FARROW'S

MILITARY ENCYCLOPEDIA

A DICTIONARY OF MILITARY KNOWLEDGE

ILLUSTRATED

WITH MAPS AND ABOUT THREE THOUSAND WOOD ENGRAVINGS

BY

EDWARD S. FARROW, U. S. ARMY,

LATE ASSISTANT INSTRUCTOR OF TACTICS AT THE UNITED STATES MILITARY ACADEMY,
WEST POINT, NEW YORK

"What is obvious is not always known, and what is known is not always present."—JOHNSON.

COMPLETE IN THREE VOLUMES. VOLUME II.

NEW YORK:
PUBLISHED BY THE AUTHOR,
240 BROADWAY.
1885.

DEDICATED

TO THE

NATIONAL GUARDS OF AMERICA

In Appreciation of their Enterprise and Valor

AND AS A TRIBUTE OF HOMAGE

TO

GALLANT SOLDIERS.

PREFATORY NOTICE.

The design of this work is that of a Library of Military Knowledge for the People—not a mere collection of elaborate treatises in alphabetical order, but a work to be readily consulted as a Dictionary on every military subject on which people generally require some distinct information—no article being longer than is absolutely necessary. The several topics are not handled with a view to the technical instruction of those who have to make a special study of particular branches of military knowledge or art. The information given may be characterized in many instances as *non-professional*, embracing those points of the several subjects which every intelligent man or woman may have occasion to speak or think about. At the same time every effort is made that the statements, so far as they go, shall be precise and scientifically accurate.

Although about 30,000 subjects have been compiled from the various publications and records of the War Department, Foreign War Offices, and Military Works of reference, more than 5000 original articles have been prepared by specialists in America and abroad. While the Tactics, Ordnance, Gun Machinery, Implements, and Equipments of all ages and of all military powers have been fully described and illustrated under appropriate headings, a complete system of cross-references enables the military student to quickly locate several hundred articles pertaining to the general subject under investigation. Thus, under the article Magazine Gun will be found the following references: *Boch*, *Buffington*, *Bullard*, *Burgess*, *Burton*, *Chaffee-Reece*, *Clemmons*, *Colt*, *Dean*, *Elliott*, *Franklin*, *Hunt*, *Lee*, *Lewis-Rice*, *Miller*, *Remington*, *Russell*, *Spencer-Lee*, *Springfield-Jones*, *Tiesing*, *Trabue*, *Whitney*, and *Winchester Magazine Guns*. Under each of these articles are references to articles describing and illustrating all other arms of the respective classes. The Compiler has made special effort to set forth in detail the numerous decisions, rendered by the War Department and Tactical Department at West Point, on the tactical points raised and submitted from time to time by the Officers of the Army and National Guard. The descriptions and illustrations of more than 500 varieties of Gun Machinery, Steam Hammers, Cranes, etc., constitute a novel feature of the work to be appreciated by those wishing to investigate the subjects of construction, testing, etc.

The original plan has been strictly adhered to throughout; and if, as the work proceeded, there has been any change in the method or quality of the execution, it may at least be affirmed that the change has not been for the worse. After some experience, it became easier to find the person specially qualified to write a particular kind of article, and thus the circle of contributors became widened, and the distribution of the work more special ized. It was also seen to be desirable, in regard to certain classes of subjects, to admit a rather ampler selection of heads. This has been effected without increasing the scale of the work, not so much by less full treatment of the subjects, as by increased care in condensing the statements and omitting everything superfluous. A great quantity of matter pertaining to Foreign Armies has been introduced in this work, so as to enable the military student to compare the organization, arms, etc., of all armies with those of his own service. The Encyclopedia contains also descriptions of ancient armor, and of arms, lately in use, which have become obsolete, as it may be of some interest to follow the changes which have taken place in the mode and means of fighting from the earliest period down to the present time. The insertion of veterinary terms and of remedies for the common complaints of horses will be found useful under conditions where a Veterinary Surgeon is not available, as is often the case in detached parties of Cavalry. A description of all tools and machines found commonly in workshops may prove acceptable to Departmental Officers on their first joining Government Manufacturing Establishments.

Of the Sciences, the least adapted to encyclopedic treatment is Mathematics. All terms of common occurrence in Gunnery, Reconnoissance, etc., however, have been introduced, and a brief exposition of the subjects given, as far as could be done in an elementary way. Natural Philosophy has received ample attention, and all the leading doctrines and facts of general interest will be found under their appropriate heads, treated in a popular way, and divested as far as possible of the technicalities of mathematics. Chemistry, some knowledge of which is becoming daily more indispensable in all departments of military life, receives a comparatively large space. Prominence has been given to those points of the subject that have either a direct practical military bearing or a special scientific interest. During the progress of the work, several changes in the nomenclature and notation of the Science have come into general use; these have been duly noted under the appropriate headings. The new and far-reaching doctrines of the Correlation of Forces and the Conservation of Energy have produced vast changes in the nomenclature and classification of the various sections of Military Physics; while the more complete investigations into the phenomena and laws of light, heat, motion, and electricity have created virtually new sections, which must find a place in any adequate survey of scientific progress. Mechanical invention has, indeed, so kept pace with the progress of Military Science and the Art of War, that in almost every department of Physics improved machines and processes have to be described, as well as new discoveries and altered points of view. The manufacture of gunpowder and high explosives is a signal instance of the extent to which in our day scientific discovery is indebted to appropriate machinery and instruments of observation and analysis. These extensive changes in Physics involve corresponding changes in the method of their exposition. The scientific department of the work is consequently treated in all its branches in the most effulgent manner, and over 1000 very fine engravings are used for the purpose of illustration.

True to its projected plan as a LIBRARY OF MILITARY KNOWLEDGE FOR THE PEOPLE, this Encyclopedia will be found to be especially rich in notices of miscellaneous military matters. Some of the subjects introduced might perhaps be considered beneath the dignity of a book aspiring to a more severely scientific character; but all of them are, if not instructive, at least curious or entertaining, and likely to occur in the course of reading or conversation. During the progress of the work, the Compiler has received numerous assurances from parents as to how highly it was prized, even though only partly issued, by their sons at Military Schools, as a repertory of the kind of things they are constantly in search of and often puzzling their elders about. This use of the Encyclopedia has been steadily kept in view; and it is gratifying to learn that it is found efficiently to serve the purpose intended.

In conclusion, the Compiler asks the indulgence of Military Critics wherever errors or discrepancies have crept into this work, and begs to acknowledge the valuable help obtained from the works of many authors, both military and scientific, through the courtesy of Messrs. John Wiley & Sons and Mr. D. Van Nostrand, publishers, and the assistance he has received from various friends. To General Stephen V. Benét, Chief of Ordnance, United States Army, he is especially indebted for courteous assistance in the preparation of the work. To economize in space and to avoid crowding up the text, the name of the author from whom information has been derived has not been inserted after each quotation; but a list of all works which have been consulted, and from which extractions have been made, will be found at the commencement of each volume.

It is intended, with the view of meeting the changes which are constantly taking place in the *matériel* of armies, new processes, military inventions, etc., to issue a Supplement at suitable intervals, containing all alterations and additions.

ABBREVIATIONS OF MODERN TERMS, PHRASES AND TITLES EMPLOYED IN FARROW'S MILITARY ENCYCLOPEDIA.

A.A.S. (*Academiæ Americanæ Socius.*) Member of the American Academy.
A.B. (*Artium Baccalaureus.*) Bachelor of Arts.
A.B.C.F.M. American Board of Commissioners for Foreign Missions.
Abp. Archbishop.
A.C. (*Ante Christum.*) Before Christ.
A. D. (*Anno Domini.*) In the year of our Lord.
Æt. (*Ætotis.*) Of age; aged.
Al. Alabama.
A.M. (*Artium Magister.*) Master of Arts; (*Ante Meridiem*) Before noon; (*Anno Mundi*) In the year of the world.
An. (*Anno.*) In the year.
Apr. April.
A.R. (*Anno Regni.*) In the year of the reign.
Ark. Arkansas.
A.U.C. (*Anno Urbis Conditæ.*) In the year from the foundation of the city.
Aug. August.
Avoir. Avoirdupois.
B. Book; (*b.*) Born.
B.A. Bachelor of Arts.
Bal. Balance.
Bart. Baronet.
Bbl. Barrel.
B.C. Before Christ.
B.C.L. Bachelor of Civil Law.
B.D. Bachelor of Divinity.
Bd. Bound.
Bds. Bound in boards.
Benj. Benjamin.
Bk. Book.
B.L. Bachelor of Laws; Breech-loading.
B.L.R. Breech-loading rifled.
Bp. Bishop.
Brig.-Gen. Brigadier-General.
C., or *Cap.* (*Caput.*) Chapter.
Cal. California.
Cam., or *Camb.* Cambridge.
Caps. Capitals.
Capt. Captain.
C.B. Companion of the Bath
C.C.P. Court of Common Pleas.
C.E. Civil Engineer.
Cent. (*Centum.*) A hundred.
C.J. Chief Justice.
C.O. Commanding officer.
Co. Company.
Col. Colonel; Colorado.
Com. Commodore.
Conn., or *Ct.* Connecticut.
Cor. Corinthian.
Cor. Sec. Corresponding Secretary.
Crim. Con. Criminal Conversation; Adultery.
Ct. Cent.
Cts. Cents.
Cwt. Hundredweight.
D., or *d.* Penny, *or* pence.
Dan. Daniel.
D.A.Q M.G. Deputy Assistant Quarter-master-General.
D C. District of Columbia.
D.C.L. Doctor of Civil Law.
D D. (*Divinitatis Doctor.*) Doctor of Divinity.
Dea. Deacon.
Dec. December.
Del. Delaware.
Dep. Deputy.
Dept. Department.
Deut. Deuteronomy.
Deft., or *dft.* Defendant.
Dist. District.
Dist. Atty. District Attorney.
ditto, or *do.* The same.
D.M. Doctor of Music.
Dols. ($) Dollars.
Doz. Dozen.
Dr. Doctor; Debtor; Dram.
D.V. (*Deo Volente.*) God willing.
Dwt. Pennyweight.
E. East.
Ed. Edition; Editor.
Edw. Edward.
E.g., or *e.g.* (*exempli gratia.*) For example.
Eliz. Elizabeth.
E.N.E. East-North-East.
Eph. Ephesians.
Esq. Esquire.
et. al. (*et alii.*) And others.
etc., or *&c.* (*et cætera.*) And so forth.
et seq. (*et sequentia.*) And what follows.
Exod. Exodus.
Expl. Explanation.
Ez. Ezra.
Ezek. Ezekiel.
Fahr. Fahrenheit.
Feb. February.
F.G. Fine grain; Field-gun.
Fl., or *Flor.* Florida.
Fred. Frederic.
F.R.S. Fellow of the Royal Society.
F.S. Field-service.
Ft. Foot, *or* feet.
Fur. Furlong.
Ga. Georgia.
G.B. Great Britain.
G.C. Good conduct.
G.C.B. Grand Cross of the Bath.
Gen. General; Genesis.
Geo. George; Georgia.
Gov. Governor.
Gov.-Gen. Governor-General.
G.S. General service.
G.S.W. General service wagon.
H., or *h.* Hour.
Hab. Habakkuk.
H.B.M. His, *or* Her, Britannic Majesty.
H.C. House of Commons.
Heb. Hebrews.
Hhd. Hogshead.
H.L. House of Lords.
H.M. His, *or* Her, Majesty.
H.M.S. His, *or* Her, Majesty's Ship, or Service.
Hon. Honorable.
Hos. Hosea.
H.R. House of Representatives.
H.R.H. His, *or* Her, Royal Highness.
Hund. Hundred.
I., or *Isl.* Island.
Ib., *Ibid.* (*Ibidem.*) In the same place.
Id. (*Idem.*) The same.
i.e. (*id est.*) That is.
I.H.S. (*Jesus Hominum Salvator.*) Jesus the Saviour of men.
Ill. Illinois.
In. Inches.
Incog. (*Incognito.*) Unknown.
Ind. Indiana.
I.N.R.I (*Jesus Nazarenus, Rex Iudæorum.*) Jesus of Nazareth, King of the Jews.
Inst. Instant (the current month).
Io. Iowa.
i.q. (*idem quod.*) The same as.
Is. Isaiah.
It. Italics.
J. Justice; Judge.
Jan. January.
Jas. James.
Jer. Jeremiah.

Usque ad nauseam. (L.) Till it was, *or* is, absolutely sickening.
Utile dulci. (L.) The useful with the sweet.
Ut infra. (L.) As below.
Ut supra. (L.) As above.
Vade mecum. (L.) Go with me; a companion.
Væ victis. (L.) Woe to the vanquished.
Vale. (L.) Farewell.
Valet de chambre. (Fr.) A servant.
Veni, vidi, vici. (L.) I came, I saw, I conquered.
Verbatim et literatim. (L.) Word for word; letter for letter.
Verbum sat sapienti. (L.) A word to the wise is sufficient.
Viâ. (L.) By way of.
Vide. (L.) See.
Videlicet. (L.) Namely.
Vinculum matrimonii. (L.) The bond of matrimony.
Vis à vis. (Fr.) Face to face.
Vis inertiæ. (L.) The force of inactivity.
Vis viva. (L.) Living force.
Vivâ voce. (L.) By the living voice.
Vive la bagatelle. (Fr.) Success to trifles.
Vive la Reine. (Fr.) Long live the Queen.
Vive l'Empereur. (Fr.) Long live the Emperor.
Vive le Roi. (Fr.) Long live the King.
Voilà. (Fr.) See there; behold.
Vox, et præterea nihil. (L.) A voice, and nothing more.
Vox populi, vox Dei. (L.) The voice of the people is the voice of God.

INDEX OF MATTERS NOT HAVING SPECIAL ARTICLES.

At the close of Volume III. will be found an Index of Subjects not having Special Articles. It has not been thought necessary to repeat in this Index the titles of the many thousand articles composing the body of the work. A person consulting the Encyclopedia is supposed, in the first instance, to look for the subject he is in quest of in its proper alphabetical place. If it is not to be found there, or by a *cross-reference*, by turning to the Index he is likely to get a reference to it under another name, or as coming in for notice in connection with some other subject. It frequently happens that subjects, having articles of their own, are further noticed under other heads; and where it seemed of importance, a reference is given in the Index to this additional information. The title of the article referred to is printed in *italics;* and when the article is of considerable length, the page is given in which the information is to be found.

CONTINUED REVISION.

The process of revising Farrow's Military Encyclopedia is constantly carried on, thus keeping up the information to the latest possible date. These revisions and additions will be supplied every few years in the shape of Supplements. A few blank pages are inserted at the close of each volume for the purpose of noting the reference to the various articles in the Supplements, which would naturally find alphabetical arrangement in the respective volumes.

HABEAS CORPUS.—A writ of *Habeas Corpus* is an order in writing, signed by the Judge who grants the same, sealed with the seal of the Court of which he is Judge, and issued in the name of a Sovereign Power where it is granted, by such a Court or a Judge thereof having lawful authority to issue the same, directed to any one having a person in his custody or under his restraint, commanding him to produce such person at a certain time and place, and to state the reason why he is held in custody or under restraint. A State Judge has no jurisdiction to issue a writ of *Habeas Corpus*, or to continue proceedings under the writ when issued, for the discharge of a person held under the authority, or claim and color of the authority, of the United States, by an officer of that Government. If upon the application for the writ it appears that the party alleged to be illegally restrained of liberty is held under the authority, or claim and color of the authority, of the United States, by an officer of that Government, the writ should be refused. If this fact do not thus appear the State Judge has a right to inquire into the cause of imprisonment, and ascertain by what authority the person is held within the limits of the State; and it is the duty of the Marshal, or other officer having the custody of the prisoner, to give, by a proper return, information in this respect. But after he is fully apprised by the return that the party is held by an officer of the United States, under the authority, or claim and color of the authority, of the United States, he can proceed no further. These principles applied to a case where a *Habeas Corpus* was issued by a Court Commissioner of one of the Counties of Wisconsin to a recruiting officer of the United States, to bring before him a person who had enlisted as a soldier in the Army of the United States, and whose discharge was sought on the alleged ground that he was a minor under the age of eighteen years at the time of his enlistment, and that he enlisted without the consent of his father. The petition for the writ alleging that the prisoner had enlisted as a soldier and been mustered into military service of the National Government, and was detained by the officer as such soldier—this Court held that the Court Commissioner had no jurisdiction to issue the writ for the discharge of the prisoner, as it thus appeared that upon the petition that the prisoner was detained under claim and color of authority of the United States by an officer of that Government; and that if he was illegally detained, it was for the courts or judicial officers alone, to grant him release. Should a writ of *Habeas Corpus* be served upon an Army Officer by a Civil Magistrate or Court of any State, commanding him to produce an enlisted man, or show cause for his detention, the officer makes respectful return that the man is a duly enlisted soldier of the United States, and that the Supreme Court of the United States has decided in such case, that a Magistrate of a Court of a State has not jurisdiction.

HABERGEON.—A short coat of mail, consisting of a jacket without sleeves. In early times, the habergeon was composed of chain mail; but in the fourteenth century, a habergeon of plate-armor was worn over the hauberk. See *Hauberk*.

HABILIMENTS OF WAR.—In ancient statutes, armor, harness, utensils, etc., without which it was supposed there could be no ability to maintain a war.

HACHE D'ARME.—A battle-axe with a narrow handle armed with a sharp blade in the form of a crescent, very much curved, terminating in two points approaching the handle on one side; the other side terminating in a point or hammer; when both sides were armed with a blade it was called *Besagne*.

HACHEE.—The ignominious punishment of carrying a saddle or dog, to which soldiers were formerly subjected in France.

HACKAMORE.—A halter used by packers. It consists of a long leather or rope strap and head-stall. It is used when leading the pack-animal, also to make the animal fast, usually to the aparejo, while preparing to pack. On the march, the strap is wrapped around the animal's neck and made fast to the head-stall.

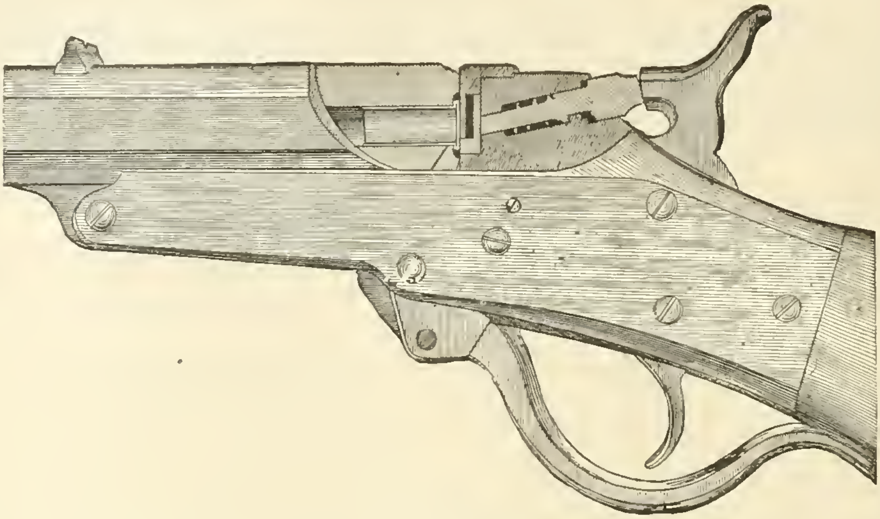
HACK-BUSH—HACK-BUSS.—A heavy hand cannon, with butt and serpentine lock. It belongs to the second half of the fifteenth century. The match is no longer loose, but fixed to the serpentine, which springs back by means of a trigger. This sort of cannon is about 40 inches in length, and it is usually provided with a hook, so that when it is placed on a wall, it cannot slip back. Without the hook it is sometimes called *Arquebuse with Matchlock*. See *Hake*.

HACQUETON.—A stuffed coat or cloak, generally of leather, mounted with metal, formerly worn in France by certain Knights of the King's Guards called *Gardes de la Manche*. It came into use during the reign of Charles V., and was discarded during the Revolution of 1789.

HACQUET-WAGON.—A four-wheeled wagon used in the Prussian service to carry pontons. The underframe of this carriage is built like that of a chariot, by which means it can turn without difficulty.

HADDAN RIFLING.—This plan of centering against the bore consists of 3 large and shallow elliptical grooves, which in the earlier forms were about 1-6 in. deep and took away nearly two-thirds of the surface of the bore. The projectile is rotated by 3 wings formed on the front of the shot, straight with its axis. In the earlier projectiles, the rear tapered, and had a shoulder for a ring-wad to stop the windage. The later projectiles have merely a wooden sabot. As the wings are on the front part of the projectile, the rifling is carried only to within one caliber of the powder-chamber, and hence is not a source of weakness at that point.

HADLEY FIRING-PIN.—A simple device for using rim-fire cartridges in rifles adapted for central-fire ammunition. It was invented for and specially applied to the Maynard rifle. This rifle is confined to central-fire ammunition in each and all of the calibers, excepting the 22; but by this device rim-fire cartridges from 22 to 38 caliber may be used. The drawing shows the nature and simplicity of the invention. It consists of a cap attached to the breech-piece by two small screws, in which is a disk with a firing-pin projecting through the cap at such a point from the center as to strike the rim of the cartridge. This disk plays freely in the cap, and is driven forward by the firing-pin in the breech-piece. To use the central-fire cartridges it is only necessary to remove the cap, change firing-pins, and insert the latter.



Hadley Firing-pin.

HAGBUT.—An arquebuse, of which the butt was bent or hooked, in order that it might be held more readily. Also written *Hagg* and *Haguebut*. See *Hack-bush*.

HAGNER MAGAZINE.—General Hagner proposed that a projection be formed on the under side of the stock, between the lower band and the guard, in which three cartridges might be placed, with their heads to the rear. This magazine differs from the *Benton fixed Magazine*, merely in its location, and holding three cartridges instead of five.

HAIDUCKS.—Originally a designation of cattle-herds in Hungary. Afterwards, the word came to signify a class of mercenary foot-soldiers ready to accept pay from any one who would employ their services, but displaying great gallantry on the field of battle. The remarkable constancy with which they stood by Bocskai throughout the War of the Revolution, was rewarded by that Prince with a grant of a district as their own possession, and at the same time with the privileges of nobility. This grant was made by a public decree of Dec. 12, 1605, and confirmed by the Diet in 1613. Except the privilege of exemption from taxes, which Charles III. took away, the Haiducks enjoy all the rights of Nobles to the present day. Their residence, the Haiduck district, remains independent of the country authorities, and is under the direct administration of the National Government. The Haiduck district lies within the country of North Bihar, between the Theiss and Transylvania, has an area of about 594 square miles and six principal Haiduck towns. The capital of the district used to be Böszörmény. The total population is about 63,000, all Magyars, and for the most part belonging to the Reformed Church. In 1876 this district was incorporated with portions of two adjoining districts into a new administrative division (called *Haidekencomitat*) with Debreczin for its capital. In course of the present century, the name Haiducks has begun to be applied to the Macers of Hungarian Courts and the Halberdiers of the Hungarian Magnates; also to the Lackeys and other Attendants in German Courts. Also written *Hajduks*, *Haiduks*, and *Hayduks*.

HAIL.—A term in military parlance, meaning to challenge, accost, or salute. A sentinel hails any one approaching his post between taps and reveille with, "Who goes (or comes) there?"

HAIR.—A spring or other contrivance in a rifle or pistol-lock, which, being unlocked by a slight pressure on the trigger, strikes the tumbler-catch, and unlocks the tumbler.

HAIR-CLOTH.—A species of cloth made of horse-hair, laid upon the floors of magazines and laboratories to prevent accidents. It is usually made up in pieces 14 feet long and 11 feet wide, each weighing 36 pounds.

HAIR-TRIGGER.—A trigger so constructed as to discharge a fire-arm by a very slight pressure, as by the touch of a hair. It is connected with the tumbler-catch by a device called the *Hair*. One of the latest improvements in sporting-arms is the addition of a set, or hair-trigger. This differs from the ordinary hair-trigger, in that it can be used precisely as if this trigger was not on the gun, if, as in hunting, it is not wanted. For fine shooting, as in target practice, it is made available thus: After setting the hammer at full-cock, the trigger should be pressed forward slightly, and it is thus set. If it is found too delicate, or not delicate enough, it can be adjusted to suit the wishes, by turning a set screw in or out. This screw will be found by the side of the trigger.

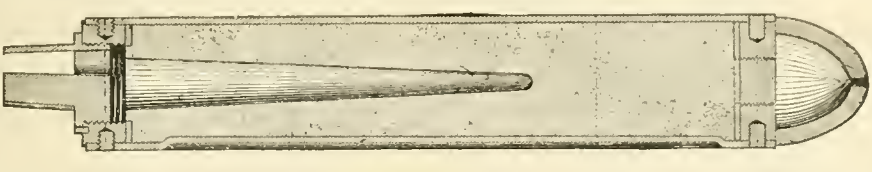
HAKE.—An old term for a hand-gun, used in ancient times, and usually fired on a rest by the manual application of a match. When the weight of these instruments was reduced, and a lock appended, so that they might be fired without a rest, they were called *calivers*. Hand-guns of this description are mentioned as having been first used at the Siege of Arras, in 1414. An inquisition taken at Huntercombe, in Yorkshire, in 1375, the record being in the Chapter-house, Westminster, mentions the attack on Manor-house of Huntercombe by 40 men armed, among other weapons, with "gonnes"—supposed to be *hand-guns*.

HALBERD—HALBERT.—A weapon borne, up to the close of the eighteenth century, by all sergeants of foot, artillery, and marines, and by companies of halberdiers in the various regiments. It consisted of a strong wooden shaft about 6 feet in length, surmounted by an instrument much resembling a bill-hook, constructed alike for cutting and thrusting, with a cross-piece of steel, less sharp, for the purpose of pushing; one end of this cross-piece was turned down as a hook, for use in tearing down works against which an attack is made. The honor of inventing the halberd is contested by the Swiss and Danes, but probably each produced something resembling it. Its name appears to be derived from the Teutonic *hild*, battle, and *bard*, axe. The halberd appears first in England about the time of Henry VII., and maintained its position for upwards of two centuries. Now it is rarely seen except on certain ceremonial occasions.

Old Halberd is a familiar term formerly used in the British Army, to signify a person who had gone through the different gradations, and risen to the rank of a commissioned officer.

HALBERDE. A term frequently given to the *guisarme*, or to one of its modifications, in the middle ages.

HALE WAR ROCKETS.—The general construction of the 12 and 24-pounders are the same, differing only in general dimensions and the number of vents and curved shields or walls, the 12-pounder having 3 and the 24-pounder 5. The rocket consists of four pieces. A head, conoidal in shape, of cast-iron, hollow for bursting, having a cylindrical hole in the base about $\frac{15}{16}$ inch diameter, with screw-thread for fuse; there is also a small hole in front, used for filling shell with combustible material, closed by a screw, but into which can, if desirable, be fitted a nipple and cap for ignition by percussion; the head is turned down at the rear $\frac{3}{4}$ inch so as to enter the body of the case about $\frac{13}{16}$ inch, and to which it is secured by six pins or screws. A *cylindrical body* of sheet-iron about $\frac{1}{8}$ inch thick, with edges lapped, riveted, and brazed at the longitudinal joints. A *thick iron disk* or annular ring fitted in and fixed by screws or pins closes the base. A *tail-piece* of cast-iron containing the vents and shields or walls is screwed into the disk which closes the base. The vents themselves are conical, the apex pressing against the curved shields, each placed in the same relative position to one of the vents, keeps the rocket point foremost in its flight, and gives the rotary motion on the turbine principle. The composition which is separated from contact with the iron by pasteboard to prevent oxidation, consists of saltpeter, sulphur, and charcoal, in the proportions of 70, 16, and 23, and is introduced into the case in successive pellets and pressed by hydraulic power; it is afterward bored out in a cone for about two-thirds of its length. The war-rockets are fired from a trough mounted on a stand, either singly or in groups of seven, by means of an ordinary friction-tube and lanyard.



Hale War-rocket.

The Hale Life-Saving Rocket differs from the above only in that the head, instead of being of cast-iron, is of wood, and in the addition of a piece of chain about 3 feet long which is connected to the center of the bottom of the tail-piece by a double swivel; to the chain is attached the life-line. This rocket is fired from an ordinary V-shaped trough, which may be given any desired elevation. As the chain is hardly long enough to prevent the burning off of the rope by the gas escaping from the vents, it is safest to wet about two fathoms of the rope next to the chain. See *Rockets*.

HALF-BASTION.—A demi-bastion. In fortification that half of a bastion cut off by the capital, consisting of one base and one front.

HALF BATTA.—An extra allowance which was granted to the whole of the officers belonging to the British East Indian Army, except Bengal, when out of the Company's district in Province of Oude. In the upper Provinces *double-batta* was allowed. All above full was paid by the native Princes, as the troops stationed in that quarter are considered as Auxiliaries. See *Batta*.

HALF-BLOCKS.—These are of the same dimensions as *blocks*, except that the cross-section is usually 4 × 8 inches, in place of 8 inches square. They are used for the same purposes as whole blocks; but, when the distance through which the piece is to be raised is only half of what it is when the whole block is used.

HALF-CAPONNIERE. In fortification, a communication in a dry ditch with one side prepared for defense, having but one parapet and glacis.

HALF-CHESS.—A short *chess* or platform board of a military bridge. See *Ponton*.

HALF COCK.—The position of the cock of a gun when retained by the first notch. See *Lock*.

HALF-DISTANCE.—Half the regular interval or space between troops drawn up in the ranks or standing column.

HALF DOUBLE SAP.—This is an ordinary line of sap pushed forward in a position where it is necessary to give temporary cover on the reverse of the trench, from a slant fire by gabions filled with sand-bags. The distance between the two rows of gabions in this case, is only 5 feet 6 inches, the single sap-roller covering in front this interval from enfilading fire. See *Sap*, and *Wing Traverses*.

HALF-FACE.—A movement, in the School of the Soldier, in order to take half the usual distance between the right or left face and front, to give an oblique direction to the line, or to fill up a gap at the corner of a square.

HALF FILE LEADER.—The foremost of a rank entire. The *Chef de Demi file* in France.

HALF-FILES.—Half the given number of any body of men drawn up two deep. They are so called in cavalry, when the men rank off singly.

HALF FULL SAP.—In siege operations, when the sappers have only a flank fire (coming in a direction nearly perpendicular to that of the sap) to fear, the sap-roller may be dispensed with. The first sapper then covers himself with the last-filled gabion whilst placing and filling the new one. This species of sap is called the half-full sap.

HALF-HITCH.—A form of hitch much used in mechanical maneuvers. It is made by passing the end of a rope round its standing part, and bringing it up through the bight. See *Cordage* and *Knots*.

HALF-MERLON.—That solid portion of a parapet which is at the right or left extremity of a battery.

HALF-MOON.—In fortification, an outwork that has two faces which form a salient angle, the gorge of which resembles a crescent. It owes its original invention to the Dutch, who used it to cover the points of their bastions. This kind of fortification is, however, defective, because it is weak on its flanks. Half-moons are now called ravelins, which species of work is constructed in front of the curtain.

HALF-PAY.—An allowance given in the British Army and Navy to Commissioned Officers not actively employed in the rank to which half-pay has reference. It corresponds to the French *demi-solde*, or pay of *non-activité*. It has long been a disputed point whether half-pay is given to officers as a retaining fee, to keep them at hand for the time when their services may be again required, or an award on account of services already rendered: but whatever the terms of the original grant, there can be little doubt that, under the present regulations, half-pay, except when distinctly named *retired* half-pay, is in the nature of a retaining fee. This allowance is on quite a different footing in the Navy and Army. In the Royal Navy of Great Britain, officers are merely appointed to serve during the period a certain ship is in commission; when this expires, their employment ceases and they revert to a state of non-activity. As there are always many more Naval Officers than appointments for them to fill, a considerable number are at all times on the non-effective list. These are placed on half-pay until again called upon to serve; the amount of such half-pay being usually about 60 per cent. of the full pay of each grade. Half-pay is thus in the Navy a recognized condition for all officers not immediately wanted afloat. In the British Army, the case is different; there, an officer on joining, is posted to a particular regiment, with which, in theory, he is supposed to serve until removed from it on attaining the rank of General. Consequently, no fund like the naval half-pay list is in any degree admitted. Army half-pay is of two natures—*temporary* and (so-called) *permanent* half-pay. The former is limited to officers incapacitated by casual sickness, to those who are without occupation, in consequence of any reduction of the corps in which they were serving, and to those serving in certain staff appointments. *Permanent* half-pay can be demanded by any officer who has served 25 years; it is also given to Majors and Lieutenant-colonels who, after serving for 5 years with a regiment in those ranks, are not re-employed. Since the abolition of purchase and sale of commissions, this last class may be expected, for the sake of promotion in the lower ranks, to increase considerably. The cost of half-pay is already very great; in 1877-78, it was £315,500 for the Army. Till lately, a large proportion of the recipients were officers placed on the list at the great reduction after the peace of 1815. There is a slightly different system or practice in the United States. There is sometimes a distinction between officers on active duty and those awaiting orders. Officers on leave, beyond the time allowed by law, are put on half-pay; and officers retired from active service receive three-fourths of their full pay. The salaries, at present, from Major-general downwards are graded as in the above tables. See *Pay*.

Officers.	Yearly Pay of Officers in Active Service.				
	1st 5 yrs.	After 5 yrs.	After 10 yrs.	After 15 yrs.	After 20 yrs.
Major-general	$7,500	....	....	....	....
Brigadier-general	5,500	....	....	....	....
Colonel	3,500	$3,850	$4,200	$4,500	$4,500
Lieutenant-colonel	3,000	3,300	3,600	3,900	4,000
Major	2,500	2,750	3,000	3,250	3,500
Captain (mounted)	2,000	2,200	2,400	2,600	2,800
" (not mounted)	1,800	1,980	2,160	2,340	2,520
1st Lieut. (mounted)	1,600	1,760	1,920	2,080	2,240
" (not mounted)	1,500	1,650	1,800	1,950	2,100
2d Lieut. (mounted)	1,500	1,650	1,800	1,950	2,100
" (not mounted)	1,400	1,540	1,680	1,820	1,960
Chaplain	1,500	1,650	1,800	1,950	2,100

Officers.	Pay of Retired Officers				
	1st 5 yrs.	After 5 yrs.	After 10 yrs.	After 15 yrs.	After 20 yrs.
Major-general	$5,625	....	....	....	....
Brigadier-general	4,125	....	....	....	....
Colonel	2,625	$2,887	$3,150	$3,375	$3,375
Lieutenant-colonel	2,250	2,475	2,700	2,925	3,000
Major	1,875	2,062	2,250	2,437	2,625
Captain (mounted)	1,500	1,650	1,800	1,950	2,100
" (not mounted)	1,350	1,485	1,620	1,755	1,890
1st Lieut (mounted)	1,200	1,320	1,440	1,560	1,680
" (not mounted)	1,125	1,237	1,350	1,462	1,575
2d Lieut. (mounted)	1,125	1,237	1,250	1,462	1,575
" (not mounted)	1,050	1,155	1,260	1,365	1,470
Chaplain	1,350	1,485	1,620	1,755	1,890

HALF-PIKE.—A short pike, formerly carried by infantry officers. See *Spontoon*.

HALF-ROLLER.—This roller has the same dimensions as the *long roller*, but is round only on one side, square on the opposite side, and has no groove. It is used resting on the square side, when, instead of rolling the gun, the object is to have a firm support on which the gun can have its ends alternately raised, as in mounting a gun on its carriage by means of blocks.

HALF-SUNKEN BATTERY.—A battery having its interior space or terre-plein sunk some inches below the natural surface, and its parapet composed of the earth thus obtained and that taken from a narrow ditch in front. This description of battery admits of being more quickly constructed than any other, as the diggers can work both in front and rear at the same time.

HALF-SWORD.—A figure within half the length of a sword; a close fight.

HALF-WROUGHT MATERIALS.—In artillery, the several parts of gun-carriages in the rough, or partly shaped to the form required. Supplies of these materials are kept in every Arsenal, and are issued to batteries on indent. Each battery in the field in England, is allowed the following half-wroughts:—

Beam..............................1
Cheeks............................2
Perch wagon.......................1
Splinter-bar......................2
Shafts, spare.....................2, complete.
Felloes...........................12
Spokes............................24

But as a spare carriage is allowed, there is no necessity to carry such ponderous articles as beams, etc.; the officer commanding a troop or battery will, therefore, use his discretion, according to the nature of the service on which he may be going, as to half-wrought materials he will carry, any in excess of the number allowed being provided at his own expense. On leaving a station where there may be an Arsenal, he can, if he thinks fit, return into store such half-wroughts as he may not wish to carry on the march, receiving from the Ordnance Officer a receipt, which will be his voucher for obtaining others free of charge at the next Arsenal. The above instructions have reference to the artillery in India, wherever the carriages are of the old pattern, viz., of wood. The new field-carriages being made of iron, the supply of half-wroughts as shown in the above list is not required, except for the wheels and other wooden parts of the carriage.

HALLECRET.—Light armor much used in the sixteenth century by the Swiss. It consisted of breastplate and gussets, often reaching to the middle of the thigh, and sometimes below the knees.

HALOXYLIN.—The name of a new kind of explosive material or blasting-powder which has been invented in Styria by two brothers, and is described as incapable of spontaneous ignition, and as quite free from smoke and noxious gases. It is composed of non-resinous sawdust, charcoal, niter, and ferrocyanide of potassium, and is twice the bulk of gunpowder, but one-half more powerful. For blasting and mining purposes it is considered as preferable to gunpowder.

HALT.—Literally, to stop; a term well known to soldiers. It is the word of command given to a body of men, or to a regiment or an army, on the move, to discontinue its march. In the march of a body of soldiers halts are very necessary for the comfort of the men, to enable them to rest themselves. On the usual daily march of a regiment in India, halts are made half-way, and coffee is served out to the men. This is a very desirable arrangement, seeing how early a regiment commences its march in that country.

HALTER.—A head-stall and strap by which an animal is hitched to a stanchion or manger. The halter was anciently used, and is shown in the sculptures of Nimroud. The army is represented in the act of crossing a river, and the horses are haltered behind the sterns of the boats, swimming in the wake.

HALTING DAYS.—The days in the week usually allotted for repose, when troops are upon the march, and there is not any particular necessity for exertion or dispatch.

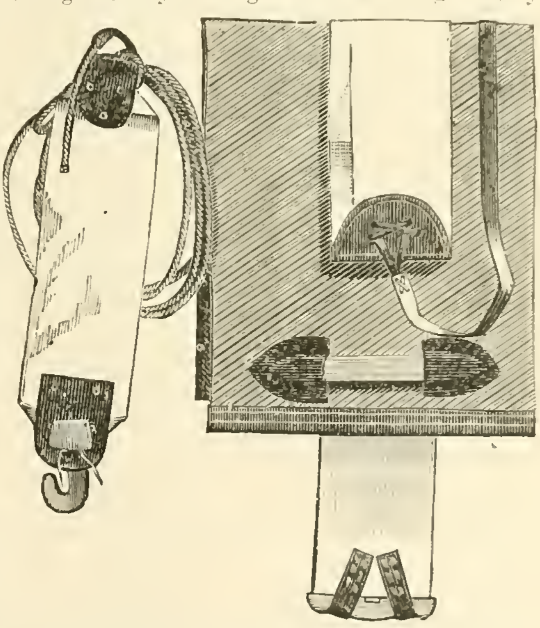
HALYARDS.—The ropes used in hoisting and lowering flags. Signal halyards are running cords of the best white hemp, passing through a pulley at the top of the flag-staff; the flags when attached to them are rolled up, and then hoisted and expanded to the wind by a jerk when the proper moment arrives.

HAMATA. A flexible cuiras composed of metal chains, and first worn by cavalry soldiers in the time of Polybius. See *Cuiras* and *Mail*.

HAMES.—Two pieces of iron encircling a horse's collar, connected at the bottom by an iron loop, and at the top by a strap and buckle. Attached to the hames are iron lugs to which the traces are linked.

HAMMER.—1. That part of a gun-lock which strikes the percussion-cap or firing-pin. It works on a spring called the *hammer-spring*. 2. The term is also applied to instruments in very general use for driving and drawing nails, beating out metals, etc. For many purposes, hammers are required of greater weight than man could wield; and a great variety of power-hammers are used. These, for the most part, are masses of iron raised by steam or other power, and then allowed to fall by their own gravity upon the work. The *helve* or *shingling hammer*, used for compressing the mass of iron drawn from the puddling furnace, and the *tilt-hammer*, used in the manufacturing of shear-steel, are important examples of such hammers. The first is a heavy bar of cast-iron about 10 feet long, weighing 3 or 4 tons and upwards, to which is attached a head of wrought-iron faced with steel, weighing nearly half a ton more. It works upon an axis at the end of the bar furthest from the head, and is raised by cams attached to a heavy wheel set in motion by steam or water-power; these cams strike or "lick" a projection extending beyond the head, and thus raise it about 18 or 20 inches at the rate of 70 to 100 times per minute. The tilt-hammer is similar, but much lighter, and is adapted for striking above 300 blows per minute. In order to obtain this velocity a short "tail" extends with a downward inclination beyond the axis, and the cams strike this downwards, and thus lift the longer arm of the lever to which the head is attached. These, when worked by steam, as they usually are in this country, are, of course, steam-hammers; but when the term steam-hammer is used without qualification, it applies to another and more elaborate machine of very different construction, invented by Mr. James Nasmyth in 1842, and subsequently modified and improved in some of its minor details. In this, the hammer is attached to the bottom of a heavy mass of iron, the "hammer-block," capable of rising and falling between upright bars or "guides"; this, again, is fixed to the rod of a piston, which works in a cylinder placed perpendicularly over the hammer-block, hammer, and anvil. As the piston rises in the cylinder, it lifts the attached mass, which is then allowed to fall from varying heights, according to an adjustment which can be made by an attendant simply touching a handle. The adjustments are so perfect that it may be made to crush a mass of iron, and at the next blow to crack a nut held in the fingers without damaging either kernel or fingers, or to crack the top of an egg in an egg-cup, as might be done with the bowl of a spoon. The mechanism by which this is effected is too elaborate to be described here in detail. One novel contrivance, viz., the "latch," which reverses the action of the steam valves at the precise moment required, is of remarkable ingenuity. See *Steam-hammer*.

HAMMER CLOTH.—When the aparejo is placed on the back of a pack-animal, it is covered with a piece of canvas or matting, made to fit it, called the *Hammer-cloth*. Two pieces of hard wood, about 1 inch thick, 2 inches wide, 20 inches long, round on the outside and beveled to an edge at the ends, are placed about 6 inches from the end of the cloth. Leather caps are stitched over the ends of the wood. To secure the hammer-cloth, aparejo and the blankets beneath it to the animal, a wide girth, called a cincha or cinch, is used. It is made of hide or strong canvas, about 6 feet long (a little too short to go around the mule's body over the aparejo), from 15 to 20 inches wide, and so folded as to bring the edges and stitching in the center. A semi-circular piece of leather, provided with holes or a ring, is stitched on one end, and two loops of strong leather and a slider of hard wood on the other. The cinch is tightened by drawing the two ends together, by



means of what is known as the latigo-strap—made of strong bridle-leather about 6 feet long, an inch and one-half wide at one end and tapering to one-half inch at the other. When the strap is sufficiently drawn, a loop is formed in the free end and the bow is pulled under the front and back lashings of the strap. To relax the cinch and set all free, it is only necessary to pull on the free end of the strap. For very small animals a short cinch (one end furnished with a ring and the other with a stick, bent into the shape of a hook), attached to a rope at the ring may be used. See *Aparejo* and *Packing*.

HAMMER-NAIL.—The pin securing the cock to the plate of the gun-lock. It is frequently called the *lock-nail.*

HAMMER PIKE.—A long-shafted weapon, like the *war-hammer*. It was carried by the subalterns in charge of the flag under the First Empire (1804-1814).

HAMMER SPRING.—The spring of a hammer in a gun-lock. Its parts are the *play-side*, the *stud-side*, the *turn*, the *flower*, the *stud*, and the *eye*; through the latter passes the rod of the spring-pin.

HAMMOCK.—A kind of bed suspended on land, between trees or posts; on board ship, between hooks. Each soldier proceeding to sea on board a troop or transport-ship is entitled to have a hammock told off to him as a resting-place of a night. The hammock suspended forms a sort of bag capable of containing the soldier's mattress, his blankets, and himself, as soon as he has acquired the far from easy knack of climbing into it. The hammocks are taken below at sunset, and hung in rows about 2 feet apart, in the men's portion of the ship. When done with in the morning, the bedding is carefully tied up within each, and the whole stowed in the hammock-netting, which is generally in the bulwarks of the waist. If the weather be not sufficiently dry, however, to allow of this, the hammocks are left below. Stowed thus in the netting, the hammocks form a strong barrier against small shot.

HANAPIER.—The front part of a cuirass, or iron breast-plate worn by light-armed soldiers. Also written *Hanepier*.

HAND.—1. The small of a gun-stock. 2. A measure four inches in length. The height of a horse is computed by so many hands and inches.

HAND ARBALEST.—A portable balista used in ancient Greece, very much like the cross-bow of the Middle Ages.

HAND ARMS.—Hand-arms are usually divided into three classes, depending on their mode of operation. 1st. *Thrusting*-arms, which act by the point. 2d. *Cutting*-arms, which act by the edge. 3d. *Thrusting and Cutting*-arms, which act either way. The object of all hand-weapons is to penetrate, directly, the person of an enemy. They may be divided into three distinct parts, viz.: 1st. The point, or edge, which attains the object; 2d. The body, or blade, which constitutes the mass of the weapon, and transmits the force of the hand to the object; and, 3d. The handle, or point of application of the motive force. The mechanical principles to which they may be referred, are lever and wedge. With a given force of the hand, acting against a given object, the penetration of a thrusting-weapon depends upon the power of the wedge formed at its point. The effect will be modified, however, by the position of the axis of the wedge, for if it do not coincide with the direction of the impelling force, there will be a component force which acts to turn the point to one side. The blade of a thrusting-weapon should, therefore, be straight, and should taper to a point. To guide it easily, the center of gravity should be found in or near the handle; this may be accomplished by grooving the blade, by making the handle heavy, or by adding a counterpoise to it.

The principal thrusting-weapons are the *straight sword*, *lance*, and *bayonet*. The straight swords as well as other swords, are composed of the *blade*, the *hilt*, and the *guard*. The blade is divided into the *point*, the *middle*, the *reinforce*, the *shoulder*, the *tang*, or portion which is inserted into the handle, and the *grooves*, the number of which is equal to the number of faces, or, from two to four. The length of blade varies from 30 to 33 inches, the width is from ½ to ¾ of an inch, and the weight 1 to 1½ lbs. The hilt is divided into the *knob*, and the *gripe*; the gripe is generally made of wood, covered with leather or sheet-brass, and wrapped with wire to give it roughness, and prevent it from slipping in the hand. The guard is composed of the *curved branch* and *cross-piece*, and the *plate*, all joined in one piece. The object of the guard is to protect the hand, the plate to ward off the point, and the branch, the edge of the enemy's sword. The *wounds* made by thrusting-swords, particularly those with three or four concave sides, are very dangerous, as they close up externally and suppurate internally. In experienced hands the straight sword is well adapted to encounter one of its kind, but it is too weak to parry the blows of a saber. It is now but little used in this country, except for ornamental purposes; the saber being preferred as a service weapon, even for infantry officers.

The lance, or pike, is composed of a sharp steel blade, fixed to the end of a long and slender handle of wood. The *blade* is generally from 8 to 10 inches long, and, in order that it may combine stiffness with lightness, is grooved after the manner of the common bayonet, leaving three or four ridges. The base of the blade has a socket, and two iron straps, for securing it to the handle. Three small staples are sometimes fastened to the handle, below the blade, for the purpose of attaching a *pennon*, which serves as an ornament, and to frighten the enemy's horses. The *handle* is made of strong, light, well-seasoned wood. The lower end is protected with a tip of iron, and a leather *loop* is attached opposite the center of gravity, to enable the arm to carry and guide the lance. The total length of a lance varies from 8½ to 11 feet, and the weight is about 4½ lbs. On horseback, and when not in use, the lance may be carried in two ways: 1st. By placing the lower end in a leather boot attached to the stirrup, and passing the right arm through the leather loop. 2d. By placing the lower end in the boot and strapping the handle to the pommel of the saddle. The first mode enables the horseman to take his lance with him when he dismounts, and is well suited to light lances. The second mode is necessary to heavy lances. In the first shock of a cavalry charge, and in the pursuit of a flying enemy, the lance is a superior weapon to the saber, as it has a greater penetration, and attains its object at a greater distance; but in the hand-to-hand conflict following a charge, the latter is superior to the former. Hence, it has been customary in certain services to arm a portion of both light and heavy cavalry with the lance. In the Russian service, the front rank of the cuirassiers, a species of heavy cavalry, is armed with the lance, and the rear rank with the long two-edged saber; and in nearly every European service, the lancers constitute an important part of the cavalry organization. It is also a favorite weapon with the mounted Indians of this country.

The bayonet is a pointed blade, attached to the end of the fire-arm, to convert it into a pike. The mode of attachment should be such that the bayonet will not interfere with the loading, aiming, and firing of the piece; and it should be so secure as not to be disengaged in conflict. The *musket-bayonet* is composed of a *blade*, a *socket*, and a *clasp*. The blade of this bayonet is made of steel, 18 inches long, and, to give it lightness and stiffness, its three faces are grooved in the direction of the length. The grooves are technically called *flutes*. The blade is joined to the socket by the *neck*, which should be strong, and free from all defects of workmanship. The *socket* is made of wrought-iron, carefully bored out to fit the barrel of the piece easily, and at the same time closely. It is secured by a stud (brazed on the barrel), which fits into a crooked channel, or *groove*, cut in the socket, and by a movable ring called the *clasp*. Short arms such as carbines and musketoons are sometimes furnished with bayonets of sufficient length to enable these arms to resist a charge of infantry or cavalry. Such bayonets are generally made in the form of a sword. The back of the handle has a groove which fits upon a stud on the barrel, and the cross-piece of the handle is perforated so as to encircle the muzzle-end of the barrel. The bayonet is prevented from slipping off by a spring catch. The handle is made of a solid piece of brass, with a hole running through it for the tang of the blade, which is secured by riveting down the point. The back of the blade is turned toward the barrel, and the body is bent outward, fixed, may be used as a poignard, for the personal defense of the soldier. The bayonet contributes very much to the efficiency of a military fire-arm, particularly as it enables infantry to resist cavalry. Too much attention cannot be paid in teaching troops the use of this arm, and inspiring them with

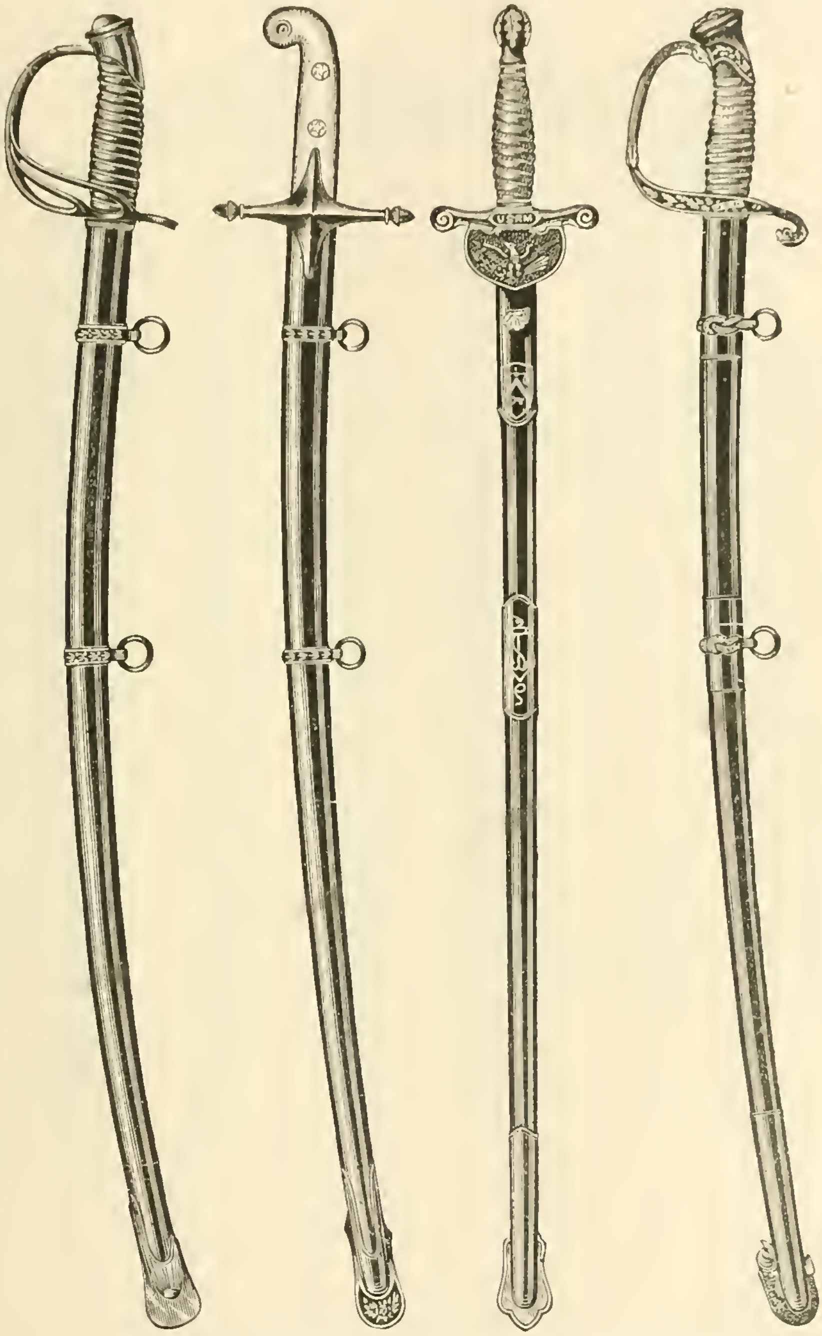


Fig. 1.

that neither may interfere with the hand in loading. Its length is about 23 inches, and its breadth $1\frac{1}{4}$ inches. The *sword-bayonet* is too heavy to be carried habitually fixed to the barrel; ordinarily it is carried as a side-arm, for which purpose it is well adapted, as it has a curved cutting-edge, as well as a sharp point. The regulation bayonet, when not confidence in it, for it very often decides the fate of a battle.

That edge of a cutting-arm will have the greatest penetration which opposes the fewest points to its object; a blade with a convex edge, will, therefore, have greater penetration than a straight one. The effect of a cutting-blade will be modified by the manner it is applied to the surface of the object; an oblique stroke, for instance, will make a deeper cut than a direct one. If the edge of the sharpest blade be submitted to a microscope, it will present to the eye numerous asperities, which give it the appearance of the cutting-edge of a saw; it is evident, therefore, that the motive force should act obliquely to the cutting-edge of the blade, as that enables it to rupture the layers of flesh upon which it acts, in de-

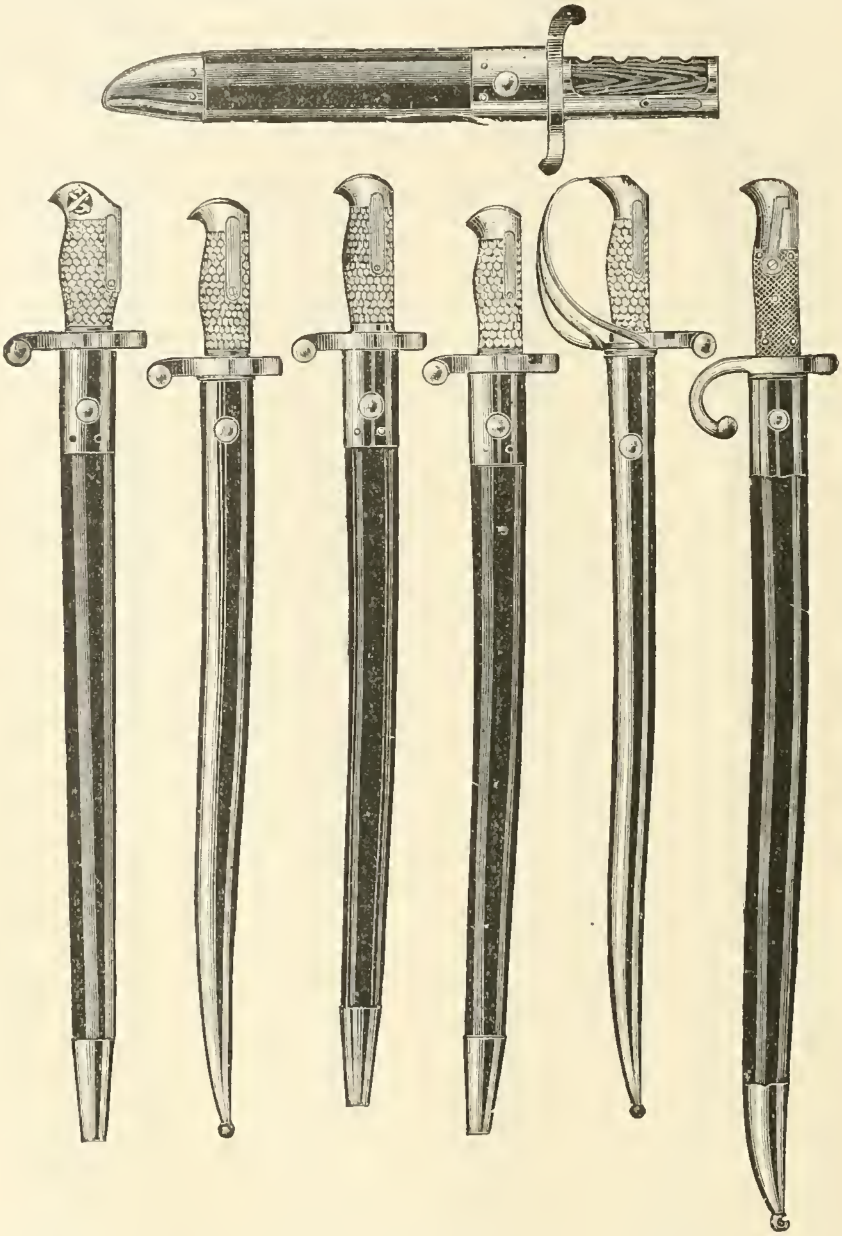

Fig. 2.

tail, and without expending its force upon the elasticity of several layers at once, which would be the case were it to act directly upon the object. When the curvature of a blade is convex on the cutting-side, the part near the point makes a deeper cut when it is pushed from the hand that moves it, as will be the case with the blows delivered in a charge of cavalry. On the contrary, a *concave* cutting-edge, like that of a sickle, acts most favorably when it is drawn toward the person using it; such is the *yataghan* of the Arabs, the shape of which is that of an elongated letter S. The facility of handling a saber, and the effect of its blow, depend upon the relative positions of the *handle*, the *center of gravity*, the *point of contact*, and the *center of percussion*. The nearer the center of gravity is to the point of contact, the more powerful will be the blow; but the difficulty of handling increases with the distance of the center of gravity from the handle. As the force of the blow is the important consideration in a saber, and the facility of handling in a thrusting-sword, it is customary to make the point of the blade heavier, and the handle lighter, in the former than in the latter. In certain light cavalry sabers, the center of gravity is placed about three or four inches from the handle. In order that no part of the force be lost, the point of contact should coincide with the center of percussion; the position of the latter point, however, depends upon the weight of the soldier's arm.

if motion takes place around the shoulder, and it therefore varies in particular cases. The principal cutting-weapon is the saber. The cutting-edge is generally convex; and the degree of its curvature is the characteristic feature of the weapon. The nomenclature of the saber is nearly the same as for the sword, the principal difference being in the structure of the guard, which is made lighter or heavier, as the saber approximates the character of a cutting or thrusting-weapon. There are two kinds of sabers used in the United States service, viz.: the *cavalry saber*, and the *light-artillery saber*. The *cavalry saber* being used, to a certain extent, for pointing as well as cutting, has only a moderate degree of curvature, a long blade (36 inches), and a "basket-hilt" to protect the hand from the point of the enemy's sword, and to carry the center of gravity toward the handle. The guard is composed of the *front*, *middle*, and *back* branches. The gripe is covered with calfskin, and bound with wire. The *light-artillery saber* being used more particularly for hand-to-hand conflicts, has a shorter (32 inches) and more curved blade, and a lighter handle than the cavalry saber. The guard is composed of a single piece of brass, terminating in a scroll. The blades of all sabres are grooved, to give them lightness. In certain services it is customary to arm the heaviest cavalry, or cuirassiers, with swords which are capable of coping with the bayonet or lance. The blades are long (from 36 to 40 inches), light, and straight, and they have a sharp point, and a single cutting-edge. The hilt is heavy, and of the basket form. The only weapon of the thrusting and cutting class used in the United States service is the foot-artillery sword, which resembles the short Roman sword in its character. The blade has two cutting-edges, is lightened toward the handle, and is 19 inches long. The guard is a simple cross-piece, formed of the same piece as the handle, which is made of brass. Figures 1 and 2 represent a variety of hand-arms, as manufactured in the United States. See *Small-arms*.

HAND BARROW.—A wooden frame which is carried around by two men, instead of being rolled forward, like a wheel-barrow. Those employed in the Ordnance Department are very useful in the erection of fortifications, as well as carrying shells and shot along the trenches. The ends of the side-rails are rounded and form the handles. Rope netting passes through holes in the side-rails and joins them. The weight of this barrow is about 20 pounds.

HAND BOARD.—A board used in the laboratory in rolling port-fire cases and similar work.

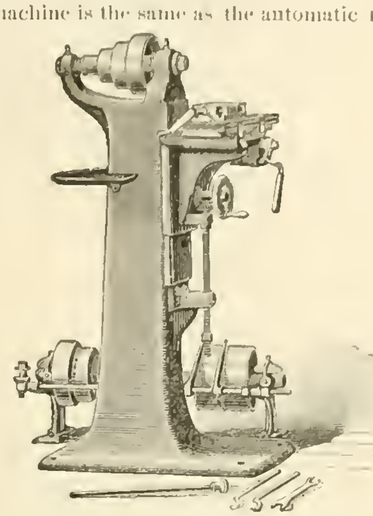
HAND CANNON.—A rudely made weapon of the fourteenth century. It was made of wrought-iron, and fastened to a piece of rough wood, so that it could not be brought to the shoulder. At first, the touch-hole was on top of the cannon, and had a covering plate on hinges to preserve it from damp. A little later the touch-hole was placed to the right of the cannon. See *Hackbush*.

HAND CART.—A light hand-truck used for the transportation of light stores from one part of a work to another. That for carrying powder, fuses, and such like articles has an arched lid-cover to keep off rain and prevent accidents from fire. The form mostly used in the United States service consists of a light body with shafts, mounted on two wheels. The shafts are joined together at the ends, and supported immediately in front of the body by iron legs. It weighs 180 pounds, and is very handy for the transportation of light stores in siege and garrison service. The drawing shows a very convenient cart, having two main fixed wheels and two heavy castors. This form is much used in transporting the heavier stores about the Armory and Arsenal.

HANDCUFF.—A fetter to secure the hands together. Handcuffs are made of iron, ring-shaped, with a lock attached, and just large enough to keep on the wrists without hurting them. Men who have deserted the service are usually manacled in this manner when being removed from one place to another.

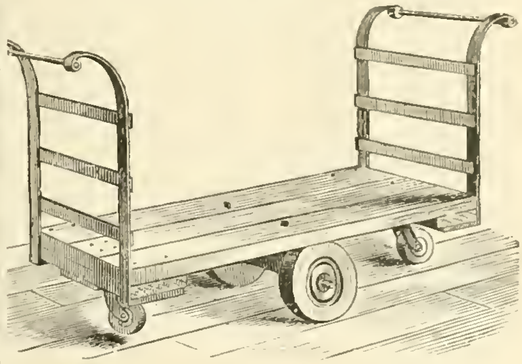
HAND CULVERIN. A small well-made cannon of the fifteenth century. The match was fastened to the weapon itself, and was held by the *Serpentin*, a sort of small linstock.

HAND FEED MILLING-MACHINE. A machine much used in the Armory for the rapid manipulation of small work, in the fabrication of fire-arms, etc. The machine is the same as the automatic machine,



Hand-feed Milling-machine.

with the exception of the automatic-feed being replaced by the hand-feed, which is operated by a lever fastened to the pinion-shaft, giving a very direct motion and quick return. Adjustable stops are placed on the table for regulating the motion. The machine



Hand-cart.

is usually furnished with a vise and a dividing-head, and is arranged for cutting gears and pinions either on centers or in a spring-chuck. The counter-shaft hangers are generally adjustable and self-oiling. See *Milling*.

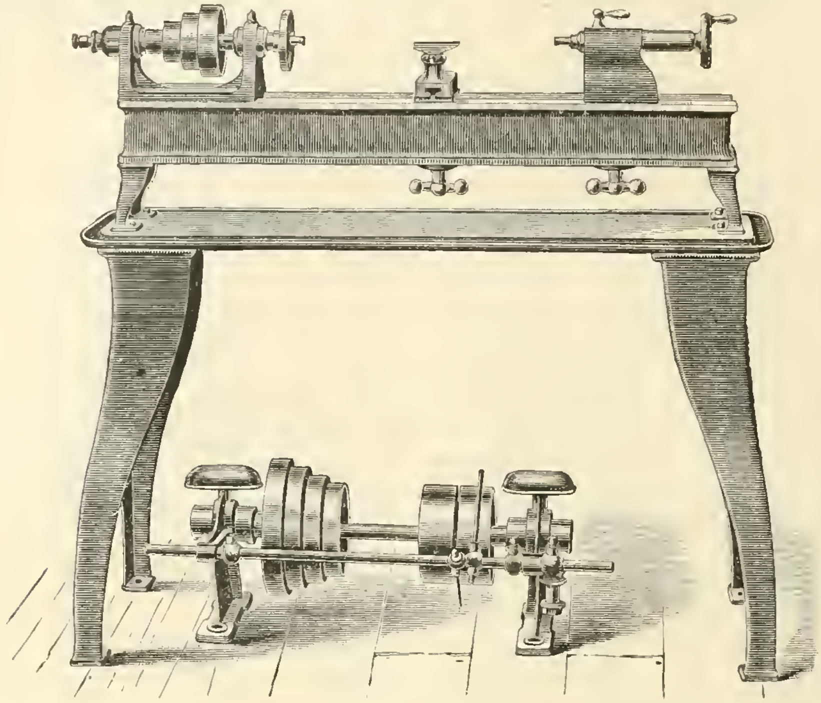
HANDFUL.—A term used figuratively, in a military sense, to denote a comparatively small number; as, "A handful of men."

HAND GALLOP.—A very slow and easy Gallop, in which the hand presses the bridle to hinder increase of speed.

HAND GRENADE. -Hand-grenades consist of small cylindrical-shaped shells, with conical ends, fitted with a plunger at the striking-end, and a directing-feather at the other. The plunger fits loosely into the cavity in the forward part of the shell, and is made to project two or three inches beyond its face, being retained in place by a light spring; it has attached to its outer end a circular piece of sheet-iron several inches in diameter. At the bottom of the cavity in which the plunger is placed a nipple is fixed, communicating with the bursting-charge, on which is placed an ordinary percussion-cap, which is exploded when the plunger is driven in violently, thereby igniting the charge. There are three sizes of grenades, 1, 3, and 5 pounds, and are intended to be thrown by the hand, and may be very effectively used in repelling attacks by boats or by persons well sheltered against others completely exposed.

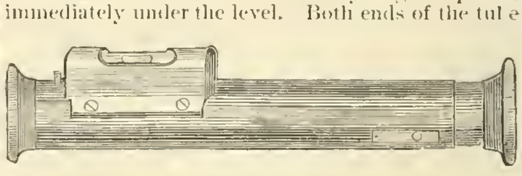
Ketchum's hand-grenade, which has lately been introduced into the American service, is a small, oblong percussion shell, which explodes on striking a slightly resisting object. To prevent accidents, the "plunger," or piece of metal which communicates the shock to the percussion cap, is not inserted in its place until the moment before the grenade is to be thrown. See *Grenade*, *Projectiles*, and *Rampart-grenade*.

HAND-LATHE.—A small lathe mounted on a bench or table and turned by a hand-crank or by a bow. It is usually portable, and may be secured by a clamp to the bench. It is extensively used in the Armory in making the small parts of small-arms. The drawing shows the Pratt and Whitney 8-inch hand-lathe, as employed in most gun-factories in the United States. The cone has four grades, for 1½-inch belt; the spindle has extra large bearings, in gun-metal boxes, and has a hole through its center ⅜-inch in diameter. The boxes are seated in tapering recesses, and are split, so that any possible wear may be taken up by means of cap-nuts. The cap-nuts contain felt linings, to prevent the introduction of dust, or of emery, when the lathe is used for polishing. A hand lever for actuating the foot-stock spindle is furnished, in addition to the hand-wheel and screw, or without hand-wheel and screw. The lathe with 30-inch bed, receives 12 inches between centers, and weighs, with the countershaft, 340 lbs. Speed of countershaft, with 7 by 2¼-inch tight and loose pulleys, 320 revolutions per minute. Larger lathes of this pattern are also used on the larger parts of small-arms. A 15-inch hand-lathe has a cone carrying a 2¼-inch belt. The head-spindle has large bearings, in cast-iron boxes lined with Babbit-metal of the best quality. The face-plate and centers interchange with those of the 13-inch engine-lathe. Hand-lathes swinging 12 inches, are of similar construction, with the exception that the boxes are of the same material and style as those of the 8-inch. The holes through the centers of the spindles are for 12-inch lathes, $\frac{7}{16}$-inch diameter; 15-inch lathe, $\frac{9}{16}$-inch. Countershafts should have speed as follows: For 12-inch lathe, tight and loose pulleys 6 or 8 by 2¼ inches, 200 to 250 revolutions per minute; for 15-inch lathe, tight and loose pulleys 8 or 12 by three inches, 175 to 250 revolutions per minute. See *Lathe*.



Hand-lathe.

HAND-LEVEL.—A small and portable instrument for indicating a horizontal line, or determining the position as to horizontality of an object or surface to which it is applied. The drawing represents Locke's hand-level, a very accurate and suitable instrument for general reconnaissance-work. It consists of a brass tube about six inches long, having a small level on top and near the object end, there being also an opening in the tube beneath, through which the bubble can be seen, as reflected by a glass prism, immediately under the level. Both ends of the tube are closed by plain glass settings to exclude the dust, and there is in the inner end of the sliding or eye-tube a semicircular convex lens, which serves to magnify the level-bubble, and cross-wire underneath, while it allows the object to be clearly seen through the open half of the tube. The cross-wire is fastened to a little frame moving under the level-tube and adjusted to its place by the small screw, shown on the edge of the level case. The level of any object in line with the eye of the observer is determined by sighting upon it through the tube and bringing the air-bubble of the level into a position where it is bisected by the cross-wire. A short telescope is some



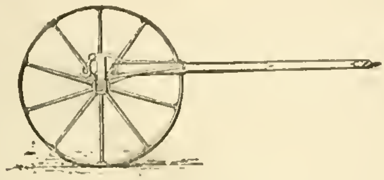
Hand-level

times applied in place of the plain glass ends, thus enabling levels to be taken at greater distance and with increased accuracy. See *Clinometer*, and *Y Level*.

HAND MALLET.—A wooden hammer with a handle, to drive fuses, or pickets, etc., in making fascines or gabion batteries.

HAND RUBBING.—The manipulation which a horse's legs undergo on the march and elsewhere, chiefly at feeding time, and which should be continued for about 20 minutes at each meal.

HAND SLING CART.—A two-wheeled carriage made entirely of iron, except the pole, which is of oak. The axle-tree is arched to make it stronger,



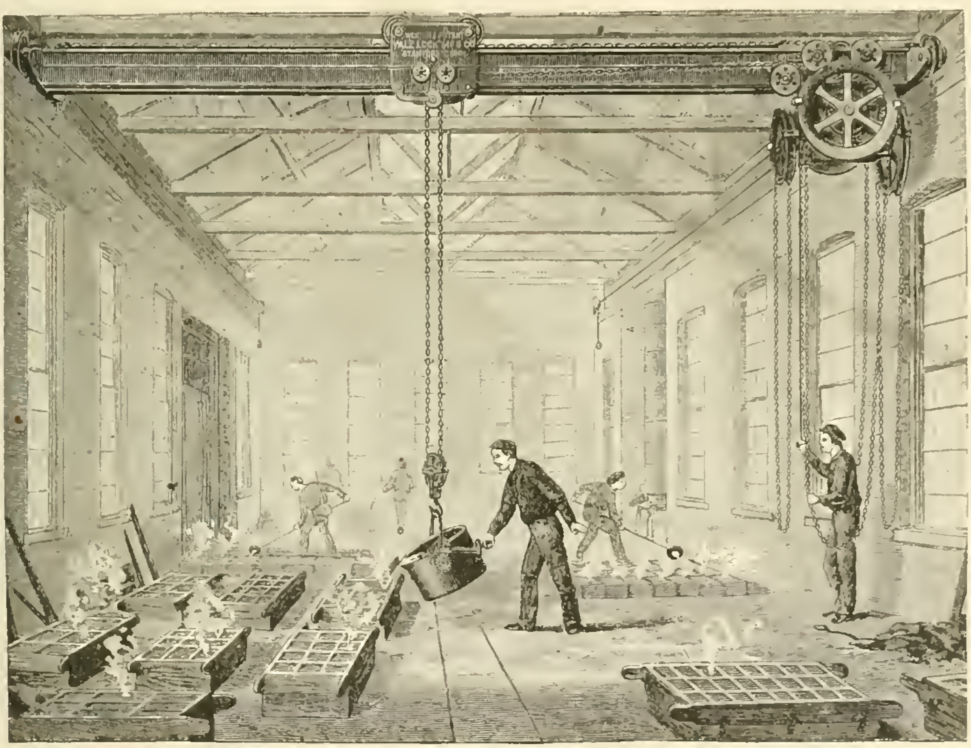
Hand Sling-cart.

and connected with the pole by strong wrought-iron straps and braces. In the rear of the axle a projection is welded to receive the end of a strong hook. The end of the pole terminates in a ferrule and an eye. The eye serves the purpose of attaching to the cart, when necessary, a limber or a horse. The diameter of the wheel is six feet. The hand sling-cart is designed for moving light weights and siege-pieces in the trenches by hand. The weight is raised by first attaching to it a sling, and then applying to the sling the hook upon the rear of the axle, by raising the pole of the cart. The pole is used as a lever, the axle and wheels being the fulcrum. It may be used for any weights not exceeding 6,000 pounds. See *Garrison Sling-cart* and *Sling-cart*.

HANDSPIKE.—A wooden or iron lever, flattened at one end and tapering towards the other, used in raising heavy weights and in moving guns into position for loading and firing. The *trail* handspike for field carriages is 53 inches in length; the *maneuvering* handspike for garrison and sea-coast carriages and for gins is 66 inches; for siege and other heavy work it is made 84 inches long and 12 lbs. weight; the *shod* handspike is particularly useful in the service of mortars and casemate and barbette carriages; the *truck* handspike for casemate carriages, of wrought-iron; the *roller* handspike, for casemate carriages. It is made of iron, 1 inch round, the point conical, whole length 34 inches.

HANDSPIKE RINGS.—The thimbles on the trail transoms of guns, for the handspike, by which they are maneuvered.

HAND TRAVELING-CRANE.—The most satisfactory construction of this crane, as exhibited in the engraving, has the mechanism attached to one end of the bridge so that the operator is somewhat removed from the load, thus adapting it especially to foundry use. The bridge is arranged to travel lengthwise upon the longitudinal tracks, and the trolley to move transversely upon the bridge, so that the entire rectangular space between the tracks is covered by the crane. Cranes of this design are built of any desired capacity up to 10 tons, and of any span. The crab containing the operating mechanism is permanently secured to the under side of the bridge at one end, and is located entirely below it, so that the bridge can be placed close to the under side of roof or ceiling. The trolley travels upon tracks on top of the bridge, and its sides extend downward close to the bridge, with the chain sheaves contained between them, thus giving the maximum amount of hoist. The Weston fixed-cable system is employed to effect the squaring of the bridge and its longitudinal motion upon the overhead tracks. The travel of the trolley upon the bridge is effected by an independent mechanism, operated by an endless hand-chain from the floor below, in a manner similar to that employed in the



Hand Traveling-crane.

jib cranes. Motion of the bridge is also effected by an endless hand-chain or rope passing over another rope-wheel. Pulling one side of this chain causes the bridge to move in one direction, and pulling the other causes it to move in the opposite direction. At each end of the crab, or housing containing the operating mechanism, are similar rope-wheels, over each of which passes an endless rope or chain. Pulling either of these in one direction causes hoisting, and in the other, lowering. One is larger than the other, thus giving two speeds; while, by pulling both simultaneously, an additional speed is obtained. The several motions of hoisting or lowering, and of moving the bridge or trolley, may each be effected independently or simultaneously.

The hoisting-gear consists of cut steel worms engaging with cut worm-wheels, with provision for thorough lubrication. The main hoisting-chain is endless and passes over pocketed chain-wheels, by which it is driven, the arrangment of parts being such as to distribute the wear equally throughout the entire length of this chain. A safety device, consisting of automatic friction-ratchets in combination with the worm-shafts, is employed, so that the load is always self-sustained in any position and cannot run down. Lowering is effected by reversing the motion of the hoisting-chains. The location of the mechanism at one end of the bridge removes the operator from proximity to the load, which is, of course, desirable in handling ladles of hot metal, and in lifting large flasks, etc. While particularly designed for foundry use, this type of crane is equally suitable for use in forges and for many of the same purposes as other cranes. See *Cranes, Power Traveling-crane*, and *Traveling-crane*.

HANDLE.—The portion of a tool, or implement, by which it is grasped. As—*helve* of a hammer or axe; the *haft* of a knife; the *hilt* of a sword; the *stock* of a drill, bit, or gun; the *shaft* of a spear, lance, or harpoon; the *crank* of a winch or crab; the *pommel* of a saddle; the *trigger* of a gun-lock; and the *dolphin* of a gun. In bronze guns of the old construction handles were usually cast over the center of gravity of the piece, for convenience of handling and slinging. These were made in the shape of a fish, and hence were called *dolphins*.

HANDLE ARMS.—In the earlier tactics, a word of command (when the men were at *ordered arms*), by which the soldier was directed to bring his right hand briskly to the muzzle of his fire-lock.

HANGED, DRAWN, AND QUARTERED.—The description of the capital sentence on a traitor, which consisted of drawing him on a hurdle to the place of execution, and after hanging him dividing the body into quarters. This punishment was substituted, for the ancient more barbarous sentence of disemboweling alive, but the Crown has power to reduce the sentence to simple beheading.

HANGER.—A term applied to a short broadsword, incurvated towards the point. The *hanger* was a Turkish sword formerly worn by the Janissaries.

HANG FIRE.—The term is applied when a gun is slow in discharging itself, from the flame being checked in its passage to the charge, either from the vent being fouled or the charge being damp. The former can scarcely happen now, as the friction tube conveys the flame to the charge with great certainty.

HANTE. The French name for an ornamental pike, having a banner attached.

HAQUETON.—A padded or quilted tunic worn by armed warriors in the Middle Ages. It was worn beneath the mail and was slightly longer than the *hauberk*.

HAR.—A syllable used in composition usually as a prefix, and signifying *army*: occurring in various forms, as *hare*, *her*, and *here*; as harisvalt, leader of an army.

HARANES. The French designation of the Hungarian Militia.

HARASS.—In the military, the act of annoying and incessantly pursuing or hanging on to the rear and flanks of a retreating force, so as, if possible, to prevent its attaining its object, and perhaps overcoming the enemy altogether. Notwithstanding the disadvantage which a retreating army has under these circumstances, history affords us examples that if the retreat be conducted by an able Commander, he has it in his power, by his ingenuity and other military qualities, to avoid the enemy, by getting into inaccessible places, or by so disposing of his troops as to make it hazardous for a pursuing army to follow him up, or any longer to endeavor to harass him.

HARBOR DEFENSES.—The entrance to a harbor may be considered, and is in fact, a defile, the defense of which follows the rules applicable to defiles generally. The means usually employed to prevent the passage of hostile ships are divided into three classes, viz.: 1st. Forts and land-batteries; 2d. Submarine mines; 3d. Floating defenses. Whenever practicable, batteries should be well strung out in groups, the strength of which should increase as they are approached from the outside. This arrangement has a peculiarly discouraging effect on an enemy. The first batteries will at least damage him and cause confusion, thus weakening his attack on the stronger, and when his discomfiture finally takes place, the batteries already passed will prevent his return and insure his total destruction. The islands, headlands, and narrows usually found at the entrances of harbors will generally, to a greater or less degree, enable this arrangement to be carried out. Experience teaches that where the channel is unobstructed steam-vessels can run past shore batteries, however well the latter may be served. But, on the other hand, where obstructions to their rapid transit exist, they have not the endurance and aggressive power to effect much damage to land defenses. In the smoke of battle and tideway of the channel they become unmanageable, get aground, or collide with each other.

It is a well-settled fact that a hostile fleet, by concentrating its fire on an open work, may temporarily silence its guns. For this reason the accumulation of guns in works exposed to such concentration should be avoided by distributing them in batteries, each containing but few pieces, due regard being had to their security from assault and capture by any force that may be landed for that purpose. The best arrangement is to place them in detached batteries of, say, 2, 4, or 6 pieces each, well secured from the enemy's fire by earthen epaulments and traverses. This arrangement makes it difficult for the enemy to discover the exact position of the guns, and every peculiarity of ground should be taken advantage of to increase this difficulty. Whatever tends to make batteries difficult to see, and consequently to hit, is as much a protection as that which makes them capable of resisting a hit when made. Guns thus dispersed have greater freedom of lateral range of fire, and do not interfere so much with each other by reason of their smoke as when concentrated—a matter of no little importance with heavy artillery, which emits such volumes as, in certain conditions of the atmosphere, to greatly interfere with accuracy of aim. When batteries are extended, a larger area will be swept by their converging fire than when the guns are assembled *en masse*. An additional advantage conferred by distributing the guns is, that while obtaining concentrated fire on an important or decisive point, a similar fire cannot be directed in return. This arrangement would, furthermore, tend to neutralize the power which a fleet might have of forming on a wide arc of a circle, and moving slowly under steam, so as to render the task of hitting the individual ships more difficult, throw a converging fire upon the works on shore.

In the design of such works, it is of primary importance that conjoint action of the various parts should be maintained; and to prevent the individual batteries from being captured by *coup de main*, small inclosed earth-works, heavily stockaded to resist escalade, and each armed with field, siege, and machine guns, and siege mortars, should be constructed so as to have complete command over all land approaches. These earth-works should contain the infantry supports. In this manner most of the existing sea-coast forts may be utilized, making of them protecting works for exterior earthen batteries. The defenses of a harbor should, in every instance, be capable of repulsing all attacks that the enemy is likely to make on them. The power and persistency of these attacks will depend upon the importance to him of the object to be gained. Large and opulent cities, naval establishments, and ship-yards are among the first prizes sought for. The aggressive power of modern navies is such as to make it quite impracticable to effectually guard every harbor on an extended coast. It is, therefore, better to entirely abandon those that are unimportant to the enemy, for whatever use he may make of them, than by feebly guarding them to invite his attacks and thus afford him the moral effect and consolation of cheap victories, and to the country the mortification and disadvantage of defeat and loss of prestige.

The number of troops required for the manning of a work erected for harbor defense depends chiefly upon the nature and amount of armament contained therein. Works of this nature are armed principally with pieces of the heaviest caliber, but, for reasons hereafter given, all kinds should generally find place. The amount of armament depends upon the extent of the work and the part it is to play in the scheme of defense. Three full detachments are necessary for each piece. Knowing the number of pieces in the work and the number of men required for the service of each, the entire strength required is obtained. Three relief detachments are necessary, for the reasons that the labor of manipulating and serving heavy artillery is very great, and when a rapid and continuous fire is to be maintained, strong fatigue parties are required in carrying ammunition from the service magazines to the pieces; damages done to the works during the day have to be repaired at night, and casualties occurring, whether from the fire of the enemy or from accidents, must be provided against, so that at any moment an efficient detachment may be at every piece. As a general rule, batteries should not be encumbered by an attempt to include musketry defense within their limits. The place for this arm is on the flanks of the batteries, and in strength sufficient to prevent an enterprising enemy from landing and assaulting the work, and from approaching to keep down the fire of the guns while his vessels run by it. However well it may have answered with the old style of artillery to have the troops serving batteries charged, in addition, with musketry duty, it certainly is not advisable with the artillery of the present. Steam-propelled iron-clads, carrying guns of enormous power, range, and accuracy, demand the undivided attention in action of those using the only weapons effective against such adversaries. The labor of handling and caring for the kind of artillery, ammunition, material, and machines now used, altogether with the construction, preservation, and repair of batteries, will require all the time and the whole attention of the troops serving guns in war. The care of infantry arms and equipments, together with the drills and parades incident thereto, have a tendency to draw away the attention of officers and men and prevent them from keeping in an efficient state of readiness, the only safeguard that stands between an enemy and the object for which he may desire to enter a harbor. When a work containing batteries for harbor defense is inclosed, the amount of musketry necessary for it is determined by allowing two muskets for each lineal yard of parapet not occupied by the batteries. Artillery being the main feature in such works, the command should be vested in an Artillery Officer. Where there are several forts and batteries guarding the entrance to a harbor or constituting a line of works, they should, for the purpose of administration and command, be united in groups, each group being under an Artillery Officer of appropriate rank, and the whole combined and commanded by the Senior Officer of Artillery present. By this means thorough co-operation is secured throughout the entire system. In order to avoid the weakening effect of divided responsibility, submarine mines, when employed in conjunction with a fort for the defense of a channel, should be under the control of the Commandant of the fort, who should select from his command the proper number of officers and men to be instructed in the method of working this branch of defense. No more troops than are necessary to carry out the foregoing rules should be crowded into a work; otherwise, unnecessary casualties from the fire of the enemy will be added, stores consumed, and unhealthiness engendered; and, besides, in time of war, when troops are not required in any one place, their services are generally needed elsewhere. The high standard of practical gunnery required of artillery demands a proportional degree of intelligence and capacity for instruction in the individual soldier. Artillerymen should be selected with a special view to this, artisans and mechanics forming a large proportion. Steam-power and the application of labor and time-saving machinery should, wherever practicable, be introduced to assist in making the defensive abilily of fortified places more perfect. In conducting the defense of a work, too much importance should not be attached to the battering of it by an enemy; for experience teaches that a place is formidable, if resolutely defended, long after it has lost all semblance of the form and symmetry possessed by it when it came from the hands of the constructing engineer. See *Defense*.

HARBORING AN ENEMY.—A crime prohibited in military law and severely punished under all circumstances. The Articles of War provide that whosoever relieves the enemy with money, victuals, or ammunition, or knowingly harbors or protects an enemy, shall suffer death, or such other punishment as a Court-Martial may direct.

HARCARRAH.—In India, a messenger employed to carry letters, and otherwise intrusted with matters of consequence that require secrecy and punctuality. They are very often Brahmins, who are well acquainted with the neighboring countries; they are sent to gain intelligence, and are used as guides in the field.

HARD-BREAD.—A component of the army ration, generally issued, instead of flour, to troops while campaigning. When hard-bread is put in boxes, (the best packages for *field* transportation), they should be made of fully seasoned wood, of a kind to impart no taste or odor to the bread, and as far as practicable of *single* pieces. When two pieces are used in making the same surface, they should be tongued and grooved together. A box, 26×17×11 inches, exterior measure, is an average box for hard-bread, under the usual circumstances of land transportation. The ends of a box of this size should be made of inch, and the remainder of five-eighths stuff, the package well strapped with green hickory or other suitable wood. Hard-bread, after *thorough* cooling and drying, should be pressed closely in its packages, each package containing a uniform weight *of bread*, for the convenience of calculation. It can be re-dried in boxes without removal therefrom, by being exposed for about forty hours to a temperature of 140 degrees Fahrenheit. *Hard-tack*, *Pilot-bread*, and *Sea-bread* are common names of the article. See *Ration*.

HARD-LABOR.—A military punishment frequently awarded by Courts-Martial. This punishment is now firmly established in the United Kingdom; and by express statute, the power of adding hard-labor to the punishment of imprisonment, has been given in most cases, both as to indictable offenses and the more disgraceful offenses which are punishable summarily. The kind of labor is prescribed by the rules of the jail or prison, where provision must be made of the proper materials for the purpose. Picking oakum, working the tread-mill, etc., form part of this labor; and in general, the number of hours for such labor, unless in case of sickness, is ten hours daily.

HARDNESS.—The hardness of a body is measured by its power of scratching other substances. Variations in the degree of hardness presented by different crystalized bodies often furnish a valuable physical sign by which one mineral may be readily distinguished from others closely resembling it. Mohs selected ten well-known minerals, each succeeding one being harder than the preceding one, and thus formed the *scale of hardness*, which has been generally adopted by subsequent Mineralogists. Each mineral in the following table is scratched by the one that follows it, and consequently by all the subsequent ones, and the hardness of any mineral may be determined by reference to the types just selected. Thus, if a body neither scratches nor is scratched by feldspar, its hardness is said to be 6; if it should scratch feldspar but not quartz, its hardness is between 6 and 7—the degrees of hardness being numbered from 1 to 10. The figures on the right indicate the number of known minerals of the same or nearly the same degree of hardness as the substance opposite to which they stand:

SCALE OF HARDNESS OF MINERALS.

1. Talc	23	6. Feldspar (cleavable)	26
2. Comp't gypsum, or r'k-salt	90	7. Limpid quartz	26
3. Calcspar(cleavable variety)	71	8. Topaz	5
4. Fluor-spar	53	9. Sapphire, or corundum	1
5 Apatite	43	10. Diamond	1

The cause of the varieties of hardness observed in different bodies is not known. The same substance—as, for example, a piece of steel—may, under the influence of different circumstances, be so soft as to take impressions from a die, or may be nearly as hard as a diamond. Without a certain degree of hardness, the shape of the bore will be rapidly altered by the compressive force of the powder and projectile, and the accuracy and safety of the piece will be destroyed. In rifle cannon hardness is particularly necessary, to enable the spiral grooves to resist this action; at least, the surface of the bore should be relatively harder than the projectile. Steel is generally hardened by heating it until the scales of oxide are loosened (heat to about a cherry-red), and plunging it into a liquid or placing it in contact with some cooling substance which suddenly chills the metal, rendering it hard and brittle. The degree of hardness will depend upon the heat and the rapidity of cooling.

HARE CARTRIDGE-BLOCK.—A block recessed for any convenient number of cartridges in one row. On one side is fixed a leather strap, between which and the block, the left hand is to be passed, the back of the hand being next to the block and holding it in a convenient position for loading. For convenience the block is curved, and the surface next to the hand covered with sheepskin. The cartridge-holes are bushed as in the Benton-block. This block is permanent in its nature, and intended to form a part of the soldier's equipment.

HARMOSTES.—A City Governor or a Prefect appointed by the Spartans in the cities subjugated by them.

HARNESS.—1. The iron covering or dress which a soldier formerly wore, and which was fastened to the body by straps and buckles; the whole accouterments, offensive and defensive. 2. The equipments of a draught-horse. The best method of attaching horses to a carriage is that which enables each one to perform a given amount of work with the *least fatigue*; or, in other words, no horse should be restrained by the efforts of another, and the direction of the traces should be most favorable for draught. Besides these conditions, artillery-harness should be so constructed that it can be put on and taken off promptly, by night as well as by day, in all states of the weather, and in cases of danger, when the drivers would be liable to lose their presence of mind. The fall of one horse should not interfere with another; a dead or a wounded horse should be easily replaced, whatever may be his position in the team. The absence of some of the horses, the unhitching or cutting of some of the traces should not arrest the movement of the carriage. Finally, the drivers, who are mounted for the better command of their horses, should not be incommoded by the pole of the carriage.

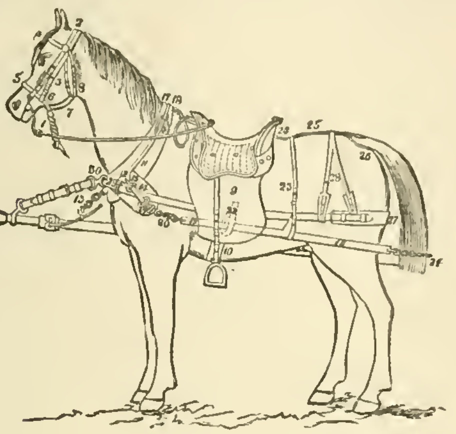
There are three general modes of attaching horses to artillery-carriages, and upon the employment of any one of which depends the construction of the harness. In the first method the wheel-horse is placed between two shafts, by which he guides and regulates the motion of the carriage. The horses may be arranged in single or double file. The former arrangement was much in vogue in artillery before the days of Gribeauval, but at present is only employed in the mountain service. This method has the merit of being well suited for drawing heavy loads over smooth roads, but is not adapted to rapid movements over ordinary roads, as much of the tractile force is lost by the continued change in the line of traction incident to long columns. The force thus lost is expended in a great measure on the shaft-horse, which by constant fatigue, is soon rendered unserviceable. In the English light artillery the horses are arranged in double file, the *off* wheel-horse being placed in shafts.

In the second method the horses are arranged in double file—a wheel-horse being placed on each side of the pole, which is attached to the first axle-tree. The pole is supported and kept steady by the pressure of the body of the carriage on the *sweep-bar*, which projects in rear of the front axle-tree. The leading horses are attached to the *swing-tree* which is fastened to the pole, and the wheel-horses are attached to a *movable splinter-bar*, the center of which is in the axis of the pole. The object of making a splinter-bar movable is to equalize the draught between two horses, one of which works more *freely* than the other. This system of attachment is used in most carriages of commerce, and so far as the draught alone is concerned, is superior to all others. It is also used in all siege-carriages and baggage-wagons of the military service, except that in the former the splinter-bar is fixed.

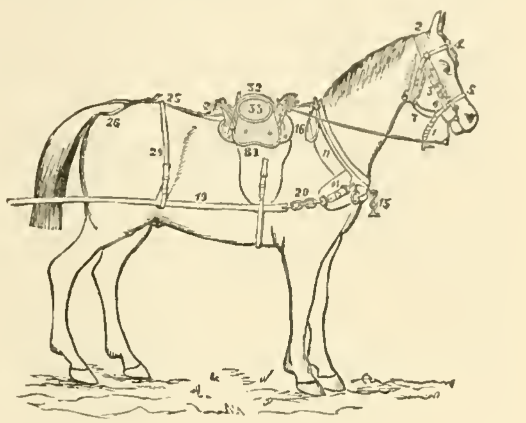
In field-carriages of late pattern the *sweep-bar* is omitted, to facilitate attaching and detaching the rear carriage in time of action; and the pole is supported by two yokes attached to the collars of the horses. The wheel-horses are attached to a fixed splinter-bar, which is strong and simple in its construction; and the traces of the leading horses are attached directly to those in the rear, giving a continuous line of traction, communicating directly with the carriage. This method of attaching artillery-horses in line is extremely simple, and at the same time it fulfils nearly all the conditions requisite for artillery harness. Its principal defect, however, is that, from the want of a sweep-bar the weight of the carriage-pole is borne on the necks of the wheel-horses, which is a serious inconvenience when making long marches.

Artillery harness is composed of the *head-gear*, to guide and hold the horse; the *saddle*, for the transportation of the driver and his valise; the *draught-harness*, which enables the horse to move the carriage forward; and the *breeching*, which enables him to hold it back, stop it, or move it to the rear. The *collar* prevents the horse's shoulders from being hurt by the two curved pieces of iron called the *hames*; to each hame is fastened a short leather tug ending in an iron ring, to which the front trace-chain is attached. The load is pulled by strong leather straps called *traces*, to the end of which chains are fastened; the front trace-chain plays back and forth in the tug-ring, and makes the wheel-horse independent of the horses in front; the rear trace-chain can be lengthened or shortened at will so as to adapt the harness to different horses. The *pole-yoke* is supported by a chain attached to the hame-clasp and to a ring which slides along the yoke; the branches of the pole-yoke are jointed to a collar near the end of the pole in such a way that they can only play in a plane passing through the axis of the pole; this device enables the horse to keep the pole steady without constraining his motion.

The *breeching* forms a part of the wheel-harness only; it completely encircles the horse, and is held up in the rear by a strap passing over the hips. The traces of the wheel-horses are usually hitched to the splinter-bar; the traces of the lead and swing-horses are hitched to those of the horses in the rear, giving a continuous line of traction from horses to carriage. When wheel-horses are hitched to a splinter-bar trace, there is always an equal bearing on both sides of the collar; this saves their necks from a great deal of chafing, particularly in changing direction.



1



2

As the limber has no sweep-bar, the weight of the pole comes on the necks of the wheel-horses: this defect is somewhat lessened when the limber-chest is loaded, its position over the axle being such as to decrease the weight at the end of the pole.

The following is the nomenclature of the harness, reference being made to Figs. 1 and 2: *Halter*, composed of *head-stall* and *hitching-strap* (1); the head-stall includes, *crown-piece* (2), *cheek-strap* (3), *brow-band* (4), *nose-band* (5), *chin-strap* (6), *throat-strap* (7), and *throat-lash* (or *throat-band*) (8). *Bridle*, composed of *head-stall*, *curb-bit*, and *reins;* the head-stall includes, *crown-piece*, *cheek-strap*, *brow-band*, and *throat-lash;* the curb-bit is of iron and brass-plated; it includes *mouth-piece*, *branches*, *cross-bar*, *curb-chain* (or *curb-strap*), and *curb-chain hook*. *Near saddle* (9), including *saddle-tree*, *seat*, *saddle-skirts*, *stirrups*, and *girth* (10); the saddle-tree consists of *pommel*, *cantle*, and *side-bars;* the girth consists of two *straps* of unequal length. *Collar* (11), including *rim*, *belly*, *pad*, *collar-straps*, *billets*. *Hames* (12), including *branches*, *double-joint loops* for trace-tugs, *links* for breast-straps, *hame-rings*, *hame-clasp*, *chain* and *toggle* (13), *safes* (14), *trace-tugs* (15), *trussing-straps* (16), *hame-strap* (17), and *collar-strap* (18). *Traces* (19): *front-trace chains* (20): *rear-trace chains* (21); *trace-loops; trace-toggles* (22); *belly-band; loin-strap* (23). *Crupper*, including *back-strap* (24), *body* (25), and *dock* (26). *Breeching* including *breech-strap* (27), *hip-strap* (28), *breast-strap* (29), and *sliding-loops* (30) for pole-straps. *Off saddle* (31), including *hook* for reins, and *valise-strap* (32). *Valise* (33). *Coupling-rein*. *Whip*, including *stock* and *lash*. *Leg-guard*, including *body*, *under-strap*, *leg-straps*, and *plate*. *Nose-bag*.

A storehouse for harness should be well ventilated – not too dry, but free from dampness. The different articles should be arranged in bundles, according to kind and class, without touching the wall or each other. Harness should be examined four times a year, at least. The leather parts are brushed and greased with neatsfoot oil as often as condition requires; if they have a reddish hue, add a little lamp-black in the oil. The hair side of the leather should be wet with a sponge dipped in warm water, and the oil applied before the surface is dry. The iron parts which are not japanned should be covered with tallow.

To Harness.—Each wheel-driver places on and buckles the collar of his off horse, smoothing the mane under the collar and adjusting the collar to the shoulders; folds and puts on the saddle-blanket, and then resumes his post in front of his harness. (2) He seizes the saddle by the girth-straps, his hands close to the saddle; raises it from the peg; holds it over his head, arms half extended; approaches the horse on the near side, and places the saddle in its proper position, taking care not to rumple or displace the blanket, and keeping the right arm extended over the horse's back to adjust the girth and traces. (3) He goes to the front of the horse; passes the breast-strap carefully over the horse's head; adjusts the hames to the collar; clasps them together at the bottom, and tightens the hame-strap. (4) He goes to the near side of the horse; lifts the breeching over the cantle; steps to the rear, and pulls it over the horse's croup; arranges the loin-strap; and adjusts and buckles the crupper, taking care that no hairs remain between the crupper and tail. (5) He sees that the harness is properly arranged, buckles and tightens the girth, and then buckles the belly-band. (6) He bridles the horse and ties the coupling-rein to the manger. Lead and swing-drivers harness and unharness in the same manner as wheel-drivers, with such omissions as are required by the difference in the harness. If there be no stable the horses are taken at the picket-line, and the harness from the rack near the carriage to which it belongs. Each driver *stands to horse* as soon as he has harnessed.

To Unharness.—Each wheel-driver ties the coupling-rein fast to the manger; takes off the leg-guard, and hangs it up; unbridles his near horse, and hangs up the bridle. (2) He unbuckles and frees the crupper; raises the breeching from the croup, and lays it over the cantle, resting its middle on the seat. (3) He goes to the front of the horse, draws the breast-strap well forward through the links, loosens the hame-strap, unclasps the hames at the bottom; passes the breast-strap up over the horse's head, and lays it and the hames over the pommel. (4) He unbuckles the belly-band, and then the girth, takes off the saddle, places it properly on its peg or rack, and covers it with the blanket. (5) He then removes and puts up the collar and secures the horse by the halter.

HARNESS-DRESSING.—A preparation for the care and protection of harness, and the leather parts of the accouterments. A variety of dressings are in common use, but the following (ingredients for two gallons of the compound) is mostly used in the service: 1 gallon of neat's-foot oil, 2 pounds of bayberry tallow, 2 pounds of beeswax, and 2 pounds of beef tallow. Put the above in a pan over a moderate fire and let them remain one hour until thoroughly dissolved; then add 2 quarts of castor oil and stir well until the mass comes to a boil so that the ingredients may become thoroughly mixed; after which add—1 ounce of lamp-black and stir well for ten minutes; then strain the liquid while hot through a cotton cloth to remove sediment of beeswax, tallow, and lamp-black, and put aside to cool. Apply this mixture to saddles and harness with a woolen cloth and leave until next day, when they should be wiped off with a woolen cloth to remove the surperfluous lamp-black. For "russet" or fair leather, use the same mixture without the lamp-black.

HARNESS-PEGS.—In artillery stables, harness-pegs for each pair of horses are arranged in the walls of the harness-room, also in the heel-posts of the stalls. The peg for the off harness is above the peg for the near harness; a small peg for the bridles is placed beneath the near harness-peg. The following arrangement is observed: Pommels of the saddles against the wall or heel-posts; breeching hanging over the cantles; breast-straps and hames over the pommels; traces, which are trussed, over the seat; whip on the hook of the off saddle; collars lying horizontally on the saddles, collar-straps against the heel-posts; bridles and leg-guard hanging on their peg: the whole covered by the harness-sack properly secured. The blankets are kept by the drivers in their quarters, but may be put away in the harness-room, or other safe place. A trace is trussed by passing the rear trace-chain through the trussing-strap, from rear to front, and securing the trace by drawing down the sliding-loop.

HAROL.—An Indian term signifying the officer who commands the van of an army. It sometimes means the van-guard itself.

HARPE.—A species of drawbridge used among the ancients, and deriving its name from the musical instrument. This bridge, which consisted of a wooden frame, and hung in perpendicular direction against the turrets that were used in those times to carry on the siege of a place, had a variety of ropes attached to it, and was let down upon the wall of a town by means of pulleys. The instant it fell, the soldiers left the turret, and rushed across the temporary platform upon the rampart.

HARPOON GUN. Agun used for shooting whales. It is frequently employed to great advantage when necessary to throw lines across rivers and the like. It is very similar to the small swivel-guns, weighing with stock complete 75 lbs., 3 feet long in the barrel and of 1¼ inch bore. The charge is very small, barely sufficient to project the arrow and line from the gun.

HARPY.—A fabulous creature in Greek mythology, considered as a minister of the vengeance of the gods. Various accounts are given of the numbers, and parentage of the harpies. Homer mentions but one, Hesiod enumerates two—Aëllo and Okypete, daughters of Thaumas by the Oceanid Electra, fair-haired and winged maidens, very swift of flight. Three are sometimes recognized by later writers, who call them variously daughters of Poseidon or of Typhon, and describe them as hideous monsters with wings, of fierce and loathsome aspect, their faces pale with hunger, living in an atmosphere of filth and stench, and contaminating everything that they approached. The most celebrated tradition regarding the harpies is connected with the blind Phineus, whose meals they carried off as soon as they were spread for him; a plague from which he was delivered by the Argonauts, on his engaging to join in their quest. The Boreads Zetes and Calais attacked the harpies, but spared their lives on their promising to cease from molesting Phineus. A harpy in Heraldry is represented as a vulture, having the head and breast of a woman.

HARQUEBUSE.—An old fire-arm resembling a musket, which was supported on a rest by a hook of iron fastened to the barrel. Many of the Yeomen of the Guard were armed with this weapon, on the first formation of that Corps in 1485. The harquebuse being frequently fired from the chest, with the butt in a right line with the barrel, it was difficult to bring the eye down low enough to take good aim; but the Germans soon introduced an improvement by giving a hooked form to the butt, which elevated the barrel. Soldiers armed with this weapon were designated Haquebutters, and were common in the time of Henry VIII.

HARROW.—An obstacle, in fortification, formed by turning an ordinary harrow upside down with the teeth upward, and the frame buried. This implement consists of a frame of a square or rhombic form in which are fixed rows of teeth, or *tines*, projecting downwards. The harrow is very ancient, having been in use beyond the dawn of history; but as in early times only the lighter soils were cultivated, it often consisted of bushes, or branches of trees, which merely scratched the ground. Subsequently, we find a wooden frame and wooden tines in use; next, the wooden frame with iron tines, a form of the instrument very much used at the present day, and especially in favor for light soils. For heavy soils, the harrow constructed wholly of iron is most used, as it is heavier and does more execution; and of this sort the zigzag form made by Mr. Howard, of Bedford, is preferred.

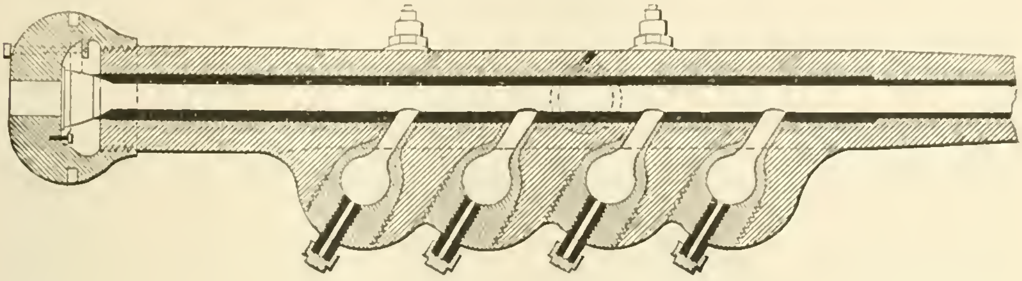
HARSEGAYE.—A kind of demi-lance, introduced about 1114. It is now obsolete.

HASKELL MULTI-CHARGE CANNON.—The Lyman accelerating-gun, patented in 1857, is worked on the principle of giving to the projectile a gradually increasing velocity while in the bore of the gun. Bomford's method of measuring powder-pressures at different points in the chamber of a cannon disclosed the fact that the great pressure on that part of the chamber occupied by the powder-charge rapidly diminished as the shot approached the muzzle, and that lateral pressures were not dangerously great on the gun after the shot was under way, unless something happened to wedge the projectile.

Lyman reasoned that if he could continue to increase the powder-pressure he might make the muzzle end of a gun as strong as the breech, and utilize the added strength to increase the velocity of a projectile in regular ratio up to the very instant of its leaving the muzzle. He accomplished something in this direction with his earlier gun, which was a cast-iron piece with tubes branching from the bore at a point between the breech and the trunnions.

The Lyman gun, as improved by J. R. Haskell, is a cast-iron, steel-lined rifle, having a number of pockets, each formed in a block of steel, which is screwed into an enlargement of the cast-metal body of the gun. Over each pocket there is a priming hole extending out through the upper portion of the gun. This hole is stopped by a bronze metal plug, which screws into place to close the hole entirely, making a smooth surface with the steel bore-tube when the plugs are screwed home. The steel pockets, as a general thing, have cleaning plugs at the bottom.

The piece is loaded by placing a projectile and cartridge of slow-burning powder in the breech, and a charge of quick-burning powder in each of the pockets. The projectile fits the bore tightly, so that no gas can leak past. When the breech-charge is fired it starts the projectile at a moderate velocity, which is rapidly increased after the shot passes the pockets by the explosion of the powder in the pockets, ignition being effected from the primary charge.



Haskell Multi-charge Cannon.

The gun in course of construction at the Scott Foundry, Reading, Pa., now nearly completed, was made under Mr. Haskell's superintendence. The gun is 6 inches bore, 25 feet long, and weighs 25 tons. The lining tube is 2½ inches thick to a point forward of the front pocket; from there to the muzzle it is 2 inches. There are four pockets in the gun, each intended for a charge of 28 pounds of quick powder. The breech charge will be about 18 pounds hexagonal powder. A projectile three calibers in length will weigh 100 lbs.—one of four calibers, 150 lbs.

Mr. Haskell expects to get an initial velocity of 3,000 feet per second with pressure nowhere exceeding 30,000 pounds per inch, and to obtain a penetration equal to 24 inches of iron. In view of the result of past experiments there is little doubt that very good penetration will be obtained, and if such velocities can be had from the moderate pressures proposed by Mr. Haskell, any armor now in existence can be pierced by guns much lighter than the 11-ton monsters used in the Italian or British Navy.

HASTATI.—Up to the time of Marius, by whom the germ of the decadence of the military art among the Romans was sown, a Consular Army consisted of two *Legions;* and of two *Wings* composed of social troops. The legion was composed of infantry of the line, light infantry, and cavalry. The infantry of the line was divided into three classes. 1. The *Hastati*. 2. *Principes*. 3. *Triarii*. These classes wore a very complete defensive armor; they were all armed with the short straight Spanish sword; the *Pilum*, a kind of javelin, about seven feet in length, used equally to hurl at a distance and in hand-to-hand engagements, was added to it for the two first; and the Triarii carried the pike.

HASTY INTRENCHMENTS.—Extemporized shelters which are quickly constructed from materials found upon the spot where the shelter is needed. In consequence of the effectiveness of modern fire-arms a body of troops can not retain a close formation for a single hour even, if in the presence and exposed to the fire of an enemy in force. The men are forced to seek shelter, by lying down on the ground, or by crouching behind any slight inequality which may exist in the surface, or behind some kind of screen which they may be able to construct. The screen may be two or three logs rolled together; a heap of fence rails, a slight mound of earth, or anything whatever its nature which will hide the soldier from the enemy's view.

The simplest forms of *hasty intrenchments*, in an open country, are the rifle pits and trenches. Hasty intrenchments were much used by both of the contending armies in the late war in the United States. They were used so frequently, and found so efficacious, that the men acquired the habit of intrenching their line immediately upon halting after a day's march, if the enemy was near. No compulsion, no orders, even, were necessary for the men to begin this work; the main difficulty was to make them delay enough to allow a proper trace to be marked, by which they might be guided in the construction of their line. Instances are known, where the men, not having intrenching-tools, executed the trench with the bayonet or the tin cup. These shelter trenches, thus rudely constructed, were deepened and strengthened until they were able to resist field artillery, if the position was to be occupied for any length of time. Slight as these defenses were during the early stages of their construction, they formed, when defended by good troops, an obstacle difficult to overcome; and they were captured only by extraordinary effort, accompanied by a great loss of life on the part of the attacking forces.

It will frequently happen that cover can be speedily obtained, and positions rendered defensible in a very short time, by taking advantage of the hedges, ditches and walls, which may be met with, or of the obstacles which may be presented by natural features of the ground. No fixed rules for proceeding under all the numerous circumstances which may occur can be given, but the drawings will show what may be effected in certain cases, and indicate the character of the operations usually required.

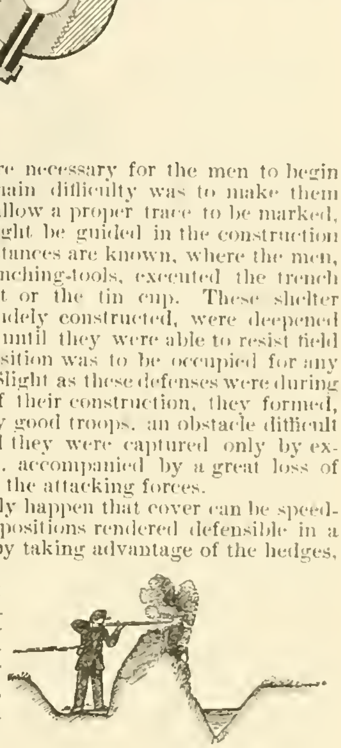


Fig. 1.

Fig. 1, represents the common hedge and ditch turned into a breastwork to be defended from the hedge-side. If the hedge be thick and planted on a bank, as is generally the case, and especially if the ditch be tolerably deep and contain water, the breastwork will be rendered strong at the expense of little labor. A shallow trench should be excavated behind the hedge, and the earth thrown up to raise the bank sufficiently to form a rough breastwork some 18 inches thick at the top. Should the hedge be more than 6 feet high, it should be cut to that height, having the branches interwoven with the lower part to strengthen it. A hedge to be defended from the ditch-side Fig. 2, is a ready-made trench and breastwork, and will become a convenient work by a little scraping of the sides and widening and levelling of the bottom of the ditch, and by the addition of a banquette. See *Walls*.

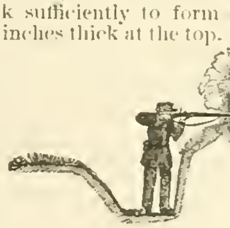

Fig. 2.

HATCHET.—A small, light sort of axe, with bevel edge on the left side, and a short handle. It is used by soldiers for cutting wood to make fascines, gabions, pickets, etc. A brass slide and snap combined is slipped upon the belt, and has a snap on the outer side, from which the hatchet can be hung. There is also a safety attachment through which the handle is passed, making a convenient and secure way of carrying the implement. *To take up the hatchet* among the Indians is to declare war and commence hostilities. *To bury the hatchet*, is to make peace.

HATCHMENT.—1. An ornament formerly much worn on the hilt of a sword. 2. The funeral escutcheon placed in front of the house of the deceased, or in some other suitable place, setting forth his rank with other circumstances. It is in the shape of a lozenge, and in its center are the arms of the deceased, single or quartered, as the case may be. The achievement of a *bachelor* represents his arms in a shield complete, accompanied with helmet, crest, mantling, motto, and various other external ornaments to which he may be entitled, on a black ground. In the achievement of an unmarried lady, her arms are placed in a lozenge on a black ground, but without external heraldic ornaments, except in the case of a peeress, when her supporters, robe of estate, and coronet are added.

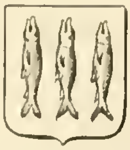
Hatchment of Husband.

The achievement of a husband whose wife survives, impales his arms with his wife's in a shield with the external ornaments to which he is entitled, the ground of the hatchment being, under his side of the shield, black, and under his wife's, white. If the wife be an heiress, her arms are not impaled, but carried in an escutcheon of pretense. The external ornaments are appended, except the insignia of any order of knighthood having a circle or collar, with which heralds do not consider it proper for a knight to encircle his wife's arms. On this account the achievement of a knight has two shields placed side by side, one containing the husband's arms only, encircled by the collar, ribbon, etc., of the order, the other containing those of husband and wife; the ground is divided perpendicularly in the middle of the second shield, and painted black and white. When the wife is a peeress in her own right, there are also two shields—the dexter containing the arms of the husband, with the lady's arms on an escutcheon of pretense ensigned with her coronet; the sinister lozenge-shaped with the lady's alone, and each accompanied with its proper external decorations. The ground is divided black and white in the middle of the dexter escutcheon. The arms of a wife whose husband survives are impaled with her husband's arms in a shield, or, in the case of an heiress, borne on an escutcheon of pretense. There is no helmet, crest, or mantling, but a peeress is entitled to her robe of estate. The ground under the dexter side of the shield is white, and under the sinister, black. The achievement of a widower differs principally from that of a husband, in the ground being entirely black. The achievement of a widow differs from that of a wife, both in having the ground entirely black, and in the form of the escutcheon, which (except in the one case of an escutcheon of pretense), is lozenge-shaped. The arms are encircled by a silver cordon or cordelière, the symbol of widowhood. On the decease of the last of a family, a death's head surmounts the shield in place of a crest. The achievement of a reigning King or Queen, whether married or not, represents the royal arms complete on a ground entirely black. That of an Archbishop or Bishop has the insignia of his See impaled with his paternal arms, and the whole surmounted by a miter, and the ground is per pale ar. and sa. The Dean of a Cathedral or Collegiate Church and a King at Arms, also impale the arms of office with their family arms. In the achievement of the wife of a Prelate, there are two shields—the first containing the impaled arms of the See and the Bishop, surmounted by a miter; and the second, the family arms of the Bishop with those of his wife. The ground is all white, except that part which is under the arms of the wife. The funeral escutcheon of Scotland, France, and Germany differs considerably from that in use in England; it indicates not merely the deceased's right to a coat-of-arms, but his gentility of descent. The hatchment is much larger, consisting of a lozenge above 6 feet square; and the arms of the deceased, which occupy the center, are surrounded by those of the 8 or 16 families from whom he derived his descent, the paternal quarterings on the right side, and the maternal on the left. The deceased is not entitled to an achievement unless all these families had a right to bear arms. On the four corners are death's heads and the initials and title of the deceased, the black interstices are powdered with tears. See *Heraldry*.

HAUBERGIER.—An individual who held a tenure by Knight's service, and was subject to the feudal system which formerly existed in France, and by which he was obliged to accompany the Lord of the Manor in that capacity whenever the latter went to war. He was called *Fief de Haubert*, and had the privilege of carrying a halbert. All vassals in ancient times served their Lords-paramont as Squires, Haubergiers, Lancemen, Bow-men, etc.

HAUBERK.—A long blouse-like garment, having short sleeves descending to the middle of the upper arm, which sometimes was formed of interwoven rings, or chain work, but more generally was constructed of a stout woven fabric, upon which were fixed rows of iron rings or plates of metal, in their form either square, triangular, or circular. This mail-shirt was fitted tightly to the person: and at the bottom it was divided, so that the wearer when mounted might wrap one division of it round each thigh, or when on foot might have his limbs covered by the cleft extremities of his hauberk without any impediment to his free movements. The hauberk was used by the Saxons, as early as the eighth century, as defensive body armor, and called by them the tunic of rings, but by the Normans the *hauberk*. Besides the hauberk of rings, there are some marked with transverse lines, so as to give the idea of being quilted, or stiched in chequers, or covered with small lozenge-shaped pieces of steel instead of rings, known about this period, A.D. 1066–1087, by the name of mascled armor, from its resemblance to the meshes of a net. Other descriptions of armor were in use, and in some instances hauberks appear to be composed of rings and mascles mixed; in others, the body is diamonded, and the cowl and arms covered with rings. On referring to a work entitled "The Conqueror and his Companions," by Mr. J. R. Planché, Somerset herald, the hauberk as worn by William the Conqueror is thus spoken of: "In the Bayeux tapestry we behold him armed in his hauberk, which was not the coat of chain-mail of the thirteenth century, but the *geringhed byrnie* of the eleventh and twelfth, consisting of iron rings, not linked together and forming a garment of themselves, but sewn or strongly fastened flat upon a tunic of leather or quilted linen, buckram, canvas, or some strong material descending to the mid-leg, and which, being open in the skirts both before and behind for convenience in riding, gave it the appearance of a jacket with short breeches attached to it, if, indeed, such was not actually the case in some instances. The sleeves were loose, and reached only just below the elbow." The habergeon of plate-armor was generally worn over the hauberk. See *Habergeon* and *Plate-armor*.

HAURIANT.—A term in heraldry applied to a fish placed upright as if to refresh itself by sucking air. Gules, three lucies (the ancient name of pikes) hauriant in fess argent, the arms of a family of the name of Lucy in Hertfordshire. See *Heraldry*.



HAUSSE.—A graduated piece attached to the barrel near the breech, which has a sliding piece retained in its place by a thumb-screw, or by the spring of the slider itself. This slider ought to have an opening through which the gun can be conveniently aimed; and is raised to such a height as we think will give the necessary elevation for the distance. The term coarse sight means a large portion of the front sight, as seen above the bottom of the rear-sight notch; and a fine sight is when but a small portion is seen. The effect of a coarse sight is to increase the range of the projectile. The *breech-sight*, the *tangent-scale*, and the *pendulum-hausse* are merely different forms of this device, the latter having a bulb at the bottom which keeps it in a vertical position when the two wheels of the carriage are not on the same level. The tangent-scale has steps, corresponding in height to the graduations on the breech-sight for guns of the same caliber and pattern; and is only applied to the gun at the moment of sighting.

HAUSSE-COL.—An ornamental plate similar to the gorget. It was formerly worn by infantry officers.

HAUTES-PAYES.—Soldiers formerly selected by the Captains of companies to attend them personally, for which service they received something more than the common pay. *Haute-pay* became afterwards a term to signify the subsistence which any body of men superior to, or distinguished from the private soldier were allowed to receive.

HAUT-LE PIED.—A term used to distinguish such persons as were formerly employed in the French armies without having any permanent appointment. *Commissaries hauts-le-pied* were known in the artillery during the Monarchy of France. They were usually under the Quartermaster-general.

HAVELOCK.—A light cloth covering for the head and neck, used by soldiers as a protection from sunstroke. This covering derived its name from Havelock, a distinguished English General.

HAVERSACK.—A bag of strong coarse linen, in which, on the march, each soldier carries his own bread and provisions. It is borne on the left side by a strap passing over the right shoulder, and is only used in the field and in cantonments. The haversack of the Roman soldier was an osier basket with a long neck; sometimes, as on the column of Trajan, a wallet carried on the spear. Its contents were salt meat, cheese, onions, and olives. It held sufficient for three days. The term haversack is also applied to the leather bag used in artillery to carry cartridges from the ammunition-chest to the piece in loading.

HAVILDAR.—The highest rank of Non-commissioned Officer among native troops in India and Ceylon. In the Hong-Kong Gun Lascars (a corps now disbanded), the Havildar received 1s. 3d. per diem; but in India his pay is somewhat less. The *Havildar-major* is the Sergeant-major of each native regiment of infantry.

HAVOCK.—A cry originally used in hunting, but afterward in war as the signal for indiscriminate slaughter. The term *havoc* is used in the sense of wide and general destruction, devastation, or waste, hence the origin of *havock*.

HAWK.—The Hawk frequently occurs as a charge in Heraldry, and may be *belled*, *jessed*, and *varveled*. The *hawk's bell*, itself used as a separate charge, is attached to the leg of the bird by *jesses* or thongs of leather. *Varvels* are rings attached to the end of the jesses. The *hawk's lure*, also a heraldic charge, consists of two wings joined with the line, to the end of which is attached a ring. The line is sometimes *nowed* or knotted.

Bell.

Lure.

HAWSER.—A rope made of three strands: it is coiled up right-handed, or what is termed "with the sun." It is one of the ropes used in lifting ordnance. See *Cordage* and *Rope*.

HAXO BASTION SYSTEM.—The siege of this system of fortification is calculated to last fifty days and there are five distinct periods of breaching batteries: 1° Against the reduit of the salient place of arms and the Ravelin. 2° Against the reduit of the reentering place of arms, the coupures and the reduit of ravelin. 3° Against the bastionet and the counterguard. 4° Against the retrenchment. 5° Against the bastion. The front is 360 yards long. The perpendicular is only 40 yards, and the faces 72 yards. The flanks are perpendicular to the lines of defense. The bastions contain interior retrenchments entirely separated from the rear by a ditch. A *chemin-des-rondes* surmounts the scarp of the enciente. The tenaille is not revetted, and it has flanks that can mount three guns. The main ditch is twenty yards wide. The ravelin is made very salient, with a casemated traverse in capital, and coupures cut across its faces. In rear is a reduit of the ordinary outline, and behind is a casemated caponiere or bastionet, the roof of which carries ten guns. The counterscarp of the main ditch is produced to within ten yards of this bastionet, and in front of it slants a glacis, which closes the ditch of the ravelin and that of the reduit. The bastionet sweeps the interior glacis and co-operates with the flanks of the inner works to impede the construction of the counterbatteries.

HAXO CASEMATE.—A work built inside the parapet, arched and covered with earth, opening in the rear to the terreplein. The guns are protected from the enemy's fire, and can be entirely hidden by masking the embrasures.

HAY.—A very important article of forage in most armies. The management of the natural grasses of which most hay consists is somewhat different, and the process is seen to perfection in Middlesex and various Counties about London. The great matter—too generally overlooked in Scotland—is to preserve the color and flavor of the grass; and this can only be done by keeping it constantly turned, and having it rapidly dried, if possible, without the deteriorating washing of repeated rains. Artificial drying best attains this end, but is of course impracticable on a large scale. In the best style of English haymaking, the grass, after being cut with a scythe or machine, and as soon as the dew is off, is shaken and spread out by means of forks or of a *tedding*-machine drawn by a horse. It is not allowed to lie long exposed to the sun, but before evening, is drawn together by rakes into *wind-rows*, which, if there is any prospect of rain, are made up into small heaps or cocks. It is again spread out next morning, or on return of favorable weather; and when the operations are expedited by wind or sun, the hay will be ready for the rick by the second or third day. There is, however, much difference in the time during which the hay requires to lie out; the bulk of the crop and the quality of the land must be especially considered. When the grasses are cut, as they should be when in bloom, and before their seeds ripen and their stems get rough and hard, they contain the greatest amount of moisture, and require careful making, but produce a very nutritive and palatable hay. As soon as thoroughly dry, it should be put at once into the stack or rick, and well trodden down. A certain amount of heating improves the flavor, and renders the hay more palatable to every sort of stock. When, as is sometimes the case, it is imperfectly made, or picked up too soon, it gets over-heated, and becomes dark brown or black, its nutritive properties are diminished; it is, moreover, apt to disagree with both horses and cattle, and can only be profitably used when mixed with straw and cut into chaff. Hay put together when damp from rain or dew does not heat, as when it contains an undue amount of natural moisture, but speedily molds. When hay has been injured and weathered by repeated rains, it may be rendered more palatable by scattering a little common salt over the rick whilst it is being built. Throughout Scotland eight or ten pounds of salt to the ton is very generally used alike for clover and grass hay. In the midland and southern districts of England the best hay is generally got up in June; but in Scotland, little is carried until the middle of July. When the crop is good, and everything done well, the cost of hand and horse labor expended upon the hay before it is safely ricked will approach 20s. per ton. The crop averages from one to two tons per acre. Hay that has stood for seed is tougher and less nutritive than that cut earlier, for the sugar, gum, and glutten of the matured seed have been abstracted from the stems, which are then apt to be little better than straw.

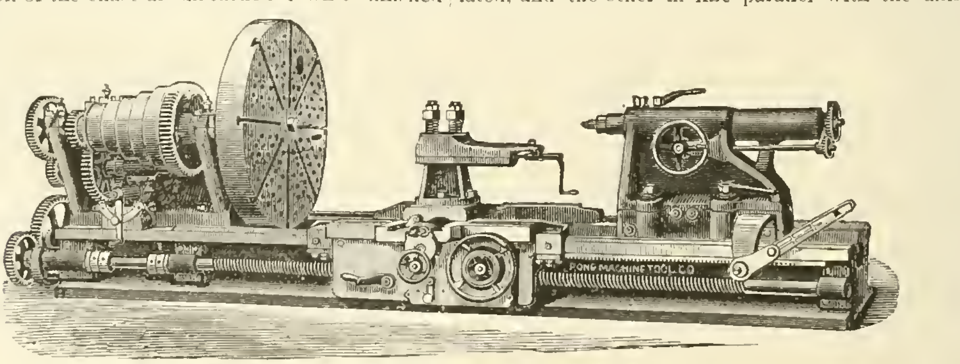
HAZAREE.—An Indian term signifying the Commander of gun-men. It is derived from *hazar*, which, in its literal interpretation, signifies a thousand.

HEAD.—In gunnery, the fore part of the cheeks of a gun or howitzer-carriage. The term *head* is employed with other words, in various military phrases as, the *head of a work*, in fortification, or the front next to the enemy, and farthest from the place; *head of an army*, or the front, whether drawn up in lines or on a march, in column, etc.; *head of a camp*, or the ground before which an army is drawn up. The *head* of a double tenaille is the salient angle in the center and the two other sides which form the re-entering angles.

HEADER.—In a revetment, a brick, stone, or sod laid with its end outward. See *Sod Revetment*.

HEADING.—1. The device of the signal-rocket; such as a *star-heading*, or a *bounce-heading*. 2. In mining, the end of a drift or gallery; the line of an intended tunnel, especially one of relatively small size, which forms a *gullet* in which the workmen labor; also a horizontal passage between the shifts or turns of the working parties.

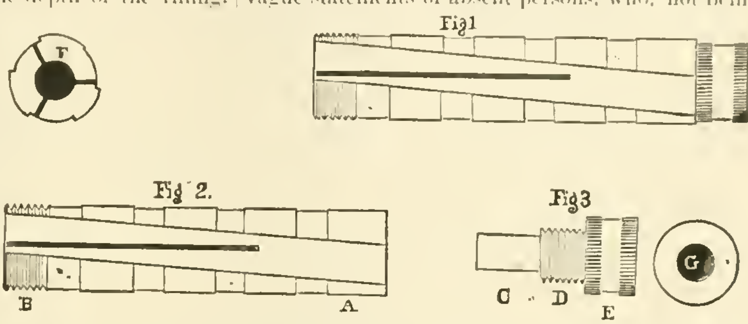
HEADING-LATHE.—A lathe used for turning down gun castings, and for preparing them for the boring-machine. The cascabel-bearing, base of breech, and a section of the chase are all turned down to finished muzzle is introduced and projects several inches beyond the face of the muzzle-ring, in which position it is approximately centered, and held firmly in place by adjustable screws in the chuck and muzzle-ring. The breech is adjusted by placing a sharp pointed instrument in the rest, and bringing it in contact with the surface of the casting near the base-line, and while turning the gun—which is done by machinery—the screws in the chuck are moved until coincidence of the line around the gun is obtained. At the muzzle a bar of iron is laid upon blocks, so that it shall be just inside the bore, and nearly in contact with its interior surface. As the gun turns, the distance between this point and the metal of the bore is observed, and equalized approximately, by the screws in the muzzle-ring bearing. A wooden disk turned to fit the bore accurately, bearing a string attached to its center, is then pushed to the bottom of the bore, and made to assume a position in a plane perpendicular to its axis. The string from the center of the disk is long enough to reach some distance outside the muzzle; the outer end being made fast to an upright the same height as the inner end or center of disk; the string is now hauled perfectly taut, and the gun again turned, a square being placed upon blocks about one foot in front of the muzzle, close to the string; and as the gun revolves, the distance, if any, which the string deviates from the square, is observed and corrected by again moving the screws in the muzzle-bearing. When properly centered, the string will remain in the same position in the square and be the same distance from the interior surface of the gun, throughout an entire revolution, showing that the axis of the gun and lathe coincide. With the hollow-cast gun it is necessary that it should be centered from the bore, as it sometimes happens that its axis does not coincide with the axis of the casting, which is one reason for casting them above the true size, to admit of being finished by the interior, or so that the axis of the cast bore shall coincide with that of the gun when turned. The gun being centered, the turning commences at the muzzle; this is done by placing a tool in the rest, which is brought in contact with the surface at the desired point, the metal being turned off as the gun revolves. The *rest*, or support which holds the tool, is arranged to move in two directions, one towards the gun, or at right angles to the axis of the lathe, by which means the depth of cut is regulated, and the other in line parallel with the axis,



Heading lathe.

dimensions while in this lathe, as the chase and rounded part of the cascabel-knob form the bearings for the boring-lathe. The cut at the muzzle, or place where the *sinking-head* is to be broken off, is also made in this lathe. The bearing in which this muzzle-ring revolves is a heavy casting, the bottom of which fits into grooves in the rack, and can be moved to or from the chuck, being adaptable to long or short guns. To make the adjustment in the lathe, the gun is lowered into place, the square knob in rear of the cascabel fitting into the chuck, while the that is from muzzle to breech. The last movement is effected by means of a *feed*, the motion being given by a fork attached to one of the trunnions, and at every revolution of the gun the rest is made to advance. The first cut is usually an inch deep, commencing at the muzzle where the sinking-head is to be cut off and extending 30 inches towards the trunnions. The second and third cuts are commenced at the same point as the first, and are about one and one-eighth inches deep; increasing as the tool advances in the gun, other cuts are made until the metal is reduced to the finishing diameter. The cut at the muzzle, or the place where the "sinking-head" is to be broken off, is next made; its depth is usually about seven inches, or to within three or four inches of the cast bore. The gun is now taken from the lathe, and the "sinking-head" broken or wedged off, at which time the appearance of the metal at the fracture should be examined as to color, form, and size of crystals, texture, and whether sharp to the touch; it is also necessary to ascertain its degree of hardness and how the metal works under the tools, in the different stages of its fabrication; all of which should be duly noted and form part of the record of the gun. See *Finishing* and *Lathe*.

HEADLESS SHELL EXTRACTOR.—This implement, devised by Lieutenant-colonel A. R. Buffington, United States Army, for the Springfield rifle and carbine, consists of two parts of tempered steel, the extractor proper, Fig. 2, and small cylindrical drift, Fig. 3, for setting out the prongs, carried screwed into end, A, of extractor. Fig. 1 shows them together as they should be habitually kept and used for all extractions from the *bore* of the rifle. The extractor proper is a hollow cylinder, rifled on the exterior to correspond with the rifling of the rifle barrel, with four transverse grooves to the depth of the rifling. Inside it is shaped at the prong-end to receive the point, C, of drift and permit a limited expansion; at the other end it is tapped for the screw-thread, D, of the drift. Three cuts longitudinally divide one end into 3 prongs, F, around which is a screw-thread, B, for taking hold of the shell *when in the chamber*. The drift is a cylindrical piece of three diameters: the head, E, thread D, and point, C. The head is sufficiently small to allow it to pass through the bore; the cavity, G, in it prevents injury to firing-pin. The thread secures it to extractor. The point, when driven between the prongs of extractor as far as possible, sets them out sufficiently to remove a shell, but not far enough to touch the walls when passed into the empty chamber.



Headless Shell-extractor.

The parts should be kept screwed together and never separated for use, in *any case*, until after passing it as a whole—solid (drift) end foremost through the bore from the muzzle—and failing to remove the shell. Passing it thus—using larger end of hammer to do so—will remove any shell or part of shell in the bore, or slightly protruding into it from the chamber. Failing to do so, unscrew the drift; insert the extractor, prong end foremost, into the chamber; close the breech; pass the drift, point foremost, into the bore at the muzzle; follow it with the larger end of rammer; drive it gently "home" between the prongs of extractor; open the breech and drive out the shell. After the shell is out, the two parts either separate or can be separated by the fingers, and the shell removed from the extractor. The prongs being in the mouth of the chamber, the point of drift invariably enters between them if the drift be passed through the bore as directed. In case of accumulated or hardened fouling or dirt in the bore, the extractor as a whole, as directed, may be passed through it with advantage either as a preliminary to cleaning or wiping, or to remove the *cause* of swelled and burst barrels. In the latter case it should be used just before each shot when at the target, or as often as convenient when hunting or in battle. See *Springfield Rifle*.

HEAD-QUARTERS.—A term generally understood to mean the residence of the Commander-in-Chief, whether in camp or elsewhere. It is also applicable to the place where the officer, commanding any independent position or body of troops, resides; hence, the center of authority or order. The headquarters of the whole British Army is at the Horse Guards, where the Commander-in-Chief has his permanent offices.

HEADSTALL.—That part of the bridle which encompasses the head; the bridle minus the bit and rein; the halter minus the hitching-strap.

HEAD STOCK.—That portion of a lathe which contains the mandrel or *live* spindle on which the work is chucked or to which it is dogged, in contradistinction to the *tail*-stock which contains the *dead* spindle. The *live*-head as distinguished from the *dead*-head.

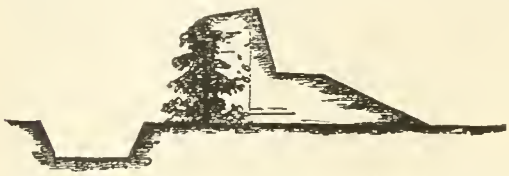
HEARSAY EVIDENCE.—Evidence given at second-hand, where the witness states not what he himself saw or heard, but what somebody else said. This evidence is, as a general rule, inadmissible, because the axiom is, that the best evidence that can be had must be produced, and therefore each witness must be confined to stating what he knows of his own personal knowledge, or what he has learned by the aid of his own senses; and as he is sworn to the truth, his truthfulness is thus secured, as far as human testimony can be so. If evidence were once admitted at second-hand, there would be no limit to its uncertainty, and there would be thus introduced vague statements of absent persons, who, not being sworn when they made them, are therefore incapable of being punished if they speak falsely, and cannot be cross-examined. Though such is the general rule, yet there are a few exceptions which are unavoidable, owing to the nature of the thing. Thus, in proving pedigrees, the hearsay evidence of persons connected with the family, and those only, is admitted in England; but in Scotland it is admitted though the persons were not connected with the family. A remarkable exception also exists in the case of dying declarations, i. e., statements made by persons mortally wounded and in the prospect of death; but in England such evidence is only admitted in criminal cases, on a charge of manslaughter or murder. In Scotland such declarations are admitted in all cases of violence, and though the party at the time did not believe he was dying. There is another exception to the non-admissibility of hearsay evidence allowed in Scotland, but not in England, viz., where the person who made the statement is dead, and therefore cannot be produced as a witness. In England there is no help for such a state of things, and the statements of the dead person cannot be admitted; but in Scotland, if there was no reason to suppose the contrary, it is presumed the dead witness spoke the truth, and what he said may be given in evidence for what it is worth, both in civil and criminal cases.

HEAUME.—A word derived from the German, which formerly signified *casque*, or helmet. The heaume has been sometimes called among the French *salade*, *armet*, and *celate* from the Latin word which means engraved, on account of the different figures which were represented upon it. The heaume covered the whole of the face, except the eyes, which were protected by small iron bars laid crosswise. It served as an armament or helmet in coats of arms and armorial bearings; it is still preserved in Heraldry, and is a distinguishing mark of nobility.

