to take a little harmless revenge on those of his friends who have been harassing him. To one, for instance, he says, "You have a finer voice than any one in this present company; but he adds, as the person addressed bows to the compliment, "it's a pity that you never give it any rest." To another, "You have certainly a great amount of wit, only you always exercise it at the expense of your friends;" and to a third, "Your eyes are certainly very bright, and that is the reason why they are always searching for their own reflection in the looking-glass ?" and so on till you have finished your round. — *The German band.* This is a joint forfeit for 3 or 4 players, each of whom is assigned some imaginary instrument, and required to personate a performer in a German band, imitating not only the actions of the player, but the sound of the instrument.—*The three salutes.* Bow to the wittiest in the room, kneel to the prettiest, and kiss the one whom you love best.

FOX AND GEESE.—A capital preparation for those who wish to become good draught or chess players. 1. The form of the board is shown in *Fig. 1.* The geese are represented by white pegs (or by pins, if the players draw their own board on a card), and the fox by a red or black one. The geese are 17 in number, ranged as in the diagram; while the fox stands in the centre of the board. The geese may be moved in the direction of the lines, one hole at a time. Their object is to block up the fox in a corner, or to surround him; while he, on his side, can take any goose which has not another in the hole

Fig. 1.

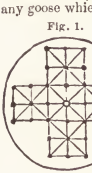


Fig. 2.

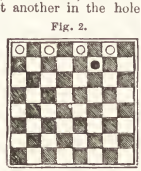


Fox and Geese.

behind it. If the fox can clear so many geese off the board that not enough are left to block him up, he wins; but if the geese are skilfully worked, they must win, by penning reynard into a corner. — 2. Another method of playing is with 4 white men, representing the geese, and 1 black one representing the fox. The geese are ranged on the 4 white squares nearest one player, and the fox may be placed where his owner pleases. The best place for him is that marked in *Fig. 2*, as he can maneuver in a very puzzling way. The geese can only move forward, but the fox moves either way. The object of the geese is to pen up the fox, and the fox has to break through. If the game is properly played, the geese must win, the secret being to keep them all in a line. The fox tries to prevent this, and if he can succeed in doubling the geese, or getting one to stand before another, he is nearly sure to pass through them.

"HOW D'YE LIKE YOUR NEIGHBOR?"—The company sit in a circle round the room, with a clear space in the middle. The chairs are placed close, and the number of chairs is one less than that of the players; for instance, if 13 players, 12 chairs. The chairless person stands in the middle of the room, and addressing one of the company, says: "Master Jones, how do you like your neighbor?" Jones may answer, "Very well indeed;" or, singling out 2, he may say, "I prefer Master A to Miss B," or "Miss A to Mr. R." If he likes both of his neighbors "very much indeed," all the players change places; if, on the contrary, he prefers Master A to Miss B, the 2 whom he names change, the others sitting still; it is the object of the person in the middle to get into one of the chairs while the changing is going on; and if he can succeed, the person left seatless must stand in the middle, and ask the players how they like their neighbors; if not, the first player has to take up his position again, and the game goes on.

"HOW, WHEN, AND WHERE DO YOU LIKE IT?"—One of the company retires, while the rest fix on some article or object. The person who has gone out is then recalled, and proceeds round the circle, asking each player in succession, "How do you like it?" Supposing the thing thought of to be money, the first may answer, "In abundance," the second "Ready," and so on. The questioner tries to gain from the answers given some clue to the nature of the thing thought of. The second question, "When do you like it?" will help him. One of the players may reply, "When I have to pay my bills;" another, "When I want a new coat," etc. The third question is certain to help a judicious questioner: "Where?" "In my pocket," one will reply; another, "At my banker's," etc. Some one is sure to drop a hint which will set the guesser upon the track. Three guesses are allowed. If he succeeds, he must point out the player whose answer gave him the clue, and the latter pays a forfeit, and goes out to be puzzled. Failing to guess in 3 trials, the first player must try another question. The art of the game consists in choosing words with more meaning than one, such as cord (chord); then the answers may be varied in a puzzling manner.

HUNT THE FOX.—Take partners and stand opposite each other in line. The one at the

head is the fox; her partner is the hunter. At a signal she starts and runs or dances down the line, her partner following. She can pass through the line as she pleases, the players standing far enough apart to allow her to pass. The hunter must follow the course of the fox; if he varies, he must pay a forfeit. When the fox is caught the first couple goes to the foot, and the next goes through the same. It adds to the jollity of the game to keep time to some tune like "Fisher's Hornpipe."

HUNT THE RING. — A long tape, with a ring strung on it, is held by the players, as they stand in a circle, with one in the middle. They pass the ring rapidly from hand to hand, and it is the business of the player in the midst to hunt the ring, and try to seize the hands that hold it; while the players make his task difficult by pretending to pass the ring to each other, when it may really be in quite another part of the circle. The person in whose hands the ring is found has to take his turn in the middle.

"I LOVE MY LOVE WITH AN A." — A well-known game, but it must be kept up briskly; for if too much time be allowed the interest flags at once. The company sit around, and each has to love his or her love with a different letter. The first (we will say a lady) begins, "I love my love with an A, because he's amiable; I hate him with an A, because he's arrogant. He took me to the sign of the 'Artichoke,' and treated me with apples and ale." "I love my love with a B," continues the second, "because she's beautiful; I hate her with a B, because she's bounceable. I took her to the sign of the 'Brown Bear,' and treated her with bread and butter, and beer." "I love my love with a C," says a third, "because he's candid; I hate him with a C, because he's captious. He took me to the sign of the 'Cart-Horse,' and treated me to curds and cream." And so the game goes on through all the letters of the alphabet. Instead of going regularly round the circle, it is better that each should have the power, after "loving his love," to call upon any one of the rest to continue the game. This gives additional interest from the unexpectedness of the summons.

INITIALS. —Any number of players can join, each one of whom tells the initials of his or her name, which the others can write on a slip of paper, if they do not prefer trusting to memory. Each invents an initial sentence, using the letters of one of the names. This sentence may be humorous or sensible, complimentary or the reverse. When all have prepared one or more sentences, the leader begins by addressing any person he pleases with a remark formed upon his initials, and each player follows his example, using the same letters. This attack is kept up indiscriminately on the person addressed by the leader, until he can answer the person who last addressed him before another of the players can say another sentence in the letters of his name, in which case the others all turn their remarks on the one thus caught.

JUDGE AND JURY.—A judge and jurors are selected; then the other players take the names of some historical personages. The judge calls up a player and questions her as to her reign or life. For any mistake in answering, the player must pay a forfeit to the jury, who inflict due punishment upon her for her lack of memory.

MAGIC MUSIC. — One of the players is sent out of the room, and a handkerchief, a pair of gloves, a brooch, or other small article, is hidden. The signal is then given for the banished one to return; and a lady or gentleman acquainted with music takes up a position at the piano. It is for the musician to indicate, by the strains of the piano, when the seeker is approaching the object hidden. As he recedes from it, the music falls to a low tone and a mournful cadence; as he approaches it, the notes swell out loud and clear, and burst into a triumphal strain as he lays his hand on the prize. If properly managed, the music may be made to have almost magnetic power. Another way, is to set the seeker some task to perform, instead of finding the handkerchief; say, for instance, he is to take a book from a bookcase, and present it to a lady. As he walks round the room, the music increases in sound as he approaches the book-case, but falls as he passes it. This tells him in what locality his task is. He takes a book, and the music sounds loudly and joyously. He begins to read—no! the music falls at once; he is faltering in his task. He carries the book round the room. As he approaches the lady, the notes burst forth loudly again, concluding with a triumphant flourish as he presents the volume to her with a gallant bow. In case of failure, a forfeit is exacted, and each player must have a task set him or her in turn.

PUSS IN THE CORNER.—4 players take up their positions at different corners, the 15th player standing out, and being known as puss. The 4 players change corners among themselves as frequently as possible, but so as to prevent puss from getting into any one of the corners. The player left without a corner becomes puss.

QUESTIONS AND ANSWERS.—All take partners and sit opposite each other. One person whispers a different question in the ear of each of those on one side of the room, and another person gives an answer to each on the opposite side. The first couple commence; one asks the question whispered to him, his partner gives the answer whispered to her. A lady should direct the gentlemen, and a gentleman the ladies. Each side asks the questions alternately; the side that was first to ask the questions being next to give the answers.

QUINZE. — Played by 2 with a full pack of cards. The cards are shuffled by both, then cut for deal, which falls to him who cuts the lowest. The dealer may shuffle them again. The ace is the lowest. When this is done the adversary cuts them, after which the dealer gives one card to his opponent and one to himself. Should the dealer's adversary not approve of his card, he is entitled to have as many cards given to him, one after the other, as will make 15, or come nearest to that number, which are usually given from the top of the pack. For example, if he should have a two and draw a five, which amounts to 7, he must go on in ex-

pectation of coming nearer to 15. If he draw an eight, which will make 15, he, as being eldest hand, is sure of winning. But, if he overdraw, and make more than 15, he loses, unless the dealer should do the same; which circumstance constitutes a drawn game, and the stakes are doubled; in this manner they persevere until one of them has won the game, by standing and being nearest to 15. At the end of each game the cards are packed and shuffled, and the players again cut for deal. The value of the cards is according to the number of their spots, ace counting for 1 only, and all the court cards being reckoned as 10 spots, following the same method as adopted in cribbage, as far as the numerical value of court cards is concerned. This game may be played by more than 2; but when a larger number play, Vingt-un, in more points than one, is generally considered preferable.

TIP. — Pour out from a paper package of assorted candy and small toys about as many pieces as the number of players, making the heap as nearly as possible in the middle of a designated space within easy reach of all. One of the party is blindfolded, and another touches an article in the pile, in order to point it out to all excepting the one whose eyes are closed. The player then opens her eyes, and is allowed to select one at a time and keep for her own all she can obtain without taking the piece that has been touched. Sometimes a player selects the tip first, in which case she gains nothing, for the moment she takes the tip she must give it up, and the turn passes to the next player on her right.

PART 6.

MISCELLANY.

Armand Sielcher

"TOO NUMEROUS TO MENTION."

MISCELLANY.

ACIDS, Injuries from.—1. Strong acids applied to the skin cause intense pain and destruction of the tissues with which the liquids come into contact, the extent of the injury varying, of course, with the amount of acid applied. When the injury has been caused by sulphuric, nitric or hydrochloric acid, apply dilute ammonia, chalk, carbonate of magnesia, or the plaster from the ceiling stirred in water. After an hour or so apply carron oil (olive oil and lime water in equal parts) on lint. For carbolic acid, apply olive oil.—2. For injuries from caustic alkalies, as strong ammonia and potash, apply a dilute acid, as vinegar; subsequently use olive oil, 1 part; carbonate of bismuth, 2 parts; spermaceti, 1 part; white wax, 1 part.

ALABASTER, To Polish.— 1. Rub first with dried shave-grass (equisetum), and afterwards with finely powdered and sifted slaked lime formed into a paste with water; then finish off by friction with powdered French chalk, until a satiny luster is produced.—2. Polish first with pumice stone, and then with a paste made of whiting, soap, and milk or water; and lastly, with dry flannel.

ALLOY, Of Cobalt and Copper.—M. Guillemin has formed a number of alloys of cobalt and copper. They are all red, have a fine fracture, and are much more tenacious than copper—even as high as from 50 to 100 per cent more so, according to the proportion of cobalt. Five per cent of cobalt is enough to give an alloy of great resistance.

AMBER, To Bend.—Drop it into hot beeswax. After it has been immersed for a few minutes, remove it, and, holding it before the fire, bend it to the desired shape.

AMBER, Imitation.— Dissolve shellac in an alkaline lye, then pass chlorine through the solution until the whole of the shellac is precipitated. After washing in water, this must be melted and kept over the fire until it runs *clear*, taking care that it does not burn; it should then be poured into moulds of the size of the pieces required.

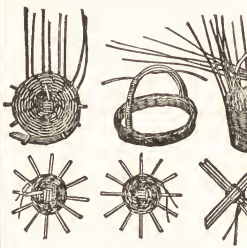
APPENDICITIS.—This is one of the most important of affections of the intestines. It occurs chiefly among the young, and far more among males than females. It is a disease of the "vermiform appendix," which is a small spiral extension from the bottom of the ascending colon, being an organ the origin or use of which science has not yet been able to explain. It is considered possible that it is a shrunken remnant of an organ formerly useful when man was in a savage state. Patients afflicted with appendicitis have usually been constipated. Foreign bodies, passing through the intestines, rarely lodge in it, and are seldom the cause of trouble, notwithstanding a popular impression to the contrary. There are much more apt to form in it oval bodies, resembling date stones, composed of a mixture of mucus, feces and lime salts. Sometimes the appendix may become diseased and disappear entirely, without any serious illness. Typhoid fever and consumption frequently bring on appendicitis. Some cases have followed the lifting of a heavy weight, a fall or a blow. In unfavorable cases, inflammation progresses to perforation of the peritonitis (inflammation of the abdominal cavity), suppuration and abscess. In many cases, the first indication of serious trouble is an acute, agonizing pain. Perforation of the abscess into various organs near by may occur, as into the bowel, the pleura, the bladder, etc. *Treatment:* This is so serious an affection that the services of a physician must be depended upon, and not amateur advice or self-treatment. Surgeons do not operate until imperatively necessary. They first resort to rest, opiates and enemas. An ice bag is placed against the seat of inflammation. If the abscess can be limited, it may disappear without an operation. When the general symptoms become severe, with increase in fever and pulse, or when a tumor is felt to be associated with these serious indications, the surgeon must act. After operation and recovery, the appendix being removed, the disease cannot return.

BAKING POWDERS.—1. Tartaric acid powder, 8 oz.; bicarbonate soda, 9 oz.; rice flour, 10 oz.; a teaspoonful to every 1 lb. flour.—2. Bicarbonate soda, 1 lb.; farina, 1 lb.; powdered alum, ¾ lb.; carbonate magnesia, ½ oz.; dry in oven separately; magnesia may be put on the

flour; tartaric acid may replace the alum.—3. Bicarbonate soda, 16 oz.; tartaric acid, 14 oz.; carbonate magnesia, 6 oz.; farina, 12 oz.; rub through a sieve.—4. Bicarbonate soda, 16 oz.; dry tartaric acid, 8 oz.; rice flour 12 oz.—5. Dry carbonate soda, 8 oz.; dry tartaric acid, 6 oz.; carbonate magnesia, 2 oz.; tumeric powder, 1 oz.; the soda and acid are properly dried before mixing, or the powder spoils by keeping; preserve in stoppered bottles.—6. Bicarbonate of soda, 4 oz.; tartaric acid, 3 oz.; farina, 16 oz.; mix together; by farina is meant any cheap farinaceous material—wheat, rice, or sago flours, etc. To make the packets requires a piece of wood, say 6 in. long for small packets, and the exact size in thickness and width that the packet is to be. The end of this piece should fit into a block of wood and go through it. Take the paper and fold it on the end of the stick, and close it at the end so as to make a square bag; now put the stick with the paper on it into the block, and withdraw the stick, leaving the paper in the block. It is more convenient to measure the powder than to weigh it. Put the powder in a small tin-plate funnel, and shake it into the paper; remove the funnel, and fold down the other end of the paper, flatten the folds with the end of the square stick, and push the packet out of the block. The whole operation of making the packet should take a very short time.—7. Tartaric acid, ½ lb.; bicarbonate soda, 12 oz.; starch, 12 oz.; dry each thoroughly previous to admixture, which is effected by passing through a fine sieve repeatedly; pack the powder down tightly, to prevent the absorption of moisture, —8. (*Goodall's.*) Rice flour, 2 parts; mixture of tartaric acid and bicarbonate soda, each, 1 part. —9. (*Horsford's.*) One powder contains acid phosphate of lime and magnesia mixed with a certain amount of flour; the other is bicarbonate soda.—10. Mix together, perfectly dry, 83 parts, by weight, of bicarbonate soda, and 188 parts of acid tartrate of potash (cream of tartar.)—11. (*Green's.*) Tartaric acid, 35 lbs.; sesquicarbonate soda, 56 lbs.; potato flour, 1 cwt.; mix as before.—12. (*Delforte's.*) Powdered tartaric acid, ¼ lb.; powdered alum, ½ lb.; bicarbonate soda, ¾ lb.; farina, 1 lb.; dry separately by a gentle heat; mix, and further add of sesquicarbonate of ammonia (in powder), 3 oz.; lastly, closely pack it in tinfoil.—13. Bicarbonate soda, 4 oz.; cream of tartar, 9 oz.; fine starch, 7 oz.; dry separately and mix thoroughly. It must be kept from moisture.

BARBER'S ITCH.—1. (*New Idea.*) Resorcin, 1 oz.; glycerine, 1 oz.; water, 1 oz.; lac sulphur, 1½ oz.; cologne, ½ oz.; alcohol, 4 oz. Apply several times a day with a soft sponge. Bathe the parts every morning with hot water. To make the preparation more pleasant, dissolve the sulphur in ½ oz. ether before adding to the mixture.—2. Resorcin, 1½ dr.; glycerine, 3 dr.; rose water, ½ oz.; lac sulphur, ½ oz.; triple extract lavender, ½ oz.; bay rum, q. s. to make 4 oz.; mix. Apply to the parts affected twice a day with a soft sponge.

BASKET-MAKING.—The majority of baskets are made of willows. French willows are firm, clean rods; Dutch willows are soft and pithy; English willows are tough and leathery, and therefore are strongest. The rods are cut from



Basket-Making.

the root of the trees, then soaked in water or boiled; the latter treatment turns the canes a light brown color After the willows have been stripped of their bark, they are exposed to the sun and air, and then placed in a dry situation. The implements required are few, and the process of weaving simple. Common baskets are made by crossing strong willows, and weaving them together with smaller pieces, for the bottom. Thinner pieces are inserted between those first crossed, as the weaving progresses. When the bottom is finished the ends are turned up to form the sides, and the smaller pieces are woven in as before.

BASKETS, Home-Made.—A way to make good baskets at home, and pretty and cheap, too, is out of corn-husks—thick, outer husks for strong baskets, and for lighter and finer ones the white inner parts are the best to use. These must be wrapped an hour or so in a damp towel, and then cut into strips of equal width. Make an ordinary braid with 6 or more strips, which may be doubled, or even trebled for greater strength. Thread a needle with heavy, waxed linen thread, and, having dampened the braid, form it into an oval, 5 or 6 in. long and 3 wide, for the bottom of the basket, and sew the adjoining edges of the braid together, as in a straw hat, but don't overlap them. Go on coiling and stitching for the sides of the basket, widening the opening until the basket is deep enough. The handles are made of a heavy, 3-stranded braid, which is sewed all around the top of the basket just inside, and looped at the middle of each side. For ornament, wind the handles with gay colored ribbon or braid, put a box-phiting of the same around the top and work a bunch of flowers on one side in bright worsteds, with long stitches. The opposite side may have a letter or a name.

BAY RUM.—1. Bay oil, 1 oz.; oil pimento, ½ oz.; alcohol, 2 gals.; water, 4 pts.—2. Bay oil, 10 dr.; pimento oil, 1 dr.; acetic ether, 2 oz.; alcohol, 3 gals.; water, 2½ gals.; mix, and after 2 weeks' rest filter.—3. A cheap bay rum can be prepared by saturating a ¼ lb. block of mag-

nesium carbonate with oil of bay; pulverize the magnesia, place it in a filter and pour water through it until the desired quantity is obtained, then add alcohol. The quantity of water and of alcohol depends on the desired strength and quantity of bay rum.—4. Bay rum is made by digesting the leaves of the bay plant, an aromatic plant grown in the West Indies, in rum, and subsequent distillation. An imitation is made as follows: 3½ fl. dr. oil of bay; ½ fl. dr. oil of pimento; 1 fl. oz. acetic ether; 1 gal. alcohol; 3 qts. water; mix, and after 2 weeks' repose filter.

BEESWAX, To Separate Honey from. — Put honeycomb and all in a tin pan upon a moderately warm stove, adding a tablespoonful of water to each lb. of honey. Stir occasionally with a piece of wire until the contents of the pan are in a liquid condition. Do not allow boiling to begin. Remove the pan from the fire and set it aside to cool. The cake of wax, to which all impurities will adhere, may then be carefully lifted off with a knife.

BELTING, Leather, to Determine Value of.—A cutting of the material, about .03 of an inch in thickness, is placed in strong vinegar. If the leather has been thoroughly acted upon by the tannin, and is hence of good quality, it will remain for months even immersed without alteration, simply becoming a little darker in color. But, on the contrary, if not well impregnated by the tannin, the fibers will quickly swell and, after a short period, become transformed into a gelatinous mass.

BELTS, Leather, Slipping of, to Prevent.—The slipping of belts is a great annoyance, not always remedied by tightening.—1. When a ready remedy is demanded for a slipping belt, the powder known as whiting, sprinkled sparingly on the inside of a belt, is least harmful of any similar application.—2. Powdered resin is bad, as it soon dries the leather and cracks the belt, while it is difficult to get it out of the leather; whereas whiting may be wiped off or washed out with water.—3. The use of water on belts, preliminary to oiling is good. The belt should be washed on shutting down at night—or Saturday, after the close of work, is better—and then the oil applied when the belt is partially dry. Never wash or oil a belt while stretched on the pulleys. If iron-faced pulleys were always lagged with leather, there would be little complaint of the slipping of belts. But often this slipping is due to too much strain on the belt; there is economy in running wide belts—wider than is the usual practice. Many a 3-in. belt has to do duty for a 4-in. belt to the annoyance of the operator and the ruin of the belt.—4. A piece of rubber belting fastened around the belt pulley of an engine, will keep the belt from slipping.—5. Use a piece of beeswax rubbed on the inside of the belt or on the pulleys, as a temporary remedy in cases of emergency, though with proper size belts and pulleys, properly put in, there should not ordinarily be any slipping.

BELTS, Military, to Whiten.—First brush the belt over with a mixture of linseed oil, 4 oz.; precipitated oxide of zinc, 1 oz.; and dry over a stove at a heat not over 160° Fah. When thoroughly dry, roughen by means of pumice powder and apply another coating. Dry as before, and varnish with amber or copal varnish.

BENZINE, To Deodorize.—1. Shake repeatedly with fresh portions of metallic quicksilver. Let it stand for 2 days, then rectify, or shake with plumbate of soda (oxide of lead dissolved in caustic soda), then rectify.—2. Digest litharge in strong solution of soda, and shake the benzine up with this.—3. Shake repeatedly with plumbate of soda, made by dissolving oxide of lead in caustic soda, and rectifying. Simply shaking with charcoal and filtering will partially remove the odor.

BEVERAGES, Frozen.—1. (*Coffee.*) Prepare 2 qts of strong, clear coffee, and sweeten to taste. When cold, put it in the freezer and turn the crank until it is like soft mush.—2. (*Tea.*) Prepare 1 qt. of tea, sweeten to taste, and when cool add a little lemon juice; freeze until mushy. — 3. (*Eggnog.*) Beat 2 eggs until light and creamy; add 2 tablespoonfuls of sugar and beat again; add 2 tablespoonfuls of wine or brandy, and 1 cup of cream or milk. Put in the freezer, and turn the crank until half frozen.

BICYCLISTS, Protector for, against Dogs. — The experience of a Brooklyn druggist, who put to flight 2 burglars in his store by throwing ammonia in their faces, and who so badly crippled one of the fleeing wretches that he was finally overtaken by the police, recalls the fact that some genius has invented an ammoniacal protector for bicyclists against vicious dogs. It may not be news to those who ride bicycles that there is a remedy of this kind put up in convenient rubber bulbs for handy use. It is called Ki-yi, and the apparatus is so arranged that by the pressure of an air bulb a stream of ammonia is directed into the face of the pursuing canine. A bicycle rider who has used the remedy says that in more than one instance he has been able to knock a dog completely over by one straight whiff of the stuff directed into its open mouth.

BIRDLIME.—Boil the middle bark of the holly, gathered in June or July, for 6 or 8 hours in water, until it becomes tender; then drain off the water, and place it in a pit under ground, in layers with fern, and surround it with stones. Leave it to ferment for 2 or 3 weeks, until it forms a sort of mucilage, which must be pounded in a mortar, into a mass, and well rubbed between the hands, in running water, until all the refuse is worked out; then place it in an earthen vessel, and leave it for 4 or 5 days to ferment and purify itself. Birdlime may also be made from mistletoe berries, the bark of the wayfaring tree and other vegetables, by a similar process. Should any of it stick to the hands, it may be removed by means of a little oil of lemon bottoms, or turpentine. It is used to rub over twigs to catch birds or small animals. It is said to be discutient when applied externally.

BISCUIT, Maryland Beat.—1 qt. sifted flour; 1 large tablespoonful of lard; 2 gills of water; 1 teaspoonful of salt; 2 gills of milk. Mix together salt and flour; rub the lard into the

flour evenly with the hands. Have the milk and water in a pitcher, and add it gradually to the flour, stirring and kneading all the time. Add only enough to moisten the flour, as the dough should be very stiff; knead 5 minutes; beat the dough well with a rolling pin for 30 minutes. (Little machines come for the purpose of making beaten biscuit, which facilitate the operation.) Then form, with the hands, into small, round biscuits, about ½ an inch thick. Prick in 3 places with a fork, and set them in a moderately quick oven for 20 to 25 minutes. The outside should be light brown, the inside white, flaky and delicious.

BLACKBOARD COVERING. — (*Bergmann's.*) Prussian blue, chrome green, equal parts; gilder's sizing, alcohol, equal parts, sufficient. Mix the powders, and add sufficient of the liquid to the consistency of cream. Use large still brush; cover quickly. In an hour's time, give second coat. In a day or two smooth the surface with hair cloth. It gives a velvety surface which will never look gray, as that made with lampblack.

BLACKING, Liquid.—1. The well-known liquid blacking of Day & Martin is prepared in the following manner: Very finely ground animal charcoal or bone black, is mixed with sperm oil till the two are thoroughly commingled. Raw sugar or molasses, mixed with a small portion of vinegar, is then added to the mass. Next a small measure of dilute sulphuric acid is introduced, which, by converting into sulphate a large proportion of the lime contained in the animal charcoal, thickens the mixture into the required pasty consistence. When all effervescence has subsided, but while the compound is still warm, vinegar is poured in until the mass is sufficiently thinned; then it is ready to be bottled for the market.—2. (*Without Vitriol.*) Take of ivory black (in very fine powder), 2 lbs.; molasses, 1½ lb.; sperm oil, ¼ pt.; mix; then add of gum Arabic, 1 oz., dissolved in strong vinegar, ½ pt.; mix well; the next day further add of good vinegar, or strong sour beer, 3 to 4 pts. (or q. s.); stir briskly for ¼ hour, and again once a day for a week. Excellent.

BLEACHING COMPOUND.—3 parts by measure of mustard seed oil; 4 parts melted paraffine; 3 parts caustic soda, 20° Be., well mixed to form a saponaceous compound. Of this, 1 part of weight and 2 parts pure tallow soap are mixed, and of this mixture 1 oz. for each gal. of water is used for the bleaching bath, and 1 oz. caustic soda, 20° Be., for each gal. is added, when the bath is heated in a close vessel, the goods entered, and boiling "until sufficiently bleached."

BLISTERS.—When arising from friction or other irritation, they should be pricked with a needle, and emptied of their contents by pressure; but the skin should on no account be broken. The following preparation may then be gently rubbed into the part: Spermaceti, 1 part; olive oil, 1 part; subnitrate of bismuth, ½ part. The part must be protected from friction, or a disagreeable sore will probably result. This is especially necessary when the blister is situated on the heel. One method of protecting it in this situation is to first place over it a piece of court plaster, and over this a good thick piece of cotton wool, at least twice the size of the blister; this should be kept on by strips of adhesive strapping. Another plan is to thickly spread a small piece of lint with the preparation recommended, to place this over the blister, and over this cotton wool.

BLUING, For Laundry Use.—1. Dissolve indigo sulphate in cold water and filter.—2. Dissolve good cotton blue (aniline blue 6 B) in cold water.—3. Dissolve fine Prussian or Berlin blue with ½ part oxalic acid in water; or use ferrocyanide of potassium, 1-12 part, in place of oxalic acid.—4. Dissolve 7 oz. of yellow prussiate of potash in 2.1 pts. of water. Make a solution of sesquichloride of iron which shall contain 1 part of the solid salt by weight to every 10 parts of water by weight. Take equal volumes of the 2 solutions, and add to each twice its volume of cold concentrated solution sulphate of soda. Finally, mix the two solutions thus obtained. The solid Prussian blue will immediately precipitate. This may be put upon a filter and washed, being kept exposed to the air for perhaps 15 or 20 days. The excess of soluble salts will first be washed away, and then the latter washings will dissolve the blue, forming a deep blue liquid, which may be used for preparations of bluing for clothing. It is, however, better to buy the soft Prussian blue than to attempt to prepare it on a small scale. 1 oz. of soft Prussian blue powdered, and put in a bottle with 1 qt. of clear rain water, acidulated by ¼ oz. of oxalic acid, is a good preparation. A very small portion suffices for a large amount of clothing. —5. (*Disinfective.*) Mix together 16 parts of Prussian blue, 2 parts of carbolic acid, 1 part of borax, and 1 part of gum Arabic into a stiff dough. Roll it out into balls as large as hazel nuts, and coat them with gelatin or gum, to prevent the carbolic acid from escaping.—6. (*Liquid Washing Blue.*) Water, 15 parts; dissolve in this 1½ parts indigo-carmine. Add ¾ part gum Arabic.

BOILERS, Filter for Removing Grease from.—A filter for removing grease, which often passes into boilers with the feed-water, consists of a metallic chamber or filter-box, in which are a series of gratings, and between these gratings are placed layers of wire gauze and flannel of a special texture, which forms the filtering medium. The feed-water from the donkey pump enters the filter-box on one side, passes upward through the filter-cloths, and thence out to the boiler, the scum passing away through another outlet. By this means it is found that all grease and greasy matter, as well as other impurities, are arrested by the filter-cloths, which can be readily taken out for cleaning, or renewal. The filter is equally applicable to land and marine boilers.

BOILERS, Incrustation of, Prevention of.—Water from wells, springs and streams holds in solution chloride of sodium, carbonate of lime, sulphate of lime, etc., besides vegetable matter. The carbonic acid, which holds the carbonate of lime, etc., in solution, being driven off by boiling, the latter forms an incrustation which adheres to the boiler, becoming thicker and

thicker, and, being a non-conductor of heat, it requires 60 per cent more fuel to raise the water to any given temperature when the scale is $\frac{1}{8}$ in. thick; the conducting power of scale compared with that of iron being 1 to 37. The red scale formed from water impregnated with salts of iron, is still more destructive to boilers. In no way can the evil be averted except by boiling the water; but this is sometimes impracticable, although many feed-water heaters are in operation. A number of substances are used to prevent incrustation, of which the following will serve as types:—1. Charcoal has a great affinity for anything that causes incrustation. That made from hard wood is best, broken in lumps of $\frac{1}{4}$ to $\frac{1}{2}$ in.; and the dust sifted out; 2 bush. will protect a boiler of 30 horse-power for 3 weeks when running, after which the old coal should be removed and fresh used.—2. Throw into the tank from which the boiler is fed, a quantity of rough bark, such as tanners use, sufficient to turn the water a brown color; if you have no tank, put into the boiler $\frac{1}{2}$ to 1 bush. of ground bark when you blow off; repeat every month, using $\frac{1}{2}$ the quantity after the first time.—3. Add a small quantity of muriate of ammonia, about 1 lb. for every 1,500 or 2,000 guls. of water evaporated. It will soften carbonate of lime and other impurities deposited during evaporation.—4. Potatoes and other vegetable substances introduced into the boiler are effectual in preventing incrustation, and animal substances, such as refuse skins, still more so.—5. Cow's feet, with shanks attached, are recommended as a preventitive; 2 in a large boiler are sufficient; and those who wish to do business economically, can get oil for lubricating cheaply by boiling the feet and shanks a few hours in a kettle, setting it aside to cool, and then skimming off the oil and using the feet for the boiler afterwards. To get rid of the hair on the shanks, use lime, etc., as done by tanner.—6. Sal soda, 40 lbs., gum catechu, 5 lbs., sal ammoniac, 5 lbs., is recommended for removing scale; 1 lb. of the mixture being added to each barrel of water in the tank; after scale is removed, use sal soda alone. By the use of 10 lbs. of soda per week, a boiler 26 ft. long, and 40 in. in diameter was cleaned from scale equal to a new one.—7. A rapid, but not good plan to scale boilers, is to throw in a few wood shavings along the bottom of the boiler and set them on fire; the heat expands the scale more than the shell of the boiler; as the heat cannot reach the latter, the scale is loosened; what remains must be removed with a hammer and chisel.—8. Potatoes 1-50 weight of water, prevent adherence of scale.—9. Twelve parts salt, $2\frac{1}{2}$ caustic soda, $\frac{1}{8}$ extract of oak bark, $\frac{1}{2}$ of potash.—10. Pieces of oak wood suspended in boiler and renewed monthly, prevent deposit.—11. Two oz. muriate of ammonia in boiler twice a week prevents incrustation and decomposes scale.—12. Coating of 3 parts black lead, 18 tallow, applied hot to inside of a boiler every few weeks, prevents scale.—13. 13 lb. molasses fed occasionally into an 8-horse boiler prevented incrustation for six months.—14. Mahogany or oak sawdust in limited quantities. The tannic acid attacks the iron, and should therefore be used with caution.—15. Slippery elm bark has been used with some success.—16. Carbonate of soda.—17. Chloride of tin.—18. Spent tanners' bark.—19. Frequent blowing off.—20. Paraffin oil has been used with excellent results in locomotive boilers.—21. Marine boilers are sometimes protected from corrosion by a very thin wash of Portland cement inside. —22. The use of glycerine is recommended to prevent incrustation in steam boilers. It increases the solubility of combinations of lime, and especially of the sulphate. It forms with these combinations soluble compounds. When the quantity of lime becomes so great that it can no longer be dissolved, nor from soluble combinations, it is deposited in a gelatinous substance, which never adheres to the surface of the iron plates. The gelatinous substances thus formed are not carried with the steam into the cylinder of the engine. Employ 1 lb. of glycerine for every 300 or 400 lb. of coal burnt. —23. For a 5-horse power boiler, fed with water, which contains calcic sulphate, take: Catechu, 2 lb.; dextrine, 1 lb.; crystallized soda, 2 lb.; potash $\frac{1}{2}$ lb.; cane sugar, $\frac{1}{2}$ lb.; alum $\frac{1}{2}$ lb.; gum arabic, $\frac{1}{2}$ lb.—24. For a boiler of the same size, fed with water which contains lime: Turmeric, 2 lb.; dextrine, 1 lb.; sodium bicarbonate, 2 lb.; potash, $\frac{1}{2}$ lb.; molasses, $\frac{1}{2}$ lb.; alum, $\frac{1}{2}$ lb.—25. For a boiler of the same size, fed with water which contains iron: Gamboge, 2 lb.; soda, 2 lb.; dextrine, 1 lb.; potash, $\frac{1}{2}$ lb.; sugar, $\frac{1}{2}$ lb.; alum, $\frac{1}{2}$ lb.; gum arabic, $\frac{1}{2}$ lb.—26. For a boiler of the same size fed with sea water: Catechu, 2 lb.; Glauber's salt, 2 lb.; dextrine, 2 lb.; alum, $\frac{1}{2}$ lb.; gum arabic, $\frac{1}{2}$ lb. When these preparations are used add 1 qt. of water, and in ordinary cases charge the boiler every month, but if the incrustation is very bad, charge every two weeks.—27. For boilers of 100 horse power fed with river water, use the following, which should be renewed whenever the boiler is emptied: Crystallized soda, 18 lb.; dextrine, 18 lb.; alum, 6 lb.; sugar, 6 lb.; potash, 3 lb.—28. For the same sized boiler, fed with sea water: Soda, 24 lb.; dextrine, 24 lb.; sugar, 12 lb.; alum, 3 lb.; potash, 3 lb.

BOOKS, To Preserve.—In certain parts of China and elsewhere, books are extremely liable to be attacked by insects. They first destroy the glue used in the backs of books, and gradually perforate the whole volume. Cockroaches, too, disfigure the covers by eating away patches of the glazing. The remedy for both these nuisances is easy: Corrosive sublimate, 5 drm.; creosote, 60 drops, rectified spirit, 2 lb. This mixture, a violent poison, is applied with a brush in the joint of the book at every six or seven pages, and as a preventitive of the ravages of cockroaches, the cover of the book is varnished with a thin, clear spirit varnish. In binding books, it would be only necessary to add a small quantity of the above mixture to the glue used, and to give a coating of spirit varnish to the cover, to secure complete protection from the attacks of insects of all kinds.

BOOKS, To Repair.—The first thing is to se-

cure the loose leaves. Odd leaves can be fixed in with paste or thin glue. If a whole section is loose, first sew it with stout thread, leaving long ends at the back, and then tie these ends to the part that goes before and the part that follows. A sheet of paper glued on the back will fix it in its place, letting a little glue go in before and after the sewed section. If the book has slipped out of the cover, leaving the cover intact, the best way is to strip all the paper off the back (not sides) of the cover, leaving the cloth (or leather, as the case may be) bare; then glue the back of the quires, and stick them on the cloth. This, with or without new end papers, will complete the job. This makes what is called a tight back; but it will open fairly well if all the padding is taken out, as directed above, and will make a strong binding. If only one cover is torn off, it can be fastened on thus: Raise the leather of the cover from the millboard with a penknife to the depth of ½ in. (or less if book is small). Get a piece of cloth, about 1 in. wide, and glue this into the opening made; do the same with the back of the book, and put in the remaining ½ in. of cloth with glue, and the job is done. They are not handsome, but are always strong.

BOTTLES, Oily or Greasy, to Clean.—Pour into them a little strong sulphuric acid; after they have been allowed to drain as much as possible, the bottle is then corked, and the acid caused to flow into every portion of it, for about five minutes. It is then washed with repeated rinsings of cold water. All traces of oil or grease left will be removed in a very expeditious manner, and no odor whatever will be left in the bottle after washing.

BREATH, Offensive. Remedy for.—Causes: The primary are constitutional, the proximate are an unhealty state of mucous membrane of the mouth, gullet and stomach. It is weak and inactive, and its cells are not properly cast off and renewed, the external layers being slowly disintegrated. Another proximate cause is the retention of undigested food in the stomach. Treatment in the main must be constitutional. —1. The odor may be corrected by washing out the mouth with Condy's fluid, and by taking the following draught twice a day: Chlorate of potash, 15 gr.; water, 1 oz.—2. *Smoker's Breath, etc.* Do not smoke bad tobacco, which leaves an abominable odor about the person and contaminates the breath almost beyond immediate remedying. The same may be said of bad cigars. The following is an old formula for removing the odor of tobacco from the mouth after smoking; it is to be used as a wash: calcium chloride, 2 drm.; water, 1 oz. Agitate for half an hour and filter. Then add, rectified spirit, 1 oz.; rose water. ½ oz. For sore tongue, the simplest remedy is to wash out the mouth with glycerine, 1 part; powdered chalk, 1 part; water, 8 parts. This will of course require to be shaken up before using. The following formulas are commended by various authors as to the several sources of fetid breath, the active materials for disinfecting being one of the following articles: Carbolic acid, chlorine water, potassium permanganate, thymol, salicylic acid, camphor, borax.—3. Camphor water; water, equal parts use as a mouth wash.—4. Thymol, 10 gr.; alcohol, 1 oz.; borax, 30 gr.; water, 19 oz.—5. Potassium permanganate, 8 gr.; water, 8 oz.—6. Chlorine water, 1 oz.; glycerine 2 fl. oz.; water, 14 oz.—7. Salicylic acid, 120 gr.; glycerine, 2 fl. oz.; water, 6 oz.—8. Borax, 240 gr.; water, 1 pt.—9. Chlorinated lime, 120 gr., sodium carbonate, 160 gr.; water, 6 oz.; alcohol, 2 oz.; rose water, 12 oz. Dissolve the sodium carbonate in 2 oz. of water, rub the chlorinated lime to a paste with water, adding in all 4 oz.; mix in a 12 oz. bottle, adding the alcohol. After the reaction, separate the clear solution, and add to the rose water.—10. Salicylic acid, sodium bicarbonate, saccharine, each 60 gr.; alcohol, water, each 4 fl. oz.; oil of peppermint, 5 drops. Of this solution, use two teaspoonfuls to a wineglass of hot water, and use as a gargle twice daily.

BRICK-MAKING.—Brick consists of clay earth, sometimes mixed with coal ashes, chalk and other substances, and then molded into a rectangular form. The different kinds may be divided into three classes, as follows: *Walling brick*, made of coarse stiff clay, requiring sand to be mixed with it to be worked with facility; *fire-brick*, of clay containing considerable silicate of alumina, and free from lime or iron; they are made by exposing them to intense heat in kilns; *paving brick*, of clay containing a great amount of silica, which causes them to become hard; *black brick* are made by dipping ordinary brick in coal tar. There are 2 methods of burning brick, as follows: *Clamp-Burnt.* Brick burnt in stacks of 500,000 to 1,000,000, with the fuel interspersed among them so that every brick may be exposed to the action of the fire. If the fire is too strong, it causes the brick to fuse and run together, and form hard, irregular masses called clinkers, but if the fire is not strong enough the brick will be soft and unfit for building purposes. About 1-10 of every clamp is lost by unequal firing and breakages; the brick also vary in color. When sufficiently baked they are divided into classes as follows: Cutters, fine close-grained brick, rather soft, and suited to work requiring cutting; picked stocks, of a uniform red tint; hard, for paving; common or ordinary brick; grizzles, or soft brick.—*Kiln-Burnt.* Called *malm* brick, made of fine clay; contains considerable carbonate of lime; great care is taken to prevent air getting to the brick while baking. These are slowly burnt in kilns; they are better for ornamental purposes, being of buff color, but not as desirable as clamp-burnt. Brick kilns are made as follows: A number of arches are built up contiguously, so as to form a solid mass; then covered with a dry wall of baked brick, the lower courses being one brick thick, and the rest ½ brick. At the bottom, a vacancy is left between the wall and the face of the arch which gives a batter to the covering wall, and affords a draught. Arch-irons, having an opening of about 1 sq. ft. are inserted in the opening, and the whole smeared over with clay.

BRICK WALL, To Estimate Number of Brick in.—First multiply the breadth by the height of

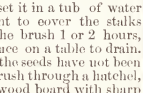
the wall in feet, obtaining the number of square feet; then obtain, in the same manner, the total amount of surface occupied by the openings or doors and windows in the wall; deduct this from the superficies of the whole wall; then, if the wall is only the thickness of one brick laid flat, or 4½ inches, multiply by 7, and the result will be the number of brick required for the wall; if it is to be a 9 inch wall, multiply by 14; if a 13 inch wall, by 21; and, for every width of brick added to the thickness of wall, add 7 to the multiplier, and so on.

BRICKWORK, White Coating on, to Prevent.—This efflorescence which is such a disfigurement, can usually be prevented by adding oil to the mortar at the rate of 1 gal. to the cask of lime. Linseed oil or any oil not saline will do. If cement is used, an extra gallon of oil must be used. When incrustations are once formed, nothing can be done except to wash with dilute hydrochloric acid.

BROOM-MAKING.—1. Take a quantity of dry brush and cut off the stalks 6 in. from the brush.

Hatchel.

Then set it in a tub of water sufficient to cover the stalks up to the brush 1 or 2 hours, and place on a table to drain. When the seeds have not been all removed, draw the brush through a hatchel, which is a piece of hard-wood board with sharp notches sawed in one end of it, and nailed to the bench. Fasten a stout string to the ceiling; make a loop for the foot near the floor, or for a lever, one end of which passes under the bench, the other to be pressed by the foot when in use. Now take enough brush to make the broom, putting the best brush on the outside, arranging evenly. Grasp the bunch firmly, wind the string around it as shown in the figure, pressing the lever to bind closely. Then roll this string close to the bunch; take the binding string, or wire either, double it, allowing the end to project at the left hand side, wind tightly to the right. When wound pass the string through the loop; grasp the other end and pull the loop end of the string under the coil. Now cut both ends close to the coil and the knots are concealed. Then flatten the broom between a couple of short boards in a vise, or, fasten 2 boards together at one end with leather nailed to each, the other ends fastened, when in use, by strings. When flattened, thread an iron, steel, or hard wood needle 6 to 8 in. long; fasten one end of the cord, then pass the needle back and forth through the brush, advancing a little each time. Repeat 2 or 3 times, fasten the thread securely, and the broom is ready for handling. Sharpen the handle; force it into the centre of the neck of the broom and fasten it by driving a nail through the coil on each side. Clip the bottom.—2. Tack one end of a 2 ft. string to the handle, 3 in. from the lower end; tie the other round a stick, which place under the feet as shown in the figure. Lay the brush on, a piece at a time; turn the handle to hold them, lifting all the time. Put on and wind 3 layers; then begin another row a little nearer the end of the handle, and then another, using the longest and finest brush for the last layer. Wind the cord tightly a few times around the whole, and fasten the end with a carpet tack. To make the broom flat put more brush upon 2 opposite sides. Sew as above described. Wire is better than string.



Winding Arrangement.

Winding the Broom.

Binding String.

Flattening Board and Needle.

BRUISES.—A bruise is the discoloration caused by the extravasation of blood from ruptured vessels, and is due either to a blow or violent compression. Apply ice or some cold object as soon as possible after the injury. Pressure will also be of service. This method of treatment should be continued for at least two hours. The appearance of a bruise may by somewhat disguised by first covering it with a paste compound of prepared chalk 1 part; glycerine 1 part. This should be gently worked into the part and the excess wiped off. Over it 1 layer of flexible collodion should be spread by means of a brush. This will make the part of a white color.

BRUSH-MAKING.—Insert the bristles in a firm support, which holds them properly and at the same time serves as a handle. Most brushes are manufactured of the bristles of the hog. First sort the bristles according to color: they are divided into black, gray, yellow, white and lilies; the last being white are preferred for tooth and shaving brushes. Then assort according to size, by passing a bunch, held in the hand, between a row of steel points, like the teeth of a comb, which catch the coarser kinds. By using a succession of combs of increasing fineness the bristles are separated into as many heaps as desirable. The brush used by house painters is made by taking a bundle of bristles and tying them firmly around their root ends; this bundle is then strongly bound between the prongs of a forked stick and covered with a coating of glue and red lead. Another method is to arrange the bristles around the small end of a conical stick, the small ends of the bristles pointing to the larger end of the stick; the bristles are secured by twine and placed in a socket with hole in the bottom to let the handle pass through; this is driven home till the large end is buried in the centre of the bundle, tightening the fastenings, when the brushes are further secured by saturating the ends with glue. Other brushes are made

by inserting little tufts of bristles into holes bored in rows into a stock of wood, etc. The operators sit around a table, each with a clamp attached to its edge for holding the stock board and each supplied with a fine brass wire, which is held in the right hand, and an apron full of bristles. A loop of the wire is passed through a hole in the stock, and, a number of bristles being laid in it, the wire is pulled tight, causing the bristles to double and be drawn into the hole. The same process is repeated with the next hole, and so on, until all are filled and held tightly in place by the wire; then clipped with a pair of shears gauged to cut the length of bristles required.

BRUSHES, To Soften. — Steep the brushes for twenty-four hours in good benzole, and then if necessary purify by washing them with soap and warm water.

BRUSHES, To Stiffen.—Immerse the bristles for a short time in cold alum water

BUGS, Bed, to Destroy.—1. Rub the joints of the bedstead with equal parts spirits of turpentine and kerosene oil, and where there are many, the cracks in the surbase of the room. Filling up all the cracks with hard soap is a good remedy.—2. Take everything out of the infested room, plug up all the windows tightly, close all chimneys, and empty about 1 oz. of powdered sulphur on a pan of hot coals, placed in the middle of the floor. Shut the doors and cover all cracks; let the sulphur burn as long as it will. Where the room is large, it is a good plan to fasten a bit of tin tube to the bottom of the pan, and to this connect enough small rubber pipe to lead out of the nearest door. By blowing into the end of the pipe with the bellows, the sulphur will be caused to burn more quickly by the draught created, and to give a denser smoke. After the sulphur has burned out, paint all the cracks in the floor and around the mop board with a strong solution of corrosive sublimate, and treat the furniture to the same before replacing it. A room frightfully infested has been completely freed by this plan.—3. Mixtures such as equal parts of turpentine and kerosene oil are used; filling up the cracks with hard soap is an excellent remedy. Benzine and gasoline will kill bedbugs as fast as they can reach them. A weak solution of zinc chloride is also said to be an effectual banisher of these pests.—4. When they have made a lodgment in the wall, fill all the apertures with a mixture of soft soap and Scotch snuff. Take the bedstead to pieces, and treat that in the same way.—5. A strong decoction of red pepper applied to bedsteads will either kill the bugs or drive them away.—6. Put the bedstead into a close room and set fire to the following composition, placed in an iron pot upon the hearth, having previously closed up the chimney, then shut the door; let them remain a day: Sulphur, 10 parts; saltpeter, powdered, 1 part. Mix. Be sure to open the door of the room 5 or 6 hours before you venture to go into it a second time.—7. Rub the bedsteads well with lamp oil; this alone is good, but to make it more effectual, get 10 cents worth of quicksilver and add to it. Put it into all the cracks around the bed, and they will soon disappear. The bedsteads should first be scalded and wiped dry; then put on with a feather.—8. Corrosive sublimate, 1 oz.; muriatic acid, 2 oz.; water, 4 oz.; dissolve, then add turpentine, 1 pt.; decoction of tobacco, 1 pt. Mix. For the decoction of tobacco boil 2 oz. of tobacco in 1 pt. of water. The mixture must be applied with a paint brush. This wash is a deadly poison.—9. Rub the bedsteads in the joints with equal parts of spirits of turpentine and kerosene oil, and the cracks of the surbase in rooms where there are many. Filling up all cracks with hard soap is an excellent remedy. March and April are the months when bedsteads should be examined to kill all the eggs.—10. Distilled vinegar, or diluted wood vinegar, 1 pt.; camphor, ½ oz.; dissolve. —11. White arsenic, 2 oz.; lard, 13 oz.; corrosive sublimate, ¼ oz.; Venetian red, ½ oz. (Deadly poison.)—12. Strong mercurial ointment, 1 oz.; soft soap, 1 oz.; oil of turpentine, 1 pt.— 13. Gasoline and coal oil are both excellent adjuncts, with cleanliness, in ridding a bed or house of these pests.—14. Benzine or gasoline will kill these pests as fast as they can be reached. By using a spring bottom oiler the fluid can be forced into all the cracks and crevices. As the fluid is inflammable, contact with fire must be avoided. The room should be well aired.

BURNS, Treatment of.—1. White lead paint has been found, after trying almost every plan of treatment hitherto proposed, to be the best and cleanest application. Mix as for painting, but considerably thicker, and apply with a brush. A very neat and satisfactory dressing in superficial burns consists in coating the surface with mucilage and then covering it with powdered lycopodium.—2. A saturated solution of picric acid applied to a burn or scald will not only remove all pain, but will prevent the formation of sores, and will bring about a complete cure in a few days. This solution should be kept on hand by all managers of iron works and engineering shops, where accidents from burning are frequent, and not uncommonly fatal. The solution is perfectly stable, cheap and free from any odor or toxic properties. It produces a temporary yellow discoloration of the skin, which can be entirely removed by the application of boric acid.

BUTTER, To Color.—1. Use a little annatto; if pure it is not injurious.—2. The coloring matters commonly employed are annatto and turmeric, or extracts of these; but there are also a number of butter-coloring compounds or mixtures sold for this purpose. For some of these it is claimed that they will not only impart the desired color to butter, but will keep it sweet and fresh for an indefinite time. The following are a few of these coloring compounds in use at present: (*Rorick's Compound.*) The materials for 1,¢90 lb. of butter are: Lard, butter, or olive oil, 6 lb.; annatto, 6 oz.; turmeric, 1 oz.; salt, 10 oz.; niter, 2-5 oz.; bromochloralum, 3½ oz.; water, q. s. The lard, butter, or oil is put into a pan and heated in a water bath. The annatto and turmeric are then

stirred into a thin paste with water, and this is gradually added to the fatty or oily matters kept at a temperature of about 110° F. The salt and nitre are next stirred in, and the mixture heated to boiling. The heating is continued for from 12 to 24 hours, or until the color of the mixture becomes dark enough. The bromochloralum is then introduced, and the mass is agitated until cold when it is put up in sealed cans.—3. (*Bogart's.*) Annattoine, 5 oz.; turmeric (pulverized), 6 oz.: saffron, 1 oz.; lard oil, 1 pt.; butter, 5 lb. The butter is first melted in a pan over the water bath and strained through a fine linen cloth. The saffron is made into a ½ pt. tincture, and, together with the turmeric and annattoine, is gradually stirred into the hot butter and oil and boiled and stirred for about fifteen minutes. It is then strained through a cloth as before and stirred until cold.—4. (*Dake's.*) Heat a quantity of fresh butter for some time with annatto, by which means the coloring matter of the butter is extracted, and straining the colored oil and stirring it until cold.

BUTTER, To Increase Yield of.—Instead of 100 pounds a week from 12 cows, it is claimed that by adding one teaspoonful black pepsin to each gallon of cream, 230 pounds excellent butter can be produced. Some say that pepsin butter is half cheese and urge that as an argument against it; of course the black pepsin does unite all the cheese that milk contains with the butter, but it is still claimed the butter looks, tastes, keeps and sells as well as any butter and is more healthful, and that is all the farmer wants.

BUTTER, To Test for Oleomargarine.—Stir a little—half a teaspoonful or less—of the suspected butter in enough sulphuric ether to dissolve it. By the time the grease is dissolved the ether will have been evaporated, and the residuum will show, to smell or taste, whether it is butter, lard, or tallow. 5 cents' worth of ether will suffice for several tests.—2. The sale of oleomargarine at grocery stores is now enormous. The prejudice against it has largely died out and some people say they prefer the flavor. Unless you buy high-priced butter, you don't get anything much sweeter or more wholesome than the very best artificial substitute. There are two infallible tests. If genuine butter is cut with a sharp knife, a water-like fluid comes out of both sections in small drops, and if it is pressed, or more strictly compressed, moisture will ooze out. If there is no moisture after either of these tests, the compound is oleomargarine and nothing else.—3. A clean piece of white paper is smeared with a little of the suspected butter. The paper is then rolled up and set on fire. If the butter is pure the smell of the burning paper is rather pleasant; but the odor is distinctly tallowy if the "butter" is made up wholly or in part of animal fats.

BUTTERMILK, To Make.—The following is a novel way of procuring delicious buttermilk without the labor of churning. The milk is permitted to sour and partially skimmed so as to allow enough cream to render it rich. It can be taken from the ice box, provided you wish it cold, and simply beat it a few moments with an egg beater (one with a handle is preferable) and you have as fine buttermilk as can be made under any process.

CALCIMINING.—1. Soak 1 lb. of white glue overnight, then dissolve it in boiling water and add 20 lb. of Paris white, diluting with water until the mixture is of the consistency of rich milk. To this any tint can be given that is desired.—2. (*Lilac.*) Add to the calcimine 2 parts of Prussian blue and 1 part vermillion, stirring the mixture thoroughly and taking care to avoid too high a color.—3. (*Brown.*) Burnt umber.—4. (*Gray.*) Raw umber, with a trifling amount of lampblack.—5. (*Rose.*) Three parts vermillion and 1 part of red lead, added in very small quantities until a delicate shade is produced.—6 (*Lavender.*) Make a light blue and tint it slightly with vermillion.—7.(*Straw.*) Chrome yellow, with a touch of Spanish brown.—8. (*Buff.*) Two parts of spruce, or Indian yellow, and one part of burnt sienna.—9. (*Blue.*) A small quantity of Prussian blue will give a soft azure tint. Dark blue is never desirable. Delicate tints in the foregoing varieties of colors are always agreeable and tasteful, and so great care must be taken that they are not too vivid. The tints will always appear brighter than in the calcimine pot, and this fact must be kept in mind when adding the coloring powders.