HEAVE.—A command given when lifting heavy weights or moving guns into position. The handspikes being in position and manned, at the command, *heave*, all bear down or up on the handspike simultaneously.

HEAVIES.—The common expression for European heavy cavalry. They receive their name in contradistinction to the light cavalry, from their equipment and weight being greater than the latter. In the British service there are 7 regiments of *Heavies*, viz., the dragoon guards. The weight the horse of *Heavies* has to carry is over 19 stone. See *Heavy Troops*.

HEDGES.—A thin-set hedge cannot be placed in a good state of defense, and should therefore be destroyed, to prevent its interfering in any manner with the defense. At the best this defense will only serve as a screen, the hedge holding the earth up. A thick-set hedge, if over six and a half feet high, should be cut down to this height, and the cuttings be set into the hedge to back the earth better; a small ditch is dug in front of the hedge, the earth from which serves to form a banquette and a slight parapet, which are thrown up against the hedge. If the hedge is less than six and a half feet high it is cut down to the height of four and a quarter feet; a ditch or trench, about three feet wide at bottom, and two feet deep, is dug behind the hedge, and the earth is thrown up against it, as in the last case. A width of two or three feet should be left between the trench and the earth thrown against the hedge to serve as a banquette. A simple ditch behind a hedge will often serve as a good cover for light troops without any other preparation. See *Walls*.



Section of Parapet behind a Hedge and a Ditch in front of it.

Section of a Hedge Defense with Trench in rear.

HEAVY-ARMED INFANTRY.—Among the early soldiery, such of the infantry as wore complete armor, and engaged with broad shields and long spears. They were the flower and strength of the Grecian armies, and had the highest rank of military honor. See *Infantry*.

HEAVY MARCHING ORDER.—An expression applied to troops equipped for permanent field service with arms, accouterments, knapsacks, canteens, and haversacks.

HEAVY METAL.—Large guns carrying balls of a large size; also, large balls for such guns.

HEAVY ORDNANCE.—Ordnance of great weight and caliber. In the United States the term is restricted in the land service to sea-coast ordnance. See *Ordnance*.

HEAVY TROOPS.—The troops which compose the *three principal arms* are generally subdivided into two classes, *heavy* and *light;* partly arising from the nature of their weapons, and partly from their destination on the field of battle. This subdivision is less marked in the infantry than in that of the other arms; for although in most foreign armies, a portion of the infantry carries a saber with the musket, still this additional weapon is of rather questionable utility; for the musket is the one which, under all circumstances of attack and defense, will be resorted to. All infantry now receive the same instruction; but whether a portion of it ought not to be reserved especially for the duties consigned to light troops, is still a disputed point. As the functions of heavy cavalry are to bear down all opposition, and present an impassable wall to the enemy's efforts, its duties are confined to the battle-field; there, placed in the reserve, it is held in hand until the decisive moment arrives, when it is launched forth to deal a blow from which the enemy hopelessly struggles to recover, either to achieve victory, or to fend off utter defeat. To light cavalry are intrusted the important duties of securing from surprise the flanks of the heavy; to watch over the safety of horse artillery, and to perform the services required of them by infantry divisions, and those of detachment service in general. The artillery, which had for a long period, and even still, preserves the character of eminent respectability, has of late years begun to infuse a dash of dare-devil spirit of the cavalier into its ranks. If it has not yet taken to charging literally, it has, on some recent occasions in our service, shown a well-considered recklessness of obstacles and dangers, fully borne out by justly deserved success. The distinction between light and heavy in this arm arises, not only from the difference of caliber in the pieces, but also in a difference of their tactical application.

HEEL.—That part of a thing corresponding in position to the human heel; the lower back part, or part on which a thing rests. In a small-arm it is the corner of the butt which is upwards in the firing position. The *heel* of a sword is the uppermost part of the blade, next to the hilt. It is generally larger and more massive than the rest of the blade.

HEEL-PIECE.—The armor for the heels; also, the plate on the butt-end of a gun-stock. This is sometimes called the *heel-plate*.

HEGEMONY.—Leadership; preponderant influence or authority; usually applied to the relations of a Government or State to its neighbors or confederates.

HEIRESS.—In Heraldry, a lady is accounted as an heiress if she has no brothers who leave issue. The husband of an heiress is entitled to bear her arms in an escutcheon of pretense, i. e., a small escutcheon in the center of his paternal shield, and the children of an heiress may quarter her arms with their paternal coat. Neither practice is of very early introduction in Heraldry. See *Marshaling of Arms*.

HELEPOLIS.—In the ancient art of war, a machine for battering down the walls of a place besieged. Its invention is ascribed to Demetrius Poliorcetes. Diodorus Siculus says that each side of the helepolis was 450 cubits broad, and 90 in height; that it had nine stages, or floors, and was carried on four strong solid wheels, 8 cubits in diameter; that it was armed with huge battering-rams, and had two roofs capable of supporting them; that in the lower stages there were different sorts of engines for casting stones, and in the middle they had large catapults for launching arrows.

HELIOGRAPHY.—The name applied to the method of communicating between distant points in which visual signals are obtained by reflecting the rays of the sun from a mirror or combination of mirrors in the required direction. This method can be only employed to advantage in places where the sky is free from clouds and the atmosphere clear for considerable periods of time, and the fact that an atmospheric change may indefinitely delay the transmission of a message is an insuperable objection to the establishment of permanent heliographic stations in most climates. In suitable localities, however, heliography possesses important advantages for military signalling over other methods, the principal being the portability of the apparatus, the great distance to which messages can be sent without retransmission, and the fact that the signals are visible to those only who are on the direct line of signalling. An interesting and instructive paper entitled "The Elements of the Heliograph," by Lieutenant Fred-

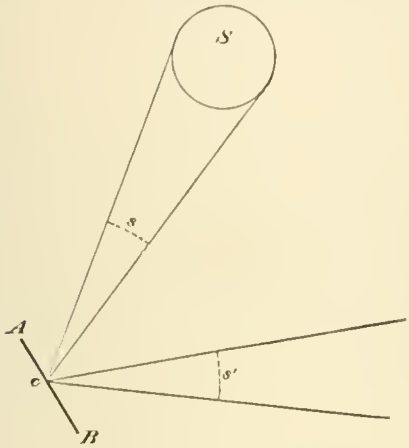


Fig. 1.

erick K. Ward, United States Army, has been published in Signal Service Notes, No. XI; and to this paper we are indebted for the substance of the following discussion.

A complete instrument consists essentially of two plane mirrors and a sighting-rod, and, when a "stand-

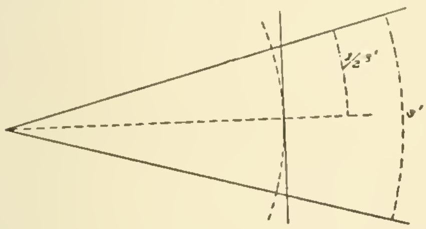

Fig. 2.

ing flash" is used, a screen. The mirrors are firmly supported, usually on a tripod, and are fitted with vertical and horizontal tangent-screws. By means of the tangent screws the mirrors can be turned on their supports so as to face in any desired direction toward the sky. When a movable flash is used, one

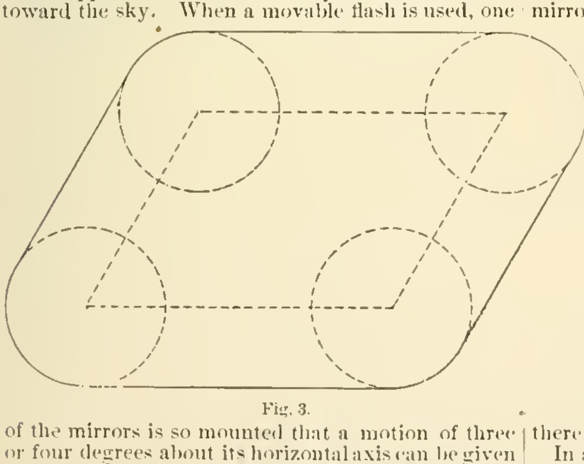

Fig. 3.

of the mirrors is so mounted that a motion of three or four degrees about its horizontal axis can be given it independently of the tangent-screw, so that the flash can be thrown on and off the receiving-station at will, and quickly. The screen, when used, is on a separate support, in order, when working, to avoid any shaking of the mirrors. Both mirrors are used when the signalman facing the receiving-station has the sun in his rear. When the sun is in his front, or nearly at his right or left, only one mirror is used. The sighting-rod, as its name implies, is an auxiliary used with the tangent-screws, to put and keep the mirrors in such a position that the flash can be thrown with certainty on the receiving-station.

The principles involved in the heliograph are few and simple: Let *S*, Fig. 1, represent the sun, and *AB* a plain mirror. Consider first the light from the sun incident on *AB* at a single point, *c*. Only two outside rays are shown in the figure. Since angles of incidence and reflection are always equal, the angle *s'* is equal to the angle *s*, and it is apparent, without further explanation, that the converging cone of light from *S*, incident at *c*, becomes, after reflection, a diverging cone of precisely the same dimensions. A spectator anywhere within this diverging cone will see the reflected light on looking toward *c*. The incident cone is a right cone with a circular base; therefore a right section of the reflected cone will be a circle whatever may be the angle of incidence. The radius of the circle will be equal to the natural tangent of $\frac{1}{2}s$, or the natural tangent of the sun's semi-diameter to a radius equal to the distance from *c* to the plane of the section. This will be apparent from Fig. 2.

Now, suppose *AB* to be a square mirror, and consider next the four cones of light reflected from the four corners. The angle at the sun subtended by the diameter of the mirror would be inappreciable, therefore the axes of these four cones are sensibly parallel. The cones themselves evidently define the figure of illumination. Pass a plane perpendicular to the axes and they will pierce it in four points, defining a parallelogram, the sides of which will not exceed those of the mirror in length. The axes proceed obliquely from the mirror, therefore the parallelogram will be oblique. This parallelogram is represented in full in Fig. 3. The cutting-plane makes a right section of the cone surrounding each axis, and we have already seen that this section is a circle having a radius equal to the natural tangent of the sun's semi-diameter to a radius equal to the distance from the cutting-plane to the apex of the cone on the mirror. With these radii describe circles about the corner points, and join these circles by tangents. The resulting enclosed figure is a right section of the solid of illumination. Now, since the axes of the four cones are parallel, the dimensions of the parallelogram will be constant for all positions of the cutting-plane. The radii of the four circles increase with the distance from the mirror. The mean value of the semi-diameter of the sun is about 16 minutes, the natural tangent of which to a radius of one mile is 24½ feet, very nearly. The mirrors used in heliographs are usually from 4 to 6 inches in diameter. Therefore at a distance of one mile, the circles will overlap and the figure of illumination will be sensibly a circle 49 feet in diameter. At a distance of 10 miles from the mirror to the cutting-plane, or from the sending to the receiving-station, the circle of illumination is 490 feet in diameter. And, generally, the diameter of the flash at the receiving-station, in feet, is equal to 49 multiplied by the distance between the stations in miles. As the diameter of the flash increases directly with the difference between the stations, the adjustment of the instrument is no more difficult for a very distant station than for one comparatively near, provided, of course, that there is some distinguishable landmark to adjust by.

In all patterns of the heliograph yet made the mirror is kept in adjustment by means of what is called the "dark spot." To explain this, let *AB*, Fig. 4, represent a glass mirror, from which the silvering has been removed from a small circle represented by *cd*, about the center of motion of the mirror. The center of the motion must lie in the plane of the silvered surface, and it is usually at the center of the mirror. Let *fcf* and *gdg*, represent the cones

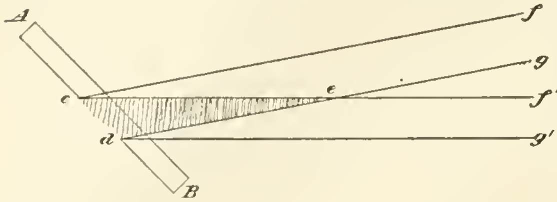

Fig. 4

of light reflected from *c* and *d*, respectively. Between *c* and *d* very little light is reflected, and a dark cone represented by *ced* is formed, the angle *ced* being equal to the diameter of the sun. To deduce a general expression for the length of the dark cone, let *c e d*, Fig. 5, represent the cone, and *me* its axis, the length of which represent by *L*. From *m* draw *m n* perpendicular to the reflecting surface. The angle *i* is equal to the mean angle of reflection or incidence. Let *d* represent the diameter of the unsilvered spot *cd*, and *s* the angle *ced*, which is equal to the diameter of the sun. Then,

$$L = \frac{\frac{1}{2}d \cdot \cos\,(i - \frac{1}{2}s)}{\sin\,\frac{1}{2}s}.$$

Returning to Fig. 4, it is evident that the axis of the dark cone is parallel to the axis of the cone of re-

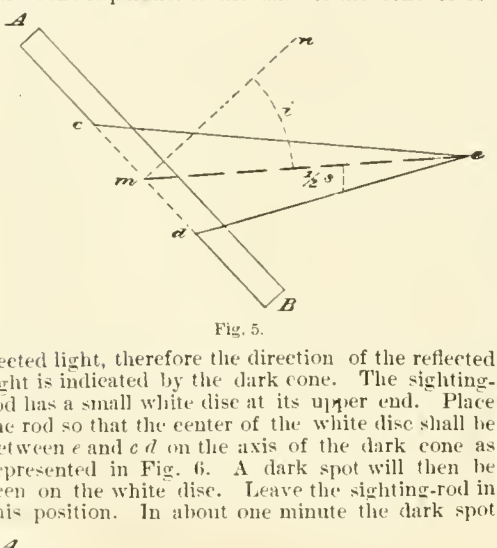

Fig. 5.

flected light, therefore the direction of the reflected light is indicated by the dark cone. The sighting-rod has a small white disc at its upper end. Place the rod so that the center of the white disc shall be between *e* and *c d* on the axis of the dark cone as represented in Fig. 6. A dark spot will then be seen on the white disc. Leave the sighting-rod in this position. In about one minute the dark spot

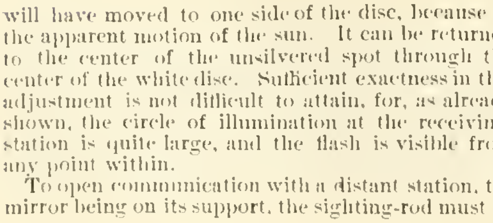

Fig. 6.

will have moved to one side of the disc, because of the apparent motion of the sun. It can be returned to the center of the unsilvered spot through the center of the white disc. Sufficient exactness in this adjustment is not difficult to attain, for, as already shown, the circle of illumination at the receiving-station is quite large, and the flash is visible from any point within.

To open communication with a distant station, the mirror being on its support, the sighting-rod must be so placed that the centers of the unsilvered spot of the white disc, and of the receiving-station, shall be on the same straight line. This may be done by looking through the unsilvered spot at the station and placing the white disc to cover it. In practice, however, it is found easier to set the sighting-rod by looking into the mirror, so placing the eye that the unsilvered spot exactly covers the reflection of the distant station, and then, without moving the eye or the mirror, bringing the sighting-rod into view by reflection, and so adjusting it that the reflection of its disc is also covered by the unsilvered spot. Then, if the mirror is turned by its tangent-screws so as to throw the reflected sunlight past the sighting-rod in such a direction as to show the dark spot on the disc, the flash will be visible from the distant station. If the instrument gives a standing flash, the screen must now be placed so as to hide or cut off the flash except when it is given to view by the operator working the screen. If the instrument gives a movable flash, the mirror must be so turned that the dark spot will appear on the white disc when the key provided to work the mirror is pressed down. When the key is not pressed down, the dark spot will be on the sighting rod a little below the disc, and the flash will not then be visible. No particular value of the angle of incidence has yet been considered. It is necessary to consider what would be the effect if the light from the sun should fall very obliquely upon the mirror. It has already been shown that the dimensions of the flash are sensibly independent of the angle of incidence. But the case is different as regards the strength of the flash, and on this the range of the instrument depends. As the obliquity increases, the mirror intercepts less and less light, the reflected flash becomes correspondingly weaker, and the maximum distance from which it can be seen distinctly, that is, the range of the instrument, is decreased; and further, the expression for the length of the dark cone shows that the length decreases as the angle of incidence increases, becoming practically zero when the angle of incidence is nearly ninety degrees. The dark cone would then fail to reach the sighting-disc and there would be no longer any means for keeping the flash on the receiving-station. These difficulties are avoided by the use of a second mirror. Fig. 7 illustrates how the two mirrors are made to serve the purpose. The figure needs no explanation. The mirror which faces the receiving-station is usually called the second mirror. The preliminary adjustment with two mirrors is very similar to that with one. In the explanation for the single mirror, mention was made of cones of diverging reflected rays only. That there are also converging reflected rays will be evident by supposing the eye placed in front of the mirror and looking into it. There would then be visible an image of the sun (see Fig. 8). This imaginary sun takes the place of a real sun situated back of the first mirror on the straight line through the centers of the two mirrors. The first mirror gives the light to the second from a fixed direction; therefore, after the preliminary adjustment of both mirrors is completed, the second should not be touched. The flash is kept on the distant station by the tangent-screws of the first mirror.

With the sun at the zenith the angle of incidence would be about 45°. Should the angle of incidence with a single mirror approach 60°, the second mirror would be brought into use to decrease it. 60° then may be assumed as the maximum angle of incidence. The maximum of the sun's semi-diameter is 16′ and 18″. The diameter of the unsilvered spot is usually about $\frac{2}{10}$ of an inch. These values in the expression for *L*, give 10 and $\frac{6}{10}$ inches as the length of the dark cone. It follows that when the unsilvered spot is $\frac{2}{10}$ of an inch in diameter, the distance from the center of the mirror to the sighting disc, or from the center of the first mirror to the center of the second, must not exceed nine inches, in order that there shall always be a distinct dark spot

It may be of interest to determine the figure and size of plane mirror requisite to give the maximum strength of flash. Let *AB*, Fig. 8, represent a plane mirror situated a short distance from the eye at *e*

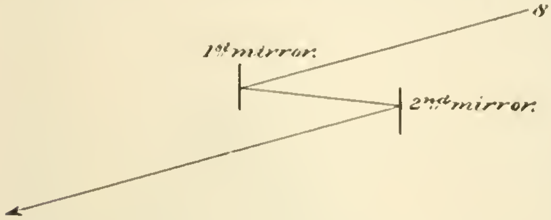

Fig 7

looking at the imaginary image of the sun, formed by reflection. The image will seem to cover a part of the surface of *AB* represented by *mn*. With a very small angle of incidence *mn* will be sensibly a circle from every point of which light is reflected to

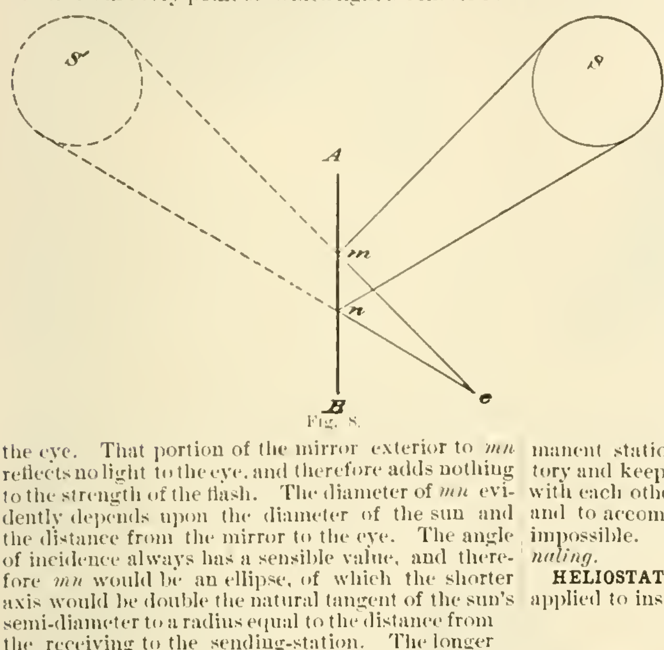

Fig. 8.

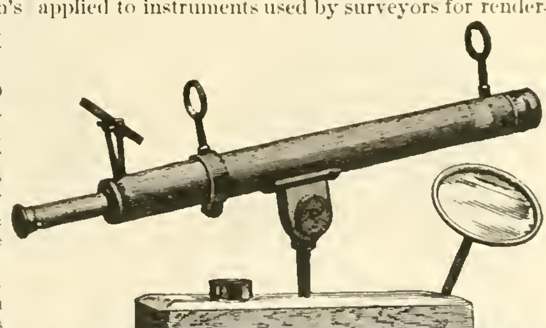
the eye. That portion of the mirror exterior to *mn* reflects no light to the eye, and therefore adds nothing to the strength of the flash. The diameter of *mn* evidently depends upon the diameter of the sun and the distance from the mirror to the eye. The angle of incidence always has a sensible value, and therefore *mn* would be an ellipse, of which the shorter axis would be double the natural tangent of the sun's semi-diameter to a radius equal to the distance from the receiving to the sending-station. The longer axis would increase with the angle of incidence. From this it appears that, at a distance of, say, 10 miles, a mirror 490 feet in diameter would be required for the maximum strength of flash. But that would be impracticable, and indeed it would never be desirable, for the flash from a 4-inch mirror has been seen with the naked eye at a distance of over 35 miles, and that from a 15-inch mirror has been seen with the aid of a small telescope at a distance accurately determined to be 192 miles.

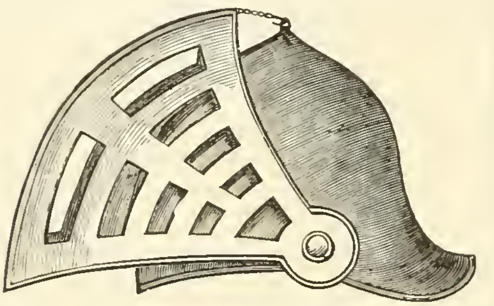
The mirrors of a heliograph should be of glass. Metallic mirrors would be hard to keep bright in service, and they are open to a still more serious objection. It is necessary that mirrors should be as nearly plane as possible. If of metal they would be liable to become bent or indented. The injury might be so slight as not to be apparent and still be sufficient to make it impossible to give a good flash to the receiving-station. Glass mirrors are free from these objections, and experience has shown that those of the small size needed are not likely to be broken. And, too, in the field it would be easier to replace a glass mirror than one of metal. The heliograph, by the reason of its greater range, is a much more valuable instrument for field signaling than the flag. The extreme range of the flag without glasses is not over two miles, and with a telescope having a power of 30 diameters it cannot be read more than twenty miles. At the latter distance it is only when the atmosphere is exceptionally clear that the flag can be seen at all. The average speed in the transmission of messages by flag is about three words per minute, and the labor of swinging is by no means light. A man well practiced in the use of the heliograph can send eight words per minute, and no manual labor is involved. It is more tiresome to receive from the heliograph than from a flag, because the concentration of attention required and the strain upon the eyes are greater. The latter trouble may be much lessened by the use of colored glasses, or better still, of a screen which will cut off the glare of the sky and ground without obstructing any of the light from the distant instrument. The flash from a field instrument can be seen with the naked eye from 35 to 50 miles, and that from a larger instrument having 8 or 9 inch mirrors, could be seen 80 miles or more without glasses. Permanent stations should be supplied with both sizes. The dust of a command can be distinguished at great distances with glasses. The flash being then thrown on the advance, the command would be almost sure to see it before having moved across and out of it, for at a distance of 30 miles it is nearly one-third of a mile wide. It would most certainly be seen by some one if the whole command was instructed to be generally on the watch for such signals. With each command there should be, of course, a heliograph. By halting a short time the Commanding Officer might obtain information of the greatest value, and at the same time give for transmission to other commands or to headquarters such information as he might possess. In a section where the natural features are favorable, it is easy to see how a few permanent stations could cover a large extent of territory and keep several commands in communication with each other, enabling them to operate in concert and to accomplish what would otherwise have been impossible. See *Heliostat* and *Looking-glass Signaling*.

HELIOSTAT.—Heliostat and heliotrope are names applied to instruments used by surveyors for render-



ing the distant stations distinctly visible. This is managed by placing a mirror at the distant station, and adjusting it so that at a particular hour of the day (arranged beforehand), the light of the sun shall be reflected from the mirror directly to the surveyor's station. The surveyor must make his observation at the instant he sees the glancing of the mirror, as the constant change of the sun's position in the heavens produces a corresponding change in the direction of the rays reflected by the mirror. Gauss invented such an instrument about 1821, which is much used in America, for Geodetic Surveys, and is said to possess such power, that a mirror 1 inch square is visible eight miles off, in average sunny weather, and appears as a brilliant star at a distance of two miles; while some heliotropes have been used so powerful as to be visible nearly 80 miles off. The term heliostat, applied by Captain Drummond to an instrument invented by him for the same purpose, more properly belongs to an instrument invented by S'Gravesande, consisting of an equatorial revolving on its polar axis, so that the sun, when once accurately in the focus of the telescope, continues steadily fixed there. Drummond's heliostat is chiefly used in Britain. The drawing shows the instrument as made by Fauth & Co., United States, for the Coast and Geodetic Survey. The telescope body is an iron tube; a wood screw with a joint is attached at the middle, so that the instrument can be screwed to any tree or post. See *Heliography*.

HELM, HELMET.—1. In Heraldry, the representation of a helmet over shields or coats of arms. From the early simple form known as the Norman, the helmet, at a later period, came to vary in shape



Helmet of the Middle Ages.

according to the degree of the person who wore it, and helmets were set over coats of arms to bear the crest, and indicate by their form the rank of the bearer. The part of the helmet which opens to show the face is called the *visor* or *beaver* (to allow

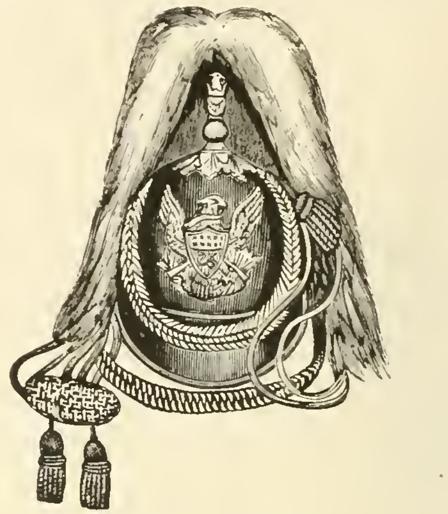
Line Officers' Helmet, U. S. Army.

Privates' Felt Helmet, U. S. Army.

Summer Helmet, with spike.

of drinking). The following forms of helmet are in use in English Heraldry: 1. The helmet assigned to the King and Princes of the blood-royal, which is full-faced, composed of gold lined with crimson, and has the vizor divided by six projecting bars. 2. The helmet of the nobility, of steel, with five bars of gold. When placed on the shield, it is exhibited in profile. 3. Knights and Baronets have the full-faced steel helmet with the vizor thrown back and without bars. 4. The helmet of Esquires, always represented in profile, of steel with the vizor closed. These distinctions are of comparatively recent date. A much greater variety of helmets is in use in Continental Heraldry. A Helmet is never placed over the arms of any woman except the Sovereign.

2. A covering of metal or leather to protect the head in warfare. The earlier Greek and Roman helmets, as shown in many extant sculptures, were surmounted by plumes, but unlike their modern successors, did not protect the face. During the Middle



Field Officers' Helmet with Plume.

Ages, helmets were made of the finest steel, often inlaid with gold, and provided with bars and flaps, to cover the face in action, and to allow of being opened at other times. As the employment of firearms became more general, helmets naturally lost their utility, especially as regarded the face. Those still remaining are in military matters limited for the most part to heavy cavalry, afford no protection to the face, and must be considered as rather for ornament than use. Firemen wear a heavy head-piece of leather and brass, to protect them as far as possible from falling ruins at conflagrations. In India and other hot climates, helmets of white felt, with the additional screen of rolls of linen, are constantly worn by military men, to protect them from the rays of the sun.

In the United States army, light helmets of the following descriptions are worn as a part of the full dress:

Helmets for Field Officers—The body: of cork or other suitable material, covered with black cloth, or of black felt, at the option of the wearer. Trimmings: cord and tassels, top-piece and plume-socket, chain chin-strap and hooks, eagle with motto, crossed cannon, rifles, or sabers, all gilt, with the number of the regiment on the shield in white: plume of buffalo-hair, white for infantry, yellow for cavalry, and red for artillery. *Helmets for other Mounted Officers and Officers of the Signal Corps*—Same as above except that the color of plume is orange for Signal Corps. *Helmets for other Officers of Foot Troops*—Same as above, except that the trimmings are as follows:—Top-piece spike, chain chin-strap with hooks and side buttons, eagle with motto, crossed rifles or cannon, all gilt, with the number of the regiment on the shield in white. *Officers' Summer Helmets*—Body: of cork, covered with white facing cloth; top-piece spike, chain chin-strap, and hooks all gilt. The helmet cords are attached to the left side of the helmet and come down to the left shoulder, where they are held together by a slide; one cord then passes to the front and the other to the rear of the neck, crossing upon the right shoulder and passing separately around to the front and rear of the right arm, where they are again united and held together by a slide under the arm; the united cords then cross the breast and are looped up to the upper button on the left side of the coat.

Helmets for all Mounted Troops—Body: of black felt, with leather chin-strap, large crossed cannons or sabers, letter of company and number of regiment, plain side buttons, top-piece and plume-socket, all brass; horse-hair plumes and cords, and band with rings of the color of the arm of service. *Helmets for all Foot Troops*—Of same pattern and material as for mounted troops, with leather chin-strap; and plain side buttons, top-piece and spike, of brass. *Trimmings*—Commissary Sergeants, a crescent of white metal; Hospital Stewards, a wreath of brass, with letters U. S. in white metal; Engineers, a castle, with letter of company; Ordnance, a shell and flame; Artillery, crossed cannons; Infantry, crossed rifles, and letter of company and number of regiment, all in brass. Cork helmets are supplied only to troops serving in extremely hot climates, in the first and third years of their enlistment, and these only in lieu of the campaign hat. The necessity for such issue must in all cases be certified to by the Department Commander. See *Chapeau Bras*.

HELM-GUN.—A breech-loading small-arm, having a fixed chamber closed by a movable barrel, which rotates about an axis parallel to the axis of the barrel. The peculiar feature of this arm is the connection of the tumbler with a movable butt-plate, so arranged that by pressing the piece against the shoulder, in aiming, the hammer may be simultaneously cocked. The cylinder also can be conveniently removed from the side, and replaced by a loaded one, if desired.

HELOTS.—The population of ancient Sparta was divided into four classes, the lowest of which was formed of serfs or slaves, called Helots (probably meaning *captives*, from *helein*, to capture). These Helots are generally supposed to have formed the original population of the country, and to have been reduced to bondage by their Dorian conquerors, the numbers, however, being swelled from time to time by the conquest of enemies. They belonged to the State, which had the power to set them at liberty; but they toiled for individual proprietors, and were *bound to the soil*, i.e., they could not be sold away from the place of their labor. They were the tillers of the land (for which they paid a rent to their masters), they served at the public meals, and were occupied on the public works. In war they served as light troops, each free-born Spartan who bore heavy armor being accompanied to battle by a number of them, sometimes as many as seven. On rare occasions they were used as heavy-armed soldiers. It is a matter of doubt whether after emancipation they could ever enjoy all the privileges of Spartan citizens. They were treated with much severity by their masters, and were subjected to degradation and indignities. They were whipped every year to keep them in mind of their servile state; they were obliged to wear a distinctive dress (clothes of sheep-skin, and a cap of dog's skin), and to intoxicate themselves, as a warning to the Spartan youth; and when multiplied to an alarming extent, they were often massacred with the most barbarous cruelty. On one occasion, 2000 of them, who had behaved bravely in war, were encouraged to come forward for emancipation, and were then most treacherously put to death. The Spartans organized, as often as necessity required it, *Secret Service Companies* of young men, who went abroad over the country armed with daggers, and both by night and day assassinated the unfortunate Helots, selecting as their special victims the strongest and most vigorous of the oppressed race.

HELVE.—1. A tilt-hammer, used for shingling the balls as they come from the puddling-furnace. 2. The wooden handle of entrenching tools, such as axes (felling and pick,) hatchets, kodalies, shovels, spades; also the handle of certain artificers' tools, axes, and sledge-hammers.

HELVETII.—A Celtic people inhabiting, according to Cæsar, the region between the mountains of Jura on the west, the Rhone on the south, and the Rhine on the east and north, the region corresponding pretty closely with modern Switzerland. They had 12 towns and 400 villages. The great and fatal event in their history is their attempted irruption into and conquest of Southern Gaul, in which they were repulsed by Cæsar with frightful slaughter. The story of this expedition is circumstantially narrated by the Roman Commander. They collected 3 months' provisions, burned their 12 cities, 400 villages, and all isolated dwellings, and made a general rendezvous by Lake Leman in the spring of 58 B. C. Cæsar hastened to Geneva, destroyed the bridge, raised two legions in Cisalpine Gaul, and when the Helvetians sent delegates to demand a passage, delayed them until he had built a wall along the Rhone, 16 feet high and about 19 Roman miles in length, flanked with redoubts. Having vainly attempted to pass this barrier, the Helvetii took another route, but were followed and defeated with a terrible slaughter at Bibracte (modern Autun, in Burgundy), and the remnant obliged to return to their own country, where they became subject to the Romans. Of 368,000 who left their homes, including 92,000 fighting-men, only 110,000 returned. In the commotions which followed the death of Nero, the Helvetians met with another terrible catastrophe. Remaining faithful to Galba, they were fallen upon by Cacina, a General of Vitellius, who gave them to the rapacity of his legions. They were massacred by thousands, multitudes were sold into slavery, and their towns pillaged and burned, their Capital destroyed, and their Governor executed. From this time they scarcely appear as a distinct people.

HEMERODROMI.—In Grecian antiquity, runners or couriers, who could hold out to run all day. In a country like Greece, where the roads were few and bad, the Hemerodromi were indispensable for the rapid diffusion of important news. Every Greek State made a point of training a number of these men who could travel great distances in an incredibly short space of time, and at every dangerous crisis they were stationed on commanding points to observe and report at head-quarters what it was necessary for the authorities to know. In the service of the Persian Kings, these men were called *Angori*, and the service *Angerion*. Among the Romans they were known as *Cursores*.

HEMP.—The fiber of certain plants grown both in Europe and India, known as the *Cannabis sativa* and *indica*, which have been pronounced identical plants. In various notices of Indian fibers, we frequently meet with the word *sunn* as indicating a particular kind of hemp. Sometimes we find it called Indian hemp, and we may often see hemp enumerated as one of the exports from India, at other times we may see either the same or another fiber mentioned by the name of brown hemp. These various names are sometimes applied to the fiber of one or two different plants, or are employed to distinguish the fiber of three distinct plants, all of which are grown for their fibers, and have been and might be exported from India; though only two of them are now usually to be found among the exports from that country. Hence, to avoid ambiguity, it is necessary to notice the plants to which these several names are correctly applicable. The true hemp (*Cannabis sativa*), *gunja* of the natives, is everywhere cultivated in the plains of India, not on account of its fibers, but for its intoxicating leaves and their secretions. In the Himalayas, however, the fiber is separated for economic purposes, and was exported from India to England during the last war, and this has been the case for many years. The fiber of the *sunn* or *taag* (*Clotalaria juncea*) is often called Indian hemp, but incorrectly. It is the kind most generally cultivated all over India on account of its fiber, and is that usually mentioned in the exports from Calcutta under the name of hemp, but also as *sunn*. The plant may be distinguished by its flowers being of a bright yellow color, and of the form of the pea and of the laburnum, while the leaves are entire and lanceolate. The fiber alluded to is very valuable for cordage, canvas, twine, etc. Madras and Bombay both export large quantities of hemp.

HENCHMEN.—The name given to the soldiers who guarded the King's person in the time of Henry VIII. The word, signifying a page or servant, is now obsolete or rare.

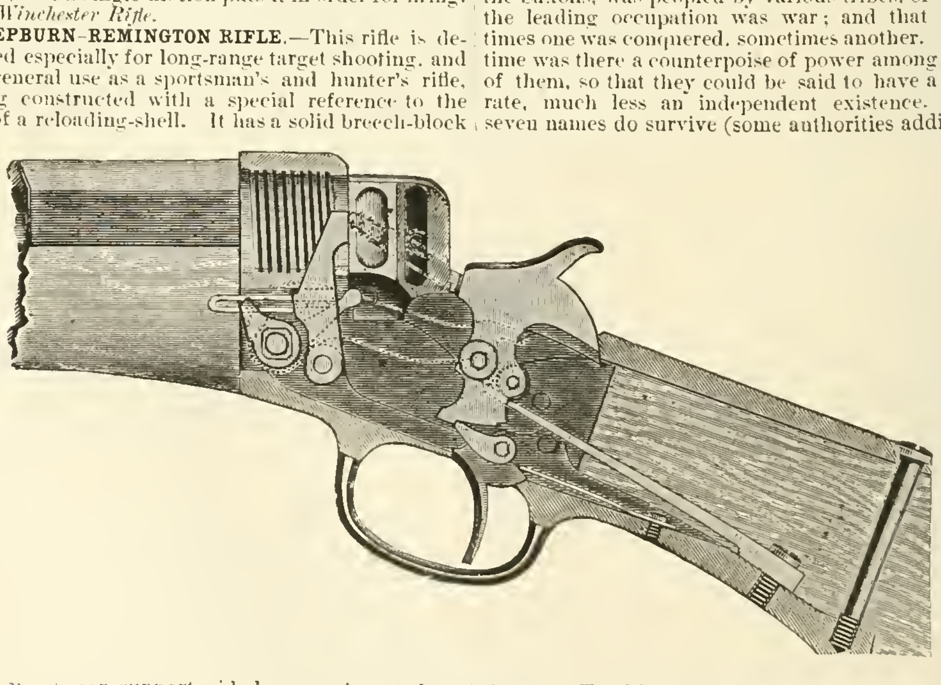
HENRY RIFLE.—This magazine-gun is now generally known as the Winchester. It may be used as a single-loader or a repeater. As a repeater, the motion of the lever withdraws the spent shell of the previous charge, raises the hammer, recharges the gun, and relocks the breech mechanism. With single loading, the cartridge is placed in the carrier-block, and a single motion puts it in order for firing. See *Winchester Rifle*.

HEPBURN-REMINGTON RIFLE.—This rifle is designed especially for long-range target shooting, and for general use as a sportsman's and hunter's rifle, being constructed with a special reference to the use of a reloading-shell. It has a solid breech-block with direct rear support, side-lever action, and rebounding hammer, so that the arm always stands with the trigger in the safety notch, thus rendering premature discharge impossible, and is believed to be the best in use for the purpose described. They are all made with pistol-grip stocks; which heretofore have been furnished only with the higher priced rifles, and are chambered for the straight 38 and 40 cal. and 45 cal. shells, using either a patched or cannelured bullet. The sectional drawing shows the arm with the breech closed.

To take the gun apart: Remove the *upper-screw* in the left-hand side, and the *breech-block* may be taken out. To take out the *hammer*, remove the next upper screw and slip the *hammer* forward into the breech-block hole. To take out the *extractor*, remove the forward screw on left-hand side. The *lever* which operates the breech-block passes through the *rocker-sleeve* with a square stud, and is held in place by a set screw directly under the *fore-stock*, which must be removed if it is ever desired to take off the *lever*. If necessary to remove the *guard*, it can be done by taking off the *butt-stock*, and taking out the *side-screws* in the usual way. The *barrel* should not be unscrewed from the frame, except by experienced hands and with proper appliances. When necessary to unscrew the *frame*, the *extractor* should be taken out, and the breech-block and guard put back in place, before putting on the wrench. If at any time the primer should be driven back into the firing-pin hole, so as to make the breech open stiffly, it can be relieved by snapping the hammer against the firing-pin. The military long-range rifle has been adopted by the National Rifle Association, who recommend it to competitors for the American Team. It has a heavy barrel, with new system of rifling, chambered for $2\frac{6}{10}$ inch, 44 caliber, straight shell, using from 85 to 100 grains of powder and water-proof patched bullet 520 and 550 grains of lead. See *Remington Rifle*.

HEPPAH.—A New Zealand fort, or space surrounded with stout palisades. Also written *Hippa*.

HEPTARCHY.—The name given to seven kingdoms said to have been established by the Saxons in England. The common idea is, that these seven kingdoms were contemporaneous; but all that can be safely asserted is, that England, in the time of the Saxons, was peopled by various tribes, of which the leading occupation was war; and that sometimes one was conquered, sometimes another. At no time was there a counterpoise of power among seven of them, so that they could be said to have a separate, much less an independent existence. Still, seven names do survive (some authorities adding an eighth). The king of the one that had the fortune to be most powerful for the time being, was styled Bretwalda or Ruler of Britain, but in most instances the power of this supposed Ruler beyond the limits of his own Territory must have been very small.



Under Egbert, Wessex rose to be supreme, and virtually swallowed up the others.

HERALD.—An officer whose duty consists in the regulation of armorial bearings, the marshalling of processions, and the superintendence of public ceremonies. In the Middle Ages, Heralds were highly honored, and enjoyed important privileges; their functions also included the bearing of messages, whether of courtesy or defiance, between royal or knightly personages; the superintending and registering of trials by battle tournaments, jousts, and all chivalric exercises; the computation of the slain after battle; and the recording of the valiant acts of the falling or surviving combatants. The office of Herald is probably as old as the origin of coat-armor. The principal heraldic officers are designated Kings-of-Arms or Kings-at-Arms, and the novitiates or learners are styled Pursuivants. Heralds were originally created with much ceremony; they are now appointed by the Earl Marshal in England, and by the Lyon King of-Arms in Scotland. There are now in England three Kings-of-Arms, named by their offices Garter, Clarencieux, and Norroy; six Heralds—Somerset, Chester, Windsor, Richmond, Lancaster, and York; and four Pursuivants, Rouge Dragan, Porteullis, Blue Mantle, and Rouge Croix. There have been at different periods other Heralds, whose titles are now laid aside; Heralds extraordinary have also sometimes been created, as Edmonson, by the title of Mowbray, in 1764. In Scotland, the principal heraldic officer is Lyon King-of-Arms; and there were till lately six Heralds—Snowdoun, Albany Ross, Rothesay, Marchmont, and Ilay; and six Pursuivants—Unicorn, Carrick, Kintyre, Ormond, Dingwall, and Bute. Recently the permanent number of Heralds and Pursuivants in Scotland has been reduced to three of each. Ireland has one King-of-Arms, Ulster; two Heralds, Cork and Dublin; and two Pursuivants, of whom the senior bears the title of Athlone, and the other is called the Pursuivant of St. Patrick. The official costume of a Herald consists of an embroidered satin tabard or surcoat of the royal arms, and a collar of SS. See *College-of-Arms*, *King-at-Arms* and *Pursuivant*.

HERALDRY.—Heraldry is properly the knowledge of the whole multifarious duties devolving on a Herald; in the more restricted sense, in which we shall here consider it, it is the science of armorial bearings. After occupying for ages the attention of the learned, and forming an important branch of a princely education, the study of Heraldry fell, in latter times, into neglect and disrepute, and was abandoned to coach-painters and undertakers, a degradation owing in part to the endless tissue of follies and mystifications that had been interwoven with it. Modern criticism has rescued Heraldry from the pedantries and follies of the Heralds, and imparted to it a new interest, as a valuable aid to historical investigations. Though we have instances in remote times of nations and individuals distinguishing themselves by particular emblems or ensigns, nothing that can properly be called armorial bearings existed before the middle of the 12th century. The shields of the French knights in the First Crusade presented a plain face of polished metal, nor is there any evidence of heraldic devices having been in use in the Second Crusade in 1147. But the Anglo-Norman poet Wace, who flourished in the latter part of the twelfth century, mentions devices or cognizances as being in use among the Normans, "that no Norman might perish by the hand of another, nor one Frenchman kill another"; and Wace is curiously corroborated by the Bayeux tapestry of the twelfth century, where there are figures of animals on the shields of the invaders, while the Saxon shields have only borders or crosses. The rude devices on these shields have nothing approaching to an armorial form or disposition, yet it is probable that systematic Heraldry sprang out of them, but it is difficult to say when they assumed that hereditary character which is essential to the idea of armorial bearings. Some sort of armorial insignia were depicted on the shields used in the Third Crusade, which took place in 1189; and in the same half-century originated the fleurs-de-lis of France and the lions of England. The transmission of arms from father to son seems to have been fully recognized in the thirteenth century, and in the practice then introduced of embroidering the family insignia on the surcoat worn over the hauberk or coat of mail, originated the expression *coat of arms*. Arms were similarly embroidered on the jupon, cyclas, and tabard, which succeeded the surcoat, a practice which survived till the time of Henry VIII., when the tabard came to be entirely disused except by Heralds, who still continue to wear on their tabards the Royal Arms. It was by slow degrees that the usage of arms grew up into the systematized form which it assumes in the works of the established writers on Heraldry. The principal existing data for tracing its progress are English rolls of arms yet extant of the times of Henry III., Edward I., and Edward III. The earliest formal treatises date no further back than the end of the fourteenth century, before which time the whole historical part of the subject had been obscured by a tissue of gratuitous fictions, which has misled most subsequent writers up to a very recent period. The Professors of the science represent the Heraldry of the tenth and fourteenth centuries as equally sharply defined with that of the fifteenth and sixteenth. The arms of William the Conqueror and his sons are described with all their differences; arms are ascribed to the Saxon Kings of England, to Charlemagne, and even to half-mythical persons and heroes of classical times. It is rather surprising to find this fictitious Heraldry understood and systematized early in the fourteenth century. The arms traditionally considered to be those of Edward the Confessor were sculptured in Westminster Abbey in the reign of Edward II.

In the infancy of Heraldry, every knight assumed what arms he pleased, not consulting the Sovereign or King-at-Arms. Animals, plants, imaginary monsters, things artificial, and objects familiar to Pilgrims, were all fixed on; and whenever it was possible, the object chosen was one whose name bore sufficient resemblance in sound to suggest the name or title of the bearer of it. There is reason to believe that early arms were generally *armes parlantes*, though the allusion has in many cases ceased to be intelligible from the old name of the object being forgotten. The charge fixed on was used with great latitude, singly or repeated, or in any way which the bearer chose, or the form of his shield suggested. But as coats of arms became more numerous, confusion often arose from different knights adopting the same symbol; and thus confusion was increased by a practice which crept in of sovereigns or feudal chiefs allowing their arms, or part of them, to be borne as a mark of honor by their followers in battle. Hence different coats of arms came in many instances so closely to resemble each other that it was imperative, for distinction's sake, that the fancy of the bearer should be restrained, and regulations laid down regarding the number and position of the charges, and the attitudes of the animals represented. This necessity led in the course of time, to the systematizing of Heraldry, a process which the rolls alluded to show us was going on gradually throughout the thirteenth and fourteenth centuries. By the time that Heraldry was consolidated into a science, its true origin had been lost sight of, and the credulity and fertility of imagination of the Heralds led them to invest the most common charges with mystical meanings, and to trace their original adoption to the desire of commemorating the adventures or achievements of the founders of the families who bore them. The legends ascribing an origin of this sort to the early armorial bearings have, in nearly all instances wherein it has been possible to investigate them, turned out to be fabrications. It was only when Heraldry began to assume the dignity of a science that augmentations of a commemorative character were granted, one of the earliest known instances being the heart added to the coat of Douglas, in commemoration of the good Sir James's pilgrimage with the heart of King Robert. After the science became thoroughly systematized, augmentations and new coats were often granted with the reference to the supposed symbolical meanings of the charges. In England, the assumption of arms by private persons was first restrained by a proclamation of Henry V., which prohibited every one who had not borne arms at Agincourt to assume them, except in virtue of inheritance or a grant from the Crown. To enforce the observance of this rule, Heralds' visitations or processions through the countries were instituted, and continued from time to time till the reign of William and Mary. Jurisdiction in questions of arms is executed by the Heralds' College in England, the Lyon Court in Scotland, and the College-of-Arms in Ireland. No one within the United Kingdom is entitled to bear arms without a hereditary claim by descent, or a grant from the competent authority; and the wrongful assumption of arms is an act for which the assumer may be subjected to penalties. The use of arms, whether rightfully or wrongfully, subjects the bearer of them to an annual tax. It is illegal to use without authority not only a coat of arms, but even a crest. Any figure or device placed on a heraldic wreath, is considered a crest in questions with the Heralds' College or Lyon Court, as well as in questions with the Commissioners of Inland Revenue. It shows how deeply the passion for outward distinction is implanted in human nature, when we find people in countries such as the United States, where all differences of rank are theoretically repudiated, assuming heraldic devices, each man at his own hand.

Besides individuals, Communities and States are entitled to the use of arms, and Heralds have classified arms, in respect of the right to bear them, under the following ten heads: 1. Arms of dominion; the arms borne by Sovereigns as annexed to their territories. 2. Arms of pretension, which Sovereigns have borne, who, though not in possession, claim a right to the territories to which the arms belong. Thus, England bore the arms of France from the time of Edward III. till 1801. 3. Arms of community; the arms of Bishops' Sees, Abbeys, Universities, Towns, and Corporations. 4. Arms of assumption; arms which one has a right to assume with the approbation of the Sovereign. Thus, it is said, the arms of a prisoner at war may be borne by his captor, and transmitted by him to his heirs. 5. Arms of patronage; added by Governors of Provinces, Lords of the Manor, Patrons of Benefices, etc., to their family arms, as a token of superiority, right, or jurisdiction. 6. Arms of succession, borne quartered with the family arms by those who inherit fiefs or manors, either by will, entail, or donation. Thus, the Dukes of Athole, as having been Lords of the Isle of Man, quarter the arms of that Island, and the Duke of Argyle quarters the arms of the Lordship of Lorne. 7. Arms of alliance, taken up by the issue of heiresses, to show their maternal descent. 8. Arms of adoption, borne by a stranger in blood, to fulfil the will of a testator. The last of a family may adopt a stranger to bear his name and arms and possess his estate. Arms of adoption can only be borne with permission of Sovereign or King-at-Arms. 9. Arms of concession; augmentations granted by a Sovereign of part of his royal arms, as a mark of distinction, a usage which, we have already observed, obtained in the earliest days of Heraldry; and hence the prevalence among armorial bearings of the lion, the fleur-de-lis, and the eagle, the bearings of the Sovereigns of England and Scotland, of France, and of Germany. 10. Paternal or hereditary arms, transmitted by the first possessor to his descendants. A coat of arms is composed of charges depicted on an escutcheon representing the old knightly shield. The word escutcheon is derived from the French *écusson*, which signified a shield with armorial bearings, in contradistinction from *écu*, a shield generally. The shields in use in England and France in the 11th and 12th centuries were in shape not unlike a boy's kite, a form which seems to have been borrowed from the Sicilians; but when they became the recipients of armorial bearings, they were gradually flattened and shortened. From the time of Henry III., the escutcheon has been most frequently represented on seals as of something approaching to a triangular form, with the point downwards, the exceptions being that the shield of a lady is lozenge-shaped, and a knight-banneret square.

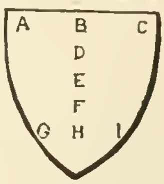


Fig. 1.

To facilitate description, the surface or field of the escutcheon has been divided into nine points, as in (Fig. 1), technically distinguished by the following names: A, the dexter chief point; B, the middle chief; C, the sinister chief; D, the honor or collar point; E, the fess point; F, the nombril or naval point; G, the dexter base point; H, the middle base; and I, the sinister base point. It will be observed that the dexter and sinister sides of the shield are so called from their position in relation not to the eye of the spectator, but of the supposed bearer of the shield.

Coats of arms are distinguished from one another, not only by the charges or objects borne on them, but by the color of these charges, and also of the field on which they are placed. The field may be of one color, or more than one, divided by a partion-line or lines varying in form. The first thing, then, to be mentioned in blazoning a shield—that is, describing it in technical language—is the color, or, as it is heraldically called, the *tincture* of the field.

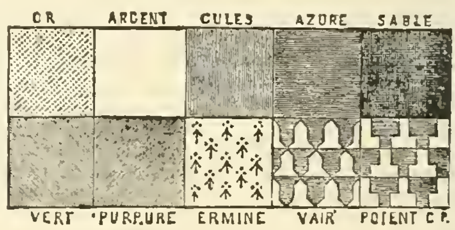

Fig. 2.

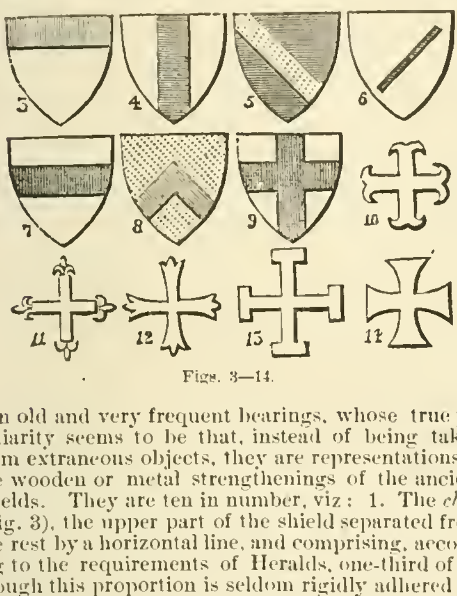
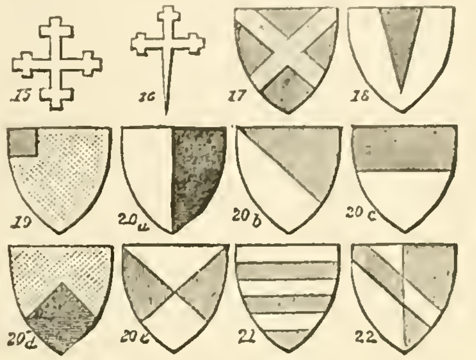
Tinctures are either of metal, color strictly so called, or fur. The metals used in Heraldry are two—gold, termed *or*, and silver, *argent*—represented in painting by yellow and white. The colors are five—red, blue, black, green, and purple, known as *gules*, *azure*, *sable*, *vert*, and *purpure*. Metals and colors are indicated in uncolored heraldic engravings by points and hatched lines, an invention ascribed to Father Silvestro di Petrasancta, an Italian Herald of the seventeenth century. *Or*, (Fig. 2) is represented by points; for *argent*, the field is left plain. *Gules* is denoted by perpendicular, and *azure*, by horizontal lines; *sable*, by lines perpendicular and horizontal crossing each other; *vert*, by diagonal lines from dexter chief to sinister base; *purpure*, by diagonal lines from sinister chief to dexter base. The *furs* were originally but two, *ermine* and *vair*. The former is represented by black spots resembling those of the fur of the animal called the ermine, on a white ground. *Vair*, said to have been taken from the fur of a squirrel, bluish-gray on the back and white on the belly, is expressed by blue and white shields, or bells in horizontal rows, the bases of the white resting on the bases of the blue. If the vair is of any other colors than white and blue, they must be specified. Various modifications of these furs were afterwards introduced, among others *ermines*, or ermine with the field sable and the spots argent; *erminites*, with a red hair on each side of the black spot; *pean*, with the field sable, and the spots or; *counter-vair*, or vair with the bells of one tincture placed base to base; and *potent counter-potent*, vair with crutch-shaped figures instead of bells. It is an established rule of Heraldry that metal should not be placed on metal, nor color on color; a rule more rigidly adhered to in English than in foreign Heraldry. We have one remarkable transgression of this in the arms of the kingdom of Jerusalem founded by the Crusaders, which are argent, a cross potent between four crosses or. A recognized exception exists wherever a charge lies over a field partly of metal and partly of color, or where an animal is (see *Infra*) attired, armed, unguled, crowned, or chained with a tincture different from that of his body. Marks of cadency, chiefs, cantons, and bordures are also occasionally exempted from the general rule, being, according to some Heralds, not laid on the shield, but *cousu*, or sewed to it.

Everything contained in the field of an escutcheon is called a *charge*. Charges are divided by Heralds into the three classes of honorable ordinaries, subordinaries, and common charges. Under the name of ordinaries or *honorable ordinaries* are included certain old and very frequent bearings, whose true peculiarity seems to be that, instead of being taken from extraneous objects, they are representations of the wooden or metal strengthenings of the ancient shields. They are ten in number, viz: 1. The *chief* (Fig. 3), the upper part of the shield separated from the rest by a horizontal line, and comprising, according to the requirements of Heralds, one-third of it, though this proportion is seldom rigidly adhered to. Its diminutive is the fillet, supposed to take up one-fourth the space of a chief, in whose lowest part it stands. 2. The *pale* (Fig. 4), a band or stripe from top to bottom, said, like the chief, to occupy one-third of the shield. It has two diminutives, the *pallet*, one-half in breadth of the pale, and the *indorse*, one-half of the pallet. 3. The *bend* (Fig. 5), a similar band crossing the shield diagonally from dexter chief to sinister base. Its diminutives are the *bendlet* or *garter*, one-half of its breadth; the *cost* or *cotise*, one-half of the bendlet; and the *riband*, one-half of the cotise. The bend is sometimes borne between two cotises, in which case it is said to be *cotised*, a term sometimes applied with doubtful propriety to the other ordinaries when accompanied with their diminutives. 4. The *bend sinister*, a diagonal band from sinister chief to dexter base. Its diminutives are the *scarpe*, one-half of the bend sinister; and the *baton* (Fig. 6), one-half of the scarpe. The baton stops short of the extremity of the field at both ends, and has been considered a mark of illegitimacy. 5. The *fess* (Fig. 7), a horizontal band in the middle of the shield, said, like the ordinaries already enumerated, to occupy one third of it. Its principal diminutive is the *bar*, containing the fifth part of the field; and there are also the *closet*, one-half of the bar, and the *barrulet*, one-half of the closet, the latter seldom borne singly. 6. The *chevron* (Fig. 8), composed of two strips descending from the center of the shield in diagonal directions like the rafters of a roof. Its diminutives are the *chevronel* of half, and the *couple-close*, one-fourth its width, the latter borne, as its name implies, in pairs, and generally accompanying the chevron—on each side of it. 7. The *cross* (Fig. 9), uniting the pale and fess, an ordinary which was originally like the rest, composed of the clamps necessary to the strength of the shield, but had also the deeper meaning of the symbol of the Christian faith. Besides its plain form, the cross was varied in numerous ways, most of these varieties being, however, rather common charges than ordinaries. Of the 39 lesser crosses mentioned by Guillim, and 109 by Edmonson, a few of the most frequently occurring are the following: The *cross moline* (Fig. 10), with the ends turned round both ways; the *cross fleury* (Fig. 11), of which each limb terminates in a fleur-de-lis; the *cross patonée* (Fig. 12), each limb of which has three points; the *cross potent* (Fig. 13), crutch-shaped at the ends; the *cross pattée* (Fig. 14), small in the center, but widening toward the ends; and the *cross crosslet* (Fig. 15), crossed at the ends. The latter is the most frequent of all, and borne oftener in numbers than singly. Any of these crosses is said to be fitchée when the lower limb terminates in a sharp point, as in Fig. 16. There is also the *cross Maltese*, whose limbs have each two points, and converge to a point in the center of the cross; though not frequent as a heraldic charge, it derives an importance from being the badge of the Knights of Malta and of many other orders. 8. The *saltire*, or St. Andrew's Cross (Fig. 17), formed by a junction of the bend dexter and bend sinister. 9. The *pile* (Fig. 18), a wedge with point downwards. A single uncharged pile should, at its upper part, occupy one-third the breadth of the shield, but if charged, it may be double that width. 10. The *quarter*, consisting of the upper right-hand fourth part of the shield cut off by a horizontal and a perpendicular line. Its diminutive is the *canton* (Fig. 19). Armorial figures may be depicted on any of these ordinaries, but not on their diminutives, with the exception of the canton.



Figs. 3—14.



Figs. 15—22.

We observed that the field of an escutcheon may be of two different tinctures, divided by a partition-line, which line may vary in direction. When divided by a partition-line in the direction of one of the ordinaries, the shield is said to be *party per* that ordinary; thus we may have (Figs. 20) a shield party per pale, bend, fess, chevron, or saltire. An escutcheon divided as by a cross is said to be quartered. A shield divided into any number of parts by lines in the direction af a pale, bend, or bar, is said to be *paly*, *bendy*, *barry*, the number of pieces being specified, as in the example Fig. 21, barry of six, argent and gules. When the field is of metal and color separated by any of the lines of partition, and the charge placed on, it is said to be *counter-changed:* this means that the part of the charge which is on the metal is of the color, and *vice versa*, as in Fig. 22, the arms borne by Chaucer the poet, per pale argent and gules, a bend counter-changed. The partition-line, or the boundary-line of an ordinary, is not always even.

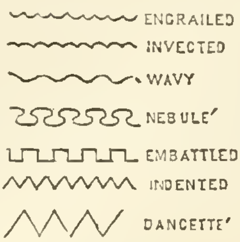


Fig. 23.

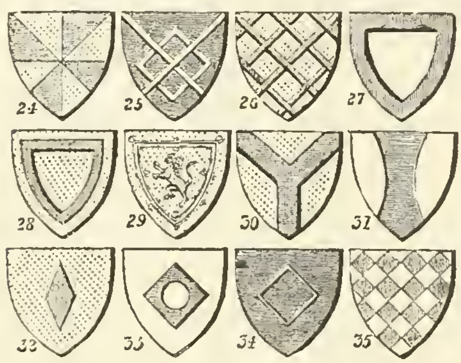
Fig. 23 shows the commonest forms of irregular partition-lines in use, viz., the *engrailed*, *invected*, *wavy*, *nebulé*, *embattled*, *indented*, and *dancetté*. An ordinary engrailed has the points of the engrailed line turned outwards, and an ordinary invected, inwards. Dancetté differs from indented by the partition-line being marked with only three indentations. The *subordinaries*, or subordinate ordinaries, are generally enumerated as the following, though there is no very broad line of demarkation between them and the common charges. 1. The *gyron*. When a shield is at once quartered and party per saltire, as in Fig. 24, the division is called *gyronny of eight* (from *gyrus* a circle), and one of the triangles, or at least that triangle in



Figs. 24—35.

dexter chief is a gyron. Gyronny of six, ten, or twelve also occasionally occur, so called according to the number of the triangles. 2. The *fret* (Fig. 25) is a cognizance derived from the banding or ornamenting of the shield, and a shield covered with this lattice-work decoration (Fig. 26) is said to be *fretty*. 3. The *bordure*, or border (Fig. 27) is a stripe encircling the shield. It is much used to distinguish different branches of a family, and is often charged with small devices, on which account it has sometimes been reckoned an honorable ordinary. 4. The *orle* (Fig. 28) differs from a bordure in not touching the extremity of the shield. 5. The *tressure*, regarded as a diminutive of the orle, is generally borne double, and flory counterflory, as in the arms of Scotland, or a lion rampant within a tressure flory counterflory gules (Fig. 29). 6. The *pall* (Fig. 30), the archiepiscopal ornament of that name, sent from Rome to metropolitans, and resembling in form the letter Y. 7. The *flanches* (Fig. 31), the dexter and sinister sides of the shield cut off by a curved line. Flanches are always borne in pairs, and sometimes charged. 8. The *lozenge*, a figure of four equal sides, with the upper and lower angles acute and the others obtuse. 9. The *fusil* (Fig. 32), longer and more acute than the lozenge. 10. The *rustre* (Fig. 33), a lozenge pierced round in the center. 11. The *mascle* (Fig. 34), a lozenge perforated, and showing a narrow border. Mascles were probably originally links of chain-armor. A field is said to be *lozengy* (Fig. 35), *fusilly* or *mascally* when divided by diagonal lines in the direction of these subordinaries. A field divided by horizontal and perpendicular lines into squares of different tinctures is said to be *checky;* in the case of a *fess checky* there are three such rows of the squares. Among the subordinaries are sometimes reckoned certain circular charges called *roundels* or *roundlets*, distinguished in English Heraldry by very different names according to their tinctures. When of or, they are called *bezants;* of argent, *plates;* of gules, *torteaux;* of azure, *hurts;* of purpure, *golpes;* and of sable, *ogresses*, or *pellets*.

We now come to the third class of figures occurring in armorial bearings. We have seen that the ordinaries and subordinaries are for the most part purely heraldic figures, connected in their origin with the shield itself; the *common charges*, on the other hand, are representations more or less conventional of familiar objects, which have no necessary relation to the shield; but are in some way emblematic as concerns family or individual history and character. The knights, in the early days of Heraldry, ransacked the animal, the vegetable, and the mineral kingdom, as well as the range of things natural and artificial, for cognizances which would be distinctive, and at the same time suggestive, of the name or title of the bearer of them. We can only enumerate a few of the charges of most frequent occurrence. Of the beasts, the *lion* requires special mention. The king of beasts is one of the most frequent of heraldic devices, and is made to assume a great variety of attitudes, for which see LION. Lions and other beasts of prey are said to be *armed* or *langued* of any tincture when their teeth and claws, or their tongue, is of that tincture. With some change of color or position, the royal beast came to be used by all who could claim kindred, however remote, with royalty, and lions were further multiplied by augmentations granted by the Sovereign to favorite followers. The heraldic *leopard*, which has been the subject of much controversy, was originally but another designation for the lion passant-gardant. Bears, boars, bulls, stags, are favorite heraldic beasts. A stag walking is said to be *trippant;* he is *at gaze* when a lion would be statant-gardant; he is *attired* of any tincture when his horns are of that tincture. The animals that possess horns and hoofs are said to be *armed* and *ungled* in respect of them. The heads and limbs of animals are often borne as charges, and they may be either *couped*, cut off in a straight line, or *erased*, cut off with jagged edge. Of birds, we have first the *eagle*. The sovereign of birds, and symbol of imperial Jove, was, next after the lion, the most favorite cognizance of royal personages, and was adopted by the German Emperors, who claimed to be successors of the Cæsars of Rome. The imperial eagle had at first but one head; the monstrosity of a second head seems to have arisen from a dimidiation of two eagles, to represent the Eastern and Western Empire. The eagle of Heraldry is most generally *displayed*, i.e., its wings are expanded; sometimes it is *preying*, or standing devouring its prey. The *alerion*, the cognizance of the Duchy of Loraine and the family of Montmorency, was originally but a synonym for the eagle assumed as an anagram for the word Loraine, but modern Heralds have degraded it into a nondescript creature without beak or claws. The *martlet* was originally a martin, a species of the swallow, which has also in course of time been deprived by heralds of its legs and beak. The pelican, the swan, the cock, the falcon, the raven, the parrot or popinjay, and the peacock, are all of tolerably frequent occurrence. The *pelican* has generally her wings *indorsed*, or placed back to back, and is depicted pecking her breast. When in her nest feeding her young, she is called a pelican *in her piety*. A *peacock* borne affronté with his tail expanded is said to be *in his* *pride*. Birds of prey are *armed* of the same color of which their beak and talons are represented. Such as have no talons are *beaked* and *membered*. The *cock* is said to be *armed*, *crested*, and *jelloped*, the latter term referring to his comb and gills. Birds having the power of flight are, in respect to their attitude, *close*, *rising*, or *volant*. Fishes and reptiles occur as charges: the former are said to be *naiant*, if drawn in a horizontal, and *hauriant*, if drawn in a perpendicular position; and the *dolphin*, in reality straight, is conventionally borne *embowed* or bent. The *escallop shell* is of frequent occurrence, and is said to be the badge of a pilgrim. Sometimes the conventional heraldic form of an animal differs from its true form, as in the case of the *antelope* of Heraldry, which has the head of the stag, a unicorn's tail, a tusk issuing from the tip of the nose, a row of tufts down the back of the neck, and similar tufts on the tail, the chest, and thighs. Of "animals phantasticall" we have among others the griffin, wyvern, dragon, unicorn, basilisk, harpy. We have the human body in whole or part, a naked man, a savage, or wild man of the woods, also arms, legs, hearts, Moors' heads, Saracens' heads, and that strange heraldic freak, the three legs conjoined, carried in the escutcheon of the Isle of Man.

Of plants, we have *roses*, *trefoils*, *cinquefoils*, *leaves*, *garbs* (sheaves of corn), *trees*, often *eradicated* or *fructuated* of some other color, and, above all, the celebrated *fleur-de-lis*, used as a badge by Louis VII. of France, before Heraldry had an existence. When a plant, or an animal, or other charge is blazone *proper*, what is meant is that it is of its natural color. The heavenly bodies, the sun, moon, and stars, are also pressed into the service of Heraldry, as are things inanimate and artificial without number, particularly such as were familiar to the warriors and pilgrims of the 12th and 13th centuries. Helmets, buckles, shields, hatchets, horseshoes, swords, arrows, battering-rams, pilgrims' staves, mullets (for spur-rowels), and water-bougets, or bags, in which in crusading times water was carried a long distance across the desert, also the clarion or war-trump, generally or erroneously called a *rest*. Even the letters of the alphabet have been used as charges. Charges may be placed either simply on the field or on one of the ordinaries; in some instances, one of the ordinaries is placed over a charge, in which case the charge is said to be *debruised* by the ordinary. Three charges of one kind are placed two above and one below, unless blazoned *in fess* or *in pale*. In the 14th and 15th centuries, the simplicity of early Heraldry began to be departed from by accumulating a variety of charges on one shield, and in later times we have sometimes a charge receiving another charge like an ordinary. The growing complexity of shields arose from the augmentations granted to distinguish the younger branches of a family, or charges assumed from the maternal coat by the descendants of an heiress. In the end of the last and beginning of the present century, a practice prevailed for a time of introducing into armorial bearings matter-of-fact landscapes, representations of sea-fights, and of medals and decorations worn by the bearer, setting all heraldic conventionalities at defiance, and dealing in details not discernible on the minutest inspection. Such charges are frequent in the arms of the heroes of the old wars; as, for an example, in the augmentation granted to Sir Alexander Campbell, bart., in addition to his paternal arms—viz., "A chief argent charged with a rock proper, subscribed *Gibraltar*, between two medals; and on the dexter representing the silver medal presented to Sir A. Campbell by the Supreme Government of India, for his services at the storming of Seringapatam, in 1799; that on the sinister representing the gold medal presented to him for his services in the battle of Talavera." The grants proceeding from the present Kings-of-Arms are made conformable to the usages of Heraldry, and do not stand in need of such lengthened explanations to make them intelligible. The arms of the different members of a family have been distinguished from one another, sometimes by the use of a bordure or other difference; and sometimes, especially by English Heralds, by the use of certain figures called *marks of cadency*, *the label*, *crescent*, *mullet*, *martlet*, *annulet*, *fleur-de-lis*, to designate the eldest, second, third, fourth, fifth, or sixth son and his descendants—an invention originating about the time of Henry VII., but which cannot consistently be carried through all the ramifications of a family for a succession of generations. *Blazonry* is an essential part of the science of arms. To blazon a coat is to so describe it that any one with an ordinary knowledge of Heraldry will be able to depict it correctly. In the language of blazonry, all tautology must be avoided. The tincture of the field is first mentioned; the ordinary, if any, follows, unless it be a chief; then the charges between which the ordinary is placed. The charges on the ordinary follow, and, lastly, we have a canton or chief, and marks of cadency. Besides the heraldic devices depicted on the shield, there are the following borne external to it—the helmet, the mantle, the wreath, the crest, the motto and scroll, the supporters, and the coronet. The *helmet*, originally a piece of defensive armor,, became in the course of time one of the usual accompaniments of the shield; and, placed over the arms, it came by its form to mark the rank of the wearer. For these distinctions, which are of comparatively recent date, and applicable only to British Heraldry, see HELMET. The *mantling* is an embellishment of scroll-work flowing down on both sides of the shield, and originating in the *cointoise*, or scarf, wrapped round the body in the days of coat-armor. From the center of the helmet, within a *wreath* of two pieces of silk of the first two colors of the armorial bearings, issues the *crest*, originally a special mark of honor worn only by heroes of great valor, or advanced to a high military command; now an inseparable adjunct of the coat of arms in English, though not in Continental Heraldry, and often assumed and changed arbitrarily without the proper authority. The *scroll*, placed over the crest or below the shield, contains a *motto* bearing in many cases an illusion to the family name or arms. *Supporters* are figures or animals standing on each side of the escutcheon, and seeming to support it. They were in their origin strictly ornamental devices, which only gradually acquired a heraldic character. In England, the right to use supporters is confined to the Royal Family, Peers, Peeresses, and Peers by courtesy, Knights of the Garter, Knights Grand Cross of the Bath, and a very few families whose ancestors bore supporters before their general use was restricted. In Scotland, supporters are also used by the Baronets of Nova Scotia and the chiefs of various families. The crown of the Sovereign, the miter of the Bishop, and the coronet of the Nobility are adjuncts appended to the shield of those whose dignity and office entitle them to that distinction. The subject of *marshaling arms*, or arranging various coats in one escutcheon, is explained in a separate article. Here it may suffice to lay down a few general rules. A husband is entitled to *impale* the arms of his wife, i.e., to place them on the same shield side by side with his own. When the wife is an heiress, the husband bears her arms in an *escutcheon of pretense*, or small escutcheon in the center of his own shield, and the descendants of the heiress may quarter her arms with their paternal coat. A Sovereign also quarters the arms of his several States, and feudal arms are quartered by subjects. An elective King may place his herditary arms on an escutcheon of pretense over the insignia of his dominions.

HERALDS' COLLEGE.—A collegiate body, founded by Richard III. in 1493, consisting of the heraldic officers of England, who were assigned a habitation in the Parish of Allhallows-the-Less, in the city of London. See *College of Arms*.

HERBORT SYSTEM OF FORTIFICATION.—In this system, the angles of the polygon are covered by casemated reduits, surrounded by barracks loop-holed for musketry and artillery. These are flanked by two redoubts, covered by a glacis, before which stands a counter-guard. The extremities of these course-faces form a low flank before the redoubts. Defensive barracks connected by an earthen parapet form a general retrenchment. An envelope of counter-guards flanked by lunettes, which have also their glacis, casemates, extra flanks, etc., surrounds the whole. The system is ingenious; but, the outlay is enormous. The unrevetted parapets and the flanks rising in tiers would expose it to an attack of vive force, and it would also suffer much from ricochet.

HERCOTECTONIQUE.—A term in fortification signifying that branch of military architecture which specifically points out the best means of defense and the surest method of providing stores. The word is derived from the Greek.

HERCULES POWDER.—A mixture of carbonate of magnesia with carbonizing and oxidizing materials, combined with nitro-glycerine in varying proportions, to produce different grades of explosiveness. Although Sobrero well established the fact that nitro-glycerine was a powerful explosive—and about 1852 the French Academy made several practical tests showing it was an agent of great importance, and scientific men occasionally wrote upon the subject—the article of glycerine had not yet been produced in large quantities, mostly on account of the expense attending its manufacture, which was still in its infancy; and hence the manufacture of nitro-glycerine had remained wholly impractical, for common mining and engineering purposes, until about the year 1862. The Hercules Powder Company, well knowing that nitro glycerine had been used as mixed with gunpowder many years before, commenced the manufacture of a high explosive, in 1868, compounded in that manner. But it was found that all these mixtures of the nitro-glycerine compounds were faulty in two particulars, viz:—1st. A tendency to decomposition when exposed to much summer heat, or long storage or use in very hot mines, etc., in consequence of some small particles of nitric acid remaining in the nitro-glycerine, rendering it more or less dangerous from decomposition. 2nd. The noxious fumes arising from this decomposition, both in storehouses and in the mines, causing nausea and headache and in some cases weakening the quality of the powder. As a remedy for the first, the carbonate of magnesia entirely neutralizes any free acid that may chance to remain in the nitro-glycerine, and converts it into nitrate of magnesia, which is explosive, and renders it so perfectly free from any liability to spontaneous combustion that it may be safely stored, for many months, in the hottest weather, or be transported through the longest voyages in the tropics, without undergoing any chemical change. The remainder of the mixture is compounded upon strict chemical principles to neutralize noxious fumes that would otherwise be generated. See *High Explosives*.

HEREFARE.—An old term from the Saxon, signifying the same as warfare.

HEREGELD.—A term derived from the Saxon, signifying a tax which was formerly levied for maintaining an army.

HERESILIA. A term derived from the Saxon, signifying a soldier who abandons his colors, or deserts the service. Also written *Heresliti*.

HERETOCH.—The leader or the commander of an army. The term frequently means a Constable or Marshal, and is sometimes written *Heretog*.

HERETUM.—A court in which the guards or military retinue that usually attended the old British Nobility and Bishops were accustomed to draw up.

HERÔATE. A term derived from the Saxon signifying a tribute which was paid in ancient times to the Lord of the Soil, to enable him to carry on war.

HERISSON.—A formidable hedge or chevaux-de-frise. It is made of one stout beam fenced by a number of iron spikes, and which, being fixed upon a pivot, revolves in every direction upon its being touched, always presenting a front of spikes.

HERLIN SYSTEM OF FORTIFICATION.—This system proposes an enciente of detached bastions and javelins, and divides the town into quarters by double cavaliers erected behind the gorge of the bastions. The ramparts are casemated with a double parapet and a fausse-braye.

HERMANDAD.—An Association of the principal cities of Castile and Aragon, bound together by a solemn league and covenant for the defense of their liberties in seasons of trouble. These Confederacies were sanctioned by the Sovereigns, as agents for suppressing the increasing powers of the Nobles, and for maintaining public security through the land with no cost to the Government. In Aragon, the first Hermandad was established in the middle of the 13th century, and in Castile about 30 years later; while in 1295, 35 cities of Castile and Leon formed a joint Confederacy, and entered into a compact, by which they pledged themselves to take summary vengeance on every Noble who had either robbed or injured a member of their Association and refused to make such atonement for the wrong; or upon any one who should attempt, even by the order of the King, to levy an unjust tax. During the long period of Anarchy in which the Christian Rulers of Spain were impotent to maintain order in their own Dominions, the *Santa Hermandad*, or Holy Brotherhood, had presented the only check against the unbounded license of the Nobles; and Isabella of Castile, seeing the beneficial effects which an extension of the Institution was capable of producing, obtained the sanction of the Cortes for its thorough reorganization and extension over the whole Kingdom in 1496. The crimes reserved for its jurisdiction were all acts of violence and theft committed on the high-roads or in the open country, and the penalties attached to each misdemeanor were specified with the greatest precision in the codes of laws which were enacted at different times in the yearly assemblies of the deputies of the Confederate cities. An annual contribution was, moreover, assessed on every hundred householders or *vecinos* for the equipment and maintenance of the horsemen and the *quadrilleros* or officials of the Brotherhood, whose duty it was to arrest offenders and enforce the sentence of the law. Although the Hermandad was regarded with much disfavor by the aristocracy, it continued for many years to exercise its functions, until the country was cleared of the banditti and the Ministers of Justice enabled to discharge their duties without hinderance from lawless disturbers of the peace. In 1498, the objects of the Hermandad having been obtained and public order established on a firm basis, the Brotherhood was disorganized, and reduced to an ordinary police, such as it has existed, with various modifications of form, until the present century. The laws enacted at different times in the Juntas or Assemblies of the Hermandad were compiled, in 1485, into a code, known as the *Quaderno de las Leyes nuevas de la Hermandad*, which was first printed at Burgos in 1527.

HEROES.—In the Homeric period, Kings, Princes, Generals, Leaders, all brave Warriors, and men who excelled in strength, courage, wisdom, and experience. Many of these had, on account of such qualities, a fabled origin, half human, half divine, and were honored, after death, with a kind of adoration or inferior worship. These heroes and demigods were recognized as the special patrons or protectors of particular countries or cities, and to them were raised temples and altars. These examples of heroic character, held up constantly to the admiration and imitation of peoples, tended to strengthen their peculiar character, and to impress them with the greatness and glory of courage, contempt of danger, and nobility of purpose. Poetry exalted the heroic sentiment to sublimity; and poems which celebrated the deeds of heroes are themselves termed heroic. The imaginary time when heroes and other semi-divine beings lived on earth was commonly called the Heroic Age.

HERRISON.—In Heraldry, the hedgehog, a charge allusively borne by families of the name of Harris.

HERSE.—In fortification, a kind of gate or portcullis, with iron bars like a harrow, set in with iron pikes, placed above gates and lowered, to impede the advance of an enemy. It is usually hung by a rope and is fastened to a moulinet, which is cut in case of a surprise, or when the first gate is forced by a petard, so that it may fall like a portcullis and stop the passage of a gate or any other entrance of a fortress.

HERSILLON.—A strong beam, whose sides are stuck full of spikes, which is thrown across the breach made by an enemy to render it impassable. See *Herse*.

HERULI.—A nomadic and warlike German tribe, who inhabited the north shores of the Black Sea, but afterwards divided into sections and wandered into different parts of Europe. They first appear in history in the third century as taking part with the Goths in their excursions against the eastern provinces of the Roman Empire. In the fourth century they acknowledged the supremacy of the Gothic King Ermanric, but when Attila, King of the Huns, made his descent upon Gaul, they joined his standard. After the overthrow of the Huns, in which they suffered considerably, they established an organized and distinct Confederacy on the banks of the Danube, and under the leadership of Odoacer, assisted in 476 in the overthrow of the Western Empire. Under their King Rudolph they, in the beginning of the sixth century, attempted the subjugation of the Longobardi, but were defeated and dispersed, some of them proceeding to Scandinavia, and others being allowed by the Emperor Anastasius to settle on the south bank of the Danube. In the time of Justinian some of them embraced Christianity. A large portion of them afterwards joined the Gepidæ in their wars against the Eastern Empire; but others fought with Justinian against the Vandals and East Goths. Towards the end of the sixth century they were merged into other nations, and disappeared from historical records. The Heruli were bold, hardy, and extremely pugnacious. For a considerable period they retained their strong individuality, and presented a firm resistance to the influences of civilization. They are said to have offered human sacrifices. Also written *Æruli*, and *Eruli*.

HESSIANS.—Troops belonging to Hesse-Cassel, Prussia. They have been frequently hired in Great Britain, particularly in the war of American Independence, when they were sold at £40 sterling a head, £9 of which was to be repaid if returned alive.

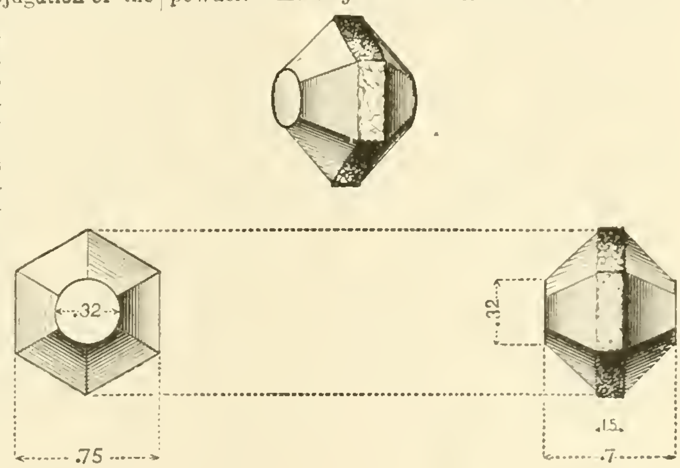
HETMAN.—The title of the Head or General of the Cossacks, now retained only among the Cossacks of the Don. From the earliest times the Hetman was elected by the voice of the assembled people; the mode of election being by throwing their fur-caps at the candidate they preferred, and the one who had the largest number of caps was declared duly elected. The power of the Hetman was very great, and extended over life and death. When the Cossacks in 1644, submitted to the Russians, the Hetman was permitted to retain his rights as formerly. The Empress Catherine entirely abolished the dignity of Hetman of the Ukraine, and substituted a Government consisting of eight members. The Don Cossacks have, indeed, retained their Hetman, and even he possesses but the shadow of his former power. The latest elective Hetman was Count Platoff, who played a prominent part in the wars with France (1812-14). After his death the Hetman was appointed by the Czar, and ultimately the title was made hereditary in the Grand Duke, the heir to the throne. Also written *Ataman*.

HEURTEQUINS.—Two pieces of iron resembling a knocker, which are placed over the trunnions, or axis of a cannon.

HEUSE.—An iron shoe, sometimes called *pedieux*, attached to the greaves of ancient armor, having an iron sole, and the upper composed of mail.

HEXAGONAL POWDER.—Experiments were made at Fort Monroe in 1872 and 1873 with what is known as hexagonal-grained powder, manufactured by the Messrs. Dupont & Co., of Wilmington, Del., which demonstrated its superiority for heavy ordnance, giving low maximum pressures, with good velocities and great uniformity of action. One of the samples was selected for proof of the converted 8 and 9-inch rifled guns in 1874. Hexagonal powder has been employed since that date in trial and proof of all 8-inch converted guns. The uniform size of grain, and their polyhedral shape, insure great uniformity in position and size of the interstices in the make-up of the cartridge; this insures with a uniform density of grain a high degree of uniformity in pressures and velocities from given charges of powder and weights of projectiles. The drawing shows the shape and dimensions of this powder, the specific gravity being 1.7511.

The proportions of the ingredients of hexagonal powder conform to the United States standard, and up to the completion of the incorporation in the wheel-mill, its manufacture is like that of ordinary powder. *Mealing*—The wheel mill-cake is revolved



in a cylinder of wire-wove cloth, with wooden-balls, until it is mealed. *Pressing*—The mealed powder is then carefully pressed between horizontal metallic plates or dies. The powder comes out in a sheet or cake of polyhedral granules united along their vertical edges, the dies being nearly perfect dodecahedrons. *Graining*—The press-cake is passed between rollers armed with brass cutting teeth at an angle of from 60° and 120° to the axis, which cut the cake into granules, their cross-section being almost *hexagonal*, whence the powder derives its name. *Glazing*—The powder is then sent to the glazing-mill and glazed. *Brushing*—The powder is next passed repeatedly through the brushing-machine. This consists of a frame with brushes revolving near an inclined plane along which the powder passes by the motion of the brushes. *Drying*—The brushing ended, the powder goes to the dry-house where it is dried. The powder is now minutely examined, its specific gravity is taken, and a count made of the granulation; a variation of two granules to the pound being enough to condemn the powder. *Re-brushing and re-drying*—If satisfactory, the powder is again passed through the brushing-machine, re-dried, and then receives a third brushing. *Packing*—The powder is finally packed in barrels and is ready for inspection. See *Gunpowder*.

HIBERNIAN ROYAL SCHOOL.—A School established in Great Britain for the maintenance of 350 children of military officers who are supported and educated at the School, at an expense of £7,000 per annum to the country.

HIDE-BOUND.—A term which, when applied to a horse, signifies that his skin cannot be pulled up or raised from his ribs and back; caused from bad keep, poverty, internal disease. The remedy consists in good grooming and diet, with gentle medicine and keeping the animal warm.

HIDES.—The skins of buffaloes, cows, bullocks, and other animals. Buffalo-hides are used in India for the manufacture of buff accouterments, belting of machinery, etc.; bullock or cow-hides for mending cartouches and priming-pouches, and a variety of other leather-work. Buffalo-hides which have undergone the process of tanning are used for covering the floors of powder-houses and charge magazines.

HIERARCHY.—The essential element for the government and service of an Army is a military hierarchy or the creation of different grades of rank, to which different functions and powers are assigned, the lower in regular subordination to the next higher in the ascending scale. It should be founded on the principle that every one acts in an Army under the orders of a Superior, who exercises his authority only within limits established by law. This authority of the Superior should be greater or less according to rank and position, and be proportioned to his responsibilities. Orders should be executed without hesitation; but responsibilities should be confined to him who gives orders in virtue of the superior authority with which he is invested; to him who takes the initiative in an order; to him who does not execute an order that he has received; and to him who usurps a command or continues illegally to exercise its functions. The military hierarchy is determined and consecrated within its sphere of action by:—1. Grades of rank created by military laws; 2. By other laws regulating the exercise of rank; 3. By military insignia; 4. By military honors: and 5. By the military oath.

HIGH-ANGLE FIRE.—The fire from guns, howitzers and mortars at all angles of elevation exceeding 15°. See *Fire*.

HIGH EXPLOSIVES.—The name given to the various nitro-glycerine compounds. The value of these compounds depends in a very great measure upon the quantity of nitro-glycerine contained in them. The table herewith gives the distinguishing marks adopted by the leading manufacturers of high explosives in the United States, and the percentage of nitro-glycerine contained in the powder they represent. See *Explosive Agents*.

HIGHLAND REGIMENTS.—The origin of the first of these regiments, the 42d, has been given under the head Black Watch. The valuable services of this regiment encouraged the Government to augment the force; and accordingly seven other Highland Regiments have been raised from time to time —viz., the 71st, in 1777; the 72d, or Duke of Albany's Own, in the same year; the 74th, in 1787; the 78th, or Ross-shire Buffs, in 1793; the 79th, or Cameron Highlanders, in 1805; the 92d, or Gordon Highlanders, in 1796; and the 93d, or Sutherland Highlanders, in 1800. The uniform of each of these corps is the Highland dress, including a distinctive tartan. The soldier wears a coatee of scarlet, a kilt (in most, but not all, of the regiments), a plaid across the shoulders, a plume, and the other attributes of the Gaelic costume. In an army where officers are appointed by general competition, nationality is necessarily disregarded; but these Corps are those in which Scotch gentlemen most frequently seek appointments, and a large proportion of the officers are Scotch. Of the men, at least 79 per cent. are Scotch, 11 per cent. English, and 10 per cent. Irish. The regiments are recruited at Stirling, Aberdeen, Perth, Fort George, and Lanark.

HIGH SEAS.—The open sea, including the whole extent of sea so far as it is not the exclusive property of any particular country. The rule of international law is that every country bordering on the sea has the exclusive sovereignty over such sea to the extent of three miles from its shore; but all beyond, and which is not within three miles of some other country, is open or common to all countries. The part of sea within three miles' distance is generally called the territorial sea of the particular country, or *mare clausum*. The distinction has little effect on the right of navigation, but as regards fishing it is otherwise. Thus, for example, foreign fishermen have no right to fish within three miles of the British coast without a license from the Crown, or unless some special treaty—as for example, the French and English treaty—has laid down other arrangements.

HIGH STEEL.—For the construction of cannon, steel may be divided into *high* and *low* steel, the difference being that the former contains more carbon that the latter. High is very hard and has a great ultimate tenacity. It has but little extensibility either within or without its elastic limit; it is therefore too brittle for use in cannon, unless used in such large masses that the elastic limit will not be exceeded by the explosive force of the powder. It melts at a lower temperature than wrought-iron, and is difficult to weld as its welding temperature is but little less than that at which it usually melts. See *Steel*.

HIGH TREASON.—Treason against the State or the security of the Sovereign, whether by imagination, word, or deed. In the United States, treason is confined to the actual levying of war against the

United States, or any adhering to their enemies, giving them aid and comfort. See *Treason*.

HILT.—The handle of a cutting instrument, especially of a knife or sword. *Hilted* is a term used in Heraldry, to indicate the tincture of the handle of a sword.

HINNY.—The hybrid produced between a horse and a female ass. It is smaller than a mule, but the body is more bulky in proportion to the legs, and its strength is inferior. It is less valuable than the mule, although it is more docile. The hinny is rare. It was described by some of the earlier naturalists as a hybrid between the ox and the ass, and even Buffon seems to have entertained this notion.

HIPPODROME.—The Greek name for the place set apart for horse and chariot races. Its dimensions were, according to the common opinion, half a mile in length and one-eighth of a mile in breadth. In construction and all important points of arrangement, it was the counterpart of the Roman circus, with the exception of the arrangement of the chariots at the starting-place. In the hippodrome, the chariots were arranged so as to form two sides of an isosceles triangle, with the apex towards the goal and a little to the right side. But as this would have given the chariots on the left side a longer course than those on the right, the hippodrome was constructed with the right side longer than the other. The start was effected by setting free the chariots on the extreme right and left, when they came opposite the next two, by setting them free also, and so on till all were in motion. The hippodrome was also much wider than the Roman circus, to allow room for the greater number of chariots, for though we have no precise information as to the number that usually started in one race, we know that Alcibiades on one occasion sent seven; Sophocles mentions ten chariots, as competing at the Pythian games; and the number at the Olympic games must have been considerably greater. There is a beautiful description of a chariot-race in Homer (*Iliad*, xxiii. 262-650). The golden age of the hippodrome was during the lower Greek Empire. The blue and green factions in the hippodrome carried their animosity into all departments of the public service, and laid the foundation of that perpetual disunion which rendered the Byzantine Empire a prey to every aggressor.

HIRCARRAH.—An Indian term for a messenger, guide, footman, or a spy. Sometimes written *Hircarra*.

HIRING OF DUTY.—Hiring of duty is forbidden in all Armies. In the United States, the Articles of War provide that no soldier, belonging to any regiment, troop, battery, or company, shall hire another to do his duty for him, or be excused from duty, except in cases of sickness, disability, or leave of absence. Every such soldier found guilty of hiring his duty, and the person so hired to do another's duty, shall be punished as a Court-Martial directs. Every Non-commissioned Officer who connives at such hiring of duty shall be reduced. Every Officer who knows and allows such practices shall be punished as a Court-Martial may direct.

HIRPINI.—A people of Italy who inhabited the south portion of Samnium. They have been considered by some authorities as merely a Samnite tribe, while by others they are looked upon as an independent nation. The country they inhabited was the wild and mountainous district traversed by the Sabatus, Calor, and Tamarus, tributaries of the Vulturnus, and on the east side of the Apennine ridge, the upper course of the Aufidus. In the early history of Rome the Hirpini are found identifying themselves with their Samnite neighbors against their common foes. They seem to have been subdued in the early part of the third century B. C., as in 268 B. C., Beneventum, the key of all their military postions, was colonized by Roman settlers. They appear in history for the first time as an independent people after the second Punic War. Revolting from their old Conquerors, they joined the Carthaginian Invaders, and though they were unable to retake the stronghold of Beneventum, they kept faithful to Hannibal till defeat at the Metaurus restored the Empire of Italy to his opponents. In the year of that event the Hirpini made peace with their old masters by betraying into their hands the garrisons of their Allies. From this time till the outbreak of the Social War, the Hirpini seemed to have continued steadfast in their allegiance. On that occasion, however, they set the example of revolt to the Allies, and might have become formidable enemies, had not the rapid successes of Sulla induced them to repair their error by a complete submission. At the close of this war the Hirpini obtained the franchise, and do not again appear in history as an independent people. Their towns were Beneventum, Aeculanum, Equus, Tuticus, Trivicum, Murgantia, and Aquilonia.

HISTORY.—Military history may be defined as a narrative or description of the several military transactions, as campaigns, battles, sieges, marches, etc., of armies. A thorough knowledge of this branch of history is necessary to make the military man apt in his profession, self-reliant, and capable of command. It is indeed the secret of many a Commander's success in the varied positions he is placed in his career, as in the study of military history he finds a precedent for every strategic emergency, and a solution of the many difficult problems in the art of war, which great Generals have overcome. The study of military history further tends to create high aspirations after military glory, from the perusal of deeds of valor performed by men who have devoted and virtually sacrificed their lives for the good of their country.

HITCH.—The name given to certain knots, such as the *timber-hitch*, *clove-hitch*, and others. These knots are very valuable for artillery and engineer purposes, the advantage being that, as long as the strain is kept upon them, they never give way. Hitches may be described as overlaying a part of a rope with itself in such a manner that a loop or loops are formed to jam on each other. See *Knots*.

HITCHCOCK FORGING.—This system of forging is designed to insure sound welding in the fabrication of large cannon. The iron is heated in a reverberatory furnace, to avoid its contact with sulphur and other impurities of coal. The gun is forged of rings of wrought-iron, or low-steel made without welds, and upset or butted together, as by Ames's process. The rings are so formed as to be united first in the center, that the superfluous cinder may be squeezed out. An anvil is seated on the piston of a hydrostatic press, so as to be lowered as the successive rings are added. A furnace is situated between the anvil and a steam-hammer, and so arranged that the rings project into it from below, and the hammer drops into it from above. The ring to form the muzzle of the gun is laid upon the movable anvil and projected sufficiently into the furnace to allow the flame to raise it to the welding heat. Meanwhile, in another part of the furnace, the rings are heated to welding in the same time, by proportioning the heat, by means of dampers to the relative bulks of the two parts. Without removing the parts from an atmosphere in which there is very little if any oxygen, they are laid together and instantly welded by a few strokes of the steam-hammer. The anvil is then lowered by the thickness of another ring, and the same process is repeated.

Although the *gun* may be of any size, the parts actually united at one operation, may be made so light by reducing their thickness, that the pressure of a hammer of moderate weight will be adequate. And when the whole operation of upsetting is confined to one joint, exactly the requisite pressure for that joint can be applied; and there is no fear of injuring other parts by setting it up soundly, because the mass of the gun below it is cold, and forms a rigid pillar—practically a continuation of the anvil. It would appear that all the conditions of sound welding may thus be attained, if the process can be practically carried out. This process was intended especially for fabricating guns of low-steel, the rings to be made without welds, by being originally cast in the form of small thick rings, and then rolled, in a modification of the tire-rolling machine, to a larger diameter and a smaller section. This treatment would develop an endless grain in the rings, in the direction of the circumference.

HOBBLE—HOPPLE.—A fetter for horses, or other animals, when turned out to graze—chiefly used in the plural. When in the vicinity of the enemy or horse-thieves, the stock may be permitted to graze,

and at the same time be secured by means of the *hopples* or *side-lines*. They are likewise of inestimable value for use on animals prone to stray far away from the camp or herds. The drawing shows the usual form of their construction, the fetlock straps being made of a thick leather, the inside smooth and soft, and the sewn edges uppermost when on the animal's legs. For military purposes, it is decidedly better to have the leglets made of steel, with a light connecting lock and chain of the same material. Leather hopples deteriorate in strength upon exposure to moisture and the weather, and may be readily cut and removed by the enemy or robbers. Steel hopples have the advantages of being less cumbersome, much more secure, lighter in weight, and can be placed on or taken off the animal with greater facility, by those having the means of unlocking them. In the absence of this very important equipment, the soldier may successfully hopple his horse with a stirrup-leather, by putting its middle round one fetlock, then twisting it half-a-dozen times, and finally buckling it round the other fetlock.

HOBILERS.—An inferior variety of cavalry used or raised in the reign of Edward II. They were stationed at Portsmouth and at other maritime places, and bound to keep a little flag for the purpose of giving notice of invasion. They wore an aketon or armor of plates, a bascinet, iron gauntlets, a sword, knife, and a lance. Also written *Hobeliers*.

HOBITS.—Small mortars of 6 or 8 inches bore, mounted on gun-carriages; they were in use before the howitzer.

HOCHE BOS.—Certain soldiers among the ancients, who were so called from their brandishing the pike. This term has likewise been applied to the pike itself.

HODOMETER. An instrument for measuring the distance traveled over by any conveyance, and consisting of an arrangement of toothed wheels, like clock-work, fixed on one side of a machine, and connected with the axle, from which motion is communicated to it. An index and dial show the exact distance the vehicle has traveled. See *Odometer*.

HOG-GUM.—The name given in the West Indies to a resinous substance, which is there extensively used as a substitute for pitch to tar boats and ropes, also for strengthening plasters, etc., and internally as a diuretic, laxative, and stimulant medicine. It is still disputed what tree produces the true hog-gum; some ascribing it to *moronobea coccinea*, of the natural order *guttiferæ*; some to *rhus metopium*, a species of sumach of the order *anacardiaceæ*; and others to *helwigia balsamifera*, of the order *amyridaceæ*. The probability seems to be that all these—and perhaps other—trees yield resinous substances of very similar quality, and commonly designated by the same name.

HOIST.—1. The perpendicular height of a flag, as opposed to the *fly*, or breadth from the staff to the outer edge. 2. A machine for hoisting ores, metals, castings, workmen, etc., in mines and foundries. A very primitive hoisting-machine, which resembles the modern capstan, is used in the Convent of St. Catharine, at the foot of Mount Sinai, to raise travelers to a door in the second story. This is a somewhat inconvenient and tedious operation, but is used in a land where robbers go on horseback. It is also worthy of remark, that the people of the land have no idea of the value of time, and so set six men to help another in at the door. The obelisks in ancient Egypt may have been raised by gradually lifting the apex and scotching up by introducing earth beneath them. The Stonehenge blocks were very probably raised in the same way. When Chersiphon built the Temple of Ephesus, in the time of Amasis of Egypt, he raised the architrave by surrounding the columns with bags of earth, which served as an inclined plane.

HOISTING APPARATUS.—In designing and building machinery for hoisting and transferring light loads, many of the same problems are presented

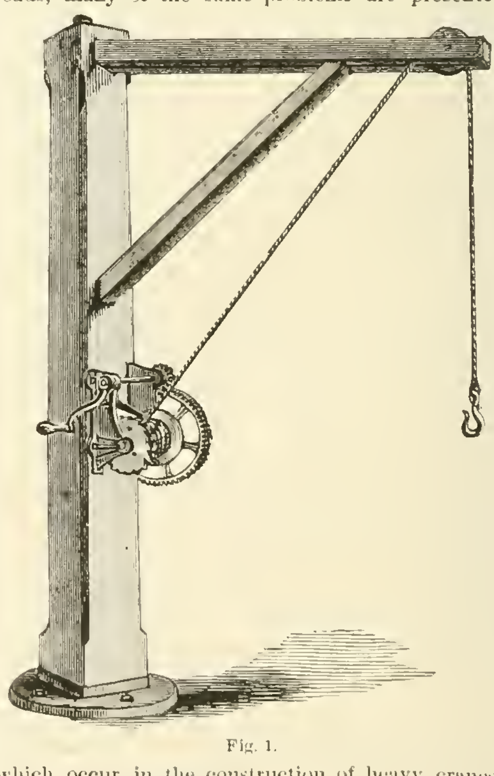

Fig. 1.

which occur in the construction of heavy cranes, and the experience gained in one is available in the other. Too much has heretofore been left to "rule of thumb" practice in the designing of light hoisting machinery, and frequent accidents to life and limb still needlessly occur from continued adherence to old types of machines in which safety, both of person and load, depends upon the care and intelligence of the operator. It is possible to so construct hand-hoisting machinery that accidents arising from carelessness in its use are practically impossible. Such construction involves no sacrifice of simplicity or efficiency, and no material increase in cost. To adhere to the old, therefore, is to assume needless risks to property and unjustifiable risks to human life. The risks referred to arise chiefly from two causes; *first*, a deficiency of material in parts subject to strain; and, *second*, the use of ratchet-wheels to hold the load suspended, and of non-automatic brakes to effect lowering. The first defect, a want of proper kind or amount of material, arises from unskilful designing and from the effort after cheapness. The second is adherent in the elements of mechanism employed, and can only be avoided by the use of new and better devices, so constructed as to be automatic in all functions where carelessness is potent to produce harm.

The active operation of *hoisting* is usually free from danger in any machine of sufficient strength. It is the *descent* of the load, whether by intent or by accident, that involves danger. During the act of hoisting the operator slowly expends power, which is stored up as latent energy in the mass he has raised, and which, if expended or given back suddenly, as in falling, is capable of working serious mischief. The mechanism should, therefore, be so constructed that the load, when lifted, shall be sustained independently of the operator, so that should he cease his efforts, or even suddenly let go the rope or handles, the load will simply cease to move and will remain suspended. Under no circumstances should the load be permitted to descend by gravity unaided by the controlling hand of the operator. This principle of construction, namely, the control of the load, at all times and under all conditions, by reliable automatic devices, is embodied in all of the hoisting appliances described in this work, designed and built by the Yale and Towne Manufacturing Company.

Winding-drums or barrels should have a diameter and length such as will enable them to receive the whole length of rope or chain to be hauled in by winding it upon their surface in one coil, without overlapping. In large cranes the load is usually carried upon four, six, or even eight parts of rope or chain, so that the length to be wound up amounts to four, six, or eight times the effective hoist, and the dimensions of the barrel thus become very large. Moreover, this barrel must either be caused to travel longitudinally on its shaft, so that the rope or chain as it leads off shall be always in the center of the crane and hoisting mechanism (which method of construction involves a serious complication and greatly widens the space occupied by the gearing), or the rope or chain, as it uncoils, be permitted to vary in position from one end to the other of the barrel, in which case it is nearly out of center, thus inducing objectionable lateral strains and causing greater friction and wear. Fig. 1 shows a simple arrangement of gears and crank, winding the lifting rope on drum or cylinder. It may be easily fastened on any post, or part of a building, or used in connection with a crane as shown.

Chain-wheels require a width only slightly greater than a single part of the chain, and a diameter merely sufficient to give the proper engagement with it, so that both dimensions become much smaller than in a winding-barrel, and the total space occupied is but a small fraction of that required for the latter device. The *chain-wheel* is fixed in direct line with the chain, and all lateral strains are avoided, while the flat bearings afforded for the chain by the pockets preserve the shape of the links and protect them from bending strains. The slack chain, after passing over the wheel, falls into a proper receptacle below. From this analysis of the facts is deduced the proposition that chains, if well made, constitute the best form of flexible cord for sustaining the load in a crane, and that a well constructed *chain-wheel* (as contradistinguished from a winding-barrel) is the best form of device for hauling in and paying out the chain; and, therefore, that the best method of crane construction involves the use of these two elements.

When using the chain-wheel system, great effort must be made to secure chains of perfectly uniform pitch. Chain-making is one of the few remaining manual trades in which modern machinery has not to a greater or less extent displaced the skill of the individual workman. Many attempts have been made to produce chains by machinery, and although some success has been attained, no machine-made chain has yet been produced having sufficient reliability and uniformity of quality to adapt it to use in cranes. The all-important operation in chain-making is the process of welding the links, and in this the personal element seems indispensable to a perfect result, no machine, however perfect, taking the place of the skill and intelligence of the workman.

As used in the Weston cranes, the pitch-chains of the smaller sizes are made entirely of Norway iron, while for the larger sizes either the Norway iron or American iron of high elasticity and ductility, is used. Each link is forged and welded with great

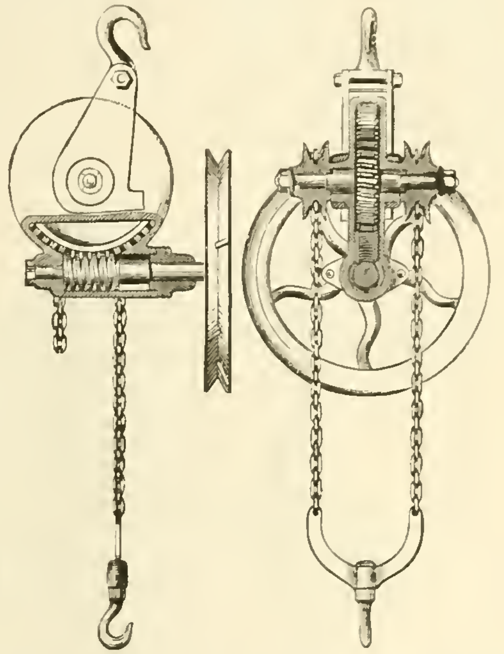

Fig. 2.

care, and much more time and labor is expended on this part of the work than is the case with common chain. All of this pitch-chain is made under a patented process, which consists in forging the chain slightly under pitch, after which it is first cleaned and brightened by "rattling," and then stretched in a special machine to the final gauge or pitch. The first process causes the several links to come into more perfect contact or bearing by removing the scale and other slight asperities from their surfaces. The second process assists in bringing their adjacent surfaces into closer contact, tends to strengthen the sides of the links, and gives the iron a slight initial set by straining it to a degree somewhat greater than that which will be caused by the load which it is intended to carry. The final step in the process is a careful and rigid inspection of each link of the chain and the removal of any which are at all imperfect. As a result of this treatment, a chain is obtained which is accurately uniform in pitch, and which, when used within the intended limit of load, will not stretch or alter its pitch. It is believed that the chain thus produced is more perfect and reliable than any made heretofore.

In determining the diameter of iron for the several sizes of chain, those sizes have been adopted which will limit the stress upon the links of the chain to a maximum of from 9,000 to 10,000 lbs. per square inch of cross-section when carrying the full load. As the pitch-chain was designed primarily for use in the Weston Differential Pulley-blocks, in which the load is always carried upon two parts of chain, the nominal capacity of the several sizes indicates in each case the maximum load intended to be carried upon *two parts* of the chain. A single part is, of course, capable of carrying a load of one-half the amount given in the table. The following table gives the dimensions of the several sizes of the pitch-chain above described.

Nom'al cap'y, Tons*	$\frac{1}{8}$	$\frac{1}{2}$	1	$1\frac{1}{2}$	2	3	4	5	6	8	10
Diam. iron, inch's...	$\frac{3}{16}$	$\frac{1}{4}$	$\frac{9}{32}$	$\frac{5}{16}$	$\frac{3}{8}$	$\frac{7}{16}$	$\frac{1}{2}$	$\frac{9}{16}$	$\frac{5}{8}$	$\frac{11}{16}$	$\frac{13}{16}$

*The upper line indicates the load which can be safely carried on two parts of the chain, i.e., as used in a one-sheave tackle-block. Each part of the chain thus carries one-half of the total load If the load is to be carried by a single chain, select a chain of a nominal capacity of twice the intended load.

Fig. 2 gives a sectional view of a double-chain screw hoisting-machine.

Many advantages accrue from the use of worm-gearing in the construction of hoisting machinery. Among these may be mentioned its compactness as compared with spur-gearing, the ability to operate shafts at right angles to each other without resort to bevel gears, and great facility in the application of automatic brakes where necessary. In well proportioned worm-gearing with cut teeth, friction cannot be relied upon to hold a suspended load from running down, but a very moderate brake resistance applied to the worm-shaft will accomplish this result. If a load suspended through a train of spur-gearing be allowed to run down, it will do so at an accelerating velocity approximating to that of a falling body. With the worm-gearing, however, very little acceleration takes place after certain speed has been attained, and gearing of this kind thus becomes a safety device which prevents undue acceleration of the load even when running free, and is a most valuable means of preventing accidents, both to the mechanism and to those operating it.

The ordinary ratchet-wheel is a disc with teeth or indentations on its periphery, and in practice it is employed in combination with a pawl or a dog arranged to engage with its teeth in such a manner that the ratchet-wheel, being attached to a rotating shaft, is entirely free to revolve in one direction, but, by the action of the pawl, is prevented from rotation in the contrary direction. Thus arranged it is generally attached to the primary shaft of a winch, or other hoisting-gear, so that, while it opposes no resistance to rotation of the shaft in the direction necessary for hoisting, it effectively prevents motion in the contrary direction. When it is desired to lower the load the pawl is thrown out of engagement with the ratchet-wheel, and the load then lowered by turning the cranks backward, or by letting go of the cranks and controlling the descent of the load by a brake applied to the shaft.

Both of these arrangements are dangerous, and are productive of serious accidents. Where lowering is effected by turning the cranks backward with the pressure due to the load upon them, it frequently happens that a heavy load overcomes the operator, in which case the cranks begin to revolve with great

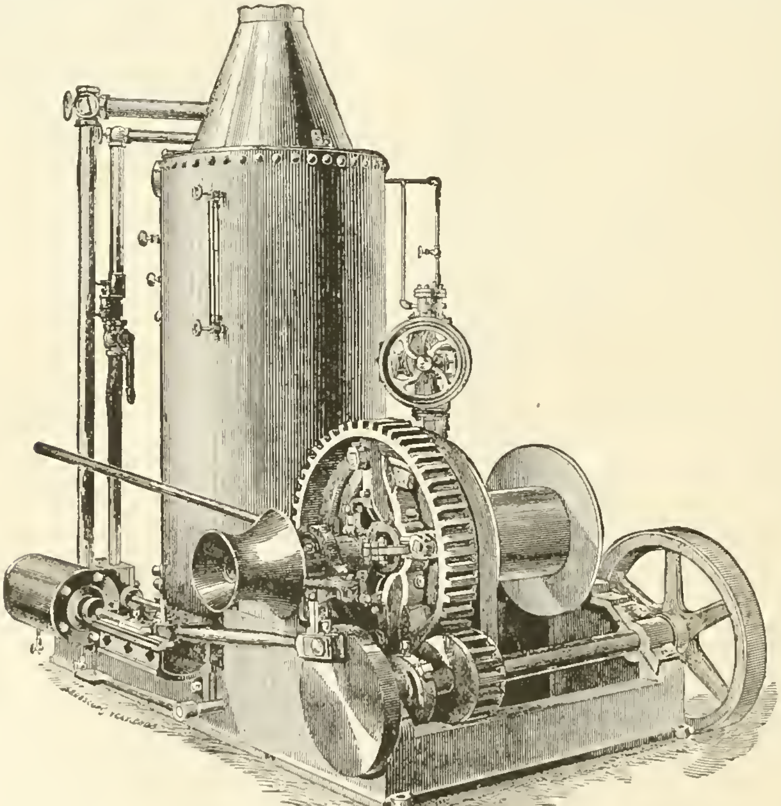

Fig. 3.

violence, and often strike the operator before he can escape from their reach. Where a brake is used, there is less danger, but even the safe descent of the load is contingent upon the skill with which the brake is used, and any lack of skill or watchfulness will result in a rapid descent of the load. In this case, if the motion is not checked the load may descend so rapidly as to cause damage, while if its motion be suddenly arrested by the brake, the shock and strain thereby induced are apt to damage the crane.

A friction ratchet is one in which the action of friction is substituted for the teeth and pawl of the common ratchet, so that the retaining action of the ratchet will take place instantly and in all positions. A safety ratchet may be defined as one in which lowering of the load is effected by reversing the motion of the shaft to which the ratchet is attached without any disengagement of the pawl or its substitute, the construction being such that so long as this backward motion is continued the load will descend, but that when it is discontinued the load will automatically come to rest, from which it follows that with a safety ratchet the cranks or handles of a hoisting-machine may be "let go" at any time, either in hoisting or in lowering, the ratchet thereupon automatically holding the load suspended and preventing "running down" or descent of the load. The great desirability of so important a result has long been conceded, but most of the devices heretofore invented for its accomplishment have been so complicated, or so uncertain in action, as to find little favor.

In cranes operated by power one or more clutches are essential to the convenient operation of the mechanism. Experience has demonstrated that the best and most reliable clutch for this purpose is that invented and patented by Mr. Thomas A. Weston, M. E., and first fully described in a paper read by him before the British Institution of Mechanical Engineers. The essential basis of the Weston clutch or coupling consists of two series of friction discs arranged alternately with each other upon a common axis, one series being carried by one shaft, and the other series connected to the other shaft or wheel which is required to be coupled with the first shaft. The great advantage arising from this alternate arrangement of the discs is that the frictional effect of any pressure applied to couple them is repeated as many times as there are discs in the two series, that is, the number of all the discs is a constant multiplier for the friction produced between a single pair of the rubbing surfaces by any given pressure.

A most perfect and an effective hoisting-engine, made by Messrs. Frisbie & Co., of Philadelphia, is represented in Fig. 3. A distinctive feature of this engine is the manner of connecting the spur-gearing to *friction-drums* by bolting directly to the rim of the drum. This does away with all torsion of the shaft and wear upon keys and feathers, which is a serious defect in most hoisting-engines, causing the shafts to split at key-way. This engine is well suited for all hard duty, such as pile-driving, hauling logs, bridge-building, and many other kinds of work where engines are liable to be broken by sudden strains. The clutch can be set so as to do the work the ropes are safe at, and then will slip, and save the engine and gearing from breaking. The motion to operate the clutch is easy and natural, and with a powerful strap-brake we can hold or lower carefully any load we can hoist. See *Cranes*, *Differential Pulley-block*, and *Mechanical Maneuvers*.

HOLD.—A place of security; a fortified place, fort, or castle. Often called a stronghold. The expression *to hold*, is frequently employed to mean the fact of being in military possession of any place; while *to hold out* means to maintain any place, ground, etc., against an enemy.

HOLDALL. A portable case for holding small articles required by soldiers. Leather bags or cases are generally used for carrying implements for the equipment of guns, and are known as "off" and "near." Each has links at the back for hanging it on the saddle.

HOLDFASTS.—The most essential subjects to be considered before any heavy weight is moved or suspended, are the nature and condition of the securing points, together with the strain that will be brought on them. Natural holdfasts—such as the piers of casemates, pintles for guns of position, trees, etc.—may frequently be found, around which straps may be placed. In such cases all corners should be protected by wood, or the rope itself *parceled* to prevent chafing. In places where holdfasts can be driven or sunk, the ordinary picket-post can be made use of, but only when light weights have to be dealt with. In securing to a holdfast from which it may become necessary to ease off, at least one complete turn must be taken before making fast; otherwise, when the strain is on it, it is difficult to cast off. Precise rules cannot be laid down as to the description of holdfast best suited for particular operations, but it should be borne in mind that it will save much time and trouble to make it in the first instance considerably more secure than seems to be absolutely necessary, as when a holdfast once begins to give, it is difficult to strengthen it. Whatever holdfast may be used, the strain should be taken by the entire structure at once; otherwise it might give way in detail when it would not do so as a whole. The drawings represent some of the methods of customary holdfasts, using pickets, anchors, heavy cannon, etc. When the strain to be sustained is very great, the holdfast shown in Fig. 2. may be used to advantage; *a b c d* is a trench from ten to fifteen feet long and two to four feet in width and depth. It is dug in a direction perpendicular to the strain. Several heavy stakes are driven into the trench far

Fig. 1.

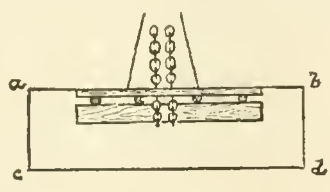

Fig. 2.

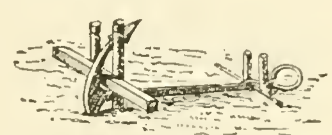

Fig. 3.

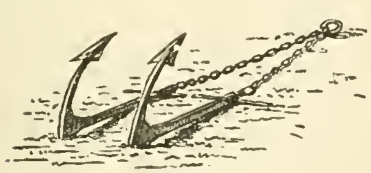

Fig. 4.

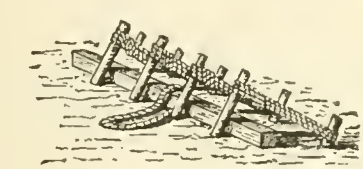

Fig. 5.

enough from the side to admit planks being placed between them and the earth. A heavy beam, with the bight of a chain around it, is then laid on at the bottom of the trench against the stakes, the ends of the chain being brought up between the planks along a trench, rising gradually to the surface so that there will be no tendency to lift the beam up when the strain is on it. The whole trench is then filled in and rammed.

HOLLOW-BALLS.—In military pyrotechny, many varieties of balls are made, differing in purpose from bomb-shells, but, like them, filled with ignitible composition. They are used either to give light, to produce very dense smoke, or to diffuse a suffocating odor. Some of them, although designated balls, are not globular in shape. *Light-balls* consist of canvas stretched over a skeleton-frame, and painted; the frame is filled with a composition of saltpeter, sulphur, resin, and linseed-oil, rammed down hard; and is provided with a fuse, the length of which determines the time that will elapse before the composition ignites. These light-balls weigh from 5 lbs. to 70 lbs. each, according to their size. They are intended to give out a brilliant light, which may reveal the operations of the enemy, during night, at a siege or in the field. *Smoke-balls* are made of several thicknesses of paper, shaped by means of a globular core or a mould. They are filled with gunpowder, saltpeter, powdered sea-coal, Swedish-pitch, and tallow; and are calculated, after being fired off, to send out a dense smoke for nearly half an hour, in order to blind or incommode the enemy. *Stink-balls* are filled with a composition which, when ignited, diffuses an odor almost intolerable. Some of the contrivances of Captain Norton and other inventors at the present day, are extensions of the same principle as these inflammable balls. It may here be added, that most of these projectiles, especially light-balls, and smoke-balls, are fired from mortars rather than from guns. See *Pyrotechny*.

HOLLOW OF THE ARM.—An expression for the slight inclination of the axle-tree-arms downwards (when the wheels have dish), so that the lowest spoke of each wheel may be vertical.

HOLLOW PROJECTILES.—Under the head of Hollow Projectiles are included shells for guns, howitzers, and mortars. These are usually made of cast-iron, and are classified according to the diameter of the bore of the piece or their weight.

A shell is a hollow projectile filled with gunpowder, which is ignited by a fuse at the required moment, the bursting of the shell causing destruction by its explosive force and by the fragments and, if the object be combustible, by setting it on fire. The thickness of metal must be such that the shell may contain as large a bursting charge as possible, but that it be strong enough to withstand the shock of the discharge within the bore of the gun. The thickness of metal in a spherical shell is about one-sixth of the diameter, and the weight of the shell is about three-fourths that of the solid shot of the same caliber. The shell of a rifle-gun being elongated, is, by giving it a greater length than the shot, brought up to the same length as the latter.

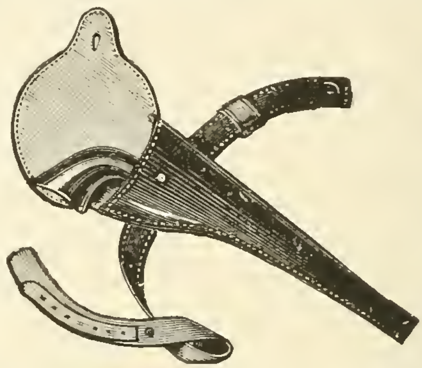
Mortar-shells are fired from mortars at high angles, being intended to fall upon and set fire to buildings, vessels, or other combustible constructions; to destroy earthworks, or by their great penetration before bursting, to explode magazines protected from other projectiles. They are fitted with two *lugs*, placed one on each side of the fuze-hole, which serve for attaching a pair of *shell-hooks*. The fuze-holes of mortar-shells are larger in diameter than those of other common shells, and they are not counter-sunk or bouched with composition. See *Projectiles* and *Shells*.

HOLLOW REVETMENT.—When arches are constructed from one counterfort to the next, the name *hollow* or *counter-arched revetment* is given to the disposition, which is both excellent and economical for high scarps.

HOLLOW SQUARE.—The form in which a body of foot is drawn up with an empty space in the middle for the colors, drums, baggage, etc. A body of troops formed into a squad to resist the charge of cavalry on critical occasions.

HOLLOW TOWER.—A rounding made of the remainder of two brisures, to join the curtain to the orillon, where the small shot are placed, that they may not be so much exposed to the view of the enemy.

HOLSTER.—The leather case which holds the pistol. Holsters are either worn on the belts, or are affixed to the pommels of the saddles. In the latter instance, they are frequently covered with wool or fur, to prevent injury to the riders in the event of being thrown forward upon them. The drawing



shows the form and construction of the regulation holster. In the English service, Lancers and Non-commissioned Officers of cavalry have two holsters attached to the front part of their saddles. Wallets have been introduced in lieu of holsters for the Staff and certain regiments of the service.

HOLY ALLIANCE.—A league formed after the fall of Napoleon by the Sovereigns of Russia, Austria, and Prussia, nominally to regulate the relations of the States of Christendom by the principles of Christian Charity, but really to preserve the power and influence of the existing Dynasties. Most of the other European Rulers acceded to it, and the treaty was formerly made public in the *Frankford Journal*, February 2, 1816. It was in virtue of this league that Austria, in 1821, crushed the Revolutions in Naples and Piedmont, and that France, in 1823, restored Absolutism in Spain. Subsequently, both France and England seceded, after which it became a mere *nominis umbra*. A special article of the treaty excluded forever the members of the Bonaparte Family from any European throne.

HOLY LEAGUES.—The name applied to certain political alliances in Europe; the principal are as follows: 1. In 1511, between the Pope, Spain, and Venice, the object being to expel the French from Italy. 2. In 1538, between Charles V. and the Roman Catholic Princes of Germany in opposition to the league of Schmalkend. 3. In 1571, the Pope, Spain, and Venice against the Turks. 4. Of the Guise family, the Pope, Spain, and the French Parliament against the Huguenots. 5. In 1609, between the Pope and the Roman Catholic States of Swabia and Bavaria. 6. In 1684, of Poland, Germany, and Venice against the Turks.

HOLY SEPULCHER.—The Knights of the Holy Sepulcher constituted an Order of Knighthood instituted, probably, by Pope Alexander VI., for the guardianship of the Holy Sepulcher, and the relief and protection of pilgrims. The Pope was originally the Grand-master, but he subsequently ceded his rights to the Guardian Father of the Holy Sepulcher. The Knights must, by the rules of the Order, be all of noble descent; they were bound to hear mass daily, to fight, to live, and to die for the Christian faith, etc. In return for these duties, the Knights had the most unusual and extraordinary privileges conferred upon them: they were exempt from taxation, could marry, and yet possess church property, legitimize bastards, and cut down and bury the bodies of criminals who had been hanged. On the recapture of Jerusalem by the Turks, the Knights retired into Italy, and settled at Perugia. After a temporary union with the Hospitalers, the Order was reconstructed in 1814 both in France and in Poland, and is still in existence within a very small circle of Knights elected by the Guardian Father from the most respectable pilgrims who come to Jerusalem.

HOLY-WATER SPRINKLER.—A name applied to the *flail*, both from its shape and from the drops of blood which started from those upon whom it was used.

HOMAGE.—The service or a show of respect due from a knight or vassal to his Lord in feudal times. The word is derived from the form of expression used in doing the service, which was—*jeo devigne vostre home*—I become your man. Since the abolition of tenures, the word has no substantial legal meaning in the law of England, except in a limited sense as to copyholds, to denote the kind of acknowledgment made by a tenant to the Lord of the Manor. The Homage Jury consisted of the tenants who did homage, and their presence was necessary to attest some acts. *Homagium reddere* was the expression, now obsolete, signifying a solem renunciation of homage or fealty to the Lord, and a defiance of him. The word homage is not used in Scotch law, though the feudal system is not obsolete in Scotland in many other repects.

HOME.—In artillery, the term used to express the position of a shot when the gun is loaded. Thus, "Is the shot well home?" is a common expression amongst artillerymen.

HOMICIDE.—The killing of one human being by another either innocently or feloniously. To say that there has been a homicide does not necessarily imply that a crime has been committed; for though every murder is a homicide, every homicide is not a murder. The law permits a man to kill another in self-defense when his own life is assailed or threatened; but the danger must be real, or in good faith and for sound reasons deemed so by the person threatened. A man may lawfully kill another, after due warning, in defense of his property, or to prevent the escape of one who has committed felony. An Officer of Justice charged with the duty of arresting a criminal or with the performance of any other lawful act, may kill a person who resists or attempts to thwart him by force. A person charged with felony, seeking to escape after arrest or any one fleeing to avoid capture, may be lawfully killed by an officer if he cannot otherwise be taken. A person engaged in committing a felony may be lawfully killed by an eyewitness if there be no other way of preventing the crime. The keeper of a prison may, if necessary, prevent the escape of a prisoner by taking his life. In all such cases, however, it must appear that the killing was resorted to as a last alternative. Justifiable homicide is the term applied by law in all such cases. Where one kills another by accident, without any intention to do him injury, and while exercising a proper degree of caution, the law deems it an excusable homicide; as, for example, when a man driving in the highway in the darkness runs over and kills another without knowing it, or, discovering the danger, has yet no time or power to avert the calamity. The line between justifiable and excusable homicide is vague and, in a legal sense, not important, since neither the one or the other exposes a man to punishment. In some of the States of the Union no distinction is made between them.

HOMING PIGEON.—The result of the investigation into the practicability of using pigeons to carry messages in time of war is not so encouraging as was hoped. Although there are instances when they have been used to great advantage, and when they have been the only means of communication, there seem to be obstacles to their certain and systematic use in the time of actual hostilities. It is a fact that, despite the greatest care in training, the pigeon sometimes fails at the critical moment. When it succeeds, however, the stake is generally very great. To attain one success it may be worth while to suffer many failures. For this reason, perhaps, those Nations who devote most time and money to the perfecting of their military systems, still systematically train large numbers of pigeons for use in war. When Paris was about to be besieged in 1870, the pigeon-fanciers in that city suggested to the military authorities that the pigeons within the city limits be sent out, and that others from the provinces be sent into the city. The latter proposition was acted upon, but the former was not, until balloons were used, when there was an opportunity to send out pigeons in the balloons, it being intended that the birds should return with messages. Pigeons had been declared contraband of war early in the Franco-Prussian war of 1870. There was taken out of Paris, in balloons, 363 pigeons. Of this number, fifty-seven only returned. These bore letters, photographed in finest characters upon scraps of paper so minute that 200 of them weighed only one-eighth of a grain. Newspapers, reduced by photography to microscopical characters, were carried by these pigeons. The magic-lantern was made use of to enlarge the letters, which, thrown upon a prepared surface, were read by the public. These 57 birds were not the only ones sent into Paris during the siege. A pigeon post service was established at Tours, for the purpose of conveying messages into the Capitol. The regular rates for this service made it possible for one bird to carry $500 worth of despatches, but, during the latter days of the siege, the Germans introduced trained hawks that were used to destroy the pigeons. These instances show sufficiently, that while the pigeon has been used for carrying messages, many causes—some understood and others not understood—unite to make them uncertain and untrustworthy means of communication.

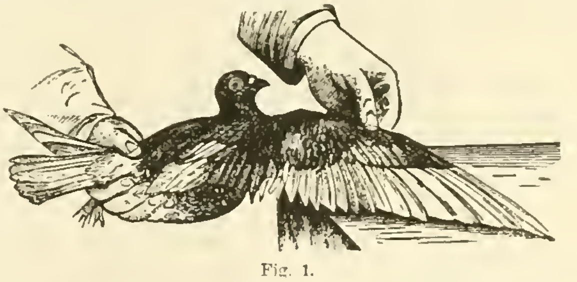


Fig. 1.

The reason why the pigeon seeks its home, the fact that makes possible its use a carrier, has never been satisfactorily given, and its discussion involves the most interesting inquiry concerning the bird. Some have believed the action of the bird due to instinct, others to training, while one of the most experienced and practical French fanciers has recently advanced the theory that the pigeon is guided in its flight by currents of electricity in the air, or by other atmospheric influences; others, again, differing from all these, believe that instinct, intelligence, and careful training, combined, account for the action of the birds. What is instinct? To this there may be many answers, but when considered in connection with the flight of birds, instinct is illustrated by the stork, which, traveling only at night, flies North in the spring and returns in the fall. Swallows and wild geese, and many other birds, move North and

South at the same seasons. They do not, however, confine all their movements to the night-time. All these move by what we term instinct. Whatever that may be, it is all-powerful in its influence on the birds. But it is not so with the homing pigeon. Experience shows that the flight of that bird is not certain unless it has been trained, and unless atmospheric conditions are favorable to its flight. Notwithstanding this, however, there are sometimes circumstances that give color to the theory that the bird flies by instinct alone.

The message should be adjusted to the middle feather of the tail, first shaving both sides to within an inch of the end; then lash the message, with waxed silk, firmly, so that the bird cannot pick it off. One person must hold the bird to prevent it from fluttering while another attaches the message. Messages should be written with lead pencil (ink runs if wet) on a very fine tissue or manifold paper, and folded very tight. Messages should be sent off on several birds, and if of very great importance, on ten or fifteen, so that some will be sure to reach the fort. The message on the middle feather of the tail will not annoy the bird, for when he is at rest it folds on top. It will not do to tie the message on the legs, as it is necessary for the bird, in flying, to hide the feet in the breast feathers so as not to offer a resistance to the air. Fig. 1 shows the best manner of holding the pigeon, when attaching the message, or when handling the bird for other purposes.

There are numerous varieties of homing pigeons remarkable for their powers of flight and their attachment to the home in which they have been reared and first flown. Prominent amongst these

Fig. 2.

are the Dragon, the well-known flying Tumbler, and the Skimmer, or a mongrel race between these two breeds. Among the pure breeds that can be flown good distances may be mentioned that called the Owl pigeon. But the varieties in which this homing faculty is developed to the highest degree is unquestionably the different races of Belgian birds, which are termed in England by the general name of Antwerps, and in Belgium are known as Smerles, Cumulets, Demi Bees, etc. Of these varieties the Smerles are the most important. They are rather small birds, and look very much as if they had been originally bred from a rather coarse blue Owl pigeon, crossed with a Blue Rock. The head is arched and the skull capacious, indicating a full development of brain, and offering a striking contrast to the flat narrow skull of the English fancy Carrier. The most striking characteristic of these birds is the firmness and great breadth of the flight feathers of the wings. These overlap each other to a great extent, and afford a strong firm wing with which the flight is urged. The keel of the breast-bone is deep and well covered with strong muscles; and there is altogether an absence of any offal or large development of any part not used in flight.

Of all the pigeon-tribe the Pouter, shown in Fig. 2, in appearance perhaps the most strange, is the furtherest removed from the ancient dove or common typical pigeon of the universe. This remarkable variety of our domesticated pigeon seems to be the extreme, the very utmost point, the greatest stretch of latitude to which the fertile imagination of man can be carried, or, indeed, to which the almost inexhaustible resources of nature might be expected to sport, or culture be extended. Here we have a pigeon which is a pigeon, but does not look like a pigeon—an estimable variety whose merits have been extolled by its admirers—a kind whose peculiarities are the cause of frequent surprise, doubt, and even ridicule. There are nine recognized kinds, or rather sub-varieties of the Pouter, viz.: black, red, yellow, blue, silver, mealy, creamy, blue-checkered, and white.

The Jacobin shown in Fig. 3, is a most popular variety, and its fanciers number some of the most earnest and painstaking breeders. It, as a bird, has proved to be a great bone of contention, and the various contestants have held so firmly to their opin-

Fig. 3.

ions and objections that for a long time there existed several types. These differences the National Peristeronic Society finally arranged. Twenty years ago the name was not known; it is an innovation and an eyesore to those who have seen the pure-bred bird.

The home of the pigeon should be as conspicuous as possible. Notwithstanding the fact that the flag at posts will generally make the home of the birds in the military service noticeable at a long distance, it is suggested that when it is possible the flagstaff be surmounted by a large spherical reflector, or a large white ball. That their arrival from a voyage may be quickly known, they should announce themselves. This could be arranged by connecting, by means of a light wire, the door of their house or loft through which they enter with a bell in a room that is to be habitually occupied. The wire need only be attached when messengers are expected. It therefore appears the Medical Department at posts should have charge of the pigeons in the military service, and that their loft be near the hospital. Not only will they then be most likely to receive constant care, but judicious attention; and in return may be expected to interest and to be a direct benefit to the patients in hospital. Although it is important to send the same message by several birds, they should not be sent off together, but tossed up at intervals of five or ten minutes. When thrown off together, especially if in good condition, they sometimes play and loiter. See *Carrier-pigeon*.

HOMME D'ARMES.—A military phrase among the French, signifying a gentlemen or cavalier who belonged to one of the old companies, who was armed *Cap-a-pie*, and always fought on horseback. In ancient times, every man of this description was accompanied by two horsemen independently of his servants. One of the mounted attendants was armed with the cross-bow, and the other with a common bow or a battle-axe; so that 100 *Hommes d'Armes* composed a body of 300 horse. It was a species of cavalry which existed from the reign of Louis XI., until the reign of Henry II.

HOMOGENEOUS. A term applied to various substances to denote that they consist of similar parts, or of parts of the same nature and kind; thus, the substance of a solid shot may be said to be homogeneous when the metal is of the same density and texture throughout. In any perfectly homogeneous shot, the center of figure and the center of gravity of the mass are coincident.

HONES.—A particular class of stones used for the purpose of sharpening all edge-tools and weapons. They are usually cut into pieces about a foot in length, and from an inch to two inches thick, and either left square or rounded, according to their intended uses. The finest kind of hones are those called oil-stones: these are hard, compact, and so very silicious that they readily wear down the hardest steel; they are varieties of slate, derived from the argillaceous schists of the paleozoic period. The best are those brought from Turkey; Bohemia is also celebrated for its hones; and very excellent ones are discovered in Persia, in the Hartz Mountains, in Syria, in America, Spain, Peru, and in Siberia. In Great Britain several localities yield hone-stones of excellent quality, and none better than the celebrated Water-of-Ayr stone, which is much used for polishing copper-plates, as well as for hones. The Welsh oil-stone or Idwall stone, and the cutler's greenstone, are obtained from Snowdon in Wales: and in the neighborhood of Tavistock the Devonshire oil-stones are procured. The hones used for sharpening scythes, etc., are usually made of coarse-grained sandstone.

HONEYCOMBS.—Flaws or defects in guns resembling the cells made by bees, worked in the metal through the action of exploded gun powder. They spread rapidly, and with continuous firing, soon eat into the metal to such an extent as to render the further use of the gun dangerous.

HONORABLE ARTILLERY COMPANY.—The oldest existing volunteer corps in Britain. Four military bodies—the *Artillery Company*, the *Sergeant-at-Arms*, the *Yeomen of the Guard*, and the *Gentlemen Pensioners*, were established as far back as the time of the Tudors; all these organizations still exist, but under greatly altered circumstances. In 1537, Henry VIII. granted a patent to three persons, appointing them "Overseers of the Science of Artillery," for long-bows, cross-bows, and hand-guns. They were to constitute a guild or a fraternity for this purpose, with power to appoint assistants and successors, to purchase lands, and to use a common seal; and their formal official name became "The Masters, Rulers, and Commonalty of the Fraternity or Guild of Artillery of Long-bows, Cross-bows, and Hand-guns." The freemen of the guild or company were empowered to keep arms, and exercise themselves in shooting. In 1605 a patent was granted by James I., intended chiefly to effect the preservation of the shooting and practicing grounds around London for the Artillery Company. In 1633 a Commission was appointed by Charles I., still further to insure this object. In 1638 the Corporation of the City of London presented to the company the plot of ground ever since called the Artillery Ground, near Moorfields, as a field for military exercise. Royal Princes frequently enrolled themselves as members of the Company, usually as "Captain General." In 1719, George I. issued an order that all commission and staff officers of the City Train-bands (a metropolitan militia) should become members of the Artillery Company, and exercise with the other members at all convenient times. The word "artillery" had heretofore been considered as applying to bows and arrows as well as to firearms; but the members of the Company, like other marksmen, had also abandoned archery, without, however, making any change in their designation. In a summons to the Company to meet for exercise on a particular day in 1682, it is said: "Those gentlemen that on that day handle muskets are desired to take care that their arms are clean and well fixed, and that they bring with them fine dry powder, and even match." The Company, like many other city guilds, has nearly outlived its original purpose. In 1780, when the "Lord George Gordon riots" afflicted the metropolis, the members of the Artillery Company effectually protected the Bank of England; in 1848, when Chartist riots were apprehended, the Company was on the alert to render good service if needed; and in the spring of 1859, when an uneasy feeling prevailed in England concerning the designs of France, the members polished their arms and looked forward to eventualities; but the Company has never been engaged in an actual warfare with an enemy. The Artillery Company consists of members elected by ballot, who pay one guinea annual subscription, and supply themselves with dress, arms, and accouterments. These payments, together with the rental received from a small amount of real property, constitute the fund out of which the expenses are defrayed. The members learn rifle-shooting as well as artillery practice; there are certain days of meeting at Moorfields; and every summer there are certain days of drill and practice at Seaford. The Corps comprises six infantry companies, a grenadier company, a light-infantry company, a rifle company, and an artillery company. Until 1849, the members elected their own officers; but since that year the Crown has appointed them on the nomination of the Lieutenancy of the City of London. The Lieutenant-colonel appoints the Non-commissioned Officers. See *Artillery Corps.*

HONORS OF WAR.—The term employed to express the privileges allowed to a garrison surrendering, either in consideration of a brave defense, or from some other cause. Many degrees of honor may be paid to a vanquished enemy, according to the generosity or judgment of the victorious Commander-in-Chief. In some cases, the garrison is allowed to march out with all its arms, drums beating, colors flying, etc.: at another time, the conquered force will only be permitted to advance silently to the front of their works, there to ground or pile arms, and then, facing about, to return to their lines as prisoners of war. Occasionally, the capitulation will provide that the garrison shall deposit their arms and warlike stores at some specified spot, and then march on to their own territory on parole of not serving during the existing war against the victors or their allies.