CANDLES, Transparent, to Make.—A French chemist makes a new kind of candle by dissolving 5 parts of colorless gelatine in twenty parts of water, adding 25 parts of glycerine and heating until a perfectly clear solution has been formed. To this is added 2 parts of tannin dissolved by heating in 10 parts of glycerine. A turbidity is produced which should vanish on further boiling. The boiling is continued until the water has been driven off. The mass is then cast into ordinary glass candle molds. The candles obtained in this way are as clear as water and burn quietly, and without spreading any odor.

CANING CHAIRS.—Splints are cut in long slips of equal width and thickness. An end of a long strip is fastened to one corner of the chair bottom; the strip is then passed backward and forward across the seat of the chair, over the rounds in one direction and under in the other, until the seat is covered. The bottom is then covered by passing splints in the opposite direction, except that on the upper side the splints are passed over and under the transverse strips, thus weaving the splints together and forming the bottom of the chair.

CASKS, To Cleanse.—1. Put a few pounds unslaked lime in the barrel, add water and cover. In a short time add more water and roll the barrel. Rinse with clean water.—2. Have the casks well scrubbed with boiling water, in which a little soda ash has been dissolved. If they are not wanted for immediate use, let them stand exposed to the air, one head out, for a month. There is no greater purifier than the atmosphere; then head up, slightly steam, blow off, and send to cellar to

be filled. If wanted for use, scrub, then gently fire until well hot through, steam, etc., as before. They should all be tested for sweetness, by chipping and smelling, before being headed up. If not wanted for use, when finished put about a pint of bisulphite of lime and water, 1 to 4 of water, and they will keep good in a cellar for 12 months.

CATARRH, or HAY FEVER, Remedy for.—1. For catarrhal or hay fever troubles a compound of lunaline, which is an oleaginous substance of about the consistency of vaseline, and made from the oil of sheep's wool, with menthol and cocaine, makes a remedy that gives instant relief. It may be applied with the finger or on a feather to the nasal passages. These are harmless but sure remedies, and are the best known.—2. A wash made of witch-hazel and cocaine should be applied to the nasal passages when the dreadful asthma comes on. It will stop the wheezing in no time, and then hay fever will have lost all its terrors.

CATERPILLARS, To Destroy.—There are no fewer than nineteen insect enemies of the grape, and of these, seven or eight assume the caterpillar form at some stage of their development. If the fruit has not been formed, they may as a general thing be destroyed by sprinkling the vines with a solution of Paris green or London purple with water, say a heaping tablespoonful of the former to 2 gal. of the latter. The vines may be dusted with a mixture of the poisons and plaster of flour, in the proportion of 1 to 100. After the fruit has formed, a kerosene soap emulsion sprinkled on the vine would be destructive to the pests without endangering human life. Take about 4 lb. of common yellow bar soap, 1 gal. of kerosene and 1 gal. of water; heat the mass over the stove, stirring it till it forms a homogeneous thick yellowish liquid, then remove the mixture from the stove and continue the stirring until it becomes cool. This should be largely diluted with warm soft water, and it will be permanent. Pyrethrum powder mixed with plaster is also used to good effect, sprinkled on the vines.

CELLULOID, To Make.—A roll of paper is slowly unwound, and at the same time saturated with a mixture of 5 parts sulphuric acid and 2 of nitric, which falls upon the paper in fine spray. This changes the cellulose of the paper into fine pyroxyline (gun cotton). The excess of acid having been expelled by pressure, the paper is washed with water until all traces of acid have been removed; it is then reduced to pulp, and passes to the bleaching trough. Most of the water having been got rid of by a strainer, the pulp is mixed with from 20 to 40 per cent, of its weight of camphor, and the mixture triturated under millstones. Coloring matter having been added in the form of powder, a second mixture and grinding follows. The pulp is then spread out in layers on slabs and from 20 to 25 layers are placed in a hydraulic press, separated from one another by sheets of blotting paper, and subjected to a pressure of 140 atmospheres until all traces of moisture have been got rid of. The plates obtained are broken up and soaked for 24 hours in alcohol, the matter then passed between rollers heated to between 140° and 150° Fahr., whence it issues in the form of sheets. Celluloid is made to imitate amber, tortoise-shell, coral, malachite, ebony, ivory, etc., and besides its employment in dentistry, is used to make mouth-pieces for pipes and cigar-holders, handles for table-knives and umbrellas, combs, shirt fronts and collars, and a number of fancy articles.

CELLULOID COLLARS AND CUFFS, To Whiten.—1. If the coloring does not disappear when the affected portions are rubbed with a woolen cloth and a little tripoli, and then polished with a clean woolen rag, the injury is a permanent one.—2. Cream of tartar is excellent. Use with a little water.

CEMENTS.—1. (*Strong and Handy.*) One of the strongest cements and very readily made, is obtained when equal quantities of gutta percha and shellac are melted together and well stirred. This is best done in an iron capsule placed on a sand bath, and heated either over a gas furnace or on top of a stove. It is a combination possessing both hardness and toughness—qualities that make it particularly desirable in mending crockery. When this cement is used, the articles to be mended should be warmed to about the melting point of the mixture, and then retained in proper position until cool, when they are ready for use.—2. (*For Bicycle Tires, etc.*) In 10 oz. carbon bisulphide dissolve 20 oz. enoutchouc; 10 oz. gutta percha; and 5 oz. fish glue. Bind the tire well with cord until set.—3. 2 parts of pitch and 1 part of gutta perch are melted together. Use hot.—4. (*For China.*) The best cement for china is Russian isinglass dissolved in pure soft water by soaking twelve hours and boiling some time at a high heat. The fractures must be free from dust or grease, and brushed with the isinglass while hot and thick, then tied to keep their place, and left 24 hours to dry. This is colorless and does not leave the yellow tinge of many of the popular china cements of commerce. Where a handle has been knocked off a cup or ewer the crack left after mending may be disguised by penciling over it a band of color to suit the decorations, or by a plain line of white or gilding. Vases may be retouched in the same way. The color when mixed with oil and fine varnish, will stand all common usage. Gilding is most easily done by the novice with a pencil and mixture of powdered gold in isinglass size, the way monks used to illuminate their parchment.—5. (*Transparent for Glass.*) Dissolve 1 part of India rubber in 64 parts of chloroform; then add gum mastic in powder, 14 to 24 parts, and digest for two days with frequent shaking. Apply with a camel's hair brush.—6. (*For Broken Ivory.*) Chipped spots in Parian may be filled with a plaster of parian dust and oyster lime, of the finest sort, mixed with the white of eggs, and smoothed with the bowl of a spoon. Dark red or black Etruscan wares need a little vermillion and burnt sienna in the cements ordinarily used to prevent unsightly

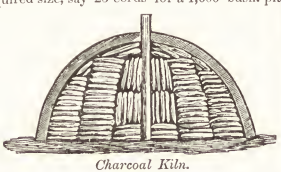
white streaks or joints. Malachite, agate and azurine, when broken, may be cemented with sulphur, melted at a low heat so as not to change its color, in which different pigments are stirred to give it proper tints like the stones.—7. (*Letter-fixing.*) Copal varnish, 15 parts; drying oil, 5 parts; oil of turpentine, 2 parts; liquefied glue (made with the least quantity of water), 5 parts; melt together in a water bath, and add fresh slaked lime (perfectly dry, and in very fine powder), 10 parts. Used to attach metal letters to plate glass in shop windows.—8. (*For Lamps.*) Common alum melted in an iron spoon over hot coals forms a very strong cement for joining glass and metal together. It is a good thing for holding glass lamps to their stands or for stopping cracks about their bases, as kerosene does not penetrate it. Housekeepers ought to keep this in remembrance, for sad accidents may be prevented by its use.—9. (*For Marble.*) A common cement for marble is made of 2 parts white virgin wax, 1 part white rosin, with 1½ parts of marble dust, which is to be found at any stonecutter's. The wax and rosin are melted, the powder sifted in, afterward the whole is well kneaded in water to mix the ingredients thoroughly. See that the parts to be joined are clean and dry, heat them; heat the cement and apply quickly and plentifully, tying the parts together until solid. The cement which oozes at the fracture may be dressed down like marble. Colored stone may be retouched with pigments ground in damar varnish to carry the veins across the cement line. —10. (*For Ornaments.*) The sticky juice of the marsh mallow root mixed with the finest chalk forms a cement for onyx, ground glass or pottery. Derbyshire or Niagara spar is mended with 7 parts of white rosin and 1 of wax, melted with a little powdered spar. Chipped places can be filled with a paste of this kind and smoothed to a level.—11. (*Pozzuolana.*) A kind of earth thrown out of volcanoes, of a rough, dusty, granular texture; its most important property consists in making a cement when mixed with ½ its weight of lime and water, which hardens very suddenly, and is more durable under water than any other. Manganese is found to be a valuable ingredient in water cements. 4 parts of gray clay are to be mixed with 6 parts of the black oxide of manganese, and about 90 of good limestone, reduced to fine powder the whole to be calcined and cooled, to be worked into the consistence of a stiff paste, with 60 parts of washed sand.

CEMENT FLOORS.—The French, who have carried the art of hardening plaster to where it is utilized for flooring, either in the place of wood or tile, use 6 parts of good quality of plaster intimately mixed with 1 part of freshly slaked white lime finely sifted. This mixture is then laid down as quickly as possible, care being taken that the trowel is not used on it for too long a time. The floor should then be allowed to become very dry, and afterward be thoroughly saturated with the sulphate of iron or zinc, the iron giving the strongest surface, the resistance to breaking 20 times the strength of ordinary plaster. With sulphate of zinc the floor remains white, but when iron is used it becomes the color of rusted iron, but if linseed oil, boiled with litharge, be applied to the surface, it becomes of a beautiful mahogany color. Especially is this the case if a coat of copal varnish is added.

CHAPS.—The effect of cold is to diminish the caliber of the cutaneous blood vessels by producing contraction of their coats. Hence there is a lessened supply of blood to the skin and a lessened nutrition, accompanied by a decreased secretion of the cutaneous glands. The deficient secretions must be replaced by an outward application. The following formula will be of service;—1. White wax, 1 part; borax, 3 parts; juice of bitter almonds, 1 part; oatmeal water, 3 parts.—2. Milk, 1 part; chalk, 2 parts; glycerine, 1 part.—3. Spermaceti, 2 parts; white wax, 1 part; glycerine, 1 part, chalk, 3 parts; oatmeal water, 2 parts.—4. (*Chaptal's Water for Chapped Breasts.*) Sulphate of alumina, 1 drm.; sulphate of zinc, ½ oz.; borate of soda, 4 gr.; rose water, 6 oz.—5. (*Cracked Hands.*) Various receipts are given for this. Camphor, 60 gr.; boric acid, 30 gr.; lanoline, white vaseline, of each ½ oz.; to make an ointment.—6. Anoint your hands with glycerine after washing and while they are still damp. If used without some water it has a drying tendency. Vaseline is no good.—7. Mix a powdered ball of sal-prunel with 2 oz. of vaseline, and rub well in.—8. Hands may be kept smooth in cold weather by avoiding the use of warm water. Wash them with cold water and soap.—9. (*Camphor Ice.*) Oil of sweet almonds, 2 oz.; spermaceti, 4 oz.; white wax, 2 oz.; camphor, ½ oz.; melt them over a water bath, run in molds of proper size and form.—10. Expressed oil of almonds and rose water, each, 1 lb. White wax and spermaceti, each, 1 oz. Camphor, 2 oz. Oil of rosemary, 1 drm. Melt together. Glycerine may be substituted in part for the oil and rose water.—11. (*Pomatum for Chapped Lips.*) Lard, 16 parts; cacao oil, 24 parts; spermaceti, 8 parts; yellow wax, 3 parts; alcanna root, 1 part. The substances are fused for a quarter of an hour at a gentle heat, then strained through a cloth and mixed with oil of lemon, oil of bergamot, of each 1-6 part; oil of bitter almonds 1-15 part; when the mass is poured into suitable vessels to cool.

CHARCOAL, To Make.—Charcoal is a form of carbon containing the incombustible portions of wood from which it is prepared, and some volatile ingredients. Oak and alder make the best; next, birch of all kinds, pine, bass-wood, poplar and spruce, hemlock is least desirable, as it makes snapping coal. The object of its preparation is its superior heat-making properties as compared with wood. The greater portion offered for sale is burned in kilns, but in thickly wooded regions much is made by charring in pits. To make a quantity of charcoal, a level place is prepared for the foundation of the pit. A chimney is then made by driving stakes of the desired height arranged in a circle

18 in. in diameter. The wood is cut 4 ft. long and hauled to the pit, large sticks being split. It is not necessary that the wood be dry, though the more seasoning the better the results. The first sticks are set up against the chimney; the next against these; then others on top; and so on, all leaning a little toward the centre until the pile has attained the required size, say 25 cords for a 1,000 bush. pit.



Charcoal Kiln.

When the pile is finished, the outer surface is filled in with chips and sticks, and the whole covered with branches, twigs, leaves, straw or moss, upon which sods or moistened earth are laid together with fine charcoal waste of previous burnings, the depth of the covering varying from 6 to 8 in., and the whole being smoothed and spatted down. Draught holes 2 or 3 in. in diameter and 4 ft. apart, are made in the covering at the bottom. A fire is kindled in the bottom of the chimney from the top, and when well burning the chimney is filled with wood and covered like the rest of the pit. Watch must be kept that the wood does not burn too rapidly, this is shown by the appearance of blue smoke; a steam-like vapor rises from the vents when the process is going on properly. When this smoke is seen, the fire is smothered by packing in green wood at the threatened point, and covering closely with straw and earth; a 1,000 bush. pit will be charred in 10 or 15 days. As the process proceeds, fill up some of the holes and open others, according as the burning progresses. Channels are made under the heap for the tarry matters which run out from the wood towards the close of the process. When completed, the coal is raked out with long-toothed iron rakes, at night, as then any remaining spark of fire can be detected and promptly extinguished by throwing coal dust or moistened earth on it. After the uncharred brands are removed the coal is ready for market.

CHEWING GUM, To Make.—Take of balsam tolu 4 oz.; white resin 16 oz.; sheep suet 1½ oz., more or less; melt together. Of above mixture take 2 oz.; white sugar, 1 oz.; oatmeal 3 oz. Soften and mix on a water bath. Roll the pieces in finely powdered sugar or flour to form sticks, etc., as desired. Paraffin with a little olive oil and glycerine may be melted together for a chewing gum. The exact mixture will vary with the season, etc.

CHILBLAINS, Cure for.—Prevention is better than cure for chilblains as for everything else. A very hot foot-bath every night for a month, followed by the most vigorous rubbing, will usually cure cold feet and set the blood in good circulation in the extremities. But if the chilblains come they may be successfully treated in several ways. A good ointment is made of castile soap melted in a little rum. If from rubbing the skin be broken the rose salve is very healing. Camphor ice cures some chilblains, and the various cerates are suited to those of other people. Peppermint essence, cologne and alcohol are recommended to allay the stinging and burning of a frost bitten heel. —2. For frost bites rub the affected parts with pure oil of peppermint. It will also prevent the after effect of chilblains. Care should be taken to use only the pure oil, and not the essence of peppermint, as the essence will not have the desired effect.

CHIMNEYS, Lamp, to Prevent Cracking.—Put the chimneys into cold water and gradually heat it until it boils, then let it as gradually cool.

CIDER, Cheap, to Make.—Mix well together 10 gal. cold water; 7½ lb. brown sugar; ¾ lb. tartaric acid; add the juice expressed from 2 or 3 lb. dried sour apples, boiled.

CIDER, To Preserve.—A pure, sweet cider is only obtainable from clean, sound fruit, and the fruit should therefore be carefully examined and wiped before grinding. In the press, use hair cloth or gunny in place of straw. As the cider runs from the press, let it pass through a hair sieve into a large open vessel that will hold as much juice as can be expressed in one day. In one day, or sometimes less, the pomace will rise to the top, and in a short time grow very thick. When little white bubbles break through it, draw off the liquid through a very small spigot placed about 3 in. from the bottom, so that the lees may be left behind. The cider must be drawn off into very clean, sweet casks, preferably fresh liquor casks, and closely watched. The moment the white bubbles, before mentioned, are perceived rising at the bunghole, rack it again. It is usually necessary to repeat this three times. Then fill up the cask with cider in every respect like that originally contained in it, add a tumbler of warm, sweet oil, and bung it up tight. For very fine cider it is customary to add at this stage of the process about ½ lb. of glucose (starch sugar) or a smaller portion of white sugar. The cask should then be allowed to remain in a cool place until the cider has aequired the desired flavor. In the meantime clean barrels for its reception should be prepared as follows: Some clean strips of rags are dipped in melted sulphur, lighted and burned in the bunghole, and the bung laid loosely on the end of the rag so as to retain the sulphur vapor within the barrel. Then tie up ½ lb. of mustard seed in a coarse muslin bag, and put it in the barrel, fill the barrel with cider, add about ½ lb. of isinglass or fine gelatine dissolved in hot water.

CIDER, To Keep Sweet.—When the cider has reached the flavor required, add 1 to 2 tumblers of grated horseradish to each barrel of cider.

CIGARETTES, To Make.—Cigarettes may be rolled in the hand or made by a machine, by

which paper and tobacco are fed in at one end, and from the other come out cigarettes. When the tobacco is brought in, it is placed on a sieve-table, set in motion by machinery; this sifts out sand and foreign bodies, operators standing on each side of the table to catch all bad leaves or stems. It is next thrown upon a ventilator, which winnows out the dust; then spread in layers on terraces where the sun can dry it; after which it is dropped into casks, and subjected to intense hydraulic pressure; then conveyed beneath a huge fly wheel, set with sharp blades, that chop it to pieces. It is again ventilated, winnowed, and sujected to a finer cutting apparatus, until it is reduced sufficiently; after which it is spread out on a floor and sprinkled with an aromatic liquid; once more dried; when it is ready for the paper envelopes. The paper is passed beneath a press which stamps it, and is then cut with a mechanical knife.

CIGARS, To Flavor.—1. Ordinary cigars may be scented by moistening with a strong tincture of cascarilla to which a little gum benzoin and storax is added; or the leaves which are to form the cigars may be soaked for a short time in a strong infusion of cascarilla, and then dried by a gentle heat. A small quantity of camphor, together with oils of cassia and cloves, is sometimes added to the tincture mentioned.—2. By simply inserting very small shreds of cascarilla bark between the leaves of the cigar, or in small slits made for the purpose.

CIGARS, To Make.—The leaf is stalked or stripped of its midrib, and damped before it passes into the hands of the roller. The envelope is cut from a smooth, unbroken leaf. It is laid flat on a table and the edge wet with a little gum water; the small pieces of leaf are then laid on it and rolled up in it, the gummed edge of the wrapper sticking it tight. One end is pointed by twisting it with the fingers and the other end is cut square.

CIGARS, To Smoke.—With a sharp knife cut off a transverse section $\frac{1}{4}$ in. from the small end, if you would avoid being troubled with particles of tobacco between your lips while smoking. Avoid licking the cigar; it spoils the excellence of the outer leaf on which much of the flavor depends. Light the end thoroughly. Do not commence to smoke a cigar half-lit. Keep it out of a draft; it is difficult to taste the fragrance of delicate tobacco in the open air. Smoke gently, and avoid burning down one side, for then all flavor is lost. If a cigar go out it may be relit without disadvantage, but a cigar lighted after becoming cold is generally nauseous.

CLEANING MIXTURE.—(*For silk, woolen and cotton fabrics.*) It is said that it will not change their color nor injure the texture. Take a pint of clean and clear soft water, and into it grate 2 good sized potatoes. Strain through a coarse sieve into a gallon of water and let the liquid settle. Pour the starchy fluid from the sediment and it is ready for use. Rub the articles gently in the liquid, rinse thoroughly in clear water, dry and press.

COAL OIL, Uses for.—Headlight oil is double refined petroleum, or refined kerosene. It is purer and cleaner than the cruder and cheaper oils, and has not so strong an odor. It is for this reason better for household purposes, although kerosene is as good in other respects.—1. For laundry work the oil is becoming well-known. The clothes are put to soak over night in warm soap suds. In the morning clean water is put in the boiler, and to it is added a bar of any good soap, shred fine, and two and one-half tablespoons of headlight or kerosene oil. The clothes being wrung from the suds, the finest and whitest go into the scalding water in the boiler and are boiled 20 minutes. When taken from the boiler for the next lot, they are sudsed in warm water, collars, cuffs and seams being rubbed if necessary. Rinsed and blued as usual, they will come forth beautifully soft and white. Knit woolen underwear, woolen socks, etc., may safely be washed in this way. The secret of washing successfully by this method is the use of plenty of soap and warm water to suds the clothes. If too little soap be used the dirt will "curdle" and settle on the clothes in "freckles." A teaspoonful of headlight oil added to a quart of made starch, stirred in while it is hot, or added to the starch before the hot water is poured upon it, will materially lessen the labor of ironing and will give to clothes either white or colored, especially muslins or other thin wash goods, a look of freshness and newness not otherwise to be attained. For cold starch, add a teaspoonful of oil for every shirt to be starched. Rub the starch well into the article, roll up tightly, and leave it for $\frac{3}{4}$ of an hour, then iron.—2. To clean windows and mirrors, add a tablespoonful of headlight or kerosene oil to a gallon of tepid water. A polish will remain on the glass that no mere friction can give.—3. If windows must be cleaned in freezing weather use no water at all. Rub them with a cloth dampened with kerosene; dry with a clean cloth and polish with soft paper.—4. A few drops of kerosene added to the water in which lamp chimneys are washed will make them easier to polish.—5. To break a glass jar or bottle evenly, put a narrow strip of cloth, saturated with kerosene, around the article where it is to be broken. Set fire to the cloth and the glass will crack off above it.—6. Tarnished lamp burners may be rendered almost as bright as new by boiling them in water to which a teaspoonful of soda and a little kerosene has been added. Then scour with kerosene and scouring brick and polish with chamois or soft leather.—7. To clean iron work rub with a cloth dampened with kerosene.—8. To prevent rust on stoves put away for the season, black them before putting away with blacking diluted with kerosene, or rub them thoroughly with kerosene alone.—9. To clean zinc, oil cloths and white paint, rub them with a cloth dipped in kerosene, and dry with a clean cloth.—10. To clean brass stair rods, brass bedsteads and other brasses, rub with kerosene and rotten stone put on with a soft cloth, and polish with a dry cloth, soft paper

or chamois.—11. To remove rust from kettles or other ironware, rub with kerosene and let them stand. Keep a day; then wash with hot water and soap, repeating if necessary.—12. To remove rust from flatirons, soak them in, or rub them with kerosene, and polish with scouring brick.—13. To remove rusty screws, drop kerosene upon them; in a few minutes they can be moved.—14. To take rust from steel implements, cover with kerosene for forty-eight hours, then scour with air-slacked lime until the stain disappears.—15. To remove paint from any kind of cloth, saturate the spot with kerosene and rub well; repeat if necessary.—16. To remove fruit stains, saturate the stain with kerosene, rub thoroughly with baking soda and leave in the sun.—17. To renew woodwork and furniture, varnish with black varnish, plentifully diluted with kerosene.—18. To soften leather hardened by repeated wettings, rub it well with kerosene.—19. To clean sewing or other machines, oil all the bearings plentifully with kerosene, operate the machine rapidly for a moment, rub the oil off and apply machine oil.—20. To remove dandruff, rub kerosene well into the roots of the hair; the dandruff can then be combed or washed out easily.—21. To make the hair grow, apply headlight oil or kerosene to the roots of the hair twice each week, rubbing it in well with the tips of the fingers. This will often produce a growth of hair when all other means fail.—22. To relieve chilblains, soak the feet in hot water and rub them with kerosene, or with kerosene and lime water.—23. To relieve calloused feet rub them frequently with kerosene.—24. To relieve the pain of rheumatism, rub the afflicted joint with kerosene.

CLOCKS, To Clean and Oil.—If it is a clock that the oil will not injure—of metal, wood, china or marble—place it in a bowl and pour about a pint of kerosene into the back. Place it face downward and let it stand over night. Even if the face be of paper and gets completely soaked with the oil, it will do no harm. The kerosene will evaporate within a few days and leave it perfectly clean. If, after this treatment, the clock will not go, it is because there is something radically wrong with it. Some essential part must be broken. The theory is very simple. The kerosene cleans the works and removes any clog of oil and dust that may be interfering with the machinery.

CLOTHES, To Prevent Fading.—Soak the clothes that fade over night in water in which has been dissolved 1 ounce of sugar of lead to a pailful of rain water.

COAL, To Make Last.—Coal over which has been sprinkled a strong solution of salt will last much longer than it otherwise will—what will be saved in coal will more than pay for the salt and the trouble. Use a pound of salt in each two quarts of water. Hot water dissolves the salt more readily than cold, though either will do. The salt in some way adds a lasting ingredient to the coal. Salt was the main constituent of the various coalines so extensively advertised some years ago, and by which so much money was made. Any one can try the experiment in a small way. First see exactly how long one scuttle full of coal will last. Next try the same amount of coal, over which the solution of salt has been sprinkled.

COCKROACHES, To Destroy.—Among other things, cinnamon is said to possess irresistible attractions for the cockroach palate, and there is a scandal to the effect that those whose business it is to reduce the cinnamon sticks to a powder are not very careful to separate the spice from the insects—which sometimes constitutes nearly half the contents of the bags—but tumble them together into the mill. This passion for cinnamon can be utilized readily to capture them. Select a tin dish with fairly deep and steep sides; put a little cinnamon on its bottom; set it in a favorite haunt of the insects; place sticks or strips of pasteboard from the edge of the dish to the floor, so as to lead up. The next day the dish will be found full of roaches, who cannot climb back on the slippery sides of the tin dish. Destroy them and set the trap again.

COFFEE, Adulterated, Tests for.—Artificial coffees can be detected in unground samples by a careful examination and separation of all beans which do not have a portion of the flue membrane with which they were originally invested still adhering in the cleft. The suspected beans should be cut open and the structure examined. The uniform structure of the artificial coffee is very distinctive, and after comparison with that of genuine coffee can never be mistaken for the latter. Pure ground, roasted coffee will float on cold water, coloring it very slightly and slowly, while the bogus coffee, chicory, roasted cereals, etc., sink, coloring the water quickly. Chicory is very easily detected by this test, since the particles in sinking leave a trail of color behind them. Cereals, when "light roasted," may escape detection by the water test, but they respond readily to iodine, giving the characteristic reaction for starch. A hot water extract of the adulterated sample containing cereals, or other starch bodies, when filtered, cooled, acidulated with sulphuric acid and decolorized by permanganate of potassium, will show a blue color on the addition of tincture of iodine. Chicory contains no starch, hence if the water is quickly colored and iodine does not give the characteristic reaction, chicory is probably present. The microscopic examination will reveal the presence of starches, if cereals, acorns, peas or beans constitute the adulterant.

COLD, Remedy for.—Trinitrate of bismuth, 6 drachms; pulverized gum Arabic, 2 drachms; hydro-chlorate of morphia, 2 grains. This is used as a snuff, creates no pain, and causes the entire disappearance of the symptoms in a few hours.

COLD SORE, Remedy for.—This complaint, generally known as "breaking out," attacks the margins of the lips, and most frequently accompanies a cold in the head. It is too well known to need description. *Treatment:* Oxide of zinc, 10 parts; oxide of bismuth, 20 parts;

powdered starch, 20 parts; oxide of iron, 2 parts; silica, 20 parts; oxide of aluminum, 8 parts; oxide of magnesium, 10 parts; powdered chalk, 10 parts. The above should be mixed into a fine powder, and then be made into a paste with an equal quantity of glycerine; this should be gently rubbed into and spread over the parts nightly.

COLOR, To Revive. — Plush goods and all articles dyed with aniline colors, faded from exposure to light will look bright as ever after being sponged with chloroform. The commercial chloroform will answer the purpose very well, and is much less expensive than the purified.

CORK, To Prepare for Bottles. — 1. Before being manufactured into stoppers, the cork is charred on each side. It is readily cut and is obtainable in sheets and squares, which can be flattened with the aid of moisture and pressure, or bent with that of heat and pressure. The knife for cutting should be broad in the blade, and kept sharp, for cork blunts the edge of the knife very soon. There are 2 kinds of cork, the white and the darker kind. The white is smooth, has a fine grain, and cuts with precision. Good corks act effectually in the exclusion of air, and do not absorb the liquid. If you have a batch of imperfect corks, dip them into a mixture composed of $\frac{3}{4}$ virgin wax and $\frac{1}{4}$ beef suet, and dry in the oven. Ordinary corks are squeezed with an instrument before they are forced into the necks of the bottles, so as to allow for their swelling; but corks prepared with this mixture require no squeezing. To insure non-evaporation through corks after they are driven, cover them with wax.—2. Paraffine is fused in a suitable vessel, the dry corks immersed therein by means of a perforated disc; the air is now easily expelled from the pores of the corks, which after about 5 minutes are removed and cooled; they may be cut and bored like wax, are easily driven into bottles, readily removed, retain their smoothness and are gas-tight.

CORK, To Soften.—Steam thoroughly, or boil it in water 1 hour or more.

CORKS, Substitutes for Glass Stoppers.—Corks that have been steeped in vaseline are an excellent substitute for glass stoppers. They are not in the least affected by acids, the fumes of chemicals do not decay them, nor do they become fixed in the bottles, from long disuse. In short, they have all the good qualities of the glass stopper without any of its disadvantages.

CORNED BEEF. — To each gallon of water add 1$\frac{1}{2}$ lb. salt, $\frac{1}{2}$ lb. of sugar, $\frac{1}{2}$ oz. saltpeter, and $\frac{1}{2}$ oz. potash. Boil, skim, and when cold pour over the meat.

CORNS AND BUNIONS, To Cure.—A corn is an abnormal growth of the epidermis, which increases in two directions—outwardly forming a callosity; inwardly dipping into the true skin. There are two kinds, hard and soft. The hard generally form over some projecting point of bone; the soft form between the toes. Causes: Irritation by pressure or friction, as from wearing tight shoes. A piece of cotton wool should be placed between or under the toes, as the case may be, to relieve the spot from friction. *Treatment:*—1. Salicylic acid, 30 gr.; cannabis Indica (Indian hemp), 5 gr.; castor oil, $\frac{1}{2}$ drm.; collodion, $\frac{1}{2}$ oz.; mix and apply morning and evening for four days. Then soak the feet in warm water. If this be done faithfully, the corns are removed without any difficulty. The result is a clear, light green solution. There should be no difficulty in its preparation. To prevent it from evaporating, keep the solution in a stoppered bottle. Be sure and use the Indian hemp, and not the American article; the latter is not easily soluble.—2. For bunions and corns Cannabis Indica and glycerine, equal parts, painted on the bunion or corn and bound around with Canton flannel, adding a few drops of the liquid to the flannel where it comes in contact with the affected parts will soon restore to health.—3. An inflamed bunion should be poulticed, and larger shoes worn. Iodine, 12 gr.; lard or spermaceti ointment, $\frac{1}{2}$ oz., make a capital ointment for bunions. It should be rubbed on gently two or three times a day.

COTTON DUCK, To Make Mildew-Proof. — Saturate the cloth in hot solution of soap, $\frac{1}{4}$ lb. to the gal. of water; wring out and digest 12 hours or more in a solution of $\frac{1}{2}$ lb. alum to 1 gal. water.

CRYING BABY, To Stop.—In the midst of its screaming press your finger gently and repeatedly across the cartilage of the nose, and inside of three minutes it will be sound asleep.

CURRY POWDER.—1. Coriander seeds, 20 parts; black pepper, 3 parts; cayenne pepper, 1 part; turmeric, 6 parts; cummin seeds, 6 parts. Reduce to powder and mix.—2. The following recipe is the closest approach to a Singapore curry powder that can be obtained outside of the tropics: One cocoanut and one lime sliced; cardamons, thoroughly ground, 2 oz.; cinnamon, thoroughly ground, 2 oz.; chillies, thoroughly ground, 1 oz.; coriander seed, thoroughly ground, 4 oz.; black pepper, thoroughly ground, 4 oz.; mustard seed, thoroughly ground, 2 oz.; turmeric, thoroughly ground, 5 oz.; ginger, thoroughly ground, 4 oz.—3. (*Ford's.*) Turmeric, 12 oz.; coriander seed, 12 oz.; ginger, 12 oz.; black pepper, 12 oz.; capsicums, 9 oz.; cardamons, 6 oz.; cummin seed, 6 oz.; mint, 3 oz. These should be ground separately into fine powder, and weighed after being ground. Mix thoroughly by sifting all together.

DAMPNESS, Remedy for. — 1. (*Apartments, Storage Cellars, etc.*) A recent test of it on a wholesale scale demonstrated its practical superiority to the fresh lime, sulphuric acid, etc., usually advised. The materials are common salt and sawdust, which are ever obtainable—as fresh lime is not, and not dangerous, as sulphuric acid is—and do the work completely and rapidly. First lay a rather thick layer (about 1 inch) of sawdust on the floor; upon this a similar layer of salt. The salt takes the moisture, and the sawdust absorbs it.—2. (*Walls.*) $\frac{3}{4}$ lb. of mottled soap to 1 gal. of water. This composition to be laid over the brick

work steadily and carefully with a large flat brush, so as not to form a froth or lather on surface. The wash to remain 24 hours, to become dry. Mix ½ lb. alum with 4 gal. water; leave it stand 24 hours, then apply it in the same manner over the coating of soap. Let this be done in dry weather.

DIAMONDS, To Test.—It doesn't require an expert to tell whether a diamond is genuine or not. The test is very simple, and it can be made in any place and in a moment. All you need is a piece of paper and a lead pencil. With the latter make a small dot on the paper, then look at it through the diamond. If you can see but one dot you can depend upon it that the stone is genuine, but if the mark is scattered, or shows more than one, you will be perfectly safe in refusing to pay 10c for a stone that may be offered you at $500. A blue stone may be tested by a bath in alcohol. Many yellow stones are made blue by an application of analine, and this is overcome by the alcohol.

DIAMONDS, Value of.—Diamonds averaging ¼ carat each, $60, per carat; ¾ carat each, $80; 1 carat each, $100; 1¼ carats each, $110; 1½ carats each, $120; 1¾ carats each, $145; 2 carats each, $175. In other words the value of the gem increases in the geometrical ratio of its weight. Four diamonds weighing together 2 carats are worth $120; but one diamond weighing just as much is worth $350. Stones weighing over 2 carats are about the same price per carat as two-carat stones; they should be dearer, but they are not, simply because the demand for them is limited. If the demand for diamonds was as imperative as the demand for beef or flour, the geometrical ratio would again come into play, and five-carat stones would be valued in the thousands.

DISINFECTANTS.— The following instructions for disinfection are intended especially for yellow fever districts, but are equally applicable in other classes of contagious diseases. No reliance can be placed on disinfectants simply because they smell of chlorine or carbolic acid, or possess the color of permanganate, and that, in general, proprietary disinfectants with high-sounding names are practically worthless, as they either have no value whatever or, if of value, cost many times as much as they are worth, and cannot be used in sufficient quantity. Explanations.—Disinfection is the destruction of the poisons of infectious and contagious diseases. Deodorizers, or substances which destroy smells, are not necessarily disinfectants, and disinfectants do not necessarily have an odor. Disinfection cannot compensate for want of cleanliness or of ventilation.—1. (*Disinfectants to be Employed.*) Roll sulphur, brimstone, for fumigation.—2. Sulphate of iron, copperas, dissolved in water in the proportion of 1½ lb. to the gal.; for soil, sewers, etc.—3. Sulphate of zinc and common salt, dissolved together in water in the proportions of 4 oz. sulphate and 2 oz. salt to the gal.; for clothing, bed linen, etc. Note.—Carbolic acid is not included in the above list for the following reasons: It is very difficult to determine the quality of the commercial article, and the purchaser can never be certain of securing it of proper strength, it is expensive, when of good quality, and experience has shown that it must be employed in comparatively large quantities to be of any use; it is liable by its strong odor to give a false sense of security.

DISINFECTANTS, How to Use.—1. (*In the Sick Room.*)—The most available are fresh air and cleanliness. The clothing, towels, bed linen, etc., should at once, on removal from the patient, be placed in a pail or tub of the zinc solution, boiling hot if possible, before removal from the room. All discharges should either be received in vessels containing copperas solution, or, when this is impracticable, should be immediately covered with copperas solution. All vessels used about the patient should be cleansed with the same solution. Unnecessary furniture—especially that which is stuffed—carpets, and hangings, when possible, should be removed from the room at the outset; otherwise, they should remain for subsequent fumigation and treatment.—2. Fumigation with sulphur is the only practicable method for disinfecting the house. For this purpose the rooms to be disinfected must be vacated. Heavy clothing, blankets, bedding, and other articles which cannot be treated with zinc solution, should be opened and exposed during fumigation, as directed below. Close the rooms as tightly as possible, place the sulphur in iron pans supported upon bricks, set it on fire by hot coals, or with the aid of a spoonful of alcohol, and allow the room to remain closed for twenty-four hours. For a room about ten feet square, at least two pounds of sulphur should be used; for larger rooms, proportionally increased quantities.—3. Premises, cellars, yards, stables, gutters, privies, cesspools, water closets, drains, sewers, etc., should be frequently and liberally treated with copperas solution. The copperas solution is easily prepared by hanging a basket containing about 60 lbs. of copperas in a barrel of water.—4. (*Body and Bed Clothing, etc.*) It is best to burn all articles which have been in contact with persons sick with contagious or infectious diseases. Articles too valuable to be destroyed should be treated as follows: *a.* Cotton, linen, flannels, blankets, etc., should be treated with the boiling hot zinc solution, introducing piece by piece, securing thorough wetting, and boiling for at least half an hour. *b.* Heavy woolen clothing, silks, furs, stuffed bed covers, beds, and other articles which cannot be treated with the zinc solution, should be hung in the room during fumigation, pockets being turned inside out, and the whole garment thoroughly exposed. Afterward they should be hung in the open air, beaten, and shaken. Pillows, beds, stuffed mattresses, upholstered furniture, etc., should be cut open, the contents spread out and thoroughly fumigated. Carpets are best fumigated on the floor, but should afterward be removed to the open air and thoroughly beaten.—5. The corpses should be thoroughly washed with a zinc solution of

double strength, then wrapped in a sheet wet with the zinc solution, and buried at once. Metallic, metal-lined, or air-tight coffins should be used when possible, certainly when the body is to be transported for any considerable distance.

DRAWINGS, To Fix.—1. Immerse the drawing in skimmed milk. A special fixative is sold for the purpose by dealers in art materials. Collodion, if very thin, might be used with advantage; often used for manuscripts.—2. Flow with very thin collodion.—3. 2 tablespoonfuls of rice boiled in 1 pt. or ½ pt. of water; strain, and pass the drawing quickly through the liquid; use a large flat dish for the liquid.—4. Prepare water starch, in the manner of the laundress, of such strength as to form a jelly when cold, and then apply with a broad camel hair brush, as in varnishing. The same may be done with thin cold isinglass water or size, or rice water.

DRINKING, Excessive, to Break off.—Anticipate the craving by supplying food in some acceptable form—a cup of hot cocoatine being an excellent substitute for, or addition to, more solid food; a cup of soup made from Liebig's extract is also useful in the same way. As an addition to food, and to supply the craving for bitter (experienced by drunken persons), an infusion of bark is said not only to afford that, but to create an actual distaste for alcohol in any form. The infusion of bark is made by pouring a pt. of boiling water upon an oz. of coarsely powdered bark, and allowing it to stand near the fire in a covered vessel for five or six hours; dose, a wineglassful two or three times a day. An infusion of quassia is also useful in the same way, made thus: Quassia chips, ¼ oz.; cold water a pt.; dose, the same as the infusion of bark. A teaspoonful or two of Malt extract may be added to either infusion if liked.

DUBBING, To Make.—Resin, 10 lb.; tallow, 5 lb.; train oil, 5 gal.

EARACHE, Cure for.—1. Wet a piece of cotton with equal parts of chloroform and laudanum, place in the ear, and cover up.—2. Put five drops of chloroform on a little cotton or wool in the bowl of a clay pipe, then blow the vapor through the stem into the aching ear.

EBONY, Artificial.—1. 60 parts of charcoal obtained from seaweeds previously treated with dilute sulphuric acid, and dried, and mixing it with 10 parts of liquid glue, 5 of gutta percha, and 2½ of India rubber, care having been taken to mix the two latter substances with coal oil tar to render them gelatinous, then 10 parts of coal tar, 5 of pulverized sulphur, 2 of powdered alum, and 5 of powdered resin are added, and the mixture heated to 300° F. After having been cooled a substance is obtained which is equal in many respects to genuine ebony wood, but is far less expensive, and capable of receiving a finer polish. It can only be prepared on a large scale.—2. The wood is immersed for 48 hours in a hot saturated solution of alum, and then brushed over several times with a logwood decoction prepared as follows: Boil 1 part best logwood with 10 parts of water, filter through linen and evaporate at a gentle heat until the volume is reduced one half. To every quart of this add from 10 to 15 drops of a saturated solution of indigo, completely neutral. After applying this dye to the wood, rub the latter with a saturated and filtered solution of verdigris in hot concentrated acetic acid, and repeat the operation until a black of the desired intensity is obtained.

EGGS, To Pack and Keep.—1. Dip the eggs into a solution of 2 oz. gum Arabic in a pint of cold water, let them dry and pack in powdered, well burned charcoal.—2. *Packing Liquid.* Lime, 1 bushel (shaked with water); common salt, 2 or 3 lb.; cream of tartar, ½ lb.; water, q. s. to form a mixture strong enough to float an egg. Used to preserve eggs, which it is said it will do for two years, by simply keeping them in it.—3. In the common "liming" process a tight barrel is half filled with cold water, into which is stirred shaked lime and salt in the proportion of about ½ lb. each for every pail or bucket of water. Some dealers use no salt, and others add a small quantity of niter—¼ lb. to the half barrel of pickle. Into this the eggs, which must be perfectly fresh and sound, are let down with a dish, when they settle to the bottom, small end down. The eggs displace the liquid, so that when the barrel is full of eggs it is also full of the pickle. Eggs thus pickled, if kept in a cool place, will ordinarily keep good for several months. Long storage in this liquid, however, is apt to make the shells brittle and impart a liny taste to their contents. This may be in a great measure avoided by anointing the egg all over with lard before putting in the pickle. Eggs thus prepared are said to keep perfectly for 6 months or more when stored in a cool cellar.—5. Melt 4 oz. clear beeswax in a porcelain dish over a gentle fire and stir in 8 oz. of olive oil. Let the resulting solution of wax in oil cool somewhat, then dip the fresh eggs one by one into it so as to coat every part of the shell. A momentary dip is sufficient, all excess of the mixture being wiped off with a cotton cloth. The oil is absorbed in the shell, the wax hermetically closing all the pores. It is claimed that eggs thus treated and packed away in powdered charcoal in a cool place have been found after two years as fresh and palatable as when newly laid.—6. Paraffine, which melts to a thin liquid at a temperature below the boiling of water, and has the advantage of being odorless, tasteless, harmless, and cheap, can be advantageously substituted for the wax and oil, and used in a similar manner. Thus coated and put into the lime pickle the eggs may be safely stored for many months; in charcoal, under favorable circumstances, for a year or more. 7.—Dry salt is frequently recommended as a good preservative packing for stored eggs, but practical experience has shown that salt alone is but little better than dry bran, especially if stored in a damp place or exposed to humid air. —8. A mixture of 8 measures of bran with 1 of powdered quicklime makes an excellent pack-

ing for eggs in transportation.—9. Water glass—silicate of soda—has recently been used in Germany for rendering the shells of eggs non-porous. A small quantity of the clear sirupy solution is smeared over the entire surface of the shell. On drying, a thin, hard, glassy film remains, which serves as an admirable protection and substitute for wax, oil, gums, etc. Eggs thus coated and stored in charcoal powder or a mixture of charcoal and bran would keep a very long time.—10. In storing eggs in charcoal the latter should be fresh and perfectly dry. If the eggs are not stored when perfectly fresh they will not keep under any circumstances. A broken egg stored with sound ones will sometimes endanger the whole lot. In packing, the small end of the egg should be placed downward; if in charcoal or other powder they must be packed so that the shell of one egg does not touch that of another, the interspaces being filled with the powder. Under all circumstances stored eggs should be kept in as cool a place as possible. Frequent change of temperature must also be avoided.

ELECTRIC BATTERIES, To Recharge.—This is sometimes exceedingly simple, but requires neatness and care. First, carefully disconnect the wires, observing closely exactly how they were attached and to what parts of the battery. Then rinse and clean out the carbon cup, the jar and the zinc. If the zinc is worn out, buy another from any electrical supply store. Replace all in the same position as before. Fill jar about half full of clear water; then take about six ounces of commercial sal ammoniac, which can be bought from any drug store, and place it in the jar; connect the wires again with care and neatness to exactly the same places as before, seeing that they do not touch anything but the points of attachment and that the attachments are not reversed from what they were before.

ENAMELLED CLOTH.—1. Cotton cloth of the best quality is used. The cloth is taken from a bale and wound upon a large cylinder preparatory to receiving its first coat. It is then passed between heavy iron rollers, from the top one of which it receives its first coating of composition, which consists of linseed oil, lampblack, resin, and a few other ingredients boiled together until they reach the consistency of melted tar. In many places the covering is spread by a knife under which the web passes. From between the cylinders it is carried to a drying frame, the shape of a reel, and subjected to a high temperature in the drying room, heated by steam pipes. After the drying process, the rough places are made smooth by rubbing with pumice stone and water. The cloth is then passed through the same operation as before; rolling, drying and rubbing, repeated from 3 to 5 times, or until required thickness has been laid. After the last scrubbing down, the fabric is taken to another department, varnished, and again passed through the heater. The cloth is next passed between heavy rollers, which cover its surface with regular indentations resembling the grain of leather, and it is then ready for market. It is used as a substitute for leather, in the covering of carriage tops, upholstering of furniture, covering of trunks and traveling bags, and in garments, etc., as a protection from water.—2. The art of enameling fabrics, as practiced in Paris seems to be a very simple matter. The enamel is prepared exactly as for copper and and the material usually chosen is a satinet or other colored tissue. This is treated with successive coats of India rubber, dissolved in benzine to the consistency of a syrup, until the cloth is water-proof. The enamel is next put on in a pattern by means of a much thicker solution of the rubber. The outer rim of enamel is cut away after the fashion of lace by hand or by a sharp punch. Another new material, said to be water-proof, is parchment cloth. This is understood to be prepared by taking cotton, linen or hemp tissue direct from the loom and without any finishing material in the yarn, and passing it through fine paper pulp. Then it is run between rolls and afterward immersed for 5 to 35 seconds in a mixture of 100 parts sulphuric acid to 16 parts of water. Afterward it is passed through lead-covered rolls, washed thoroughly and neutralized in dilute ammonia. After the alkaline bath it is washed once more and submitted to a high pressure between steel plates, being finally dried in a calender.

ENGRAVINGS, Old, to Clean.—1. Place them, one or two at a time, in a shallow dish, and pour water over them until they are completely soaked or saturated with it. Then carefully pour off the water, and pour on to the prints a solution of chloride of lime (1 part liquor calcis chloratæ to 39 parts of of water). As a general rule, the stains disappear as if by magic, but occasionally they are obstinate. When that is the case, pour on the spot pure liquor calcis chloratæ, and if that does not succeed add a little dilute nitro-muriatic acid. As soon as they are clean they must be carefully washed with successive portions of water until the whole of the chlorine is got rid of. They should then be placed in a very weak solution of isinglass or glue, and many collectors color this solution with coffee grounds, etc., to give a yellow tint to the print. They should be dried between folds of blotting paper, either in a press or under a heavy book, and finally ironed with an ordinary flat iron to restore the gloss, placing clean paper between the iron and the print. Grease stains are much more difficult. Benzine is best. Small grease spots may be removed by powdered French chalk being placed over them, a piece of clean blotting paper over the chalk, and a hot iron over that.—2. Instead of carbonate of soda, use the bicarbonate, in slight excess, for decomposing chloride of lime. The reaction is very violent, and Javelle water is easily separated from the precipitate produced. Old engravings, wood-cuts and all kinds of printed matter that have turned yellow are completely restored by being immersed in it only for one minute, without the least injury to the paper, if the precaution is taken to thoroughly wash the article in water containing a

little hyposulphite of soda. Undyed linen and cotton goods of all kinds, however soiled or dirty, are rendered snowy white in a very short time by merely placing them in the liquid mentioned. For the preparation of Javelle water, take 4 lbs. bicarbonate of soda, 1 lb. of chloride of lime; put the soda into a kettle over the fire, add 1 gallon of boiling water, let it boil from 10 to 15 minutes, then stir in the chloride of lime, avoiding lumps. When cold the liquid can be kept in a jug ready for use.

EUCHRE, Progressive.—A series of games of euchre played by three or more sets of four persons each. The table nearest the front door is said to be at the head of the row, and the corresponding one at the other end of the room is said to be at the foot. The players being thus seated four at a table, one of those at the head table strikes a bell, and the game begins. Everybody plays as fast as he or she can, and while each is striving to make as many points as possible before the bell is tapped, and is of the opinion that he holds enough trumps to gain the five tricks, you can play alone against your opponents. Should you gain them you are entitled to four points. The excitement is great until the sound of the bell announces that a couple at the head table have finished their game. Immediately all the other players stop playing, and the winners at each table change places and take the table next above them, the ultimate object being to get to the head table. The losing couple at the head table go down to the foot, and at every table the partners change, so that your partner in the previous round becomes your enemy in the round now beginning. The game continues in this way until the time previously chosen by the host or hostess has expired. This time is usually two hours or two hours and a half, when the final reckoning is taken, and the prizes are awarded. To the lady and gentleman who have won the most points a prize apiece is awarded, and this may be of any description or cost, although good taste seems to dictate that its pecuniary value be not large. To the lady and gentleman, on the other hand, who have lost the most while sitting at the lowest table, a mock prize apiece is awarded, consisting, say, of a cheap doll, fantastically dressed, or other ludicrous exponent of unsuccesssful effort.

EYES, Watery, Treatment of.—The eyes are tender, cannot bear a strong light, and there is an abundant secretion of tears. *Treatment:* If acute, that is, coming on suddenly and from some injury due to dust, etc., they should be bathed in—1. Warm water, 1 part; poppy decoction, 1 part. Chronic cases are best treated by astringents, as—2. Sulphate of zinc, 1½ gr.; water, 1 oz.—3. Alum, 2 gr.; water, 1 oz.—4. Sulphate of copper, 1½ gr.; water, 1 oz.—5. Nitrate of silver, 1 gr.; water, 1 oz.—6. Acetate of zinc, 1½ gr.; water, 1 oz.—7. Diacetate of lead, 11 gr.; water, 1 oz. The subsequent treatment of acute cases, after the inflammation has subsided, may be similar to that of the chronic. Rectified spirit, 1 part, and water, 8 parts, may be used as a lotion to chronic cases. (*Eye Waters*).—8. Distilled vinegar, 1 fl. oz.; distilled water, 9 fl. oz. Mix. In simple chronic ophthalmia, weak and blear eyes, etc.; also to remove minute particles of lime from the eyes. One-half fl. oz. of rectified spirit or 1 fl. oz. of good brandy is often added and improves it where there is laxness of the membranes.—9. Sulphate of zinc, 20 gr.; distilled water, ½ pt.; dissolve. An excellent astringent eye water, for chronic ophthalmia and in ordinary ophthalmia, as soon as the inflammatory symptoms subside; also in weak, lax, watery, irritable eyes. etc., If there be much pain and irritability, 5 or 6 grains of acetate of morphia (not hydrochlorate) or 2 fl. dr. of wine of opium may be added. —10. Alum (crushed small), 10 gr.; sulphate of zinc, 10 gr.; distilled water, ½ pt.; dissolve. Use, etc., as the last.—11. Acetate (sugar) of lead, 10 to 12 gr.; distilled vinegar, 1 teaspoonful; distilled water, ½ pt.; dissolve. Use, etc., as No. 9, particularly for children.

FEATHERS, To Bleach.—1. It is also possible to bleach the feathers in a bath of 1 part barium peroxide in 100 parts of water at 86° F. (30° C.) Leave forty-eight hours in this solution, wash, pass through weak acid bath, and wash.—2. Feathers may be bleached by exposure to the vapor of burning sulphur (sulphurous acid) in a moist atmosphere, but it is usually necessary to remove the oily matters from them before they can be satisfactorily so bleached. This may be accomplished by immersing them for a short time in good naphtha or benzine, rinsing in a second vessel of the same, and thoroughly drying by exposure to the air. This treatment does not injure the feathers.

FEET, Care of.—A person will never be in good health and never do his best work if his feet are constantly cold. Grave diseases of the throat and lungs are caused by cold feet alone, and these troubles are always aggravated by a frigid condition of the lower extremities. If proper footwear does not give relief, consult a physician, for the chances are the system is "run down" and radical measures are necessary. In nine cases out of ten, however, the foot covering is to blame, either because of its shape or its material. Save in warm weather and for low-cut shoes leather, as ordinarily prepared, has serious objections. It lacks two prime qualities—porosity and capacity for absorption —being in this respect too much like rubber. No foot can remain either comfortable or healthy if kept in a perpetual bath of its own emanations and excretions. Leather, especially that of the more porous varieties, may be tolerated for the outside, but for cold weather it should always be lined with woolen, cloth, or, better, with wool felt. In fact, for all cold climates and for winter wear in all climates where there is any winter, a footgear made from all-wool felt approaches the ideal. According to modern notions any illness in one part of the body may be occasioned by some irritating cause far removed from the seat of the trouble. Just how this is cannot always be clearly explained, but that such connection does sometimes exist is beyond dispute. In the matter

under discussion, if the nerves of the whole body are irritated by a tight shoe or the extreme coldness of the extremities makes extra demand upon the blood supply, there is neither nerve force nor blood enough left for other functions.

FEET, Lotion for.—1. Permanganate of potash, 15 parts; distilled water, 1,000 parts. The feet to be washed twice a day with the lotion. They are then to be carefully dried, and powdered either with potato starch or lycopodium. —2. (*Offensive.*) This condition is caused by excessive sweating of the feet, and the sweat, being confined, does not evaporate, and so decomposes. *Treatment:* The feet should be washed daily in cold water, and afterward rubbed thoroughly dry; the water may contain ½ oz. powdered alum to the quart. Also at least once daily; especially after exercise, lave the feet with a solution of chlorinated lime, or permanganate of potash, 80 gr.; water, 1 pt. Also before putting on the socks or stockings the feet should be thickly powdered, especially between the toes, with chlorinated lime, 1 part; prepared chalk, 1 part; starch powder, 1 part. The socks or stockings should be of thin flannel.

FERTILIZERS.—1. (*Huxtable.*) Crude potash, 28 lb.; common salt, 1 cwt; bone dust and gypsum, each 2 cwt.; wood ashes, 15 bu. For either corn, turnips or grass.—2. (*Johnstone.*) Sodium sulphate (dry), 11 lb.; wood ashes, 28 lb.; common salt, ¾ cwt.; crude ammonium sulphate, 1 cwt.; bone dust, 7 bu. As a substitute for guano.—3. (*Liquid.*) Dissolve 25 lb. guano in 5 gal. of water. For use add 2½ oz. of this solution to 5 gal. water.—4. Sheeps' dung, ½ peck to 15 gal. of water; sulphate of ammonia, ⅛ oz. to every gal.—5. (*From Soot.*) Save the soot that falls from the chimneys when the latter are cleaned. Twelve qt. soot to 1 hhd. water makes a good liquid manure, to be applied to the roots of plants.—6. To produce 50 bushels of corn more than the natural product to the acre, use nitrogen, 64 lb., in the form of sulphate of ammonia.—7. Potash, 77 lb., in the form of chloride of potash.—8. Phosphoric acid, 31 lb., in the form of muriate of superphosphates.—9. To grow 1 ton of hay to the acre more than the natural product, use nitrogen, 36 lb., in the form of sulphate of ammonia. —10. Potash, 31 lb., in the form of chloride of potash.—11. Phosphoric acid, 12 lb., in the form of superphosphate.—12. To produce 100 bushels of potatoes per acre and their usual proportion of tops more than the natural proportion of the land, and other quantities proportionally, use nitrogen, 21 lb., in the form of sulphate of ammonia.—13. Potash, 34 lb., in the form of sulphate of potash.—14. Phosphoric acid, 11 lb., in the form of superphosphate.— 15. To produce 25 bushels of oats and the usual proportion of straw per acre more than the natural product of the soil, and in proportion for other quantities, use nitrogen, 10 lb., in the form of sulphate of ammonia.—16. Potash, 31 lb., in the form of chloride of potash.—17. Phosphoric acid, 8 lb., in the form of superphosphate.—18. To produce 1,500 lb. of dried leaf tobacco with the usual proportion of stalk more than the natural yield per acre of land, use nitrogen, 149 lb., in the form of sulphate of ammonia.—19. Potash, 172 lb., in the form of sulphate of potash.—20. Phosphoric acid, 16 lb., in the form of superphosphate.—21. Lime, 160 lb., in the form of sulphate of lime (lime plaster). These mixtures should be sown over the land broadcast when the ground is well prepared, before planting, and not put in the hills, so that the roots may seek the food and not concentrate and thereby cause the plants to burn up.—22. (*Cheap, from Fish.*)—Pass fish refuse through mincing machine and expose in layers 3 in. deep in a kiln heated to 300° F. until properly dried.—23. (*Cotton, Vegetable and Orange.*) An orange fertilizer should have the following composition: ammonia, 3.25 pr. ct.; available phosphoric acid, 3.50 pr. ct.; potash, 14.50 pr. ct. Cotton fertilizer: ammonia, 2.50 pr. ct.; available phosphoric acid, 7.50 pr. ct.; potash, 4 pr. ct. The formula for the vegetable fertilizer varies with the kind of vegetable which is cultivated: Ammonia, 5 pr. ct. to 7 pr. ct.; available phosphoric acid, 6 pr. ct.; potash, 8 pr. ct. to 12 pr. ct.—24. A cheap fertilizer consists of sulphate of ammonia, 60 lb; nitrate of soda, 40 lb.; ground bone, 250 lb.; plaster, 250 lb.; salt, ½ bu.; wood ashes, 3 bu.; stable manure, 20 bu. Apply the above amount to six acres. Labor in preparing included, it costs about $15. It is said to give as good results as most of the commercial fertilizers costing $50 per ton.—25. (*Fertilizing Powder.*) Bone dust, 9 parts (very fine); plaster Paris, ½ part; sulphate ammonia, ½ part. Steep the seed in the drainings of a dunghill; drain, but while still wet, sprinkle with the powder and dry.—26. One of the very best fertilizers is composed of lime and salt water. Wherever it has been used it has been found superior to almost any fertilizer on the market, and the preparation is very simple. Slack the lime to a thin plaster with a strong solution of salt in water. The muriate of lime is one of the hydroscopic or water absorbing substances known among chemists as reagents, and when it exists in the soil the warmth of the sun, especially during a dry summer, has much less influence. In countries subject to drouth this treatment of the soil is invaluable; and there are very few places to which it is not adapted. Salt is a good fertilizer in itself, as is lime, and the combination is superior to anything else that can be used, and is cheaper than almost anything else that can be bought for the purpose.

FIRE EXTINGUISHERS.—1. (*Vienna Fire Extinguishing Agent.*) A solution of 5 parts ferrous sulphate (copperas); 20 parts ammonium sulphate; 125 parts water.—2. Alum, 24 pr. ct.; ammonium sulphate, 52 pr. ct.; ferrous sulphate, 4 pr. ct.—3. Boric acid, 16 parts, by weight; alum, 24 parts; ferrous sulphate, 20 parts: dissolve in 160 parts of water. The solution is slowly poured into a cold solution of sodium hyposulphite 24 parts by weight; water glass, 40 parts; water, 640 parts.—4. (*Johnstone's.*) Make a mixture of equal parts

of pyrolusite (manganese dioxide); potassium chlorate; potassium nitrate. Moisten with water glass and press into a block. Place the block in a pasteboard box. Several boxes connected by fuses, are suspended from the ceiling of a room.—5. (*Bucher's.*) 59 parts saltpeter; 36 parts of sulphur: 4 parts of charcoal; 1 part of oxide of iron.—6. One of the best solutions for the extinction of incipient fires consists of crude calcium chloride 20 parts; salt 5 parts; dissolved in water, 75 parts. Keep at hand and apply with a hand pump. —7. (*Hand Grenades.*) Fill thin, spherical bottles of blue glass with a solution of calcinm chloride, salammoniac or borax.—8. Take 20 lbs. of common salt and 10 lbs of sal ammoniac (muriate of ammonia) and dissolve in 7 gal. of water. When dissolved it can be bottled and kept in each room in the house, to be used in an emergency. In case of a fire occurring, one or two bottles should be immediately thrown with force into the burning place so as to break them; the fire will certainly be extinguished.—9. Flour is an excellent thing to extinguish the flames of burning gasoline. Sprinkle it on the burning oil and the fire will immediately go out.

FLAVORINGS, Fruit.—Among the juicy fruits are strawberries, raspberries, blackberries, cherries and currants; among non-juicy fruits are the apples, pears, peaches, quinces, apricots, and plums. Mash the juicy fruits in a basin to a pulp. Place on the fire and make scalding hot. Now pour into a hair sieve and allow the juice to strain through. Put into bottles and securely tie down. Place these bottles in a caldren of cold water and boil for twenty minutes. Remove from the fire and allow to remain in the caldron until cold. Then set away for use. In the case of non-juicy fruits, such as apples, pears, peaches, etc., put the fruit into a basin. Cover with water and boil to a pulp. Now place on a hair sieve and allow to drain without any pressing. Observe now that it is only the liquor which passes through the sieve without pressing which is to be used for flavoring purposes. What remains in the form of pulp is not adapted for these uses. Now put the juice obtained as above into bottles, and proceed to treat as already laid down for the juicy fruits. The foregoing processes are to be gone through with in the case where the extracts are to be kept transparent and clear, as for sirups, cordials and beverages. In case the flavorings are to be used for any purpose where transparency or clearness is not desirable, such as for ice creams, fruit ices, or bonbons, then use not only the clear fluid, but the pulp of the fruit also. Save and utilize everything of the fruit except the skins and seeds. This pulp is to be treated as already laid down. As thus obtained and preserved our confectioners can supply themselves with a quantity of perfectly pure extracts of all their favorite fruits, and which can always be at hand, for flavoring every description of pastry, cakes, pies, tarts, puddings, creams, ices and beverages, and at any season of the year. Especially when there is any one in the house who is sick or feverish, cordials may be flavored with these delightful sub-acids—these remedies and restoratives of kind mother Nature herself—such as will shoot through all the veins of the most debilitated and infirm the most delicious sensations of happiness and hope.

FLIES, To Destroy.— 1. ½ teaspoonful of black pepper, finely ground, should be mixed with double the quantity of brown sugar, and the compound to be moistened with cream. The flies will generally eat greedily of this mixture if placed where they can easily reach it, but it will be their last meal, for the least taste of it is to a fly rank poison. If watched they will often be seen to drop dead within a few feet of the plate which they have just left, and some of the healthiest eaters do not live to leave the plate.— 2. Pour a little simple oxymel (an article to be obtained at the druggists) into a common tumbler glass, and place in the glass a piece of cap paper, made into the shape of the upper part of a funnel, with a hole at the bottom to admit the flies. Attracted by the smell, they readily enter the trap in swarms, and by the thousands soon collected prove that they have not the wit or the disposition to return.

FLOOR DRESSINGS AND CARE.—1. A good dressing for the diming-room, hall or kitchen floor is the following; it dries hard, glossy, and will not scratch: 1 pint of good coach varnish, 1 pint of boiled oil, ½ pint of turpentine; mix.— 2. (*Waxing Hard Wood.*) Take 1 lb. of the best beeswax, cut it up into very small pieces, and let it thoroughly dissolve in 3 pt. of turpentine, stirring occasionally if necessary. The mixture should be only a trifle thicker than the clear turpentine. Apply it with a rag to the surface of the floor, which should be smooth and perfectly clean. This is the difficult part of the work, for if you put on either too much or too little, a good polish will be impossible. The right amount varies, less being required for hard, close grained wood, and more if the wood is soft and open grained. Even professional waxers are sometimes obliged to experiment, and novices should always try a square foot or two first. Put on what you think will be enough, and leave the place untouched and unstepped on for twenty-four hours, or longer if needful. When it is thoroughly dry, rub it with a hard brush until it shines. If it polishes well, repeat the process over the entire floor. If it does not, remove the wax with fine sandpaper and try again, using more or less than before, as may be necessary, and continue your experimenting until you secure the desired result. If the mixture is slow in drying, add a little of the common driers sold by paint dealers, japan, for instance, in the proportion of 1 part of the drier to 6 parts of turpentine. When the floor is a large one, you may vary the tedious work of polishing by strapping a brush to each foot and skating over it.—3. Linseed oil, 100 parts; litharge, 10 parts; the best yellow wax, 75 parts; tallow, 7 parts; molasses, 90 parts; lampblack, 50 parts; oil of turpentine, 140 parts; alcohol, 17 parts; shellac, 2½ parts; aniline vio-

let, 1 part. Boil the litharge for an hour with linseed oil, then add the melted wax and tallow and the molasses. Heat the whole to a temperature of 230° F. over a water bath until all the water has evaporated; then add the coloring matter.

FLOUR, Self-Raising.—The following are the compositions of several of these powders in extensive use:—1. Bicarbonate soda, 23 oz.; burnt alum, 19 oz.; starch, 57 oz.—2. Bicarbonate soda, 24½ oz.; sesquicarbonate soda, 2½ oz; starch, 47 oz.; burnt alum, 26½ oz.—3. Bicarbonate soda, 31 oz.; burnt alum, 29½ oz.; starch, 39 oz.

FREEZING PIPES.—1. (*To Prevent.*) Glycerine is one of those substances that always seem to be lending themselves to new and unsuspected applications. It is found that the freezing of water in the pipes of hydraulic machinery—a very serious source of trouble in the winter months—is entirely prevented by the simple expedient of mixing a small percentage of glycerine with the water in the pumps. This precaution is now taken in the operation of the hydraulic jacks on all the ships of the English navy.—2. (*To Open.*) Directly it begins to freeze there is a demand on plumbers to open frozen pipes. It is strange that in nineteen cases out of twenty it is the escape pipe from the sink, and not the supply pipe, that freezes, although the latter is always full of water. Pipes indoors seldom freeze, and more than half the time the escape pipe is blocked with rubbish. The bend is generally half full of fragments which have been forced through the trap holes. Then, when it gets very cold the greasy water that is poured down settles quickly, and the whole becomes a congealed mass, which is only tightened by attempts to force water through it. Boiling water, in which as much sal soda as it will take has been dissolved, should be poured down, or if the pipe is full of cold water the next best thing is to get as much soda into it as possible. This will soften the mass below and make it as soluble as soap, and in a few hours all will pass away. This beats trying to thaw out a lead pipe with a red-hot poker, which process is equivalent to killing a man to avoid hurting him. A lead pipe will melt under such circumstances before enough heat can be got through it to dissolve ice if there is any there.

FROZEN PUDDING.—Any rich ice-cream highly flavored with wine, brandy, Jamaica rum, or maraschino, and made quite thick with a variety of fruits, nuts, etc., and served with a cold, rich sauce, may be called a "frozen pudding." Sometimes the cream is moulded in cake-lined moulds, or served in a hollow loaf of cake (a cake with the inside cut out, leaving an inch thickness of crust on the bottom and sides) and ornamented with whipped cream. Follow the receipt for ice-cream with gelatine. While the cream is cooling prepare the fruit and nuts, and make the sauce. Use 1 lb. of assorted French fruit; or 1 pt. of brandy peaches; or 1 lb. of mixed raisins, currants, and citron; use figs and dates if you like, or use half fruit and half nuts, almonds, walnuts, or pistachios; or use half fruit and half crumbs of macaroons, dry cake, etc. French fruit should be cut fine and softened by soaking in hot syrup. Canned fruit should be drained and sprinkled with sugar. Dried fruit should be washed, picked over, stoned or seeded, and cut fine. Raisins should be steeped in boiling water, enough to cover, till swollen and tender, then drained, seeded, and cut in quarters. Citron should be shaved in small, thin slices, and if very hard, steeped before cutting. Mix half the fruit and nuts with the frozen cream. Butter a melon mould slightly and line it with lady fingers or thin sponge cake. Fit it in tightly, then sprinkle a layer of mixed fruit over the cake. Pack the frozen cream in nearly to the top, then the remainder of the fruit, and cover with cake. Cover closely and bind a strip of buttered cloth round the edge of the cover, or cover the edge thick with butter. Pack in ice and salt for one or two hours. When ready to serve dip quickly into warm water and turn out carefully and serve with a sauce.

FRUIT, To Crystallize.—Make a syrup of 1 lb. of sugar and ½ pt. of water, stir until the sugar is dissolved, then boil quickly about three or four minutes. Try by dipping a little in cold water. If it forms a small ball when rolled between the thumb and finger it has attained the desired degree, known as the ball. Throw the fruit to be conserved a little at a time into this syrup, let it simmer for a moment, lift with a skimmer, draining free from all syrup. Sprinkle sugar thickly over boards or tin pans, place the fruit over it in a single layer, sprinkle over thickly with granulated sugar and place in the oven or sun to dry. When dry, make a syrup as before, and just before it reaches the ball degree add the fruit, stir with a wooden spoon until it begins to grain and sticks to the fruit. When cold, sift off the sugar and put out again to dry. When dry, place in boxes in layers between sheets of waxed paper. Keep in a cool, dry place.

FRUITS, Frozen.—1. (*Apricots.*) Cut one can of apricots into small pieces, add 1 pt. of sugar and 1 qt. of water. When the sugar is dissolved, freeze. When it begins to harden, add 1 pt. of whipped cream, measured after whipping. This is delicious without the cream. Peaches, pine-apples, cherries, and strawberries are delicious when frozen. Vary the amount of sugar as the fruit requires. These differ from the sherbets in that the fruit is cut in small pieces and not sifted. They may be made with equal parts of fruit and water, with sugar to taste, and a little cream, or not, as you please.—2. (*Tutti Frutti.*) This form of ice should always have a mixture of fruits, as its name implies. It is usually made by mixing fruits with sherbets or water ices. But some confectioners serve a mixture of cream ices and fruits as "Tutti Frutti," and others arrange layers of cream ices and water ices, each having fruit in them, and serve it under the same name. *a.* To one quart of water ice allow ½ lb. of any firm canned fruit, carefully drained

from the syrup, cut into dice, and sprinkled with powdered sugar. Make either of the receipts for water ice, and when frozen mix the prepared fruit with it and let it stand till firm enough to serve. Or use ½ lb. of assorted French fruit, cut fine and soaked till soft in ½ cup each of sugar and water made boiling hot. Or use half fruit and half nuts, almonds, walnuts, or pistachios. Chop the nuts fine, and soak them with the fruit in the hot syrup. Drain them before using. *b.* Make either 1 qt. of lemon ice and one of raspberry or grape sherbet, or make one of orange and one of pineapple. Line a two-quart melon mould with part of one kind of sherbet, and mix the fruit and nuts with the other variety. Pack this in the center of the mould and cover with the remaining sherbet. Keep the mould in salt and ice until wanted. *c.* Make 1 qt. of ice-cream after either receipt, and flavor with lemon, wine, maraschino, or pine-apple. When partly frozen, add 1 lb. of French fruit. Use a mixture of cherries, plums, apricots, pears, strawberries, angelica, Canton ginger, Chinese oranges, etc., or use figs, dates, raisins, currants, and citron.

FUEL.—1. (*Patent.*) This cement used for the agglomeration of coal dust and the manufacture of patent fuel, consists of coal tar, gluten and starch. The quantities of these substances vary according to the quality and property of coal dust. About 2 pr. ct. of this mixture (say containing 2½ parts tar, 1 part gluten, ½ part starch) would be suitable for coal dust of an average quality of bituminous coal.—2. (*Solid Petroleum.*) Fuel bricks of crude petroleum are extensively used in the Italian navy, and are made as follows: The mixture, which is made in the proportion of 1¾ pints of petroleum, 10 per cent of rosin, 5½ ounces of powdered soap and 11½ ounces of caustic soda, is heated and stirred at the same time. Solidification begins in about ten minutes, and the operation must then be carefully watched. If there is a tendency to remain liquid a little more soda is added. After the mixture has been stirred until the mass becomes nearly solid, the thick paste is poured into the molds, which are placed for ten or fifteen minutes in a drying-stove. The briquettes, which are of the same size and form as those largely used in France and Germany, are then cooled, and are ready for use in a few hours. The addition of 20 per cent of wood sawdust and 20 per cent of clay or sand makes the briquettes both cheaper and more solid. In trials made at Marseilles on several tug boats the petroleum briquettes furnished about three times as much heat as coal briquettes of the same size. They were burned in the ordinary boiler furnace, without any special preparation, gave out very little smoke, and left little or no ash. The advantages claimed for the petroleum briquettes are absence of smoke and a large reduction in bulk of fuel which must be carried, as compared with coal, while the risks attending the carrying of liquid fuel are avoided.

FURNITURE, Bruises in, to Remove. — Wet the part with warm water, double a piece of brown paper five or six times, soak it and lay it on the place; apply on that a hot flatiron till the moisture is evaporated. If the bruise be not gone, repeat the process. After two or three applications, the dent or bruise will be raised level with the surface. If the bruise be small, merely soak it with warm water, and apply a red hot poker very near the surface; keep it continually wet, and in a few minutes the bruise will disappear.

GILDING, Tarnished, to Improve.—Heavy tarnished gilding may be improved by going over the work with strong parchment-size and gold powder, touching bare spots, or by painting the frame entirely over with enamel color. The darkened gilding was covered with a thick coat of white paint, which relieved the eye. Gilding and mirrors sometimes are too much for the nerves taken together with the gay colors of modern drawing rooms.

GLASS, To Cut.—1. Glaziers use for cutting glass a diamond splinter mounted in a holder. —2. To cut glass vessels in a neat manner, heat a rod of iron to redness, and having filled the vessel, the exact height you wish it to be cut, with oil of any kind, gradually dip the red hot iron into the oil, which, heating along the surface, the glass chips and cracks right round, when you can lift off the upper portion clean. —3. A good plan for cutting glass is to use a piece of iron, heated to redness, an angle or corner of which is to be applied to the tube at the point where it is to be cut, and then, if the fracture is not at once effected, plunge suddenly into cold water.—4. After having made a notch with a file or the edge of a flint, introduce into it a very little water, and bring close upon it the point of a wire, previously heated to the melting point. This application of heat and moisture obliges the notch to fly round the glass.—5. For tubes of great diameter, employ a fine iron wire stretched into a bow; or, the glass cutter's wheel; with either of these, assisted by a mixture of emery and water, cut a circular trace round a large tube, and then divide it.—6. Glass may be easily cut with scissors by keeping it level in the water while the scissors are being dextrously applied; to avoid risk, begin the cutting by taking off small pieces at the corners and along the edges, and so reduce the shape to that required, as, if any attempt is made to cut the glass all at once to the shape, it will most likely break just where it is not wanted. Some kinds of glass would cut much better than others, the softer glass being the best for this purpose. The scissors need not be at all sharp, as their action does not appear to depend on the state of the edge presented to the glass. When the operation goes on well the glass breaks away from the scissors in small pieces in a straight line with the blades. This method has often been of service when a diamond has not been at hand, for cutting ovals and segments, and though the edges are not so smooth as might be desired, yet it will answer in a great many cases.—7. (*Bottles.*) Turn the bottle as evenly as possible over a low gaslight flame for about 10

minutes; then hold in water, and the sudden cooling will cause a regular crack to encircle the side of the heated place, allowing the portions to be easily separated.

GLASS, To Drill.—1. Take a common drill, run a little fast; do not press; the weight of the drill press is enough; drill from both sides, keeping the glass and drill wet with turpentine; be careful when the 2 holes meet not to let the drill catch. After a hole is made large enough for a small round file, file to the desired size, keeping file and glass wet with turpentine.—2. Stick a piece of putty on the part where you wish to make the hole. Make a hole in the putty the size you want, the hole reaching to the glass; into this pour a little molten lead, when, unless very thick glass, the piece will drop out.—3. In drilling glass and porcelain, or to cut them after a design, there are difficulties which lead to failure. Some adopt this plan: Discs of soft metal 5.5 to 9.8 inches in diameter are covered with diamond dust. These discs are mounted on arbors which revole at a high rate of speed. Glass or porcelain can be cut by the discs in a few seconds after any design. Cylinders constructed on the same principle drill holes in hard substanees quickly. The instruments do a great deal of work without showing any deterioration.

GLASS, Frosted, with Figures.—For the production of such, glass crystal or finished glass, no matter whether hollow or plate, is taken, the surface of which must be frosted. Upon this surface a thick, watery solution of ordinary glue is spread. In the case of plate glass it is advisable to spread this coat about 1-6 inch thick and as uniformly as possible. It is then dried at a moderate temperature of about 31-37° C. After perfect drying the glue coat contracts and becomes cracked. The edges of these cracks turn upward and the scales of glue formed thereby show the desire to peel off. The glue having entered the pores of the frosted glass surface, the glue scales, in peeling off, carry small splinters of the frosted glass surface with them, whereby bright, shining, shell-like indentations are formed. The peeling off of the glue and the tearing off of the glass splinters connected with it takes place irregularly, sometimes in closely adjoining, longer stripes, sending out broader or narrower leaf-like branches, which form a pattern similar to fern, as is seen in the ice on a window pane. The best results of this working method are obtained in the summer, when the glass articles treated with the glue are simply exposed to the rays of the sun, which cause the glue coat to peel off within three or four hours. The glue scales can be collected and dissolved by boiling in water. The glass splinters sink to the bottom, while the upper, pure solution of glue is poured off and used again.

GLASS, Soluble.—1. Silica, 1 part; carbonate of soda, 2 parts; fuse together.—2. Carbonate of soda (dry), 54 parts; dry carbonate of potassa, 70 parts; silica, 192 parts; soluble in boiling water, yielding a fine, transparent semi-elastic varnish.—3. Carbonate of potassa (dry), 10 parts; powdered quartz (or sand free from iron or alumina), 15 parts; charcoal, 1 part; all fused together. Soluble in five or six times its weight boiling water. The filtered solution, evaporated to dryness, yields a transparent glass, permanent in the air.—Melt 1½ lbs. white sand, free from alumina and carbonate of lime; 1 lb. carbonate of potash, containing a small proportion chloride of potassium, and 1-10 lb. powdered charcoal. Mix well, and melt in a large crucible until homogenous.

GLAZING.—Sashes are primed before glazing; the glass laid in with the crown or convex side out; the tins driven in with a glazing hammer; four tins to each glass on the long sides, ¼ distance from the corners. If tins are put in the centre, they are apt to break the glass, especially in cold weather. In good work and medium sized glass, after glazing, and putty being well set, fill spaces on the inside. Use putty soft, or it will press the glass out. Bedding, for superior work and large glass, is the best. Glaze the rabbet with soft putty, and press the glass down into it close, pressing on the edges only; then glaze as usual. Where the molding of the sash is to go outside, the crown side of the glass should be out. The line of the putty should come even with the line of the molding on the other side of the glass.

GLUES.—1. (*Insoluble.*) In order to render glue insoluble in water, even hot water, it is only necessary, when dissolving glue for use, to add a little potassium bichromate to the water and expose the glued part to the light. The proportion of bichromate will vary with circumstances; but for most purposes, about 1-50 the amount of glue will suffice.—2. (*Liquid.*) Break a good quality of glue into bits, put into a bottle and cover with whisky. Let stand three or four days, when it will be ready for use without the trouble of heating. The bottle must be kept tightly corked to prevent evaporation.—3. Dissolve in 100 kilogrammes of water, 60 kilogrammes of borax; add to the solution when boiling 4 kilogrammes of 90 per cent. calcined potash, and then add this mixture while boiling to 1450 kilogrammes of hot glue liquor having a density of 12° Baume.—4. With any desired quantity of glue use ordinary whisky instead of water. Break the glue in small fragments and introduce these into a suitable glass vessel, and pour the whisky over them. Cork tightly, and set aside for three or four days, when it will be ready for use. The whisky must not be too strong, and a little heat is generally required.—5. (*For Mending Wood.*) White wood carvings are best mended with glass glue. Walnut is best mended with dark glue; any chipped places filled with putty, which is then stained to a proper depth with raw linseed oil mixed with vandyke brown, burnt sienna or burnt umber. This takes weeks to dry, and the carving should be protected from dust.—6. (*For Leather to Cardboard.*) To attach leather to cardboard dissolve good glue (softened by swelling in water) with a little turpentine and a sufficiency of water in an ordinary glue pot,

and then having made a thick paste with starch in the proportion of two parts, by weight, of starch powder for every 1 part, by weight, of dry glue, mix the compounds and allow the mixture to become cold before application to the cardboard.—7. (*Spalding's.*) To 1 lb. of common glue put 3 pts. of water; soak for 10 hours; melt; then pour in 1 qt. of crude wood naptha, and 3 oz. of unrefined glycerine; mix thoroughly. The above is for wood, binding, and heavy purposes. For paste add to the above 1 gal. of the naptha and 2 gals. of water. The above is based on 1 lb. of glue.

GOLD. Substitute for.—It is produced by alloying 94 parts of copper with 6 parts of antimony, the copper being first melted and the antimony afterward added. To this a quantity of magnesium carbonate is added to increase its specific gravity. The alloy is capable of being drawn out, wrought and soldered just as gold is, and is said to take and retain as fine a polish as gold. Its cost is a shilling a pound.

GREASE SPOTS, In Cloth, to Remove.—Grease spots in cloth may be taken out by applying a solution of salt in alcohol.

GUM, Artificial.—10 kilogrammes linseed are boiled in 80 kilogrammes sulphuric acid and 100 litres of of water for three or four hours. The liquid is then filtered, and four times its volume of alcohol is added. The precipitate is collected, washed and dried. The product is amorphous, colorless, insipid, and gives, with water, a thick mucilage.

HAIR.—1. (*To Bleach.*) A recipe stated to bleach human hair white instead of blond or yellow. Mix 1 lb. hydrogen peroxide with 1 oz. ammonia; mix 4 oz. hydrogen peroxide with 1 oz. cream of tartar dissolved in 1 oz. soda. Blend the two solutions and steep 1 lb. of the hair in it for three hours. Then wash in clean water with "soapine," in a bath of pottery or clay, and thoroughly dry. Repeat the process fifteen or sixteen times, but thoroughly mix and shake up the hair after the twelfth and every succeeding time. Finally draw the hair through a solution of blue aniline and alcohol.—2. A hot dilute solution of nitric acid is most effectual. Brown hair, when carefully treated, is turned the most brilliant golden, resembling golden spun glass. The method employed is to put the hair in a porcelain dish with dilute NO_2HO (about 1 part strong acid to 10 of water), then gradually heat, and soon as the required shade is obtained, take out and wash. If the acid is too strong, or the heat too great, the fiber of the hair is spoiled. Dark brown hair acquires generally a reddish color, and black hair will turn nearly white.—3. (*To Curl.*) Olive oil, 1 lb.; oil of origanum, 1 drm.; oil of rosemary, 1½ dr.—4. (*Bandoline.*) Iceland or Irish moss boiled in water, strained and perfumed.—5. Boil in 2 lb of water until it is reduced one-half, 1 teaspoonful quince seed, 2 tablespoonfuls flaxseed, a pinch white mustard seed. Perfume with oil of almonds.—6. Two tablespoonfuls flaxseed, 3½ pt. water. Boil 5 minutes.—7. Heat 3 oz. isinglass in 2 lb. water, until dissolved. Add 4 oz. alcohol. Perfume with oil of almonds.—7. Put 2 parts powdered gum tragacanth in 60 parts rose water. Digest for three days. Strain and perfume with essential oil of rose.—9. (*Beard Promoter.*) Croton oil 12 drops; sweet oil of almonds, ½ oz. troy. Mix and rub on skin twice a day. If too irritating, double the amount of sweet almond oil. It is poisonous.—10. (*Eau de Quinine.*) A favorite hair wash that is much used in Berlin and Liepzig contains 2 grm. balsam of Peru; 6 grm. castor oil; 60 grm. rum; 35 grm. water; 5 grm. tincture of red chinchona. Its constituents are at least harmless, which can be said of but few of our American preparations for the hair.—11. (*Quinine Hair Tonic.*) Quinine sulphate, 20 gr.; tincture of cantharides, 2 fl. dr.; fld. ext. of jaborandi, 2 fl. dr.; alcohol, 2 fl. oz.; glycerine, 2 fl. oz.; bay rum, 6 fl. oz.; rose water—enough to make 15 fl. oz.

HAIRBALLS, In Horses.—Prof. T. V. Colville, botanist in the Department of Agriculture at Washington, has rendered good service to practical botany by examining the hairballs found in the intestines of some dead horses, in cases where the death was supposed to be from feeding on crimson clover, Trifolium incarnatum. He finds the mass forming the balls is made up of hairs, which, under a microscope are exactly like the hair found on the calices of mature crimson clover. He concludes that the death does occur from this cause, as the owners of the horses believe. The whole subject is interesting and deserves further investigation. These balls, occasionally found in the stomach and bowels of horses, have hitherto been regarded as coming from horses licking themselves. The balls are supposed to be made up of their own hair. But as they do not take this hair all at once, it is not clear how it takes on the perfectly globular form, often several inches in diameter. Prof. Coville notes that some of these balls have been found to be composed of the beards or awns of grain. Careful records of this do not appear in usual works of reference. As these are extremely brittle, it would seem difficult to have them wound into balls. In like manner, it seems difficult to understand why a plant hair should not be as dissolvable by the gastric juice as well as a piece of straw, or the chaff of the grain on which the awns grow. But Prof. Coville reports three balls in the bowels, that must have been a long time previously being formed in the stomach. A remarkable feature of the case is that all the hairs are said to be so arranged in the ball that the larger ends are directed toward the center of the ball. As some of these balls, if made of plant hairs in this way, must have been weeks, if not months in the construction of a ball, 3 or 4 inches in diameter, and which is described as almost as solid as wood, the attendant phenomena seem so little in accord with the general knowledge of things which should have some connection therewith, that there seems a wide field yet left for original discovery.

HAMS, To Cure.—1. Few persons understand the proper ingredients and exact proportions

to make a suitable pickle for curing hams. This information will doubtless prove of value. The desideratum is to cure the meat so that it will keep in hot weather, with the use of as little salt as possible. Pickle made in the following manner, it is believed, will accomplish this: 1¾ lb. salt—coarse or alum salt is best; ½ oz. saltpeter; 1 pt. molasses or 1 lb. brown sugar; 1 teaspoonful saleratus; let these be added to 1 gal. of water, and the amount increased in the same proportions to make the quantity required. Bring the liquor to a boil, taking care to skim just before it begins to boil. Let the pickle cool, and pour it over the meat until entirely covered. The meat should be packed in clean, tight casks, and should remain in the pickle six or seven weeks, when it will be fit to smoke. Green hickory wood is the best article for this purpose. Shoulders prepared in the same way are nearly as good as hams. This pickle is just the thing to make nice corned beef, or corned beef tongues; or any lean meat for drying.—2. To 1 gal. water, take 1½ lb. salt; ½ lb. sugar; ½ oz. saltpeter; ½ oz. potash. In this ratio the pickle can be increased to any quantity desired. Let these be boiled together until all the dirt from the sugar rises to the top, and is skimmed off. Then throw it into a tub to cool, and when cold, pour it over your beef or pork, to remain the usual time—say four or five weeks. The meat must be well covered with pickle, and should not be put down for at least two days after the killing, during which time it should be slightly sprinkled with powdered saltpeter, which removes all the surface blood, etc., leaving the meat fresh and clean. Some omit boiling the pickle, and find it to answer well, though the operation of boiling purifies the pickle by throwing off the dirt always to be found in salt and sugar.—3. Take a large cask (if possible one between 100 and 120 gal.), and after covering the bottom with salt, lay in a ham with the skin side to the bottom, then sprinkle another layer of salt, put in another ham, etc., till the cask is full. A fluid is then made of the proportions of 3 gals. water; 4½ lb. salt; 2 lb. brown sugar; 1½ oz. saltpeter; 1 oz. saleratus. When this is skimmed, scalded, and has gotten cold, it is poured over the hams until it covers them entirely. They should remain in this pickle for from thirteen to fourteen weeks.

HARNESS DRESSING. — The government harness dressing is as follows: One gal. neatsfoot oil; 2 lb. Bayberry tallow; 2 lb. beeswax; 2 lb. beef tallow. Put the above in a pan over a moderate fire. When thoroughly dissolved add 2 qt. castor oil; then, while on the fire, stir in one oz. lampblack. Mix well and strain through a fine cloth to remove sediment, let cool, and you have as fine a dressing for harness or leather of any kind as can be had.

HATS, To Bleach.—To bleach Panama hats, wash the goods clean, and while slightly damp, expose to the fumes of burning sulphur in a closed vessel. To color one dozen hats, take 12 lb. logwood; 1 lb. sulphate of iron; and ¾ lb. verdigris. Digest the logwood for some time. Add the sulphate of iron and the verdigris. Dip the hats into the bath several times and hang in the open air. By the peroxidizement of the iron with the atmospheric oxygen the hats will be more completely blackened. When fully dried wash in running water.

HAT, Silk, to Restore Gloss to.—When a silk hat becomes wet, or from other causes has lost its smoothness and gloss, cleanse it carefully from all dust, then with a silk-handkerchief apply petrolatum evenly, and smooth down with the same handkerchief until it is dry, smooth and glossy. This will make a silk hat look as good as new.

HEADACHE, Causes and Cure of.—1. The ordinary headache which is so extremely common among the inhabitants of our Atlantic seaboard towns is the outcome of conditions affecting the nerves through impoverished blood containing poisonous matter absorbed from badly digested food. So-called liver torpidity and the catarrhal affections due to our changeable climate also aid in effecting its spread. Nervous exhaustion, due to irregular and fast living, plays an important part in its causation. Nervous strain, especially of the eyes, and inflamed tissues about the internal bones of the nose are special causes. Nerve irritation, which is but poorly understood by the general reader, is a prolific cause of so-called nervous headache. There is no more dangerous practice than to treat headache pain blindly with drugs. Of course, outdoor exercise is the best possible thing for permanent cure. It is very easy to relieve most forms of headache by means of the coal tar derivatives, of which so many are in the drug market. These form the basis of the many headache cures found on the druggist's shelves. Their use is not entirely without danger, for they are powerful heart depressants if taken in doses of any considerable size. A hot bath, a stroll in the fresh air, shampooing the head in weak soda water, or a timely nap in a cool, quiet room will sometimes stop a nervous headache. When overfatigued from shopping or sightseeing a sponge dipped in very hot water and pressed repeatedly over the back of the neck between the ears will be found exceedingly refreshing, especially if the face and temples are afterward subjected to the same treatment. Neuralgia is caused, not only by cold air, but by acidity of the stomach, starved nerves, imperfect teeth, or by indolence combined with a too generous diet. Heat is the best and quickest cure for this distressing pain. A hot flatiron, passed rapidly and deftly over several folds of flannel laid on the affected spot, will often give relief in less than ten minutes, without the aid of medicine. Hot fomentations are of equal value; though when the skin is very tender it is more advisable to use dry heat, nothing being better for the purpose than bags of heated salt, flour or sand, which retain warmth for a long time. Cold water, applied by the finger tips to the nerves in front of the ear, has been known to dispel neuralgic pains like magic. When caused by acidity a dose of charcoal or soda will usually act as a corrective. Sick headache is accompanied by bilious

symptoms, and attacks usually come on when the person is overtired, or below par physically. This is a disease of the first half of life, and often stops of its own accord after middle age. A careful diet is imperative in every case; sweetmeats and pastry being especially pernicious.—2. The most general variety is that known especially as the nervous headache, which means that the nerves, exhausted by being called upon for more than they are able to perform, have rebelled, and, ceasing their action on the arteries, have left them full of blood, the heart still sending the blood to the head, but the arteries distended with the continual pressure, having become inelastic, and having lost the power to contract, and so dilating and making the pressure on the brain that is the cause of pain and stupor. The headache which seems to be rheumatic, and is the result of exposure to cold or draught or sudden changes, is best treated with hot applications, hot-water bags, and gentle friction of the place of pain, which readily relieve it for a time. But when the pain is persistent, keeping up its sharp torment day after day, it indicates an irritation of the finer filaments of the branches of nerves about the face and head that no mild household remedies may reach, and that require the physician's oversight. There are many ways of easing the nervous and congestive headaches. Perhaps the best way is not to have them—that is, by undertaking no more than the strength is equal to, by not wearing one's self out with too perfect or too laborious housekeeping, with too much care or study or work of any kind, by dismissing anxieties, by bathing, by living in sweet and fresh air, and by taking sufficient sleep. Although it is not possible at the time the headache is on in full force to make much movement, an almost sure impediment to its frequent recurrence is to be found in easy physical exercises which will call the blood from the dilated vessels of the head to warm the hands and to fill the arteries in the arms and legs and main body. A teacher of gymnastics can best avail here; but in the absence of such there are simple movements easily made which, if undertaken daily and continued for some time, will be of great use—the circular swinging of the arms extended crosswise, the raising and bending of the legs alternately, and stretching out first one and then the other horizontally in front while standing on the other, and swinging it in a circle, clasping the hands behind the head and leaning the body over sidewise to right and left. All this, pursued reasonably will take but a few moments morning and night, and will oblige the blood to forsake the head vessels, and thus give those time to assume their normal condition, and do much to prevent the habit of congestion.

HEKTOGRAPH.—1. The hektograph, or copying pad, is very useful in copying writing or drawings when only a limited number of copies is required. A practical hektograph may be prepared according to the following directions: Soak an ounce of Cooper's gelatine overnight in enough cold water to cover it well, taking care that all the gelatine is swelled. Prepare a salt water bath by dissolving 2 oz. of common salt in 1 pt of water. Heat 6 to 7 oz. of pure glycerine over the salt water bath to a temperature of 200° Fah. Pour off from the gelatine all the water remaining unabsorbed and add the gelatine to the hot glycerine. Continue the heating for an hour, carefully stirring the mixture occasionally, avoiding as much as possible the formation of bubbles or froth. Finally add 20 drops of oil of cloves to prevent decomposition. The composition is now ready for pouring into the vessel designed to hold it while in use. This vessel may be made especially for the purpose, or a shallow cake tin may be used. After the tin is filled with the composition it must be placed in a level position, in a cool place, free from dust, and allowed to remain for at least five hours. To prepare the pad for use it is necessary to pass a wet sponge lightly over the face of the gelatine and allow it to nearly dry before taking the first copy. If this precaution is neglected the face of the pad will be ruined by the first transfer. The writing or drawing to be copied must be made with hektograph ink, using a new steel pen. After the writing becomes dry it is placed face down on the pad and rubbed gently on the back to insure the perfect contact of every part. After remaining on the pad for about a minute remove the original and proceed to take the copies by placing the paper on the pad and removing it therefrom, always beginning at the corner. After taking the desired number of copies or when the impression is exhausted, the pad is to be washed lightly with a sponge wet in cold water. The pad is then allowed to dry before being used again. The washing is unnecessary when the pad is left unused for two or three days, as the ink will be absorbed so as not to interfere with making a new transfer. The pad unavoidably wastes away in use. If its surface should become uneven or should it be injured in any way, it can be restored by reheating it over the salt water bath and allowing it to cool as before described. Failure in making the hektograph results from either of the following causes: Inattention to the instructions; insufficient heating of the composition; use of too much glycerine, which prevents gelatinization. The obvious remedy for the last difficulty is to use less glycerine or more gelatine.—2. The following is a composition by Lebaeque: gelatine, 100 parts; water, 375 parts; glycerine, 375 parts; kaolin, 50 parts.

HICCOUGHS. Cure for.—1. Hiccoughs are the result of sudden spasmodic contractions of the diaphragm, causing jars of the abdomen and thorax. The sharp, inarticulate sound is produced by the tightening and vibration of the edges of the glottis. They sometimes appear during the evolution of complaints that are entirely different—such as disorders of the digestive tract, abscesses of the throat and in stenosis of the esophagus. They also appear in the diseases of the respiratory organs, in cases of poisoning and in nervous complaints

These are the rare forms, however, the more common being what are termed the emotional, appearing after a moral shock, a fright or some other emotion. Thus, when there is an epidemic of hiccoughs, it is connected, undoubtedly, with hysterical contagion, and is due to the nervous predisposition of the individuals attacked. Put five or six drops of nitrate of amyle on a lace handkerchief, to be pressed close to the patient's nose and kept there until relief follows. It has been applied in many cases, and it has always afforded great relief, if not bringing about absolute recovery. —2. A new method of stopping hiccough is said to have been accidentally discovered in a French hospital. It consists in thrusting the tongue out of the mouth and holding it thus for a short time.

HONEY, Artificial.—Five lb. white sugar; 2 lb. water; gradually bring to a boil and skim well. When cool add 1 lb. bees' honey and 4 drops peppermint. To make of better quality add less water and more real honey.

HONEY, To Purify.—1. Beat 5 lb. of honey with the white of one egg till it froths, add water until the mixture is of the consistency of syrup. Next boil until the white of egg can be skimmed off. Pour into a vessel which has a faucet near the bottom; let it settle for some weeks, then draw off the pure honey.—2. Soft water, 6 lb.; pure best honey, 3 lb.; white moist sugar, 20 lb.; cream of tartar, 80 gr.; essence of roses, 24 drops. Mix the above in a brass kettle, boil over a charcoal fire five minutes, take it off, add the whites of two eggs well beaten; when almost cold, add 2 lb. more honey. A decoction of slippery elm will improve the honey if it be added while cooling, but it will ferment in warm weather and rise to the surface.—3. Take 15 lb. of Havana sugar, 6 lb. water, 60 gr. cream tartar, 15 drops essence of peppermint, 4½ lb. honey; dissolve the sugar in the water over a moderate fire, take off the scum; dissolve the cream tartar in a little warm water, add, stirring; then add the honey heated to the boiling point, then the essence of peppermint. Stir a few minutes, let it cool.

HORN COMBS.—Separate the true horn from the bony core by soaking the horns in water 1 month or six weeks, according to the temperature; next saw off the tip of the horn, that is, the whole of its solid part, which is used for knife-handles, buttons, and sundry other purposes. The remainder of the horn is left entire or is sawn across into lengths, according to the use it is destined. Next immerse the horn in boiling water ½ hour; and, while hot, hold it in the flame of a fire, taking care to bring the inside and outside of the horn (if from an old animal) in contact with the blaze till it becomes soft; then slit it lengthwise by a strong pointed knife, and by means of 2 pairs of pincers, applied one to each edge of the slit, open the cylinder nearly flat; place these flats on their edges between alternate plates of iron, ½ in. thick and 8 in. sq. (previously heated and greased) in a strong horizontal iron trough, and powerfully compress them by means of wedges driven in at the ends; place these plates, one by one, on a board covered with bull's hide, and fasten them down by a wedge; then scrape them with a draw-knife having a wire edge turned by means of a steel rubber; when reduced to a proper thickness and smoothed they are polished (see *Horn, To Polish*). The combs are shaped by rasps and scrapers, after having been roughed out by a hatchet or saw; the teeth are cut by a double saw fixed in a back, the two blades being set to different depths, so that the first cuts the tooth only ⅛ down, followed by the other which cuts full depth; the teeth are then finished and pointed by triangular rasps.

HORN CUPS.—The horn being sawed the required length, is scalded and roasted as described; but instead of being slit and opened, is placed while hot in a conical mold of wood; a corresponding plug of wood is then driven hard in to bring the horn to shape. Here it remains till cold, and is then taken out and fixed by the large end on the mandrel of a lathe, where it is turned and polished inside and outside, and a groove or chine cut by a gauge tool within the small end for receiving the bottom. The horn is then taken off the lathe and laid before the fire, where it becomes flexible; a round, flat piece of horn, of proper size (cut out of a plate by means of a kind of crown saw) is dropped in and forced down till it reaches the chine, and becomes fixed in this situation, and water-tight by the subsequent contraction of the horn as it cools.

HORN, To Weld.—Pieces of horn may be joined by heating the edges until they are soft and pressing together until cold.

HORNS, On Cattle, to Prevent Growth of.—Use plain concentrated lye and apply it only once. Watch closely the calf's development, and as soon as the nob of a horn begins to swell the skin on the top of the head rub a little of the lye on the bulbs and then about twelve hours later put a good coating of grease on top of that. This method is a safe and reliable one for all farmers who desire to raise cattle without horns. The grease is applied to neutralize the effect of the lye and prevent its injuring the animal. Care must be taken also that the calf does not injure the cow's udder by bringing the lye in contact with it when sucking. The calves seem never to suffer at all from the application of the lye.

HORSERADISH, To Bottle.—Six tablespoonfuls scraped or grated horseradish; 1 tablespoonful white sugar; 1 qt. vinegar. Scald the vinegar; pour boiling hot water over the horseradish. Steep a week, strain, and bottle. Exposure to the air will discolor.

HORSE TRADING.—If a horse has its ears thrown back it is a sign of bad temper. If you want to buy a horse don't believe your own brother. Take no man's word. Your eye is your own market. Never buy a horse in harness. Unhitch him and take off everything but the halter and lead him about. If he has a corn or is stiff, or has any other like failing, you can see it. Now, a horse might have

bright eyes and not be able to see. Let him walk off by himself, and if he runs against anything he is blind. Another thing—a horse may go at a great pace and look ever so nice, and yet have fits, so that although you ought to back him before you buy, it isn't everything. Then, again, the horse may have a weak back. Touch him up with the whip. If he goes for a mile or two and then suddenly stops in the road his back's no good. After a rest he starts again, but he soon stops again for good and hardly anything will make him move. You can see the weak points in a horse better when he is standing than while moving. If he is sound he'll stand square and firmly on his limbs without moving—the feet flatly on the ground, with the legs plump and naturally poised. If the foot is lifted from the ground and the weight taken from it you may suspect some disease or at least some tenderness which will lead to disease. If the horse stands with his legs wide apart, or "straddles" with his hind legs, there's a weakness in his loins, and the kidneys are disordered. Heavy pulling bends the knees. If the horse has bluish, milky cast about the eyes he's moonblind, or something worse. A kicking brute generally has scarred legs, and a stumbling horse always has bruises about the knees. If you feel the skin of a horse and find that it is rough and harsh, and doesn't move readily to the touch, the horse is a heavy feeder and has a bad digestion. Never buy a horse that has anything wrong with his breathing apparatus. Place your ear at the side of his heart, and if you hear a wheezy sound don't have anything to do with him. Horses are much troubled with toothache. If you see a horse when standing lifting a foot now and then, and striking the ground, when no flies are around, ten chances to one he has bad teeth and is suffering.

HORSE, To Make Lively.—Fasten the horse by two short ropes, one attached to each side of its bit, so that it cannot move its head right or left, and cut the hair out of the inside of its ears with a pair of scissors. Sounds will appear to him to be about twice as loud for a few days as they have before, and noises in the city to which he has become entirely accustomed will throw him into a panic. He will jump and shy and back and run and fret and fume for apparently no reason at all but just youthful spirits, till he gets used to the change.

HYDROPHOBIA.—It is the part of wisdom to give a vicious dog, mad or not mad, a wide berth, both in the summer months and when the mercury is around the zero point. But it is encouraging to be informed by distinguished professors of medicine and surgery that hydrophobia is at best a theory; it belongs to a class of simulated diseases. It is said that the bite of a dog is no more dangerous than the scratch of a pin or the puncture of an infectious nail. Because of exaggerated printed and oral accounts the picture of hydrophobia is so stamped upon the public mind that the thought of it, after being bitten by a dog, throws imaginative people into panics of nervous excitement, in which they unconsciously reproduce its supposed symptoms. It is also said that there is no such specific malady as hydrophobia, and that there is not a case on record which can be conclusively proved to have resulted from the bite of a dog or any other cause. The records of the London Hospital showed 2668 persons bitten by angry dogs, but none of them developed hydrophobia. St. George's Hospital, London, treated 4000 patients bitten by dogs supposed to be mad, but not a case of hydrophobia. At the Pennsylvania Hospital, Philadelphia, only two cases which were supposed to be hydrophobia have occurred in 140 years. One of these was submitted to bacteriological tests, but the diagnosis of hydrophobia was not confirmed, and the municipal authorities refused to accept the death as one from that disease. At the Philadelphia dog pound, 150,000 dogs have been handled in the past twenty-five years, and many of the keepers and employes have been bitten, yet there has never been a case of hydrophobia. Much of the observation of suspicious dogs is made through optics disturbed by fear and by persons incompetent to interpret what they see. The testimony of medical men of wide experience is invariably to the effect that if hydrophobia develops in human beings at all, it is only on very rare occasions, and that the condition of hysterical excitement usually described as hydrophobia is merely a series of symptoms due to dread of the disease.

HYPNOTIZING.—With one hand a bright object, such as a faceted piece of glass, is held eight to twelve inches from the subject, so that there is a considerable convergence of the eyes, and rather above the level of the eyes, so that he is obliged to look upward. The subject is told to look steadily at the piece of glass, and to keep his whole attention fixed upon it. This position is kept up from five to ten minutes, during this time the pupils will probably dilate considerably, often assuming a slight rhythmic contraction and dilation; when this is the case the free hand is moved slowly from the object toward the eyes. If the subject is sensitive the eyes will usually close with a vibratory motion. In some cases the subject is then unable to open them, and the usual mesmeric phenomena can be obtained. If, when the operator brings his hand near the eyes of the subject, the subject, instead of closing them, follows the movements of the fingers, the whole proceeding is repeated, but the subject is told to close his eyes when the fingers are brought near them, but to keep them fixed in the same direction as before, and to continue to think of the object, and that only. The operator then for some minutes makes "passes," bringing his warm hands over and close to the subject in one direction. When the subject is inclined to pass into the cataleptic state an indication of his condition may be obtained by gently raising his arm; if he is beginning to be mesmerized, the arm remains in the position in which it is placed. If the arm falls, the mesmeric state may not infrequently be hastened on by telling the subject to keep his arm extended while he is still gaz-

ing at the subject, or while the passes are being made. And that is the whole process. The man thus mesmerized sinks from manhood to a highly complicated piece of machinery. He is a machine which for a time is conscious, and in which ideas can be excited by appropriate stimulation; any one acquainted with the machinery can set it in action.

ICE, To Store.—1. Build a round brick well, with a small grating for drain at bottom for the escape of water from melted ice. Cover the bottom with a thick layer of good wheat straw. Pack the ice in layers of ice and straw. Fix a wooden cover to the well.—2. Fire-brick, from its feeble conducting power, is the best material to line an ice-house with. The house is generally made circular and larger at the top than the bottom, where a drain should be provided to run off any water that may accumulate. As small a surface of ice as possible should be exposed to the atmosphere; therefore each piece of ice should be dipped in water before stowing away, which, by the subsequent freezing of the pieces into one mass, will remain unmelted for a long time.—3. A very cheap way of storing ice has been described. The ice stack is made on sloping ground close to the pond whence the ice is derived. The ice is beaten small, well rammed, and gradually worked up into a cone or mound 15 ft. high, with a base of 27 feet., and protected by a compact covering of fern 3 ft. thick. A dry situation and sloping surface are essential with this plan, and a small ditch should surround the heap, to carry rapidly away any water that may come from melted ice or other sources.—4. Put the ice on a dish and cover it with a napkin, then set the dish upon a feather bed or pillow, and place another bed or pillow on the top of it. In this way a few lbs. of ice may be kept for a week or more. Wrap the ice in a piece of old flannel, and if not required immediately bury it in the ground.

ICE, Strength of.—Ice 2 in. thick will bear infantry. Ice 4 in. thick will bear cavalry or light guns. Ice 6 in. thick will bear heavy field guns. Ice 8 in. thick will bear 24-pounder guns on sledges; weight not over 1000 lb. to a square foot.

ICE CREAMS.—1. *Almond.* Select the best paper shell almonds. Remove the shell and put them into boiling water for a minute, or until the skin can be rubbed off easily. Then drain, put them in cold water and remove the brown skin. Dry them on a towel. There should be a ½ lb. of the selected nuts. Pound them in a mortar, with a few drops of rose water and ½ of a cup each of sugar and cream, till like a fine paste. Make the Neapolitan ice-cream with a scant cup of sugar, and add to it when well chilled, a few drops of bitter almond extract, a teaspoonful of vanilla, and the nut paste. Mix it thoroughly, freeze again, and when hard let it stand two hours to ripen. Nut ice-creams require a long time to freeze and ripen, owing to their oily nature.

2. *Apricot.* 1 qt. can apricots; 1 qt. cream; 2 cups sugar; scald the cream and melt in it one cup of the sugar, then set away to cool, and freeze. Drain off the apricot juice and save it for pudding sauce. Rub the apricot pulp through a puree sieve. When the cream is partly frozen add the fruit pulp and freeze as usual.

3. *Banana.* Peel six ripe bananas, split, and remove the seeds and dark portion in the center. Rub the pulp through a puree strainer. Add to it the juice of 1 lemon, a saltspoonful of salt, and sugar to make it quite sweet. Add this pulp to either receipt for ice-cream, and freeze as usual.

4. *Biscuit Glace.* Ice-cream and sherbet are often served in small forms or in fancy paper cases, one case serving for each guest. Make and freeze the cream, and fill the paper cases with two kinds, either sherbet and plain ice-cream, or sherbet and tutti frutti, or sherbet and a mousse, or any combination that will be agreeable in flavor and harmonize in color. Pack the cases in a freezer can or a large plain mould, with a layer of stiff, white paper between each layer of cases. Keep the can in ice and salt till ready to serve. Serve on a lace paper napkin laid on a fancy plate. Sometimes the biscuits are covered with a meringue and colored slightly with a salamander just before serving. Small forms of various shapes, imitating birds, animals, fruits, vegetables, flowers, etc., may be obtained at kitchen furnishing stores, and used in moulding creams. When served garnished with spun sugar, the effect is very pleasing. The spun sugar may be obtained at a confectioner's; also the paper cases and napkins in various patterns and designs.

5. *Bisgue.* Bisque, as applied to ice-creams, means any ice-cream which has the addition of dried and sifted crumbs. Make a rich ice-cream, flavor it delicately with almond, coffee, vanilla, caramel, wine, or maraschino. Add 1 cupful of crumbs; either angel cake, sponge, or fruit cake; dried meringues or kisses; cocoanut cakes or macaroons; wine biscuit or graham wafers; or vanilla cigarette, or other fancy wafers.

6. *Caramel.* Put ½ cup of granulated sugar in a saucepan over the fire, and stir till melted and dark brown. Add ½ cup of boiling water and simmer ten minutes. Make either ice-cream you prefer, using only half the sugar given in the receipt. Add enough of this caramel to give the desired flavor and color. Caramel may be added to vanilla or coffee ice-cream. Whipped cream may be served with it, or stirred in when the caramel cream is partly frozen.