HONORS PAID BY TROOPS.—The following officers are received with standards and colors dropping, the officers and troops saluting, and the bands, trumpets, or field-music playing, as is indicated in each case: 1. The President. Music: "The President's March." 2. The General Commanding-in-Chief. Music: "The General's March." 3. The Lieutenant-general. Trumpets sounding the flourishes, or drums beating the ruffles. 4. A Major-general. Two flourishes, or two ruffles. 5. A Brigadier-general. One flourish, or one ruffle. Officers of the Navy are received with the honors due their assimilated rank, which is as follows: Admiral, General; Vice admiral, Lieutenant-General; Rear admiral, Major-general; Commodore, Brigadier-general; Captain, Colonel; Commander, Lieutenant-colonel; Lieutenant-commander, Major; Lieutenant, Captain: Master, First Lieutenant, : Ensign, Second Lieutenant. Officers of Marines, and Officers of Volunteers and Militia in the service of the United States, receive the honors due to their relative rank. To the Vice President, the members of the Cabinet, the Chief Justice, the President of the Senate, the Speaker of the House of Representatives of the United States, and to Governors, within their respective States and Territories, the same honors are paid as to a General Commanding-in-Chief. American and Foreign Envoys or Ministers are received with the compliments due to a Lieutenant-general. Officers of a foreign service are complimented with the honors due to their rank. The national or regimental colors passing a guard or other armed body are saluted, the trumpets sounding, and the drums beating a march. No honors are paid when troops are *en route*, on marches, or in trenches; and no salute is rendered when marching in double time, at trot or gallop. The Commanding Officer is saluted by all Commissioned Officers in command of troops or detachments. Courtesy among military men is indispensable to discipline; respect to superiors is not confined to obedience on duty, but extended on all occasions.

All officers salute each other on meeting, and in making or receiving official reports. When under arms, the salute is made with the sword or saber, if drawn; otherwise with the hand. A mounted officer dismounts before addressing a superior not mounted. In all cases the junior first salutes. On official occasions officers when under arms indoors, do not uncover, but they salute with the sword or hand, according as the sword is drawn or in the scabbard; when indoors and not under arms they uncover and stand at attention, but do not salute. A Non-commissioned Officer or private in command of a detachment without arms salutes all officers with the hand. If the detachment be on foot, and armed with the rifle or carbine, he brings the pieces to a carry, and salutes as prescribed for a Sergeant. The Commanding Officer is saluted by all Commissioned Officers in command of troops or detachments. The *Sergeant's Salute* is also used by privates out of ranks armed with the musket, and by sentinels in saluting all officers not entitled to a present. Whenever a Non-commissioned Officer or soldier without arms passes an officer, he salutes him, using the hand farthest from the officer. A Non-commissioned Officer or soldier being seated, and without particular occupation, rises on the approach of an officer, faces toward him and salutes; if standing, he faces toward the officer for the same purpose. If the parties remain in the same place or on the same ground, such compliments are not repeated. If actually at work, soldiers do not cease it to salute an officer unless addressed by him. A Non-commissoned Officer, or soldier, with musket or drawn sword, makes the prescribed salute with the musket or sword before addressing an officer; he also makes the same salute after receiving the reply. A Non-commissioned Officer, or soldier, with sword or bayonet in the scabbard, and when unarmed, salutes with the hand. Indoors, a Non-commissioned Officer or soldier, when unarmed, uncovers and stands at attention, but does not salute; in all other cases, he salutes as just prescribed, without uncovering. A mounted soldier dismounts before addressing an officer not mounted. An officer mounted dismounts before addressing a superior officer not mounted. When an officer enters a room where there are soldiers, the word "*attention*" is given by some one who perceives him, when all rise, remain standing in the position of the soldier, and preserve silence until the officer leaves the room: if at meals, they do not rise. Soldiers at all times, and in all situations, pay the same compliments to officers of the Army, Navy, and Marines, and to all officers of tha Volunteers and Militia in the service of the United States, as to officers of their own particular regiments and corps. Officers in citizens' dress are saluted in the same manner as when in uniform. Officers will at all times acknowledge the courtesies of enlisted men. When returning the salute of the enlisted men, officers salute as prescribed in the tactics. When several officers in company are saluted, all who are entitled to the salute return it.

Officers arriving at Head-quarters of a Military Geographical Division, or Department, or of any organized Military Command, or at a Military Post, as soon thereafter as may be practicable, call upon the Commander thereof, and, if there be time, register their names in the office of the Assistant Adjutant-general or Adjutant of the command. If the visiting officer be senior to the Commander the former may send a card, when it will become the duty of the Commander to make the first call.

HOOD.—A term applied to the leather cover for the stirrup of a saddle. It is the same as the Spanish *Tapadera*.

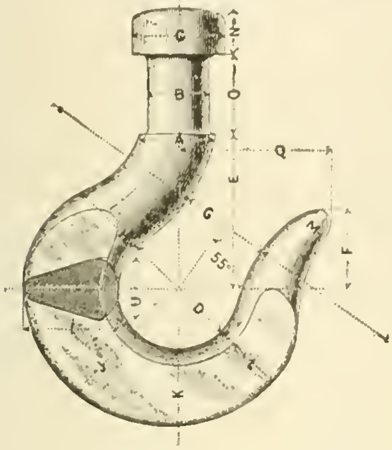
HOOF-PAD.—A device attached to the hoof of a horse to keep the foot, or the shoe of the foot to which it is attached, from cutting the fellow foot or the fetlock. A device to prevent *interfering*.

HOOFS.—The healthy soundness of the horse's foot is mainly preserved by permitting it to grow uninjured by the rasp and knife (see Horse-shoeing), whilst its toughness is secured, and undue dryness and evaporation is prevented, by smearing daily the crust, sole, and frog with a little glycerine, or a mixture made by melting together a quarter of a pound each of tar, honey, beeswax, and glycerine, with a pound of lard. Softness and brittleness of the hoof, which are fruitful sources of cracks and corns, may be remedied by the regular use of such dressings, by placing the feet for several hours daily in thick woolen swabs, kept cool and moist by frequent applications of cold water, and by encouraging a more healthy growth of horn by occasional mild blisters round the coronary band. Cracks, or sand-cracks, as they are termed, mostly occur amongst horses much upon the road, cause lameness and constitute unsoundness. When serious and recent, poulticing, thinning away of the crust about the crack, and perfect rest are essential. After the earlier heat and tenderness are removed, a hot iron should be drawn at right angles to the crack, both above and below, so as to separate the diseased from the sound horn. Waxed thread or fine wire should be wound round the hoof, and a sound growth of horn stimulated by a blister round the coronet.

HOOKS.—A small but important element of the suspending apparatus of a crane or hoisting-machine is the hook which terminates it, and by which the hoisting mechanism is attached to or is connected with the load to be lifted. Investigation has shown that the strains developed in hooks are of an exceedingly complex character, and the determination of the correct proportions of the several parts was only reached, after much study and discussion, by means of mathematical calculations of much intricacy and based upon the results of numerous experiments. Without undertaking here to disclose the intermediate steps of the investigation, we will simply give the final results in the form of the working formulæ. The drawing represents, to a scale of one-sixth natural size, a 5-ton hook of the dimensions and shape determined by the following formulæ, which give the dimensions of the several parts of hooks of capacities from 250 lbs. (or one-eighth of a ton) up to 20,000 lbs. (or 10 tons). For hooks of larger sizes the formulæ become slightly different, the general proportions, however, remaining the same. For economy of manufacture each size of hook is made from some regular commercial size of round-iron. The basis, or initial point, in each case is, therefore, the size of iron of which the hook is to be made, which is indicated by the dimension, A, in the diagram. The dimension, D, is arbitrarily assumed. The other dimensions, as given by the formulæ, are those which, while preserving a proper bearing-face on the interior of the hook for the ropes or chains which may be passed through it, give the greatest resistance to spreading and to ultimate rupture, which the amount of material in the original bar admits of. The symbol Δ is used in the formulæ to indicate the *nominal capacity* of the hook in tons of 2,000 pounds. The formulæ which determine the lines of the other parts of the hooks of the different sizes are as follows, the measurements being all expressed in inches:

$D = .5\,\Delta + 1.25$, $E = .64\,\Delta + 1.60$, $F = .33\,\Delta + .85$, $H = 1.08A$, $I = 1.33A$, $J = 1.20A$, $K = 1.13A$, $G = .75\,D$, $O = .363\,\Delta + .66$, $Q = .64\,\Delta + 1.60$, $L = 1.05A$, $M = .50A$, $N = .85B - .16$, $U = .866A$.

The dimensions, A, are necessarily based upon the ordinary merchant sizes of round-iron. The sizes which it has been found best to select are the following: Capacity of Hook, $\frac{1}{8}$, $\frac{1}{4}$, $\frac{1}{2}$, 1, $1\frac{1}{2}$, 2, 3, 4, 5,



6, 8, 10 tons; Dimension A. $\frac{5}{8}$, $\frac{11}{16}$, $\frac{3}{4}$, $1\frac{1}{16}$, $1\frac{1}{4}$, $1\frac{3}{8}$, $1\frac{3}{4}$, 2, $2\frac{1}{4}$, $2\frac{1}{2}$, $2\frac{3}{4}$, $3\frac{1}{4}$ inches. The formulæ which give the sections of the hook at the several points are all expressed in terms of A and can therefore be readily ascertained by reference to the foregoing scale.

Experiment has shown that hooks made according to the above formulæ will give way first by opening of the jaw, which, however, would not occur except with a load much in excess of the nominal capacity of the hook. This yielding of the hook when loaded to excess becomes a source of safety, as it constitutes a signal of danger which cannot very readily be over-looked, and which must proceed to some considerable distance before rupture will occur and the load be dropped. A comparison of these hooks with most of those in ordinary use will show that the latter are, as a rule, badly proportioned, and frequently dangerously weak. Hooks proportioned by the above formulæ are used in all the Weston cranes. See *Cranes*.

HOOK-SWIVEL.—A device intended for dispensing with the necessity of the triangular bayonet in stacking arms. It is of great value in connection with the trowel-bayonet, the use of which in digging, would deprive the muskets of the means of stacking them when necessarily set aside for this purpose. The swivels are so attached to the upper bands, that it is easy to insert each hook into the swivels of the two remaining guns necessary to complete the stack. The process of stacking is very simple. The men being at *order arms*, bayonets unfixed, the Instructor commands:

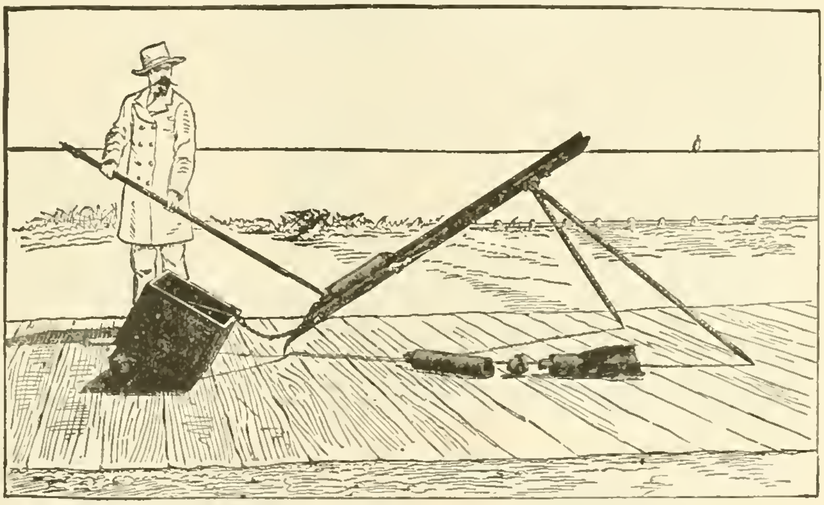
1. Stack, 2. Arms.

At the command *stack*, each even number of the front rank turns his piece, barrel to the front (the barrel turning to the left), and inclines his piece slightly forward, grasping it with the left hand at the upper band, the thumb and forefinger raising the hook-swivel; each even number of the rear-rank then passes his piece to his file-leader who grasps it between the bands with his right hand and throws it, barrel to the rear, two feet in front of his own piece, the right hand slipping to the upper band, the thumb and forefinger raising the hook-swivel, which he engages with that of his own piece, and inclines both to the right. Each odd number of the front rank grasps his piece with the right hand between the bands, the left hand guiding the hook-swivel, which he holds near the hook-swivels of the other pieces.

At the command *arms*, each odd number of the front rank engages the hook of his piece with the free hook of the piece of the even number of the rear rank. He then turns the barrel downward and to the right between the other two—so that it shall rest upon their intersection—and rests the butt about fifteen inches in front of his right foot.

If in single rank, number two of each four makes the stack, using the piece of number three as explained for the even numbered rear-rank man; number one using his own piece as explained for the odd numbered front-rank man, and the loose pieces are passed and laid on as before. In breaking the stack the loose pieces are passed as before, and the stack is broken as when in two ranks, number two taking his own piece in his right hand and that of number three in his left, which he passes to him on breaking the stack. Number one grasps his own piece with his right hand.

HOOKUM.—An Indian word, signifying order or command. *Hookummaumeh* signifies a letter of instructions, or the paper that contains orders.



HOOPER LIFE-SAVING ROCKET.—This rocket is a modification of the Hale rocket. The body is cylindrical in form, and is of sheet-metal 0″.165 thick. The point of the rocket or head is ogival in form, made of wood, and has a cylindrical tenon 1″.1 in length, which is inserted into the front end of the body. The head is held in position by several screws passing through the rocket-case into the tenon. The rear end of the case is closed by a metallic base carrying a double-swivel and perforated with five vents or gas escapes, each one-half an inch in diameter. On one side of these vents are fluted projections extending 2″.3 towards the rear, so curved as to leave the opposite sides open for the unimpeded escape of the gases evolved by combustion. The object of this arrangement is to produce a motion of rotation about the longer axis of the rocket, and thus secure greater steadiness of flight. This cast-iron base is held in position by pins passing through the case. To the swivel is attached a chain a little over 3 feet long, to which the line is made fast. The rocket is fired by breaking the paper covering of one or more of the vents, and inserting a piece of slow match and igniting the outer end.

The following are the principal dimensions and weights of the rocket:

			Inches.	Centimeters.
Length of body			14.5	36.82
Diameter of body	Exterior		3.75	9.40
	Interior		3.42	8.64
Head	Total length		3.6	9.14
	Length of ogival part		2.5	6.35
	Diameter		3.75	9.40
	Tenon:	Length	1.1	2.79
		Diameter	3.42	8.64
Length of base outside of case			2.7	6.86
Total length of rocket			19.7	50.03
Length filled with composition			12.0	30.48
Diameter of vents			0.5	1.27
Number of vents			Five.	
Length of chain and swivel			38".5	96.65
			Lbs.	Kilos.
Average weight of rocket and chain			19.25	8.73

The following directions should be observed when using this rocket and its stand. 1. The elevation required for the stand to be ascertained by means of a small quadrant; 25° will carry the line 300 yards with ease. 2. It is suggested, in order to save time, that every rocket-line should be spliced to a spring-swivel that it might *at once* be attached to the end of the rocket-chain. 3. In all cases three fathoms of the rocket-line to be wetted before being attached to the chain. 4. Place the rocket in the trough or stand with its shoulder against the small iron projection at its base, and have the chain hanging down through the slot. 5. To fire the rocket: With a pointed stick break the oil-paper covering each of the flange-holes, insert into one of them a slow match, light and retire to an angle of 45° to the rear of the stand. See *Life-saving Rockets*.

HOPLITAL.—Foot-soldiers among the Greeks, who bore heavy armor, and engaged with broad shields and long spears. These took precedence of all other foot-soldiers, and never went into action except in their own proper positions in the phalanx.

HOPPER.—A device, employed in machine-guns, very nearly of the form of a cartridge, and tapered downward. Its sides serve to guide the cartridges into the carrier singly, so that they can be removed one by one. The front end of the aperture is projected downward nearly into the carrier next the barrels, and thus serves to cut off the entrance to that particular barrel which is in front of it while in this position, and the cartridge which lies upon the one already in the groove from sliding forward and prematurely entering the opposite barrel. See *Gatling Gun*.

HOPPER-PLATE.—A component part of most ma-

chine-guns. It is a brass-curved plate, *I*, hinged to the frame-work of the gun on the right side, and covering the *carrier-block*. It is provided with a *hopper*, *K*, through which the cartridges descend to their places in the grooves of the carrier-block; whereupon they are instantly taken possession of by the locks, forced into the barrels, and fired. A short distance in front of the hopper is an upright pin, *I'*, on which the *feed-drum* rests and revolves. The upper side of the plate is flat and circular. See *Gatling Gun*.

HORDE.—A wandering troop or gang; especially a clan or tribe of a nomadic people possessing no fixed habitations but migrating from place to place for the sake of pasturage, plunder, or like cause.

HORDEARIUM.—The money which the Romans gave their cavalry for the sustenance of their horses.

HORION.—A term which formerly signified a helmet, and which in the vulgar acceptation of it at the present time among the French, means a blow upon the head.

HORIZON.—The circular line formed by the apparent meeting of the earth and sky: this, in astronomical phrase, is called the *sensible horizon*. The *rational horizon* is the circle formed by the plane passing through the center of the earth, parallel to the sensible horizon, and produced so as to meet the heavens.

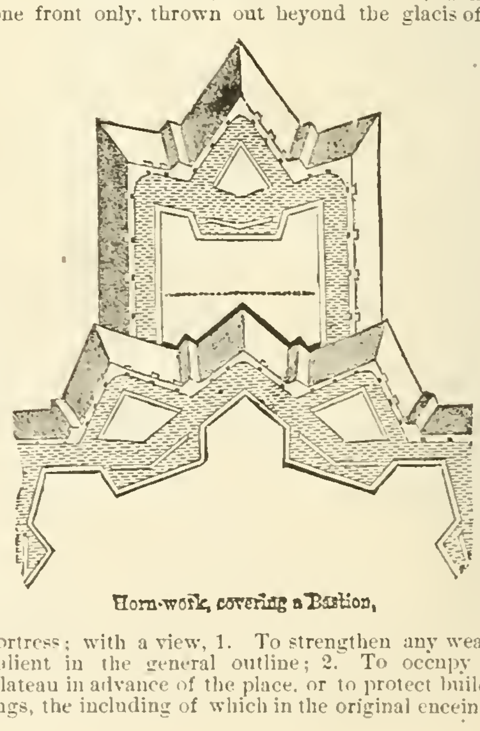
HORIZONTAL FIRE.—In gunnery, the fire of guns and howitzers under low angles of elevation. See *Fire*.

HORIZONTAL RANGE—In gunnery, the distance to which a piece of ordnance will project a ball on a horizontal plane. Supposing no resistance from the atmosphere, the greatest range would be when the piece is elevated at an angle of 45°, and in all other positions the *horizontal range* would be as the sine of twice the angle of elevation. In a resisting medium the maximum horizontal range requires the elevation to be less than 45°. It is found by experience that, with ordinary velocity, a cannon-shot ranges farthest when the elevation of the piece is about 30°.

HORIZONTAL VELOCITY.—A projectile's velocity at any point resolved in the horizontal direction. Thus, if V be the velocity of a projectile moving at an angle E to the horizon,

$$\text{Horizontal Velocity} = V \cos e.$$

HORN-WORK.—That work, in fortification, having one front only, thrown out beyond the glacis of a



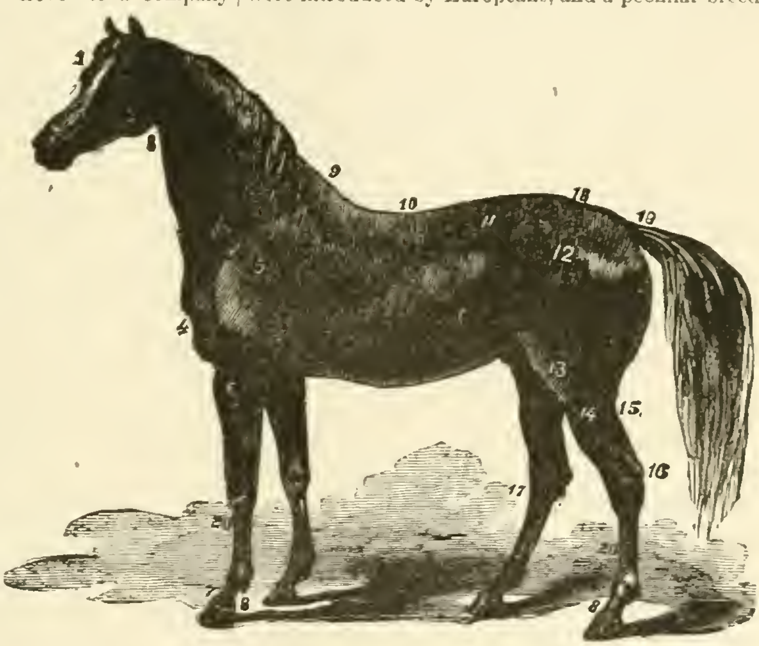
Horn-work, covering a Bastion,

fortress; with a view, 1. To strengthen any weak salient in the general outline; 2. To occupy a plateau in advance of the place, or to protect buildings, the including of which in the original enceinte would have extended it to an inconvenient degree; 3. To occupy a tongue of land protected on its sides; 4. To bar a defile; 5. To cover the head of a bridge; 6. To occupy rising ground, the possession of which would render the enemy more than necessarily dangerous. The front of a horn-work consists of two demi-bastions connected by a curtain, and usually defended in front, as in the fortress itself, by a tenaille, ravelin, and covert-way. The flanks, protected by ditches, run straight upon the ravelin, bastion, or curtain of the main defenses, so that the ditch may be swept by the fire of the latter. The flanks should not be too long for easy musketry range. In most of the earlier works of this nature, the ditch of the horn-work was united with the ditch of the main works by being cut through the glacis and covert-way, but in modern works the horn-work is constructed entirely beyond the glacis. Occasionally, horn-works are very useful; but all modern Engineers generally prefer constructing detached and advanced works. See *Crown-work*.

HORS DE COMBAT.—The French term, literally meaning "beyond the battle," used to signify a combatant, or body of combatants, so completely beaten either by physical force or strategy, as to be incapable of further action in the struggle which is actually under consideration.

HORSE.—1. A military term for a body of Cavalry. 2. We can go back 35 centuries, to Job the afflicted inhabitant of Uz, for the most wonderfully poetical description of the true horse. Solomon, later, does not hesitate to compare his "Love" to a company of horses in Pharaoh's chariots. Homer portrays the horse as a sensitive being, and relates that the steeds of Achilles wept at the death of that hero. Virgil tells us that the charger of Pallas followed the remains of his master to his burial, his eyes filled with tears. Pliny, the naturalist, positively asserts that horses often bewail the loss of their masters. Buffon, a hundred years ago, said: "The noblest conquest achieved by man is that of this proud and mettlesome animal, which shares with him alike the hardships of war and the glory of a conflict. He likewise shares his pleasures in the chase, in tournay, in the race; he glows with brilliancy and ardor." The native country of the horse is uncertain. Some contend for Asia, and some for Africa; some suppose that the horse was first domesticated in Egypt, and quote Scripture in support of their opinion, but to no better purpose than to show that at a very early period it was in use as a domesticated and valued animal among the ancient Egyptians: whilst others adduce arguments not more conclusive to show that it was originally domesticated in the north-east of Asia; some think it not improbable that Europe also, and even Britain, had indigenous horses. Whether certain wild races of Central Asia and the north of Africa are indigenous to the regions in which they are found, or the offspring of animals which have escaped from domestication, like those of America, and whether the origin of the domestic horse is to be referred to one original form, or to several forms somewhat different, and belonging to different countries, are questions also uncertain; and the last of them is very similar to that which is so much agitated respecting the dog, although it must be admitted that the diversities are not so great as in that case. The lips and teeth of a horse adapt it for cropping the short herbage of dry plains or hills, so that it finds abundance where the ox would be very insufficiently supplied. The feet are also adapted to dry rather than to soft or swampy ground. On soft ground, not only is the foot apt to sink, not being very broad, but the horny foot is softened, and a diseased state of the feet is the result, as in the case of a great many dray-horses in London, reared in the alluvial districts of the east of England. The horse, however, requires a liberal supply of water; and during the dry season, in the hot plains of South America, great troops of wild horses often rush furiously to the rivers, and as they approach the drinking-place, trample one another under foot, vast numbers of skeletons remaining to bleach in the sun.

Wild horses are found on the plains of Central Asia. Some also inhabit mountainous or hilly districts both there and in the north of Africa. They abound still more in the grassy plains of North and South America, although they were first introduced into America by Europeans; and certain tribes of Indians, both in North and South America, have become at least as equestrian in their habits as any of the Tartars of the East. Wild horses are also found in the Falkland Islands, into which they were introduced by Europeans, and a peculiar breed has been found in a wild state in the Island of Celebes. The races or varieties of the horse have an evident relation to the climate of the countries in which they occur. Those of cold and stormy regions are comparatively small and rough-haired; those of more favored climates, large and sleek. There are differences, more evidently to be ascribed to domestication, according to which certain breeds of horses are particularly suited to certain kinds of work some excelling in fleetness, some in endurance, some in mere strength for burden or draught. The



NOMENCLATURE.

1. Forehead.	6. Arm.	11. Loin.	16. Point of the Hock.
2. Jaw.	7. Large Pastern.	12. Hip.	17. Hock.
3. Throat.	8. Small Pastern.	13. Stifle.	18. Croup or Rump.
4. Breast.	9. Withers.	14. Thigh.	19. Dock.
5. Shoulder.	10. Back.	15. Hamstring.	20. Cannon-bones.

slender form of the race-horse or hunter contrasts almost as strongly with the ponderous solidity of the dray-horse, as the great size of the latter does with the diminutiveness of the Shetland pony. Wild horses generally congregate in troops, sometimes small in number, but sometimes of many hundreds. The males have fierce contests for the supremacy, and males that have contended unsuccessfully are often driven off to a solitary life. On the appearance of danger, the chief stallion of a small troop seems to direct the movements of all, and even the largest troops seem instinctively to move in a kind of concert, so that when they are assailed, the stronger animals oppose the enemy, and protect the younger and weaker. Wolves, even when in packs, attack with success only weakened stragglers, and even the jaguar is repelled. In fighting, horses either raise themselves on their hind-feet, and bring down the fore-feet with great force on the enemy, or wheeling about, kick violently with the hind-feet.

The *tarpan* of Tartary is one of those races of wild horses which are sometimes regarded as original, and not as descended from domesticated animals. It is of a reddish color, with a very black stripe along the back, and black mane and tail. The eye is small and vicious. Tarpans are sometimes caught by the Tartars, but are with great difficulty reduced to subjection. In some of the steppes of Central Asia, are wild horses of a white or dappled-gray color. The wild horse of South America is there called the *mustang*. It exhibits considerable diversity of color, but bay-brown is the most prevalent. It is strong and active, and is often taken with the lasso, and employed in the service of man. A curious method is practiced by some Indian tribes of promptly subduing its wild nature, and rendering it tractable, by blowing strongly with the mouth into its nostrils. By other tribes, it is subdued more rudely. It is thrown on the ground, and ere it can recover, a man gets upon its back, whom, when it rises, it cannot shake off, and who retains his seat until it is quite submissive. The *koomrah* of North Africa is regarded by Col. Hamilton Smith as a distinct species. It has no forelock, but woolly hair on the forehead, is of reddish-bay color, without stripe on the back or any white about the limbs, has limbs of somewhat ass-like shape, and the tail covered with a short hair for several inches at the root. It is an inhabitant of mountainous regions.

When full mouthed, the horse will have forty teeth, twenty in each jaw. The mare possesses only thirty-six. The age of the horse may be determined by observing the teeth, the times at which they appear, are shed and replaced, and the alterations in their form and markings;—2 years, all milch teeth, which are easily distinguished from the permanent by being smaller, whiter, and by having necks;—3 years, two permanent teeth, central incisors;—4 years, four permanent teeth, central and lateral incisors;—5 years, all are permanent teeth. From this time on, the age of the horse is decided by the marks on the teeth;—6 years, the marks on the central incisors are worn out, and the points of the tushes are blunted;—7 years, the marks on the central and lateral incisors are worn out, those on the corner incisors still showing;—8 years, all the cavities are filled up. Beyond this age the criteria are uncertain. For the military service the horse should possess the general features shown in the above drawing, and should not be less than 14 nor more than 16 hands high; weigh not less than 750, nor more than 1,100 lbs.; age not less than 5 or more than 8 years; head and ears small; forehead broad; eyes large and prominent; the shoulders long and sloping well back; fore-legs straight and standing well under; chest broad and deep; barrel large, and increasing from girdle to flank; withers elevated; back short and straight; loins and haunches broad and muscular; hocks well bent and under the horse; pasterns slanting; and feet small and sound.

In the matter of the treatment and qualities of the horse, we can not do better than remember a few axioms and aphorisms current among a people with whom the raising and training of horses are matters of religion, and to whom the Prophet has said, "Whoever raiseth and traineth a horse for the Lord is counted in the number of those who give alms night and day." "Make your horses work, and make them work again. Inaction and fat are the great peril of a horse, and the main cause of all his vices and disease." "As you would shun the plague so shun a horse with shrunken breast and straight shoulders. But one whose croup is as long as his back and loins together take with closed eyes." "If you would know at a glance the value of a horse, measure him from the last joint of the tail to the middle of the withers, and from the middle of the withers to the tip of the upper lip, on a line between the ears. If the hind measure is the longer, the horse is of little worth; but if the forepart is longer, rest assured the animal has distinguished qualities, and the greater the difference the greater will be his value." "Never run your horse up or down hill if you can avoid it." "To prepare a too fleshy horse for fatigues make him thin by exercise; never by withholding his food." "Do not beat your horses, nor speak to them in a loud tone of voice; do not be angry with them, but kindly reprove their faults; they will do better thereafter, for they understand the language of man and its meaning. If by chance you meet with a horse insensible to kindness, hesitate not to employ the power of your spurs, but in such wise that he never forgets the punishment." "The man who gives not a steady walk to his horse excites pity. The walk is the gallop of always." See *Cavalry-horses*, *Artillery-Horses*, *Pack-animals*, and *Draught-animals*.

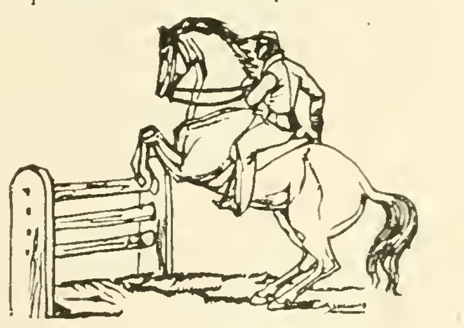
HORSE-ARTILLERY.—A portion of the artillery which generally serves with cavalry. One of the mounted branches of the British service is Horse-artillery. The formation of this branch dates back to the year 1793, when two troops were raised at Woolwich. Each troop consisted of 4 guns, but in November of the same year 2 more troops were added, and each troop had 6 guns. Subsequently it was raised to 12 troops. This branch of the service has been further augmented to the extent, at the present day, of 6 brigades, of 5 batteries each, each battery having 6 guns. The present equipment of the Horse-artillery is made up of 9-pdr. M.L.R. guns. The gun is made of a steel tube with a wrought-iron jacket; caliber, 3 inches; weight, 6 cwt.; length of rifling, 62·3 inches; rifling, three grooves, with a uniform pitch of 1 to 30 calibers; charge, 1.75 lb The carriages for these guns are of wrought-iron.

The Horse-artillery is held in hand for all decisive moments. When launched forth, its arrival and execution should be unexpected and instantaneous. Ready to repair all disasters and partial reverses, it, at one moment, temporarily replaces a battery of foot, and at the next is on another point of the field, to force back an enemy's column. In preparing the attacks of cavalry, this arm is often indispensable and aways invaluable; brought with rapidity in front of a line, or opposite to squares of infantry, within the range of canister, its well-directed fire, in a few discharges, opens a gap, or so shakes the entire mass, that the cavalier finds but a feeble obstacle, where, without this aid, he would in vain have exhausted all his powers.

HORSE-GRENADIERS.—The Flying Grenadiers, who fight both on foot and on horseback. They were first established in France by Louis XIV., in 1676, formed in squadrons, and called *Grenadiers Volans*.

HORSE-GUARDS.—1. The name applied to a large public office in Whitehall, appropriated to the departments under the General Commanding-in-Chief. The word Horse-guards is used conventionally to signify the Military Authorities at the head of Army Affairs, in contradistinction to the Civil Chief, or the Secretary of State for War. 2. The Royal Horse-guards, or Oxford Blues, is the third heavy cavalry regiment of the Household Brigade. The regiment was raised in 1661 from the remnants of the disbanded Army of the late Commonwealth. It has ever proved a loyal corps, although it readily transferred its allegiance from James II. to William III. It took part in Marlborough's campaigns; served under the Duke of Wellington in the Peninsula and at Waterloo, and has always been considered one of the finest heavy cavalry corps in the world. The Guards of State for the Sovereign are taken either from its ranks or from those of the Life-guards. The present uniform consists of a steel helmet, with plume, a steel cuirass over a blue coatee, leather breeches, and knee-boots; the horses are black. The establishment of the regiment consists of 1,302 of all ranks, with 825 horses, exclusive of officers' chargers. See *Cavalry* and *Dragoon*.

HORSEMANSHIP.—Throughout history the art of managing the horse and riding on his back has ranked high among useful and graceful accomplishments. According to Cæsar and Livy, the Numidians and Mauritanians rode their horses without either bit or saddle, and guided them solely by using a small switch, which was applied to either side of the neck, according as they wished to turn. The Persians trained their horses to kneel to receive their riders, and were the first to introduce saddles. Stirrups were used in the 5th century, but were not common even in the 12th. The two essentials for riding are a firm seat and a light hand, as without a combination of the two no one can become a good horseman. In every description of riding, the light or delicate "hand," just feeling the mouth of the horse, and playing the bit in accordance with his movement, will insure success; and it is to this delicacy of wrist that we must attribute the ease and skill with which ladies so often ride the most high-spirited animals, which, in rougher hands would be unmanageable. The first lesson in horsemanship is to learn to mount safely and easily; and the ordinary and on the whole least objectionable way is as follows: Stand at the shoulder of the horse, looking towards his tail, and taking the reins in the right hand, divide them by the middle finger of the left till you feel the horse's



mouth; then take hold with the left hand of a lock of the mane, lift the left foot into the stirrup, and using the mane as a slight hold, spring into the air, taking hold of the back of the saddle to assist in getting the right leg easily over the horse, steadying the fall of the body by the right hand on the pommel, and then arranging the stirrups. In dismounting exactly the reverse of this process is followed, or both feet may be disengaged from the stirrups at once, and the rider may vault from the saddle to the ground with great rapidity, and less risk of falling if the horse chance to move on.

There are four different styles of riding practiced among modern civilized nations—viz., the military, road, hunting, and racing styles. The military style differs in many particulars from the others, as, owing to the long stirrups used, the soldier is obliged to sit well down in his saddle, with his body erect, the seat being preserved more by balance than by a tight hold by the leg or thigh. In rapid movements or when charging over irregular fields, a very firm seat is necessary; the stirrup-leathers are then about two holes shorter, and the feet pressed "home" in the stirrups, which otherwise would be apt to be lost in jumping; the leg from thigh to the knee well forward, and nearly at right angles to the upper part of the body inclined forward; the legs perpendicular, the heel well down, and the toe pointing nearly straightforward. This seat the trooper has in common with all equestrian nations, as the Arabs, Tartars, Persians, Egyptians, Cossacks, Magyars, and Circassians, the last mentioned nation carrying it to such an extreme that the leg assumes the form of the letter V, having the knee for the apex. In riding at the bars or hurdle "collect" the horse into the pace at which he goes with most ease to himself; keep him straight at the fence till he rises; "ease" his mouth by leaning forward; take especial care not to confine it when he is making his effort, or you will pull him into the fence as he descends; lean well back in the saddle, and gently take hold of his mouth to support him when landing. Do not gallop with a loose rein (except down hill, when the horse requires his head free), for the horse will go with a straggling pace, which is very undesirable. For rapid movements, the essentials are a good and powerful seat, good "hands," a great knowledge of pace, and quickness to take advantage of any chances of success.

As the strongest part of a horse, and also the center of action, is situated at a point just behind his shoulder-blades, the nearer we can ride to this the better, and riding rather forward in the saddle is a relief to the horse, while leaning back, as it bears upon his loins—his weakest part—is a cause of fatigue. The grip in riding should be maintained by the knees, the thighs, and the calves slightly. The thigh is the most essential part of a good and strong seat. Few riders whose thighs are short and round, have a good seat; while, on the other hand, jockeys and tall thin men, whose thighs are long, and more or less hollowed on the under side, are generally very firm. No one pretends to horsemanship without a knowledge of the proper action for emergencies. If a horse runs away, do not exhaust yourself by vain pulling, but guide him out of danger, and let him run till he is tired. A Bucephalus noseband is a great security against bolting. If a horse rears, loosen the reins, and lean forward: in hunting, the "art of falling" consists in getting clear of your horse. In case of a horse kicking, keep his head up as much as possible, and sit firm in the saddle. The art of riding teaches and shows the position to be taken on horseback, so as to be there with the greatest security and ease. It at the same time affords the means of leading and directing the horse with the utmost of facility, and of obtaining from him by the simplest method and with the least fatigue the most exact and perfect obedience in everything which his strength and conformation allow. He is the good horseman, therefore, who, firm and easy in his seat, has acquired both the knowledge of what he may ask of his horse and the practice of the best means of enforcing obedience. And that is the well-trained horse which understands the intentions of his rider from the slightest of his movements, according to given principles, and executes them with promptness, agility, and vigor.

HORSE MEDICINES.—In a military point of view, the medicines issued to an army or command for the treatment of diseased or disabled animals. A *Supply Table* is usually authorized for an army, the medicines are all procured on requisition, and the Veterinary Surgeons dispense them. The following

Name of Drug.	Action and Use.	Dose.	Antidote.
Aloes.	Laxative and Tonic.	½ to 1 oz.	
Alum.	Astringent.	2 to 3 drs.	
Anise Seed.	Aromatic and Stomachic.	½ to 2 ozs.	
Aqua Ammonia.	Stimulant and Antacid.	1 to 4 drs.	Vinegar.
Arsenic.	Alterative and tonic, used for Paralysis, Mange, etc.	1 to 5 grs.	Magnesia and oil.
Assafœtida.	Anti-spasmodic, Coughs, etc.	1 to 3 drs.	
Bicarbonate of Potash.	Diuretic and Antacid. Good for Rheumatism.	3 to 5 drs.	Vinegar and raw Linseed-oil.
Bismuth.	For Chronic Diarrhœa, etc.	½ to 1 oz.	
Black Antimony.	Promotes the Secretions.	¼ to ½ dr.	Infusion of oak bark. Give also Lins'd-oil
Blue Vitriol.	Astringent and Tonic.	½ to 1 dr.	Eggs, Milk, etc.
Calomel.	Cathartic.	10 to 40 grs.	Eggs and Milk.
Camphor.	Anti-spasmodic.	½ to 1 dr.	
Cantharides.	Diuretic and Stimulant.	3 to 6 grs.	
Carbolic Acid.	Externally and Disinfectant.		Eggs; soap; gruel.
Castor Oil.	Cathartic.	½ to 1 pt.	
Cayenne.	Stimulant and Carminative.	5 to 25 grs.	
Chlorate of Potash.	Diuretic. Given for bloating, etc.	1 to 2 drs.	
Copperas.	Tonic and Astringent.	½ to 1½ drs.	
Croton-oil.	Powerful purgative.	10 to 15 drops	Opium.
Digitalis leaf.	Sedative and Diuretic.	10 to 20 grs.	Stimulate.
Epsom Salts.	Cathartic and febrifuge.	2 to 8 ozs.	
Ether.	Anti-spasmodic.	½ to 2 ozs.	
Fowler's Solution.	Used for skin diseases. See Arsenic.	1 to 4 drs.	Hydrated peroxide of iron.
Gentian Root.	Tonic.	1 to 2 drs.	
Ginger.	Tonic, Stimulant, and Stomachic. Used for flatulent colic, dyspepsia, etc.	2 to 5 drs.	
Glauber Salts.	Cathartic.	6 to 12 ozs.	
Iodide of Potassium	Diuretic and Alterative. Employed for Rheumatism, Dropsy, Enlarged Glands, etc.	½ to 1½ drs.	Give very freely starch or flour, with water largely.
Linseed-oil, raw.	Cathartic and Nutritive.	1 to 2 pts.	
Magnesia.	For colts as an antacid and laxative.	¼ to 1 oz.	
Mercurial Ointment	Used for Mange, itch, lice, and other parasites.		Whites of eggs with milk given freely.
Nux Vomica.	Nervous stimulant—used for Paralysis.	15 to 25 grs.	Saleratus, followed quickly by copperas, both dissolved in water.
Opium.	Anodyne and Anti-spasmodic. Given in Colic, Inflammation of Bowels, Diarrhœa, etc.	¼ to 1 dr.	Belladonna, strong coffee, brandy and ammonia. Dash very cold water on and keep the horse moving.
Prepared Chalk.	Antacid.	½ to 1 oz.	
Quinine.	Tonic, given during convalescence.	15 to 50 grs	Linseed-oil largely. Raw.
Saltpetre.	Diuretic and Febrifuge.	1 to 3 drs.	
Soda Bicarb.	Similar to Bicarb. Potash.	3 to 8 drs.	
Soda Sulphite.	Antiseptic and Alterative, used for blood diseases.	½ to 1 oz.	
Solution of Lime.	Antacid, used as an antidote to poisoning by acids.	4 to 6 oz.	
Spirits of Chloroform.	Anodyne and Anti-spasmodic.	1 to 2 oz.	
Strychnia.	Tonic and Stimulant. Used for Paralysis.	½ to 1 gr.	Tobacco.
Sulphur.	Alterative and Laxative. Used for Skin diseases and Rheumatism.	½ to 2 ozs.	
Sweet Spirits of Niter.	Diuretic and Diaphoretic.	½ to 1½ ozs.	
Tannic Acid.	Astringent.	20 to 40 grs.	
Tartar Emetic.	Sedative and Alterative.	⅛ to ½ dr.	Tannic Acid.
Tincture of Aconite Root.	Sedative. Used for lung fever, etc.	15 to 35 drops	Give small doses of Nux Vomica, use stimulants largely, and keep moving.
Tincture of Cantharides.	Stimulant and Tonic.	1 to 2 ozs.	
Tincture Ergot.	Parturient.	1 to 2 ozs.	
Tincture Iodine.	Used externally.		
Tincture Iron.	Tonic and Astringent. Used for Typhoid diseases.	½ to 1 oz.	
Tr. Nux Vomica.	Tonic. Stimulant in Paralysis and Dyspepsia.	2 to 4 drs.	See Nux Vomica
Tincture Opium.	Anodyne and Anti-spasmodic.	1 to 2 ozs.	See Opium.
White Vitriol.	Astringent. Used for cuts, wounds, and sores, in solution.	5 to 15 grs.	Milk, eggs, and flour.

For a colt one month old, give one twenty-fourth of the full dose for an adult horse as given above; three months old, one twelfth; six months old, one-sixth; one year old, one-third; two years old, one-half; three years old, three-fourths.

doses for the horse, prescribed by the eminent Veterinarian, Dr. Kendall, are found on all Army Supply Tables, and may be administered by any intelligent soldier, in the absence of the Veterinary Surgeon. See *Veterinary Art*.

HORSE POWER.—A term used in expressing the force of a motive power. It is based upon the assumption that horses in general perform a certain constant amount of work in a specified time; an assumption which is evidently erroneous. The fundamental unit of work is the foot-pound; but in measuring the work of a horse by this unit, the estimates of most celebrated Engineers differ widely from each other; Boulton and Watt, basing their calculations upon the work of London dray-horses (working eight hours a day), estimated it at 33,000 foot-pounds per minute. D'Aubuisson, taking the work done by horses in whims at Freiberg, estimated the work at 16,440 foot-pounds, working eight hours a day; under all similar circumstances, Desaguliers's estimate was 44,000; Smeaton's 22,000; and Tredgold's 27,500 foot-pounds; 17,400 is thought to be near the truth. It matters little, however, what number is assumed, provided the same be always used: and accordingly the original estimate of Watt is still counted a horse-power. In calculating the power of a steam-engine in terms of this unit, the general rule is to multiply together the pressure in pounds on a square inch of the piston, the area of the piston in inches, the length of the stroke in feet, and the number of strokes per minute; the result obtained by this operation, divided by 33,000, will give the horse-power. It is generally necessary to deduct about one-tenth of the whole, as an allowance for friction.

HORSE SHOE.—In fortification, a very small round or oval work, with a parapet; generally made in a ditch, or marsh.

HORSE-SHOEING.—The ordinary system of horse-shoeing is rude and irrational, and is the main cause of most lamenesses and of the majority of falls in riding and driving. Chief amongst its faults are the attempts to fit the foot to the shoe, instead of the shoe to the foot, and the wholesale cutting and rasping, and consequent injury of the several parts of the foot. After the cautious removal of the old shoe, the crust on which it rested generally requires to be pared down with a drawing-knife, and its edge afterwards rounded with the rasp. Any ragged portions of the frog may also be taken off, and this includes the whole of the allowable paring or dressing of the horse's foot. The horny sole intended as a covering and protection of the sensitive parts beneath; the tough elastic frog, an insensible pad which obviates concussion, and preserves the foot wide and free from contraction; the bars, an involution of the crust, which help it to support weight, and give it lateral support, are all too valuable to be ruthlessly cut away, and in all ordinary cases must be scrupulously preserved from both knife and rasp. For sound healthy feet treated as advised, a plain shoe is preferable for saddle or harness horses; the web need not exceed three-fourths of an inch, must fit the crust closely and accurately all the way round to the heels, where its inner edge will rest upon the strong uncut bars. Nowhere must there be any overlapping, which only renders the shoe more apt to cut the opposite limb, and be torn off in heavy ground. To lessen the chances of tripping, and make the shoe wear equally, it should for the fore-feet be turned up very slightly, and its ground surface hollowed out a little at the toe, so as

Fig. 1.

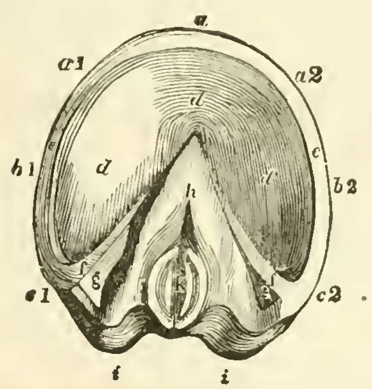


Fig. 2.

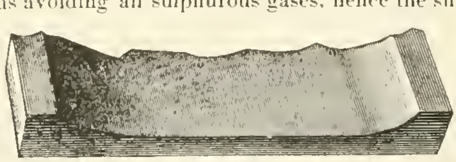
to present the appearance of an ordinary shoe which has been worn for a fortnight or three weeks; and which, as every one knows, is therefore rendered more safe and comfortable. By turing up at the toe, these advantages are secured at once. For saddle and light harness work three nails on the out—and two on the inside will firmly secure any well-made, well-fitting shoe. The nail-holes should be countersunk, be nearly in the center of the web, and pass straight through it, thus giving the nails a firmer hold of the stout unrasped crust. The points of the nails when driven home should be broken over and laid down with the hammer, but not touched with the rasp. The rasping of the crust which smiths fondly regard as their finishing and polishing stroke, is very injurious, removes the unctuous protecting portion of the crust, and renders it weak, brittle, and liable to crack. Shoes should be replaced every three weeks or a month at furthest. In shoeing the hind-feet the outside web is generally turned slightly down behind, whilst to give an equal bearing the inside heel is thickened. For heavy draught, both hind and fore shoes should have moderate tips and heels, which enable the horse to exert his entire powers without so much risk of slipping. Instead of the five nails used for the lighter horses, seven or eight are requisite.

Figure 1 shows an excellent form of front shoe and the proper positions of nail-holes; *a,a*, are the heels, of the same thickness as the rest of the shoe; *b,b*, are the points at which the heels of the hoof terminate; *c,c*, show the seating; and *d,e*, the positions of nail-heels. Figure 2 represents the ground surface of the hoof prepared for the shoe; *a*, *a* 1, *a* 2, show the front, inner, and outer toe; *b* 1, *b* 2, the inner and outer quarter; *c* 1, *c* 2, the inner and outer heel; *d,d,d*, the sole; *e,e*, the crust or wall of the hoof; *f,f*, the bars; *g,g*, the commissures; *h,k,l*, the frog (*h* being directly under the navicular joint); and *i,i*, the bulbs of the heels.

Horses with weak, tender, or bruised soles may for a time require leather or water-proof pads, but as the sole grows, these should be discontinued, and are never required in healthy feet, where the sole, which is the best and most natural protection, is allowed to grow undisturbed by the knife. Horses with corns should have their shoes made with a wide inside web, which rests upon the bars, or have for a time a bar-shoe. The last nail on the inside should also be dispensed with, and the seat of the corn or bruise carefully pared out, but without injuring frog or bars. If, from constant cutting, the bars are unfit to aid the crust in carrying the shoe, it will often be advisable to shoe for a time with tips or half-shoes, keeping the horse as much as is possible on soft ground, and waiting the healthy growth of the foot. In troublesome cases of thrush, such tips are also most serviceable, allowing the frog the natural and healthy pressure for which it is intended, and with astringents and cleanliness greatly expediting a cure. Groggy horses should have the toe shortened, and turned up, as already advised: the frog and sole must be untouched, and the shoes made light and nicely fitted. Over-reach, or cutting of the heel of the fore-foot with the shoe of the hind, is remedied by filing round the posterior edge of the offending toe, and keeping that shoe as far back as possible on the foot. For speedy cut, which is common in horses with in-turned knees, the shoe should be carefully fitted and no projecting portions be left; the clinches must also be well hammered down. See *Charlier System of Horse-shoeing*, *Seymour Shoe*, and *Snow-shoe*.

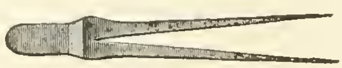
HORSE-SHOE NAILS.—The nail for a horse's foot differs materially from every other kind of nail, not only in shape, but also in the quality of iron from which it is made, as well as the process of manufacture. The slightest deviation from shape and quality of the iron renders the horse-shoe nail comparatively useless. From the days of Tubal Cain to the present time fire has been the only element with which iron could be properly wrought. Every other method has resulted in producing articles of great inferiority where strength and durability are required, and in no place are these two requisites more necessary than in the horse's shoe-nail. The Ancients used only charcoal in the working of iron, thus avoiding all sulphurous gases, hence the supe-



riority of their weapons. The old Damascus blades owe their superiority in part to the use of asphalt when being forged, thus avoiding the presence of sulphur, which is so ruinous to all kinds of iron and

A

steel. Profiting by this knowledge, the manufacturers of the Putnam nail avoid the use of coal and coke in forging, use only pure carbon gas made from petroleum, and thereby obtain a much higher tem-



B

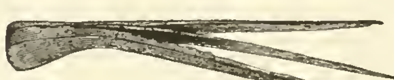
perature in the working of the iron. This hot-forged nail, when made of pure iron, has no equal in the known world.

The first drawing shows a cross-section of iron from which the cold-punched and sheard-nails are

C

made by forcing blanks therefrom by means of a punch. These blanks are put through a series of rollers and drawn into the form of A, with an indentation on the thin end for the *scarfed* points, which conduct the nail out of the hoof. B represents the piece which is removed by shearing the blade of A, so as to leave the nail, C, complete.

D



The rolling of iron *cold* produces lamination, causing the iron to separate in layers, as shown in D. But as the compression of shearing holds the edges together, it does not show itself until driven into the hoof, when the horny fibers cause them to separate while being driven, and one portion is forced *into* the foot and the other *out* through the wall of the hoof, thus causing lameness, lock-jaw, and death, as the records of State courts, as well as the testimony of horse owners, abundantly show.

One of these nails made by the *cold-cut* process, and slivered when being driven in by the shoer, is shown at E. The pain caused by a slight sliver of wood under the finger-nail will give one a slight idea as to how painful such a nail must be in the foot of the horse, there to remain until the shoe is removed. If the shoer is so fortunate as to draw it out without *breaking*, the lameness will disappear, but not until the horse has been laid up for a considerable time. Should the nail break, the result is far more serious.

It requires but little observation and reflection to arrive at the conclusion as to the kind of nails to be used in the horse's foot, whether a mangled piece of

E

iron, rendered dangerous by the *cold-rolling and cutting* process, or one made from the rod at a welding heat, where all the fibers remain intact, and a perfect *oneness* maintained, making it utterly impossible to sliver; likewise a greater amount of tenacity and ductility is obtained, by which the shoes are retained on the feet for a much longer time.

Having selected the best nails, the shoer should drive as small and few nails as will hold the shoe firmly and securely to its place. He should see that the nails fill the holes and the heads the crease, leaving little, if any, to project beyond the ground surface when finished, thus preventing the clinch from rising when brought in contact with stones, and saving the injuring of the ankle. See *Putnam Nail.*

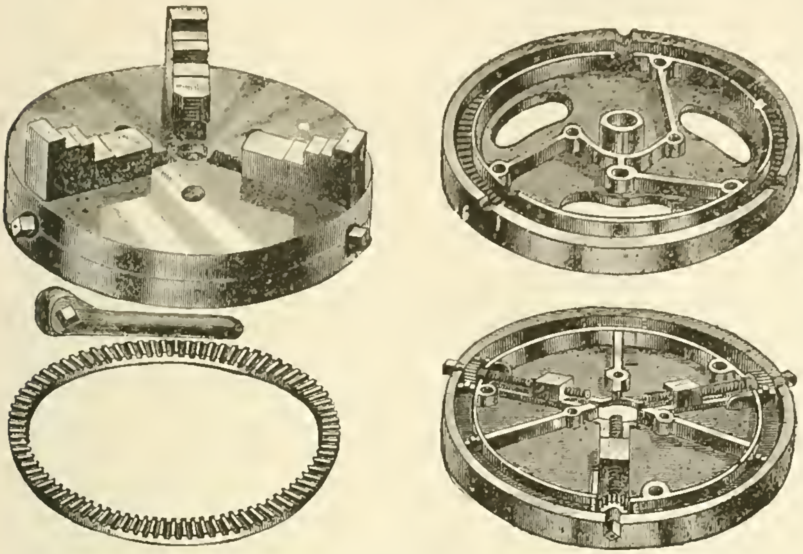
HORSE-TAIL.—Turkish Standard Commanders are distinguished by the number of horse-tails carried before them, or planted in front of their tents. Thus, the Sultan has seven, the Grand Vizier five, and the Pashas three, two, or one.

HORSFALL-GUN.—This gun is a solid forging of wrought-iron, bored out. The trunnions are forged upon a separate ring, which is held in place by a key. The dimensions of the gun are as follows:—Length, 15 ft. 10 in.; the diameter over the chamber, 3 ft. 7 in.; length of bore, 13 ft. 4 in.; diameter of bore, 13.014 in. The weight is 53,846 lbs. The usual windage is $\frac{1}{5}$ of an inch, and the gun is not rifled. The unequal shrinkage of the solid breech of this gun, during its fabrication, caused a crack, which was afterwards covered with a breech-plug, or false bottom in the chamber, to prevent the lodgment of any burning material. This gun is noted for its remarkable endurance, and terrible effect, at short range, in target practice at Shoeburyness.

HORSLEY-POWDER.—An explosive agent, composed of chlorate of potassa and gall-nuts, in proportion by weight of three to one, used principally in charging torpedoes. Its disruptive action in relation to the best gunpowder, volume for volume, is about 15 to 1.

HORTON LATHE-CHUCK.—A chuck of the universal type variously employed in the Arsenal. The drawings present a view of the device together and in its parts. The jaws are moved to and from the center simultaneously by means of the geared screws and the circular rack, which is enclosed in the deep groove or recess in the back-plate, the center faces of the front and back-plates making a perfectly tight casing for the gearing, so that no dirt, chips, etc., can possibly get into them to clog and injure the chuck. When the rack is taken out, especially from the fore-jaw, it makes a superior independent jaw-chuck, making two chucks in one. See *Chuck.*

HOSE-TROUGH.—The hose-trough is a small wooden channel, in which is placed a linen bag termed the *powder-hose*, filled with powder, to fire the charge. The bag should be of close texture, and well sewed. These troughs are made $1\frac{1}{2}$ in. square in the clear. The four pieces of which they are composed, the sill, sides, and top, or cover, are from $\frac{1}{4}$ to $\frac{1}{2}$ in. each in thickness. A trough should penetrate the powder-case about 4 in., and should exactly fit the opening left for it. It is fastened to the floor of the branch by nails, through the sill, which enter small pickets driven to receive them. Sometimes the sides of the trough are confined by pickets to prevent it being disturbed. The different lengths of the trough should be cut to fit exactly. Each portion of the trough should have its cover well fitted and secured with one peg only, in order that it may readily be removed to introduce the powder-hose. The trough is said to make an elbow when it changes its direction. The pieces forming an elbow should be solidly yet simply connected. When several mines are to be fired at the same moment, it is necessary so to



Horton Lathe-chuck.

proportion the trains to explode them, that, starting from the same point, the distances in time from that point to the charges may be all equal. The following cases show the manner of obtaining this result: For two charges place a trough on the shortest line from the one to the other, mark the center of it, and let the principal trough join it at that point. For three charges connect, as above, the two which are nearest. Let a trough lead from the middle point of this to the third charge; bisect the whole length of trough between this third charge and either of the others; then let the principal trough be joined to this last point. For four charges first connect them two and two, then join the central points and proceed as above. The elbows of a trough impede the communication of the fire, for which an allowance must be made when proportioning the trains, each elbow being valued at 3 in. Square elbows impede somewhat more than oblique ones.

HOSPITAL.—The principles of hospital construction were pointed out by a Commission of the French Academy of Sciences in 1778, and improved in several details by Miss Nightingale, Galton, and others, and in the late American and Franco-German wars. The general principles may be gathered from the following directions. The most important part of a hospital is the ward; that is, the special apartment, or system of apartments, for the reception and care of the patients. It should, if large, be arranged in separate pavilions of one, or at most not more than two stories. These buildings should be about 25 feet wide, 14 feet high, and of a length allowing not less than 100 square-feet per bed. In warm climates the height should be greater, and also the floor-space, allowing at least 120 square-feet per bed. No one ward should contain more than 32 beds. The windows should be opposite, reaching from 3 feet above the floor to one foot from the ceiling, and occupy one-third of the wall-space. The floors should be of hard pine or oak (Georgia pine in this country), and perfectly tight. In regard to the walls, there are differences of opinion, but it is probable that a plastering of mortar over laths, whitewashed with milk of lime, is the best, on account of its absorbing power, noxious gases being undoubtedly disposed of in this way by oxidation within the porous spaces. A plan of hospital was not unusual in the armies during the late War of the Rebellion in America, in which the wards or pavilions were disposed in a radiating form around a circular court, from 100 to 150 feet in diameter, according to the size of the hospital. A plan of Hicks Hospital near Baltimore, Md., is sometimes given as a model. This has a mess dining-room in one of the radiating buildings, rather larger than the others, and offices and other administrative buildings in the court. A better plan was carried out in the hospital at Point Lookout, Md., in which the Administration Apartments, Dispensary, Mess rooms, and Surgeons' Quarters were placed in a large building occupying a site among the other radiating buildings. The advantage is apparent in the open court that is unobstructed in regard to currents of air, and in the great cheerfulness of such arrangement, which admits of a free view from one ward to all the others, allowing the convalescent patients who may be sitting in their respective porticoes to greet each other; for wounded and sick soldiers, when they are able to be so, are a very social fraternity. The central court can then be laid out in plats of grass and flower-beds, in the care of which the patients take great pleasure during their often long confinement and absence from family. The plan of the Lincoln Hospital at Washington was the arrangement of the wards in the form of an isosceles triangle, they being placed *en echelon*, with the base of the triangle being left open. The triangular space between the wards was occupied by the various Administration Buildings.

In England there are several grades of hospitals. The smallest is the Regimental Hospital, under the Medical Officers of the Regiment; next, there is the Divisional Hospital, presided over by Staff Medical Officers, for the benefit of all the Corps in the Division; and, lastly, there is the General Hospital, applicable to the whole force. In these hospitals the Medical Officers are responsible directly to the Secretary of State for War for all purely medical functions. With regard to discipline, inspections, and other military duties, the principal Medical Officer is responsible to the Commandant of the Regiment or Division, who in his turn is answerable to the General-in-Chief for the state of the hospitals in his command. Soldiers while in hospital are subjected to a stoppage of 7d. a day from their pay, unless in hospital on account of wounds received in action or on service in the field; but their whole pay is stopped if detention in hospital be certified to have become necessary from their own misconduct. There are some large Military Hospitals at home, such as Netley, Fort Pitt, for lunatic soldiers, Woolwich, etc.

In the French Army the service of the Field Hospitals forms part of the intendance of the Army, the Medical Officers in charge being under the supreme control of the Intendant-general.

HOSPITALERS.—Charitable brotherhoods founded at various times and in different countries for the care of the sick in hospitals. The vow to devote themselves to this work of mercy is, in all these brotherhoods, superadded to the ordinary vows of poverty, chastity, and obedience, which are common to all the religious orders in the Church of Rome. One of the earliest recorded instances of a hospital served by such a brotherhood is that of Constance in the 13th century. The Knights of St. John, of Jerusalem, as also the Teutonic Knights were originally Hospitalers. The Hospitalers of Our Lady of Christian Charity were founded near Chalons in the end of the 13th century by Guy de Joinville; a smaller body at Paris in 1294; and the Hospitalers of Our Lady Della Scala about the same time at Siena. The history of the Brethren of Mercy, founded by St. John of God, will be found interesting. There are many other local institutes or congregations, all of which, however, recognize the same general rules, and follow the same general organization.

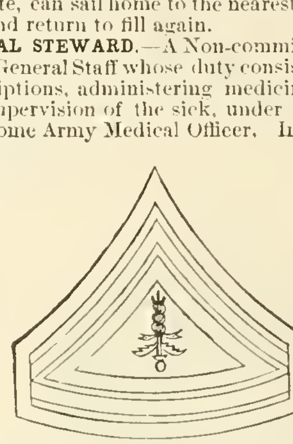
HOSPITAL FLAG.—A flag used to indicate the location of a hospital or ambulance. These flags in the United States Army are as follows: For general hospitals, yellow bunting 9 by 5 ft., with the letter H, 24 in. long, of green bunting, in center. For post and field hospitals, yellow bunting 6 by 4 ft., with letter H, 24 in. long, of green bunting, in center. For ambulance and guidons to mark the way to field hospitals, yellow bunting, 14 by 28 in., with a border, 1 in. deep, of green.

HOSPITAL FOR INSANE SOLDIERS.—The Insane of the military service are sent by Department Commanders, under proper escort, to Washington, where the patients are reported to the Adjutant General of the Army to procure the order of the Secretary of War. The application for admission to the Hospital should be forwarded in time to reach the Adjutant General at least one day before the arrival of the patient in Washington. The application sets forth a full description of the patient, and is accompanied by a certificate from a Medical Officer as to duration of insanity, whether developed before enlistment or employment in the military service, and, if possible, a diagnosis of the case. If the patient be a soldier, his descriptive list and clothing account is also furnished. On the departure of the patient from his station, the Commanding Officer gives such orders to the person in charge as will provide for the transportation of the necessary attendance to the Institution and back again to their posts, and for their subsistence, either in kind or by commutation, during their absence. To obtain the release of a patient when cured, or his delivery to the care of friends, application is made to the Adjutant General, accompanied by the recommendation of the Superintendent of the Hospital. After a soldier has, in the usual manner, been reported a fit subject for admission to the Government Hospital for the Insane, and is ordered to be sent to Washington, his Company Commander forwards, with his "descriptive list," certificates of disability made out and signed in the usual manner. The man is not discharged at the post, nor is the order given for his discharge by the Department Commander, but his discharge is ordered from the Adjutant General's Office, after his arrival at the Hospital.

HOSPITAL FUND.—The saving arising from an economical use of the rations of the sick and attendants in a hospital constitute the Hospital Fund. The amount is paid over to the senior Medical Officer at the station, and is accounted for and expended by him exclusively for the benefit of the men in the hospital, in the purchase of such articles of diet, comfort, or convenience as may be required, according to instructions received from the Surgeon General.

HOSPITAL SHIPS.—Ships fitted out as hospitals in all expeditions beyond the sea, for the care of the sick and wounded; they have been found invaluable in many foreign expeditions. In China, in 1860, four were fitted out, and ships for this purpose formed part of the expedition to the Gold Coast in 1874. They serve either as stationary hospitals or, if sick accumulate, can sail home to the nearest station, discharge, and return to fill again.

HOSPITAL STEWARD.—A Non-commissioned Officer of the General Staff whose duty consists in making up prescriptions, administering medicines, and in a general supervision of the sick, under the instructions of some Army Medical Officer. In the United



States Army, there is one Hospital Steward for each millitary post, and the Secretary of War may appoint from the enlisted men of the Army, or cause to be enlisted, as many Hospital Stewards, as the service may require. They are graded as 1st, 2nd. and 3rd class, are permanently attached to the Medical Corps, under such regulations as the Secretary of War may prescribe. The chevron worn by the Hospital Stewards is shown in the drawing. The senior Medical Officer of a hospital requiring a Steward may recommend a competent Non-commissioned Officer or soldier to be appointed, which recommendation the Commanding Officer forwards to the Adjutant General of the Army, with his remarks thereon, and with the remarks of the Company Commander. And, as the object of these more permanent appointments is to procure the services of a more competent body of Hospital Stewards, no soldier nor citizen must be recommended for appointment who is not *known* to be temperate, honest, and in every way reliable, as well as sufficiently intelligent, and skilled in Pharmacy, for the proper discharge of the responsible duties likely to be devolved upon him.

HOSPITAL TENT.—A large tent used for hospital purposes. It is usually made of heavy cotton-duck. In the United States service it is 14 feet long, 15 feet wide, and 15 feet high (center); with a wall 4½ feet high, and a *fly* of appropriate size. The ridge-pole is made into two sections, and measures 14 feet when joined. This tent accommodates from 8 to 10 persons comfortably.

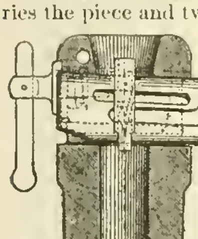
HOSPITAL WAGON.—A carriage on four wheels, having four or six springs, used for carrying the wounded of an Army. The Prussian hospital wagons are fitted up with combination cases, in which are packed everything supposed to be necessary in a hospital for wounded, including bandages, splints, drugs and anæsthetics, blankets, and an amputating-table, besides an assortment of tags, on one of which the surgeon writes his orders as to what is to be done in each case, attaches it to the patient, and leaves him to the care of others. Five ambulances, three supply-wagons (carrying food, bedding, and tents), and two Surgeons' wagons constitute a hospital-train for a division, and will accommodate 200 patients, requiring 13 Surgeons and 74 men for their care.

HOSPODAR.—A Slavonic title once very commonly given to the Governors of Moldavia and Walachia, whereas the Prince of Roumania is now known under the native Romanic title of *Domnu*. Another Slavonic term, *Wojewod*, was also given to the Hospodar, the term Wojewod signifying the right and dignity of leading the Army (being thus identical with Duke), while the Nospodar (Gospodar, Gospod, Gospodin, in the various Slavonic dialects) means simply, Master (Dominus). Formerly, the Lithuanian Princes were likewise called *Hospodars*, and the Polish Kings, down to the time of Sobieski, assumed this title in their diplomatic negotiations with Russia. *Gosudar* (Ruler, Monarch) is even now the title of the Emperor of Russia, and in conversation signifies Master.

HOSTAGE.—A person accepted as a pledge for the performance of conditions. When a town capitulates, victors and vanquished usually give into the custody, one of the other, several officers, as pledges that each party will duly carry out the terms stipulated. When the terms are fulfilled, the hostages are exchanged; but if the terms be evaded, the opposite side holds the right to put to death, or otherwise punish, the hostages in its possession. It is needless, however, to add that, in modern civilized warfare, the circumstances would have to be very remarkable indeed to be held to justify so cruel a measure as the execution of a hostage.

HOSTILITIES.—A rupture between the natives of different countries. The first hostile deed that is committed by either party is considered the commencement of hostilities. Between natives, the first act of hostility presupposes a declaration of war.

HOTCHKISS BREECH-LOADING MOUNTAIN RIFLE.—This gun, having been devised especially with reference to the mountain service, is made as light as practicable. It weighs only 116.6 lbs., and one man is able to place it upon the back of a mule. The weight of the carriage being but 220 lbs., the packing, unpacking, and mounting of the gun and its carriage require only two men. For transportation the material is distributed as follows: One mule carries the piece and two small chests containing accessories; another mule carries the carriage and shaft, and others carry the ammunition-chests. The construction of the Hotchkiss gun is based upon the use of a metallic cartridge, by which the obturation of the breech is accomplished. The extraction of the cartridge-case is effected automatically by the opening of the breech. The gun



is made of Whitworth steel, compressed in the fluid state. The mechanism of the breech consists simply of a prismatic bolt, with a cam, entering a cavity recessed in the breech. It is operated by a lever with handles, by which the bolt is withdrawn, or the reverse. As metallic cartridges are employed, a close fit of the breech-block is unnecessary, and the bolt is adjusted freely to its slot, which is an advantage over other breech-loading systems, which require great nicety in the fit of the breech-mechanism in order to insure a perfect obturation. The cartridge-extractor is a simple prismatic piece of metal, bearing at its forward extremity a hook; it is guided in a cavity in the upper part of the breech, parallel to the axis of the piece; on its lower face is fitted a tenon, which slides in a groove cut in the upper face of the breech-block. The groove is straight on the sides towards the handle, but curved at the other extremity—towards the opening for charging—so that in withdrawing the breech-block the tenon of the extractor slides for a time in the straight part of the groove, but as soon as the block is so far withdrawn that the opening for charging comes against the face of the chamber the tenon becomes engaged in the inclined portion of groove, and is suddenly drawn backwards, by which motion the empty case is thrown out of the gun. The movement of the breech-block is arrested by a stop-screw sliding in the recess upon the upper face of the block. The ammunition is composed of a metallic case which contains the powder, and is united to the projectile—an explosive shell by "choking," in the same manner as the cartridges for modern small-arms. The cartridge is of brass; the head being strengthened by cup-shaped reinforces. It is not primed, but is ignited by the ordinary friction primer. In the base of the cartridge is a valve formed by the cup reinforces; the gas from the primer opens the valve, which closes automatically, after the ignition of the charge, by the pressure of the gas inside, thereby preventing the escape of gas through the vent. The cartridge can be recharged, on an average, about eight times. The projectile is of a cylindro-ogival form, about 3½ calibers in length; it being furnished with a middle band of a soft brass, which takes the rifling. Upon the cast-iron body of the projectile are turned a number of grooves, of little depth and width, between which are narrow and sharp ridges. The band covers this portion of the projectile, and at the moment of firing the pressure of the gas which sursounds the projectile in the chamber molds exactly upon the brass the corresponding grooves and ridges that are on the cast-iron. This method of banding offers the advantage of securing a perfect adherence between the brass band and the projectile, and also permits regulating with great nicety the forcing whereby the friction necessary to produce rotation may be reduced to a minimum. The band of brass obviates the fouling of the bore. The piece can be fired a great many times without any necessity for using the sponge. The shells are fitted with percussion fuses of the Hotchkiss pattern. The following are the principal weights and dimensions:

Caliber	1.65 inches.
Length of bore	24.72 calibers.
Weight of piece	116.60 pounds.
Weight of carriage	220.00 pounds.
Weight of cartridge complete	2 pounds 10 oz.
Effective range	4,200 yards.
Number of helicoidal grooves	10
Twist (to the right)	49.21 inches
Depth of grooves (uniform)	0.12 inches

HOTCHKISS MAGAZINE-GUN.—This gun, invented by Mr. B. B. Hotchkiss, an American, lately residing in Paris, was first brought to this country by him in the spring of 1876, and exhibited at the Centennial, at Philadelphia. It was found necessary to make many changes in the arm originally introduced by Mr. Hotchkiss, and for these improvements patents have since been granted. The gun thus improved has been approved by two Boards of Officers, appointed by the Chief of Ordnance of the Army, for the purpose of examining small-arms. As now offered, it was a second time recommended for trial in the hands of the troops by the Ordnance Board of 1881-82. It embodies the experience of six years' manufacturing, and the valuable suggestions of many experienced officers who have used it in the field. It is a most simple and solid repeating-gun, capable of doing good service under the most disadvantageous circumstances. The drawing shows the working parts, with nomenclature, of the latest improved model of 1883.

The operation of the gun is very simple. 1. To open the breech-bolt: Hold the stock firmly with the left hand a little in front of the receiver; and with the right hand raise the handle, and draw back the bolt, making but one motion. 2. Close the bolt by an inverse motion. This operation cocks the piece. 3. To cock the piece without withdrawing the bolt: Raise the handle as before, and immediately turn it down. 4. To load the magazine: Raise the handle, and draw back the bolt. Take a cartridge between the thumb and middle finger, placing the point of the fore-finger on the bullet; insert the head of the cartridge in the receiver, just in front of the point at which it narrows down, and press it back in the magazine until a distant click—the head passing the cartridge-stop—is heard. Repeat the operation until five cartridges have been inserted. Another may then be placed in the chamber.

The magazine may be unloaded in two ways:

1. Raise the handle, and draw back the bolt: the cartridge will be then thrown out. Holding the muzzle of the arm well up, push forward the bolt (do not turn it down), the thumb of the right hand pushing the knob of the cocking-piece, and pull the trigger. Draw back the bolt by the knob of the cocking-piece: and the cartridge will be pushed forward, and remain in the receiver. Remove the cartridge, and proceed as before. 2. Raise the handle; place the wrist of the right hand against the handle of the lock-tube, the thumb being extended across the bolt in front of the handle, and the fore-finger resting upon the barrel. Draw back the bolt (keeping the hand in the same position) by pressing the back of the thumb near the wrist against the front of the handle: remove the cartridge with the thumb and fingers, which are thus at liberty to receive it. Push forward the bolt (do not turn it down), and pull the trigger. Withdraw the bolt with the back of the thumb as before, and stop the cartridge coming from the magazine with the fore or index finger. Remove the cartridge, and proceed as before until the magazine is exhausted.

The magazine cut-off is found on the right of the piece, just in the rear of the bolt-handle. It serves to lock the magazine so that the arm may be used as a single loader while the contents of the magazine are held in reserve. When the thumb-piece is pushed forward, however, the arrangement of the mechanism is such that no cartridges can escape from the magazine to the chamber, and the weapon is practically a single loader. The bolt-lock is placed on the left side of the receiver, opposite the magazine cut-off, and serves at the same time to lock the bolt and the trigger in such a manner that the bolt cannot be turned or drawn back, nor the arm fired. To lock the bolt and trigger push forward the thumb-piece of the bolt-lock; this can only be done when the bolt is closed and the gun cocked. To unlock the bolt, push back the thumb-piece of the bolt-lock.

To dismount the gun:—1. Take out the bolt. To do this, raise the handle, and draw back the bolt until the forward end of the cocking-piece just clears the rear end of the receiver; then after letting go the handle, take hold of the cocking-piece, and turn it down to the right until the projection on the bolt-head leaves the groove under the front end of the locking-tube. The latter may then be drawn out at the rear, and the bolt-head removed at the front of the receiver. To return the bolt, the head must be inserted from the front, and the other part from the rear. 2. Take off the butt-plate, by removing the two butt-plate screws. 3. Take out the magazine nut. 4. Take out the magazine spring and follower. 5. Take out all the guard side-screws. 6. Take out the guard-screws and the upper tang-screw. 7. Take off the butt-stock, by drawing it backward from between the guard and upper tang, and off from the magazine tube. 8. Take out the guard. 9. Take out the bolt-lock and magazine cut-off springs. It will aid persons unacquainted with the gun, when endeavoring to replace these parts, to remember that the flat sides of the springs lie next the receiver. 10. Take out the bolt-lock and magazine cut-off. While these parts resemble each other exteriorly, it will be observed that the bolt-lock has a short pivot, and is assembled on the right of the arm, while the magazine cut-off has a much longer pivot, and is assembled on the left. 11. Take out the magazine tube. This is accomplished by drawing back the magazine tube from its seat in the frame, and turning it slightly to the right, so that it may

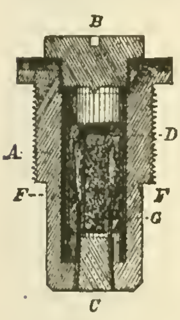
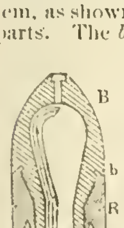
pass the trigger. 12. Take out the wiping-rod. 13. Take of the bands. 14. Remove the tip-stock. This is best done by separating the tip-stock, or fore-arm, from the barrel; first at the forward end of the tip-stock, separating them until the stud on the receiver is withdrawn from the slot in the rear end of the tip-stock. 15. Take out the trigger, by removing the trigger-screw. 16. Take off the barrel. This should be attempted only by persons provided with proper tools, as the barrel and receiver are very firmly assembled together. 17. The cartridge-stop may be dismounted from the guard, by unscrewing the cartridge-stop screw, and driving out, from the left to the right, the stop-pin.

To dismount the breech-bolt :- 1. Remove the bolt-head. To do this, hold the cocking-piece firmly in the left hand, and with the right turn down the handles as in the act of locking the bolt. The head will then slip off. 2. Turn out the firing-pin screw. 3. Slip the bolt-head partly on the projecting end of the firing-pin, and use it as a wrench to unscrew the pin. The main-spring may then be removed. 4. Remove the extractor by tapping gently on its projecting end with a piece of wood. To assemble proceed in the inverse order of the operations given above. See *Magazine-gun*.

HOTCHKISS PERCUSSION FUSE.—This fuse consists of a metal body, *A*, closed at the front end with a screw cap, *B*. It has a conical hole in the rear, which is closed with a lead plug, *C*, (the safety-plug), pressed in very tightly, so that the plug projects a little through the base of the body-case, toward the inside. The plunger, *D*, is composed of lead cast into a brass casing to strengthen it, and to prevent the lead being upset by the shock of discharge. Two brass wires, *F*, cast into the lead on opposite sides of the plunger, hold it suspended in the case, the wires going through the holes in the bottom of the case, and being held securely in position by the safety-plug. The plunger has a nipple cast into the lead, and is primed with an ordinary percussion-cap; in its axis it has a powder-chamber, *G*, which contains the igniting-charge. The operation of the fuse is thus: The safety-plug is dislodged backward into the interior of the projectile by the shock of discharge; the wires then being not held so tight in the hole, the plunger is disengaged and rests on the bottom of the fuse-case, and is free to move in the line of axis. When the flight of the projectile is suddenly retarded by its striking an object, the plunger, in consequence of its inertia, is driven forward, and the primer strikes against the screw-cap, thus igniting the powder in the channel, and so firing the bursting-charge of the projectile. See *Fuse*.



HOTCHKISS PROJECTILES.—Projectiles of this system, as shown in the drawing, are composed of three parts. The *body*, B, and the *cup*, C, are of cast-iron, and the *ring*, R, of lead. The ring is locked into the body and the cup by the grooves (b) and (c), all the parts being thus held securely together. The action of the charge is to drive the cup forward, thereby expanding the soft metal into the rifling of the gun, and at the same time binding the lead so that it cannot revolve upon the projectile; this last is assisted by a few grooves on the cast-iron under the lead. The amount of expansion is controlled by the distance the cup can move before coming in contact with the end of the body. All those projectiles with which time fuses are used have three longitudinal grooves on the outside, to insure the passage of the flame to the fuse. The ring, being placed much nearer the center of gravity of the projectile than if at the base, tends to steady the projectile in the bore, and increase the accuracy of fire. A Hotchkiss projectile, lately introduced for breech-loading guns, is of cast-iron, in one piece; a band of soft brass, about one caliber long, is forced into a recess in the projectile, situated well over the center of gravity; two longitudinal grooves prevent the band from turning. Upon the outside of the band is cut a number of saw-toothed grooves, to reduce the strain due to compression of the brass as the projectile is forced into the bore. See *Expanding Projectiles* and *Projectiles*.



HOTCHKISS REVOLVING CANNON.—The Hotchkiss revolving cannon cannot be classed with mitrailleuses in the ordinary sense of the latter term, as explosive shells are fired with the former, and it has a range equal to that of field-artillery. The system of this gun may be explained as follows; Five barrels, grouped around a common axis, are revolved in front of a solid breech-block, which has in one part an opening to introduce the cartridges, and another opening through which to extract the empty shells, while the cartridges are fired after being revolved and while motionless in front of the solid portion of the breech. Fig. 1. The exterior aspect of this revolving cannon resembles the Gatling mitrailleuse, it being, on the other hand, entirely different in its interior mechanism. The system is composed of two distinct parts, viz., the barrels with their disks and shaft, and the frame and breech containing the mechanism. The five barrels, made of the finest oil-tempered cast-steel, are mounted around a common axis, between two disks, on a central shaft. The series of barrels are in this way placed in a rectangular frame, which is attached to the breech, the near end of the shaft penetrating the same to receive the rotary motion from the driving-gear. Fig. 2. The breech of the revolving cannon is composed of a solid cast-iron breech-block, weighing about 386 lbs. This absorbs the greater part of the recoil. It has a door at the rear end, which can be easily opened, so that the mechanism is freely accessible, and can, if necessary, be dismounted and put back into its place in a few minutes, without the aid of any special tools. A peculiar feature of this gun consists in the barrels remaining *still* during the discharge, so that there is no movement of any kind to impede the accuracy of the fire. This stop or lost motion is obtained by the shaping of the driving-worm, which is so constructed that the inclined driving-thread only covers half its circumference, the other half of the thread being straight. The effect of this is that the barrels only revolve during half a revolution of the worm, and stand still during the other half revolution. The combination of the mechanism is so arranged that the loading, firing, and extracting takes place during this pause. This feature is of great importance for the accuracy of fire and the durability of the system. The worm-shaft projects through the breech on the right side, and has a crank with which the whole system is moved; on the left side of the worm-shaft a small crank is attached, by which the loading and extraction of the cartridge-shells are effected in the following manner: On the interior face of the left side of the breech a cog-wheel is mounted, with two horizontal racks, the one being placed above the other under this cog-wheel, and parallel to the axis of the barrels, so that in moving either of these racks the other is moved by the cog-wheel in the opposite direction. Part of the lower rack forms a vertical slot, in which the small crank on the left side of the worm-shaft works. The rotation of the latter consequently gives an alternating and opposite movement to the two racks, so that while the one is going forward the other moves back, and reciprocally.

The under rack forms the extractor; the upper one moves a piston which drives the cartridge into the barrels, the cartridge being placed before the piston, in the trough in which it moves; and during the time the barrels are motionless it is introduced into the one standing before the trough. The cartridge is not "driven home" entirely, but its head is in view of an inclined plane, cut into the metal of

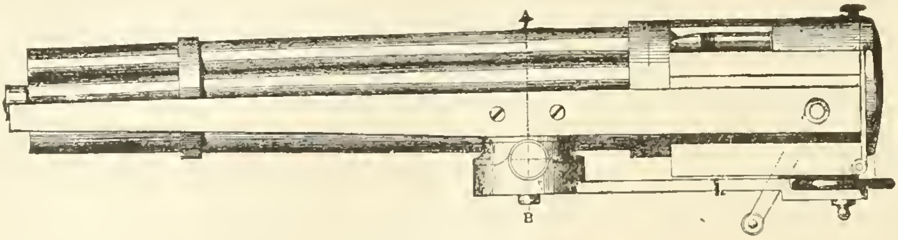


Fig. 1. Side Elevation.

the breech, on which it slides when it is moved by the rotation of the barrels. This completes the introduction of the cartridge into its chamber. The piston itself is a simple cylinder connected with the rack, and running in a slot in the conducting-trough. When the racks are in their extreme positions they

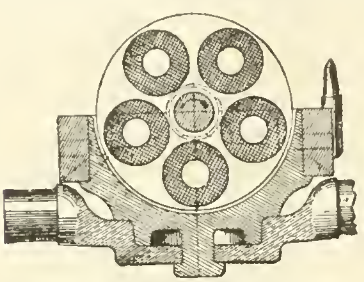

Fig. 2. Vertical Section through AB.

remain still a moment. This stop is obtained by giving the slot in its center part a circular shape concentrically to the shaft of the crank. This is necessary, because at the moment of the barrels arriving at the end of their course the head of the cartridge-case becomes engaged in the hooks of the extractor, which would not be possible if it were in motion at the time. The extractor is a large double hook at the end of the bottom rack; it is very solid,

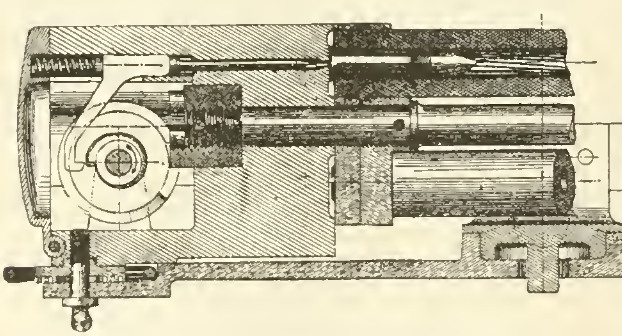

Fig. 3. Longitudinal Section Through the line of Axis.

and its proper working is certain under all circumstances. After the cartridge is extracted from the barrel it strikes against an ejector, which pushes it out of the extractor, and it falls to the ground through an opening in the under part of the breech. The firing-pin has an elongation, pointing downward, which, by the operation of a spring, is pressed against a cam on the worm, and as the worm rotates, the cam drives the firing-pin back and compresses the spring. The moment the firing-pin becomes liberated, it strikes the primer of the cartridge and the discharge takes place. To obviate the difficulties which exist in other systems, when the cartridges are piled one upon the other, the opening of the introduction-trough is closed by a little door, which goes down by the weight of the cartridges, the first of which drops into the trough, and then the piston in moving forward, raises the same door and allows no more cartridges to enter until at the proper time. All parts of the mechanism are very strong and durable, and hardly exceed in number those of an ordinary small-arm, there being, besides the group of barrels, thirteen parts, viz.:—1, 2. The breech-block, with its door for closing the rear end. 3, 4, 5. The crank-shaft, with its worm for moving the barrels, and small crank for working the loader and extractor. 6. The crank. 7, 8. The firing-pin and spiral spring. 9. The extractor. 10, 11. The loading-piston and rack for moving it. 12. The cog-wheel for transmitting the movement of the extractor to the loading-piston. 13. The door for regulating the feed of cartridges.

The operation of the mechanism may be described as follows, supposing the crank to be in continual motion: A cartridge is placed in the introduction-trough, the piston pushes it into the barrel, then the barrels begin to revolve, and the cartridge is carried on till it arrives before the firing-pin, which penetrates the solid part of the breech, and which has in the meantime been retracted by action of the cam. Fig. 3. Then, as soon as the cartridge has arrived into this position, the barrels cease to revolve, and the primer of the cartridge is struck by the firing-pin and discharged; then the revolution of the barrels begins again, and the fired cartridge-shell is carried on until it comes to the extractor; this, in the meantime, has arrived up to the barrels and the cartridge-head rolls into it. As soon as the head is laid hold of by the extractor, the barrels again cease to revolve, and during this period the cartridge-shell is withdrawn and dropped to the ground. As during every stoppage of the barrels the gun is supplied with a new cartridge, and the firing and extraction is also performed, during this time a continuous but slow fire is kept up. By supplying the gun in this manner with single cartridges, about thirty rounds per minute may be fired. Should rapid firing be required, the gun is then supplied, not with single cartridges, but with "feed cases," containing groups of ten cartridges each, and in this manner from sixty to eighty rounds per minute can be fired, with only three men to work the gun; viz.—one man to train the gun and revolve the crank; one man to place the "feed-cases" containing the cartridges into the "feed-trough"; and a third man at the ammunition-chest to charge the "feed-cases" and to hand them to the charger. Attached to the frame is a turn-table which connects the cannon to the "trunnion-saddle," arranged in such manner that without displacing the carriage a certain amount of lateral motion as well as of elevation may be given to the gun. Thus the gun is made to sweep horizontally along a line, by adjustment, between each single shot, or during rapid discharge.

The ammunition for the revolving cannon consists of a center-fire metallic cartridge of special construction, holding in each one the powder, the projectile, and the lubricating-wad, arranged like the similar ammunition generally used for small-arms. Two different kinds of projectiles are used, the one an explosive shell and the other a case-shot. Nothing need be said of the latter, as it does not differ from the common case or canister-shot used in ordinary cannon. The shell is of a novel construction; it is of cast-iron, of a cylindro-ogival shape, slightly rounded at the rear end. The packing consists of a brass coat of about one caliber in length, and placed equidistantly from the center of gravity. This coat is of soft brass tubing, contracted with great pressure over the body of the projectile, it being provided with longitudinal grooves, and two grooves encircling it at the top and bottom ends of the packing. The coating is forced into these grooves, and any disturbance of it on the body at starting is thus jectile, and the rifling is impressed on the ribs only covered by the tubing. Its dimensions and weights are as follows: Length of body, 3.66 inches; entire length with fuse, 4.27 inches; length of brass coating, 1.5 inches.

The cartridge-case is composed of a spirally-rolled tube of sheet-brass, strengthened at the head with an inside and outside cup. The head is punched out of sheet-iron, and is fastened to the cups with three rivets. The primer consists of a case holding the anvil, and is closed at the bottom end by the cap containing fulminate; it is fitted into a hole which penetrates the head and both cups, and it projects through into the inside of the cartridge-case. This cartridge, which can be manufactured with great facility, on account of its simplicity, has proved itself to be of a very durable quality, and it can be used repeatedly. The construction of the body of

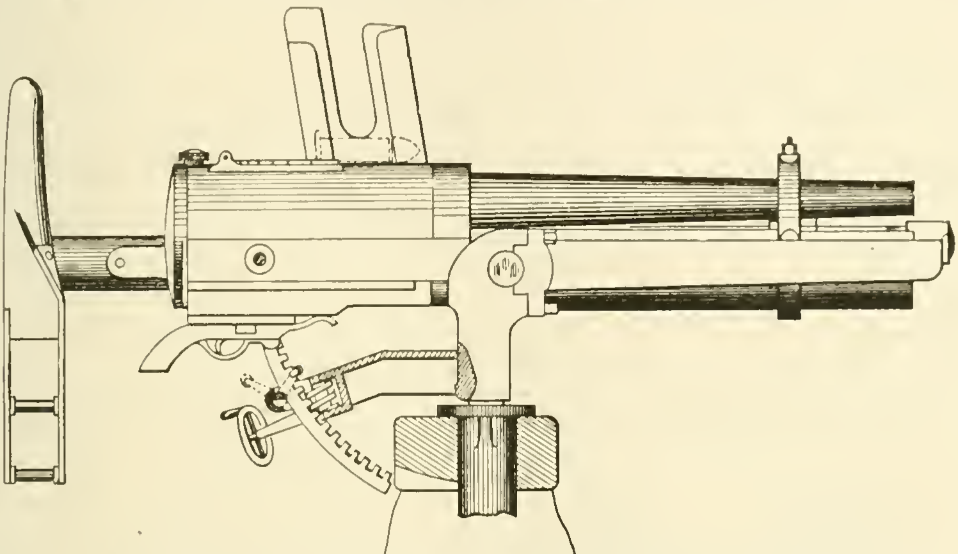

Fig. 4. Hotchkiss Revolving Cannon, with Shoulder-piece, Pistol-grip Stock, and Firing-trigger.

obviated. These grooves serve at the same time as breaking-lines of the shell. After the coating is attached to the projectile, some small saw-tooth-like grooves are cut into it, to reduce the strain while being forced through the rifling of the barrel. These grooves can be filled with a lubricating substance, and this is then carried perfectly between the projectile and the bore of the barrel. The coating of the projectile is conical at its front part, corresponding with the cone in the projectile-chamber, so that it is exactly centered in the bore as soon as the forward movement commences. Its rear end is cylindrical to within about one-third of its length. The shell is turned smooth all over, and is nearly 0″.016 in diameter less than the bore of the barrel. This projectile is made with great care and exactness, with only a very small deviation in dimension.

The fuse employed is that known as the Hotchkiss percussion-fuse, used in large quantities during the last war in America, and described above. The improved Hotchkiss shell is with its fuse a little less than three calibers in length, or about seven-sixteenths inch shorter than the one just described, from which it differs, with the above exception, in the following particulars only: The new shell has four circumferential grooves separated by ribs about one-twentieth inch wide, and longitudinal cuts between ribs. The tubing, about one caliber in length and one-sixteenth of an inch thick, instead of being corrugated on the exterior, as in the old shell, is perfectly smooth, and is contracted into place by a *slight* pressure only. The gas from the discharge presses the packing so firmly into the grooves and cuts that it cannot rotate independently of the pro-

the cartridge allows it to expand to the chamber of the gun without the metal being stretched, so that after the discharge it contracts itself again to its previous diameter, thus leaving the fired case perfectly loose in the chamber for extraction. The lubricator consists of a wad of felt about 0″.236 thick, dipped in a solution of mixed tallow and beeswax. A paper disk is placed between the lubricating-wad and the charge to prevent the powder getting damaged by the greasy surface of the lubricator. The projectile is merely pressed into the neck of the cartridge and is not clenched, as there is enough friction to hold it absolutely secure. Of course the ammunition is, as in the case of all of the modern small-arm ammunition, which it resembles, rendered safe against influences of weather and danger of explosion. The following are the principal dimensions and weights, etc., of the gun.

Caliber	1.457 inches.
Total length of bore	4 feet 2.236 inches.
Length of rifling	3 feet 8.882 inches.
Rifling, one turn in	4 feet 1.212 inches.
(Twist and depth of groove uniform.)	
Number of grooves	12
Width of lands	0.098 inches.
Depth of grooves	0.019 inches.
Number of barrels	5
Diameter of barrel over powder-chamber	3.464 inches.
Diameter of barrel at the muzzle	2.440 inches.
Weight of each barrel	77.166 pounds.
Radius of sights	2′ 3″·047
Vertical distance of the line of sight from the common axis of the barrels	2.0866 inches.
Horizontal distance of the line of sight from the common axis of the barrels	6.496 inches.
Weight of gun	1,047.25 pounds.
Total weight of gun with traversing apparatus	1,157.48 pounds.

For the revolving cannon a special carriage has been constructed. This was found necessary, as the ordinary field-gun carriage is not provided with the means for procuring an excellent and immovable rest for this gun. The trail of the carriage consists of two brackets of steel-plate, connected by three transoms and bolts, the rear end being connected by the trail eye-piece. The brackets diverge against the trunnions. The trunnion-bearings, and the bearings for the axle-tree, are riveted to the outside of the brackets and are fitted in the ordinary manner. The axle-tree is of steel, the arms being slightly conical. The wheels have metallic naves and ring-tires. The nave consists of two parts, the inside flange, with the pipe-box, and the outside flange. The spokes are cut in a conical form at their "hub" ends, so that they fill the nave-flanges, and the two parts of the nave are bolted together with the spokes with six screws. These wheels are very strong, and have been found practical and economical in service, and they allow spokes to be easily substituted for others when broken.

The elevating arrangement consists of a screw working in a gun-metal nut, resting in the oscillating bearing. This nut is revolved by conical gear-wheels from the left side of the trail, the top-end of the screw being attached to the trunnion saddle-plate. The handspike is hinged to the trail so as to fold back in traveling. A tool-box is placed between the trail; this at the same time makes a solid connection of the trail-brackets. The carriage of the revolving cannon is usually provided with a light steel shield for the protection of the gunners from small-arms fire. This shield is of three parts, made to fold together, thus forming seats for two men. It can immediately, when coming into action, be unfolded, and only the muzzles of the barrels and the wheels of the carriage are exposed to the enemy. The steel plates are about 0.236 inch in thickness. Two boxes are attached to the axle-tree, each to carry three feed-cases loaded with ten rounds of ammunition. On the carriages not provided with a shield, these ammunition-boxes are protected by light steel plates in front, and have a lid of steel, which, when raised, forms a small protecting-shield, and when closed they form seats for two gunners, so that with two or three gunners on the limber a sufficient number of men to serve the piece would be taken into action with the gun itself.

The gun shown in Fig. 4 is intended specially for use against torpedo boats, and is mounted on the rail of a ship, as shown in the drawing. The recoil is taken up by the pivot, and the gun is so nicely balanced as to be easily trained by the gunner, who stands with his left shoulder against the "cross" or breech extension, and with his right hand grasping the pistol stock at the right of the gun has as complete control of the weapon as if it were a fowling-piece, or the gun may be held by the rack. See *Machine-gun.*

HOTCHKISS SHELLS.—The first variety has three walls, parallel, or nearly so, with each other, and united to a solid base. In producing it, the middle wall, is first cast by the ordinary process. This wall is then suspended upon a core-piece, whose dimensions are such as will leave a space between its exterior and the interior surface of this wall, equal to the thickness desired for the inner wall. This core and middle wall are then suspended in a mold of the common construction, which mold has an inner contour the shape of the exterior of the complete shell. The metal poured into this mold envelopes the middle wall, and forms the shell as shown in Figure 1. The object of this peculiar form of construction is to produce a shell which will be broken into a larger number of pieces than shells of the ordinary construction. Near the forward and rear ends of the cylindrical portion of the shell cannelures are turned to receive the packing or soft brass bands, which are pressed and crimped into place. The base of the shell is slightly chamfered.

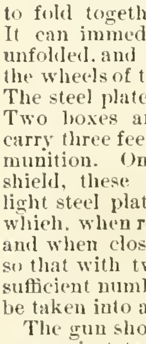

Fig. 1.

The Hotchkiss field-shells of ordinary pattern, as shown in Figure 2, are one inch longer than those described above, and have greater powder capacity. They are cast in the usual way for casting shells, and have the same general shape as the triple-wall shells. The packing as originally made consisted of a soft brass tubing about 4 inches in length, running for nearly two-thirds the length of the cylindrical portion of the shell; it was pressed and crimped into a recess turned on the shell to receive it. Cannelures were turned on the exterior of the tubing to diminish the bearing portion of the packing to be cut through by the rifling of the gun. Before these shells were fired, and to insure suitable rotation, Mr. Hotchkiss had added a smooth brass tubing about $1\frac{1}{4}$ in. long, which was also pressed and crimped into the recess turned for it. In turning this recess two annular rings were left. An examination of the results of a recent experimental firing shows an average of 17.4 hits per shot for the triple-wall against 10.4 for the common shells. The liability to premature explosion or breaking up in the gun seems to be about as great for one as for the other. Experiment fully demonstrates the superior destructive effects of the triple-wall over the common shell. See *Shells.*

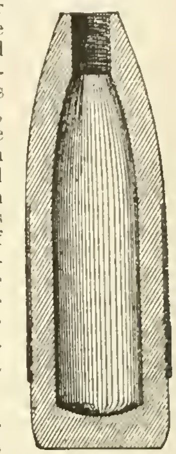

Fig. 2.

HOTEL DES INVALIDES.—An Establishment in Paris, maintained at the expense of the State, where a number of old French soldiers are quartered. Its chapel contains the tomb of the great Napoleon, and is an object of much attraction to all visitors. It was founded by Louis XIV. in 1671, and during his reign and for a long time afterwards was a place of retirement for the aged servants of Court Favorites as well as Invalided Soldiers; but this abuse was put an end to by St. Germain in Louis XV.'s reign. In 1789 the Hôtel had a revenue of £68,000, but during the time of the Republic its property was alienated and the Institution supported from the public revenue. The Hôtel can accommodate 5,000 men, and the actual number of inmates is not much below this. See *Soldiers' Homes.*

HOT-SHOT.—Hot-shot may be fired for the purpose of setting fire to vessels or buildings, though they are rarely used. Shot of low gauge should be chosen for this purpose and with reduced charges. They can be made red-hot in from 15 to 30 minutes, but care must be taken not to bring them beyond a *bright red,* as they are then liable to fuse and become misshapen. The part resting on the furnace-bars heats more quickly than the upper part, so they must frequently be turned. Shot expand $\frac{1}{16}$ of their diameter when brought to a red-heat; therefore, to prevent any accidents, each shot should be passed through a red-hot shot-gauge before being taken from the fire-room. Should the shot jam in the bore it must be cooled by pouring water in at the muzzle; but if that fails, the charge must be drowned before attempting to blow out the shot.

Junk and grommet-wads which have been soaked in water for two or three hours, having the water pressed out of them, are to be used in loading. The junk-wads must be small enough to fit easily when swelled by being soaked. The cartridge must be perfectly tight, so that powder will not be scattered along the bore. Sufficient elevation having been given to enable the shot to roll home, first enter the cartridge, a dry junk-wad, and then a wet junk-wad, and ram them home. Bring the shot in a bearer and enter it, with a wet grommet-wad on top; since it cools rapidly, no time should be lost. Quantities of smoke will come up through the vent, but a red-hot shot does not burn more than the outer yarns of a well-soaked junk-wad, even if left in the gun till it becomes cold. See *Fireworks* and *Projectiles*.

HOT-SHOT FORK.—A fork made of iron, fastened to a wooden handle, and is used to pull the shot out of the furnace. It has two prongs, which curve inwards and upwards, so as to retain the shot between them when once in position.

HOT-SHOT WADS.—Wads for firing hot-shot, and other like purposes, may be made of hay wrapped with rope yarn, and are made in the same way as junk-wads; or they may be made entirely of hay, by twisting from the hay a rope of an inch or an inch and a half in diameter, and then commencing at one end and doubling it up about one caliber in length, and twisting it all the time, until it becomes nearly large enough, when the rope is to be wound around the wad perpendicular to its axis, and fastened with a hitch.

HOTTE.—A sort of hand-basket, which is often made use of in the construction of batteries and other works, and serves to carry earth from one place to another. Hence the word *hod*, a well-known contrivance for carrying bricks.

HOUGINES.—Parts of ancient armor covering the thighs, legs, and arms.

HOUNDS.—1. Pieces of wood used in the construction of limbers for gun-carriages to connect the splinter-bars with the axles. 2. The blood-hounds employed for military purposes. The Russians have strengthened their army by the novel addition to each company of a pack of powerfully and carefully trained dogs. These watchful animals are sent out with the sentinels on picket duty, where their chary ear and still keener scent prove an impregnable barrier to the lurking spies of the enemy. The dogs used are a species of blood-hound from the Ural Mountains. The dog is selected because of its habitual silence. It growls but never barks—a matter of the first importance to soldiers near an enemy's camp. The Ural hound is gifted with an exceedingly fine sense of smell, keen ears, and is ever alert. Most comforting of all to the lonely picket the dog is said to be especially courageous in defending its master. It is curious that, with the example of the King Charles spaniels before us, no one thought before of using these intelligent animals as sentinels. The value of the plan is self-evident. The Muscovites have gone further, and are training swift hounds as well as these same Ural dogs, to act as dispatch bearers, much as the carrier pigeons were employed in 1871. They certainly would be hard messengers to catch, when stealing through the woods at night. See *Blood-hound*.

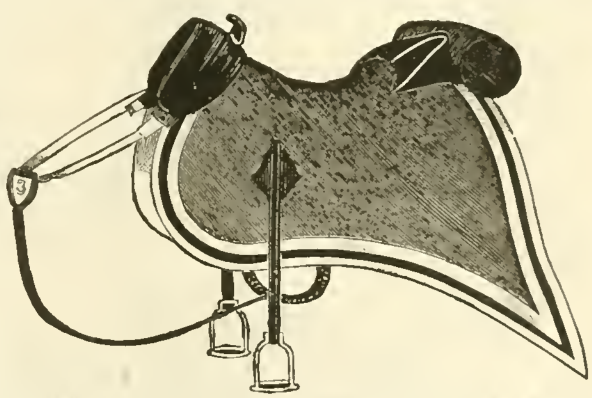
HOURGLASS.—A glass vessel filled with sand, and compressed and attenuated at its center into the shape of the figure 8, whereby the sand can only run through the connecting orifice in a given time. This vessel is contained in a wooden stand. Formerly each English regiment was furnished with this hourglass; and even at the present day native regiments in India use it. A common mode of keeping the time by native guards is by means of a metal bowl having a small hole in the bottom of it, which is allowed to swim on the surface of the water, and to fill in the space of an hour. This rough and ready mode of ascertaining time, though not always correct, gives a near approximation to the lapse of an hour. This nature of time-clock was the first instrument to measure the lapse of time independently of the sunshine. A simple time-keeper is also kept, but the arrangement is inverted, the bowl being filled with water, and the water allowed to escape into a receptacle in the same space of time, through a hole in the bottom of the bowl.

HOURS OF SITTING.—The hours during which a Court-Martial is authorized to hold its sessions. The law provides that the proceedings of trials shall be carried on only between the hours of eight in the morning and three in the afternoon, excepting in cases which, in the opinion of the Officer appointing the Court, require immediate example. In the latter case, the order appointing the Court-Martial must clearly state that "The Court is authorized to sit without regard to hours."

HOUSE.—A term anciently applied to the blocks of wood or frame structures, upon which the early bombards were fixed. See *Fust*.

HOUSEHOLD TROOPS.—Those troops whose especial duty it is to attend the Sovereign, and to guard the Metropolis. These forces comprise three regiments of cavalry—the 1st and 2d Life Guards, and the Royal Horse Guards, and three regiments of Foot Guards (which include seven battalions), the Grenadier, Coldstream, and the Scots Fusilier Guards. The cost of these corps, for pay and allowances only, reaches the sum of £230,000 a year; and they number in all ranks 1,302 cavalry and 5,950 infantry, who are justly held to be the flower of the British Army.

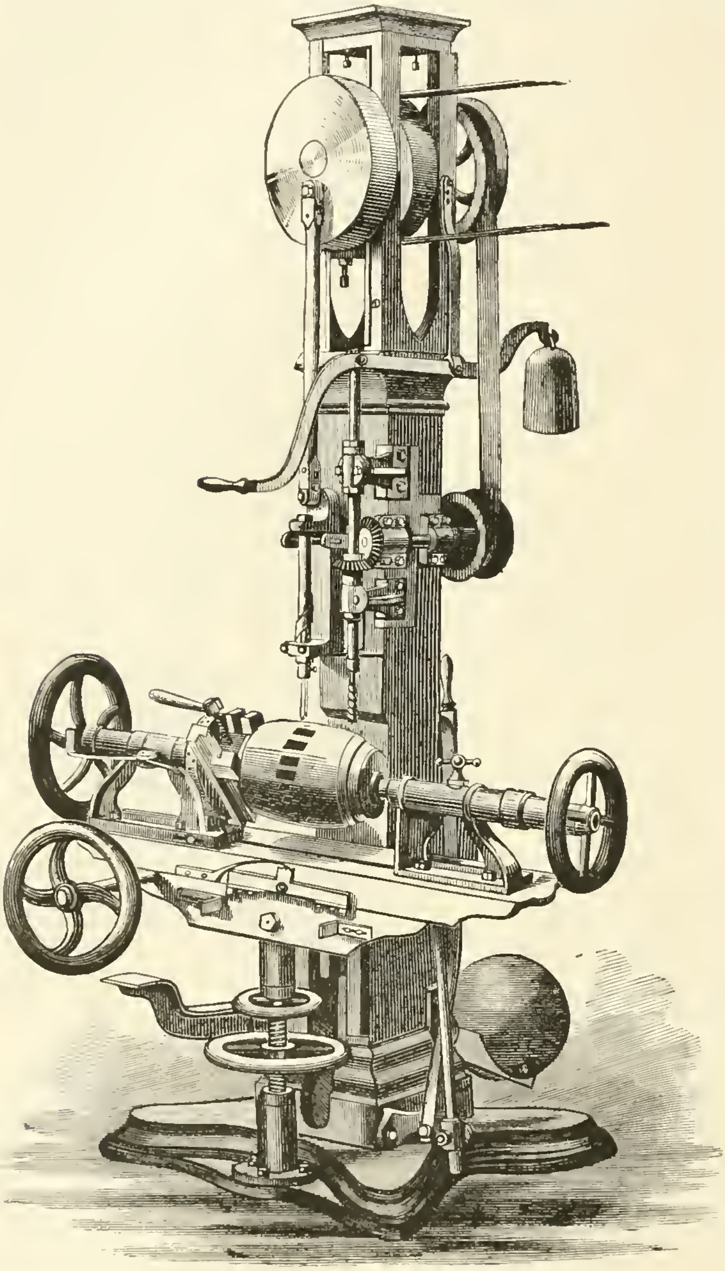
HOUSING.—The cover or cloth over or under a horse's saddle, used for cleanliness or as an ornamental or military appendage. In the United States Army, housing is prescribed as follows: *For General Officers*—To be worn over the saddle; of dark blue cloth, trimmed with two rows of gold lace, the outer row one inch and five-eighths wide, the inner row two inches and one-fourth; to be made full, so as to cover the horse's haunches and to bear on each flank corner the following ornaments, distinctive of rank, to wit: *For the General of the Army*—A gold embroidered spread eagle with two stars and "Arms of the United States" between them; *For Lieutenant General*—A gold embroidered spread eagle and three stars; *For Major Generals*—A gold embroidered spread eagle with two stars; and *For Brigadier Generals*—A gold embroidered spread eagle and one star. See *Saddle-cloth*.



HOWITZER.—From the earliest days of artillery there existed short, chambered pieces, which projected stone balls under great angles of elevation. In 1478, an attempt was made to use in these pieces, hollow projectiles filled with powder, to which was attached a burning match to set the powder on fire; but it is probable that the accidents which accompanied their use caused them to be abandoned for the time. In 1634, however, means were devised to overcome this difficulty; and, thus perfected, these pieces were introduced into the French service as a class of cannon now known as mortars. In the reign of Louis XIV., a great variety of mortars were used;

and some of them, called Comminges, after their inventor, threw bombs weighing 550 pounds. Early attempts were also made to throw hollow projectiles from perrieres and culverins, or guns; but great difficulties were experienced in loading them, and the accidents to which they were liable, as in the case of mortars, caused them to be abandoned. Subsequently, however, the Dutch artillerists conceived the idea of reducing their length, so that the projectile could be inserted in its place by hand; and, thus improved, these cannon rapidly came into use, under the name of howitzers, from the German, *Haubitz*. The howitzer combines in some degree the accuracy of a cannon with the caliber of a mortar; and, while equally effective at short ranges, is far more portable than either. That the powder, on its expansion, may act with full force on the shell, it is confined in a hemispherical chamber of smaller diameter than the rest of the bore, the mouth of which is completely closed by the shell when rammed home. The Coehorn howitzer, much used in India for mountain service, is a small gun, light enough to be borne by a horse up hilly defiles, etc. See *Howitzer*, *Ordnance*, and *Twenty-four-pounder Howitzer*.

HUB MORTISING-MACHINE.—A machine in which a wheel-hub is held upon a mandrel or stake, so disposed that a reciprocating chisel may cut therein the mortises for the spokes. The hub is dogged or clamped so as to prevent rotation while the mortise is being cut, and is then rotated at a determinate number of degrees to present the next spot. The drawing shows a power hub mortising-machine used in making the wheels for gun-carriages and Government wagons. Those hubs to be mortised are held fast in a screw-chuck, one end turning in cups fitted to each size. The chuck has a dial attached to it, accurately spaced for 10, 12, 14, 16, and 18 spokes, thus obviating the necessity for setting out the mortises. The bed also has stops which regulate the length, and is arranged with a lever and stops, to give any required bevel or dish to the mortise. It is supported by a standard, bolted to the base of the machine, making it firm and solid, and is raised and moved for the mortise by hand-wheels. The chisel is reversed by hand, and brought down by the new double lever or treadle, which is very easy for the operator. The bit-shaft has the new arrangement of lever and weight for working it, and is driven direct from the counter-shaft. The machines are complete in every respect, and are made in the best possible manner. This size works hubs 12 by 16 inches and under. It can be fitted with a bed for common mortising, if desired. The counter-shaft has tight and loose pulleys, 12 inch diameter, 4 inch face, and should make 350 revolutions. The counter-shaft should be placed on a level with the pulley in top of machine, and 8 or 10 feet distant. Weight of machine, 2,600 lbs. See *Mortising-machine*.



HUE AND CRY.—In Great Britain, the Official Gazette, which serves to advertise deserters from Her Majesty's service. The phrase is derived from the old process of pursuit with horn and voice, used in English law to describe the pursuit of felons. Whoever arrested the person thus pursued was so far protected that he required no warrant to justify the arrest; and even if the party turned out to be no felon, no action could be brought if the arrest was *bona fide*. But it was not only a ground of action, but an offense subject to fine and imprisonment, to maliciously and wantonly raise the hue and cry against a person. It was the duty of all persons to join in a hue and cry, and if a person who had been robbed, or knew of a robbery, failed to raise the hue and cry, he was liable to fine or imprisonment, or, according to some authors, to indictment. Hue and cry is now substantially abolished.

HUISSIER D'ARMES.—Tipstaff; an officer so-called in France, who was attached to the Royal Household. They were at first distinguished by the name of *Sergens d'Armes*, or Sergeants-at-Arms. Some were directed to bear the mace before the King during the day, and obtained on that account the appellation of *Huissiers d'Armes;* in later times they were called the Huissiers, or Tipstaffs of the King's Chamber. Others kept watch in the King's bed-chamber during the night, and were sworn to expose their lives for the safety of his person, whence they obtained the name of *Archers de la Garde*, which term was changed to *Gardes du Corps*, or the Body-guards.

HULK.—A name given to any old ship unfit for sea-service, which is used in harbor as a depôt of some sort. In the great naval harbors, there are coal-hulks, powder-hulks, convict-hulks, and hulks to which the crew of vessels repairing are turned over.

HUMETTY.—A term in Heraldry, applied to a cross or other ordinary which is cut off, and nowhere reaches the edge of the shield. See *Heraldry*.

HUNS.—The name of a considerable nation of antiquity, which, from time to time, made incursions upon the Roman Dominions, and which eventually, under Attila, the most renowned of all its leaders, brought the Empires of both the East and the West to the very verge of destruction.

The Huns were of Asiatic origin, and, in all probability, of the Mongolian or Tartar stock; therefore akin to, and perhaps to be identified with the Scythians and Turks. According to De Guignes, whose theory has been accepted by Gibbon, the Huns who invaded the Roman Empire were lineally descended from the Hiongnou, whose ancient seat was an extensive but barren tract of country immediately to the North of the great Wall of China. About the year 200 B. C., these people overran the Chinese Empire, defeated the Chinese armies in numerous engagements, and even drove the Emperor Kao-ti himself to an ignominious capitulation and treaty. During the reign of Vou-ti (141-87 B. C.), the power of the Huns was very much broken. Eventually they broke into two distinct camps, one of which, amounting to about 50,000 families, went Southwards, while the other endeavored to maintain itself in its original seat. This, however, was very difficult for them to do: and eventually the most warlike and enterprising went West and North-west in search of new homes. Of those that went North-west, a large number established themselves for a while on the banks of the Volga. Then crossing this river, they advanced into the territories of the Alani, a pastoral people dwelling between the Volga and the Don. At what period this took place is uncertain, but probably early in the 4th century. The Alani, who had long dwelt in these plains, resisted the incursions of the Huns with much bravery and some effect, until at length a bloody and decisive battle was fought on the banks of the Don, in which the Alan King was slain, and his army utterly routed; the vast majority of the survivors joined the invaders.

HUNTING HORN.—The Hunting Horn or Bugle Horn is a frequent bearing in Heraldry. When adorned with rings, it is said to be *garnished*. If the mouth and strings of the instrument are of different tincture from the horn, this must be named in blazon. See *Heraldry*.

HUNT LIFE-SAVING PROJECTILE.—This apparatus consists of a projectile and a tin can known as the shore-can. It is intended for life-saving purposes, to be used in connection with a gun or mortar of suitable dimensions.

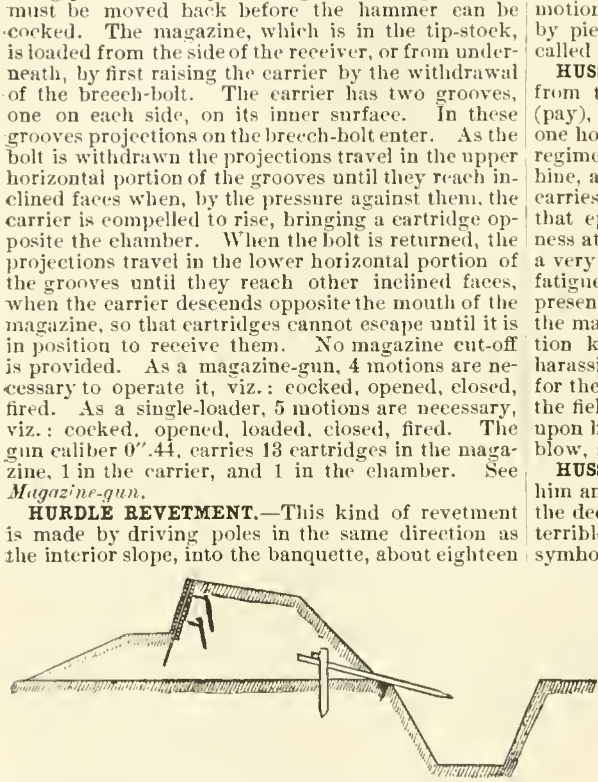
The body of the shot or projectile is composed of a tin tube closed at the front end by a disk of iron. The head or point is made of lead cast upon the end of the tin tube. The lead extends up the sides of the tube, forming a thin coating for a distance of 3″.2 from the plane of the head. The diameter of the flat head is 2.9 inches, but when fired expands to the full size of the bore. The tube is reinforced for 6 inches of its length above the lead with a galvanized sheet-iron tube. The object of this reinforce is to strengthen the tube and prevent upsetting when fired. Near the rear end of the tube four trapeziform pieces of tin, termed "wings," are soldered to the tube at right angles to each other and equidistant circumferentially for the purpose of guiding the projectile in its flight after the manner of the barbs of an arrow. About 250 yards of small line is coiled on a spindle in a lathe, after passing through a saturating solution of paraffine. This coil is wrapped with a thickness of laboratory paper, and as soon as withdrawn from the lathe-spindle is placed in the tin tube. The exterior end of the line is made fast to a wire loop which projects from the rear end of the tube. The wire is soldered to the tube. The rear end of the tube is then closed with a wooden plug one inch in thickness and of the same diameter as the inside of the cylinder. An axial hole one inch in diameter serves for the line to pass through in escaping from the shot. A paper disk is pasted over this end of the projectile, which must be removed before firing in order to secure and withdraw the end of the line.

The shore-can contains the shore-line and is made of tin. It is a short cylindrical tube, of greater diameter than the body of the shot. The lower end is closed by a bottom of the same material as the cylindrical body. To the bottom a ring is attached in which is tied a line, or through which a stake is driven, to prevent the can from being carried off in firing. Holes are punched through the bottom over each side of the ring-seat, through which the end of the line belonging to the outer coil is passed and tied to secure the line to the can. This shore-can contains about 250 yards of small line, coiled in a lathe and saturated with paraffine in the same manner as the line in the shot. After coiling, the line is placed in the can and the tin cover put on. The cover has a central hole 1″.6 in diameter through which the line is paid out. A strip of laboratory paper is pasted around the can so as to overlap the junction of the cover and body of the can and prevent the removal of the former. A paper disk, which must be broken before firing, is pasted over the hole in the top.

The method of using this apparatus is as follows: Suppose the gun, projectiles, and shore-can placed on the firing-ground and the gun in position for firing. Insert the powder-charge, tear the paper cap from the rear end of the projectile, and draw out a couple of feet of the line: place the projectile in the bore with the flat leaden head first. Then tear the paper cap from the hole in the top of the shore-can and pull out about 2 feet of line; tie the ends of the line together and place the shore-can near the gun on the windward side. The proper elevation is then given to the piece, the priming-wire inserted in the vent, a friction-primer put in, and the gun fired. See *Life-saving Rockets*.

HUNT MAGAZINE GUN.—This gun belongs to that system in which a fixed chamber is closed by a bolt, by direct action. The receiver has a slot in its upper surface for the purpose of loading the chamber direct when the piece is used as a single-loader; it is also bored through at the rear for the reception of the breech-bolt. The latter is composed of two parts, the body and the locking-tube, which are connected by a left-hand screw-thread. The bolt is locked by two lugs, turning in corresponding cuts in the receiver. These lugs are so shaped on their rear surfaces as to cam the bolt against the base of the cartridge during the locking. A cam on the inner surface of the rear end of the locking-tube forces the bolt slightly to the rear, starting the shell, during the unlocking. The opening of the joint in the breech-bolt (the thread being left-handed) during the locking aids in the camming forward of the bolt, while the closing, by drawing the forward portion to the rear, aids the starting of the shell. When the bolt is withdrawn the extractor, which is of the spring-hook pattern, pulls on the upper side of the head of the shell while the under side abuts against a forked post. By this means the shell is thrown clear of the gun. In order to insure the ejection of the shell a quick motion of the bolt is necessary. The forked post acts also as a guide for the breech-bolt. A slot in the rear of the bolt receives the nose of the hammer, allowing it to strike the firing-pin only when the piece is locked. A slide prevents the hammer being pulled back by catching of clothing, etc. It must be moved back before the hammer can be cocked. The magazine, which is in the tip-stock, is loaded from the side of the receiver, or from underneath, by first raising the carrier by the withdrawal of the breech-bolt. The carrier has two grooves, one on each side, on its inner surface. In these grooves projections on the breech-bolt enter. As the bolt is withdrawn the projections travel in the upper horizontal portion of the grooves until they reach inclined faces when, by the pressure against them, the carrier is compelled to rise, bringing a cartridge opposite the chamber. When the bolt is returned, the projections travel in the lower horizontal portion of the grooves until they reach other inclined faces, when the carrier descends opposite the mouth of the magazine, so that cartridges cannot escape until it is in position to receive them. No magazine cut-off is provided. As a magazine-gun, 4 motions are necessary to operate it, viz.: cocked, opened, closed, fired. As a single-loader, 5 motions are necessary, viz.: cocked, opened, loaded, closed, fired. The gun caliber 0".44, carries 13 cartridges in the magazine, 1 in the carrier, and 1 in the chamber. See *Magazine-gun.*

HURDLE REVETMENT.—This kind of revetment is made by driving poles in the same direction as the interior slope, into the banquette, about eighteen



inches below the tread, and then forming a wicker-work, by interlacing twigs between them in a similar manner to basket-work. The poles should be nine inches apart, and their diameter about one-and-a-half inches. They should be secured to the parapet by long withes. The drawing shows a hurdle revetment and fraise. See *Revetment.*

HURDLES.—Straight and flat rectangles of strong wicker-work, about 6 feet long, and 2 feet 9 inches high. They are useful in many ways, both in military and civil life, either as fencing, as barriers, or in fortification, in the construction of *hurdle-batteries.* These last were the invention of Sir William Congreve, who devised them as the speediest means of throwing up earthworks; three hurdles are fastened at their ends in the form of a triangle, and the central space is filled in a short time with earth. These triangles can be constructed to any ground-plan, and with their aid, a body of soldiers can intrench themselves in a few minutes. The hurdle is composed of wattles interwoven round stakes or pickets, the latter during the manufacture being fixed upright and firmly in the ground.

HURRAH.—A shout of encouragement and applause, characteristically English. It serves also as a war cry. As an engagement at sea commences, the crews of the English vessels send up deafening hurrahs; in a charge on shore, the English soldiers hurrah when they rush upon the enemy. There is something strangely exciting in this simple sound, and the combatants work themselves, as they shout, into a frenzied forgetfulness of danger.

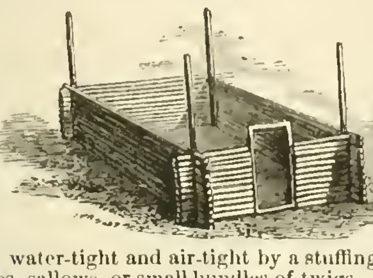
HURST.—A charge in Heraldry employed to represent a small group of trees, generally borne upon a mount in base.

HURTER — HEURTER — HEURTOIR. — A square beam placed at the foot of a parapet where there is an embrasure to prevent the wheels from injuring the interior slope, when the gun is moved in battery. A short fascine or fagot is sometimes used as a substitute for the beam. A hurter is placed on the front part of a siege platform, under the wheels. The motion of gun-carriages is checked, front and rear, by pieces of wood or iron, bolted to the top-rails, called *hurters* and *counter-hurters.*

HUSSARS.—Light cavalry. The name is derived from the Hungarian words *husz* (twenty), and *ar* (pay), because every twenty houses had to provide one horse-soldier. In the British Army there are 13 regiments. The men are armed with a saber, carbine, and pistol. The weight the horse of a hussar carries is about 18 stone. The dashing bold hussar, that epitome of military impudence and recklessness at the tavern, should present those qualities in a very sublimated form on the field. Regardless of fatigue and danger, his imagination should never present to itself an obstacle as insurmountable. On the march, constantly at the enemy's heels; in position keeping him at all moments on the alert, harassing him either with fatigue, or apprehension for the security of his rear and communications: on the field careering with a falcon's speed and glance upon his quarry, however it may seek to elude his blow, such should be the hussar.

HUSSITES.—The followers of Huss. Honoring him and Jerome of Prague as martyrs, they despised the decrees and anathemas of the Council, and took terrible revenge on the Priests and Monks. The symbol of their Confederacy was the cup, the use of which in the Lord's Supper they extended to the Laity, as James de Misa had already done with the approbation of Huss. In 1417 King Wenceslaus was constrained to grant them the use of many churches. After his death, August 13, 1419, the majority of the States refused to acknowledge his brother, the Emperor Sigismund, who had broken his safe conduct to Huss. And the papal instructions to the Cardinal Legate, John Dominico, requiring him to employ violent measures for the conversion of the Hussites, an insurrection ensued, and the war began which is known in history as the Hussite War. Convents and churches were reduced to ashes, and Priests and Monks were slain. The Hussites divided into two parties—the *Calixtine* and the *Taborites.* See *Huss et la Guerre des Hussites,* by Ernest Denis (1879).

HUT.—A structure more or less rough in its details, for the housing of troops. It is substituted very often for the tent, when the sojourn in a camp or cantonment is likely to be of consideration, as, for instance, through a winter—a hut, however rude, which is wind and water-tight, being as superior in comfort to a tent as the latter is to the open air. Huts may be made of almost any size, and are sometimes for one officer; at others for as many as one hundred men. The principal hut encampments in England are Aldershott, Shorncliffe, Colchester, and the Curragh of Kildare; in British North America, hut-camps are situated at intervals of a day's march on the route from New Brunswick to Quebec, and the troops who made that winter-march in 1861 to 1862 found their shelter truly welcome. The quarters occupied by the United States troops on the American frontiers, are very frequently huts made of timber by the troops. A good hut may be readily constructed on suitable ground or hillside by excavating and covering with a roof; but if timber is convenient, it is better to build a *log* hut, covering with bark skins, bushes, reed mats, sea-weeds, or any suitable material procurable. In building the hut four poles are planted in the ground where the corners are to rest. The logs are then piled one above another against these poles, as shown in the drawing, being notched where they cross so as to bring their sides together. The space between the logs is then



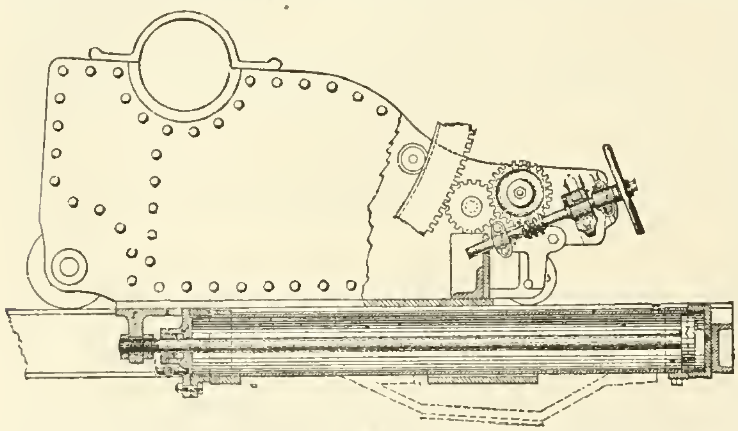
made water-tight and air-tight by a stuffing of clay, wattles, sallows, or small bundles of twigs. Within, the joints should be lined with laths, or the whole be supported by a scantling, and may consist of overlapping boards, or boards laid flush and shingled, or laths and shingles, or even birch-bark alone. The door is usually ledged, and there are one or two windows, with glazed sashes and shutters. A hut thus formed makes a snug habitation, and will last for many years; exclusive of the sashes, two men can erect in about a week, a hut of rough logs which shall be sufficiently large for their residence—that is, with an interior area of about 15 feet. When circumstances permit the logs are occasionally squared, which enables them to be fitted more accurately to each other, and adds, of course, to the solidity and finish of the whole structure, as well as to its durability. In this case the corner logs, instead of crossing each other, are joined by a dovetail, or cutting the end of each to an angle of 45°. The *framed* hut has the advantage over the log hut of allowing more exactness of finish, and from its lightness and portability being easily transported to any place where logs for hut-building may not be forthcoming. It consists of a strong framework of squared wood, properly fitted together, and covered with overlapping planks or weather-boards. The pieces should be sawn to the proper size, fitted to each other, and numbered; then packed together in small compass for conveyance to the intended site, where the structure can soon be erected. It is usually estimated that one of these huts, 30 feet long, 16 broad, and 10 high, makes a good barrack-room for 20 soldiers. The camps at Aldershott and the Curragh are mainly formed of framed huts. Where extra warmth is desired, the spaces between the uprights are built up roughly with bricks, burned or unburned. *Pisé* huts, common in the south of France, and very useful where wood is scarce, as well as very comfortable, are walled with blocks of clayey earth, and rammed with great pressure into wooden molds until they assume the forms of stones. These are laid one above the other much as stones themselves would be by a mason, and the wall so formed is both durable and sightly. The most critical operation for the non-professional hut-builder is roofing. This is usually thatch, shingles, paper, or felt, if lightness be an object; and of stones, bricks, or tiles, if the walls be calculated to bear their pressure. A roof of split logs gouged out in the center, like a long curved gutter, is good. A layer is placed side by side, with the hollow side up, and a second layer is put on them, with the hollow side down. The roof should have a pitch of not less than 45° to keep out the rain. All cracks should be carefully filled with grass, mud, clay, etc. The huts of Indians and all Savages are generally round or approximate to the circular form, probably because of the maximum house for a minimum cover. In building huts, it might be well to remember that logs split better from the crown or small end toward the butt.

HYDER.—The Arabic term for lion. This title is frequently given to men of rank in India.

HYDRAULIC BUFFER.—A recoil check, in construction very similar to the air-cylinder. A liquid is used instead of air, but the principles of operation are similar. This buffer is, at present, furnished only with the converted guns in the United States service. In its usual form it consists of a cast-iron cylinder 78 inches long, with an interior diameter of 8 inches, closed at either end by a cast-iron cap. Near the rear end of the top of the cylinder is a hole for the purpose of filling it with water, or some non-freezing liquid. A hole in the front end, closed with a screw-plug, permits the fluid to be withdrawn. Nine and one-half gallons (precisely) of fluid are required. A wrought-iron piston-rod passes through the rear cap, and is secured to the rear of the top-carriage by a wrought-iron cross-head. The piston-head, of wrought-iron, 15 inches thick, is pierced near its circumference, on opposite sides of the rod, with two holes seven-eighths of an inch in diameter. These holes flare out both ways 25 inches, allowing free passage to the fluid from the rear to the front of the piston, permitting the top-carriage to run back without strain. Upon the top of the rear end of each rail of the chassis of No. 3, is bolted a wedge or incline, having a rise of 2.5 inches in 64 inches; near the rear end of this, is attached a brass angle-plate, to which are secured three rubber counter-hurters. A similar angle-plate with hurters is attached to the front part of the chassis. Water or any other free-flowing liquid answers for filling the cylinder. In cold weather a non-freezing liquid, as a mixture of glycerine and water, methyl and water, or some of the non-freezing oils, must be used. The greatest care must be observed to have in the cylinder the exact amount required. The difficulty of properly regulating all of these matters makes the hydraulic buffer greatly inferior to the air-cylinders.

The recoil of the gun is controlled in all Prussian carriages for the land service by the Hydraulic Buffer. As generally used, it consists of a wrought-iron lap-welded cylinder, with cast-iron cover-cap and flange, and wrought-iron piston-head and rod, a packing-gland and emptying-cock of brass. The cylinder is 77.375 inches long in the clear, and 8.07 inches in diameter, and holds 12 gallons 5 pints. The cap closes the rear end, being screwed on. The flange is screwed on the front end, and the cover is bolted to the flange. Both the flange and cover are flat on top, to allow the top-carriage to pass over them without striking. To secure perfectly tight joints, a mineral composition is spread over the screw-threads of the cylinder before the cap and flange are put on, and the same, mixed with chopped hemp, is laid between the flange and cover before they are bolted together. The packing used to make a tight joint around the piston-rod consists of a piece of tow about 1.25 inches in circumference and 3 feet 7 inches long, greased with tallow, and wound round the rod and pushed into the recess in the cover. It is held in place by the packing-gland, which is made to squeeze the packing by being screwed into the cover until the rod can be just moved by the strength of one man. A zinc pan is suspended from the front end of the cylinder to catch any oil that may drip from the gland in firing.

A filling-hole is bored and tapped in the upper surface of the cylinder near the rear end, and is closed by a wrought-iron screw-plug, which is secured to the chassis by a short chain. An emptying-cock of brass is provided in the lower part of the cover. The piston-head, 8.04 inches in diameter, has four holes drilled in it, each 1.25 inches diameter, for the 7-inch gun: .9 inch for the 9, 11, and 12-inch, and .8 for the 10-inch, and .7 for the 12-inch of 25 tons. The piston-rod screws into the head, and is prevented from turning by a screw. The collar-nut screws on to the rod a few inches from the end, and the connecting-nut on the extreme end. The cross-head is held between the two nuts, with a play of about one-tenth of an inch, and the hole in the cross-head for the piston-rod is made oval, to allow of the top-carriage being thrown on its truck-wheels without bending the piston-rod. The cylinder is secured to the chassis by means of iron bands which pass over the cylinder, and are bolted down to the rear bottom-plate at the rear end, and at the front end to a bearing-plate which is bolted to the diagonal braces. The rear bottom-plate and the lower flange of the rear transom are hollowed out to form a bed for the end of the cylinder. The top flange of the rear transom is cut away from the cap of the cylinder. The cylinder, before being bolted down on the chassis, is brought to bear squarely against the rear transom, with the flat edges of the flange and screwed into a piece to which the cover is held by screws. There is a hole in the bottom piece for filling the cylinder; it is stopped with a screw and a cock in the cover for emptying it. The piston-head, with four holes bored in it, fits the cylinder closely, and to it the piston-rod of cast-steel is fastened, and passes through the cylinder-head, the joint being packed with hemp-packing and bronze packing-box. The end of the piston-rod is fastened to the cross-head, which is bolted to the bottom transom of the top-carriage. The Hydraulic Buffer operates in this manner: The cylinder is filled almost full with glycerine, which is preferable to water in that it does not evaporate or freeze. A certain amount of air is always left in the cylinder. In the recoil of the carriage the piston-head connected to it by the piston-rod and cross-head compresses the glycerine in the



rear end of the cylinder, and causes the liquid to flow rapidly through the holes in the piston-head, gradually bringing the carriage to a state of rest. The air in the cylinder acts as a cushion when the gun is fired, and lessens the shock which is then communicated to the different parts. The resistance of the liquid to a slow motion of the piston-head being very small, no difficulty is experienced in running the gun slowly into battery.

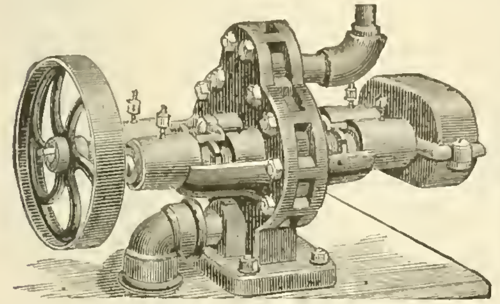
The Hydraulic Buffer should be the object of especial attention, although there is little to do to it after it has been secured in its place in the shops. First, attention should be paid to the preservation of the glycerine in the cylinder at its proper height, which can be discovered at the filling-hole. If the glycerine falls below the prescribed depth, it does not matter from what cause, it must be replenished. For this purpose, take out the filling-hole screw and insert the funnel in the hole. The purest glycerine is always to be preferred, of a density of 1.19, which neither evaporates nor freezes, even with the greatest cold, and has no action on the metals. In cases of emergency the deficiency may be made up with pure water without altering its qualities sensibly, but this addition of water should never exceed one-fourth of the whole. In filling the cylinder the prescribed quantity marked in figures on the end should under no circumstances be exceeded. In some carriages the proper height of the glycerine is marked by a screw. To prevent it from leaking, it is absolutely necessary, in the first place, to keep the filling-hole screw always tight by wrapping it with a hempen thread, with white lead or tallow when necessary; secondly, to tighten the hemp packing whenever the least leaking of the liquid is observed, by screwing up the packing-gland; and, thirdly, to keep the emptying-cock always tight and well closed. It is advisable to close it with a wooden plug. Before the firing, the carriage, and particularly the hydraulic buffer, should, as far as possible, be minutely inspected, the bolts, nuts, etc., which may have got loose tightened up, and the working of the different parts tested. See *Pneumatic Buffer*.