7. *Chocolate.* Make the foundation cream after either receipt, and whip 1 pt. of cream to serve with it. Heat 2 bars of sweetened vanilla chocolate with 2 table-spoonfuls of water, or enough to melt it. When smooth add gradually a little of the hot cream or custard, and strain through a fine strainer or cloth into the remainder of the cream. If unsweetened chocolate be used, add 2 table-spoonfuls of sugar to it while melting. Half of a level tea-

spoonful of Ceylon cinnamon may be mixed with the chocolate, or half an inch of stick cinnamon may be boiled with the cream or milk; it gives a rich, spicy flavor. Or you may have another variety by the addition of 1 table-spoonful of caramel.

8. *Coffee.* (*a.*) Make a ¼ of a cup of filtered coffee, or, if you have no filter coffee pot, put 2 heaping table-spoonfuls of fine ground coffee in a fine strainer placed in a bowl. Then pour through it ¼ of a cup of boiling water. Pour the liquid through a second time, and if not clear strain it through a fine cloth. Add this clear liquid to the hot cream or custard, and make the ice-cream after either receipt. (*b.*) Steep ¼ cup of coarsely ground coffee in 1 pint of cream or milk twenty minutes. Remove it; let it settle, and pour off carefully, then strain it and add it to the remainder of the cream or custard. This is sufficient for 1 qt. of ice-cream, made according to either receipt.

9. *Fruit.* (*a.*) ½ can apricots; 3 oranges; 3 lemons; 3 bananas; 3 cups sugar; 3 cups water. Put a puree strainer or sieve over a large granite pan or bowl, turn in the apricots and rub all but the skin through. Peel the bananas, remove the seeds and dark portions and sift the pulp. Pour the water in gradually to help the pulp go through the strainer. Squeeze the oranges and lemons, and strain through into the fruit pulp. Add the sugar, and when dissolved freeze as usual. From 1 cup to 1 pt. of cream may be mixed with the fruit just before freezing, but it is delicious without it, as the fruit pulp gives body to the frozen mixture. (*b.*) Prepare 1 pt. of any ripe, firm fruit, or canned fruit, drained, such as peaches, apricots, cherries, etc. Rub it through a puree strainer, and sweeten to taste; then stir in quickly 1 qt. of whipped cream. Freeze as usual.

10. *Lemon.* Make ice-cream by either receipt. Pare off all the rind from a lemon, cut it in halves, remove the seeds, and squeeze out the juice. If the rind and seeds are pressed with the pulp, much of their bitter flavor will be given to the juice. Strain the juice (there should be about 2 tablespoonfuls) and mix with it an equal amount of sugar. Boil until clear and stir it into the cream just before freezing. 1 tablespoonful of lemon extract may be used if preferred.

11. *Macaroon.* Dry 1 doz. stale macaroons, roll or pound them fine, and sift through a fine gravy strainer. Add them to ice-cream made after either receipt and flavored with extract of almond or sherry wine. Stir them in when the cream is partly frozen.

12. *Neapolitan.* (*a.*) 1 qt. cream; 4 eggs; 1 cup sugar; flavoring. Under this name may be included all the varieties made with eggs and cream. The foundation is the same for all the varieties taking their name from the flavoring used. Directions for preparing the flavoring will be found under each special head. (*b.*) Scald the cream; beat the yolks till thick and creamy, add the sugar and beat again. Beat the whites stiff, and beat them well into the yolks. Pour the hot cream into the eggs, and when well mixed, turn back into the double boiler and cook like a boiled custard. Stir constantly until the foam disappears and the custard has thickened enough to coat the spoon. Strain at once, and when cold add the flavoring and freeze. (*c.*) Make the custard as in (*b*), using the yolks only. Beat the whites until just foamy but not stiff, strain the hot custard into them, beating thoroughly. Or, add the beaten whites when the custard is partly frozen.

13. *Nut.* (*a.*) *Filbert, Hazelnut, or Chestnut.* Shell and blanch the nuts, then either boil till soft, mash to a pulp and press through a strainer; or, roast slightly, chop, pound to a paste and sift; pound again all that does not go through. Then cook the nut paste with the cream or custard. Allow 1 cup of nuts to either receipt for ice-cream. (*b.*) *English Walnut.* Shell, blanch, chop fine, sift, and stir into the cream when partly frozen. (*c.*) *American Walnut or Shellbark, and Pecan Nuts.* Shell, chop fine without blanching, sift, and stir them into the cream just before freezing, or as soon as thoroughly chilled. In using pecans, avoid taking any of the puckery brown substance which often adheres to the meat. Rinse them quickly in hot water and dry them before chopping. (*d.*) *Butternuts* and the three-sided cream nuts are too oily to use in ice-cream. Ice cream made with nuts should be salted more than other creams.

14. *Peach.* Pare 2 qts. of ripe, white peaches, cut them fine and mash quickly with a wooden masher; then add 1 cup of sugar and a few of the peach-stone meats, and keep it closely covered until the sugar is dissolved. Make the ice-cream after either receipt, and when the cream is thoroughly chilled strain the peach pulp through coarse cheese-cloth and stir it into the cream. Freeze as usual.

15. *Philadelphia.* 1 qt. cream; 1 scant cup sugar; flavor to taste. This is a name generally applied in this country to all ice-creams made with pure cream and no eggs. There are three ways of making this ice-cream. (*a.*) Mix the sugar and flavoring with the cream, and when the sugar is dissolved strain it into the freezer. This is the quickest and easiest method; the cream increases in bulk considerably and is of a light, snowy texture. (*b.*) Whip the cream until you have taken off a quart of the froth, mix the sugar and flavoring with the unwhipped cream, strain into the freezer, and when partly frozen add the whipped cream and freeze again until stiff. This gives a very light delicate texture to the cream. (*c.*) Heat the cream in a double boiler until scalding hot, melt the sugar in it, and when cold add the flavoring. This is considered by many the best method, as the cream has a rich body and flavor, and a peculiarly smooth, velvety appearance. It also prevents the cream from turning sour. The cream may be whipped first, and the froth removed until you have a pint; then scald the remainder of the cream with the sugar, and when cold add the whipped cream. Thin cream, or single cream, is rich enough for ice-cream, but it should be

all cream, not thick cream diluted with milk. When milk is used with thick cream, eggs or flour should be used to thicken the milk, or the milk should be well scalded with the cream.

16. *Pine-apple.* (*a.*) Drain off the juice from ½ can of grated pine-apple, mix with it 1 tablespoonful of lemon juice and 2 tablespoonfuls of orange juice. Mash the pine-apple pulp through a puree or gravy-strainer, taking only what will go through easily. Mix the sifted pulp with the juice and add sugar to taste. Mix this with partly frozen cream made after the receipt for Philadelphia ice-cream. (*b.*) Pare a fresh, ripe pine-apple, remove the eyes and core, then chop fine and sprinkle with ½ cup of sugar to 1 pt. of the fruit. Let it stand half-an-hour, then press through a strainer as much pulp as will go through. Add the juice of one lemon and more sugar if needed. Add this to ice-cream made like Neapolitan cream, and freeze as usual.

17. *Pistachio.* Shell, blanch and pound 4 oz. of pistachio nuts, as directed for almonds in the preceding receipt. Make the Neapolitan or Philadelphia ice-cream, and scant the proportion of sugar. Flavor it with a delicate flavor of vanilla and almond and add the pistachio paste. Color it a pale green with spinach coloring, by mixing the spinach sugar with a little of the cream till smooth. Use enough to give the desired shade, then freeze as usual.

18. *Plain.* 1 pt. milk; 1 pt. cream; 1 cup sugar; 2 eggs; 2 scant tablespoonfuls flour; 1 saltspoonful salt; 2 tablespoonfuls flavoring. Boil the milk and cream, reserving ¼ of a cup of milk. Mix the sugar, flour and salt thoroughly. Beat the eggs till light, add the cold milk and the sugar mixture, and when well mixed add the boiling milk. Turn back into the double boiler and cook twenty minutes. Stir constantly till smooth, and after that occasionally. Strain through a gravy strainer, add more sugar if needed, and when cold, add the flavoring. Freeze as usual. This is a good foundation for an inexpensive cream, and if a larger quantity be desired, more cream and sugar may be added with the flavoring. If the milk be boiling when the flour is added, and cooked thoroughly, there will be no taste of the flour. If you have no cream, use all milk, 4 eggs, and add 1 rounding tablespoonful of butter when you take the thickened milk from the fire.—(*With Gelatine.*) 1 qt milk; 1 pt. cream; 8 eggs; 1½ cups sugar; 1 saltspoon salt; ½ box Nelson's gelatine; lemon, coffee, wine, of any strong flavoring. Soak the gelatine in ½ cup of the measure of cold milk. Boil the remainder of the milk and cream. Beat the eggs till creamy, add the sugar and salt and beat again. Add the hot milk, then put into the double boiler, stir constantly, and cook till it thickens and coats the spoon. Add the soaked gelatine, and more sugar if needed, and when dissolved strain it and set away to cool. When cold, flavor highly with lemon, wine, or any flavoring strong enough to disguise the taste of the gelatine.

19. *Strawberry.* (*a.*) Sprinkle 2 cups of sugar over 2 qts. of strawberries. Mash them and let them stand half an hour, or until the sugar is dissolved. Meanwhile prepare the ice and pack the freezer. Turn the berries into a large square of cheese-cloth which has been placed over a bowl. Gather up the edges of the cloth, twist them, and squeeze as long as any juice or pulp will come. Then empty the pulp and seeds left in the cloth into a pan and pour on gradually about 1 pt. of milk, mix it well with the pulp, until the pulp is separated from the seeds. Squeeze again until perfectly dry. There should be nothing left in the cloth save a ball of seeds. The pulp will thicken the milk, and it is much nicer than the juice alone. Add to this pulpy juice as much cream as you may have, from 1 cup to 3 pts., and sugar to make it very sweet. The cream should be scalded and cooled. Freeze as usual. This is delicious, and a great improvement over that made by simply mashing the fruit, where the presence of the seed is objectionable. (*b.*) Allow 1 pt. of canned strawberry juice to 1 qt. of cream; sweeten to taste. If preserved strawberries are used, the juice of 1 lemon will be an improvement, as the berries are usually too sweet. The cream should be scalded, and when cold mixed with the juice. Freeze as usual.

20. *Vanilla* (*a.*) The simplest way to make vanilla ice-cream is to make either of the kinds given as a foundation, and, just before freezing, flavor with from 1 to 2 tablespoonfuls of the vanilla extract. The amount will depend upon the strength and purity of the extract. (*b.*) Make whichever foundation cream is preferred and use a quarter less than the sugar given in the receipt. Just before freezing add from 1 to 2 tablespoonfuls of vanilla sugar, or enough to give the flavor desired.

ICE HOUSE, To Build.—Lay a good stone foundation in lime mortar, as you would for any other building, raising it about 18 inches above the surface of the earth—10 feet by 15 feet is large enough for the necessities of almost any private family. Have your studs 12 inches broad by 2 inches thick—rafters the same—10 feet from the sills to the plates. Run a partition around the corner, that the entrance may be about 5 feet square—doors 2½ feet wide. Fill the space within the foundation wall 3 or 4 inches above the top of the sill with tan bark, so that it shall be at least 2 feet deep after being well stamped down. Then board the inside tight with well-seasoned boards (roof and side); nail on a board all round the outside and fill the space with tan bark well jammed in, and so proceed till you arrive at the ridge, making every space and vacancy tight with the bark. Afterwards shingle and clapboard as you like. Thatch, well put on, would probably be best, but shingles are well enough. The partition should be double, and a space of 6 inches filled with tan bark. The doors should be so constructed as to be filled 4 inches thick with bark. The whole, except the doors and casings, may be of rough hemlock lumber. This is much after the West India manner of build-

ing ice houses, where the ice is kept many months, always entirely above ground, with the thermometer averaging about 80 degrees Fahrenheit. Great care should be taken in packing ice, which should be well covered with straw, with water sprinkled over it, and stowed away during the coldest weather. The doors of the ice house should be left open during some of the coldest days and nights immediately succeeding, then close all tight.

INDIGESTION. To Cure.—Glycerine is recommended as a sure cure for indigestion. A small teaspoonful should be mixed in half a wineglassful of water, and taken with or immediately after each meal until the trouble is past, which, in an ordinary case, will be in two or three days' time, and in an obstinate one probably from ten to fifteen days. The treatment will have to be renewed if the indigestion manifests itself again.

INK. For Ticket Writing.—The following recipe is said to make a remarkably good quality of ink for ticket writing: Take 4 oz. of white wax and 1½ oz. of white soap. Melt, and when well amalgamated add of lampblack ½ oz. Mix well, heat strongly and add of shellac 1 oz. Again heat it, mix it well, cool and bottle for use. You will find that with this ink lines may be drawn from the finest to the fullest without danger of its spreading.

INK, To Remove.—1. (*From the Fingers.*) Rub vaseline well into the skin at the stained parts and then rub off with a piece of soft paper before applying soap. In this way the hands may be washed perfectly clean.—2. (*From Paper, Cloth, Etc.*) By the combined use of the two following fluids writing inks may be removed from paper, cloth, etc., without injury to the texture. Solution No. 1 consists of 2 qts. of distilled water, in which are dissolved 4 oz. of citric acid, and to which are added 6 oz. of a strong solution of borax. No. 2 consists of 2 qts. of distilled water, ¾ lb. of chloride of lime; after standing for five or six days filter, and add 6 oz. of strong solution of borax. To remove the ink spots, apply solution No. 1 thoroughly, after which the second composition should be applied in a similar manner, when the paper will be found to be again in a condition suitable for writing upon. —3. Sulphuric ether gently applied with cotton wool, away from the light, is effective for removing printer's ink from paper, if sufficient pains be taken. Put blotting paper beneath the one from which the ink is to be removed, and use clean, white blotting paper to absorb the color after each application of the ether.

INSECTS, To Destroy.—1. (*On Fruit Trees.*) The Arsenites—London Purple, Paris Green and White Arsenic—are of the greatest service against all mandibulate insects, as larvæ and beetles, and they furnish the most satisfactory means of controlling most leaf feeders and the best wholesale remedy against the codling moth. Caution must be used in applying them on account of the liability of burning or scalding the foliage. The poisons should be thoroughly mixed with water at the rate of from 1 lb. to 100-250 gal. water, and applied with a force pump or hand spray nozzle. In preparing the wash it will be best to first mix the poison with a small quantity of water, making a thick batter, and then dilute the latter and add to the reservoir or spray tank, mixing the whole thoroughly. — 2. When freshly mixed, either London purple or Paris green may be applied to apple, plum and other fruit trees except the peach, at the rate of 1 lb. to 150-200 gal., the latter amount being recommended for the plum, which is somewhat more susceptible to scalding than the apple. White arsenic does little if any injury at the rate of 1 lb. to 50 gal. of water. When allowed to remain for some time (two weeks or more) in water, the white arsenic acts with wonderful energy, scalding, when used at the rate of 1 lb. to 100 gal., from 10 pr. ct. to 90 pr. ct. of the foliage. The action of the other arsenites remains practically the same, with, perhaps, a slight increase in the case of London purple. —3. With the peach these poisons, when applied alone, even at the rate of 1 lb. to 300 or more gallons of water, are injurious in their action, causing the loss of much of the foliage. —4. By the addition of a little lime to the mixture, London purple and Paris green may be safely applied at the rate of 1 lb. to 125 to 150 gal. of water, to the peach or the tenderest foliage, or in much greater strength to strong foliage, such as that of the apple or most shade trees.—5. Whenever, therefore, the application is made to tender foliage or when the treating with a strong mixture is desirable, lime water, milky, but not heavy enough to close the nozzle, should be added at the rate of about 2 gal. to 100 gal. of the poison. Pure arsenic, however, should never be used with lime, as the latter greatly increases its action.—6. With the apple, in spraying for the codling moth, at least two applications should be made —the first on the falling of the blossoms, the apples being about the size of peas, and the second a week or ten days later; but the poison should never be applied after the fruit turns down on the stem, on account of the danger of the poison collecting and remaining permanently in the stem cavity.—(*To Clean Canary Birds of Mites.*) Put a clean white cloth over the cage at night. In the morning destroy the mites, which leave the bird, and will be found on the cloth. Take the cage apart and wash thoroughly.—8. (*In Water.*) Go to the nearest river or pond, and with a small net (a piece of old mosquito bar will do), collect a dozen or more of the small fishes known as minnows, and put them into your cistern; and in a short time you will have clear water, the wiggletails and reddish-colored bugs or lice being gobbled up by the fishes.

INSECTICIDES.—1. (*Kerosene Emulsion.*) One of the most satisfactory formulas is as follows: Kerosene, 2 gal.; common soap or whale oil soap, ½ lb.; water, 1 gal.; heat the solution of soap and add it boiling hot to the kerosene. Churn the mixture by means of a force pump and spray nozzle for five or ten minutes. The emulsion, if perfect, forms a cream which thickens upon cooling and should adhere with-

out oiliness to the surface of glass. For use against scale insects dilute 1 part of the emulsion with 9 parts of water. For most other insects dilute 1 part of the emulsion with 15 parts of water. For soft insects like plant lice the dilution may be carried to from 20 to 25 parts of water.—2. The milk emulsion is produced by the same methods as the above.—3. (*The Resin Washes.*) These insecticides act by contact, and also, in the case of scale insects, by forming an impervious coating which effectually smothers the insects treated. These resin washes vary in efficacy according to the insect treated. Experience has shown that the best formula for the red scale (*Aonidia aurantii* Maskell) and its yellow variety (*A. citrinus* Coquillett) is as follows: Resin, 18 lb.; caustic soda (70 per cent strength), 5 lb.; fish oil, 2½ pt.; water to make, 100 gals.; the necessary ingredients are placed in a kettle and a sufficient quantity of cold water added to cover them; they are then boiled until dissolved, being occasionally stirred in the meantime, and after the materials are dissolved the boiling should be continued about an hour, and a considerable degree of heat should be employed, so as to keep the preparation in a brisk state of ebullition, cold water being added in small quantities whenever there are indications of the preparation boiling over. Too much cold water, however, should not be added at one time, or the boiling process will be arrested and thereby delayed, but by a little practice the operator will learn how much water to add so as to keep the preparation boiling actively. Stirring the preparation is quite unnecessary during this stage of the work. When boiled sufficiently it will assimilate perfectly with water, and should then be diluted with the proper quantity of cold water, adding it slowly at first and stirring occasionally during the process. The undiluted preparation is pale yellowish in color, but by the addition of water it becomes a very dark brown. Before being sprayed on the trees it should be strained through a fine wire sieve, or through a piece of Swiss muslin, and this is usually accomplished when pouring the liquid into the spraying tank, by means of a strainer placed over the opening through which the preparation is introduced into the tank. The preparing of this compound will be greatly accelerated if the resin and caustic soda are first pulverized before being placed in the boiler, but this is quite a difficult task to perform. Both of these substances are put up in large cakes for the wholesale trade, the resin being in wooden barrels, each barrel containing a single cake weighing about 375 lb., while the caustic soda is put up in iron drums containing a single cake each, weighing about 800 lb. The soda is the most difficult to dissolve, but this could doubtless be obviated by first dissolving it in cold water and then using the solution as required. This insecticide may be applied at any time during the growing season.

INVALIDS, Concentrated Food for.—Bartholow's food, first made by Dr. Bartholow, of Philadelphia, is better known to nurses than others. It is a very concentrated food, useful in nourishing a patient who is on a liquid diet. It is made from one cupful of beef-tea, two level tablespoonfuls of sago, the yolk of an egg, a cupful of sweet milk and a little salt. The sago is given for the starch it contains, arrowroot and sago being the most easily digested forms of starch. In making the food first put the sago into the cup of milk and heat until the grain swells and thickens the milk. Stir the mixture frequently, and if you can not give it constant attention, cook in a double boiler. If scorched, the food will be a failure. When cooked the mixture should look clear. Take from the fire and stir in the cup of beef-tea, break an egg, drain off the white, and beat the yolk in the shell for economy's sake. Beat in the yolk of the egg, salt to taste and serve. Do not give the patient more than 2 oz. or ½ cupful at one feeding, and when you rewarm the food, put the required quantity in a cup and set it in a pan of hot water. Simmer until heated. The simmering point of water is 180° Fahrenheit. The temperature of rapidly boiling water is 212°.

IRON, Coating for.—A simple process for covering iron with a black coating similar to enamel, exceedingly evenly and regularly distributed over the surface of the metal, is described. In a vessel about 18 in. high enough powdered coal is placed to cover the bottom to a depth of about ¾ in. An inch higher than the coal there is a grating for supporting the article to be coated. When the contents of the vessel are in place the mouth is luted down and the vessel is placed on a brisk fire, which is maintained for about half an hour. When the vessel is removed, cooled and opened the iron articles, as a result of the action of the vapors generated in its interior, are seen to be covered with a fine, elastic and tenacious enamel.

IRON, To Render Malleable.—The continuous heating of cast iron for several days in a vacuum causes the metal to become malleable, and to have a uniformly black surface, dotted with black grains of amorphous graphite. The heating must not reach the melting point.

IRON WORK, Preservative for.—Red lead paint is the best preservative. Although red lead is a highly oxidizing substance, it produces a skin of the unoxidizable and protective black of magnetic oxide on the iron itself under the paint.

IVORY, Artificial.—1. Make a paste of isinglass, egg-shell in powder, and brandy; give it the desired color, and pour warm into oiled molds; leave the paste in the molds until hard. —2. Dissolve 2 lb. pure india-rubber in 32 lb. chloroform, and saturate the solution with purified ammoniacal gas; then distill off at a temperature of 185° F., and mix the residue with pulverized phosphate of calcium or carbonate of zinc; press into molds and cool.—3. 4 parts of shellac mixed with 16 parts of ammonia. Place in revolving cylinders for five hours at a temperature of 99.5° F. A complete solution of the consistency of a thin syrup will be the result. Add to this 20 parts

zinc oxide, mix thoroughly and grind in a color mill. The ammonia is driven off by heating. Press into molds.—4. The following is a description of a new process for making artificial ivory from the bones of sheep and goats and the waste of white skins, such as kid, deer, etc. The bones are macerated for ten or fifteen hours in a solution of chloride of lime, and afterward washed in clean water and allowed to dry. Then they are put with all the scraps of hide, etc., into a specially constructed boiler, dissolved by steam so as to form a fluid mass, to which is added 2½ pr. ct. of alum. The foam is skimmed off as it rises, until the mass is clear and transparent. Any convenient coloring matter is then added, and while the mass is still warm it is strained through cloth of appropriate coarseness and received in a cooler and allowed to cool until it has acquired a certain consisteney so that it can be spread out on the canvass without passing through it. It is dried on frames in the air, and forms sheets of convenient thickness. It is then necessary to harden it, which is accomplished by keeping it for eight or ten hours in an alum bath that has been used before. The quantity of alum necessary for this operation amounts to 50 pr. ct. by weight of the gelatine sheets. When they have acquired sufficient hardness, they are washed in cold water and let dry on frames, as at first. This material works more easily and takes as fine a polish as real ivory.—5. Mix 20 parts by weight of white shellac, 16 parts of ivory dust, 9 parts of acetate of lead and 10 parts of camphor. Heat these ingredients, dry, powder and press.—6. One of the disadvantages of celluloid is the fact that it burns very readily when a flame is applied; but a new compound, said to be fireproof, and suitable as a substitute for ivory, is thus made. A solution is prepared of 200 parts of casein in 50 parts of ammonia and 400 of water, or one hundred and fifty parts of albumen in 400 of water. To the solution the following are added: Quicklime, 240 parts; acetate of alumina, 150 parts, alum, 50 parts; sulphate of lime, 1,200 parts; oil, 100 parts. The oil is to be mixed in last. When dark objects are to be made, from 75 to 100 parts of tannin are to be substituted for the acetate of alumina. When the mixture has been well kneaded together, and made into a smooth paste, it is passed through rollers to form plates of the desired shape. These are dried and pressed into metallic moulds previously heated, or they may be reduced to a very fine powder, which is introduced into heated moulds and submitted to a strong pressure. The objects are afterward dipped into the following bath: Water, 100 parts; white glue, 1 part; phosphoric acid, 10 parts. Finally, they are dried, polished, and varnished with shellac.—7. Lactite is the name of the new product which hails from Norway, and is said to have for the starting point of its materials the article known as skim milk. It is readily combined with various coloring matters and is said to answer well as a substitute for ivory or celluloid, and is being adopted for similar purposes.

IVORY, Black.—Burn shavings and waste pieces of ivory from the ivory turners, in a covered crucible, till no smoke issues; cover close while cooling; then wash with diluted hydrochloric acid, then with water till no longer acid; dry, and heat in a covered crucible. It is of a deeper color than bone black, and is used as a pigment, tooth powder and to decolorize syrups and other liquids.

IVORY, To Gild.—Immerse it in a solution of nitro-muriate of gold; then expose it to hydrogen gas while damp; afterwards wash in clean water.

IVORY, To Make Transparent.—Cut ivory in pieces 1-20 in. and place in phosphoric acid sp. gr. 1.131, until transparent; then take from the bath, wash in water, and dry with a clean linen cloth. Dry in the air without heat, and soften under warm water.

IVORY, To Remove Cracks From.—Wash the ivory in soap and warm water with a brush till the cracks disappear; then place under glass.

IVORY, To Render Flexible.—1. Immerse in a solution of phosphoric acid until transparent; then take out, plunge into water, and dry with a soft cloth; it will become flexible as leather, but will resume its hardness when exposed to the sun.—2. Slice ½ lb. mandrake; put 1 qt. best vinegar with it; put the ivory into this mixture, and stand the vessel in a warm place 48 hours, and you will be able to bend the ivory to suit.

IVORY, To Silver.—Pound in a small piece of nitrate of silver in a mortar, add soft water to it, mix together, and keep in a vial for use. When you wish to silver any article, immerse it in this solution; let it remain until it turns deep yellow; then place it in clear water, and expose it to the rays of the sun. To depicture a figure, name, or cipher, on ivory, dip a camel's hair pencil in the solution and draw the subject on the ivory. After it has turned deep yellow, wash it with water, and place it in the sunshine, occasionally wetting it with pure water. In a short time it will turn of a deep black color, which, if well rubbed, will change to a brilliant silver.

IVORY, To Whiten.—1. Slake lime in water; put the ivory into it after decanting from the grounds, and boil it till white. To polish, set it in the turner's wheel; after having worked, take rushes and pumice stones, subtile powder, with water, and rub it till it looks smooth; then heat it by turning it against a piece of linen or sheepskin leather; when hot rub it over with a little whiting diluted in oil of olive; then with a little dry whiting alone, and finally with a piece of soft white rag.—2. First clean the ivory by boiling it with a paste composed of burned pumice stone and water. After cleansing place the article under a glass vessel, and expose it to the sun's rays until it assumes its original whiteness. The ivory should be kept moist with water while bleaching. If the first operation does not succeed perfectly, it should be repeated.—3. Mix a thin lime paste and heat over a moderate fire. Place the ivory in this paste, and leave it until it bleaches white, after which remove the paste, dry and polish.—

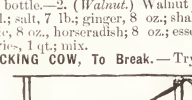
4. (*Piano Keys.*) The reason piano keys turn yellow is because they absorb the grease from the fingers; it will, therefore, be necessary to remove this. If a paste made from whiting and a solution of potash is laid on and allowed to remain for about twenty-four hours, the ivories will be restored very nearly, if not quite, to their original color, without removing them from the keys.

IVY. Poisoning from.—1. The effect of barely coming in contact with any portion of this innocent looking species of the genus Rhus is most severe and lasting, contrary to general belief. Not until a day has passed does the individual realize that he or she has been infected; but when it does appear it is sudden and unsuspected, a very short time elapsing between the first itch and the nasty-looking patches of small water blisters, surrounded by larger patches of inflamed skin. What makes things worse for the sufferers is that if he or she be tempted by the continued itching to scratch or rub the places, the whole body will soon become as badly diseased as the wrists and hands, where it usually first appears. And if the blisters be opened the watery matter oozes to other parts and scalds more blisters or papules, as they are known. Many believe that after once having in the system this poison; a second or third appearance will be suffered rather than a succession prevented. This is probably true; for cases have often been known where the persons once subjected thus were afraid even to drive along a suburban or country road for fear of another infection, not only by direct contact with the plant, but with the air so likely to be impregnated with the ethereal, poisonous oil of the plant. This is not superstition, nor mere fancy; sufficient proof has not been given to down the claim that the oil is volatile. After the first infection, if it be a severe one, the papules are liable to appear at almost any time and on any portion of the body, often between the fingers and toes, unnoticed by the patient, with but slight irritation of the surface of the skin. Rhus poisoning, that of poison oak or poison ivy, which are one and the same, is the most common form of what we call dermatitis venenata, or cases in which the skin receives the poison through accidental contact, from the use of vegetable, mineral or animal agencies in the processes of the arts and sciences, and from exposure to their irritative influences otherwise. The poisonous principle is called toxicodendric acid, found in the sap of the plant in the form of an oil. The effect depends largely upon the susceptibility of the person. The immunity of some people is truly remarkable. Many can with impunity handle the leaves and stems of the plant without experiencing the irritating, inflaming and blistering effects. On the other hand, many are so sensitive that the mere exposure to the volatile principle of the plant, yet not having come in contact with it, excites the most violent infection. The eruption of poison oak is generally of an eczematous nature, appearing in numerous papules or vesicles on an inflamed base. When it breaks out upon the face swelling takes place. Starting, as a rule, from the hands and wrists, it spreads rapidly up the arms, and then over the body and face. When the vesicles are ruptured from scratching or rubbing, the exposed surfaces become covered with crusts or scabs. Intense and aggravating itching is the marked characteristic of the eruption. This poison differs from others in general in its sudden appearance. The favorite treatment is that of alkaline lotions applied to the disturbed portions; bathing with a solution of bicarbonate of soda and water is exceptionally effective; some physicians find success in painting with sweet spirits of niter. After the acute inflammation has subsided an ointment containing camphor and carbolic acid is recommended. Another efficacious treatment is that of a wash of bromine solution together with internal applications of sulphide of calcium. For some time Harvard's scientists have been investigating poison oak, and have finally proven the poison to be in the form of an oil. But they claim that it is non-volatile, which is the opposite of the general and former opinion. There was a time when it was thought to be in the form of a powder or pollen, but that has now entirely been exploded. It is truly peculiar how some people become infected without, they claim, having come in contact with the vine. This oil, which contains an acid, toxicodendric acid, the poisonous principle, is found not only in the leaves and stems, but also in the aged portions of the vine. A solution of alcohol and water of acetate of lead (lead water) has been used effectually in preventing the progress of infection by removing the oleaginous poison from the skin. It is the alcohol which removes the poisonous matter from the surface of the skin before it has had time to take effect—twenty-four hours after contact is the limit of prevention. Where many make a mistake is in plain water to wash off any of the oily poison. Soap and water will have some good effect, but this solution is the only one recommended. No difficulty should be experienced in distinguishing the plant, nor its name and relation to other poisonous growths. The word "sumac" is the name of the plant genus Rhus; which includes the several poisonous and non-poisonous species of sumac and poison oak or ivy. Some make a difference between the oak and ivy mentioned, but this is not accepted. The distinction made is that one species grows on and along the ground and the other climbs. The plant has little rootlets or tendrils which enable it to climb. It is very bold and grows to heights exceeding the common ivy. Shady and moist places are its habitat; rocks, bushes, trees and even buildings are its supports. The leaves are of three leaflets, "rhombic ovate," variously notched and lobed, sometimes even entire; the flowers are in loose auxiliary panicles; the berries are pale brown. When bruised or cut it exudes a nasty juice which the air changes from its original milky appearance to a black varnish color.—2. A case of complete and immediate relief from the

effects of ivy poisoning is reported. The patient was swollen from head to foot, but in an hour after bathing in a solution of sodium hyposulphite was attending to business as if nothing had happened.

KETCHUP or CATSUP, To Make.—1. (*Mushroom.*) Sprinkle the trimmed tops with salt, stir them occasionally for two or three days, then slightly press out the juice; add to each gal. of this ½ oz. each of bruised mustard seed and cloves and 1 oz. each bruised allspice, black pepper, and gently simmer for an hour in a porcelain-lined iron vessel; cool, strain, and bottle.—2. (*Walnut.*) Walnut shell juice, 3 gal.; salt, 7 lb.; ginger, 8 oz.; shallots, 8 oz.; garlic, 8 oz., horseradish; 8 oz.; essence of anchovies, 1 qt.; mix.

KICKING COW, To Break.—Try the plan



illustrated. It is recommended as very efficient. Loop the rope around the leg first and bring it up to the front drawing it tight.

KINDLINGS, To Prepare.—1. Save the corn cobs for kindlings, especially if wood is not going to be plentiful next winter. To prepare them, melt together 60 parts resin and 40 parts tar. Dip in the cobs and dry on sheet metal heated to about the temperature of boiling water.—2. Dip the wood in melted resin. The following composition is sometimes used: 60 parts melted resin and 40 parts tar, in which the wood is dipped for a moment. Or, take 1 qt. of tar and 2 lb. of resin, melt them, then cool; mix as much sawdust with a little charcoal added as can be worked in. Spread out on a board and when cold break up into lumps the size of a hickory nut, and you will have enough kindling to last a good while.

LABELS, for Metal.—Paper pasted, gummed, or glued on to metal, especially if it has a bright surface, usually comes off on the slightest provocation, leaving the adhesive material on the back of the paper with a surface bright and slippery as ice. To overcome this it is suggested that the metal be first dipped into a strong and hot solution of washing soda, afterwards scrubbing perfectly dry with a clean rag. Onion juice is then to be applied to the surface of the metal, and the label pasted and fixed in the ordinary way. It is said to be almost impossible to separate paper and metal thus joined.

LABELS, Insoluble.—Lay a coat of strained white of egg over the label, and immediately put the vessel in the upper portion of a common steam pan, or otherwise expose it to a gentle heat till the albumen coagulates and turns opaque, and then take it out and dry it in an oven, at a heat of about 212° F.; the opaque white film will then become hard and transparent, and resist the action of oils, spirits and water. The labels on bottles containing acids or alkaline solutions, should be either etched upon the glass by fluoric acid or be written with incorrodible ink.

LABELS, Plant.—1. Common lead pencil on zinc labels are almost indelible and become more distinct with age.—2. Chloride of platinum solution, and better, sulphate of copper, may be used, and are perhaps somewhat more distinct.

LABELS, To Preserve.—1. (*Wooden.*) Thoroughly soak labels in iron sulphate, then lay them, after they are dry, in lime water.—2. The following method of preserving wooden labels that are to be used on trees or in exposed places is recommended: Thoroughly soak the pieces of wood in a strong solution of sulphate of iron; then lay them, after they are dry, in lime water. This causes the formation of sulphate of lime, a very insoluble salt, in the wood. The rapid destruction of the labels by the weather is thus prevented. Bast, mats, twine and other substances used in tying or covering up trees and plants, when treated in the same manner, are similarly preserved. At a recent meeting of a horticultural society in Berlin wooden labels, thus treated, were shown, which had been constantly exposed to the weather during two years without being affected thereby.—3. (*Zinc, Garden.*) For zinc plates, use with quill pens only. Dissolve muriate of ammonia and crude sal ammoniac in strong vinegar.—4. For large labels, dip your pen in concentrated sulphuric acid, and write on the zinc, previously greased; a sharp point of copper wire is better than the pen; quench in water; wash thoroughly from fluid when your writing is plain enough.—5. Dissolve about seventy-five cents' worth of chloride of platinum in hot distilled water, adding a very few drops of aqua regia. The liquid should be of a pale amber color; enough for hundreds of labels.

LACE, To Clean.—To clean the most delicate lace spread it out carefully on wrapping paper and then sprinkle it with calcined magnesia. Place another paper over it and then put it between the leaves of a book, or between two table leaves if the lace is a large piece. Leave it two or three days, then give it a gentle shake to remove the powder, and then the lace is fresh and clean, with every thread as good as it was. The magnesia can be had at any drug store.

LACQUER, Japanese.—The utility of Japanese lacquer as a preservative of surfaces of metal, wood and paper has never received the attention it deserves from engineers. The general idea that its application is one of art and is only adaptable to bric-a-brac is wholly erroneous. The Japanese use it for an infinite variety of purposes—acid tanks, coating the keels of ships, highly finished coach and decorative panels, and articles for domestic use resisting hot water, soap and alkaline solutions.

There is no reason why the lacquer tree should not thrive in this country. Its sap, which is used as the material for all lacquer work, is a natural essence and vastly superior to any varnishes used here. It is unlike even copal, which is an artificial mixture of rosin, fatty oils and turpentine. Japanese lacquer is a ready made product of nature that hardens into a mirror-like smoothness, never splits nor cracks, and is of great durability. The art lacquer work of Japan is essentially individual and ought not to be treated as an undistinguishable whole. There is a wide distinction between the ordinary lacquer tray or cabinet of commerce and the exquisite lacs of the great Japanese artists. Each of the great masters of lacquer has created a style of his own, and has founded a school of which the traditions have been kept alive by his successors for centuries. At the Centennial Exhibition of 1876 there were exhibited in the Japanese department plates, pans and other objects, evidently of a common quality of lacquer used by sailors and others for domestic purposes, also some samples of a finer grade in trays and cabinets which had been sunk in the sea over fifty years, and though covered with barnacles and other marine growths, were practically unharmed, so perfectly had they been protected by the lacquer. It seems almost incredible that so valuable an article, which can be produced as cheaply as maple sap, has remained comparatively unknown in this country and Europe, at least so far as applying it to the palpable protective purpose that nature evidently designed it for.

LA GRIPPE.—1. An infectious disease with great prostration, and often with discharges from the respiratory organs, stomach and intestines. Pneumonia commonly follows. Epidemics appear and spread rapidly over areas of country. The disease has been known for centuries under different names. The disease is believed to be due to a specific virus or bacillus, but at this writing it is not discovered, nor any specific remedy. In the young and strong, recovery is the rule; among the delicate and aged only do we see fatalities, and then only from the fever of profound depression. In many cases the attack closely resembles any ordinary cold, with slight fever, dryness, swelling, and increase in discharge from the nostrils. Striking features are great nervousness, headache, pains in the back and legs, and a general soreness, similar to the pains of dengue and small-pox. There may be marked delirium. Prostration follows, and weakness of the heart. The pulse is feeble and irregular. Death may result from heart failure. Mental disorders are common with severe attacks, besides great depression and inability for exertion. Affections of the respiratory organs are the most serious. Sometimes there will be bronchitis. But the gravest consequence is pneumonia. *Treatment:* The disease should always be regarded as serious and the patient confined to the bed. The patient should be supported with careful feeding and nursing. The bowels should be opened by calomel or a saline aperient. At night, 10 gr. of Dover's powder may be given. At the onset a warm bath is sometimes grateful, to remove the pains in back and limbs, and great care should be taken to have the bed well warmed, and after retiring a drink of hot lemonade should be given. If the fever is high and there is delirium, small doses of antipyrin may be given and an ice-cap applied to the head. But fever reducing medicines must be used with caution, as profound prostration sometimes develops. In cases where heart weakness develops, stimulants should be given, and, through convalescence, strychnine. When bronchitis or pneumonia result, they should be treated as directed in this volume. Convalescence may require weeks or months. A good nutritious diet, change of air and pleasant surroundings, are essentials.—2. A vigorous rubbing of all parts of the body with warm turpentine is suggested as a cure for the grip. It is said that it will cure in twenty-four hours, and that no medicine should be taken.

LARD, To Try.—1. Cleanliness is the great point in treating lard. The fat is freed from all adhering fleshy or discolored matter by cutting. It is then cut up into small pieces and washed until the water runs off clear. It is next melted by direct fire or steam coil until it becomes perfectly clear. It is run through close linen filters into the barrels, in which it is stirred until white and opaque, but only thickly fluid. The great point is when to cease stirring. It is then cooled and tightly covered. Air makes it rancid.—2. In preparing lard for the market, it should first be cut into pieces about the size of a walnut, and these should be allowed to stand in water for half an hour. Then work the material with the hands in five or six successive portions of water. Next pour off the water, melt the lard in a water bath, and strain through fine linen. In the first straining, it will be impossible to get rid of all the water; so that after cooling and draining, it will be necessary to remelt the lard and finally to filter it through paper in a warm closet.—3. Set a large kettle over a fire in some sheltered place, out of doors, on a still day. It will cook much quicker in large quantities. Put into the kettle, while the lard is cold, a little saleratus, say one tablespoonful to every 20 lb.; stir almost constantly when nearly done, till the scraps are brown or crisp, or until the steam ceases to rise, then there is no danger of its moulding; strain out into pans, and the first will be ready to empty into crocks when the last is strained.

LARD, To Keep Sweet.—Even during the warmest weather lard can be kept sweet by the following plan: When rendering (melting) it, throw into each kettle a handful of fresh slippery elm bark. No further preparation is necessary. No salt must be added to it at any time. The jars in which the lard is to be kept must be thoroughly cleansed.

LEAD, To Protect Against Corrosion.—The following is a process for the protection of lead against corrosion, which consists in coating it with a film of sulphide of lead. Take 16 grm. of solid caustic soda, dissolve it in 1.75

liters of water, and add to the liquid 17 grm. of nitrate of lead, or an equivalent of other lead salt, with 250 cubic centimeters of water; raise the temperature of the mixture to 90° C. If sufficient lead salt has been added the liquid will remain somewhat turbid after heating, and must then be rapidly strained or filtered through asbestos, glass wool, or other suitable material, into a convenient vessel. The filtered liquid is then well mixed with 100 cubic centimeters of hot water, containing in solution 4 grm. of sulpho-urea or thio-carbamide. If the temperature of the mixture be maintained at about 70° C., deposition of sulphide of lead or galena, in the form of a fine adherent film or layer, quickly takes place on any object immersed in or covered with the liquid, provided the object be in a perfectly clean condition and suitable for the purpose.

LEAD PIPE, To Protect.—The interior of a lead pipe can be covered with an incrustation of sulphide of lead by making a warm concentrated solution of sulphide of potash flow through it for ten or fifteen minutes. Pipes thus treated seem to be covered with grayish varnish, which prevents the water flowing through them from acting upon the lead.

LEATHER, Transparent, To Prepare.—After the hair has been removed from the hide, the latter, tightly stretched upon a frame, is rubbed with the following mixture: Glycerine (26 degrees B.), 1000 parts; salicylic acid, 2 parts; picric acid, 2 parts; boric acid, 25 parts. Before the hide is absolutely dry it is placed in a room which the rays of the sun do not penetrate, and it is saturated with a solution of bichromate of potash. When the hide is very dry, there is applied to its surface an alcoholic solution of tortoise shell, and a transparent aspect is thus obtained. This leather is exceedingly flexible. It is used for the manufacture of toilet articles, but there is nothing to prevent it from being used for foot-gear, and perhaps with fancy stockings shoes made of it would not prove unpleasing to the sight. They would at least have the advantage of novelty.

LEATHER-COVERED FURNITURE, Care of.—1. A leathered-covered easy chair and couch have been kept in excellent condition for years by rubbing the leather part occasionally with salad-oil and vinegar. Rub on a little of the oil with an old silk handkerchief, and with another give the leather a thorough polishing. If too much of the mixture is applied, or the rubbing is too light, the leather will be left in a sticky, oily condition.—2. Leather chair seats may be revived by rubbing with egg-white well beaten.

LEMONS, To Keep Fresh.—Lemons will be kept fresh for weeks if covered with water; the water must be changed often.

LEMONS, In Summer.—On hot mornings, when the appetite fails and the sight of food disgusts one, try sliced lemons for breakfast. Peel carefully, remove every particle of pith, slice down instead of across into a deep glass saucer and strew liberally with sugar.

LICE.—1. (*On Cattle.*) Take 1 pt. fish oil, pour it on the animal gradually, from the back of the horns to the root of the tail. To cure the cow itch or scratches: Paint the pastern joint well with white lead and oil; any kind of vegetable or animal oil will answer. Keep the cow haltered so she cannot lick her feet or go into water for one week. One application of each remedy is sufficient. On using the oil for lice a cow in seven days' time sheds her coat and in fourteen days' time a new and beautiful coat of hair takes its place; she takes on fat so very fast that in thirty days' time she will be ready to kill for beef, and good beef at that. This in all is thirty days from the time she has been served with the dose of oil on her back.—2. (*Chickens.*) Throw some leaves of the male persimmon into the nests on the hen house floor, and in less than one hour the house will be free from the vermin. To boil the leaves and sprinkle with the decoction will be as effective.—3. (*On Turkeys.*) Put a tablespoonful of sulphur in the nest as soon as the hens or turkeys are set. The heat of the fowls causes the fumes of the sulphur to penetrate every part of their bodies, every louse is killed, and, as all nits are hatched within ten days, when the mother leaves the nest with her brood she is perfectly free from nits or lice.

LIGHTNING RODS.—From what has been said it is evident that if we could make a path for the electricity from the clouds to the earth, it would act as a protection to any object (not too far distant) which did not conduct the electricity as well as it. As the electric fluid will leave any medium for one which offers less resistance to its passage, we can protect an object by making a conducting path, not all the way, but part of the distance from the earth to the cloud. This path must be made of material offering little resistance to its passage. Such a material is a conductor, and any substance that offers a great resistance to its passage is a "non-conductor." The best conductors make the best lightning protectors. The following is a list of the principal conductors and non-conductors:

CONDUCTORS.	NON-CONDUCTORS.
Metals.	Resin and Shellac are the best.
Charcoal.	Amber, Sulphur.
Plumbago.	Wax, Fat.
Pure Water.	Glass.
Moist Snow.	Silk, Wool, Hair, Feathers.
Steam and Smoke.	Cotton Paper.
Vegetables.	Dry Air, Baked Wood.
Animals.	India Rubber.

The conditions that determine a perfect lightning conductor are that it shall expose, in some prominent position on a building, a metallic point, and that it shall offer from this point to the earth little or no resistance to the current. Ordinary galvanized iron wire No. 4, $\frac{1}{4}$ in. in diameter, it is contended, is amply sufficient for any dwelling house. The precautions necessary are: 1. The conductor must be solid and continuous. There should be no joint, unless well-soldered. 2. The ground connection must be good. 3. Each conductor should have a

separate ground connection, but all should be connected together. It is unnecessary to insulate these. There should be no points or acute angle in the conductors—the straighter their course to the earth the better. It is safest to consider that the area protected by the conductor is equal to its height above ground. The following instructions are given: The rod should consist of round iron 1 in. in diameter; its parts in perfect metallic continuity, secured by coupling ferrules; coated with black paint, and terminate in a single platinum point. The shorter the course of the rod, the better; bendings should be rounded, and not in acute angles; fastened to the building by iron eyes, and insulated from these by cylinders of glass. The rod should be connected with the earth in contact with gas-pipes or water-pipes by a ribbon of copper or iron soldered to the end of the rod at one of its extremities, and wrapped around the pipe at the other. If impracticable, the rod should be continued horizontally to the nearest well, and turned vertically down until the end enters the water at its lowest level. The horizontal part of the rod may be buried in pounded charcoal and ashes. The rod should be placed on the west side of the building, and may be put up by a blacksmith. An easily constructed rod can be constructed thus: Get a coil of wire of the length required, and as large as telegraph wire; fasten one end over the chimney-top, run along the ridge and down the end of the house; fasten with blind-staples, and let the lower end terminate in moist earth or in a well, not a cistern. Among the essentials to be observed in attaching lightning conductors to houses, there should be no joint, unless it be a well-soldered one—chain-link rods, braided rope, tubing, etc., are to be avoided; the ground connection must be sound and good; each conductor, if there be more than one, should have a separate ground connection, but are also to be connected together, also to be connected with the lead roofing and all masses of metal in their neighborhood. It is not necessary to insulate these conductors, and there should be no points or acute angles in the conductor—the straighter and more direct its course to the earth the better. Telegraphic wire, $\frac{1}{4}$ in. in diameter, is claimed to be superior for this purpose, and is largely employed in England. It is also believed to be a safe estimate that the area protected by the conductor is equal to its height above the ground.

LIGHT. Substitute for.—The following ingenious contrivance to take the place of matches is used by the watchmen of Paris in all the magazines where explosives or inflammable materials are kept. Take an oblong vial of the whitest and clearest glass, and put into it a piece of phosphorus about the size of a pea. Pour some olive oil heated to the boiling point upon the phosphorus, fill the vial about $\frac{3}{4}$ full and then cork it tightly. To use the novel light remove the cork, allow the air to enter the vial and then recork it. This empty space in the vial will become luminous, and the light obtained is equal to that of a lamp. When the light becomes dim its power can be increased by taking out the cork and allowing a fresh supply of air to enter the vial.

LIME WATER, To Make.—To make lime water, agitate an oz. of pure caustic lime in a pt. bottle nearly filled with water and after the lime has subsided decant the clear liquid. Keep in a well stoppered bottle.

MALACHITE, Artificial.—Artificial malachite, which is susceptible to a fine polish, is made by precipitating a solution of sulphate of copper in the cold by carbonate of soda, or of potash. The precipitate, which is voluminous, should be allowed first to cohere, and is then dried and washed.

MALARIA. To Cure.—1. When the sunflowers ripen and the morning-glory vines begin to die in the back yards, then is the season of malarial and catarrhal troubles at hand. If people would let quinine alone and take one-grain doses, three times a day, of picrate of ammonia after each meal, and a wine-glassful of some laxative water in the mornings before breakfast, malaria would soon vanish. Picrate of ammonia can be put up in capsules, costs but little and does its work thoroughly, acting upon the liver and kidneys. A laxative is necessary in the mornings while taking the picrate, which should be continued about fifteen days.—2. Allow 1 pt. of water to one lemon—four lemons make sufficient for many a dose; cut up the lemons, rind, pulp and all, in the water and boil until the whole is reduced to 1 pt.; a teaspoonful before each meal is the dose.

MARBLE, Artificial.—1. In the production of this marble, slabs are made as follows: To $1\frac{1}{2}$ tons paper pulp, add a solution composed of 40 lbs. glue, $1\frac{1}{2}$ lbs. bichromate of potash, 50 lbs. alum, and 2 lbs. soluble glass or other silicate. This solution is mixed with the paper pulp, and the composition made into sheets by paper making machinery, the sheets being, however, subjected to more than ordinary pressure between rollers, so as to give great density; 2 or more sheets are now coated with the solution, and placed with their faces in contact, after which they are passed between pressure rollers, to cause their faces to become united and the whole homogeneous. The alum and silicate render the slab fire-proof to withstand the heat necessary during marbleizing, which latter is the same as ordinarily employed in marbleizing slate. The artificial marble has about the weight of poplar wood, is far more tough and durable than slate, and cannot be be dented or injured by ordinary use, while nothing but violence can break or bend a slab.—2. Soak plaster of Paris in a solution of alum; bake in an oven; then grind to a powder. In using, mix it with water, and to produce the clouds and veins, stir in any dry color you wish; this will become hard, and is susceptible of high polish.

MARBLE, To Cut.—This is done with the marble saw, which is a thin plate of soft iron, supplied, during its sawing motion, with water and sharp sand. The sawing of moderate pieces is performed by hand; that of large

slabs is done by a mill. Marble is generally cut up in the same direction in which it is quarried. Sometimes it is necessary to cut against the grain, which renders them more difficult to work. Some varieties of marble can only be sawn in the direction in which it is cut up. The marble worker is often obliged to rough hew and work without the help of the saw, casings, columns, and other articles with curved outlines; sometimes he re-works with the chisel badly executed sawings; he then squares each piece with the saw or chisel to the required dimensions, and finally mounts the marble upon its stone core, and sets up the work in its place. The working of moldings takes time and trouble; the first operation is to saw the arris, then to work with a notched chisel, making several successive groovings, on account of the contour and expansion, in which but small pieces of the material are taken, for fear of splintering; finish with small common chisels, sharp and well tempered. Cylindrical pieces, as round pedestals, columns, urns and vases, are worked with a chisel, and then, if portable, finished on a turning lathe.

MARBLE, To Polish.—If the piece is a plain surface, it is first rubbed by another piece of marble, with the intervention of two sorts of sand and water; first with fine river sand, and then with common house or white sand, which latter leaves the surface smooth for the process of gritting. The grit stone is rubbed on the surface with water alone; reducing it to that closeness of texture which fits it for glazing by means of a wooden block having a thick piece of woolen stuff wound tightly round it; the interstices of the fibres of this are filled with prepared putty powder, or peroxide of tin, and moistened with water; this being laid on the marble and loaded, it is drawn up and down the marble by means of a handle, being occasionally wetted, until gloss is produced. The polishing of moldings is done with the same materials, but with rubbers in shape according to that of the molding. The block is not used; in its stead a piece of linen cloth, folded to make a handful, which contains the putty and water. Sand rubbers to polish a slab of large dimensions should never exceed $\frac{2}{3}$ of its length, nor $\frac{1}{4}$ of its width; but if the piece of marble is small, it may be sanded itself on a larger piece of stone. Grit rubber are never larger than can be easily held in one hand; the largest block is about 14 in. in length and 4½ in. in breadth.

MARSHMALLOW DROPS.—Dissolve ½ pound of gum Arabic in 1 pint of water; strain and add ½ pound white sugar, and place over the fire, stirring constantly until the syrup is dissolved, and of the consistency of honey; then add gradually the whites of 4 eggs well beaten. Stir the mixture until it becomes somewhat thin and does not adhere to the fingers. Flavor to taste, and pour all into a pan slightly dusted with powdered starch, and when cool, divide into small squares.

MATCHES.—Matches consist of 2 parts, a stem and an igniting composition. In the case of common matches, the stem is made generally of soft pine, which is sawed in blocks to fit a machine. The wood, having been cut into the splints, is taken out and tied into bundles of 1,000, and then dried by being left in a heated chamber. The next process is to dip the ends in melted sulphur, commonly done by hand, the dipper giving to the bundle a twist which makes the ends spread out a little, so that they get coated all round with sulphur, and do not stick together in cooling. Each end is dipped in turn, and, when dry, the bundles are cut through the middle by a circular saw. Where sulphur is not used, the ends of the splints are carbonized by pressing them a moment upon a plate of red-hot iron, and then touched with melted stearine or paraffine, a small quantity of which is at once absorbed by the wood. The next step is to apply the material to be the source of fire. This composition is made into a pasty mass, the important ingredient being phosphorus. Chlorate of potash, a highly explosive substance, is free from some of the objections attaching to phosphorus, and it is substituted for it by some. Most, however, use a little of each. These are the 2 principal light-bearing ingredients. The rest are glue or gum, to give coherence; some find sand or pulverized glass, to give increased friction; and some substances which will readily give up a large amount of oxygen, as nitrate of potash, the peroxides of lead or manganese, and sulphide of antimony, to promote rapid ignition. Some mineral coloring matter is added, according to fancy.

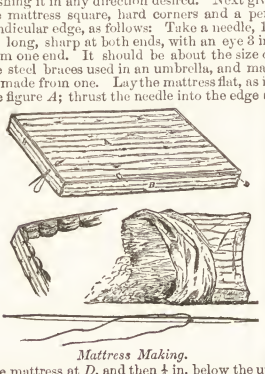
MATCHES, For Instantaneous Light.—Chlorate of potash, separately powdered, 6 dr.; vermillion, 1 dr.; lycopodium, 1 dr.; fine flour, 2 dr.; mix carefully the chlorate with the flour and lycopodium, avoiding friction, then add the vermillion, and mix the whole with a mucilage made with 1 dr. powdered gum Arabic; 10 gr. tragacanth; 2 dr. flour; 4 oz. hot water; mix; add sufficient water to bring it to a proper consistence, and dip in it the wood, previously dipped in a solution of 1 oz. of gum thus, and ½ oz. of camphor, in 6 oz. oil of turpentine.

MATCHES, Safety.—Chloride of potash, 4 to 6 parts; bichromate of potash, 2 parts; ferric oxide, 2 parts; strong glue, 3 parts; mix thoroughly, and use in the usual manner. Matches made by this method will not ignite on sandpaper, or by ordinary means, but require a surface especially prepared for them, as follows: Sulphide of antimony, 20 parts; bichromate of potash, 2 to 4 parts; oxide of iron, lead, or manganese, 4 to 6 parts; glass powder, 2 parts; strong glue or gum, 2 to 3 parts. This preparation is spread like paint, in a warm condition, on suitable paper, which is fastened on the boxes containing the matches.

MATS, To Make.—Flags, rushes, straw, cocoanut fibre, grass, rattan, strands of rope, and the inner bark of trees are used; they are also made from the inner bark of linden or basswood, made into strands and woven and twisted. Mats are usually 1½ to 2 yds. sq. In making straw mats, use 2 frames of board 3 in. wide and 1 in. thick and as large as the mat required. Have 5 or 6 pieces in each frame, running lengthwise. Place one frame on the ground

and cover with straw as high as 1 in., laying the straw at right angles with the cross-pieces; then fasten the other frame over the straw, and screw them together; having the cross-pieces in each frame opposite each other. Turn the frame upon edge and with 2 large needles, threaded with tarred twine, sew the mat by pushing one needle through the straw between the first 2 slats; the other needle is then pushed through at the same place, which thus makes a shoe-maker's stitch. Continue this until the mat is finished, and then remove the frames.

MATTRESS, To Make.—Make a top and bottom of ticking, the size wanted for the mattress, and sew them together, inserting $\frac{1}{8}$ in. piece of ticking between the edges. It is better to use only inside husks, split or whole, and the silks. The seam is left open in the centre $\frac{1}{3}$ way across the tick, the open end being turned over and drawn $\frac{1}{3}$ way back over the rest of the tick. The unturned end is then filled with husks, when the tick is drawn out full length, filled and sewed up, after which the husks are to be evened in the tick with a large wire or needle, running through the tick and pushing it in any direction desired. Next give the mattress square, hard corners and a perpendicular edge, as follows: Take a needle, 18 in. long, sharp at both ends, with an eye 3 in. from one end. It should be about the size of the steel braces used in an umbrella, and may be made from one. Lay the mattress flat, as in the figure *A*; thrust the needle into the edge of



Mattress Making.

the mattress at *D*, and then $\frac{1}{4}$ in. below the upper edge *C* at *E*, holding the needle horizontal as it passes into a depth of 8 in.; then elevate the point and bring it out at *A*. Do not pull it clear out, but leave the other point just under the top *A*, and carry it back again until it reaches the ticking *B*. Then depress it to a level with the point where intended, and bring it out through the edge $B\frac{3}{4}$ in. from where it entered and draw tight. This is to draw a roll of husks into the corner and hold it there. These stitches are continued all around the top and bottom, making the edges even. When this is done the husks are leveled, and the mattress is tacked like a comfort.

MEAT, Tough, to Make Tender.—If a tablespoonful of vinegar is added to the water in which tough meats or fowls are boiled, it will serve to make them tender.

MEAT, To Preserve.—It is said that putrefactive changes in meat are due to the decomposition of the water contained in the tissues. The means which have been found to arrest this decomposition are, first, a low temperature; second, a high state of desiccation; third, the application of antiseptics; fourth, the exclusion of air.—1. (*Antiseptic.*) The quarter carcasses are soaked for 24 to 36 hours in a solution composed of 3 parts borax, 2 parts boracic acid, 3 saltpeter, and 1 salt, in 100 parts water; they are then packed with some of the same. Before use they need 24 hours' soaking in fresh water. —2. (*Refrigeration.*) Subjection to a low temperature is a thoroughly effective way of preserving meat, but it can be considered only as temporary, decomposition ensuing when the cold state is abandoned. Nevertheless, its effects are sufficiently lasting to serve practical ends, and the process seems most likely to solve the problem of conveying large quantities of fresh meat to foreign countries. Numerous plans have been devised, all aiming at the production of a sufficiently low temperature at a remunerative cost. The principal are: —3. (*Harrison's.*) The meat is first frozen and is then packed in a chamber on board ship, the air of which is maintained in a thoroughly dry state, so as to keep up a slow but constant evaporation from the surface of the meat. The meat is placed in tanks, which are kept cool by directing a stream of brine among ice, and regulating the strength of the brine so as to produce the desired degree of cold. The ice and brine are kept in tanks above the meat, and from them streams constantly trickle over and around the meat tanks. The consumption of ice is less than 50 tons for 50 tons of meat, and the proportion decreases with larger quantities. The meat retains its full flavor and will keep good in a temperature of 63° to 68° F. (17° to 20° C.) for seventy or eighty hours after removal from the tanks. The drawback is the bulk of ice required.—4. (*Tellier's.*) The joints of meat are placed in a chamber; through which is passed a current of air charged with ether or other volatile substance, so as to reduce the temperature sufficiently low to preserve the meat without freezing its juices.—5. (*Mort and Nicolle's.*) In this process the freezing agent is ammonia solution under a pressure of 50 to 70 lb. a square inch. The freezing room is kept below 32.5° F. (0° C.) and the meat is frozen quite hard.—6. (*Poggiale's.*) A low temperature is maintained by the evaporation of methylic ether and circulation of chloride of calcium.—7. The process for curing meat by submitting it to the action of acetate of soda is very simple. Arrange the meat in a barrel, deposit about and on it powdered acetate of soda to about the quarter of the weight of the meat. In summer the action takes place immediately; in winter it is necessary to place the vessel in a room warmed to about 68° F. The salt absorbs the water of the meat; after 24 hours the pieces are turned and the lower placed uppermost. In forty-eight hours the action is finished and the pieces are

packed in barrels with their brine, or dry in the air. If the barrels are not full, it suffices to fill up with the brine made by dissolving 1 part (by weight) of the acetate of soda in three parts of water. The pieces may be of ordinary size, and when required for use may be freed from the salt by washing in running water. The dry acetate of soda may be recovered from the brine by evaporating off the water over a fire. —8. The composition of some of the preparations employed in commerce for the preservation of meat is as follows: (*Sozolithe.*) Sulphate of ammonia, 37.3 pr. ct.; sulphurous acid, 39.7 pr. ct.; soda, 21 pr. ct.; water, 2 pr. ct. —9. (*Concentrated Berlinite.*) Crystallized borax, 82.7 pr. ct.; boric acid, 9.8 pr. ct.; chloride of sodium, 7.5 pr. ct.—10. (*Poechel Berlinite.*) Chloride of sodium, 45.9 pr. ct.; nitrate of potash, 32.3 pr. ct.; boric acid, 19.3 pr. ct.; water, 2.5 pr. ct.—11. (*Minerva Chinese Preservative Powder.*) Chloride of sodium, 25 pr. ct.; boric acid, 17.7 pr. ct.; sulphate of soda, 38.8 pr. ct.; sulphite of soda, 9.2 pr. ct.; water, 9.3 pr. ct. —12. (*Australian Salt.*) Crystallized borax, 91 pr. ct.; chloride of sodium, 5.5 pr. ct.; with 0.5 pr. ct. of some hydrocarburet.—13. (*Ruger's Barmenite.*) Boric acid, 50 pr. ct.; chloride of sodium, 50 pr. ct.—14. (*The True Australian Meat Preservative.*) According to analyses of three specimens from different sources, this is bisulphite of lime. This is what is unwittingly employed in solutions by butchers, on summer afternoons, for painting their meat. It is sold to them under various fantastic names. The liquid is nothing but a solution of lime in sulphurous acid, and is used every day in brewing as a disinfecting agent. The bisulphite of lime, applied to meat, preserves it from the attack of flies and keeps it looking well. There is no danger attending the use of it, since a portion of the sulphurous acid volatilizes, and the sulphite changes into sulphate of lime, or plaster, which, as well known, is innocuous. A simple washing, moreover, suffices to remove the sulphite completely at the moment of preparing the meat. This preservative agent is particularly valuable during the heat of summer, and the use of it can be very safely recommended. In commerce, it is found in a more or less concentrated solution containing sulphite of lime, No. 1, 36.73 pr. ct.; No. 2, 11.04 pr. ct.; sulphurous acid, No. 1, 20.46 pr. ct.; No. 2, 30.04 pr. ct.

MEERSCHAUM, Artificial.—1. Made with fine stiffened plaster of Paris, baked a few hours and thrown warm into melted wax or linseed oil; the resemblance may be increased by a coloring solution of gamboge and dragon's blood.—2. Place a peeled potato in sulphuric acid and water, 8 parts of the former to 100 of the latter; let it remain in this liquid 36 hours; then dry with blotting paper and submit to pressure, so that when it becomes material it can be readily carved.—3. (*Viennese.*) Prepared by mixing 100 parts silicate of soda with 60 parts carbonate of magnesia and 80 parts native meerschaum or pure alumina. This mixture is then pulverized with care and passed through a sieve of fine silk or horsehair; add water, and boil it for 10 minutes; then pour the whole into molds, placed so that the water will separate easily.

MICE, To Destroy.—1. Use tartar emetic mingled with some favorite food. The mice will leave the premises.—2. Take 1 part calomel, 5 parts wheat flour, 1 part sugar, and 1-10 part of ultramarine. Mix together in a fine powder and place in a dish. This is a most efficient poison for mice.—3. Any one desirous of keeping seeds from the depredations of mice can do so by mixing pieces of camphor gum in with the seeds. Camphor placed in drawers or trunks will prevent mice from doing them injury. The little animal objects to the odor and keeps a good distance from it. He will seek food elsewhere.—4. Gather any kind of mint and scatter about your shelves, and they will forsake the premises.

MICROBES, To Destroy.—It is said that no living germ of disease can resist the antiseptic power of essence of cinnamon for more than a few hours. It destroys microbes as effectively, if not as rapidly, as corrosive sublimate. Even the scent of it is fatal, and a decoction of cinnamon ought to be taken freely by persons living in places affected by typhoid or cholera. There is nothing new in all this. In the oldest known medical prescriptions for infectious diseases cinnamon was a prominent ingredient, and it was in great request during the plague in London. There is no reason for doubting that the physicians of those days were as familiar with its medical properties as with its odor.

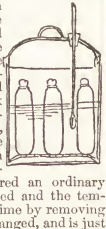
MILK, To Test for Water.—A German chemist furnishes a very simple procedure for testing the amount of water in milk. All that is required is a small quantity of plaster of Paris, say, 1 oz. This is mixed with the milk to a stiff paste and then allowed to stand. With milk of 1,030 specific gravity and a temperature of 60° F., it will harden in ten hours; if 25 pr. ct. of water is present, in two hours; if 50 per ct., in one hour and a half; and with 75 pr. ct. in thirty minutes. Skimmed milk which has been standing for twenty-four hours, and is of 1,033 specific gravity, sets in four hours; with 50 pr. ct. of water in one hour, and with 75 pr. ct. in thirty minutes. Heat should not be applied, as then the use of the thermometer would be required. This test is certainly very simple and not costly.

MIRRORS, Damaged, to Repair.—1. Pour upon a sheet of tin foil 3 dr. quicksilver to the sq. ft. of foil; rub with buckskin until the foil has become brilliant; lay the glass upon a flat table, face down; place the foil upon the damaged portion; lay a sheet of paper over the foil, and place upon it a piece of marble with a flat surface; put upon it sufficient weight to press it down; let it remain a few hours; the foil will adhere to the glass.—2. Remove the silvering from the glass around the scratch so that the clear space will be ½ in. wide; clean the space with a cloth and alcohol; near the edge of a broken piece of looking-glass mark out a piece of silvering larger than the space on the mirror; place a minute drop of mercury on the center of the patch, and allow it to remain a few minutes; clear away the silvering around the patch,

and then slide the latter from the glass; place it over the clear spot on the mirror, and gently press it down with a tuft of cotton. This is a difficult operation, and requires a little practice before trying on a large mirror.

MILK, To Sterilize.—The sterilization of milk for children, now quite extensively practiced in order to destroy the injurious germs which it may contain, can be satisfactorily accomplished with very simple apparatus. The vessel containing the milk, which may be the bottle from which it is to be used or any other suitable vessel, is placed inside of a larger vessel of metal, which contains the water. If a bottle, it is plugged with absorbent cotton, if this is at hand, or, in its absence, other clean cotton will answer. A small fruit jar, loosely covered, may be used instead of a bottle. The requirements are simply that the interior vessel shall be raised about half an inch above the bottom of the other, and that the water shall reach nearly or quite as high as the milk. The apparatus is then heated on a range or stove until the water reaches a temperature of 155° Fahrenheit, when it is removed from the heat and kept tightly covered for half an hour. The milk bottles are then taken out and kept in a cool place. The milk may be used any time within twenty-four hours. A temperature of 150° maintained for half an hour is sufficient to destroy any germs likely to be present in the milk, and it is found in practice that raising the temperature to 155° and then allowing it to stand in the heated water for half an hour insures the proper temperature for the required time. The temperature should not be raised above 155°, otherwise the taste and quality of the milk will be impaired.

The simplest plan is to take a tin pail and invert a perforated tin pie-plate in the bottom, or have made for it a removable false bottom perforated with holes and having legs half an inch high, to allow circulation of the water. The milk bottle is set on this false bottom, and sufficient water is put into the pail to reach the level of the surface of the milk in the bottle. A hole may be punched in the cover of the pail, a cork inserted, and a chemical thermometer put through the cork, so that the bulb dips into the water. The temperature can thus be watched without removing the cover. If preferred an ordinary dairy thermometer may be used and the temperature tested from time to time by removing the lid. This is very easily arranged, and is just as satisfactory as the patented apparatus sold for the same purpose. The accompanying illustrations show the form of apparatus described.



MIRRORS, To Silver.—1. A sheet of tin-foil the size of the plate of glass is evenly spread on a smooth and solid marble table; every wrinkle on its surface is rubbed down with a brush; a portion of mercury is then poured on, and rubbed over the foil with a piece of soft woolen stuff, or a hare's foot, after which two rules are applied to the edges, and mercury poured on to the depth of a silver dollar; any oxide on the surface is removed, and the glass, made clean and dry, is slid along over the surface of the liquid metal, so that no air, dirt, or oxide can remain or get between them. When the glass has arrived at its proper position, gentle pressure is applied, and the table sloped a little to carry off the waste mercury, after which it is covered with flannel and loaded with heavy weights; in 24 hours it is removed to a wooden table and further slanted, and this position is progressively increased during a month, until it becomes perpendicular.—2. A mixture is first made of nitrate of silver (in course powder), 1 oz.; ammonia, ½ oz.; water, 2 oz.; after standing 24 hours this is filtered (the deposit upon the filter, which is silver, being preserved); spirit or naptha, 3 oz., is added; 20 to 30 drops oil of cassia are then added; after remaining 6 hours longer the solution is ready for use. The glass to be silvered (first cleaned and polished) is placed in a horizontal position, and a wall of putty formed around it; the above solution is then poured over it to the depth of from ¼ to ½ in.; 6 to 12 drops of a mixture of oil of cloves and spirit of wine (1 part. by measure, of oil of cloves, to 3 of spirit of wine) are next dropped into it, at different places; or the diluted oil of cloves may be mixed with the solution before it is poured upon the glass; a larger quantity, in both cases, increasing the rate of the deposit. When the glass is silvered, the solution is poured off, as soon as the silver on the glass is dry, it is varnished with a composition formed by melting together equal quantities of beeswax and tallow. The solution, after being poured off, is allowed to stand 3 or four days, in a close vessel; as it still contains silver, and may be again employed after filtration, and the addition of fresh ingredients to supply the place of those used. 18 gr. nitrate of silver are sufficient for 1 sq. ft. of glass.

MOTH, Buffalo, To Destroy.—To any who has had experience with the insect variously known as the carpet bug or buffalo moth the following recipe will be invaluable, for it is said to be sure death to them: 1 oz. of alum; 1 oz. of chloride zinc; 3 oz. of salt. Mix with 2 qts. of water and let it stand over night in a covered vessel. In the morning pour it carefully into another vessel, so that all sediment may be left behind. Dilute this with 2 qts. of water and apply by sprinkling the edges of the carpet for the distance of a foot from the wall. This is all that is necessary.

MOLASSES, To Clarify.—Common molasses may be clarified and rendered much more palatable by heating it over the fire and pouring in sweet milk in the proportion of 1 pt. to a gal. of molasses. When the molasses boils up once, the albumen in the milk collects all the impurities in a thick scum upon the top, which must be carefully removed. and the molasses

is then fit for use. Bullock's blood is also used for this purpose, but milk is more agreeable in many ways for domestic use.

MIXTURES, Freezing.—In the production of ice or an extreme degree of cold, by saline mixtures, the salts should be crystallized, and as rich as possible in water, without being damp. They should be coarsely pulverized at the time of using, and not mixed until immediately before throwing them into the liquid ingredients. The mixture should be made in a thick vessel, well clothed, to prevent accession of external heat, and the substance to be acted upon should be contained in a thin vessel so as to expose it to the action of the mixture. The following table will be found useful in making ice:

FRIGORIFIC MIXTURES.

Ingredients.	Parts.	Thermometer Sinks from.	Deg. of Cold.
Snow or pounded ice	2	Any temperature to −5°	—
Chloride of sodium	1		
Snow or pounded ice	5	Any temperature to −12°	—
Chloride of sodium	2		
Sal Ammoniac	1		
Snow or pounded ice	12	Any temperature to −25°	—
Chloride of sodium	5		
Nitrate of ammonia	5		
Snow	8	+32° to −27°	59°
Hydrochloric acid, concentrated	5		
Snow	2	+32° to −50°	82°
Crystallized chloride of calcium	3		
Sal ammoniac	5	+50° to +10°	40°
Nitrate of potassa	5		
Water	16		
Nitrate of ammonia	1	+50° to +4°	46°
Water	1		
Nitrate of ammonia	1	+50° to +7°	57°
Carbonate of soda	1		
Water	1		
Phosphate of soda	9	+50 to −21°	71°
Nitrate of ammonia	6		
Diluted nitrous acid[1]	4		
Sulphate of soda	8	+50° to 0°	50°
Hydrochloric acid	5		
Snow	3	0 to −46°	46°
Diluted nitrous acid[1]	2		
Snow	2	−20° to −60°	40°
Sulphuric acid[2]	1		
Water	1		
Snow	1	0° to −66°	66°
Crystallized chloride of calcium	2		
Snow	1	−40° to −73°	33°
Crystallized chloride of calcium	3		
Snow	8	−68° to −91°	23°
Sulphuric acid	5		
Water	5		

MOLES, To Destroy.—1. Insert in the mole tracks or burrows a sufficient number of bits of raw beef soaked in a solution of strychnine. There is no doubt about the mole being a useful animal. It subsists mainly on grubs and worms, destroying vast numbers of cutworms, and other enemies to vegetation.—2. The ground mole, which is such a pest in lawns and gardens has a great liking for sweet corn. Soak sweet corn in a solution of strychnine, Paris green or arsenic, and strew the poisoned grain at intervals in runs made by the moles. They will eat it and be killed.

MORTAR, To Toughen.—A mortar that can hardly be picked to pieces is made as follows: Mix equal parts of lime and brown sugar with water, and be sure the lime is thoroughly air slaked. This mortar is equal to Portland cement, and is of extraordinary strength.—2. (*Impenetrable.*) Mix thoroughly ½ of fresh unslaked lime with ¾ of sand; and let 5 laborers make mortar of these ingredients, by pouring on water with trowels, to supply one mason, who must, when the materials are sufficiently mixed, apply it instantly as cement or plaster, and it will become as hard as stone. The lime used should be stone lime; previous to its use it should be preserved from the access of air or wet, and the plaster screened for some time from the sun and wind.—3. (*Khorussar or Turkish.*) One part powdered brick and tiles; 2 parts fine sifted lime. Mix with water to the desired consisteney, put on layers of 5 or 6 inches in thickness, between the courses of brick or stone. This mortar is used where great solidity is required in buildings.—4. (*Waterproof.*) Instead of slaking in the usual manner use a solution of copperas dissolved in warm water, and use only fine quartz sand.

MOSQUITOES, Remedies for.—1. Kerosene is effective in getting rid of mosquitoes. Pour a little coal oil in rain barrels, stagnant pools, and wherever water has collected. A teaspoonful is sufficient for a barrel of water.—2. To clear a room of mosquitoes, take a small piece of gum camphor in a tin vessel and evaporate it over a flame, taking care it does not ignite. A sponge dipped in camphorated spirits and made fast to the top of the bed-tend will be found serviceable in the sleeping room. Decoction of pennyroyal, applied to the exposed parts, will effectually keep off these troublesome insects.—3. A small amount of pennyroyal sprinkled around the room will drive away mosquitoes.—4. Burning a small amount of Persian insect powder in a room is said to be efficient in driving away mosquitoes.—5. (*Mosquito and Gnat Bites.*) Carbolate of lime, 10 gr.; water, 1 dr. It is said that a weak solution of carbolic acid—1 part in 50—used as a wash, will prevent their attacks. To alleviate the unpleasant sensation caused by the bite of the mosquito, various remedies have been suggested. Among them are oil of cloves, ammonia, bicarbonate of soda, chloroform, thymol and ordinary soap. Doctors say, we have in our own experience obtained more relief from solution of cocaine, 4 pr. ct., than from anything else.—6. (*Mosquito Oil.*) Oil of tar, 1 oz.; olive oil, 1 oz.; oil of pennyroyal, ½ oz.; spirit of camphor, ½ oz.; glycerine, ½ oz.; carbolic acid, 2 drm.; mix, shake well before using.—7. (*Mosquito Tincture.*) Eucalyptol, 10 parts; acetic ether, 5 parts; eau de cologne, 40 parts; tincture of insect powder (1 to 5 S. V. R), 50 parts; mix. For sponging the skin a mixture of 1 part of this with 3 to 6 parts of water may

be used. The tincture is also useful for spraying in apartments; for this purpose 1 part may be mixed with 10 parts water, and used in a spray producer.—8. The pain can be alleviated by bathing with warm water in which honey has been put. The proportion is 2 teaspoonfuls of honey to a pt. of boiling water.—9. A lotion made of menthol and alcohol will be found of great use in subduing irritation and swelling.—10. One dr. of pennyroyal and 1 oz. of eau de cologne washed over the skin often prevents their biting, and they are said to dislike the smell of scented verbena. In some seaside places there is a very troublesome insect, the sand-fly, that is so small as to be almost invisible. This bites the ankles unmercifully, as well as the hands, and can be warded off by the remedies given above and by not wearing open-work stockings. In all cases of severe stings it is well to keep quiet for a day or two, have a very light diet, avoid wine and spirits, and take cooling drinks.

MOTH, Coddling, To Exterminate.—The greatest enemy to our export apple is the "coddling moth." But the entire crop can be made wormless if the orchards of the United States will use the following receipts: Use Paris green at the rate of 1 lb. to 150 gal. of water. Weigh sufficient poison for the capacity of the land used and make it into thin paint with a small quantity of water and add powdered or quick lime equal to the weight of the poison used, mixing thoroughly. The lime takes up the free arsenic and removes the danger of scalding. Strain the mixture into the spray tank, taking care to pulverize and wash all the poison through the strainer. During the operation of spraying see that the liquid is agitated with sufficient frequency to prevent the settling of the poison. Let the first spraying follow within a week after the falling of the blossoms of either apple or pear, and follow this with a second treatment just before the fruit turns down on the stem, or when it is from a quarter to half an inch in diameter. The first spraying reaches the eggs laid by the moth in the flower end of the fruit shortly after the falling of the blossoms, and the second the later eggs laid by belated moths. Do not spray trees when in bloom, and if a washing rain immediately follows treatment repeat the application.

MOTHER'S MARKS, To Remove.—Nævus, commonly called mother's marks or port wine mark, is caused by the dilatation and increased growth of the small blood vessels of the skin. This may be arterial, venous or capillary. In size nævi vary from a pin's head to nearly the whole extent of the face. No patient should himself operate on a nævus greater in circumference than a small pea. The simplest method of removal is by means of a concentrated nitric or hydrochloric acid. A match or similar piece of wood should have one end bitten out into a form of brush; this should be dipped into the acid, and one large drop placed on the nævus, the skin around which should be thickly covered with lard. The acid should be brought into contact with the whole extent of the nævus. Then, over the scab formed, may be laid the following paste: Carbonate of bismuth, 1 part; glycerine, 1 part; extract of belladonna, 1 part; hydrocyanic acid, 1 part. The use of the acid causes a good deal of pain, but it is a very effectual method of removal. A certain amount of inflammation is sure to follow any operation on a nævus, but when the latter is of small extent this is seldom of a violent character and the formula given will prove a sufficient remedy. After three days the paste may be gently washed off with warm water, and the following preparation gently but effectually rubbed into the the scab, over which a thickish layer should be afterward placed and the whole covered by court plaster. Common cream, 1 part; white wax, 2 parts; glycerine, 1 part; spermaceti, 1 part. The scab should now be allowed to fall off without further interference. Another method of removing nævi is to keep them constantly moistened with a very dilute acid solution. One oz. dilute nitric acid to 4 oz. water. If an operation be objected to, and the patient wishes to hide the deformity, the following will be found a harmless effectual paint. If properly made it should dry like enamel and not crack: Wood charocal, 1 part; carmine, 1 part; chalk, 10 parts; glycerine, 3 parts; flexible collodion, 8 parts; rectified spirits, 2 parts. The color of this may be varied by the relative amounts of carbon, chalk and carmine used. Another and a simpler method is to powder the nævus, say of a white color, and then apply a layer of flexible collodion. The nævus should be moistened before the powder is applied.

MOTHS, To Exterminate.—1. Take equal parts of camphor and spirits of turpentine. Soak blotting paper in the mixture. Let the paper dry, then lay among furs or clothing.—2. Lupulin, 1 dr.; snuff, 2 oz.; camphor, 1 oz.; cedar sawdust, 4 oz; mix. This is to be used for sprinkling where the moths frequent.—3. Carbolic acid, gum camphor, each, 1 oz.; benzine, 1 pt.; dissolve the gum and the carbolic acid in the benzine. Apply by saturating a piece of blotting paper, or use it in form of spray by use of an atomizer.—4. The following is recommended for sprinkling among furs, clothes, etc., to prevent the ravages of moths: Patchouly herbs, 100 parts; valerian, 50 parts: camphor, 40 parts; orris, sumbul, each, 50 parts; oil of patchouly, otto of roses, each, 1 part. The various ingredients are broken up as small as possible, passed through a wide sieve to separate the coarser pieces; and freed from dust by a fine sieve. The oils are mixed with the orris root, and all the ingredients are then combined.—5. Powdered cloves, 50 parts; powdered black pepper, 100 parts; powdered quassia, 100 parts; sprinkle with oil of cassia, oil of bergamot, each, 2 parts; camphor, 5 parts; previously dissolved in ether, 20 parts; then mix with carbonate of ammonium, 20 parts; powdered orris, 20 parts.—6. (*Moth liquid.*) Spirit of wine, 500 parts; naphtaline, 10 parts; carbolic acid, 10 parts; camphor, 5 parts; essence of lemon, 5 parts; oils of thyme, lavender and savine (of each), 2 parts; this can

be used by sprinkling over furs, clothes, carpets, furniture, etc., or, better still, by application by a spray producer.—7. (*Moth and Roach Exterminator.*) Benzine is said to be more effective than anything else for exterminating moths, roaches, etc.—8. A little alum or borax solution in hot water injected into the cracks and applied by a cloth to the wood work in the vicinity of these hiding places is usually effectual.—9. Common salt is also very highly recommended.—10. (*In Furniture.*) There are two species of moths which infest furniture. One is a large fly of silvery white color; the worm of the same is shaped like a chestnut worm, and is familiarly known. It rarely infests furniture. The other is a small fly of a dark drab color; the worm is about ¼ of an inch long, and tapering from the head to the tail. It was first observed by upholsterers about thirteen years ago. This fly penetrates a sofa or chair, generally between the back and seats of sofas, or under the seats, where the vacancy among the springs affords a safe retreat. It may make a lodgment in one week after the furniture is placed in the house. If such should be the case, in two months the worm will appear; and the continual process of procreation in a few months increases the number to thousands. This moth has no season. It destroys in winter and summer alike, and is kept in active life by the constant heat of the house. We find at the same time, in the same piece of furniture, the fly, the worm, and the eggs; thus showing that they are breeding and destroying all the time. It does not eat pure curled hair, but fastens its cocoon to it, the elasticity of which prevents its being disturbed. The inside of furniture is used by it only for the purposes of propagation. The worm when ready for food crawls out and destroys the covering, if of woolen or plush material, and falling to the carpet, destroys it. It rarely cuts through plush from the inside, as it is of cotton back, but there are instances where the worms have cut up muslin on the outside back of sofas. There is no protection against them but continual care. New furniture should be removed from the walls at least twice a week in the spring and summer, and should be well whisked all round, and particularly under the seats, to prevent the fly from lodging. This is an effectual preventive, and the only one known.—11. Cayenne pepper.—12. Scotch snuff.—13. Camphor.—14. Turpentine, and all other remedies for protection from the large moth are of little or no avail against the furniture moths.—15. Saturation with alcohol will not destroy them when in a piece of furniture. If the furniture is infested, they may be removed by taking off the muslin from under the seats and off the outside ends and backs, where they congregate most, and exposing to the air as much as possible. Beat well with a whisk or the open hand, and kill all the flies and worms which show themselves. This done often will disturb them, and may make them leave the furniture, in their desire to be left in quiet. When the furniture is free from moths and is to be left during the summer months without attention, it may be protected by camphor in small bags or highly concentrated patchouly. The safest way is to have the furniture well whisked twice a week.—16. If the moths attack the carpet, spread a wet sheet on the carpet, and run a hot flat iron over it quickly; the steam will effectually destroy both worms and eggs.—17. (*Pleasant Perfume and Preventive against.*) Take of cloves, caraway seeds, nutmeg, mace, cinnamon and Tonquin beans, of each 1 oz.; then add as much Florentine orris root as will equal the other ingredients put together; grind the whole well to powder, and then put it in little bags among your clothes, etc. Almost anything aromatic will keep off moths. The common bog myrtle which grows so freely in swampy places, is an excellent antidote. A piece of linen, moistened with turpentine and put into the wardrobe or drawers for a single day, two or three times a year, is also a sufficient preservative against moths.—18. (*To Keep from Sleigh Robes.*) Alcohol, 1 pt.; camphor, ½ oz; dissolve. Spray with this liquid before storing.

MUCILAGE, Thin, to Make.—A paste that will not draw engravings when pasted down on paper must be thin. A mixture of equal parts of gum tragacanth and gum Arabic forms with water thinner mucilage than either one alone.

MUSK, Artificial.—1 molecule of water is removed from camphor by the action of melted zinc chloride or phosphoric anhydride, and the products of the reaction are submitted to fractional distillation. All that passes over between 180° and 230° C. is rectified over calcium chloride, and is mixed with 1 volume of amylic alcohol. The solution is introduced, a little at a time, into 5 times its volume of sulphuric acid of Nordhausen and 7 volumes of sulphuric acid of 66°. After agitating three or four hours the liquid is diluted with water and neutralized with sodium carbonate. It is again agitated with amylic alcohol and the amylic solution separated by decantation, agitated with lead acetate and the yellowish supernatant fluid decanted. Afterward it is evaporated by very gentle heat. The amorphous product thus obtained is treated with a mixture of equal parts of fuming nitric acid and sulphuric acid of 66° and then thrown into cold water. The precipitate, re-crystallized and purified, has the odor of natural musk.

NAILS, To Drive into Hard Wood.—Nails may be driven into hard wood without bending double if first dipped in lard or oil.

NESSELRODE PUDDING.—Shell 1 pt. of chestnuts, blanch and boil half an hour; then mash to a pulp, rub through a strainer and add them to the hot cream, made after the receipt for Neapolitan or Philadelphia ice-cream. When partly frozen, add 1 pt. of fruit, either of the varieties given in the *Ice Creams*. Mould in cake or not, as you please, and serve with whipped cream sauce. The chestnuts are the distinguishing feature of this pudding.

NETS AND SEINES.—Nets for fishing, snaring and gardening purposes are made of hemp, flax or cotton. They are extensively made by machines, allied in construction to those by which

stockings are woven. The selvages of nets so made are subsequently strengthened by the addition of several thicknesses of twine. Nets made of rope are used for naval purposes. In making nets there is a peculiar arrangement of a single thread by which meshes are formed and secured at each juncture by a knot, which prevents the enlargement or diminution of the meshes. In the making of a secure knot lies the difficulty of netting, but a little practice will enable the worker to overcome it. The implements required are ivory meshes of various sizes and a netting needle.

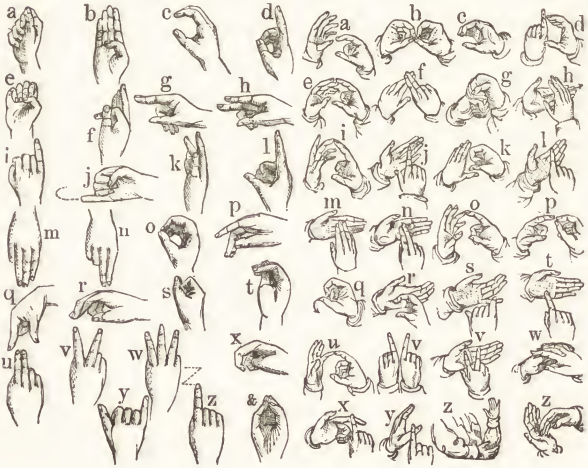
NEURALGIA, To Cure.—The most stubborn cases of neuralgia are apt to yield to a hot-water treatment. Wherever the pain is located there a hot-water bag should be applied. The suffering part should be wrapped in a blanket, and the unfortunate patient should be put to bed and covered with more blankets and induced to drink at least three cups of water as hot as the palate can stand. This treatment may seem severe, but is sure to bring relief.

NOISE, To Keep Out.—If the sufferer will take a bit of spermaceti ointment of about the size of a pea, tie it up in a small square of fine linen and place it deep in the ear, working it round till it takes the shape of the orifice, leaving the end to hang out, not a murmur of sound can be heard; the atmosphere is sweet and serene, the nerves are quite at rest, all exasperation is subdued, and when the noise is over, or the necessary season of quiet has been had, the little plug can be removed, the murmur of the world allowed to return, and no harm is done.

NICKEL, Solders for.—For fine or high grade nickel: Three parts of yellow brass, 1 part of sterling silver. For low grade nickel: Fifteen parts of yellow brass, 5 parts of sterling silver, 4 parts of zinc (pure or plate zinc). Melt the brass and silver with borax for a flux, and add the zinc in small pieces, stir with an iron rod, pour into a slab mould, and cool slowly, when it can be rolled thin for cutting.

OVEN, Test for Heat of.—A French authority on cooking gives these rules for testing the heat of an oven: Try it with a piece of white paper. If too hot, the paper will blacken or blaze up. if it becomes a light brown, it is fit for pastry; if it turns dark yellow, it is fit for bread and the heavier kinds of cake; if light yellow, the oven is ready for sponge-cake and the lighter kinds of dessert.

MUTE ALPHABETS.



THE first mute alphabet on the preceding page, is the "Single-Hand," and is that universally adopted in America by deaf mutes, having been imported from France, and being the system in vogue for Continental Europe. It is far preferable to the English "Double-Hand" system shown by its side, which is not much used in America, except outside mute circles. The "Full Length Figure" alphabet shown below is very rare and little used; but is valuable for communication across considerable distances. By the help of an opera or spy glass conversation can be carried on miles apart, and the system made useful for secret signaling in warlike operations, and for many other exigencies, as well as being highly amusing at any time.

Full Length Figure Alphabet.

OATMEAL-BAGS, For the Bath.—If you want to make your bath luxurious at slight expense, make a dozen oatmeal-bags. Take 5 lbs. of oatmeal, ground fine, ½ lb. of pure castile soap, reduced to powder, and 1 lb. of Italian orris-root. Cut a yard of cheese-cloth into bags about four inches square, sewing them on the machine, and take care not to leave any untied threads where a break may let the contents ooze out. Mix the soap, oatmeal and orris-root thoroughly, and fill the bags loosely. Sew up the opening in each, and lay them away to use as required. They are used as a sponge, dipped in warm water, making a thick, velvety lather and wonderfully softening the skin.

OLIVE OIL, To Test.—It is said that the following test will distinguish cotton-seed oil from olive oil: Take pure colorless nitric acid of 1.40 density and mix it with half the quantity of oil in a test-tube closed with an India rubber plug. After shaking it for several seconds, allow the tube to rest in a vertical position for five or six minutes. If olive oil is present the liquid is at first pale or colorless, changing to an ashy gray, with a slight yellowish hue. A coffee-brown color will be seen if cotton-seed oil is present. The reaction is delicate enough to detect an adulteration of 5 per cent. of cotton-seed oil.

ORANGE CAKE.—Rub thoroughly to a cream 2 cups of sugar and ½ of a cup of butter, adding 3 eggs beaten separately. Squeeze the juice of 2 large oranges into a cup, adding enough water to fill it. Stir this into the mixture, together with 3½ cups of flour, 2 even teaspoonfuls of cream of tartar, 1 of soda, and a little of the orange rind, grated. Bake in layer tins. For the filling, use 1 egg; yolk and white. Grate a little of the orange rind into this and the juice of ½ an orange, adding sugar enough to thicken.

ORANGES, Good, to Select.—There are over 30 varieties of sweet oranges, not to mention the natural stock, which is a larger and handsomer fruit than the sweet orange, and it is excellent for orangeade and marmalade, but, being very sour, is seldom shipped North. The medium sizes are apt to be the choicest, and probably the very sweetest orange that is marketed is the rusty-coated and rather ill-looking orange, which might be considered inferior by an amateur. The way to detect oranges is to "heft" them in your hands; pick out the thin-skinned heavy fruit, and you will be all right. The light-weight fruit is apt to be juiceless, a condition caused either by a slight freezing while on the tree, or more probably by the poverty of the soil in which it grew. All this applies to the sweet oranges. The "kid glove" oranges are grown in Florida from two stocks brought, respectively, from China and Tangiers. Hence they are called Mandarin and Tangarine oranges. Both are small; the skin is loose and easily removed, and the sections fall apart so readily that a lady can eat one without soiling her gloves, hence the name.

OZONIZED AIR, To Obtain.—The ozone is not prepared by chemical means—as ozone contains many impurities when prepared in this way—but by electricity, using a tube made by Siemens for the silent discharge. This tube should be an inch in diameter and a foot long, being operated with four Bunsen cells and an induction coil that would give a spark nearly an inch long when the battery is in good order. The ozone tube is connected with a chloride of calcium cylinder charged with eight inches of coarsely powdered chloride of calcium, between plugs of glass-wool. The air to be ozonized has to pass through this tube, which filters and dries it sufficiently—the former being of importance for the purity of the ozone, the latter for the quantity. The ozone thus prepared, when conducted into water recently distilled over permanganate of potash and then made slightly alkaline, shows no trace of nitric or nitrous acid.

PAINT.—1. (*Durable.*) A fire-proof and water-proof substitute for paint for use in boiler and engine rooms consists of 6 qts. of freshly slaked lime, well sifted, to which is added 1 qt. of rock salt and a gal. of water, the mixture being then well boiled and skimmed clean. To 5 gal. of this mixture are added 1 lb. of alum, ½ lb. of copperas (stirred in slowly), ¾ lb. of potash and 4 qts. of fine sand or hard-wood ashes, well sifted. To this may be added any coloring desired. It is said to be as durable as slate, and to be especially applicable to brickwork and similar surfaces.—2. (*Luminous.*) Nearly everyone has heard of luminous paint—the sulphide of calcium—but it is probable that comparatively few persons know much about the behavior of this interesting compound. When of good quality it is quite white, as seen by reflected light, but the light that is emitted by it in the dark, immediately after exposure to the direct rays of the sun, is quite blue, and the emitted light is of a lavender hue directly after subjection to the action of ordinary diffused daylight. Both of these colors, however, in a dark room rapidly fade into a white light that is more luminous. A greater luminosity is produced by a short and near exposure to an ordinary artificial light, or by being placed near a window, about sunset on a rainy day. The direct rays of a bright, full moon, falling on it for several minutes, have very little effect, making it barely visible in a dark room. After ten seconds' exposure to good, diffused daylight, which is as effective as an exposure of ten hours, this substance will give out considerable light for ten or twelve hours, and its luminosity will not entirely disappear in less than thirty hours. This great difference in the time required for the absorption and emission of light is quite remarkable, and it makes it seem as if the light emitted were many times greater than that absorbed.—3. (*Marine.*) A Scotchinventor recently brought to notice a new and valuable marine paint, the object of the article being a capacity of application in a cold state to the submerged and various other parts of ships or other craft, the effect being that of quick-drying, anti-fouling zinc and tallow paint. For the accomplishment of this purpose a composition has been devised, consisting of 40 per cent. of oxide of zinc, 12 per cent. of linseed oil, 28 per cent. of tallow and 20 per cent. of thinnings—

the latter substances being composed of 60 per cent. of shale naptha, benzoline, or other similar spirits, 30 per cent. of gum dammar and 10 per cent. of rosin; these proportions are alterable to suit different waters and conditions.—4. (*For Stoves.*) Paint the stove with paint made of powdered black lead and linseed oil, and polish in the ordinary way when dry. It may be left out in all kinds of weather without injury to the polish.

PAINT, To Remove.—1. Scraping or burning it off is extremely laborious, and too slow for general purposes. A more thorough and expeditious way is by chemical process, using for that purpose a solution of soda and quicklime in equal proportions. The solution may be made as follows: The soda is dissolved in water, the lime is then added, and the solution is applied with a brush to the old paint. A few moments are sufficient to remove the coats of paint, which may be washed off with hot water. The oldest paint may be removed by a paste of the soda and quicklime. The wood should be afterward washed with vinegar or an acid solution before repainting, to remove all traces of the alkali.—2. Wet the place with naptha, repeating as often as is required; but frequently one application will dissolve the paint. As soon as it is softened rub the surface clean. Chloroform, mixed with a small quantity of spirit ammonia, composed of strong ammoniac, has been employed very successfully to remove the stains of dry paint from wood, silk, and other substances.—3. (*From Floors.*) Take 1 lb. American pearlash; 3 lb. quick stone lime; slake the lime in water, then add the pearlash, and make the whole about the consistence of paint. Lay the mixture over the whole body of the work which is required to be cleaned, with an old brush; let it remain for 12 or 14 hours, when the paint can be easily scraped off.—4. (*From Wearing Apparel.*) Take fresh paint out of wearing apparel by rubbing with gasoline.—5. (*To Soften Putty and Remove Old Paint.*) Take 3 lb. of quick stone lime, slake the lime in water, and then add 1 lb. of American pearlash. Apply this to both sides of the glass, and let it remain for 12 hours, when the putty will be softened, and the glass may be taken out without being broken. To destroy paint apply it to the whole body of the work which is required to be cleaned; use an old brush, as it will spoil a new one; let it remain about 12 or fourteen hours and then the paint may be easily scraped off.—6. To remove paint from old doors, etc., and to soften putty in window frames, so that the glass may be taken out without breakage or cutting, take 1 lb. of pearlash and 3 lb. of quick lime; slake the lime in water, and then add the pearlash, and make the whole about the consistence of paint. Apply it to both sides of the glass, and let it remain for 12 hours, when the putty will be so softened that the glass may be taken out of the frame without being cut and with the greatest facility. To destroy paint, lay the above over the whole body of the work which is required to be cleaned, using an old brush (as it will spoil a new one); let it remain for 12 or 14 hours, when the paint can be easily scraped off.

PAINT BRUSHES, To Clean.—1. When a paint brush is stiff and hard through drying with paint on it, put some turpentine in a shallow dish and set on fire. Let it burn for a minute until hot, then smother the flame and work the pencil in the fingers, dipping it frequently into hot spirits. Rinse all paint brushes, pencils, etc., in turpentine, grease with a mixture of sweet oil and tallow, to prevent them from drying hard, and put them away in a closed box.—2. To soften brushes that have become hard, soak them 24 hours in raw linseed oil, and rinse them out in hot turpentine, repeating the process until clean; or wash them in hot soda and water and soft soap.

PAINTINGS, Old, to Line.—1. Take a piece of unbleached calico, stretch on a frame and size it with weak size. When dry, take ½ oz. spirits of turpentine, 1 dr. camphor; dissolve it in 4 oz. cold-drawn linseed oil, 2 oz. white lead, stiff ground do umber, 4 oz. finely washed and dried whiting. Mix all togcther; apply to the calico well, rubbing it in; after the second coat, pumice. Give the picture a coat, and pumice that; then coat both, and put them together upon a level board, face down, upon brown paper well sized. Well press, and rub the air out, to bring them in contact, and in a few days it may be tacked upon a frame.—2. Make a temporary stretcher; let it measure inside a little larger than the outside of the picture to be lined; on it stretch unbleached calico; trim the picture square, cutting off all old nails and ragged edges. Oil a piece of paper the size of picture with linseed oil, and lay it on a flat surface; lay the picture face down on the oiled paper, and coat it with glue or paste until there is sufficient to make it stick; then lay the unbleached calico on, rub well with the flat of the hand and iron it with flat iron till dry; take care to put a piece of paper between the calico and the iron, or it may stick. Be sure the iron is not too hot, and if it is a large picture, have two irons, one getting hot while the other is in use. When the picture is dry, it is ready for putting on the new stretcher, which should be one with two cross-bars.

PAINTINGS, To Preserve.—1. Many paintings suffer premature decay from the attacks of a species of acarus, or mite. To prevent this, add a little creosote dissolved in brandy or vinegar, or a few grains each of corrosive sublimate and sal ammoniac dissolved in a little water, to the paste and glue used to line the picture, as well as add a few drops of pure creosote, or of an alcoholic or ethereal solution of corrosive sublimate, to the varnish, when any is to be applied. If the destruction has already commenced, the painting should be at once carefully cleaned and re-lined, observing to employ one or other of the remedies mentioned.—2. The most appropriate and safe situation to keep paintings, is where there is a pure and moderately dry atmosphere. To protect pictures from the effects of damp, dip the canvas into a solution of silicate of potash, and after-

wards dry, previous to its being used. Impure air abounds in carbonic acid and sulphuretted hydrogen. It is the presence of the last in the air that blackens the lights, and causes most of the middle tints and shades to fade; exposure to damp produces moldiness and decay of the canvas. For this reason paintings should not be kept in the churches, nor suspended against heavy walls, especially in badly ventilated buildings. Excess of light acts injuriously on paintings, since it bleaches some colors and darkens others.—3. Pictures that have commenced to scale or crack may be preserved as follows: Mix equal parts of linseed oil and methylated chloroform, which pour over the painting if the colors are too brittle to bear the friction of a soft brush. After remaining on the painting a day or two, excess of oil may be removed by a piece of cotton wool or a soft brush, a fresh portion of the preservative applied, and the excess removed as before. The process must be repeated until the colors are firmly fixed, when the painting will bear friction, and may be submitted to the cleaning process or varnished. It is advisable to remove as much of the dirt as possible from the picture, by washing with soft water previous to the application of the fixing agent. The mixture will not restore the cracks in a painting, but simply fix the colors, and render the painting elastic. A mixture of 1 part of methylated chloroform, and 2 of linseed oil, is used for reviving the colors of paintings. A small portion is rubbed over the pictures after washing, with cotton wool, and on the following day the painting is wiped with a soft silk handkerchief. Oil and chloloform, when used in the proportion given, possess the property of restoring faded colors, and developing colors which have perished, to the eye, by age.

PAINTINGS, To Take Indentations from.—Subject the picture to pressure after being thoroughly wetted, after which it should be left to dry in some cool place.

PAPER, Blotting, for Removing Ink Stains.—Pass ordinary blotting paper or card through a concentrated solution of oxalic acid. Care must be taken that no crystals appear, which would injure the porosity of the paper. This will dry a blot and bleach the remainder of it.

PAPER, Luminous.—1. Prepared by adding phosphorescent powder and gelatine to the pulp. The proportions are: 10 parts water, 40 parts paper pulp, 20 parts phosphorescent powder (preferably slaked 24 hours), 1 part gelatine. I part saturated solution potash bichromate. This is waterproof.—2. 40 parts of paper pulp, 10 parts of water, 1 part of gelatine and 1 part of bichromate of potash, with 10 parts of phosphorescent powder, will make a paper which will shine in the dark, and which will be suitable for labels, signs, etc.

PAPER, To Remove Grease from.—Burnt Roche-alum and flour of brimstone, an equal quantity of each, reduce to a fine powder; wet the paper a little, put a small quantity over the greased place, and the grease will disappear.—2. Cover the stained paper with a sheet of blotting paper and pass an iron over it several times. When the paper is warmed, dip a small brush in the essential oil of well rectified spirits of turpentine heated almost to boiling point, and pass it gently over both sides of the paper, which must be kept warm. Repeat as many times as the quantity of grease in the paper or the thickness of the paper may render necessary. When the grease is removed, dip another brush in highly rectified spirits of wine, and draw it over the place and around the edges, to remove the border that would present a stain.—3. (See *Wall Paper, To Remove Grease from, 1*, in Household Cleaning.)

PAPER, Safety.—1. Paper having passed through a solution of glue with 5 per cent. potassium cyanate and antimony sulphide, is immersed in a dilute solution of magnesium or copper sulphate, and dried. Nothing written on this with ink prepared from galls and iron salts, can be destroyed by acids, etc., nor by erasing.—2. Paper may be prepared for bank checks and other documents so that any writing in ink once made thereon cannot be altered without leaving plainly visible marks, by passing the sheets through a solution composed of 0.015 gr. gallic acid to 1 gill distilled water.

PAPER, Smoothing Wrinkled.—Lay the paper face down on a sheet of unsized white paper; cover with another sheet of same, slightly damped, and iron with a warm flat iron.

PAPER, To Split.—1. Get a piece of plate glass and place on it a sheet of paper; let the latter be soaked. With care and dexterity the sheet can be split by the top surface being removed.—2. Paste a piece of cloth or strong paper to each side of the sheet to be split; when dry, pull the two pieces asunder, when part of the sheet will be found to have adhered to one and part to the other; soften the paste in water and remove from the cloth.

PAPER, To Water-Proof.—1. Add a little acetic acid to a weak solution of carpenter's glue; dissolve a small quantity of bichromate of potash in distilled water, and mix both together. The sheets of paper are drawn separately through the solution, and hung up to dry.—2. By plunging a sheet of paper into an ammoniacal solution of copper for an instant, then passing it between the cylinders and drying it, it is rendered impermeable to water, and may be boiled without disintegrating.—3. (*See Luminous.*)

PAPER, To Whiten.—1. Printed paper, stained or discolored, may be whitened by wetting it with pure clean water, then plunging it into a dilute solution of chloride of lime, passing it through water soured with hydrochloric acid, and then through pure water until every trace of acid is removed. This process may be improved by dipping into a weak solution of some antichlor, and washing before finally drying.—2. Expose the article, previously moistened, to the fumes of burning sulphur; then pass it through a vessel of pure water.

PAPIER-MACHE.—Formed of cuttings of white or brown paper boiled in water and beaten to a paste in a mortar; then mixed with a solution of gum Arabic in size, to give tenacity. It is variously manufactured by be-

ing pressed into oiled molds; afterwards dried, covered with a mixture of size and lamp-black and varnished.

PASTES.—1. (*Impervious.*) Soak ordinary glue in water until it softens; remove it before it has lost its original shape, and dissolve in ordinary linseed oil on a gentle fire until it acquires the consistency of a jelly. This paste may now be used for all kinds of substances, as, besides strength and hardness, it possesses also the advantage of resisting the action of water. —2. (*For Photographs.*) Cooking gelatine, 1 oz.; alcohol, 95 pr. ct., 10 oz.; glycerine, ½ to 1 oz.; soak gelatine in cold water for an hour or more, take out and drain off all the water which will go, add to alcohol in wide-mouthed bottle. Add ½ to 1 oz. glycerine, according as gelatine is of a hard or soft kind. Put bottle in hot water, with occasional shaking, until gelatine is quite dissolved. Will keep indefinitely, and has only to be heated when wanted for use.—3. (*Nelson's No. 1.*) Gelatine, 4 oz.; water, 16 oz.; glycerine, 1 oz.; alcohol, 5 oz.; dissolve the gelatine in the water, then add the glycerine, and lastly the alcohol.—4. (*Permanent.*) Arrowroot, 10 parts; water, 100 parts; gelatine, 1 part; alcohol, 10 parts; soak the gelatine in the water, add the arrowroot, which has first been thoroughly mixed with a small quantity of the water, and boil four or five minutes. After cooling add the alcohol and a few drops of carbolic acid or oil of cloves.—5. (*For Paper Labels.*) It is said that the following preparation is very useful for making a first-class mucilage for gumming large sheets of paper, which may be kept on hand ready for use; when wet they will stick well on glass: Starch, 2 dr.; white sugar, 1 oz.; gum Arabic, 2 dr.; to be boiled with a sufficient quantity of water.—6. Best Bermuda arrowroot, 1¾ oz.; sheet gelatine or best Russian glue, 80 gr.; water, 15 oz.; methylated spirit, 1 oz.; put the arrowroot into a small pan, add 1 oz. water and mix it thoroughly up with a spoon, or the ordinary mounting brush, until it is like thick cream; then add 14 oz. water and the gelatine broken into small fragments. Boil for four or five minutes, set it aside until partially cold, then add the methylated spirit and 6 drops of pure carbolic acid. Be very particular to add the spirit in a gentle stream, stirring rapidly all the time. Keep it in a corked stock bottle and take out as much as may be required for the time and work it up nicely with the brush.—7. (*Starch Paste.*) Pour cold water on good laundry starch to barely moisten it. Then stir in cold water until proper consistency is reached. Squeeze through canvas if not free from lumps. Starch paste should be freshly made for each batch of prints.—8. Allow four parts by weight of hard gelatine to soften in 15 parts of water for several hours, and then moderately heat until the solution is quite clear, when 65 parts of boiling water should be added while stirring. Stir in another vessel 80 parts starch paste with 20 parts cold water, so that a thin milky fluid is obtained without lumps. Into this the boiling gelatine solution should be poured while constantly stirring and the whole kept at a boiling temperature. When cool add to the whole 10 drops carbolic acid to prevent souring. This makes a very tenacious paste.—9. (*Casein Mucilage.*) Heat milk with a little tartaric acid, whereby casein is separated. Treat the latter while still moist with a solution of 6 parts borax to 100 parts water and warm gently while stirring, which will cause the casein to be dissolved. Of the borax solution enough should be used to leave only a little undissolved casein behind. —10. (*Good Mounting Paste.*) Add to 250 c. cm. concentrated gum solution, 2 parts gum to 5 parts water, a solution of 1 grm. sulphate alumina in 20 c. cm. water. Alum does not answer the purpose as well. The addition of the sulphate is effective, in that this gum is not so readily softened by moisture, and besides, wood can be fastened to wood by means of it. Its adhesive qualities are, in general, greater than those of pure gum Arabic.—11. Glue, 8 oz.; water, 8 oz.; nitric acid, 2½ oz.; dissolve the glue in the water by immersing vessel containing same in hot water. When solution is effected, add the acid. Effervescence will take place with the evolution of orange nitrous fumes. Now cool. It should be kept in a well stoppered bottle, and will remain permanently liquid.