HYDRAULIC CRANES.—Wherever a large number of cranes have to be worked near each other, water-power is by far the most manageable, economical, and convenient method of working them. Sir W. Armstrong & Co., of Newcastle, have taken the lead in introducing this kind of machinery. They have fitted up a great many railway goods stations with complete systems of hydraulic cranes.

The pressure usually employed in working the hydraulic cranes is greatly in excess of the pressure admissible in the case of steam. Six or seven hundred pounds to the square inch is usually employed as the working pressure. It is got up to this great pressure by means of an arrangement called an accumulator, which consists of a large hydraulic ram of 16 or 18 inches in diameter, carrying a wrought-iron cylinder. This cylinder is filled up with stones or gravel to the weight of 60 or 70 tons. A powerful horizontal steam-engine forces water into a cylinder and slowly raises the ram with its enormous load. Pipes lead away from the cylinder to the cranes in the different parts of the station, and are thus supplied with water under the great pressure caused by the load forcing the ram into the cylinder. The load is constantly rising and falling a little as these cranes draw their supplies from the cylinder. If the cranes were supplied direct from the force-pumps of the steam-engine, without the intervention of this accumulator, their action would be jerky and unsteady. The accumulator acts as a reservoir of power, and when it happens that a great number of cranes are drawing off water at the same moment, and in excess of what the engine force-pumps can supply, the ram descends, keeping up the while the full 700 lbs. pressure; and then, when the cranes are demanding less abundant supplies, the engine overtakes its works, and sends the ram up again. When it arrives at the top it touches a lever communicating with the throttle-valve of the engine, and thus slows or stops the engine when the accumulator has mounted to its maximum height. The moment it begins to descend, the lever is relieved, the throttle-valve opens, and the engine goes on again with such speed as the work demands. See *Cranes*.

HYDRAULIC ENGINES.—These engines are frequently used in foundries and arsenals, where water of a high pressure is obtainable. They do not differ in any essential particular from a steam-engine. As the pressure under which they work is from five to ten times greater than that of a steam-engine, they are much smaller. A common form is that of three small cylinders in which three plungers work. The water is admitted into the cylinders by means of valves, and forces the plungers outwards. These plungers are connected with a three-throw crank, and when they have completed their outward travel, or working-stroke, the water is allowed to escape from the cylinder, the plunger then slides inwards, to be again forced outwards by a fresh rush of water admitted at the proper instant into the cylinder by the action of the valve.

Roots Rotary Hydraulic Engine, extensively used in the United States and abroad, is represented in the drawing. In order to realize the full benefits that may be derived from this, or any other Hydraulic Engine, it is of the utmost importance that the supply or feed-pipe be sufficiently large to deliver the water to the engine when running, at the same pressure as at the mains. Anything less than



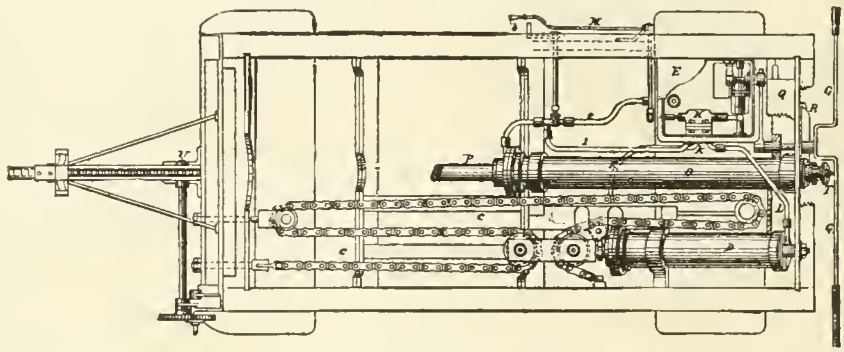
this cripples the engine, and causes it to use an unnecessarily large amount of water. In a long service-pipe of small size the pressure is so reduced by the friction of the water in passing through the pipe, that though it may supply a sufficient volume of water, it would be at such a diminished pressure that it would have but little power; for instance, if an engine used fifty gallons of water per minute, with forty pounds pressure per square inch at the mains, and yet by the use of a small service-pipe, reduced the pressure at the engine when running to ten pounds per square inch (which is often done), it is evident that while the same quantity of water is used, that only one-fourth of the useful effect would be obtained from it, that would be if the same pressure was maintained at the engines as at the main. It is also plain that to do the work that could be done with the 50 gallons at 40 pounds pressure, that four times as much water would be required at 10 pounds pressure, or 200 gallons; thus plainly showing that with a given work to be done, much less water will be required with a large pipe than with a small one, hence the importance and economy of having the feed-pipe amply large. This engine being a pressure-engine, the water is confined and cannot escape until it has exerted its whole force in turning the engine. When the engine does not turn, no water is discharged except from a slight leakage. It can only receive and use a sufficient quantity of water to fill the engine, each revolution. The engine is a water-meter as well as a water-engine, therefore the quantity of water used is not determined by the size of the pipe, but by the number of revolutions of the engine. If the pipes were ten times as large, the engine would not use any more water per revolution than with a very small pipe, but the amount of power resulting from a given amount of water would be in proportion to the difference in pressure, as shown before.

The engine should be placed on a solid foundation perfectly level from end to end, and be firmly secured, so that it will not get out of position from the strain of the belt or other attachment. But care must be taken to have an equal bearing on the foundation; otherwise, when it is fastened down, it will be on a strain and cause it to work hard. Care must also be taken in fitting on the feed and discharge-pipes, and making the connections, that they are not on a strain, for this may also spring the machine and cause it to run hard. The discharge-pipe should always have a syphon or trap between the engine and the sewer-pipe into which it discharges, for the purpose of keeping the discharge-pipe full of water, by keeping out the air. The size of the pulley should be such that, when all the machinery is on that the engine is to drive, and running at full speed, the regulating-valve should be wide open. If the speed is too high, the driving-pulley should be enlarged; if too slow, it should be diminished.

HYDRAULIC FORGING.—Forging with the hydraulic-press instead of the hammer and anvil. The process is analogous to that of rolling. The advantages claimed for the process are that it is, in many operations, more expeditious than the ordinary modes, and also that it produces a better structural condition of the particles of the material, the force being less superficial than the sudden impact of a hammer, and moving the particles of matter near the center to a greater extent, thus rendering the forged bar more homogeneous. Every forger and observant person has noticed that in the ordinary mode of forging a bar of iron there is, when the bar is thick enough, a protrusion of material at the edges, leaving a groove in the middle of the thickness, because of the superficial portions of the iron bar having received the greatest spread. Rolling or forging by pressure avoids this. Forging by hydraulic pressure is practiced in Europe. At Vienna there are several presses in operation, one with a piston 24 inches in diameter transmitting a pressure of 2,400,000 lbs.

HYDRAULIC GUN-CARRIAGE.—The renowned 35-ton Hydraulic Carriage was constructed at Woolwich, under the direction of the Commanding Officer of the Carriage Department. A detailed description of this carriage will suffice for all others. The hydraulic apparatus with which it is provided is used to check the recoil in firing, run the gun into battery or from battery, and also to traverse the carriage to the right or left. These different operations are performed by means of two hydraulic cylinders, O and D, and the double-action pump in the reservoir, E, which contains a mixture of alcohol and water. The pump, worked by means of the brake, G, drives the liquid into the distributing-chest, H, which sends it through the tubes, I K L, either to the front end of the cylinder O, or to one or other end of the cylinder D. The desired position of the valve is given by means of the lever, M, attached to the right side of the chassis. The cylinder, D, has a piston, the rod of which is fastened to the chain *c, c*, which engages a wheel mounted on the same axle as the pinion that drives the bevel wheels, intended to give motion to the rear traverse-wheels. The motion of the piston in either direction carries the chain, *c*, with it, thus causing the pinion to turn, and by its means the traverse-wheels. To traverse the carriage to the right or left it is sufficient to turn the distributing-valve so as to send the liquid on one or the other face of the piston, and then to work the pump by means of the brake, G. The chain moves on the wheel with a velocity four times greater than that of the piston; a slight motion, therefore, of the latter is sufficient to traverse the chassis through a considerable arc. A piston is also fitted to the cylinder, D, which is used to check the recoil in firing, and to run the gun into battery. The piston has a leather packing on either face, and the front end of the rod is fastened to the carriage. The front end of the cylinder is placed in communication with the distributing-chest by a pipe, and the rear end by a passage, R, with a second reservoir, Q. The passage, R, can be contracted more or less by a conical valve, which is regulated by means of the regulator, I. To use the apparatus as a hydraulic buffer, close the communication of the front part of the cylinder, O, with the pump through the distributing-valve, H, and reduce the section of the orifice for the stream according as circumstances may require. When the gun is fired, the carriage as it recoils forces the piston in, and drives the liquid into the reservoir, Q, through the opening around the conical valve: the recoil is checked as in the ordinary hydraulic buffer, by the resistance that the liquid meets with in passing through the narrow orifice. The entire distance through which the valve may be moved is one inch, and the part of the valve-stem that projects is graduated into tenths of an inch. In firing with maximum charges the valve-stem is turned in up to the division of eight-tenths.

To run the gun from battery without firing, it is sufficient to open the communication of the pipe, I, with the pump, and to work the latter. The pressure of the liquid on the front face of the piston forces it into the cylinder, O, and draws the carriage, being attached to the rod, P, back with it. The liquid which is in rear of the piston escapes as before, but without meeting any resistance in its passage around the conical valve on account of the slowness of the motion. To run the gun into battery,



the front of the cylinder, O, and the tube, T, are placed in communication with the discharge-pipe by means of the distributing-valve, H. The carriage then runs into battery of itself by reason of the inclination of the rails of the chassis. Its velocity is checked by the resistance that the liquid meets with in passing through the tube, T. If it be wished that the gun shall run into battery more quickly, a special tube, *c*, is provided, of larger cross-section, which allows the water to pass more quickly; it will be sufficient to open the valve, by means of the handle, to reduce the time of running in to a few seconds. By turning this handle the motion of the carriage may be regulated at pleasure, and it may be even stopped at any point on the chassis by closing the valve altogether. The ordinary position of the valves is that represented in the drawing, the apparatus being arranged for running the gun from battery. The liquid which is forced by the pumps passes into the tube, T, while K, and L, communicate with the discharge-pipe. If the valve be moved farther to the right, L, remains in connection with the discharge-pipe, N. T is closed while one of the orifices of admission comes opposite the outlet, K. If, on the contrary, it is pushed to the left, I, and K, communicate with the discharge-pipe, and L, with the other opening. These two extreme positions of the valve correspond with the traversing of the chassis in one or other direction, and the last also to running the gun into battery automatically. A direction-plate is attached to the chassis on the right side, giving the positions of the lever, M, corresponding to those of the valve for traversing the gun to the left, from battery, gun to the right, and into battery. One man at the valve-lever and two men at the pumps are sufficient to execute all of the maneuvers, though it is preferable to have four men at the pumps. The time required to traverse the gun through an arc of 54° is two minutes, and the same for running the gun from battery 6½ feet. The loading apparatus is decidedly novel. It is composed essentially of a chain with the links constructed like the joint of a carpenter's rule, so that it can turn only in one direction, while it is as stiff as a solid rod in every other. The links of this chain are made as follows: The angles of the links on top are square, while those underneath are rounded; two adjoining links thus abut against each other when an effort is made to bend the chain outward, while it can be readily bent in the opposite direction. It is guided in its motion by a kind of tube inclosed between two sheet-iron plates. A spur-wheel and pinion supply the means of raising the tube out of its bed, and raising the chain up to the bore of the gun. The tube is held at a convenient height by a pawl. A rammer or sponge is fitted to the front end of the chain according as it is wished to load or sponge the piece, and by working the crank-handles the chain is forced down the bore as if it were a rigid staff. The trials with this arrangement have given satisfactory results. A still more original mode of loading, based on the use of a pneumatic apparatus, has been applied to a 65-ton gun in the experimental casemate battery at Woolwich. This arrangement has the advantage of requiring only very little room. See *Sea-coast and Garrison Carriages*.

HYDRAULIC JACK.—A machine which often takes the place of the jack-screw for raising heavy weights. It is simply a form of hydraulic press, which may be placed beneath heavy ordnance, or any great weight which it is desired to raise, and generally consisting of a stout frame furnished with upright grooves, in which a follower may be forced upward by a hydraulic cylinder. By proper appliances the power may be rendered almost immeasurably great. The enormous multiplying power given by this machine has been employed for a great variety of useful purposes such as compressing bales of cotton, paper, etc., expressing oils, bending of iron plates and bars, and raising weights. This was the means employed for launching the *Great Eastern*, at Millwall, and for raising to their position the tubes of the Britannia bridge. The *jacks*, as manufactured by Watson and Stillman, New York, up to 30 tons capacity appear to the eye, when depressed, a simple cylinder with a head; and when elevated, like one cylinder sliding within another. The cylinder is from two to six or more inches in diameter, according to the power desired. The head (which is screwed on to the inner cylinder, called the ram) has a socket for the reception of the lever by which the force-pump is worked. The force-pump is contained inside of the ram, and consequently is not seen in the following drawings. The ram, with the head, contains only as much fluid as is required to fill the vacancy in the cylinder, caused by the raising of the ram in the act of lifting, and when this is accomplished, the fluid is returned into its original reservoir by a valve operated by the lever that works the pump. The lever is detached, and may be put on at pleasure. The claw attachment is an iron tube, screwed into the lower side of the head, and passing down to the bottom of the jack outside of the cylinder, on the lower end of which is a claw that supports the weight to be raised. These jacks are light, portable, and of easy application—a jack to raise 5 tons weighs only 20 lbs., and one to raise 100 tons not more than 375 lbs. They are all worked by the labor of one man only, who is capable of raising 10 tons through a space of one foot in one and a half minutes, or 100 tons the same distance in ten minutes. The horizontal jacks have an enlarged reservoir, containing fluid sufficient to run them out their entire length in a horizontal position. To use the jack, place the head (or if a claw-jack the claw or head) under the weight to be raised, place in the lever with the projection downward, then work it perpendicularly until the weight is at the required height, or the number of inches the jack runs out. To lower the weight, push the lever to the bottom of the stroke, take it out, turn it with the projection upward, and with a slight pressure of the hand, the weight may be lowered as slow as required, or stopped at any point. Sometimes it happens that another stroke of the lever would raise the weight too high; then raise the lever a little, and push it down slowly, by which the stroke will be missed. Should the valve stick to its seat, and prevent the jack working, by striking the lever a few sharp blows up and down, the valve will be released.

Fig. 1 shows the style used when the jack stands upon the ground or light board, and can be placed under the work, or where steadiness is required. Fig. 2 shows the style used when there is not sufficient room to get the head of the jack under the work, and is the pattern used for moving heavy guns, boilers, machinery, etc. Fig. 3 shows a form of lifting-jack used for dry docks, pressing flanges on wagon wheel hubs, etc. The piston is entirely enclosed, thus preventing all grit or foreign material getting into the pump and cutting it or preventing its working. The cylinder and bottom, on which it rests, are made from one piece of steel, thus relieving the reservoir-casing of strain, and dispensing with one very troublesome packing and making a jack stronger and lighter than one having a wrought-iron cylinder. There is nothing difficult of access, or which an ordinary mechanic cannot keep in good order. Fig. 4 shows a double pump-jack, having pumps with pistons $\frac{3}{4}$ inch and $1\frac{1}{4}$ inch diameter, the larger giving about one-third the pressure of the smaller, and working three times as fast. This style of jack is used where there is a variety of work, or where the jack has to work under varying loads. Fig. 5 shows the hydraulic pulling-jack, used for hoisting or pulling heavy weights in engine rooms, or in other circumscribed places, setting up rigging, pile-drawing, etc. This jack appears like a plain cylinder with rings at each end, by which to attach the body to be moved. They are three or more inches in diameter, and one and a half or more feet long, according to the power required, or the distance the weight is to be moved. It has a force-pump on the outside, worked by a lever, which forces the fluid contained in the cylinder to the opposite side of a piston, to the rod of which one of the rings at the end is attached. By this operation the jack is forced together, drawing with it the body to be moved. It will work vertically, horizontally, or at any angle. To use the jack, fill it through the screw in the side of the cylinder with whiskey and a few drops of oil. To pull or lift anything, make it fast to the jack by chains or ropes through the rings at each end, having first extended it as far as it will go. This is done by giving the thumb-screw in the force-pump two or three turns inward, and pulling out the piston, then turn out the thumb-screw until it stops. Put in the lever and pump as much as required. See *Jack-screw*.

HYDRAULIC LOADING APPARATUS.—A system of apparatus used when maneuvering heavy turret-guns. This apparatus was thoroughly tested, in working the 100-ton guns, belonging to the Italian Government, in experiments at Spezzia, 1876. The working of the gun, including all the operations of loading and sponging, is effected by the means of hydraulic pumps, which are all operated by one small steam-engine. The gun is placed with its trunnions resting on two heavy blocks of metal, which, being retained by guides, slide on large beams or girders built in the floor of the turret. In front and rear of the blocks are pistons, working in cylinders in the direction of the floor-beams. These pistons, under the influence of water-pressure, move the gun in and out of battery. The breech is raised and lowered by similar means. When the gun is to be loaded, it is run forward and the muzzle depressed till it is in front of an armored hood, which shields an iron door in the main deck. The door slides back, a sponge appears on the end of a staff, which enters the bore and lengthens itself like a telescope till the bottom is reached, when, in obedience to the touch of a valve, a flood of water is ejected from the sponge to extinguish fire and wash the bore. The shot and cartridge next appear, lifted from below on a small truck, which is run out on a trap-door. The cartridge is lifted in front of the muzzle, the sponge (now converted into a rammer) pushes it a short distance into the gun, is then withdrawn, and when the shot rises pushes both to the bottom of the bore. The sponge is withdrawn below deck and the trap closes. Each of these movements is effected entirely by water-pressure, the course of the water and the corresponding operation being determined by manipulating the proper valve. The only defect in the principle was developed by the bursting of the English 38-ton gun on the *Thunderer*, in 1879.

If the slipping of a shot is to cause the bursting of a gun, anything that tends to produce this slipping is to be deprecated, and as the hydraulic loading-gear requires the gun to be inclined downward at a considerable angle, it would appear that the machinery was open to objection. But a similar difficulty presented itself years ago with broadside guns. These were found to start their projectiles freely, not so much by the rolling of the ship as by the jerk of running the gun out. Wedge wads were employed expressly to prevent this, and guns are generally dependent on the efficiency of these wads for the fixing of their projectiles.

HYDRAULIC POWER.—The use made of hydraulic power is probably greater at Elswick than at any other Establishment in the world. This might naturally be expected, when it is remembered that the world is indebted to Sir William Armstrong for the advance made in this direction. The system of hydraulics at Elswick extends to all parts of the grounds, reaching all the shops, wharves, and water-front. Pumping-engines are established at convenient intervals, only one working at a time, and the connection of pipes being continuous, the uniform working of the system is established by five or six accumulators with 18-inch rams. The working of the pumping-engine is made automatic. The accumulator nearest to it is slightly more heavily loaded than the others to give a lead in rising to the distant one, and is connected with a steam regulating valve to act as a governor for adjusting the speed of the engine to the varying demand of the hydraulic machines. The pressure sustained throughout the system is 750 pounds to the square inch. The pipes are usually 5 inches in diameter, the largest being 6 inches. Hydraulic power is used for the forge and foundry-cranes, also for the movable cranes which operate along the water-front. For the accommodation of these last, pipes are run, in junction with the pressure main, with hydrants from 18 to 36 feet apart, from which connection is made with the cranes by means of telescopic tubes. Two or more cranes can thus be brought into operation on any vessel at the water-front. On the eastern end of the wharf are erected large hydraulic shears, worked by a direct-acting hydraulic cylinder, 40 feet stroke, lifting 120 tons. The back leg moves so as to bring the lifting cylinder about 30 feet out; the foot is moved by a screw 50 feet long, with hydraulic engine and gear. The most notable hydraulic crane that has yet been produced from these works is one erected in the Italian naval arsenal at Spezzia, which is capable of lifting 160 tons through a range of 40 feet. It is carried upon a ring of line rollers supported by a pedestal of masonry, and the slewing is effected by an hydraulic engine applied to a pinion which gears with a circular rack. The rake of the jib or projection from the center of rotation is 65 feet, and its height from the quay-level is 105 feet. The crane is counterbalanced on the side opposite to the load. About the grounds at Elswick, particularly at the approaches to the shops, there are numerous small capstans worked by hydraulic engines, which are of great service in hauling heavy loads into or out of shops, and in transporting them from shop to shop. It is almost unnecessary to add that it is at Elswick that the applications for working heavy guns by hydraulic power have been designed and manufactured. No foundry or gun factory can be considered efficiently equipped without being provided with arrangements for the plentiful supply of hydraulic power.

We can but briefly describe a system of hydraulic supply within the limits of this work, although the subject is a very important one, and is, at present, receiving the attention of the United States authorities in connection with the proposed establishment of a Government foundry, for the manufacture of heavy ordnance adapted to modern warfare. The Holly System of Water Supply, an invention of Birdsill Holly, of Lockport, New York, and the most perfected system of which we have knowledge, is designed not only to supply water for ordinary purposes, at any desired elevation, without the use of a reservoir or stand-pipe, or any other contrivance for calling into requisition the principle of the hydrostatic equilibrium, but also to furnish the means of extinguishing fires at several points at the same time, if necessary, and all this without the use of any movable engine for that purpose. This result is accomplished by placing a set of Holly pumping machinery, which is of peculiar construction, within a suitable building, located at a convenient point where the supply of water is accessible, and from whence by a proper system of mains and pipes the water can be conducted wherever it is needed. The pumping machinery, which may be propelled by either steam or water-power, must be adequate to the service required, having a reserve of power for extraordinary occasions. To guard against contingencies the machinery is duplicated, or so constructed that the breaking of a part does not disable the whole. In order to maintain steady pressure, the operation of the machinery is continuous; but as the demand for water is subject to constant variation, means are provided for the automatic regulation and government of the pumps, so that the amount of water delivered is in exact accordance with the requirements of the moment. The means of regulation which thus forms such an important feature in the Holly system is an exceedingly simple mechanical device depending for its operation upon the degree of pressure in the mains. If this pressure falls, owing to an unusual drain, the regulator instantly acts so as to admit steam for a longer period into the cylinders of the engines, and the pumps are thus at once caused to operate more rapidly and powerfully. When the pressure in the mains increases, owing to but small drafts being made on them, the reverse takes place and less water is pumped. The normal pressure is adjusted by the engineer in accordance with average requirements. The fire protection afforded by the Holly system is of the most efficient character. Water is not merely distributed to hydrants, but sent there under pressure, so all that is required is to couple on the hose and turn on the stream. The adjustment of the engine to give a quick supply under heavy pressure, in response to a sudden alarm of fire, is the work of an instant. The mere opening of a hydrant causes sufficient diminution of pressure in the pipes to operate a valve, which in turn communicates with a whistle, the sounding of which is the alarm for the engineer to turn on the fire pressure.

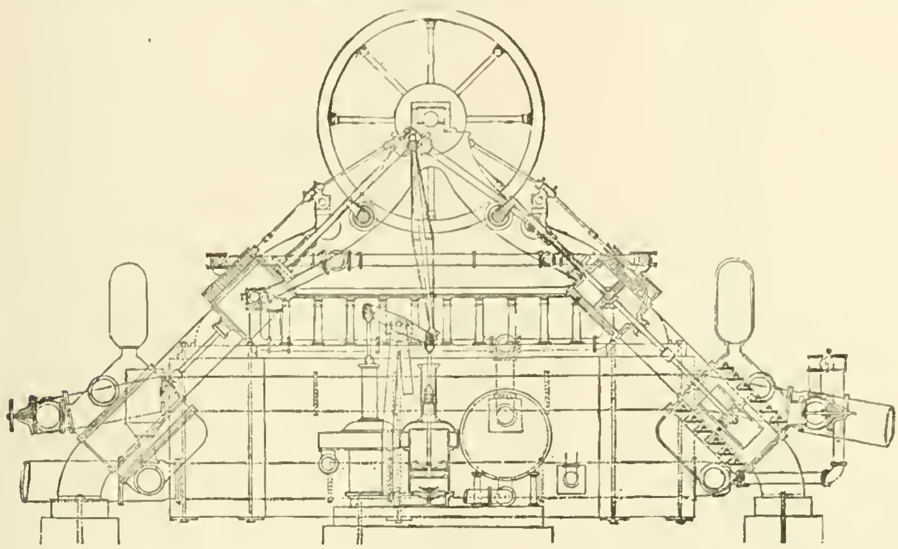

Fig. 1.

The Holly quadruplex pumping-engine is represented in sectional elevation in Fig. 1. It has four steam-cylinders inclined at an angle of forty-five degrees, and four pumps, one of which is in a direct line with each cylinder. The steam-cylinders and their pumps are arranged in pairs on opposite sides of a heavy iron frame, the two cylinders of each pair being connected to a common crank-pin, and the crank for one pair of cylinders being set 135 degrees in advance of that on the opposite side. The engines are of the reciprocating piston form, with guides and connecting rods. A connecting rod affixed to the back crank-pin actuates an air-pump beam, giving motion to two single-acting air-pumps and two boiler feed-pumps, one of which draws water from the hot well, and the other from the steam-jackets which surround the sides of all the steam-cylinders. The steam from the jackets passes through a feed water-heater, so that the temperature of the feed can be raised to any desired point by increasing the amount of steam supplied to the jackets. The connection of the pumps with the steam-cylinders and the steam piston-rods with the pumps, is by means of keys, so that any engine or pump can readily be thrown out of action. The steam-piston is packed by cast-iron rings set out by springs, the set-screw of which projects beyond the face of the piston, and there are bonnets in the lower cylinder-heads, so that the piston rings can be adjusted without opening the cylinder. The pumps are of the piston variety, double-acting, the pump barrel being secured in a chamber containing the valve by a rib which forms a partition between valves on the opposite ends. The pump valves are flat discs of rubber, secured to iron discs having stems working in guides. These iron discs are of sufficient weight to bring the valves to their seats promptly, and no springs are used. The valves seat on metal gratings. The steam and exhaust-pipe of the several steam-cylinders are so arranged that steam from the boilers can be admitted directly into all the cylinders and exhausted into the condenser, or live steam can be admitted to but one cylinder, and exhausted into the other three, then passing the condenser, forming a compound-engine at pleasure. To change from direct to compound, it is only necessary to manipulate three stop-valves, one connecting the steam-pipe of three cylinders with the boilers, one connecting the exhaust-pipe of the fourth cylinder with the condenser, and the third connecting the exhaust-pipe of one cylinder with the steam-pipes of the three. The valve gear of each steam-cylinder consists of a slide valve moved by an eccentric in the usual manner and admitting steam throughout the whole stroke. A double puppet-valve in the steam-chest regulates the point of cut-off, being actuated by a revolving spiral cam which can be moved in an axial direction, and thus vary the periods of admissions from zero to full stroke. The manner in which this cam is moved so as to regulate the speed and power exerted, is an important peculiarity of the Holly pumping-engine. The adjustment is effected by means of a regulator connected with the water-main in such a manner that any change in water pressure is immediately corrected by an adjustment of the cut-off, resulting in a practically uniform water pressure under the most varying conditions of supply. If the water pressure tends to fall, owing to an unusual draft upon the main, the cut-off is immediately lengthened and the engines exert a sufficient power to maintain the original pressure; if the consumption is suddenly lessened so that there is a tendency for the water pressure to increase, the cut-off is at once shortened, diminishing the power of the engine sufficiently to maintain the original pressure under the reduced supply, and if all consumption of water suddenly ceases the engine will immediately stop. The regulator is represented in Fig. 2.

It is evident from the foregoing description that the Holly regulator acts in an essentially different manner from the ordinary governor, which would increase the cut-off as the water pressure augmented, and shorten the cut-off as the same diminished. The details of the regulator are briefly as follows: A small water-cylinder, containing a solid piston, is connected directly with the main, and a weight is attached to the piston so as to counter-balance the water pressure. This is effected by suspending the weight from a strap which passes over a cam that rotates as the pressure changes, thus altering the lever arm of the counter-balance, and keeping it in equilibrium with the water pressure, however much the latter may vary. The cut-off cams of the steam-cylinders are moved axially, either to shorten or to lengthen the cut-off when the regulator throws a friction-clutch into gear, which it does whenever the water pressure varies from a given amount. A weighted lever would maintain this friction-clutch in gear, were it not for the action of the regulator. The shaft on which the counter-balance cam rotates has an index-wheel, and the index can be set at any desired water pressure. So long as the water pressure varies from the figure at which the index is set, the friction-clutch is kept in gear by the weighted

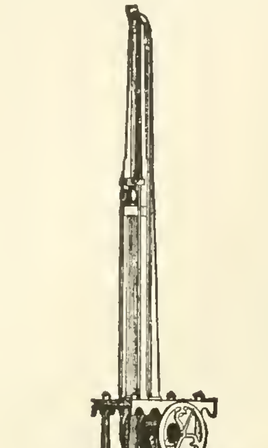

Fig. 2.

lever, and the cut-off is adjusted until the required pressure is reached. At this point the index engages with the weighted lever, and throws the friction-clutch out of gear. Whenever the water pressure varies, the friction-clutch is thrown into gear again, changing the cut-off so as to maintain the water pressure constant. It will be seen that the cut-off is regulated by positive gear driven by the engine, and the only work required of the regulator is to connect or disconnect this gear. Should the pressure rise very suddenly, however, a piston in the safety cylinder raises a lever to which the cut-off gear is connected, and throws the cut-off to zero instantly, if this is requisite.

Following the quadruple engine, the Company has brought out a novel horizontal compound condensing-engine, designed by Mr. Harvey F. Gaskill, Engineer and Superintendent of the Works. It was the purpose of the Company in bringing out this engine to provide one less costly than the quadruplex, and better adapted for pumping larger quantities of water; also to stand in the first rank as to economy. Following is a description of the engine, reference being made to Figures 3 and 4. On a pair of iron bed-plates are mounted the two pumps, and in direct line therewith the two low-pressure steam-cylinders connected to the pump piston-rods. Between the pumps and steam-cylinders are placed beam supports, which are firmly bolted to the bed-plates, and also rigidly stayed by wrought-iron struts to the pumps and steam-cylinders. These beam supports carry the beam shafts and beams, the lower end of the latter being connected to the cross-heads of the low-pressure cylinders by means of links. On the top of the pumps are placed the main shaft bearings, which support the shaft, fly-wheel, and cranks, the latter being keyed to the shaft at right angles to each other. On top of the low-pressure steam-cylinders are mounted the two high-pressure steam-cylinders, with their centers in the same horizontal plane as the center of the main crank shafts. The cross-heads of the high-pressure steam-cylinders are connected by means of connecting rods to the crank-pins. From the high-pressure steam-cylinders heavy cast-iron girders extend to the pillow-blocks. On the inner end of each of the beam centers an arm is keyed, from which the air-pumps are driven. The valves of the steam-cylinders are operated by means of eccentrics on a shaft, which is driven from the main shaft through small bevel gears. The admission-valves to the high-pressure steam-cylinders are of the double-beat puppet pattern, so arranged as to open at the proper time and to close at any desired point of the stroke. The exhaust-valves from the high-pressure cylinder are also the admission-valves to the low-pressure steam-cylinders, and are ordinary slide-valves, remaining open somewhat less than the time required to make one complete stroke. The exhaust-valves from the low-pressure cylinders are also plain slide valves, operating the same as the high-pressure exhaust-valves. The pump-plungers are arranged to work through glands in the center of the pumps, and are accessible from the covers at the end of the machine. The pump-valves are placed on horizontal plates below and above the line of plunger travel. The glands above-mentioned divide the valves of one end of the pump from those of the other end at the center of the valve plates. The operation of the machine is as follows: Steam is admitted through the automatic cut-off valves into the high pressure steam-cylinders, urging the pistons forward under full boiler pressure until the point of cut-off is reached. The valve then closes and the remaining portion of the stroke is accomplished by the elastic force of the steam. When the piston has nearly reached the end of its travel, the exhaust valve between the high and low pressure cylinder opens and the steam remaining in the high pressure cylinder rushes into the low pressure cylinder and against its piston, which at that time is at the end of its travel and at the opposite of the high pressure piston. The low pressure cylinder-piston is then in turn urged forward by the incoming steam, which is expanded to four times the volume it occupied in the high pressure cylinder at the time of its release therefrom. The release from the low pressure cylinders is accomplished by means of the exhaust-valves in the return strokes. This operation is repeated on each side and at each end at proper times. The close connection between the two cylinders reduces the clearance spaces to a minimum, which with thorough jacketing insures the most economical use of steam.

This engine is also built to operate as a non-compound engine, in which case the upper or high pressure steam-cylinders and connections are omitted, and the lower steam-cylinders are provided with automatic cut-off valves. Steam is admitted into these cylinders direct from the boiler and exhausted into the condenser. This mode of construction is adapted to small places, and to cities and villages where the cheapness of fuel renders the first cost

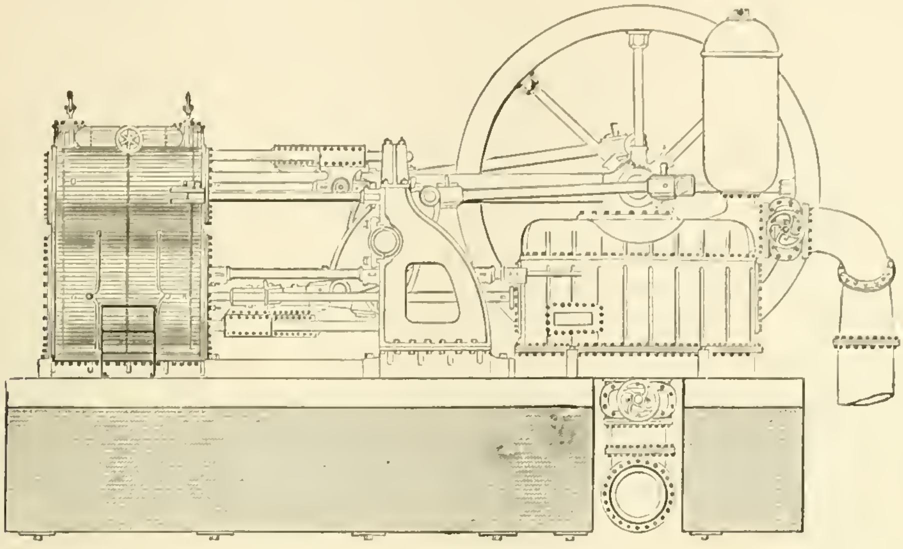

Fig. 3.

of the machine a matter more to be considered than the annual saving in the fuel. Although even when constructed as a non-compound engine, a duty of

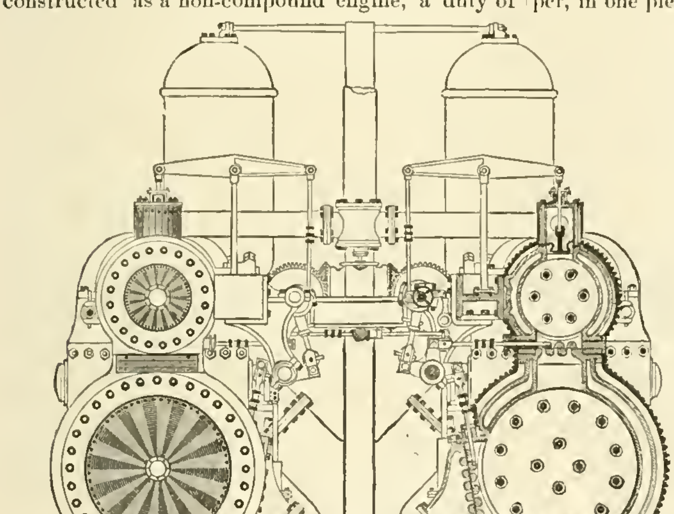

Fig. 4.

50,000,000 foot-pounds of work can be obtained from 100 pounds of coal. See *Steam-engine*, *Turbine*, and *Water-wheels*.

HYDROMETER. An instrument employed to determine specific gravities. The drawing exhibits the form of the instrument used in determining the specific gravity of metals. It is constructed on the principle of Nicholson's hydrometer; having a bulb 7.5 inches diameter and 8 inches high, made of copper, in one piece, without seam. The copper is .03 in. thick, and deposited on a mold, of low fusible metal, by the electro-galvanic process. A handle of brass wire, with broad flanges at the ends, is inserted in the bottom of the mold, before the copper is deposited, the copper covering and uniting with both. The brass cone is bored through its axis, and screw-threads are cut in it. After the bulb is formed, the fusible mold is melted, and withdrawn through the aperture in the brass cone. The aperture is then closed by a small screw and made air-tight by close fitting, and by sealing-wax spread over it. A solid stem of brass is then screwed into the bottom of the bulb. A vertical index-stem, made of steel, is inserted in the upper part of the handle. The upper end of the stem receives the weight-pan, which is supported in its place by a conical socket on its underside. The height of the hydrometer, from the bottom of the ball to the weight pan, is 21 inches. All of the exterior surface is protected by electro-gilding. The weight of the bulb, including the handle and brass cone, is about 15,850 grains; the lower stem and ball weigh about 20,320 grains, and the weight-pan is 660 grains; making the total weight of the hydrometer about 36,830 grains. Its general form, and the distribution of the metal within it, place the centers of gravity and buoyancy so far apart that it readily takes a vertical position when immersed, and will deviate very little from it, however irregularly it may be loaded. The maximum buoyancy of the hydrometer is 14,600 grains, and, when loaded to zero, it displaces 51,430 grains of water. The buoyancy may be reduced one-half by increments of 500 grains each, by placing one or more of the adjusting weights over the ball, at the bottom of the stem. Such a reduction of the buoyancy is found convenient in practice, when weighing small samples, as it prevents the necessity for placing and displacing numerous weights on the pan. The index stem is .071 inch diameter; a length of 1 inch displaces one grain of water. Four points of silver wire, made thin and sloping at the ends, are attached near the stem so as to form a scale of weights, in tenths of a grain. The two nearest opposite points are one-tenth of an inch apart. When the instrument rests with one of these points above, and the other beneath the surface of the water, it is at zero. When either of them touches or is even with the surface, the load is one-tenth of a grain too heavy, or too light, and if either passes through the surface, the error is then two-tenths of a grain. If either of the two points which are more distant from the zero touches the surface of the water, the load is then deficient, or in excess, three-tenths of a grain; and if the heel of either of these points passes the surface, the error is then four-tenths of a grain. Careful observation of the position of these points, when the hydrometer is immersed and at rest, will serve to indicate the true balance, when the zero mark may be above or below the surface of the water, within a given limit. By this method, the inconvenience and delay of bringing the zero to the surface of the water by the decimal parts of the grain weight is thus avoided. The water in which the hydrometer is immersed is contained in a cistern of glass, 25 inches deep, and not less than 12 inches diameter. If the bottom of the cistern is not level a flat plate should be placed over it and supported horizontally on three legs. The height of the water in the cistern should be such that when the bottom of the hydrometer descends to the plate the weight-pan should be one-quarter of an inch above the surface of the water. This will prevent an immersion of the pan when overloaded. The weight-pan is attached to the index stem by an open socket, on its under side, in order that it may be removed with its load from the hydrometer and placed on a table where the weights may be safely and accurately counted. As the weights often consist of many pieces, errors may occur in counting, or in the record of them; it is a good precaution to verify them by a recount after making the record. A thermometer, with a scale of about 5° to the inch, sub-divided in quarters of a degree, is suspended in the water while weighing samples and the temperature should be noted at each weighing. The weighings are made at temperatures varying with the state of the weather at the time, and as the density of water varies with its temperature, the latter is noted in order that the proper corrections may be made. The unit adopted is distilled water at the temperature of 60° Fahr.

The hydrometer may be employed to determine the relative density of distilled and any other kind of water. The weight of the hydrometer, added to its balance-weight in distilled water, at the temperature of 60°, gives the weight of a quantity of pure standard water which is equal in bulk to the immersed part of the instrument. The weight of the hydrometer, with its load, when immersed in like manner in any other kind of water at the same temperature, gives the weight of an equal bulk of the latter; and this weight, divided by the former, gives the multiplier for correcting the density when ascertained in any other than pure distilled water. Rain or river water may be used instead of distilled water, if its relative density be first accurately determined and the proper correction be made. At the foundries, generally, river water is found to be sufficiently pure for use without needing any correction. In using the hydrometer, first load the pan with the grain weights until the instrument rests at zero, and record the sum of these weights as the *Balance of the Hydrometer*. Next, place in the pan the sample, together with as many weights as will again bring the instrument to its zero, and record these weights as the *Sample Balance in Air*. The difference between these balances is equal to the weight of the sample in air. Then place the sample on the bulb of the instrument and immerse both until the hydrometer again rests at zero, and record the weights on the pan as the *Sample Balance in Water*. The difference between this balance and that in air is equal to the weight of the water displaced by the immersed sample. The temperature of the water at the time of weighing is noted, and if it is not at 60° divide the weight displayed by the the sample by that number in the following table which is opposite the noted temperature, and the quotient will give the corrected displacement for the temperature of 60°. Then, the weight of the sample in air, divided by the corrected displacement, gives the density of the sample. The hydrometer may be employed in determining the varying density of the same water at different degrees of temperature. The weight of the water it displaces at any other temperature than 60°, divided by its displacement in the same water at 60°, will give the proportionate weight of water displaced by the same instrument at other temperatures. See *Areometer* and *Specific Gravity*.

HYDRO-PNEUMATIC CARRIAGE.—A hydro-pneumatic carriage has lately been proposed by Major Moncrieff for the use of siege-carriages, somewhat on the system of his counterweight carriages for heavy guns. The object obtained is lightness, the facility of loading the gun when out of sight of the enemy, and raising it *en barbette* without any difficulty, thus obviating the necessity of cutting embrasures in the parapet. The carriage is designed for siege purposes, and it seems not improbable that the development of its principle may altogether revolutionize that branch of military operations. Batteries of attacks have hitherto been protected by embankments hastily thrown up, while the guns have been fired through embrasures. But the deadly precision of improved artillery sends shot after shot into the embrasures, while its penetrating power makes ordinary earthworks but very indifferent protection. Major Moncrieff's idea is to adapt to the attack the system he has been elaborating for coast defenses. He digs a hole and buries his gun in it. The soil, when it is excavated, is carried to the rear, and the enemy has no mark to guide his aim; after each discharge the gun sinks out of sight, and the indication of its precise whereabouts vanishes with the smoke. In the sieges in the late war, the Germans found that they must withdraw their batteries to immense distances, whence the fire was vague and relatively ineffective. Major Moncrieff undertakes to place his guns within 500 yards of the enemy's works. By his very well-known idea of the counterweight he had attained his object of elevating the gun out, and returning it to cover, and so enabling the gunners to work in comparative safety by storing the force of the recoil. But the objection to applying the system to siege operations was the unwieldy weight of carriages fitted with the counterweight, where lightness and facility of movement were primary considerations. The hydro-pneumatic system dispenses with this ponderous counterweight, replacing it very ingeniously with a simple cylinder only containing air and water, which oscillates between the cheeks of the gun-carriage. It is a feature in the carriage that it can be secured on an improvised platform without any heavy and costly appliances. It is fastened by a chain passed loosely round somè balks of timber buried in the ground, and the fastening acts as a rude pivot, on which it revolves. When in position for firing, the gun is raised to a height of some 7 feet upon a pair of arms or elevators which lay hold of the trunnions, and their action is regulated by racks, which are arranged to work in c nnection with a radial connecting-rod. Between these is the head of the piston which works in the hydro-pneumatic cylinder. With the discharge of the gun the head of the cylinder sways backwards, the piston is forced down by the recoil, and, as the piston slowly goes down in this cylinder, the gun descends with it to the normal position for loading. The internal adjustments of the cylinder are, of course, the essence of the invention. The piston descends in a tube of water, communicating at the bottom of the cylinder with a couple of side-chambers which are filled with air. As the water is forced down in the central tube, it necessarily rushes into the side ones, and the elasticity of the air it violently compresses is the motive power that is to be stored for use. There is just sufficient water to fill the central cylinder and to cover all the valves and joints, and there is nothing but strong and solid metal in those parts of the side-chambers in which the compressed air is to be confined. At the bottom of the cylinder, between it and the air-valve, and immediately in rear of the latter, is a "throttle-valve." The throttle-valve consists of a small, circular, perforated cylinder, revolving within a larger one, and its purpose is to neutralize, by the application of water friction, any excess of energy in the recoil. Indeed, next to employing air and water, as light and convenient materials of enormous power to work those heavy siege guns, the idea is to use those elements so as to avoid friction and concussion. Instead of the very violent recoil which threatened to shake the strongest carriage to pieces when it was arrested sharply by the resistance of screws and iron, according to this hydro-pneumatic system the recoil is made to exhaust itself upon air-springs and water-cushions. The first shock is broken upon the mass of water in the middle cylinder, and the throttle-valve disposes, as it were, of any of the subsequent vibrations. Theoretically, therefore, if we may use the expression, the recoil should be all self-contained. It was very nearly so in all practice; the carriage moved slightly to the first shot, as the chain tightened that secured it to the balks; but the shot that followed made no perceptible change in its position. It must be remembered that under the old system, and before Major Moncrieff had invented his counterpoise, or thought of his hydro-pneumatic cylinder, the gun would have wrenched itself away from such a rough-and-ready fastening. When the piece is raised for firing, it is managed by a worm-wheel at the side, which regulates the angle of elevation, and which turns easily to the touch. To sum up the merits of the invention, if it realizes the advantages claimed for it—and as it confessed to be a mechanical success, we can scarcely see how it can fail to do so—it will enable siege-batteries to be established and worked with comparative impunity at an extraordinary short distance from the formidable guns which are mounted on modern fortresses: siege-guns may be secured in position anywhere with materials that are always ready to hand; and carriages on constant service will be exposed to the very *minimum* of strain. Moreover, Major Moncrieff's new apparatus can be easily adapted to ordinary siege-carriages, and a cart and a couple of horses will transport its extra weight. If it proves successful with the heavy 40-pr. siege-guns, *à fortiori* it must succeed with the 46-pr. to be employed for coast batteries, as suggested in Major Moncrieff's pamphlet on defenses.

HYGROMETER.—An instrument for measuring the quantity of moisture in the atmosphere. The earlier forms of hygrometer depended upon the property possessed by some substances of readily absorbing moisture from the air, and being thereby changed in dimensions or in weight. Of this kind was the hair hygrometer of Saussure, in which a hair, which expands and contracts in length according as the air is more or less moist, was made to move an index; a similar instrument was the whalebone instrument of Deluc; but as other causes as well as moisture affect such instruments, they afford no accurate indications. The most perfect hygrometer, theoretically, is that of J. F. Daniell. It consists of two bulbs connected by a very strong bent tube, and enclosing a thermometer, together with some ether and the vapor of ether, the air having been first expelled. This hygrometer was employed at the Royal Observatory, Greenwich, from 1840—the commencement of meteorological observations—till 1847, when it was superseded by the more convenient instrument, the Wet and Dry Bulb Thermometer of usual form. This instrument consists of two ordinary thermometers—one has its bulb bare, and thus shows the temperature of the air; the other has its bulb covered with muslin, which is kept wet by a cotton wick dipping into water. The evaporation from the muslin, and the consequent cooling of the bulb, being in proportion to the dryness of the air, the difference between the readings of the two thermometers is greatest when the air is dryest, and zero when it is completely saturated. The readings of the thermometers then being taken, the elastic force of vapor at the dew-point is calculated by the formula of Dr. Apjohn:

$$(1)\ F = f - \frac{d}{88} . \frac{h}{30};\quad (2)\ F = f - \frac{d}{96} . \frac{h}{30};$$

the first formula is to be used when the wet thermometer is above, and the second whenever it is below, the freezing-point (32°). In these formulæ, F is the elastic force of vapor at the dew-point, which has been determined for different temperatures by Regnault from carefully conducted experiments; *f*, the elastic force at temperature of evaporation (or reading of wet bulb); *d*, the difference between the dry and wet bulbs; and *h*, the height of the barometer. From this the quantity of moisture in one cubic foot of air, etc., can be found as before. To dispense with these troublesome calculations, the *Hygrometric Tables* of Mr. Glashier may be nsed. Mason's hygrometer, represented in Fig. 1, is a very convenient and satisfactory instrument for practical use. It consists of two thermometers, as nearly as possible similar mounted parallel upon a frame and marked respectively "wet" and "dry." The bulb of the one marked *wet* is covered with thin muslin or silk, and kept moist from a fountain which is usually attached. The principle of its action is, that unless the air is saturated with moisture, evaporation is continually going on. And as no evaporation can take place without an expenditure of the heat, the temperature of the wet bulb thermometer, under the evaporation from the moistened bulb, fails until a certain point is reached, intermediate between the dew-point and the temperature of the air, as shown by the thermometer. To find the dew-point, the absolute dryness, and the weight in grains of a cubic foot of air, tables have been constructed empirically from experiments at Greenwich, combined with Regnault's

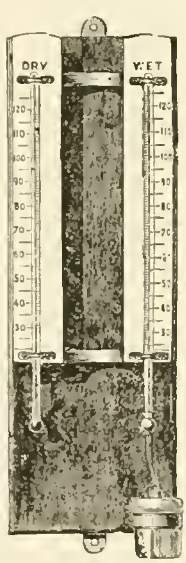

Fig. 1.

Tables of Vapor Tension. When using this instrument, if the air be very dry, the difference between the two thermometers will be great; if moist, less in proportion, and when fully saturated, both will be alike. For different purposes, different degrees of humidity are required, and even in household use, that hygrometrical condition of the atmosphere most beneficial to one person, may frequently be found altogether unsuitable for another. "Dry" bulb 70° and "wet" bulb 62° to 64° indicate average healthful hygrometrical conditions; any other relative condition required may easily be found by experiment, and then, dispensing with calculations, or reference tables, it is only necessary to see that the two thermometers stand in the required relation to each other. The hygrodyke, shown in Fig. 2, is on the principle of Mason's hygrometer, but is arranged with a dial and pointer so that the absolute and also the relative dryness and the dew-point may be read off without calculation. Regnault's hygrometer, with aspirator, is represented in Fig. 3. By means of this instrument instantaneous observations may be readily made. It consists of a thin and highly-polished tubular vessel of silver, A, having one end somewhat longer than the other. A rather delicate thermometer is introduced into the tube at the smaller end, to which end of the tubular vessel, also, a flexible rubber tube with ivory mouth-piece is attached. A sufficient quantity of ether to cover the bulb of the thermometer, being poured into the silver vessel, the ether is agitated by breathing through the flexible tube. A rapid evaporation ensues until at the moment the dew-point is reached, the moisture is seen to condense upon the exterior surface of the polished silver tube. The reading of the thermometer at this precise moment gives the dew-point.

Lieutenant James Allen, United States Army, has made an ingenious and novel application of the hygrometer, in *foretelling frost* by the determination of the dew-point. Lieutenant Allen uses, in his investigations, a dry and wet-bulb hygrometer of a special construction, consisting of two mercurial thermometers, which, being placed side by side, will indicate the same temperature. The dry-bulb is but a common thermometer, intended to show the temperature of the air. The wet-bulb is also a common thermometer, but having its bulb covered with a piece of thin muslin, from which passes a few threads of darning-cotton or narrow strip of muslin into a small vessel containing rain-water. Water rises by capillary attraction from the vessel and thus keeps the muslin constantly wet. When the air is dry, evaporation from the muslin proceeds rapidly, and on account of the heat lost in this way, the wet-bulb indicates a lower temperature than the dry-bulb; when the air is damp evaporation is slower, and the difference between these two thermometers grows less, and where the air is completely saturated evaporation ceases, and the two thermometers indicate the same temperature. To keep this instrument in working order, several things require special attention. The thermometers must be alike, for if one should be filled with mercury and the other should contain spirit, or if they should be filled with different quantities of the same fluid, the readings will be vitiated. All starch or foreign matter should be washed out of the thin muslin covering and the cotton wicking. The water used should be pure; for if lime or other salts be dissolved in it, the muslin will soon be coated with a calcareous or other incrustation. Rain or distilled water should be used. The muslin ought to be changed when covered with dust or other impurities, and care should be taken not to touch the muslin with the fingers, otherwise it will get slightly greased, and capillary attraction will be thereby interfered with. The bulbs of the thermometers should be made to project 1½ or 2 inches below the scales. The thermometers should also be a little apart from each other, and the vessel containing the water ought to be placed as far removed as possible from the dry-bulb. The thermometers should be exposed to the air where the circulation is unobstructed. They should face the north and be always in the shade. They should be removed at least a foot from the wall of any building, and should be about ten feet from the ground. They should be protected against the heat reflected by the neighboring objects, such as buildings or a sandy soil, and they should be sheltered from the rain. If the dry-bulb should become moistened by rain, the bulb should be carefully dried about five minutes before making the observation: since drops of water, by their evaporation, would lower the temperature of the mercury in the bulb. By means of this contrivance and the foregoing table, the dew-point can be determined with a sufficient degree of nicety. To determine the dew-point, at any time, substract the reading of the wet-bulb from that of the dry-bulb; find the temperature of the dry-bulb in the left hand column of the Table, opposite which in the column that is marked at the top with the difference between the dry and wet-bulb, is to be found the dew-point sought.

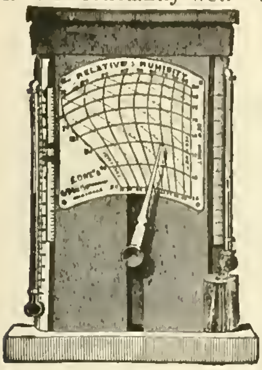

Fig. 2.

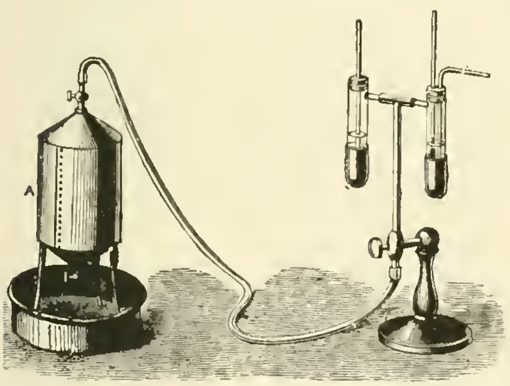

Fig. 3.

Having ascertained the dew-point with certainty, the approach of low temperatures or of frost may be foreseen and provided against. Thus, suppose on a fine clear day, towards evening, that the dry-bulb is 50° and the wet-bulb 40°, the dew-point at the time (per Table) is 22° F. Frost on the ground may then be predicted with certainty, and no time ought to be lost in protecting the tender plants of the garden. If, on the other hand, with a sky quite as clear, the dry-bulb is 50° and the wet-bulb 47°, the dew-point is 43°, and no frost need be feared.

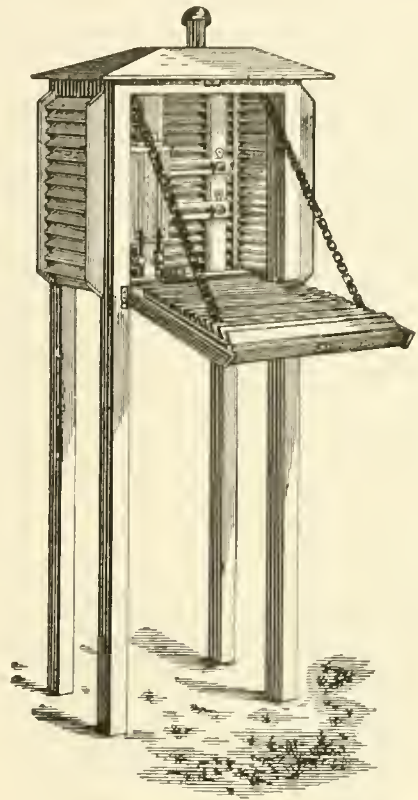

Fig. 4.

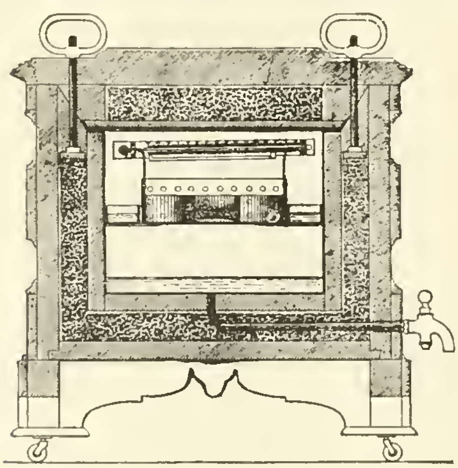
Assuming the sky to remain perfectly clear of all haze or clouds, the raising or depressing of the dew-point during the night, (usually with a change of wind), are the only circumstances that can happen to interfere with the predictions founded on the hygrometer. Frequently the presence of any haze at high altitudes during the night prevents the radiation of heat from the earth and thereby the frost which otherwise would have occurred. Hoar-frost is formed under the same circumstances as dew, with the single exception of a lower temperature. When the temperature of the surface of plants falls below 32° the moisture of the air is condensed upon them in the solid state and forms a layer of snow-crystals, like spongy ice. Hoar-frost therefore is not frozen dew, but the moisture of the air is deposited in the solid form, without having passed through the liquid condition. Hoar-frost, however, like dew, is deposited chiefly upon those bodies which radiate best, such as plants and the leaves of vegetables, and the deposit is made principally on those parts which are turned toward the sky. Since plants sometimes become cooled by radiation from 12° to 15° below the temperature of the surrounding air, a frost may occur although a thermometer a few feet above the ground, in an instrument-shelter, may not sink to 32°. During a clear and still night, when a thermometer which is six feet above the ground sinks to 36° or less, a heavy frost may be expected; and a slight frost may occur when the same thermometer sinks only to 47°. Whenever it is practicable, an instrument-shelter should be built. The Stevenson pattern, shown in Fig. 4, is a very suitable one. The louvres are double, sloping in opposite directions, so that while there is access of the air to the inside, the radiant heat and rain are effectually excluded. A single lattice, however, will answer the purpose very well. This screen should be erected on legs four feet high, and should stand over grass on open ground. It should not be under the shadow of trees nor within twenty feet of any wall. See *Thermometer*.

HYGROSCOPE.—The form of hygrometer employed to determine the ability of powder to resist moisture. It is usually an air-tight box in which the powder is subjected to a damp atmosphere at a uniform temperature for 24 hours. It consists of a box lined with copper, with a space of two inches between packed with hair. The lid is double also, like the sides, in construction; an India-rubber gasket covers the edges of the top, which is screwed firmly down with thumb-screws. Inside the box is a movable perforated tray of copper resting on ledges 8.5 inches by 8.5 inches. The intervening spaces have water-tight trays on ledges filled with a solution of niter.

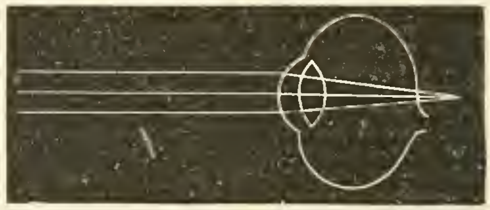
The powder to be tested is placed in circular cups of copper having fine wire-gauze bottoms, affording free access of moisture to all the parts of the sample under test. The percentage of gain is determined by weighing the powder in carefully prepared bottles



on opening the hygroscope. A careful record is kept of the barometer, the hygrometer, external and maximum and minimum internal thermometers. See *Gunpowder* and *Inspection of Gunpowder*.

HYPERMETROPIA.—An anomaly in the refraction of the eye which, by law, disqualifies a recruit for enlistment in the Army. This defect is dependent on a condition of the eye exactly the reverse of myopia. It is the condition in which rays from distant objects come to a focus *behind* the retina. A glance at the drawing will explain this condition. Hypermetropia is due to a formation of the eye, which is present from birth. It is also hereditary, being transmitted through entire families. Hypermetropic eyes are usually flat and shallow in appearance.

Although present from birth, it is often, unless of a high degree, not manifested until the duties of the school-room begin, and, in the slighter grades, it may not be noticed until adolescence or middle-life; neverthelesss the defect has existed all the while, but it has been masked and overcome by the exertions of the little ciliary muscle. Distinct vision is one of the instincts of our senses, and our eyes unconsciously adjust themselves so as best to secure it. Any change of the convexity of the lens is effected by the action of the ciliary muscle; now, since the focus for the rays falls behind the retina, the convex-



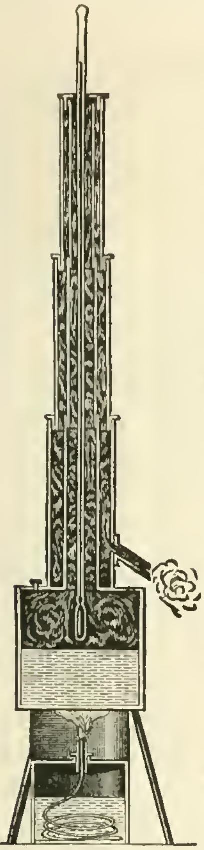
ity of the lens of the eye must be increased in order to bring the focal point on the retina, and hence the little muscle is called upon to do the work; but, since this condition of the eye is permanent, so also this muscular contraction is almost constant while the eyes are employed. Besides this constant exertion, the muscle must also act with vigor enough to give the ordinary power of accommodation for near objects.

In youth the ciliary is in its greatest vigor, and it then overcomes this defect even when of considerable degree, but as age advances, the power of the muscles diminishes and then it is that the defect begins to manifest itself. The great cause of all these symptoms is the overstrain and eventual exhaustion of the ciliary muscle. So long as it is able to accomplish its excessive task, it overcomes, or rather masks the defect, but as soon as its power gives out, the accommodation fails and indistinctness of near objects results, in addition to which we have the long chain of distressing symptoms which arise from the overstrain; many an obstinate headache has its sound in an unrecognized hypermetropia.

Since in this state of the eye the focus falls behind the retina, the remedy is found in a glass which will increase the refractive power of the eye, thus bringing the focus of the rays of light *on* the retina: such a result is obtained by the proper *convex* glass. As, however, the ciliary muscle is able to mask a certain amount of the defect, even after it has become apparent, the convex lens, which most improves distant vision, will correct but the portion of hypermetropia which is "manifest," and, indeed, frequently the patient may reject all convex glasses as failing to improve his distant vision, and yet be hypermetropic to a considerable degree.

The glass which corrects the manifest defect will often greatly conduce to the patient's comfort, yet to select the glass which will correct the entire defect, the accommodation of the eye must be temporarily suspended by putting the ciliary muscle at rest by means of a solution of atropia, when the entire defect becomes apparent and may be carefully measured by the oculist. See *Recruits*.

HYPSOMETRICAL THERMOMETER. It is generally assumed that water boils at 212° Fahrenheit, but this is true only at the sea-level, under a barometric pressure of 29.922, in latitude 45, at a temperature of 32° Fahrenheit, and with chemically pure water. The boiling-point, therefore, varies with the latitude, the height above sea-level, the pressure of the atmosphere and the temperature. Thus, at Philadelphia, under the mean barometic pressure of that locality, of 29.922 at 32° Fahrenheit, water boils at a temperature of 211.994 Fahrenheit. As there is an evident relation between the boiling-point and the elevation of a place, as shown by the decreased barometric pressure as we ascend, it would seem a comparatively simple matter to measure the height of a mountain by the temperature at which the ebullition of water occurs. The barometric pressure, however, for the same place, is continually varying, and with it, the boiling temperature of fluids. It follows, therefore, that in order to determine elevations with any degree of accuracy, by means of a boiling-point thermometer, it is necessary in the first place, that the thermometer employed should be most accurately graduated and compared with the reading of a standard barometer, reduced for temperature and latitude. It is necessary, also, that observations should be made, with as little interval of time between as possible, at the lower point from which the elevation of the higher point is to be determined, as well as at the higher point itself, and that these observations be repeatedly made. In relation to the necessity of a thoroughly acute thermometer, Admiral Fitzroy says, in his "Notes on Meteorology:" "Each degree of the boiling-point thermometer is equivalent to almost 550 ft. of ascent, or one-tenth to 55 ft.; therefore, the smallest error in the graduation of the thermometer itself, will affect the height deduced materially." Having prepared to make observations with accuracy, it will become necessary to ascertain the means of deducing the height from the observations made. The following Table gives very nearly the elevations in feet corresponding to a fall of 1°, in the temperature of boiling-water. When the barometer falls, or when a part of the pressure is in any other way removed, it boils before coming to 212°, and when the pressure is increased the boiling-point rises. An elevation of 105 feet above the sea-level makes a diminution of one degree; at higher levels the difference of elevation corresponding to a degree of temperature in the boiling-point increases. At the City of Mexico, 7,000 feet above the sea, water boils at 200°; at Quito, 9,000 feet above the sea, at 194°; and on Donkia Mountain, in the Himalayas, at the height of 18,000 feet, Dr. Hooker found it to boil at 180°. The knowledge of the effect of diminished pressure is largely turned to account in processes where the substances are apt to be injured by a high temperature.



Ebullition between	Elevation in Feet for each degree.
214 and 210	520
210 " 200	530
200 " 190	550
190 " 180	570

It is assumed that the boiling-point will be diminished 1° for each 520 feet of ascent until the temperature becomes 210°, then 530 feet of elevation will lower it one degree until the water boils at 200°, and so on, the air being at 32° Fahrenheit. As, according to Regnault, the air expands .002036 of its volume at 32° for each degree increase in temperature, it is necessary to find the mean temperature of the air between the two points, and applying the correction due to the difference between that and 32°, the formula will be as follows: Let H represent the vertical height in feet between the stations; B and b the boiling-points of water at the lower and upper stations respectively; and f, the factor found in the above table. Then $H=f$ (B b). Let m be the mean temperature of the stratum of air between the stations. Calling the correction due to the mean temperature of air C, its value will be found from the equation, $C=H\ (m-32)\ .002036$. Calling the corrected height H', it will be found from the formula

$$H'=H+H\ (m-32)\ .002036,$$

that is $H'=H\ [1+(m-32)\ .002036.]$

When an accurately made and carefully compared thermometer is employed in accordance with the foregoing rules and instructions, very accurate and valuable results may be obtained with the hypsometrical apparatus. But it is manifest that with thermometers as ordinarily made, whose freezing-points have been fixed without regard to the condition of a true zero, and with observations which leave entirely out of account many of the factors necessary to even approximate correctness, the results so obtained must often be of little value. See *Barometer* and *Thermometer*.

I

IBERIAN SWORD.—A small sword somewhat resembling a dagger and much worn by the Roman foot-soldiers, on the right side.

ICE.—In high latitudes, during the winter, rivers are frequently covered with ice of sufficient thickness to sustain the heaviest loads. This means of communication should be used with great circumspection. A change of temperature may not only suddenly destroy this natural bridge, but render the river impassable by any method for a considerable time in consequence of the floating ice. When from three to four inches thick, ice will sustain infantry marching in single file. With the thickness of 4.5 inches, cavalry and light guns can pass over it; with six inches, heavy field-pieces; eight inches will support siege-guns, but, for greater security the wheels should be locked and secured upon way-planks which slide upon the ice, the pieces being moved by hand. In very cold weather the thickness of the ice may be increased by covering it with a layer of straw or brush and throwing water over it, or two rows of logs may be laid at a distance apart equal to the width of the roadway; a layer of earth is spread between them and water is thrown on and allowed to freeze. This operation is repeated until a solid roadway is formed. Troops working in concert can accomplish in this manner a very strong crossing in a short while.

Ice, when very thick, and therefore difficult to remove, may be broken up by charges of powder in water-tight cans or bags, fixed underneath or placed in holes bored in it. Charges of from five to ten pounds of the powder placed in ice two feet thick will break up an area twenty feet in diameter. Eight ounces of dynamite will produce the like or even a greater result.

ICENI.—A warlike tribe of ancient Britain, occupying, as is supposed, that part of the country which corresponds nearly with the present counties of Norfolk and Suffolk. Under their Queen Boadicea they rebelled against the Romans.

ICH DIEN.—The motto of the Prince of Wales. According to one theory of its derivation, the phrase was employed by Edward I. on presenting his new-born son, Edward of Carnarvon, to the Welsh, using the expression in its Welsh signification—*Eich dyn*, "Behold the man." Another view attributes it to the occasion of the killing of John, King of Bohemia, by the Black Prince at Cressy, and asserts that the latter found the motto under the plume worn by the dead King, and assumed it to imply that "he served under the King, his father."

ICHNOGRAPHY.—The plan or representation of the length or breadth of a fortification, the distinct parts of which are marked out either on the ground itself, or on paper. A plan upon the correct principles of *ichnography* represents a work as it would appear if it were leveled to its foundations, and shows only the expanse of ground on which it had been erected. The science does not represent either the elevation or the different parts belonging to a fortification. This properly comes under the title PROFILE, which does not, however, include length.

ICICLES.—In Heraldry, charges of the same shape as drops in the bearing called gutté, but reversed. They have also been called clubs, locks of hair, and guttés reversed.

IGNITIBLE EXPLOSIVES.—Substances which on a match, tube, or detonating composition being applied to them, ignite, such as gunpowder, gun-cotton, nitro-glycerine, dynamite, and glyacyline, all of which can be used as explosive agents, for submarine as well as land purposes.

IGNITION.—The act of setting fire to, or of taking fire, as opposed to combustion or burning, which is the consequence of ignition. Gunpowder may be ignited by the electric spark, by contact with an ignited body, or by a sudden heat of 572° Fahrenheit. A gradual heat decomposes powder without explosion by subliming the sulphur. Flame will not ignite gunpowder unless it remains long enough in contact with the grains to heat them to redness. Thus, the blaze from burning paper may be touched to grains of powder without igniting them, owing to the slight density of the flame, and the cooling effect of the grains. It may be ignited by friction, or a shock between two solid bodies, even when these are not very hard. Experiments in France, in 1825, show that powder may be ignited by the shock of copper against copper, copper against iron, lead against lead, and even lead against wood; in handling gunpowder, therefore, violent shocks between all solid bodies should be avoided. The time necessary for the ignition of powder varies according to circumstances. For instance, damp powder requires a longer time for ignition than powder perfectly dry, owing to the loss of heat consequent on the evaporation of the water; a powder the grain of which has an angular shape and rough surface, will be more easily ignited than one of rounded shape and smooth surface; a light powder, more easily than a dense one; and a powder made of a black charcoal, more easily than one made of red, inasmuch as the latter is compelled to give up its volatile ingredients before it is acted on by the niter. See *Explosion* and *Gunpowder*.

IGNORANCE OF THE LAW.—*Ignorantia Juris*, or ignorance of the law, is held to be no excuse for any breach of contract or duty, nor for crime or other offense. It is absolutely necessary to start with this maxim, otherwise it would be quite impossible to administer the law, for if once a contrary maxim were allowed, it would not only be a premium to ignorance, but would lead to endless and abortive inquiries into the interior of a man's mind. Ignorance of a fact, however, is a different thing. Another kindred maxim of the law is that every man intends the consequences of his own acts. Thus, if he shoot at or give poison to a person, it is presumed that he intended to kill such person. So, if he leaves a trap-door open in a street or thoroughfare, it is held that he intended people to fall into it and be injured. There is, however, a doctrine called *bona fides*, which, in the case of petty offenses punishable by Justices, often tempers the strict and rigid application of the maxim *ignorantia juris neminem excusat*; and even in crimes a Court always takes into consideration, when passing judgment, whether the prisoner was an ignorant or intelligent person.

ILIYATES—EELIAUTS.—A nomadic tribe of Persia and Turkistan, and mostly of Turkish, Arabic, or Kurdish descent. They are Mohammedans of the Sunni sect. They have no settled abode, but live in tents, moving from place to place, according to climate or season. They have large flocks and herds, and some tribes live by plunder. Each tribe pays tribute in cattle for the use of grazing ground, money not being known among them. Also written *Eeliauts*.

IMAGINARY QUANTITY.—In the working of gunnery problems, it often happens that the root of a negative quantity must be extracted; if the root is odd, the operation can be performed, but if even, the root can only be *formally* extracted, and is in consequence called an *impossible* or *imaginary* quantity. For instance, the cube root of — 64 is not an imaginary quantity, for $-4 \times -4 \times -4 = -64$, and therefore $\sqrt[3]{-64} = -4$; but the square root of — 64 is an impossible quantity, for no possible quantity (whether it be + or —) multiplied by itself can produce a negative quantity; similarly and *à fortiori*, the fourth root — 64 is an impossible quantity, and the same is true of all even roots. Imaginary quantities are, however, generally reduced to one denomination as multiples of $\sqrt{-1}$, in the following manner: $\sqrt{-64} = \sqrt{64 \times -1} = \sqrt{64} \times \sqrt{-1} = 8\sqrt{-1}$; and again, $\sqrt{-18a^5} = \sqrt{9a^4 \times -2a} = \sqrt{9a^4} \times \sqrt{2a} \times \sqrt{-1} = 3a^2\sqrt{2a}\sqrt{-1}$. These forms very frequently occur in higher algebra.

IMBRUED.—An expression used in Heraldry to signify bloody, or dropping with blood. Weapons thus blazoned are drawn with drops of blood falling from them. Also written *Embrued*.

IMMORTALS.—In antiquity, the name of a body of 10,000 troops, constituting the guard of the King of Persia: so called because they were always of the same number; for as soon as any of them died, the vacancy was immediately filled up. They were distinguished from all the other troops by the richness of their armor, and still more by their bravery. The same term was applied to the life-guards of the Roman Emperors.

IMPACT OF PROJECTILES.—In order to arrive at a clear understanding of what takes place when the motion of a projectile is arrested by any resisting medium, it is necessary to recall some of the elementary principles upon which these phenomena depend. The manner in which a projectile acquires its velocity, is a good illustration of the manner in which its motion is destroyed. If the mean pressure, P, of the gas be multiplied by the space, S, passed over by the projectile while acquiring its velocity, the result will be the measure of the work done by the charge of powder; and it will also be equal to the work of stopping the same projectile, no matter how or by what means it may be brought to rest. The same result is generally arrived at by measuring the velocity imparted to the projectile under the circumstances mentioned, and multiplying the square of the velocity by one-half of the mass of the projectile; or, since the mass is equal to the weight divided by the force of gravity, the expression for the work stored in the projectile, and which must be expended in bringing it to rest, $= \frac{W v^2}{2g}$, where

W = weight of the projectile in pounds, v = velocity of the projectile in feet, and g = the force of gravity in feet, or the velocity which a body will acquire by its own weight in one second of time. This expression involves indirectly the same quantities as that first mentioned; namely, the mean pressure of the gas and the distance passed over by the projectile: assuming this measure for the work stored in the projectile, it remains to consider how this work is expended.

The following are the different effects produced by the impact of a projectile upon any solid body; some of these being so connected as to render their relative importance extremely doubtful.

Compression—The first effort of impact is to compress or drive back those portions of both projectiles and target first coming in contact upon those immediately behind them; the amount of this compression depending upon the material and velocity of impact, as well as upon the form of the projectile.

Elongation—The greater part of the work of the projectile in penetrating wrought-iron and similar materials is expended in overcoming the tenacity of the material, or in elongating the fiber. This is evident when we consider that punching or shearing consists not so much in cutting the fiber, as in bending it, and afterwards pulling it in two lengthwise.

Shearing—This, as just stated, consists chiefly in the two strains already mentioned.

Bending.—This also implies tension and compression; the back of the target being elongated, and the front compressed.

Pulverizing—a portion of the material. This takes place only in case of hard materials, as a stone or cast-iron, and it then absorbs a very great amount of work. Like bending and shearing, it involves compression and elongation, the material being compressed until it yields laterally to a tensile strain.

Motion—While the work is being expended, a certain amount of time is allowed for the force of the projectile to impart motion to the target, especially that portion immediately in front of the projectile.

Friction—The friction is very great, especially in the case of the more pointed form of projectile, and varies inversely with the velocity of the projectile.

Heat—This is due to friction, both external and internal, that is, of the projectile and the fragments against the target, and against each other during the distortion of the material, from compression, bending, etc. The suddenness with which this heat is generated is almost unequalled by any known source of heat. It is well known that the heat developed in the interior of loaded shells, on striking violently a thick iron plate, is sufficient to ignite the powder, and this fact has been utilized in dispensing with fuses for exploding armor-punching shells.

The effect of a projectile on striking a mass or target of any form or material, may be divided into two general portions,—one being entirely local, while the other is distributed over more or less surface according to circumstances. The former is the *penetration*, and the latter may be called *concussion*. See *Penetration of Projectiles*.

IMPALE.—In Heraldry, to arrange any two coats of arms side by side in one shield divided per pale. It is usual thus to exhibit the conjoined coats of husband and wife, the husband's arms occupying the dexter side or place of honor, and the wife's the sinister side of the escutcheon. When a man marries a second wife, heralds say that he may divide the sinister half of the shield per fess into two compartments, placing the family arms of his deceased wife in chief, and of his second wife in base. A husband impaling his wife's coat with his own, is not allowed to surround the former with the collar or the insignia of any order or knighthood to which he may belong. Bishops, Deans, Heads of Colleges, and Kings of Arms impale their arms with their insignia of office, giving the dexter side to the former. In early Heraldry, when two coats were represented in one shield side by side, only half of each was exhibited, an arrangement which has been called *dimidiation*. Sometimes the one coat only was dimidiated. A reminiscence of dimidiation is preserved in the practice of omitting the bordures, orles, and tressures in impaled arms on the side bounded by the line of impalement. See *Heraldry*.

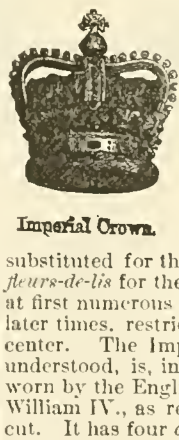
Impale.

IMPEDIMENTA. All the accompaniments to an army received from the Romans the name of *impedimenta*. They consist in a general sense of munitions, equipments, provisions, hospital supplies, tents, engineering tools, bridge equipage, boats, baggage, cooking utensils, etc., necessary for the use of an army moving against an enemy. This requires the use of large numbers of wagons and draught animals, or shipping, and necessarily impedes the movement of an army.

IMPENETRABILITY.—One of the essential properties of matter which implies that no two bodies can at the same time occupy the same space. If a nail be driven into a piece of wood it does not, properly speaking, *penetrate* the wood, since the fibers are driven aside before the nail can enter. If a vessel be filled with fluid, and a solid body be then placed in it, as much water will run over as is equal in bulk to the solid body, in this way making room for it. The lightest gases are really as impenetrable as the densest solid; although, owing to their compressibility, it is not readily made apparent.

IMPERATOR.—An old Roman title signifying Commander, which was applied to the Rulers of Provinces, the Consuls, Pro-Consuls, etc., or to anybody who had an *Imperium* assigned him. After a victory the Roman soldiers frequently saluted their Commander by this title. See *Emperor*.

IMPERIAL CROWN.—Properly the crown borne by the German Emperor; it is in form a circle of gold, adorned with precious stones and *fleurs-de-lis*, bordered and seeded with pearls, and raised in the form of a cap voided at the top like a crescent. From the middle of the cap rises an arched fillet enriched with pearls, and surmounted by a globe, on which is a cross of pearls. The name Imperial Crown is, however, in English Heraldry, applied to the crown worn in times past by the Kings of England. From the 12th century onwards, the Crown of the English Sovereigns underwent repeated changes in form and enrichment. That of Edward II. was formed of four large and four small strawberry leaves, rising in curves from the jewelled circlet, and having eight small flowers alternating with the leaves. In the crown of Henry IV. eight strawberry leaves, and as many *fleurs-de-lis* alternated with sixteen small groups of pearls, three in each. Under Henry V. the enriched circlet was for the first time arched over with jewelled bands of gold, and the apex of the arches were surmounted with a mound and a cross, while *crosses patées* were substituted for the strawberry leaves, and roses or *fleurs-de-lis* for the clusters of pearls. The arches, at first numerous and elevated to a point, became in later times, restricted to four, and depressed in the center. The Imperial Crown of Heraldry, as now understood, is, in point of fact, the form of crown worn by the English Sovereigns from Charles II. to William IV., as represented in the subjoined woodcut. It has four *crosses patées* and four *fleurs-de-lis* set alternately on the circlet, while four pearl-studded arches, rising from within the crosses, carry at their intersection the mound and cross. The State Crown of Queen Victoria differs considerably from this, having a far more enriched character. It is



Imperial Crown.

covered with diamonds and studded with gems, and the arches are wrought into wreaths of rose, thistle, and shamrock formed of brilliants. A charge, crest, or supporter, crowned with a regal crown, is said to be *imperially crowned.*

IMPERIAL GUARDS.—The name of a body of select troops, organized by the French Emperor, Napoleon I., which greatly distinguished themselves at Austerlitz.

IMPERIALISTS.—A designation chiefly applied to the subjects of, or forces employed by the House of Austria, when opposed to the troops of other German Powers.

IMPETUS.—In gunnery, the altitude through which a heavy body must fall to acquire a velocity equal to that with which a ball is discharged from a piece.

IMPLEMENTS.— Artillery implements are employed in loading, pointing, and firing cannon, and in the maneuver of artillery-carriages. The implements for loading cannon are :—1st. The *rammer-head* is a short cylindrical piece of beech or other tough wood, fixed to the end of a long stick of ash, called a *staff*, and is employed to push the charge to its place in the bore or chamber of a cannon. 2d. The *sponge* is a *woollen* brush, Fig. 1, attached to the end of a staff, for the purpose of cleaning the interior of cannon, and extinguishing any burning fragments of the cartridge that may remain after firing. In the field and mountain services, the rammer-head and sponge are attached to the opposite ends of the same staff; in the siege and sea-coast services they are attached to separate staves. To protect the sponge from the weather, it should, when not in use, be enclosed in a *cover* made of canvas and painted. 3d. The *ladle* is a copper scoop attached to the end of a staff for the purpose of withdrawing the projectile of a loaded piece. Ladles are only used for siege and sea-coast cannon, as field and mountain cannon can be unloaded by raising the trail of the carriage, which permits the projectile to slip out by its own weight. 4th. The *worm*, Fig. 2 is a species of double cork-screw, attached to a staff, and is used in field and siege cannon to withdraw a cartridge. 5th. The *gunner's haversack* is made of leather, and suspended to the side of a cannonier by a shoulder-strap. It is used to carry cartridges from the ammunition-chest to the piece, in loading. 6th. The *pass-box* is a wooden box closed with a lid, and carried by a handle attached to one end. It takes the place of the haversack in siege and sea-coast service, where the cartridge is large. 7th. The *tube-pouch* is a small leather pouch attached to the person of a cannonier by a waist-belt. It contains the friction-tubes, lanyard, priming-wire, the thumb-stall, etc. 8th. The *budge-barrel* is an oak barrel bound with copper hoops. To the top is attached a leather cover, which is gathered with a string, after the manner of the mouth of a bag. It is employed to carry cartridges from the magazine to the battery, in siege and sea-coast services. 9th. The *priming-wire* is used to prick a hole in a cartridge for the passage of the flame from the vent. It is a piece of wire, pointed at one end, and the other is formed into a ring which serves as a handle. 10th. The *thumb-stall* is a buckskin cushion, attached to the finger to close the vent in sponging. 11th. The *fuse-setter* is a brass drift for driving a wooden fuse into a shell. 12th. The *fuse-mallet*, Fig. 3 is made of hard wood, and is used in connection with the setter. 13th. The *fuse-saw* is a 10-inch tenon saw for cutting wooden or paper fuses to a proper length. 14th. The *fuse-gimlet* is a common gimlet, which may be employed in place of the saw to open a communication with the fuse composition. 15th. The *fuse-*

Fig. 1.

Fig. 2.

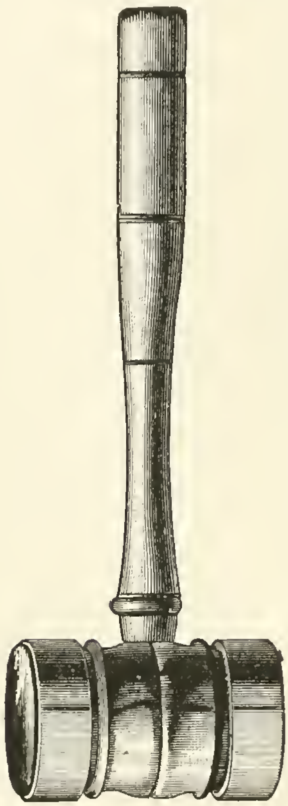


Fig. 3.

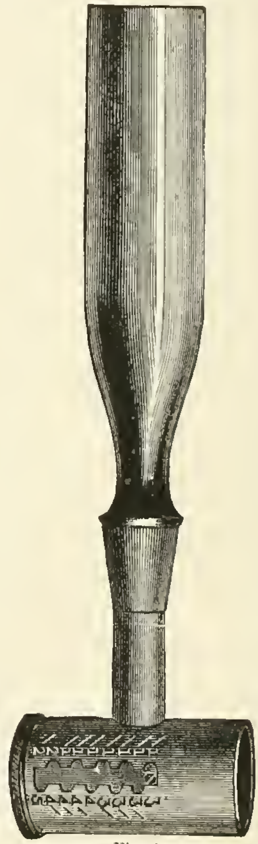

Fig. 4.

auger is an instrument for regulating the time of burning of a fuse, by removing a certain portion of the composition from the exterior. For this purpose it has a movable graduated scale, which regulates the depth to which the auger should penetrate. 16th. The *fuse-rasp* is a coarse file employed in fitting a fuse-plug to a shell. 17th. The *fuse-plug reamer* is used to enlarge the cavity of a fuse-plug, after it has been driven into a projectile, to enable it to receive a paper fuse. 18th. The *shell-plug screw* is a wood screw with a handle; it is used to extract a plug from a fuse-hole. 19th. The *fuse-extractor* is worked by a screw, and is a more powerful instrument than the preceding: it is used for extracting wooden fuses from loaded shells. 20th. The *mortar-scraper* is a slender piece of iron with a spoon at one end, and a scraper at the other, for cleaning the chamber of a mortar. 21st. The *gunner's sleeves* are made of flannel or serge, and are intended to be drawn over the coat-sleeves of the gunner, and prevent them from being soiled while loading a mortar. 22d. The *funnel* is made of copper, and is used in pouring the bursting charge into a shell. 23d. The *powder-measures*, Fig. 4, are made of copper, of a cylindrical form, and of various sizes, for the purpose of determining the charges of shells and cannon, by measurement. 24th. The *lanyard* is a cord, one end of which has a small iron hook, and the other a wooden handle. It is used to explode the friction-tubes with which cannon for the land service are now fired. 25th. The *gunner's pincers, gimlet*, and *vent-punch* are instruments carried in the tube-pouch for removing ordinary obstructions from the vent. 26th. The *shell-hooks* is an instrument constructed to fasten into the ears of a shell, for the purpose of lifting it to the muzzle of the piece.

The implements for pointing are: 1st. The *gunner's level* is an instrument for determining the highest points of the breech and muzzle of a cannon when the carriage-wheels stand on even ground. It is made of a *brass plate*, the lower edge of which is terminated by two *steel points* which rest upon the surface of the piece. A *spirit-level* is attached to the plate with its axis parallel to the line joining the points of contact. When the level is in position, the vertical *slide* is pressed down with the finger to mark the required point. 2d. The *tangent-scale* is a brass plate, the lower edge of which is cut to the curve of the base-ring of the piece, and the upper edge is formed into offsets which correspond to differences of elevation of a quarter of a degree. It is used in pointing, by placing the curved edge on the base-ring, with the radius of the offset corresponding with the highest point of the ring, and sighting over the center of the offset and the highest point of the swell of the muzzle. 3d. The *breech-sight*, is a more accurate form of the tangent-scale. It consists of a *vertical scale* graduated to degrees and eighths of degrees, and a curved *base* which rests upon the breech of the gun. A slide is attached to the vertical piece, which has a small hole or notch cut on its upper edge, through which the aim is taken. The slide is fixed at any point by a thumbscrew. 4th. The *pendulum hausse* is used to point field-pieces, and at the same time to obviate the error which will arise when the wheels of the carriage stand on uneven ground. It is composed of a *scale* arranged like a pendulum, a *suspension-piece*, and a *seat* which is screwed to the breech of the gun. A slot is cut in the suspension-piece into which the scale is inserted, and fastened by a pivot, which allows it to vibrate in a lateral direction. The scale also vibrates in a longitudinal direction, as the journals of the suspension-piece are free to turn in the grooves cut in the seat to receive them, thus assuming a vertical position independently of the surface of the ground on which the carriage stands. 5th. The *gunner's quadrant* is a wooden instrument for measuring the angles of elevation and depression of cannon, and particularly of mortars. The nature of the instrument and its mode of application are very simple. The plumb-line and bob when not in use, are carried in a hole formed in the end of the long branch, and covered with a brass plate.

The principal maneuvering implements are: 1st. The *trail-handspike*, which is made of wood, and attached to the trail of a field-carriage for the purpose of giving direction to the piece when aiming. When the carriage is limbered, the handspike is attached to the cheek by means of a ring and hook. 2d. The *maneuvering-handspike* is likewise made of wood, but it is longer and stouter than the preceding; it is used for siege and sea-coast carriages and gins. 3d. The *shod-handspike* is made of wood, armed with an iron point, which is turned up in a way to prevent slipping on the platform. It is particularly useful in the service of mortars and sea-coast carriages. 4th. The *truck-handspike* is made of iron, and is employed to work the maneuvering wheels of sea-coast carriages, by inserting it in the holes formed in the circumference of the wheels. 5th. The *eccentric-handspike* is used to throw the eccentric axis of the maneuvering wheels of the sea-coast carriages into and out of gear, for this purpose it has a head with a hexagonal hole which fits upon the extremities of the eccentric axle-tree. 6th. The *roller-handspike* supplies the place of rear maneuvering wheels in certain of the new sea-coast gun-carriages. It is operated by inserting the point of the handspike under the heel of the carriage-shoe, and pressing down the long arm of the lever: in this way the weight of the rear portion of the carriage is thrown upon the roller, which moves upon the rail of the chassis. 7th. The *prolonge* is a stout hemp rope, occasionally employed in field-service to connect the lunette of the carriage and pintle-hook of the limber when the piece is fired. It is terminated at one end with a hook, at the other with a toggle, and has two intermediate rings, into which the hook and toggle are fastened whenever it is necessary to shorten the distance between the carriages. 8th. The *sponge-bucket* is made of sheet-iron, and is attached to field-carriages; it is used for washing the bore of the piece. 9th. The *tar-bucket* is also made of sheet-iron, and is used to carry the grease for the wheels. 10th. The *watering-bucket* is made of sole-leather, riveted at the seams, and is used to water the horses. The gutta-percha watering-buckets are sometimes used. 11th. The *water-buckets* are made of wood, and bound with iron hoops. There are two kinds, one for the traveling-forge, and the other for the service of the garrison-batteries. 12th. The *drag-rope* has a hook at one end, a loop at the other, and six wooden handles placed about four feet apart. It is used whenever it may be necessary to employ a number of men in hauling loads, or extricating a carriage from a difficult part of a road. 13th. The *men's-harness* is very similar to the drag-rope, except that the rope is stouter, and the handles are replaced by leather loops which pass over the shoulders of the men, to enable them to exert their strength to advantage. 14th. The *bill-hook*, or hand-bill, is used for cutting twigs. 15th. The *screw-jack* is a lifting-machine, composed of a screw worked by a *movable nut* supported on a *cast-iron stand*. It is useful in greasing carriage-wheels.

IMPREGNABLE.—Not to be stormed or taken by assault; incapable of being reduced by force; able successfully to resist attack; as an impregnable fortress.

IMPRESSION-TAKER.—A device employed for recording impressions of vents and interiors of bores in the inspection of cannon. In its usual form, it consists of a wooden head, one-half of which is cylindrical, and the other half is of the shape of the chamber, both being rather smaller than the parts of the bore for which they are intended. The staff, flattened on its upper side and rounded on its under side to fit the curve of the bore, is mortised into the cylindrical portion of the head. A mortise is cut through the chamber part of the head, extending several inches in the rear and the front of the position of the vent. Into this mortise a loose piece is fitted, capable of free motion upwards and downwards, the top of which is pierced with holes to secure the wax or composition which is spread over its surface. This movable piece rests on a wedge attached to a flat rod running through a slot in this rod about four inches long, a pin passing through it into the staff.

To use the instrument, withdraw the rod as far as the slot will permit, which will allow the movable piece upon which the composition has been spread to drop below the surface of the head, and protect it. Push the head to the bottom of the chamber and arrange the position of the staff, so that the movable piece will cover the vent, then press the end of the rod home. This motion will throw out the composition, and a distinct impression of the vent and of *fire-cracks* (should there be any) will be left on the surface; draw the rod back as far as the slot will allow, and withdraw the instrument; the impression, being protected thereby, will come out uninjured. Impressions of injuries or cavities in the bore may easily be taken by a similar contrivance. See *Gutta-percha Impressions*, *Inspection of Ordnance*, and *Vent Impressions*.

IMPRISONMENT.—Officers may be sentenced to imprisonment by a general Court-Martial in any case where the Court may have discretionary authority. General, Garrison, or Regimental Courts-Martial may sentence soldiers to imprisonment, solitary or otherwise, with or without hard labor for various offenses enumerated in the Articles of War. A Garrison or Regimental Court-Martial, in awarding imprisonment, is limited to a period not exceeding thirty days. When a Court awards solitary imprisonment as a punishment, it is necessary the words "Solitary Confinement" should be expresed in the sentence. The legal imprisonment in the United States is confinement, solitary confinement, and a confinement on bread and water; the latter does not extend over 14 days at a time, with intervals between the periods of such confinement not less than such periods, and not exceeding 84 days in any one year.

IN BATTERY.—A command in heavy artillery service for moving the gun forward into position, prior to aiming and firing. For instance, at the siege-battery, as soon as the piece is loaded, Nos. 1 and 2 unchock the wheels (if they have been chocked), and with Nos. 3, 4, 5, and 6, all facing towards the epaulment, embar; Nos. 1 and 2 through the front spokes of the wheels, near the fellies, under and perpendicular to the cheeks; Nos. 3 and 4 under the rear of the wheels, and Nos. 5 and 6 under and perpendicular to the stock, near the trail. All being ready, the gunner commands: HEAVE, and the piece is run into battery, Nos. 5 and 6 being careful to guide the muzzle into the middle of the embrasure. As soon as the wheels touch the hurter, he commands: HALT. All unbar, and Nos. 1, 2, 3, and 4 resume their posts.

INCAPABLE.—A term of disgrace, frequently annexed to military sentences, when an officer has been cashiered by the sentence of a General Court-Martial, and rendered incapable of ever serving his country in either a civil or military capacity.

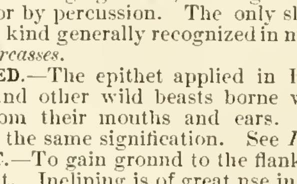
INCENDIARY MATCH.—A preparation in pyrotechny, made by boiling slow-match in a saturated solution of niter, drying it, cutting it into pieces, and plunging it into melted fire-stone. It is principally used in loaded shells. See *Fireworks*.

INCENDIARY SHELL.—A hollow projectile charged with incendiary composition, and designed for setting fire to buildings, ships, and other objects. Hollow balls filled with fire, appear to be among the earliest projectiles used in warfare after the introduction of the Greek-fire, though these were not fired from cannon; but descriptions are given of balls of fire used by the Saracens in Spain, which seem to correspond closely with modern incendiary-shells. The use of incendiary compounds appears to have gradually become obsolete, as we hear little or nothing of their employment until toward the close of the 18th century, hot shot being used as a substitute. About 1797, Chevallier, in France, invented an incendiary compound, which seems to have been tried to a limited extent by the French Government, for filling shells. Since then, many inventors have exercised their ingenuity upon this subject, the principal object being to obtain an inextinguishable composition for charging shells, to be ignited either by time-fuse or by percussion. The only shells of the incendiary kind generally recognized in modern warfare are *carcasses*.

INCENSED.—The epithet applied in Heraldry to panthers and other wild beasts borne with flames issuing from their mouths and ears. The term *Ammé* has the same signification. See *Heraldry*.

INCLINE.—To gain ground to the flank, as well as to the front. Inclining is of great use in the marching of the line in front, to correct any irregularities that may happen. It is equivalent to the quarter facing and to the oblique marching of the infantry. It enables us to gain the enemy's flank without exposing our own, or without wheeling or altering the parallel front of the company.

INCLINED PLANE.—The inclined plane is reckoned as one of the mechanical powers, because, by rolling it up a plane, a man may raise a weight which he could not lift. This principle is extensively made use of, chiefly in the raising of weights and in road-making. It is here unnecessary to go into a mathematical investigation of the theory of the inclined plane, as it may be seen in the common books on mechanics, but the result is as follows: The force required to lift a body (viz., its weight) bears to the force required to keep it from rolling down an in-

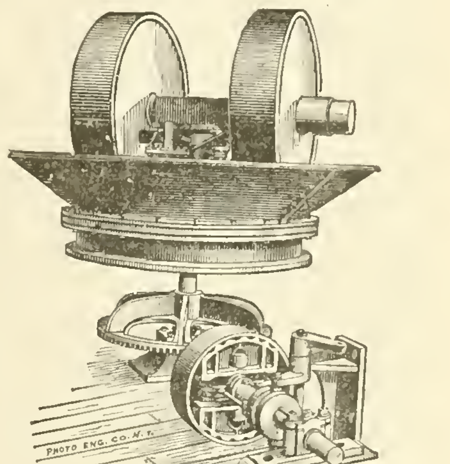


clined plane, the same proportion that the length of the inclined plane bears to its height; also the weight of the body bears to the weight which tends to bend or break the inclined plane, the same proportion that the length of the plane bears to its base. Let us suppose a plane, whose length, AB, is thirteen feet; base, AC, twelve feet; and height, BC, five feet; and let the weight be 780 pounds. Then the force, P, which can sustain 780 pounds on the inclined plane, is $\frac{5}{13}$ths of 780, or 300 pounds (*i. e.*, a force which could just lift 300 pounds); also the force, R, which presses perpendicularly on the plane, is $\frac{12}{13}$ths of 780, or 720 pounds. When the weight has not only to be sustained on the plane but drawn up to it, the resistance of friction has to be added to the power necessary to sustain the weight. In common roads, Engineers are agreed that the height of an incline should not exceed $\frac{1}{20}$th of the length, or, as they phrase it, the *gradient* should not be greater than one in twenty. It may here be mentioned that knives, chisels, axes, wedges, and screws, are mere modifications of the inclined plane, but the last two being generally classed as distinct mechanical powers, will be treated each under its own head. See *Mechanical Powers*.

INCLOSED WORKS.—Inclosed works are assailable on all sides, and must, for security, present an unbroken line to the assault. They are usually divided into three classes, viz.: 1st. Polygonal works or redoubts; 2d. Tenailled works or star forts; 3d. Bastioned works. The redoubts may be inclosed on all sides of a square, polygonal, or circular figure. The latter form is rarely used, being unsuitable to ground in general, and from the impossibility of giving any flanking defense to the ditch. Redoubts on level ground are generally square or pentagonal. On a hill or rising ground their outline will, in most cases, follow the contour of the summit of the hill. The dimensions of all inclosed works should be proportioned to the number of men they are to contain. One file, that is, two men, are required for the defense of every lineal yard of parapet; the number of yards in the crest line of any redoubt should not, therefore, exceed half the number of men to be contained in it. Again, as every man in an inclosed work requires 10 square feet of the interior space, that space clear of the banquette must not contain less than ten times as many square feet as the number of men to be contained in it. From these considerations it follows: 1st. To find the least number of men sufficient to man the parapet of an inclosed work, multiply the number of yards in the crest line by two. 2d. To find the greatest number of men that an inclosed work can contain, find the area, clear of the banquette, in square feet, and divide this number by 10. When the work contains guns, 324 square feet must be allowed for each gun, and this quantity, multiplied by the number of guns, must be subtracted from the whole interior space. The remaining number of square feet, divided by 10, will give the number of men which the redoubt can hold. The side of a square redoubt should, under no circumstances, be less than 50 feet. The great objections to small inclosed works are: 1st, the liability of their faces to be enfiladed from without; 2d, the difficulty of providing an effective flanking defense for their ditches; 3d, the weakness of their salient angles, the ground in front of them being undefended by a direct fire. In tracing redoubts and all inclosed field works, care must be taken to direct as much as possible their faces upon inaccessible ground, so as to reduce to a minimum the effects of an enemy's enfilade, while approach on the salients must be rendered difficult by abatis, trous-de-loup, and obstacles of all available descriptions. It will henceforward be very difficult to guard the interior of inclosed works from the effects of distant musketry. Well-trained troops from a distance of 900 yards could throw with certainty every shot into the interior of even a small redoubt; while the angle at which they fall, some 15° to 20°, would enable them to sweep the whole interior and make every part of the redoubt too hot. It seems to be a question whether such a work can be protected by traverses from such a plunging fire. See *Bastioned Forts*, *Field Fortification*, *Redoubt*, and *Star Forts*.

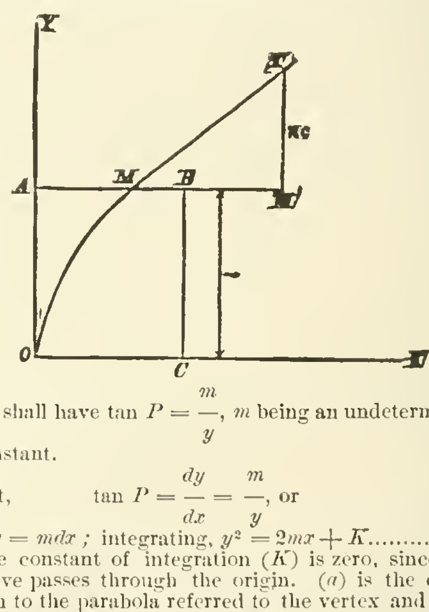
INCOMMODER L'ENNEMI.—To get possession of a fort, eminence, etc., from which the enemy may be harassed, or which is necessary to his security.

INCORPORATING MILL.—The incorporation, or grinding together, of the three ingredients that form gunpowder is by far the most important process in the whole manufacture, for unless the minute particles of the three ingredients be thoroughly blended and brought into the closest contact with each other, all subsequent operations—however well performed—will not compensate for the error. The incorporating mill, which is shown in the drawing, consists of two large and heavy "hard chill" cast-iron edge runners, revolving on a circular cast-iron bed; the peculiar action of these runners or rollers is well adapted for thoroughly grinding and incorporating the several ingredients; their great weight is for crushing the ingredients; which are also ground together by the twisting action produced by the rollers traveling round in so small a circle. Each roller travels over the bed in a separate track, and is assisted by the plough (hereafter described), which mixes the material, so that it is subjected to crushing, grinding, and mixing by the one operation. Incorporating mills in a gunpowder factory are usually grouped together, and the motive power may either be water or steam; in either case the power provided should be capable of driving four or more pairs of runners. Each pair is so arranged that it can be disengaged or put in gear at pleasure by means of a friction-clutch, without interfering with the steady working of the engine or water-wheel. When the latter is employed, the speed is regulated by a governor in connection with the sluice; by this means the flow of water is caused to immediately increase or diminish as a pair of runners is put into motion or stopped, and thus a regular speed is always maintained. The runners travel round the bed at the rate of 8 revolutions per minute; they are 6′ 6″ in diameter by 15″ broad on the face, and they each weigh four tons. As already stated, the two travel on different paths, the one being near to the outside rim or curb of the bed, while the other travels near to the inside curb or "cheese." A horizontal shaft or spindle common to both runners passes through their centers, and between them is a crosshead, fixed on a vertical shaft driven by means of a bevel wheel and pinion, the latter being secured on the main driving-shaft that passes underneath the bed of each mill, and is common to all. The vertical shaft passes through



the crosshead, and is provided with brass bushes, which allow the runners to rise or fall according to the irregularity in the thickness of the material under them. On each side of the crosshead and projecting outwards is an iron bracket, having a plough (made of a wedge-shaped piece of wood shod with felt and leather) fitted to it, and so arranged as to sweep the bed and to keep the composition under the runners. The one plough sweeps against the outside curb, immediately in front of the runner that travels round the larger circle, and the other against the cheese or inside curb, immediately in front of the runner that travels round the smaller circle. The inside of the outer curb, as well as the outside of the cheese where the ploughs work and rub against them, are covered with copper or gun-metal. The composition attains a body in about one hour after the runners are set in motion, and the action of the ploughs in moving the whole of the material on and across the bed thoroughly mixes it, and subjects every particle to the same amount of pressure. Each pair of runners is provided with a tell-tale dial, which shows the attendant the time that the mill has to run, and enables him to judge the condition of the cake from time to time. From three to four hours is the period a charge should be on the mill, providing the engine or water-wheel is maintained at its proper speed. This timing of a charge is a very important point in the manufacture where powder of an equal quality is required, and the attendant has to watch for any change in the atmosphere, so that he may work the charge dry or moist, as the humidity of the air leads him to determine. The ingredients, or charge, as it comes from the mixing-machine—50 lbs. in weight—is spread equally over the bed of the mill, and moistened with from 4 to 8 pints of distilled water by means of a rose-ended watering-pot, the quantity being regulated according to the state of the atmosphere, and as the experience of the attendant shows him to be necessary. The cake should be of a blackish-gray color, and, when broken, of a uniform appearance, without any white or yellow specks in it; the presence of these would indicate insufficient incorporation or grinding. Further, it should not be more than half an inch in thickness, in order to be thoroughly incorporated, nor should it be less than a quarter of an inch thick to insure safety, because if the runners are allowed to come in contact with the bed, the friction caused by their twisting action is so great that an explosion would almost certainly be the result. At the expiration of three or four hours under the before mentioned conditions, a charge will have attained all the properties of gunpowder, nor will the powder be improved by heavier runners or an increase of speed. For fine sporting gunpowder, however, the operation of incorporating is continued in some cases for as long as 8 hours, and with heavier rollers, but it is doubtful whether the powder is much, if at all, improved thereby; the purity of the ingredients is of more consequence, inasmuch that on this the quality of powder depends much more than upon a long or short period of incorporation, for if regularity be observed and the runners are of one size and weight, and the charges are worked for an equal length of time and under the same conditions, a fairly uniform powder will be the result. A method used by some for testing whether the incorporation has been well performed, is to take half an ounce of the cake granulated by hand and flash it off on a glass plate; if a slight residue only is left on the surface it is a sign that the attendant has done his work thoroughly. It has already been stated that incorporating-mills are generally in groups: it becomes necessary, therefore, to prevent explosions spreading amongst these mills. This is very effectually done by the use of a drenching apparatus, which consists of a large board acting as a flapper, and placed horizontally over each pair of runners. This flapper is attached to a shaft running throughout the entire group of mills, and in connexion with it, and immediately over each set of runners, is a copper cistern holding about 40 gallons of water, so arranged and poised that when the flapper is raised by an explosion the catch is disengaged, and the cistern overbalancing empties its contents upon the mill. This, of course does not prevent damage being done to the mill in which the explosion first occurs, but as the whole are connected to each other by means of the shaft referred to, all the cisterns of the group are emptied at the same time, thereby drenching the charges in the other mills, and thus confining the damage to that mill wherein it originated. In addition to this, an arrangement is provided whereby the attendant can, in case of an explosion in any part of the works or in his immediate neighborhood, upset the cisterns of water from the outside, and thus prevent the explosion spreading. In a well-constructed incorporating mill all the movable parts, such as bolts, nuts, etc., are fitted with the greatest care, and at each end of the runner-shaft, and also over and under the cross-head between the runners, large gun-metal discs or drip-pans are fitted: these not only prevent any oil or greasy matter dropping into the charge, but likewise any bolt, nut, or pin that may have become loose in the vicinity of these parts, falling down into the charge, and possibly producing an explosion, if the mill is at work. Further, where steam is employed as the motive-power in a gunpowder works, care must be taken at all times to prevent sparks being emitted from the boiler chimney; this may be effected in several ways, either by using anthracite coal, or coal and coke, for the boiler furnace, or by having a spark-catcher or arrester fitted inside the flue near the base of the chimney, or a number of baffle-plates being placed in the chimney itself in a zig-zag manner. If proper precautions are taken, and the flues are regularly cleaned out, there will be no risk whatever in using steam-power. See *Gunpowder*.

INCREASING TWIST.—For an increasing twist, the edges of the angle-board must be curved accordingly, and as it is the property of the parabola to increase uniformly, it has been adopted as the curve of the rifling for those guns having an increased twist. When this system is adopted, the grooves start in a direction parallel to the axis of the bore, and the twist increases uniformly towards the muzzle. In the drawing, ABCO denotes the development of the bore, and OM that of a groove. The origin of the co-ordinate axes is taken at the commencement of the groove at the bottom of the bore; the axis of Y is parallel to the axis of the bore. The curve OM is tangent to OA at O, since the projectile starts in the direction OA. Let P denote the variable angle between OX and the direction of the curve OM. If the twist increases uniformly, tan P will *decrease* uniformly as the ordinate *increases*, and



we shall have $\tan P = \dfrac{m}{y}$, m being an undetermined constant.

But, $$\tan P = \frac{dy}{dx} = \frac{m}{y}, \text{ or}$$

$ydy = mdx$; integrating, $y^2 = 2mx + K$............(a)
The constant of integration (K) is zero, since the curve passes through the origin. (a) is the equation to the parabola referred to the vertex and principal axes. In the figure, MT is the tangent at M, and MM′ equals AB $= \pi c$, c being the caliber of the gun. Also M′T is put equal to nc, n denoting the number of calibers in which the projectile makes one turn after leaving the muzzle. To determine m, putting P', for the value which P has at M we have

$$\tan P' = \frac{m}{l};$$

also,
$$\tan P' = \frac{nc}{\pi c} = \frac{n}{\pi};$$

$$\therefore \quad m = \frac{ln}{\pi}$$

Whence the equation to the curve is

$$x = \frac{\pi y^2}{2ln} \text{...............................} (b)$$

By means of equation (b) the curve is easily traced. The advantages claimed for this method of rifling are, that the projectile, not being forced to take the whole twist of the rifling at once, moves more readily from its seat, and thus the initial strain upon the breech of the gun is reduced, thereby prolonging its life; also that the bearings on the projectile are not liable to be torn off. Theoretically it would seem that a system of rifling which permits the projectile to move directly from its seat, at the moment of ignition of the charge, must be more favorable to endurance than one which, by impeding the first movement of the projectile in the bore, narrows the space for the expanding gas, and consequently brings a greater pressure on the breech of the gun. But practically this method does not appear to be successful in the enormous cannon of recent construction. The greatest objection to the increasing twist is that it cannot be used with a long bearing of projectile. Indeed, the theoretical bearing, whether it is a soft metal ring, a strip, or a stud, is infinitely short a mere line—and practically, length of bearing only obtained by a constant molding of the projectile to the new angle of rifling, so that the portion of the projectile intended to take the grooves, must be short and also soft, for if it cannot obtain, by changing its figure, more bearing on the grooves than on a mere line, it will undoubtedly cut the grooves, thus increasing friction, and soon ruining the bore. In the absence of further experiments, it would hardly be safe to conclude that long bearings will not prove indispensable to the heavy projectiles and high velocities that are now required. A projectile, if balanced on weakening studs in each groove, is liable to break up through the stud-holes, thereby injuring the gun. To rapidly rotate an iron cylinder, say twelve inches in diameter and three calibers in length, weighing nearly a third of a ton, by a ring of such points, is very likely to produce a *wabbling* motion and unsteady movements in flight, with reduced range. Very rapid twist, although it conduces to steadiness of motion, cannot be given because small bearings will not endure the great effort necessary. See *Grooves*, *Rifling*, and *Twist*.

INDEMNIFICATION.—In the French and English Armies, there is an indemnification established for losses in the military service, and other allowances are also made in the nature of indemnifications; as for *furniture; fuel* and *light; forage; expenses of divine worship; command money* to General and Field Officers; *quarters; expenses upon routes*; *provisions; gratuity at the beginning of a campaign; field allowances; mess; carriage of baggage; blood-money; permanent pensions; temporary pensions*, or *gratuities* in lieu thereof; *rewards* for meritorious conduct; and *pensions* to widows and children of officers.

In the United States service, the law provides that if a horse be lost in battle, an officer may receive not exceeding two hundred dollars for his horse, and allowances are made for quarters, fuel, forage, provision and transportation of baggage, and command money in certain cases.

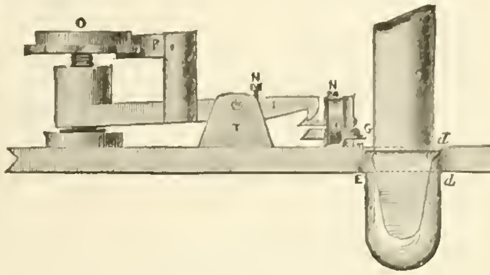
INDENT.—A word particularly made use of in India for the dispatch of military business. It is of the same import and meaning as *to draw upon*. It likewise means an order for military stores, arms, etc., as an indent for new supplies, etc.

INDENTED.—In Heraldry, one of the partition lines of the shield, similarly notched to dancetté, but with the notches much smaller, and not limited in number. See *Heraldry*.

INDENTED LINE.—In fortification, a serrated line, forming several angles, so that the one side defends another. The faces are longer than the flanks. Indented lines are used on the banks of rivers, where they enter a town. The parapet of the covered-way is also often indented.

INDENTER.—This active element of the chronoscope, as shown in the drawing in section, consists of the circular knife, G, fixed in the mainspring, H, which can be cocked by means of the catch on the lever, I. On the breaking of the first circuit, the chronometer falls vertically; on the rupture of the second the registrar falls in its turn, depresses the free end of the lever, I, and thus releases the mainspring; the knife juts forward, strikes the falling chronometer, and indents the upper recorder. As shown below, a very simple relation holds between the dent thus obtained and the velocity of the projectile which caused it. A moment's thought will show that the lower the velocity the higher up shall the recorder be indented.

The chronometer is used in leveling the chronoscope; for this purpose attach it to its magnet, *having previously cocked the indenter*; then, by means of the tripod-screws, bring it to its normal position. In



leveling from front to rear, let the beveled shoulder of the bob, opposite the numbered face, rest lightly against the projecting edge, *e e*, of the triangular base; in leveling laterally, align the right face with the edge *d d*, of the salient angle of the above projection. In cocking the indenter, be careful not to disturb the level of the instrument; the left hand alone is therefore used; the fingers grasp the tube, L, while the thumb pulls pack the spring until it catches in the lever, I. The screw, M, which is tapped through the lever and rests on the fulcrum-mortise will regulate the hold of the catch, which should be as light as possible. The knife is a circular rowel of tempered cast-steel fastened in a slot of the mainspring by the axial screw, N, the loosening of which permits the presentation of a new edge, should the old one be blunted. See *Le Boulengé Chronograph*.

INDENTING FORCE.—The comparative softness or hardness of metal is determined by the bulk of the cavities or indentations made by equal pressure: the softness being as the bulk directly, and the hardness as the bulk inversely. Of the different forms of cavity made by indenting-tools that of the pyramid is preferred, because of its simplicity and the ease with which its volume may be computed. The indenting part of the tool is in the form of a pyramid, having a rhombus for its base, the diagonals of which are, respectively, one inch and two-tenths of an inch, the height of the pyramid one-tenth of an inch. In late experiments the form of the pyramid has been changed and improved somewhat by causing it to make a longer line and mark minute differences more accurately. See *Rodman Cutter*.

INDENTING PISTONS.—The indenting-pistons that are used in the service are found to vary in their diameters. The pressure of the gas is exerted upon their inner ends, and varies directly with the area pressed. It is desirable to have a series of pistons adopted which shall have the same area of cross-section. In practice, the area of these pistons has generally been assumed to be one-tenth of one square inch. The following Table gives the diameters, areas, and pressures upon those pistons of which the dimensions are known, neglecting friction, and supposing the pressure per square inch to be 100,000 pounds.

Little is known in regard to the effect of friction upon these short pistons. The friction of the gas-check against the walls of the hole would render the indicated, less than the actual pressures. A uniform system of pistons and cutters should be established in order to render the results obtained comparable. The more nearly the conditions are assimilated the greater will be the approximation of the relative pressures to an agreement. At the present time each piston necessitates a separate Table of Pressures, and when the length of the cuts is required to determine the pressures, a Table must be constructed for each cutter. See *Circular Cutter* and *Pressure-gauge.*

Pistons.	Diameter of pistons.	Area of pistons.	Pressure upon pistons.	Remarks.
	Inches.	Sq. in.	Lbs.

West Point internal pressure-gauge	.355	.0989798	9897.98	

INDEPENDENT.—In a strict military sense, a term which distinguishes from the rest of the army those companies which have been raised by individuals for rank, and were afterwards drafted into corps that were short of their complement of men. An *Independent Company* or *Troop*, is one that is not incorporated into any regiment.

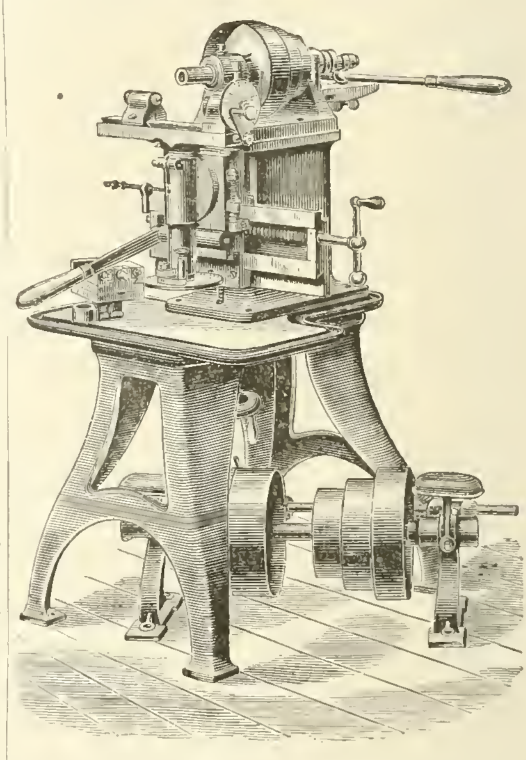
INDEPENDENT SCARP.—A wall 3 feet thick erected at the foot of the exterior slope, and when it is breached the parapet cannot fall. It is loop-holed and provided with a banquette. Its height should not be less than 20 feet.

INDEX MILLING-MACHINE.—A machine adapted to a great variety of work on metals, in the Armory. The small machines of this class, weighing about 600 pounds, mill 10½ inches long and 7½ inches high, and will cut gears up to 8 inches in diameter. The use of the inconvenient counter-shaft, with binder, weight, etc., commonly used with this class of machines, is avoided in the Armory, an ordinary overhead shaft being used, and the compensation for rise and fall of mill-spindle and carrier obtained by a splined shaft passing through the lower gear. When not in use for cutting gears, the index-spindle is solidly clamped, so that when using a vise, centers, or spiral-cutter, no strain or injury can come upon the index-plate or pointer.

The larger machines, weighing about 1,400 pounds, are perfect gear cutters within certain limits of size, cutting fast and smoothly, and, in addition, having provision for using a vise, centers, and spiral cutter without injury to the delicate dividing mechanism, thus practically furnishing two machines. They mill 18 inches in length and 11 inches in height; cut spur-gears up to 21 inches in diameter; also worm and bevel-gears. An adjustable rim-rest supports the gear-blank while being cut, and prevents chattering. The mill-arbor has an outside center support, which can be removed if required. The cutter-head may be worked by the screw in front, or by an adjustable lever, connected with rack and pinion at the back, and is balanced by a weight under the machine.

The *index-plate* is 14 inches in diameter, has 3,800 holes, in 25 circles, and divides all numbers to 50, all even numbers to 100, and every fourth number to 200.

The drawing represents the machine most commonly used. It is adapted to cutting mills, spur or bevel-gears, up to 6 inches diameter. The index-plate is attached to the bottom of a hollow spindle having a graduated disc. The spindle is pivoted to a vertical slide, and with its attachments, as vise or centers, may be moved and secured at any angle in a vertical plane of 180°, or 90° on either side of an upright position. This slide, carrying the index-spindle, etc., has a perpendicular movement of two inches. The upward and downward movement of the main slide, to which the vertical is attached, is 6 inches, and its side traverse 12 inches. The centers shown in the engraving as attached to the index-spindle, will receive work 3¼ inches in diameter and 8½ inches in length. The spindle is of steel, and slides in a cast-iron sheath or shell, which runs in cast-iron boxes lined with Babbitt-metal. The horizontal movement of the spindle and the vertical move-



ment of the slides are made by adjustable hand-levers, and limited by check-nuts. The head has a longitudinal adjustment by a screw to the extent of 2½ inches. The machine weighs, with countershaft, vise, and centers, 650 pounds. Speed of countershaft, having 8 and 5 by 2½ inch tight and loose pulleys, 100 revolutions per minute. See *Milling.*

INDIAN ARMY.—The Indian Army in the days of Clive, which was composed of both the British and native troops, was comparatively small, barely sufficient to hold its own; but even in those days it did great deeds of valor, as the battle of Assaye and other battles testify. By degrees, as the East India Company increased its territory, a larger Army was found necessary, and both British and native troops

were augmented. In 1857 the mutiny of the native Army took place, which necessitated a change in the organization of the Army involving a large increase of the British force. From this date the Army of the East India Company became a part of her Majesty's Army, paid out of the revenues of India.

The Army of India at present consists of 62,850 British troops and 128,500 native troops. More than half the former are stationed in the Bengal Presidency, 38,000 men being in garrison along the valley of the Ganges, Oude, and in the Punjab, while the strength of the native Army for the same Presidency amounts to 49,000. Bengal proper alone requires about 7,000 English troops for its guard, or nearly one-ninth of the total number of the British employed in India. The remainder are distributed amongst the North-west Provinces and in the Presidencies of Madras and Bombay. See *East India Army*.

INDIAN COUNTRY.—"The Indian country," within the meaning of the Trade and Intercourse Acts, may be defined in general as:

1. Indian reservations occupied by Indian tribes.
2. Other districts so occupied to which the Indian title has not been extinguished.

Furthermore, the operation of the said Acts may be retained by treaty or extended by Act of Congress over districts not in other respects Indian country. If any special case shall occur which, in the view of the Department Commander, may not appear to be embraced within the definition above stated, he reports the case, with all its facts and circumstances, to the Secretary of War, in order that the question whether the locality is "Indian country" may be referred to the Secretary of the Interior.

Where lands are secured to the Indians, by treaty, against occupation by the whites, the Military Commanders keep intruders off, by military force, if necessary, until such time as Indian title is extinguished, or the lands are opened by Congress for settlement.

There is no jurisdiction conferred upon State or Territorial Courts to try an Indian charged with the murder of another Indian. Section 2146 of the Revised Statutes of the United States, as amended by the Act of February 18, 1875, entitled "An Act to correct errors and supply omissions in the Revised Statutes of the United States," provides that section 2145 shall not be construed to extend to crimes committed by one Indian against the person or property of another Indian, nor to any Indian committing an offense in the Indian country who has been punished by the local law of the tribe.

When questions arise as to the ownership of animals in possession of Indians, the Commanding Officer of the nearest military post is authorized and directed to act in conjunction with the Indian Agent in charge of the said Indians in the investigation and determination of the ownership.

Whatever may be the rule in the time of war and in the presence of actual hostilities, military officers can no more than civilians protect themselves for wrongs commited in time of peace under orders emanating from a source which is in itself without authority in the premises. Hence a military officer, seizing liquors supposed to be in Indian country, when they are not, is liable to action as trespasser. The difference between the value of the goods so seized, at the place where they were taken and the place where they were returned to the owners, is the proper measure of damages.

Supplies, stores, or property of any kind, procured out of Army appropriations, are not transferred, in any way or under any circumstances, for the use of Indians, except under authority first obtained from the Secretary of War. Any officer violating the terms of this regulation is charged with the money value of the supplies, stores, or property transfered, and in addition is otherwise held accountable, according to circumstances. No issues of arms, ammunition, or any other Ordnance stores are made to Indians not in the employ of the War Department as scouts.

To carry into effect the joint resolution adopted by Congress, August 5, 1876, the sale of fixed ammunition or metallic cartridges, by any trader or other person, in any district of the Indian country occupied by hostile Indians, or over which they roam, is prohibited: and all such ammunition or cartridges introduced into said country, by traders or other persons, and that are liable in any way or manner directly or indirectly, to be received by such hostile Indians, is always deemed contraband of war, and seized by any military officer, and confiscated; and the district of country to which this prohibition shall apply, during the continuance of hostilities, is designated as that which embraces all Indian country, or country occupied by Indians or subject to their visits, lying within the Territories of Montana, Dakota, and Wyoming, and the States of Nebraska and Colorado.

By virtue of authority conferred upon the President of the United States in section 2132, Revised Statutes, the introduction into the Indian country or district occupied by any tribe of hostile Indians, for the purpose of sale or exchange to them of arms or ammunition of any description, and the sale or exchange thereof to or with such Indians, is prohibited. All military commanders are charged with the duty of assisting in the execution of this order, and of Executive Order of November 23, 1876, the provisions of which are extended to include all Indian country within the Territories of Idaho, Utah, and Washington, and the States of Nevada and Oregon. See *Indian Territory*.

INDIAN FILE.—Single file; the arrangement of men in a row following one after another, as is customary among Indians when traversing the woods or mountains.

INDIAN FIRE.—A bright white signal-light, produced by burning a mixture of 7 parts of sulphur, 2 of realgar, and 24 of niter.

INDIAN INK.—The cakes of this substance, which is a mechanical mixture, and not, like the true inks, a chemical compound, are composed of lampblack and size or animal glue, with a little perfume. The lampblack must be remarkably fine, and is said to be made in China by collecting the smoke of the oil of sesame. A little camphor (about 2 per cent.) is also found in the ink made in China, and is thought to improve it. This substance is used in that country with a brush both for writing and for painting upon paper of native manufacture, while in this country, it is extensively employed for designs in black and white, and all intermediate shades of color. Much curious information on this pigment may be found in Merimée's treatise, *De la Peinture*.

INDIAN PONY.—The square-built, large-trunked, and short-legged pony used by the North American Indians and elsewhere. This pony, generally believed to be the result of a cross between the Southern mustang and a small type of the Canadian, is never fed, stabled, combed, shod nor doctored; and when not under the saddle is left to shift for himself. In the winter he is a mere animated skeleton. His proportions vary according to the localities in which he is found, but he seldom exceeds thirteen hands in height. He is wonderfully sagacious and sure-footed. He can climb a steep, rocky hill with assurance and activity, and rush down a precipitous declivity with much indifference. He will get over and through places, which appear utterly impracticable, with ease and rapidity, while the American horse would labor to travel at a walk. He particularly excels in the passage of swamps, marshy places, and sands perforated with gopher holes.

INDIANS.—The collective name now generally given to the various nations and tribes inhabiting North and South America, at the time of their discovery by the Spaniards, and to such of their descendants as survive at the present day. The name of Indians was first given to the natives of America from the mistaken notion of the early voyagers, Columbus himself included, that the newly found Continent was in reality a part of India. This was soon shown to be an error; but the name of Indians, thus wrongly applied to the inhabitants, continued to be used in every narrative of voyage and discovery, and has descended even to our own times, only that we now qualify it in some measure by speaking of them as *American Indians*. In the classification of Blumenbach the American Indians are treated as a distinct variety of the human race; but in the threefold division of mankind laid down by Dr. Latham, they are ranked among the Mongolidæ. Other Ethnologists also regard them as a branch of the great Mongolian family, which, at a remote period of the world's history, found its way from Asia to the American Continent, and there remained for thousands of years separate from the rest of mankind, passing meanwhile through various alternations of barbarism and civilization. Morton, however, the distinguished American Ethnologist, and his disciples Nott and Gliddon, claim for them a distinct origin, one as indegenous to the Continent itself as its fauna and flora. Pritchard, whose views generally differ from those of Morton, acknowledges that "On comparing the American tribes together, we find reasons to believe that they must have subsisted as a separate department of nations from the earliest ages of the world. Hence, in attempting to trace relations between them and the rest of mankind, we cannot expect to discover proofs of their derivation from any particular tribe or nation in the Old Continent. The era of their existence as a distinct and insulated race must probably be dated as far back as that time which separated into nations the inhabitants of the Old World, and gave to each branch of the human family its primitive language and individuality." Dr. Robert Brown, in his "Races of Mankind," the latest authority on the subject, attributes to the American race an Asiatic origin. He says: "Not only are the Western Indians in appearance very like their nearest neighbors, the North-eastern Asiatics, but in language and tradition, it is confidentially affirmed, there is a blending of the people. The Eskimo, on the American, and the Tchuktchis, on the Asiatic side, understand each other perfectly." In fact, modern Anthropologists incline to think that Japan, the Kuriles, and the neighboring regions may be regarded as the original home of the greater part of the American race. It is also admitted by Anthropologists that between these various tribes, from the Arctic Sea to Cape Horn, there is greater uniformity of physical structure and personal characteristic than is seen in any other quarter of the globe. The "Red Men," as they are called, of the United States and Canada, differ in many respects from the Guranis of Paraguay, and both from the wild tribes of California, but all exhibit the clearest evidence of belonging to the same great branch of the human family. Upon this point the testimony of a writer like Humboldt is very important. "The Indians of New Spain," says Humboldt, "bear a general resemblance to those who inhabit Canada, Florida, Peru, and Brazil. We think we can perceive them all to be descended from the same stock, notwithstanding the prodigious diversity of their languages. In the portrait drawn by Volney of the Canadian Indians, we recognize the tribe scattered over the Savannahs of the Apure and the Carony. The same style of features exists in both Americas." The Mongolian cast of features is most marked in the tribes nearest to the Mongol coast, *i. e.*, on the shores of the Pacific, and gets less noticeable as we go Eastward. Their traditions, too, indicate that the tribes on the eastern seaboard came from the West, and the western tribes even came from regions still further west.

Generally the physical characteristics of the American Indians are as follows; a square head, having a low, but broad forehead, the back of the head flattened, full-face, and powerful jaws; cheek-bones prominent; lips full; eyes dark, and deeply set; the hair long, not absolutely straight, but wavy, something like a horse's mane, and like that, of a glossy hue; little or no beard—where it does appear, it is carefully eradicated with tweezers; color of the skin reddish or copper; the height of the men about the average, but looking taller from their erect posture and slender figure; the women rather shorter, and more inclined to obesity, but many of them with symmetrical figure and pleasing countenance; hands and feet of both men and women small. As before said, however, there being some hundreds of tribes among the American Indians, there are many departures from these general characteristics, not only in individuals, but entire septs. "The Americans," says Pritchard, "are not all of the hue denominated *red*, that is, of a copper color; some tribes are as white as many European nations; others brown or yellow; others are black, or, at least, they are described by travelers as very much resembling in color the negroes of Africa. Anatomists have distinguished what they have termed the American form of the human skull; they were led into the mistake by regarding the strongly marked characteristics of some particular tribes as universal. The American nations are spread over a vast space, and live in different climates, and the shape of their heads is different in different parts. Nor will any epithets derived from their habits of life apply to all the tribes of this department. The native Americans are not all hunters; there are many fishing tribes among them; some are nomadic; others cultivate the earth, and live in settled habitations; and of these some part were agriculturists before the arrival of the Europeans; others have learned of their Conquerors to till the soil, and have changed the ancient habits of their race, which, as we may hence infer, were not the necessary result of organization or congenital and instinctive propensity." Dr. Morton's views on this subject substantially agree with those of Pritchard, and both concur in adopting the test of language as a proof of one common origin for the various native tribes of both North and South America. The linguistic conclusion, now generally acquiesced in, is thus briefly stated by Mr. Albert Gallatin: "Amidst the great diversity of the American languages, considered only in reference to their vocabularies, the similarity of their structure and grammatical forms has been observed and pointed out by the American Philologists. The result appears to confirm the opinion already entertained on that subject by Mr. Du Ponceau, Mr. Pickering, and others; and to prove that all the languages, not only of our own Indians, but of the native inhabitants of America, from the Arctic Ocean to Cape Horn, have, as far as they have been investigated, a distinct character common to all, and apparently differing from any of those of the other Continents with which we are most familiar."

The next question that comes under consideration is: Whence does it arise that, with all this similarity of physical conformation and language, there should have been only two nations among so many millions—namely, the Mexicans and Peruvians—who attained to any high degree of civilization? When the Spaniards entered Mexico they found in it a rich, powerful, and warlike nation, living in walled cities, in which were palaces and other sumptous residences. They were ruled over by an Emperor or King whose sway extended over many other nations besides his own. They worshipped the sun, and had an organized Hierarchy; they had also fixed laws, were acquainted with many of the arts and sciences, especially astronomy; they practiced agriculture, worked mines, and displayed considerable skill in manufactures, both industrial and ornamental. The Nation thus discovered was that of the Aztecs, who professed to have among them evidences of antiquity dating as far back as the year 554 of our era. A few

years later, in Peru, the Spaniards found another Nation, also exceedingly rich, numerous, and powerful with a civilization fully as much extended as that of the Aztecs, yet differing from that in many essential particulars. This was the Nation of Quichuas, frequently termed Incas (more correctly *Yncas*), associated with whom were the Aymaras, whose country had been subjugated by the Incas two or three centuries before the arrival of Pizarro, in Peru. Each of these Nations—the Mexicans and Peruvians —is supposed to have slowly developed its own civilization during a long process of ages. In every other part of America European settlers and explorers have found only complete or semi-barbarism. Such was the case in Virginia; such in New England, Canada, the Hudson's Bay Territory, California, and Patagonia. In Central America, however, there have been found extensive remains of architecture and other traces of civilization, which would seem to date back to even a more remote period than that of the Mexican or Peruvian Empires. Immense artificial mounds also exist in the valley of the Mississippi and elsewhere throughout America, supposed to be the work of the ancestors of the present wandering tribes. If so, there may be some truth in the theory of Dr. Martius, a distinguished German Ethnologist, "That the nations of the new world are not in a state of primitive barbarism or living in the original simplicity of uncultivated nature, but that they are, on the contrary, the last remains of a people once high in the scale of civilization and mental improvement, now almost worn out and perishing, and sunk into the lowest grade of decline and degradation." Dr. Pritchard appears inclined to the same view, adding: "Attentive observers have been struck with manifestations of greater energy and mental vigor, of more intense and deeper feeling, of a more reflective mind, of greater fortitude, and more consistent perseverance in enterprises and all pursuits when they have compared the natives of the New World with the sensual and volatile, and almost animalized Savages who are still to be found in some quarters of the Old Continent, They have been equally impressed by the sullen and unsocial character, by the proud apathetic endurance, by the feeble influence of social affections, by the intensity of hatred and revenge, and the deep malice-concealing dissimulation so remarkable amid the dark solitudes of the American forests."

Dr. Robert Brown adopts a geographical classification of the American tribes, which is, on the whole, at least unsatisfactory. There are Arctic tribes; North-western tribes inhabiting the region west of the Rocky Mountains between California and Alaska; Californian tribes; Indians of the Central Plains; Prairie tribes; North-eastern Indians; Canadian Indians; and Central American Indians. The chief existing tribes are; Eskimo, Cowichans, Tsongeisths, Nanaimos, Quakwolths, Nuchultaws, Koskeemos, Seshahts, Nittinahts in Vancouver Island; Hydahs (Queen Charlotte Islanders); Tsimpsheans, Bellacoolas, Chilcoatins, Shuswaps in British Columbia; Cayuse, Snakes, Klamaths in Oregon; the Digger or Californian Indians, the most degraded of all the tribes; the Comanches, Apaches, Navajos, Hualpais, Yampas, in the Central Plains; the Moqui, Pueblos, Pimas, Papagos in New Mexico; Utahs, Pahutas, Pahides, Soshones, Loo-coo-rekahs, Goships, Cheyennes, Arrapahoes, Kwivas, Arickarees, Poncas, Yanktons, Gros-Ventres, and Sioux or Dahcotahs, Assiniboines, Blackfeet, Crows, Omahas, Ottoes, Pawnees, etc., are all Prairie tribes; the Delawares, Mo-hee-conneughs (Mohicans), Oneidas, Tuskaroras, Senecas, Shawnees, Cherokees, Choctaws, Creeks, Seminoles, Osages, Kaskias, Weeahs, Potowatomies, Quapaws, Peorias, Kanzans, Sanks, Foxes, Puncas, etc., in the North-eastern States; the Crees, Santeux or Ojebways, Chippewayans, the Sacliss or Shewhapmuch in Canada; Tehuantepecs, Mosquitos, Smoos, Twakas, Toonglas, Payas, Ramas, and Cookras in Central America. Again, M. d'Orbigny has classified all the Indians of South America under three great groups, viz., the Andian group, the Mediterranean group, and the Basilio-Guarani group; and these he subdivides into thirty-nine distinct nations; viz., '1. Quichua; 2. Aymara; 3. Chango; 4. Atacama; 5. Yuracares; 6. Mocetenes; 7. Tacana; 8. Maropa; 9. Apolista; 10. Araucananian; 11. Fuegian; 12. Patagonian; 13. Puelche; 14. Charrua; 15. Mbocobi; 16. Mataguayo; 17. Abipones; 18. Lengua; 19. Samuco; 20. Chiquito; 21. Saraveca; 22. Otuke; 23. Curuminaca; 24. Covareca; 25. Curaves; 26. Tapiis; 27. Curucaneca; 28. Paiconeca; 29. Corabeca; 30. Moxo; 31. Chapacura; 32. Itonama; 33. Canichana; 34. Movima; 35. Cayuvava; 36. Pacaguara; 37. Itenes; 38. Guarani; 39. Botocudo.' Other classifications have been attempted, but all more or less arbitrary. Morton is content with two grand divisions, viz., the 'Toltecan Nations' and the 'Barbarous Tribes,' the former embracing the ancient Mexicans and Peruvians, and the latter all the uncivilized or semi-civilized tribes from the extreme North to the extreme South. The Toltecans are said to be the builders of the remarkable series of mounds found throughout North America.

The Indians are yearly decreasing in numbers. A fair estimate would probably give Alaska 20,000; British Columbia, 20,000; Vancouver's Island, 9,000; Canada, 5,000; California, Oregon, and States north of it, 10,000; Prairie-lands west of the Rocky Mountains, 10,000; other portions of the United States, 2,000; in New Mexico and Central America, 20,000. This would gives us a total of about 110,000 for the whole of North America, exclusive of half-breeds, &c. Some twenty tribes have become partially civilized, and live by agriculture, under the protection of the American Government, on what are called 'Indian Reservations.' There are in these Indian communities many men and women whom education has developed into most valuable, intelligent, and even polished members of a highly civilized community. Two tribes (Choctaws and Cherokees) have become wholly civilized, and have a settled form of government modelled on that of the United States. The Cherokees stand alone amongst modern nations in having produced a second Cadmus, one Sequoyah, or George Guess, who actually invented an alphabet. It must be stated, however, that fully one-half of these civilized tribes are, like Sequoyah, half-breeds. Even the whites marrying Choctaw or Cherokee women are admitted, if they choose, into these tribes.

Both the early English and French settlers of North America were often at war with the Indians, either in self-defence or instigated by a desire for their lands. In Virginia the Indians who had combined to exterminate the Whites were subdued after a ten years' war. In New England (1637) the Colonists of Connecticut and Massachusetts destroyed the warlike Pequods, and in 1643 the Narragansetts. The war of Phillip, king of the Wampanoags, ended, 1676, in the almost total destruction of that tribe. The Dutch in New Amsterdam and the English in North and South Carolina suffered greatly from the Indians. In the Seven Years War between the English and French the Indians were used by both sides and terrible atrocities were committed. In 1763 a number of tribes were united under Pontiac, the Chief of the Ottawas, in a general conspiracy to exterminate their Conquerors, but they were finally subdued. When the American Revolution began the Indians, who were Allies of the English, ravaged on the frontiers. The United States, by the Constitution of 1787, claiming sovereignty over the whole territory, made treaties with the Indians for the purpose of obtaining their lands; but in 1790 the Miamis and other tribes conspired and defeated the army under Gen. Harmar, and the following year under General St. Clair, but were subdued by General Wayne. In 1811 they recommenced hostilities under Tecumseh, but were defeated at Tippecanoe by General Harrison, who also in 1812, defeated the combined forces of the English and Indians, and killed Tecumseh. In the South the Creeks were conquered by Jackson in 1813, and the Seminoles of Florida in 1817. In 1832 the Sacs and Foxes, under their Chief, Black Hawk, harassed the frontier Settlements, and from time to time the Sioux, the Comanches, and Apaches, often joined by other tribes have given the Government great trouble. In 1838 the Cherokees and Creeks were removed from Georgia to the Indian Territory, West of the Mississippi, which the Government had established to be the permanent home for all the Indians. The Seminoles of Florida refusing to remove, a bloody war ensued, which lasted 7 years and cost $15,000,000. After the removal of the Choctaws, Creeks, and other tribes to the Indian Teritory, other reservations were formed in several States. In 1871 there were on reservations 237,478, which, added to 60,000 in Alaska, and about 50,000 others not yet placed in reservations make the total number of Indians in the United States, as estimated by the Indian Department, 350,000. The number in the British Colonies is estimated at 150,000.

The five civilized tribes of the Indian Territory had under cultivation (1879) 237,000 acres, on which they raised over 3,000,000 bushels of cereals, and were engaged largely in the raising of stock. The Indians on other reservations had under cultivation 157,056 acres, and raised over 1,500,000 bushels, and all together about 225,000 tons of hay. The Indians are scattered over a large extent of country, and the difficulty of managing them is increased by the attempts of bold and unscrupulous white men to invade their reservations for trade, which often involves fraud, and for the sake of the mineral deposits known to be there. The Utes in Colorado and Apaches in New Mexico, especially, have given the Government much trouble. The Utes are fierce and warlike, and resist all efforts to induce them to abandon their wandering life and cultivate the soil.

Earnest attempts have been made at different periods by individuals and Societies to Christianize and civilize the Indians, some have been remarkably successful. The French and Spanish in connection with their Colonies, had Missions among the Iroquois, Chippewas, Creeks, and other tribes. In Florida, Texas, New Mexico, and California, they had prosperous Missions. In 1643 Thomas Mayhew labored with success for three years at Martha's Vineyard, Mass., followed in the same work by his father, and by others of the family for five generations. In 1646 the Legislature of Massachusetts passed an Act for the propagation of the Gospel among the Indians, and in the same year John Eliot began his labors at Nonantum, churches were formed, and the Bible and other Christian books translated. The Brainards labored with effect in New Jersey and Pennsylvania. The Moravians and Friends have been active in instructing the Indians. The various Protestant Denominations, through organized Societies have had for many years Missions among the Cherokees, Choctaws, Ottawas, Chickasaws, Creeks, Dacotahs, and some other tribes, instructing them not only in religion, but also in the arts of civilized life. The Indian problem, always troublesome to the U. S. Government is now seen to involve grave, moral, and political issues not at first recognized. The governmental policy has been one of expediency rather than of justice. Treaties have been made with the tribes as with sovereign nations, but have been set aside on easy pretexts. Indians have not been considered as citizens under the law; their ownership of property, as recognized, has been tribal and not individual. They have been allowed to be the pray of rapacious speculators in land, and thievish traders. Of late years the Government has sought to apply a better policy, but the evil has been found too vast and deep for easy reform; and a wave of popular feeling is now rising, bearing in upon the Government with strong demands in different directions. There are signs that the discussions will result in better processes of dealing with the Indians, and that the Government will find or make its way to a system that shall be wise and just. See *Indian Territory.*

INDIAN TERRITORY.—The home of civilized or partially civilized remnants of once powerful aboriginal tribes, removed by the Government from time to time from differen' parts of the Union, and which, upon separate reservations and under forms of government established by themselves, are living at peace with each other and with the United States. In June, 1830, Congress passed an Act setting apart "All that part of the United States west of the Mississippi, and not within the States of Missouri and Louisiana or the Territory of Arkansas," to be known as the Indian Country. The region thus described formed a part of the Louisiana purchase of 1803 from France. Portions thereof have since been organized into new States and Territories, and only a remnant of the original Indian Country now remains. To it has been added, however, a narrow adjoining strip of land west of the 100th meridian which was ceded to the United States by Texas. The Territory contains 20 reservations, the names of which, with the extent of each in square miles are as follows:—Arrapahoe and Cheyenne, 6,715; Cherokee, 7,861; Chickasaw, 7,267; Choctaw, 10,450; Creek, 5,024; Kansas, 154½; Kiowa and Comanche, 4,369; Modoc, 6; Osage, 2,291; Ottawa, 28½; Pawnee, 442; Peoria, 78½; Pottawatamie, 900; Quapaw, 88½; Sac and Fox, 750; Seminole, 312⅜; Senaca, 81; Shawnee, 21; Wichita, 1,162; Wyandotte, 38½; total area appropriated, 47,039 square miles; unassigned, about 22,000 square miles. White speculators and adventurers have often attempted to enter the Territory and appropriate the lands not included in the reservations, but the Government of the United States, in fulfillment of its treaty stipulations to the Indians, has prevented them. A late movement of this kind was made in 1879, when the President issued his proclamation warning those engaged therein to desist, and informing them that if they should enter the Territory they would be expelled, if necessary, by an armed force. A Bill was lately introduced in Congress to erect the Indian Country into a regular Territory of the United States, thus, opening its unsettled lands to the whites and subjecting the Indians to the very encroachments to avoid which they consented to go upon the reservations. It has been proposed in some quarters to make the Indians citizens, to place them under Territorial Government, and finally to admit them as a State to the Union. But to this plan there are some serious obstacles, not the least of which is the unwillingness of the Indians themselves to sacrifice the autonomy of their respective tribes and the Governments of their own already existing. Though this may ultimately be arrived at, it is not easy to see how the Government of the United States could suddenly force such a change upon them without violating the most solemn treaty obligations. The population of the Territory, exclusive of white residents, is reported to number 74,140. The number of whites legally there is about 12,000, and besides them there are 3,000 others who would be excluded if the law was strictly enforced. Agents representing the United States live among the various tribes, exercising a paternal oversight of their affairs, and protecting them from encroachments. They are appointed by the President with the consent of the Senate, and, under the existing regulations of the Indian Bureau, are nominated by the Religious Denominations which have Missions among the tribes. Each tribe has its own inner government, but the United States Courts have jurisdiction in civil actions where a white man is a party, in cases of crime against a white man, and of violations of the laws regulating trade and intercourse with the Indians. See *Indian Country.*

INDICATOR.—1. An invention of General George W. Wingate, of the New York Militia, for instructing men in aiming the musket. A steel rod, passing through a brass tompion in the muzzle, is projected forwards by the firing-pin. The rod carries a sharp point in the line of the sights, which punctures a miniature target a foot or so in front of the muzzle.

2. In connection with the testing-machine it has been found desirable to have an instrument which would give a continuous curve representing the elongations and corresponding tensile strains for specimens of various kinds, in order to arrive at the exact dynamical value of the metal. An instrument has been devised for this purpose, as represented in Fig 1. It consists of a brass frame, AB, supporting a vertical cylinder, C, revolved by the endless screw, S; this screw being turned by the tape, T, which draws around the pulley, P, as the weight,

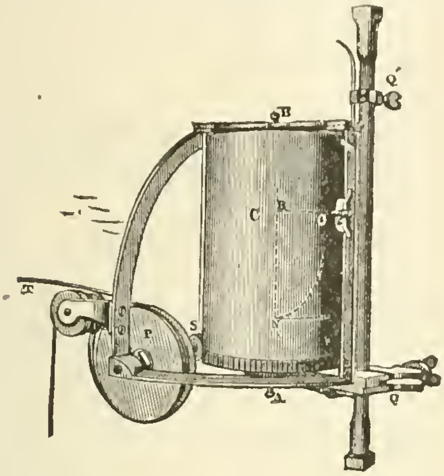

Fig. 1.

W, is wound along the scale-beam. When the chain was used as a weight, the cylinder revolved as the chain was paid into the scale. This arrangement causes the cylinder to revolve as the weight or strain upon the specimen increases or diminishes, and if the marker M, remains stationary, it will describe a horizontal circle upon the paper with which the cylinder is covered. Starting from the zero-point of the scale, the length of any arc of the circle will represent the strain upon the specimen at the instant the marker has arrived at the end of the arc. If now the elongation of a given portion of the specimen carries the marker in a direction parallel to the axis of the cylinder, it is clear that the curve, NO, described upon the paper, will accurately and continuously represent the relation between the elongation of the specimen and the corresponding strain upon it. In order to move the marker in this manner, it is connected with one end of the specimen by the clamp Q', which fits into a center-punch-mark on the specimen, while the frame and cylinder are attached to the other end, Q, of the specimen in a similar manner. The portion of the specimen between the two center-punch-marks is evidently the only portion whose elongation will move the marker along the paper, and the space passed over by the marker divided by the original length of this portion will give the elongation per unit of length of the specimen, or the per cent. of elongation; and the area bounded by the curve, NO, and the co-ordinates, NR and RO, measures the *work* of breaking the specimen.

3. A steam-engine indicator is an instrument used to draw a diagram, showing, upon a reduced scale, the motion of the piston and the pressure acting upon it at each point of its stroke. It consists essentially of a small steam cylinder and a small drum upon which is rolled the paper for taking the diagram. The cylinder is provided with a piston whose motion is resisted by a spiral spring. Steam may be admitted beneath this piston and cause it to rise, or a vacuum created beneath it and cause it to fall, the amount of movement being a measure of the pressure, as in a spring-balance. Motion from the piston is conveyed by a series of levers to a pencil, which is made to press against a slip of paper rolled upon the drum. When the instrument is in use, its cylinder is connected to either end of the large cylinder of the engine, and the drum is made by suitable means to revolve back and forth, having a motion which corresponds to that of the engine piston, only it is on a much reduced scale. Until steam is admitted to the indicator there is no pressure upon its piston, and if the pencil point is then pressed against the paper on the drum, it will, as the latter moves back and forth, trace a straight line, which is the line of atmospheric pressure. When steam is allowed to enter, the indicator piston rises against the resistance of the spring to a height corresponding to the steam pressure, and if this pressure remains unchanged during a stroke, a straight line parallel to the atmospheric line will be traced; when release takes place the piston instantly falls and the pencil moves with it, and when a return stroke of the engine occurs, the pencil will trace a line corresponding to the back pressure against which the engine piston is moving. This gives an idea of the process of tracing a diagram when steam follows full stroke; when a cut-off is used, the pencil traces the same line as before until the cut-off valve closes, when, as the pressures fall, there is traced a curve which gives the pressure at each point of the forward motion according to the law for expansion of steam. The length of a diagram drawn in this way represents on a smaller scale the stroke of the engine, and the line traced by the pencil shows the pressures

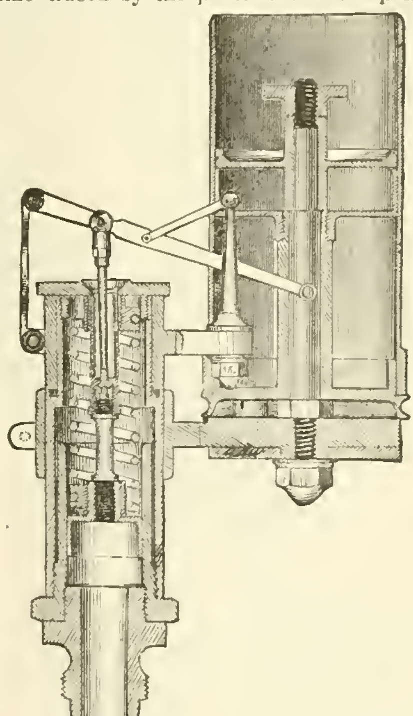

Fig. 2.

acting upon the piston. These pressures are measured by the movement of the spring contained in the indicator, an inch of movement, or an inch of height above the atmospheric line on the diagram, representing so many pounds pressure, according to the spring used; thus a 30 lb. spring would be compressed, so as to give the pencil a movement of one inch for 30 lbs. steam pressure, and a 40 lb. spring, one inch for 40 lbs. pressure, and so on. Having then, a scale, in which one inch is divided into 30 or 40 parts, or any other number of parts such as ordinarily used, we can readily measure any pressure dreetly from the diagram when once we are permitted to know what scale or spring has been employed.

Fig. 3 shows a neat construction of the theoretical expansion curve, which should always be drawn upon the diagram in order to compare it with the actual line traced by the indicator. To make the construction it is necessary to know the clearance space so as to draw the clearance line, B V, from which expansion is reckoned, to draw B C, the line of boiler pressure and also V V', the line of perfect vacuum. Then take any point such as O, on the expansion line of the diagram; this point must not be later than F, the point of release, because here the exhaust line begins; from O draw O P at right angles to B C, and O N at right angles to B V, join V and P and at N, where V P intersects O N, draw N M parallel to B V. Then M is the theoretical point of cut-off. The space M P can be divided into any number of parts which need not be equal, and lines drawn from V to points **a, b, c, etc.**, cut the line M N in points a', b', c', etc. From a and a' are drawn lines parallel to M N and O N respectively and where they intersect is one point of the curve. The same operation for b and b', gives another point and so on. When a little skill is acquired these lines need not be entirely drawn in, but only so much as to show the intersection which determines a point of the curve, and it is thus a very easy and expeditious method for drawing the true curve upon an indicator diagram. Fig. 2, is a sectional view of

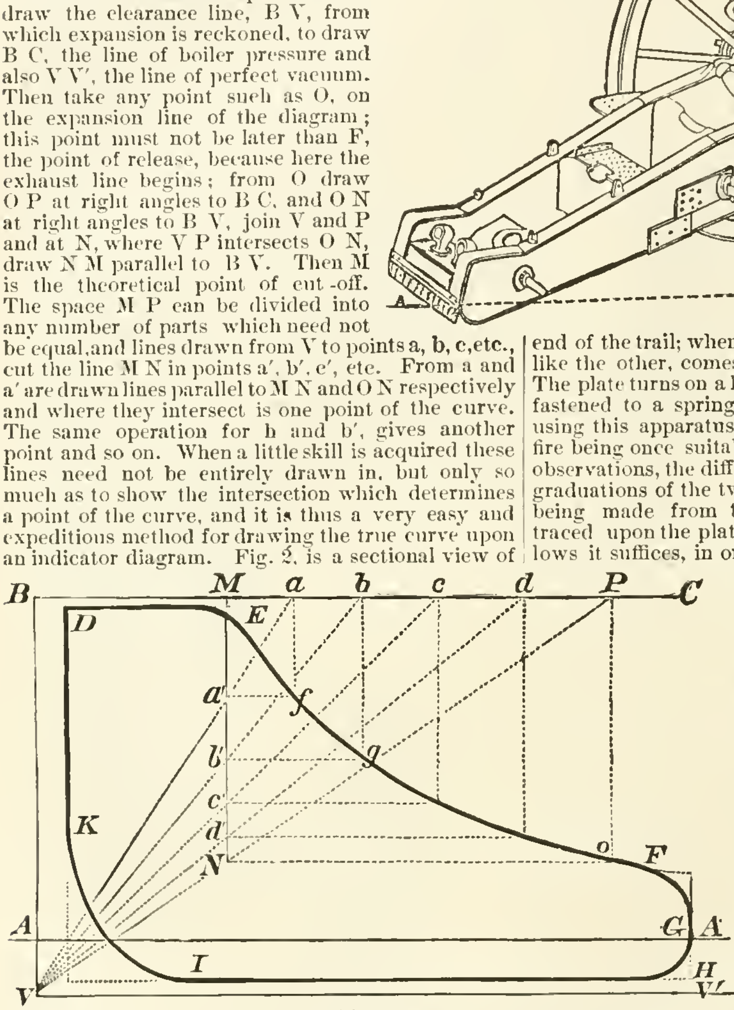

Fig. 3.

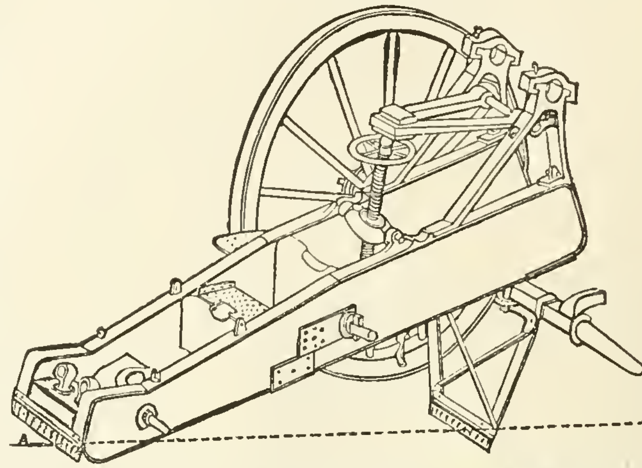
the Thompson Indicator, which is considered as the standard of this country and Europe. See *Planimeter* and *Thompson Indicator*.

INDICATOR RING.—A thin narrow ring of wrought iron, fitted on the breech-screw of a breech-loading gun, with a raised line of brass on it, which shows by its coincidence with a similar line on the top end of the breech-screw whether the vent is properly screwed up.

INDIRECT POINTING APPARATUS.—Varius apparatus for pointing guns indirectly have been employed from time to time. That employed by the Prussians in the sieges of the war of 1870-1871 and represented in the drawing is favorably endorsed by all officers who have employed the method. The apparatus is composed, 1st, of a trapezoidal frame of ron attached to the axle by means of straps; under the lower side, and parallel thereto, is fixed a graduated plate of brass. When the frame is lowered, the graduated plate touches the platform; but when not required for use it is raised up and secured by hooking it to some rings on the under side of the cheeks. 2d. of a plate similar in form and gradnation to the one already mentioned, which is attached to the butt



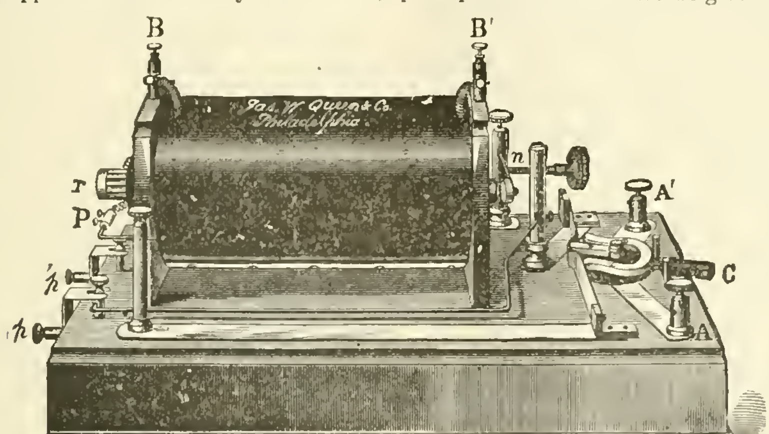
end of the trail; when the latter is lowered, this plate like the other, comes in contact with the platform. The plate turns on a hinge, and may be raised up and fastened to a spring-hook on the rear transom. In using this apparatus it is operated as follows: The fire being once suitably adjusted by means of direct observations, the difference which exists between the graduations of the two plates is noted, the readings being made from the zero to the directrix, AB, traced upon the platform. In all the firing that follows it suffices, in order to point the piece, to read the graduation of the first plate that coincides with the directrix, and then to shift the trail to the right or left until the difference between the graduations of the plates shall be equal to that originally noted. The graduation of the plate is arbitrary. In the Prussian artillery the principal divisions are 40 m. m. apart, and these intervals subdivided into 10 equal parts. These graduated scales permit of maintaining to a great exactness and without renewed pointing, a line of sight once established, which is of the greatest importance in firing at an object concealed from the view; they also permit of varying, laterally, the point of fall for distances, by displacing horizontally the point of departure of the line of sight, an operation required in breeching masonry, for making the horizontal cut. This method of pointing was employed by the Prussians with great success at the siege of Strasbourg, in batteries without embrasures, for breeching walls of masonry by a plunging fire.

INDORSED.—A term applied in Heraldry to two animals placed back to back. Two keys, two wings, etc., may also be indorsed, and a pelican is always drawn with his wings indorsed. The terms *Addorsed* and *Indorsed* have the same application.

INDUCTION OF ELECTRIC CURRENTS.—The discovery of the power of electric currents to induce currents in neighboring conducting circuits is due to Faraday. His researches on the subject, named by him *volta-electric* induction, were published in the Philosophical Transactions (1831-32). Henry (1832) observed that when contact was broken in a long galvanic circuit a bright spark occurred, which did not occur when the circuit was short. This was shown by Faraday (1834) to be due to the extra current induced by the various parts of the circuit in each other. Bachhoffnor and Sturgeon (1837) showed the superior action, in induction apparatus, of a bundle of iron wires to that of a solid bar of iron. Henry (1841) studied the indicative action of induced currents of different orders. De la Rive designed, in 1843, an electro-chemical condenser, consisting of a primary coil, which, by means of the extra current, could enable a single galvanic cell to decompose water. The same decomposition, however, had been effected by Wright in 1840. Ruhmkorff constructed (1850 or 1851) the first so-called *induction coil*, the excellence of which was chiefly attained by the proper insulation of the secondary coil. Fizeau (1853) increased immensely the power of the coil, by providing it with a condenser. Of late years coils of great power have been constructed, rivaling, if not exceeding the most powerful electric machines in length and power of spark.

The Fundamental law of current induction may be thus shown: Two long copper wires are fixed so as to be parallel and close to each other. The extremities of the one are in connection with the poles of a galvanic battery, and those of the other, with the binding-screws of a galvanometer. The instant the circuit of the battery is completed, and the current sent along one wire, a current in the opposite direction is induced in the other wire, which is shown by the deflection of the needle of the galvanometer. This induced current is only momentary, for though the current continues to circulate in the first wire, the needle soon falls back to its original position of rest, and the wire then gives free passage to other currents, and appears to be in no way affected. If, however, as the primary wire remains in any one position, all evidence of electricity in the secondary wire disappears; but if in this position the strength of the primary current should be increased or diminished, momentary currents in the secondary wire would again mark the changes in the primary, the increase causing an inverse, and the decrease a direct current. Hence we conclude, that *a current which begins, a current which approaches, or a current which increases in strength, induces an inverse momentary current in a neighboring conducting circuit*, and that *a current which stops, a current which retires, or a current which decreases in strength, induces a direct momentary current in a neighboring circuit.* For inverse, the word *negative*, and for direct, the word *positive*, are frequently employed in reference to induced currents.

In experiments like the above, it is much more convenient to wind the primary and secondary wires side by side round a bobbin, so as to form a coil. The wires are insulated from each other by a covering of wool or silk. Not only does such a disposition admit of very long wires being used, but it also disposes the wires employed to greater advantage, for each single turn of the primary wire acts not only on the corresponding turn of the secondary wire but on all the turns near it. The inductive effect of such a coil is much greater than that which would be obtained by the same extent of wires running side by side in a straight or crooked line. It is not even necessary that the two wires be wound round together, each may be wound on a separate bobbin, and the one placed inside the other. The primary coil is made of wire one-twelfth of an inch in diameter, covered with wool; and the secondary coil of silk-covered wire, one-eighteenth of an inch, much longer than the primary wire. With two such coils, many principles of induction can be given.



now, when the needle is at rest, the battery circuit be broken, and the current stopped, another momentary current is indicated by the galvanometer needle but in this case in the same direction as the inducing current. The inducing wire and current are called *primary*, and so are distinguished from the induced wire and current, which are termed *secondary*. The passive condition of the wire while thus under induction has been described by Faraday as electrotonic. An electric throb, so to speak, makes the setting in of this state, and another its vanishing; the former in the opposite direction to that of the inducing current, and the latter in the same direction. If the primary wire be movable, so that it can be suddenly brought near to, and withdrawn from the secondary, while the battery current passes steadily, currents are induced as in the former case, the approach of the wire being marked by an inverse current, and its withdrawal by a direct one. As long,

Let us place the primary coil within the secondary; let the primary, along with the self-acting rheotom, be put in the circuit of a galvanic cell, and let the secondary coil be connected with a galvanometer. The interruption in the primary current being effected by the rheotom with great rapidity, the induced inverse and direct currents are sent out with corresponding rapidity through the coil of the galvanometer. If this last be of a short and thick wire, so as not to tax the tension of the current transmitted, the induced currents will not deflect the needle; or if they should happen, through the unsteady action of the break, to do so, it only oscillates round its position of rest. This proves that *the quantity of electricity transmitted by the induced inverse and direct currents is the same*, for they each exert the same influence on the needles. But if the coil of the galvanometer consist of a long fine wire, the needle is kept deviated in a direction which argues the action of the direct current. This leads us to conclude that *both currents, though equal in quantity, are unequal in tension, the direct current having the highest tension*, for it has more power to force its way through the fine wire of the galvanometer than the inverse, Other proofs of the same principles may be easily furnished. The difference of the tension of the two induced currents, is accounted for in this way: when a change takes place in the primary current, the quantity of the electricity induced by it in the secondary wire is the same whether this change takes place quickly or slowly; the tension, however, is very different. When the change takes place slowly the total quantity of electricity in circulation continues to pass as slowly, and there is little in motion at one time; but when the same occurs quickly, it is sent with momentum, so to speak, and the quantity in circualtion at one time is as much greater, in comparison with the former case, as the time is shorter. It is this quick dispatch of electricity which constitutes the tension of the current. Now, as it takes some time before the primary current is fully established, the inverse induced current is slow and of low tension; but when the contact is broken, the primary current ceases much more suddenly than it began, and the direct induced current is quick and of high tension. This view of the matter is borne out by experiment, for it is found, that *whatever favors the suddenness of the changes of the primary current, heightens the tension of the currents induced by these changes*. The break, from this circumstance, forms an important element in the construction of all induction apparatus. The inductive power of the primary coil is immensely increased by placing a bundle of soft iron rods or wires in the center of it. The magnetism which begins and ceases in these at each passage of the current acts in conjunction with the inducing force of the coil. The center of the bobbin is hollow, to receive a bundle of this kind. The greater part of the inductive action is due to the iron core, and the induced currents got with and without it are not to be compared in point of energy. A solid bar of soft iron may also be used, but with much less advantage, for the induced currents which linger in it after the stoppage of the main current acting themselves inductively, impair the suddenness with which the current disappears from the primary wire and magnetism from the core. The thin layer of oxide which forms on the rods insulates them sufficiently from one another, and prevents the formation of such currents. It is partly for the same reason that metal tubes cannot be used for bobbins for either primary or secondary coils. If such were used, *closed circuits* would be formed in them, the reaction of which, however, would prolong the changes of the primary inducers and consequently impair the tension of the secondary current. Metal bobbins would not be open to this objection if they had a longitudinal slit, which would make the tranverse section a broken ring and circuit. The excitation of magnetism in the core is the principal aim of the primary coil, and as a strong current is essential to that object, it is made of thick wire and of moderate length. In the secondary coil, the tension of the induced current alone is aimed at, and with this view it is made of as thin wire as can be made, so as to admit of as many turns as posssible being brought within the influence of the core and primary coil. The electric conformation of the secondary coil is sometimes looked upon in the same light of that of a galvanic battery. The total electromotive force of the coil is the sum of that of all the turns in it, in the same way that the electro-motive force of the battery is proportionate to the number of cells.

Not only does a galvanic current induce electricity in a neighboring circuit, but it also acts inductively on itself. When contact is broken in a battery circuit, the galvanic spark is seen. When the wire is short, the spark is feeble, but it increases in brilliancy with the length of the circuit, and this becomes particularly observable, when the wire is wound round in a coil. This certainly does not arise from the current being strong with the long wire, and weak with the short one, for quite the reverse is the case, as might be shown with the aid of a galvanometer. The real cause of superior brilliancy of the galvanic spark with the long circuit is to be found in the induction of the primary current on the various parts of itself, exciting, as they are called, *extra currents* in the primary wire. It has been fully attested by experiment, that at the instant *a galvanic current begins and ends, extra currents are induced by the action of the several parts of its circuit upon each other, that at the beginning of the current being inverse, and that at the end direct*. As the extra current inverse acts opposite to the main current, it does not appear as a separate current but only retards the instantaneous passage of the main current. The extra current direct succeeds the main current, and has consequently a separate existence. It is what is generally referred to when the extra current is spoken of. This extra current is of much higher tension than the original current. The effect of the extra current on the direct induced current of the secondary coil is to lessen very decidedly its tension. If a way be made for the extra current, the tension of the induced current falls prodigiously. In a large coil-machine, which gives freely sparks of 1 or 2 in. in length, when the two portions of the break are joined by a thin wire, so as to allow the extra current to pass, sparks will not travel between the two poles, however near they are brought. When no such communication exists, a portion of the extra current leaps over between the separating parts of the break, and in so far diminishes the intensity of the secondary current. The condenser of the coil-machine, to be afterwards described, has for its object the absorption or suppression of the extra current, but the manner in which it effects this is not yet properly explained. The prejudicial effect of the extra current on the induced current is easily understood, when we bear in mind that it prolongs the cessation of the magnetism of the core and of the current in the primary coil, and thus imparing the suddenness of this change, reduces the tension of the induced current.

The essential parts of the induction coil have been already described in detail. A primary coil with its core of iron wire, and a secondary coil exterior to and insulated from a primary coil, form the main portion of the instrument. The primary coil is connected with the poles of a galvanic battery, and in the circuit a rheotom is introduced, to effect the interruptions of the current essential to its inductive action. The only parts not yet referred to are the condenser and the commutator. The condenser consists of several sheets of tinfoil and oiled silk, laid alternately the one above the other. The first, third, fifth, etc., sheets of tinfoil are connected by strips of the same material; so are the second, fourth, sixth, etc.; the whole forming a condensing apparatus like a Leyden jar, the odd sheets forming the one coating, and the even sheets the other. Each set of sheets is connected with one of the wires of the primary coil. The condenser is generally placed in the sole of the instrument, and does not meet the eye. The commutator consists of an ivory cylinder covered with conducting plates on two sides, and is so constructed that it can break contact, or transmit the current through the coil in either direction.

The drawing represents Queen's dissected Ruhmkorff coil, which is mostly adopted for the operations of mines, torpedoes, etc. A, A′, are binding posts, to connect with the battery; C is the Bertin commutator used in reversing the current; at P, the battery current enters the primary coil; this latter can be removed, as also can the core, r; at n, the battery current is automatically broken. The brass plates, p, p′, connect the condenser with the primary circuit; the condenser is contained in a sliding drawer, which can be very easily removed. B, B' are the terminals of the secondary coil. A copper conducting wire, which is insulated by one or two coats of gutta-percha, connects the charges with the galvanic apparatus. The charge is exploded by passing a spark through a very small portion of fulminate of mercury inserted between the ends of two copper wires, which are enclosed within a short tube of gutta-percha, coated within with sulphuret of copper. The wires are bent near the end of the tube and twisted around each other. A little meal powder is thrown around the fulminate and the tube, which, with the tube and the bent part of the wire, is tightly closed in a small gutta-percha bag, to keep out moisture. To fire a single mine, one end of the twist is soldered to the conducting wire and the other inserted into the earth to complete the circle. For several mines to be exploded at the same time, conducting wires connect the mines, and the ends of the twist are soldered one to each conductor, except the end one, which has one of its ends inserted into the earth. By this combination the series will be exploded without any sensible difference of time between the nearest and furthest mine. See *Galvanism*.

INERTIA.—A term expressive of that indifference to a state of rest or motion which is a universal property of matter, and may be expressed by saying *that a body in motion will continue in motion, and a body at rest will remain at rest, unless acted upon by some external force*. The latter part of this principle was known to the Ancients, and by them attributed to a certain repugnance to motion, which was a characteristic of all matter; but it was shown by Galileo that the former part was equally true and general. This property of matter has been called by Kepler *vis inertiæ*.

INESCUTCHEON.-In Heraldry, a single shield borne as a charge. When there are two or more, they are simply called escutcheons, for an inescutcheon, it is said, must always occupy the fess point of the shield. An inescutcheon is to be distinguished from an escutcheon of pretense, which is not a charge, but a separate coat. See *Heraldry*.

INFAMED.—In Heraldry, an epithet applied to a lion or other animal which has lost its tail, the loss being supposed to disgrace or defame it. *Defamed looking backwards* occurs in ancient blazon for counter-rampant regardant, the lion being supposed to be flying from an enemy . Often written *Defamed*.

INFAMOUS BEHAVIOR.—Disgrace with infamy and infamous behavior are terms in use in the military and naval codes to designate conduct (and penalty) which is not only opposed to discipline, but also disgraceful in a social sense. As infamous behavior, have been always classed in all countries desertion of colors on the field of battle, failure to attempt to succor comrades in danger, cold-blooded cruelty, and other crimes which are greatly subversive of morality. If a man is found guilty of any of these crimes by a Court-Martial, and not sentenced to death, the sentence is ordinarily discharge—or dismissal—with ignominy or infamy. So severe an enactment greatly adds to the force of the penalty, and stigmatizes the offender for life as a disgrace to his country and his cloth.

INFANTRY.—The term infantry was originally applied to a body of men collected by the *Infante* of Spain, for the purpose of rescuing his father from the Moors. The attempt being successful, the term was afterwards applied to foot-soldiers in general, as opposed to cavalry. Among the ancient nations of Europe the foot-soldiers constituted the chief strength of the armies. In the best days of the Grecian and Roman States, battles were won mainly by the force and discipline of the phalanges and legions, and the number of the infantry in the field far exceeded that of the cavalry. The cavalry were then, as at present employed chiefly in protecting the wings of the army and in completing a victory gained by the infantry. The ancient Franks, when they left the forests of Germany, were accustomed to march and fight on foot; and they persevered in this practice even after they had obtained possession of the country of the Gauls, which abounded with horses. But soon after the time of Charlemagne Institutions of Chivalry began to be generally adopted in the kingdoms of Europe. These led to frequent exhibitions of martial exercises on horseback in presence of the Sovereigns and assembled Nobles; and the interest inspired by the achievements of the Knights on those occasions was naturally followed by a high regard for that order of men. By degrees the cavalry, which was composed of persons possessing rank and property, and completely armed, acquired the reputation of being the principal arm; while the foot-soldiers, badly armed and disciplined, were held in comparatively small estimation. This continued 400 years, and although war was the principal occupation of mankind, military science fell into neglect. But Rulers were forced by the power of feudalism to make an alliance with the despised class of foot-soldiers, and in 1214 we find that some of the German infantry was recognized to be "very good, and trained to fight on the level even against cavalry." The cavalry of France was routed at Courtrai by the infantry during the next century, and the Austrians suffered defeat by the efficient work of the Swiss pike at Morgarten (1315), Sempach (1386), and Nafels (1388). At Cressy and Poictiers (1346–1356) the Knights of England dismounted to fight beside the successful infantry. The principal weapons of the infantry before the invention of gunpowder were long-bows, halberds, cross-bows, spiked clubs, axes, pikes, staight-swords, shields, corselets, mail-jackets, helmets and partisans. In the 16th century, however, these weapons were replaced by fire-arms, and in the 18th century, the musket was in general use. It became customary during the Thirty Years' War to form battalions of infantry composed of 500 men, which were massed into dense columns during battle in spite of the deadly effect of the enemy's artillery and fire-arms. The absurdity of this formation was first exposed by Gustav Adolph, who recognizing the destructiveness of fire-arms, arranged his battalions with a view to increasing the effectiveness of the fire of his troops, while avoiding exposure to that from the enemy. His tactics were so successful at Breitenfeld and Lutzen (1631-32) that they were soon afterwards universally adopted. The bayonet came into use in 1670, and the socket-bayonet about 1699. Fredrick the Great made many improvements till then comparatively unknown. The rapidity with which his infantry troops performed their evolutions during battle contributed largely toward his famous victories in the Seven Years' War. In fact the Prussian infantry have ever since his time served as models for other European countries. The superiority of this arm consists in the troops being able to act on ground where cavalry cannot, and it is obvious that the latter must be nearly useless in the attack of fortified towns. During the War of the Rebellion in this country skirmishing was in vogue in the northern and southern armies. It had been in use during the Revolutionary War, and was well suited to the American character. Skirmishing has since been adopted in Prussia, and the skirmish line is recognized as the proper formation in battle to avoid the destructive effect of the breech-loaders. The co-operation, however, of cavalry and infantry troops was neglected by American Generals. Artillery fire usually opened the battle, and was followed by the advance of the whole line on the run in a final charge. The Infantry Tactics in general use were those of Casey, founded on those of Scott. Casey's Tactics, however, were abandoned for those of Hardee, and in 1867 those of Upton were finally adopted.

INFANTRY COLORS.—In the United States, each Regiment of Infantry has two silken Colors. The first, or the National Color, of stars and stripes, as described for the garrison flag; the number and name of the regiment is embroidered with silver on the center stripe. The second, or Regimental Color, is blue, with the arms of the United States embroidered in silk on the center. The name of the regiment in a scroll, underneath the eagle. The size of each Color is six feet six inches fly, and six feet deep on the pike. The length of the pike, including the spear and ferrule is nine feet ten inches. The fringe, yellow; cords and tassels, blue and white silk intermixed. See *Colors*.

INFERIOR.—A term signifying, in a military sense, junior in rank. Inferior officers are those of the lower ranks or grades.

INFERNAL MACHINE.—A term applied to various deadly contrivances; for instance, to the battery-gun with which the attempt to assassinate Louis Philippe was made, and the devices used on similar historical occasions. A noted *infernal machine* was the fire-ship used by the English at St. Malo. This was a three-decker charged with powder on the first deck; shells, carcasses, etc., on the second; and with barrels filled with combustibles on the third; the gun deck was covered with old guns overloaded. It was intended to destroy ships, bridges, etc.

INFLAMMATION.—When grains of powder are united to form a charge, and fire is communicated to one of them, the heated and expansive gases evolved insinuate themselves into the interstices of the charge, envelop the grains, and ignite them one after another. This propagation of ignition is called *inflammation*, and its velocity, *the velocity of inflammation*. It is much greater than that of combustion, and it should not be confounded with it. When powder is burned in an open train, fine powder inflames more rapidly than coarse; such, however, is not the case in fire-arms, owing to the diminution of the interstices. If a charge were composed of mealed powder, the flame could no longer find its way through the interstices, and the velocity of inflammation and combustion would become the same. Now supposing one grain or particle alone be ignited, it will first be inflamed over its whole surface, and the progressive combustion will take place from the exterior to the interior. Its *rate of combustion* will therefore depend upon both its shape and size, leaving out entirely, for the present, the question of density and hardness. A particle of spherical or cubical form will expose less surface to ignition in proportion to its volume than one of an elongated or flat shape, and will consequently require a longer period for the combustion of its entire mass; the larger the particle, also, the longer will be the time required for its combustion. Looking, then, at one grain of powder by itself, we may say that the larger it is, and the more nearly its form approaches a sphere, the longer will its combustion take, and the slower will be the evolution of the gas. When, however, we come to regard the action of an aggregation of such particles, as in the charge of a gun, the *rate of ignition* of the whole charge is also affected by the size and shape of the grain. The part of the charge first ignited is that near the vent, and the remainder is inflamed by contact with the heated gas generated by the combustion of this portion, so that the rate of ignition of the whole mass will be regulated by the greater or less facility with which the gas can penetrate throughout the charge, which is itself dependent upon the shape and size of the interstices between the grains. If the grains be spherical and regular in form, the interstices will be comparatively large and uniform, and the gas will penetrate the mass with facility; again, the larger the grains, the larger the interstices between them. If, on the other hand, they be flat or flaky and irregular in shape, the passage of the gas will be more difficult, and the rate of inflammation of the charge reduced. We see, therefore, that the considerations which affect the more or less rapid combustion of an individual grain of gunpowder, also affect the rate of ignition of a charge of such grains, but in an opposite direction; so that a form of grain which will individually burn rapidly may offer an increased resistance to the passage of the heated gas through the charge, and thereby retard its ignition, while a grain which will burn more slowly may allow of the charge being more rapidly ignited. By varying the size and shape of the grain alone, a powder may therefore be obtained, a charge of which shall be ignited rapidly throughout, but burn comparatively slowly, or one which shall be ignited more slowly, but when once inflamed burn very rapidly. It is necessary to draw a clear distinction between a rapidly igniting and a quickly burning powder. The heat developed increases with the charge, and as the velocity of the gases increases with their temperature, it is therefore evident that a large charge is consumed quicker than a small one; it is also true that the loss of heat absorbed by the surface of the bore is much less sensible when the charge is great than when it is small; that is, the quantity absorbed is proportional to the surface or the square of the caliber of the gun and the heat developed increases as the cube of the caliber. With proper data we can readily determine the density of the gaseous products at any particular moment of combustion. For this purpose, take the case in which the inflammation of the whole charge is considered instantaneous, and let P be the weight of the charge; d' the density of the composition of which the powder is made; V the space in which the gases expand; t' the time of combustion of a single grain; t the time since the combustion began; d the density of the gases at a given instant.

The weight of powder remaining after a time, t, will be equal to $P\left(1-\frac{t}{t'}\right)^3$, and the volume will be equal to $\frac{P}{d'}\left(1-\frac{t}{t'}\right)^3$; the weight of gaseous products evolved will be equal to

$$P\left(1-\left(1-\frac{t}{t'}\right)^3\right)$$

; and their density will be equal to this quantity divided by the space, V, diminished by the space occupied by the powder unburnt at the end of the time, t.

Or,

$$d=\frac{P\left(1-\left(1-\frac{t}{t'}\right)^3\right)}{V-\frac{P}{d'}\left(1-\frac{t}{t'}\right)^3}.$$

Let K, represent the ratio of the weight of powder which would fill the space V, to the weight of the charge P, and D, the gravimetric density, or weight of a unit of volume of powder, we shall have the equation,

$$\frac{DV}{P}=K, \text{ or } \frac{V}{P}=\frac{K}{D};$$

and the formula for the density of the gaseous products becomes,

$$d=\frac{1-\left(1-\frac{t}{t'}\right)^3}{\frac{K}{D}-\frac{1}{d'}\left(1-\frac{t}{t'}\right)}=D\frac{1-\left(1-\frac{t}{t'}\right)^3}{\left(1-\frac{t}{t'}\right)^3\frac{D}{d'}}.$$

If the charge fills the entire space V, $K=1$, and

$$d = D\frac{1-\left(1-\frac{t}{t'}\right)^3}{1-\left(1-\frac{t}{t'}\right)^3\frac{D}{d'}}.$$

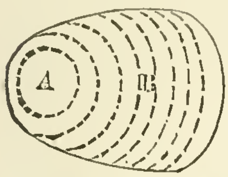
When the grains are sumed, $t=t'$, and $d=\frac{D}{K}$; and if $K=1$, $d=D$.

Having determined the mean density of the gaseous products at any instant of the combustion, we can determine the pressure exerted on the enclosing surfaces by means of Rumford's formula

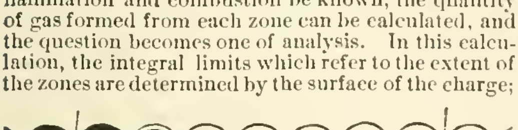
$$P=1.841\ (905d)^{1+0.362}.$$

This value of P supposes that the entire charge is inflamed at the same time—a supposition that is not strictly correct, except for small and lightly-rammed charges. When the charge is large, and well-rammed, as in cannon, it is necessary to take into consideration the time of inflammation.

In a majority of cases the preceding formulas will give the relation between the density and expansive force of gunpowder, without sensible error; but when the grains are small, and the charge is compressed by ramming, the interstices are diminished in size, and the inflammation is comparatively less rapid; besides, the size and form of the charge exert an influence which increases with its length. It is proposed to modify the formulas, and adapt them to the most general case, by considering the inflammation progressive. Take a charge of powder, of any form whatever, and consider it ignited at the point, A, the inflammation will reach the surface of the concentric zone, B, the radius of which is tv, in the time t, v being the velocity of inflammation. There will be portions of the charge situated within this zone which the flame will not have reached; others in which the combustion is completed; and others, between these two, in which the inflammation is completed, but the combustion is only partially completed, as represented.



The extent of the inflamed zones being determined by the form and dimensions of the charge, exerts a great influence on the development of the gases, and consequently on their density. If the velocities of inflammation and combustion be known, the quantity of gas formed from each zone can be calculated, and the question becomes one of analysis. In this calculation, the integral limits which refer to the extent of the zones are determined by the surface of the charge;



and those which refer to the progress of the combustion of the grains will be the point of ignition and the surface of inflammation; or, if ϕ be the time necessary for the flame to reach the surface of the zone, the radius of which is x, the time of partial combustion of a grain of this zone will be $t-\phi$, and its complete combustion is expressed by the relation $t=t'+\phi$.

For this zone the density of the gaseous products at the instant of inflammation will be $d=0$, as when completely consumed $d=D$.

The intermediate values maybe determined by formula (1)

$$d = \frac{D\left(1-\left(1-\frac{t}{t'}\right)^3\right)}{K-\left(1-\frac{t}{t'}\right)^3\frac{D}{d'}};$$

by substituting $t-\phi$ for t, and supposing $K=1$, should the charge completely fill the space in which it is burned. Integrating between the determined limits, we obtain the mean density of the gases developed. The solution of this question, in a general sense, is very difficult, and requires the aid of the differential calculus. There are particular cases, however, where the solution is not difficult; for instance, where the charge is of cylindrical form and is placed at the bottom of the bore of a gun. See *Explosion* and *Gunpowder*.

INFORMANT.—In case a civil person is the complainant, he becomes the principal witness before a Court-Martial, and after giving his evidence may remain in Court, in order that the Judge-Advocate may refer to him.

INFORMERS.—In the British service, soldiers who gave information of false musters, or of pay illegally detained; and were, for said services, entitled to their discharge.

INGAUNI.—A tribe dwelling on the mountains and seacost of Genoa in the first and second centuries B.C. They were very active in the wars between the Romans and Ligurians, and were Allies of the Carthaginians in the second Punic War. They were regarded as a distinct tribe in the time of Pliny and Strabo, but after the battle with Emilius Paulus, 181 B. C., in which they lost 15,000 men, very little was heard of them. The town Albenga, then called Albium Ingaurium, was their Capital.

INITIAL TENSION.—The system of *initial tension* consists in making a gun of concentric tubes, by putting on each successive layer, proceeding outward from the center, with an initial tension exceeding that of those below it; in other words, so that each hoop shall compress the one within it. The inner layer is thus in compression while the outer layer is in the highest tension. The inner layer is able to sustain the first and greatest stretch, and the outer layer, although stretched less by the explosion of the powder, has already been stretched into high tension, and thus has to do an equal amount of work. The intermediate layers bear the same relation to the initial strain, and to the strain of the powder, so that, in short, all the layers contribute equally of their tensile strength to resist the strain of the explosion. Each hoop, or tube, has this element of weakness, that its inner circumference is more stretched than its outer one. Absolute perfection would necessitate infinitely thin hoops, and, practically, the thinner the layers the greater will be the strength, provided the mechanical difficulties in construction, and more especially in applying, a great number of thin strata with the proper tension do not outweigh the advantages. The two principal methods of applying the system are by *shrinking* on, or by *forcing* on, the hoops. If the hoops are put on by shrinking, two embarrassments arise: *First*. The hoop must be accurately bored, and after each layer has been put on, the gun must be put in a lathe and the outside turned. Great accuracy of labor is required—labor of the most expensive class. *Secondly*. The process of shrinking on is not to be depended upon; nowhere is there a difficulty in insuring the exact temperature required, but scarcely any two pieces of iron will shrink identically. The fitting of hoops with nice adjustment would be difficult, theoretically; practically, it would not be done. But the chief embarrassment is the uneoual effect of heat.

In the first place, heating the layers over a fire to expand them subjects one part to more heat than another; the temperature of the surface and interior are unequal, thus causing irregular strains. This may be remedied by boiling the hoops in oil, which would toughen as well as expand the hoops. In the second place, the hoops are often heated to redness, when oxidation takes place. The internal diameter of the hoop is increased, and scale is left between some parts and not between others. In the third place, cast-iron and steel sensibly and permanently enlarge in proportion to the amount of carbon they contain when subjected to the heat.

Whitworth and Blakely advocate the method of forcing the hoops on with hydrostatic pressure. The forcing of a slightly conical ring over a correspondingly conical tube obviates the necessity of great accuracy in the diameter of either pieces. The truth of the cone depends upon the correctness of the lathe. The truth of the surfaces is also a question of good tools. The tension of the ring depends on the distance to which it is forced in the conical tube, and this may be regulated by the safety-valve of the hydrostatic-press. With special tools, and when correctness depends upon the mechanical appliances, which can be adjusted with the utmost nicety, an inexpert workman could hardly fail to do well. See *Built-up Guns*, *Cannon*, *Ordnance*, and *Varying Elasticity*.

INITIAL VELOCITY.—In gunnery, the speed with which the ball leaves the muzzle of the gun. This was formerly calculated from the momentum as shown by the Ballistic Pendulum. A very great improvement of late years is the Electro-ballistic Pendulum, the invention of a Major Navez of the Belgian service, which actually measures the interval of time during which the shot traverses a short space of ground. The apparatus consists of a steel pendulum falling at the side of a graduated sector of a circle. Behind the segment is a piece of iron capable of being magnetised by a galvanic battery adjoining. The wires for completing the circuit between the battery and the magnet are so arranged that they are in connection with two targets of paper or other thin material in the line of the projectile's fire. So long as the circuit is complete, and before the experiment, the magnet holds the pendulum at its highest point. When the shot pierces the first target, the circuit is broken, iron demagnetised, and the pendulum released; these effects being absolutely simultaneous. With equal simultaneity, the piercing the second target re-establishes the circuit, magnetises the iron, and arrests the pendulum in its descent. The distance between the targets is known, and the accumulating resistance of the atmosphere within that time; the sector being finely graduated, the distance traversed by the pendulum shows exactly the fraction of a second occupied, and from these data the initial velocity is a matter of simple computation. Of an ordinary smooth-bore cannon, the initial velocity is near to 1600 feet per second. See *Ballistic Pendulum*, *Chronoscope*, *Gun-pendulum*, and *Velocity*.

INITAL VELOCITY OF ROTATION.—Let V be the initial velocity of the projectile, or space which it would pass over in one second, in the direction of flight, moving with the velocity with which it leaves the piece, and l the distance passed over by the projectile in making one revolution; then $\frac{V}{l}$ will be the number of revolutions in one second, and $2\pi\frac{V}{l}$ the *angular velocity* of the projectile at the muzzle. The velocity of rotation of a point on the surface is given by the expression,

$$rw=2\pi r\frac{V}{l},$$

in which r is its distance from the axis of motion, and w is the angular velocity. See *Grooves*, *Rotation*, and *Velocity of Rotation*.

INITIATIVE.—In offensive warfare, to take the *initiative* is the power of compelling your adversary to make his movements dependent on your own, the result of which is to give the invader of a territory great advantage. It is also explained as the success obtained by the invader of a territory, suitable for military movements, and defended only by an army, not by fortifications; not only is the advantage in his first onset, but in subsequent engagements, thus disconcerting and to some extent crippling his adversary so as to frustrate or deprive him of the power of carrying out offensive measures.

INJURIES.—In the exercise of professional duty by military officers, injuries may frequently be occasioned to other officers, or to private individuals, whose legal remedies are here considered. As between officers themselves, the language of the Articles of War is sufficiently comprehensive to bring most of such cases within the cognizance of a Court-Martial; but a Court-Martial has no power to award pecuniary damages for injurious conduct. Its jurisdiction is criminal, and its judgments are penal. It may happen, too, that the common feeling of the service, to which the offending or the complaining party belongs, would in many cases render an application to such a tribunal utterly fruitless; as the general sentiment of the members of a particular profession or class of society, respecting a matter of professional or corporate right or conduct, is often found to be at variance with the public law of the land. Civil actions are therefore maintainable against commissioned officers, for exceeding their powers, or for exercising them in an oppressive, injurious, and improper manner, whether towards military persons or others. Extreme difficulties, however, lie in the way of plaintiffs in actions of this nature, for no such action is maintainable for an injury, unless it be accompanied by malice or injustice: and the knowledge of this, while it can never check the conduct of good men, may form a check on the bad. Where an officer makes a slip in form, great latitude ought to be allowed; but for a corrupt abuse of authority none can be made. It will be convenient to consider the law upon this subject; 1st, as it applies to wrongs committed by officers towards persons under military authority; and, 2dly, as it applies to persons not subject to such authority. Some of the decisions that will be quoted were pronounced in cases where naval officers were concerned; but the principle of the decisions applies equally to both services. I. *Wrongs towards Persons under Military Authority.*—A notion appears to have at one time extensively prevailed that an officer could have no remedy against ill treatment received from his superiors in the course of professional duty, except by bringing the offending party to a Court-Martial, and subjecting him to the penalties of the Articles of War. This opinion, however, was quite unfounded in point of law; and such a state of things might often be productive of the worst consequences. The point was distinctly raised in Grant *v.* Shand, where an action was brought by an officer in the army against his superior officer for oppressive, insulting, and violent conduct. The plaintiff was directed to give a military order: and it appeared that he sent two persons, who failed. The defendant thereupon said to the plaintiff, "What a stupid person you are," and twice struck him; and although the circumstances occurred at Gibraltar, and in the actual execution of military service, it was held at the trial that the action was maintainable; and a verdict was found for the plaintiff. An application was afterwards made to the Court of King's Bench to set aside the verdict; and Lord Mansfield, the Chief-Justice, was very desirous to grant a new trial; but the Court, after argument, refused to disturb the verdict. So also an action will lie for unjust treatment under the form of discipline, as in Swinton *v.* Molloy, where the defendant, who was Captain of the *Trident* man-of-war, put the Purser into confinement, kept him imprisoned for three days without inquiring into the case, and then released him on hearing his defence. The Purser brought his action against Captain Molloy, for all his unlawful detention in custody; and, upon the evidence, Lord Mansfield said, that such conduct on the part of the Captain did not appear to have been a discharge of his duty, and therefore that his justification under the discipline of the navy had failed him. The jury gave £1,000 damages. In the foregoing case no want of uprightness was attributed to Captain Molloy; and the decision rested wholly on the circumstance of his having committed an injustice, although without a corrupt intention. Cruelty or unnecessary severity, when wilfully committed in the exercise of superior authority, are also good causes of action. Thus in Wall *v.* Macnamara, the action was brought by the plaintiff, as Captain in the African Corps, against the defendant, Lieutenant Governor and Military Commandant of Senegambia, for imprisoning the plaintiff for the space of nine months at Gambia, in Africa. The defense was a justification of the imprisonment under the Mutiny Act, for the disobedience of orders. At the trial it appeared that the imprisonment of Captain Wall, which was at first legal, namely, for leaving his post without leave from his Superior Officer, though in a bad state of health, was aggravated with many circumstances of cruelty, which were adverted to by Lord Mansfield, in the following extract from his charge to the jury: "It is admitted that the plaintiff was to blame in leaving his post. But there was no enemy, no mutiny, no danger. His health was declining, and he trusted to the benevolence of the defendant to consider the circumstances under which he acted. But supposing it to have been the defendant's duty to call the plaintiff to a military account for his misconduct, what apology is there for denying him the use of the common air in a sultry climate, and shutting him up in a gloomy prison, when there was no possibility of bringing him to a trial for several months, there not being a sufficient number of officers to form a Court-Martial? These circumstances, independent of the direct evidence of malice, as sworn to by one of the witnesses, are sufficient for you to presume a bad, malignant motive in the defendant, which would destroy his justification, had it even been within the powers delegated to the defendant by his commission. The jury thereupon, after deliberation, found a verdict for Captain Wall, with £1,000 damages. An undue assumption of authority in matter not within the range of military discipline, is also a good ground of action against a Superior Officer. This appears from the case of Warden *v.* Bailey, where the plaintiff was a permanent Sergeant in the Bedford regiment of local militia, of which the defendant was the Adjutant. In November, 1809, the Lieutenant-colonel issued a regimental order for establishing an evening school at Bedford. He appointed the Sergeant-major the Master and ordered all Sergeants and Corporals, including the plaintiff, to attend and pay eight-pence a week towards the expenses of the school. The plaintiff and some other of the scholars having afterwards omitted to attend, several were tried by Court-Martial and punished. The plaintiff, however, was only reprimanded, and he promised regular attendance in future. Shortly afterwards he was ordered to attend a drill on parade, when the defendant, who appears to have been a shopkeeper, shook his fist at the Plaintiff, called him a rascal, and told him he deserved to be shot. The defendant then directed a Sergeant to draw his sword and hold it over the plaintiff's head, and if he should stir to run him through; and, by the defendant's direction, a Corporal took off the plaintiff's sash and sword. The plaintiff was then conducted, by the defendant's order, to Bedford gaol, with directions that he should be locked up in solitary confinement, and kept on bread and water. He was thus imprisoned for three days. He was then brought up before the Colonel and the defendant, and other officers of the regiment, and again remanded to the gaol. The plaintiff's health having been impaired by the continuance of this treatment for several weeks, he was afterwards conducted to his own house, and there kept a close prisoner until January 1810, when he was escorted by a file of Corporals from Bedford to Stilton, to be tried by Court-Martial for mutinous words spoken on parade at the time of his arrest, and for thereby exciting others to disobedience. He was tried accordingly, but liberated in March, 1810. Upon this he brought his action against the Adjutant for the wrongful imprisonment, when an objection was taken that the question of the propriety of the arrest was not within the jurisdiction of the Civil Courts. The Courts of Common Pleas, however, overruled this objection. Sir James Mansfield, C. J.; "It might be very convenient that a military officer might be enabled to make the man under his command learn to read or write,—it might be very useful, but is not a part of military discipline. Then, there is a tax of 8*d.* a week for learning to read and write. . . . . . The subject cannot be taxed, even in the most indirect way, unless it originates in the Lower House of Parliament." Mr Justice Lawrence: "It is no part of military duty to attend a school, and learn to write and read. If writing is necessary to Corporals and Sergeants, the Superior Officers must select men who *can* write and read; and if they do not continue to do it well, they may be reduced to the ranks. Nor is it any part of military duty to pay for keeping a school light and warm: this very far exceeds the power of any Colonel to order." In a subsequent stage of the same case, when it was attempted to justify or defend the mutinous expressions used by Warden on parade as above stated, on the ground of the illegality of the order which gave rise to them, the Court held, that although Warden had been unlawfully arrested for disobedience to that order, such a circumstance afforded no warrant for insubordinate language on Warden's part, and therefore no exemption from military arrest and punishment for the same. "Nor will he (said Lord Ellenborough, C. J.) be less an object of military punishment, because the order of the Lieutenant-colonel, to which this language referred, might not be a valid one, and such as he was strictly competent to make. . . . . . There may be disorderly conduct to the prejudice of good and military discipline, in the manner and terms used and adopted by one soldier in dissuading another soldier not to obey an order not strictly legal. If any erroneous order on the part of a Commanding Officer would not only justify the individual disobedience of it by the soldier, but would justify him in making inflammatory and reproachful public comments upon same to his fellow-soldiers, equally the objects of such order with himself, is it possible that military order and discipline could be maintained?" The common defence of officers, against whom actions of this nature are brought, is a justification of their conduct as agreeable to the discipline of the service, and contributary to the maintenance of that discipline. And there can be no doubt that where the conduct brought into question is not an oppressive, malicious, or unreasonable exercise of power, and does not amount to an excess or abuse of authority, an action is wholly unsustainable. The principles upon which the Courts of Law proceed in actions arising out of the abuse of military power, will receive further illustration from the language of Lord Mansfield, in summing up the evidence to the jury in Wall v. Macnamara. His Lordship thus expressed himself: "In trying the legality of acts done by military officers in the exercise of their duty, particularly beyond the seas, where cases may occur without the possibility of application for proper advice, greater latitude ought to be allowed: and they ought not to suffer for a slip of form, if their intention appears by the evidence to have been upright. It is the same as when complaints are brought against inferior Civil Magistrates, as Justices of the Peace, for acts done by them in the exercise of their civil duty. There the principal inquiry to be made by a Court of Justice is, *how the heart stood?* and if there appear to be nothing wrong there, great latitude will be allowed for misapprehension or mistake. But, on the other hand, if the heart is wrong—if cruelty, malice, and oppression appear to have occasioned or aggravated the imprisonment, or other injury complained of they shall not cover themselves with the thin veil of legal forms, nor escape under cover of a justification the most technically regular, from that punishment, which it is your province and your duty to inflict on so scandalous an abuse of public trust." It is no legal objection to an action for the abuse of military authority, that the defendant has not been tried and convicted by a Court-Martial, for that argument holds in no case short of felony. The infliction of an unjust or illegal sentence, pronounced by a Court-Martial, is a good cause of action by the prisoner, against all or any of the Members of the Court, and all persons concerned in the execution of the sentence; such a sentence, if it exceeds the authorized measure of punishment, being not merely invalid for the excess, but absolutely void altogether. The most remarkable case on record of this kind is that of Lieutenant Frye, of the Marines, who, after on unnecessary previous imprisonment for fourteen months, was brought to trial before a Naval Court-Martial at Port Royal in the West Indies, and sentenced to be imprisoned for 15 years, for disobedience of orders, in refusing to assist in the imprisonment of another officer, without an order in writing from the Captain of Her Majesty's ship *Oxford*, on board of which Lieutenant Frye was serving. At the trial the written depositions of several illiterate Blacks were improperly received in evidence against him, in lieu of their oral testimony, which might have been obtained and sifted by cross-examination; and the sentence pronounced was itself illegal for its excessiveness, the Act 22, George II., which contains the naval Articles of War, not allowing any imprisonment beyond the term of two years. On the return to England of Admiral Sir Chaloner Ogle, the president of the Court-Martial, Lieutenant Frye brought an action against him in the Court of Common Pleas for his illegal conduct at the trial, when the jury under the direction of the Lord Chief Justice Willis, gave a verdict for the Plaintiff, with £1,000 damages. The Chief Justice at the same time informed Lieutenant Frye that he might have an action against all or any of the other members of his Court-Martial; and Lieutenant Frye accordingly issued writs against Rear Admiral Mayne and Captain Renton, upon whom the same were served as they were coming ashore at the conclusion of the proceedings of the day at another Court-Martial, of which they were acting members, for the trial of Vice Admiral Lestock, for his conduct in a naval engagement with the French fleet off Toulon, in the early part of the same year. This was deemed a great insult by the members of the sitting Court-Martial, who accordingly passed some resolutions or remonstrances in strong language, highly derogatory to the Chief Justice, which they forwarded to the Lords of the Admiralty, by whom the affair was reported to the King. His Majesty, through the Duke of Newcastle signified to the Admiralty "his great displeasure at the insult offered to the Court-Martial, by which the military discipline of the navy is so much affected; and the King highly disapproved of the behavior of Lieutenant Frye on the occasion." The Lord Chief Justice, as soon as he heard of the resolutions of the Court-Martial, ordered every member of it to be taken into custody, and was proceeding to uphold the dignity of his Court, in a very decided manner, when the whole affair was terminated in November, 1746, by the Members of the Court-Martial signing and sending to his Lordship a very ample written apology for their conduct. On the reception of this paper in the Court of Common Pleas it was read aloud, and ordered to be registered among the records as a "Memorial," said the Lord Chief Justice, "to the present and future ages, that whoever set themselves up in opposition to the laws, or think themselves above the law, will in the end find themselves mistaken. The proceedings and the apology were also published in the *London Gazette* of 15th November, 1746. It may be useful to mention here, as a legal point giving rights of redress between military men, that a Superior Officer cannot safely deal for his own advantage, in money matters, with a Junior Officer under his command. The influence which a Senior Officer can exercise over his Junior is such as to destroy, or at least to control, in the purview of a Court of Equity, that entire feeling which is very proper and essential to the perfection of a bargain or contract; and if a Regimental Officer places himself in a position where such influence may operate to the prejudice of the Junior, the transactions between them are liable to be set aside for want of fairness or conscientiousness. This is the rule applied to dealings between a guardian and his ward, a physician and his patient, a landlord and his steward, a clergyman and a penitent, and all other cases where the existence of just and unavoidable influence may lead to abuse.

II. *Wrongs towards Persons not under Military Authority.*—Injuries may be occasioned to persons not subject to military authority, by officers mistaking or exceeding their powers, or exercising them with malice, negligence, or unskilfulness; but for acts of this kind a remedy lies only in the Civil Courts; the military tribunals, as already observed, having no power to grant pecuniary compensation by way of damages, and non-military persons having no *locus standi* as prosecutors before such Courts, which are instituted solely for the maintenance of order and discipline among the armed forces.

In cases of the kind now under consideration, it is quite immaterial whether the cause of action has arisen within the realm, or beyond the seas; though this proposition was not finally established until the year 1774, when the great case of Fabrigas *v.* Mostyn was determined in the Court of King's Bench, and put an end to all further question or doubt upon the subject. The Plaintiff was a native of Minorca, of which Island the defendant, General Mostyn, was Governor. The General had by his own absolute authority imprisoned the plaintiff and banished him from the Island without a trial. The defence was, that in the peculiar district of Minorca, where the offence occurred, no ordinary Court or Magistrate could have had jurisdiction. But the proof of this defence failed, and the jury gave the plaintiff £3,000 damages. The objection, however, was taken that the action did not lie, by reason of the foreign locality of the cause of it, and the point was twice argued at great length; but judgement was eventually pronounced against General Mostyn, in accordance with the verdict of the jury. It should be noticed also that as General Mostyn, happened to be a Governor, his appointment gave him the character of a Viceroy, so that *locally and during his government* no civil or criminal action lay against him. On principles of public justice, therefore, it was necessary that a remedy should be had in England. The *undue assumption* or *mistaken* exercise of authority by officers towards non-military persons, is a clear ground of action against them in the Civil Courts, even though there be no malice accompanying the transaction.

Captain Gambier, of the Navy, under the orders of Admiral Boscawen, pulled down the houses of some sutlers on the coast of Nova Scotia, who supplied the the seamen of the fleet with spirituous liquors. The act was done with good intention on the part of the Admiral; for the health of the sailors had been affected by frequenting these houses. Captain Gambier, on his return to England, incautiously brought home in his ship one of the sutlers whose houses had been thus demolished. The man would never otherwise have got to England; but on his arrival he was advised to bring an action against Captain Gambier. He did so, and recovered £1,000 damages. But as the Captain had acted by the orders of Admiral Boscawen, the representatives of the Admiral defended the action, and paid the damages and costs. This was a favorable, case, unaccompanied by any malicious feeling; but the parties concerned did not attempt to disturb the verdict. Admiral Sir Hugh

Palliser was defendant in similar action for destroying fishing huts on the Labrador coast. After the Treaty of Paris, the Canadians, early in the season, erected huts for fishing, and by such means obtained an advantage over the fishermen who came from England. It was a nice question upon the rights of the Canadians. But the Admiral on the grounds of public policy, ordered the huts to be destroyed. An action was brought against him in England by one of the injured parties, and the case ended in arbitration. But on the part of the Admiral it was never contended that the action did not lie by reason of the subject-matter of occurrence beyond the seas.

"I remember," said Lord Mansfield, "early in my time being counsel in an action brought by a carpenter in the train of artillery against Governor Sabine, who was Governor of Gibralter, and who had barely confirmed the sentence of a Court-Martial, by which the plaintiff had been tried and sentenced to be whipped. The Governor was very ably defended, but nobody ever thought the action would not lie; and it being proved that the tradesmen who followed the train were not liable to martial law, the Court were of that opinion, and the jury found the defendant guilty of the trespass, as having had a share in the sentence, and gave £700 damages." The following case, involving the same principle, occurred in India, and was there tried before the Supreme Court of Madras. Mr. H. Smith was agent, at Secunderabad, of a mercantile house at Madras, from whom he received a very handsome salary. He became indebted to a soldier of H. M.'s 33d regiment for some work intrusted to him, and a dispute having arisen between them as to the amount, this led to a violent altercation between Mr. Smith and the Superintendent of the Bazaar acting under the local military regulations. Lieutenant-colonel Gore thereupon sent a file of men to arrest the Plaintiff, who was accordingly seized about six o'clock in the evening, and marched from his house through the streets of the cantonment to the main guard at Secunderabad, where he was kept till twelve o'clock the next day. In consequence of these proceedings, he brought an action against Colonel Gore for false imprisonment. Secunderabad was an open cantonment for a part of the subsidiary force serving in the Territories of the Nizam; the force consisting partly of British and partly native troops. It had barracks, and the men were hutted. It was also upon a field establishment, constantly ready for immediate service. The Article of War then in force, was thus intituted, "Of duties in quarters, in garrison, and in the field;" and it enacted, "that all sutlers and retainers to the camp, and all persons whatsoever serving with forces *in the field*, though not enlisted soldiers, are to be subject to orders, according to rules and discipline of war." Sir Thomas Strange, C. J.: "The question was, whether the troops, *being cantoned*, were in the state to which the cited Articles of War applied. The Court thought they were not. It might have been a field force, being upon a field establishment, so as to be ready to move at the shortest notice. There might be great similarity in the arrangements adopted for an army, whether in the field or cantoned. A respectable witness, Brigade-major Lyne, intimated as much. Still, so far as the Court could form a judgment upon a question of this nature, there seemed to be a difference between a camp and a cantonment, which appeared material. . . . . . When in the field, not only the army, but its appendages, must be under the immediate control of the Officer Commanding it, according to the rules and discipline of war. So situated, the sutler, who chose to follow the camp, identified himself in a manner with the soldier for every purpose almost but that of fighting. . . . . . The plaintiff called upon the Court to say, whether the force in question, under the command of the defendant, was at the time in the field. It seemed impossible to say that it was, without confounding ideas apparently very distinct. . . . . . The defendant appeared to have acted under a mistake of his authority, for which he was liable to answer, as it had been productive of serious injury to the plaintiff." Judgment was therefore given against Colonel Gore, with fifty pagodas damages. In the foregoing case reference was made to an action brought by Mr. Robert Bailie, an up-country trader in the province of Bengal, against Major General Robert Stewart, for an assault and false imprisonment. Mr. Bailie had resided within the cantonments of Cawnpore for many years, and dealt in European articles, which he principally disposed of to the military stationed there. In October, 1797, upon a complaint made to him by one of the people of his Zenanah, he tied up and very severely flogged one of his *Chowkydars*. For this act Major-General Stewart ordered Mr. Bailie to be tried by Court-Martial; and as he acknowledged to have used no less than six switch whips in the flogging, alleging as his reason, that as they were new whips he was afraid of breaking them and spoiling their sale, the Court-Martial sentenced him to five days' imprisonment, and to make an apology to the Commanding Officer. This sentence General Stewart, thought he did not approve of it, confirmed; and issued orders for Mr. Bailie to depart the camp as soon after his enlargement as possible. The Supreme Court of Calcutta held Mr. Bailie to be a sutler within the meaning of the Articles of War, so as to render him amenable to military law. But in the above mentioned action of Smith *v.* Lieutenant-colonel Gore, the Chief Justice, Sir T. Strange, declined to be governed by the decision in General Stewart's case, as the note furnished to the Court did not clearly show whether or not the army was in the field when the transaction occurred. An *unreasonable* or *malicious* exercise of power will, in like manner, render an officer liable to an action for damages. An instance of this occurred in the year 1783, when an action was brought against General Murray, Governor of Minorca, for improperly suspending the Judge of the Vice-admiralty Court of that Island. The General had professed himself ready to restore the Judge on his making a particular apology; and on reference to the Home Authorities, the King approved of the suspension, unless the Governor's terms were complied with. There was no doubt as to General Murray's power to suspend the Judge for proper cause; yet, on the proof of his having unreasonably and improperly exercised the authority, and notwithstanding the King's approbation of his proceedings, damages to the amount of £5,000 were awarded against him by a jury; and, as Mr. Baron Eyre observed, it never occurred to any lawyer that there was any pretence for questioning the verdict. *Negligence* or *unskilfulness* in the exercise of an officer's duty may also be a cause of action for damages in respect of private injuries thus occasioned; and in such cases the approval of an officer's conduct by the Government, or by the superior military authorities, will neither relieve him from liability to an action, nor have any influence upon the decision of the Courts of Westminster Hall. Those tribunals investigate such matters on independent evidence, according to their own rules, and pay no regard to the previous conclusions of official functionaries, however high their rank may be.

It is a rule of English law, in unison with the law of nations, by which all civilized States are governed, that no officer engaged in military operations in his country's cause, by the order or with the sanction of the constituted authorities, shall incur any individual or private responsibility for acts done by virtue of his commission or official instructions. Such transactions being of a public nature, redress or satisfaction for injuries to which they give birth, is to be sought by public means alone, from the sovereign power of the belligerent or offending state, according to the principles of international law, and the general usages of civilization, which never suffer such matters to be litigated before ordinary tribunals. If, in time of peace, the citizens of a friendly Foreign State sustain a private injury at the hands of a naval or military officer serving under the orders of the British Government, but unauthorized by his commission or instructions to do the act complained of, the ordinary tribunals of England afford the same redress against him as in the case of a British subject similarly aggrieved; and this rule applies even in those cases where the violated rights of the foreigner are such as the law of England denies or prohibits to its own subjects. But if the British Government have expressly instructed the officer to commit the act which constitutes or gives occasion to the grievance, the matter becomes an affair of state which is not cognizable by the Courts of Law, and must be adjusted by diplomatic arrangement between the two Governments concerned. In such cases also it is quite sufficient, if the officer's proceedings, though not originally directed or authorized by the terms of his instructions, are afterward sanctioned and adopted by the Government; for this renders them public acts, over which courts of law have no jurisdiction.

INJURIES TO CANNON.—With the exception of the bending of the trunnions of bronze cannon by long firing, the principal injuries to which cannon are subject, are internal, and arise from the separate actions of the powder and the projectile. They increase in extent with the caliber, whatever may be the nature of the piece, but are modified by the material of which it is made.

The injuries from the powder generally occur in the rear of the projectile. They are, 1st. The *enlargement* of that portion of the bore which contains the powder, arising from the compression of the metal. This injury is more marked when a sabot or wad is placed between the powder and the projectile, and is greatest in a vertical direction. 2d. *Cavities*, produced by the melting away of a portion of the metal by the heat of combustion of the charge. 3d. *Cracks*, arising from tearing asunder of the particles of the metal at the surface of the bore. At first a crack of this kind is scarcely perceptible, but it is increased by the continued firing until it extends completely through the side of the piece. It generally commences at the junction of the chamber with the bore, as this portion is less supported than others. 4th. *Furrows*, produced by the erosive action of the inflamed gases. This injury is most apparent where the current of the gas is most rapid, or at the inner orifice of the vent, and on the surface of the bore, immediately over the seat of the projectile. The wear of the vents of bronze cannon is obviated by inserting a copper vent-piece. The effect of continuous firing on the vents of iron cannon is to produce a uniform enlargement of the inner orifice, and to seriously weaken the piece. The appearance of a vent thus enlarged, is irregular and angular, with its greatest diameter in the direction of the axis of the bore. To obviate the serious consequences that result from this injury Captain Dahlgren has placed in his naval guns two vents, each a short distance from, and on opposite sides of the vertical plane, passing through the axis of the piece. One of them is filled with melted zinc, the other is used until it becomes so much enlarged as to endanger the safety of the piece; it is then filled with zinc, and the first one opened.

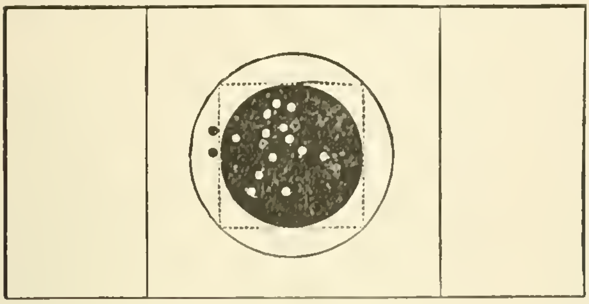
The injuries arising from the action of the projectile occur around the projectile, and in front of it. They are, 1st. *The lodgement*. This is an indentation in the lower side of the bore, produced by the pressure upon the ball by the escape of the gas through the windage, before the ball has moved from its seat. The elasticity of the metal, and the *burr*, or *crowding up*, of the metal in front of the projectile, cause it to rebound, and being carried forward by the force of the charge, to strike against the upper side of the bore, a short distance in front of the trunnions. From this it is reflected against the bottom, and re-reflected against the top of the bore, and so on until it leaves the piece. The first indentation is called the *lodgement*; the other *enlargements*. In pieces of ordinary length, there are generally three enlargements, when this injury first makes its appearance, but their number is increased as the *lodgement* is deepened and the angle of incidence increased. Bronze pieces are considered unserviceable when the depth of the lodgement is .18 in., and the depth of an enlargement is .16 in. The effect of this bounding motion, is to alternately raise and depress the piece in its trunnion-beds, and to diminish the accuracy of fire, until finally, the piece becomes unfit for service. It is principally from this injury that bronze guns become unserviceable. Mortars and howitzers are not much affected by it. The principal means used to obviate this injury, are to wrap the projectile with cloth or paper (as the cylinder-cap of the cartridge used with field-guns), and to shift the seat of the projectile. The latter may be done by a wad, or lengthened sabot, or by reducing the diameter and increasing the length of the cartridge. The last of these methods is considered the most practical as well as the most effective; and it has an additional advantage of diminishing the strain on the bore, by increasing the space in which the charge expands before the ball can be moved. The French bronze siege-guns, which formerly were rendered unserviceable in 600 service-rounds, now endure, by this method, 2,500 service-rounds. 2d. *Scratches*, or furrows made upon the surface of the bore by rough projectiles, or by case-shot. This is not a serious injury. 3d. *Cuts*, made by the fragments of projectiles which break in the bore. 4th. *Wearing away of the lands of rifle-cannon*, especially at the driving edges. 5th. *Enlargement of the muzzle*, arising from the forcing outward of the metal by the striking of the projectile against the side of the bore, as it leaves the piece. By this action, the shape of the muzzle is elongated in a vertical direction. 6th. *Cracks on the exterior*. These are formed by the compression of the metal within, generally at the chase, where the metal is thinnest. This portion of a bronze-gun is the first to give way by long firing, whereas, cast-iron cannon are burst in rear of the trunnion, and the fracture passes through the vent, if it be much enlarged.

The principal injuries to which cast-iron cannon are liable are the wearing away of the metal of the bore above and below the projectile, and at the interior corners of the vent. In guns which have seen much service the enlargements thus occasioned have been known to exceed one inch in both cases. It has been seen that the strength of cast-iron cannon is diminished by repeated firing, and that there is a limit beyond which they should not be used. For American cannon this limit has been fixed at one thousand service-rounds. The number of times which an iron piece has been fired may be approximately determined by the size of the bore, and vent if it be not bushed. The first is taken with the "star gauge," and the second by an impression in wax. Slight cracks in the surface of the bore, particularly about the seat of the charge, indicate the approaching fracture of a cast-iron gun. The injuries to which wrought-iron cannon are most subject, are the enlargement of the bore by the extension or compression of the metal around it, and the rapid enlargement of slight cracks and cavities by the flame of the powder. See *Cannon*.

INLYING PICKET.—A body of infantry or cavalry in campaign, detailed to march, if called upon, and held ready for that purpose in camp or quarters

INNER.—The name given to a certain part of a target. A shot striking in this space (a circular ring) on the Creedmoor target counts 3. On the regulation target, the smallest circle, always painted black, is called the *bull's-eye;* the ring embraced between the bull's-eye and the circumference of the next larger circle is called the *center*; the ring between the second and third circles is called the *inner;* and the space outside the larger circle is called the *outer*. In the target represented on next page, the space between the second circle and the vertical lines is the *inner*, and the space outside the vertical lines is the *outer*.

INNER FLANK.—That which is nearer the point on which a line rests, or which is farther from the enemy. In drill, it is always that flank which is nearer the point from which the line is dressed.



Inner.

INNISKILLINERS.—In the British service, officers and soldiers of the Sixth Dragoons and the Twenty-seventh Foot; so called from the two regiments having been originally raised at Inniskillen, a town of Ulster, where the inhabitants distinguished themselves in favor of King William against James II. Often written *Enniskilliners*.

INROAD.—The entrance of an enemy into a country with purposes of hostility; a sudden or desultory incursion or invasion; encroachment, notwithstanding efforts to prevent it.

INSCONCED.—In the military art, when any part of an army has fortified itself with a sconce, or small work, in order to defend some pass, etc., it is said to be insconced. *Ensconce* signifies in a general sense to cover as with a fort.

INSPECTION.—Divisions and brigades are inspected between the fifteenth and twentieth of each month by inspecting officers designated for the purpose. The Commanders of regiments and posts make an inspection of their commands on the last day of every month. Captains inspect their companies every Sunday morning, and no soldier is excused from Sunday inspection except the guard, the sick, and the necessary attendants in the hospital. Medical officers having charge of hospitals make a thorough inspection of them every Sunday morning. Troops are inspected when mustered for payment. Besides these inspections, frequent visits are made during the month by the Commanding Officer, company and medical officers, to the men's quarters, the hospital, guard-house, etc. Except when otherwise specially provided for by the Secretary of War or the General of the Army, every military post, station, and command in the Army is inspected at least once every year by Division or Department Inspectors, under the direction of their respective Commanders. In addition to these inspections, post, station, and other permanent Commanders, between the first and fifth days of September in each year, make thorough inspections of their respective commands, and forward reports thereof, through the proper military channels, to the Inspector General's Office, at the Headquarters of the Army, so as to reach that office not later than October 1st. These reports do not interfere or dispense with those of the inspecting officers.

Inspections are made under specific orders clearly defining their object, which will be exhibited to the officers whose troops or affairs are to be examined. Commanding Officers are to see that every facility is afforded for such examination. Inspectors give orders only when specially authorized to do so; and then give them in the name of the officer authorizing it. They must report with strict impartiality all irregularities. They should refrain from informal conversation on the subjects of investigation, and from all expression of approval or disapprobation. Inspectors take care that no injustice be done to organizations or individuals by reports not fully sustained by thorough personal examination. Before leaving a command, the Inspector publicly informs the troops that opportunity will be given any soldier to lay before him a well-grounded complaint without any of his officers being present.

The sphere of inquiry of Inspectors generally includes every branch of military affairs, and whether the military laws and regulations are fully complied with. In specific cases, it is defined and limited by the orders they receive. Generally, report is made as to zeal and ability of Commanding Officers, and whether they possess the requisite professional knowledge for the proper exercise of their command; whether they preserve harmony and unanimity in the command, and observe the system of instruction and treatment of subordinates enjoined by the Regulations; whether the officers are properly instructed and efficient. Special report is also to be made in case of any officer of intemperate or immoral habits, or who has proper assosociates, or who is addicted to gaming, or is unfit for active service by infirmity or any other cause; whether the number of men in ranks at inspection corresponds with the returns, and how absentees are accounted for; whether the band exceeds the authorized number, and any men not musicians are mustered with it; as to the discipline, military appearance, and bearing of the troops; their instruction in all military exercises and duties; the nature and frequency of exercises and recitations in tactics; the target practice; whether they are practiced in marching with the full kit; the state of their batteries, or arms, equipments, and accouterments of all kinds; the sufficiency, uniformity, and fit of their clothing; when the troops were last paid, and, if payment be deferred, the cause of delay.

In the inspection of a post, it should be reported when and by whom the post was last inspected; whether it be sufficiently garrisoned, and the armament and supplies of all kinds sufficient in kind and quantity; the strength of the garrison and its armament; whether the Commanding Officer is familiar with the design and capacity for defense of the work, the ground in its vicinity, and the principles of defense of fortified places; in case of frontier and sea-coast forts, whether the Commanders understand and properly execute the laws relating to neutrality, quarantine, etc., and the regulations prescribing international courtesy; as to the cleanliness, state of repair, and sanitary condition of barracks and quarters; as to the kitchens and messes, the sufficiency, variety, and preparation of food; of the guard-house, prisons, bake-house; of the hospital, and whether the sick are properly cared for; of the stables, harness, means of transportation and animals, the number unserviceable; in the case of Cavalry and Artillery horses, as to their grooming, shoeing, veterinary treatment, and general condition; as to the capacity of the officers conducting the Administrative and Staff services, the fidelity and economy of their disbursements, and whether payments and issues are made strictly in accordance with law and the Regulations. The regularity of issues and payments; whether supplies reported on hand are verified; whether the labor of the supply departments is performed by troops or by civilians. If by civilians, their number, the cost, and reasons in justification of their employment; as to the condition of all public property and stores, and whether any is used for private purposes; whether buildings and property are properly secured against fire, theft, exposure, and damage; whether forage, wood, and Subsistence supplies are properly protected and under sentinels; as to the neighboring Indian tribes, their number, disposition, and other information useful in a military view; as to the population, resources, routes, and means of travel, etc., of the surrounding country.

INSPECTION ARMS.—A command in the Manual of Arms, directing that the piece be placed in a prescribed position, preparatory to its inspection. The movement is executed as follows: The recruits being at order arms, bayonets fixed, the Instructor commands—

1. *Inspection*, 2. ARMS.

Commencing on the right, the Instructor inspects the pieces in succession. Each recruit, as the Instructor approaches him, tosses his piece quickly with the right hand opposite the left eye, catching it with the left hand between the rear-sight and the lower band, the thumb extended along the stock, the barrel to the right, and inclined slightly to the front, the hand at the height of the chin; he then passes his right hand quickly to the lock, placing the thumb on the hammer, the elbow raised as high as the hand, the fingers, closed together, extending in front of lock. (Two.) The recruit presses the thumb on the hammer, lowering the elbow at the same time, and brings the hammer to the half-cock; then drops the right hand by the side; the Instructor takes the piece with the right hand at the small of the stock (the recruit dropping the left hand by the side), inspects, and hands it back to the recruit, who receives it with the left hand in the position prescribed in the first motion, passes his right hand, as before, to the hammer, and the fore-finger to the trigger, which he pulls, at the same time pressing the hammer downward to free it from the half-cock notch, thus bringing the hammer to the safety-notch; the piece is then lowered with the left hand, seized near the middle band with the right, and brought to the position of *order*. As the Instructor returns the piece, the recruit next on the left throws up his piece to the position of *inspection*, and so throughout the squad. Should the piece be inspected without handling, the recruit resumes the *order* as the Inspector passes to the next man, who immediately tosses up his piece.

INSPECTION MARKS.—All cannon are required to be weighed, and to be marked as follows, viz.: the *number of the gun*, *the initials of the Inspector's name*, on the face of the muzzle—the numbers in a separate series, for each kind and caliber at each foundry; the initial letters of the name of the *founder* and the *foundry*, on the end of the right trunnion; the *year of fabrication*, on the end of the left trunnion; the *foundry number*, on the end of the right rimbase, above the trunnion; the *weight of the piece in pounds*, on the base of the breech; the letters U. S., on the upper surface of the piece, near the end of the reinforce. The *natural line of sight*, when the axis of the trunnions is horizontal, should be marked on the base-ring and on the swell of the muzzle, whilst the piece is in the trunnion-lathe. Cannon *rejected* on inspection, are marked XC, on the face of the muzzle; if condemned for erroneous dimensions which cannot be remedied, add XD; if by powder-proof, XP; if by water-proof, XW. Converted guns are marked as follows: The *number of the gun*; the *weight of the piece in pounds*; the *initials of the Inspector's name*, and that of the *foundry where the gun is converted*, and the *year of the conversion* on the face of the tube, in a circle concentric with the bore, in letters and figures at least one inch long. The initials of the *foundry where the tube is made*, and the *number of the tube*, in small type, on the face of the tube, under the initials of the Inspector. The results of all final measurements and examinations are noted on the inspection report of the gun. See *Inspection of Ordnance*.

INSPECTION OF ACCOUNTS.—The Inspections of Disbursing Officers' accounts, which are required by law, are made quarterly, or four times within the year, with a reasonable interval between any two examinations. Division and Department Commanders usually provide for the inspection of Disbursing Officers' accounts through the Inspectors attached to their headquarters, or by detail of suitable officers within their commands for the purpose. The law provides, in regard to Inspection of Accounts, "that no officer so detailed shall be in any way connected with the Department or Corps making the disbursement." The Inspector makes a minute and thorough inspection of the accounts of Disbursing Officers, and compares the result in each case with the officer's balance at his place of deposit; and each Inspector is held responsible for any defalcation or misapplication of the public money or property which may occur within the command to which he is assigned that an active vigilance on his part might have detected.

INSPECTION OF CONDEMNED PROPERTY.—Inspectors are the only officers authorized to inspect public property with a view to condemnation. The final disposition of condemned property, except it be worthless, can only be ordered by Commanding Generals of Departments. All surveys and reports having in view the *condemnation* of public property, for whatever cause, should be made by Inspector Generals, or Inspectors specially designated by the Commander of a Department or an army in the field, or by higher authority. Such surveys and reports having a different object from those of Boards of Survey, are required independently of any preliminary action of a Board on the same matter.

An officer commanding a Department, or an army in the field, may give orders, on the report of authorized Inspectors, to sell, destroy, or make such other disposition of any condemned property as the case may require—ordnance and ordnance stores alone excepted, for which the orders of the War Department must always be taken. But if the property be of very considerable value, and there should be reason to suppose that it could be advantageously applied or disposed of elsewhere than within his command, he should refer the matter to the Chief of the Staff Department to which it belongs, for the orders of the War Department. No other persons than those above designated, or the General-in-Chief, can order the final disposition of condemned property, saving only in the case of horses, which should be killed at once to prevent contagion, and of provisions or other stores which are rapidly deteriorating, when the immediate Commander may have to act perforce. Inventories of condemned property are made in triplicate, one to be retained by the person accountable, one to accompany his accounts, and one to be forwarded through the Department, or other superior headquarters, to the Chief of the Staff Department to which the property belongs.

Officers inspecting public property cause the destruction, in their presence, of all property found to be worthless, and which is without any money value at the place of inspection. The action of an Inspector, on property of this character, is final, and his inspection report on the same is a valid voucher for the officer responsible for the property. In the discharge of the duty devolved upon Inspectors in this regulation, they are regarded as answerable that their action is proper and judicious according to the circumstances of the case. Unserviceable arms and stores will be inspected and disposed of in like manner with other property. Their *sale* can be ordered by the Secretary of War only.

INSPECTION OF ORDNANCE.—The objects of inspecting cannon are to verify their dimensions, particularly those which affect the accuracy of fire, and the relation of the piece to its carriage, and to detect any defects of metal and workmanship, that would be likely to impair their strength and endurance. Smooth-bore cannon presented for inspection and proof are placed on skids for the convenience of turning and moving them easily. They are first examined carefully on the exterior to ascertain whether there be any flaws or cracks in the metal, whether they be finished as prescribed, and to judge, as well as practicable, of the quality of the metal. They must not be covered with paint, lacker, or any other composition. If it be ascertained that an attempt has been made to conceal any flaws or cavities by plugging or filling them with cement or any substance, the gun is rejected without further examination. After this preliminary examination, the Inspector proceeds to verify the dimensions of the piece. The interior of the bore is first examined by reflecting the sun's rays into it from the mirror, or, if the sun be obscured, by a lighted candle or a lamp placed on the end of a rod and inserted into the bore. The cylinder-gauge screwed on the staff is then pushed gently to the bottom of the cylindrical part of the bore and withdrawn; it must go to the bottom or the bore is too small. The bore of the piece is then measured with the star-gauge, beginning at bottom. Measurements should be made at intervals of ¼ inch to the front of seat of shot, and at intervals of 1 inch from that point to the muzzle. In rifled guns the measurements are taken from land to land, and afterwards from groove to groove, the head of the star-gauge being fitted with the suitable "guide" to insure the proper position of the measuring points. The position of the trunnions with regard to the axis of the bore and to each other is next ascertained. To verify the position of the axis of the trunnions, set the trunnion-square on the trunnions, and see that the lower edges of its branches touch them throughout their whole length; push the slide down till it touches the surface of the piece, and secure it in that position by the thumb-screw; turn the gun over, and apply the trunnion-square to the opposite side, and if, when the point of the slide touches the surface of the piece, the lower edges of the branches rest on the trunnions, the axis of the trunnions is in the same plane with the axis of the bore; if they do not touch the trunnions, their axis is above the axis of the bore by half the space between; and if the edges touch the trunnions and the point of the slide does not touch the surface of the piece, their axis is below the axis of the bore. If the alignment of the trunnions be accurate, the edges of the trunnion-square will fit on them when applied to different parts of their surface; their diameter and cylindrical form and the diameter of the rimbases are verified with the trunnion-gauge. To ascertain the length of the bore, screw the guide-plate and measuring-point on the cylinder-staff and push them to the bottom of the bore; place a half-tompion in the muzzle and rest the staff in its groove; apply a straight-edge to the face of the muzzle and read the length of the bore on the staff. The exterior lengths are measured by the rule or by a profile, the accuracy of which is first verified; the exterior diameters are measured with the calipers and graduated by a rule. The position of the interior orifice of the vent is found from the mark made on the rammer-head by the vent-gauge inserted in the vent, while the rammer-head is held against the bottom of the bore. Two impressions are taken. The position of the exterior orifice of the vent is also verified. The vent is examined with gauges, and the vent-searcher is to ascertain if there are any cavities in it. All smooth-bore bronze ordnance should be bored under size from .04 to .05 inch, and, after proof, reamed out to the exact caliber. Whitish spots show a separation of the tin from the copper, and, if extensive, should condemn the piece. A great variation from the true weight, which the dimensions do not account for, shows a defect in the alloy. In mortars, the dimensions of the chambers and the form of the breech may be verified with patterns made of plate-iron. After the powder proof the bore is washed and wiped clean, and the bore and vent are again examined, and the bore remeasured. The results of each of the measurements and examinations are noted on the inspection report against the number of the gun. A proper discretion must be exercised in the inspection of ordnance; such slight imperfections as do not injure a piece for service may be disregarded, whilst the instructions should be strictly enforced with regard to defects which may impair its utility.

The duties of the inspection of converted guns commence with the inception of the work, and the most important are performed before the gun is completed. The breech-cup is verified by the steel templet before it is screwed into place. The different shoulders and the shape and pitch of screw-threads are similarly gauged before the parts are united; diameters of tubes are verified, and the base of the tube and recess for the muzzle-collar before the insertion. The dimensions of the casing are also proven. When the gun is presented for final inspection it is placed horizontally on the skids, and inspected as explained above for smooth-bore cannon.

That the finished bore of a bronze piece may not be injured by the proof-charge, it is bored out under size, from .04 to .05 inch, and, after proof, reamed out to the true size. When the powder-proof is finished, the bore should be cleaned and examined; the vent should be stopped up with a greased wooden plug, the muzzle raised, and the gun filled with water, to which pressure should be applied to force it into any cavities that exist; or the water should be allowed to remain in the bore twenty-four hours. The bore must then be sponged dry and clean, and viewed with a mirror or candle, to discover if any water oozes from cracks or cavities, and also, if any enlargement has taken place. The quantity that runs out of a crack or honey-comb will indicate the extent of the defect; and if it exceed a few drops, the piece should be rejected, although the measured depth of the cavity may not exceed the allowance. After the bore has been reamed out to its proper size, its dimensions are again verified, and an examination of the bore and vent is made, to detect any defects which may have been caused or developed by the proof. Whitish spots show a separation of the tin from the copper, and, if extensive, should condemn the piece. A great variation from the true weight which the dimensions do not account for, shows a defect in the alloy.

Bronze cannon should be rejected for the following sized cavities or honey-combs: *Exterior.* Any hole or cavity 0.25 in. deep in front of the trunnions, and 0.2 in. deep at or behind the trunnions. *Interior.* From the muzzle to the reinforce, any cavity 0.15 in. deep. Any cavity from the reinforce to bottom of the bore. In all other respects, the inspection of cast-iron and bronze cannon are alike. See *Calipers, Cascabel-block, Chamber-gauge, Cylinder-gauge, Disk, Impression-taker, Measuring-staff, Mirror, Profile-boards, Proof of Ordnance, Rammer-head, Searcher, Star-gauge, Template, Trunnion-gauge, Trunnion-rule, Trunnion-square, Vent-gauges, Vent-guide,* and *Vent-searcher.*

INSPECTION OF POWDER.—The Inspector of gunpowder should satisfy himself before its reception as to the purity of the ingredients employed by the manufacturer, and that their proper preparation and careful manipulation through all the various stages of manufacture have been rigidly observed. Before powder for the military service is received from the manufacturer, it is inspected and proved. For this purpose at least 50 barrels are thoroughly mixed together. One barrel of this is proved. Musket powder should be fired three rounds with service charges. Mortar and cannon powder should be fired three rounds with heaviest charges in a field and siege-gun respectively. Mammoth, hexagonal, cubical, prismatic, or other special powders, three rounds with battering charges from guns in which these powders are to be used. The density and granulation of the powder, as well as the velocity and pressure obtained in its proof, should conform to the Ordnance Regulation in these respects, for the particular service or piece for which the powder is required, within the allowed limits of variation.

Gunpowder should be of an even-sized grain, angular and irregular in form, without sharp corners, and very hard. When new, it should leave no trace of dust when poured on the back of the hand, and when flashed in quantities of 10 grains on copper plate it should leave no bead or foulness. It should give the required initial velocity to the ball, and not more than the maximum pressure on the gun, and should absorb but little moisture from the air.

The size of the grain is tested by standard sieves made of sheet brass pierced with round holes. Two sieves are used for each kind of powder, Nos. 1 and 2 for musket, 3 and 4 for mortar, 5 and 6 for cannon and 7 and 8 for mammoth powder.

A compact shape of grain approaching the cube or sphere, is desirable. Elongated flat scales are objectionable. The number of grains in the several weighed samples should be counted.

Diam. of holes for musket-powder..No. 1, 0.03 in.; No. 2, 0.06 in.
Diam. of holes for mortar-powder...No. 3, 0.10 in.; No. 4, 0.25 in.
Diam. of holes for cannon-powder..No. 5, 0.25 in.; No. 6, 0.50 in.
Diam. of holes for mammoth-powder No. 7, 0.75 in.; No. 8, 0.90 in.
Hexagonal, Cubical, Prismatic. } Dimensions of these powders vary with the caliber of the gun in which they are used, and have not as yet been definitely determined upon in our service.

Gravimetric density is the weight of a given measured quantity. It is usually expressed by the weight of a cubic foot in ounces. This cannot be relied upon for the true density when accuracy is desired, as the shape of the grain may make the denser powder seem the lighter. Its only value is a fair idea of the value of air space in a given weight. The specific gravity of gunpowder varies from 1.65 to 1.8. It is important that it should be determined with accuracy. Alcohol and water saturated with saltpeter have been used for this purpose; but they do not furnish accurate results. Mercury only is to be relied upon. Hardness is tested by breaking the grains between the fingers; the hardness is judged of by experience. It is very necessary that the density or specific gravity of the powder should be most accurately determined. For this delicate operation a very ingenious instrument has been devised by Colonel Mallet, of the French Army, called a Mercury Densimeter.

Initial velocity is determined by any of the electro-ballistic machines available; the Boulengé chronograph is one of the simplest and most generally used for proof of powder. The strain upon the gun is determined by the Rodman pressure-gauge, or some suitable contrivance. The amount of moisture in powder is determined by drying samples in an oven with a water bottom. A vessel of tin, double-walled, except the face containing the door, is fitted at the top with an opening for the introduction of water; the door is double; the inner skin-lining has perforations at the top to allow the escape of moisture given up by the powder. Ledges on the inside of the oven support the powder-trays. Before use, the water space is filled with boiling water; a spirit lamp keeps up the heat; the supply of water is kept up to compensate for evaporation. The powder is subjected to heat as long as it loses weight, the loss indicating the percentage of moisture driven off. On being removed from the oven it should be transferred at once to perfectly clean, dry, and air-tight weighing bottles. The ability to resist moisture is determined by subjecting samples which have been dried to exposure, first in open air, then in a hygroscope containing a solution of niter at 100° cooled to 80° Fahr.

On breaking the grains, a fine ashen-gray color throughout should appear; the grain texture should be close, without white specks even when magnified. "Flashing" on glass or porcelain plates, small copper measures for fine-grain powders inverted on the plates, keeps the heap nearly the same at each trial. The powder should be in small conical heaps; if the incorporation is good, only smoke marks remain on the plate after flashing; if bad, specks of undecomposed niter and sulphur will form a dirty residue. The test requires experience to insure good judgment. The relative incorporation is determined by the balance; the greater increase of weight on the plate, the less satisfactory the powder in this respect. Moist powder flashes badly. The report of inspection should show the place and date of fabrication and of proof, the kind of powder and its general qualities, as the number of grains in 100 grains, its specific gravity; whether hard or soft, round or angular, of uniform or irregular size; whether free from dust or not; the initial velocities and pressures per square inch obtained in each fire; the amount of moisture absorbed; and, finally, the height of the barometer and hygrometer at the time of proof. Each barrel is marked on both heads, (in white oil-colors, the head painted black), with the number of the barrel, the name of the manufacturer, year of fabrication, and the kind of powder, *cannon*, *mortar*, or *musket*, *etc.*, the mean initial velocity, the pressure per square inch on the pressure-piston, and density. Each time the powder is proved, the initial velocity is marked below the former proofs, and the date of the trial opposite to it. See *Analysis of Powder*, *Densimeter*, *Gunpowder*, and *Hygroscope*.

INSPECTION OF PROJECTILES.—The principal points to be observed in inspecting shot and shells are to see that they are of the proper form and size; that they are made of suitable metal; and that they have no defects, concealed or otherwise, which will endanger their use, or impair the accuracy of their fire. As it is impracticable to make all projectiles of exact dimensions, certain variations are allowed in fabrication. They should be inspected whilst perfectly clean, and before becoming rusty, so that flaws and imperfections in the metal can be detected by the eye.

Spherical Projectiles.—The inspecting instruments required for shot are one *large* and one *small gauge* and one *cylindrical-gauge* for each caliber. The cylinder-gauge has the same diameter as the large gauge; it is Constructed of cast-iron and is five calibers long. The large and small gauges are made with a difference in diameter of 0.02 inch for projectiles turned in a lathe, and 0.04 inch for those not so turned. All these gauges should be verified from time to time, and when they have become 0.01 inch larger than their true diameter they should no longer be used. One *hammer* having a flat face and a conical point. One *searcher* of steel wire. One *cold-chisel. Steel punches. Figure-stamps.*

The shot should be inspected before they become rusty; after being well cleaned each shot should be carefully examined to see that its surface is smooth, that the metal is sound and free from seams, flaws, and blisters. If cavities or small holes appear on the surface, strike the point of the hammer or punch into them and ascertain their depth with the searcher; if the depth of the cavity exceeds 0.2 inch, the shot should be rejected. The discovery of any attempt on the part of those engaged in the fabrication of the shot to conceal such defects by filling up the holes should insure rejection. The shot must pass in every direction through the large gauge and not at all through the small one, and the mean of their diameters should be nearer that of the former gauge than of the latter.

After having been thus examined, the shot are passed through the cylinder-gauge, which is placed at an inclination of about two inches between the two ends, and supported on blocks of wood in such a manner as to be easily turned from time to time to prevent its being worn into furrows. Shot which *slide* or *stick* in the cylinder should be rejected. The average weight of shot of 10 inches and under is deduced from that of three parcels of 20 to 50 each, taken indiscriminately from the pile; some of those which appear to be the smallest should be also weighed, and if they fall short of the prescribed weight of their caliber by more than one thirty-second part, they should be rejected. Shot of larger caliber than 10 inches should each one be weighed by itself and its weight stamped upon it near one of the ears for the shell-hooks.

The dimensions of grape and canister shot are verified by means of a large and small gauge attached to the same handle. The surface of the shot should be smooth and free from seams and cavities. For the inspection of shells and case-shot, the following inspecting instruments are required in addition to those used in inspecting shot, viz: *Calipers* for measuring the thickness of the projectiles at the side. *Calipers* for measuring the thickness at the bottom. *Gauges* for the dimensions of the fuse-hole, and for the thickness of metal at the fuse-hole. *A pair of hand-bellows; wooden plugs* to fit the fuse-hole and bored through to receive the muzzle of the bellows.

The surface of the shell and its exterior dimensions are examined as in the case of shot, particular attention being paid to the hemisphere opposite the other indication of the soundness of the metal, as the parts containing cavities will dry more slowly than the other parts. The mean weight of shells of 10 inches and under is ascertained in the same manner as that of shot, and larger ones should be weighed and stamped the same as with shot of like caliber. All projectiles rejected in the inspection should be marked with an X made with a cold-chisel; on shot near the gate; or, when turned, near one ear, and on hollow projectiles near the fuse-hole.

Elongated Projectiles.—The following Table will show the points upon which the Inspecting Officer must inform himself and report before accepting shot, and the variations he is authorized to allow:

Subject of measurement.	Allowed variations
Projectile:	
Length of cylindrical portion of body }	±0.4
Length of head }	
Length of base for sabot	±0.5
Total length of projectile	+ .15 / .1
Diameter of cylindrical portion	±0.2
Diameter of base over threads	± .01
Pitch of threads	0
Radius of head	± .05
Thickness of bottom	.1
Length of interior cavity	± .1
Thickness of walls at—inches from—	
Thickness of walls at—inches from—	
Eccentricity of axis of interior cavity at——from base	0.1
Diameter of fuse (or screw-plug) hole.	± .01
Pitch of thread on fuse (or screw-plug hole)	0
Length of thread on fuse (or screw-plug) hole	± .1
Diameter of hole for shell-hooks	± .01
Depth of hole for shell-hooks	± .05
Distance from base of projectile	± .02
Weight of projectile, pounds	± .2
Sabot:	
Height of sabot	± .02
Exterior diameter of sabot	± .02
Interior diameter of sabot	± .01
Maximum thickness of outer lip	± .01
Minimum thickness of outer lip	± .01
Depth of cannelure	± .03
Maximum width	± .01
Weight of sabot	
Weight of sabot and projectile, pounds	± .2

No. of—— inch —— examined	Weight of total number accepted
No. rejected for erroneous dimensions of head.	Mean weight of projectile.
No. rejected for erroneous dimensions of cylindric body or base	No. of sabots examined...
No. rejected for erroneous dimensions of interior cavity	No. of sabots rejected for erroneous dimensions...
No. rejected for eccentricity of interior cavity...	No. sabots rejected for defects in material or finish
No. rejected for defects in material or finish	Total number of sabots rejected
Total number rejected....	No. of sabots accepted....
Total number accepted....	Weight of total number accepted
Weight of heaviest one accepted	Mean weight of sabot......
Weight of lightest one accepted	Weight of total number of shot and sabots accepted

fuse-hole. Cavities and imperfections in casting are generally found about 30° from the top of the shell when in the position in which it was cast. Shells should be rejected for rough casting, projecting seams, sand-flaws, a collection of dross, cavities or honey-combs of more than two-tenths of an inch in depth, whatever their diameter, or a number of small holes giving the projectiles a spongy appearance.

The shell is next struck with the hammer to judge by the sound whether it be free from cracks; the position and dimensions of the ears are verified. The thickness of the metal is then measured at several points on the great circle perpendicular to the axis of the fuse-hole. The diameter of the fuse-hole, which should be accurately reamed, is then verified, and the soundness of the metal about the inside of the hole is ascertained by inserting the finger.

The shell is now placed upon a trivet in a tub containing water deep enough to cover it nearly to the fuse-hole; the bellows and plug are inserted into the fuse-hole, and the air forced well into the shell. If there be any holes in the shell, the air will rise in bubbles through the water. This test also gives an-

The following instruments are required and used as indictated:

1. One large ring-gauge, with handle; interior diameter 0″.03 less than the diameter of bore of gun.

2. One small ring-gauge, with handle; interior diameter 0″.07 less than the diameter of bore of gun.

3. One cylinder-gauge made of cast-iron and five calibers in length; interior diameter same as large ring.

4. Calipers for measuring the thickness of the walls of the shot or shell and determining the eccentricity. This instrument consists of two parallel arms, formed by a continuous steel strap. One arm is terminated by a curved point, and is graduated into inches and quarters, from the end toward the center; the other arm carries a socket, at right angles to its length, through which slides a graduated measuring-rod. The zero of the scale corresponds to the position of the rod when it is in contact with the curved point, and a vernier-scale on the socket permits measurements to 0″.01. To use the instrument, the arm with the curved point is inserted into the cavity through the screw-plug hole, and the clamp is screwed fast

at the required point. Two short cylindrical arms on the clamp serve as bearers, and allow a motion of the instrument only on its own plane. The eccentricity of a spherical projectile is measured by the distance of the center of gravity from the center of figure. In oblong shot, however, it varies directly for each cross-section from the seat of the core, which is near the screw-plug hole, to the head of the cavity, and is measured by the angle made by the axis of the cavity with the axis of the projectile. To determine the axis of the cavity, the greatest and least thickness of the walls are measured at two or more depths. Half the difference between the two will give the distance between the axis of the cavity and that of the projectile for that particular section. It is ordinarily considered sufficient, however, to determine the eccentricity of but one cross-section near the center of gravity and compare it with the known results of previous experiments.

5. The first intimation of eccentricity is shown upon the *rolling-table*, which consists of a heavy cast-iron plate, beveled with great care, and two parallel rails attached to it and separated from each other by a distance slightly less than the length of the cylindrical part of the shot. When a shot is rolled upon the rails, the heaviest side must come to rest beneath, and a more or less readiness to assume a particular point of rest indicates approximately the amount of eccentricity.

6. *Measuring-rod* for determining the length of cavity; made of steel and graduated into tenths of an inch for a short distance on each side of the point indicating the proper length.

7. *Gauge*, for length of screw-plug hole; made and graduated like the preceding.

8. *Templet*, for gauging the profile of the shot; made of steel; graduated to indicate the length of head, position of shell-hook holes, length of cylindrical part, and total length.

9. *Gauge* for the Butler sabot. This is made of steel and in two parts; the one screwed upon the other when not in use. The lower part gauges the sabot as regards pitch and length of thread, length and thickness of ring; the upper part gauges the length and pitch of the thread upon the base of the shot. A *small templet* gauges the depth and width of cannelure and thickness of outer lip.

10. One *hammer*, weighing half-a-pound, having a flat face and conical point.

11. One *searcher* of steel wire No. 20, with handle; *steel punches* and a *cold-chisel*.

The shot should be inspected before it becomes rusty. It is first placed upon the rolling-table and examined with the eye for defects in material, which in shot cast with the head down, are apt to occur as cavities in and about the base. These, when discovered, are probed with the "searcher" or steel punch; if more than 0".2 deep, or of such character as to suggest weak, imperfect metal, the shot is condemned. The head of the shot is struck with the hammer at its junction with the cylindrical part, for the purpose of detecting cracks liable to be produced there in cooling chilled shot. A dull sound indicates the existence of such a defect, which is further tested by hammering with a sledge. It is then rolled, and, should the amount of eccentricity be considered doubtful as regards that allowed, is measured with the calipers. The length of cavity and of screw-plug hole are then verified, and the templet applied to the profile. Rolling it from the table, it is stood on end and the gauge screwed to the base. The sabot is then screwed to its gauge, the dimensions of the cannelure verified with the small templet, and the character of the metal examined. The sabot and screw-plug are then fitted to the shot, and it is again stood on its head and the ring-gauges are applied to it. The smaller should not pass over the shot at all; the larger should pass over its entire length. It is then passed through the cylinder-gauge, which is fastened, slightly inclined, to a block of wood; the weight is finally determined and stamped at once upon the body of the shot near the sabot. Shot and shell rejected during inspection are marked with an X made with a cold-chisel.

With each lot of shot, and from the same metal, is cast a cylindrical column about 2 feet high and 2½ inches in diameter in a sand mold, and the head of a projectile in the usual iron mold. As soon as cool and before the shot have been sent to the "finishing shop" a test specimen is cut from the column, its specific gravity determined, then broken in the testing-machine, and its fracture examined. The chilled head is split under a hammer to expose the depth of chill, and the results so determined are compared with an occasional shot cut open along its axis. Should the tenacity, density, or chill be unsatisfactory the entire lot is condemned.

Chilled shot are intended for the penetration of wrought-iron plates, and were the result of experiments to substitute for the steel projectiles first used one of cheaper material of the requisite hardness.

A fracture of the head of a chilled shot presents the following appearance: The exterior layer is white, of crystalline structure, the crystals being disposed normal to the exterior surface. The central part is dark, granular, and less compact than the rest of the mass, showing the presence of considerable graphitic carbon, while the intermediate layers show less graphite and grow harder and denser as they approach and finally blend with the exterior.

Different metallurgic processes, and among them the repeated fusion of iron, qualify it for chilling. The desired result has been obtained in England by adding to a mixture of gray iron and shot scrap four per cent. of ilmenite, an ore of iron in combination with titanic acid, and containing—

Iron oxide (equivalent to 45.3 metallic iron)	61.4
Titanic acid	33.2
Silica	4.2
Tin oxide	1.2
Manganese	Trace.

In consequence of the chilling process, the head is so hard as to resist even a file, while the cylindrical body is soft mottled iron. The head is not touched after casting in order to preserve intact the skin, which is the soundest and densest part.

The chilling power of the metal-mold, which depends upon its heat-conducting power, varies with its thickness and somewhat with its own temperature and that of the melted metal when poured into it. The specific gravity of chilled cast-iron is greater than that of gray or mottled iron, and this fact is used in discovering the depth of chill of a shot by weighing the shot first in air and then in water, and comparing the results with those obtained from a standard projectile of the same weight in air. The shot which weighs the less in water will be chilled to the less extent, since the discrepancy must be due to the lower density of its chilled head. See *Projectiles* and *Shell-gauge*.

INSPECTION OF SMALL ARMS.—All the materials used in the manufacture of arms must be of the best quality, and they should be tested by the Inspectors according to the prescribed methods. The wood for gunstocks should be seasoned at least three years and kept in a dry place two years before being worked. It must be free from knots and sap, and no wood which is brash or light or worm-eaten, or in any degree decayed, or which is cut across the grain at the handle of the stock, or which is kiln-dried, should be used or received. The following rules for inspection apply to all small-arms, whether made at the national armories or by contract at private establishments. The attention of the inspecting officers should be directed as much as possible to the operation of the workmen in the course of the fabrication of arms. Each component part is first inspected by itself and afterward the arm in a finished state. The material and the forms and dimensions of all the parts must conform strictly to those of established patterns, the workmanship and finish must equal those of the model arms, and the several parts must be browned, blued, case-hardened, or polished, as in the standard model. The forms and dimensions of the parts are verified by means of standard gauges.

The barrels are inspected in each of the following stages: Rolled, first straightened, first bored, second bored, third turned, third bored, second milled, ground, proved, fourth bored, fifth bored, second polished, rifled, second muzzle filed, sixth milled, seventh milled, fourth turned, fifth turned, cut, profiled, filed, and browned. In these inspections the Inspector will verify the barrel with proper gauges for each stage. He will see that the thread for the receiver on the barrel is well cut and the bayonet-stud well brazed on; that the exterior and interior dimensions of the barrel are correct; that there are no interior hammer-marks, ring-bores, cinder-holes, flaws, cracks, or other defects which will not disappear in finishing.

The barrels rejected for defects that can be remedied will be stamped on the upper side near the breech with the mark of condemnation, which is always the letter C. If the defect be of such a nature as not to prevent the use of the barrel for a shorter arm when cut off, the mark will be made on the defective part.

The barrels will be proved in the ground stage. They wlll be fired twice with the following charges:

First Charge.			Second Charge.			Size of Ball.	
Powder.	Ball.	W'ds.	Powder.	Ball.	W'ds.	Weight.	Diameter.
Grains. 280	No. 1	No. 2	Grains. 250	No. 1	No. 2	Grains. 500	Inches .43

The wad is formed by rolling up a strip of paper 0".01 thick, 1" wide, and 12" long.

One wad is placed on the powder and the other on the ball, and the charge is well rammed with a copper rod. The wad occupies, when rammed, about ¾" in the length of the barrel. The barrels are closed for proof with proving-plugs, having vents in them. During the loading the vents are closed by leather thongs. The barrels are clamped down in a semicircular bed capable of holding about 40, with the proving-plugs abutting against set-screws working through a rim around the bed. The barrels are prevented from moving forward, under pressure of the set screws, by collars screwed on the barrels at their rear ends, which abut against a rim parallel to the one mentioned. In order to prevent accidents, it is prescribed that each barrel as soon as loaded shall be carried to the proof-room and placed in the bed. When the bed is full the leather thongs are removed. A powder-train is laid in a groove containing the vents. The train is fired from the outside of the room by means of a percussion lock and cap.

Musket powder will be used for proving the barrels of rifles and carbines; the powder must be of the best quality as regards the initial velocity and pressure; it must be proved immediately before being used, unless it shall have been proved within one year and the Inspector has no reason to suppose that it has become deteriorated. The measures for the proof-charges should be of a conical form, with the mouth as small as may be convenient, in order that there may be less variation in the quantity of the powder. Before commencing the proof of barrels, the Inspector will satisfy himself as to the quality and proof of the powder, the size of the balls and of the wads. After each discharge he will pass the ramrod into each barrel, and those which have missed fire will be reprimed and discharged before proceeding to the proof of another lot. After each proof-charge the Inspector will examine the barrels which have burst and note the cause of the defect, whether in the material or workmanship. He will examine those which have not burst, and will condemn any which are evidentally defective. He will stamp the letter P after each round on every barrel which successfully endures the test. The letter is stamped on the under side of the barrel and near its breech-end. To avoid errors, the stamping is done in the proof-room. After the second polishing, the barrel receives the final stamp, viz: V. for viewed, P. for proved, and the eagle's head under them, placed on its upper left side just in front of the receiver. After firing, the barrels should be washed clean in hot water. The examination is then made. They should be inspected in the interior and on the exterior.

The Inspector will reject such as are too large in the bore, and such as have holes, cross-cracks, scales, seams, or ring-bores; he will examine the brazing of the bayonet-stud and see that the barrel is not notched too deeply or indented inside. The barrels having been reduced to their ultimate dimensions, straightened, and completely finished, are again carefully inspected to verify the straightness of the bore, the exterior and interior diameters, and their weight, which should not vary more than one ounce from the standard weight. The straightness of the barrel may be ascertained by holding it up to the light and reflecting a straight edge on the different parts of the bore, by which means an experienced eye readily detects any inaccuracy in the bore. The small or standard gauge should pass freely through the whole length of the barrel, and the bore should not admit the large or limit plug. The grooves should be carefully examined to see that they are formed according to the pattern, and that they are even and uniform throughout. The breech-screws and receivers will be examined to see that they are of the proper dimensions, are sound in every part, and have good threads. They are case-hardened. The screw must be tried in the receiver to see that it occupies all the threads in the tap of the receiver. *Marks*—Barrels condemned for defects detected after proof, or at any time in the course of inspection, are marked with the letter C, struck in deeply. The breech-blocks are stamped "U. S. Model;" also with the year of adoption of model, just in rear of the hinge. The number of the gun is stamped on the upper rear portion of the receiver. The barrel, receiver, and breech-block having been assembled, they are placed in a skeleton frame. One round is fired with 80 grains charge: "P" is then stamped on the barrel, immediately below the eagle's head. The gun is then completely assembled, and fired five rounds with service-ammunition to see that all the parts are in perfect working order. If all be found satisfactory, "P" is stamped on the under side of the stock, in rear of the guard-plate.

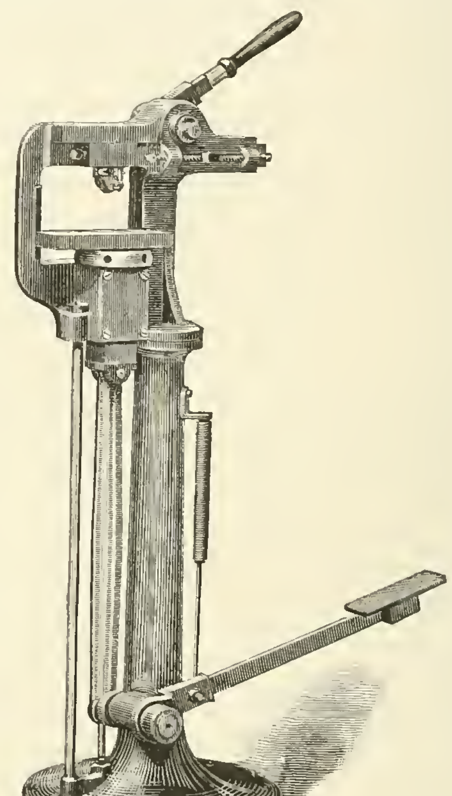
The locks having been put together the Inspector observes; 1st. That they are clean in the inside; 2d. That the sear works freely when the sear-screw is driven as far as it will go, and that the nose is sufficiently strong and falls properly into the notches of the tumbler; 3d. That the bridle has no cracks or flaws about the holes for the tumbler-pivot and screws; 4th. That the springs are well bent and of good proportion, that the fixed branches fit close to the lock-plate, and that the movable branches swing clear of it without having too much play; 5th. That the slits of the screw-heads are not defective; 6th. That the arbor and pivot of the tumbler fit accurately in their holes; 7th. That the hook of the tumbler does not fall below the edge of the lock-plate when the cock is drawn; 8th. That the notches of the tumbler are sound and smooth, and that the tumbler fits and turns well; 9th. That the main-spring swivel is sound by snapping the hammer several times on the bare cone; 10th. That the hammer fits well on the square of the tumbler, and that it does not rest on the lock-plate when screwed up tight, and that it has the proper set in relation to the firing-pin; 11th. That all the parts work well together. The lock is adjusted so that when cocked a scale attached midway of the finger-piece of trigger will pull off at from five to seven pounds. When mounted in stock the pull on the trigger should be not less than six nor more than eight pounds. The place of fabrication is stamped on the lock-plate, with the letters "U. S." over it. An eagle is stamped just in rear of the former stamps. The initials of the Master Armorer or principal Inspector are stamped on the stock opposite the rear end of the lock with italic letters.

The soundness and freedom of the ramrod from flaws and cross-cracks are ascertained by the sound it gives when suspended by one end and gently struck with a piece of metal, and by bending over a curved piece of oak plank, 31½ inches long and 5 inches high at its middle point, one end of the rod being held by a staple. The rod should be turned at the same time so as to present the different portions of the surface successively to inspection. The diameter and length of rod are verified by proper gauges. The fitting of the groove is ascertained by drawing and returning the rod smartly several times to see that it holds well and does not stick too tight; the ramrod must bear on the rod-stop, and in that position its head should not project beyond the end of the barrel; it should fill the groove well; the open part of the groove should be in the center of the stock, the covered part in the middle of the thickness of the stock, between the outside and the bottom of the barrel-groove, and the rod should not interfere with the front side-screw.

The form and dimensions of the bayonet are verified with the proper gauges. The temper is tried by springing the bayonet attached to a barrel, the point resting on the floor. The bayonet is also tested in the following manner: A curved piece of oak plank, 16⅝ inches long, 3 inches high at each end, and four inches at the middle is securely attached to the workbench. A staple is fastened at one end of the curve, and a metal bridge ½ inch high at the other. The point of the bayonet-blade is placed in the staple, and the bayonet, fixed on a barrel, is bent, face and back alternately, over the plank. In this situation the blade is also examined for flaws and cross-cracks. It should not remain bent after this trial. The Inspector then seizes the blade near the point, and strikes the elbow on the workbench to ascertain that the welding is sound. If the proof shows no defects, he verifies the dimensions and bore of the socket and the accuracy of the channels. He examines the dimensions of the clasp to see that it fits well to the shoulder; that it turns evenly without binding in any part; that the stop is well placed and firmly set; that the clasp-screw and its thread in the stud of the clasp are well cut; that the elbow has the proper form and dimensions. Bayonets are marked on the face of the blade, near the neck. Those rejected for defects that cannot be remedied are marked with the stamp of condemnation.

The examination of the stock is directed—1st. To the quality of wood; that it has good straight grain, is well seasoned, and free from sap and worm-holes. The degree of seasoning is indicated by the smell of wood; by the appearance of the lock and barrel, etc., when removed from the stock; they will be rusted by unseasoned wood; by rolling a thin shaving between the fingers it will crumble if the wood be well seasoned, otherwise it will be tough and will bend. The medium weight of a well-seasoned rifle-stock is 1 pound 14 ounces; of a carbine-stock, 1 pound 11 ounces. Stocks made of good walnut will not weigh more than three ounces less than these weights. 2d. To the workmanship; that it is free from splits, especially about the barrel-groove and heading; that the grooves and beds are of the proper forms and dimensions; that the roundings for the bands are smooth and accurate; that the stock has the proper *fall* or crook, and is of the right length; that the holes are well drilled, and that those for the wood screws have good threads. In examining the bed of the lock, see—1st. That all the edges are sharp and smooth; 2d. That the beds of the sear-screw and sear-spring screw are not bored down to the trigger or to the breech-screw; 3d. That the beds of the main-spring and main-spring screw do not penetrate to the barrel; 4th. That the holes for the tang of the sear are as small as possible, so that the sear shall not be wood-bound; 5th. That the wires fit well in their holes *Marks*—The stocks inspected are marked on the left side with the stamp of approval (the initial of the Inspector's name), or of condemnation, as the case may be.

The front part of the trigger at half-cock should be nearly perpendicular to the surface of the guard-plate; the slit of the trigger should be of the exact width, so that the trigger shall have no lateral motion. It is important that the guard-plate should bear firmly on the wood in every part, as otherwise by driving the tang-screw too hard the trigger might be brought too close to the sear, and the action of the lock be thus interfered with. The butt-plate should be well fitted in the center of the stock. The bands should fit smoothly at the shoulders, and closely to the stock and barrel, but not so tight as to



require a great effort to remove them. The band-springs should not be too deeply set; they should spring back freely when pressed down; the holes for the wires should not interfere with the barrel or ramrod grooves. All the mountings should fit smoothly to the stock. The stock should have the proper fall or crook, which is ascertained by applying the pattern, and by trying the piece in the position of aiming. By sighting along the barrel it will be seen whether it is well stocked; whether the bands, the front and rear sights, and the bayonet, are well set.

The Inspector is not restricted to the particular examinations above mentioned; he will make any other examinations which he may deem necessary to ascertain the quality of any part of the arms and their conformity to the standard models; if he discover or suspect any attempts on the part of the workmen to cover or conceal serious defects, he will subject the arms to the most severe scrutiny in order to detect such defects. In the inspection of contract arms the Inspector will judge of the quality of materials and workmanship by the rules which govern in like cases at the national armories without exacting in any case more rigid conditions than are enforced at those establishments. The Ordnance Officer charged with the inspection of arms, or the Master Armorer at the national armory, will cause at least one in twenty of each lot of arms passed by a Sub-inspector to be taken to pieces in his presence, and he will examine them strictly, agreeably to the foregoing directions, before affixing his stamp of approval on the finished arms, all of which must be examined by him. As a general rule, every part condemned, on inspection, will be indelibly marked with the letter C, and every principal part approved will be marked with the initials of the Inspector's name. Care must be taken that the marks of approval are not stamped so deep as to be injurious. Finished arms approved in inspection will be marked on the left face of the stock with the initials of the name of the principal Inspector and the year of inspection. The drawing shows the marking-machine used for stamping the letters etc., on the finished work. It is so constructed that roller dies may be used on flat surfaces, or flat dies on work of cylindrical form. The die is fastened to a sliding carriage, or rack, is made to traverse the work by a hand-lever, and is brought to bear on the work by a foot-lever, the work being held on the tables by a suitable fixture. The machine has both horizontal and vertical adjustments, and is mounted on a column of convenient height.

The inspection of revolvers should include the following: 1. *Bluing*—Examine the polishing and bluing of the cylinder, barrel, and frame, and see that all sharp edges and corners have been removed. 2. *Opening*—Bring the hammer to half cock, and open in usual manner. 3. *Testing in "skeleton" revolver*—Remove the cylinder from the frame and place it in a "skeleton" revolver carefully made for the purpose, and test the cylinder and ratchet to see that they will interchange. The cylinder is removed by turning the cylinder-catch-cam screw back one-half turn, thus liberating the cylinder-catch. 4. *Extractor*—Examine the extractor and extractor-spring; see that the extractor is held to place in cavity in cylinder; that the spline and steady-pin do not allow the extractor to project over the chambers of cylinder; and that the extractor fits the cavity in the cylinder, see that extractor-spring is properly wound and holds extractor to place. Test extractor-stem, turning the stem back one-eighth turn by placing pin in the hole of head. Test the screw by bringing it back firmly to place. 5. *Cylinder-catch*—Cylinder removed, revolver at half cock. Test cylinder-catch-cam screw, turning to place; see that cylinder-catch cam brings the cylinder-catch to place, firmly holding the same, and that the mark on head of catch-cam screw corresponds with the mark on the cylinder-catch. Test cylinder-catch with frame and barrel-catch. Closing the revolver, holding the barrel-catch back by thumb of right hand, see that cylinder-catch passes over incline of frame freely, yet rides over same, having a bearing on rear surface; that tang of barrel strikes on top of the post of frame, not allowing the cylinder-catch to rest on the frame except at incline. 6. *Barrel-catch*. See that barrel-catch opens sufficiently, passes over cylinder-catch freely, and holds same firmly to place; that it is clear of the barrel-tang at all points except where it engages with hook on cylinder-catch. Test the barrel-catch spring and barrel-catch screw. 7. *Action of barrel and cylinder catches*—Open the revolver, let the hammer down, and endeavor to close the revolver; see that barrel-catch prevents by being forced back on hammer; bring revolver to half-cock; close it; see that barrel-catch is forced back by under side of cylinder-catch hook, properly engaging with same under the influence of barrel-catch spring. 8. *Hammer-nose or firing-pin*—Bring the hammer to full cock. Snap off. Examine nose of hammer and see that it projects sufficiently. See that the bearing for the extractor-stud is correct. 9. *Cylinder, etc.*—Examine rachet and extractor-stud; test stud with a socket-wrench; test extractor with chambers of cylinder with a plug-gauge. 10. *Lock-work*—Bring hammer to full cock. Examine the hand and test hand-spring. Test the stop-spring. Examine base-pin. 11. *Adjustment*—Set the hammer to half-cock; turn the cylinder-catch-cam screw back one-half turn; open cylinder-catch; replace the cylinder and turn the catch-cam screw back to place. Close the revolver. See that the cylinder is free and properly adjusted with the cylinder-catch; that it revolves freely on the base-pin; that it rotates in either direction; that the gas-ring is free from the barrel; that the hand does not rest against the ratchet; that the extractor-stud is properly adjusted to the recoil-plate, holding the cylinder on end of base-pin, allowing no longitudinal play. Gauge distance of cylinders from barrel, limits 0″.006 and 0″.008. Gauge distance of cylinder from recoil-plate, which should be 0″.065. 12. *Joint and limb work*—Work the joint of the barrel and frame, testing and adjusting it by the joint-pivot screw. See that the friction-collar moves freely on the joint pivot. By working the joint of the barrel and frame, test the extractor, extractor-spring, lifter, friction-collar, pawl and pawl-springs. See that extractor works freely, projects to the proper distance, and returns when released from lifter by the pawl; that extractor-spring works freely, is of proper strength, returns the extractor quickly and holds it firmly in its place; see that the lifter works freely on joint-pivot, engaging with pawl and is held by same under the influence of pawl-spring until released. See that pawl works freely on pawl-pin, in frame; that the catch on the front end of the pawl engages promptly with catch on the lifter, under the influence of the pawl-spring at the rear end of the pawl, and is released by front end of the pawl passing up the incline in front of joint; that the pawl-spring is of proper strength. 13. *Screws and pins*—Examine and test the cylinder-catch, hammer-stud, side-plate, guard and stock screws. Try each screw, bringing it down to its bearing, if not down; turn back one-eighth of a turn, then back to place; see if the parts come together. This verifies the countersinking of the holes, thickness of head, and length of screw. Examine and test pawl, stop, and trigger pins. 14. *Stock*—Examine material and workmanship. 15. *Pull*—Weigh the pulling off, which should be 9 pounds, with limits, 8 pounds and 10 pounds. See that it cannot be pulled off when at half-cock. 16. *Alignment of barrel and cylinder*—This may be tested by placing steel "thimbles" in the chambers, bringing to full cock and inserting a caliber-gauge at the muzzle. The lower end of this gauge has a tenon which fits the inside of the "thimble." If the axis of the chamber does not coincide with that of the barrel, the gauge will not go down. The "thimbles" are similar in form to the cartridge-shell 17. *Action of revolver*—To test: Grasp the revolver with left hand, near joint, barrel resting between thumb and forefinger, the index-finger resting on barrel, the second finger against cylinder-catch and on the cylinder with the third finger; thereby allowing the necessary amount of friction to be applied to test the lock-work. Slowly cocking the revolver with the right hand, test the working of the hand and ratchet, hand-spring, stop and stop-spring, stop and stop notch in cylinder. See that stop leaves stop notch in cylinder before the hand takes hold of ratchet; that sear enters the half and full cock-notches of hammer promptly, and does not "creep" when released by pressure on trigger; that hammer works freely in frame; that the mainspring has proper action on hammer and is correctly adjusted by the strain-screw. Rest butt of revolver firmly, cock rapidly, and see if the stop notch in cylinder is thrown past the stop bolt; try each notch. 18. See that the arms are properly stamped and numbered, and that they have sustained no damage during assembling and inspection. See *Fabrication of Fire-arms*, and *Small-arms*.

INSPECTION OF TRANSPORTS.—In inspecting water transportation for troops, the Inspector must be governed by circumstances and necessities. Military emergency is not unfrequently a controlling consideration, but should never cause undue risk to life. In an ordinary condition of things, and especially in voyages of any length, Inspectors are to see that the vessels provided are such as promise reasonable comfort to passengers. If there be anything to indicate necessity for a critical inspection, the services of an expert are to be employed.

The Inspector should examine the contract and see that its stipulations are complied with, and ascertain how the vessel is rated at the underwriters; the age of the hull and machinery, and their existing conditions, so far as he can judge. He should inquire when the vessel was last in dock, the condition of the boilers, and when last put in. He should examine whether the outfit of tackle, spare spars, etc., is sufficient; whether there is an ample provision of boats, life-buoys, and deck-room enough for quarters for officers and enlisted men, and if the limit of the Act of Congress defining the relation of tonnage to passengers is not exceeded. He should see that the vessel's crew is large enough for her proper working, and inquire into the competency of the officers; that there are the proper instruments of navigation, compasses, etc.; report if the chronometers have been rated, and if there is a supply of charts. The water tanks and butts are to be looked at to see if there is water for passengers and crew. He should specially inspect the cooking arrangements, see that the vessel is clean, and that the portion occupied by troops is dry and well ventilated.

In order that the paddles may be secure from the action of the waves, in a side-wheel sea-going steamer, the projection on the sides under the guards, called the sponsons, should be covered up to make that portion as solid as any other part of the ship; the keel, stern-apron or inner stern, futtocks, floor-timbers, dead-wood, stern-post, transom, inner post, frame and filling timbers abreast of the engine, the wales, the rudder and rudder fastenings, should be increased in strength twenty-five per cent. over those of river steamers. The weight of machinery should be below the water-line. The vessel should be high between decks and well ventilated by hatches, wind-sails, and side-lights. There ought to be water-closet and temporary bath arrangements. Provision for sufficient masts and sails in the event of accident to the motive power, should be made, and there ought not to be less than a fore and aft sail to each mast set upon a gaff, and a trysail to each mast to be set in a storm. See *Transports.*

INSPECTION OF TROOPS.—A close examination of troops is generally made each Sunday morning and previous to muster. In the United States Army, a battalion is inspected as follows; *Dismounted Troops.* The battalion being in line, bayonets fixed, the Colonel causes it to break into column of companies, right in front, and commands; *Rear open order*, 2. MARCH. At the first command, the right and left guides of each company step three yards to the rear to mark the alignment for the rear rank. Each Captain hastens to the right, verifies the position of the guides, and then places himself facing the left, three yards in front of the right file. The Adjutant places himself on the left of the color-guard, and commands: 1. *Forward*, 2. *Guide left*. At the command *march*, the ranks are opened in each company; the Adjutant conducts the color-guard to the head of the column, posts it twelve yards in front of the center of the leading company, and then brings it to rear open order. The Drum-major conducts the band, passing by the right flank of the battalion, to the rear of the column, and posts it, facing to the front, twelve yards in rear of the rear company. The Colonel next commands: 1. *Field and staff to the front*, 2. MARCH. The commissioned officers, thus designated, form in the order of rank from right to left, fieldofficers on the right, on a line equal to the front of the column, six yards in front of the colors, the non-commissioned staff form in a similar manner, three yards in rear of the field-officers. The Colonel, seeing the movement executed, takes post on the right of the Lieutenant-colonel, and awaits the approach of the inspecting officer. Such field and staff officers as may be superior in rank to the Inspector do not take post in front of the column, but accompany the inspecting officer. After inspecting the field and staff, the Colonel commands: 1. *Order*, 2. ARMS, and the Inspector, accompanied by these officers, passes down the open column, looking at every rank, front and rear. The field and staff return their swords as soon as inspected. The Colonel now commands: 1. *In place*, 2. REST. When the Inspector, commencing at the head of the column, proceeds to make a minute inspection of the non-commissioned staff, color-guard, and the several companies in succession. The Adjutant gives the necessary commands for the inspection of the color-guard. The non-commissioned staff and color-guard may be dismissed as soon as inspected. As the Inspector successively approaches the companies, the Captains command: 1. *Company*, 2. ATTENTION, 3. *Inspection*, 4. ARMS. The Captain, as soon as inspected, returns his sword, and accompanies the inspecting officer; Lieutenants, when the Inspector begins the inspection of the front rank, face about and stand in place rest; the arms, accouterments, and dress of each soldier having been minutely inspected, the Captain commands: 1. *Open*, 2. BOXES: when the ammunition and boxes are examined. The Captain then closes ranks, stacks arms, opens ranks, and commands: 1. *Front rank*, 2. ABOUT, 3. FACE, 4. *Unsling*, 5. KNAPSACKS, 6. *Open*, 7. KNAPSACKS. The men of the front rank having faced about take a short step forward so as to be free from the stacks. At the command *unsling*, each man unfastens his knapsack, and, standing erect, holds it by the straps in front of the knees, flap from him; at the command *knapsacks*, he places the knapsack on the ground, flap upward, the great-coat six inches from the feet, and then stands at attention; at the seventh command, he opens the knapsack, turning the flap toward the feet, the flap resting on the great-coat; he then stands at attention. The Inspector having inspected the knapsacks, the Captain commands: 1. *Repack*, 2. KNAPSACKS. At the command *knapsacks*, each soldier repacks and buckles up his knapsack, leaving it in the same position as before opening it, and then stands at attention. The Captain then commands; 1. *Sling*, 2. KNAPSACKS. At the command *sling*, each man grasps the unbuckled strap of the knapsack with the right hand, the buckled strap with the left hand, the right hand uppermost, and stands erect, the flap of the knapsack from him; at the second command, he replaces the knapsack on his back. The Captain then commands; 1. *Front rank*, 2. ABOUT, 3. FACE. The men of the front rank having faced about, step forward to the line of stacks; the Captain then closes the ranks, takes arms, and on intimation from the Inspector, marches the company to its quarters and dismisses it. In a long column, some of the rearmost companies after the inspection of dress and general appearance, may be permitted to stack arms and break ranks until just before the Inspector approaches them, when they *take arms*, and resume their position. The band plays during the inspection of the companies, and is brought to rear open order by the Drum-major on the approach of the Inspector. Each man as the Inspector approaches him raises his instrument in front of the body, reverses it so as to show both sides, and then returns it to its former position. In column of several companies, the inspection of dress and general appearance may be dispensed with, the battalion being brought to an order, and in place rest, as soon as the field and staff have been inspected. At inspection of quarters, the Inspector is accompanied by all the officers, or by such of them as he may designate; the men, with gloves and accouterments, stand covered in front of their respective bunks; in camp they stand in front of their tents; the senior non-commissioned officer upon the approach of the Inspector, commands: 1. *Company* (or *squad*), 2. ATTENTION.

Mounted Troops.—The battalion being in line, the Major causes it to break into column of companies, right in front, and commands: 1. *Rear open order*, 2. MARCH. At the first command, the Adjutant places himself on the left of the guard of the standard, if the standard be with the battalion, and commands: 1. *Forward*, 2. *Guide left*. At the command *march*, the ranks are opened in each company; the Adjutant conducts the guard of the standard to the head of the column, and posts it six yards in front of the officers of the leading company, opposite the center of the company. The band, if there be one, passes by the right flank of the battalion, to the rear of the column, and takes post, facing to the front, twelve yards in rear of the rear company. The trumpeters of the battalion, if consolidated with the band, return to their respective companies; the Major's trumpeter places himself on the right of the trumpeters of the leading company. The Major nexts commands: 1. *Field and staff to the front*, 2. MARCH. The commissioned officers, thus designated, form in the order of rank from right to left, field-officers on the right, on a line equal to the front of the column, fifteen yards in front of the standard; the non-commissioned staff form in a similar manner, six yards in rear of the field-officers. The Major, seeing the movement executed, takes post on the right of the field and staff, and awaits the approach of the inspecting officer. Such field and staff officers as may be superior in rank to the Inspector do not take post in front of the column, but accompany the inspecting officer. After inspecting the field and staff, the Inspector, accompanied by these officers, passes down the open column, looking at every rank, front and rear. The field and staff return their sabers as soon as inspected. The Inspector, having returned to the head of the column, proceeds to make a minute inspection of the non-commissioned staff, guard of the standard, and the several companies in succession. The Adjutant gives the necessary commands for the inspection of the guard of the standard. The non-commissioned staff and guard of the standard may be dismissed as soon as inspected. As the Inspector successively approaches the companies, the Captains command: 1. *Inspection*, 2. ARMS. The Captain, as soon as inspected, returns his saber, and accompanies the inspecting officer; the Lieutenants, when the Inspector begins the inspection of the rank, face about and remain at ease, unless otherwise instructed.

After inspection of dress and general appearance, if the Inspector desires to inspect the companies dismounted, instead of mounted, the Major dismounts the battalion and forms rank. The horses of the officers are held by trumpeters. The inspection is conducted in the same order as before. At the command: 1. *Inspection*, 2. ARMS, the men take the reins off the horses' necks, pass the right arm through the reins, face to the front, and *unsling carbine*. The arms are then inspected as prescribed in the School of the Soldier Dismounted. The inspection being completed, the Captain, on intimation from the Inspector, causes carbines to be slung, then mounts the company, and dismisses it.

Inspection of a Battery.—The battery being in line, the Captain commands: 1. *Prepare for inspection*, 2. *Action*, 3. FRONT, 4. *Right*, 5. DRESS, 6. FRONT, 7. DRAW, 8. SABER. These commands are executed as prescribed for review, the trumpeters also drawing saber; if the inspection has been preceded by a review, the Captain may omit the seventh and eighth commands, cautioning the trumpeters to draw saber. The inspecting officer inspects the Captain, and then the chiefs of platoon, beginning on the right; passing around the left of the battery, he inspects the chief of caissons, then goes to the right and inspects the trumpeters and guidon; the Inspector next goes to the right section of the right platoon and inspects the section; beginning with the chief, who executes *inspection saber*, he passes in front of the piece, along the right of the section, and in rear of the caisson, returning by the left of the section to the front; he then goes to the left section of the right platoon and inspects it, as prescribed for the right section; he then inspects the other sections in like manner. As the Inspector approaches each limber, No. 6 opens the lid of the chest so as to show its contents; he closes the lid as soon as the Inspector passes the limber on its left. The caisson corporal opens and closes the lid of the caisson limber-chest, as explained for No. 6; he also, when so directed, opens and closes the lids of the other chests. The trumpeters, chiefs of section, first-sergeant, quartermaster-sergeant, and the artificers when mounted, execute *inspection saber* as the Inspector approaches them. The Captain, as soon as inspected, returns saber and accompanies the Inspector. Each chief of platoon accompanies the Inspector during the inspection of his platoon; he then returns to his post, faces to the rear, and remains at ease. As soon as the forge and battery-wagon, after the commands *action, front*, have taken their places in line with the limbers and caissons, the senior blacksmith opens the lid of the limber-chest of the forge, and the wheelwright opens the battery-wagon; they then resume their posts. If mounted, they dismount and give the reins of their horses to the wheel-drivers of the forge and battery-wagon, respectively, and then conform to what has been just prescribed. The forge and battery-wagon having been inspected, each is closed by the proper artificers, who resume their posts. If they have horses, after closing the forge and battery-wagon they mount, return to their posts, and draw saber. The inspection of the battery-wagon being completed, the Captain returns to the front and center of the battery, faces toward it, and commands: 1. *Drivers*, 2. PREPARE TO DISMOUNT, 3. DISMOUNT, 4. INSPECTION KNAPSACKS AND VALISES. At the command *dismount*, all the officers and mounted men dismount; the horses of the Captain, chiefs of platoon, and chief of caissons, are held by the trumpeters, assisted by the guidon if necessary. At the fourth command, each cannoneer takes his knapsack from the carriage, returns to his post, places his knapsack on the ground, flap upward, the great-coat six inches from the feet, opens his knapsack, turning the flap toward the feet, the flap resting on the great-coat, and then stands at attention; each mounted man unstraps his valise from the saddle, and places it at his feet in the position of stand to horse, opens his valise, and then stands to horse. The Inspector, accompanied by the Captain, then inspects the knapsacks and valises, passing through the battery as before prescribed, each chief of platoon accompanying him during inspection of his platoon. The Captain then commands: REPACK KNAPSACKS AND VALISES. At this command, the knapsacks and valises are closed and strapped in their proper places; the cannoneers then resume their posts and the drivers stand to horse. The knapsack of each cannoneer rests vertically on the foot-boards of the chest on which he mounts, so as to be under his legs, the flap from the chest; the knapsacks are secured to the chest by means of a strap which is passed in front of the knapsacks, and is fastened to the ends of the chest. The knapsacks of the first-sergeant, quartermaster-sergeant, chiefs of section, trumpeters, guidon, and the artificers when mounted, are usually inspected in quarters; on the march their knapsacks, unless otherwise prescribed by the

Captain, are carried on the foot-boards of the limber-chests of the forge and battery-wagon, and in the baggage-wagons. The knapsacks and valises having been inspected, the officers mount; the Captain then commands: 1. *Drivers*, 2. PREPARE TO MOUNT 3. MOUNT. At the third command, all the mounted men mount. The inspection being completed, the Captain, upon some intimation from the Inspector, forms line, marches the battery to its park, and dismisses it. The battery is frequently inspected in full marching order—the men in blouses, and equipped with haversacks and canteens; knapsacks and valises packed; overcoats, when not worn, rolled and strapped to the knapsacks or saddles; horses equipped with nose-bags and halters; caissons loaded with a day's forage.

INSPECTION REPORTS.—Reports of the various kinds of inspections, for the information of the Inspector General. Inspecting officers, before transmitting their reports to their Commanders, indorse thereon the remedies that have been applied by the local Commanders for the correction of irregularities that may have been brought to their notice. All Superior Commanders in forwarding the reports, indorse them with their action, and such remarks as may be of importance for the information of the Commander of the Army.

Copies of all non-confidential Inspection Reports are forwarded to the Inspector General, through the ascending channels of communication. Commanding Officers only may forward copies of confidential reports.

INSPECTOR GENERAL.—Inspector and Inspector General are terms in military affairs, having a somewhat vague signification. There are Inspectors General of Cavalry, Infantry, Artillery, Engineers, Militia, and Volunteers, whose duties are really those which their names infer—viz., the periodical inspection of the several corps of their respective arms, and the pointing out of deficiences, the corps being under the command, however, of its own officers, and not of the Inspector General. The Inspectors General of Musketry and Gunnery Instruction in the English Army are charged with the direct superintendence and ordering of such instruction throughout the army. In the Medical Department, the Inspectors General of Hospitals constitute the highest grade of surgeons, under the Director General of the whole department. Inspectors are employed in many capacities. Inspectors of Volunteers are Staff Officers charged with the administration and organizing of the detached corps of Volunteers in their several districts. The post of Inspector General of Auxiliary Forces has lately been abolished, and his duties transferred to the Department of the Adjutant General, in order to bring the Militia and Volunteers more immediately under the supervision of the Commander-in-Chief.

INSPECTOR GENERAL'S DEPARTMENT.—In the United States, the law at present provides for one Inspector General, with the rank of Brigadier General; two Inspectors General, with the rank of Lieutenant-colonel; and two with the rank of Major. Also, that the Secretary of War may, in addition, detail Officers of the Line, not to exceed four, to act as Inspectors General. In the British service, the Inspectors Generals are officers appointed by the Horse Guards, with the exception of the Inspector General of Fortifications, to carry out, in the most searching manner, the duties of inspection in their respective branches, and to bring to the notice of the Commander-in-Chief all points with which he should be made acquainted. They are assisted in their duties by *Inspectors*, who act under their instructions.

INSUBORDINATION. Disobedience to lawful authority, under the following phases, viz.: 1. Striking a Superior Officer; 2. Using or offering violence against a Superior Officer; 3. Offering violence in a military prison; 4. Disobeying the command of a Superior Officer; 5. Using threatening language to a Superior. For either of the above offenses an officer or soldier is to be tried by a General Court-Martial.

INSULT.—In a military sense, to attack boldly and in open day, without going through the slow operations of trenches, working by mines and laps, or having recourse to those usual forms of war by advancing gradually towards the object in view. An enemy is said to *insult* a coast when he suddenly appears upon it, and debarks troops with an immediate purpose to attack.

INSURGENTS.—Soldiers or people generally in a state of insurrection. The term, however, admits of one exception. Hungarian Insurgents (*Insurgenten die Ungarischen*) mean the Hungarian Militia, called out or summoned by general proclamation, as under the old feudal system.

INSURRECTION.—A rising of people in arms against their Government, or a portion of it, or against one or more of its laws, or against an officer or officers of the Government. It may be confined to mere armed resistance, or it may have greater ends in view. See *Civil War* and *Rebellion*.

INTELLIGENCE DEPARTMENT—A branch of the Quartermaster General's Department, presided over by the Deputy Quartermaster General. It has for its object the collecting, sifting, and arranging of all information on subjects useful to the Government or Army in peace or war. This Department in England is comparatively of recent date. Its functions comprise:—Topography; Strategical and Tactical Questions; Concentrations; Collection of all data bearing on the organization of foreign armies; Home and Colonial Defense, etc. The information to be obtained on the above subjects is gathered in time of peace, so that, when war breaks out, the General commanding an expedition may have put into his hands the most detailed information that maps can contain of the country in which operations are to be carried on, and all such other information needful for the vigorous prosecution of the war. Formerly, whatever information the General received was through the Quartermaster General's Department, then imperfectly organized for obtaining such intelligence as is now afforded, and also by reconnoisances a day or two in advance of the Army. Now-a-days, the General is made acquainted with the country he has to traverse before he sets out, and is thus often enabled to map out his future movements before commencing operations. To the Intelligence Department may be attributed, to a great extent, the success of the German arms during the war of 1870—71. Before starting on the campaign, maps of the country the Army was to invade were largely distributed, and also handbooks containing information on many valuable points such as railways, localities, power of districts to afford food, etc.—in short, all information tending to the successful issue of the war. The Intelligence Department of England is modelled after that on the Continent, but only for defensive purposes; It is composed of Staff Officers, whose education and intelligence fit them well for the duties they have to perform. The Department may be said to be at present merely the nucleus of what will be, it is to be hoped, a still larger one. There is ample field for an increased number of Staff Officers, and in comparison with the Continental Department, the establishment is small. The following extract from a lecture given at the United Service Institution, in February 1875, by Major Brackenbury, R. A., D. A. Q. M. G. an officer of the Intelligence Department, will put the reader in possession of the information to be acquired, and the work to be performed by the Staff Officers of such a Department, as carried out in Prussia, Austria and France:—

"1. A thorough military acquaintance with the topography and resources of all lands belonging to the nation and its neighborhood.

"2. An intimate acquaintance with the armies and military institutions of foreign powers, as well as of the home armies and institutions.

"3. A scheme for movement of troops by railway, road, or water, according to probable eventualities. This is based on a study of home and foreign means of communication.

"4. Military history, which is always a mine of information if honestly drawn up according to official knowledge.

"5. Selections from the above items of knowledge carefully drawn up and published for the information of the army. This requires frequent use of the printing-press.

"6. In the three countries the Staff is charged with the issue of the requisite maps in case of war, and, for this purpose, is in close intimacy with the great map-making establishments represented by the Ordnance Survey, which is a civil branch, though conducted by officers of the Royal Engineers."

In time of war, the duties of this department would be similar to those performed by that section of the General Staff in Continental armies, with this exception, that in consequence of the paucity of officers employed in this branch of the service, it would have to be supplemented by special Staff Officers, in connection with the Quartermaster General's Department. Preparatory to the commencement of hostilities, all the information concerning the country in which the operations are to be carried on—collected and collated by the Intellgence Department in time of peace—will be furnished to the General in command, who will next have to obtain further information through this Department as to the enemy's positions, *moral*, etc., by means of outposts, reconnoissances, spies, and emissaries. The names of the enemy's Generals, the organization and the dress of his troops can then be learnt, as the capture of a single prisoner or patrol may show, even by his uniform, buttons, or lace, the presence of a particular corps. Newspapers may furnish information of great value. During the Prusso-Austrian war of 1866, the first authentic information the Prussians received of Benedeck's march from Olmütz to Vienna was derived from Brackenbury's letters. The information obtained by the means of outposts is of very great importance; and the first step taken by the Staff of Continental armies, after the declaration of war, is to draw a *cordon* of light cavalry; to this force one or two officers of the Intelligence Department are attached. One sphere of action is up to the enemy's outposts, whose movements must be watched, and all information concerning them be obtained through the videttes, reconnoissances, etc., without driving them in, to do which would need a reconnoissance in force a measure of doubtful value, as it often leads to a general engagement. The Officer Commanding an outpost is responsible for the amount, as well as for the correctness, of all the information he sends to the Officer Commanding; he has, therefore, to exercise his discretion as to what intelligence he sends in, and this should be rather too much than too little. In transmitting any knowledge he has acquired, he must adhere as much as possible to the words of the informant; but if the information be of great value, the person from whom it has been obtained, such as a prisoner, deserter, or patrol leader, should be sent in to headquarters. The information obtained from prisoners, deserters, and persons from the enemy's side, is always valuable. The first two classes do not as a rule know much, but travelers, and particularly boys, are great sources of information, as they are close observers, and are less likely to be influenced by patriotism, and a small bribe will suffice as remuneration for the news supplied.

The real rank and file of an Intelligence Department, before and after hostilities have begun, are the regular paid spies. Officers commanding outposts can make use of local spies, but the main body of these men remain attached to the headquarters, for specific purposes, under an officer specially appointed for that duty, who should possess the following qualifications:—

1. Thorough reticency.
2. Keen knowledge of human nature.
3. Distrust of all unsupported information.

Lack of information is not the difficulty in war time, for the shifting tendency of men's fears is to exaggerate dangers; the number of spies, therefore, may be safely reduced. There are two classes of spies as shown above:—1. *Local Spies.*—These are men accidentally employed, and whose business may take them into the enemy's lines. They are to be trusted in gaining intelligence; moreover, their powers of information are naturally confined to a small area, and as they are probably well acquainted with that area, and their being on business, they are not so liable to suspicion. 2. *Paid Spies.*—These should always be kept apart and in ignorance of each other. They should receive liberal pay, according to the result of work. In India, the plan formerly adopted in paying the native spies was to put a bucketful of gol mohurs before the man, and to allow him to take away as many as his two hands could hold. Some military writers lay down that all the information obtained by the Intelligence Department should be published to the army, as experience has shown that, by acting thus, surprises and panics have been guarded against, great fatigue saved, and that the best marches have been made when the men knew the object of the undertaking. Having collected the required information, the next point will be the transmission of such intelligence. This is performed in three ways:—

1. By the electric telegraph.
2. By visual signalling.
3. By mounted orderlies.

Sometimes the three are combined. The electric telegraph is applicable for long distances, between stationary points and along main lines; between camps at some distance from one another, field telegraphs may be laid down. Visual signalling is useful in broken ground, across obstacles, with ships at sea, and also for moderate distances, where the points are not stationary for any time, such as the outposts. It was found particularly useful in the Looshai expedition on the borders of Assam. For short distances mounted orderlies can be used, between points constantly moving, as well as for transmission of news in wooded countries. The following have been found good distances to transmit intelligence by the modes indicated:—

Electric telegraph, above 8 miles;
Visual signalling, 1½ to 8 miles;
Orderlies, 1 to 1½ mile.

INTENDANCE.—In Continental Armies, an establishment corresponding to the English branch of the Control Department.

In the German army it is a small Department, and the duties are more restricted and entirely civil. Until 1866, Prussia had no combatant officers attached to the Intendance. It has much less independent responsibility, and clashes less with the War Department, because it only refers to matters beyond general control, and large funds are always placed at its disposal by the military authorities; nearly two-thirds of the army expenditure is paid by it, like the Clothing Department. In France, the Intendance possesses the direction and control of everything that concerns pay, provisions (*munitions de bouche*,) contracts for the same, Clothing Department, etc. This Department is officered exclusively by officers of the army, of no lower rank than that of Captain, and whose age does not exceed 35 years; they have to pass an examination before a Board of Officers. Their functions are purely administrative, and they have no relative rank.

INTENDANT.—INTENDANT MILITAIRE.—An officer in the French army charged with the organization and direction of all the civil services attending a force in the field. The officers acting under his orders are those in charge of all the finance services, the provisions, stores, hospitals, artillery train, and transport departments, besides the interpreters, guides, and such like temporary services. The *Intendant-en-Chief* of an army is the Representative of the Minister of War; and, short of superseding the General's orders, can exercise, in case of need, all the functions of that high officer of state. The Intendance is divided into Intendants, ranking with General Officers, Sub-Intendants with Colonels, and Assistant-Intendants with Majors; besides Cadets, who receive no pay, and constitute a probationary grade.

Intendant was the name given in France before the Revolution to the Overseer of a Province. Such permanent officers were first appointed by Henry II. (1551). Under the complete system of centralization established by Richelieu, these Intendants, as they were now called, became the mere organs of the Royal Minister, to the exclusion of all provincial action. To them belonged the proportioning of assessments, the levying of soldiers, etc. The National Assembly in 1789, established in each department an elective administration. Napoleon virtually restored the Intendants, but exchanged the hated name for that of *Prefects*.

INTERCHANGEABLE.—The meaning of this word is self-evident, viz.; that which may be given and taken mutually. In military *matériel*, the term is used to express that an article which suits or fits any part of a machine, a lock of a gun, a wheel, etc., will fit corresponding parts of a like article; and thus all parts of *matériel* are for the most part made interchangeable.

INTERIOR ECONOMY—Applied to military affairs relates to the whole management of a regiment, the responsibility of which lies with the Commanding Officer, as he is the mover and director of everything pertaining to his command. It includes all duties in which the officers and men are interested, such in the former case, as their mess, band, funds, etc., and in the latter, to the messes of the non commissioned officers and soldiers, their amusements, libraries, in fact, everything tending to the good order and welfare of the regiment.

INTERIOR FLANKING ANGLE.—In fortification, the angle formed by the meeting of the line of defense and the curtain.

INTERIOR FORM OF CANNON.—The aim in all gun construction is to obtain the maximum amount of work from a given charge and weight of piece, this within the limits of safety to the piece itself. To attain this, the relations between the interior dimensions, the charge, and the projectile, have to be in each case studied and regulated with the greatest care. The dimensions of a piece are also governed somewhat by the nature of its service, and circumstances under which it is to be fired. The interior of cannon may be divided into three distinct parts; 1st, The *vent*, or channel which communicates fire to the charge; 2d, *The seat of the charge*, or chamber, if its diameter be different from the rest of the bore; 3d, The *cylinder*, or that portion of the bore passed over by the projectile. See these parts under proper headings.

INTERIOR RETRENCHMENTS.—When a breach is made in the enciente, although military usage and a point of honor require of the garrison to sustain at least one assault, the consequences of defeat are of too serious a character to expect such an effort, unless a place of safety be provided, into which the garrison may retreat after defending the breach and obtain an honorable capitulation. On this account, and also to lengthen the defence, *interior retrenchments* are made in the bastions. These works may be either of a temporary or permanent character, but it is generally conceded that the latter class alone offers a serious obstacle to the enemy. The former, moreover, requires that the retrenchment should be thrown up during the siege, an undertaking of great difficulty, both from the annoyance of the enemy's fire and the fatigued state of the garrison, occasioned by its ordinary duties. The works may be placed within the bastions, which are the parts of the enciente usually breached, or in rear of their gorges. Those which are placed within the bastions extend across them either between the faces or between the flanks. When placed at the gorge they connect the two adjacent curtains. They may be divided into four classes, viz.: 1st, those that rest against the faces of the bastions; 2d, those that rest against the flanks; 3d, those that rest against the two adjacent urtains; 4th, and those that comprehend several bastions. The plan of these works varies with their position, the size of the bastions, or the more or less openness of their salient angles. In small bastions with very acute salients, when the retrenchment rests upon the faces, it usually receives the form of a tenaille or an inverted redan, the angle of the tenaille being about 100δ. When the bastions are large and the salient angle quite open or obtuse, the retrenchment may receive the form of a small bastion front resting upon the faces. Either of these forms may in like manner be used when the retrenchment rests upon the flanks of the bastion. But as this position enables a retrenchment of the form of an ordinary redan to have its ditches swept by the fire of the flanks of the adjacent bastions, this form is in some cases used in preference. When placed between two curtains at the gorge of a bastion the plan of the retrenchment is always a bastioned front. See *Interior Works* and *Permanent Fortifications*.

INTERIOR SLOPE.—In fortification, the surface connecting the superior slope with the banquette tread. It is well to make the interior slope vertical (and it is oftentimes made so) for the reason that defenders in that case can stand close to the parapet in delivering their fire. A vertical slope would require a strong construction of some kind, to retain the earth in position, and to resist the horizontal thrust produced by the prism of rupture. When the materials for making this construction are abundant and convenient, a vertical slope, or one nearly so, may be used. A steep slope requires a strong revetment, otherwise it is to be preferred. A gentler slope requires a slighter protection, but has the disadvantage of placing the soldier too far from the interior crest when he is in a standing position: and it exposes him more to projectiles grazing the interior crest. The rarity of hand-to-hand conflicts on the parapet, and the use of breech-loading weapons, allow the use of gentler slopes for the interior of the work than were formerly regarded as admissible. Gentle slopes are accompanied, however, by the disadvantage of requiring the soldier to occupy a recumbent position when firing his piece. See *Field-fortification*.

INTERIOR WORKS.—Besides the works exterior to the enceinte, the object of which is to retard the assailant in his attempts to enter it by breaching, Engineers have placed within it other works, termed *interior works*. They are placed on such points as are exposed to be breached by the enemy's artillery, and are intended to cut these off from that portion of the enceinte not so exposed. By them the garrison is enabled to make an effectual defense of the breach when the assault upon it is made. When intended for the defense of the breach alone, they are called *interior retrenchments*. They are of various forms, being adapted to the position they occupy and the degree of resistance to be offered, and are usually constructed with a revetted scarp and counterscarp to secure them against an open assault. When a considerable command is given to an interior work over the one in which it is placed with the view of obtaining a plunging fire on points which the enemy may occupy on the exterior, it receives the name of a *cavalier*. When an interior work is detached from the enceinte and is organized to receive the garrison and rely on its own resources after the main work has fallen, it is termed a *citadel*. See *Interior Retrenchments*.

INTERN.—A term used in a military sense to express the act of giving shelter to troops which have taken refuge on neutral territory. On passing the frontier the men are disarmed and sent to the different quarters allotted to them, generally in the interior of the country; they are treated on the same footing as the soldiers of the country, and the officers are allowed to keep their arms, horses, and baggage, but have to give their parole that they will not attempt to escape. Towards the end of the war of 1870 71, Bourbaki's Army, sorely pressed by the Germans took refuge in Switzerland, to escape being taken prisoners and were interned there.

INTERNAL PRESSURE GAUGE. Various forms of the Internal Pressure-gauge have been proposed. That by Doctor W. E. Woodbridge is found satisfactory. It consists essentially of a piston having a conical cavity, pressed by the powder-gauge against a disk of copper which enters the cavity in proportion as it is crushed. The surface of the cavity is formed with a fine spiral thread, continuous from the face of the piston to the apex of the cone—the turns of their threads being divided into tenths by lines radiating from the apex. These are impressed upon the copper according to the extent that the metal has been forced into the cavity, and a reading of the number of turns of the spiral affords an indication of the pressure to which the piston has been subjected. It may be considered to be a modification of a form of Internal Gauge proposed by Captain Henry Metcalfe, Ordnance Department, the spiral cutter of which is convex. The cut on the disk is divided for facility of reading the pressure. See *Pressure-Gauge*.

INTERNATIONAL DATE LINE.—The line at which dates change, being made later by one day by those who cross the line from east to west, and earlier by one day by those crossing it from west to east. If a person start at midday, that is, when the sun was shining perpendicularly on the meridian that passes through the place of starting, and travel westward, keeping pace with the sun, thus keeping the sun directly over the meridian of the place at which he might be, he would make a complete journey around the globe in twenty-four hours; and return to his place of starting at noon the next day. Twenty-four hours would have passed, but to the traveler the sun would have been shining perpendicularly as at noon all the time; and the question arises, when or at what point did the traveler change from noon of one day to noon of the next? For instance, if he should start at Monday noon and keep the sun in the zenith, he would arrive at the place of starting Tuesday noon—it would be noon-day to him during the whole journey of twenty-four hours—Monday noon would change to Tuesday noon without an intervening night; where would the change occur? It is to him apparently still Monday noon, and to obtain the correct date he must drop a day. The reason for dropping a day can be more fully shown as follows:—Remembering that the earth makes one complete revolution on its axis in twenty-four hours, and thus the sun in its apparent diurnal revolution moves over 360 degrees of space in twenty-four hours, it thus moves over 15 degrees of space in one hour, from which it is evident that the difference in longitude which causes the difference in the relative time, may be estimated in time, allowing 15 degrees to an hour, or one degree to four minutes. Therefore, suppose a man starting from any given point, travel one degree west, his watch, instead of marking twelve o'clock at noon, according to the correct time at that place, would mark four minutes after twelve. Let him travel west 15 degrees, and he will find that 1 o'clock by his watch will be noon-day by the sun. Let him go on to 120 degrees, and when the sun is in the zenith his watch will indicate eight o'clock P. M. Completing his journey around the globe, he will have gained, in this manner, twenty-four hours. From this it will be seen that in order to obtain the correct date twenty-four hours must be subtracted from his time. On the other hand, if a person could travel eastward at the same speed with which the sun apparently travels westward (the same rate of speed with which the earth revolves on its axis), if he should start on his journey at noon-day, he would meet the sun when exactly on the opposite side of the earth from the place of starting, and continuing the journey would again meet the sun at the place of starting, thus seeing three noon-days within the twenty-four hours, or apparently gaining a day. This we know to be impossible, since only twenty-four hours of time have passed, while in reality an extra period of light has been gained, and thus to obtain the correct local date a day must be added to your time. From this we see that, for every time a person travels around the earth in either direction, there is a difference in time of one day, and the result is the same regardless of the rate of speed. To avoid the confusion of dates which must necessarily result from this constant gain on one side and loss on the other, it has been proposed to determine upon some line at which eastern bound travelers shall add one day, and westward bound travelers shall drop a day from their reckoning, and thus prevent a disagreement in regard to the day of the week. The line at which this addition or subtraction shall be made is what is meant by the date-line.

INTERNATIONAL LAW.—The body of rules, derived from custom, or treaty, by which nations, either tacitly or expressly, agree to be governed in their intercourse with each other. Some of the rules have existed from the beginning of history; their number has gradually increased, their scope widened, and their quality improved. The Amphictyonic Council, formed in very early times and limited to Grecian tribes, required that after a battle an exchange of prisoners should be made, and a truce declared in order that the dead might be buried. They also bound themselves not to destroy any city included in the alliance, or to cut it off from running water in war or peace. The Romans in their early days established a College of Heralds for declaring war, and allowed only sworn soldiers to take part in it. The influence of Christianity, declaring the universal brotherhood of man as one of its fundamental truths, has been great and beneficent in the sphere of national character and intercourse. Many barbarities fell at once before it, and many others have been gradually mitigated and subdued.

International Law has two natural divisions—the one containing rules for the intercourse of nations during peace, and the other regulating the changes made by war.

RIGHTS AND DUTIES OF NATIONS DURING PEACE.—1. Individuals cannot be parties to International Law; but may, if strangers, claim humane treatment under the law of nature broader than that of nations. Only independent, organized communities are nations, and have the power of making treaties with other nations. Protected or dependent States, Provinces and Colonies, the members of Confederacies, and separate Kingdoms made one by a permanent compact, must conduct all their intercourse with other nations through that nation on which they are dependent, or of which they are a part. No particular form of government and no difference of religious belief necessarily excludes a nation from the obligations and advantages of International Law. Independent States have equal duties and rights, without reference to their size or other relative differences, and are sovereign in the sense of having no political superior. The individual States of the American Union may be said to have a certain local and relative sovereignty; but with respect to other nations the United States only constitute a Sovereign State. International Law deals only with State *de facto*. While a body, hitherto dependent or forming a part of a nation, is striving to effect its independence, other nations cannot help it, without creating a state of war with the parent State. A State cannot evade its obligations by change of Constitution. Denmark and Norway, when separating in 1814, each took its share of the debt of the United Kingdom; and the United States assumed the debts of the preceding Confederation. The independence of a State implies, first of all, freedom in the conduct of its internal affairs. Generally there can be no legal interference with them by anothre State. Yet when a State, by external alliances, is increasing its power in a degree that endangers the welfare or tranquility of its neighbors, the right of interfering in order to preserve the balance of power is claimed and has been exercised; as, for example, in the war of the Spanish Succession, and after the French Revolution and the fall of Napoleon. On the other hand, when circumstances do not require or warrant such an interference, there have been national declarations designed to forestall and prevent it. An instance of this was furnished by what is called the Monroe Doctrine—President Monroe's declaration made in order to prevent European interference in what had been Spanish America—that "The United States would consider any attempt on the part of the allied European Powers to extend their system to any portion of our hemisphere as dangerous to our peace and safety." Also, when any great cruelty has been practiced by the strong against the weak the right of interference by other nations is claimed. A signal instance was furnished in 1827, during the struggle for independence by the Greeks against the Turks, when the allied fleets of Great Britain, France, and Russia destroyed the Turkish fleet.

2. A State has a sovereign right to its territories and property. Its property consists of public buildings, forts, ships, lands, money, and similar possessions. All private property, also, within its limits is under its protection. Its territory includes all the surface of land or water within its limits; of harbors, gulfs, and straits within certain headlands; and of the sea within a league from the shore. Outside of this limit the sea is free to all nations for commerce and fishing. But while foreigners are free to catch fish in any part of the ocean contiguous to the territory of a State—as on the banks of Newfoundland—they cannot dry their nets or cure their fish on the adjoining coasts unless the privilege has been granted by treaty. A ship owned by inhabitants of a country cannot be regarded as national territory, but is simply private property under the protection of the national flag. In a foreign port it may be attached for debt, and its crew are accountable to the laws of the port and of the country for any misconduct which they may commit. Rivers between two countries, unless a contrary provision is made by treaty, are common to both, and the boundary runs through the principal channel. When a river rises in one State and enters the sea in another, each portion, strictly speaking, is subject to the State within whose limits it is contained. The dwellers on the upper shores have no right, except by concession, to descend to the sea through the lower territory. Yet there seems to be an equitable claim to the privilege almost amounting to a right; and within the present century almost all such navigable rivers in the Christian world have been opened by treaty to the use of those who live on their upper waters. Among these may be mentioned the Rhine, Scheldt, Danube, La Plata and its tributaries, Amazon, and St. Lawrence.

3. Duties which foreigners coming into a country owe to its laws and government. Aliens, sojourning in a country, must submit to its laws unless released from their jurisdiction by special treaty or international custom. They are secure in the enjoyment of their property, the use of the Courts, and the transaction of lawful business. They can dispose of their property by will to persons residing abroad, or can transmit it to their own country. They have also the protection of Consuls and Ambassadors appointed by their own country. Several classes of persons are specially exempt, in a greater or less degree, from the jurisdiction of local laws; as, for example, Sovereigns traveling through a foreign country, Ambassadors accredited to it, the officers and men of national ships in its ports, and foreign armies when passing through it by permission. In England formerly no one born a subject could lawfully expatriate himself, nor could any foreigner be naturalized except by Special Act of Parliament. But in 1884 provision was made for granting foreigners all the rights of native-born subjects except membership of the Privy Council or of Parliament. In the United States a foreigner may be legally naturalized after five years' residence, and three years after he has formally declared his intention to renounce his former nationality and become a citizen. Persons who have committed offense against the laws of their country often flee for refuge into another. If the offense be political only, the nations which are most free themselves generally allow the fugitives to remain; but if they have committed, or are charged with crime, they may be delivered up for trial to their own country when demanded according to the provisions of treaties made for the purpose. An Ambassador in very ancient times was considered a sacred person; and, as national intercourse and comity have been enlarged, there has been a proportionate increase in his rights and privileges. His person, dwelling-place, property, family, and attendants, are, in a great degree and as a rule, exempt from the criminal and civil jurisdiction of the country to which he is sent. He has liberty of worship, according to the customs of his country and to his own choice, for himself, his household, and by extension of courtesy, for other persons belonging to his nation. In some countries this liberty has been restricted to worship in his own house. Consuls are agents who have no diplomatic character, but are sent to reside in certain districts to protect the interests, chiefly commercial, of the country which appoints them. Their duties are imposed by their own Government, and are performed by permission of the foreign power. They are honored and protected by the flag of their country; but their privileges are, in general, much less than those of Ambassadors, except in Mohammedan countries, where, having often been required to perform diplomatic duties, they have acquired corresponding rights. The modern office of Consul arose in the commercial times of the Middle Ages, when companies of merchants, going to reside in the eastern parts of the Mediterranean, had officers, chosen at first by themselves and afterward by their governments, to settle disputes that arose in conducting business affairs. Treaties are compacts between nations for the regulation of intercourse between both governments and people. They comprise, in a great measure the history of International Law. The power to make them is determined by the Constitution of individual States. In the United States they are negotiated under the direction of the President, and are ratified by a two-thirds vote of the Senate. When they promise the payment of money it must be appropriated for the purpose by a vote of the House of Representatives.

II. International Relations as Modified by War. 1. War is a contention by force of arms between two or more nations. In order to be just it must be necessarily undertaken to repel an injury or to obtain a righteous demand. The power of deciding for what purpose and when it is to be waged must be left to each nation, because there can be no other judge. A nation that has been wronged, or thinks it has, may take no notice of the wrong, or employ only peaceful measures to obtain redress, or accept the offered mediation of a friendly power, or propose arbitration, or use armed force. In general, other nations have no right to interfere. Yet, in some cases, war between two nations may become to other nations a cause for war. Mediation offers a way for escaping war which may be equally honorable and advantageous to both parties. Yet it can only give advice which may be rejected by one or both of the parties. Arbitration, in special cases, may be simple, easy, and effective. The parties agree on the Arbitrators, the points to be considered, the time and place, and the law which is to govern the case; and they bind themselves to abide by the decision. The success which has, in numerous instances within the present century, been attained by arbitration, and especially in the recent important case between the United States and Great Britain arising out of the war for the suppression of the Southern Rebellion, warrants the hope that war may often, in a similar way, be avoided. After the happy settlement in the instance last mentioned, the British House of Commons presented an address to the Queen, praying that measures might be taken "With a view to further improvement in International Law and the establishment of a general and permanent system of international arbitration."

2. War between two nations interrupts all recognized intercourse between the individual members of each. The relations of commerce, the right given by treaty to reside in either country, and all communication by direct channels between them, come to an end. Sometimes permission is granted to remain still in the country; and generally time is granted to remove with property and effects. The treaty of 1794 between the United States and Great Britain stipulates that "Neither the debts due from individuals of the one nation to individuals of the other, nor shares nor moneys which they may have in the public funds or in the public or private banks, shall ever, in any event of war or national difference, be sequestered or confiscated." According to Chancellor Kent, "As a general rule, the obligations of treaties are dissipated by hostilities." It is said also by another writer that "Great Britain, in practice, admits of no exception to the rule that all treaties, as such, are brought to an end by a subsequent war between the parties." The peace of Westphalia and the treaty of Utrecht have been renewed several times when the nations concerned in them, after having been at war, were making new treaties of peace.

3. The interests of humanity demand that, during warlike operations on land, non-combatants should be molested as little as possible in the prosecution of their peaceful interests and in the enjoyment of their homes. On the sea, ships and cargoes belonging to enemies have, until recently, been accounted lawful prey; but in the enlarged commercial relations of the world much progress has been made towards exempting innocent traffic on the seas from interruption during war.

4. The forces lawfully employed in war are, on land, Regular Armies, Militia, and Volunteers; and, on the sea, national ships and private vessels commissioned by national authority. But as privateering is necessarily attended with great evils, earnest efforts have been made to restrict or abolish it. In 1856 the parties to the Declaration of Paris adopted four rules concerning maritime warfare, one of which declares that "Privateering is and remains abolished." Other nations were asked to accept them on condition that they would be bound by them all; and almost all Christian States did agree to them. The United States withheld their assent because, as it is their policy to maintain only a small navy, the right to resort to privateering in case of war offers the only way by which they can cope with the large navies of other nations. They agreed, however, to adopt all the rules, provided the signers of the declaration would consent to exempt from capture all innocent traffic of enemies on the sea. In 1861 the offer was made to two of the principal European powers, by the Secretary of State, on the part of the United States, to come under the operation of the four rules; but as it was made for the whole Republic the rebellious as well as the loyal States—it was declined.

5 The rights and duties of neutral nations. In recent times the commercial intercourse among people of different nations has become so general and constant, that they are practically united almost into a confederacy so as to be entitled to a voice in deciding whether war between individual nations shall, in any particular case, be permitted. Sometimes, in view of peculiarities in its position, a territory is made permanently neutral so that armies cannot cross its boundaries nor can it engage in war. Switzerland and part of Savoy, since 1815, and Belgium, since 1830, have been in this condition. Sometimes several Powers unite in an armed neutrality in order to maintain certain maritime rights against both belligerents. But such a league is liable to result in war. A neutral State must be impartial in its dealings with both belligerents; must keep itself, its territory and subjects, as detached as possible from the war; and be equally humane to both parties when storm, disaster or hunger casts them on its shores or within its bounds. By the treaty of Washington, in 1871, Great Britain and the United States adopted three rules to be applied in settling difficulties then existing between them, to be observed by them in the future, and to be urged on the acceptance of other nations. These rules are—that "A neutral government is bound *first*, to use due diligence to prevent the fitting out, arming or equipping, within its jurisdiction, of any vessel which it has reasonable ground to believe is intended to cruise or to carry on war against a power with which it is at peace; and also to use like diligence to prevent the departure from its jurisdiction of any vessel intended to cruise or carry on war as above, such vessel having been specially adapted, in whole or in part, within such jurisdiction, to warlike use; *second*, not to permit or suffer either belligerent to make use of its ports or waters as the base of naval operations against the other; or for the purpose of the renewal or augmentation of military supplies or arms, or the recruitment of men; *third*, to exercise due diligence in its own ports and waters, and as to all persons within its jurisdiction, to prevent any violation of the foregoing obligations and duties."

6. The liabilities and rights of neutral trade. By the rules set forth in the Declaration of Paris, a "neutral flag covers the enemy's goods with the exception of contraband of war," and "neutral goods, with the exception of contraband of war, are not liable to capture under an enemy's flag." The term "contraband of war" is used to denote articles which directly aid warlike operations. According to a formula adopted by the United States, the list includes all kinds of guns, fire-arms, ammunition, weapons, armor, military clothing, equipments for men and cavalry horses, and all instruments, of any material, manufactured and prepared for making war by sea or land. The right of blockade in time of war is universally admitted, but in general is available only for harbors, mouths of rivers, and limited districts of coast. As a blockade begins and ends at definite times, previous notification, of both its beginning and ending, must be given to traders and neutral governments. To be legal, it must be maintained by armed force sufficient to show that it is actual, and to prevent all ordinary and open attempts to pass it. All merely formal, or, as they have been called, paper blockades, like Napoleon's Berlin and Milan Decrees, and the two counter British Orders in Council in 1807, are regarded by International Law as futile and void. When a vessel is captured and found guilty of attempting to enter or leave a blockaded port, the penalty it incurs is the confiscation of itself and its cargo. In carrying out the international rules adopted concerning contraband goods, enemies' goods on enemies' ships, and blockades, search is often necessary to determine the nationality of the vessel and the nature of its cargo. It must be submitted to by the vessel, but it must not be so conducted as to give unnecessary annoyance. The right of search is a war right, applicable to merchant vessels only in time of war, and to those suspected of piracy at any time, inasmuch as piracy involving attack on the peaceful and unarmed, is held as war against the human race.

INTERNATIONAL SALUTE.—A salute of 21 guns to a national flag. This salute is the only one which is returned, and this is invariably done as soon as possible. The time intervening must never exceed twenty-four hours. The failure to return such salute is regarded as a discourtesy or lack of friendship justifying the other party in asking explanation. In the presence of the President of the United States, however, no salute, other than the *national salute*, and that specified for him, is to be fired. It is the custom for saluting vessels-of-war, upon anchoring in presence of a fort, to hoist at the fore the flag of the Country in whose waters they are, and to fire the first salute. A failure to do so is a proper subject for explanation. Notice of an intention to salute the flag is usually given by the vessel direct to the fort; but as giving notice involves delay, vessels frequently salute without it. Vessels mounting less than ten guns do not fire salutes requiring the guns to be reloaded. Surveying vessels, store-ships, or transports do not salute. If there be several forts or batteries in sight, or within six miles of each other, one of them is designated in orders to return international salutes. Either of the others receiving notice from a saluting vessel of intention to salute the flag, immediately notifies the one designated as the saluting fort, and informs the vessel of the fact. If a vessel salutes without giving notice, the fort designated as the saluting fort returns it. United States vessels return salutes to the flag in United States waters, only where there is no fort or battery to do so. United States vessels do not salute United States forts or posts. Salutes to the flag are in no sense to be considered as personal. See *Salutes*.

INTERVAL.—In drill, the lateral space between men or corps. The following are the usual intervals in line between the different branches of the service: 1. Between files when formed in squadron, 6 inches from knee to knee. 2. Between the guns of a battery in line, full intervals, 19 yards. 3. Between squadrons in line, the breadth of a division, but never less than 12 yards. 4. Between cavalry regiments in line, or between cavalry and infantry in line, as for squadrons. 5. Between battalions in line, 30 paces. 6. Between batteries in line, or between artillery and other troops, 28½ yards. 7. Between cavalry regiments in contiguous columns, as for squadrons. 8. Between battalions in contiguous columns, 12 or 30 paces, as ordered.

INTO GEAR.—For most pieces, the motion of the top-carriage to and from battery is regulated by a pair of truck-wheels, one on each side; which work on an eccentric axle placed underneath and a little in front of the axis of the trunnions. The wheels are thrown *into gear* by means of handspikes inserted into sockets upon the ends of the eccentric axle; the wheels then rest upon the top of the chassis rails; and only the rear part of the soles of the top-carriage rest on the chassis rails and have sliding friction. The wheels are thrown *out of gear* in the same manner; the entire soles then having sliding friction upon the chassis rails, thus checking recoil. In the 15-inch gun-carriage there are two pairs of truck-wheels, one pair being placed in front, as just described, and the other pair near the rear end of the carriage; the rear wheels only are on eccentric axles, and when these are *out of gear* the soles of the top-carriage rest fairly on the chassis rails, and the motion is on sliding friction. When the rear wheels are *in gear* the front wheels also touch the chassis rails, and the top-carriage moves on rolling friction. To prevent the rear wheels from working *out of gear* while the gun is being run from the battery, or jumping *in gear* when the piece is fired, pawls are provided for locking the rear axle. When the rear wheels are *in gear*, motion is communicated to the carriage by means of a handspike on each end of the front axle. This handspike carries a double pawl, which works in ratchets or cogs on the truck-wheels. The handspike is arranged with a counterpoise, consisting of a heavy piece of iron placed on the short arm of the lever. See *Out of Gear*.

INTRENCH.—To secure a position or body of men against the attack of an enemy, by digging a ditch or trench. An army may intrench itself either by a *continued* or an *interrupted line;* in the former case, the line may be composed of parts so connected as to leave no uncovered space between them; in the latter, those parts may be isolated from each other, and uncovered intervals left between them.

INTRENCHED CAMPS.—Troops, when within striking distance of the enemy, should, to avoid the consequences of a surprise, be encamped always in order of battle. The modern practice of armies is to intrench, if encamped even for one night. Such intrenchments are usually of the slightest and most hastily-constructed kind, merely sufficient to afford shelter against a night attack. The artillery in this case is only that usually accompanying troops on the march, and for it gun-pits will suffice. These are made by simply throwing up the earth in front of each piece so as to form for it a crescent-shaped epaulment. If rails or any similar material are convenient, a slight revetment may be constructed to support the earth on the side towards the piece. In dry weather the earth may be dug from the inside and thrown up in front, thus forming a depressed position or hole for the piece to stand in. The chest of the limber will hold sufficient ammunition for immediate use. To protect it, the limber is turned with its pole *from* the piece, and is covered with an epaulment similar to that for the gun; or, removing the horses, it may be backed up near to and on one side of the piece, occupying with the latter a portion of the gun-pit. The caissons, horses, and other material of the battery may be placed in some sheltered position a little way to the rear. The positions occupied by artillery on such a line ought to be those that would be selected for it on any well-arranged line of battle. When, in consequence of attack by the enemy, or of his threatening attitude, the Army stands upon the defensive, the slight intrenchments of a temporary camp are increased and strengthened until they become a strong *intrenched line of battle.* See *Field-service, Intrenchment, Line of Circumvallation*, and *Line of Countervallation*.

INTRENCHING-TOOL.—An implement used for intrenching. The value of a hasty intrenchment was well understood by the Roman legions, for they executed works of this kind, in the presence of an enemy, with wonderful skill and rapidity. "It was by moving earth that they conquered the world." Napoleon said. "There are five things from which the soldier must never be separated; his ammunition, his haversack, his rations for four days and an *intrenching-tool.*"

Never has the utility of rapid field intrenchments been so clearly demonstrated, as in our last war, and never have they been used with greater success. The skill shown in improvising serviceable intrenchments was really very astonishing; frequently, for want of spades they used knives, cans, bowls—in one word, anything that came to hand. The art of utilizing cover is of great importance, and the soldier who carries in compact form the means of erecting cover at will is indeed fortunate. Whether the soldier shall carry his intrenching-tool, or have it carried for him; whether only a portion of the troops should carry tools, or whether each soldier should carry his own, are questions now under discussion. See *Clitz Intrenching-tool, Farrow Knife-trowel and Tent-peg, Trowel Bayonet*, and *Zalinski Intrenching-tool*.

INTRENCHMENT.—In a general sense an intrenchment is any work, consisting of not less than a parapet and a ditch, which fortifies a post against the attack of an enemy. As a means of prolonging the defense in a regular work of permanent fortification, intrenchments are made in various parts, to which the defenders successively retire when driven in from forward works. Bastions are ordinarily intrenched at the gorge by a breastwork and a ditch, forming either a re-entering angle or a small front of fortification. Such a work across the gorge of the redan at Sebastopol caused the repulse of the British attack in Sept., 1855. A cavalier, with a ditch, is also an intrenchment. An army in the field often strengthens its position by intrenchments, as by a *continued line* of parapet and ditch, broken into redans and curtains, or by a *line with intervals*, consisting of detached works of more or less pretention flanking each other.

INTREPIDITY.—An unqualified contempt of death and indifference to fortune, as far as regards personal safety; a fearlessness of heart, and a daring enterprise of mind. According to Rochefoucault, intrepidity, especially with regard to military daring, implies *firmness* of character, great *confidence* of mind, and extraordinary *strength* of soul. Buoyed up and supported by these qualities (which are sometimes natural and sometimes acquired), men become superior to every emotion of alarm, and are insensible to those perturbations of the heart which the prospect of imminent danger almost always engenders.

INUNDATIONS.—This obstacle is formed by damming back a shallow water-course, so as to make it overflow its valley. To be effective, an inundation should be six feet deep. When this depth cannot be procured, trous-de-loup, or else short ditches, placed in a quincunx order, are dug, and the whole is covered with a sheet of water, which, at the ditches, must be at least six feet in depth. The *dams* used to form an inundation are made of good binding earth, or of crib-work of logs filled in with stone, gravel, and earth, or of successive layers of fascines and gravel. If the dams are to stand for some time they may be faced on the upper side with boards. They cannot, in general, be raised higher than ten feet; they need not be thicker than five feet at top, unless they are exposed to a fire of artillery, in which case they should be regulated in the same way as a parapet. The slope of the dam down-stream should be the natural slope of the earth; but up-stream the slope should have a base twice that of the natural slope. *Sluices* are made in the dams, in a similar manner to the sluices of a mill-dam, for the purpose of regulating the level of the water in the pool above, in case of heavy rains. *Waste-weirs* are also serviceable for the same purpose, but unless carefully made they may endanger the safety of the dam. The distance of the dams apart will depend on the slope of the stream. The level of each pool should be at least eighteen inches below the top of the dam, and the depth of water below each dam should be at least six feet. These data will suffice to determine the center line, or *axis*, of each dam.

Artificial inundations seldom admit of being turned to an effective use, owing to the difficulties in forming them, and the ease with which they can be drained by the enemy. But when it is practicable to procure only a shallow sheet of water, it should not be neglected, as it will cause some apprehension to the enemy. In some cases, by damming back a brook, the water may be raised to a level sufficient to be conducted into the ditches of the work, and render some parts unassailable. The ditches in such cases should be made very wide, and to hold about a depth of six feet. During freezing weather the ice should be broken in the middle of the ditch, and a channel of twelve feet at least be kept open, if practicable. The ice taken out should be piled up irregularly on each side of the channel; and, as a farther precaution against a surprise, water should be thrown on the parapet to freeze. In a system of inundations the dams should, as far as practicable, be built at points the least exposed to the fire of the assailed. The head of each dam on the side of the enemy should be secured from surprise by a redan, stoccade, or other defense, and the dam itself and its approaches should be swept by musketry and artillery.

Inundations must be made with great care and forethought. The nature of the soil and the time necessary to effect the required inundation must be particularly noticed. When the supply of water is small, evaporation and filtration may become very prejudicial. The quantity of water V furnished per second by a stream is found from the formulas, $V = w \times d \times v$; and $V = -.07 + \sqrt{.005 + 3233 \frac{w d i}{w + 2d}}$; in which w represents the width of bed, d the mean depth, v the mean velocity per second, i the fall. The volume of water may also be calculated by measuring the section of the bed, and multiplying it by the mean velocity. The mean velocity V' is found from the formula $V' = \frac{V + (\sqrt{V} - 1)^2}{2}$, in which V represents, in inches, the velocity at the surface. In ordinary weather, the evaporation varies from $\frac{1}{18}$ to $\frac{1}{12}$ of an inch per day, and filtration in common soil may be reckoned at one inch in 12 hours. It is quite dangerous in winter time to fill the ditches of fieldworks with water; and when a garrison is compelled to remain a long time in an inundated country, fever does more damage than the enemy. See *Accessory Means of Defense*.

INVALIDES.—Wounded veterans of the French Army, maintained at the expense of the State. Many of these old soldiers are quartered at the Hotel des Invalides, an Establishment in Paris. See *Hotel des Invalides*.

INVALID ESTABLISHMENT.—An Establisment in the Indian Army for the transfer of officers who may be declared to be unfit for further service. It consists of —1. The Invalid Battalion: for officers who, although disqualified for further active service, are still equal to the discharge of garrison duties. 2. The Invalid Pension List: for officers disqualified for both active and garrison duties, either from age, wounds, or decline of health. They are transferred to this list, as stated in the government order, "Provided their conduct and habits are such as not to affect the character of that Institution, which is designed as an honorable retreat to the worn-out or disabled but deserving officers." The several orders issued on the subject of this Establishment will be found in the regulations applicable to the European officers in India, part III., by the late G. E. Cochrane, Assistant Military Secretary, India Office, and in the orders issued by the Government of India.

INVALIDING.—A term signifying the return home or to a more healthy climate, of soldiers or sailors whom wounds or the severity of foreign service has rendered incapable of active duty. The man invalided returns to his duty as soon as his restored health justifies the step.

INVALIDS.—Worn out or maimed soldiers, or those who from permanent sickness are unable to remain in the Army. There are some invalids who from change of climate recover their health; these men join the ranks again. In the British service, disabled men are periodically invalided and sent home from India and the Colonies. Besides Chelsea Hospital, for the reception of worn out and disabled men, the Corps of Commissionaires is open to pensioned soldiers; whilst so attached, they can add to their livelihood by giving their services as messengers or watchmen. Many invalids, known as *Out-pensioners*, are allowed to reside where they choose. See *Soldiers' Homes*.

INVASION.—The hostile entrance or attack of an enemy on the dominions of another; the passing of the regular line of frontier of any country, in order to take possession of the interior.

INVENTORY OF EFFECTS OF DECEASED OFFICERS AND SOLDIERS.—In the United States Service, in case of death of any officer, the Major of his regiment, or the officer doing the Major's duty, or the second officer in command at any post or garrison, as the case may be, immediately secures all his effects then in camp or quarters, and makes and transmits to the office of the Department of War, an inventory thereof. The Articles of War also provide that in case of the death of any soldier, the Commanding Officer of his troop, battery, or company shall immediately secure all his effects then in camp or quarters, and shall, in the presence of two other officers, make an inventory thereof, which he shall transmit to the office of the Department of War.

INVERSION.—In tactics, the subdivisions of the unit have their habitual position in the order of battle. This is necessary, in order that the mechanism of the unit may have that simplicity and uniformity in which there will be no difficulty in its being comprehended and retained by ordinary minds, to the end that every movement may be executed with promptitude. Still cases may occur in which the requisite rapidity to meet an attack, or to move in a given direction, cannot be attained without changing the habitual order. Such cases are provided for by what are termed *inversions*, in which the subdivisions temporarily change places and parts.

Inversions are very important in the field, and they offer such great advantages, that Bonaparte strongly advised their employment in many circumstances. Our tactics admit the employment of inversions in the formations to the right and left in line of battle, and also in the successive formations, except in that of *faced to the rear into line of battle*.

INVESTMENT.—The main objects of this operation are to cut off all communication between the garrison and the exterior; to prevent succors of every kind from being thrown into the work; to sweep off every thing in its vicinity that might, in any way, be serviceable to the garrison; and, finally, to cover a close reconnoissance of the defenses by engineer and other officers. For a successful attainment of these ends, the investing force, which should be mainly if not solely composed of cavalry, moves upon the work with celerity and secrecy; and, after surrounding and securing all avenues to it, sends out detachments to scour the environs up to the very gates of the work, if practicable, and bring off with them, or destroy, all persons, cattle, provisions, etc., met with. A chain of posts and sentinels is in the meantime established in the best positions to prevent all access to the work, or egress from it; care being taken to select for the posts points which are not exposed to the artillery of the work, or are beyond its range. The posts occupied by the troops during the day-time, and termed the *Daily Cordon*, are shifted at dark, and points nearer the work are taken up, to form the *Nightly Cordon* and hem the work in more closely. The posts and sentinels for this purpose should be pushed as far forward as they can find shelters from the musketry of the defenses; and under their protection the reconnoitering officers should spare no efforts to gain an exact idea of all the ground exterior to the work, and of the character of the defenses. The main body of the besieging army, with the engineer and artillery siege-trains, follows closely upon the investing corps, to prevent the line taken up by the latter, which, from its extent, is necessarily weak, from being forced either by the garrison, or by strong detachments from without. The positions for the camps of the various corps are designated by the Commanding General, after a careful reconnoissance. These are placed beyond the range of the heavy artillery of the works, with their color fronts facing from the works; and, as far as practicable, on points favorable to the health and comfort of the troops, and the defense. Whenever natural obstacles, of marshes, rivers, etc., occur between the camps they must be crossed by good lines of communication, so that no impediment may be offered to the speedy concentration of the troops upon any point threatened from without. See *Siege*.

IRELAND.—The insignia of Ireland have been variously given by early writers. In the reign of Edward IV., a commission appointed to inquire what were the Arms of Ireland found them to be three crowns in pale. It has been supposed that these crowns were abandoned at the Reformation, from an idea that they might denote the feudal sovereignty of the Pope, whose Vassal the King of England was, as Lord of Ireland. However, in a MS. in the Herald's College of the time of Henry VII., the Arms of Ireland are blazoned azure, a harp or, stringed argent; and when they were for the first time placed on the royal shield on the accession of James I. they were thus delineated; the crest is on a wreath or and azure, a tower (sometimes triple-towered) or, from the port, a hart springing argent. Another crest is a harp or. The national flag of Ireland exhibits the harp in a field vert. The Royal Badge of Ireland, as settled by sign-manual in 1801, is a harp or, stringed argent, and a trefoil vert, both ensigned with the Imperial Crown.

IRISH BRIGADE.—A body of men who followed the fortunes of James II., and were formed into regiments under the Monarchy of France.

IRON.—This most important metal in ordnance constructions will be most conveniently considered under the two following heads: 1. *Chemistry of Iron.* Chemically pure iron is of so little general interest that we shall confine our remarks on the properties of this metal to those which are exhibited by bar or wrought iron. Its color is gray or bluish-white; it is hard and lustrous, takes a high polish, is fibrous in texture, and when broken across, exhibits a ragged fracture. It requires a very intense heat for its fusion, but before melting passes into a soft pasty condition, in which state two pieces of iron may, by being hammered together, be united or welded so completely as to form, to all intents and purposes, a single portion. At a red heat, it may be readily forged into any shape; but at ordinary temperatures it possesses very little malleability, as compared with gold and silver. In ductility, it stands very high, being barely exceeded by gold, silver, and platinum; and in tenacity, it is only exceeded by cobalt and nickel. Its susceptibility to magnetism is one of its most remarkable characteristics. At a high temperature, it burns readily, as may be seen at the forge, or (more strikingly) when a glowing wire is introduced into a jar of oxygen. In dry air, and at ordinary temperatures, the lustrous surface of the metal remains unchanged; but in a moist atmosphere the surface rapidly becomes oxidized and covered with rust, which consists mainly of the hydrated oxide of iron. At a red heat, iron decomposes water, and liberates hydrogen, the oxygen combining with the iron to form the black or magnetic oxide (Fe^3O^4), which occurs in minute crystals. This is one of the ordinary methods of obtaining hydrogen. The affinities of iron for most of the non-metallic elements are very powerful. The chief of the iron compounds are—

a. Oxides of Iron—Iron forms four definite compounds with oxygen—viz. (1), the *protoxide* (FeO), which is the base of the green or ferrous salts of iron; (2), the *sesquioxide* or *peroxide* (Fe_2O_3), which is the base of the red or *ferric salts;* (3), the *black* or *magnetic oxide* (Fe_3O_4), which is regarded by some chemists as a compound of the two preceding oxides; and (4), *ferric acid* (FeO_3). The *protoxide* cannot be obtained in an isolated form, but it forms the base of various ferrous salts, and combines with water to form a hydrate (FeO,HO), which, on the addition of an alkali, falls in white flakes. The most important protosalts of iron, or ferrous salts, are the carbonate, the sulphate, the phosphate, and the silicate. *Carbonate of Iron* (FeO,CO_2) exists naturally in various minerals, and may be obtained artificially by precipitating a soluble protosalt of iron with carbonate of potash or soda, when the carbonate falls in white flakes. On exposure to the air, it absorbs oxygen, and gives off carbonic acid, and is thus converted into the hydrated peroxide. *Sulphate of iron* (FeO,SO_3+7HO) is obtained by the solution of iron, or its sulphide, in dilute sulphuric acid; in the former case,

there is an evolution of hydrogen, and in the latter, of sulphureted hydrogen. On evaporation of the solution, the salt is obtained in clear bluish-green rhomboidal crystals, containing seven atoms of water. This salt is commercially known as copperas or green vitriol. *Phosphate of iron* is obtained by precipitating a solution of a protosalt of iron with phosphate of soda, when a white precipitate of phosphate of iron is thrown down. All these salts, especially the carbonate and sulphate, are extensively used in medicine. *Silicate* and phosphate of iron occur naturally in several minerals. The *peroxide of iron*, termed also sesquioxide, red oxide, or ferric oxide, is obtained in an anhydrous form by igniting the protosulphate, and is known in the arts under the names *colcothar*, *crocus of Mars*, or *rouge*, according to the degree of levigation to which it has been submitted. It is employed for polishing glass, jewelry, etc., and is also used as a pigment. It occurs both in the anhydrous and in the hydrated form in various minerals. The *hydrated peroxide* ($2Fe_2O_3.3HO$) is obtained by precipitating a solution of a persalt of iron, or of a ferric salt, with an excess of potash, ammonia, or alkaline carbonate. It falls as a yellowish-brown flocculent precipitate, which when dried forms a dense brown mass. This hydrated peroxide of iron, when freshly prepared and suspended in water, is regarded as an antidote in arsenical poisoning. Rust, as has been already mentioned, is a hydrated peroxide, combined with a little ammonia. The most important of the persalts of iron, or ferric salts, are the neutral and the basic sulphate, whose formulæ are $FeO_2, 3SO_3$ and $Fe_2O_3, 3SO_2.5Fe_2O_3$ respectively, the nitrate ($Fe_2O_3.3NO_5$), the phosphate, and the silicate. The nitrate which is obtained by the solution of iron in nitric acid, is a useful medicinal agent. The *black* or *magnetic oxide* and *ferric acid*, which has not been obtained in a free state, and is only known as a constituent of certain salts, must be passed over without comment.

b. Haloid salts of iron—the chlorides, bromides, and iodides—next require notice. There are two chlorides—viz., a protochloride (FeCl) and a perchloride or sesquichloride (Fe_2Cl_3). The latter may be obtained by dissolving peroxide of iron in hydrochloric acid. The tincture of the sesquichloride of iron is perhaps more generally employed in medicine than any other preparation of this metal. The protiodide is an extremely valuable therapeutic agent.

c. There are probably several *sulphides* or *sulphurets of iron*. The ordinary sulphide is a protosulphide (FeS). It occurs in small quantity in meteoric iron. It may be obtained artificially by the direct union of the two elements at a high temperature, or by the precipitation of a protosalt of iron by sulphide of ammonium. It exists in glistening masses, varying in color from a grayish yellow to a reddish brown. It is insoluble in water, but in moist air becomes rapidly oxidized into protosulphate of iron. With acids, it develops sulphureted hydrogen. The bisulphide of iron (FeS_2) is the *iron pyrites* of Mineralogists, and the *mundic* of commerce. Under the latter name, it it used extensively in the preparation of oil of vitriol. There are also other sulphides of less importance.

2. *Manufacture of iron*—The increasing use of iron is a prominent characteristic of the present age, and every day sees some new application of it in the arts of life. Although the most useful of the metals, it was not the first known. The difficulty of reducing it from its ores would naturally make it a later acquisition than gold, silver, and copper. The reduction of the ore known as the black oxide of iron, however, has been carried on in India from a very early time. In Europe the rich specular and other ores of Spain and Elba were much used during the Roman period; in Greece, also, iron was known, though, as among the Romans, its use was subsequent to that of bronze. We are informed, too, by the Roman historians that this metal was employed by the ancient Britains for the manufacture of spears and lances. The Romans, during their occupation of Britain, manufactured iron to a considerable extent, as is evidenced by the cinder-heaps in the forest of Dean and other places. The rude processes then in use left so much iron in the cinders that those of Dean forest furnished the chief supply of ore to 20 furnaces for between 200 and 300 years. In those early times, the iron ores were reduced in a simple conical furnace, called an air-bloomery, erected on the top of a hill, in order to obtain the greatest blast of wind. The furnaces were subsequently enlarged and supplied with an artificial blast. Charcoal was the only fuel used in smelting till 1618, when Lord Dudley introduced coal for this purpose; but the iron-masters being unanimously opposed to the change, Dudley's improvement died with himself. It was not reintroduced till Abraham Derby, in 1713, employed it in his furnace at Coalbrook Dale. But as this method was not properly understood, the production of English iron declined with the change of fuel, till, in 1740, it was only three-fourths of what it had formerly been. About 10 years after this, however, the introduction of coke gave renewed vigor to the iron-trade, and then followed in rapid succession those great improvements in the manufacture which have given to the history of iron the interest of a romance. The introduction of Watt's steam-engine in 1770, the processes of puddling and rolling invented by Henry Cort in 1784, and the employment of the hot-blast by Neilson of Glasgow in 1830, have each been of inestimable service. The greatest improvement introduced into the iron manufacture in recent times is the process of Mr. Bessemer for the production of steel, patented in 1856. The "Siemens-Martin" method of making steel has also of late come into extensive use.

Iron ores are abundantly distributed all over the globe; the chief kinds being—1. Magnetic iron ore; 2. Red hematite, specular, or red iron ore; 3. Brown hematite, or brown iron ore; 4. Carbonate of iron, including spathic ore, clay ironstone, and blackband ironstone. The ore richest in the metal is the *magnetic*, or *black oxide of iron*. When pure it contains nothing but oxygen and iron, its chemical formula being Fe_3O_4, which gives 73 per cent. of iron by weight. It occurs in dark heavy masses of black crystals, and is found in the old primary rocks. Sweden is famous for this ore, and for the iron produced from it, which is esteemed the best in Europe. The celebrated mines of Dannemora, in that country, have been constantly worked since the 15th century. Russia, too, has great iron works in the Ural Mountains, which are supplied with this ore. So, also, have Canada and several of the American States, as Virginia, Pennsylvania, New Jersey, etc. The rock formations in which magnetic iron ore occurs very rarely contain coal, hence it is almost always smelted with wood-charcoal, which, as it contains no sulphur, is one great cause of the superiority of the iron produced from it. *Red hematite* differs from the last only in containing proportionally a little more oxygen, its formula being Fe_2O_3, that is to say, 70 per cent. of iron by weight. There are several varieties of this ore, but only two need be referred to. The first of these, *specular iron*, so called from its bright metallic luster, occurs in large and beautiful crystalline masses in the Island of Elba, where it has been worked for more than 2,000 years, and is likewise found in many other parts of the world. It is of a steel-gray color, assuming a red tint in thin fragments and when scratched. The other variety is *kidney ore*, whose origin is still a curious problem, as its deposits occur sometimes in veins and sometimes in apparently regular beds. Its characteristic form is in large kidney-shaped nodules, with a fine radiated structure. This shape, however, is only assumed in the cavities of massive deposits. Red hematite is sometimes called blood-stone. It is used for polishing metals, and yields a blood-red powder, used as a pigment. This valuable iron ore is found in many Countries, but in few places in greater abundance than at Whitehaven and Ulverstone, in England, where splendid masses of it occur, 15, 30, and even 60 feet in thickness.

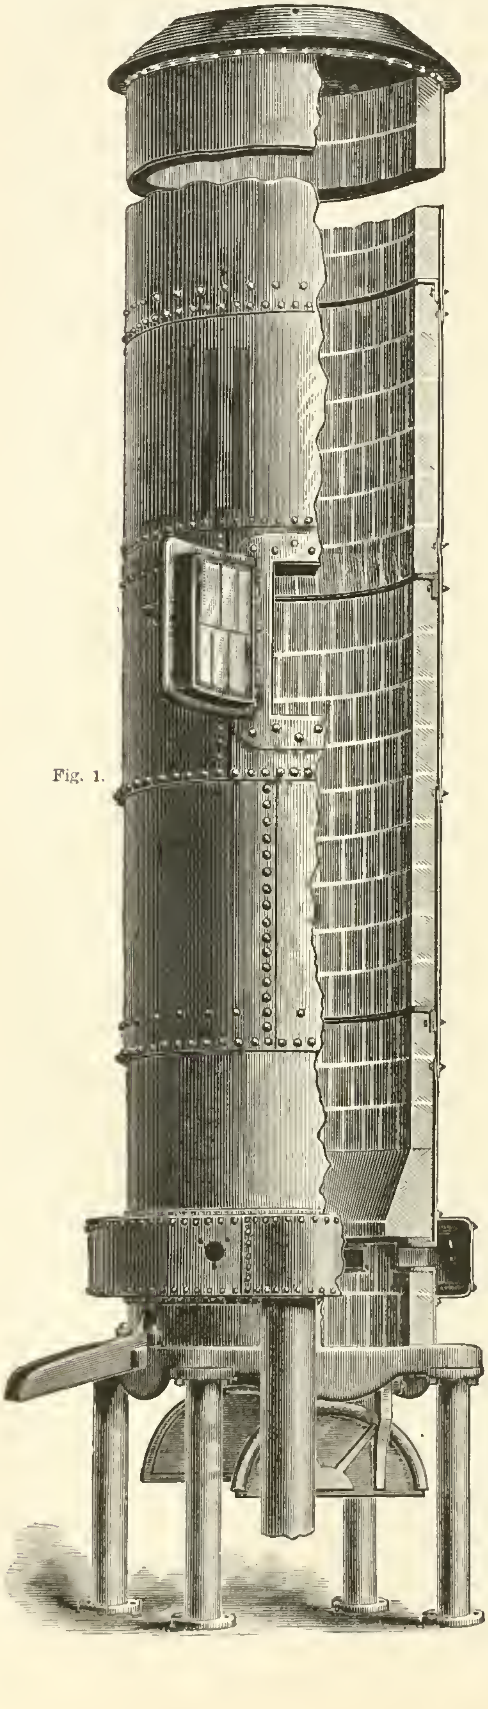

Fig. 1.

Brown hematite, or brown iron ore, is hydrated peroxide of iron, and has the same composition as red hematite, except that it contains about 14 per cent. of water. It is generally found massive, more rarely crystalline, and a variety occurring in small rounded nodules is called pea iron ore. When mixed with earth or clay, it forms the pigments yellow ocher and brown umber. Brown hematite is now an important ore in Great Britain, about 2,000,000 tons being annually raised. It occurs in different geological formations, chiefly in Devonshire, the forest of Dean, South Wales, and in Antrim, in Ireland ; also in an earthy form in Northamptonshire. It is the ore chiefly smelted in France and Germany. *Bog iron ore* is a variety of brown hematite, usually containing phosphorus, which occurs in marshy districts of recent formation. *Carbonate of iron*, when found in a comparatively pure crystallized state, is known as *spathic*, *spathose*, or *sparry iron ore ;* but when impure and earthy,as *clay ironstone* and *blackband ironstone*. Spathic ore was little worked in England previous to 1851, soon after which it was discovered in Somersetshire. It forms mountain masses in various parts of Prussia and Austria, and is now much in demand to yield the spiegeleisen required in the Bessemer process. In its purest form it contains 48 per cent. of iron; and in color it varies from white to buff or dark brown, some specimens of it taking a beautiful polish and looking like marble. The clay and blackband ironstones are essentially mixtures of carbonate of iron with clay, blackband having also a considerable proportion of coaly or bituminous matter. These dull earthy-looking ores occur abundantly in Great Britain, and form, after coal, the greatest of her mineral treasures. Fully one-third of all the ore mined in the country is obtained from the coal-measures, where fortunately both the fuel and the limestone, indispensable for the reduction of the iron, are also found. The ore occurs as balls or nodules in the shales, or in continuous beds. Some of these seams are full of fossil shells, and the ore is then called " musselband " ironstone.

Iron ore is still reduced to some extent in Europe by the old and imperfect process of the Catalan forge, not unlike a common smith's forge. In America. however, as well as in all other Countries where iron is largely smelted, the blast-furnace is now universally employed, by means of which the metal is obtained in the state of crude or cast iron. For the finer kinds of iron, charcoal is the fuel employed, because, unlike coal or coke, it contains no sulphuret of iron or other injurious ingredients. The Russian and Swedish furnaces smelt with charcoal, and on this, as much as on their pure ores, depends the high reputation of their iron. A solitary charcoal-furnace at Ulverstone in England, and another at Lorn in Scotland, are still working—the only relics of times past, when this was the only fuel employed.

As a preliminary process to the actual smelting in the blast furnace, clay and blackband ironstones are generally roasted. This is accomplished by breaking the ore into small pieces, spreading it in open heaps on the ground, and mingling it more or less with small coal according to the nature of the ore. Blackband commonly contains enough of carbonaceous matter to burn without the addition of coal. The pile, which may contain from one to several thousand tons of ore, is lighted at the windward end, and burns gradually along, aided by occasional fires in the sides, until the whole heap has undergone calcination, the time required for this purpose being generally about a month. Sometimes the operation of roasting is performed in close kilns instead of open heaps, a mode by which the ore is considered to be more uniformly roasted, and with considerably less fuel. Of late years, the kilns are often heated by the waste gases of the blast-furnace. By calcination, clay ironstone loses from 25 to 30, and blackband from 40 to 50 per cent. of its weight, the loss consisting chiefly of corbonic acid and water, but sulphur and other volatile substances are also dissipated in the process. The roasting also converts the protoxide and corbonate of iron into peroxide, which prevents the formation of any slags of silicate of iron, such slags, owing to the difficulty of reducing them, causing a loss of iron. In England the rich ores like the magnetic or red hematite are not subjected to calcination, but they are so in Sweden. The older type of blast-furnace consists of a massive tower of stone or brick-work strengthened with iron binders; the newer plan is to build it of comparatively thin brick-work, and surround it entirely with strong iron plates. In either case an inner lining of refractory fire-brick is given to it, which is separated from the outer portion of the wall by a narrow space filled with sand. Internally they vary very much in form, but perhaps the barrel shape is the most prevalent, and most of them contract towards the bottom in the shape of an inverted cone. Recent ones have been built from 80 to 100 feet in height, instead of not more than 60 as formerly. The blast-pipe, with its tuyere-branches, surrounds the hearth, and on one side there is a recess and openings for running off the metal and slag. Fig. 1. shows the construction of the Bigelow furnace or cupola, and will serve to illustrate the modern advancement in this line.

The operation of smelting is thus performed: The roasted ore, coal and lime (flux) are either hoisted, or, if the nature of the ground permits, moved along a platform or gangway to the gallery near the top of the furnace, and fed into it at intervals through the openings in the side, when the mouth is open, or by lowering the cone, when the mouth is closed. We may here state that the furnace is kept continually burning except when under repair. The materials are of course raised to a very high heat, and gradually fuse into a softened mass. The clay of the ironstone then unites with the lime to form a coarse glass or slag, the oxide of iron at the same time gives up its oxygen to the fuel, and allows the metal itself to collect on the hearth at the bottom of the furnace, united with from 3 to 5 per cent. of carbon, which it takes from the fuel, forming the variety called cast-iron. Every 12, and sometimes every 8 hours, the metal is run off from the furnace, by means of a tap-hole at the bottom of the hearth, into rows of parallel molds, called pigs, which are formed in the sand, hence the name "pig-iron." The slag which floats on the melted iron is run off by an opening at the top of the hearth. If the furnace is working well, the slag should be of a light-gray color; any dark-brown or black color shows that too much iron is passing into it. The quantity of materials necessary to yield a ton of pig-iron may be taken roundly as follows: 2 tons of calcined ironstone; 2½ tons of coal, of which about 8 cwts. are taken for the blowing-engine and hot-air pipes; and 12 to 16 cwts. of broken limestone. The proportions, however, vary in different districts according to the nature of the fuel and ore. The weekly produce of a single blast-furnace varies extremely —from under 100 to more than 500 tons in some of the larger furnaces.

Different districts classify their pig-irons in slightly different ways, but, as a rule, No. 1 to No. 4 are known as gray iron. No. 1 is largest and brighest in the grain, brings the highest price, and is best adapted for fine castings. Nos. 2, 3, and 4 become successively less in the grain, of a duller luster, and lighter in color, but up to No. 3 are known as foundry pigs. After No. 4 the metal ceases to be gray, and though higher numbers are sometimes employed, the other qualities are more usually known as forge, mottled, and white pig-iron. Gray iron has its carbon partly in the chemically combined, but chiefly in the uncombined or graphitic state, and requires a higher temperature to melt it than white iron, though very fluid when melted. White iron has its carbon wholly in the combined state, and is chiefly available for conversion into malleable iron. Hematite pig-iron suitable for making Bessemer steel has an exceptionally high value. The hot-blast process which has been described before was introduced in 1830 by Mr. James B. Neilson, of Glasgow, and has been productive of very remarkable effects on the iron trade. The whole invention consists in simply heating the air blown into the furnace, and yet the saving of fuel by this is about one half, and the production of iron, since it came into use, has enormously increased. The "cold-blast" is still, however, to a limited extent employed, and produces the strongest iron, though necessarily at a much higher cost. The difference in quality appears to be caused by the greater heat in the case of the hot blast facilitating the passage of impurities into the iron. Of late years much attention has been given to plans for saving fuel in the blast-furnace. Previous to the introduction of the hot-blast as much as 8 tons of coal, as coke, were consumed for every ton of pig-iron made. Even when this is reduced to under 3 tons of raw coal per ton of pig-iron, fully three-fourths of all the heat produced is still wasted in open-mouthed furnaces. The method of saving the waste gases by closing the mouth of the furnace, now generally adopted when coke is used is attended with so much economy, that, in the Cleveland district alone, over 600,000 tons of coal yearly are saved by adopting it. There being a difficulty in closing the mouth of the furnace when raw coal is used, Mr. Ferrie, of Monkland, a short time ago, patented a self-coking blast-furnace, by which, among other advantages, the gases can be saved. It has now been in use for some years in Scotland, and produces a ton of pig-iron with 34 instead of 53 cwts. of coal previously required. Raising the temperature of the blast from 900° to 1000° F. has also been attended with a saving, and so likewise, in some districts, has an addition to the height of the furnace.

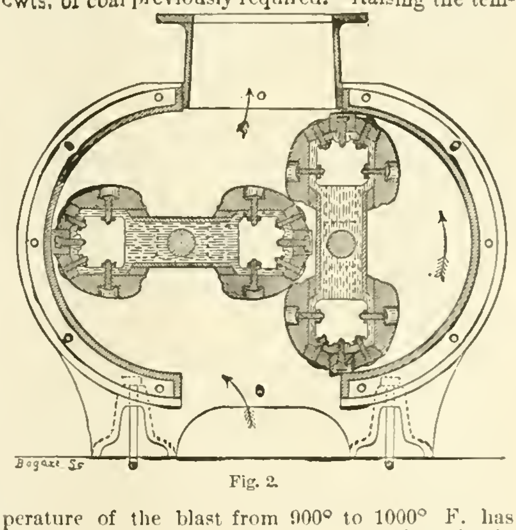

Fig. 2.

It will be readily understood that there is a certain degree of heat necessary to be maintained in a cupola to melt the largest amount of iron in the shortest time, with the least amount of fuel, as a ton of coal might be consumed without melting a single pound of iron if the temperature is not sufficiently elevated. It will be equally apparent, that any departure from the proper temperature, will just to that degree occasion loss in all these respects. To secure the best results, the proportions between the amount of iron to be melted, the fuel used, and the quantity of air supplied in a given time, should be fixed and unvarying. This can only be done by a machine giving a force blast, as with Blowing Cylinders, or Root's Rotary Blower, which measures and forces forward a definite quantity of air every revolution, so that when by experiment the maximum result is obtained, it can always be maintained at that point without any variation whatever. As a fan does not give a force blast, the quantity of air delivered varies with every change of condition, with the manner of charging the cupola, the kind of iron or fuel used, and the amount of stock in the cupola—but, more than by all other causes combined, the slag or cinders in the cupola. As it becomes foul, and the tuyeres become obstructed, the blast constantly diminishes, until melting in many cases entirely ceases, and it becomes necessary to drop the bottom. Thus the conditions absolutely necessary to secure uniform results can never be obtained with a fan blast, as no certain supply of air can ever be predicated upon the operation of a fan. A force blast, on the contrary, helps to keep the tuyeres open and free from obstruction; but in case of their being obstructed, the pressure is increased by the obstruction, and the same amount of air still continues to be forced through the diminished openings, and must continue to do so, or the machine must stop. With a fan this is not the case. Only a limited pressure can be obtained, and when this is reached, diminishing the outlet does not in the least degree increase the pressure, but rather the reverse. The Piston Blower undoubtedly gives a force blast, and, when properly arranged, is far superior to any species of fan whatever, but not nearly so good as the Rotary Blower for cupolas, for the following reasons, viz.: The blast is irregular and comes in puffs with every motion of the piston, and requires a large receiver to equalize the blast; this is both bulky and expensive. In addition to this, the machinery and fixtures are heavy and cumbrous, requiring a large amount of power to operate them. Besides, their cost is so great as to place them beyond the range of the large majority of establishments.

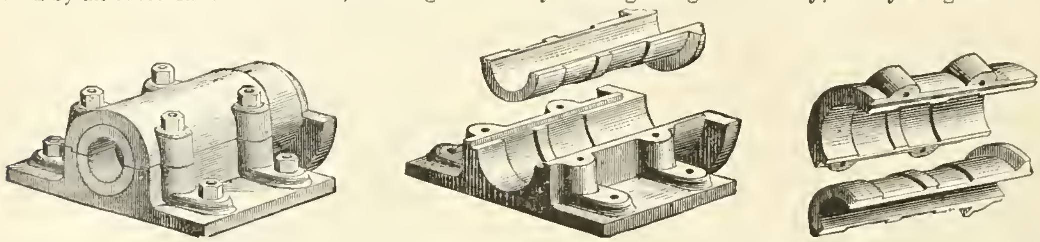

Fig. 3.

The importance of a force blast will be more fully realized when we consider the enormous amount of air required in the combustion of coal in melting iron. Accurate experiments have shown that about 33,000 cubic feet of air are consumed in melting a ton of iron, which, if reduced to a solid, would weigh about 3,600 pounds, or 1,200 lbs. more than both the iron and coal. The melting point of cast iron is about 2,800°, and a considerably higher temperature than this is required to render the iron perfectly fluid. Root's Rotary Blower is shown in section in Fig. 2. These famous Blowers have the improved arrangement for journal boxes, shown in Fig. 3. The box consists of two parts—the thimble or bearing, and the box proper. The bearings are made of phosphor or carbon-bronze. The thimble or lining is bored out to fit the journal with perfect accuracy, and is also turned off on the outside so as to be precisely concentric with the shaft. The box which holds the lining or bearing is also bored out to the exact size to receive the bearing, which is held from turning by set-screws in the cap. The advantages of this arrangement are that, if from gross neglect or inattention the journal-boxes have been allowed to cut or wear, and need renewal, it is only necessary to remove the cap and push the lower half of the bearing out, inserting the upper half or a new one in its place. This brings the shaft exactly in its original position, without any adjustment whatever. This arrangement obviates the necessity of taking the blower apart to renew the journal-boxes, as was necessary with machines built at an early date, thus saving much trouble and expense. It will be observed by an examination of the internal parts of this Positive Blower, as shown in Fig. 2, that it does not operate at all on the principle of a fan, that is, by imparting momentum to the air by running at a great velocity, but by a regular displacement of the air at each revolution, whether it runs fast or slow. When the air enters the case at the opening for induction, and is closed in by the wings of the revolvers, it is absolutely confined, and positively forced forward until brought to the eduction pipe, where it must be discharged or the machine stop if perfectly tight, as there can be no backward escapement of the air after it once enters the case, the contact being kept up at all times in the center of the blower between the pistons, or revolvers, thus preventing any escape of the air in that direction.

We pass now to the consideration of malleable or wrought iron. It differs from cast-iron in being almost free of carbon. The great object in the processes adopted for the conversion of cast into malleable iron, accordingly, is to deprive the former of its carbon. But it is also very desirable to get rid of deleterious ingredients, such as silicon, sulphur, and phosphorus, which latter are generally present in minute quantities in the cast-iron. The ordinary processes for the manufacture of malleable iron are *refining*, *puddling*, *shingling* or *hammering*, and *rolling*. The refinery consists of a flat hearth, covered with sand or loam, and surrounded with metal troughs, through which a stream of water is constantly flowing, to keep the sides from melting. The cast-iron is melted with coke on the hearth, and a blast of air kept blowing over it, which causes its carbon to unite with the oxygen of the air, and pass off as carbonic oxide gas. Oxygen also unites with silicon to form silica, and with iron to form the oxide. The silica of the sand uniting with oxide of iron, produces a slag of silicate of iron. The refined metal is finally run out in cakes on a bed of cast-iron, kept cool by a stream of water. Being only partially decarbonized by this process, it is next broken up for the puddling furnace. About 10 per cent of iron is lost in the refinery.

White pig-iron, or at least such kinds as contain carbon in the combined state only, are best suited for puddling, because they become pasty, and so more easily worked than gray iron containing graphitic carbon, which does not soften into this condition previous to fusion. It is only in some districts that the "refining" process is much used, in others a portion only of the puddling furnace charge is refined; and in making inferior kinds of malleable iron, the pig-iron is not previously refined at all. There are two ways of puddling now practiced; the first or older way best applicable to refined iron, is called *dry puddling*, and in it the decarburization is produced chiefly by a strong current of air passing through the furnace; the second or newer process, is called *wet puddling* or *boiling*, in which case the oxidizing of the carbon is effected chiefly by hematite, magnetic ore, basic slags, and other easily reduced materials, but to some extent also by the air. The operation of puddling, though differing in details according to circumstances, is in a general way conducted as follows: A charge of from 4½ to 5 cwts. of metal, including some hammer slag and iron scale, is placed on the bed of the furnace while still hot from previous working. In about half an hour, when the furnace is in working order, the charge is melted, and is then stirred or "rabbled" for a considerable time, when it begins to "boil" by the formation and escape of carbonic oxide, which forms jets of blue flame all over the surface. Gradually, as the carbon of the pig-iron is more and more oxidized, pasty masses of malleable iron separate, and these are removed in balls commonly weighing about 80 lbs., but sometimes larger. About an hour and a half is required to work off a charge, and it takes from 22 to 26 cwts. of pig-iron to produce a ton of malleable iron. Siemen's regenerative gas-furnace, in which inferior fuels can be utilized, is applied to puddling as well as to other metallurgical processes; and the more recent revolving puddling furnace of Mr. Danks is the most promising of any of the attempts yet made to puddle iron by mechanical means. The process immediately following the puddling or boiling is called "shingling," and consists in hammering the puddled balls with either the helve or steam-hammer, or in passing them through a *squeezer* till they are sufficiently consolidated, and the greater part of the cinders forced out. For a description of the steam-hammer, which is much used for heavy forgings as well as for shingling, see that head. Puddled balls which have undergone the process of shingling are called *slabs* or *blooms*. These are next passed through heavy rollers termed "forge" or "puddle-bar rolls," and reduced to the form of a flat bar. For all the better kinds of iron the bars thus treated are cut into short lengths, piled together, reheated in a furnace, and again passed through the forge rolls. Once more the iron is cut, piled, and heated, and is then passed through the "mill-train," consisting of what are termed the "bolting" or "rough rolls," and finally through the "finishing rolls." Both these sets of rolls in the case of plates and sheets are plain, but in the case of bars are grooved, so as to form them into the required shape, such as flat, square, round, octagonal, or T-shaped iron.

There is still another important variety of iron, viz., *steel*, the manufacture of which remains to be described. Steel differs from malleable iron in containing a varying proportion of carbon, usually from .5 to 1.8 per cent. When rich in carbon, it closely resembles cast-iron in composition, except that it is more free from impurities. Steel can be made by adding carbon during the direct reduction of a pure iron ore in a furnace or crucible, but the results of this method are scarcely ever uniform. The finer kinds of steel are still made by the old cementation process—that is, by the roundabout plan of first converting cast into malleable iron, by depriving the former of its carbon, and then adding carbon again by heating the iron with charcoal. In making any kind of steel, however, the getting rid of silicon, phosphorus, and sulphur is as important, and a matter of more difficulty than the securing of any required proportion of carbon. As blistered steel is full of cavities, it is necessary to render it dense and uniform, especially for the finer purposes to which steel is applied. By one method it is converted into what is called "shear steel." This is done by breaking the bars of blister steel into short lengths, heating them in bundles, and partially welding with a forge-hammer. The rod so formed is heated again, and now brought under the action of the tilt-hammer. Here, by a succession of blows, it is formed into bars, which are much more compact and malleable than blister steel, and consequently better fitted for edge-tools and the like. If the single-shear steel is doubled upon itself, and again welded and drawn into bars, it is called double-shear steel. By another method, viz., that of melting the blister steel in fire-clay crucibles, and casting it into ingots, "cast-steel" is made. This is the best kind of steel, being finely granular, homogeneous, dense, and well adapted for the finest cutting instruments.

Steel is now largely made directly from pig-iron by puddling, much in the same way as that process is applied to the production of malleable iron. By another plan (Uchatius's process), pig-iron is granulated and heated in a crucible with the oxides of iron and manganese, and fire-clay, the result being cast-steel. This process has succeeded well in Sweden. The Siemens-Martin process consists in melting pig-iron along with malleable iron and Bessemer steel scrap, about 7 per cent of spiegeleisen being added towards the end of the process. The operation is conducted in the Siemens regenerative furnace, and the product in this case is also cast-steel. There are also several modes of manufacturing steel direct from the ore, such as by the old way in the Catalan forge, and by Chenot's process, in which hydrocarbons are used. It would appear from the results of recent experiments made on the large scale at Middlesborough, that Messrs. Thomas & Gilchrist have succeeded, by a comparatively simple device, in practically eliminating the phosphorus from Cleveland pig-iron during the conversion of the latter into steel in the Bessemer converter. The great importance of this discovery will be at once understood when we state that the Cleveland iron is the cheapest in Great Britain, and that the Cleveland ore yields one-fourth of all the iron made in the Country. Hitherto it has not been remunerative to make steel from this pig-iron on account of the exceptionally high percentage of phosphorus it contains, and the difficulty there has been of removing an ingredient so deleterious to steel. Success, however, has at length been achieved by obtaining, through the use of lime and oxide of iron, a basic slag in the converter, and by lining this vessel with bricks made chiefly of magnesian limestone, fired at a very high heat. A basic lining is given to the converter instead of the ordinary siliceous one, which is acid, and so a base is furnished with which the phosphoric acid can combine without the certainity of the lining being eaten away by the basic slag, as would be the case when this lining is siliceous. It is only as respects the nature of the slag in the converter, and the kind of lining used for this vessel, that Thomas & Gilchrist's mode of making steel, as far as it has yet been tried, differs from Bessemer's; except that for the latter a high-priced pig-iron is required. Of course steel can be made by the new process from other low-priced irons besides Cleveland.

We will now take a glance at the properties of each of the three principal kinds of iron, and the purposes to which it is chiefly applied. *Cast-iron*, as the crudest, cheapest, and most fusible, is used, as a general thing, for the heavy portions of all engineering and ordnance work, such as the bed-plates for machines, cylinders, columns, cisterns, low-pressure boilers, water and gas pipes, rollers, girders, and a large variety of the like. A large quantity is also consumed in the manufactnre of "hollow-ware," which includes pots, pans, and other cooking vessels. For all kinds of ornamental objects, again, it is almost exclusively used, because here its property of being readily cast into molds gives it a great advantage on the score of cheapness. *Malleable* iron differs considerably in its properties from cast iron. The latter is practically incompressible, but it can be comparatively easily torn asunder. Malleable *iron*, on the contrary, possesses great tenacity; it is, moreover, very malleable and ductile, especially at a high temperature, so that it can be rolled into sheets as thin as paper, or drawn into the finest wire. Further, it possesses the valuable property of welding—that is, two pieces can be completely united together by hammering at a white heat. Malleable iron is largely employed for the innumerable variety of articles included under the general term "hardware," such as locks, keys, hinges, bolts, nails, screws, wire-work, and the so-called tin-plate, which is merely sheet-iron dipped in melted tin. It is the mainstay of the railways and the electric telegraph, and has almost displaced timber as a material for steamships and sailing-vessels. It is also much used for roofs and bridges of large size. Rolled armor-plates for war-ships and fortifications are now made of malleable iron from 5 to 22 inches thick. *Steel* possesses several valuable properties which do not belong to either cast or wrought iron. It is harder, denser, and whiter in color. It is also more elastic, takes a higher polish, and rusts less easily. Like malleable iron, it is also weldable. But its most characteristic property consists in its admitting of being tempered at will to any degree of hardness. If, for instance, a piece of steel be heated to redness and plunged into water, it is made hard and brittle; but if it be again heated and slowly cooled, its original softness is restored. By gently reheating the steel it will acquire a gradation of tints indicating various degrees of hardness, beginning with pale straw color, and passing successively to full yellow, brown, purple, and finally blue. The straw color is the result of a temperature of 440°, and the blue 570° F., the former being the hardest and the latter the softest tempering. The use of steel is no longer confined to such small articles as files, edge-tools, knives, etc. By means of improved machinery and processes, steel is at present manufactured on a scale that was little dreamed of thirty years ago, so that such objects as field-guns, heavy shafting, tires, rails, armor-plates, and the like are now being made of this material. The superior tensile strength of steel, which is about double that of malleable iron, gives it a great advantage where lightness is required. Large numbers of steamships are now building of steel. See *Cannon-metals*, *Cast-iron*, *Metallurgy*, *Piling*, *Puddling*, *Rolling-mill*, *Smelting*, *Steel*, *Welding*, and *Wrought-iron*.

IRON-CLAD OATH.—An oath of allegiance prescribed by Statute of the United States, for those taking office under the National or State Government, in accordance with the provisions of the 14th Amendment to the Constitution. The oath as administered reads as follows:

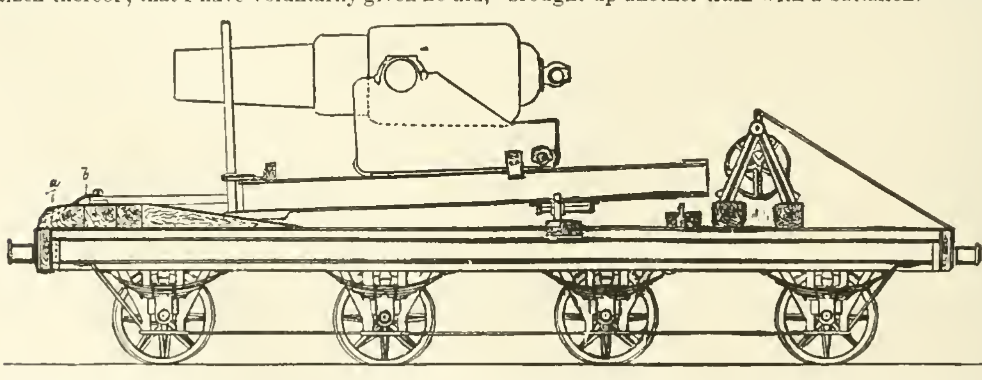
"I, ————, residing at ————, do solemnly swear that I have never voluntarily borne arms against the United States since I have been a citizen thereof; that I have voluntarily given no aid, countenance, counsel, or encouragement to persons engaged in armed hostility thereto; that I have neither sought, nor accepted, nor attempted to exercise the functions of any office whatever under any authority or pretended authority in hostility to the United States; that I have not yielded a voluntary support to any pretended government, authority, power, or constitution within the United States, hostile or inimical thereto. And I do further swear that, to the best of my knowledge and ability, I will support and defend the Constitution of the United States against all enemies, foreign and domestic; that I will bear true faith and allegiance to the same · that I take this obligation freely, without any mental reservation or purpose of evasion; and that I will well and faithfully discharge the duties of the office on which I am about to enter. So help me God."

Sworn to before me, this —— day of ——, 188—.

U. S. Commissioner.

This oath is still administered to officers under the U. S. Government, but its application has been restricted by special Acts of Congress, relieving, in certain instances, classes and individuals from the effect of its provisions.

IRON-CLAD TRAINS.—Trains were utilized as a means of reconnoitering during the American war of Secession, and during the war of 1870-71, in Europe, but no heavier guns than those usually employed as field artillery were mounted on them. Recently, however, it has been demonstrated that guns as heavy as a 40-pounder may be mounted and fought on trains with satisfactory results, there being little or no straining in either the trucks or rails. Experience has shown the following to be the best way of making up the train: 1st truck, empty, so as to guard against the line being mined. 2d truck, a machine-gun in front, spare rails for repairing the line. 3d truck, spare rails, bowls, chairs, etc., for repairing the line. 4th truck, 40-pr. gun and crew. 5th truck, ammunition wagon. This is protected all round by thin iron, and the magazine is covered in front by a pile of short railway iron a little higher than a powder-case. On each side is a baulk of timber, and on top a layer of rails, three or four of which are bolted down. The powder is in half metal-lined cases. This truck also contain fuses, tin cups, tools, four cases of wet and one of dry gun-cotton, Bickford's fuse, detonators, lantern and candles, slings for lifting the guns and carriage, bearers for the gun, a collapsible boat, stretchers, and arm-racks for the covering party of twenty-eight men. 6th truck, protected with thin iron plates, carrying two Gatlings with their crews. 7th truck, two 9-prs. with their limbers, two 7-prs. and their crews. 8th truck, steam-crane. 9th engine, protected with railway iron laid horizontally along the boiler, $\frac{1}{4}$-inch and $\frac{3}{4}$-inch iron plates round the working parts, and sand-bags. 10th truck, protected by iron plates, carrying the covering party, and with a Gatling in rear. A reserve engine always followed, usually on the other line, and if necessary brought up another train with a battalion.



During the recent Egyptian Campaign, the English mounted a 9-inch Armstrong M. L. R. gun in the manner described, and shewn in the drawing. A truck, which had been constructed some time back to transport a 26-ton boiler from Alexandria to Suez, was found in the store and appropriated. It was longer than the ordinary trucks, and much stronger built, running on eight wheels close together, and with especially constructed springs. Three baulks of timber were placed across the front part of the truck, and bolted through the floor. A $\frac{3}{4}$ inch iron plate, two feet wide, was bent over these, and bolted to the bottom of the truck, and in the center fo this platform the pivoting bolt *a* was placed. As a support a piece of ¾-inch iron, four inches wide was fixed to the top of the bolt, when the bars were in position, and also bolted under the carriage, *b*. The slide, which was of the land service pattern with high rollers, had to be cut down so as to bring the weight as low as possible. The rollers were taken off and the axeltrees cut. An extempore rear-axle was made out of a bar of iron, and the rear rollers of a 10-inch gun carriage were used as rear-slide rollers, the fore part of the slide working without rollers, on an iron skid plate. The rear rollers were so far forward that the slide was very liable to tip up when the gun recoiled —in fact, several guns were disabled in the forts during the bombardment in this manner. An arrangement was therefore fitted to the fore part of the slide which prevented this, and, at the same time, allowed lateral motion to the slide for training. In rear of the rear-slide rollers a baulk of timber was placed, projecting about two feet on either side, with bolts for the training tackles, *c*. When the gun was out and the training on, a wedge was driven in between this baulk and the rear of the slide, so as to take some of the weight of the gun on recoil off the rear axle, which was rather weak, and also to distribute the weight more evenly over the truck. In order to run the gun in, some sort of a purchase was necessary, and nothing could be found to answer the purpose better than the crab of the Moncrieff gun at Fort Ras-el-tin. The gun was then mounted by a crane, and everything worked satisfactorily. About 58 of training was obtained on either side, which in this case was sufficient to cover the principal works at Kafr-Dowar, particularly as there was a sharp bend in the line, and a very much larger arc could be covered by a judicious selection of points to fire from. See *Railway Communications*.

IRON CROSS.—A Prussian order of knighthood, instituted on Mar. 10, 1813, by Frederick William III., and conferred for distinguished services in the war which was then being carried on. The decoration is an iron cross with silver mounting. The grand cross, a cross of double the size, was presented exclusively for the gaining of a decisive battle, or the capture or brave defense of a fortress.

IRON CROWN.—The crown of the ancient Longobardian Kings, given according to an unauthenticated tradition, by Pope Gregory the Great to Queen Theodolinda, and preserved till lately in the Cathedral of Monza. Henry, in 1311, is the first German Emperor who is known to have worn it. It was removed by the Austrians to Vienna after 1859, but was presented to the King of Italy in 1866. The outer part of the crown consists of a golden hoop, with enameled flowers and precious stones, in form like an ancient diadem, within which is a thin plate or fillet of iron, which is declared by a tradition long opposed by the Church at Milan, but adopted by the Congregation "*dei sacri riti*" at Rome, to have been hammered from one of the nails of the true cross. When Napoleon I. was elected King of Italy in 1805, he took this relic and crowned himself with it, disdaining to receive it from the hands of a Bishop; and at the same time he founded an order of knighthood, taking its name from the Iron Crown. The order—forgotten after the fall of Napoleon—was restored and remodeled in 1816 by the Emperor Francis I., who gave it the name of the Austrian Order of the Iron Crown.

IRON CYLINDER GAUGE.—An instrument adapted for testing the body, studs, and pitch of rifling of muzzle-loading projectiles, at one operation. When

	Diameter over body.	Diameter over studs.	Diameter low over studs.
	Inches.	Inches.	Inches.
16-pr.	3·58	3·812	3·795
9-pr.	2·98	2·212	—
7-pr.	2·98	3·182	3·165

the present number of this nature of gauge is used up, *iron ring gauges* will be introduced for general issue; the cylinder gauges being restricted to stations of inspection. The foregoing are the dimensions of the gauges for rifled field guns.

IRON FILINGS.—Small portions or particles of iron rubbed off by the act of filing; they are used in the manufacture of fireworks and for other purposes.

IRONS.—Shackles of iron into which the ankles of a prisoner are fixed, and which slide on a long iron bar. Refractory soldiers, who evince violent behavior, and become unmanageable, are commonly put in irons, several being placed side by side along the same bar. In cases of extreme violence the wrists may be similarly treated, but instances of this latter punishment are rare. The punishment of "putting in irons" is more common in the Navy than in the Army. Commonly called *Bilboes*.

IRONSIDES.—A Cuirassier. The term is specially applied to Cromwell's Cavalry. As Captain of a troop of horse, Cromwell exhibited astonishing military genius; and against the men trained by himself —"Cromwell's Ironsides" the battle-shock of the fiery Rupert, which at the beginning of the parliamentary struggle none else could withstand, spent itself in vain.

IRREGULAR FORTIFICATION. Those in which, from the nature of the ground or other causes the several works have not their due proportions according to rule; irregularity, however, does not necessarily imply weakness.

IRREGULARITY.—A violation of the customs of service—a deliquency which is subject to censure, but not serious enough to be brought before a Court-Martial.

IRREGULAR SITES.—The problem presented for solution to the engineer in irregular sites is frequently one of no ordinary complexity; demanding a minute and laborious study of the natural features of the position in their relations to the defense; connected with a tentative process of which the object is so to modify the plan, relief, and details ordinarily adopted, as to adapt them in the best manner to the given position. No rules but of a very general character can be laid down for the guidance of the engineer in such cases. The more plunging the fire of the work, the more efficacious will it prove to be. The efficiency of this fire will depend upon two causes: 1. The command of the work over the point to be attained. 2. The direction of the ground with respect to the lines by which it is swept.

As to the command of the work over the exterior ground, it has already been shown that motives of economy restrict it, in most cases, within very narrow limits, where, to obtain it, artificial embankments have to be employed.

To augment, therefore, in the greatest degree this element of the defense, advantage should be taken of the natural features of the locality, by placing the principal lines, from which the exterior ground can be seen, on the most commanding points of the site.

If, with this position given to the principal lines, the ground swept falls or slopes towards them, a most favorable combination for an efficacious plunging fire will be obtained; for, with this direction of the ground, the enemy will meet with far greater difficulty, to put himself under shelter by his works, than where the ground falls or slopes from the line by which it is swept; as the surface, in the latter case, descending in the rear of the cover thrown up by the enemy, will be screened to a greater extent than in the former, where it rises in rear of the cover. When this, however, cannot be effected, the next best thing to be done is so to place the principal lines with respect to the surface to be swept that it shall be seen by a part of these lines, thus bringing to bear upon it a flank fire from these parts.

The general rule, therefore, which the engineer is to take as a guide, in order to satisfy the condition of bringing the exterior ground under an efficacious fire from the work, is:

1. To place the principal lines of his work on the

most commanding points of the site, and in such directions as to bring the exterior ground to be swept in a position sloping towards these lines in such a manner that they can bring their entire fire to bear upon it, or else bring a portion of it to sweep it in front.

This will generally be best effected by placing the salient points of the work on the most commanding and salient points of the site; as, in this position of the salients, the faces, which are usually the principal lines bearing on the exterior ground, will occupy the salient and commanding portions of the site, whilst the re-enterings, being thrown on the re-entering and lower portions of the site, will be in the best position for sweeping the ground immediately in the advance of the faces by a flank fire: and at the same time these re-enterings will be masked by the faces from the enemy's view, and thus preserved from serious injury up to the moment when their action may be rendered most effective; that is when the enemy, despite the fire from the faces, has succeeded in planting himself upon point on which this fire cannot longer be brought to bear. To carry these precepts into practice, a wide margin is left to the engineer's judgment in which he will find it necessary in some cases to extend the lines of his works beyond what a strict regard to economy might prescribe, so as to include within his defenses ground from which he can best sweep what is exterior to it, or which, being occupied by the assailant, might make his own position less tenable, in this way necessarily forcing him to extend out his lines so as to embrace all the crests within them that overlook the valleys beyond them; and in very many cases to throw his own lines further back in order to avoid enfilading or plunging views from points which are too, far to be brought within his defenses. 2. The condition of leaving no dead spaces, that is, no point of the defenses unguarded by their fire, will depend in a great degree for its fulfilment on the same rule as the preceding. But where both conditions cannot be satisfied, the distant defense should be sacrificed to the near; as upon the latter the more or less of obstinacy of resistance depends; since the fire of the work and the action of the garrison are the more effective as the point to be guarded is the nearer to the defenses. 3. The condition that the troops and materiel within the defenses shall be sheltered from the enemy's fire, from all commanding points without, will depend upon the relative positions of the principal lines and the exterior commanding points; and as far, therefore, as it can be done, without sacrificing either of the preceding and more important conditions, the plan of the work should be so arranged that the principal lines shall present themselves in the most favorable direction to the exterior ground to avoid plunging, enfilading, or reverse views upon their terre-pleins from any point of it. To effect these objects, when the work is in the vicinity of commanding heights within cannon range, and the crests of these heights, as seen from the work, present a nearly horizontal outline, the principal lines of the work, fronting the heights, should receive a direction as nearly parallel as practicable to that of the commanding crests. When the outline of the crests presents a nearly continuous line, but one which declines or slopes towards the site of the work, the principle lines towards the height should receive a direction converging toward the point where the line of the crests, as seen, if prolonged, would join the site. The reasons for the positions assigned to the principle lines in these cases respectively, may not, at a first glance, be obvious; but by examining the relative positions of the crests of the heights and of the principal lines, as here laid down, it will without difficulty be seen that they can be brought in the same plane, and the latter be so placed as to give a nearly uniform command to the parapets of the principal lines over the site; and that by keeping the terre-pleins of these lines in planes parallel to the one in which the crests of the heights and those of the parapets are held, and at suitable levels below it, the parapets will be made to cover the terre-pleins from the fire of the heights in the simplest manner. The foregoing general methods for determining the direction of the principal lines fronting commanding heights, so as to cover from direct fire, in the easiest manner, by their parapets, the space to the rear, occupied by the troops and *materiel*, present, at the same time, the simplest cases of the adaptation of the plan of a work to the features of the locality, to subserve the object in view. In most cases, all that can be done is to avoid giving such directions to any of the principal lines, as shall be favorable to enfilading or reverse views of the enemy; which may be effected by so placing them that their prolongations shall fall on points where the enemy cannot establish his works; or those which, if occupied by him, will afford disadvantageous positions for his batteries either for enfilading or reverse fires. As the attack derives its great advantage from its enveloping position, by which enfilading views and a concentrated fire can be brought to bear on the assailed point, so, in the general disposition of his defenses, the engineer should endeaver ro reduce these salient and assailable points to the fewest number, and to accumulate upon them such surplus strength that in spite of their natural weakness they will cost their assailant a great deal of time and a large sacrifice of means to get possession. This consideration has led engineers to propose for the general outline of their defensive polygon a triangle in which the principal development of their work being a number of fronts on a right line, they can neither be enveloped nor their principal lines be enfiladed by the assailant's trenches, thus leaving only the three angular points as assailable, and which they propose to strengthen by an accumulation of works upon them. See *Fortification*, and *Permanent Fortification*.

IRREGULAR TROOPS.—Troops which, though in the pay of a nation, do not belong to the regular forces. In the British army there are no such troops. In India there are two or three irregular forces, composed of cavalry and infantry, for the protection of native states. The present native cavalry regiments in her Majesty's Indian army were originally raised as irregular troops. They found their own horses, arms, clothing, etc., for which they received a certain monthly sum; but this has been modified of late years, and they are no longer styled irregular cavalry.

ISABELLA.—The Order of Isabella the Catholic is a Spanish Order of Knighthood founded by Ferdinand VII. in 1815, as a reward of loyalty, and for the defense of the possessions of Spanish America. It is now conferred for all kinds of merit. The Sovereign is the head of the Order, which is divided in to the three classes of Grand Crosses, Commanders, and Knights.

Order of Isabella the Catholic.

IHSOCHRONISM.—A pendulum is isochronous when its vibrations are performed in equal times, whether these vibrations be large or small; but it can only possess this property by being constrained to move in a cycloidal arc. This is managed by causing the string to wrap and unwrap itself round two equal cycloidal cheeks, the diameter of whose generating circle is equal to half length of pendulum. Isochronism is closely approximated in practice by causing the pendulum to describe a very small circular arc.

ISOLE.—A word used among the French, to express any thing which is detached from another. It is variously applied in fortification: As, for instance, a parapet is said to be *isole* when there is an interval of 4 or 5 feet existing between the rampart and its wall, which interval serves as a path for the rounds.

ISOMERISM.—Isomeric bodies may be considered as naturally divided into physical isomers and chemical isomers. The physical are more strictly or perfectly isomeric than the chemical, and on account of their similar molecular or radical composition when they are subjected to the action of different forces or reagents exhibit the same behavior. Thus there are several hydrocarbons known as terpenes, having the composition $C_{10}H_{16}$, as the oils of lemon, bergamot, and turpentine, which show the same reactions under the influence of chemical agents, except their difference of odor and action or polarized light. Chemical isomers merely, do not carry their isomerism so far, for although they may have the same proportion of elements, and also the same molecular weight, they do not exhibit the same behavior under reagents. Thus, the molecular formula, $C_3H_6O_2$ represents three different bodies which decompose differently when acted upon by caustic alkalies, proprionic acid, C_3H_5O,HO, being converted at common temperatures into proprionate of potassium, C_3H_5O,KO. Acetate of methyl, C_2H_3O,CH_3O, is not changed at ordinary temperatures by caustic potash, but when heated with it, acetate of potassium and methylic alcohol are produced. Again, formate of ethyl, CHO,C_2H_5O, when heated with caustic potash, is changed into forate of potassium, CHO,KO, and ethyl alcohol, C_2H_5HO. These chemical isomers are the metameres mentioned in the preceding article, their behavior depending upon the manner in which organic radicals enter into their composition. Another class of these bodies are called polymeres.

ISOMETRIC PROJECTIOM.—A kind of drawing used by engineers for purposes of construction. It is an orthographic projection in which one plane or projection is employed, and therefore the measurement is without regard to the rules of perspective, the plane of the drawing being supposed to be at an infinite distance from the eye. It is used to delineate structures whose principle lines are parallel to three rectangular axes, and the plane of projection makes equal angles with these axes, which are called coordinate axes, and the planes, taken two and two, are called co-ordinate planes. The plane of projection passes through the point of intersection of the three axes, and this point is the center of projection. The projections of the co-ordinate axes are the directing lines of the projection, and form equal angles of 1208 with each other.

ISSUE.—A term applied to the distribution of rations and supplies. In the British service, *issues* are certain sums of money which are, at stated periods, given to public accountants for public service; and for the honest distribution of which, every individual so intrusted is responsible to Parliament. *Regimental issues* are moneys paid by regimental agents, acting under the authority of their respective Colonels, for regimental purposes.

ITALIAN ARMY.—Italy, like most of the Continental Nations, has adopted the compulsory system in raising her Army, similar to France and Germany. The yearly contingent is put down at 100,000 men, 70,000 of which serve in the first category or active army. In this, they remain for 3 years (in the cavalry 5 years); 5 in the reserve of the active Army, and 4 in the *mobile milizia*. The length of service therefore is altogether 12 years, and the age of joining the colors is 18 years. The men who have not been called to do duty in the active service form the second category, in which they have to serve 5 years in the reserve of the active army and 4 in the militia. They are only assembled for a few months every year. By the law of the 30th September, 1873, Italy is divided into 7 military commands or army corps, five of which have 2 and two 3 military territorial divisions. Each military division consists of from 1 to 6 military districts, giving a total of 16 territorial divisions and 62 military districts. Further, the kingdom is divided into 6 commands of artillery, of 1 or 2 divisions each (total 12) and into 6 commands of engineers of 2 or 3 divisions (total 16). The land territorial forces comprise the *permanent army* and the *mobile milizia*. The *permanent army* consists of the staff, the artillery, and engineers, the infantry, the cavalry, a corps of *gendarmerie*, and the civil departments (commissariat, medical administratives, etc.) The *mobile milizia* comprizes 232 battalions of infantry, 24 companies of rifles, 15 companies of *bersaglieri*, and 40 companies of field and 20 batteries of siege artillery, together with 10 companies of engineers. By this system, it is computed that Italy can place under arms the following numbers: Active army, 395,951; Reserve, 148,004; *Mobile milizia*, 279,-872; total, 823,827 men. These forces in war time are organized into 20 divisions, forming 10 *Corps d'Armée*.

ITALIAN SYSTEM OF FORTIFICATION.—A system of fortification constructed on the interior polygon. The front, from 250 to 300 yards, was divided into six equal parts: the flanks perpendicular to it were equal to ⅙, and the curtain to ⅝ of the whole length. The flanks were perpendicular to the curtain because fortresses were not unfrequently attacked on the curtain before the invention of the ravelin; and the faces of the bastions were directed so as to receive flank defense from the curtain. The ditches were deep and wide, with counterscarp parallel to the faces of the bastions and marking part of the flank defense. The revetments were high, from 40 to 50 feet, rather massive and much exposed, since the besiegers could see from 15 to 17 feet of the masonry from a distance.

ITINERARY.—A rough sketch of the country through which troops have to march; giving the roads and villages; noting the number of inhabitants and houses, whether of stone, brick or wood; and conveying as much information of the country as can be gathered in a short space of time.

In the United States Army, the Commanding Officer of every body of troops ordered to march selects a competent person—preferably a Commissioned Officer—to whom is intrusted the special duty of making the field-notes and sketches, and keeping the journal necessary for the preparation of a map and report of the route traversed. The person so selected is, if possible relieved of a part of his routine duties to enable him to give due attention to this subject. The Commanding Officer daily, or more frequently if necessary, inspects and verifies the notes and journals. If there be no competent subordinate to perform the duty, the Commanding Officer himself makes the notes and keeps the journal. When a detachment leaves the main column, the point on the "*route*" is noted, and the reason given in the *remarks*. The Commander of the Detachment sees that the notes and journals are continued over his new line of march, and after its completion transmits them to the Commanding Officer of the main body. On the completion of the march, the notes and journals are sent, through the regular channels, to the Department Headquarters, where their contents are embodied upon the maps in course of preparation there. The notes and journals are then forwarded to the Chief of Engineers at Washington. Suitable instruments and note-books for use in keeping itineraries of march are obtained through the officer on Engineer duty at the Headquarters of Geographical Departments, who from time to time renews his supply by requisition on the Chief of the Corps of Engineers.

The name Itinerary was given by the Romans to a table of the stages between two places of importance, with the distances from one to another. The itineraries of the ancients contribute much to our acquaintance with ancient geography. Of these, the most important are the *Itineraria Antonini* and the *Itinerarium Hierosolymitanum*. The *Itineraria Antonini* are two in number, the *Itinerarium Provinciarum* and the

Itinerarium Marinum, the former containing the routes through the Roman provinces in Europe, Asia and Africa; and the latter the principal routes of navigators, who then sailed only along the coasts. They take their name from Antoninus Caracalla, by whom they were published, as corrected up to his time, but they seem to have been originally prepared at an earlier date. The *Itinerarium Hierosolymitanum* was drawn up 333 A. D., for the use of pilgrims from Burdigala (Bordeaux) to Jerusalem. Of these itineraries, various editions have been published. See *Journals of March.*

J

JACARANDA WOOD.—A very hard, heavy, brown wood, also called *rosewood*, from its faint agreeable smell of roses. It is brought from South America, and is produced by several trees of the genus *jacaranda*, of the natural order *bignoniaceæ*. Several species of this genus are called *caroba* in Brazil, and are there accounted anti-syphilitic. Several species of the nearly allied genus *tecoma* also have an extremely hard wood, as *T. pentaphylla*, a native of the Caribbean Islands. The Brazilian Indians make their bows of the wood of *T. toxiphora* or *pao d'arco*. All varieties are very desirable for gun-stocks, etc.

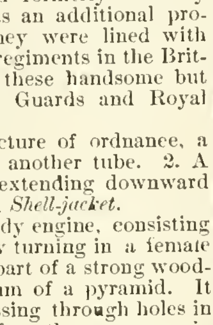
JACK.—A pompoint, or quilted tunic, made of leather and well padded. It was worn by foot soldiers in the 14th century. Also written *Jaque*, and the name of a form of *habergeon* worn in the 16th century.

JACK BOOTS.—Tall boots of tough, thick leather, reaching above the knee, and formerly worn by cavalry. In some instances, as an additional protection against sword-cuts, they were lined with thin plates of iron. The only regiments in the British service which still retain these handsome but cumbrous boots are the Life Guards and Royal Horse-Guards.

JACKET.—1. In the manufacture of ordnance, a tube inclosing and reinforcing another tube. 2. A short and close military coat, extending downward to the hips. Commonly called *Shell-jacket*.

JACK IN THE BOX.—A handy engine, consisting of a large wooden male screw turning in a female screw, which forms the upper part of a strong wooden box, shaped like the frustum of a pyramid. It is used, by means of levers passing through holes in it, as a press in packing, and for other purposes in the arsenal and laboratory.

JACK SCREW. — A machine for raising heavy weights, chiefly buildings of various kinds, as houses and ships. It has various forms, the most powerful being a differential screw. The most convenient form, however, is a single screw and net, the inclined plane of the screw being as near a horizontal as is consistent with the thickness of the thread and diameter of the screw. Other devices of the kind are employed, as the hydraulic jack. The drawing shows what is known in the arsenal as the "Rapid Moving Screw Jack," so called, because the screw, when the load is off, can be raised immediately to any desired point, and when up can be as quickly let down; thus saving the tedious operation of turning the screw up and down as in all the other screw jacks. To raise the screw to any desired height for the work, it is only necessary to lift the same by taking hold of the lever; to lower it, take hold of one of the handles with the left hand, and inclining the jack to an angle of about 45 degrees, with the other hand holding the lever, let the screw down.



The two segmental nuts are made of gun metal, and are supported on steel pins moving in angular slots so as to allow them in and out of the gear. The frame, lever, ratchet and cap are made of malleable iron, and the pawl of cast steel. The following sizes and weights are usually employed for artillery purposes:

No.	Height.	Raise.	Bar.	Weight.	Caacity .
24	22	11	2 in.	48 lbs.	8 tons,
25	27	15	2½ "	90 "	30 "
27	36	24	2½ "	137 "	30 "
26	29	14	3 "	210 "	50 "

No. 26 is provided with a detachable hook for ground lifting and bridge-work. See *Hydraulic Jack*.

JACK TREE.—A well-known tree in India. It yields an excellent timber, first yellow, fading to brown, hard and brittle, resembling satin; warps if not properly seasoned. A cubic foot of unseasoned wood weighs 50 lbs. The timber is used in the Bombay arsenals for packing-cases. The fruit of this tree is very much esteemed by the natives in the southern parts of India.

JACK WAMBASIUM.—A sort of coat armor, formerly worn by horsemen, not of solid iron, but of many plates fastened together, which some persons by tenure were bound to furnish upon any invasion.

JACOBINS.—The members of a political club which exercised a very great influence during the French Revolution. It was originally called the *Club Breton*, and was formed at Versailles, when the States-General assembled there in 1789. It then consisted exclusively of members of the States-General, all more or less liberal or revolutionary, but of very different shades of opinion. On the removal of the Court and National Assembly to Paris, this club began to acquire importance. It now met in a hall of the former Jacobin Convent in Paris, whence it received the name of the Jacobin club, which was first given to it by its enemies; the name which it adopted being that of the *Society of Friends of the Constitution*. It now also admitted members who were not members of the National Assembly, and held regular, and public sittings. It exercised a great influence over the agitation, of which the chief seat and focus was in the capital, and this influence was extended over the whole country by affiliated societies. Its power increased until it became greater than that of the National Assembly. It formed branch societies of clubs throughout France, of which there were soon not less than 1200. When the National Assembly dissolved itself in September, 1791, the election of the Legislative Assembly was mainly accomplished under the influence of the Jacobin Club. Almost all the great events which followed in rapid succession were determined by the voice of the Club, whose deliberations were regarded with more interest than those of the Legislative Assembly. It reached the zenith of its power when the National Convention met in Sept., 1792. The agitation for the death of the King, the storm which destroyed the Girondists, the excitement of the lowest classes against the *bourgeoisie* or middle classes, and the reign of terror over all France, were the work of the Jacobins. But the overthrow of Robespierre on the 9th Thermidor, 1794, gave also the deathblow to the Jacobin Club. The magic of its name was destroyed; and the Jacobins sought in vain to contend against a reaction which increased daily both in the Convention and among the people. A law of Oct. 16 forbade the affiliation of clubs, and on Nov. 9, 1794, the Jacobin Club was finally closed. Its place of meeting was soon after demolished.—The term Jacobins is often employed to designate persons of extreme revolutionary sentiments.

JACOBITES.—The name given to the adherents of the male line of the House of Stuart in Great Britain and Ireland after the Revolution of 1688. Many of the most devoted royalists followed James II. into France; but the greater part of the Jacobites remaining in their native land made a greater or less show of submission to the new government, while they secretly supported the cause of the Pretender. Their intrigues and conspiracies were incessant till the middle of the 18th century. Their hostility to the House of Hanover broke out in rebellions in 1715 and 1745, in consequence of which not a few of them lost their lives upon the scaffold, titles were attainted, and estates confiscated. After 1745 their cause became so obviously hopeless that their activity in a great measure ceased; and it was not long till it ceased altogether, and those who still retained their attachment to the exiled family acquiesced in the order of things established by the Revolution. In Scotland, the hopes and wishes of the Jacobite Party were expressed in many spirited songs, which form an interesting part of the national literature. The Jacobites of England were also *Tories*. They were generally distinguished by warm attachment to the Church of England, as opposed to all dissent, if they were not members of the Church of Rome, and held very strongly the doctrine of *non-resistance*, or the duty of absolute submission to the King. The Jacobites of Scotland were also generally Episcopalians and Roman Catholics. Macaulay, however, points out that the Highland clans which espoused the Jacobite cause did so on other grounds than the English Jacobites, and were far from having previously received the doctrine of non-resistance. In Ireland, the Jacobite cause was that also of the Celts, as opposed to the Saxons, or the native race against the English *Colonists*, and of the Roman Catholics against the Protestants. These diversities prevented a complete union, and greatly weakened the Jacobites.

JACOB'S LADDER.—1. A term originally applied on shipboard to a short rope-ladder with wooden steps, to give easy access to the shrouds and tops, but latterly applied to any short ladder of similar construction used in fortification for passing from one level to another, in the absence of ramps, etc. 2. An apparatus for raising light weights a considerable height. One form much used in arsenals and laboratories is shown in the drawing and consists of an endless chain of buckets, filling themselves at the bottom of the chain, and emptying at the top.

JACQUERIE.—The name given to the insurgent peasants in France in the middle of the 14th century, in the reign of John. The insurrection of the Jacquerie broke out in the year 1358, when the French King was a prisoner in England, and France in a state of the greatest disorder and anarchy. The immediate occasion of it was the enormities perpetrated by Charles the Bad, King of Navarre, and his adherents; but it was really caused by long-continued oppression on the part of the Nobles. Suddenly rising against their Lords, the peasants laid hundreds of castles in ruins, murdered the Nobles, and violated their wives and daughters, practicing every enormity, and acting, as they said, on the principle of doing as had been done to them. The insurrection broke out in the neighborhood of Paris, but extended to the banks of the Marne and the Oise. For some weeks this part of France was entirely at their mercy; but the magnitude of the danger induced the quarrelsome Nobles to make common cause against them, and on June 9 the peasants were defeated with great slaughter near Meaux by Captal de Buch and Gaston Phebus, Count of Foix. This put an end to the insurrection.

JADE.—A name somewhat vaguely applied to a number of minerals not very dissimilar—nephrite, axestone, serpentine, etc. Nephrite and axestone appear to be the minerals of which *jade* ornaments are generally made. But Yu, or Chinese jade, of which very beautiful vases and other articles are made in China, is supposed to be prebnite. Jade of all kinds has a greenish color, and when polished, has a rather dull and greasy aspect. Jade is much used in Poland and Turkey for the handles of swords and sabers.

JAGHIRE.—An Indian term, signifying the assignment of the revenues of a district to a servant or dependent of government, who is called *Jaghirdar*. Jaghires are frequently given in India to persons as a reward and compensation for their military services. *Jaghire Asham* is a term signifying land granted for the support of troops.

JALONS.—Long poles with wisps of straw at the top. They are fixed at different places and in different roads, to serve as signals of observation to advancing columns, when the country is inclosed, etc. They are likewise used as camp colors to mark out the ground on days of exercise.

JAMBEAUX.—Armor for the legs, made of waxed leather or metal, and much worn in the Middle Ages. Commonly written *Jambes*. See *Greaves*.

JAMES OF THE SWORD.—The Military Order of Saint James of the Sword was first instituted in Spain, in the reign of Ferdinand II. King of Leon and Gallicia. In the first instance it was organized with a view to stopping the inroads of the Moors, and its members pledged themselves to secure the safety of the roads. They entered into a league with the Brethren of St. Eloy, and the Order was confirmed by the Pope in 1175. The highest rank in the Order is that of Grand Master, which is united to the Crown of Spain. The Knights were obliged to prove their noble descent at least four generations back, and to show that they numbered among their ancestors no Jews, Saracens, or Heretics, and had never been cited by the Inquisition.

JAMES PROJECTILE.—A cylindro-conoidal missile of cast-iron, having a compound envelop of canvas-sheet-tin, and lead, called packing, encircling nearly the entire length of the body of the cylinder. The canvass being the external portion of the packing, is well saturated with a tallow lubric, which renders the loading easy, and cleans the gun at each discharge. The head of the projectile may be solid, or, if it has a prepared cavity, the missile then becomes a shell. The average weight of the projectile for a 42-pounder gun is, if a solid, 81¼ lbs., if a shell, 64¼ lbs., of which in either case 6½ lbs. is the weight of the packing. Its length is 13 inches, of which 6¼ inches is the measurement of the conical head, and 6¾ inches is the length of its cylindrical body. The diameter of the cylinder is designed to be 6¾ inches, or ¼ of an inch less than the bore of a 42-pounder gun. It retains its full diameter with accuracy for ¾ of an inch of its length at each end; then for the intermediate space, the diameter is shortened half an inch, thereby forming a recess round the body of the cylinder, between the ends, Fig. 1. The shortening of the diameter, and consequent loss of iron to the circumference of the body of the cylinder, is replaced by the before-named packing, when the projectile is prepared for use, Fig. 2. The solidity of the conical head is continued into, and forms the solid end of the cylinder. The base, or opposite end of projectile, has a central orifice, of 3½ inches in diameter, which extends 2½ inches into the cylinder; and from which *ten* rectangular openings diverge (like the mortises for spokes in the hub of a wheel), through the body, to the periphery of the cylinder, in the recess of its circumference. The packing is formed by a plate of sheet tin, of the length of the greatest circle of the cylinder; and in width, equal to the length of the recess caused by the shortening of the diameter.

This plate of tin is laid on a piece of strong canvas, which is two inches wider, but of the same length of the plate; and the canvas is folded over the side edges of the plate, and firmly secured by cross sewing. The tin plate, when so prepared, or half covered, is folded round the body of the missile in the recess, and retained in position by an iron collar clamp. The space between the inner surface of the envelop and the body of the cylinder is filled with melted lead, which, adhering to the tin and iron, forms a compact mass round the body of the projectile. When the charge is fired, the power or gas generated by the burning of the powder, in its effort to expel the projectile and to escape from the gun, is forced into the orifice in the base of the missile, and through the *ten* openings against the packing,

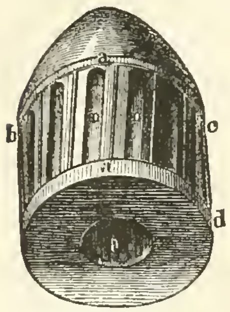


FIG. 1. BEFORE THE APPLICATION OF THE PACKING.

a. Band ¾ inch wide at ends of cylinder.
b,c,d. Recess round body of cylinder.
m. Rectangular openings through to recess.
n. Orifice in base, leading to the recess.

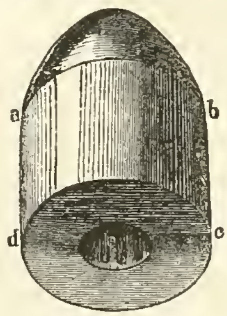

FIG. 2. AFTER THE APPLICATION OF THE PACKING, AND READY FOR USE.

a,b,c,d. Belt of canvas, tin, and lead, called packing.
e. Orifice in base, leading to recess.

which is thereby pressed into the grooves, in the gun's bore, and by its firm hold in them the rifle motion is imparted to the projectile.

When the projectile is a shell, its fuse-orifice is in its head and axis. The length of the orifice for a 42-pounder shell is 2½ inches. For two inches of its length, its diameter is 1 inch, and for the remainder of the length, the diameter is reduced to ¾ of an inch; forming a shoulder in the fuse-orifice, to prevent the fuse-plug from being driven into the cavity of the shell, when, by firing, the missile is expelled from the gun. The threads of a female screw are cut in the head of the fuse-orifice for the reception of the body of the fuse-orifice cap. This cap is of brass. Its diameter is an inch, its length half an inch; its head is convexed, and has a slot cut in it for the reception of a screw-driver; the base end is deeply cupped to admit the nipple of a musket cone, and to give more play to the fuse-plug. The fuse-plug is of wrought iron, surmounted by a musket cone; and its action in the fuse-orifice is like the ordinary working of a piston. Its length is 1¼ inches, of which the quarter is the length of its shoulder. The diameter of its shoulder and body, is very nearly the same as the two diameters of the fuze-orifice. Its vent is in its axis, and in size to receive the male screw of the musket cone. The threads of a female screw are cut in the head end of the vent of sufficient length to receive the screw end of the said cone. When the shell is loaded, care should be taken not to overfill its cavity, and thereby prevent the working of the fuse-plug. The powder should be cleaned from the fuse-orifice; the plug should be oiled to ensure its free and sure action. Its cone should be capped, but before the application the percussion cap should be carefully examined to see that it is perfect, and of the best quality. The fuse-plug, when so prepared, is then inserted into the fuse-orifice, and it should enter freely, but not by its own weight until the shoulders of the fuse-plug and orifice are in contact. The cap for the fuse-orifice should be then firmly screwed in, which completes the charging of the shells. If after the shell is loaded the fuse-plug should be disturbed by handling; that is, if the plug has slidden forward, it will be forced back to its proper position by the impulse given to the missile, by the firing of the gun charge; and it will so remain during the flight, until the shell impinges against any hard substance; as ground, wood, etc., which, by obstructing the progress of the missile, causes the fuse-plug to slide forward with violence, and by the collision of the cone's point against the bottom of the fuse-orifice cap-plug, the percussion cap on the cone will be exploded, and the bursting charge of the shell fired. See *Expanding Projectiles.*

JAM-NUT.—A nut of frequent occurrence in the construction of artillery carriages, the elevating gears, etc. See *Lock-nut.*

JANGAR.—A kind of ponton constructed of two boats with a platform laid across them, which is used by the natives in the East Indies to convey horses, supplies, etc., across rivers.

JANISSARIES—JANIZARIES.—A Turkish military force, originally formed by the Osmanli Sultan Orkhan, about 1330, of young Christian prisoners compelled to embrace Mohammedanism; and more perfectly organized by Sultan Amurath I. after 1362, when the number was raised to about 10,000, and especial privileges were conferred on them. They were for some time recruited from Christian prisoners, but their privileges soon induced many young Turks to seek admission into their body. There were two classes of Janizaries, one regularly organized, dwelling in barracks in Constantinople and a few other towns, and whose number at one time amounted to 60,000, but was afterwards reduced to 25,000; and the other composed of irregular troops, called *Jamaks*, scattered throughout all the towns of the Empire, and amounting in number to 300,000 or 400,000. At the head of the whole Janizary force was the *Aga* of the Janizaries, whose power was limited only by the danger of revolt, and extended to life and death. The Janizaries were always ready to break out into deeds of violence if their pay or perquisites were withheld. In times of peace they acted as a police force. They served on foot; generally formed the reserve of the Turkish Army, and were noted for the wild impetuosity of their attack. The Sultan's body-guard was formed of them. The Janizaries, however, soon began to be very unruly; and their history abounds in conspiracies, assassinations of Sultans, Viziers, Agas, etc., and atrocities of every kind; so that, by degrees, they became more dangerous to the Sultans than any foreign enemies. The attempts of the Sultans to reform or dissolve them were always unsuccessful, till Sultan Mahmoud II., in 1826, being opposed in some of his measures by the Janizaries in Constantinople, displayed the flag of the prophet, and succeeded in arousing on his own behalf the fanatical zeal of other portions of his troops. The Janizaries, deserted by their Aga and other principal officers, who remained faithful to the Sultan, were defeated and their barracks burned, when 8,000 of them perished in the flames. A proclamation of June 17, 1826, declared the Janizary force forever dissolved. All opposition was defeated with bloodshed. Not fewer than 15,000 were executed, and more than 20,000 were banished.

JANUARIUS.—The order of Saint Januarius was founded by King Charles of Sicily (afterward Charles III. of Spain), on July 6, 1738. It was abolished after the French Invasion of 1806, and reintroduced in 1814. The badge is a gold octagonal white and red enameled cross, with gold lilies in the upper and side angles. The obverse represents St. Januarius in episcopal robes, with an open book. The round middle of the reverse shows a golden open book, and two phials partly filled with blood. The Knights are either *Cavalieri di Giustizia*, who must count four noble generations, or *Cavalieri di Grazia.*

JAPANNING—A laboratory process, giving a coating of varnish and other materials to certain manufactures, by which a resemblance is produced to the beautiful lacquered wares of Japan and China. The term is more generally applied in this country to metal works upon which a dark-colored varnish is applied with heat; but the process is quite as extensively applied to papier-mâché works. The japanning material consists of anime or copal varnish, alone, or mixed with ivory-black, to produce a black japan; or with asphalt, to produce a dark or light brown, according to the quantity used. For tinned wares, a single coating is all that is usually given. After being varnished they are put into a heated oven for a time, after which they are ready for use; but in the case of more substantial articles several coats of varnish are applied, each being dried in the oven previous to the application of the next, so that a coating of sufficient substance to bear polishing is thus obtained. Rotten-stone and Tripoli powder are used by the polisher, and a beautiful surface is obtained, in no respect inferior to that of polished jet. The polishing powders are at first applied with leather, but the finishing is done by women, who use the palms of their hands only, with small quantities of Tripoli.

JATS—JAUTS.—The name of a people of Hindustan, first mentioned in history at the beginning of the 11th century. They opposed the invasion of Mahmoud the Gazne Vide, and are said to have gathered a fleet of as many as 8,000 boats in the Indus, where they were attacked by the invader and completely defeated. In the reign of Aurungzebe, the Jats appeared as banditti in the mountains in the interior of India. They increased in strength and daring, until they finally became formidable, and under their Chief, Sooraje Mull, even dictated the policy of the Mogul Court. The invasion of northern India by Ahmed Shah, Sovereign of Cabul, put an end to the prestige of Sooraje Mull, who, after allying himself to the Mahrattas, deserted them before the battle of Panniput, and joined Ahmed Shah. His services on the occasion of this battle were rewarded by the possession of Agra and its district. At the time of the establishment of British power in northern India, the since celebrated Runjeet Singh was Rajah of the Jats, and by a treaty with Lord Lake, was permitted to remain in control of his territories without paying tribute. Disagreement between the English authority and that of the Rajah brought about a conflict, and early in 1826 the almost impregnable fortress of Deeg, the stronghold of the Jats, was invested by a large force of British soldiers under Lord Combermere. On Jan. 18 the fortress was stormed and captured, and the power of the Jats was at an end.

JAVELIN.—A short and light spear used for darting against an enemy. In the Roman legion, the first and second lines (the hastati and the principes) were both armed with two javelins to each man. Each javelin was in all about $6\frac{3}{4}$ ft. in length: the shaft $4\frac{1}{2}$ ft. long, of tough wood, an inch in diameter; and the remainder given to the barbed pyramidal head. In action, the legionary hurled one javelin on the enemy at the first onset; the second he retained as a defense against cavalry. The Goths and other barbarians used a javelin. At present, javelins are used in Europe in hunting the boar, and by many savage nations in ordinary hunting. The assegai of the Caffre is a javelin of native iron.

JAZERAN.—A coat of scale armor, first worn in the Middle Ages. This garment was sleeveless and somewhat lighter than the hauberk. Commonly written *Jazerant*.

JEFFREY POJECTILE.—In this projectile, the lead is affixed to the rear of the projectile by dovetails, into which it is cast; a hollow, resembling that of the Minnié bullet, is left at the bottom, for the purpose of causing the lead to be driven into the rifling. A wad or covering, consisting of flannel coated with soft soap, is wrapped around the rear of the projectile, to facilitate loading, decrease windage, and lubricate the bore.

JELOUDAR.—An East Indian term, signifying to belong to the train or equipage.

JEMADAR.—A native officer in the Indian Army, whose position corresponds with that of a subaltern in a company of European infantry. The name is also given to the head man of a native establishment in a factory, and indeed to any man who exercises authority over a number or gang of men.

JE MAINTIEDRAI.—The motto of the House of Nassau. When William III. came to the throne of England, he continued this, but added the "liberties of England and the Protestant religion," at the same time ordering that the old motto of the royal arms, "Dieu et mon droit" should be retained on the great seal, 1689.

JENIZER-EFFENDI.—An appointment among the Turks, which in some degree resembles that of Provost-Marshal in European armies. The only functions which this officer is permitted to exercise are those of judge to the company. He sits on particular days for the purpose of hearing the complaints of the soldiers, and of settling their differences. If a case of peculiar difficulty should occur, he reports the case to the Aga, whose opinion and determination are final.

JENNIFER SADDLE.—A saddle very extensively used in the United States and other countries, prior to the invention of the *Whitman saddle*. While considered one of the best saddles in its time, it had the serious defects of being too short in the seat, too short in the bearing, and too much rounded on its under side, inclining it too "rock" and sore the back in the center; also sharp pommel and too straight in cantle.

JERKIN.—A buff military coat, on which was worn a light collar. The *jerkin* took the place of armor towards the end of the 16th century.

JERRID.—A slender javellin used as a dart by the soldiers of the East, in the Midde lAges.

JESSANT.—In Heraldry, springing forth, a term frequently used as synonymous with *Issuant*, rising, as a demi-lion is often represented doing, from the bottom line of a field, or upper line of an ordinary. Jessant is sometimes used improperly for *naissant*, or rising from the middle of an ordinary. The phrase *jessant-de-lis* is used with respect to a strange heraldic device depicting a leopard's head *affronte* with fleur-de-lis passing through it. The family of Moreley, Hants, bears sable, a leopard's head argent jessant-de-lis; and gules, three leopard's heads jessant-de-lis or, are the arms of the family of Cantelupe. See *Heraldry*.

Jessant-de-lis.

JET.—1. A term signifying the motion of any body that is urged forward by main force; it likewise means the space which is gone over by any propelled body; and sometimes the instrument from which anything is thrown or shot; as the cross-bow, etc. *Jet des bombes* is a phrase used instead of *tir*, which formerly expressed the course that a shell took when it was thrown out of a mortar by the power of gunpowder. 2. In pyrotechny, *jets* are rocket-cases filled with a burning composition; they are attached to the circumference of a wheel, or the end of a movable arm to set it in motion.

JEWELS.—By an egregiously absurd and unnecessary complication of nomenclature, introduced by way of adding dignity to the science of Heraldry, the tinctures of the arms of peers have sometimes been designated by the names of precious stones; argent is pearl or crystal; or, topaz; gules, ruby; azure, sapphire; sable, diamond; vert, emerald; and purpure, amethyst.

JEWEL TARGET.—A canvas target, having framework and machinery made of iron. The mechanism permits of the use of a target of any class by taking out the frame and legs of one target and substituting therefor those of another. A framework supporting the target works upon a center-pin or spindle (12 inches long) securely fastened to a heavy timber at the back of the pit, and revolves the target to the right or left such distance as may be required. When a shot strikes the target, the marker by suitable contrivances pulls the target over, and hangs a disk, denoting the value of the shot, in the shot-hole, patches the last hole (if any), and swings the target back into position ready for the next shot. The marker for this target is provided with small disks made of wood, tin, or iron, with hooks in the center and each side of them, and painted to represent certain values.

JIB-CRANE.—The mode of operating the hoisting and traversing mechanism of the larger sizes of the Weston jib-cranes is fully explained in the article TROLLEYS. The details of the gearing whereby these several motions are affected are as follows. Fig. 1 is a cross-section taken at the foot of the mast of a large jib-crane. A is the mast, to each side of which is bolted a housing containing the gearing for operating the two parts, X, and Y, of the main hoisting chain. Each of these housings is provided with a horizontal shaft, revolving upon which is the worm wheel P, the hub of which covers the entire length

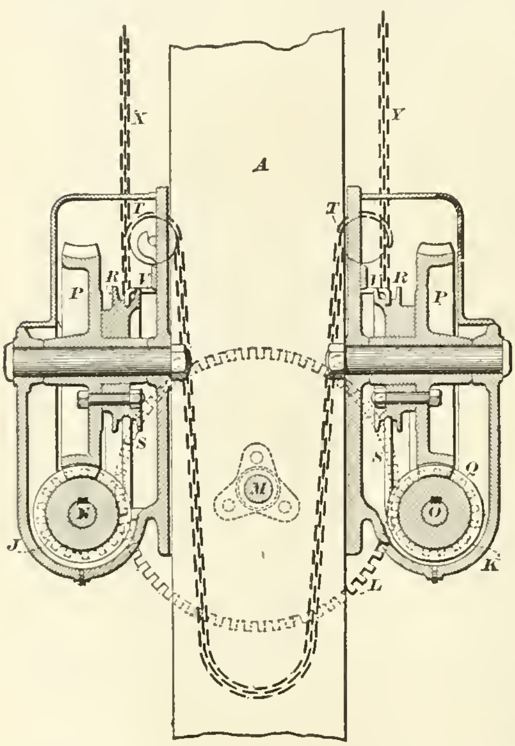

Fig. 1.

of the pin or shaft between its bearings. Over the hub of this wheel, is the pocketed chain-wheel R, with the chain stripper V, and a chain guide, S. The chain wheel is made separately from the worm wheel to admit of easy removal and renewal when worn out. Referring now to the right hand housing in the drawing, O is the crank shaft extending through the housing at right angles to the worm wheel shaft above. Q is the worm, fitted upon the shaft, O, at its center, and gearing into the worm wheel, P. K. is a spur pinion, fitted to one end of the shaft, O, and capable of sliding longitudinally thereon. T is a small guide sheave over which the slack of the chain falls after passing around the lower semi-circumference of the chainwheel, R. The arrangement of the opposite or left hand housing, and its contained gearing, is the same as that just described.

Fig. 2, is a detail view of one of the chain wheels, R, with the chain guide, S, and stripper, V, showing

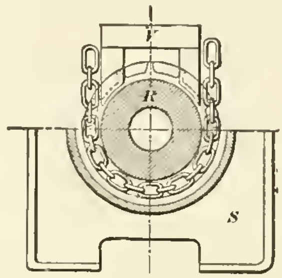

Fig. 2.

the manner in which the chain is guided during its contact with the wheel, and the provision, by means of the stripper, V, for compelling it to leave the wheel, R, at the proper point in whichever direction the wheel is being turned. The slack part of the chain, after passing over the guide sheave, T, falls into a receptacle between the housings at the foot of the mast. The chain being endless, the two parts, X and Y, come together in the receptacle just referred to, and are there united, the amount of slack chain contained in the box varying with the position of the running block.

Fig. 3 is a horizontal cross-section taken through both housings and the mast of the crane, the several

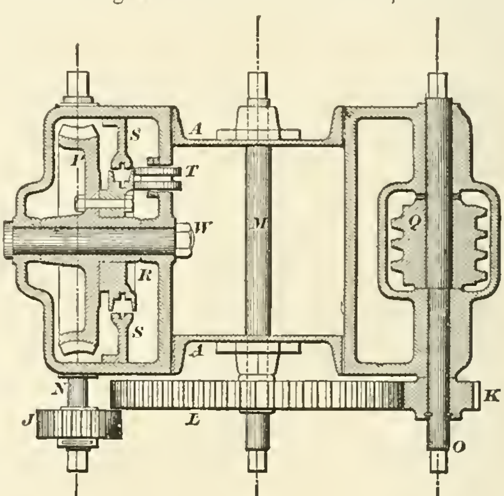

Fig. 3.

parts being designated by the same letters in Fig. 1. M is a shaft parallel to the crank shafts, O and N extending through the mast and carrying at one end the large spur wheel, L. The pinions, J, and K, as previously explained, are arranged to slip upon their shafts so as to bring them into or out of coincidence with the intermediate wheel, L, and the pinion, J, is disengaged. If now the crank be applied to the shaft, N, and turned in the proper direction, the chain, X, will be hauled in and the load raised. The same effect will result from rotation of the shaft, O. If both be turned simultaneously, hoisting will be effected at double speed. By applying the crank to the shaft, M, motion will be communicated through the wheel- L, and pinion, K, to the shaft, O, and hoisting will occur at a rapid speed proportionate to the relative diameters of the wheels, L and K. Three speeds are thus obtained for hoisting, all of which are equally applicable to lowering by reversing the motion of the cranks.

To effect the proper travel of the trolley, both pinions, J and K, are slipped into engagement with the wheel, L. By then turning either of the shafts, N or O, in the proper direction, one part of the hoisting chain, X, for example, will be hauled in, and the opposite part, Y, paid out at equal speeds, the effect of which is to cause the trolley to move horizontally upon the jib. By applying the crank to the shaft, M, these motions are accelerated, and a rapid movement of the trolley results.

Two cranks are furnished with each crane, and it is to be noted that the construction admits of the employment of both cranks upon any one of the shafts M, N, or O, so that the entire energy of all the men employed upon the crane is transmitted through that shaft, while, if more rapid action is desired, one of the cranks may be placed upon the right hand end of the shaft, N, and the other upon the opposite or left hand end of the shaft, O. In either case the two shafts, being on opposite sides of the crane, do not in any way interfere with one another, and are thus always available for the full number of men who can effectively be employed upon them.

The compactness and simplicity of this mechanism will be apparent from the foregoing description. The entire operating mechanism of the crane consists of two worm wheels and worms, and of the spur wheel L with its two pinions. The worm wheels and worms are entirely contained within the two housings, the upper parts of which latter are arranged to lift off to give access to the gearing. Each of the worms runs in an oil well, thus insuring perfect lubrication, and each of these wells is provided with a drainage-tap at the bottom to draw off the lubricant when desired.

Fig. 4 represents a jib-crane of medium size, each member of the frame consisting of two parts, separated so as to permit the chain and block to pass between them, so that the load can be moved close into the mast. The hoisting mechanism is attached to the mast near its foot, and the running block which carries the load, is suspended from a trolley travelling on the jib and capable of movement in and out by means of independent gearing attached to the jib at its intersection with the mast. Cranes of this design are built of any desired capacity from 1 ton to 5 tons. The frame consists of wrought iron channel beams, each of the three members of the frame being composed of two such channel irons. The dimensions are such as to give the accepted factor of safety, and the several parts are very securely connected together at their intersections by riveting.

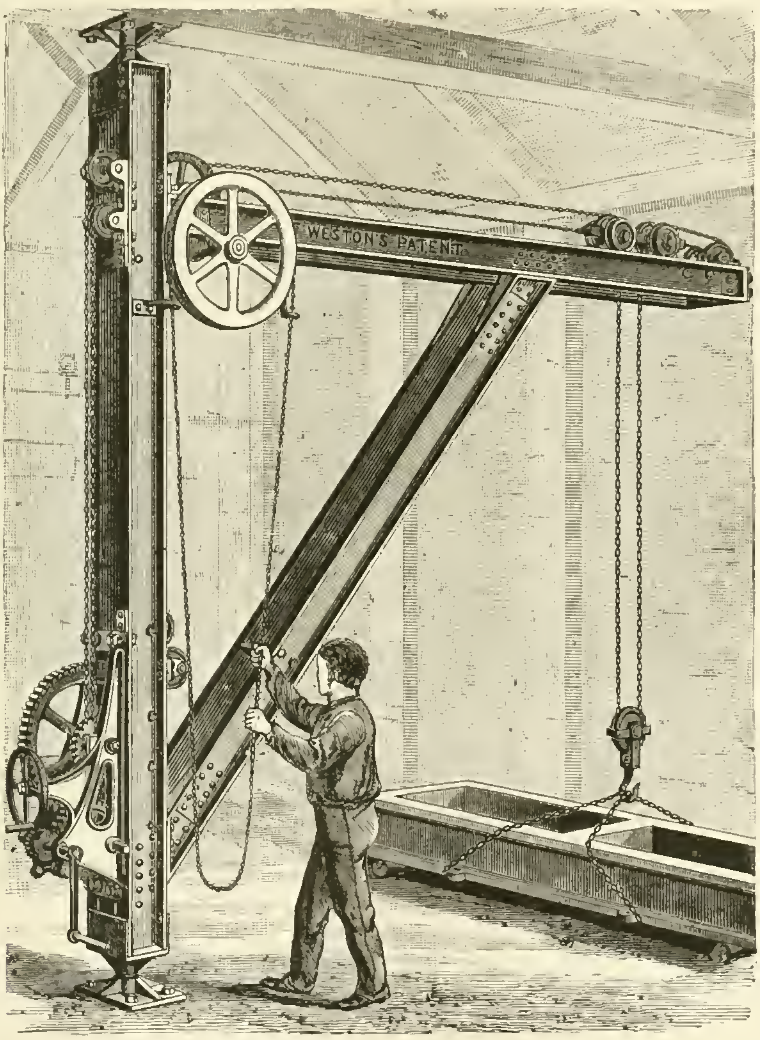

Fig. 4.

Hoisting is effected through a train of spur gearing operated by crank in the usual way, and provided with an automatic safety ratchet. Lowering is effected by a separate mechanism consisting of a turned worm wheel and worm, operated by a light hand wheel, as shown in the cut, this mechanism being also available for raising light loads. Thus arranged, the machine is self-sustaining and can be left at any time with the load in suspension without danger of the load running down or the handles flying back. The construction gives three changes of speed, and embodies the endless chain system, which insures an even distribution of wear over the entire length of chain.

Rotation is easily effected by pushing or pulling the suspended load, the pintles in top and bottom bearings being of steel and turning in bronze boxes. Motion of the trolley on the jib, in either direction, is effected by gearing operated from below by an endless hand chain, as shown in the cut. The self-sustaining construction of the hoisting gear holds the load suspended at any height while the trolley is moved in and out on the jib.

Cranes of this type are adapted for use in arsenals for handling and mounting heavy guns, in foundries, forges, rolling mills, etc. See *Cranes* and *Trolleys*.

JIGGER.—In mechanical maneuvers, an apparatus consisting of a strong rope with a block at one end, and a sheave at the other, used in maintaining the tension of—or, technically, in "holding on" to—the cable as it is thrown off from the capstan or windlass, around which it only takes two or three turns.

JIM CROW.—One of the tools used by railway platelayers for bending rails, and forms one of a set of platelayers' tools attached to the royal engineer siege equipment. It is suitable for bending the 24 lb. rails of the trench railway.

JINGAL.—A small, portable piece of ordnance to be fired from the ground or on a wall, resting on a long, slender butt-end, and two legs. This piece was commonly used in India. Sometimes written *Jingall*. See *Gingals*.

JOAR.—An East Indian term, signifying a general massacre of the women and children, which is sometimes performed by the Hindoos, when they find they cannot prevent the enemy from taking the town. When this dreadful and unnatural ceremony is to take place, a spot is selected which is filled with wood, straw, oil, etc. The victims are inclosed and the whole is set on fire.

JOHN BULL.—A familiar synonym for the English people. Its origin is attributed to Dean Swift, but Arbuthnot first gave it literary currency in his *History of John Bull* (1712), a political allegory intended to satirize the Duke of Marlborough, and to increase feeling against the war with France. In art John Bull is well known as a burly country squire, impetuous, honest, narrow-minded, dogmatic, and easily imposed upon.

JOHN OF JERUSALEM.—The Order of Knights of Saint John of Jerusalem, otherwise called Knights of Rhodes, and after of Malta is the most celebrated of all the military and religious orders of the Middle Ages.

It originated in 1048 in an Hospital dedicated to St. John the Baptist, which some merchants of Amalfi were permitted by the Calif of Egypt to build for the reception of the Pilgrims from Europe who visited the Holy Sepulcher. The nurses were at first known as the Hospitaler Brothers of St. John the Baptist of Jerusalem. The Seljuk Turks, who succeeded the Egyptian and Arabian Saracens in Palestine, plundered the Hospice, and on the Conquest of Jerusalem by the Crusaders under Geoffroy de Bouillon in 1099, the first Superior, Gérard, was found in prison. Released from durance, he resumed his duties in the Hospice, gave material aid to the sick and wounded, and was joined by several of the Crusaders, who devoted themselves to the service of the poor Pilgrims. By advice of Gérard, the brethren took vows of poverty, chastity, and obedience before the Patriarch of Jerusalem. Pope Pascal II. gave his sanction to the Institution 1113. Raymond du Puy, the successor of Gérard in the office of Superior, drew up a body of Statutes for the Order, which was confirmed by Pope Calixtus II. To the former obligations was afterward added those of fighting against the Infidels and defending the Holy Sepulcher. Various Hospices, called *Commanderies*, were established in different maritime towns of Europe as resting places for Pilgrims, who were there provided with the means of setting out for Palestine. The Order having become military as well as religious, was recruited by persons of high rank and influence, and wealth flowed in on it from all quarters. On the Conquest of Jerusalem by Saladin in 1187, the Hospitalers retired to Margat in Phenicia, whence the progress of infidel arms drove them first in 1285, to Acre, and afterwards, in 1291, to Limisso, where Henry II., King of Cyprus, assigned them a residence. By the Statutes of Raymond, the Brethren consisted of three classes, Knights, Chaplains, and Serving Brothers; these last being fighting Squires, who followed the Knights in their expeditions. The Order was subsequently divided into eight languages—Provence, Auvergne, France, Italy, Aragon, England, Germany, and Castile. Each nation possessed several Grand Priories, under which were a number of Commanderies. The chief establishment in England was the Priory at Clerkenwell, whose head had a seat in the Upper House of Parliament, and was styled First Baron of England.

In 1310, the Knights under their Grand-Master, Foulkes de Villaret, in conjunction with a party of Crusaders from Italy captured Rhodes and seven adjacent islands from the Greek and Saracen Pirates by whom it was then occupied, and carried on from thence a successful war against the Saracens. In 1523, they were compelled to surrender Rhodes to Sultan Solyman, and retired first to Candia and afterward to Vitebo. In 1530, Charles V. assigned them the Island of Malta, with Tripoli and Gozo. The Knights continued for some time to be a powerful bulwark against the Turks; but after the Reformation a moral degeneracy overspread the Order, and it rapidly declined in political importance; and in 1798, through the treachery of some French Knights, and the cowardice of the Grand Master, D'Hompsech, Malta was surrendered to the French. The lands still remaining to the Order were also about this time confiscated in almost all the European States; but though extinct as a Sovereign Body, the Order has continued during the present century to drag on a lingering existence in some parts of Italy, as well as in Russia and Spain. Since 1801 the office of Grand-Master has not been filled up: a Deputy Grand-Master has instead been appointed, who has his residence in Spain. The Order at first wore a long black habit with a pointed hood, adorned with a cross of white silk of the form called Maltese on the left breast, as also a golden cross in the middle of the breast. In their military capacity, they wore red surcoats with the silver cross before and behind. The badge worn by all the Knights is a Maltese cross, enameled white, and edged with gold; it is suspended by a black ribbon, and the embellishments attached to it differ in the different countries where the Order still exists.

JOHNSON LOADING-APPARATUS.—The aim of the inventor in planning this apparatus has been to produce a loading device which may be applied without altering the present style of gun-carriages, and which may be operated from a position considerably below the muzzle of the gun. A staff-carriage is supported by rods which may be raised or lowered by racks and pinions. The staff-carriage carries a short shaft, upon which there is a pinion for driving the sponge staff or rammer staff, also two drums for receiving the rope by which it is rotated. The first operation in cleaning the gun is to raise the staff-carriage; the sponge staff is then run through the carriage as far as convenient; the free end of the staff is then raised by means of a rod filled with a fork for the purpose. As soon as the teeth of a rack with which the sponge staff is provided, engage the teeth of the pinion in the carriage, the pinion is turned by means of the ropes, forcing the sponge into the bore of the gun. The sponge staff carries a drum by means of which it may be revolved when the sponge reaches the end of the bore. The sponge staff is withdrawn by reversing the motion of the pinion in the carriage. A cartridge rest receives the cartridge shell, or shot, and carries it to the muzzle of the gun. The rammer staff is then inserted and operated in much the same manner as the sponge staff. After loading, the staff-carriage and the cartridge-rest are lowered out of the way to permit of the ready adjustment of the gun. This very ingenious apparatus is the invention of Lieutenant David D. Johnson, United States Army.

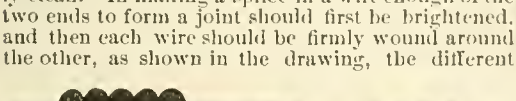
JOHUR DE RAJAH. An Indian sword used early in the seventeenth century.

JOIN.—A technical word used in the service, signifying to effect the junction of one military body with another. In a more limited sense, it means the accession of an individual, voluntary or otherwise, to a corps or army. If an officer, on being ordered to join, omits to do so wilfully, he is liable to trial by a General Court-Martial, or to be peremptorily suspended for being absent without leave.

JOINTEE-JYNTEE.—A wood whose charcoal has been much used in the Government powder works at Ishapore, near Calcutta, in the manufacture of gunpowder. The jointee grows from seed, and flowers after the first year; it then increases in size till it becomes a small tree; at three or four years old, it makes the best charcoal, the fibers being then large and defined, and well separated; the charcoal is of a lightish color, and is not dense to the eye or touch. The tree flourishes best on the banks of small nullahs or water-courses. Jointee charcoal is not so soft as that of the urhur or dhall stalk, but it is more dry, brittle, and hard. An averaged-sized tree of three years' growth will occupy about 5 square yards, and produce about three maunds of wood, which will yield about 30 lbs. of charcoal, the quantity required for two 100-lb. barrels of gunpowder. Therefore 10,000 barrels would require about sixty beegahs of land under constant cultivation, one-third to be cut each year. The average specific gravity of jointee wood is .767, and sp. gr. of the charcoal produced from it .275; and it yields 25 per cent. of charcoal. Experience has shown that this wood is not so good for gunpowder purposes as the dhall bush, and therefore should only be used in case of a failure of that crop.

JOINTS.—This is a very important point in connection with a system of mines. In many instances it will be found necessary to join either two lengths of cable, or an insulated wire and a cable, together, in both of which cases great care must be used in making the joints, so hat the insulation and the continuity of the circuit may be perfect.

As oxides of metals can scarcely be considered conductors, all joints in a wire, over which an electric current is to pass, should, when formed, be perfectly clean. In making a splice in a wire enough of the two ends to form a joint should first be brightened, and then each wire should be firmly wound around the other, as shown in the drawing, the different



evolutions touching one another, and passing, as near as may be, at right angles with the wire which they surround. A wire, in being spliced, must never be bent back and wound upon itself, forming a loose loop, which, for telegraphic purposes, is rather unreliable. In making a joint under water, a great object is to totally exclude the ingress of water, or even moisture, which would at once afford a path for the current and cause a loss or a leak in the cable.—See *Mines*.

JONES GABION.—A useful gabion made of ten bands of galvanised sheet-iron, worked over twelve wood pickets, the ends brought together and connected by two buttons at one end, fitting into two slots at the other. Each band is 77 inches long, 3¼ inches wide, of No. 20 gauge, or about 0·05 inch thick; weight of ten, 29 lbs. The buttons and button-holes are required to stand a weight of 672 lbs., the band itself will support about 1,500 lbs.; each band has four holes to admit of combination to form bridges, beds, stretchers, and for other incidental applications; little or no instruction is required for making these gabions.

Two expert men can make a gabion in five minutes.

JOODAY PERRAPUT.—An East Indian term, signifying a slave taken in war.

JOSLYN TOMES GUN.—A breech-loading rifle having a fixed chamber closed by a movable breech-block which slides in the line of the barrel by direct action. It is opened by cocking the hammer. In so doing a hook-shaped shoulder on its forward portion is disengaged from a corresponding recess in the receiver; and the whole bolt containing the hammer and lock, is free to move backward to its full extent. The firing-pin being linked to the hammer is also positively withdrawn from the face of the bolt. The piece is closed by reversing the motion of the bolt. It is held closed by a spring-catch (friction-pin) on its side. It is locked by the descent of the hooked portion of the hammer into the recess of the receiver, when the piece may be fired by a back-action lock concealed in the bolt, the trigger alone being detached. The firing-pin descends with the hammer along an inclined groove in the face of the bolt leading to the site of the fulmintae in the center of the cartridge-head. Extraction is accomplished by a spring-hook recessed in the side of the bolt, and riding over the rim of the cartridge when the piece is closed. Ejection is caused by the cartridge-shell being quickly withdrawn on two longitudinal guides, one on each side of the receiver, and ejected by the head striking first a stop on one guide; and then almost simultaneously a stop to the rear of the first, on the other guide.

JOURNAL.—A public record or general orderly book kept in the French service, and in which every transaction that occured during a siege is entered by the Governor of the town, for the inspection of a Superior Authority. The General Officer who carried on the siege of a place likewise kept a document of the same kind, and minuted down every thing that happened under his command. So that the Journal which was kept in this manner was a circumstantial detail of what occurred, day after day, during the attack and defense of a town.

JOURNAL OF ATTACK.—In actual siege operations a daily record is made by each Engineer Officer on duty in the trenches, of the amount of work done, the time required, the means of execution, etc., with any observations that may seem of value. These records are transmitted to the headquarters of the Commanding Engineer, where they are filed away for reference, and from them the progress of the trenches is carefully laid down upon the original directing plan of the attack. From the data furnished by such records, and from the results obtained in the Schools for training engineer troops, the average time required for executing the various portions of the siege works, under ordinary circumstances, during the different epochs into which they have been divided, has been laid down by writers on this subject. This mode of calculation has also been applied to test the relative value of different systems of permanent fortifications, by submitting them to a fictitious siege, and estimating from the time, as shown in this way, required for their reduction, how much longer the one system would hold out than the other. However ingenious this method may at first appear, it affords no real practical test of any importance; the duration of sieges depending upon moral and physical laws, as their whole history has shown, that no mode of calculation can reach. The immediate successors of Vauban, who made use of these calculations in theoretical sieges, have usually allowed nine days, from the opening of the trenches to the completion of the 3d parallel; estimating that all the batteries, along the front of the 1st and 2d parallels, would be completed on the sixth day, and the fire of the defenses be brought under in twenty-four hours after the batteries were in full play.

JOURNAL OF DEFENSE.—In the American service, during war, the Commander of a place and the Chiefs of Engineers and of Artillery are required to keep Journals of Defense, in which are entered in order of date, without blank or interlineation, the orders given or received, the manner in which they are executed, their results, and every event and circumstance of importance in the progress of the defense. These Journals are sent after the siege to the War Department.

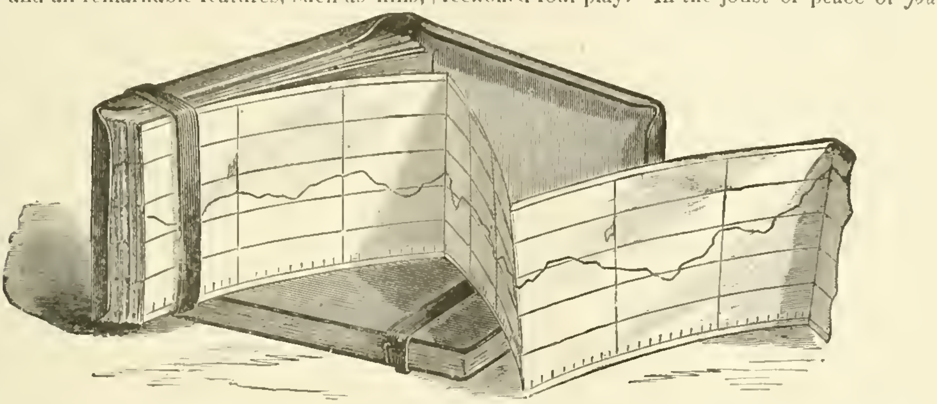
JOURNALS OF MARCH.—Commanding officers of troops marching through a country little known,

JOURNAL of the march of [*here insert the names of the regiments or companies composing the column*], commanded by ——— ———, from [*here insert the point of departure*] to [*the stopping place*], pursuant to [*here gvie the No. and date of order for the march*].

Date.	Hour.	Weather.	Distance.	REMARKS.
1860.			Total, 19	
July 8.	5. A. M.	Cloudy, with wind.—Cold early in morning.—Cloudy.	3	Road rocky; but little grass; good water. Plenty of timber on the summit of hills, extending 3 miles; road to right of hills.
	1. P. M.		8	Good shelter for camp at foot of peak; fuel plenty. Springs of sweet water, with good grass near. Road to this point rather more sandy.
	10.		3	Road runs through a canyon ½ mile long, to right of a small stream; marsh on left of stream; water sweet; grass excellent. Halted to graze two hours. No Indian signs.
	6.30.		1	Companies F, G, and I, 3d ——, detached at Mt. P——, under command of ——— ———, (see par. 3, General Orders, No. ——), to take road to ———. A small creek, easily forded.
	6.		4	Road turns short to right at top of hill after crossing river; crossing good, but a little boggy on right bank. This bottom shows signs of recent overflow, when it must have been impassable; banks low; water sweet; no wood near crossing; road hard and good up to river.
July 7.	4.30.			
			Total, 47	
July 9.	4.30 A. M.	Rain.	5	At the point where the roads fork, turn to the right. The left-hand road leads to a deep ravine, which cannot be crossed.
	4.30 P. M.	Very pleasant; cloudy in the P. M.	3	After the road strikes the ravine, it runs one mile along its bank before coming to the crossing-place. The camping ground is at springs, half a mile beyond the ravine. Old Indian signs at the springs.
	3 P. M.		15	Road less rocky; last three miles rather sandy; no water. Passed at one point an Indian grave.
	9. "		5	Road still rocky; good springs, where casks should be filled. No more water for twenty miles after leaving springs. Occasional hills to left of road; no wood or grass.
July 8.	6.30 A. M.			
			19	

keep journals of their marches according to a form laid down in Army Regulations. At the end of the march a copy of the journal is retained at the station where the troops arrive, and the original is forwarded to the Headquarters of the Department or Corps d'Armée. Thence after a copy has been taken, it is transmitted, through the Headquarters of the Army, to the Adjutant General, for the information of the War Department. The drawing represents Ketcham's continuous profile-book, which is mostly used for route-sketching and general field notes. When this cannot be obtained, a book made of sheets of paper folded to half the letter size will answer. The record should run from the bottom to the top of each page.

Referring to the form on page 144, it is understood that the distance, in miles, between each of the horizontal divisions, will be noted in the column headed "*Distance*," which will be summed up at the top of each column, and the sum carried to the bottom of the next column. The notes within each horizontal division are to show the general directions of the march, and every object of interest observed in passing over the distance represented thereby; and all remarkable features, such as hills,



streams with their names, fords, springs, houses, villages, forests, marches, etc., and the places of encampment, will be sketched in their relative positions. The "*Remarks*," corresponding to each division, will be upon the soil, productions, quantity and quality of timber, grass, water and fords, nature of the roads, etc., and important incidents. They should show where provisions, forage, fuel, and water can be obtained; whether the streams to be crossed are fordable, miry, have quicksands or steep banks, and whether they overflow their banks in wet seasons; also the quality of the water; and, in brief, everything of practical importance. When a detachment leaves the main column, the point on the "route" will be noted, and the reason given in the *Remarks*. The Commander of the detachment will be furnished with a copy of the journal up to the point, and will continue it over his new line of march.

JOURNEE.—A term used among the French to express any particular engagement or battle; as *La journée de Marengo*. We frequently adopt the word in the same sense; thus, a hard-fought *day* signifies a hard-fought *battle*.

JOURS.—The tours of duty which are done in the course of a day and a night. *Etre de jour* is to be Officer of the Day, or to command a body of troops at a siege or otherwise in the capacity of a General Officer, etc.

JOURT.—The Kirghis-jourt is a capacious, solid, warm, and fire-proof structure, that admits of being pitched or taken to pieces in an hour, and withstands the cold and violent winds of the steppes of Central Asia, in a way that no tent or combination of tents could pretend to effect. A jourt of from 20 to 25, or even 30 feet in diameter, forms two camel-loads, or about half a ton in weight. One camel carries the felt, the other the wood-work. There are four separate parts in its structure: 1. The *door-way*, a solid piece of ornamental carpentering, that takes to pieces instantly. 2. The *sides* which consist of lengths of wood-work, that shut up on the principle of the *lazy-tongs*. 3. The *roof-ribs*. The bottom of each of these is tied to the sides of the jourt, and its top fits into a socket in 4. the *roof-ring*, which is a hoop of wood strengthened by transverse bars. Over this framework broad sheets of felt are thrown; their own weight makes them lie steadily, for they are quite an inch in thickness; however, in very stormy weather, they are weighted with stones. There is no metal in the structure.

JOUSTS.—Exercises of arms and horsemanship, performed in the Middle Ages by Knights and Nobles. In the joust the combatants engaged one another singly, each against his antagonist, and not in a troop, as in the tournament. The number of courses to be run and strokes to be given was generally three, but sometimes a larger number. The weapon most in use in the joust was the lance, but sometimes the battle-axe and sword were employed. To direct the lance anywhere but at the body of the antagonist was reckoned foul play. In the joust of peace or *joute de plaisance*, a foot encounter preceded the mounted combat. In the 15th century the usages of jousting had come to differ in different countries to such an extent that an elaborate treatise was written in explanation of the various modes distinguishing the characteristic differences.

JOUTE.—A close fight between two individuals. It likewise means an engagement at sea.

JOVES.—In fortification, the two sides in the epaulment of a battery which form the embrasure.

JOWHER.—A kind of watering in Oriental sword-blades and Damascus gun-barrels.

JOYEUSE.—The name given to the sword of Charlemagne.

JOZERAUNT.—Ancient armor; a jacket strengthened with plate. Also written *Jozerine*.

JUDGE ADVOCATE.—The title of an official attached to Military Commissions or Courts-Martial, whose duties are analagous to those of Prosecuting Attorneys in Civil Courts; but whose functions in relation to military law, are also similar to those of a District Attorney, or Corporation Counsel, in being of an advisory character. The appointment of Judge-Advocates for special Courts rests in the authority which appoints the Court, whether that be the President, the Secretary of War, or the Commander of the Army. But there is also in the United States Army a Corps of seven Judge Advocates with the rank of Major, who are under the general direction of the Judge Advocate General, and who can be detailed on Courts-Martial or Military Commissions, but are usually stationed at the Headquarters of the Military Departments, where they act as legal advisers to the Department Commanders, and may be appointed by them to Court-Martial duty. The official duties of a Judge Advocate during a trial by Court-Martial or Military Commission, or examination by a Court of Inquiry, are as follows: Preparation of the case for the prosecution, procuring of witnesses, administering the oath, opening the case for the prosecution with the necessary argument, questioning the witnesses, and submitting the case to the Court. But besides these duties the Judge Advocate has still another—seemingly anomalous in this connection—that of protecting the witness from improper or leading questions, and to that extent also acting as counsel for the accused. In the English military service the duties of the Judge Advocate have been so far modified that he does not act as Prosecutor, but solely in his advisory capacity in connection with the Court, and as the Recorder of its proceedings.

The Articles of War are silent on the subject of the Judge Advocate's assisting the Court with his counsel and advice as to any matters of form or law; it nevertheless is his duty, by custom, to explain any doubts which may arise in the course of its deliberations, and to prevent any irregularities or deviations from the regular form of proceedings. The duty assigned the Judge Advocate is more especially incumbent on him in cases where the prisoner has not the aid of professional counsel to direct him, which generally happens in the trials of private soldiers, who having had few advantages of education, or opportunities for mental improvement, stand greatly in need of advice under circumstances often sufficient to overwhelm the acutest intellect, and embarrass or suspend the powers of the most cultivated understanding. It is certainly not to be understood that, in discharging this office, which is prescribed solely by humanity, the Judge Advocate should, in the strictest sense consider himself as bound to the duty of counsel, by exerting his ingenuity to defend the prisoner, at all hazards, against those charges which, in his capacity of Prosecutor, he is, on the other hand, bound to urge and sustain by proof; for, understood to this extent, the one duty is utterly inconsistent with the other. All that is required is, that in the same manner as in Civil Courts of Criminal Jurisdiction, the Judges are understood to be counsel for the person accused, the Judge Advocate, in Court-Martial, shall do justice to the cause of the prisoner, by giving full weight to every circumstance or argument in his favor; shall bring the same fairly and completely into the view of the Court; shall suggest the supplying of all omissions in exculpatory evidence; shall engross in the written proceedings all matters which, either directly or by presumption, tend to the prisoners's defense; and finally, shall not avail himself of any advantage which superior knowledge, ability, or his influence with the Court may give him in, enforcing the conviction, rather than the acquittal, of the person accused.

When a Court-Martial is summoned by the proper authority, for the trial of any military offender, the Judge Advocate being required to attend to his duty, and furnished with articles of charge or accusation, on which he is to prosecute, must, from the information of the accuser, or other sources, instruct himself in all the circumstances of the case, and by what evidence the whole particulars are to be proved against the prisoner. Of these, it is proper that he should prepare, in writing, a short analysis, or plan, for his own regulation in the conduct of the trial, and examination of the witnesses. He ought then, if it has not been done by some other functionary, to give information to the prisoner of the time and place appointed for his trial, and furnish him, at the same time, with a copy of the charges that are to be exhibited against him, and likewise a correct detail of the Members of the Court. The Judge Advocate ought then to hand in to the Adjutant General, or Staff Officer charged with the details, a list of witnesses for the prosecution, in order that they may be summoned to give their attendance at the time and place appointed. It is proper, likewise, that he should desire the prisoner to make a similar application, to insure the attendance of the witnesses necessary for his defense. These measures ought to be taken as early as possible, that there may be sufficient time for the arrival of witnesses who may be at a distance. When the Court is met for trial, and the members are regularly sworn, the Judge Advocate, after opening the prosecution by a recital of the charges, together with such detail of circumstances as he may deem necessary, proceeds to examine his witnesses in support of the charges, while at the same time he acts as the Recorder or Clerk of the Court, in taking down the evidence in writing at full length, and as nearly as possible in the words of the witnesses. At the close of the business of each day, and in the interval before the next meeting of the Court, it is the duty of the Judge Advocate to make a fair copy of the proceedings; which he continues thus regularly to engross till the conclusion of the trial, when the whole is read over by him to the Court, before the Members proceed to deliberate and form their opinions. The sentence of the Court must be fairly engrossed and subjoined to the record copy of the proceedings; and the whole must be authenticated by the signature of the President of the Court and that of the Judge Advocate.

It is required by the Articles of War, that "Every Judge Advocate, or person officiating as such, at any General Court-Martial, shall transmit, with as much expedition as the opportunity of time and distance of place can admit, the original proceedings and sentence of such Court-Martial, to the Secretary of War; which said original proceedings and sentence shall be carefully kept and preserved in the office of the said Secretary, to the end that the persons entitled thereto, may be enabled, upon application to the said office, to obtain copies thereof." The Judge Advocate sends the proceedings to the Secretary of War through the Adjutant General. See *Court-Martial*.

JUDGE ADVOCATE GENERAL.—In England, the Supreme Judge, under the Mutiny Act and Articles of War, of the proceedings of Courts-Martial. This officer is also the adviser, in legal matters, of the Commander-in-Chief and Secretary of State for War. Before confirmation the sentences of all Courts-Martial, with the evidence adduced, are submitted to him; and it is for him to represent to the Commander-in-Chief any illegality of procedure, or other circumstance rendering it undesirable that the Queen should be advised to confirm the Court's decision. The Judge-Advocate-General receives a salary of £2,000, and is a member of the House of Commons and of the Ministry—changing, of course, with the latter. As it is essential that the Judge Advocate General should have an intimate acquaintance with the military law, as well as with the general law of the land, he is provided with an assistant or *Deputy*, whose office is permanent, and who is selected from among barristers of eminence. The *Deputy Judge Advocate* is an officer holding a temporary commission as Public Prosecutor in every Court-Martial. He must be an officer of intelligence, as it is part of his duty to examine and cross-examine witnesses, to warn the members of the Court of any illegality in their proceedings, and generally to fulfill, in the limited area of the Court, the functions which belong to the Judge Advocate General.

In the United States, the Judge Advocate General is the Chief of the Bureau of Military Justice at Washington with the rank of Brigadier General. To him the proceedings of all Courts-Martial, Courts of Inquiry, and Military Commissions are forwarded for revision and record. In England the Judge Advocate General is the final legal authority for the Army, and the adviser of the Crown in cases where any action of the Sovereign is required. His power is supreme as to reviewing the proceedings of Courts-Martial, etc. See *Bureau of Military Justice*.

JUDGE-MARTIAL.—In former years the Supreme Judge in Martial Law, as to the jurisdiction and powers of Military Courts in the British system.

JUDSON POWDER.—A low grade high-explosive, invented by Egbert Judson, of San Francisco, California, and patented in 1876, since which time it has been manufactured in large quantities at Berkley, California, and has grown rapidly in favor with all who have used it, taking the place of black powder in heavy work. It is not a high explosive and cannot be used for such work as is intended for Giant, Atlas or Hercules powder, but wherever black powder is in use Judson powder can be substituted to great advantage. As this powder contains nitro-glycerine it becomes hard in cold weather (at about 45° F). When in this state it readily breaks up into grains by a little pressure and can then be poured like sand into the smallest crevice. When using frozen powder, it is necessary to use a priming cartridge of Giant, and to always have this cartridge soft. For blasting or quarry work, Judson powder is put up in water-proof paper-bags, containing 6¼, 12½ and 25 pounds each, and 8, 4 and 2 bags respectively are put in wooden boxes holding 50 pounds. It is also put up in water-proof cartridges of any size desired for special purposes. See *High Explosives*.

JUMP.—A gun-barrel made of a ribbon of iron, or laminated iron and steel, coiled around a mandrel at a red heat, then raised to a welding heat and placed on a cylindrical rod, which is struck heavily and vertically on the ground, is said to be *jumped*. The effect is to cause the edges of the ribbon to unite, a junction which is completed by the hammer on an anvil, the mandrel retaining its position. Such barrels are said to be *twisted*. The twist is *stub*, *wire*, or *Damascus*, according to the mode of manufacture of the ribbon. See *Gun-barrel*, and *Twist*.

JUMP OF A GUN.—The increased angle of departure at which a projectile leaves a gun, after the gun has been truly levelled at the target or object to be struck. The method usually pursued to ascertain the "jump" of a gun is to place a target at 120 feet from the gun which has been truly levelled, so as to be horizontal. On firing the gun, the position of the hits on the target determines the "jump" as, if above the level on the target, it shows that the projectile has left the piece with a certain amount of elevation; if it had not been so, gravity would have brought the shot below the level on the target. This "jump" is due to the tendency the gun and carriage have to rotate on the trail. Experiment has shown that the "jump" which the system makes before the projectile leaves the muzzle is much affected by the nature of the rifling. A breech-loading gun in which the shot is forced through the bore, "jumps" more than a muzzle-loading gun of the same weight and length.

JUNCTION-BOX.—In submarine mining, when it is necessary to employ a multiple cable, a junction-box is used to facilitate the connection of the several separate wires diverging from the extremities of such a cable. In one angle of such a box the multiple cable is introduced, while the cables make their exit on the opposite sides and pass to different mines. The ends of the cables are secured from pulling out by hooked nippers. Each multiple cable is composed of seven cores, and each of these is connected by means of joints with the mine cables within the junction-box. The boxes are usually made of cast metal and must, as an essential condition, be perfectly water-tight. They are of various forms, depending upon the object for which each is to be used. They should be supplied with the other apparatus for laying mines.

A junction-box should be placed in such position as to be easily attained, even in the presence of an enemy, and its buoy should, if possible, not be seen. It is also very essential that it should be in a safe and guarded position, for any injury to the junction-box or multiple cable would be fatal to the group of mines in connection.

JUNIOR.—Any one having a lower rank. When the grade is the same, the junior has the more recent commission or warrant.

JUNK.—1. Pieces of old cable or cordage, used for making points, gaskets, etc. When picked to pieces, it is much used in the arsenal instead of oakum. 2. A familiar term in the British Army and Navy for the salt meat supplied for long trips—the name being probably derived from the fact that it becomes as hard and tough as old rope, pieces of which are officially styled junk.

JUNK WADS.—Wads used for proving cannon. Wad-molds for each caliber, consisting of two cast-iron cylinders of different diameters set in oak, or of two strong pieces, strapped with iron, and joined by a hinge, are employed in their manufacture. The junk, after having been picked, is compressed by being beaten in the smaller mold with a *maul* and *cylindrical drift*—the latter nearly of the size of the mold—until it assumes the requisite dimensions; it is then taken out by raising the upper part of the mold, and closely wrapped with rope-yarn passed over it in the direction of the axis of the cylinder, and fastened by a few turns around the middle of the wad. It is then placed in the large mold, and again beaten with the maul and drift until its diameter is increased to that of the mold; when it is taken out and its diameter verified by a wooden gauge corresponding to the large shot-gauge of the caliber.

JUPON—JUST AU CORPS.—A surcoat. The name jupon is chiefly applied to the short, tight form of that military garment in use in the 14th century. It was a sleeveless jacket or overcoat, composed of several thicknesses of material sewed through, and faced with silk or velvet, upon which were embroidered the arms of the wearer. It fitted closely to the body, and, descending below the hips, terminated in an enriched border of various patterns.

JURISDICTION.—All officers, conductors, gunners, matrosses, drivers, or other persons whatsoever, receiving pay, or hire, in the service of the Artillery, or Corps of Engineers of the United States, are subject to be tried by Courts-Martial, in like manner with the officers and soldiers of the other troops in the service of the United States. The officers and soldiers of any troops, whether militia or others, being mustered and in pay of the United States, are at all times and in all places, when joined or acting in conjunction with the regular forces of the United States, governed by these Rules and Articles of War, and are subject to be tried by Courts-Martial, in like manner with the officers and soldiers in the regular forces, save only that such Courts-Martial are composed entirely of militia officers. No person is liable to be tried and punished by a General Court-Martial for any offense which shall appear to have been committed more than two years before the issuing of the order for such trial, unless the person, by reason of having absented himself, or some other manifest impediment, shall not have been amenable to justice within that period.

Can Courts-Martial and Civil Courts have concurrent jurisdiction over offenses committed by soldiers? Or, in other words, if a soldier is guilty of an offense which renders him amenable for trial before the Civil Courts of the land, can he also be tried for that offense (if its specification should establish a violation of the Rules and Articles of War) by a Court-Martial? By the Constitution of the United States Congress is authorized "To make rules for the government and regulation of the land and naval forces;" and Congress, pursuant to this authority, has established Rules and Articles for the government of the armies of the United States. These Rules are an additional code, to which every citizen who becomes a soldier subjects himself for the preservation of good order and military dicipline. The soldier, however, is still only a citizen of the United States. He has not, by assuming the military character become, as is the case in very many European countries, a member of any fully privileged body who may claim trial for all offenses by Courts-Martial. He is still amenable to the ordinary Common Law Courts for any offenses against the persons or property of any citizen of any of the United States, such as is punishable by the known laws of the land. An examination of the Rules and Articles of War will show that the offenses therein described, and against which punishment is denounced, are purely military. They are crimes which impair the efficiency of the military body, and even in cases in which they would be recognized as offenses by the ordinary Common Law Courts, they could not be considered the *same offenses*. Take, for instance, Article 21, which inflicts the punishment of death, or other punishment, according to the nature of his offense, upon any officer or soldier who shall strike his Superior Officer. Here is an offense punishable under the known laws of the land as an assault and battery, and, as such, it could be tried by the Common Law Courts. But such trial would not prevent a Court-Martial from afterwards taking cognizance of it under Article 21; for the offense before the Common Law Court would be striking an *equal*, while before the Military Court it would have essentially changed its character. Again, suppose an officer had been guilty of stealing, he might be prosecuted before the Common Law Court for the felony, and afterwards charged with conduct unbecoming an officer and a gentleman, and dismissed the service. It can hardly be contended that the offenses in either of the cases cited would be the *same* before the different Courts; and if not, the Article which forbids a trial a second time for the same offense, could not be pleaded in bar of trial. Recognizing, then, the principle that the soldier, as a citizen, is subject to the Common Law Courts for offenses committed against the well-being of the State, it must also be recollected that he is subject to trial by a Court-Martial for any violation of the Rules and Articles of War. In the case of "Eels, plaintiff in error, *v.* the People of the State of Illinois," it was urged that the Act of the State of Illinois under which Eels was tried was void, as it would subject the delinquent to a double punishment for the same offense, the crime with which he was charged being actionable under a law of the United States. The Supreme Court decided that, admitting the plaintiff in error to be liable to an action under the Act of Congress, it did not follow he would be twice punished for the same *offense*, and gave the following definition of that term:

An offense in its legal signification means the transgression of a law. A man may be compelled to make reparation in damages to the injured party and be liable also to punishment for a breach of the public peace in consequence of the same act, and may be said, in common parlance, to be twice punished for the same offense. Every citizen of the United States is also a citizen of a State or Territory. He may be said to owe allegiance to two Sovereigns and may be liable to punishment for an infraction of the laws of either. The same act may be an offense or transgression of the laws of both. Thus an assault upon the Marshal of the United States and hindering him in the execution of legal process is a high offense against the United States, for which the perpetrator is liable to punishment; and the same act may also be a gross breach of the peace of the State, a riot, assault, or a murder, and subject the same person to a punishment under the State laws for a misdemeanor or felony. That either or both may, if they see fit, punish such an offender cannot be doubted. Yet it cannot be truly averred that the offender has been twice punished for the same offense, but only that by one act he has committed two offenses, for each of which he is justly punishable. He could not plead the punishment by one in bar to a conviction by the other.

JUSTAUCORPS.—An ancient tight-fitting coat, having a military appearance and constructed of cords. A simple primitive prototype of mail-armor.

JUSTIFIABLE HOMICIDE.—The killing of a human creature without incurring legal guilt, as where a man is duly sentenced to be hanged; where one, in self-defense, necessarily kills another to preserve his own life, etc.

JUTE.—The jute of commerce is a fiber produced from two species of *tiliaceae*, the *corchorus olitorius* and *corchorus capsularis*, two plants, alike in qualities, though slightly different in appearance, and sown indiscriminately; the first having round seed-pods and reddish stalk, the latter long seed-pods and bright green stalk. From the fiber, which is the cheapest known are produced gunnies, gunny-cloth and cordage, and from the finer qualities, carpets, shirting, coat-linings, etc., are made. It is extensively used for mixing with silk, cotton, and woolen fabrics, and also in paper-making, while the leaves are eaten in many places as food. The first mention of the word jute is in 1796, in the manuscript commercial index of the Court of Directors of the East India Company. It is the Bengali name used by the natives of Cuttack and Balasore, where the first European manufactories were established in the middle of the last century. In 1829 the total export from Calcutta was 20 tons, value £60. In 1833 it had increased sixteen fold, and about 1864-65 the increased demand caused jute cultivation to extend to other districts, the exportation in 1872-73 reaching the enormous amount of 300,000 tons, value £3,500,000. England, Bombay, and America originally divided the exports of jute, and up to the time of the civil war North America took the largest share of the gunnies. Jute and gunnies are now exported from Bengal largely to France, Australia, and other parts of the world. Jute grown in England is not remunerative. It has been successfully grown in small quantities in America, however. Gunnies are classed as Nos. 1, 2, and 3. No. 1, thick and close woven, is used for sugar, fine grains such as linseed or rape-seed, and similar products; No. 2, also close woven, but thinner, for rice and all the larger grains; No. 3, very thick, coarse, and open, is principally suited for the outer covering of double bags. The manufacture of gunny with primitive looms is a common form of convict labor in Bengal. Near the Himalayas, in north-eastern Bengal, the natives wear a fine cloth of their own manufacture, made of jute, or of jute and cotton. Increased demand has lately induced jute production in Burmah, Italy, Queensland, and America, etc; and a European Company has been started to cultivate jute in British Burmah on a large scale. The manufacture, again, is largely carried on in Great Britain, and is the chief industry of Dundee and Belfast. In Bengal jute valued at about a million sterling is annually manufactured, mostly for local consumption, the bulk being turned out by the English mills, of which there are several near Calcutta, employing thousands of hands, the Gauripore and Barnagore mills being the principal.

JUZAIL. A very heavy rifle used by the Afghans.

K

KABBADE.—A military garment of the Modern Greeks. It was generally made of wool, without sleeves, and fastened by a girdle around the waist. It was also frequently worn by both the Romans and Gauls. See *Sagum*.

KAISER.—The German title of Emperor. It was derived from that of Cæsar, permitted by Diocletian to be used by the governing Prince of Dalmatia, Croatia, and the line of the Danube, who was Heir Presumptive to the Imperial Throne. The term was employed by the German Emperors of the Middle Ages, and later by the Emperors of Austria. In 1871 it was assumed by William I., of Prussia, on his being crowned Emperor of Germany.

KAJAWAHS.—An Indian term. Large panniers, placed across a camel's back, in which camp kettles, pots, etc., are carried on the march. The panniers are large enough to carry disabled men with much ease and comfort.

KAKTOWDA.—A term applied in the East Indies to the fine mold used in making butts for archery practice.

KALAI.—A Turkish fortress. The term is rather particularly applied to stoccades or very similar structures.

KALMUCKS.—The Kalmucks, or, as they call themselves, the Derben-Ueirat (the four relatives), and also designated by the name of Eleutes and Khalimik (apostates), are the most numerous and celebrated of the Mongol Nations. They are divided into four tribes, the first of which, the *Khoskôts* (warriors) number nearly 60,000 families, and inhabit the country round the Koko-nur, which they consider the native country of the race. One portion of this tribe migrated to the banks of the Irtisch, and became subsequently incorporated with the second tribe, the Dzûngars; another portion migrated to the banks of the Volga, in the 17th century, and is found at the present day in the goverment of Astrakhan. The second tribe are the *Dzûngars*, who give the name to a large territory (Dzûngaria) in the west of Chinese Tartary; at the present day they number about 20,000 families. The third tribe are the *Derbets* or *Tchoros*, who deserted Dzûngaria, and finally, to the number of 15,000 families, removed a few years ago to the plains of the Ili and the Don, where they are being rapidly incorporated with the Don Cossacks. The fourth great tribe of the Kalmucks are the *Torgots*, who, about 1660, separated from the Dzûngars, and settled in the plains of the Volga whence they were called the *Kalmucks of the Volga;* but finding the Russian rule too severe, the majority returned to Dzûngaria.

No Mongol or Turkish race presents such characteristic traits as the Kalmucks; indeed they answer exactly to the description given of them by Jornandes 13 centuries ago, when, under the name of Huns, they devastated southern Europe. The Kalmuck is short in stature, with broad shoulders and a large head; has small, black eyes, always appearing to be half shut, and slanting downwards towards the nose, which is flat, with wide nostrils; the hair is black, coarse, and straight, and the complexion deeply swarthy. The Kalmuck is considered as the original type of the Mongol and Manchû races, and his ugliness is the index of the purity of his descent. They are a nomad, predatory, and warlike race, and pass the greater part of their lives in the saddle. Their usual food is barley-flour soaked with water, and their drink is the "koumiss" (made from fermented mare's milk). In 1829 Russia established a Kalmuck Institute for the training of interpreters and government officials for the Kalmucks of Russia, and she has since been making great efforts to introduce civilization among them. Most of the Kalmucks are Buddhists, but a few have adopted Mohammedanism or Christianity.

KALSA CUTCHERRY.—The room of business, where matters pertaining to the Indian Army are transacted, and all matters of litigation on that branch of service are determined.

KAMPAK.—A kind of hatchet saber of the Middle Ages, without a hilt or cross-guard. The handle is made quite straight, and it forms with the blade a Latin cross.

KAMPTULICON.—The name given to a kind of floor-cloth, which is said to be made of india rubber and cork; much of it however, consists of oxidized linseed-oil and cork. The cork is reduced to a state resembling very fine sawdust, and kneaded up with the real caoutchouc, or with the artificial kind made of oxidized linseed-oil, the whole being kept very soft by heat. The mass is then made into sheets by passing through cylinder rollers heated with steam. The sheets, when cold, are ready for use, when no ornamental surface is required; but very excellent designs may be painted upon it, the same as upon ordinary floor-cloth. Kamptulicon, notwithstanding the ease with which it is made, is more expensive than floor-cloth made by painting hempen or linen fabrics; it has, however qualities which render it very valuable for special purposes; its elasticity to the tread not only makes it agreeable to walk on, but it is noiseless, and is consequently well adapted for hospital passages and other positions in which quiet is desirable; it is also impervious to damp, and thereby well suited to damp stone floors. It is also very suitable for floor-cloths in powder-houses, but is not so durable as leather hides.

KANAUT.—A term used in India to designate the wall of a canvas tent. Sometimes written *Kanat.*

KANDGIAR.—A Turkish sword very much like the yataghans and flissas. It is generally single-edged, without guards. It is very often ornamented with diamonds and other precious stones. Also written *Kangiar.*

KAPIGI-BACHI.—The officer in charge of the gates of the Sultan's Palace. The name is also applied to a Turkish warrior. The name *Karauls* is given to the Sultan's body-guards.

KARTTIKEYA.—The Hindu Mars, or god of war, a being represented by the Purânic legends as sprung from Siva, after a most miraculous fashion. The germ of Karttikeya having fallen into the Ganges, it was on the banks of this river, in a meadow of Sara grass, that the offspring of Siva arose; and as it happened that he was seen by six Nymphs, the *Krittikâs* (or Pleiades), the child assumed six faces, to receive nurture from each. Grown up, he fulfilled his mission in killing Târaka, the demon king, whose power, acquired by penances and austerities, threatened the very existence of the gods. He accomplished, besides, other heroic deeds in his battles with the giants, and became the Commander-in-Chief of the divine armies. Having been brought up by the Krittikâs, he is called *Kârttikeya*, or *Shânmâtura*, the son of six mothers; and from the circumstances adverted to, he bears also the names of *Gângeya*, the son of Gangâ; *Sarabhû*, reared in Sara grass; *Shanmukha*, the god with the six faces, etc. One of his common appellations is *Kumarâ*, youthful, since he is generally represented as a fine youth; and as he is riding on a peacock, he receives sometimes an epithet like *Sikhivâhâna*, or "the god whose vehicle is the peacock."

KATAITYX.—A Greek casque, of the 8th century, B.C. It was made of leather and provided with a chin-strap, but had no crest.

KATAN.—A Japanese sword. Commonly called *Cattan.*

KATZENKOPF.—The German name for the *wheel-lock* and *mortar* pistol of the eleventh century.

KAVASS.—In Turkey, an armed Constable. The term is also applied to a government servant or courier.

KECHERKLECHI.—Guards attached to the person of the King of Persia: they are armed with a musket of an extraordinary size and caliber. The Kecherklechi were enlisted and formed into a regular Corps about the middle of the 18th century.

KEENE-REMINGTON MAGAZINE-GUN.—This gun is now made for the United States military cartridge, forty-five caliber, seventy grains of powder, but can be adapted to the use of other forms of military cartridge, such as the Spanish and Russian. The magazine is located under the barrel, thereby enabling it to carry the greatest possible number of cartridges within a given weight and length of barrel. It is believed that this is, for many reasons, the best position in which to carry the cartridges of a magazine-gun.

All of the motions are direct and positive. The cartridges are held securely in position while passing from the magazine over the carrier to the chamber in the barrel, in which respect it has a decided advantage over other magazine-arms. The cartridge does not pass on to the carrier until the gun is opened for the purpose of loading, so that there is no danger of a cartridge being exploded in the carrier in case a defective cartridge is fired in the gun.

ing the finger from the trigger; in this last respect differing from other magazine-guns, which can only be cocked by removing the hand from the trigger.

The parts are all large and strong, and can be readily removed and replaced for the purpose of cleaning or inspection. The magazine is so arranged that it can be charged while the breech is closed, thus avoiding the entrance of dirt into the working parts of the gun. The gun may be held either barrel up or reversed for this purpose. The drawing exhibits the parts with the nomenclature.

To charge the magazine.—Hold the arm in the left hand, the butt-stock under the right arm. Grasp the

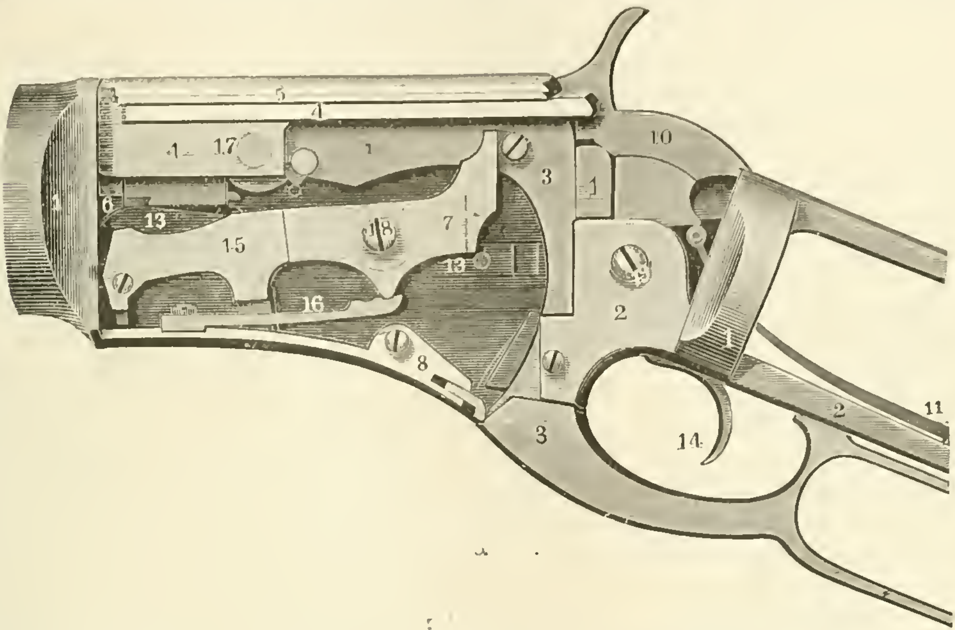
The arm is always left at half-cock, and the breech locked so that it cannot be jarred open and the cartridge lost out. From the half-cock it can be brought to the full-cock readily and quickly while the arm is being carried to the shoulder, and without *remov-*

cartridge between the thumb and the forefinger of right hand, and press it forward, bullet first, into the magazine with the end of the thumb, which may be held sideways for that purpose. The magazine may be charged with the breech either open or closed, and with the cut-off lever in its forward or backward position; but it is more convenient to do so with the breech *closed* and the cut-off lever *back*.

To load from the magazine.—First. If the arm has been fired or the hammer is down, unlock and draw back the breech-bolt *quickly* and with sufficient force to bring it *clear back*, thereby raising and locking the carrier and bringing up a cartridge. Shove the bolt forward and lock it; the hammer will remain at half-cock. If it is desired to fire, the hammer may be brought to full-cock while the arm is being lifted to the shoulder, the forefinger remaining on the trigger. Second. If the arm has been closed and left at half-cock, lower the hammer and then proceed as before. After the cartridge has been transferred from the magazine to the chamber, it should either be fired or removed from the gun before another cartridge is passed through the carrier.



1, receiver; 2, bottom tang; 3, lever; 4, breech-block; 5, top cover; 6, ejector; 7, carrier-block; 8, bottom plate; 10, hammer; 11, main spring; 13, side-loading spring cover, as seen from the back; 14, trigger; 15, carrier-block clamp; 16, carrier-block spring; 17, breech-block pin; 18, carrier-block screw.

To use the arm as a single loader, with the magazine in reserve, push the cut-off lever forward. This cuts off the passage of the cartridge from the magazine. The arm may then be used as a single loader. This gun is so made as to be left at half-cock after loading; but if it is preferred to have it left at full-cock, it is only necessary to remove the hammer fly, No. 37, which is let into the tumbler to carry the trigger over the full-cock notch. See *Magazine-gun*.

KEEP.—In mediæval fortification, a keep was the central and principal tower or building of a castle, and that to which the garrison retired, as a last resort, when the outer ramparts had fallen. A fine specimen of the ancient keep is still extant amid the ruins of the Rochester castle. The keep was similar to what the classical ancients called the citadel, inner fort. See *Castle*, *Fortification* and *Safety Redoubt*.

KEIR-METAL.—An alloy patented in England, which differs from *sterro-metal* mainly in having no tin. This alloy consists of copper 100, zinc 75, iron 10.

KELT.—A very early war-axe. It seems to have been spread in every direction, and to have belonged to no country in particular. It was also called *Celt*.

KENNEDY RIFLE.—A novel rifle developed and introduced by the Whitney Arms Company. It is a repeating or magazine-rifle, with the magazine placed under the barrel, and is operated by a lever, the backward and forward movement of which cocks the hammer, opens the breech, throws out the empty shell, and brings a new cartridge into place, ready for discharge. The drawing shows the action.

The following may be noted as the advantages of this arm:—It has all the requirements requisite to a first-class magazine-gun. It is of simple construction, and has fewer parts than any other magazine-rifle operated by a lever. It is strong. The parts are of such size and form as not to be liable to break or get out of order. It is made of the best material, wrought iron or steel, as is most suitable for each part. It is very easily manipulated, and can readily be understood by any person who is at all familiar with fire-arms. It is safe, accidents from premature discharge being impossible. The resistance to the discharge is in direct line with the bore of the barrel. The firing pin cannot reach the head of the cartridge until the breech is fully closed—consequently, the piece can only be fired when the breech is locked. *The cartridge used is the 45-caliber center-fire, United States Government standard, containing 70 grains of powder and 400 grains of lead.* When a lighter charge is desired, the United States carbine cartridge—the same length as the above—but loaded with only 55 grains of powder, may be used. The magazine is charged through the side of the receiver when the breech is closed, and the rifle can be used as a single loader, the charged magazine being held in reserve.

The arm is made in three styles:—The *musket* weighs 9 lbs. 4 oz. The barrel is 33 inch. It carries when loaded, 11 cartridges. The *carbine* weighs 7 lbs. 8 oz. The barrel is 22 inch. It carries when loaded, 7 cartridges. The *sporting rifle* weighs 9 to 10 lbs. The barrel is 28 inch. It carries when loaded, 9 cartridges. See *Phoenix* and *Whitney Rifle*.

KENT-BUGLE.—The key-bugle invented by Logier early in this century, and named after the Duke of Kent, the father of Queen Victoria. It has six keys, and is the predecessor of the great tribe of cornets. It will traverse chromatically a compass of more than two octaves, beginning from B flat beneath the stave up to the C above. The bugle with pistons or with cylinders has a lower compass than the preceding.

KENTLEDGE.—Old cast-iron articles which have become unserviceable, such as condemned guns, shot and shell, etc.

KERANA.—A long trumpet, similar in shape and size to the speaking-trumpet. The Persians use it whenever they wish to make any extraordinary noise, and they frequently blow it with hautboys, kettle-drums, and other instruments, at retreat or sunset, and two hours after mid-night.

KERN.—A name applied formerly to Irish and Gaelic infantry soldiers. The men in those days were armed with a sword and a dart or javelin, which was tied to a small cord, so that after they had thrown it at the enemy they could instantly recover it, and use it in any way they thought proper. The javelin was called *skene* which is also the Irish for a knife.

KET'S REBELLION.— An outbreak which took place in England, in 1549, under the leadership of William Ket, a tanner, living in Wymondham, Norfolk. He is said to have had 20,000 followers; but the rising was suppressed by the Earl of Warwick, after an engagement in which more than 2,000 of Insurgents were killed. The leader, Ket, with others, suffered death on the gallows.

KETTLE-DRUM.—1. A drum formed by stretching vellum over the circular edge of a hemispherical vessel of brass or copper. This instrument, which gives forth a sharp ringing sound, is used by regiments of cavalry and horse-artillery in lieu of the ordinary cylindrical drum, which would, from its shape, be inconvenient on horseback

The small military drum is frequently called by this name. They are still used in pairs, in the English and Prussian armies, and elsewhere, slung on each side of the withers of a cavalry-horse. One

drum is tuned to the keynote, and the other to the fifth of the key. The tuning is by a hoop and screws. Kettle-drums are not used in the United States military service, but are much used in orchestras supported upon a tripod, as shown in the drawing. 2. Kettle-drum, as applied to a social gathering, originated in the British army in India. It sometimes happened in the emergencies of camp life that in an entertainment given by officers and their wives there was a lack of requisite furniture, and the heads of kettle-drums were made to serve in place of tables to hold the cups of tea. So by metonymy the article used gave name to the occasion on which it was used. The name came to mean an informal party, and specifically an afternoon party, in which elaborate dress and costly viands gave place to every-day attire for ladies and business suits for gentlemen, with very simple side-table refreshments. This kind of visit was introduced into England at a time of general financial depression by some who wished to meet their friends socially, yet could not, as before, dress expensively and entertain sumptuously.

KETTLE-DRUM CART.—A four-wheeled carriage drawn by four horses, which was used exclusively by the British Artillery as a pageant. The Ordnance flag was painted on the fore part, and the drummer, with two kettle-drums, was seated, as in a chair of state, on the back part. This cart, which is finely engraved and richly gilt, has not been in the field since 1743, when the King was present. It is at present kept in the Tower of London.

KETTLE-HAT.—A cap of iron worn by knights in the Middle Ages.

KEY.—1. A bolt used on artillery carriages to secure cap-squares and for analogous purposes. A *key-chain*, is attached to the key to prevent it from being lost. 2. A common heraldic bearing in the insignia of sees and religious houses—particularly such as are under the patronage of St. Peter. Two keys in saltire are frequent, and keys are sometimes *interlaced* or linked together at the *bows*—i.e., rings. Keys *indorsed* are placed side by side, the wards away from each other. In secular Heraldry, keys sometimes denote Office in the State. See *Key-point.*

KEY-POINT.—A point the possession of which gives the control of that position or country. Great care must be taken to always direct an assault upon the key-point of the position in order that the main attack, when successful, may produce a lasting benefit. When about to commence the operations of a siege, the General is called upon to decide the following: 1. Which part of the position is easiest to carry; 2. Which part, carried, gives possession of the rest; or, which part is the *key-point;* 3. Which side of the part selected is the best on which to make his approaches; and, 4. Which part selected would be the best, taking into consideration the establishment of his depots and lines of supply, and the probabilities of an attempt to relieve the besieged. These questions are partially answered before the posting of the besieging army is completed, as it would be bad policy to have the troops encamped too far from the ground where the main operations of the siege are to be conducted. See *Point of Attack.*

KEYSERLICKS.—A name commonly applied to the Austrian troops. The term was indeed common among the British soldiers, when they did duty with the Austrians, and invaded France in 1794. See *Imperialists*

KHALASSIE.—An Indian sailor. This race of men come chiefly from the Chittagong district. Besides a sea life, khalassies take service on shore, and form a large portion of the native establishment attached to arsenals in India, bordering on the seaside. During the march of a regiment in that country, they are employed in looking after the camp equipage.

KHAN.—A title of Mongolian or Tartar Sovereigns and Lords. A *Khanate* is a principality. *Khagan* means "Khan of Khans," but has seldom been applied. The word Khan is probably of the same origin as King.

KHEDIVE.—One of the titles of the Ruler of Egypt, a tributary prince of the Sublime Porte, who, since 1867, has exercised absolute power within his own dominions. The first Khedive was Ismaïl, Sovereign of Nubia, Soudan, Kordofan, and Darfour, son of Ibrahim Pasha (eldest son of Mohammed Ali Pasha, founder of the dynasty), was born in 1830, and succeeded his uncle, Saïd Pasha, in 1863, as the fourth Viceroy of Egypt. He traveled through the Capitals of Europe, informing himself concerning their manners and customs, and these he introduced into his own dominions on his return. He fell under the displeasure of the Sultan, through the jealous fears of the latter regarding European ascendency in Egypt, but succeeded in obtaining from him important concessions. By a firman dated May 21, 1866, he gained the right of the succession in the direct masculine line in his branch; by that of June 8, 1867, the title *Khedive*, or Sovereign, was granted him; and by the firman of Sept. 29, 1872, he obtained the right to increase his army and navy at his pleasure, and to borrow money. Finally, he was conceded, in 1873, the right to conclude treaties of commerce, with the full autonomy of the administration of the Country. Yet despite all this, the Sultan retained in his hands the disposition of the Government in Egypt, since, in April, 1879, he proposed to the Western Powers to dispose Ismaïl in favor of his uncle, Halim Pasha, the rightful heir. This proposition was not received favorably, though repeated in June, and the Sultan was finally induced to issue a firman deposing Ismaïl in favor of his son, Prince Mohammed Tevfik. This was on June 26, and the firman abolished that of 1873, and deprived the Khedive of the power to conclude treaties with Foreign Powers, and to maintain a standing army. Ismaïl Pasha accordingly quitting the throne, his son was proclaimed Khedive, under the title of Tevfik I.

KHODADAUD SIRCAR.—The Government or Ruler blessed or beloved of God; it was a title assumed by Tippoo Sahib, the Sovereign of the Kingdom of Mysore, who fell in defense of his Capital, Seringapatam, when it was stormed, May 4, 1799, by the British forces under Lieutenant General Haiarri.

KHOP.—An early Egyptian iron weapon, about 6 inches long and roughly formed, from stone, in the shape of a sceax.

KHOUTTAR.—A Hindoo weapon, having a large blade like the Italian *anelace*, fixed on to a square handle, into which the hand is slipped, and thus protected as far as the wrist. There are *Khouttars* in which the blade is divided into two points, but they are not common. Such are called serpent-tongued.

KHYBER PASS.—The most practicable of all openings, four in number, through the Khyber Mountains, and the only one by which cannon are conveyed between the plain of Peshawur, on the right bank of the upper Indus, and the plain of Jelalabad, in northern Afghanistan. It is 30 miles in length, being here and there merely a narrow ravine between almost perpendicular rocks of at lest 600 feet in height. It may be said to have been the key of the adjacent regions in either direction from the days of Alexander the Great to the Afghan Wars of 1839-42, during which it was twice forced by a British army, in spite of an obstinate defense by the natives. The first fighting in the Afghan War of 1878-79 was in forcing an entrance into this pass, over which, as was stipulated in the conditions of peace, the Anglo-Indian authorities are henceforth to have full control.

KIBEE.—A flaw produced in the bore of a gun by a shot striking against it.

KICKING-STRAP.—A strap used in draught to control a violent horse. One or two should be attached to each horse battery. It is fastened to the shafts, and passes over the croup of the horse, thereby preventing him from kicking.

KIDNAPPERS.—A name formerly applied to parties who by improper means decoyed the unwary into the army.

KILLA.—The Indian term for castle, fort, or fortress. The Governor or Commandant of a Killa is known as *Killadar*.

KILLESE.—A name commonly given to the groove in a cross-bow.

KILMAINHAM HOSPITAL.—An institution near Dublin for the reception of wounded and pensioned soldiers. It was originally founded by King Charles II., and is conducted on similar principles to the sister Institution, Chelsea Hospital. Kilmainham Hospital is maintained by annual Parliamentary grant, and provides everything necessary for the comfort of upwards of 250 veterans and officers. The General Commanding the Forces in Ireland for the time being is *ex officio* the Master of Kilmainham Hospital, and has his residence on the estate.

KILN.—A name applied to various kinds of furnaces, ovens, or other devices made of stone, brick, or iron, or of the material itself to be operated upon. They may be divided into intermittent and continuous, or perpetual; or into furnace-kilns, oven-kilns, and what may be termed mound-kilns, such as are used in making charcoal; and also a kind which are intermediate between oven and mound-kilns, as certain kinds of brick-kilns, where the raw-brick is a part of the kiln, and forms a structure which cannot be strictly called an oven. The *furnace-kiln*, for burning lime-stone, may be of an intermittent or of a perpetual kind. An intermittent kiln is one in which the fire is let to go out after the charge is burned; a continuous kiln is one which is so arranged that the charge may be removed and a fresh one put in while the fire is kept burning, and the furnace kept at its reducing heat. An intermittent furnace-kiln may be made of stone or brick of an oval form, like an egg standing on either end. That form resembling an egg standing on its larger end is perhaps the most common, although some lime-kilns are shaped more like deep bowls, without much contraction at the top. Where wood is very plentiful and cheap, and the lime is burned for agricultural purposes, so that ashes is a desirable ingredient, a common bowl shape is perhaps preferable, because it is readily charged with both limestone and wood, and a mass of wood may be placed upon the top in addition to what is used in the charge, by which thorough burning will be secured. In a furnace-kiln, a grating of iron is placed at the bottom, or an arch of open brickwork, and then the charge is ingeniously placed, first with fuel, and then with the broken masses of limestone in such a manner as to allow the flame to pass through and thoroughly perform the work of heating. These kilns may be from 10 to 30 feet high, or even higher. Intermittent oval kilns are used in burning Portland and other kinds of hydraulic cement, and they are 40 to 50 feet high, and employ coke or coal for fuel. The charge is usually composed of one part of coke or coal and two parts of raw cement. There are, however, several kinds of cement which do not require so prolonged high heat as Portland cement, and these might be burned in a kind of kiln so constructed as not to require the fire to go out when the burned contents are removed so frequently. These kilns are cylindrical, except at the bottom, where they have the shape of an inverted cone, and a chamber below and a kind of spout leading into it from the bottom of the cone, so that the charge when burned may be raked down from time to time with a suitable apparatus, and removed, while it may be renewed at the top. Cement-kilns should be lined with fire-brick. A preferable form of continuous kiln is one in which the kiln-cylinder is charged only with the material to be burned, and a current of flame or heated gas is introduced at the side near the bottom. The heat thus passing up through the material reduces it to the proper condition, without adding any portion of the ashes of the fuel to it.

KILT.—A dress worn by men living in the Highlands of Scotland, and by a few regiments in the British Army. It consists of a loose petticoat extending from the waist to the knees. The kilt was worn by British chiefs as early as the beginning of the 7th century; it was made of skin, but striped kilts were common, and it is said that, in all probability, the Scottish kilt was known among the British earlier than is generally supposed, from the inhabitants of North Britain being on intimate terms with their neighbors, and likely to have assumed the dress.

KING.—The person vested with supreme power in a State. According to feudal usages the King was the source from which all command, honor, and authority flowed; and he delegated to his followers the power by which they exercised subordinate rule in certain districts. The Kingdom was divided into separate Baronies, in each of which a Baron ruled, Lord both of the lands, which he held under the obligation of rendering military service to the King, and in many cases also of the people, who were vassals of the soil, and his liege subjects. In modern times the kingly power often represents only a limited measure of sovereignty, various constitutional checks being in operation in different countries to control the royal prerogative. The King may succeed to the throne by descent or inheritance, or he may be elected by the suffrages of some body of persons selected out of the nation, as was the case in Poland. Even when the kingly power is hereditary, some form is gone through on the accession of a new King to signify a recognition by the people of his right, and a claim that he should pledge himself to perform certain duties, accompanied by a religious ceremony, in which anointing with oil and placing a crown on his head are included as acts. By the anointing a certain sacredness is supposed to be thrown round the royal person, while the coronation symbolizes his supremacy. There is now no very clearly marked distinction between a King and an Emperor. A Queen-regnant or Princess who has inherited the sovereign power in countries where female succession to the throne is recognized, possesses all the political rights of a King.

In England it is said that the King never dies, which means that he succeeds to the throne immediately on the death of his predecessor, without the necessity of previous recognition on the part of the people. He makes oath at his coronation to govern according to law, to cause justice to be administered, and to maintain the Protestant Church. He is the source from which all hereditary titles are derived, and he nominates Judges and other Officers of State, Officers of the Army and Navy, Governors of Colonies, Bishops, and Deans. He must concur in every legislative enactment, and sends Embassies, makes treaties, and even enters into wars, without consulting Parliament. The royal person is sacred, and the King cannot be called to account for any of his acts; but he can only act politically by his Ministers, who are not protected by the same irresponsibility. A further control on the royal prerogative is exercised by the continual necessity of applying to Parliament for supplies of money, which practically renders it necessary to obtain the sanction of that body to every important measure. The crown now in use as the emblem of sovereignty differs considerably in form in different countries of modern Europe; but in all cases it is distinguished from the coronets of the nobility in being closed above.

KING-AT-ARMS—KING-OF-ARMS.—The principal Heraldic Officer of any country. There are four Kings-at-Arms in England, named respectively Garter, Clarencieux, Norroy, and Bath, but the first three only are members of the College of Arms.

Garter Principal King-of-Arms was instituted by Henry V., 1417 A. D., for the service of the Order of the Garter. His duties include the regulation of the arms of peers and the Knights of the Bath. In the capacity of King-of-Arms of the Order of the Garter, he has apartments within the Castle of Windsor, and a mantle of blue satin, with the arms of St. George on the left shoulder, besides a badge and scepter. His official costume as Principal King-of-Arms of England is a surcoat of velvet, richly embroidered with the arms of the Sovereign, a crown, and a collar of SS. The insignia of this office are borne by Garter impaled with his paternal arms, the latter on the dexter side of the shield. These are argent, St. George's cross, on a chief gules a ducal coronet encircled with a garter, between a lion of England on the dexter side and a fleur-de-lis on the sinister, all or.

Clarencieux and Norroy are Provincial Kings-of-Arms, with jurisdiction to the South and North of the Trent respectively. They arrange a register, alone or conjointly with Garter, the arms of all below the rank of the peerage. The official arms of Clarencieux are argent St. George's cross, on a chief gules a lion of England ducally crowned or. Those of Norroy are argent St. George's cross on a chief per pale azure and gules a lion of England ducally crowned between a fleur-de-lis on the dexter side, and a key, wards in chief, on the sinister, all or. Both Provincial Kings have a crown collar and surcoat. The crown is of silver gilt.

The crown of a King-of-Arms is of silver gilt, and consists of a circle inscribed with the words, *Miserere mei Deus secundum magnam misericordiam tuam*, supporting 16 oak leaves, each alternate leaf higher than the rest. Within the crown is a cap of crimson satin turned up with ermine, and surmounted by a tassel wrought of gold silk. Kings-of-Arms were formerly entitled to wear their crowns on all occasions when the Sovereign wore his; now they assume them only when peers put on their coronets. The installation of Kings-at-Arms anciently took place with great state, and always on a Sunday or Festival-day, the ceremony being performed by the King, the Earl Marshal, or some other person duly appointed by royal warrant.

Bath King-of-Arms, though not a member of the College, takes precedence next after Garter. His office was created in 1725 for the service of the Order of the Bath. On Jan. 14, 1726, he was constituted Gloucester King-of-Arms (an office originally created by Richard III., in whose reign it also became extinct), and principal Herald of Wales. He was at the same time empowered, either alone or jointly with Garter, to grant arms to persons residing within the principality.

The chief Heraldic Officer for Scotland is called Lyon King-of-Arms, who since the union has ranked next to Garter. His title is derived from the lion rampant in the Scottish royal insignia, and he holds his office immediately from the Sovereign, and not as the English King-at-Arms, from the Earl Marshal. His official costume includes a crimson velvet robe embroidered with the royal arms, a triple row of gold chains round the neck with an oval gold medal, with the royal arms on one side and St. Andrew's cross on the other; and a baton of gold enameled green, powdered with the badges of the Kingdom. His crown is of the same form with the imperial crown of the Kingdom, but not set with stones. Before the Revolution he was crowned by the Sovereign, or his Commissioner, on entry on office.

There is one King-of-Arms in Ireland, the Ulster. In the 14th century there existed a King-of-Arms called Ireland, but the office seems to have become extinct, and Edward VI. created Ulster to supply the deficiency. His arms are argent, St. George's cross, upon a chief gules a lion between a harp and a portcullis, all or. The royal ordinance relative to the Order of St. Patrick, issued May 17, 1833, declares that in all ceremonials and assemblies Ulster King-of-Arms shall have place immediately *after* the Lyon. See *Herald*.

KINK.—A twist in a rope or cord, caused by the tightness of the coil, and a relaxation of pressure in the direction of its length. The best rope, however, rarely kinks. In uncoiling a new coil of rope, pass the end at the core to the opposite side and draw it out; the turns of the rope will then run out without kinking.

KIRK RIFLE.—A breech-loading small-arm having a fixed chamber closed by a movable breech-block, which rotates about a horizontal axis at 90° to the axis of the barrel, lying below the axis of the barrel and in front—being moved from below by a lever.

This piece is a modification of the well-known Spencer repeating rifle, containing in an unwieldy butt-stock, six magazine tubes instead of the single one usually carried. These are connected on a central spindle and revolved into place by hand.

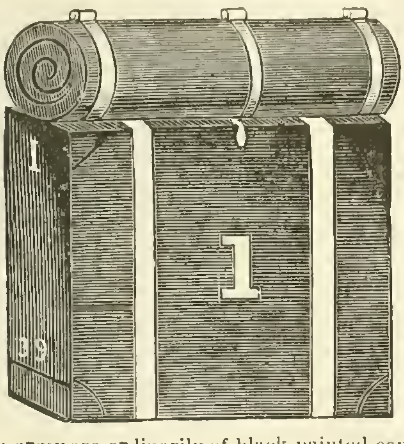
KISSELBACHES.—A name commonly applied to the soldiers of India.

KIT.—1. A cement for stuffing canvas to place over the vents of carcasses to keep out the damp. 2. In military language, the equipment in necessaries, such as shirts, boots, brushes, etc., of a soldier, but not applicable to his uniform, arms, or accouterments. Formerly, a high bounty was given, and then severely encroached upon, by making the recruit pay for his kit. The fairer principle is now adopted of issuing a free kit to each recruit, with a smaller bounty. The soldier has still to replace necessaries, worn out or lost, at his own expense, but he obtains the articles at wholesale, and very low prices. As these necessaries are so cheaply procured, it is held a very heavy military offense to make away with them.

KITCHEN CART.—A traveling-kitchen to accompany troops in the field. These carts are usually supplied at the rate of one to a battalion for 1000 soups. They should be provided with boilers *a la Papin* with an interior fire-place. These constitute the body of the cart, the superior part of which is furnished with plank to be used as a table. At the extremity of the cart there are two foot-boards upon which the cooks may rest while working during the march. Papin's digester is essential to cook well and rapidly. The interior arrangement of the fire-place which is suited to baking is very economical in fuel. See *Traveling-kitchen*.

KLICKET.—A small postern or gate in a palisade for the passage of a sallying party. Also written *Klinket*.

KNAPSACK.—A bag of canvas or skin, containing the soldier's necessaries, and worn suspended by straps between the shoulders. Those used in the



British army are ordinarily of black painted canvas; but some other nations, as the Swiss, make them of thick goat-skin, dressed with the hair on. The knapsack affords by far the easiest way of carrying light personal luggage during a march or walking tour.

KNEBELSPIESS.—A German lance used about the beginning of the 9th century.

KNIGHT BACHELOR. The lowest grade of knighthood, now only conferred in the United Kingdom. Originally, like all knighthood, a military distinction, knighthood of this description came to be often bestowed on civilians, and in recent times it has frequently been conferred for no weightier service than carrying a congratulatory address to Court. It is generally conferred by the Sovereign by a verbal declaration accompanied with the imposition of the sword, and without any patent or instrument. The person who is to receive the honor kneels down before the Sovereign, who touches him on the shoulder with a naked sword, saying, in French: "*Sois chevalier au nom de Dieu*" (Be a knight in God's name), and then adds: "Rise, Sir A. B." In exceptional cases, persons have been made Knights Bachelor by patent. The Lord Lieutenant of Ireland occasionally exercises a right of conferring knighthood.

KNIGHT-ERRANT.— A wandering knight; or any knight who traveled in search of adventures, for the purpose of exhibiting military skill, prowess and generosity. See *Knights*.

KNIGHTS.—Originally Men-at-Arms bound to the performance of certain duties, among others to attend their Sovereign or Feudal Superior on horseback in time of war. The institution of knighthood, as conferred by investiture, and with certain oath and ceremonies, arose gradually throughout Europe as an adjunct of the feudal system. The character of the knight was at once military and religious. The defense and recovery of the holy sepulcher, and the protection of pilgrims, were the objects to which, in the early times of the institution, he especially devoted himself. The system of knight-service, introduced into England by William the Conqueror, empowered the King, or even a Superior Lord who was a subject, to compel every holder of a certain extent of land, called a *Knight's Fee*, to become a member of the knightly order; his investiture being accounted proof that he possessed the requisite knightly arms, and was sufficiently trained in their use. The "Statute of Knights," of the first year of Edward II., regulating the causes that were to be held valid to excuse a man from knightly service, shows that in the 14th century the knightly office was not always eagerly coveted; yet its social dignity was very considerable, for even Dukes, if not admitted into the order, were obliged to yield precedence in any royal pageant or public ceremony. In time of war, each knight was bound to attend the king for 40 days, computed from the day when the enemy arrived in the country. After the long war between France and England, it became the practice for the Sovereign to receive money compensations from subjects who were unwilling to receive knighthood, a system out of which grew a series of grievances, leading eventually to the total abolition of knight-service in the reign of Charles II.

Knighthood, originally but a military distinction, came, in the 16th century, to be occasionally conferred on civilians as a reward for valuable services rendered to the Crown or community. The first civil knight in England was sir William Walworth, Lord Mayor of London, who won that distinction by slaying the rebel Wat Tyler in presence of the King. Since the abolition of the knight-service, knighthood has been conferred without any regard to property, as a mark of the Sovereign's esteem, or a reward for services of any kind, civil or military. In recent times it has been bestowed at least as often on scholars, lawyers, artists, or citizens, as on soldiers, and in many cases for no weightier service than carrying a congratulatory address to Court. The ceremonies practiced in conferring knighthood have varied at different periods. In general, fasting and bathing were in early times necessary preparatives. In the 11th century, the creation of a knight was preceded by solemn confession, and a midnight vigil in the church, and followed by the reception of the Eucharist. The new knight offered his sword on the altar, to signify his devotion to the Church, and determination to lead a holy life. The sword was redeemed in a sum of money, had a benediction pronounced over it, and was girded on by the highest ecclesiastic present. The title was conferred by binding the sword and spurs on the candidate, after which a blow was dealt him on the cheek or shoulder, as the last affront which he was to receive unrequited. He then took an oath to protect the distressed, maintain right against might, and never by word or deed to stain his character as a knight or a Christian. A knight might be degraded for the infringement of any part of his oath (an event of very rare occurence), in which case his spurs were chopped off with a hatchet, his sword broken, his escutcheon reversed, and some religious observances were added, during which each piece of armor was taken off in succession, and cast from the recreant knight.

It has been said that knighthood could originally be conferred by any person of knightly condition, but if so, the right to bestow it was early restricted to persons of rank, and afterwards to the Sovereign or his representative, as the Commander of an Army. In England the Sovereign now bestows knighthood by a verbal declaration, accompanied with a simple ceremony of imposition of the sword, and without any patent or written instrument. In some few instances, knighthood has been conferred by patent, when the persons knighted could not conveniently come into the presence of royalty, as in the case of Governors of Colonies, or other persons occupying prominent situations abroad. The Lord Lieutenant of Ireland also occasionally, but rarely, exercises a delegated power of conferring knighthood. The monosyllable "Sir" is prefixed to the Christian names of knights and baronets, and their wives had the legal designation of "Dame," which in common intercourse becomes "Lady." Persons who are simply knights without belonging to any order are called in England, knights *bachelors*, a name probably corrupted from *bas chevalier*. Knighthood of this kind is now only conferred in Great Britain. A degree of knighthood called *banneret* formerly existed in England and France, which was given on the field of battle in reward for the performance of some heroic act. For the mode in which that dignity was conferred, see BANNERET. No knight-banneret has been created in the field since the time of Charles I., when that honor was bestowed on one Sir John Smith, for rescuing the royal standard from the hands of the rebels. George III. twice conferred the title on occasion of a review, but the proceeding was considered irregular, and the rank of the knights not generally recognized. The form of helmet which the requirements of the later Heraldry have appropriated to knights, entitling them to place it over their arms, is full-faced, of steel, decorated with bars, and with the visor a little open. For the different orders of knighthood, see separate articles, under their appropriate headings, in this work.

KNIGHT-SERVICE.—A tenure of lands held by knights on condition of performing military service. It was abolished in the time of Charles II. of England. See *Knights*.

KNIGHTS TEMPLAR.—A celebrated Religious and Military Order, founded at Jerusalem in the begin-

ning of the 12th century, by Hugues de Paganes quired from the Abbot and Canons of the Church and Convent of the Temple, whence the Order obtained the name of the "Poor soldiers of the Temple of Solomon," afterward abbreviated into Templars. The knights were bound by their rule to hear the holy office every day, or if prevented by their military duties, to say a certain number of paternosters instead: they were to abstain from flesh four days in the week, and from eggs and milk on Fridays. They might have three horses and an esquire each, but were forbidden to hunt or fowl. In the earlier period of their history, the Templars made a great show of poverty, contrasting much with their later condition. After the conquest of Jerusalem by the Saracens, they spread over Europe; their valor became everywhere celebrated; immense donations in money and land were showered on them; and members of the most distinguished families thought themselves honored by enrolment in the Order. In every country where they existed, they had their Governor, called the Master of the Temple or of the Militia of the Temple. The Templars had settlements in England from an early period. The first was in London, on the site of Southampton Buildings, Holborn; but from 1185 their principal seat was in Fleet Street, still known as the Temple. The Round Church which bears their name was dedicated by Heraclius in 1185.

The Templars were at first all laymen and of noble birth. Pope Alexander III., however, in 1162, authorized the admission of spiritual persons not bound by previous vows, as Chaplains to the Order, who were not required to adopt the military vows. A third class was afterward introduced, consisting of laymen not of noble birth, who entered as serving brothers, some of them being attendants on the knights, and others exercising trades in the houses or lands of the Order. Eventually, many persons became affiliated members without taking the vows, for the sake of the protection afforded them. As the power and prosperity of the Templars increased, so did their luxury, arrogance, and other vices, which gave the French Kings pretext for endeavoring to suppress them, and lay hold of their possessions. Accusations, many

Regular Jewels—Knights Templar.

Geoffroy de St. Omer, and seven other French knights for the protection of the Holy Sepulcher, and of Pilgrims resorting thither. Baldwin II., King of Jerusalem, bestowed on this order their first place of residence; and an additional building was ac-

of which were absurd and incredible, were brought against them by two members of their own body. Their principal enemy was Philippe IV. of France, who induced Pope Clement V. to accede to a scheme by which the whole members of the Order were seized and imprisoned, their lands confiscated, and many of them tried, convicted, and executed for capital crimes. The English Templars were arrested by command of Edward II., and a Council held in London in 1309 having convicted them of various crimes, most of which were probably imaginary, the King seized their possessions. In 1312 the whole Order throughout Europe was suppressed by the Council of Vienne, and its property bestowed on the Knights of St. John, to which latter Order their English possessions were formally transferred by a Statute of Edward II. in 1323. The habit of the Templars was white, with a red cross of eight points of the Maltese form worn on the left shoulder. Their war-cry was "Beau Séant;" and their banner, which bore the same name, was parted per fess sable and argent. They also displayed above their lances a white banner charged with the Cross of the Order. Their badges were the *Agnus Dei*, and a representation of two Knights mounted on one horse—indicative of the original poverty of the Order.

KNOTS.—1. Knots of different kinds are borne by different families as heraldic badges, and are occasionally introduced as charges in shields. The forms of some of them appear to be suggested by the initial letter of the name or title of the bearer. In the Wake and Ormonde knot it is not difficult to trace a *W* and two *Os*. The Bourchier knot, as seen on the tomb of Archbishop Bourchier, at Canterbury, bears a resemblance to two *Bs*, and the Stafford knot to two *Ss*. The Lacy knot contains within it a rebus on the four letters of the name Lacy.

2. A twist or loop in a rope or cord, so made that the motion of one piece of the line over the other shall be stopped. The knot owes its power of passive resistance to the friction of the rope. The uses of knots are infinite; in the commonest occasions of life one or two simple knots are indispensable; in building, mining, and moving ordnance, knots of curious form are employed; while on shipboard, they may be numbered by the dozen, and each is appropriated to a specific duty. The following are the more important knots employed in mechanical maneuvers:

Two half hitches—Pass the end of a rope round the standing part and bring it up through the bight. This is a half hitch. Take it round again in the same manner for two half hitches.

A clove hitch—Pass the end of a rope round a spar, over, and bringing it under and round behind its standing part, over the spar again and up through its own part. It may then, if necessary, be stopped or hitched to its own part; the only difference between two half hitches and a clove hitch being that one is hitched round its own standing part and the other is hitched round a spar or another rope.

Round turn and two half hitches—Take a round turn around the stakes or posts, and secure the end by two half hitches around the standing part. This is useful in securing the guys of the gin to the stakes.

A bowline knot—Take the end of a rope in your right hand and the standing part in your left; lay the end over the standing part, and with the left hand make a bight of the standing part over it; take the end under the lower standing part up over the cross, and down through the bight. This is very useful in forming a temporary eye at the end of a rope.

Square knot—Take an overhand knot round a spar; take an end in each hand and cross them on the same side of the standing part upon which they came up; pass one end round the other, and bring it up through the bight. This is, sometimes called a *reef knot*. If the ends are crsssed the wrong way, sailors call it a *granny knot*.

A timber hitch—Take the end of a rope round the spar, lead it under and over the standing part, and pass two or more round turns around its own part; pass the first turn *over* the end part instead of through the bight, as in a half hitch. Used in securing the ends of the trace-ropes to the maneuvering bolts.

A rolling hitch—Pass the end of the rope round a spar; take it round the second time, nearer to the standing part; then carry it across the standing part, over and round the spar and up through the bight. A strap or a tail-block is fastened to a rope by this hitch. Used in shifting the fall from one end of the windlass to the other.

A blackwall hitch—Form the bight by putting the end of a rope across and under the standing part; put the hook of a tackle through it, the center of the bight resting against the back of the hook, and the end jammed in the bight of the hook by the standing part of the rope.

A cats-paw—Take a large bight in the rope, and spread it open, putting one hand at one part of the bight and the other at the other, and letting the standing part and end come together; turn the bight over from you three times, and a small bite will be formed in each hand; bring the two small bites together, and put the hook of a tackle through them both. This is very useful in applying a purchase or tackle to the fall of another.

A sheet bend, (weavers knot)—Pass the end of a rope up through the bight of another, round both parts of the other, and under its own part.

Carrick bend—Form a bight in the rope and lay the end across the standing part; stick the bight of another rope up through the loop thus formed, and carry the end over the end of the first rope under the standing part, and through the loop formed by its own bight; stop each end to its own standing-part.

Fisherman's bend (anchor knot)—Take two turns around the gun-sling or spar with the end of the rope; hitch the end around the standing part and through both turns, and then pass the end over the second and under the first turn.

A sheep shank—Make two long bights in a rope which shall overlay one another; take a half hitch over the end of each bight with the standing part which is next to it.

A marlinspike hitch.—Lay the marlinspike upon the seizing stuff, and bring the end over the standing part so as to form a bight; lay this bight back over the standing part, putting the marlinspike down through the bight, under the standing part, and up through the bight again. Very useful in putting on lashings etc. *Stopping* is fastening two parts of a rope together, as for a round seizing, without a crossing or riding. *Nippering* is fastening them by taking turns crosswise between the parts to jam them, and sometimes with a round turn before each cross. They are called *racking turns*. Pass *riders* over these and fasten the end. This is a convenient way to secure a fall while it is being shifted on the windlass. *A screw* is applied by weaving a light strap through the different parts of a fall, bringing the two ends together, and screwing the whole up tight by means of a stick or bar passed through the bights. *A strap*, or *sling*, is formed by knotting or splicing together the ends of a short strand or rope. It is used for hooking tackles into.

Pointing—Unlay the end of a rope and stop it; take out as many yarns as are necessary, and split each yarn in two, and take two parts of different yarns and twist them up taut into *nettles*; the rest of the yarns are combed down with a knife; lay half the nettles down on the scraped part, the rest back upon the ropes, and pass three turns of twine taut round the part where the nettles separate, and hitch the twine, which is called the *warp*; lay the nettles backward and forward as before, passing the warp each time. The ends may be whipped and snaked with twine, or the nettles hitched over the warp and hauled taut. The upper seizing must be snaked. If the upper part is too weak for pointing, put in a piece of stick. This is an elaborate way of whipping ropes, and requires considerable practice.

Seizing a rope is connecting the two parts with smaller rope, or spun-yarn. Take a piece of spun-yarn and double it; pass the bight under the two parts of the rope to be seized; put both ends through it and haul taut, using a level applied with the marlinspike hitch; separate the ends, pass them around the rope in opposite directions until enough turns are taken, hauling each turn taut, and seeing that they lay close and smooth. Cross the seizing by passing the ends in opposite directions between the ropes and around the seizing, and finish with a square knot.

A lashing is applied on the same principles. After sufficient turns have been taken, the lashing is *frapped* by taking the ends around the turns, hauling them close together, and making the lashing tighter, of course. *To pass a shear lashing.*—Middle the lashing and take a turn round both legs at the cross; pass one end up and the other down, around and over the cross, until half of the lashing is expended; then ride both ends back again on their own parts and knot them in the middle; frap the first and riding turns together on each side with sennit. This will be useful in rigging shears for hoisting guns, when a gin is not available. Any two spars that will support the weight can be used.

The knots most frequently used and the manner of forming them are described under the appropriate headings.

KNOUT—KNUT.—A scourge composed of many thongs of skin, plaited, and interwoven with wire, which was formerly the favorite instrument of punishment in Russia for all classes and degrees of criminals. The offender was tied to two stakes, stripped, and received on the back the specified number of lashes; 100 or 120 were equivalent to sentence of death, but in many cases the victim died under the operation long before this number was completed. If a culprit survived this punishment he was banished for life to Siberia. The whipping was inflicted by a criminal, who preferred this office to exile to Siberia, and who was constantly kept in prison, except when his services were required. The nobility were legally exempt from the knout, but this privilege was not always respected. In earlier times the nose was slit, the ears were cut off, and the letter V for *vor* (rogue) was branded on the forehead; but this aggravation was abolished by Alexander I. The knout was abolished by the Emperor Nicholas, who substituted the *pleti*, a kind of lash.

KODALLIE.—An Indian term. A tool used by the natives of India in digging all kinds of earthwork. The face of the tool is shaped like a hoe, and has a short handle nearly parallel to the face. It is used in a kneeling or sitting position.

KONKRI.—A sword of the Middle Ages, without a hilt or crossguard. The handle is straight and forms with the blade a Latin cross.

KORAZIN.—A short hauberk or jacket of scales. It is frequently called *Jazeran*. The term is also applied to a large imbricated hauberk, covered with overlapping plates, somewhat like the small hauberk of the 8th century.

KOT DUFFADAR.—A non-commissioned officer in the East Indian Native Cavalry, corresponding with a troop Sergeant Major. See *Duffadar Major*.

KOUL.—A soldier belonging to a noble corps in Persia. The *Kouls* constitute the third corps of the King's Household Troops. They are men of note and rank, and no person can arrive at any considerable post or situation in Persia who has not served among the Kouls. The Commander of the Kouls is known as the Kouler-Agasi, and is usually Governor of a considerable Province.

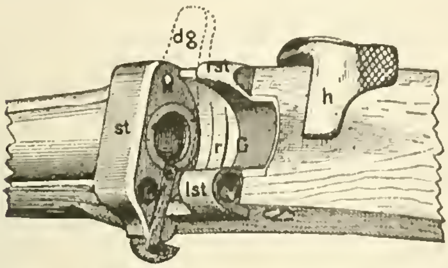
KRANKENTRAGER.—A special corps organized by the German Army; its duty is to carry the sick and wounded. The men are mostly taken from the *Landwehr*, but some are students from hospitals and universities. The former are in uniform, and the latter in plain clothes; but all wear the red cross on their arm, and are under the protection of the Geneva Convention. They are men of two years' service, intelligent, of good character, and have received some theoretical instruction in surgery and medicine. The instruction imparted to these men is directed by Superior Officers, assisted by Surgeons. They are taught to give the first care to the wounded; to carry them on stretchers and to form the stretchers, from any improvised material; to transport the wounded to the ambulance wagons; to prepare the wagons for that purpose; and to perform all such duties as shall be required of them during a battle.

KREBS.—A complete suit of armor, composed of imbricated plates.

KRIEGSSPIEL.—This German war game was contrived by a Prussian, Councillor Reiswitz, in order to follow with greater facility the campaigns of Napoleon I. His son, an artillery officer, found it, by reproducing the campaigns on a map, an easy method of studying the different movements of troops, and caused the game to be adopted in about 1824 by Feldmarschall von Müffling. The *Kriegsspiel* eventually became familiar with the Army, and was finally introduced in the military schools as the best means of studying strategy and tactics. This game was not only a study, but a favorite pastime, of VonMoltke's, Blumenthal's, Prince Frederick Charles, and of other German officers, who took a prominent part during the war of 1870–71. It is stated that they carefully studied for years, by means of this game, the ground on which they carried out their operations in France. The *Kriegsspiel* was first introduced in England after the Franco-German war (1870–71), and is now frequently played in all the large garrison towns of this country. A club has been formed at Aldershott for that purpose. The necessary apparatus for playing the *Kriegsspiel* is composed of maps carefully prepared on a scale of 6 or 8 inches to the mile; of metal blocks, made to scale, as nearly as possible, representing all the different branches of the service, from regiments to skirmishers; and strings of beads, for cavalry reconnoitering. The number of persons taking part in the game consists of the officers commanding the two armies, of a judge or chief umpire, supported generally by two or three umpires. The umpires alone see the ground occupied by the two forces. Instructions are given as to their positions; the time of the year, the length of the days, the state of the roads, etc., are settled beforehand. The losses made on both sides are calculated by means of tables carefully prepared; they form a large volume, and were published, in 1870, by Colonel von Trotha. Other circumstances, such as troops sheltered by earthworks, artillery firing out of range, are taken into consideration; those that have not been laid down in the rules are decided by a throw of the dice. Thus the action gradually develops itself as each Army advances on the contested ground, till victory is declared for one side or the other. The principal utility of the game appears to be in the arrangements previous to and during the early conduct of an action. When the troops get to close quarters, the element of chance enters so largely into the game that it destroys to a very great extent, the dependence that may be placed on the issue of the battle. The game, howevery, affords great practice in the drawing up of the order of march of columns previous to an action, and the development of the columns of march into formation for attack. In the hands of men having some military experience, this game becomes a certain means of acquiring and perfecting a Science which in time of peace cannot be easily acquired. It raises questions which are strategical problems of great interest. See *Strategos*.

KRIS.—A dagger or poniard, the universal weapon of the inhabitants of the Malayan Archipelago. It is made of many different forms, short or long, straight or crooked. The hilt and scabbard are often much ornamented. Men of all ranks wear this weapon; and those of high rank, when in full dress, sometimes carry three or four. In Java, women sometimes wear it. Also written *Creese* and *Krees*.

KRNKA GUN.—The system of altered breech-loading muskets of the Russian service is the invention of Sylvester Krnka, a regimental armorer of the Austrian army. Its chief features are simplicity and compactness. The drawing represents the breech system with the breech-block removed. The following are the principal parts, viz: *s t*, is that portion of



the breech-frame or receiver into which the barrel is screwed; *r*, is the slot or well in which the breech-block rests when the chamber is closed; *m* is the hole into which is screwed the point of the hinge-pin around which the breech-block revolves; *l s t*, is the lug in rear of the breech-block through which the hinge-pin passes; *c*, is the groove by which the cartridge is inserted into the chamber; *r s t*, is the lug which serves as a support for the breech-block and a stop for the hammer, *h*; *e*, represents the extractor in position; *k*, is a small catch-pin actuated by a spring which presses into a small indent in the front face of the breech-block and holds the block in place with slight friction; *d g*, are broken lines, showing the position of the thumb-piece of the breech-block when closed but not locked down by the hammer.

The lower portion of the block is semicircular in form, and has a groove, into which fits a raised band or rib, *r*. The object of this arrangement is to increase the strength of the parts to resist the force of the charge. The rear corner of this rib is rounded off to prevent it from interfering with the insertion of the cartridge; the firing-pin is pushed back, when the block is opened by the oblique surface of the notch, and also in closing the block, by the chamfered corner of the receiver, *s t*. The extractor is a lever of the first order, and is operated by opening the breech smartly, in which case the shell is thrown out clear from the receiver. The cartridge belongs to the center-fire system of Berdan. The shell is made of brass; the head is folded and strengthened with a re-enforcing-cap. The caliber of the Russian altered arms is 60, or 0″.6. See *Small-arms*.

KRUPP GUN.—The fabrication of cannon is the matter of chief personal interest to Herr Krupp, who watches with the closest interest what governments in every part of the world are doing, and proposing to do, in relation to their armaments. Nearly every government, except England and the United States, has been a purchaser of Krupp guns, and there seems to be no cessation in the demand for them. At present Italy and China are his best customers, and the 125-ton guns for the Italian government which he has now in hand are the most prodigious pieces of ordnance which have ever been made. Krupp's pre-eminence as a gun-maker is unquestionably due to his early perception of the fact that steel must supplant iron in the fabrication of ordnance, and to his possession of such unrivaled facilities for the manufacture of steel in his own works. New ideas in the construction of ordnance Herr Krupp does not claim to have developed, but he was one of the first to perceive that breech-loading cannon would completely take the place of muzzle-loaders. It was this change which definitely forced the abandonment of iron in the construction of cannon in Europe. Krupp satisfied himself that the wedge system of breech-closing was the best, and in spite of the conclusion of the French and English authorities that the French interlocking system is superior, Krupp goes ahead and shows no sign of giving up the system with which his name has come to be identified. The 125-ton guns are 35 calibers in length—that is, over 55 feet. The inner tube is covered with steel rings to the muzzle, and the outer jacket at the breech in which the breech-closer is placed is an enormous piece of steel. Not a single part of these extraordinary guns could be produced by any establishment in the United States, for we have no means in America of hammering or working such enormous masses of metal. The largest caliber is 40 centimeters, or something over 16 inches, and the boring of a tube of this size is an important operation. The core, when the boring is completed, is still a ponderous cylinder, which can itself be bored and used as a tube of a smaller gun. The cutting of the rifle grooves in a large gun is a very simple operation and not a protracted one, as these grooves are cut simultaneously, and the work is done by the machines with mathematical accuracy. Every gun is tested on the grounds near the shops by being fired four times, and the large guns are then sent to Meppen, in north Germany, to be tested by the agents of the governments which purchase them—if such tests be desired. Krupp often conducts experiments of his own at Meppen, and occasionally large numbers of foreign officers are invited to be present. The drawback to such elaborate experiments is the enormous expense which they entail. Considering that the butts are wholly artificial structures of sand and masonry, and that the largest cannon are here fired at close ranges, it will be seen that great strength and security are required. The workman in charge is pointed out as a person who has "fired more cannon" than any other man in the world. The trials at Meppen are all for the purpose of testing the range of the gun, those at the Works to test the strength of the gun. Near the firing-grounds at Essen is the Ordnance Museum, where are retained specimens of everything that Herr Krupp has accomplished in the development of artillery.

The principal feature in the Meppen programme of 1879 was the trial of Krupp's 40-centimeter (15.75 inch) breech-loading gun, weighing about 70 tons 17 cwt., known commonly as the 71-ton gun. The trial was specially important for three reasons: 1st. It is the first breech-loader whose power approaches that of the 100 and 80-ton guns made in England; 2d. It is a steel gun; 3d. Its proportions are based on results obtained during the last few years.

All these questions are interesting, and deserving of so much attention that it would be difficult here to deal fairly with all. For the purpose in hand, however, it is not necessary to discuss the question of the respective *metals* of the guns, because it can easily be shown that there was nothing in these experiments that bears upon this point beyond the negative fact that the steel guns in no respect exhibited any fault. We may safely say that the Woolwich guns would have done equally well, as far as the material is concerned, for the pressures in Krupp's guns were by no means excessive. The 71-ton gun, for example, was not subjected to as high a pressure as the English 80-ton gun has borne. A test which tries neither gun obviously furnishes us with no means of comparison, and hence the Meppen trials in no way furnish data for the discussion of the relative merits of wrought-iron and steel guns, but bear entirely on the two other questions, namely, that of breech-loading and proportions—the former, as concerns ease in working, and the latter power, and good shooting.

The 71-ton gun was mounted as for coast defense, on a traversing platform, and a carriage nearly of the English pattern in all respects. The brackets were made of wrought-iron, the gun being elevated by multiple gear, acting on elevating arcs, fixed on the gun. Beneath the carriage were two hydraulic buffers. A modified form of Cunningham's chain gear, was used for traversing the platform, which ran on trucks on three concentric racers, the pivot being about six feet in front of the carriage when run up. A lifting crane was attached to the platform, fixed on a sort of axle, with a counter-lever with powerful spring, which required considerable force to compress it by bending down the crane, and which decreased the work of lifting the projectiles by the same amount, thus dividing the labor of lifting the projectiles into two operations.

The gun was easily worked by a detachment of fifteen men. Ten rounds, with chilled projectiles were first fired; the time occupied by the last five rounds was twenty-four minutes. The breech piece moved easily. A good deal of oil was used on it. The breech-loading certainly saved the men much labor, not only in the actually ramming home but also in bringing up the projectiles, since it was not necessary for them to cross of the racers or the Cunningham chain. The charge was made up in four cartridges, each containing 110 pounds of prismatic powder. The least satisfactory part of the service of the gun considering everything, was the difficulty experienced in the ignition of the charge and in remedying miss-fires. The vent was in the axis of the piece, and a disk of calico was torn off the bottom of the cartridge last entered, to expose the powder to the flash of the tube. The latter was of a bad pattern, short and weak. No stress is to be laid on this, as the remedy is obvious. A primer or a stronger tube would rectify this fault. A more important question is the shooting of the gun as regards power and accuracy. The chilled projectiles had 0.078 in. windage, which is about the same as that in Woolwich projectiles, namely, 0.08 inch over a copper rim. The common shell subsequently fired, however, had the unpractical windage of about 0.01 inch over an iron body. The target diagrams show a remarkable degree of accuracy, chiefly in the vertical direction, which argues well for the regularity of the charge, which surely must be attributed to the prismatic powder employed. It stands to reason that a charge composed of a fixed number of prisms of uniform size and density gives promise of greater uniformity being attainable than when pebbles are employed; and there seems no reason to doubt that, whatever difficulties were at first experienced, this has been achieved. Surely if two attempts are made to obtain regularity in powder—one by employing prisms each uniform in size and shape, and if possible pressed uniformly, and another by means of pebbles of an accidental shape from uniformly pressed powder-cakes—the former, though it may be difficult, offers promise of ultimate success in the higher degree. As to the windage, stress can hardly be laid on the great reduction in the case of the common shell; the two kinds of projectiles made pretty nearly equally good practice.

Lastly, *as to the proportions of the bore and chamber.* The bore of the 71-ton gun is only 20 inches shorter than that of the 100-ton gun and 55 inches longer than that of the 80-ton gun. The chamber in length is 60.6 inches, that of the 100-ton gun being 59.7 and of the 80-ton gun 59.6. The caliber of the 71-ton gun is 15.75, against 16 in the 80 and 17.72 in the 100-ton gun. Consequently, the bore of the 71-ton gun is 21.8 calibers long, against 18 in the 80 and 20.5 in the 100-ton gun. The diameter of the chamber of the 71-ton gun is 17.32 inches, that of the 80 and 100-ton guns being 18.0 and 19.7 inches, respectively—that is to say it is 1.57 inches greater than that of bore, as compared with 2.0 inches increase in the 80 and 1.98 inches in the 100-ton gun. Speaking generally, then, the bore of Krupp's gun is relatively rather longer and the chamber less enlarged than in the 100-ton gun, while in the 80-ton gun the bore is actually the shortest and the enlargement of the chamber actually the greatest of the three. On these proportions mainly depends the power of the guns. To be able to make a comparison between them, discrimination is necessary. It would not be right to take equal or proportionate *charges* as the basis of the comparison, because the principle on which a long gun is advocated is that any greater result can thus be got from a gun with a given strain on it, but at the expense of some waste of powder. It is clear, then, that looking to the endurance of the gun rather than the expenditure of powder, the basis of comparison should be *proportionate pressures.* It would scarcely be right to say *equal* pressures, because the thicker gun can fairly be expected to bear a greater strain than the thinner one. Now, the best results obtained from these three guns are as follows: The 80-ton gun at Woolwich, with a proof-charge of 445 pounds, giving a pressure of 21.5 tons, discharged a projectile weighing 1,728 pounds with a velocity of 1,657 feet per second—having 32,938 foot-tons stored up work, or 658.37 foot-tons per inch circumference—equivalent to a penetration of a 32.34 inches plate of wrought-iron. The 71-ton gun at Meppen is reported on one occasion, with a charge of 485.1 pounds, giving a pressure on the gun of 20.92 tons, to have discharged a projectile weighing 1,715 pounds with a velocity of 1,703 feet per second—having therefore 34.489 foot-tons stored-up work, or 697.02 foot-tons per inch circumference—equivalent to the penetration of a plate 33.5 inches thick. During the public trials in August the 71-ton gun was not tested so severely, and it is therefore right to class the above in the same category as the Woolwich proof round above metioned. In August the average weight of the chilled projectiles was 1,712.6 pounds. The firing charge was 452 pounds, the initial velocity was 1,648 feet, the stored-up work was 32,241 foot-tons, the work per inch circumference 651.59 foot-tons, equivalant to a penetratian of 32.12 inches. The pressure on the bore was 19.85 tons. The highest result hitherto obtained with the 100-ton gun, of 17.72 inches caliber, has recently been furnished by Captain Noble; it is as follows: Charge, 573 pounds; projectile, 2,000 pounds, about; velocity, 1,725.5 feet; stored-up work, about, 41,300 foot-tons, or 742 foot-tons per inch circumference, which is equivalent to a penetration of nearly 35 inches of armor. The pressure on the bore was about 18.0 tons. It is quite clear, from the above, that the 71-ton gun is a much better weapon than the 80-ton gun, inasmuch as it beats it in every respect. It fires a heavier projectile with a higher velocity, which has therefore more energy or stored-up work and an inch and a half more penetration, and all this is done with less pressure on the bore of the gun. The reason is that it is a better proportioned gun, its main advantage being its greater length. The 100-ton gun compares much more favorably with Krupp's gun, but, nevertheless, would do so better if its length were greater. The main difference in the guns depends on the difference in length; and the question naturally arises with those investigating, how is it that the English Government is now completing and issuing 80-ton guns so inferior in power to Krupp's 71-ton gun, which has already achieved the results we speak of. The answer is, that the guns were designed for the "Inflexible," and that, being muzzle-loaders, the vessel had to be made with portions of the deck corresponding to the length of the gun, to make provision for its loading. All this was determined years ago. Since that time *investigations* have shown the desirability of greatly increasing the length; but the gun being a muzzle-loader, it is impossible to do so. For the ship in question, a muzzle-loader is limited as to its length by inflexible conditions; and all that can be done is, by enlarging the chamber, to utilize to the fullest extent the disproportionate thickness of metal. Apart from the trying instance, however, it is clear that every increase in length is in favor of the breech-loader, because the labor and inconvenience of muzzle-loading increase in an increasing ratio; and, in the case of turret guns, and probably in some guns in casemates and cupolas, muzzle-loading becomes eventually almost impossible.

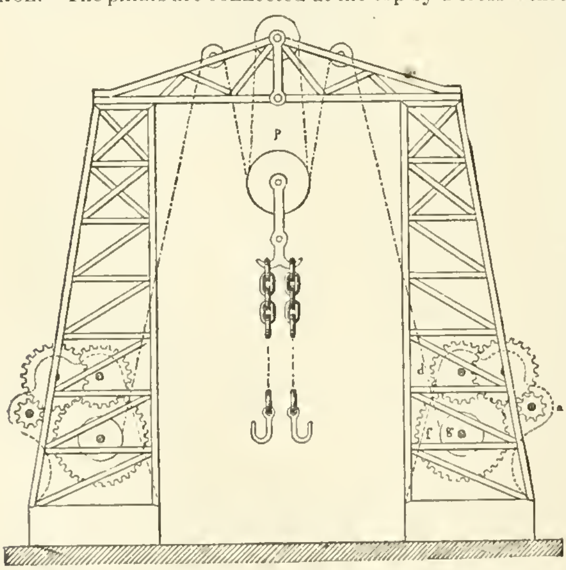
Very remarkable results were obtained with smaller guns. An excellent 51-ton 14-inch gun was tried, the behavior of which closely resembled that of the 71-ton gun, including the method of working, occasional miss-fires, and the like. An 11-inch (28-centimeter) howitzer, a 4.13-inch (10.5 centimeter) siege gun, and a 3.78-inch (9.6 centimeter) were fired, which did well but need not be here noticed in detail. A long 5.9-inch (15-centimeter) gun on a special sea service carriage with oil buffer gave good results; also an 8.27-inch (21-centimeter) howitzer, and a 5.9-inch (15 centimeter) mortar, were fired at dummy guns in a battery with good effect, notwithstanding that some of the fuses failed to act. Two remarkably characteristic guns, 3.4-inch (8.7 centimeter), were fired, fixed on pivots, one with little, and the other with absolutely no provision for recoil. With these is naturally connected another non-recoil arrangement of Krupp's, now well known, consisting of 6.1-inch (15 centimeter) gun, muzzle pivoting, the muzzle being ball-shaped and working in a socket in an armor-plate. These three guns possess peculiarities deserving of attention.'

One piece, 3.4 inches in caliber, was 14 feet 3¼ inches long. Its chamber was enlarged to an extraordinary extent, being 5.9 inches in diameter. The cartridge was a long bag, very loose on the powder, made so as to admit of being adjusted in the chamber by hand. The charge was 7.7 pounds. Two kinds of projectiles were fired—long ones, 12.5 inches in length, weighing 22 pounds, and shorter ones 9.5 inches in length, weighing 15 pounds. The initial velocities of these projectiles were 1,829 and 2,098 feet respectively. The maximum pressure was 11.6 tons. During this extraordinary performance the gun was held rigidly, being fixed on a strong vertical steel pivot, and so steady was it that small coins placed on its barrel were not shaken off on firing except near the muzzle. Eventually a Dutch officer displayed sufficient confidence to sit astride on the gun while it was fired, with the projectile shooting between his legs at the rate of about 2,000 feet per second. The second 3.4 gun somewhat resembled the above, but had provision for slight recoil, the pivot moving on its lower end as a center, the gun forcing the upper end back against a piston or buffer. The muzzle pivoting 6.1 gun was worked easily, the armor absorbing the shock of recoil, and suffering in no way apparently beyond the structure appearing to spring a little in the earth. A man laid it while riding on a saddle placed on the chase of the piece; he employed sights directed through a small hole at a convenient height above the gun, and he fired the gun himself by pulling the lanyard while still sitting on the piece. This system has been tried by one Goverment experiment, but has not hitherto found favor. It certainly appears as if a heavy gun so fixed to a shield, and impressing its work on it every round, must soon destroy the structure; but apparently it would take a very long time for a medium gun to do so, and it is possible that a gun so completely protected and able to fire with such great rapidity might perform admirable service before it failed in this way, so that, under some conditions, such a gun might be very valuable.

The ball portion of the muzzle can be readily unscrewed, and so can the disk containing the socket into which it fits in the plate. This operation can be safely performed, a shutter being run up which completely covers the opening from the enemy. It still appears possible, however, that a blow from a very heavy shot might distort and jam the screwed portion of the plate. Against ordinary siege guns such a gun working with all the speed due to non-recoil, and with such an extraordinary measure of security, might effect much. Two trials against armor took place, one to show the comparative effects of firing against chilled and soft hammered iron structures. As both were manufactured by Herr Krupp, the trial cannot be regarded as a representative one of the system he opposes, and it would be a mistake to discuss it here. The other was the firing of a 9.45-inch (24-centimeter) gun, with a charge of 165.3 pounds and a steel projectile weighing 348.3 pounds, at a target which consisted of a front 12-inch wrought-iron plate, a wood layer of 2 inches, and a back wrought-iron plate of 8 inches. The plates were rolled at Dillingen. The shot had a striking velocity of 1,876 feet, which would give 8,492 foot-tons energy or stored-up work, a penetrating figure of 288.5 foot-tons per inch circumference, and a penetration of 19.32 inches of iron. The projectile, however of each of two rounds fired passed completely through the entire 20 inches of iron and grazed about 2,000 meters farther up the range. The plates were indifferently rolled, and contained some phosphorus, it is said; but the penetration of the shot was, after making all allowances, extraordinary. They were scarcely deformed in appearance when recovered. The steel was excellent. They had ogival points, the heads being struck with a radius of two diameters.

To sum up, the features which chiefly concern us in these extraordinary trials are—1st. The success of the breech-loading system. 2d. The great results obtained as to power and accuracy of fire. 3d. The muzzle-pivoting and non-recoil systems. Although these have been noticed in the short relation already given, one or two words may be useful to lead a discussion. First, it must not be supposed that equally good results have not been obtained as to power when guns have been made in accordance with the conditions arrived at by recent experiments, as may be seen from the following examples: *Two years ago* the new type Elswick 6-inch gun was fired with a charge of 33 pounds and a projectile of 82 pounds, the initial velocity being 1,902 feet, and the total energy 2,057 foot-tons: the same gun, with a charge of 37.5 pounds, discharged a projectile of 82 pounds weight with a velocity of 2,031 feet, having 2,362 foot-tons total energy. With this may naturally be compared Krupp's 5.9-inch gun, fired at Meppen, with 33.1 pounds charge, and with projectiles weighing 88.2 and 112.5 pounds, giving velocities of 1,835.3 and 1,668.7 feet, and total energy of 2,060 and 2,171 foot-tons respectively. On one occasion it is recorded in Krupp's printed tables as having fired a shot of 69 pounds weight with a charge of 37.5 pounds with a velocity of 2,135.8 feet, having 2,183 foot-tons energy. In these comparisons the Elswick gun has slightly the advantage. It can scarcely fail to be observed, however, that to rival the results of Krupp, Elswick achievements, and not of Government guns, are instanced. In some measure this may be accounted for by the fact that private manufacturers are untrammeled by routine, and a master of the question seizes lessons taught by experiments and works them as he judges best. The Government does not encourage the manufacturing departments to aim at taking the lead in experimental investigation. There are however, one or two serious lessons that we might learn from foreign trials. Take, for example, the three cases of breech-loading guns, breech-loading small-arm rifles, and prismatic powder. All these have been taken up, tried, and discarded, while they were steadily worked out to a successful issue by Germany. About 1853 the needle-gun was tried and rejected in England. Prussia, acting on her own judgment, patiently worked at it, and in 1863 or 1864 the entire superiority of breech-loading arms became indisputably proved and they were universally adopted. About 1866 the English tried prismatic or pellet powder, and rejected it; and after adopting breech-loading guns about 1858, they gradually superseded them about 1866 by muzzle-loading ordnance: and now, after Germany has steadily worked out these questions to a successful issue they are trying both one and the other again, and those who have weighed the results obtained by them, as compared with those of their own guns and powder, can hardly doubt that both will be eventually adopted. Until recently, the Italians and English were the main supporters of muzzle-loading guns. These guns were characterized also by being made of wrought-iron, which complicates the comparison we now wish to make. Still, the fact remained that England and Italy had muzzle-loading guns of 100 and 80 tons weight, and of a power that no breech-loading ordnance could rival. The Meppen trials have exhibited a gun which entirely surpasses the last-mentioned piece, and, for its weight, compares well with the former. Instead of dealing with a theoretical gun existing only on paper, then, we have one in thoroughly good working order, loading and firing by hand with a rapidity, and shooting with a power and accuracy, far beyond the achievements of the 80-ton gun up to the present time. This result is not due to a want of knowledge but to the impossibility of applying knowledge to the case of the 80-ton gun. With muzzle-loading guns on the present English system they have greater labor in loading, and have to commit themselves to the length of their gun three or four years before they bring it into service. To argue that breech-loaders should be at once adopted would be to commit the fault we have complained of above, but surely we have sufficient reason to give them a trial on a large scale. If breech-loaders have the advantages of ease and rapidity in working, of the possibility of changing their length without revolutionizing the surrounding structure of the ship, and of affording greater cover, especially when nonrecoil carriages of any kind are employed, they surely deserve a full trial even at the cost of having both breech and muzzle-loading guns in the service. See *Krupp Sea-coast Carriages*, and *Krupp Steel Works.*

KRUPP GUN-LIFT.—It consists of two quadrangular pyramidal pillars 23 feet high, made of angle-iron riveted together and strongly braced, as shown in engraving, resting each on a solid base of cast-iron. The pillars are connected at the top by a cross-



beam 19½ feet long, made of two principal trussed beams strongly secured by cross-ties, and carrying at the middle a double pulley, and at about 4 feet distant, on either side, a single pulley. A long chain is secured at its ends to the windlasses, *g*, passing over the pulleys and around the triple block, which is provided with a double hook to receive the ends of the sling-chains. The alphabetical order of the letters indicates the manner in which the wheels and pinions actuate each other. The chain thus makes a half turn on each single pulley, one turn on the double pulley, and one and a half turns on the triple block, as shown in the drawing, the ends of the chain being double between the pulley and block. It is easy to see how a limited number of men, operating on the cranks of the windlasses on both sides, are able to raise as heavy a weight as a 12 or 14 inch gun. See *Gun-lift*, and *Prussian Gun-lift.*

KRUPP SEA-COAST CARRIAGES.—The top carriage is composed of two cheeks connected together by a front, rear and bottom transom. The latter, of boiler-plate, extends under the bottom of the cheeks their entire length, and is shod on the under side where it comes in contact with the rails with brass shoes screwed fast to it. The cheeks for the 6-inch gun are made of a single plate 1 inch thick. For the larger calibers they are made of two plates riveted together, with a wrought-iron frame between them; in the upper side of the frame the trunnion-beds are formed to receive the trunnions, which have bronze friction-rings fitted on them. Cap-squares are used for all carriages. Both cheeks are provided on their outer faces with an apparatus for giving the elevation. It is composed of a cog-wheel operating a circular rack fastened to the gun by a bronze stud. The rack is held in place engaged with the teeth of the cog-wheels by a small roller with its axis in the cheek.

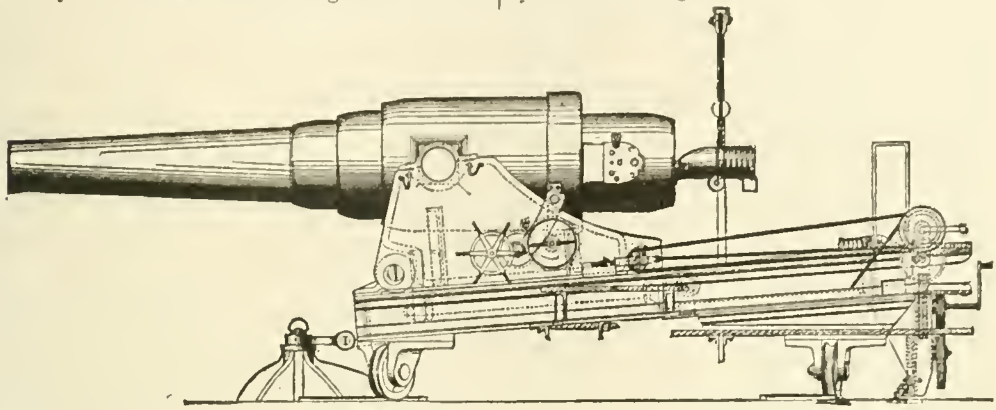
To elevate or depress the gun there is a wheel on the left side, with holes in its periphery to take a handspike; and on the right side there is a wheel with handles. In carriages for heavy guns this wheel is not on the same axis as the cog-wheel, but works in a pinion to gain power to raise the gun. The gun is held in any desired position by turning a check-screw which presses the wheel against the cheek. In firing, the top carriage rests on the chassis rail throughout the entire length of the shoe, in order to distribute the pressure arising from the discharge over a greater surface. To run the gun into battery the top carriage is provided with four truck-wheels. The rear pair are on eccentric axles, and can be thrown in gear by turning the axles part way round; this brings the front wheels in play, which turn on fixed axles. In the 6-inch gun-carriage each pair of wheels has a common axle, which has its bearings in the two cheeks, and the wheels are close up to them on the inside. The bottom transom has two openings left in it to allow the rear wheels to bear on the rails. The lever of the rear wheels on the left end of the axle is kept in position by a latch on the cheek. In carriages for heavier guns, beginning with the 6.7 inch gun, the truck-wheels are placed between the two plates of the cheek, in front or rear of the frame. Each wheel has its own axle.

An automatic arrangement is made to run the gun into battery after firing, without any action on the part of the gunner. This device consists of two wedge-shaped pieces of iron screwed fast to the top of the rails in rear of the top carriage. When the gun recoils, the rear wheels run up these inclined planes, the rear end of the carriage is raised till the front wheels are brought to bear also, and after the recoil the carriage runs down the inclined planes into battery, ready for the next fire. The eccentric axle is kept from turning by a key in the cheek. To run the carriage from the battery this key is taken out, and the wheels may also be thrown in gear by turning the axle with a handspike in the handspike-socket. To provide for the possible wear of the front wheels, and preserve an equal and quick motion when running into battery, the front wheels are also mounted on axles with eccentric boxes, which are kept in position by a small screw in each. To make this adjustment, remove the screw and turn the box, which, on account of its eccentricity, will lower the axle; it is held in the new position by the screw placed in a second hole. Two angle-irons are fastened to the bottom transom to guide the top carriage in its recoil; and two guide-hooks which pass under the flange of the rail prevent the top carriage from balloting on it. India-rubber hurters and counter-hurters are provided to limit the recoil both to the front and rear. In the 6-inch carriage the hurters are replaced by the curve of the end of the angle-irons which join the bottom transom to the cheeks. Two rings are fastened to the rear end of the cheeks, near the bottom, to hook the ropes to for pulling the top carriage from battery.

The hydraulic buffer is used to regulate and check the recoil of the gun. It consists of a forged cast-steel cylinder bored out and turned. Its rear end is closed by the bottom, screwed on and fastened to the rear transom of the chassis by screws. The front end of the cylinder is also screwed into a piece to which the cover is held by screws. There is a hole in the bottom piece for filling the cylinder; it is stopped with a screw and a cock in the cover for emptying it. The piston-head, with four holes bored in it, fits the cylinder closely, and to it, the piston-rod of cast steel is fastened, and passes through the cylinder head, the joint being packed with hemp-packing and bronze packing-box. The end of the piston-rod is fastened to the cross-head, which is bolted to the bottom transom of the top carriage.

The chassis is composed of two rails, connected together by transoms. The rails are wrought iron, I-shaped, rolled in a single piece for the smaller guns, and built up for the 11-inch gun, and all of larger caliber. The front transom is composed of two plates, the upper and lower joined together in the middle by cross-pieces of the same profile as the rails. The rear transom is also composed of an upper and lower plate, united by two cross-pieces riveted to the plates with angle-irons. The rear end of the hydraulic cylinder is bolted to the front one of these cross-pieces through an intermediate piece. The middle transom, composed of a plate, re-enforced with angle-irons, supports the front end of the cylinder, which is secured to it by its brace. The front and rear transoms of the 6-inch carriage are made of single plates, placed vertically, and re-enforced at top and bottom by angle-irons. The traverse-wheel forks are made fast to a front and rear bolster, which are bolted to the chassis. Each bolster is composed of two vertical side plates, one horizontal plate and one vertical plate, with the necessary angle-irons to unite the parts together. The rear bolster is made enough higher than the front one that the four wheels may be all of the same size, notwithstanding the inclination of the chassis, which is necessary to make the gun run into battery after firing. The traverse-wheel forks, composed each of a front and rear branch, are bolted to the under side of the horizontal plate of the bolsters.

The traverse-wheels are of cast steel, with a deep semicircular groove cut in their periphery to fit over the traverse-circle, which is nearly semicircular in cross-section, so that a large part of the recoil of the chassis is transmitted directly to it. The rear wheels have several holes bored radially into them to receive the end of a handspike to traverse the carriage in giving the proper direction to the gun. Hurters and counter-hurters are placed on the front and rear ends of the rails, or the front and rear transoms, to stop the carriage running into or from battery. These hurters are made each of a steel piston, fitting in a box, and holding between the head and box a number of India-rubber disks, separated from each other by sheet-iron rings.



A hinged tongue, bolted to the front transom of the chassis, connects it to the pintle in front. A windlass, attached to the rear end of the chassis, is used to run the gun from battery. It has a drum with raised sides for the rope, and is operated by a crank turning a wheel and pinion. For guns of very large caliber a double set of wheels and pinions is added between the crank and drum. All of these parts are fastened to a stirrup, which is secured by means of a tenon to the rear end of the rail. To run the gun from battery, hook the ropes on each side to the rings in the top carriage, take a turn around the drum, tighten the ropes and work the cranks. In the carriage for the 6-inch gun the arrangement is replaced by a simple block-and-tackle, which is hooked in the rings in the rear end of the chassis.

In the other carriages these rings are fastened to the windlass-frame, and are also used in traversing the carriage. For this purpose, commencing with the 8-inch sea-coast carriage, a windlass is used, fastened to the rear end of the chassis by a boiler-plate frame, strengthened by angle-irons, to which all of the moveable parts are attached. The principal part is the drum, around the circumference of which the chain works, fastened at its two ends to rings outside the platform. A pair of horizontal and vertical leading wheels on each side prevent the chain from leaving the drum. If the drum be turned by means of the crank which communicates with it through the wheel and pinion, the drum moves on the stationary chain, traversing the chassis with an easy but rapid enough motion. In case the chain breaks, the chassis may be traversed with handspikes. A crane is provided for the heavy carriages, commencing with the 8-inch, for elevating the projectile. It is placed on the right side of the chassis, on a direct line with the breech of the gun, when it is in battery. It consists of a curved iron upright, which is held in a vertical position by a pillow-block and collar, and is readily turned by the handle. The drum is near the foot of the upright. By turning the crank, motion is given to the rope, either directly or by a wheel and pinion. One end of the rope is fastened to the drum, and thence it passes over two fixed pulleys on the upright. The other end has a hook fastened to it. This hook is inserted in the upper ring of the shot-cart, which, holding the projectile, is hoisted up, the tongue being first taken out. The crane is turned until the carriage touches the gun, to which it is hooked. The shot being rammed home, the crane is turned, and the empty cart is lowered. Steps are attached to the chassis at several places for the convenience of the gunners (angle-irons are fastened to the rails, and oak planks, secured to them), as the step for the gunner in pointing in rear and across the chassis, on both sides of the chassis, and between the rails, for the men serving the gun, inserting the projectile, the charge, etc.

The foundation of the platform is of brick masonry, from 3 to 6 feet thick, according to the caliber of the gun. The stability of the foundation being the essential condition of the continued good working of the carriage, the masonry should first of all have a solid bed. If the soil be not firm, as often happens on the sea-coast, the foundation should be made by driving piles, on which a good bed of concrete should be laid, and may be made still more solid by pieces of railroad iron.

The following implements are supplied for the carriages: Two wooden handspikes (ash), having ends shod with iron and made to fit in the holes of the elevating-wheel, in the rear truck-wheels, and rear traverse-wheels; one wrench for the packing-box; a wrench for the cock and the filling-hole screw in the hydraulic cylinder; a screw-wrench, and a shot-cart. The body of the cart is a piece of curved sheet-iron, on which the projectile lies. It is held in place by an iron strap passing over it, through which two screws pass and press against the shot between two bands. An eye-bolt and ring is provided on the top of this strap, into which the hook of the crane-rope is passed to hoist the shot. The front end of the cart has a flange, with two hooks to hang it to the breech of the gun, where it rests and serves as a guide in loading. The axle and two bronze wheels are placed a little in front the center of gravity, and a sheet-iron prop at the rear end, and also the pole, which can be taken off, but is held in place when in use by two hooks below and two studs above.

To load the cart, the projectile is first placedon its base and the cart over it; the screws for holding the projectile are turned down; the cart is then righted and the pole put in place. For every battery, or in large batteries for every three guns, there is added a pair of windlasses like that already described and used in running the top carriage back, and a funnel with a graduated scale inside giving its contents in gallons. Its bottom orifice is closed by a cock, and is used in filling the cylinder with glycerine. An extra block and tackle is added to those carriages which have no windlasses.

The carriages having been all mounted and proved in the Shops by firing and working them, it is only required for mounting them in battery that the corresponding parts should be secured to the platform, which should be level and firm. The pintle-plate should be laid down so that the pintle shall be exactly vertical. The rear traverse-circles should be placed on the arc of a circle described with the pintle as a center, and a mean radius of 15 feet, for all sea-coast carriages from 6 to 11 inch caliber.

The 12-inch carriage is similar in its genera. construction to those above described. It admits of an elevation of the gun of 17°, and a depression of 7°. The axis of the trunnion-beds is 93.7 inches above the platform. The elevating apparatus is provided with a wheel on either side of the carriage, having radial handles with which to operate it. This wheel carries a pinion, which is connected by an intermediate wheel to that which works the circular rack, thus gaining power to raise the breech. The rails have a depth of 17.7 inches, a width on top of 6.29 inches,and an inclination of 4°. The piston-head of the hydraulic cylinder is pierced with 4 holes .76 inch in diameter; 19½ gallons is the maximum quantity of glycerine that should be put in the cylinder. The weight of the top carriage is 12,456 pounds; the chassis, 33,842 pounds.

The 14-inch carriage differs from the 12-inch only in some minor details. The axis of the trunnion-beds is 105 inches above the platform. The carriage admits of the gun being fired over a parapet of 78 inches in height, with an elevation of 19° and a depression of 6°. A dial-train is attached to the circular rack of the elevating apparatus, and shows to the gunner working the wheel the degree of elevation given to the gun. The hydraulic buffer has two cylinders 9 inches interior diameter, in place of a single one. They are placed close to the rail on each side of the chassis. Three traverse-circles and three sets of traverse-wheels are used instead of two.

A graduated arc of a circle is traced on the platform in rear of the chassis, with a pointer fastened to the end of the rail to give direction to the gun when the object fired at cannot be seen on account of darkness, smoke, or fog. Weight of the top carriage and chassis, 74,961 pounds. See *Hydraulic Buffer*, *Krupp Gun*, *Platforms*, *Sea-coast and Garrison Carriages*, and *Siege Carriages*.

KRUPP RIFLING.—In this system the grooves are quite shallow, their sides being radial and forming sharp angles with the bore. The rifling has a uniform twist of one turn in 45 calibers generally. The grooves are wider at the bottom of the bore than at the muzzle, so that the compression of the lead-coated projectile is gradual, and less force is expended in changing the shape of the projectile. This change of shape is effected by making the whole groove of the same size as at the muzzle, and then cutting away gradually on the loading-edge of the groove. Of course, as the twist is uniform, the driving-side of the groove cannot vary. The outer surface of the lead coating of the projectile is in raised rings with grooves between, to allow space for its being drawn down in passing through the bore. The advantages of this, or the *compressing* system, are that the projectile is centered during its passage through the bore, which prevents balloting; the angles of departure and the initial velocities are therefore more uniform, and the stability of the axis of rotation on leaving the bore is better assured; from which result great regularity and precision of fire. There is little or no difficulty as to erosion of the metal caused by the gas forcing its way between the projectile and the bore. The lead jacket of the forced projectile does not prevent the employment of heavy charges. Forced projectiles do not wedge in the bore. The regularity of the movement of these projectiles does not wear or injure the bore. The soft metal coating prevents damage to the lands. The bursting of a projectile covered with soft metal has comparatively no baneful effect on the gun.

The objections to the system are the severe strains on the gun by suddenly stopping windage, by fouling, and by forcing the projectile into a bore of smaller diameter. The compressed projectile must be fired from a *breech-loading* gun, and the increasing-twist is impracticable from the great length of the soft-metal bearing. The soft coating of the projectile is liable to injury in handling and in store; also to be stripped on firing.

KRUPP STEEL WORKS.—The widespread reputation of the steel produced in the great works of Herr Krupp, at Essen, in Prussia, has induced us to give it a brief notice. His manufactory, always a large one, has been gradually increasing in size during the last half century, untill it now covers nearly 1000 acres, and gives employment to some 14,000 persons. For large metallurgical works, Essen is favorably situated, being in the center of a coal-bearing area, where coal of the purest kind can be comparatively cheaply procured. There is also at hand the manganiferous iron ores of Prussia, which have been found so excellently adapted for the manufacture of steel; but it is believed that the admirable organization of every part of his manufactory has conduced, as much as anything, to the great success of Krupp. With laborers and mechanics who have passed the regulation-time in the Prussian army, overseers trained in the German technical schools, and a small staff of experienced analytical chemists, he has obviously a great advantage in conducting operations where order, system, and skill are of paramount importance. But even with these benefits, Krupp's productions would not have gained their celebrity, were it not for the scrupulous care with which he performs every manipulation. In the article IRON we have described the manufacture of steel by the *cementation* and *Bessemer* processes, but there are several other methods of making it, and one of these is by the decarburization of cast-iron in the puddling furnace. This is the process by which Krupp makes his steel, in the first instance; and the material he most largely employs is *spiegeleisen*, or specular cast-iron, a highly crystalline variety, usually containing about 4 per cent of manganese. This iron is admirably suited for conversion into steel. The puddling process for steel is similar to that employed for iron, except that the former is conducted at a lower temperature, and requires nicer management; but in the case of steel, the cast-iron to be operated upon is never previously refined. Cast-iron to the extent of about 4 cwts. is melted in the puddling furnace, mixed with a quantity of slag or cinder (chiefly silicate of iron), and stirred with a rabble. During this operation, the carbon in the cast-iron (usually about 5 per cent) is gradually oxidized by the oxygen present in the cinder; carbonic oxide is produced, and as it escapes, what is technically termed "boiling" takes place. When the ebullition becomes active, the temperature is raised until the appearance of incipient solidification occurs; the heat is then lowered, and the ordinary process of balling proceeded with. Steel thus produced usually contains from 0.5 to 1 per cent of carbon; but if the temperature is not skillfully regulated, the carbon becomes wholly burned away, and malleable iron instead of steel is produced.

Puddled steel, although useful for most purposes in the arts (except cutlery), nevertheless wants homogeneity, on account of a certain intermixture of cinder, which is difficult to get rid of without fusion—a defect which is apt to prevent it from welding perfectly. In Krupp's Works the puddled steel is remelted into crucibles, in order to convert it into cast-steel; and it is the wonderful uniformity of quality with which he manufactures this in very large masses, that constitutes the superiority of, and gives so great an interest to, his productions. The crucibles employed are made with extreme care, mainly from fire-clay, to which a little plumbago is added; their capacity varies from 50 to 100 lbs., and it is reported that as many as 100,000 are kept drying at the same time. After being once used, the crucibles are broken up, and mixed with other material, to make new ones. In the casting-house, where the large ingots are run, the furnaces, which contain about 1,200 crucibles, are arranged along the sides of the building; and in the central portion the steel molds, varying in capacity from 100 lbs. to 50 tons, are disposed in line between two pairs of rails, upon which runs a movable crane. It is in the casting of such an enormous ingot as 50 tons of steel (the largest yet produced) from crucibles of small capacity that the perfect organization of Krupp's Establishment becomes more strikingly apparent. At a given signal, one gang of workmen remove the crucibles from the furnaces, while another seize them with tongs for the purpose, and pour their contents into narrow canals of wrought-iron, lined with fire-clay, which converge into the opening by which the mold is filled. This is the critical stage of the operation, the difficulty being to deposit in the mold a continuous stream of melted steel of about the same degree of heat, so as to cool uniformly, and to solidify into a perfectly homogeneous mass. Of such uniform soundness are some of Krupp's large steel ingots, that one—shown in the London Exhibition of 1862, 9 feet high, 44 inches in diameter, and weighing 21 tons—when broken across did not show the slightest flaw, even when examined with a lens. In order to manipulate these extraordinary masses of steel, there is a steel hammer, weighing 50 tons—the mechanical marvel of the Works at Essen—which has a cylinder nearly six feet in diameter. It has a 50-ton crane at each of its four corners, and behind each of these again there are four heating furnaces. A movable bench on low massive wheels serves to remove a large ingot from any of the furnaces, which is then, by means of the powerful cranes, and a system of pulleys and crabs, placed on the anvil, and worked into any desired shape. The anvil-face weighs 185 tons.

The quantity of steel manufactured by Herr Krupp annually amounts to about 125,000 tons, representing a value of about £3,000,000. It consists chiefly of rails, tires, crank-axles, shafts, mining pump-rods, and guns—the proportion of ordnance being about two-fifths of the whole. Guns have been made at Essen for the Prussians, Austrians, Belgians, Dutch, Italians, Turks, Japanese, and also for the English, although not directly ordered by the Government. In 1874 the works included 1,100 smelting and other furnaces, 275 coke-ovens, 264 forges, 300 steam boilers, 71 steam-hammers, 286 steam-engines of 10,000-horse power, 1,056 machine tools, 30 miles of railway, 80 telegraph stations, a chemical laboratory, and photographic, lithographic, printing, and bookbinding establishments. There is a fire-brigade of 70 men, besides 166 watchmen. In 1876 the consumption of coal and coke together amounted to 612,000 tons; that of gas, 7,300,000 cubic meters in 20,342 burners. Krupp has built good houses, hospitals, etc., for his men. Besides the works at Essen, the firm possesses several mines and smelting works. In the Paris Exhibition of 1867, Krupp showed a huge gun intended for a coast battery to defend the attacks of plated ships. It was made entirely of cast-steel, weighed 50 tons, and could propel a shot weighing 1,080 lbs. It took 16 months, working day and night without interruption, to manufacture. The price of the gun alone was £15,750, and of its carriage and turn-table, which weighed respectively 15 and 25 tons, £6,000 more. In the Vienna Exhibition of 1873, Krupp showed, in a pavilion by themselves, a number of most interesting objects in steel. Among them were a huge gun like that shown at Paris, about 4 feet 6 inches in its greatest diameter; an octagonal ingot, weighing fully 50 tons; and a marine-engine shaft, 15 inches in diameter. He also exhibited at Philadelphia in 1876. See *Krupp gun*.

KSHATRIYA.—The second or military caste in the Brahmanical social system.

KU-KLUX—KU-KLUX KLAN.—The title of a Secret Association which existed in the Southern States from 1866 to 1872, and which terrorized that section of the country during the period in question. It was first made known as an active agency in Tennessee, in 1867, when the Governor of that State, William G. Brownlow, called upon the U. S. military authorities, to suppress violence and public disturbances in the State, which were traced to this organization. The history of the Ku-klux shows that at the close of the war various Societies of a political character were formed in the States of Alabama, Arkansas, Georgia, Kentucky, Mississippi, North and South Carolina, Tennessee, and Texas, under the names of the Knights of the White Camellia, White Brotherhood, Constitutional Union Guards, Pale Faces, Invisible Empires, Invisible Circle, etc., all of which were eventually lost in the broader scope and more powerful and permanent influence of the Ku-klux Klan. From the evidence afforded it would appear that the origin of these Secret Societies, and more particularly of the one we are specially considering, is to be found in the dislocation of poltical and social interests in the Southern States consequent to the aggressive influence of a long and devastating condition of warfare. In explanation of their foundations, ex-Confederates claim that they were preceded by organization of loyal leagues, which, as they allege, were formed among the Negroes in the South through the efforts of "Carpet-baggers," so-called radical leaders intriguing in the interest of the perpetuation of the power of the Republican Party in the Southern States. It is also claimed in behalf of the Southern people that, through the action of the 14th and 15th Amendments to the Constitution of the United States, the Southern white population was greatly endangered both in its homes and its social relations, the emancipated Blacks being generally considered in the light of a race angered by long and bitter servitude, now armed and equipped by law and public sentiment, and only waiting opportunity for an uprising and to grasp the balance of power among the high-spirited people to whom they had been slaves for more than two centuries. This is the Southern explanation of the rise of the Ku-klux. Whatever may be the measure of truth contained in it, this in no wise militates against the justness of public condemnation of its acts. By Joint Resolution, dated April 20, 1871, the two Houses of Congress ordered an investigation into the condition of affairs in the States recently in a condition of insurrection. For three years the press had been filled with detailed statements describing acts of atrocity attributed to the secret and terrible Ku-klux Klan, which rivaled the worst instances recorded against the Spanish domination in the Netherlands, and the bloody scenes of the French Revolution. In every Southern State except Virginia, West Virginia, Delaware, Maryland, and Florida, assassination of Negroes and white Republicans were of daily occurrence. The gift of suffrage to the colored man had been nullified in its outcome as a political influence through the system of terrorizing which utterly precluded the free suffrage of the emancipated Blacks. Besides instances of special massacres covering large numbers, and of which there occurred many in South Carolina, Louisiana, Mississippi, Texas and Tennessee, the daily and nightly assassinations, whippings, burnings, and other outrages were innumerable, and were never recorded. In reporting the state of society in Texas, the evidence given is to the effect that the Negroes were murdered with such frequency that there was no possibility of keeping an accurate record of the details. On the basis of reports of this nature, and stimulated, doubtless by the intense public feeling in the North, created by the gradually spreading conviction of the lamentable deficiency in the power of the law as applied in the South, Congress, through its Committee, proceeded to the investigation ordered by the Joint Resolution to which we have already referred. The result of this investigation appears in the 12 octavo volumes reporting the testimony taken and published among the official documents (Senate) of the year 1872. An immense mass of evidence displays the nature and acts of the Ku-klux, and fully justifies the title "Conspiracy," which Congress bestowed upon that organization. While the Ku-klux may have originated for a minor purpose, it is difficult to believe that this tremendous association of men sworn to fidelity; having its ramifications in every Southern State, and the power of life and death in most of them; with a ritual, oath, grips, pass-words, and all the other secret and systematic machinery necessary to the carrying out of the most hidden and dangerous purposes—it is difficult to believe that the real motive and intention of the Order were not the subversion of the Government of the United States, and the rehabilitation of the leaders of the Rebellion. To this end, the negation of the suffrage in the South, and the efforts to defeat reconstruction, may reasonably be supposed to have tended. And whatever diverse opinions may be held regarding the good sense, judgment, and patriotism displayed in the Reconstruction Acts and the methods adopted to carry them into effect, it is impossible to view without the severest censure the nature of the opposition to them, as conducted by a bloody and revengeful association of exceedingly cruel and implacable men, intensely crazed by the facility with which murder and incendiarism could be made to do duty for what its members chose to consider retributive justice. Following is the oath of the Ku-klux Klan, as it was offered in evidence before the Investigating Committee of Congress: "I (name), before the great immaculate Judge of heaven and earth, and upon the holy evangelists of Almighty God, do, of my own free will and accord, subscribe to the following sacred binding obligation. I. I am on the side of justice and humanity and constitutional liberty, as bequeathed to us by our forefathers. II. I reject and oppose the principles of the radical party. III. I pledge aid to a brother of the Ku-klux Klan in sickness, distress, or pecuniary embarrassment. Females, friends, widows, and their households shall be the special object of my care and protection. IV. Should I ever divulge, or cause to be divulged, any of the secrets of this Order, or any of the foregoing obligations, I must meet with the fearful punishment of death and traitor's doom, which is death, death, death, at the hands of the brethren." This sufficiently theatrical obligation becomes impressive when one reflects that its various sections were carried out with absolute rigor, and that disobedience of the orders of the Chief of a klan was actually visited with instant death. Thus were the customs of the *Carbonari* paralleled among so prosaic and conventional a people as the Americans so late as 1871. The members of the Order were obliged to deny their membership, even when answering as witnesses in a Court of law, and were obligated to clear each other by their testimony in such cases or when acting as jurors. The Ku-klux gradually died out as an active organization after the investigation of 1871; and although certain of their methods continued to obtain during the progress of elections in the South, the return to sounder sense and better feeling on the part of the people of that section, and the improving condition of the relations between the North and the South, gradually died away with the passions in which the organization originated. It is reported that there were at one time 550,000 members of the Ku-klux Klan in the South, of which number 40,000 are said to have been in Tennessee.

KUL.—The Turkish word for slave to the Prince. The Grand Vizier, the Bachas, the Beigler Beys, and all persons who receive pay or subsistence from situations dependent upon the Crown, are so called. This title is in high estimation among the Turkish military, as it authorizes all who are invested with it to insult, strike, and otherwise illuse the common people, without being responsible for the most flagrant breach of humanity.

KULLUM. (*Nauclea parviflora*).—A wood used in the Bombay Presidency for fuses. It is a very light, soft, close, and even-grained wood, of a light brown color, not very durable, and will rot when exposed to wet.

KUNDA DE RAJAH.—An Indian sword of the 16th century, $3\frac{1}{4}$ feet long, and entirely made of iron. The blade is damascened, and the handle, guard and hilt are beautifully engraved.

KURROL.—The Indian term for the advanced-guard of a main army.

KURTCHI.—The Persian name of a Militia. It consists of one body of Cavalry, which is composed of the first Nobility of the Kingdom, and of the lineal decendants of the Turkish Conquerors, who placed Ismael Sophi on the throne. They wear a red turban of twelve folds, which is made of particular stuff. This turban was originally given them by Ismael, in consideration of their attachment to the religion and family of Ali. In consequence of their wearing this turban, the Persians are always called by the Turks *Kitilbaschi* or Red-heads. The Kurtchi compose a body of nearly 18,000 men. The Commanding Officer of the Kurteki is known as *Kurtchi-baschi*, who formerly had the identical authority that was originally possessed by the Constable of France.

KYANIZING. A process for preserving ordnance timber, etc., from dry rot or decay. This most efficacious method, which consists of injecting into the pores of the wood a solution of corrosive sublimate, was invented by John H. Kyan, who was born in Dublin, Nov. 27, 1774, and died in 1850.

L

LABARUM.—The famous standard of the Roman Emperor Constantine, designed to commemorate the miraculous vision of the cross in the sky, which is said to have appeared to him on his way to attack Maxentius, and to have been the moving cause of his conversion to Christianity. It was a long pipe or lance, with a short transverse bar of wood attached near its extremity, so as to form something like a cross. On the point of the lance was a golden crown sparkling with gems, and in its center the mysterious monogram of the cross and the initial letters of the name of Christ, with the occasional addition of the Greek letters *Alpha* and *Omega*. From the cross-beam depended a purple banner, decorated with precious stones, and fully surrounded by a rich border of gold embroidery. The cross was substituted for the eagle, formerly depicted on the Roman standards, and there were sometimes other emblems of the Saviour. Between the crown and the cross were heads of the Emperor and his family, and sometimes a figure of Christ woven in gold. See *Standard*.

LABEL—LAMBEL.—In Heraldry, the mark of cadency which distinguishes the eldest son in his father's lifetime, familiar to us from its entering into the composition of the arms of the Prince of Wales and other members of the royal family. It consists of a horizontal stripe or fillet, with three points depending from it. When the mark of cadency itself is designated a *file*, its points are called *labels*. It is said that the eldest son's eldest son should wear a label of five points in his grandfather's lifetime, and, similarly, the great-grandson a label of seven points, two points being added for each generation. The label extended originally quite across the shield, and sometimes occupied the upper, though now it is always placed in the lower part of the chief; the points, at first rectangular, assumed in later times the form called pattée, dove-tailed, or wedge-shaped, and more recently, the label ceased to be connected with the edges of the shield. Edward I., in his father's lifetime, bore the arms of England within a label not of three, but of five points azure, joined to the head of the shield, and interlaced with the tail of the uppermost lion. Edward II., when Prince of Wales, used indifferently the label of three or five points, as also did Edward III.; but from the time of the Black Prince downwards, the eldest son of the King of England has invariably differenced his arms with a label of three points argent, and the practice has been for the younger sons also to bear labels, which are sometimes of other colors and more points, and differenced by being charged with fleurs-de-lis, castles, torteaux, hearts, crosses, etc., as directed by the Sovereign by sign-manual registered in the College of Arms. The practice of differencing by the label which is thus *in viridi observantia* in our own and other royal families, is less used by subjects. Like other marks of cadency, labels are sometimes borne as permanent distinctions by a particular branch of a family. See *Heraldry*.

LABORATORY.—This term is generally applied to establishments for conducting chemical or physical investigations, or for chemical manufacture. Chemical laboratories may be for purposes of instruction, as are those which are attached to colleges or other high schools. These institutions also sometimes have special laboratories for research. All large private manufacturing establishments where chemical processes are employed, to a considerable extent have laboratories attached to them in which investigations are carried on; many of them in the nature of preparatory trials of processes, to facilitate the process of manufacture. A government manufactory is sometimes called a laboratory, and so are many smaller private establishments, as metallurgical laboratories, telegraph laboratories, etc. The following fixtures and furniture should be provided for a government laboratory.

1. *Cartridge-house.*—A table for making cartridges for small arms, 12 feet long and 2½ feet wide, for 12 men or boys to work at, and the length in that proportion for any greater number; tables for cutting paper and flannel, and for rolling cases on; choker for rocket-cases; press for rocket and port-fire cases; benches for cartridge-tables; stools. Closets should be partitioned off from these rooms and furnished with cases, drawers, racks, and shelves for materials and tools. 2. *Filling-house.*—A shelf, 2 feet wide, for weighing on; other shelves with closets under them; tables with raised borders for filling, folding, etc.; budge-barrels, or powder-barrels, with copper hoops and covers; stools for seats; footstools; a step-ladder; stands and gutters for emptying powder-barrels. 3. *Packing-house.*—Tables, benches and stools. 4. *Store-house.*—Shelf for weighing on the shelves, drawers, and closets; tables, scales, stools, seats, step-ladder. 5. *Driving-house.*—Blocks set in the ground or pavement; benches and stools. In favorable weather, a porch attached to the building, or a tent, may be used for a driving-room. 6. *Mixing-house.*—Tables with raised edges; sieves, etc. 7. *Furnace-house.*—Furnaces; work-benches; platform-balance or large scales; a tinner's bench and tools, with a vise, an anvil, and a chest for tools, a smith's forge, shovel and poker, stools, etc. 8. *Carpenter-shop.*—Turning-lathe and tools; carpenter's benches and tools. 9. *Magazine.*—Shelves and frames for boxes and barrels.

Two kinds of furnaces are used in the laboratory: In the first, the flame circulates around both the bottom and sides of the kettle; in the second, it comes in contact only with the bottom; the latter are used for compositions of which gunpowder forms a part. Furnaces are built of bricks. The kettle is of cast-iron, about 2 feet in diameter at the top, having a rounded bottom and a flange about 4 inches wide around the top, or else strong handles to set it by. The bottom is .75 inch thick, and the sides .5 inch. By setting it in an iron plate pierced with holes, encircling the bottom, a furnace of the first kind may be converted into one of the second kind by stopping the holes.

Furnace for reducing the oxide of lead or dross.—This furnace is built in the open air, on a stone or brick foundation. It is composed of a cylinder of sheet-iron, 16 inches by 30 inches, lined with refractory clay from 2 to 3 inches thick. The interior has a form of an inverted frustum of a cone, terminating below in a basin, the bottom of which is inclined toward a tap-hole. The fire is made in the furnace, and the draught supplied by a bellows, the nozzle of which enters at the top of the reservoir. The dross and the charcoal intended for its reduction, are thrown on the fire from the top of the furnace. The metal, as it is reduced, flows into the basin and escapes through the tap-hole into an iron vessel and is cast into bars or pigs as desired. In the field, furnaces may be built with sods, or sunk in the earth, if bricks cannot be readily procured.

Furnace built with sods.—Let the kettle rest on a trivet, the feet of which may stand on any piece of flat iron, such as the bottom of a shot-canister, or stand for grape, the bottom of the kettle about 1 foot from the ground; build round it with sods. The door of the furnace is 10 inches square; the flue of the chimney, opposite to the door, 6 inches square, and commencing about 6 inches from the ground; the first part of the flue inclined at an angle of about 15°, the rest vertical, and placed, if circumstances permit, against a wall; the top of the door and of the flue may be supported by small bars of iron.

Furnace sunk in the earth.—The edge of the kettle should be about 1 inch above ground, and the bottom 12 to 15 inches above the hearth of the furnace; the earth is dug down vertically 1 foot from the kettle for the front of the furnace, and the door is cut 10 inches square. The earth is removed and sloped out, so as to give access to the door; the flue is bored out on the opposite side with a crowbar; it commences 6 inches above the hearth, and comes out of the ground 18 inches from the furnace, whence it is carried horizontally about 13 feet.

In furnaces of the second kind mentioned above, the trivet may be omitted, and the kettle may rest on the sod or earth for about 1 inch all round, and the earth rammed in against the sides of the kettle.

It is important to observe the following precautions against accidents:

Avoid as much as possible, the use of iron in the construction of the buildings, fixtures, tables, benches, boxes, etc., of the laboratory; sink the heads of iron nails, if used, and fill over them with putty, or paste several thicknesses of paper over them. Before the men go to work cover the floor with carpets or paulins, which are taken up carefully, after the men leave, and carried at least 50 yards from the building, and there shaken thoroughly and swept. During the work have the carpets frequently swept. Place the stores in cloth bags in the windows exposed to the sun. Prevent persons from entering with sabers, swords, or canes, etc., or with matches about their persons. Direct all who work where there is powder to wear moccasins or socks, and to take them off when they leave. Direct the men not to drag their feet in walking. Make the doors and windows to open and close easily, without friction; keep them open whenever the weather permits. Never keep in the laboratory more powder than is necessary, and have the ammunition and other work taken to the magazine as fast as it is finished. Let powder-barrels be carried in hand-barrows made with leather or with slings of rope or canvas, and the ammunition in boxes. Let everything that is to be moved be lifted, and not dragged or rolled on the floor. Never drive rockets, port-fires, etc., or strap shot or shells in a room where there is any powder or composition except that used at the time. Loading and unloading shells, driving rockets, pulverizing the materials, the preparation of compositions requiring the use of fire, and in which the components of gunpowder enter, ought to be done, in all cases when possible, in the open air or under a tent far from the laboratory and magazine. Never enter the laboratory at night, unless it is indispensable, and then use a close lantern, with a wax or oil light carefully trimmed. Allow no smoking of tobacco near the laboratory. In meling lead, be sure that it contains no moisture; put the pigs in carefully, and do not use more than will fill the pot two-thirds full. Use the same precaution in melting all fatty substances. See *Fireworks*, *Laboratory Materials*, and *Royal Laboratory*.

LABORATORY MATERIALS. Laboratory materials may be classified as follows: 1st. Those for producing light, heat, and explosion. 2d. Those for coloring flames and producing brilliant sparks. 3d. Those used in preparing compositions. 4th. Those used in making tools, cases, cartridge-bags, and for miscellaneous purposes.

MATERIALS FOR LIGHT, HEAT, AND EXPLOSION.—*Potassium nitrate* (*niter*), KNO_3.—For use in the laboratory, niter should be freed from all foreign substances and be reduced to a fine powder or else to very minute crystals. It is best pulverized by hand in the rolling-barrels at the powder-mills; but it may be pulverized by hand in the laboratory as follows: Put into a *rolling-barrel* 50 pounds of dry, refined niter and 100 pounds of bronze balls; turn the barrel for two hours and a half at thirty revolutions a minute, striking it cautiously at the same time with a mallet to prevent the niter from adhering to the sides. Separate the balls by means of a brass-wire screen, and the foreign substances with a hair sieve. Niter may also be pulverized by pounding it in a brass mortar, or by solution as follows: Put 14 pounds of refined niter with 5 pints of clear water, in a broad and shallow copper pan, over a slow fire, and as the niter dissolves skim off the impurities; stir the solution with a wooden spatula until the water is all evaporated, when the niter will be very white and fine. Should it boil too much, the pan must be lifted from the fire and set upon wet sand or earth, and the niter should be stirred until it dries, to prevent it from adhering to the pan.

Potassium chlorate, $KClO_3$, is a white salt; crystallized in white scales; anhydrous; not altered by exposure to the air; soluble in water, more in warm than in cold; insoluble in alcohol; density, 1.989; decrepitates and fuses at about 500°; at about 720° it is decomposed into oxygen and potassium chloride. This salt is one of the most energetic of oxidizing bodies, because it parts with its oxygen so readily, of which it contains a very great quantity (.3915 of its weight). Thrown on burning coals, it melts quickly. It explodes by simple contact with sulphuric acid; mixed with a combustible body, the mixture may be exploded by friction or by a blow. It should be purchased crystallized, and should not contain more than one-thousandth of its weight of chloride of sodium or potassium. Its purity is tested by means of the nitrate of silver dissolved in distilled water, 73½ grains in one-quarter of a pint. Dissolve 77 grains of the chlorate in 300 grains of warm water, and let the solution get cold; the chlorate will be precipitated in crystals Add to the liquid about two drops of the solution of the nitrate of silver. After filtering, the liquid ought not to give a precipitate by the addition of more nitrate of silver.

Mercury fulminate, $CNC(NO_2)Hg$, is a gray salt, crystallized in fine silky needles; soluble in water, more so in warm than in cold water. It is an extremely dangerous substance to operate upon in a dry state, owing to the readiness and violence with which it explodes. It detonates strongly when struck by a hard body; but sometimes trifling friction may serve to produce this effect, even when employed in a moist state. Heated to 300° it explodes, evolving an exceedingly bright flame. It is decomposed, with explosion, by the electric spark, and contact with strong nitric and sulphuric acids. The products of detonation are carbonic acid, nitrogen, and vapor of mercury. It should always be manipulated moistened with at least 30 per cent. of water.

To prepare fulminate of mercury.—Dissolve in a glass retort capable of holding about a half-gallon, 10 ounces of pure mercury in five pounds nitric acid (aqua-fortis), of the specific gravity of 1.40. The solution is made by placing the retort in a water or sand bath of about 120°, or exposed to the sun's rays on a warm day. The vapors which come over are very deleterious, and should not be inhaled. It requires about eight hours to thoroughly dissolve the mercury. When the solution is complete, pour the liquor into a wide-mouthed glass vessel capable of holding 8 to 10 gallons, into which 5.675 pounds of alcohol (ethyl), about 6½ pints, of the specific gravity of .85 have been previously poured. Care must be taken to *pour the nitrate of mercury on the alcohol*, as the reverse mode of mixing the compound is very dangerous. Great heat is evolved during the effervescence which ensues from the mixture, and the glass vessels used should be well annealed, and of a form to bear a high heat without breaking. Carboys of thin flint-glass, without mouth-rings or any abrupt change in thickness, are best. The operation should be performed at a safe distance from the fire, as the vapors of ether disengaged are highly inflammable. When reddish fumes begin to appear, they must be reduced by adding alcohol in small quantities. The proportion of alcohol used in the whole operation varies according to the strength of the acid and alcohol, and also with the state of the weather. The proper quantity is that which is just sufficient to keep down the reddish fumes, and is determined by trial with the materials used. When the effervescence has ceased, the fulminate of mercury is found at the bottom of the vessel as a brownish precipitate. A small quantity of water is poured in, and the contents transferred to the washing-tub, where it is repeatedly washed in soft water, until the water no longer reddens litmus-paper. The fulminate is in the form of very small crystals, of a light gray color and brilliant surface. If the operation be well and carefully performed, no metallic mercury will be reproduced. The weight of the fulminate when well dried will be about 14 per cent. greater than that of the mercury used. If the proper proportions be not used (or if the materials be not of good quality), the product will be, instead of fulminate, an impalpable yellow powder which is incombustible. When this is observed, the result may generally be corrected by varying the proportion of alcohol in the mixture. The fulminate of mercury is kept under water, in stone jars, which should be preserved from frost. *Roll brimstone* is used for melting, and flowers of sulphur may be used instead of roll sulphur pulverized. The purity of the flowers is more to be depended upon than that of the roll sulphur. When mixed with potassium chlorate, however, it should be washed to remove sulphuric acid. Sulphur facilitates the ignition and combustion of compositions to which it is added.

Gunpowder—For compositions, gunpowder is *mealed*, either by rolling it for two hours with once and a half of its weight of balls, or by beating it an equal length of time in a leather bag, or by grinding it with a muller on a mealing-table. Mealed powder, and pulverized saltpeter, charcoal, and sulphur are generally obtained from the powder-mills.

Antimony (regulus of antimony) is a grayish-white metal, very brilliant, with a highly lamellated structure. Specific gravity, 6.7; melting point, 809°. It is easily reduced to powder, and by its combustion with sulphur produces a strong light and heat, with a blue or white flame. Antimony is never found pure in the shops; that which is sold under the name of regulus of antimony always contains a little sulphuret of antimony, arsenic, and sometimes the sulphuret of iron.

Lampblack is the result of the incomplete combustion of resinous substances. It is composed of 80 parts of carbon and 20 of impurities. It is employed to quicken the combustion of certain substances; but before it is used it should be washed with a hot alkaline solution, to remove all traces of empyreumatic oil.

Coloring Materials. A flame is colored by introducing into the composition which produces it a substance, the particles of which, being interspersed through the flame and rendered incandescent, give it the required color. Coloring substances do not generally take part in the combustion, and their presence more or less retards it. It is for this reason that potassium chlorate, a more powerful oxidizing agent than niter, is used in lieu of it in compositions for colored fires. There are a great variety of substances which give color to flames, the principal of which are strontium nitrate and sulphate for red, barium nitrate for green, the bicarbonate of soda for yellow, copper sulphate for purple, copper carbonate and acetate for blue. Lampblack is employed to give a train of rose-colored fire in the air, and powdered flint glass for white flames. Sparks are produced by introducing into the composition filings or thin chips of wrought or cast iron, zinc, steel, copper, or fragments of charcoal.

Iron. Filings and very thin chips give most brilliant sparks and stars, the effects of which depend almost entirely on the size of the particles used. The filings must be made when wanted, or be very carefully preserved from rust.

Cast-iron—Pulverized, it gives very large and white sparks, in fireworks (*Chinese fire*). Select the white cast-iron, or take the pieces of utensils with thin sides. To pulverize it more easily, heat it to a red heat and throw it into cold water.

Steel.—In fireworks, filings and small pieces give the most brilliant sparks.

Zinc is a bluish-white metal, usually brittle, and its fracture shows a crystalline structure. Specific gravity, 6.9; melts at 680°; is volatilized at a red heat, and takes fire in the air, burning with a light flame. At 400° it is easily reduced to a powder in a mortar. Granulated zinc is used to produce a bluish flame. An alloy of zinc and antimony pulverized gives beautiful blue drops. The oxide of zinc (*flowers of zinc*) produces the appearance called gold rain. It ought to be purchased in scales, not in a powder, as in this latter case it may be mixed with foreign substances.

Copper filings are used to give reddish sparks and a greenish blue flame.

Preparing Compositions. Turpentine, spirits of turpentine, Venice turpentine, tar, pitch, and rosin, are chiefly employed in the preparation of compositions for producing light. Alcohol, whisky, brandy, or vinegar is used in mixing compositions into which niter enters, as it does not dissolve niter. It should be strong. To prevent it being drunk, mix a little asafetida with it. Beeswax and mutton tallow are employed in mixing compositions intended to produce heat and light.

Gum arabic should be transparent, yellowish-white, brittle, insipid, inodorous, soluble in water and vinegar, insoluble in alcohol. It is used in solution to give body and tenacity to compositions, or to make them burn more slowly. It should be prepared as required, for when in solution it undergoes a decomposition.

Miscellaneous Materials—*Copper* is a red, brilliant metal, possessing great tenacity, ductility, and malleability. Specific gravity, 8.9; fusible at about 1980°. Copper, being but slightly acted on by saltpeter, is employed for powder measures, utensils for refining saltpeter, etc. Copper vessels should not be exposed to a great heat, or used for heating compositions containing sulphur, as the copper would be rapidly oxidized.

Bronze is used in the laboratory for utensils and implements which receive blows or act by percussion, and replaces steel and iron wherever there is danger of an explosion from a blow or from friction.

Brass is an alloy of about two parts of copper and one of zinc. Brass wire is used for ligatures, for screens and sieves.

Sheet-iron—Select the softest and most pliable. When it is substituted for tin, in strapping projectiles, it should be first annealed by heating it to a dull red heat, and letting it cool very gradually under warm ashes, not exposed to the air.

Lead is a bluish-white metal, bright, but tarnishes quickly in the air. Specific gravity, when pure, 11.48; melts at 600°, and volatilizes at a red heat. The purity of lead is judged of by its specific gravity. To determine this, after having weighed the pig, suspend it with a wire in a vessel of water, so that it shall be completely immersed, without touching the sides, and weigh it again. The weight in the air, divided by the difference between the weight in air and water, will give the specific gravity, which ought to be 11.35 for lead of commerce. Lead melted in contact with air is soon covered by a coat of gray oxide, which rapidly increases in thickness. The formation of this oxide, or dross, is prevented by covering the lead with powdered charcoal or rosin.

To reduce the oxide of lead—Put in a kettle about 50 pounds of lead, with $\frac{1}{10}$ of its weight of powdered charcoal or grease; cover the kettle, and raise to a red heat; stir the mass, and add gradually more coal, as it assumes a yellow color, using in all $\frac{1}{8}$ of the weight of oxide; dip out the lead with an iron ladle, and pour it into iron molds or pans. After having obtained in this way two-thirds of the weight of oxide, in lead, throw the dross into a tub of water, and wash it, to separate the ashes and coal; dry the remaining oxide and grains of lead, and put them in a ladle with $\frac{1}{20}$ of their weight of rosin; raise to a red heat, set fire to the rosin, shake the ladle and pour off the lead. A further addition of rosin will produce more lead; $\frac{1}{14}$ of the weight of dross is generally used. Tallow may be used in place of rosin. When the quantity of dross is considerable, it may be reduced, in a similar manner, in a small cupola-furnace.

Plumbers' solder is an alloy of lead and tin, in the proportion of two parts of the former to one of the latter.

Paper.—Paper for cartridge-box wrappers should be homogeneous, and without any trace of stalks; well sized, even, pliable, with a good body without being too thick, free from folds or rents. The sheet when moistened ought to present a uniform hue, without spots or marblings. Taken out of the water and suspended for a moment by the extremities of the short sides, it ought not to tear from its own weight. The sheet crumpled in the hand or pinched with the nails, ought not to tear in the folds, and when torn the rent should be fibrous. A strip of paper 4 inches wide ought not to break under a weight of 40 pounds, in the direction of its least strength. In testing the strength of paper, the two ends are held by two vises of hard wood. Each vise is composed of two rectangular jaws, which can be brought against each other and held firmly by means of screws, or by tenons on one jaw passing through the other and keyed firmly to it. A strip of paper 4 inches wide is cut and inserted in the vises, so that the length between them shall be exactly 12 inches. The jaws are closed tightly, and one vise is suspended from a fixed point by means of a cord or hook, and to the other is made fast the pan of a balance. It is loaded gradually, with care, until the paper gives way. The strips should not be taken from the edges of the sheets only, but from all parts, and from the length and breath successively, for in these two directions the strength is very different. Five sheets are generally taken from each ream, in which only one sheet can have less strength than that allowed. If this condition be not fulfilled, the ream is rejected.

Size and weight of paper.

	Inches.	Weight, pounds.	Proof weight, pounds.
No. 1. For musket-cartridges…	13 ×16½	……	40
No. 2. For musket-cartridge wrapper…	18 ×20	36	101
No. 3. Wrapper for Cartridge-box…	16 ×14	21	30
	18 ×16	27	
	20 ×20	37½	
	24 ×20	45	
No. 4. Rockets and Portfires…	19 ×28	65	180
No. 5. Fixed ammuntion	23½×24	60	225
No. 6. Cannon-cartridges	19 ×23	70	315
No. 7. Fireworks…	13 ×16½	20	85

The other papers are tested in the same way, and should possess the same general characteristics.

Tow should be entirely of hemp or flax, clean, dry, sound, free from stalks and foreign substances.

Merino or *serge*, for cartridge-bags, should be made entirely of wool; it should be strong, closely woven, twilled, and not frayed; the width should be even in the same piece; that $\frac{3}{4}$ yard wide is convenient and the most common. The colors are to be preferred in the following order; green, gray, yellow, blue, red, white; reject black, which is almost always burnt and weak.

Canvas should be the strongest and closest woven; it is used for the sacks for fire-balls.

Twine should be strong, smooth, and well twisted .03 inch thick for sewing fire-balls, etc.; from .06 inch to .08 inch for fixing ammunition, etc.

Rope should be even and well twisted, pliant without being soft, made of hemp of good quality, water-rotted, and entirely freed from stalk. Its size should be uniform throughout its whole length. The rope most commonly used in the laboratory is white-hemp rope, from 1 inch to 1.5 inch in girth.

Thread—Saddler's thread, of flax, three strands; used with paper boxes for revolver cartridges.

Glue should be hard, dry, transparent, of a brownish red color, and free from smell.

To Prepare Pastes and Glue.—*Flour paste*—Sift the flour and mix it with 8½ times its weight of water; heat it gently, stir it, and let it boil for three-quarters of an hour; when it becomes ropy pour it into bowls and pass it through a sieve before it is quite cold. The flour yields 7 times its weight of paste. Time required to make it, one hour and a half. It is best made of rye flour.

Starch paste.—Mix wheat starch with twice its weight of water, pour it gradually into 6½ times its weight of boiling water, and let it boil for ten minutes, stirring it all the time; then proceed as before. Starch yields 8 times its weight of paste. Time required, one hour.

Paste for pasteboard.—Mix the flour or starch with 12 times its weight of water; this yields 9 times the weight of flour and 11 times the weight of starch.

Paste mixed with glue.—The addition of $\frac{1}{16}$ of glue makes the paste fit for pasting sheets of parchment together or for pasting paper on wood. Dissolve the glue separately and pour it into the cold water with which the flour or starch is mixed.

Cheese paste is made of fresh white cheese and also quicklime. Pound the cheese in a mortar with boiling water; let it stand and decant it; repeat this operation three or four times. Pound together 3 parts of this cheese thus prepared and one part of quicklime, moistening it with pure water till the paste ropes like honey. Prepare only a little at a time. It is used in pasting parchment and parchment paper. These different kinds of paste should be used cold. A supply for not more than two or three days should be made at one time; but it may be preserved longer by adding alum in the proportion of $\frac{1}{10}$ of the weight of flour. The depredations of rats may be prevented by dissolving a like proportion of colocynth in the water with which the paste is made.

Hair sieves for mixing compositions.	No. 1.	50 meshes in 1 inch, or 2,500 in a square inch, a single hair in one direction, 2 in the other.
	No. 2.	25 meshes in 1 inch or 625 in a square inch, 2 hairs side by side in each direction.
	No 3.	12.5 meshes in 1 inch or 156 in one square inch, 3 hairs side by side in each direction.
	No. 4.	180 meshes in a square inch, brass wire.

The *sieves* for the laboratory are made of brass wire, hair, or silk, and may be square or round.

Brass sieves ought to be used only for dry materials. A silk sieve of 120 meshes to the linear inch is used in preparing glass dust for priming compositions.

Glue is dissolved in its own weight of boiling water. A glue-pot with a water-bath should be used to avoid burning the glue. Remove the pot from the fire as soon as the glue is found to be entirely dissolved. See *Fireworks*.

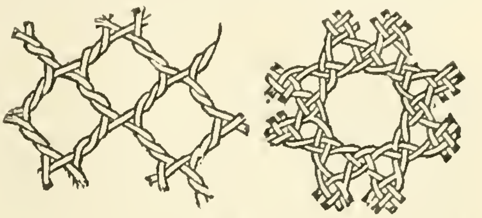
LABORER.—In a military sense, any direct and concentrated effort which is made to destroy a fortification. The term likewise applies to the working of a bomb or shell, which excavates, plows up, and scatters the earth about wherever it bursts. *Laborer un rampart*, signifies to bring several pieces of ordnance discharged from two oblique directions to bear upon one center. Shells are generally used on these occasions, and the chief design is to second the operations of the miner in some particular part from which the explosion is to take place.

LAC.—A substance obtained from incrustations made by an insect (*Coccus lacca*) on the branches and twigs of many trees in India. The lac is formed by the insect into cells, somewhat resembling a honeycomb, in which the insect is generally found entire, and owing to whose presence stick-lac yields by proper treatment a red dye, nearly, if not quite, as bright as that obtained from cochineal, and more permanent. Lac is found encircling the branches of these trees in the form of a tube; the broken branches with incrustations at various distances are called in commerce *stick-lac*, which ought to be semi-transparent. The coloring matter exhibited by grinding stick-lac, and then treating it with water, constitutes *seed-lac*, which, when melted up into masses, is called *lump-lac*. Shell-lac is obtained by further purifying the seed-lac. Lac dye consists of the coloring matter extracted from the stick-lac. It is met with in small squares similar to indigo, and is used as red dye instead of cochineal. Lac dye is largely manufactured in India and exported to England. In Bengal, lac is chiefly produced in the forests of Sylhet and at Burdwan; it is also procurable in the Deccan; but Siam and Pegu afford the largest supplies. Shell-lac is used for the manufacture of sealing-wax, also as varnish; in the latter form it is applied for setting the fulminating charge in gun-caps, and in coating Boxer's fuses and friction tubes.

LACAY.—A name formerly given to an old French militia. The word is found among the public documents which were kept by the Treasurers belonging to the Dukes of Britany in the 15th century.

LACE.—An ornamental fabric of linen, cotton, or silk thread, made either by the hands, somewhat after the manner of embroidery, or with machinery. The manufacture of lace by hand is an operation of exceeding nicety, and requires both skill and patience of no ordinary kind, and the best productions of this fabric surpass all other applications of textile materials in costliness and beauty.

Whether the ancients really had any knowledge of lace-making, excepting gold-lace, which will be mentioned at the end of this article, is not known, nor is it known with any certainty when this art came into practice in Europe; but there is good reason to suppose that *point-lace*, the oldest variety known, was the work of Nuns during the latter half of the 14th and the beginning of the 15th centuries. This point-lace is very characteristic, and is truly an art production. The artistic character of the patterns, and the wonderful patience and labor shown in carrying them out, places them, as female productions, on a parallel with the decorative works in stone, wood, and metal of the Monks. They indicate no tiresome efforts to copy natural objects, but masterly conceptions of graceful forms and tasteful combinations. It will readily be supposed that an art depending so much on individual skill and taste, would be likely to vary exceedingly; nevertheless, all the varieties esolve themselves into few well-marked groups, under three distinct classes. The first class is the *Guipure*, which comprises all the true needle-worked lace, whether ancient or modern; its varieties are: *Rose-point*, in which the figures are in high relief, having a rich embossed appearance; *Venetian-point*, *Portuguese-point*, *Maltese-point*; in all of these the pattern is flatter than in the *Rose-point*, *Point d'Alencon*, and *Brussels-point*. The last two are still made, the modern Point d'Alencon quite equaling in beauty and value that made in the middle of the 17th century, when its manufacture was introduced by the celebrated Colbert, Chief Minister of Louis XIV. The Point d'Alencon has very distinctive characteristics. When the pattern is once designed, each portion may be worked by a separate person, and the various figures are then connected by a groundwork of threads, which are so passed from one figure to another as to represent a web of wonderful delicacy and regulari-



ty; small spots or other figures are here and there skillfully worked in where the threads cross each other; these are called *modes*, and not only add much to the strength of the fabric, but greatly increase its richness of effect. In all these varieties, but two kinds of stitches are employed, and these differ chiefly in the greater or less closeness of the threads employed. First, a series of threads are laid down all in one direction, so as to cover the pattern, and then a certain number of these are taken up and covered by loops of the cross-stitches, or are more lightly held together. The second class is *pillow-lace*, sometimes called cushion or bobbin lace, from the pillow or cushion being used to work the pattern upon, and the various threads of which the figures are made up, each being wound upon a bobbin, usually of an ornamental character, to distinguish one from the other. The pattern, on parchment or paper, being attached to the *pillow* or cushion, pins are stuck in at regular intervals in the lines of the pattern, and the threads of the bobbins are twisted or plaited round them so as to form the net-work arrangement which is characteristic of this class of lace, the patterns, or figured portions, being worked out by a crossing of threads, which, although actually plaiting, gives the effect of weaving. The varieties of this lace are: *Spanish*, *grounded Spanish*, *Saxony Brussels*, *Flemish Brussels*, *Mechlin*, *Valenciennes*, *Dutch*, *Lisle*, *Chantilly*, *silk and cotton blonde*, *Limerick*, *Buckinghamshire* and *Honiton*. The last has of late years become the most beautiful of all the varieties made in Great Britain. The Irish or Limerick lace has also taken a high position. The third class is machine-made lace, which, by its wonderful improvement and rapid development, has worked a complete revolution in the lace trade, so that the prices formerly obtained for hand-made lace can no longer be commanded, whilst machine lace, of great beauty, has become so cheap and plentiful as to be worn by all classes. The lace-machine, or *frame*, as it is technically called, is so complicated that it would be hopeless to convey any really intelligible appreciation of it without a voluminous description of all its parts. One or two points of chief importance may, however, remove any difficulty in understanding its general principles. First, then, as in the loom, there is a series of warp-threads, placed, however, perpendicularly instead of horizontally, and not so close as in ordinary weaving, the space between each being sufficiently wide to admit of a shilling passing edgeways between them. Behind these threads, and corresponding to the inter-spaces, is a row of ingeniously constructed flat bobbins or reels resting in an arrangement called a *comb-bar* or *bolt-bar*. These are so placed that, with the first movement of the machine, each bobbin, which carries its thread with it, passes through two of the parallel and perpindicular threads of the warp, and is lodged in another and similar bolt-bar in front of the warp. But this front bolt-bar, besides an advancing and receding motion, has another movement called *shogging*—from right to left. When it receives a bobbin by its forward motion, it draws back, bringing the bobbin and thread through two of the upright threads; it then *shogs* or moves to one side, and goes forward again, taking the thread through the next two warp-threads, and lodging the bobbin on the back bolt-bar again, one distance beyond its last space; this it recovers by the next movement, and it again passes through the first space, to be again received by the front bolt-bar. By these movements the bobbin-thread is twisted quite round one upright thread of the warp; another movement then shifts the bobbin, so that it will pass through the next pair of upright threads, and so carry on its work, the warp-threads moving at the same time, unwinding from the lower beam, and being rolled on the upper one. There being twice as many bobbins as there are threads in the warp, each bolt-bar having a set which it exchanges with the other, and all being regulated with great nicety, a width of lace is made in far less time than has been required to write this short description. The various additions to, and variations upon, these operations, which only apply to bobbinnet, for the production of patterns, are so numerous and complicated—each pattern requiring new complications—that it will be useless attempting to describe them; suffice it to say, they all depend upon the variations which can be given to the movements of the flat, disk-like bobbins. The history of the lace-machine is not very clear; it is said to have been originally invented by a *frame-work* knitter of Nottingham, from studying the lace on his wife's cap; but it has continually received improvements, among which those of Heathcote, in 1809—the first to work successfully—Morley, in 1811 and 1824; those of Leaver and Turton, and of Clark and Marl, all in 1811. The manufacture of lace by machinery is chiefly located in Nottingham, whence it is sent to all parts of the world; but we have no means of knowing to what extent, for, with that strange perversity which distinguishes the statistical administration, only *thread-lace* is mentioned in the lists of exports, whilst the vast production of cotton-lace is mixed up with the returns of calico and other fabrics of that material. —*Gold-lace* and *Silver-lace*, properly speaking, are laces woven, either by the hand or by machinery; from exceedingly fine threads of the metals, or from linen, silk, or cotton threads which are coated with still finer threads of gold and silver; but in this country it is too common to designate as gold or silver lace, not only that which is rightly so-called, but also fringe made of the materials, and also gold and silver embroidery, such as is seen on trappings, and upon some ecclesiastical dresses, etc. Gold-lace is made in London, but considerable quantities of that used for decorating uniforms and other dresses, etc., in this country, is obtained from Belgium, where it is an important branch of manufacture. France supplies much of the gold and silver thread used, and excels all other countries in its production, in some of the more artistic varieties of gold and silver lace and embroidery. Italy has lately shown great taste and skill. The works of Luigi Martini of Milan attained great celebrity, and were recently said to produce about £16,000 worth per annum.

LACERNE.—The short woolen military cloak of the Romans.

LACHETE.—An opprobrious term which is frequently used among the French, and applied in all instances of cowardice, want of spirit, etc.

LACHICHE SYSTEM OF FORTIFICATION.—This system has a front similar to that of Cormontaigne, except that the perpendicular equals $\frac{1}{4}$ of the front, and that the salient places of arms have fleches for reduits. In order to avoid the effects of ricochet and vertical fires, the artillery is placed under casemates. The curtain, the reduits of re-entering place of arms, and the faces of ravelin have casemates open at the rear. The lower gallery serves for musketry, and facilitates the ventilation of the upper casemates. The glacis has a sufficient command to mask all the masonry. The fleches protect the covered-way against enfilade.

LACKERS—LACQUERS.—Varnishes prepared for coating metal-work. The formula usually employed is for gold color: alcohol, 2 gallons; powdered turmeric 1 pound; macerate for a week, and then filter with a covered filter, to prevent waste from evaporation; to this add, of the lightest-colored shell-lac, 12 ounces; gamboge, 4 ounces; gum-sandarach, $3\frac{1}{2}$ pounds. This is put in a warm place until the whole is dissolved, when 1 quart of common turpentine varnish is added. A red lacquer, prepared by substituting 3 pounds of annotta for the turmeric, and 1 pound of dragon's blood for gamboge, is extensively used.

The following lackers are used for iron ordnance: 1. Black lead, pulverized, 12 parts; red lead, 12 parts; litharge, 5 parts; lampblack, 5 parts; and linseed-oil, 66 parts. The mixture is boiled gently about twenty minutes, during which time it is constantly stirred. 2. Umber, ground, $3\frac{3}{4}$ parts; gum shellac, pulverized, $3\frac{3}{4}$ parts; ivory-black, $3\frac{3}{4}$ parts; litharge, $3\frac{3}{4}$ parts; linseed-oil, 78 parts; and spirits of turpentine, $7\frac{1}{4}$ parts. The oil must be boiled half an hour. The mixture is then boiled 24 hours, poured off from sediment, and put in jugs, corked. 3. Coal-tar (of good quality) 2 gallons; and spirits of turpentine, 1 pint. The turpentine to be added in small quantities during the application of the lacker. In applying lacker, the surface of the iron must be first cleaned with a scraper and a wire brush, if necessary, and the lacker applied hot, in two thin coats, with a paint-brush. It is best done in summer, when the metal is heated by the sun's rays, with gloves made of sheep-skin, the wool turned outwards, cut 0.4 inch long, the thumb alone being free. Old lacker should be removed with a scraper, or by scouring, and not by heating the guns or balls, by which the metal is injured. About 5 gallons of lacker are required for 100 field-guns and 1,000 shot; about 1 quart for a sea-coast gun.

The lacker for small-arms is composed of beeswax, 13 pounds; spirits of turpentine, 13 gallons; and boiled linseed-oil, 1 gallon.

All the ingredients should be pure and of the best quality. Heat them together in a copper or earthen vessel, over a gentle fire, in a water-bath, until they are well mixed. For holsters, scabbards, etc., the following is used: Prussian blue (in lumps), 4 parts; sugar of lead, $\frac{7}{10}$ parts; aqua-fortis, $\frac{7}{10}$ parts; linseed oil, boiled, 70 parts; and spirits of turpentine, 24.6 parts. This mixture is used for the first and second coats. The ingredients, except the turpentine, are boiled together in an iron kettle eight hours, when the mixture will assume a brilliant black color. When the varnish is nearly cool, stir in the turpentine. The kettle in which the varnish is made should be of a capacity to hold double the quantity of varnish to be boiled. For the third or finishing coat, the following is used: Gum copal (in clean lump), $26\frac{1}{2}$ parts; boiled linseed-oil, $42\frac{1}{2}$ parts; and spirits of turpentine, 31 parts. To make this varnish, put the copal in the vessel, set it on a charcoal fire for one hour, in which time it will melt, and all the watery particles will evaporate. Add the oil while the copal is warm, but not boiling hot. When nearly cool add the turpentine. For 5 pounds copal and the proper proportions of oil and turpentine the vessel should hold 6 gallons. See *Paints*.

LACS D'AMOUR.—In Heraldry, a cord of running knots used as an external decoration to surround the arms of widows and unmarried women; the *Cordelier*, which differs but slightly from it, being used similarly with the shields of married women.

LACUNETTE.—An early term in fortification, signifying a small fosse or ditch. The word *Cunette* has since been adopted.

LADDER BRIDGE.—A temporary bridge, formed by running a cart or gun limber into the stream and securing it there, with the shafts in a vertical position, by ropes from both sides of the river, one end of a ladder from each bank resting upon it, and covering the steps or rungs with planks.

LADLE.—1. For carrying the shot to the pieces, there are two kinds of ladles. The first consists of a ring and stem of iron, fastened to a wooden handle two feet long. The inner top edge of the ring is grooved out to receive the shot. The other ladle, for carrying the largest shot, consists of a similar ring, to which stems are fixed for connecting one single and one double handle, so that two men can be employed to carry the shot, the double handle being to prevent the ladle from turning over.

2. An implement for removing the powder or projectiles from guns, when it is not desired to discharge them. It consists of a ladle-head, made of the same kind of wood and in the same way as a rammer-head, and the ladle proper, which is of sheet-brass or copper, fastened to the head with copper nails.

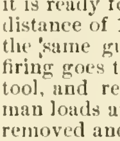
LADY OF MERCY, OUR.—The Spanish Order of Knighthood, founded in 1218, by James I. of Aragon, in fulfillment of a vow made to the Virgin during his captivity in France. The object for which the Order was instituted was the redemption of Christian captives from among the Moors, each knight at his inauguration vowing that, if necessary for their ransom, he would remain himself a captive in their stead. Within the first six years of the existence of the Order, no fewer than 400 captives are said to have been ransomed by its means. On the expulsion of the Moors from Spain, the labors of the knights were transferred to Africa. Their badge is a shield party per fess gules and or, in chief a cross pattée argent, in base four pallets gules for Aragon, the shield crowned with a ducal coronet. The Order was extended to ladies in 1261.

LADY OF MONTESA, OUR.—Order of Knighthood, founded in 1317, by King James II. of Aragon, who, on the abrogation of the Order of the Templars, urged Pope Clement V. to allow him to employ all their estates within his territory in founding a new Knightly Order for the protection of the Christians against the Moors. His request was acceded to by the following Pope, John XXII., who granted him for this purpose all the estates of the Templars and of the Knights of St. John situated in Valencia. Out of these was founded the new Order, which King James named after the town and castle of Montesa, which he assigned as its headquarters. The Order is now conferred merely as a mark of royal favor, though the provisions of its statutes are still nominally observed on new creations. The badge is a red cross edged with gold, the costume a long white woolen mantle, decorated with a cross on the left breast, and tied with very long white cords.

LAIDLEY PRACTICE-MUSKET.—In the construction of this gun the same form and motions of loading and firing as in the service-rifle have been retained as nearly as possible, consistent with a moderate expenditure in its production. An old smooth-bore musket is taken, reamed out for a length of eleven inches, for the reception of a coil ribbon-spring, on one end of which a closely-fitting piston is placed, having a stem of about five inches attached to its center; a hole is bored through the breech-screw and a cut made on its under side to receive a spring; a circular disk with a flaring hole through its center is secured in the barrel just in front of the end of the breech-screw; a short lever crosses the end of the barrel just in front of this disk, and is held in position by the spring already referred to; the hole in the cone is enlarged and receives a small spindle with a collar at its middle, which prevents it from coming out. About twelve inches from the breech a horizontal cut is made through the top of the barrel, leaving an opening of two inches in length; a cylindrical plug, having a hole through its axle, is inserted in the barrel at this place, and a handle screwed in. An inner barrel, having a bore of .22 inch and a length of 17 inches, its upper end counter-bored, is inserted in the barrel and secured by a screw; the length of the block is such as to close the space between the chambered recess and the end of the inner barrel. A hole is bored through the side of the stock to communicate with the hole through the breech-screw. To load the piece, bring the hammer to the half-cock and compress the spring. This is most conveniently done by fixing the ramrod in a cast-iron block at an angle of about 45° with the horizon. Seize the musket as at charge bayonet, insert the end of the rammer in the muzzle, and press the musket down until the spring is caught; withdraw the musket, hold it in the left hand near the lower band, the muzzle inclined downwards; seize the handle with the right hand, turn it, and draw it back; take a dart between the thumb and fore-finger, insert it in the bore, and push it well home with the thumb. Be sure that no part of it projects; close the breech-block and secure it by turning the handle. Cock the piece, and it is ready for firing. The men in firing stand at a distance of 15 paces from the target. Two men use the same gun, firing alternately. Each man after firing goes to the target, extracts the dart with a claw tool, and records the value of his shot. The other man loads and fires as soon as the preceding dart is removed and the target is clear. In order to give the soldier the benefit of practice-firing at objects at long ranges, the difficulty increasing greatly with the distance of the target, owing to the blur on the sight when the eye is adjusted to the proper focus to see distant objects, place a target at 500 or 600 yards distant, or as far off as convenient, so that it can be seen through the open window; place a target 15 paces from the firing-stand, at such a height that the distant target may be seen 4 or 5 inches below the middle of its lower edge; mark on the floor the position for the feet of the man when firing, raise the longer leaf of the sight, aim at the distant bull's-eye, and fire; the shots will strike the near target if correctly placed, and the accuracy of aim will be shown by the score thus made. The height of the target may have to be adjusted after the first few shots.

LAISCHES.—Thin metal plates which the ancient Gauls placed upon the buff-coats of infantry, between the buff and the lining.

LAMBEAUX.—In Heraldry, a cross formed in the upper like a cross pattée, but with the lower limb not widened, but terminating in a label of three points, "having," according to Sylvanus Morgan, "a great deal of mystery in relation to the top, whereon the first-born Son of God did suffer, sending out three streams from his hands, feet, and sides."



Lambeaux.

LAMBOYS.—In ancient armor, laminated skirts of small overlapping steel plates. These took the places of both the *taces* and *tuilles* of the somewhat earlier times.

LAMBREQUIN.—1. A word used in Heraldry in three senses: 1. The mantling attached to the helmet, and represented as depending over the shield. 2. A wreath; 3. The point of a label. See *Label*.

2. A leathern strap or flap hanging from a cuirass, which is often highly ornamented and made to reach as far as the thighs. Lambrequins frequently cover the helmet to protect it from wet and heat.

LAMPION DE PARAPET. A lamp generally used on a parapet or elsewhere in a besieged place. It is a small iron vessel filled with pitch and tar, which is lighted by the troops as occasion may require.

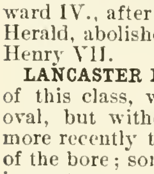
LANCASTER GUN.—A species of rifled cannon, which has been partially adopted in the British service. When the great difficulty of rifling heavy ordnance to an extent to give a sufficient rotary motion to the projectile became apparent, Mr. Lancaster devised a plan by which grooves might be dispensed with altogether. Instead of a strictly circular bore, he gave his gun an elliptical bore, the elipse being of very small eccentricity. The major axis was not in one plane from end to end of the gun, but was made to revolve in the length, until it had moved round one-fourth the periphery of the elipse. The projectiles are, of course, elliptical also; elongated, and somewhat pointed in front. When the shell is projected, it must follow the twist in the bore, and the rotary motion thus imparted is retained to the end of the range. Several Lancaster guns were employed at the siege of Sebastopol, and some of them burst. But these were scarcely fair specimens, being service 8-inch guns (with circular bore) bored to Mr. Lancaster's elliptical standard, and therefore weakened. The wrought-iron guns on his special model have given, however, more certain results. The special advantage claimed for the Lancaster gun is that it fouls less than any of the other guns in use. See *Ordnance.*

LANCASTER HERALD.—One of the six Heralds of England, ranking second in point of seniority. His office is said to have been instituted by Edward III., in the 34th year of his reign, when he created his son, John of Gaunt, Duke of Lancaster. Henry IV. raised Lancaster to the dignity of a King-at-Arms. Edward IV., after reducing him back to the status of a Herald, abolished his office, which was revived by Henry VII.

LANCASTER PROJECTILE.—The earlier projectiles of this class, were made of wrought-iron, simply oval, but without any rifle-twist upon them; but more recently the shot have been bent to the shape of the bore; some of these had a wrought-iron casing put over a cast-iron projectile, and this, projecting four inches to the rear, carried a lubricant which the wooden wedges at the bottom sent out while expanding the casing so as to fill the bore. The weight of this projectile was 44 pounds, and its capacity for bursting charge, $4\frac{1}{2}$ pounds. It was thick in the rear, and thin in the front, tapering to a point.

LANCASTER RIFLE.—A small-arm having a slightly oblate bore. The twist, as found by experience to be most advantageous, is one turn in 52 inches. The approved diameter of the bore is .498 inch, the length of the barrel being 32 inches. An eccentricity of .01 inch in half an inch is found sufficient to make the bullet spin on its axis to the extreme verge of its flight. The length of the bullet found to answer best with these rifles is $2\frac{1}{4}$ diameters in length with a windage of .004 or .005 of an inch.

LANCASTER RIFLING.—This plan of centering the shot was used with partial success by the English in the Crimea. The gun is rifled with two rounded grooves, each about one-third the circumference in width, so that the cross section of the bore is oval. Only a trace of the original bore is left at its minor axis. The major axis in the 32-pounder is 6.97 in., and the minor axis 6.37 in., so that, considered as a two-grooved rifle, the grooves are 3-inch deep at the centers. The absence of shoulders to the two grooves converts the two places of contact of the projectile with the rifling, into circular wedges tending to burst the gun or to compress the projectile.



LANCASTER.

LANCE.—1. A weapon of war composed of a sharp steel blade, from 8 to 10 inches long, grooved like a common bayonet with a socket at its base and two iron straps for attaching it to the handle. The handle is of strong, light wood, with a tip of iron at its lower end and a leathern loop at its center of gravity to support and guide the lance. It is usually from $8\frac{1}{2}$ to 11 feet long, and weighs about $4\frac{1}{2}$ lbs. This weapon is not used in the United States service. The Russians have their regular and irregular Cossacks armed with the lance. The Austrians, also, have Lancers; but the Polish cavalry use the lance better than any other people. The lance, when not in use, rests in a leather boot attached to the stirrup, the right arm being passed through the leather loop of the lance; or by putting the lower end in the boot and strapping the handle to the pommel of the saddle. Lancers are more formidable than other cavalry because they are able to reach further. Skill in combating a lancer consists in keeping to his left, in order to shun his lance. Pressed too nearly, the Lancer must have resource to his saber and let his lance rest upon his arm. The moment in which he attempts to seize his saber is dangerous to him. The Mexican cavalry are generally Lancers. 2. An iron rod which is fixed across the earthen mold of a shell, and which keeps it suspended in the air when it is cast. As soon as the shell is formed, this rod must be broken, and carefully taken out with instruments made for that purpose. Shells ought to be scrupulously examined with respect to this article, as they could not be charged were the lance, or any part of it, to remain within. 3. An instrument which conveys the charge of a piece of ordnance and forces it home to the bore.

LANCE A FEU.—A species of artificial firework which is made in the shape of a fuse, and is used for various purposes. Its composition consists of 3 parts of best refined saltpeter, 2 parts of flour of sulphur, and 2 parts of antimony; the whole being pounded and mixed together. The chief use of the *Lance à feu* is to throw occasional light across the platform, whilst artificial fireworks are preparing. They likewise serve to set fire to fuses, as they can be taken hold of without danger. *Lance de feu* is a species of squib, which is used by the garrison of a besieged town against a scaling party. See *Lances.*

LANCE A FEU PUANT.—A stink-fire lance prepared in the same manner as a stink-pot, and used by miners. When a sapper or miner has so far penetrated towards the enemy as to hear the voices of persons in any places contiguous to his own excavation, he first of all bores a hole with his probe, then discharges several pistols through the aperture, and lastly forces in a *Lance a feu puant,* taking care to close up the hole on his side to prevent the smoke from returning towards himself. The exhalation and stinking hot vapor which issue from the lance, and remain confined on the side of the enemy, infect the air so much, that it is impossible to approach the quarter for several days. Sometimes, indeed, they have had so instantaneous an effect, that in order to save their lives, miners, who would persevere, have been dragged out by the legs in an apparent state of suffocation. See *Lances.*

LANCE-CORPORAL.—The assistant to a Corporal; a private performing the duties of a Corporal. The Lance-corporal ranks above a private in the line, and usually performs the duties and possesses the authority of a Corporal, but does not receive a Corporal's pay.

LANCE KNIGHT.—A German foot-soldier; originally one of the serfs who followed the camp in the service of the common soldiers. See *Lansquenets.*

LANCE-REST.—A projection like a bracket, on the right side of a breast-plate in armor, to aid in bearing a lance.

LANCERS.—A description of cavalry soldiers who are armed with lances. The type and perfection of Lancers are the Russian Cossacks, whose long lances enable them to combat with enemies at a distance from which they themselves take little harm. The Lancers were brought into European notice by Napoleon, who greatly relied upon some Polish regiments. After the peace of 1815, the arm was adopted in the English service, but it is thought by many that the British Lancer has a weapon too short to enable him to charge on an infantry square with any chance of success.

The Lancer, like the Poet, "is born not fashioned." In the hands of the Pole, the lance, whether used to charge in line or in the dispersion of pursuit, is a truly fearful weapon; but to those to whom long practice in its use has not made it a second nature, it is only embarrassing, and more to be avoided by a comrade than by a foeman. Still the apprehension of being run through has a powerful moral effect upon a man; and there is no sound more appalling to a flying enemy than "Here come the Lancers."

LANCES.—Small paper cases, .2 to .4 inch diameter, filled with one or more compositions, each burning with a flame of a particular color. They are used to mark the outlines of figures, and are attached to light frames of wood or sticks of bamboo. To make the cases, cut the paper into rectangles of a length equal to the required length of the case and of such widths as to make the case three thicknesses of No. 7 paper. The length of the case is generally about ten times its exterior diameter, depending on the composition with which it is to be filled and the time it is required to burn. Paste the rectangle and roll it on an iron former with the hand. When the cases are dry, cut them to their proper length.

Place the cases in holes bored in a block of hard wood, the holes .02 inch larger than the case, and their depth .25 inch less than the length of the case. Drive in the bottom of each case a ladleful of clay. Insert in the top of the case a small funnel; pass the drift through the funnel into the case; fill the funnel with composition; raise the drift one inch above the top of the case; press it to the bottom and give it three light blows with a rocket-drift; continue in the same way, raising the drift above the top of the case between each volley until the case is filled to .25 inch of the top. Prime the lance with mealed powder, moistened with gummed water, and dip the end while moist in rifle-powder. When the case is to be filled with two different compositions, drive the case with the first composition till it is about .2 inch above the required height; remove the surplus to the exact height with a gauge, and proceed with the second composition as with the first.

Bore holes .02 inch larger than the lances, and .5 inch deep, from 2 to 4 inches apart, according to the size of lance. The holes should be bored so that the lance shall be horizontal when the frame is in position. Dip the end of the lance in glue, and press it firmly in the hole, arranging the lances parallel to each other. Or they may be fastened to the frame by means of sharp nails or tacks, driven into the frame and projecting about .4 inch. The end of the lance is pierced with an awl, dipped in glue, and thrust on the point of the nails, arranging them perpendicularly to the frame. See *Fireworks*.

LANCE-SERGEANT.—An acting Sergeant. This position is given to Corporals when additional Non-commissioned officers are required to assist the officers of troops and companies in the discharge of their duty. If the Lance-sergeants prove themselves efficient, they are usually promoted as vacancies occur.

LANCES LEVEES.—Uplifted lances, indicating that the enemy was beaten, and that the Chevaliers or Gendarmes should close the day by giving a final blow to the disordered ranks.

LANCE-SOCKET.—A leather socket which supports the butt of the lance when carried on horseback; called also *lance-bucket*. See *Lance*.

LANCE WOOD.—A wood valuable for its great strength and elasticity. It is produced by the small tree *guatteria virgata* (natural order *anonaceæ*). Another species, *G. laurifolia*, yields the wood called white lance-wood. The latter is not much used. Lance-wood is of great value in carriage constructions, when it is used for shafts and carriage-poles, for which it is especially fitted. The part used is the main trunk of the tree, which is very straight, and rarely more than 9 inches in diameter, with the bark on. It comes in small quantities from the West Indies, chiefly, however, from Jamaica.

LANDGRAVE. A German nobleman of a rank corresponding to an English Earl. The wife of a Landgrave is known as Landgravine.

LANDING.—In fortification, the portion of the floor of the gallery, between the frames that bound the entrance to a return, is termed a *landing*. The landing is in all cases horizontal, as well as that portion of an oblique return between the oblique frame and the one next succeeding, which last should not be placed further than an ordinary interval from the furthest point of the oblique frame. See *Gallery*.

LANDS.—In ordnance, the spaces between the furrows or grooves in the barrel of a rifled gun. See *Barrel*.

LANDSBERG SYSTEM OF FORTIFICATION.—This system consists of three unrevetted enceintes: the first of tenailles of 60° with small redans in the re-entering angles; the second, of a fausse-braye, with bonnets at salient; the third of an envelope of 125 to 225 yards faces replacing the covered-way. In the main ditch there are casemated redoubts for musketry and artillery. The ramparts are much exposed to enfilade; and all the more so since there is no traverse; the absence of a covered-way exposes the place to an attack of vive force; the relief being small, escalade may be resorted to; there is no provision made for sorties; and the space left for houses is very limited. Landsberg calculates that the outlay will be much less than for Vauban's hexagon, and that a vigorous defense may be expected from a garrison of 20,000 men and 60 guns.

LANDSTURM.—The Third Reserve of the German Army. The German soldier, after remaining 3 years in the Active Army, 4 in the Reserve, and 5 years in the *Landwehr*, is draughted into the *Landsturm*, which owes its origin to the wars of the First Empire, and was formerly a force raised for home defense only. But, in 1874, a bill was passed by which the Emperor can summon that force of his own authority in case of urgency, and the men of the Third Reserve can be draughted into the *Landwehr* if their services are needed. It is computed that this new organization will increase the strength of the German Army up to nearly two millions of men.

LAND SURVEYING.—The measurement of the area of a portion, whether small or large, of the earth's surface, is an important application of mathematics, and involves a thorough acquaintance with geometry, trigonometry, and the theory and use of the instruments employed for the determination of angles. Fields or portions of ground of small extent are measured easily and with sufficient accuracy by a chain (for distances), and a box-compass or cross-staff (for angles). For larger areas, the use of the surveyor's table is requisite; and for those of still greater extent, in which the greatest accuracy is requisite in the determination of the angles, the astrolabe, theodolite, sextant, circle, reflector, micrometer, etc., are used. The surface to be measured is divided into triangles, which are separately measured and calculated; but when a large extent is included in the measurement, it is not enough to proceed from one triangle to another, in which way an error at the outset may be propagated with continual increase; but a base line, as long as circumstances admit of, must, in the first instance, be accurately measured, upon which, by means of the measurement of angles, all the subsequent calculations are made to depend, and lines subsequently measured are only intended to be corrective of the results obtained by calculation. When the extent of surface is still greater, as when a whole country is to be measured, points here and there are astronomically determined, their meridians are accurately laid down, and a complicated system of triangles is employed to insure accuracy. This is called *triangulation.*

LAND TRANSPORT.—A branch of the Control Department. It comprises men of the Transport Companies, and cattle for the draught or otherwise of the stores and baggage of an army. Carts or wagons of the lightest nature should be used, and the horses employed to draw them should be driven and not ridden. Pack animals should only be used on emergency, when a sufficient number of carts cannot be obtained. In mountainous countries, resort must be had to this kind of transport, as was the case in Abyssinia. But, as a rule, pack animals are to be avoided as being the worst and most difficult transport to manage. In India, the transport consists of bullock carts of the country, elephants, and camels. See *Military Train.*

LANDWEHR.—A military force in several of the German States; somewhat corresponding to the militia of Great Britain. It is not always retained under arms. During peace, its members spend most of their time in civil pursuits, and are called out for military service only in times of war or of commotion—care being taken, however, that they are sufficiently exercised to make them ready for such service when necessary. The name Landwehr was first applied to the Tyrolese, who rose against the French; and in 1805 a similar force was raised in the other German Provinces of Austria, which, however, the Emperor has recently abolished. By far the most elaborate and complete system of land-defense was the Prussian, which was called into existence in 1813, when all Germany rose against Napoleon. As early, indeed, as 1806, or earlier, Marshal Knesebeck, then a Major in the Prussian Army, had proposed such a thing; but it was not till the opening of the campaign of 1813 that the Prussian Landwehr was organized according to Scharnhorst's plan by a Royal Edict, dated Mar. 17. At first, it was designed solely as a land-defense, properly so called, and not, what is now the case, as an integral part of the regular army. It was called out in two separate levies, the first comprising all men from 26 to 32, and the second those from 32 to 39. The old men up to 60 belonged to the *Landsturm*, which was called out only for the defense of house and hearth. After the second peace of Paris appeared the *Landwehrordnung* (Landwehr-regulation)of April 21, 1815, according to which the country was divided into 104 districts, each of which had to furnish a battalion of Landwehr. To every battalion of Landwehr was attached one squadron of Uhlans; three battalions formed a regiment; two regiments, a Landwehr brigade, which, along with the brigades of cavalry and infantry, was placed under a General of Division. By the Constitution of April, 1871, the Prussian obligation to serve in the army was extended to the whole German Empire. Every German capable of bearing arms, after serving in the standing army for seven years, has to enter the Landwehr, and remain in it for another five years.

LANE.—The term applied to a body of soldiers in two ranks standing face to face, forming, in fact, a street, passage, or lane. The French call this formation *haie*, or hedge. It is used when troops form a guard of honor for persons of rank to pass through.

LANGREL.—A villainous case-shot made up of various fragments of iron of irregular shape and size, so as to fit the bore of the cannon from which it is to be discharged. It was formerly much used for disabling sails and rigging of ships. Also written *Langrage.*

LANGUED.—In Heraldry, an animal whose tongue is of a different color from its body, is said to be *langued* of that color. It is understood in England that unless the blazon direct otherwise, all animals are langued gules whose tincture is not gules, and an animal gules is langued azure. This rule does not hold good in Scottish Heraldry, where "when the tongue, teeth, and claws are of different tinctures from their bodies, they are to be mentioned as armed and langued of such a tincture."—*Nisbet.* When a beast or bird is represented without teeth or claws, this is expressed in blazon "sans langue and arms." The term Lampassé is used in the same sense.

LANGUE DE BOEUF.—A sword of the 15th century, with a tapering blade, about 25 inches long and 5 inches wide at the handle end. It was double edged, and very much resembled the *parazonium*, or small sword, of the ancient Greeks and Romans, which they carried on the left side.

LANGUET.—A small slip of metal on the hilt of a sword, which overhangs the scabbard: the ear of a sword.

LANSQUENETS.—German foot soldiers raised towards the end of the 15th century. They enlisted voluntarily, and hired themselves out as mercenaries to any power that was willing to pay them. Charles VII. of France first added them to his infantry. After the 16th century the name fell into disuse.

LANSQUENETTE.—A short, wide, two-edged, and pointed sword of the 16th century. The handle was like a truncated cone, and flattened at the end to form the pommel.

LANTERN.—A contrivance for the purpose of giving light; it is made of glass or any transparent matter. There are two kinds of lanterns, *dark* and *Muscovy*, which are used at night in batteries or on the line of march.

LANTERNE.—1. An implement made of copper, resembling a round spoon or ladle. It is fixed to a long pole and serves to convey gunpowder into a piece of ordnance. 2 A Swiss cannon rammer, on a long shaft, the end of which contains a wadding screw. It was first used in the 15th century.

LANTERN SLIDES.—Contrivances used in transcribing microscopic despatches sent by carrier pigeons in time of war. The *negative* should be very delicate and full of details; rather thin without being flat, and clear in the shadows. Intensification should be avoided, except in the case of line work. Especial care should be taken in adjusting and focussing the camera, as the subsequent enlargement greatly magnifies all defects. The *slide* is simply a positive taken from the negative, and may be of the same size, though it is generally reduced. This operation is best performed in a darkened room with a wooden shutter in the window. An opening in the shutter, of the proper size, is arranged to hold the negative, and the camera is so adjusted that the positive will be of the proper size for a slide. In this case, transmitted instead of reflected light is the active agent, and the length of exposure is very much reduced. The same care as before is necessary in the adjustment and focussing of the camera. The light passing directly through the negative should come from a clear sky. In case the horizon line is near the prolongation of the axis of lens, the negative will be unequally illuminated, and the positive will not be of uniform density. *Wet plates* are preferable for both negatives and positives, as the most skillful and careful manipulation will not insure clear glass for the highest lights of the latter when sensitive dry plates are used. The *Collodion* should be of a shiny color and the negative bath only faintly acid. Give free exposure, and rather under-develop with an acid developer in order to obtain the requisite density. Use 45 minims of glacialacetic acid per ounce of Instantaneous Developer. After the plate is fixed, should the lights be found veiled, the plate may be *cleaned* by flooding it with the following solution:

Potassium Cyanide......................!.....20 grains.
Water...1 ounce.

Saturated with iodine until clear. *Toning* is best done with a 10-grain solution of platinic chloride. It will frequently be necessary to use dry plates for lantern slides instead of wet plates because of the inconvenience attending the use of the latter. See *Photography.*

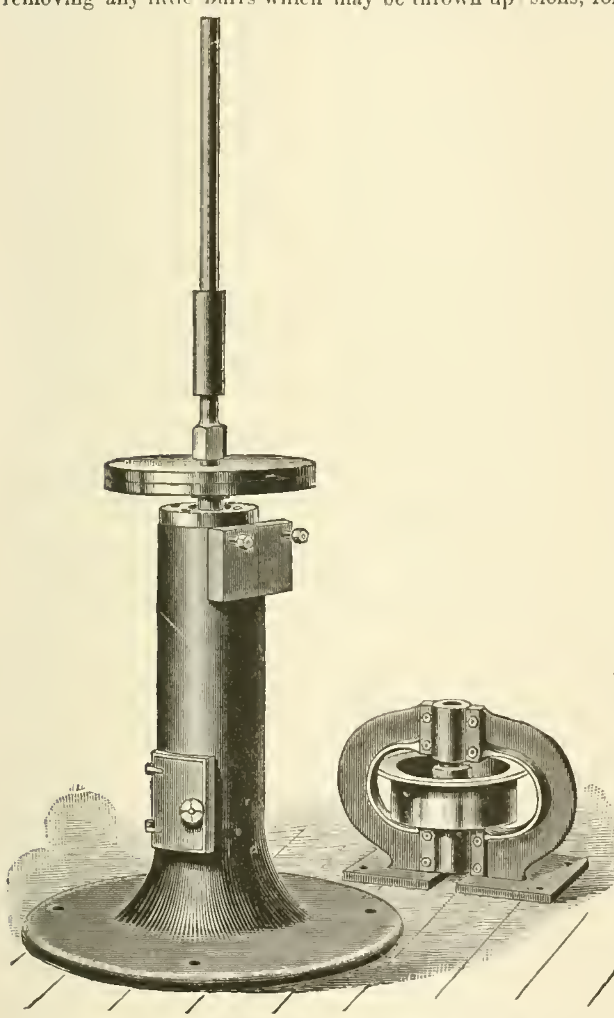
LANYARD.—A strong cord, one end of which has a small iron hook, and the other a wooden handle. It is used for exploding the friction-primer when a piece is to be fired.

A new form of lanyard has a sliding handle, which strikes a fixed button on the cord, and thus explodes the primer. The farther end of the lanyard is held by the left hand at the height of the breast, while the right hand slides the handle until it strikes the button, usually opposite the right side.

LAPEL.—The facings of a coat. Until the introduction of epaulettes in 1812, the white lapel was synonymous with a Lieutenant's commission in the British service. Commonly written *Lapelle.*

LAPITHAE.—A wild race inhabiting, in ancient times, the mountains of Thessaly. They derived their name from a mythical ancestor, *Lapithes*, a son of Apollo, and the brother of Centauros, the equally mythical ancestor of the Centaurs. A bloody war is said to have been waged between the kindred races in prehistoric times, which ended in the defeat of the Centaurs, but the Lapithæ were in their turn subdued by Hercules.

LAPPING.—1. The process a gun undergoes after being rifled, also after "proof," for the purpose of removing any little burrs which may be thrown up



on the edge of the grooves by the proof rounds. The lapping-machine, represented in the drawing, is extensively used in government arsenals and armories for grinding thin, flat pieces that cannot well be clamped for milling without retaining their winding irregularities. With this machine an unskilled workman can grind a true surface at much less expense than milling would cost. Diameter of lap, 18 inches; weight of machine, 600 pounds; speed of lap, 1,500 revolutions per minute; speed of counter-shaft, 6 by 5 inch tight and loose pulleys, 625 revolutions per minute. 2. The wearing away the land-surface in a rifled gun to ease the entrance of the projectile.

LAPSE.—An expression formerly used in the British Army to signify the reversion of any military property. Thus, upon the sale or purchase of one commission at the regulated difference, another (where there are two) is said to lapse to government. Commissions lapse or fall into the patronage of government, when vacancies happen by death, by officers being superseded, or where officers apply to sell who have only purchased a part of their commissions, and have not served long enough to be entitled to sell the whole; in which case they are only permitted to sell what they actually purchased, and the remainder is the gift of the government.

LAP-WELD.—A weld in which the welding edges are made thin, lapped one over the other, and welded.

LARGESSE.—Money which, in early time, it was the practice to grant to Heralds on certain state occasions, for proclaiming the style and title of the Sovereign and his Nobles. The regular fees, as recorded in one of the Ashmolean MSS., were: "At the coronacion of the king of England £100 apparalled in scarlet. At the displaying of the kinge's banner in any campe, 100 markes. At the displaying of a duke's banner, £20; at a marquis', 20 markes; at an earle's, 10 markes. The king marrying a wife, £50, with the gifts of the kinge's and queene's uppermost garments; at the birth of the kinge's eldest son, 100 markes; at the birth of younger children, £20. The king being at any syge with the crown on his head, £5."

LARIAT.—A long cord or thong of leather with a noose. The term is now commonly applied to a rope $1\frac{1}{4}$ inches in circumference and 30 feet long, made of Italian hemp, which is much used in the United States Cavalry service to picket the horses while grazing. See *Lasso.*

LARMES.—A term employed in Heraldry. When the field is bestrewed with an indefinite number of drops of a blue color, it is said to be *gutte de larmes*, a nomenclature peculiar to British Heraldry.

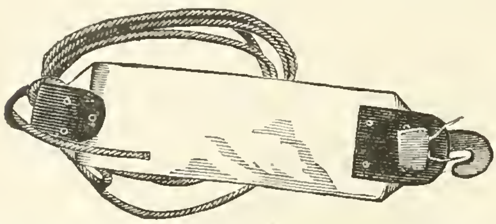
LASCAR.—In the East Indies, a term signifying properly a camp-follower, but generally applied to native sailors on board of British ships. The Lascars make good seamen, but being of an excessively irritable and revengeful nature, are generally kept in the minority in a ship's crew. Such men, under the name of *Khalassies*, are employed in some of the Indian arsenals. At Hong Kong and in Ceylon there are companies of Lascars in the pay of the British Government.

LASHES.—Formerly General Court-Martials could sentence a soldier to receive a certain number of lashes. At present this mode of punishment is prohibited, and no person in the military service is punished by flogging, or by branding, marking, or tattooing on the body.

LASHING.—The securing together any bodies by means of ropes; there are two modes generally used, viz., *square* and *diagonal*. The nature of rope depends on the work to be done. In securing sheers, guns, and any articles that require to be fixed, lashing is resorted to. There are three kinds of rope used for lashing—*log* line, *seizing* line, and *Hambro'* line. Lashing used in mounting and dismounting guns are of different dimensions.

LASHING RINGS.—Rings fixed on the sides of artillery traveling-carriages, to lash the tarpaulin, as also to tie the sponge, rammer, and ladle.

LASH-ROPE.—A rope used in packing. The packs or loads are made fast and retained on the animal's back by means of a cinch and lash-rope. The cinch is made of strong canvas, about eleven inches wide and one yard long, doubled so that the edges are in the middle. Strong pieces of leather are firmly



stitched on both ends and on both sides, with the canvas cinch between, as shown in the drawing. A three-inch iron ring is made fast at one end, and a hook of hard wood at the other. Natural shapes are usually selected for the hooks. The lash rope is of $1\frac{1}{4}$ inch hemp rope or rawhide, about 35 feet long, with one end spliced to the cinch-ring, the other end served. See *Packing*.

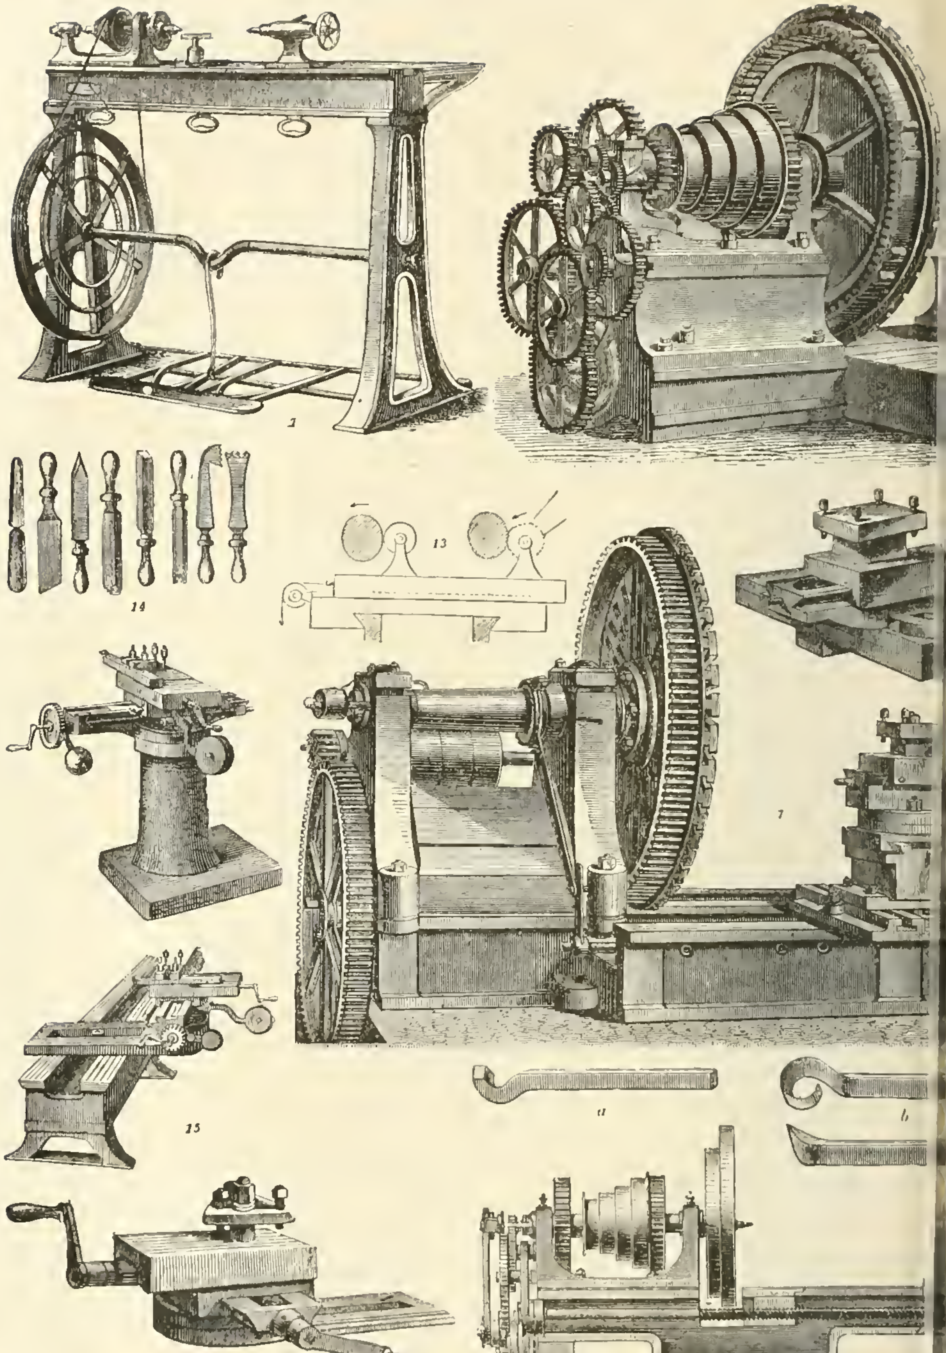
LASSO.—A long stout cord or thong of skin, with a leaden ball at each end, employed by the South Americans in capturing wild horses, oxen, etc. It is thrown in such a manner, that when it strikes the neck or leg of the animal to be captured, the impetus of the ball causes the cord to coil round the limb. The hunter's horse is furnished with a saddle having a high pommel, so that the hunter may coil his end of the lasso round it, or even fix it, if he chooses, though this latter practice often leads to dangerous consequences. The lasso was frequently used against European soldiers during the contest of the South American Republics for Independence; and, though with very little success, by the barbarians of the Russian Army against the French sentinels during the Crimean War. Similar in its name and application is another implement consisting of a stout thong of hide with a slip-noose, used in many countries; but chiefly among the South American and Mexican hunters. It requires much greater address to use it successfully. In Mexico the lasso is called a lariat.

LASSO HARNESS.—A harness consisting of a brown leather surcingle and one trace. The surcingle is rather wider than a common girth, and is composed of two pieces (joined together by rings), one of which is placed over the saddle, and the other round the belly of the horse. There are also rings at the end of the surcingle, which is drawn very firmly round the horse, and fastened tight by lapping a white leather thong (fixed at one end of the surcingle) through these rings. There are two descriptions of traces, one being 8 and the other 12 feet long. They have hooks at each end, and when the lasso harness is made use of by cavalry, etc., to assist draught-horses in moving very heavy carriages, or in dragging guns, etc., up steep hills, one of these hooks is fastened to a ring in the surcingle, and the other to the carriage. When two horses are in draught, the traces must be inside, and each rider should keep his horse's croup a little outwards.

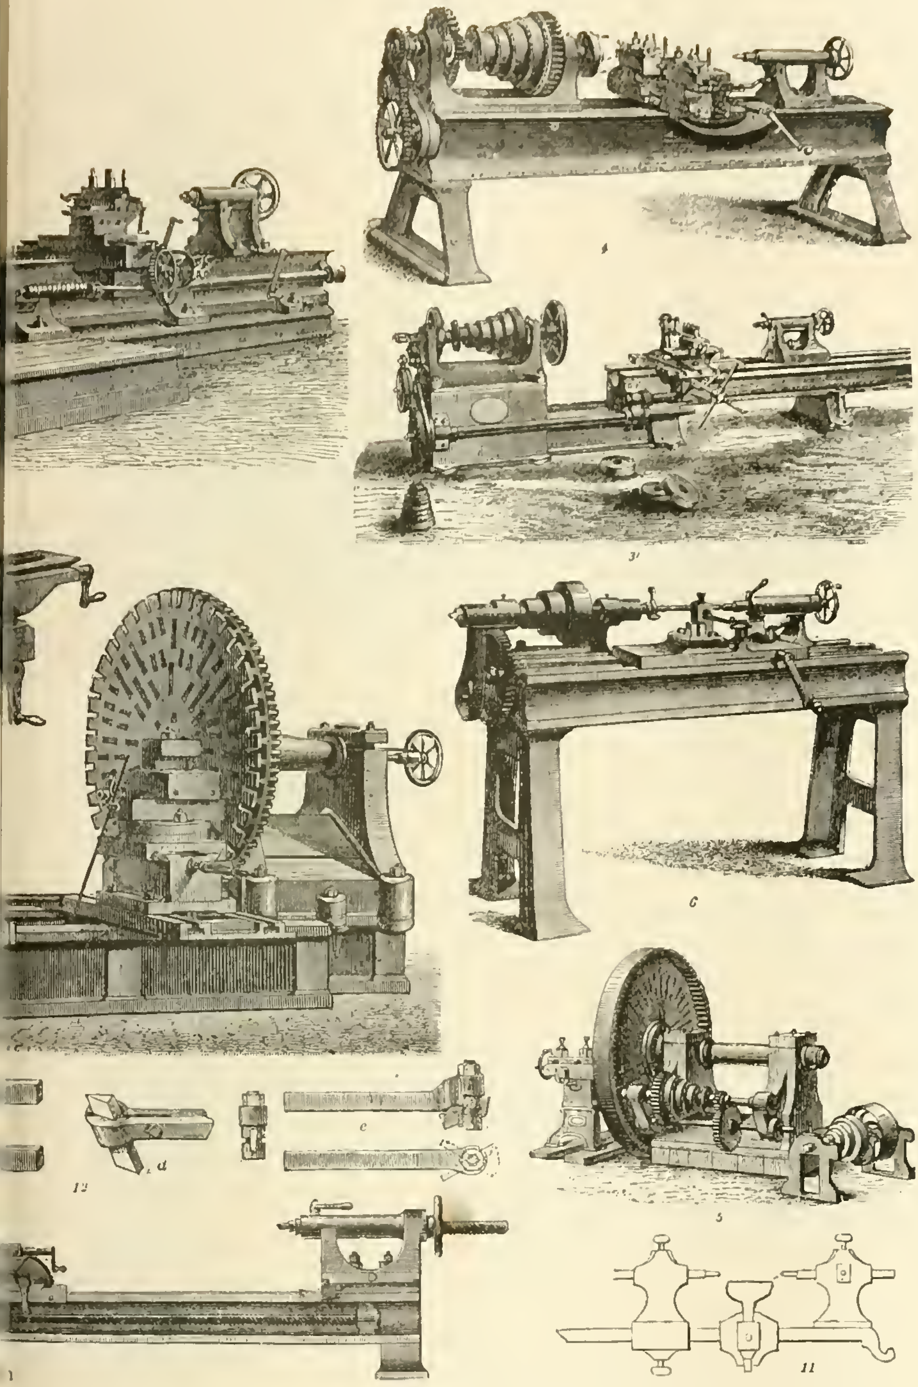
LATCH CROSS BOW.—A form of crossbow, specially adapted for sieges and for shooting at a mark. This was the weapon used by the Genoese at Agincourt in 1420.

LATERAL COMMUNICATIONS.—In warfare, communications which should be kept up between the different portions of an army when moving from one common base by different roads towards an enemy, so that, in case of a concentration being required on any particular point, instructions and orders can be readily carried out, and the different portions of the army brought together with rapidity. To prevent any obstruction to communications being kept up, especially when advancing towards the enemy, the several roads on which the army marches should not, if possible, be separated by rivers, morasses, or a mountain ridge; rivers would not be so objectionable, as they might be forded or crossed by bridges. Several roads tending in the same direction, with easy means of concentration, is the most satisfactory way of moving an army.

LATHE.—A machine in which the object revolves while it is shaped by a cutting tool applied to it. The art of turning is of great importance in gun-construction and is extensively applied in mechanics, the most delicate articles of luxury and ornament, equally with most ponderous machineries being produced by it. As an art, it dates from a very early period, and Theodorus of Samos (about 560 B. C.) is named by Pliny as its inventor; but long before this period, the *potters wheel*, the earliest and the simplest form of turning machine, was in general use, as is evidenced by numerous references in Holy Writ. The immense variety of work performed by lathes or turning machines necessitates great variations in their construction; but their mode of operation is always the same, and consists in fixing the work in position by two pivots or otherwise, causing it to revolve freely round an axis of revolution, of which the two pivots are the poles, and holding a chisel or other cutting tool so as to meet it during its revolution, taking care that the cutting tool be held firmly and steadily, and moved about to different parts of the work till the required shape be obtained. Lathes are generally divided, with respect to the mode of setting them in motion, into *pole*-lathes, *foot*-lathes, *hand-wheel* lathes; and *power*-lathes; with respect to the species of work they have to perform, into *center*-lathes, which form the outside surface, and *spindle*, *mandrel* or *chuck* lathes, which perform hollow or inside work, though this distinction is for the most part useless, as all lathes of good construction are now fitted for both kinds of work. *Bed*-lathes are those used by turners in wood, and *bar*-lathes for the best sort of metal work; and the small metal center-lathe employed by watchmakers is known as a *turn-bench*. The primitive and most simple form of lathe for wood-cutting is the pole-lathe. It consists of two planks or beams placed horizontally side by side with a narrow space between them, which, being firmly supported at a convenient height, constitute the *bed;* of two uprights or *puppets* rising from the bed, one of them stationery at the left end, and the other sliding along over the slit between the beams, and capable of being fastened at any required point by a projecting tenon and wedge beneath; of a *treadle* below and parallel to the bed: and of an elastic *pole* or *lath* (whence some derive the name lathe) fixed to the ceiling above. This form of lathe is well adapted for turning long thin cylinders of wood, the piece to be turned being held fast at each end by the conical iron or steel point projecting from the inner face of each puppet. Motion is communicated to the work by a cord which is fastened to the lathe overhead, wound twice or thrice round the work, and then attached to the treadle below. When the workman presses his foot on the treadle, the work commences to revolve rapidly, unwinding the cord towards the treadle, and winding it up on the side next the pole, causing the latter to bend considerably. During this period, the workman has been holding his cutting-instrument to the work; but after the treadle has been quite pressed down, he removes his foot, and the reaction of the bent pole causes the work to revolve in an opposite direction, till the pole has straightened itself; and during this latter revolution, no cutting is done. When the whole piece is to be turned, the cord must be moved from an unfinished to a finished part of the work. For the pole, an elastic steel bow and string are substituted



GEARING, LATHES, etc. 1. Foot-lathe. 2. Screw-cutting lathe. 3. Spindle-lathe. 4. Lathe with two drills
pivot-lathe. 12. Wood and metal-turner's tools. 13. Copying turning bench. 14. Turner's tools. 15



ver-lathe. 6. Small power-lathe. 7. Wheel-lathe. 8, 9. Cross support. 10. Spindle-lathe. 11. Jeweler's
support.

when the work is light or fine, the cord being attached to the middle of the string, and the bow fastened to the ceiling by its center. The advantage of the pole-lathe is that it never acquires an impetus in the direction of the cutting motion, for whenever the pressure on the treadle is removed the reaction of the pole takes effect; but the great waste of time during the straightening of the pole and rising of the treadle has caused the abandonment of this machine for the foot-lathe. The foot-lathe, the most common and generally useful form of lathe, differs from the former in having a *head-stock* or *fast-head* in place of the left-hand stationary puppet. This head-stock, consists of two supports or puppets firmly connected at their base, and fastened at right angles to the bed by means of screws. The outer puppet is pierced for a screw and the inner one is supplied with a steel collar, within which the mandrel carrying the speed-pulleys turns. The left end of the mandrel is concave, so as to allow the steel point of the screw to fit closely. A rest, which slides along the slit between the two beams of the bed, and which may be clamped at any point, and elevated or depressed as is found necessary, is used by the workman for the purpose of leaning his cutting-tool upon, in order to afford it a greater steadiness. The pulleys on the spindle and mandrel are of different sizes, and so arranged that when the endless band is placed on the left-hand pulleys, an extremely rapid motion is communicated to the mandrel, the motion being reduced more and more as the band is transferred more to the right, till, at the extreme right, the rotatory motion is much slower than that of the spindle. When the foot-lathe is required for center-work, the inner end of the mandrel, is furnished with a point; but when hollow or inside work is to be done, it must be armed with a screw. In this latter case, certain contrivances, known as *chucks*, for holding the work, are screwed on to the end of the mandrel. Some of these most commonly used are the *screw-chuck*, which shows on its right side a flat circular surface, from the center of which projects a large, coarse, conical screw for holding firmly any large piece of wooden work; the *hollow chuck*, a strong, circular cup with perpendicular sides, into which one end of the work is firmly fastened by a mallet, or, if too small, by four screws working inward through its sides; the *drill-chuck*, of a cylindrical form similar to the last, but with a square cavity for holding drills, the instrument, and not the work, being made to rotate in this instance; and the *concentric chuck*, a most ingenious piece of mechanism—a flat plate with two slits almost to the center, and in line of a diameter, within which slits works a spindle, with screw-ends carrying two steel studs, whose heads project through the slits above the surface on the right side; these heads carry two curved pieces, which serve as clamps to hold the work; and as the spindle-screws are of the same fineness, and with right and left threads, the revolution of the spindle either removes both further from the center or brings both nearer to it; hence, when the studs are once set at equal distances from the center, they always remain so, and the work may be removed and replaced without danger of destroying the adjustment. All these chucks are of metal, and are mostly employed for heavy work; turners of wood or ivory preferring wood-chucks, which can be altered as required, and secured by an iron ring round the outside, to prevent splitting. The cutting-tools employed are various; gouges are used to rough out the work—if soft wood—after which chisels with a straight oblique edge are employed; the instruments for harder materials, such as ivory or bone, are smaller than the former, and have their sharp edges "better backed;" for inside-work, drills are first employed to make an opening, and then cutting-tools of various shapes are employed, according to the form which is wished to be given to the interior surface. Fig. 2 represents a full set of twelve tools for use with the lathe. To avoid the imperfections in the workmanship arising from unsteadiness of hand in the workman, the *slide-rest* is employed. This valuable addition is furnished with two motions, one toward the work, and the

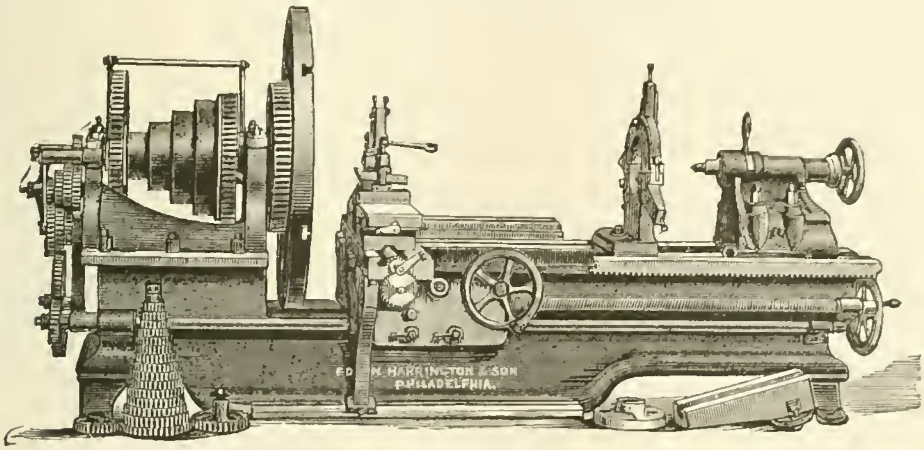


Fig. 1.

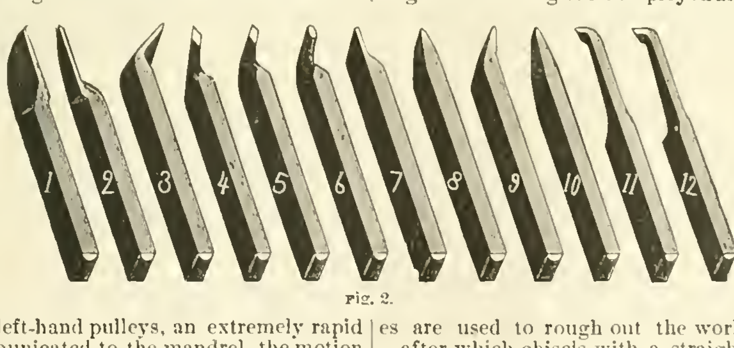

Fig. 2.

other along, parallel, or at any inclination to it, according as cylindrical or conical figures are required; there is a socket for the chisel, which is firmly held in its place by a screw; and after the slide-rest has been adjusted, the operator has only to move the rest forward or sideways, as may be required, the motions being effected by two screws and winches. The *hand-wheel* lathe is similar to the former, but so much larger as to require two workmen, one of whom is employed in setting the instrument in motion by turning a wheel. The *power*-lathe, represented in Fig. 1, is similarly set in motion by horse, water, or steam power, and is used for heavy metal-work, as piston-rods, iron columns of various kinds, wheels, artillery, etc. This machine differs from the foot-lathe chiefly in the substitution of rack-work, and wheels and pinions, for the endless band, and for manual labor, in the various adjustments of the machine, such as in moving forward the tail-stock, etc.; and in the mandrel being supported by both puppets of the head-stock. Fig. 3. shows an improved shafting attachment, and when used in connection with the lathe, makes a convenient arrangement for turning a large amount of shafting. The latest patented device in this line is the Pond shaft turning attachment with a rotary force pump. It consists of a reservoir bolted to the sliding rest, having strong housings to be bored to receive plain split rings for size and steadying, or fluted rings that will mill to size. Three cutting tools precede and one water polishing tool follows above rings, and are all on front side of shaft to be turned; on back of shaft opposite the cutting tools is an adjustable support. The pump attached to reservoir driven from lathe-counter, forces water on to each cutting tool. Pressure of each stream can be regulated as desired. The reservoir is so constructed that it catches the falling water which is pumped again without waste. The reservoir may be readily removed, leaving regular lathe for general work.

In wood-turning, the wood is prepared by an axe and rasp, must be lightly though firmly pressed against by the cutting-tool; while metal-work must be cleaned from the sand of the mold or scales of the forge, and in turning, requires less care. Soft woods must be made to revolve with great rapidity; very hard woods and brass require much less velocity; wrought iron and copper, still less; steel, a further diminution of speed; and cast iron, the least velocity of all. After the work has been duly shaped, it requires to be polished; and this is effected while it is still in the lathe and rotating, by applying shark's skin to wood, pumice-stone and chalk to ivory and horn, and emery, tripoli, or putty powder to metals. Hitherto, we have supposed that the axis of revolution of the work is fixed, and consequently that all work was turned to present a transverse circular section; but other forms of section may be easily obtained. The general mode of obtaining these non-circular figures is by screwing on to the mandrel an apparatus, by means of which the work can be thrown out of the center of rotation at regular intervals; but as each different class of form requires a separate kind of apparatus, it is impossible here to describe the operations in detail. One species, however, known as *rose-engine turning*, and employed for producing involved curvilineal figures, such as appear on bank-notes and on ornamented gold, silver, or gilt work, is so peculiar and ingenious as to call for more special notice. In this species, the standards which support the mandrel are no longer fixed at right angles to the bed, but are capable of oscillating backward or forward in a plane parallel to the plane of rotation of the mandrel, and are so acted on by a spring that when pushed to one side they are at once restored to their former position on the pressure being withdrawn. Suppose, then, a metal wheel with its rim waved or indented, fastened concentrically on the mandrel, and the mandrel, pushed aside by a fixed steel point or roller, applied to the rim of the wheel; the reaction of the spring against the pressure of the roller will keep the latter in close contact with the waved rim throughout, and will produce a definite oscillatory movement of the mandrel of the chuck, and the work fastened on it, and consequently—the cutting or graving tool being firmly held by the slide-rest—definite deviations from a circle in the lines marked on the face of the work. The wave-rimmed wheel, called a *rosette*, may be replaced by another, and that by a third, and so on till a sufficient number of different waved lines are obtained. A number of rosettes are generally strung at once on the mandrel, and the fixed guide is brought into gearing by means of a steel band called a rubber, with one rosette after another. Similar concentric curves of greater or less perimeter are obtained by removing the slide-rest from, or bringing it nearer to, the axis of revolution. See *Axle-lathe*, *Engine-lathe*, *Hand-lathe*, *Heading-lathe*, *Shafting-lathe*, *Spinning-lathe*, and *Turning*.

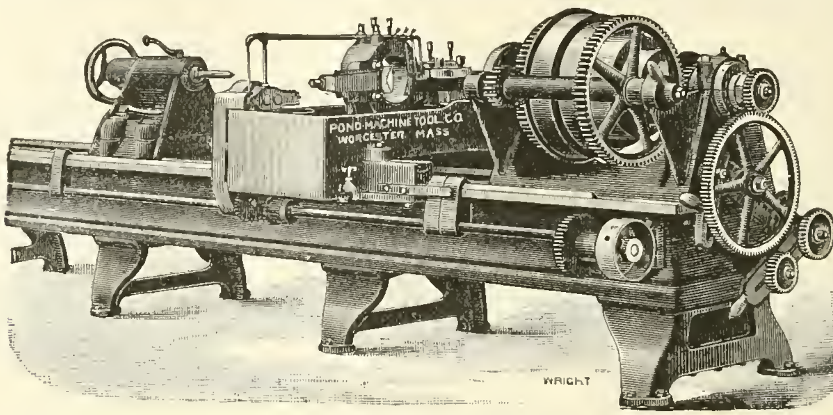

Fig. 3.

LATIGO STRAP.—A strong strap of leather used with the aparejo-cincha to tighten the aparejo. It is about 6 feet long, 1½ inches wide at one end and tapering to ½ inch at the other. See *Hammer-cloth* and *Packing*.

LATRINES.—Conveniences for soldiers in camps and barracks. Much attention has of late been devoted to their construction, a large percentage of the army sickness having been traced to their defective and impure condition.

LATTE.—A *straight* saber used by the cuirassiers in France.

LATTICED.—Latticed, or Treille, in Heraldry is a term applied to a shield covered with a decoration resembling fretty, but differing in this respect, that the pieces do not cross over and under each other: those directed from dexter chief to sinister base are placed uppermost and *cloué*, that is have nails inserted at the joints. See *Heraldry*,

LAUNCH.—To launch a gun or other object forward or backward is to move it in the direction of its axis. If the weight is such as to require levers or handspikes, they are placed, usually, on opposite sides, and the power applied by bearing down, at the same time carrying the free end of the lever in a direction contrary to that in which the object is to be moved,

LAUNDRESS.—A camp woman, usually the wife of a soldier, employed to wash soldier's clothing.

LAUREL.—By the ancient Greeks, the laurel was called *daphne*; it was sacred to Apollo. Berry-bearing twigs of it were wound round the forehead of victorious heroes and poets; and in later times, the degree of Doctor was conferred with this ceremony whence the term *Laureation*; and, according to some the term *Bachelor*. And to this day a laurel crown is the emblem of honor to which poets, artists and warriors aspire.

LAVURE.—The grains, dust, or detached pieces of metal which fall in casting cannon.

LAW.—Blackstone says Law means the rules of human action or conduct. This definition is too wide, for it is confined only to such rules as Courts, supported by proper authority, will enforce. The Law of Nature consists of those laws which are common to all mankind, and are supposed to be, as nearly as can be conjectured, independent of the accidents of time and place. The Civil or Municipal Law of a nation is what is commonly understood by the term Law, when applied to a particular country. The "Civil Law" is also sometimes used *par excellence* to denote the old Roman Law as embodied in the *Institutes* of Justinian, the Code, and other parts of what is commonly called the *Corpus Juris Civilis*, Many of the leading doctrines of that Law have been adopted by modern nations. England is the civilized country which has adopted the least from the Code of Law, while Scotland follows Continental nations in adopting the Roman or Civil Law to a large extent, and on many subjects in adopting it entirely. The Law of Nations is subdivided into Public International Law, and Private International Law, or the *comitas gentium*. Law is often used in England as contradistinguished from equity, but this is chiefly due to the accidental circumstance that there is a subdivision of Courts into Courts of Law and Equity, according to the nature of the remedy given. Law is also often in popular parlance distinguished from Justice, the latter being supposed to be perfect in its nature, or as near the standard of perfection as can be supposed; whereas there are numberless cases of injury, hardship, and oppression which, owing to human infirmity, no system of human laws can adequately redress; and this is often adduced as confirmation of the doctrine of future rewards and punishments. Law is also sometimes subdivided into Criminal Law, Constitutional Law, etc., according to the particular subject matter. See *Articles of War*, *Execution of Laws*, *International Law*, *Martial Law*, and *Military Law*.

LAW OF ARMS.—Certain acknowledged rules, regulations, and precepts, which relate to war, and are observed by all civilized nations. The Law of Arms also shows how to proclaim war, to attack the enemy, and to punish offenders in the camp, etc.

LAW OF NATIONS.—Such general rules as regard the Embassies, reception and entertainment of strangers, intercourse of merchants, exchange of prisoners, suspension of arms, etc. See *International Law*.

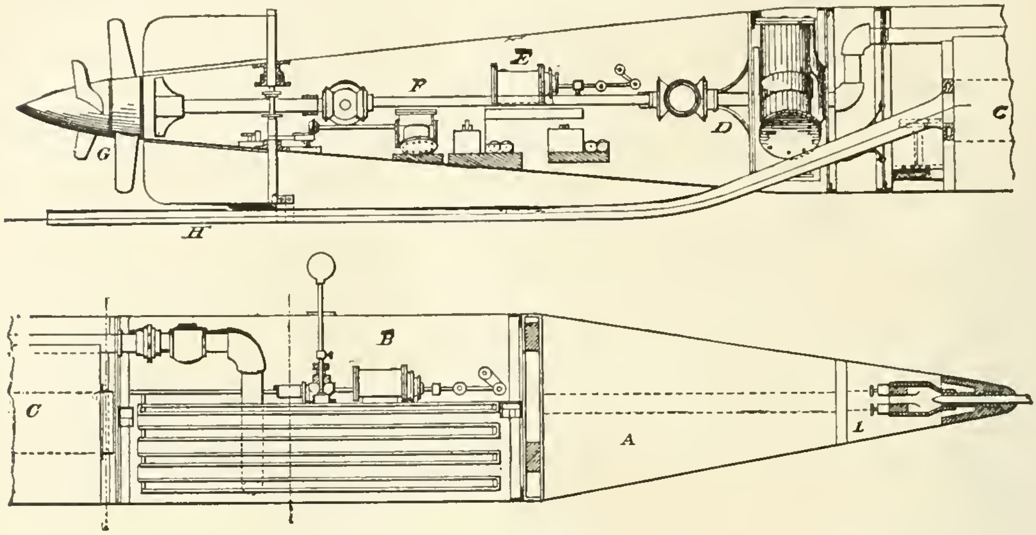
LAWS OF WAR.—The recognized rules for the conduct of civilized warfare. These rules relate to the treatment of prisoners, non-combatants, spies, traitors, etc.; the disposition of private property, the rights of capture, occupation and conquest, the establishment of blockades, the rights and obligations of neutrals, etc.

LAYETTE.—A three-sided tray or box without a cover, used to carry powder from one mortar to another in powder-mills.

LAYING A GUN. In gunnery, pointing a gun so that the projectile shall strike the object aimed at. This is effected by bringing the top of the notch of the hind sight, the apex of the foresight (whether muzzle or trunnion), and the object in line. In laying a rifled gun, the scales for elevation and deflection must be first adjusted. This being done, No. 1 of the gun's crew proceeds to lay the gun. He places himself in rear of the gun, bringing his eye to a level with the top of the hind sight, and about 6 inches in rear of it, and, when laying guns where it is necessary to stoop, places his feet so that the body is well balanced, steadying himself by leaning on the gun with his arm, and gives the necessary orders for elevating or traversing, until the gun is laid as above; with field guns he himself elevates or depresses. With guns fitted with a traversing bar, the final adjustment is given by No. 1 himself. In laying a gun, it is well to avoid putting the back of the nail on the top of the sight, the hand to cover the eye, holding the tangent scale, or other peculiarity. In breech-loading and muzzle loading rifled guns, provision is made in the sighting to meet what is known as the *constant deflection* of such guns caused by rifling. To provide also against deflection by wind or other inaccuracies, such as one wheel being higher than another, a deflection scale is attached to each gun. Formerly, guns which had no tangent scale were elevated by means of the quarter sights or quadrant.

LAY TORPEDO.—From the date of the destruction of the rebel ram *Albermarle*, in 1864, by a spar torpedo invented by W. W. Wood and John L. Lay, Col. Lay has devoted his entire time to the invention and construction of submarine torpedoes. Several forms of Lay spar torpedoes to be operated on ship-board are in use in the Russian Navy. The torpedo or explosive charge, usually of dynamite, is fixed to the end of a long spar, and is thrust out from a swift torpedo boat, or armor-clad ship, under the hull of a vessel sought to be destroyed, and there exploded. The electrical self-propelled torpedo boat of Lay's invention is in extensive use in Europe, especially in Russia; and two such boats are owned by the United States Government. Some of the Russian boats were built in the United States. The boat is a spindle; in length, some twelve or fifteen times its diameter. The boats are built from 600 pounds to 2½ tons in weight, and cost from $3,000 to $15,000 each. Each boat carries a propelling engine, the motive power being usually carbonic acid gas, retained in a chamber or reservoir, under a pressure of 600 to 1,000 pounds per inch when the reservoir is first charged. The throttle valve is opened and closed by a magnet, or by a gas cylinder actuated by a magnet. The boat carries a coil of telegraph cable, of about the specific gravity of water. As the boat advances, the cable is reeled off, and passes out of the boat through a pipe, which conveys it back past the screw propeller. When the cable reels out, sea-water is permitted to enter the cable compartment, and so maintain the specific gravity of the boat. The rudder can be set to port or starboard, or held amidships, by means of an engine controlled by a magnet in connection with the telegraphic cable.

The boat will usually run just under the surface of the water, but can be raised or lowered in the water by the admission or ejection of water-ballast, the water being forced out of the ballast chambers by the pressure of gas from the gas reservoir when a cock controlled through the wire is turned; or the boat may have rudders to deflect it upward or downward in the water, these rudders being controlled in the same way as the steering rudder. The sight rods, or target rods which project above the water have the forward side painted of a color such as not to be easily distinguished from the water; the side toward the operator is bright colored. These target rods may be fixed on the boat, or may be made to turn down or to telescope into the boat, the movement being controlled in such case by a gas cylinder controlled by a magnet. The firing-pin when thrust in, by encountering an obstacle, cuts out a resistance coil and closes an electric circuit through the cable to fire the charge, which is in the front part of the boat; or the operator on shore or ship-board who directs the boat through the telegraphic cable may fire the charge by a touch of the firing key on the key-board. The shore or operating end of the cable is connected with an electric battery through a switch-board. Suitable keys on the switch-board control the throttle-valve, steering-gear, and all other operative mechanisms on the boat, by a current through a single electric wire. The ingenious electrical devices by which so much is accomplished, are the inventions of Mr. George Haight, Colonel Lay's idea having been to have a separate wire in the cable for each machine on the boat. The front end of the boat, which carries the charge, is sometimes made detachable, and is thrown off from the boat before firing; generally, however, the boat is to be sacrificed with the enemy which it seeks to destroy. The operator, by watching the sight targets through a telescope, is enabled to guide his boat to the enemy with certainty, or, if the enemy is beyond his reach, he can direct the boat back, and by cutting out the firing circuit on his switch-board the boat can be safely handled, as it carries no percussion firing mechanism. The lay torpedo boat can be controlled at a distance of more than a mile and a half. As recently improved, it will run for distances of nearly a mile at the rate of about thirteen knots. The difficulty in obtaining higher speed has been the tendency of the compressed gas to freeze by expansion. Dr. Kellogg, of Hartford, Conn., and Mr. Haight have each devised apparatus to utilize the heat of seawater to prevent freezing, and with the sea at summer temperatures, very good results have been obtained, in increasing the speed of the boat. Mr. G. H. Reynolds, of the Delameter Works, New York, has also made valuable improvements. Messrs. Geo. Haight, W. H. Wood, and William Winsor, of New York, have recently invented an improvement by which the danger of freezing of the gas is substantially done away with, and a speed at the rate of sixteen knots is said to have been attained, with a probability of still further increase. The mechanism by which this increase of speed is obtained is not yet divulged. The Whitehead fish torpedo, of English invention, is somewhat like the Lay torpedo in the fact that it is of spindle shape, is driven by a screw from a gas engine inside, and carries a bursting charge. Here the resemblance ends, as the torpedo, when once pointed and started, is no longer under control, but must go its course, wherever that may tend. As it has less speed and is much more expensive than a rocket of equal size, it would seem to be much less desirable. See *Torpedoes*.



THE LAY TORPEDO (Longitudinal Section).

A. Dynamite Chamber. D. Propelling Engine. G. Propellers.
B. Gas Reservoir Compartment. E. Engine for Operating Diving Rudders. H. Cable Tube.
C. Cable Compartment. F. Steering Engine. I. Firing-pin.

LAZARUS.—A military Order formed at Jerusalem by the Christians of the West when they were masters of the Holy Land. They received pilgrims under their care, and guarded them on the roads from the insults of the Mohammedans. This Order was instituted in the year 1119, and was confirmed by a Bull of Pope Alexander IV. in (1255), who gave it the rule of St. Augustine.

LAZY TONGS.—Before the *lazy tongs*, or pantograph, as it is now known, was introduced much time was spent in contriving some ingenious make-shift to properly transmit the reduced motion from the cross-head or trunnion of the engine. Fig. 1 shows how the Bacon pantograph attachment is applied to one of the adjusting nuts which steady the cross-head on the brass ways, while the cross-head lies in a horizontal plane, as in many of our old-fashioned horizontal engines. One of these adjusting screws is lifted a little, the two long links are shut under each side of the screw underneath the head, and the head then screwed down upon them, making it perfectly rigid, but at the same time not altering any adjustment of the engine. Here a little point must be borne in mind by the party who is applying this device. It will be seen, by reference to Fig. 1, that we have attached the device to the back end of the cross-head on the outside of the guide, and that we must allow the cross-head to travel precisely as far one way as the other, and must take the end of that side of the cross-head to which we have made the attachment for our center line, and not calculate from the center nut shown on that side of the cross-head. Now the post, the top of which is shown in Fig. 2, which supports the other end of the pantograph, must be exactly square with the portion of the cross-head to which we have attached the pantograph, when the cross-head is in precisely the center of its travel. In other words, we must allow the difference between the central nut and the one on the end, as shown, from which to obtain our central line. The arms of the pantograph are shown shut up as much as they can be when attached properly. The support of that end of the pantograph from the post, which is shown at its outer arms, and the cord-screw in the short cross-bar, must be precisely in line when the pantograph is in this position,

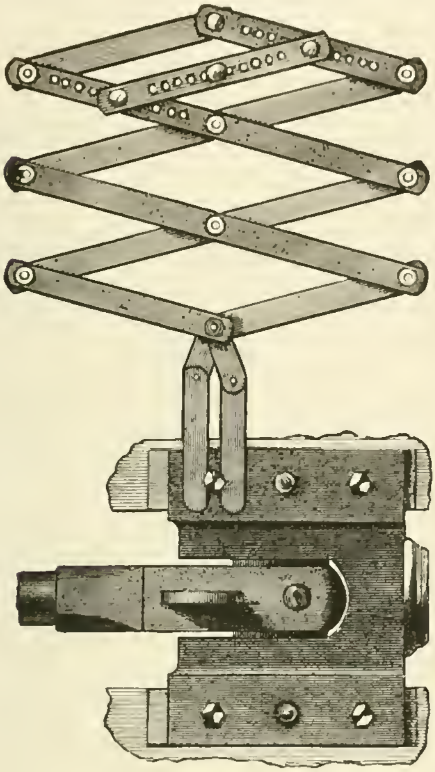


Fig. 1.

else the diagram is worthless. The end of the post must be high enough, so that the pantograph lies perfectly easy and without any cross-friction or draught. Fig. 2. shows the application of the attachment to a

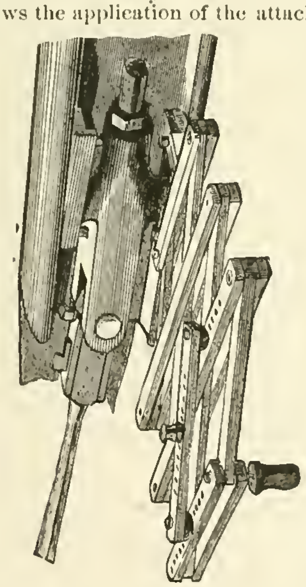

Fig. 2.

perpendicular guide or cross-head, which is vertical. In this particular case the two links are run under the connection between the cross-head proper and the brasses or guides. The head of the post is also shown in Fig. 2. In Fig. 3, we have the Corliss guide where the links are put under the adjusting screw at the top. This may be done by boring a hole into the cross-head and screwing in a piece of three-eighths round iron, the outer end of which is flattened, and has an eye drilled through it, then drop the tapering stud on the out end of the pantograph into the eye whenever it is desired to use the pantograph. Fig. 4 shows the old-fashioned pendulum attached to a vertical guide or way. In this case, a little slot in the lower end of the pantograph

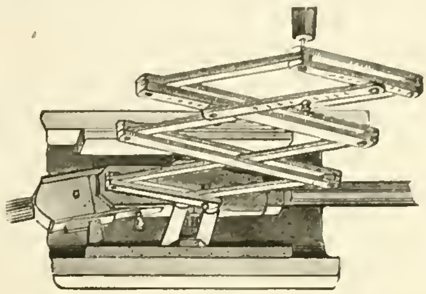

Fig. 3.

is necessary; the links may not necessarily be used in the positions shown, but may be brought up at right angles, leaving the slot to make allowance for the circle described. This attachment avoids drilling, tapping, taking out the screws that confine the gibs, or defacing the engine anywhere. On slow-moving or condensing engines these attachments can be applied so that the pantograph can at any time be hooked on while running, and diagrams can be taken from the high or low pressure cylinder, from the pumps, standpipe, or anywhere that is necessary. It is a simple little convenience, and, as has been

Fig. 4.

so clearly and frequently shown, it saves a great deal of vexation and delay, and ensures more accuracy in the work, if only a little pains are taken. One point must also be observed in using the pantograph—that is, to allow a little leeway between the carrying pulleys of the indicator and the cord-peg. This attachment is solely manufactured and for sale by the American Steam Gauge Company, of Boston. It costs very little, and it is certainly a labor-saving and an annoyance-preventing device. See *Pantograph.*

LEAD.—1. The slight *forward* inclination of the axle-tree-arm is called the *lead;* the *hollow of the arm* and *lead* together are termed the *let* of the arm. 2. A bluish-white metal of considerable brilliancy, which soon disappears on exposure to the air, owing to the formation of a thin film of oxide. It is so soft that it may be cut or beaten into thin sheets, but in ductility and tenacity it is low in the scale of metals. It is readily fusible at a temperature of about 625°, and at a higher temperature it absorbs oxygen rapidly from the air, and the oxide thus formed volatilizes in the form of white fumes. The combined action of air and water on lead is a subject of great practical importance, in consequence of the metal being so frequently employed in the construction of cisterns and water-pipes. The lead becomes oxidized at the surface, and the water dissolves the oxide; this solution absorbs the carbonic acid of the atmosphere, a film of hydrated oxycarbonate of lead ($PbO.HO + PbO,CO_2$) is deposited in silky scales, and a fresh portion of oxide of lead is formed and dissolved, and in this way a rapid corrosion of the metal ensues. This action is materially increased by the presence of some salts and diminished by the presence of other salts in the water.

Pure lead is of very rare occurrence. Almost all the lead of commerce is obtained from galena, the native sulphite of lead, by a process to be presently explained. The lead thus obtained is often *nearly* pure, and to obtain it *perfectly* pure it should be reduced with black flux from oxide left by igniting pure nitrate or carbonate. The compounds of lead with oxygen are four in number—viz., a suboxide Pb_2O, which is a black powder of no importance; a protoxide, PbO, which is the base of the ordinary salts of the metal; a binoxide, PbO_2: and red lead, which is a compound of the two last-named oxides, and is usually represented by the formula $2PbO,PbO_2$. The protoxide is commonly known as *Litharge.* It is obtained on a large scale by the oxidation of lead in a current of air, when it forms a scaly mass of a yellow or reddish tint. If the oxidation be effected at a temperature below that required for the fusion of oxide, a yellow powder, termed *Massicot*, is obtained. Litharge is much used by the assayer as a flux; it enters largely into the composition of the glaze of common earthenware, and it is employed in pharmacy in the preparation of plasters. A mixture of 1 part of Massicot with 10 of brickdust, made into a paste with linseed-oil, forms the compound known as *Dhil Mastic*, which, from the hardness with which it sets, is frequently employed to repair defects in stone-facings.

The most important of the salts of the protoxide of lead are—1. The *Carbonate* (PbO,CO_2) which occurs native as a beautiful mineral in transparent needles or fibrous masses, and which is prepared under the name of *White Lead* on a large scale as a pigment by a process to be subsequently described. The carbonate is insoluble in water, unless it is largely charged with carbonic acid. It is quickly blackened by exposure to hydrosulphuric acid (sulphureted hydrogen), either in the form of gas or in solution, and this is a serious drawback to the use of the lead salts as pigments. 2. The *Sulphate* (PbO,SO_3), which occurs native in white prismatic crystals, and is formed as a heavy white precipitate on adding sulphuric acid or a soluble sulphate to a soluble lead salt. 3. The *Nitrate* (PbO,NO_5), which is formed by dissolving lead or its protoxide in dilute nitric acid. 4. The *Chromates*, of which the principal are the neutral chromate or *Chrome Yellow* (PbO,CrO_3), and the dichromate or *Orange Chrome.* These are much used in pigments, and in calico-dyeing. 5. The *Acetates.* The ordinary or neutral acetate ($PbO,C_4H_3O_3+3aq.$) is prepared on a large scale by the solution of litharge in distilled vinegar, and evaporation, when the salt is obtained in four-sided prisms, or more commonly in a mass of confused minute white crystals, which at 212° lose their water of crystallization. From its appearance, and from its sweetish taste, it derives its name of *Sugar of Lead.* It is much used both in medicine and in the arts. Basic acetate of lead, regarded by some chemists as a diacetate, and by others as a triacetate, and commonly known as *Goulard's Extract*, is prepared by boiling a solution of sugar of lead with litharge, and adding alcohol, when the salt separates in minute transparent needles. It is the active ingredient of *Goulard Water*, which is imitated by the *Liquor Plumbi Diacetatis Dilutus*, and of *Goulard's Cerate*, which is imitated by the *Ceratum Plumbi Compositum* of the London pharmaeopœia. The best tests for solutions of the salts of lead are the formation of a black sulphide with hydrosulphuric acid, or hydrosulphate of ammonia, insoluble in an excess of the reagent; of a white insoluble sulphate with sulphuric acid, or a soluble sulphate; of a yellow chromate with chromate of potash; and a yellow iodide with iodide of potassium. All the salts of lead, insoluble in water, are soluble in a solution of potash. Before the blow-pipe on charcoal, the salts of lead yield a soft, white bead of the metal, surrounded by a yellow ring of oxide.

Lead was largely worked by the Romans in Great Britain, and pigs with Latin inscriptions have been frequently found near old smelting-works. The mining of lead in England was formerly regulated by curious laws; some places, such as the King's Field, in Derbyshire, having special and peculiar privileges. It was the custom in this district not to allow the ore under any circumstances to leave the mine till it was measured in the presence of an official called a *bar-master*, who set aside a 25th part as the King's cope or lot. Up to a comparatively recent period, persons were allowed to search for veins of the ore without being liable for any damage done to the soil or crops. Lead ore is pretty generally distributed, but by far the largest supply of this metal is obtained from Great