PASTILS, Mouth.—1. They are largely used by smokers and persons with impure breath. The gilding or silvering is effected in the way usually adopted for pills, viz.: A leaf or two of gold or silver is placed in a gallipot; on this an appropriate number of pills or pastils, and then another leaf of the metal. The mouth of the gallipot is next covered with a piece of smooth writing paper, and on this the palm of the hand is placed, when a sudden and rapid circular motion is given to the whole for a second or two. Another method is to shake them, in a similar manner, with a little gold dust or silver dust. When pills are gilded or silvered immediately after being prepared, they are usually sufficiently moist or sticky to cause the leaf or dust to adhere; but should they be otherwise, they should be previously breathed on, or placed in damp air for a few minutes, or rubbed between the fingers or the palms of the hands, very slightly moistened with thin mucilage, so as to render them somewhat sticky, but not wet. Mouth pastils are preferably not coated until they are dry and hard, and hence generally require one or other of these modes of treatment. The products of the following formulæ are among those most highly esteemed:—2. Take of soft extract of licorice, ½ oz.; catechu, in fine powder, 1 oz.; white sugar, 1 oz.; gum tragacanth, ½ oz.; oil of cloves, 1 fl. drm.; oil of cassia, ½ fl. drm.; oil of nutmeg, essence of ambergris (royale), of each 12 drops; mix as before explained; beat the mixture to a firm uniform mass with eau de rose, or eau de fleurs d'oranges, q. s., and form it into 1 gr. or 2 gr. pills. Lastly, when dry, silver them. The stock of them should be kept in bottles or tin canisters, and only a sufficient number of boxes for present sale filled at once.—3. Take of fresh roasted coffee in fine powder, 1½ oz.; chocolate, do., 1½ oz.; white sugar, do., 1½ oz.; vanilla, do., 1 oz.;

charcoal, (recent), do., 1 oz.; mucilage of tragacanth, to mix q. s. The preceding, sucked *ad libitum*, are used to sweeten and perfume the breath; the last also acts by chemically deodorizing it. They are great favorites in the fashionable world among smokers.—4. Take of chloride of lime, good dry, 1 dr.; white sugar, powdered, 3 oz.; gum tragacanth, do., 1 oz.; mix; add of oil of cloves or peppermint, ½ fl. dr.; mix thoroughly and beat up the mass with rose water. This acts chemically as a disinfectant, deodorizer and bleacher, but should be only occasionally and sparingly used, as the chloride in them attacks the enamel of the teeth. One at a time is sufficient. The saliva should not be swallowed, and the mouth should be rinsed with water soon afterward.

PATENT LEATHER SHOES, Care of.—Patent leather is very delicate, especially when new, and in cold weather a very slight pressure will crack it, so that before putting on shoes of this leather they should be placed before the fire, not too close, for a short time, in order to make the leather pliant. Patent leather shoes should be rubbed to the shape of the foot with the hand and they will not then be so liable to wrinkle and crack when wearing. When they are getting dull and losing their gloss rub white of egg on them.

PARCHMENT, Paper.—1. To convert paper into vegetable parchment, immerse it a few seconds in a cold mixture of 1 volume of water and 2 volumes sulphuric acid; wash out rapidly by plunging into a quantity of cold water; then immerse it in water to which a small quantity of ammonia has been added; attach it to a frame while wet, or dry under a press, to keep it from contracting. Paper thus prepared is transparent, and can be used for copying by tracing, and as a substitute for parchment from sheep skin for diplomas, etc.—2. Immerse any paper of even fibre in a concentrated solution of chloride of zinc.

PARCHMENT, To Remove Wrinkles from.—Place the document, face down, upon a clean piece of blotting paper; beat to a froth, with a few drops of clove oil, the whites of several fresh eggs, and spread this over the back of the sheet with the fingers, and rub in until the parchment becomes soft; then spread out smoothly, cover with a piece of oiled silk, put on it a piece of smooth board with a weight, and place in a cool place 24 hours; then remove board and silk and lay on a piece of fine linen cloth; and press with a hot iron until all wrinkles disappear.

PEACH DUMPLINGS.—Boil eight large potatoes. When done drain and stand on the back of the range until they are thoroughly dry. Then beat with a silver fork until they are very light; then add ½ pt. of warm milk, 1 oz. of butter and saltspoonful of salt, and beat until the butter is melted and all the ingredients are well mixed together. Add enough flour to make a dough. Knead well and roll out on a well-floured pastry board. Lay a saucer on the dough and cut around it, using the dough about ½ in. thick. Pare and cut in halves 1 doz. peaches. Remove the stones and place the halves together. Place a peach in each round of dough and tie in pieces of well-floured cloth. Put into boiling water and boil for half an hour, watching carefully that the water boils constantly, otherwise the dumplings will be heavy. If you use a steamer, which is much better than boiling, knit rounds of white knitting cotton about the size of a saucer; put a string around the top and tie. Serve with rich cream or with hard sauce, made by creaming together ½ lb. of pulverized sugar with 2 oz. of butter, the well-beaten white of an egg and a tablespoonful of sherry wine, or you can use a teaspoonful of vanilla, if you prefer it. Grate a little nutmeg over it, and stand in a cold place (on ice if possible) for an hour before using.

PEARS, Desserts Made with.—1. Pears are a fruit easily prepared for winter use, and they are a general favorite at the table in whatever form they may appear. The pear, combined with other fruit, makes an attractive centerpiece. The golden Bartlett pear, the purple plum, the blushing peach and the pale green Niagara grapes, encircled by a vine or blossoms form a handsome combination.—2. A ripe, highly flavored pear may be peeled and sliced thin, as you would a peach, sprinkled with a little powdered sugar, and then covered with whipped cream. So served it makes an appetizing dish. Pears are also delicious when baked or stewed and served with rich cream poured over them.—3. One way of baking pears is thus: Wash the fruit, cut them into halves, and remove the cores. Lay the pieces in a porcelain or earthenware dish, arranging them in layers close together, and sprinkle each layer with sugar and just a suspicion of powdered cinnamon. Fill the dish to the top and pour over the whole a teacup of water. Cover the dish with an earthen plate and put the dish upon a grate in a slow oven and let it bake three or four hours, or the pears may remain in an oven with a slow fire all night, to be served for breakfast. An old-fashioned but good method is to sweeten baked pears with part molasses and part sugar.—4. For a compote of pears use firm fruit, not too ripe. Wash the pears, cut them into halves lengthwise, and carefully take out the core. Make a syrup in the proportion of 2 cups of sugar to 1 cup of water. When the syrup is boiling put in the pieces of pears and cook them until tender. Take them out with a skimmer and arrange them in a pyramid form, the stem end up, on a pretty dish. Slice an unpeeled lemon very thin and put it into the syrup. Let the syrup cook until it will be thick when cold, put the lemon slices over the fruit, and pour the syrup over the whole by the spoonful when a little cool, so that it will not all run to the bottom of the dish. Place the compote where it will become perfectly cold before serving.—5. An excellent way to serve pears in a pudding is thus: Wash and remove the cores and stems. Put them on a plate, place them in a steamer and cover them until they are tender, but not soft enough to lose their shape. Carefully lift the pears out and fill the space left by the core with small

bits of preserved ginger and syrup. Arrange the fruit on a plate that can be put into the oven. Sift some powdered sugar over them, and squeeze a little lemon juice over the whole. Cover the fruit with a thick meringue. Put the plate into a moderate oven and let it remain until the meringue is a delicate brown. This is a very palatable and wholesome dessert.—6. Pears may be made into a pudding with tapioca like peaches or apples, and with equally good results. Soak 1 cupful of tapioca over night in water enough to just cover the tapioca when it swells. In the morning add $\frac{3}{4}$ of a cup of sugar, a pinch of salt, the grated yellow rind of a lemon and half the juice. Peel and cut into halves ripe pears and take out the cores. Half fill a baking dish with the pears; pour the soaked tapioca mixture over them and bake until the pears are done. Serve this pudding partly cold with sweetened cream. If lemon flavoring is not desired, some pieces of cinnamon may be stuck in the tapioca; remove them before sending the dish to the table.

PENCILS, Black Lead.—The easiest way of producing, not only black lead, but all sorts of pencils, is by the following process: Take white or pipe clay; put it into a tub of clean water; soak 12 hours; then agitate until it resembles milk; let it rest 2 or 3 minutes and pour off the supernatant milky liquor into a second vessel; allow it to settle, pour off the clear and dry the residue on a filter; then add black lead sufficient. Powder it and calcine it at a white heat in a loosely covered crucible; cool, and carefully repulverize; then add prepared clay and prepared plumbago, equal parts; water to mix; make them into a paste and put into oiled molds of the size required; dry gradually, and apply sufficient heat to give the required hardness; then take carefully from the molds and place in the grooves of the cedar. The more clay and heat employed, the harder the crayon. The shade of black may be varied in the same way. Each mold must be made of 4 pieces of wood nicely fitted together.

PENCILS, Copying.—1. Pencils made to produce marks from which copies can be obtained in an ordinary copying press, have usually the disadvantage that the color fades soon. This may be overcome by preparing the pencils as follows: 10 lbs. best logwood boiled repeatedly with 100 lbs. of water, and the decoction evaporated to 100 lbs.; heat the liquid to the boiling point, and add small quantities of the nitrate of oxide of chromium till the bronze-colored precipitate formed at first is redissolved in a deep dark blue color. Now evaporate to the consisteney of a syrup and add fine levigated fat clay, 1 part for every 3 or $3\frac{1}{2}$ parts of the extract. To form a mass to manipulate, add a little mucilage of gum tragacanth. The quantity of nitrate of chromium must be in the right proportion to the extract; a surplus prevents easy writing, and a deficiency prevents easy solubility of the mass for copying. No other salt of chromium will answer. The nitrate is prepared as follows: 20 lbs. chrome alum, dissolved in 200 lbs. boiling water. To the solution gradually add a solution of carbonate of sodium of the same strength, till the hydrated oxide of chromium has been precipitated. After subsidence of the precipitate, the supernatant liquid is decanted and the precipitate washed with distilled water till the filtrate does not contain any traces of sulphate of potassium and sodium, as may be shown by the addition of a little solution of chloride of barium. To the precipitate collected on the filter successively add small portions of heated pure nitric acid, previously diluted by its own volume of distilled water, in such quantity that, on boiling, a small quantity of the hydrated oxide remains undissolved. The writing furnished by these pencils is transferable; it is of a penetrating black color. Alkalies and acids have no effect on the ink.—2. Faber's pencil for copying writing or designs is made of different degrees of hardness, combining the advantages of the best lead pencils. Four kinds are manufactured: No. 1, very soft, composed of 50 parts of aniline, 37.5 graphite, and 12.5 kaolin; No. 2, soft, 46 parts aniline, 34 graphite, and 24 kaolin; No. 3, hard, 30 parts aniline, 30 graphite, and 40 kaolin; No. 4, very hard, 25 parts aniline, 25 graphite, and 50 kaolin. These materials are pounded and mixed with great care, and afterwards made into a paste with cold water. After the paste has been well worked, it is passed through a wire screen, which divides it into strips of suitable dimensions. These are dried in an ordinary room, and afterwards fitted and glued into wooden cases like common lead pencils.

PENCILS, Indelible.—1. Buy a genuine Faber, No. 1; prepare the label (cedar is the best material), and on the part you wish to write, rub a little linseed oil and write before it gets dry. This writing will remain indelible for years. If a little Japan varnish is added to the oil, it is better. A little white lead might be used in the oil, but is not absolutely necessary.—2. Reduce nitrate of silver to an impalpable powder, add just enough lampblack to give it a black color and enough of a thick solution of gum Arabic in hot water to make the powder coherent. Rub these ingredients well together, form into thin sticks and dry.—3. Kaolin, 8 parts; finely powdered manganese dioxide, 2 parts; silver nitrate, 3 parts; mix and knead intimately with 5 parts distilled water, then dry the mass and inclose it in wood.—4. Mix 4 parts powdered pyrolusite with 16 parts of thoroughly dried alumina. Add to this a solution of 6 parts nitrate of silver in 10 parts distilled water. Rub and knead the mass thoroughly. Pencils are formed from this and dried. Used for marking linen.

PENCILS, Slate.—These are made either by cutting slate into thin sticks and rounding them, or by cutting them into fine square slips, and encasing them in wood as black lead pencils, etc.

PENCIL WRITING, To Fix.—Pencil writing may be fixed almost as indelibly as ink, by passing the moistened tongue over it. Even breathing slowly over the lines after writing, renders them less liable to erasure. Brushing the writing or a drawing with skim milk, will also act in the same manner.

PERPETUAL CALENDAR.—

FOR FINDING THE DAY OF THE WEEK CORRESPONDING TO ANY DATE OF THE CHRISTIAN ERA, TO A. D. 2099.

Explanation of Old and New Style.

Old Style to be used in general history up to the 4th of October, 1582. In English history up to the 2d September, 1752. Always in Russia and in countries following the Greek Church. *Rule:* Find in *A* the current year of the century, then in *B* on the same line and under the Century will be found the number of the Calendar of that year. In leap years, before the 29th of February, take the day next preceding that found by the Rule.

B. CENTURIES.

PENCILS. For Writing on Glass.—The colors are mixed with the fats in warmed vessels, levigated with the same, and are then allowed to cool until they have acquired proper consistency for being transferred to the presses. In these the mass is treated and shaped similarly as the graphite in the presses for ordinary pencils:—*Black.* Lampblack, 10 parts; white wax, 40 parts; tallow, 10 parts.—*Blue, Dark.* Prussian blue, 15 parts; gum Arabic, 5 parts; tallow, 10 parts.—*Blue, Light.* Prussian blue, 10 parts; white wax, 20 parts; tallow, 10 parts.—*White.* Zinc white, 40 parts; white wax, 20 parts; tallow, 10 parts.—*Yellow.* Chrome yellow, 10 parts; wax, 20 parts; tallow, 10 parts.

PERFUME. Hygienic Value of.—A pretty and interesting story has been told by a French specialist of many months' hard wrestling with the secrets of scents, and especially of their influence on bacteria. He finds that many essential oils and other perfumes are powerful germ destroyers. One of his experiments was to take 100 bacteria and see how many would be destroyed in forty-eight hours when exposed at a temperature of 15 degrees Centigrade to various agencies. Essential oil of bitter almonds killed 99 of the micro-organisms, and oil of thyme the same number. Oil of cummin accounted for 95 per cent; mint, 93; wallflower, 92; neroli, 90; lemon, 88; lavender, 75; eucalyptus, 74; rosemary, 73; turpentine and camphor, only 66. Popular opinion would have placed eucalyptus, turpentine and camphor very much higher on the list; but, although the results given are somewhat different than might be expected, it must be remembered that the experiments were made with essences, and not with their spirituous or water decoctions—the perfumes of commerce. But it is satisfactory to know that many scents which have a great charm for the olfactory nerves of some people are now numbered among the useful allies of hygiene.

PHARAOH'S SERPENTS, Harmless, to Make.—A new method of making the curious chemical toys called Pharaoh's Serpents has been suggested. The black liquor which results as a useless product when coal oil is purified with sulphuric acid is to be treated with fuming nitric acid. The dark colored resinous matter which swims on the surface is then collected, washed and dried, when it forms a yellowish brown mass having about the consistency of sulphur which has been melted and poured into water. When this mass is ignited it undergoes such a wonderful increase in bulk that a cylinder 1 in. long will give a snake about 4 ft. in length.

PERSPIRATION, Remedies for.—1. When perspiration is excessive it may be regulated by using as a wash, once a day, not oftener, for about two minutes, liquor atropiæ, 2 dr.; water, 1 pt. The face and other parts may also be washed as often as desired with alum, 1 oz.; glycerine, 1 oz.; water, 10 oz.—2. (*For Excessive Perspiration of Hands or Feet.*) Carbolic acid, 1 part; burnt alum, 4 parts; starch, 200 parts; French chalk, 50 parts; oil of lemon, 2 parts; make a fine powder, to be applied to the hands and feet, or to be sprinkled inside the gloves or stockings.—3. By applying boric acid thoroughly to the feet, particularly about the nails, between and under the toes, and to the soles, two or three times a week or oftener, as the case may need, dressing them while there is a good coating of powder on the skin, sweating of the feet may be effectually relieved.—4. (*Prevention of.*) Acid tannic, 2 scr.; aqua rosal, ½ oz.; spt. vin. rect., 2½ oz.; aquæ, 3 oz.; use as a wash, each night and morning, with a soft sponge. The skin should be thoroughly cleansed with soap and warm water, and carefully dried, and then apply the wash as directed.—5. (*Foot Powder.*) An unfailing remedy for sweaty feet and bad odor of the feet: Powdered alum, 21 parts; maize meal, 1 part.

PHYLLOXERA, Remedy for.—The introduction of American plants to replace those destroyed by parasites in French vineyards has not arrested the use of insecticides for the protection of French vines still attacked by phylloxera, and for this purpose carbon bisulphide (either pure or dissolved in water), sulpho-carbonates, and submersion continue to be employed with more or less success. The carbon bisulphide is by far the more efficient, but is too volatile and does not diffuse with sufficient rapidity. When, however, it is mixed with vaseline, its volatility is reduced and its diffusibility is increased, the former proving advantageous in light and calcareous soils, the latter in heavy soils, in accordance with theoretical considerations. The vaselined sulphide is applied in the same way as the ordinary sulphide, depositing some at the foot of the vine stock and spreading the rest over the surface; this treatment is found to be effectual; with it phylloxera is no longer seen in the roots, vegetation is luxuriant, and numerous new rootlets indicate a decisive increase in vitality; the manuring on a test tract of land had not been altered for six years, therefore the improvement was solely due to the insecticide.

PHOSPHORESCENT SUBSTANCES.—Phosphorescence, or the emission of light without flame or sensible elevation of temperature, is a phenomenon exhibited in a greater or lesser degree by many substances—mineral, animal and vegetable—and is developed under a variety of conditions. In a few substances the light is developed by chemical change or a process of slow combustion, as in the case of phosphorus, from which the name phosphorescence has been derived. In others the substance suffers no appreciable change, only requiring exposure to a strong light to shine themselves when taken into the dark. The diamond and many mineral substances develop light in this way, and it is supposed that these substances have the property of absorbing light in the same way they do heat, and of slowly parting with it when taken into the dark, much in the same way that hot bodies part with their heat when removed from the source of heat. With some of these substances the application of heat causes the development of brighter light (though for a shorter time than would be otherwise required to exhaust the supply), and again, there are some substances, such as fluorspar, that ab-

sorb light, but do not give it out until heated. Many substances also become phosphorescent while crystallizing. The color of the light developed by many of these substances varies with their nature and the degrees of heat to which they have been exposed. A certain scale of light and color may, therefore, be produced by grouping together different substances or samples of the same substances previously heated at different temperatures.

PICTURES, To Frame.—Frame your pictures simply. The frame should not be noticeable except where it is needed for decorative purposes. Oils require the gold (not gilt) frame. The shadows in a gold frame are neutral and do not interfere with the color scheme of a painting. Aquarelles should be given usually a wide white mat, which will give the delicate tones a chance for life. A narrow white molding will never offend the eye. Do not use the natural wood in frames, except on architectural subjects or mechanical drawings; then they are consistent. Frame photographs either with a mat or without; this, of course, depends upon the size. The flat oak moldings stained a dark green and close up to the photograph is good, or use a gray or green mat passepartout. Engravings, etchings or drawings are more satisfactory in black frames. They seem to lend color to pictures in monochrome.

PICTURES, Newspaper, to Transfer.—The liquid to be used is made by dissolving 1½ dr. common yellow soap in 1 pt. of hot water, adding, when nearly cold, 3½ fl. oz. spirits turpentine, and shaking thoroughly together. This fluid is applied liberally to the surface of the printed matter with a soft brush or sponge (being careful not to smear the ink, which soon becomes softened) and allowed to soak for a few minutes; then well damp the plain paper on which the transfer is to be made, place it upon the engraving and subject the whole to moderate pressure for about one minute. On separating them a reversed transfer will be found on the paper.

PICTURES, Newspaper, to Make.—Most interesting of the processes employed in newspaper illustration, from the point of view of simplicity, is what may be termed the "chalk method." Take a thin bed of smooth chalk laid upon a metal surface, and draw upon it with a fine steel point any picture you may desire. The steel point will cut the lines of the picture out of the chalk to the metal, and thus you will have it in the shape of an intaglio. Make a stereotype from this intaglio, and you have your metal plate to print the picture from.—1. (*Drawing on a Bed of Chalk.*) Such is the idea of the chalk process. In applying it, instead of pure chalk various mixtures are used, such as plaster of Paris, which is merely chalk in another shape, with a certain proportion of a white Carolina clay. The stuff, pulverized and stirred up with water, is spread over a rectangular sheet of polished steel, as you would spread a slice of bread with butter, to an even thickness of about 1-32 of an inch. Now you are ready to begin operations as soon as you have baked the steel plate in an oven for a while, until the chalk layer has been rendered perfectly hard. It will hardly do for you to attempt to draw your picture directly upon the chalk, lest you make mistakes. The best way is to make your sketch on a piece of paper, and then, laying it down upon the chalk surface, go over the lines with a pencil point, which will indent the paper and leave marks beneath upon the chalk. Lift the drawing and you find under it, in the chalk, its reproduction. Now you apply your steel point directly to the chalk, cutting all the lines of the drawing down through the chalk to the surface of the steel plate. When you finish this operation the dark steel of the plate shows through the chalk in all the lines of the sketch. And these lines are perfectly clean and sharp, thanks to the keenness of the knife-like steel point employed. All you have to do for the rest is to pour molten lead over the chalk surface in a mould and let it get cold. The lines that are cut out of chalk will be reproduced in relief upon the lead, and thus you will have your metal engraving to print the newspaper picture from, mounting it for the purpose on an iron block, thick enough to make it level with the type.—2. (*Zinc Etching.*) Though so advantageous for its simplicity, the chalk method is not so good for fine work in the way of sketches and portraits as the "zinc process," so-called. The former, however, by reason of its cheapness, is most useful to provincial newspapers, which cannot afford the comparatively expensive photographic plant required by the latter. In the zinc process, to begin with, an ordinary photograph, reduced to the required size, is taken with a camera of the pen-and-ink sketch drawn on cardboard by the artist. Next a smooth plate of zinc is "flowed over" with an albumen solution that forms a sensitized skin on the surface; the glass negative of the picture is laid upon this zinc plate and the two are put together in the sunlight. What are to be the black lines of the printed drawings are, of course, white and transparent in the negative. The sunlight goes through wherever the negative is transparent, and has the effect of hardening the sensitized skin beneath, so that it clings tightly to the zinc. It requires only one minute to perform this operation. Now the zinc plate is taken and given a coating over the sensitized skin of lithographer's ink, rubbed on with a roller, after which the plate is washed. In all places where the sunlight has not struck the zinc, owing to the opacity of the glass negative, the sensitized skin readily washes off, together with the ink that covers it; elsewhere it clings. Thus, after the washing, the perfect drawing in ink remains upon the zinc plate. To make the ink lines harder the plate is brushed with powdered dragon's blood. Then it is plunged into a bath of acid, which eats away the zinc wherever it is not protected by the ink, so that when it is taken out the lines of the drawing are found all raised above the rest of the surface of the plate, like a map for the blind, and when mounted "type high" on a metal base, you have your "cut" ready to print from. The zinc method seems to be the most available for jour-

nals of the period. At all events, it is employed by a majority of the big newspapers of the country.

PICTURES, Old, to Restore Blackened Lights of.—Touch them with peroxide of hydrogen, diluted with 6 or 8 times its weight of pure water. The part must be afterwards washed with a clean sponge and water.

PICTURES, Old, to Remove Blisters from.—Puncture holes in the blister with a needle; rub rye flour paste gently over the swelling, allowing it to penetrate the holes. Carefully wipe the paste from the swollen parts, and soften them with a soft brush dipped in warm linseed oil. Several thicknesses of clean white paper being placed over the place, pass over the whole rapidly with a warm iron.

PIE, Banana.—1. Beat the yolks of 2 eggs very light with 1 cup of crumbled cake, ½ cup of sugar, butter the size of a walnut and a little rich cream. Flavor with lemon or vanilla, then stir in two large bananas cut in thin slices; pour the mixture into a pie pan lined with good paste and bake in a quick oven. While it is baking beat the whites of the eggs very light with a little rosewater and 3 tablespoonfuls of powdered sugar. Take out the pie, drop the meringue in clots over top of it and set back in the oven until it is a pale brown.

PLANTS, To Preserve Colors of.—A recent improved receipt for preserving plants with their natural colors is to dissolve 1 pt. salicylic acid in 600 parts alcohol, heat the solution up to boiling point in an evaporating vessel and draw the plants slowly through it. Shake them to get rid of any superfluous moisture and then dry between sheets of blotting paper under pressure in the ordinary manner. Too prolonged immersion discolors violet flowers, and in all cases the blotting paper must be frequently renewed. The novelty appears to be the salycilic acid.

PLASTER OF PARIS, Firmness of, to Increase.—Much of the inconvenience arising from the too rapid consolidation of plaster of Paris may be remedied by the simple addition to the mass of from 2 to 4 per cent. of marshmallow root, finely powdered. With this treatment it is found the plaster will not set for an hour at least; and, moreover, the mixture becomes so hard, on drying, that it may be sawn, filed or turned, and in this condition is applicable to the manufacture of dominoes, dice, and numerous other small articles. If the addition of the marshmallow root be carried to the extent of say 8 per cent., the time of setting is still further prolonged, and the hardness of the mass of plaster, when cold, greatly augmented. Such a composition may also, while still soft, be rolled out on a glass tube, and thin sheets be produced, which possess the advantage of not cracking when drying, and which may afterward be easily detached and polished by mere friction. It is found practicable to incorporate colors with the mixture, and by this means good imitations of some kinds of marble are produced by careful manipulation, or the sheets or slabs may be painted upon when dry, and rendered quite impermeable by a process of polishing and varnishing, the appearance being thus rendered quite attractive, and at a compartively small cost.

POLISHES, For Furniture.—1. One pt. 90 per cent. alcohol; ¾ oz. gum copal; ¼ oz. gum Arabic; 1 oz. shellac. Bruise the gums and sift them through a piece of muslin. Place the spirits and gums together in a vessel closely corked, near a warm stove, and frequently shake them; in two or three days they will be dissolved. Strain through a piece of muslin, and keep corked tight.—2. Shellac, 6 oz.; naphtha, 1 qt.; benzoin, ¾ oz.; sandarac, 1 oz.—3. Dissolve 1½ oz. shellac, ½ oz. sandarac, in ½ pt. naphtha. To apply the polish, fold a piece of flannel into a sort of cushion, wet it well with the polish, then lay a piece of clean linen rag over the flannel, apply 1 drop of linseed oil; rub your work in a circular direction, lightly at first. To finish off, use a little naphtha, applied the same as the polish.—4. Pale shellac, 2¼ lb.; mastic sandarac, each 3 oz.; spirits, 1 gal. Dissolve, and add copal varnish, 1 pt.; mix well by agitation.—5. Shellac, 12 oz.; wood naphtha, 1 qt.; dissolve, and add ½ pt. linseed oil.—6. Crush 3 oz. shellac with ½ oz. gum mastic, add 1 pt. methylated spirits of wine, and dissolve.—7. Shellac, 12 oz.; gum elemi, 2 oz.; gum copal, 3 oz.; spirits of wine, 1 gal.; dissolve.—8. Shellac, 1¼ oz.; gum juniper, ½ oz.; benzoin, ½ oz.; methylated alcohol, ½ pt.—9. One oz. each of gums mastic, sandarac, seed lac, shellac, and gum Arabic; reduce to powder, then add ½ oz. virgin wax; dissolve in a bottle with 1 qt. rectified spirits of wine. Let stand for 12 hours, and it is then fit for use.—10. One oz. gum lac, 2 dr. mastic in drops, 4 dr. sandarac, 3 oz. shellac, ½ oz. gum dragon. Reduce the whole to powder.—11. Yellow wax, 4 oz.; yellow soap, 2 oz.; water, 50 oz.; boil, with constant stirring, and add boiled oil and oil of turpentine, each 5 oz.—12. Soft water, 1 gal.; soap 4 oz.; white wax, in shavings, 1 lb. Boil together, and add 2 oz. pearlash. To be diluted with water, laid on with a paint brush, and polished off with a hard brush or cloth.—13. Wax, 3 oz.; pearlash, 2 oz.; water, 6 oz. Heat together, and add 4 oz. boiled oil and 5 oz. spirits of turpentine.—14. Raw linseed oil, 6 oz.; white wine vinegar, 3 oz.; methylated spirit, 3 oz.; butter of antimony, ½ oz.; mix the linseed oil with the vinegar by degrees, and shake well so as to prevent separation; add the spirit and antimony, and mix thoroughly.—15. Boiled linseed oil, 1 pt.; yellow wax, 4 oz.; melt, and color with alkanet root.—16. Acetic acid, 2 dr.; oil of lavender, ½ dr.; rectified spirit, 1 dr.; linseed oil, 4 oz.—17. Linseed oil, 1 pt.; alkanet root, 2 oz.; heat, strain, and add lac varnish, 1 oz.—18. (*French Polish Reviver.*) Linseed oil, ½ pt.; spirits of camphor, 1 oz.; vinegar, 2 oz.; butter of antimony, ½ oz.; spirit of hartshorn, ¼ oz.—19. Naphtha, 1 lb.; shellac, 4 oz.; oxalic acid, ½ oz. Let it stand till dissolved; then add 3 oz. linseed oil.—20. (*Red.*) 16 oz. oil of turpentine; 4 dr. alkanet; 4 oz. beeswax; digest the alkanet in the oil until sufficiently colored; then scrape the beeswax fine, and form a homogeneous mixture by digesting over a water-bath. For a pale polish, omit the

alkanet.—21. (*White.*) 1 lb. white wax; 32 oz. solution of potash; boil to proper consistency. (*For Fine Carved Wood.*) 8 oz. of linseed oil; 8 oz. of old ale; 1 egg (the white); 1 oz. of spirit; 1 oz. of spirits of salt; to be well shaken before using. A little is to be applied to the face of a soft linen pad and lightly rubbed for a minute or two over the article to be restored, which must afterwards be polished off with an old silk handkerchief. This will keep any length of time if well corked.—22. (*For Delicate Cabinet and Papier-mache Work.*) 32 oz. linseed oil; 8 oz. spirit; 8 oz. vinegar; 8 oz. butter of antimony; 8 oz. oil of turpentine; shake well before using, and apply with a woolen rubber.—23. 16 oz. oil of turpentine; 16 oz. rectified oil of amber; 16 oz. olive oil; 1 oz. oil of lavender; 4 dr. tincture of alkanet; mix. A cotton rubber is saturated with this polish, which is thus applied to the wood. The latter is then well rubbed with soft, dry, cotton rags and wiped dry.

POLISHES, For Shells.—1. Boil in a strong solution of potash; then polish with hydrochloric acid and putty powder.—2. Clean the surface with hydrochloric acid until the outer skin is removed. Wash in warm water, dry in sawdust and polish with chamois skin. If the shell is destitute of natural luster, rub with tripoli powder and turpentine applied with a chamois skin, and finally finish with olive oil.—3. Porcelainous shells are so hard as to require the apparatus of a lapidary to cut or polish them, but they are generally so smooth as to require no rough grinding. They may be polished by using a felt wheel and applying putty powder. Nacreous shells, or those of the pearl variety, may be filed and cut without a great deal of difficulty. Pieces to be turned are first roughly shaped on the grindstone, then turned and polished with pumice stone, putting on the final polish with rotten stone. Irregularly shaped pieces are filed and ground, then smoothed with pumice stone and water, and finished with rottenstone. The rottenstone is sometimes mixed with sulphuric acid full strength, or slightly diluted, to heighten the polish.—4. Rough shells are polished by first grinding them on a coarse stone, then smoothing them with pumice stone and water on a buffer wheel or with a hand polisher, and finishing with rottenstone.

POWDER, Luminous Face.—1. The blue and yellow rays of light falling upon the face and shoulders of ladies in full dress give them in the case of electric light often a ghastly appearance, and in the case of gas a sallow look. The separating of these rays, and thus lessening their effect, is easily done in chemistry by a solution of bichloride of potash. The electric light is especially rich in rays of violet, and these have a most unpleasant optical effect upon the human face. And to the avoidance of this effect a certain French student has recently been giving his attention, with the result that he has produced a face powder that is as delicate and fine as the popular article made from rice. The foundation of this luminous powder is sulphate of quinine, which has been dissolved in alcohol and is mixed with sulphate of zinc. It is called phosphorescent or fluorescent, because it retains its brilliancy for several hours in the hottest sun. In addition to being an adjunct of womankind to heighten beauty, it has been found to protect its user from the depressing effect of the sun. The face is first dampened by the lotion made from the quinine and alcohol and is then powdered with the sulphate of zinc. The powder wards off from the complexion the damaging colored rays that are in the spectrum, and thereby purifies the tint of the skin so that it is freed from all blemishes of nature or the artificial blemishes brought by the light, and becomes so pure almost as to be transparent.—2. The power of sulphate of zinc to absorb sunlight and give it back in the dark has been revealed. Poudre de riz made with this mineral gives a soft luminosity to a fair young face. A lady cyclist dusted all over with this powder is in herself a lamp on a pitch dark night. The luminous pigment is not liable to be spoiled by damp, by carbolic acid, or by any weak acid. It resists rain if united to some strongly adhesive body. There is a house in the Rue de Longchamps where a windowless set of rooms is lighted with it. The lady of the house receives there her friends at "5 o'clocks."

PRINTING, Sizes of Type.—The various sizes or bodies of type, and the proportion which they bear to each other are approximated in the following examples; but as each foundry varies the faces to suit itself, some faces are more extended and others more condensed than what are generally designated as the standard. As the different type foundries of the world varied also slightly in the bodies of the type, much inconvenience was caused in printing offices. But within a few years a "Standard Point System" has been adopted by American foundries, each "point" being one-twelfth pica in height, which has proved of great advantage. 11 sizes (or faces) are shown below, in order of gradation; Diamond, or 4½ point; Pearl, or 5 point; Agate, 5½ point; Nonpareil, 6 point; Minion, 7 point; Brevier, 8 point; Bourgeois, 9 point; Long Primer, 10 point; Small Pica, 11 point; Pica, 12 point; English, 14 point; Great Primer, 18 point. These are the sizes most commonly used in book and newspaper printing; but there are larger and even smaller faces, the latter, however, of no practical value.

POTATO BUGS, To Exterminate. — In using Paris green to exterminate the potato bugs, the poison should be mixed with the cheapest grade of flour, 1 lb. of green to 10 lb. of flour. A good way of applying it to the plants is to take an old 2 qt. tin fruit can, melt off the top, and put in a wooden head in which insert a broom handle. Bore a hole in the head also to pour the powder in, and then punch the bottom full of holes about the size of No. 6 shot. Walk alongside the rows, when the vines are wet with dew or rain, and make one shoot at each hill.

POTATOES, To Preserve. — For preserving potatoes in store, the floor is sprinkled with fine quicklime; this is covered with a layer (4 to 5 in. thick) of potatoes; this by a sprinkling of quicklime again, and so on, using the lime in the proportion of about 1 measure to 40 measures of potatoes. This method checks disease when it is present, and improves the potatoes if they are watery or waxy. Layers of straw and powdered plaster of Paris may be substituted for the lime.

POWDERS, Washing.—1. (*English Washing Crystal.*) An impure, half efflorescent crystallized soda, containing a large proportion of sulphate of soda and common salt.—2. (*Washing Crystals.*) Simply a filtered solution of borax and soda.—3. (*English Patent Cleansing Crystal.*) A half efflorescent soda, containing about 25 per cent. of Glauber's salts.—4. (*Washing and Cleansing Crystals.*) Pure crystallized soda, with 1 to 2 per cent. of borax.—5. (*Wool Washing Composition.*) A mixture of 35 parts of dried soda; 10 parts of soap powder; and 10 parts of sal ammoniac.—6. (*Wool Washer.*) A mixture of 90 parts of efflorescd soda crystals with 10 parts of soap powder.—7. (*Universal Washing Powder.*) A water glass containing soda, with a small percentage of tallow soap and starch powder.—8. (*Soap Extract.*) A mixture of crystallized soda and soda soap, containing water (soap 14.3, anhydrous soda 30, and water 55).—9. A washing powder for the finest white linen is a powdery mixture of 90 parts of efflorescd soda; 10 parts of hyposulphite of soda; 2 parts of borax.—10. (*Finest Brilliant Elastic Starch.*) A mixture of about 7 to 8 parts of stearine, with 150 parts of wheaten starch (melted stearine is mixed with about 15 times its weight of starch, and after cooling powdered and combined with the rest of the starch).—11. (*Berlin Prepared Brilliant Dressing Starch.*) Is good wheaten starch, mixed with 2 to 2½ per cent. of borax.

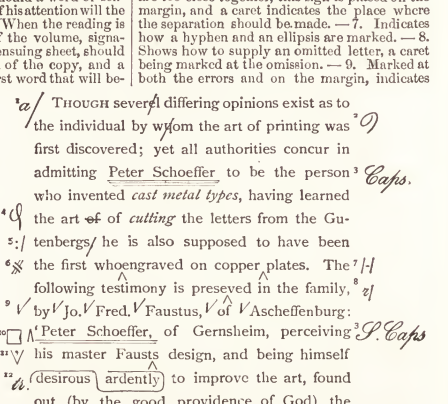
PRINTERS' ROLLER COMPOSITIONS.—1. Take an equal quantity of good glue and concentrated glycerine; soften the former by soaking in cold water, then melt it over the water bath, gradually adding the glycerine. Continue the heat until the excess of water has been driven off, meantime constantly stirring. Cast in brass or bronze moulds well oiled.—2. To 8 lb. transparent glue add enough water to cover it; let it stand with occasional stirring seven or eight hours. After 24 hours, all the water should be absorbed. Heat it in a water bath, as glue is always heated as soon as melted, and when both rise, remove from fire, and add 7 lb. molasses that has been made quite hot. Heat with frequent stirring for half an hour. The moulds should be clean and greased. Pour into moulds after it has cooled a little, and allow to stand 8 or 10 hours in winter; longer in summer. Some use fair more molasses, three to four times above quantity, and less water. In this case, after soaking one to one and a half hours, the glue is left on a board over night, and then melted with addition of no more water, and three or four times its weight of molasses added. Two hours' cooking is recommended in this case.—3. Resin soap and small quantities of oil and earthy matters are occasionally introduced. The heating must be continued until the greater part of the water has been expelled, when the composition is ready for casting in copper moulds, oiled and warmed.—4. Best glue, 10½ lb.; black molasses or honey, 2½ gal.; India rubber, dissolved in oil of turpentine, 1 lb.; Venice turpentine, 2 oz.; glycerine, 12 oz.; vinegar, 4 oz. The above formula is given for the mysterious black composition, so durable and elastic, and known to but very few persons until recently. Purified India rubber only is used. To recast, add 20 per cent. new material. The old home receipt is, 2 lb. best glue, soaked over night, to 1 gal. of New Orleans molasses. Will not recast.

PRICKLY HEAT, Remedy for.—Common salt in the bath will bring instant relief. It is as good as "iodinized sea salt" at 10c per pound, such as is sold in the drug stores. A little common washing soda will be found efficacious for children. If the affliction is severe, almost to the point of eczema, a spoonful of sulphurus acid in a full bucket of water, to be used in a sponge bath, will act like a charm. This is every bit as good as the sulphur vapor bath once so popular.

POLISHING-CLOTHS, For Silver.—Polishing cloths such as jewelers use are warranted to keep silver in brilliant condition. They prevent the scratching which the application of powders to the metal usually produces. To make them, boil soft rags in a mixture of fresh milk and hartshorn-powder, an ounce of the powder being used to a pint of the milk. When they have boiled for five minutes they should be hastily passed through cold water, so that they will be cool enough to wring out and dry before the fire. After the silver is washed and dried each day, it should be polished with a cloth prepared in this manner.

PROOF-READING. — Proofs are now taken by a hand press instead of by planer and mallet. The reader examines the folded sheet to see if the signature, head-lines and paging are correct. The person holding the copy should read clearly and at a moderate pace. It is absolutely essential that the proof-reader should have a desk away from the possibility of detraction by any noises resulting from the conversation or questions of others. No good proof-reading is possible under such circumstances, and the reader should not be held responsible for errors. The eye of the reader should not follow but precede the voice of the one reading; by this mode he will

anticipate the copy; and should a word or sentence be missing in the proof his attention will the more readily be arrested. When the reading is concluded, the number of the volume, signature and first word of the ensuing sheet, should be marked on the margin of the copy, and a bracket made before the first word that will begin the next sheet; the reader will thus be certain that the commencement is right when he gets the succeeding sheet. After the errors have been corrected in the form, a revise is pulled and the reader compares the corrected sheet with the one first read, to ascertain if the corrections have been properly made; and, if the work be a reprint, or the author is not to examine the proof, he proceeds to read it carefully for press. Some proofs are so foul, that it is almost impossible to correct the marks at one time, and it is necessary to have the errors corrected and another sheet pulled before the proof is read finally. In revising a proof, the reader should not only look at the word marked, but glance at every line in which an alteration has been made. Should outs or doubles occur in a proof, such parts ought to be again examined by copy. The illustrations show the manner of correcting a proof, and the same matter after correction: The markings of the corrections are designated by a number for each kind. — 1. A wrong letter or word is corrected by marking a line through it, and putting the right letter or word on the margin of the page, behind a short line. — 2. This signifies that the letter marked is upside down, and should be turned. — 3. When it is desired to change the character of the letters to that of "lower case" (small letters), "caps" (capitals), "small caps" (small capitals), or to italics, it is done by underlining the words as indicated, and writing these abbreviations on the margin. — 4. Take out the marked letters or words. — 5. Put in or change a punctuation point; encircle the correction on margin. — 6. When two letters or words are too close together, this sign is placed on the margin, and a caret indicates the place where the separation should be made. — 7. Indicates how a hyphen and an ellipsis are marked. — 8. Shows how to supply an omitted letter, a caret being marked at the omission. — 9. Marked at both the errors and on the margin, indicates that there is too much space between the letters or words. — 10. Shows that a new paragraph is wanted there, where a caret is marked. — 11. Exhibits the manner of supplying the apostrophe and all other marks, the position of which is on the upper part of a line. — 12. Shows how to mark letters and words that are out of their proper order, that they may be re-arranged. — 13. Indi-



cates how to restore words that have once been marked out, but afterwards are decided to be retained, by underlining with dots and writing the word "stet," in the margin.—14. When a space sticks up between two words, a line under it and this mark on the margin, indicate it is to be pushed down.—15. Shows how to supply omitted words which are too many to be written on the margin. When the omission is too large, it is usual to write on the margin, "Out, see copy," and the copy is returned with the words inclosed in brackets and "out" marked on its margin.—16. Indicates that the letters hang or stand crooked, and should be straightened up.—17. "W.f." is an abbreviation for "wrong font," and signifies that a letter of the same face with the rest of the word must be used.—18. If a line begins wrongly with an indentation as a paragraph, this sign, signifying "no paragraph," is used, with a line connecting the last and first words of the separation.—19. When a word is to be supplied, a caret indicates where, and the word is written on the margin behind a short line.—20. A broken or faulty letter is marked, and a cross placed on the margin.—21. Shows where a word has been accidentally separated by a space.

THOUGH several differing opinions exist as to the individual by whom the art of printing was first discovered; yet all authorities concur in admitting PETER SCHOEFFER to be the person who invented *cast metal types*, having learned the art of *cutting* the letters from the Gutenbergs: he is also supposed to have been the first who engraved on copper plates. The following testimony is preserved in the family, by Jo. Fred. Faustus, of Aschеffenburg;

'PETER SCHOEFFER, of Gernsheim, perceiving his master Faust's design, and being himself ardently desirous to improve the art, found out (by the good providence of God) the method of cutting (*incidendi*) the characters in a matrix, that the letters might easily be singly *cast*, instead of being *cut*. He privately *cut matrices* for the whole alphabet: and when he showed his master the letters cast from these matrices, Faust was so pleased with the contrivance, that he promised Peter to give him his only daughter Christina in marriage, a promise which he soon after performed. But there were as many difficulties at first with these letters as there had been before with wooden ones, the metal being too soft to support the force of the impression: but this defect was soon remedied, by mixing a substance with the metal which sufficiently hardened it.'

POLISH, For Piano Keys. — The frame would not hold the keys sufficiently level or firm. A better way would be to handscrew a few at a time on a board, and scrape them in that position. They should be finished with flour paper, care being taken that they do not get too hot during the process. Unless the keys are very hollow or much discolored, it would perhaps be better to dispense with the scraper altogether, using a coarser glasspaper in its stead. They should be polished singly, on a board covered with several thicknesses of cloth; this should be placed on a bench, and the ivories vigorously rubbed, lengthwise and face downward, until a good polish is obtained. Putty powder is the best polishing material, though pumice might first be used to take out any marks left by the paper. A very brilliant polish may be got by finishing the keys with a similar board covered with wash leather, and sprinkled with rouge. A liberal supply of water is necessary during the process.

POWDERS, Sachet. — The material is either to be ground in a mill or powdered in a mortar, and afterward sifted. — 1. (*Acacia.*) Cassie flower heads, 1 lb; orris powder, 1 lb.—2. (*Scent Powder.*) The following recipe for scent powder to be used for wardrobes, boxes, etc., gives an article far superior to the mixtures sold in the shops: Coriander, 1 oz.; orris root, 1 oz.; rose leaves, 1 oz.; and aromatic calamus, 1 oz.; lavender flowers, 2 oz.; rhodium wood, ½ dr.; musk, 5 gr. These are reduced to a coarse powder. The scent on the clothes is as if all fragsant flowers had been pressed in their folds. — 3. Take of reindeer moss, in coarse powder, any quantity, and very strongly scent it with any of the compound fragrant essences, or with the perfumes of which they are made, or with mixed essential oils, at will.

PRESERVING CUT FLOWERS.—Plants vary in their nature, and different causes lead to decay. Certain flowers, like the flag, the lily, the pansy and others, slough away when put into water. Cut off the end of the stems very frequently. Wild flowers develop and fall more quickly than those from the garden. Flowers plucked in the

bud last longer. Flowers should always be placed in water as soon as possible after being picked; when received by post in a somewhat wilted condition, an immediate plunge into hot water, with a little sal volatile will accomplish wonders. If you are fond of flowers in your hair or corsage, they can be made to last an entire evening if the ends are sealed with a bit of wax.

PRESERVING FRUIT, Table of Time for.—

Fruit.	Time for boiling.	Sugar to qt. of fruit.
Cherries	5 min.	6 oz.
Raspberries	6 min.	4 oz.
Blackberries	6 min.	4 oz.
Strawberries	8 min.	8 oz.
Plums	10 min.	10 oz.
Whortleberries	5 min.	8 oz.
Pie plant	10 min.	8 oz.
Sour pears (whole)	30 min.	4 oz.
Bartlett pears (halves)	20 min.	6 oz.
Peaches (halves)	8 min.	4 oz.
Peaches (whole)	15 min.	4 oz.
Pineapples (sliced)	15 min.	6 oz.
Crab apples	25 min.	8 oz.
Sour apples	10 min.	5 oz.
Ripe currants	6 min.	8 oz.
Gooseberries	8 min.	8 oz.
Wild grapes	10 min.	8 oz.
Quinces (sliced)	15 min.	10 oz.
Tomatoes	20 min.	½ teaspoonful of salt.

RAIN-GUAGE.—A convenient rain-guage sufficient for ordinary agricultural purposes may be made of a common funnel and a large-sized bottle. The upper rim of the funnel should be made so that no water falling into it will splash out. The large opening of the funnel must be circular and exactly 8 in. in diameter, and the water caught by it is collected in the large bottle. The bottle must be graduated; to do this, set it on a level table and pour into it 3½ oz. clean water. On the bottle make a mark at the level at which the water stands. Now add 3½ oz. more, and make another mark; continue this until the scale is finished. Each of these marks means ½ in. of rain fall. This scale may be marked off on paper and pasted in the proper position on the bottle. In using the rain-guage never set it on sloping ground, but on a level surface, at a distance from shrubs, trees, walls, buildings, at least as many feet from their base as they are in height. The guage must be set so that it will withstand a gale of wind. When snow or sleet collects in the guage it should be removed to a warm room for the snow to melt, the quantity of water produced being noted as in the case of rain.

RATS.—1. (*To Catch.*) It is said that rats can not resist sunflower seeds. A trap baited with these seeds is the most effectual method of catching them.—2. (*To Drive Away Alive.*) Somebody who has tried it recommends putting pulverized potash, which soon becomes sticky when exposed to the air, in all the rat-holes about the house. The special detestation of a rat is anything which will stick to his silky coat. Some persons find a mixture of equal parts of cayenne pepper and Scotch snuff sprinkled well into the holes still more efficacious.

RAZOR PASTE.—1. (*Pradier.*) Best putty powder, 1½ oz.; jewelers' rouge, 1½ oz.; scales of iron, ¾ oz.; levigated Turkey ston stone, 4½ oz.; beef suet, 2½ oz.—2. Put equal parts of dried sulphate of iron and salt in a closed vessel and apply a gradually increased heat. Pulverize, elutriate, mix with lard or tallow.

REMEDIAL FOODS.—Celery is invaluable as a food for those suffering from any form of rheumatism, for diseases of the nerves and nervous dyspepsia.—Lettuce is useful to those suffering from insomnia.—Water cress is a remedy for scurvy.—Peanuts for indigestion. They are especially recommended for corpulent diabetes. Peanuts are made into a wholesome and nutritious soup, are brewed and used as coffee, are eaten as a relish simply baked, or are prepared and served as salted almonds.—Onions are almost the best nervine known. No medicine is so useful in cases of nervous prostration, and there is nothing else that will so quickly relieve and tone up a worn out system. Onions are useful in all cases of coughs, colds and influenza; in consumption, insomnia, hydrophobia, scurvy, gravel and kindred liver complaints. Eaten every other day, they soon have a clearing and whitening effect on the complexion.—Spinach is useful to those suffering with gravel. Asparagus is used to induce perspiration.—Carrots for sufferers from asthma.—Turnips for nervous disorders and for scurvy.—Raw beef proves of great benefit to persons of frail constitution, and to those suffering from consumption. It is chopped fine, seasoned with salt and heated by placing it in a dish in hot water. It assimilates rapidly, and affords the best nourishment.—Eggs contain a large amount of nutriment in a compact, quickly available form. Beaten up raw, with sugar, they are used to clear and strengthen the voice. With sugar and lemon juice the beaten white of egg is used to relieve hoarseness.—Honey is wholesome, strengthening, cleansing, healing and nourishing.—Fresh ripe fruits are excellent for purifying the blood and toning up the system. As specific remedies, oranges are aperient. Sour oranges are highly recommended for rheumatism.—Cranberries for erysipelas are used externally as well as internally.—Lemons for feverish thirst in sickness, for biliousness, low fevers, rheumatism, colds, coughs, liver complaint, etc.—Blackberries as a tonic. Useful in all forms of diarrhœa.—Tomatoes are a powerful aperient for the liver, a sovereign remedy for dyspepsia and indigestion. Tomatoes are invaluable in all conditions of the system in which the use of calomel is indicated.—Figs are aperient and wholesome. They are said to be valuable as a food for those suffering from cancer; they are used externally as well as internally.—Apples are useful in nervous dyspepsia; they are nutritious, medicinal and vitalizing; they aid digestion, clear the voice, correct the acidity of the stomach, are valuable in rheumatism, insomnia and liver trouble. An apple contains as much nutriment as a potato in a

pleasanter and more wholesome form.—Grapes dissolve and dislodge gravel and calculi, and bring the stomach and bowels to a healthy condition.—Pie plant is wholesome and aperient; is excellent for rheumatic sufferers and useful for purifying the blood.

RICE, To Boil.—Pick your rice clean and wash it in two cold waters, not draining off the last water until you are ready to put the rice on the fire. Prepare a saucepan with water and a little salt. When it boils, sprinkle in the rice gradually, so as not to stop the boiling. Boil hard for twenty minutes, keeping the pot covered. Then take it from the back of the fire and pour off the water, after which set the pot on the back of the stove to allow the rice to dry and the grains to separate. Remember to boil rapidly from the time you cover the pot until you take it off; this allows each grain to swell to three times its normal size, and the motion prevents the grains from sticking together. Don't stir it, as this will cause it to fall to the bottom and burn. When properly boiled, rice should be snowy-white, perfectly dry, soft, and every grain separate.

RING, Tight, to Remove.—A ring which is so tight on the finger as to preclude removal by the ordinary methods, can be easily removed by thoroughly cleaning the finger and ring from all dirt and grease, and then dipping them in a deep cup of mercury, on the top of which a small quantity of a saturated solution of oxalic acid has been poured. Amalgamation of the ring rapidly occurs, and it can be broken in pieces without difficulty. If it is a gold ring, the acid is not necessary, but if brass or copper it must be dipped in the acid or the mercury will not attack it.

ROSES, White, to Make Blue.—Water the trees throughout the winter with a solution of Prussian blue, and if you want them to be green use sulphate of copper.

ROTATION OF CROPS.—It is well to have some system of rotation adapted to the soil and farm under cultivation, thus bringing every part of the farm into grass again, at intervals of 10 or 15 years. If five acres of sod be broken yearly, and five acres be put down to grass, ten acres will be annually under the plow; which, for one hundred acres, would give meadows of ten years' standing. Under such a system it will be seen, the land could be thoroughly cultivated and enriched, and made to produce larger returns both in grain and grass.—1. The following is a *rotation of four years*, which is greatly approved of by practical men, as it has the merit of substituting alternate and continuous rotation for triennial rotation. It is carried out according to the following plan: First year, potatoes; second, wheat; third, clover; fourth, wheat.—2. First year, beetroot; second, wheat; third, clover; fourth, wheat.—3. (*Rotation of Five Years.*) First year, potatoes; second, wheat; third, clover; fourth, colza; fifth, wheat.—4. First year, potatoes; second, wheat; third, clover; fourth, wheat; fifth, oats.—5. First year, colza; second, beetroot; third, wheat; fourth, clover; fifth, wheat.—6. (*Rotation of Six Years.*) Linseed, beetroot, wheat, colza, wheat, oats, rye, or barley.—7. Flax, beetroot, wheat, colza, wheat, oats, barley, or rye.

ROUND SHOULDERS, To Cure.—Anybody can cure round shoulders by a very simple system of exercise. The round-shouldered man should go into the open air three or four times a day, let his hands drop to his sides and then, while inhaling fresh air, raise himself on his toes as high as he can. The filling of the lungs pushes the shoulders back to their normal condition, and if the practice is steadily followed for a couple of months, the worst pair of stoop shoulders in time will become as straight as a drill sergeant's.

RUBBER, Artificial.—1. Prepared by mixing a thick solution of glue with tungstate of soda and hydrochloric acid. A compound of tungstic acid and glue is precipitated, which at 86° to 104° Fahr. is sufficiently elastic to admit of being drawn out into thin sheets. On cooling this mass becomes solid and brittle, but on being heated is again soft and plastic. This compound can be used for many of the purposes to which rubber is adapted.—2. Heat in an iron kettle, ½ filled, 10 lbs. sulphur and 20 lbs. rapeseed oil, with constant stirring until the sulphur is melted, and the mass begins to swell; then pour it into a mold dusted with some kind of powder, or upon a slab moistened with water, when it will harden at once. Linseed oil may take the place of rapeseed, when less sulphur must be used.

RUBBER, To Dissolve.—1. A mixture of 6 parts absolute alcohol with 100 of sulphate of carbon; the latter is the real solvent; the alcohol has an indirect action. The quantity of solvent required depends on the consistency of solution required; if moderate heat is used and the mixture shaken, the whole dissolves; but a better solution is obtained for adhesive properties by using a large quantity of solvent; not shaking, but drawing off the clear glazy liquid. —2. For a small quantity, place 1 fl. dr. sulphuric acid and the same quantity of water in a vial, and shake together; great heat is evolved; allow to stand till cool; then add 2 fl. oz. spts. turpentine and shake well; great heat will be evolved and the color changed to deep cinnamon. Allow to stand 24 hours, after which a strong, dark sediment will have settled at the bottom of the bottle. Pour off the clear into another bottle, and add 1½ dr. (apothecaries' weight) common India rubber cut into shreds, and then place it uncorked over a gentle heat, and boil slowly 5 hours. At the end of that time the India rubber should be dissolved. It can be concentrated by longer boiling, or thinned by addition of turpentine.—3. The solution of India rubber or gutta percha in chloroform or benzole, frequently called for in photographic work, is usually attended with so many difficulties and drawbacks that in nine cases out of ten, where the solution is required the experimentalist usually purchases it ready made. Yet there need be no difficulty about the matter. First, pure rubber should be obtained. When vulcanized, it is perfectly insoluble. Secondly, pure solvents are necessary. Chloroform containing a large excess of alcohol and water will

fail to act even upon the purest rubber. Again, under the most satisfactory conditions, the action is very slow, and the amount of rubber capable of being taken up is proportionately very small. The plan usually adopted is to place a large amount of shredded rubber in a bottle, which is then filled up with the solvent, and shaken at intervals a few times; and when the shreds do not dissolve like pieces of sugar the whole is thrown aside, and we are written to for an explanation of the failure. If a small quantity of rubber had been placed in the bottle, and the liquid added, it would have been observed gradually to swell out very considerably after the lapse of some time, and a mixture of the whole would be facilitated by stirring with a glass rod or a splinter of wood. The rapidity with which the rubber absorbs the solvent will depend upon its condition; but the action is never very quick, nor is it in any way analogous to the dissolution of a crystal. One cause of the failure of chloroform to act upon the caoutchouc may arise from the presence of alcohol in too great a proportion. Chloroform as sold almost always contains alcohol in small quantity, owing to the fact that when none is present it cannot be prevented from decomposing spontaneously, more especially in the light. It is, however, stated that when entirely protected from light absolute chloroform will not undergo any change. A solution of gutta percha in chloroform has a use which is not generally known. It forms, when carefully made and filtered quite bright, the best possible material for obscuring glass for focusing screens. For fine microscopic work it is said by those whose opinions are of weight to be unequaled. —4. This new solvent consists of a mixture of methylated ether and petroleum spirit—the common benzoline used for burning in sponge lamps. This forms the most rapid and, perhaps, the best solvent; the mixture is as much superior in power to either of its constituents singly as the ether-alcohol is to plain ether in its action on pyroxylin. A very thick solution can be made by dissolving 60 gr. of good India rubber in 2 oz. of benzoline and 1 oz. of sulphuric ether. If the India rubber be cut up fine and the mixture shaken occasionally, the solution will be complete in two or three hours, when it may be diluted to any required strength with benzoline alone. The India rubber should be as light colored as possible, and all the outer oxidized portions must be cut away. Shred the clean India rubber with a pair of scissors, and throw it at once into the solvent.

RUBBER, Elasticity of, to Restore.—Immerse the articles in a mixture of water of ammonia, 1 part; and water, 2 parts; for a time varying from a few mintes to 1 hour, according to circumstances. When the mixture has acted on the rubber it will be found to have recovered its elasticity, smoothness and softness.

RUBBER HOSE, Composition for.—Grind together Java rubber, 20 lbs.; Para rubber, 10 lbs.; white lead, 14 lbs.; red lead, 14 lbs.; yellow sulphur, 1½ lbs. Spread on flax cloth, which weighs 10, 16, and 32 oz. to the sq. yd.

RUBBER HOSE, To Repair.—Cut the hose apart where it is defective; obtain from any gas fitter a piece of iron pipe 2 or 3 in. long; twist the hose over it until the ends meet; wrap with strong twine well waxed, and it will last a long time.

RUBBER, To Preserve.—To keep rubber from cracking, use a mixture of 1 part aqua ammonia with 2 parts water, in which the articles should be immersed until they assume their former elasticity, smoothness and softness, the time required varying from a few minutes to 1 hour.

RUBBER, To Vulcanize.—1. The vulcanizing process consists in incorporating with the rubber 3 to 10 per cent. sulphur, together with various metallic oxides, chiefly lead and zinc, the quantity of the latter articles being regulated by the degree of elasticity required. The goods of large establishments are vulcanized in cylindrical wrought iron steam heaters, over 50 ft. long, and 5 to 6 ft. in diameter. These heaters have doors opening on hinges at one end, and through these the goods are introduced on a sort of railway carriage; then, after the door is shut, steam is let on, and a temperature of 250° to 300° of heat is kept up for several hours, the degree of heat ascertained by thermometers attached to the heaters. The value, solidity and quality of the goods is increased by keeping the articles under the pressure of metallic molds or sheets while undergoing this process. The process requires careful manipulation and great experience to conduct it properly.—2. In vulcanizing rubber in contact with iron, so that the vulcanized rubber and metal will cohere, coat the iron all over with a melted mixture of equal parts of genuine asphaltum and gutta percha. Soft rubber containing 6 per cent. of sulphur, when firmly pressed into contact with this coating and then vulcanized by steam heat, adheres strongly to the metal after cooling.

RUGS, To Make from Old Carpets.—There are three methods of forming old ingrain carpets into rugs pretty and serviceable. They are, in fact, prettier than almost any other style of home-made rugs. In the first method, cut the carpeting, after it has been thoroughly cleaned and dried, into narrow strips across the width. Three-fourths of an inch is the right width. Then draw the strips through the hands a few times to fray the edges somewhat. They are then sewed together by joining the selvedges in a strong over-cast stitch and wound into balls the same as all carpet rags are when prepared for the loom. Made in this way, the rugs when woven do not have as nice a nap as when made by the following methods, but as there is no waste of material the benefit is evident. Of course, all-wool ingrain is the best kind for this purpose. The amount necessary for a rug made in this way is 2½ pounds if 1 yard square, while in the second, 4 pounds are required. In this second method the strips are cut lengthwise of the width, the same size as the other, and then fringed a quarter of an inch on each side. Thus a fine nap is formed when the rug is woven; but when we consider the waste of good material and the tedious work necessary, we conclude that it does not pay. In sewing these strips to-

gether care must be exercised in lapping the ends neatly, so that they will not show when the rug is woven. Then form into balls. Any one who weaves rag carpets well can weave these rugs, but they must be woven good in order to be a success. Loose, careless weaving spoils their appearance. There must be enough warp woven on each end of the rug to serve for the purpose of hemming. Usually the looms are intended to weave only one yard in width, but in some places there are those who make a specialty of rug-weaving and can weave them 12 feet wide. Made in this width, for somewhat less, and woven with a heavy warp, much coarser than that used in rag carpets, they make handsome center squares for parlor or dining room, and will cost for weaving and warp about $5, and are as handsome as those bought at the stores costing five times as much. No matter if the old carpet is old and faded, and worn all to pieces, there are great possibilities in it. Just go to work, wash and dry it, and cut it up; the faded browns and yellows become a lovely mottled brown rug, in tint like the dead leaves of autumn. The carpets, whose colors were chiefly green and red, become an attractive mossy-looking rug.

RUST, To Prevent.—1. (*On Grates or Fire-irons.*) To preserve bright grates or fire-irons from rust, make a strong paste of fresh lime and water, and with a fine brush smear it as thickly as possible all over the polished surface requiring preservation. By this simple means all the grates and fire-irons in an empty house may be kept for months free from harm without further care.—2. (*On Iron and Steel Surfaces.*) Caoutchouc oil is said to have proved efficient in preventing rust, and to have been adopted by the German army. It only requires to be spread with a piece of flannel in a very thin layer over the metallic surface and allowed to dry up. Such a coating will afford security against all atmospheric influences and will not show any cracks under the microscope after a year's standing. To remove it, the article has simply to be treated with caoutchoc oil again, and washed after twelve to twenty-four hours.—3. A solution of India rubber in benzine has been used for years as a coating for steel, iron and lead, and has been found a simple means of keeping them from oxidizing. It can be easily applied with a brush and is as easily rubbed off. It should be made about the consistency of cream.—4. All steel articles can be perfectly preserved from rust by putting a lump of freshly burnt lime in the drawer or case in which they are kept. If the things are to be moved (as a gun in its case, for instance), put the lime in a muslin bag. This is especially valuable for specimens of iron when fractured, for in a moderately dry place the lime will not want renewing for many years, as it is capable of absorbing a large quantity of moisture. Articles in use should be placed in a box nearly filled with thoroughly pulverized slaked lime. Before using them rub well with a woolen cloth.—5. The following mixture forms an excellent brown coating for protecting iron and steel from rust: Dissolve 2 parts crystallized iron chloride, 2 parts antimony chloride and 1 part tannin, in 4 parts water and apply with a sponge or rag and let dry. Then another coat of the paint is applied, and again another, if necessary, until the color becomes as dark as desired. When dry, it is washed with water, allowed to dry again, and the surface polished with boiled linseed oil. The antimony chloride must be as nearly neutral as possible.—6. (*On Iron, Underground.*) Cottonseed or linseed oils, 1 lb.; coal tar, 1 lb.; sulphur, 1 lb.; heat separately; mix thoroughly and heat to 300° F. for about one hour, at the end of which it becomes pasty. Heat the metal to which it is applied.—7. (*Within Show Cases.*) It is well known that the rusting of bright steel goods is due to the precipitation of atmospheric moisture upon the metal. This may be obviated by keeping the air surrounding the goods in a dry condition, and a saucer of powdered quicklime placed in an ordinary show-case will usually suffice to prevent the rusting of the cutlery exhibited therein, as the lime will take up the moisture.

RUST, To Remove.—Articles of iron and steel can be easily and thoroughly cleaned from rust by being plunged into a strong solution of chloride of zinc and allowed to remain for twelve hours, or even longer if the rust be very thick. Upon removal the metal should be washed with plain water and then with ammonia water, and quickly dried. Rubbing with putz-pomade will then give them a brilliant polish.

SALAD DRESSING.—This is excellent both for salad and for sliced tomatoes in summer. Take the yolk of 1 fresh egg and mix it with 2 tablespoonfuls of olive oil very slowly, add 1½ spoonfuls of mustard, 3 spoonfuls of salt, a little pepper, and last of all, 2 spoonfuls of vinegar. Beat the white of the egg to a stiff froth, and lightly stir in.

SALAD, Egg.—Of all the delicate bites the egg salad should surely have the palm. It is easily made, and can be arranged early in the morning, leaving the dressing to be the very last duty before the guests arrive. This salad of egg is really of stuffed eggs; and one cup should be given to each person. Boil 10 eggs 20 minutes. Peel off the shells and cut each egg in half, so as to form two cups. From the end of each cup cut a small slice, so they will stand firm. Remove from each egg the yolk and put all the yolks in a bowl. Mix together in an earthen sauce pan 2 eggs well beaten, 1 teaspoonful of dry mustard, 3 tablespoonfuls of sweet cream, 1 teaspoonful of salt, 1 teaspoonful of pepper, 2 tablespoonfuls of olive oil and 2 tablespoonfuls of vinegar. Boil until thick as custard and mix with the hard boiled yolks. Fill the cups made from the white with the mixture and set on ice until cold. Serve each cup with a leaf of lettuce and pour over egg and lettuce some mayonnaise sauce. On the plate should also be a slice or two of thin bread and butter and a cup of Russian tea in which sugar and cream is added. A teaspoonful of rum is a great improvement.

SALTED PECAN NUTS.—Purchase the ready-shelled pecan nuts from a confectioner's. Have a small wire strainer; place the nuts in it. Put

into a small saucepan into which the strainer will fit nicely equal parts of butter and lard. When boiling stand the strainer of nuts into it, and allow it to remain for an instant; remove, drain on brown paper and sprinkle with salt. Stand instantly in a cold place and they will become crisp.

SANDWICHES, To Make.—1. (*Cabbage.*) Substituting finely chopped cabbage for the celery. (See CELERY.)—2. (*Celery.*) Chop celery very fine, heart and all, and add enough salad dressing to spread it easily.—3. (*Cheese.*) Split small crackers, spread thickly with grated cheese, place together, lay on a pan, sprinkle well with salt, and set in the oven until only slightly browned. These make deliciously crisp sandwiches that are very relishable served with tiny cucumber pickles.—4. (*Cucumber.*) Chop very fine tart cucumber pickles, add one-half the amount of hard-boiled egg yolks rubbed smooth, and enough melted butter, and vinegar from the pickle to form a paste. Mix thoroughly and spread.—5. (*Fruit.*) Dainty fruit sandwiches are a novelty for afternoon tea. Cut the bread very thin and butter it lightly, then spread with raisins, dates or candied cherries that have been chopped fine and moistened with orange juice, sherry or madeira. Roll and tie with baby ribbons. When used for light evening refreshments, lemonade or punch is served with these.—6. (*Lemon.*) Into a teacupful of nicest butter slightly softened beat the raw yolk of an egg and a teaspoonful of French mustard. Rub smooth the yolks of two eggs that have been boiled for three-quarters of an hour; rub into them one-fourth of the butter, a scant half teaspoonful of salt and a teaspoonful of lemon juice. Add another fourth of the butter and a teaspoonful of lemon juice, and so on until all the butter and two tablespoonfuls of lemon juice have been used, rubbing completely until all is smooth and fine, and spread moderately thick. These are as appetizing as anything could well be.—7. (*Mixed.*) Chop very fine any cold meat or bits of fowl; two or three kinds may be used; add one-half the amount of finely chopped cabbage or celery; mix with sufficient salad dressing to thoroughly moisten, and let it stand two or three hours before spreading between the slices of bread.—8. (*Nut.*) Chop hickory-nuts, walnuts or hazel-nuts until fine, and mix with salad dressing; or with the rolling-pin roll to a paste, sprinkle well with salt, and spread very thickly between slices of bread cut as thinly as possible.—9. (*Peach.*) Pare very ripe peaches, slice thinly, sprinkle well with sugar, and let stand for two or three hours. Spread bread thickly with fresh, sweet country butter, add plenty of the sliced peaches, and serve at once. Almost any seedless fruit may be used for sandwiches. If for a picnic, slices of sponge-cake may be used instead of bread, and whipped cream substituted for butter, and served for dessert.—10. (*Peanut.*) Peanuts mixed with mayonnaise dressing make an acceptable filling for bread sandwiches and are the thing to be served for the 5 o'clock tea. Take freshly roasted peanuts, chop them very fine, or, better still, roll them to a fine meal; then mix with the dressing; spread on buttered bread, covered with shredded lettuce.—11. (*Tomato.*) Pare very ripe tomatoes, and press through a sieve to remove the seeds; mix thoroughly with mayonnaise dressing.

SALTED ALMONDS.—Heat 1 tablespoonful best butter, or 1 scant teaspoonful olive oil, smoking hot. Then add ½ lb. Jordan Almonds, blanched. When the almonds begin to brown, sprinkle over them 1 scant tablespoonful salt, and stir and shake until all are a golden brown. Oil gives a higher glaze than butter.

SALTED PEANUTS.—Buy raw; shell; put in oven and bake until the skin cracks. Brush the skins off, and proceed as with almonds.

SAUCEPAN or KETTLE, To Mend.—A hole in a granite saucepan or kettle may be mended by using a copper rivet. These rivets, which come in several sizes, may usually be bought from a harness-maker. The rivet is put in the hole, and over the end of it is put a copper washer, which is a part of it. Flatten the end of the rivet with a tack-hammer, and the kettle is good for service for many days. When the enamel is chipped from a spot in the bottom of the saucepan, the weak spot may be re-enforced in the same way.

SAUCES, To Make.—1. (*Fish.*) Port wine, 1 gal.; mountain, 1 qt.; walnut ketchup, 2 qt.; anchovies and liquor, 2 lb.; 8 lemons; 36 shallots; scraped horseradish, 1½ lb.; flour of mustard, 8 oz.; mace, 1 oz.; cayenne, q. s.; boil up gently, strain and bottle.—2. Twenty-four anchovies; 10 shallots; scraped horseradish, 3 spoonfuls; mace and cloves, of each ½ oz.; 2 sliced lemons; anchovy liquor, 8 oz.; water, 1 pt.; Hock or Rhenish wine, 1 bottle; walnut ketchup, ½ pt.; boil to 2½ lb.; strain and bottle.—3. (*Quin's.*) Walnut pickle and port wine, of each, 1 pt.; mushroom ketchup, 1 qt.; anchovies, and shallots, chopped, of each, 2 doz.; soy, ½ pt.; cayenne, ½ oz.; simmer for 10 minutes, strain and bottle.—4. Walnut pickle, mushroom ketchup and soy, of each, 1 pt.; chopped cloves of garlic and anchovies, of each, 1 doz.; cayenne and bruised cloves, of each 1 dr. As last.—5. (*Sauce Superlative.*) Port wine and mushroom ketchup, of each 1 qt.; walnut pickle, 1 pt.; pounded anchovies, ½ lb.; lemon peel, minced shallots and scraped horseradish, of each 2 oz.; allspice and black pepper, bruised, of each 1 oz.; cayenne pepper and bruised celery seed, of each ½ oz. (or currie powder ¾ oz.); digest 14 days, strain and bottle.—6. (*Tomato.*) Bruised tomatoes, 1 gal.; salt, ½ lb.; in three days press out the juice; to each qt. add shallots, 2 oz.; black pepper, 1 dr.; boil for 30 minutes; strain, add mace, allspice, ginger and nutmeg, of each ½ oz.; coriander seed and cochineal, of each 1 dr.; simmer gently for fifteen minutes, strain, cool and bottle.

SAWS, To Mend.—File to a powder pure brass, 3 parts; pure silver, 2½ parts; pure copper, 1½ parts. Mix thoroughly. Put the saw on an anvil, the broken edges in contact. Put a line of the above mixture along the seam, cover with powdered charcoal. Take a spirit lamp and a blowpipe, hold the coal dust in place, and blow just enough to melt the solder

Set the joint smooth with a hammer. File away the superfluous solder.

SCAB. Apple, to Prevent.—Apple scab, the worst fungus disease of the apple in this country, was very largely controlled in orchards sprayed once before the buds started in the spring with copper sulphate (2 pounds to 50 gallons of water), and four times subsequently with Bordeaux mixture. The Bordeaux mixture was applied in various strengths, from 1 lb. to 6 lbs. of copper sulphate and the same weight of lime to 50 gal. of water. The 3 and 4-pound solutions gave as good results as the 6-pound solution the first season, and the second season, after systematic spraying was begun, the 1 and 2-pound solutions were sufficient to hold the scab almost entirely in check. In unsprayed orchards the scab ripens, its spores germinate upon the fruit and leaves, causing a second crop of the fungus, that appears as clouds or blotches on the apple in autumn. On sprayed trees no trace of this second crop of scab could be found, while on unsprayed apples it was almost universal.

SCARS. To Remove.—The cicatrices, scars or marks left by various diseases, burns or wounds of divers kinds, are often less obstinately permanent than is generally supposed, and from some facts which have lately come under notice, it is thought that their prevention or removal in many cases may be accomplished by some mild but effectual antiseptic. Among the exemplifications of the efficacy of the formula, is the case of a gentleman whose face was so severely burnt by the violent spurting of a quantity of melted lead (owing to a workman having incautiously dropped a wet pipe into it), that his eyes were only saved by pebble spectacles from utter destruction. At first, of course, carron oil was the sole application, and as for weeks afterward particles of the granulated metal had literally to be dug out of the flesh, a deeply scarred countenance was naturally predicted by all, except the patient himself. One mark of an almost imperceptible character alone remained after the expiration of 6 months, owing to the whole face being bathed twice or three times a day, as soon as the oil treatment could be discontinued, with a lotion of the simplest character, as is readily seen by glancing at its constituents. Lint soaked in the same solution and allowed to remain on some little time, will frequently mitigate the visible results of smallpox, and one case ringworm treated in this way left no scar whatever. The following is a convenient formula: Borax, ½ oz.; salicylic acid 12 gr.; glycerine, 3 dr.; rose water, 6 oz. Make a lotion.

SCORCHING CAKES. To Prevent.—When baking cakes, set a dish of water in the oven with them, and they will not be in much danger from scorching.

SEA-SICKNESS. To Prevent and Cure.—1. It is asserted that the reason so little attention has been paid to seasickness, especially by those not subject to it, is that there was a fallacious idea that to be seasick did a person good; that it cleared out the system, and, therefore, nature should be allowed to take its course. There is neither advantage in nor need for the ailment. It must be prevented, and the battle of prevention must be fought on land before sailing. For three days before the voyage doses of bromide of sodium must be taken—in preference to bromide of potassium, and this course must be continued for three or four days after sailing. One pleasant effect of this bromization is the sound and refreshing nature of the sleep it induces. The dose is 30 gr. of bromide of sodium three times a day for three days before the voyage, and for three or four days after starting. This treatment has been invariably found to be an absolute preventive. It is said that no evil effects have been found from the use of the bromide of sodium, taken for the prevention of seasickness.—2. It is said that there is no remedy like Worcestershire sauce, in teaspoonful doses, given without water, for both preventing and curing seasickness. It should be supplemented in some cases by the application of a tightly-applied bandage, and resting on the right side, taking frequently small quantities of fluid food, such as good beef tea with cayenne pepper in it. No stimulants must be taken, and the feet should be kept warm with hot brick or bottle. This treatment is very effective. As a remedy for warding off the evil, apply with a brush collodion in three successive layers on the epigastric region over the stomach and neighboring parts. It acts as a powerful antiemetic. The diet and state of health should be looked after for a week before the trip or a voyage on the ocean. Pastry and all rich foods should be avoided, and a course of cooling medicine taken to cleanse and purify the blood. A strong cup of pure, black, unsweetened coffee, taken an hour before starting and three hours after a substantial but easily digested meal, is also a great preventive.—3. There is no remedy for this which will answer in all cases. Some people will always be sick. A dose of 30, 60 or 90 gr. of bromide of sodium three times a day is recommended. A recumbent position is best suited to the patient if ill. Every effort should be made to keep to the deck and a waterproof blanket will be found of use. Keep the bowels free and try to eat. Crackers, beef tea and olives are best relished.

SEWER GAS, To Detect.—1. A suspected joint in a sewer or drain pipe may be tested by wrapping it with a single layer of white muslin, moistened with a solution of acetate of lead. As the gas escapes through the meshes of the cloth it will be blackened by the sulphur compounds.—2. It is usual to detect gas escapes by applying a lighted taper or candle to the suspected place of leakage. This is dangerous, and many explosions have thus been occasioned. A safer mode is as follows: Mix dark soap and water in the proportion of 2 lb. of the former to 5 or 7 pt. of the latter. The sticky paste or liquid so obtained is ready to be applied by the brush to the gas pipe, when, if an escape is taking place, bubbles will readily be seen on the liquid; thus the positions of the gas escapes are indicated without any danger.—3. Saturate unglazed paper with a solution of 1 oz. of pure lead acetate in ½ pt. of rain water; let it par-

tially dry, then expose in the room suspected of containing sewer gas. The presence of the latter in any considerable quantity soon darkens or blackens the test paper.

SHAVING, Easy.—1. Never fail to well wash your beard with soap and cold water, and to rub it dry, immediately before you apply the lather, of which the more you use, and the thicker it is, the easier you will shave.—2. Never use warm water, which makes a tender face.—3. The moment you leave your bed (or bath) is the best time to shave.—4. Always wipe your razor clean, and strop it before putting it away; and always put your shaving brush away with the lather on it.—5. The razor (being only a very fine saw) should be moved in a sloping or sawing direction, and held nearly flat to your face, care being taken to draw the skin as tight as possible with the left hand, so as present an even surface and throw out the beard.—6. The practice of pressing on the edge of a razor in stropping it soon rounds it; the pressure should be directed to the back, which should never be raised from the strop. If you shave from heel to point of the razor, strop it from point to heel; but if you begin with the point in shaving, then strop it from heel to point.—7. If you only once put away your razor without stropping it, or otherwise cleaning the edge, you must no longer expect to shave well and easy, the soap and damp so soon rust the fine teeth and edge.—8. A piece of soft plate leather should always be kept with razors, to wipe them with.—9. (*Shaving Cream.*) Curd soap, 8 oz.; almond oil, 2 oz.; glycerine, 1 oz.; spermaceti, ½ oz.; carbonate of potassium, ¾ oz.; water, 16 oz.; cut the curd soap into shreds, and dissolve it by the aid of a water bath in 14 oz. of water. Dissolve the spermaceti in the almond oil, and while warm mix it with glycerine, potash, and remainder of the water; transfer to a warm mortar, gradually and steadily incorporate the warm soap solution, and continue to stir until a smooth paste is formed. With this incorporate a suitable perfume.

SHERBETS.—1. (*Lemon.*) Four lemons; 1 pt. sugar; 1 qt. boiling water. Shave off the peel from 2 lemons in thin, wafer-like parings, being careful to take none of the lighter colored rind below the oil cells. Put the parings into a bowl, add the boiling water and let it stand ten minues, closely covered. Cut the lemons in halves, remove the seeds, squeeze out the juice and add it with the sugar to the water. Add more sugar if needed. When cold, strain it through a fine strainer into the can and freeze. *a. With Gelatine.* One tablespoonful of gelatine; 6 lemons; 1 pt. sugar; 3½ cups cold water; ½ cup boiling water. Soak the gelatine in ½ a cup of cold water, 20 minutes. Put the sugar and the remaining cold water into a large lip bowl or pitcher. Pare the lemons, cut in halves, remove all the seeds, and press out the juice with a lemon-squeezer; add it to the syrup. Dissolve the soaked gelatine in the boiling water, add it to the other mixture. If liked sweeter, add more sugar. When the sugar is dissolved strain through a fine wire strainer or cheese-cloth, turn into the freezer can and freeze as directed. Sherbet made in this way has none of the volatile lemon oil, which, to a delicate stomach, often proves indigestible. *b. With White of Egg.* Two qts. boiling water; 8 lemons; 1 egg (white); 1 qt. sugar. Spread part of the sugar on a shallow plate or board, and after wiping the lemons with a clean damp cloth, roll them in the sugar to extract the oil. Then cut in halves, remove the seeds, and squeeze out the juice. Boil all the sugar and water until clear. Remove the scum as it rises. Add the lemon juice to the syrup, strain it, and pour it gradually into the beaten egg. Then freeze as usual.—2. (*Orange.*) One tablespoonful gelatine; 6 oranges or 1 pt. orange juice; 1 scant pt. cold water; 1 cup sugar; ½ cup boiling water. Soak the gelatine in ½ a cup of the cold water ten minutes. Put the sugar and remainder of the cold water in a large pitcher. Cut the oranges in halves, remove the seeds, and squeeze all the juice into the pitcher. Add more sugar, if the oranges are very sour. Dissolve the gelatine in the boiling water, and add it to the mixture. Strain it into the can and freeze. —3. (*Pomegranate.*) One doz. blood oranges; 1 qt. water; 1 pt. sugar. Peel the oranges, cut them in halves across the sections, remove the seeds, and press out the juice with a patent potato sifter. Add the sugar and water, and when the sugar is dissolved, strain into the can and freeze. This will have a fine color and no bitter flavor of the rind.—4. (*Pine-apple.*) One pt. of fresh, or 1 can of grated pine-apple; 1 pt. water; 1 tablespoonful gelatine; 1 pt. sugar; 1 lemon. Pare the pine-apple, remove all the eyes, and pick off the tender part with a fork, rejecting all the hard core. If still too coarse, chop it a little. Add the sugar, water, lemon juice and gelatine, which should be first soaked in cold water and then dissolved in boiling water. Freeze as usual.—5. (*Strawberry or Blackberry.*) One qt. berries, or enough to make 1 pt. of juice; 1 pt. of sugar; 1 lemon. Mash the berries, add the sugar, and after standing till the sugar is dissolved, add the water and lemon juice. Press through fine cheese-cloth, and freeze. Vary the sugar as the fruit requires. All of these fresh fruits are improved by the addition of the lemon.

SHEEPSKINS, To Prepare for Mats.—1. Make a strong lather with hot water and let it stand till cold; wash the skin in it, carefully squeezing out all of the dirt from the wool; wash it in cold water till all the soap is taken out. Dissolve 1 lb. each of salt and alum in 2 gal. of hot water, and put the skin into a tub sufficient to cover it; let it soak for 12 hours, and hang it over a pole to drain. When well drained stretch it carefully on a board to dry, and stretch several times while drying. Before it is quite dry, sprinkle on the flesh side 1 oz. each of finely pulverized alum and saltpeter, rubbing it in well. Try if the wool be firm on the skin; if not, let it remain a day or two, then rub again with alum; fold the flesh sides together and hang in the shade for two or three days, turning them over each day till quite dry. Scrape the flesh side with a blunt knife and rub it with pumice or rotten stone.—2. First remove all the

useless parts and soften the skin by soaking, then remove the fatty matter from the inside and soak it in warm water for an hour. Next mix equal parts of borax, saltpeter, and sulphate of soda in the proportion of about ½ oz. of each for each skin, with sufficient water to make a thin paste; spread this with a brush over the inside of the skin, applying more on the thicker parts than on the thinner; double the skin together, flesh side inward, and place it in a cool place. After standing twenty-four hours wash the skin clean, and apply in the same manner as before a mixture of 1 oz. sal soda, ½ oz. borax, and 2 oz. hard white soap, melted slowly together without being allowed to boil; fold together and put away in a warm place for twenty-four hours. After this, dissolve 4 oz. alum, 8 oz. salt, and 2 oz. saleratus in sufficient hot rain water to saturate the skin; when cool enough not to scald the hands, soak the skin in it for 12 hours; then wring out and hang it up to dry. When dry repeat the soaking and drying two or three times till the skin is sufficiently soft. Lastly, smooth the inside with fine sandpaper and pumice stone.—3. Wash while fresh, in strong soapsuds, first picking from the wool all the dirt that will come out. A little paraffine, a tablespoonful to 3 gal. of water, will aid in removing the impurities. Continue to wash the skin in fresh suds till it is white and clean. Then dissolve ½ lb. each of salt and alum in 3 pt. of boiling water, put into it water enough to cover the skin, which should soak in the solution 12 hours, and then be hung on a line to drain. When nearly dry nail it, wool side in, on a board, or the side of a barn, to dry. Rub into the skin an oz. each of pulverized alum and saltpeter, and if the skin is large double the quantity. Rub for an hour or two. Fold the skin sides together, and hang the skin away for three days, rubbing it every day or till perfectly dry. Then with a blunt knife clear the skin of impurities, rub it with pumice or rotten stone, trim it into shape, and you have a door mat that will last a lifetime. If it is to be dyed, have a shallow vessel as large as the skin in which to prepare the dye, so that the skin can be laid wool side down smoothly into the vessel, that all parts may be equally immersed in the dye. This should not be more than an inch deep, otherwise the skin might be injured by the hot dye. After coloring, again stretch the skin to dry, and then comb with a wool or cotton card.

SHOE DRESSINGS.—1. (*For Patent Leather.*) Add to some pure wax which has been melted in a water bath some olive oil, and then some lard. Mix thoroughly by stirring over a moderate fire. Add some oil of turpentine, then a little oil of lavender. This will form a paste which should be put in boxes. Apply with a linen rag. The paste keeps the leather soft and restores the gloss.—2. (*For Preserving the Gloss of Patent Leather and to Prevent Cracking.*) Melt wax with a little oil of turpentine, olive oil and lard. Mix thoroughly together. When cool it should be a thick paste. Vaseline is excellent. Allow it to remain on one-half hour, then dry with Canton flannel.—3. (*For Russet Leather.*) Mix together 1 part palm oil and 3 parts common soap, and heat up to 100° F.; then add 4 parts oleic acid, and 1⅓ of tanning solution, containing at least 1-16 of tannic acid (all parts by weight) and stir until cold. This is recommended as a valuable grease for russet leather, and as a preventive of gumming.—4. (*For Tan Shoes.*) Beeswax, 1 part; oil of turpentine, 4 parts.—5. (*For Boots and Shoes.*) Boil together 1 pt. linseed oil, ½ lb. of mutton suet, the same quantity of beeswax, and a small piece of resin, and when the mixture becomes milk warm apply it with a hair brush. After two applications the article will become water-proof. Great caution must be exercised in melting the above ingredients.—6. Common tar may be made warm, and brushed over the soles of boots and shoes. They are then placed near the fire, so that the tar may be absorbed. When the absorption has taken place, a second or third application may be given with advantage. This application is not suitable for the upper leathers.—7. (*Elastic and Clean, for Ladies' Shoes.*) Three lbs. of rain water placed in a pot over fire, and when well boiling there are added 4 oz. white pulverized wax, 1 oz. clear, transparent glue, in small pieces, 2 oz. pulverized gum Senegal, 2 oz. white soap scraped fine, 2 oz. brown pulverized sugar; the ingredients are placed in one by one, and every time stirred up; it is well to take the pot from the fire every time a substance is added, to prevent boiling over; when all is added, the pot is removed from the fire; when sufficiently cooled, 3 oz. alcohol are added, and finally 3 oz. fine Frankfort black, well incorporated by continued stirring. This varnish is put on the leather with a brush, and very valuable for boots and shoes, as it can be afterward polished with a large brush, like ordinary shoeblacking; shows a high polish, and does not soil the clothing.—8. (*For the Edges of.*) Alcohol, 8 fl. oz.; shellac, 2 oz.; resin, 1 oz.; turpentine, ½ oz.; lampblack, ¼ or ½ oz.—9. (*Self-Shining Blacking.*) Gum Arabic, 4 oz.; molasses or coarse moist sugar, 1½ oz.; good black ink, ½ pt.; strong vinegar, 2 oz.; rectified spirit of wine and sweet oil, of each 1 oz.; dissolve the gum in the ink, add the oil, and rub them in a mortar or shake them together for some time, until they are thoroughly united, then add the vinegar and lastly the spirit.—10. Dissolve 8 oz. gum Arabic in 8 oz. of best black ink, then add 2 oz. of olive oil. Mix thoroughly and then add 4 oz. strong vinegar, 3 oz. brown sugar, 2 oz. alcohol.—11. (*Waterproof.*) Shoes can easily be made waterproof and snow-resisting by the aid of a little paraffine dissolved in benzine. A very little paraffine is needed, and only enough benzine to dissolve it and make it flow easily. The preparation can be brushed over the uppers and even the soles, and as it dries almost as fast as put on the shoes are ready for wear without any delay. The paraffine presents a firm water-proof surface and does not look amiss, although it will not take a shine like unprepared leather. But it will resist any amount of wet, and is very convenient in snowy weather. The preparation differs from the bulk of waterproofers in that instead of making the leather

stiff and hard, it makes it very soft and pliable. The mixture can be applied to patent leather tips and to uppers composed entirely of that material, but it takes off the brilliancy of these stylish articles too completely to be used very extensively for the purpose, although when the paraffine has worn off the polish appears as brilliant as ever.

SIZES, In Clothes.—A "size" in a coat is an inch; in underwear, it is two inches; in a sock, one inch; in a collar, one-half inch; in a shirt, one-half inch; in shoes, one-sixth of an inch; in pants, one inch; gloves, one-quarter of an inch; and in hats, one-eighth of an inch.

SKIN. Care and Treatment of.—1. Ladies wishing a smooth skin made without harm can obtain it by purchasing 10 cents worth of tincture of benzoin. Dissolve it in a pt. of wine and use on the face at night. The face should first be washed with pure and fine soap, and then rinsed off in clear, cold water. The benzoin can be dissolved in water, but wine is preferable.—2. For a rough or sunburnt skin, use 2 oz. of distilled water, 1 oz. of glycerine, 1 oz. of alcohol, and ½ oz. of tincture of benzoin. Without the water, and with the addition of 2 oz. of prepared chalk, free from bismuth, it makes a fine cosmetic for whitening the face, and is not injurious, like the expensive "balms" or "blooms" so highly advertised.—3. Boil a small piece of green benzoin in spirits of wine until it becomes a rich tincture. 15 drops of this poured into a glass of water will produce a liquid that looks like milk, and emits a most agreeable perfume. This wash, while an excellent remedy for spots, pimples and eruptions, renders the skin clear and brilliant, and the cheeks a beautifully rosy color.—4. Another wash is made of medicated soap, which can be bought of any druggist, melted and made into balls, with finely-ground oatmeal. Oatmeal and buttermilk together possess wonderful beautifying qualities, and oatmeal by itself now occupies a place on many dressing-tables. Steeped in water in small quantities, its balsamic qualities and glutinous oiliness makes the flesh beautifully soft and white. A little lemon-juice may be added advantageously.—5. If a remedy is wanted to produce immediate and wonderful effects in whitening the skin, use tar and olive oil, heated together and cooled. Use upon the face when going to bed, with a mask of thin, old linen or muslin, put on to prevent coming off—further protecting the pillows by an old sheet thrown over them. In the morning a bath of white castile soap and water brings the face out pure and softly tinted as a child's. This is not only the best, but one of the most harmless and cheapest preparations that can be procured.—6. If the skin be coarse-looking, and you desire to improve the texture, bathe it before going to bed in very hot water and good toilet soap, and rub thoroughly with a course Turkish towel.—7. Wrinkles are less apparent under a kind of varnish containing 36 grm. of turpentine and 3 dr. of alcohol, allowed to dry on the face.—8. For pimples on the face use this recipe: 30 gr. of bicarbonate of soda, 1 dr. of glycerine, and 1 oz. of spermaceti ointment. Rub on the face; let it remain for a quarter of an hour, and wipe off all but a slight film, with a soft cloth.—9. To remove moth patches, wash the patches with a solution of common bicarbonate of soda and water several times during the day, for two days, or until the patches are removed, which will usually be in forty-eight hours. After this process, wash with some nice toilet soap and the skin will be left clean and free from patches.—10. Peroxide of hydrogen rubbed on the face two or three times a day, for ten days, will also free the skin of any discoloration. A simple remedy for removing freckles is to put 1 oz. of alum and the same of lemon-juice in a pint of rose water; apply at night.—11. To remove moles, moisten a stick of nitrate of silver and touch the mole; it will turn black and sore, but will soon dry up and fall off. If not successful the first time, try again.—12. Rice-powder for the face, though inexpensive, is warranted perfectly harmless. Refined chalk is the safest thing to use, and costs far less than if put up under some other name and sold in boxes. Cascarilla powder is much used by Cuban ladies, and is considered harmless. Wash the face with thick suds of glycerine soap, and when dry, dust on the powder with a puff or piece of chamois-skin.—13. When the feet are sore, as from long walking, take a teaspoonful of Epsom salts, 5 or 6 drops of tincture of capsicum, and put in a shallow basin of water—just enough to cover the soles of the feet—and soak them twenty minutes. One will be surprised at the relief this will give. It will also cure burning of the feet that so many are troubled with in the summer.—14. If you must bathe in your bedroom, then get a square of white enameled cloth, or heavy Turkish toweling, sew a heavy rope around the edge tightly, and you can get a shower bath without getting the water on the carpet. In bathing, use the wrong side of the oil-cloth, as the right side is apt to chill one. For a weak person bathing, especially in summer, a gill of ammonia in a small tub of water, or some rock salt, is a wonderful invigorator, almost as good as a sea bath. The feet should be kept as clean as the hands, and if the nails are cut as often, and attended to as carefully, it will be a means of warding off corns and bunions. The best time to bathe is just before going to bed. It will assist one's sleep, giving a quiet, restful feeling. Never take a bath just after a meal.

SKIN, Washes for.—1. (*Cucumber Cold Cream.*) Almond oil, 1 lb.; green oil, 1 oz.; juice of cucumbers, 1 lb.; wax and sperm, each, 1 oz.; essence of cucumber, 2 oz.—2. Purchase from a trustworthy druggist 4 ounces of almond oil, add a quarter of an ounce each of white wax and of spermaceti. Put these ingredients in a jar, and set the jar in a saucepan with warm water reaching up to within 2 inches of the rim. Let the water boil. A marmalade jar is just about the right size to use. When the wax and spermaceti are melted into the oil add five tablespoonfuls of the thick juice of a large, nearly ripened cucumber. Obtain the juice by pressing the pulp on a fine hair sieve. Color the cream with a few drops of spinach green. Use

enough to give a very delicate tint of green. Pour it to harden into several small jars. It is an excellent cure for sunburn, and is very healing and soothing for the skin. Wash the skin at night thoroughly with warm water before applying the cream. Dry off all the moisture a soft damask towel will absorb, and rub the cream of cucumbers gently into the skin. In the morning wash it off with warm water, and tone the skin with a bath of cold water to make the tissues firm.—3. (*Bloom of Roses.*) It is used for lips as well as cheeks. The difficulty is to get pure carmine, which is very rare in the market. You can make your own carmine thus: Take 9 oz. of carbonate of soda and dissolve 27 qts. of rain water, to which are added 8½ oz. citric acid; boil; then add 1½ lbs. best cochineal, ground fine, and boil for one hour and a quarter. Strain and cool. Boil again with 9½ oz. alum for ten minutes, draw off and let cool. The sediment is to be filtered, washed in clean, soft cold water and let dry in the air. This is your carmine. A glossier tint is got by replacing 1-9 part of the alum by its weight of saline salt of tin. But the reader is cautioned that salts of metals are apt to be poisonous, especially those of lead. Make the carmine on a clear day; good weather favors a good result for some utterly unknown reason.—4. (*Glycerine Lotion.*) It is much recommended as a beautifier and softener of the skin, is made with 1 gal. orange flower water, 8 oz. of glycerine and 1 oz. of borax.—5. (*To Whiten the Hands.*) Take a wineglassful of eau de cologne and another of lemon juice; then scrape two cakes brown Windsor soap to a powder and mix well in a mould. When hard, it will be excellent for whitening the hands.—6. (*Lait Virginal.*) Rose water, 1 qt.; tincture of tolu, ½ oz.; add the water very slowly to the tincture; adding the tincture to the water spoils the operation.—7. (*Milk of Almonds.*) Bitter almonds, blanched, 10 oz.; rose water, 1 qt.; spirits of wine, 85 per cent. pure, ¾ pt.; otto of almonds, ½ dr.; otto of bergamot, 2 dr.; wax, spermaceti, almond oil, curd soap, each, ½ oz.—8. (*Milk of Cucumber.*) Sweet almonds, 4 oz.; expressed juice of cucumbers, 1 pt.; spirits of wine, 85 per cent. pure, 8 oz.; essence of cucumbers, ½ pt.; green oil, wax, curd soap, ½ oz. each. Boil the cucumber juice for thirty seconds, cool as quickly as possible, strain through fine muslin, and then proceed as usual.—9. (*Milk of Dandelion.*) Sweet almonds, 4 oz.; rose water, 1 pt.; expressed juice of dandelion root (be sure it is quite fresh), 1 oz.; esprit of tube rose, 8 oz.; green oil, wax and curd soap, each, ½ oz. Put the dandelion juice into the mortar as soon as the almonds are broken.—10. (*Milk of Roses.*) Take of Valentia almonds, blanched, ½ lb.; of rose water, 1 qt.; of spirits of wine, 85 per cent. pure, ¼ pt.; of otto of rose, 1 dr.; and of white wax, spermaceti and oil soap, ½ oz. each. Shave up the soap and put it in a vessel that can be placed within another vessel, the space between the two being filled with heavy brine. The object of this is to prevent direct contact of the vessel containing the soap with the fire, and it should be so arranged as to have water space between it and the larger vessel underneath also. Salt water boils at a higher temperature than sweet water, therefore it is used that the full benefit of the fire may be obtained. If sweet water were used in the outer vessel, being nearer the fire, it would use up the heat in boiling away, while the inner pot would be scarcely at simmering temperature. This arrangement is called the water bath, or more properly Bain Marie. Add to the shaved soap 2 or 3 oz. of rose water, and when it is melted add the wax and spermaceti in lumps, not cutting them smaller than is necessary to get the correct weights. This insures their melting slowly and becoming partly saponified by the liquid soap. Be very careful about the almonds. They must be perfect. After blanching them, beat them up in a mortar or some equivalent, being sure it is perfectly clean, meanwhile letting the rose water trickle slowly and steadily upon them. A glass syphon from the rose water bottle to a point above the mortar will save much trouble of pouring; or a tin-can with a stopcock to it will do well. When the almonds are beaten up finely and evenly in the rose water, the emulsion, as the result of such an operation is called, must be filled without pressure—an important point—through clean muslin. Use washed muslin, for the new often contains starch, flour, gum, etc. Now put the soap mixture into the mortar and run the emulsion into it at a steady trickle. When you come to the end of the emulsion run the spirits of wine into the mixture, having first stirred the otto into the spirit. Be very careful to let the scented spirit trickle in very slowly, for its sudden addition might curdle the milk. As it is, the milk will be heated, and all precautions should be taken to keep the mortar cool and its contents stirred. Put the resultant milk of roses in a glass bottle having a tap one-quarter of an inch from the bottom. If prepared carefully according to directions this milk will keep pure almost forever without any deposit or floating film forming in it. It will be found a most refreshing face wash.—11. (*For Pallid Skin.*) This is generally only a local indication of a general condition, and that condition is debility. There may be no apparent physical weakness, but, nevertheless, the system lacks that tone which is essential to the proper performance of those bodily functions the integrity of which constitutes health. Anæmia is often present. The causes may, at their commencement, be: 1, dissipation, study, or any excessive demand on the nervous centers; 2, loss of blood or other vital fluids; 3, insufficient supply of food or oxygen. In any case the nervous centers become affected. As local measures for the treatment of pallid skin, cold bathing may be recommended, followed by friction with a soft towel. The following may be used for the cheeks: Dilute liquid ammonia, 1 oz.; glycerine, 2 oz.; water, 4 oz. This should be applied once daily for about three minutes, being well worked into the skin, afterward a soft towel should be used for three or four minutes. If any irritation follows, the glycerine may be doubled in quantity. —12. (*For Red Skin.*) Red spots, with ray-

like blood-vessels seemingly issuing from their centers, are a species of nævus, and may be treated in the same way. Sometimes great numbers appear on the cheeks; they are then very small, and frequently connected over the whole surface of the skin by red lines, which mark the course of dilated blood vessels. This condition is most frequently seen in patients suffering from heart or lung disease, and is due to impeded circulation and consequent congestion of the blood vessels. Let the face be washed twice daily in warm water, and afterwards well rubbed. Dry friction with a soft towel should be freely practiced. The following will be of service if applied once daily: Chloride of lime, 1 oz.; warm water, 12 oz. Redness may be due to plethora of full bloodedness. The whole skin of the face is then of a reddish tint, and subject to flushing; the eyes are moist. The patient is frequently subject to fits of profuse perspiration and attacks of nose bleeding. *Treatment:* This must be constitutional. Locally, the following cooling washes may be used as often as desired: Carbonate of soda, 1 part; prepared chalk, 1 part; borax, 1 part; glycerine, 3 parts; oatmeal water, 6 parts. —13. (*Rose Cold Cream.*) 1 lb. each of almond oil and of rose water, 1 oz. each of white wax and spermaceti, ½ dr. of otto of rose. To prepare it, take a well glazed, thick porcelain vessel; one that is deep is preferable to a shallow one, and it must be able to hold twice the quantity of cream intended to be made. Put the wax and spermaceti into the jar and the jar into a Bain Marie above described; when the wax and spermaceti are melted, add the oil, and continue boiling till the liquid is even and there are no fragments floating in it; then remove the jar and trickle the rose water into it; A tin can with a tap will hold the rose water and allow the flow to be exactly regulated. Such a can is used for the rose milk explained above. Keep stirring and do not let the cream set on the sides of the jar. In cool weather the rose water should be a little warm, lest the cream set before it has been beaten enough, and then, just before the end, add the otto. Add perfumes last, as a rule, to prevent unnecessary evaporation. This cream will set in the jars it is poured into and keep very well. By varying the otto various perfumes are obtained. The method of manufacture does not vary. Violet cold cream, 1 lb. each of huile violette and of violet water, 1 oz. each of wax and of spermacetti, 5 drops of otto of almonds.—14. (*Rose Lip Salve.*) ½ lb. of almond oil, 2 oz. of spermaceti and of wax and alkanet root and ½ oz. otto of rose. The alkanet root is the ordinary blood-root familiar to children. Place the wax, oil and alkanet root into the water bath, and after the first three are melted let them digest four to six hours on the alkanet root to extract its color. Finally strain through muslin and add the perfume just before the salve sets.—15. (*Rusma.*) Rusma is a mixture that removes undesirable hairs quickly. To make it, take in proportions of 3 lbs. best slaked lime to ½ lb. of orpiment in a powder. Mix in a drum sieve and keep well corked. To use, mix with water to a cream. Apply to the objectionable hair for five minutes or till the skin smarts. Scrape it away with a bone or ivory paper knife, wash the place treated plentifully and apply cold cream.—16. (*Tincture of Tolu.*) Dissolve 1 oz. of tolu of balsam in 1 pt. of spirits of wine, 85 pr. ct. pure, so the small quantity used had best be bought. Also, you may use tincture of benzoin instead of tiucture of tolu, and you may vary the water at pleasure, using elder-flower water, orange-flower water, etc.

SLATE, Artificial Writing.—Fine sand, 41 parts; lampblack, 4 parts; boiled linseed or cotton seed oil, 5 parts. Boil thoroughly together. Reduce the mixture by adding spirits of turpentine, so that it may be easily applied to a thin piece of pasteboard. Give three coats, drying between each coat; finish by rubbing smooth, with a piece of cotton waste, soaked in spirits of turpentine. Makes excellent memorandum books, etc. Use a slate pencil.

SLEEPLESSNESS, Treatment of.—A well-known professor, in lecturing to his class of medical students, gave the following advice concerning sleeplessness, which will be found of value for the hardworker who suspects a tendency toward insomnia: He said that he would advise three remedies for insomnia; each one is simple and easy of access: (1) to abstain from all mental work, no matter what the consequences, and give up any habits that over-excite the nervous system. If duty enforces labor of the intellect, then confine it, if possible, to the hours of from 10 a. m. to 3 p. m., and a free use of hot baths will materially assist. (2) Drink freely of skimmed milk from 1 to 2 qts. a day and eat of the plainest and most digestible food, masticating thoroughly and slowly, and avoid wine of any kind, for it only deceives the drowsy brain by its intoxicating influence, demanding full pay the next day. Just before retiring let the patient take an old-fashioned tumbler of bread and milk. This serves to cause the flow of blood to go to the stomach instead of the head; and if the head be placed rather high in bed, it will effectually aid gravity to lessen its fullness. (3) If his means can afford it, a quiet, long, open-air drive in a comfortable carriage, with perfect silence, will induce sleep.

SLUGS, To Trap.—Slugs may be readily trapped. Cut large potatoes in two, and scrape the cut surface until it is cup-like or deeply concave. Place these, with the hollow surface down, in the various places where the slugs are troublesome, and examine them every morning, destroying the pests that are trapped. These traps will also allure the sow-bugs and millipedes which may be around, and which are often as troublesome as the slugs. Pansies, lobelias, and many other soft-stemmed plants frequently suffer from the ravages of the nocturnal pests above referred to. They eat the tenderest part of the stem near the surface of the ground. It may be that this is the cause of the pansies "damping off" at the roots and dying.

SNAKE BITES, Cure for.—A lotion for the

cure of viper bites, consists of 1 part of chromic acid dissolved in 100 parts of water.

SOLDERING MIXTURE.—Lactic acid and glycerine, mixed with water in the proportion of 1 lb. of each to 8 lbs. of water, make a soldering mixture for tin cans in which fruit, flesh or vegetables are to be contained, which is reported harmless from a health point of view. It has been tried successfully in canning fish, and has none of the poisonous properties of the chloride of zinc in common use.

SPINACH COLORING, For Confectionery.—Pick over 2 qts. of spinach, remove the coarse stems, wash, drain, and chop or bruise it. Lay a piece of cheese-cloth over a patent potato sifter, or over a puree strainer, put in a portion of the bruised leaves and press out the liquid. Repeat until all are pressed; or you may squeeze the juice out through a coarse cheese-cloth. Heat this liquid gently, stirring all the time, and as soon as the green coloring separates from the water, pour it through a fine cloth which is laid over a strainer. The green curd will be left on the cloth. When the water has all drained through, rub the green pulp through the cloth into a plate. Dry it and mix with an equal amount of sugar. Use it for coloring creams, candies or frostings, by mixing a small portion with the sugar or cream until the desired shade.

SPONGES, To Bleach.—Sponges can be bleached by first soaking in hydrochloric acid diluted with 1½ parts water, until no more carbonic acid is given off; then wash in pure water, and afterwards leave in a bath composed of 2 lbs. hydrochloric acid. If the sponge be afterward dipped in glycerine, and pressed to remove excess of liquid, it remains elastic, and can be used for mattresses, cushions, and general upholstery.

SQUEAKING SHOES. Remedy for.—1. Inject powdered French chalk through a perforation in the inner sole. The free use of the same substance between soles when boots are being made will effectually prevent any trouble of this nature.—2. Bore a few holes half through the soles and let out the air that is doing the mischief.

STARCH GLOSS.—1. (*Lustrine Alsacienne.*) Borax, 2½ oz.; gum Arabic, 2½ oz.; spermaceti, 2½ oz.; glycerine, 6¾ oz.; distilled water, 2¼ pt.; a few drops of some sweet scented essence. Add 6 spoonfuls lustrine to 6¾ oz. boiling starch.—2. (*Laundry Starch.*) Rub 1 oz. best potato starch up with a little cold water, so as to reduce all the lumps; add a tablespoonful of best loaf sugar, an equal quantity of dextrin, a little soluble indigo, and a lump of pure paraffin about the size of a nutmeg. Then add a pt. of boiling water, and boil, with occasional stirring, for half an hour (not less). The starch should be strained through a linen cloth before using.—3. (*Liquid.*) One oz. each of gum Arabic and borax are dissolved in 10 oz. of water; 1 oz. each of white wax and spermaceti are melted, and while liquid are rubbed with the solution of borax and 10 drops oil of cloves to make emulsion, mixing them thoroughly. A teaspoonful of this mixture in a pt. of starch gives a fine polish. It may also be applied after starching by rubbing over the starch with a cloth and then polishing with the iron.—4. Borax, saturated solution, 2 parts; tragacanth mucilage, 1 part; mix. 1 tablespoonful to 1 pt. of starch.—5. (*To Improve Starch.*) To each bowl of starch, add 1 teaspoonful of Epsom salts, and dissolve in the usual way by boiling. Articles starched with this will be stiffer, and will be rendered to a certain degree fireproof. Use corn starch, boil to smooth paste, cool and starch the goods; dry quickly. Before ironing, dampen down in thin, raw (unboiled) starch water. A little gum Arabic or pure white wax is often added to the boiled starch to afford fine gloss. Iron in the usual way, with a common sad iron; then dampen slightly with a clean cloth and the starch (raw) water, and polish briskly with a polishing iron.

STEEL AND IRON, Microscopic Determination of.—Thus the crystals of iron are double pyramids, in which the proportion of the axis to the bases varies with the quality of iron; the smallness of the crystals and the height of the pyramids composing each element are in proportion to the quality and density of the metal, which are seen also in the fineness of the surface; and, as the proportion of the carbon diminishes in the steel, the pyramids have so much the less height. In pig-iron and the lower qualities of hard steel the crystals approach more closely the cubic form. Forged iron has its pyramids flattened and reduced to superposed parallel leaves, whose structure constitutes what is called the nerve of steel; and the best quality of steel has all its crystals disposed in parallel lines, each crystal filling in the interstices between the angles of these adjoining, these crystals having their axis in the direction of the percussion they undergo during the working. Practically, good steel has the appearance, microscopically, of large groups of beautiful crystals.

STING, Of the Jelly-Fish.—It is not known whether it is a sting like that of a wasp or a nettle, that is inflicted, or whether a secretion, acrid in kind, is thrown upon the surface, and acts directly as an irritant fluid. On the whole, it is supposed it is a fluid, or organic acid, which is the cause of the irritation. For the resultant erythema local alkaline treatment is particularly effective. In the throat case bicarbonate of soda with *mel boracis* proves very grateful and useful.

STOVE BLACKINGS.—1. Mix 2 parts of black lead, 4 parts of copperas, and 2 parts of bone black, with water, so as to form a creamy paste. This is an excellent polish, as the copperas produces a jet black enamel, causing the black lead to adhere to the iron.—2. Plumbago, 2 lb.; water, 8 oz.; turpentine, 8 oz.; sugar, 2 oz. Knead thoroughly and keep in tin boxes. Apply with a brush.—3. Plumbago, make into a thin paste with sodium silicate or water glass. This makes an excellent stove polish and should be brushed thoroughly.—4. Pulverized black lead, 2 lb.; spirits of turpentine, 2 gal.; water, 2 oz.; sugar, 2 oz. Mix.—5. Mix 5 parts black lead, 5 parts bone black, and 10 parts of iron sulphate. Use water q. s. to form a paste. This

is an excellent preparation and the coating is very permanent.—6. Reduce graphite to an impalpable powder by grinding in a mill with water, dry; use with water first, then dry and polish. This is the base of nearly all commercial stove polishes.—7. Turpentine and black varnish, put with any good stove polish, is the blacking used by hardware dealers for polishing heating stoves. If properly put on, it will last throughout the season.—8. (*Paste.*) Pulverized black lead, 2 lb.; spirits of turpentine, 2 gal.; water, 2 oz.; sugar, 2 oz.; mix.—9. (*Liquid.*) Bone black, 2½ parts; pulverized graphites, 2½ parts; copperas, 5 parts; water, q. s. to form a creamy paste.—10. (*Liquid Black Lead.*) Pulverized black lead, 1½ lb.; turpentine, 1½ gill; water, 1½ gill; sugar, 1½ oz.—11. (*Bone Black.*) Mix 2 parts copperas, 1 part powdered bone black, and 1 part black lead, with enough water to give proper consistency, like thick cream. Two applications are to be recommended.—12. (*Brunswick Black for Grates, etc.*) Asphaltum, 5 lb.; melt and add boiled oil, 2 lb.; spirits of turpentine, 1 gal.; mix.

SUGAR, Maple, Artificial.—Decoctions or extracts of the wood or bark of trees are frequently used for flavoring syrups or sugars. Different extracts differ in taste. The hickory tree, it is said, yields an extract that will impart the flavor of the maple, and Daily's method of producing artificial maple syrup or sugar is as follows: Make an extract of hickory bark or wood by allowing water to percolate through the same. The bark or wood may be ground, or sawdust therefrom used. Hot water may be used, or the material boiled in water. The strength of the extract may be increased by increase of the quantity of the wood or bark. To 1 gal. of hot or boiling sugar syrup add, say, 3 tablespoonfuls of the hickory extract. It is said the effect of the extract is to produce a flavor that renders the syrup indistinguishable from genuine maple sugar. If the syrup is boiled down, a sugar resembling maple sugar in taste is produced.

SWEET CORN, To Pack.—Cook the corn on the cob the same as for table use, then shave off as for drying. Take a gallon crock, scatter a layer of salt over the bottom, then about two inches of corn and one inch of salt alternately until the crock is full. Every layer of corn must be packed down solid with a potato masher or something similar. Over the whole put a saucer or small weight, to keep the corn under the brine. When wanted for use, it is better to take out the corn, rinse with cold water several times to take out the salt, and let soak over night. When sufficiently freshened, cook as fresh corn, adding a little sugar.

SWEET OIL, Uses of.—1. If green blinds are dingy and faded, wash and rub on a little sweet-oil.—2. For the earache, drop one drop of the sweet-oil up in the ear and place a piece of cotton in the outer ear.—3. A few drops of sweet-oil will greatly help the running of the carpet-sweeper, sewing-machine and clothes-wringer.—4. Sweet-oil and putty powder, followed by soap and water, make one of the best medicines for brightening brass or copper.—5. To keep polished steel from rusting after cleaning, or when not in use, take a cloth with a little sweet-oil on it and wipe the steel over so that the surface may have a very light but warm coating of oil.—6. Pure sweet-oil rubbed thoroughly all over the body, rubbing in all that the skin will absorb, will be found of great benefit to infants, delicate children, the aged, and any one who is thin or not strong. It is nutritions and strengthening, and given in this way the system is furnished with fats it needs and could appropriate in no other way, as in case of weakened digestion, etc.

SYRUPS, To Make.—1. (*Apple Syrup.*) Proceed with apples as for pineapple syrups.—2. (*Banana Syrup.*) Oil of banana 2 dr.; tartaric acid, 1 dr.; simple syrup, 6 pt.; proceed with bananas as for pineapple syrups.—3. (*Corn Cob.*) Twelve clean cobs are put in a gallon of water and boiled until soft. Then the juice is strained off and a gallon of dark brown sugar added. This is boiled a little while, with the result of a fine quality of syrup. This makes a new use for the corn cob.—4. (*Pear Syrup.*) Proceed with it same as pineapple syrups.—5. (*Pine Apple Syrup.*) The hard nature of this fruit requires pounding with a heavy billet of wood (not metal) in a tub with a strong bottom; when well mashed it will require great pressure to extract all the juice from this fruit; a cider press will answer the purpose; add 14 lb. of sugar to a gallon of juice and a little pure acetic acid; put it on a slow fire and stir until the sugar dissolves; when cold, bottle and tie down.—6. Take a convenient number of the fruit; pare and mash them in a marble or porcelain mortar, with a small quantity of sugar; express the juice; for each quart of juice take 1½ pt. of water and 6 lb. of sugar; boil the sugar and water and add the juice; remove from the fire; skim and strain.—7. Oil of pineapple, 1 dr.; tartaric acid, 1 dr.; simple syrup, 6 pt.

TAN, SUNBURN, Etc., to Remove.—1. Wash the face in watermelon juice. The result is a great beautifying of countenance. No matter what is wrong with the face, the juice of the watermelon will rectify it and produce a clear skin.—2. There is nothing that equals fresh buttermilk for removing tan, freckles, sunburn or moth spots. It has the great advantage that it does not injure the skin, but renders it soft like a little child's. Take a soft cloth or sponge and bathe the face, neck and arms thoroughly with buttermilk before retiring for the night, then wipe off the drops lightly. In the morning wash it thoroughly and wipe dry with a crash towel. Two or three such baths will take off all the tan and freckles. It will keep the hands soft and smooth.—3. The following is a perfectly harmless preparation for removing freckles of the skin: Take 2 oz. of lemon juice, ½ dr. of powdered borax, and 1 dr. of white sugar. Mix them, and let them stand a few days in a glass-stoppered bottle till the liquor is fit for use; then rub it on the hands and face occasionally.

TAPEWORM, Cure for.—Forbid the patient to take any breakfast the day on which it is intended to remove the worm, and give him a large dose of Rochelle salts the preceding

night. At 10 o'clock in the morning he has the following at one dose: Recipe—bark of pomegranate root, ½ oz; pumpkin seed, ½ dr.; ethereal extract of male fern, 1 dr.; powdered ergot, ½ dr.; powdered gum Arabic, 2 dr; Croton oil, 2 drops. The pomegranate bark and pumpkin seed are thoroughly bruised, and, with the ergot, boiled in 8 oz. of water for fifteen minutes, then strained through a coarse cloth. The Croton oil is first well rubbed up with the acacia and extract of male fern, and then formed into an emulsion with the decoction. The worm is expelled alive and entire within two hours. No unpleasant effects follow.

TATTOOING. To Remove.—1. The operation is performed by applying nitric acid with the stopper of the bottle (a better instrument would be a glass rod pointed, to carry the acid), just sufficient to cover the stain, so as to avoid making a larger scar than needful, the acid to remain about one and a half minutes, until the *cutis vera* is penetrated and a crusted appearance shown, then washed off with clean cold water. In a few days after this treatment a scab forms, which contains the tattoo mark or stain. Remove it, and should inflammation supervene, poultice and bathe with warm water. In this way the skin with the stain is not only removed almost painlessly, but the nitric acid at the same time, to a certain extent, seems to decolorize the stain. Of course large tattoo marks, greatly extending over the surface, must necessitate the operation being performed differently.—2. Tattoo the skin, in the usual way, with a concentrated solution of tannin, following the original design. Then apply a crayon of nitrate of silver until the part tattooed with the tannin blackens. Wipe off excess of moisture and allow matters to take their own course. Slight pain continues for two to four days, and after two months the cicatrix which results will almost disappear.—3. These are best removed by the following plan: Wash the part thoroughly with common dilute acetic acid. Half an hour later use caustic potash, 4 gr.; water, 1 oz.; after the lapse of another half hour, use dilute hydrochloric acid, 1 dr.; water, 1 oz. This should be repeated daily. Stronger solutions may be used, if they can be borne.—4. It is said that milk pricked under the skin in the same way as the ink was originally applied will change the blue color to red and finally cause it to disappear.—5. It is stated that if the tattooing is performed with some carbonaceous matter, the marks can be made to disappear by being first well rubbed with a salve of pure acetic acid and lard, then with a solution of potash, and finally with hydrochloric acid. A dermatologist should be consulted if possible.

TEETH, Care of, and Washes for.—Decay is not the only enemy of the teeth, but the accumulation of tartar upon them has an equally bad effect. This must in any case be removed by an experienced dentist, and after that the teeth must be carefully attended to. Simple measures, regularly attended to, are sufficient for healthy mouths. A tooth-powder for a healthy condition of the mouth and teeth should be purely a mechanical agent, possessing a hardness sufficient for the removal, without liability to injure the enamel, of slight accumulations of food and tartar. The brush should be moderately soft, the bristles should be long and elastic and of uneven lengths, so as to facilitate their introduction between the teeth. Once daily is quite enough to use a powder, if any is used at all, and the best time to use it is just before retiring. After meals it is sufficient to use a little tepid water. As a frictional powder, precipitated chalk is a soft and generally efficient agent.—1. (*Tooth Wash.*) Dissolve 2 oz. of borax in 3 pt. water; before quite cold add thereto 1 teaspoonful of tincture of myrrh and 1 tablespoonful of spirits of camphor; bottle for use. One wineglassful of the solution, added to ½ pt. of tepid water, is sufficient for each application. This solution, applied daily, preserves and beautifies the teeth, extirpates tartarous adhesion, produces a pearl like whiteness, arrests decay, and induces a healthy action to the gums.—2. (*Foaming Tooth Wash.*) Quillaia bark, in coarse powder, 4 oz.; glycerine, 3 oz.; rectified spirit, 5 oz.; water, 30 oz.; macerate for seven days and filter through 2 dr. of magnes. carb. with which have been mixed oil of wintergreen, 20 drops, and oils of neroli and cloves, 4 drops each. Finally add 1 dr. each of benzoic acid and tincture of pellitory; color with cochineal or saffron.—3. (*Camphorated Chalk.*) Camphor, 1 oz.; precipitated chalk, 15 oz. Prepared chalk may be used in lieu of precipitated chalk. Less white and velvety, but cleans the teeth better than the softer article.—4. (*For Toothache.*) 2 grains of permanganate of potash, dissolved in a pint of water, forms a toothache remedy par excellence. A tablespoonful of this mixture held in the mouth from one to three minutes, then ejected, will drive away the most violent case of toothache known. A two-grain solution is strong enough, yet is harmless. It must be kept in a bottle of colored glass or in a dark place.

TEMPERING CHISELS.—When tempering cold chisels or any other steel articles, heat to a very dull red and rub with a piece of hard soap, then finish heating and harden in clear, cool water. The potash of the soap prevents the oxygen of the atmosphere from uniting with the steel and forming rust or black oxide of iron. The article will need no polishing to enable the colors to be seen. This will be appreciated when tempering taps, dies or various complex forms not easy to polish. Never "upset" a cold chisel. It is sure death to the steel.

THROAT, Sore, Remedy for.—A teaspoonful of alum and one tablespoonful of best French brandy, put in a half tumbler of water, or a half-pint of water will modify it better. This gargle should be used several times during the day, and at night if the irritation or pain is troublesome. It will be found invaluable.

TOBACCO PIPES, To Clean.—A very simple and effective plan. Cut ½ in. from the end of an ordinary cork, and fit it tightly into the bowl of the pipe. Then with a knife cut a hole

through the cork wide enough to admit the nozzle of a water tap with a little pressure turn on the water gently until the flow through the stem is sufficiently strong, and let it run until the pipe is clean.

TOMATO JELLY.—It is made from a can of strained tomatoes. Season the juice well, remembering that tomatoes stand generous salting, and add hot to a half box of dissolved gelatine. Serve it, when set, with celery mayonnaise, cold slaw, lettuce salad, or anything that sliced tomatoes would be offered with.

TORTOISE SHELL, Imitation.—1. The appearance of tortoise-shell may be given to horn by brushing it over with a paste of 2 parts lime, 1 part litharge and a little soap-lye, which is allowed to dry. This acts by forming sulphuret of lead with the sulphur contained in the albumen of the horn, producing dark spots, which contrast with the brighter color of the horn.—2. Mix an equal quantity of quicklime and red lead with soap lees; lay it on the horn with a small brush in imitatioo of the mottle of tortoise-shell. When it is dry, repeat it two or three times.—3. Take a piece of lunar caustic the size of a pea; grind with it water on a stone and mix with it sufficient gum Arabic to make it of a proper consistence; apply it with a brush to the horn in imitation of the veins of tortoise-shell. A little red lead mixed with it to give it a body, is of advantage. It will stain the horn quite through without hurting its texture or quality. Be careful when the horn is stained to let it soak some hours in water previous to finishing and polishing it.—4. Paint a ground of salmon color; then when dry and smoothed off, coat it over with rose pink, mixed in varnish and turpentine; then, with a flat piece of glass, press on the surface, and remove the glass quickly, being careful not to push it over the paint so as to disturb the curious figures which the pressure will form thereon. Varnish when dry, and you will have a beautiful imitation of tortoise-shell.

TORTOISE-SHELL, To Weld.—Bring the edges of the pieces of shell to fit each other observing to give the same inclination of grain to each; then secure them in a piece of paper and place them between hot irons or pincers; apply pressure, and let them cool. The heat must not be so great as to burn the shell; therefore try it first on a white piece of paper.

TREES, Fruit, Care of.—1. (*Coating for Amputated Branches and Wounds in.*) Shellac, dissolved in alcohol, forms an excellent coating for amputated branches and for wounds of fruit trees, making a water-proof artificial skin, under which the wood grows until the wound is healed.—2. (*To Prevent Ants from Injuring.*) Make a line of gas tar round the stem of the tree, or if it be trained on a wall, make a horizontal line near the ground on the wall, and one around the stem; this will prevent ants from ascending.—3. (*To Protect from Mice.*) A mixture of tallow, 3 parts; tar, 1 part. Applied to the bark while hot, will protect fruit trees against mice.

TRUNK, To Pack.—The cardinal point is to wrap up every delicate garment separately; of course it should be folded smoothly, and to teach how to fold clothes in print is not easy. Any good dressmaker, however, can give you points on that, and the wrapping is the more important thing; pin towels or sheets of tissue paper about your garment, but remember that newspapers are what you should fold between each layer of pretty things in the trunk. It is useless to try to arrange heavy things at the bottom, light on top; the baggage smashers know no top and no bottom; just concentrate yourself on keeping a smooth, even surface for each successive layer. Bows and sleeves can be stuffed out with newspapers better than anything else. Be sure that your wrappings are pinned firmly, so that there will be no coming undonc; they are your bulwarks. In packing breakable articles it is astonishing how many people will jam them down in corners and sides where they get the full force of every concussion against the unyielding walls. Tie on your corks well with bits of rag and twine, and put your bottles near the middle of a compartment, and you may carry ink and shoe dressing safely around the world. In packing such things as delicate hats, bonnets and fancy waists of such a frou-frou nature that no pressure can be allowed on them, it is still better to fill up the empty space of the boxes allotted them with lightly twisted sheets of tissue paper than to give them a chance to move, and with all due respect to the best packing in the world, it is still well to unpack as soon as you can.

VERDIGRIS, To Prevent on Electrotypes.—When electrotypes are not in use they should be well oiled to prevent verdigris, and stored face down to prevent warping. Wood engravings should be oiled and stored on end, for the same reasons.

VERMIN, To Keep from Trees.—The tying of a piece of wool round a tree stem to keep down the bugs and vermin is a poor idea, because it is based on the supposition that all these nuisances ascend from the ground, whereas in most instances the eggs are laid in the foliage above the supposed guard. The only actual preventive involves a delicate operation, which, however, can be successfully performed by a man with a steady hand. It consists in boring a small hole in the tree near the ground and filling it with sulphur. The sap carries this over the tree and there will be few insects settle or crawl on any part of it. The spring is the best time to do this, but with a strong healthy tree it can be done at any time with perfect safety.

VINEGAR, Raspberry, to Make.—1. Bruised ripe raspberries, 3 pt.; white wine vinegar, 3 pt.; macerate for three days, press, strain, and to each pint add 1 lb. white sugar. Boil, skim, cool, and bottle at once; two oz. of brandy to each pint is sometimes added. Cherry and strawberry vinegar may be made in a similar manner.—2. Bruised ripe raspberries and white wine vinegar of each 3 pt.; macerate for three days, press, strain, and to each pt. add 1 lb. of white sugar. Boil, skim, cool, and bottle at once. Some persons add 2 fl. oz. of brandy to each pt.—3. Fresh raspberries 3 lb.; good vine-

gar 2 lb.; macerate in glass for two weeks, then strain without pressure. In a similar manner strawberry vinegar, cherry vinegar, and the vinegars of like fruits may be made.—4. Add ½ pt. good vinegar to every qt. of raspberries, and let them soak for two or three days; then bruise the berries, express the liquid, and to each pt. add 1 lb. of sugar. Boil it for twenty minutes, skim it, and when thoroughly cool, bottle it.

VINEGAR, To Test.—1 Put a wineglassful of the vinegar into a china teacup, and let the cup float in water in a pt. cup of tin or other metal that will stand heat. Boil the water till half the vinegar has evaporated, then drop into the cup a piece of (cane) loaf sugar about the size of a gr. of wheat. Continue the boiling till the liquid in the cup has evaporated, when, if the vinegar contains free sulphuric acid, the dry residue will be found to be blackened. The charring of the sugar is due to free sulphuric acid.—2. To detect the mineral acids with which vinegar is frequently adulterated, and which are very prejudicial to health, a little sulphide of zinc is added to the vinegar previously heated in a test tube. If any of the mineral acids be present, the sulphide is decomposed, and sulphuretted hydrogen given off; this can be readily detected by lead paper. Acetic acid, the one which should be found in vinegar, does not have this action.

WALKING BACKWARD, Cure for Headache.—An apostle of physical culture says that an excellent and never-failing cure for nervous headache is the simple act of walking backward. Ten minutes is as long as is usually necessary to promenade. It sometimes, however, requires more than ten minutes to walk at all, if one is very nervous. Any kind of walking will do, provided it is backward. It is well to get in a long, narrow room, where the windows are high, and walk very slowly, placing first the ball of the foot on the floor, and then the heel. Besides curing the headache, this exercise promotes a graceful carriage.

WALL PAPER, To Clean.—1. Make 10 lbs. rye bread; take off top crust while hot; mix 3 gr. each powdered salts of tartar and ammonia, and sprinkle over the bread; press the bread together as solidly as possible and let dry for a day; just before using pare all the outside rind off. This composition, when pieces of it are drawn over the surface of soiled wall paper, performs wonders in removing deposits of dust and smoke; but it will be only partially effective if the walls have been dusted beforehand, as the marks of the dusty feathers or other agents employed cannot be erased.—2. Rye or Graham flour, 2 qts.; add 1 teaspoonful of emery dust. Mix with water to stiff dough. Bake till barely done; cut off crust and while hot, press into balls the size required and let dry 24 hours. Then use. Will keep four days.—3. Three lbs. wheat flour; 3 lbs. rye flour; 1 tablespoonful pulverized emery; ½ teaspoonful aniline red—("absorene").—4. To remove all stains or marks where people have rested their heads, from wall papers, mix pipe clay with water to the consistency of cream, lay it on the spot, and allow it to remain till the following day, when it may be easily removed with a penknife or brush.—5. If not very dirty, the paper of any room will be much improved by brushing it over in straight lines with a soft broom, covered with a clean, soft cloth; if, however, the paper be much soiled, very stale bread is the best thing to clean it with. Cut a very stale quatern loaf into slices, and, in the lightest manner possible, wipe the paper with it in a downward direction. Clean about a yard at a time, all one way, and be careful to leave no marks. By this process very dirty paper hangings may be made to look almost like new.

WALL PAPER, Measuring Room for.—1. The following table shows how many rolls of wall paper are required to cover a room of the dimensions indicated by the figures in the left hand column, also the number of yards of border necessary:

Size of Room.	Height of Ceiling.	Number of Doors.	Number of Windows.	Rolls of Paper.	Yards of Border.
7 by 9	8	1	1	6	11
7 by 9	9	1	1	7	11
7 by 9	10	1	1	8	11
7 by 9	12	1	1	10	11
8 by 10	8	1	1	7	12
8 by 10	9	1	1	8	12
8 by 10	10	1	1	9	12
8 by 10	12	1	1	11	12
9 by 11	8	1	1	8	14

14 by 18	10	2	2	15	22
14 by 18	12	2	2	19	22
15 by 16	10	2	2	15	21
15 by 17	12	2	2	19	22

Deduct one-half roll of paper for each ordinary door or window extra—size 4 by 7 feet.—

2. The following rules are given for the measurement of rooms to determine the exact amount of paper required to cover its surfaces. As most paper when trimmed is 18 inches wide and 24 feet to a single piece, a piece will contain 36 square feet. Measure the length and height of each wall in feet and multiply. Add together the number of square feet of each wall, getting the total number of square feet. Divide this total by 36, which will give you the number of pieces required for side wall. Allow one-half piece of paper for each door and window. To allow for waste in matching it is safer to divide by 33 instead of 36. To find number of single pieces required for ceiling, multiply length by width in feet and divide by 33.

WALL PAPER, Arsenic, to Detect in.—To detect arsenic in paper, immerse the suspected paper in strong ammonia on a white plate or saucer; if the ammonia becomes blue, the presence of salt of copper is proved; then drop a crystal of nitrate of silver into the blue liquid, and, if arsenic be present, the crystal will become coated with yellow arseniate of silver, which will disappear on stirring.

WALLS, Smoky, to Clean.—Brush well, wash with a strong solution of pearlash, rinse at once with clear water. Then give the walls when dry a thin coat of fresh slaked lime, with considerable alum dissolved in hot water added. After this has dried apply whiting and good size.

WATER, Hot, Medical Virtues of.—The uses of hot water are many. There is nothing that so promptly cuts short congestion of the lungs, sore throat or rheumatism as hot water when applied promptly and thoroughly. Headache almost always yields to the simultaneous application of hot water to the feet and back of the neck. A towel folded several times and dipped in hot water, and quickly wrung out and applied over the painful part in toothache or neuralgia, will generally afford prompt relief. A strip of flannel or napkin folded lengthwise and dipped in hot water and wrung out, and then applied around the neck of a child that has the croup, will sometimes bring relief in ten minutes. Hot water taken freely half an hour before bedtime is helpful in the case of constipation, while it has a most soothing effect upon the stomach and bowels. A goblet of hot water taken just after rising, before breakfast, has cured thousands of indigestion, and no simple remedy is more widely recommended by physicians to dyspeptics. Very hot water will stop dangerous bleeding.

WATER, Muddy, to Clarify.—1. It is stated that the suspended matter in the water is nothing but common chalk, and that when this is precipitated by the aid of chloride of iron the highly poisonous and corrosive chloride of calcium is left in solution. Now, as these remarks are wide of the truth, it should be stated that different matter besides "chalk" is contained in our river water to which its turbidness may be attributed, viz., mud—a composition of the silicates (clay and sand) with organic matter in addition to the calcium carbonate. The "highly poisonous chloride of calcium" (?) is a frequent constituent of mineral waters, and it is given, medicinally, in doses of 10 to 20 gr. As 6 or 7 drops of the solution of chloride of iron (representing 2 or 3 gr. of the salt) is quite sufficient to clarify a gal. of the water, it may be readily seen that no ill results would follow its use. A word as to the statement that calcium chloride is poisonous. So, indeed, is sodium chloride (common salt) when swallowed in excessive quantities. However, if this form of iron would prove objectionable for potable purposes, the ferrous sulphate (copperas) may be used in the proportion of 4 or 5 gr. to the gal. It may be of interest to note the fact that the water supplied to the inhabitants of several European cities is purified by the iron process. The impure water is agitated with small particles of iron, usually in the form of filings, and allowed to settle. The iron having an affinity for the suspended matter collects it on its downward course, leaving the water pure and clear above, ready to be drawn off and fit for use.—2. Take the muddy water and pour in a few drops of ferric-chloride. Allow this to filter through cotton placed at the bottom of a funnel. The result is water clear as crystal, with no taint of iron, and moreover soft. As ferric-chloride can be had for a song, this is the cheapest way that is known of purifying water. There is an old woman's way of using almond shells, but that requires time and fills the water with the shells.—3. The quickest and best way is the use of nascent iron carbonate (ferrous carbonate). This is obtained by the use of any ferrous salt and alkaline carbonate. Ferrous chloride or sulphate and sodium carbonate, or bicarbonate, answers admirably. We prefer the ferrous chloride and sodium carbonate; 4 or 5 gr. of each to the gal. of water is quite sufficient. The ferrous carbonate forms at once in flocculent masses, which, in precipitating, carry down with them all mud and other matter. The taste of the water is not affected in the slightest by the operation, and three or four hours is all that is required for the reaction. If done overnight the water will be crystal clear in the morning.

WATER, Distilled Mineral, etc.—1. (*Aerated or Carbonated Waters.*) These require the aid of the powerful machine employed by soda water manufacturers, to charge the waters strongly with carbonic acid gas. The gas is made from marble dust and diluted sulphuric acid, and is forced by a pump into the watery solution. Sometimes the gas is produced by the mutual action of the ingredients introduced into the bottle of water, which must be instantly closed; but this method is found practically inconvenient, and is only adopted in the absence of proper apparatus. The quantity of gas introduced is directed, in the French and American pharmacopœias, in most cases, to be 5 times the volume of liquid. For chalybeate and sulphureted waters the water should be previously deprived of the air it naturally contains, by boiling, and allowing it to cool in a closed vessel.—2. (*Simple Aerated Water.*) Carbonic acid gas water. Water charged with 5 or more volumes of carbonic acid gas.—3.

(*Alkaline Aerated Waters.*) Aerated soda and potash waters should be made by dissolving a dr. of the carbonated alkali in each pt. of water, and charging it strongly with carbonic acid gas. The soda water of the shops generally contains but little (or no) soda.—4. (*Aerated Magnesia Water.*) This is made of various strengths.—5. (*Mialhe's Aerated Chalybeate Water.*) Water, 1 pt.; citric acid, 1 dr.; citrate of iron, 15 gr.; dissolve, and add 75 gr. of bicarbonate of soda.—6. (*Trosseau's Martial Aerated Water.*) Potassio-tartrate of iron, 10 gr.; artificial seltzer water, 1 pt.—7. (*Bourchardat's Gaseous Purgative.*) Phosphate of soda, 1½ oz.; carbonated water, 1 pt.—8. (*Mialhe's Iodurcted Gaseous Water.*) Iodide of potassium, 15 gr.; bicarbonate of soda, 75 gr.; water, 1 pt.; dissolve and add sulphuric acid diluted with its weight of water, 75 gr. Cork immediately.—9. (*Dupasquier's Gaseous Water of Iodide of Iron.*) Solution of iodide of iron (containing 1-10 of dry iodide), 30 gr.; syrup of gum, 2½ oz.; aerated water, 17½ oz.—10. (*Murray's and Dinneford's Fluid Magnesia.*) To a boiling solution of 16 oz. of sulphate of magnesia in 6 pt. of water add a solution of 19 oz. of crystallized carbonate of soda in the same quantity of water; boil the mixture till the gas ceases to escape, stirring constantly, then set it aside to settle; pour off the liquid, and wash the precipitate on a cotton or linen cloth, with warm water, till the latter passes tasteless. Mix the precipitate, without drying it, with a gal. of water, and force carbonic acid gas into it under strong pressure, till a complete solution is effected. The eau magnesienne of the French codex is about a third of this strength.

WARTS AND TUMORS, Caustics for.—1. A painless caustic for the removal of warts and tumors may be made as follows: Arsenious acid, 1 part; sulphate of morphine, 1 part; calomel, 8 parts; powdered gum Arabic, 48 parts; this is to be sprinkled over the cuticle daily, the surface of which has been previously denuded by knife or blister.—2. Cauquoin's paste for the same purpose is composed of 10 parts of chloride of zinc, 2 parts of alcohol (60°), and 15 parts of wheat flour. The zinc in fine is added to the alcohol, then incorporated with the flour in a mortar, strongly pressing with the pestle. As soon as homogeneous it is spread with a roller, into sheets an eighth of an inch thick, and after a few hours put into a well corked bottle.—3. Latour's nitrochloride of zinc paste is also an excellent preparation, and is made by dissolving 50 parts of the chloride and 100 parts of the nitrate of zinc in 80 parts of water. The solution is made by the aid of heat. When it cools, 75 parts of wheat flour is incorporated with 100 parts of the solution, as with Cauquoin's paste.

WASHING, New Method of.—A new method of washing is being extensively adopted in Germany and Belgium. One of its special advantages is that it counteracts the ill effects of soda, which is much used in Europe, upon linen. Two lbs. of soda are dissolved in 3 gal. of water, and to this is added a teaspoonful of turpentine and 3 of liquid ammonia. When the mixture has been well stirred the linen is steeped in it for two or three hours. During the operation the vessel is closed as tightly as possible, and afterwards the clothes are washed out and rinsed in the usual manner. The soap and water may be used again with the addition of ½ a teaspoonful of turpentine and a tablespoonful of ammonia. The process is said to save time, labor and fuel. As there is no necessity for rubbing, the linen scarcely suffers, and its cleanliness and color are perfect. The ammonia evaporates immediately, and the smell of the turpentine is said to disappear entirely during the drying of the clothes. Paraffin has long been used in this country for a similar purpose.

WATCH COMPASS.—Any watch with an accurate dial plate is a compass. As a matter of fact, every watch is a compass three times a day—at 6 a. m., at noon and at 6 p. m. If the hour hand is pointed to the sun, the figure midway between that hand and the figure XII is south. That is to say, at 6 o'clock, if the hour hand is pointed to the sun, the figure III indicates the south. At odd times in the day the watch compass is a trifle out, but not greatly so, and a man losing his way can tell the points of the compass with practical accuracy at any time by following the simple rule indicated.

WATER, Examination of.—Smell and taste are powerful agents in detecting substances dissolved in water. Pure water is free from taste and smell, and is cooling to the tongue and stomach. *Rain water* has a soft taste, resembling weak lye. In case the taste is not sufficient to decide whether spring water is pure, pour some clear soap water into it; if it becomes turbid, the water is hard, and contains some foreign substance. *Spring water*, well water, and water from the interior of the earth, is adulterated with saline matter. A small quantity of foreign matter imparts to water a cooling and refreshing effect, like the water of springs and wells. *Mineral water.* If the amount of foreign matter is increased, or of a certain kind, it is called mineral water. The taste is not agreeable. Water of crystalline purity and an agreeable taste, contains pure carbonic acid gas. If this cannot be decided by taste, it may be detected by allowing a tumblerful of water to stand in a warm room a few hours, when the inside of the glass will be covered with bubbles; the more gas the greater will be the quantity of the bubbles adhering to the glass. To decide positively whether there is any in water, we must pour into it a little clear vinegar, and stir it; after this pour in a little powdered sugar, when the gas will rise in bubbles; if there is much, it will occasion ebullition. By inhaling the gas through the nostrils, it produces a refreshing sensation. Water possessing the smell and taste of rotten eggs, is sulphurous; if the quantity is not too large, the taste is not repulsive, but the smell is decidedly so. Waters of this description possess medicinal properties. If water has a cool taste, but an earthy after-taste, it contains lime. Magnesia causes water to have a bitter taste. Solutions of iron taste like black ink. Potash and soda do not give distinct tastes to water. These salts in mineral waters

produce the taste of salt. If the sulphates of potash or soda are present, they impart a bitter taste, resembling magnesia, but more repulsive. Some waters contain clay, and have an acid taste. It is necessary to use other means than the tongue to distinguish the acid. Saline waters are more impregnated with foreign matter than mineral waters, are repulsive, and have a strong medicinal effect. Saline waters are chiefly those which contain considerable chloride of sodium, as sea water and brine springs; they also contain sulphates, discovered by their bitter taste. *Turbid water.* If water is turbid, the amount of solid matter held in solution may be ascertained as follows: Fill a vessel with water; let it remain until the suspended matter has settled; then pour off the clear water from the precipitate, which may be dried and tested in the same manner as any other mineral. The sides of the vessel should be perpendicular; in that way the sediment settles sooner. Such sediments, next to those of alumina, vegetable matter, iron, etc., consist of siliceous matter. The sediment appears like mud, and should be put in a white porcelain dish and dried. If it shows a tendency to contract, while drying, separating into flakes, the sediment contains alumina; if the flakes shrink, it contains more alumina. Silica does not shrink, but forms a continuous covering; lime and other matter act similarly. A dark sediment indicates vegetable matter, proved by sprinkling some of it on a red hot iron; if it loses its dark appearance, the coloring is caused by vegetable matter. If the color changes to red the sediment contains iron. If desired to ascertain the amount of solid matter in water, it should be measured or weighed, and the dried sediment will give, when weighed, the portion of solid matter.

WATERMELONS, To Select.—A good watermelon may be known by pressing the thumb on the rind, near the center. If the melon yields a little to the pressure and the indent appears by that pressure and disappears after it is removed, the melon is ripe and healthy. If no indent can be made, the fruit is unripe. If the indent is easily made and remains after the thumb is lifted from the melon, it is overripe and unfit to eat. When the watermelon is thoroughly ripe and of good quality the interior of the rind should be a greenish white and the meat reddish pink in color. The rind of a watermelon generally becomes hard and the pulp becomes brittle. If left on the vine until probably matured, the part in contact with the ground will be changed from a white to a pale yellow, and upon close examination numerous small pimples, like the measles, will be noticed on the surface, particularly on the outer edge. With these signs, if the melon be frequently pressed and it cracks inside, it may be regarded as ripe.

WATERPROOF, To Make Cloth.—There is surely no better method than putting ½ lb. of sugar of lead and ½ lb. of alum in a pail of soft water, stirring it often until it becomes clear, pouring it off into another pail, and putting the cloth or garment into it, to remain there for twenty-four hours. The material should then be hung up to dry without wringing. It is said that garments thus treated will keep the wearer absolutely dry in the heaviest rain storm; the rain simply hangs in globules upon the cloth. Waterproof cloth is more healthy to wear than rubber goods.

WAX, Tree, to Make.—60 parts finely powdered lime, 20 parts of fine charcoal are mixed with q. s. of linseed oil. Apply with a brush.

WEATHER INDICATORS, Nature's.—Nature's barometers are the only ones of which most country folk have any knowledge. These they may consult at all times, and they know them by heart. The farmer has been so beaten about by wind and weather that he himself is scarcely sensible to changing atmospheric conditions; but that does not prevent his observing its influence on the things about him. Before rain his dogs grow sleepy and dull; the cat constantly licks herself; geese gaggle in the pond, fowls and pigeons go early to roost and the farm horses grow restless. Abroad, the ants are all hurry and scurry, rushing hither and thither; spiders crowd on the wall; toads emerge from their holes, and the garden paths are everywhere covered with slugs and snails. When the chaffinch says "Weet, weet," it is an infallible sign of rain. As the rain draws nearer, peacocks cry and frogs croak clamorously from the ditches. These are signs which almost every one has heard who lives in the country, though one of the surest ways of predicting weather changes is by observing the habits of snails. Snails never drink, but imbibe moisture during rain and exude it afterward. They are seldom seen abroad except before rain, when they commence climbing trees and getting upon the leaves. The tree snail is so sensitive to weather that it will commence to climb two days before the rain comes. If the down-pour is to be prolonged the snail seeks the under part of the leaf, but if a short or light rain is coming it stays on the outside. There is another species, which is yellow before rain and bluish after it. Others indicate change by dents and protuberances resembling tubercles. These begin to show themselves ten days before rain, and when it comes the pores of the tubercles open and draw in the moisture. In others, again, deep indentations, beginning at the head, between the horns, and ending with the jointure of the tail, appear a few days before a storm. One of the simplest of nature's barometers is a spider's web. When there is a prospect of wind or rain, the spider shortens the filaments by which its web is sustained and leaves it in this state as long as the weather is variable. If it elongates its threads, it is a sign of fine calm weather, the duration of which may be judged by the length to which the threads are let out. If the spider remains inactive, it is a sign of rain; if it keeps at work during rain, the down-pour will not last long, and will be followed by fine weather. Observation has taught that the spider makes changes in its web every twenty-four hours, and that if such changes are made in the evening, just before sunset, the night will be clear and beautiful. The constant iteration of the green woodpecker's cry before a storm has given it the names of rain-bird, rain-pie and rain-fowl.

Stormcock is a provincial name, shared by this bird and the missel-thrush, the latter often singing through gales of wind and rain. Stormbird is also applied to the field-fare. The abhorrence in which mariners hold the swallow-like storm-petrel is well known; its appearance is believed to denote wild weather. This little bird is the Mother Carey's chicken of sailors, and is also called storm-finch and water-witch. Herons flying up and down in the evening, as if doubtful where to rest, "presage some evil approaching weather"—a legend as old as Virgil, though probably devoid of foundation. Concerning gulls in general, children who live by the sea say, "Sea-gull, sea-gull, sit on the sand; it's never good weather while you're on land;" and fisher-folk know that when the sea-mews fly out early and far to the seaward fair weather may be expected. To Scotch shepherds the drumming of the snipe indicate dry weather and frost at night; and woodcocks have been observed to be remarkably listless against snowy foul weather, while, according to another author, their early arrival and continued abode "foretells a liberal harvest." The saw-like note of the great titmouse is said to foretell rain; that of the blue-tilt cold. In the south of France so much store is set by the wisdom of the magpie that if it builds its nest on the summit of a tree, the country folk expect a season of calm; but if lower down, winds and tempests are sure to follow. In Germany, dwellers in the country lack faith in the skylark's song as announcing fine weather; but when the lark and the cuckoo sing together they know that summer has come. The robin, buzzard, lapwing, starling and a number of other birds are said to foretell weather changes; it has been noticed that in nearly all the species named the various cries and calls are closely connected with the bird's food supply. Sleeping is characteristic of certain plants, and though it was at one time thought that this might have reference to the habits of insects, it is now believed to be more dependent on the weather. The tiny scarlet pimpernel, the "old man's weather-glass," opens at 7 o'clock and closes soon after 2. The daisy unfolds its flower at sunrise and sleeps at sunset. Dandelions close up at about 5 o'clock, at which time the white water lily has been asleep an hour and the mouse-ear hawkweed two hours. Local circumstances influence the flowers in their opening and closing, though they are pretty constant from day to day. Many flowers close their petals during rain—probably to prevent the honey and pollen from being rendered useless or washed away.

WEATHER, As Indicated by Clouds.—There can be no doubt that those who observe the clouds can make pretty shrewd guesses as to the weather for the next twenty-four hours. Anvil-shaped clouds are very likely to be followed by a gale of wind. If the sky becomes darker, without much rain, and divides into two layers of clouds, expect sudden gusts of wind. Brassy-colored clouds in the west at sunset indicate wind. If you see clouds going cross wind, there is a storm in the air. When on clear days isolated clouds drive over the zenith from the rain-wind side, storm and rain follow within twenty-four hours. If the clouds be of different heights, the sky being grayish or dirty blue, with hardly any wind stirring, the wind, however, changing from west to south, expect storm. Black clouds in the north in winter indicate approaching snow. If on a fair day in winter a white bank of clouds arise in the south, expect snow. Small black clouds drifting from the southwest is a sign of rain. If in winter the clouds appear fleecy, with a very blue sky expect cold rain or snow. If a layer of thin clouds drive up from the northwest, and under other clouds moving more to the south, expect fine weather. Clouds in the east, obscuring the sun, indicate fair weather. If clouds at the same height drive up with the wind and gradually become thinner and descend, expect fine weather. Enough blue sky in the northwest to make a Scotchman a jacket, is a sign of approaching clear weather. When clouds hang on the mountain side after a rain, and the sun shines on top of the mountains, the storm is over.

WEEDS, To Destroy.—1. The best way to apply salt to paths, to destroy weeds, is as follows: Boil the salt in water, 1 lb. to 1 gal., and apply the mixture boiling hot with a watering pot that has a spreading rose; this will keep weeds and worms away for two or three years. Put 1 lb. to the square yd. the first year; afterward a weaker solution may be applied when required.—2. The plants should be cut off close to the ground and a few drops of coal oil poured on to the crowns. They immediately commence to decay and are utterly destroyed. Troublesome weeds on the lawn can thus be speedily disposed of, but others will likely take their place.

WELLS, To Test Purity of.—A simple method of determining whether a cesspool communicates with a well of drinking water is suggested. Pour into the cesspool about 1 pt. of fluorescin—8 oz. to 1½ pts. of water. In a very short time, if any communication exists, the well will be colored a deep red.

WHALEBONE, Substitute for. — (*Balenite.*) Caoutchouc, 5 parts; burnt magnesia, 1 part; ruby shellac, 1 part; arsenic trisulphide, 1 part; sulphur, 1 part

WHITEWASH, U. S., to Make.—Here is the United States Government formula for mixing a whitewash, that when properly made and applied gives a white that does not easily wash or rub off: To 10 parts of freshly slaked lime add 1 part of the best hydraulic cement. Mix well with salt watr and apply quite thin. Sylvester's process for excluding moisture from external walls consists in using two washes or solutions for covering the surface of brick walls, one composed of soap and water and one of alum and water. The proportions are ¾ lb. of soap to 1 gal. of water, and ½ lb. of alum to 4 gal. of water. Both substances must be perfectly dissolved in water before using. The walls should be perfectly clean and dry, and the temperature of the air should not be below 50° F. when the compositions are applied. The first, or soap wash, should be laid on when at boiling

heat with a flat brush, taking care not to form a froth on the brick work. This froth should remain twenty-four hours, so as to become dry and hard before the second, or alum wash, is applied, which should be done in the same manner as the first. The temperature of this wash when applied may be 60° or 70°, and it should also remain twenty-four hours before a second coat of the soap-wash is put on, and these coats are to be repeated alternately until the walls are made impervious to water. The alum and soap thus combined form an insoluble compound, filling the pores of the masonry, and entirely preventing the water from penetrating the walls. Four coatings will render bricks impenetrable.

WILLOW, To Color Black.—To give a black color to the willow used for baskets and other woven ware the following process has been recommended: Let the material remain from twelve to twenty-four hours in lukewarm water, and then dip it a sufficient length of time in a dye composed of 5 parts of ground fustic, 3 of sulphate of copper, 5 of sulphate of iron, and 4 of cream of tartar. The dye should be kept at a boiling heat for half an hour to extract the color from the fustic and dissolve the other ingredients, after which it may be allowed to cool. A small quantity of logwood added will sometimes improve the color. The same process may be used for coloring the various fabrics of which summer hats are made, such as straw, palmleaf, grass, etc.

WILLOWS, Swamp, to Kill.—May is the month in which to kill swamp-willows. Take a hatchet or ax and merely cut through the bark three or four feet from the ground, then loosen the bark and strip it down to the ground but don't pull it off entirely; let it lie on the ground. Then loosen the bark above the place girdled and let it hang.

WINDOWS, To Clean.—Choose a dull day, or at least a time when the sun is not shining on the window; when the sun shines on the window it causes it to be dry-streaked, no matter how much it is rubbed. Take a painter's brush and dust them inside and out, washing all the wood-work inside before touching the glass. The latter must be washed simply in warm water diluted with ammonia. Do not use soap. Use a small cloth with a pointed stick to get the dust out of the corners; wipe dry with a soft piece of cloth. Do not use linen, as it makes the glass linty when dry. Polish with tissue paper or old newspapers. This can be done in half the time taken where soap is used, and the result will be brighter windows.

WINDOWS, Frosty, to Prevent.—1. Sponge the window with pure alcohol, and as long as the glass is kept perfectly dry this answers, but as soon as the humidity of the store deposits on the window glass there is another sponging due. A weak solution of glycerine (1 to 8) in pure alcohol is also a good wash, and this will act even better than the pure alcohol, but requires a perfectly dry and clean window to start with. The fixing of an electric fan at the side of the window and the throwing of a continuous current of air against the glass will also have the desired effect, but this lowers the temperature of the store, and so is objected to by some dealers. To those who will spend a dollar or so, and whose window permits of the simple arrangement, the following is undoubtedly the best plan. Run an inch pipe of tin along the lower inside edge of the window, this tube being perforated with small holes at every inch or so, the holes being on the upper side of the tube; carry this tube right across the window, having one end closed, and the other running under the window base, and terminating in an inverted tin funnel. Under this funnel place an ordinary kerosene lamp or a gas jet, and keep it lit all day and night. The hot air will rise through the funnel, travel along the tube, and escape through the perforations to the window, ascending up the face of the glass to the top of the window, displacing the heavier colder air. When other dealers' windows are frosted, the window which is not, where the display can be clearly seen, is doing true yeoman's service for the store.—2. Frost can be prevented from appearing on windows in winter, although scientists say that such a thing is impossible. Rub a pane of glass with an oil-saturated cloth. During the entire winter no frost will appear on that pane.

WINDOWS, Steaming, to Prevent.—1. It is thought that if a window is coated with a preparation consisting of 3 parts methylated spirits and 2 parts glycerine, there will be no condensation. The windows should be air-tight, and kept carefully closed. On a very cold day, if the shop is very warm, open them very occasionally, and shut them again almost directly.—2. A remedy found out some years ago has never been found to fail: 1st. Don't put gas lights into your windows. 2d. Put a ventilator as near the ceiling as you can get it, so as to let out the heat. 3d. Keep your door open and let the heat out and your customers in, and show the public that you do not only want them to look into your clean bright windows, but that you invite them inside of your bright and cheerful shop.

WINES, To Test.—1. The presence of lead or litharge in wine may be detected by sulphuretted hydrogen, or a solution of any alkaline sulphhydrate, which will produce a black precipitate.—2. Potassa or soda, improperly present, is detected by a small portion of the wine being evaporated nearly to dryness, and then agitated with rectified spirit; the filtered tincture, holding in solution acetate of potassa, is then divided into 2 portions, 1 of which is tested for acetic acid, and the other for the alkali.—3. A portion of the wine is evaporated to dryness and ignited; the residuum is then treated with a small quantity of hydrochloric acid; the mixture evaporated to dryness; again treated with dilute hydrochloric acid, and tested with liquor potassa. If a white precipitate forms, soluble in an excess of caustic potassa, and reprecipitated by a solution of sal ammoniac, the sample examined contains alum.—4. A drop or two of suspected wine may be poured upon a piece of paper, then dried before the fire. Pure wine stains the paper, but one containing sulphuric acid causes it to become charred and rotten. The effect is more marked on paper smeared

with starch paste.—5. Pure red wine is perfectly decolored by agitation with recent hydrate of lime.—6. Dissolve a piece of caustic potash in a small quantity of the liquid to be experimented upon. If no deposit is formed, and the wine assumes a greenish shade, there is no artificial coloration. A violet colored deposit indicates elderberries or mulberries; a red one indicates beet root or Brazil wood; red violet, that of logwood; blue violet, privet berries, and pale violet, litmus.

WOOD, To Petrify.—Gem salt, rock alum, white vinegar, chalk and peebles powder, equal parts; mix together. If, after the ebullition is over, you throw into this any wood or porous substance, it will petrify it.

WOOD. To Preserve.—1. (*To Prevent Worms in Marine Building.*) A mixture of lime, sulphur, and colocynth with pitch.—2. Saturate the pores with coal tar, either alone or after a solution of corrosive sublimate has been soaked and dried into the wood.—3. Sheathing with thin copper over tarred felt is esteemed the best protection for the bottoms of ships for all marine animals; the joints should be stopped with tarred oakum.—4. Stud the parts under water with short broad-headed nails.—5. (*To Destroy Ants and Insects in Wood.*) Corrosive sublimate is an effectual poison to them.—6. Oils, especially essential oils, are good preventives.—7. Cajeput oil has been proved effectual for destroying the red ant.—8. Dust the parts with pounded quicklime, and then water them with the ammoniacal liquor of gas works, when the ammonia will be instantly disengaged by the quicklime, and this is destructive to insect life. 9. For the black ant, use powdered borax; or smear the parts frequented by them with petroleum oil; or syringe their nests with fluoric acid or spirits of tar, to be done with a leaden syringe; or pour down the holes boiling water to destroy their nests, and then stop up the holes with cement. Ants dislike arsenic, camphor and creosote.

WOODWORK AND FLOORS, Care of.—1. It is of prime importance to select for exposed floors good lumber, and then to take good care of it. A thick coating of boiled linseed oil, applied while hot, is one of the very best of preservatives. The floor must be thoroughly dry and clean. Heat the oil in a tin pail or can placed in a kettle of boiling water. It may safely remain on the stove until wanted if care is taken not to spill or spatter the oil in any way, as this might cause a most disastrous conflagration. Never heat oil merely by putting the vessel containing it upon the stove, but always with hot water surrounding it. When ready for use, lift the kettle of water with the vessel containing the oil from the stove and carry to the corner of the room farthest from the door. With a wide, flat brush or a mop made of strips of woolen cloth, apply the oil, working rapidly and rubbing lengthwise of the boards. It is surprising how quickly hot oil will sink into the wood, and as this absorption is the secret of success, it may be gone over again as soon as the first coating has disappeared. Finish the job by backing out of the door, then leave the room undisturbed for some hours if possible. When it is necessary to use the room at once, it is well to heat an old smoothing iron quite hot and iron the floor, or rub with a bag filled with hot sand. This will cause the oil to absorb at once, and will leave the boards dry and clean. Then rub thoroughly with a thick cloth, and the room may be used at pleasure. If there is time and strength at command, an admirable floor finish may be made by melting about 4 lbs. of common yellow beeswax with 1 gal. of boiled oil. Rub the floor with hot irons until the boards are as warm as they can be made, apply the preparation when at the boiling point, and iron it with relays of hot irons, repeating the application until the wood will absorb no more. Then go over with clear, hot, boiled oil, leave it for a few hours and polish with a soft flannel. This will give a surface that dampness or use will not injure for a long time. Halls and stairs treated in this way are easily kept clean and always look well. With careful management they will not need renewing for years. Sometimes a dark finish is preferred, but this shows dust more readily and is much more difficult to take care of. If desired, it may be made by adding very finely ground burnt umber to the oil. This process of floor-finishing is very simple and easily managed, and any person of average intelligence will have no trouble in making it a success. The only precaution to be taken is in regard to fire, as if the oil boils over or is spilled upon the hot stove, the house might take fire; and as the oil burns so fiercely the fire would doubtless prove very difficult to subdue.—2. (*Polished Floors.*) No rollers should be used on furniture over polished floors. Each part which touches the wood should be fitted with a piece of thick felt securely glued on. This protects the floor and allows easy movement. These floors require only the sweeping with a hair brush and the wiping with a dust mop or soft cloth. Wax, alone, gives the highest polish; but is always slippery. It should be rubbed on evenly. Any little bits remaining will show as black specks after the polishing. The brush should be used across the grain at first, afterward with the grain. Wax and turpentine furnish a less degree of polish, which is, therefore, less slippery, while the addition of paraffine oil lessens it still more. If it be desired to keep the floor very light, the oil mixture should not be used, for oil always darkens wood. Water is the worst thing that can be applied to any waxed surface. A damp cloth may be used. All spatters or drops of any liquid should be wiped up immediately. When spots come—as come they will—rub them hard with a piece of thick felt under the foot or with a flannel moistened in turpentine. Remember to keep the surface well polished, then dirt cannot stick and substances spilled cannot reach the wood and make spots. With all these precautions the floors which are constantly used will need an entire renovation occasionally. They should then be rubbed all over with steel wool till every spot is scraped out. If the wood has grown dark it

may be whitened by a wash of oxalic acid. Rub perfectly smooth and clean before applying the wax or other encaustic. A good encaustic which will clean and polish at the same time may be made from wax, sal soda and any good soap. The wax and soap should be shaved and dissolved in boiling water. Stir frequently and add the soda. Put the mixture in something which may be closely covered and stir constantly until cool. This may be applied to floors, furniture, marbles, tiles, bricks, etc. It will remove ink from polished surfaces. The French use white wax on white marbles, but this is not absolutely necessary.

WORM, Army, to Destroy.—Going over the field with a heavy roller, drawn by a couple of horses, will crush most of the worms, while Paris green in water, sprinkled over them from a garden hose, will kill every one it touches. But in case there is no roller convenient, or the Paris green is not to be had in time, the worms may all be destroyed with very little trouble and expense in another way. They always march in a straight line, and fire nor flood will turn them from their course. When they appear in a neighborhood the farmers find out the direction in which they are moving, and then, at right angles to their course, plow a straight furrow. The "land side" is then made perfectly perpendicular by dressing it with spades, and at intervals of 50 or 100 feet holes, like post holes, are dug, from 1 to 2 feet deep. The worms come to the trench, try to climb up and fail, but having no idea of going back the way they came, they crawl along the trench and fall into the holes. They would soon die there, but most farmers make a sure job by putting an armful of straw in each hole and setting it on fire. If the army worm knew how to change his line of march he would no doubt give more trouble than he does, but his brain power is limited, and he walks into the post holes with his eyes wide open.

WOUNDS, To Heal.—1. When any one runs a nail or a wire in the flesh hold the wound over burning sugar as soon as possible and it will prevent soreness.—2. Procure from your druggist a small bottle of tincture of benzoin and apply to any flesh wound. It will heal immediately and not get sore.

WRINKLES, To Remove.—Wrinkles caused by facial contractions cannot be removed while their cause continues in operation. Withering and puckering of skin, the result of years, may be remedied by: Alum, 1 dr.; glycerine, 1 oz.; water, 1 pt.; to be used three times daily as a wash; or glycerine, 2 dr.; tannin, 1 dr.; rectified spirit, 1 dr.; water, 4 oz.; to be used as a wash three times daily. These washes are astringent, and they do not harm, whereas, some of the much vaunted lotions sold by the perfumers are most injurious if used for any length of time. The skin should be frequently bathed in cold water, and rubbed vigorously with the towel afterward.

YEAST, To Make.—1. (*Without Ferment.*) Boil ½ peck malt in 3 qt. water; pour off 2 qt., keep in a warm place 30 hours; add 4 qt. of a similar decoction, and stir well; again ferment, repeat the addition of 4 qt. until sufficient yeast is obtained.—2. (*Brewer's.*) Brewer's yeast is prepared as follows: 72 lb. unkilned malt and a handful of hops are gradually stirred in a clean tub containing 7 gal. of water of 170° F.; and to this 5½ gal. water of 200° are added. The tub is then covered tightly and left quiet. After some time it is cooled rapidly. This is accomplished by setting in cans filled with cold water. When the temperature of the mash has reached 70°, the tub is covered again and allowed to stand for some twelve hours longer, when 1½ gal. fresh beer yeast are to be stirred in. After another twelve hours have elapsed, pierce a hole in the layer formed by the husks of the malt and dip 3½ gal. of the liquor beneath, then stir the whole up and dip 1¾ gal. from it (husks and liquor). This is the mother leaven, from which yeast can be generated all the year round by using it in the way described instead of the ordinary beer leaven. To the remainder in the tub add 5 gal. wort of 90°, and make use of it within two hours. The mother yeast also must be used the same day for fermenting another portion.

ZINC, To Prepare for Painting.—Dissolve 1 part of chloride of copper, 1 part of nitrate of copper, and 1 part of sal ammoniac, in 64 parts of water, and add 1 part of commercial hydrochloric acid. Brush the zinc over with this which gives it a deep black; leave to dry 24 hours, when any oil color will firmly adhere to it, and withstand both heat and damp.

INDEX.

It must be borne in mind that when information is not found under one name it may yet be found under some one of several other similar meaning words, names, or forms of names, and the search be persevered in. Long dashes signify that the first named word is *repeated*. To aid in finding information wanted, also study the "CONTENTS AND ANALYSIS" in front portion of the volume.
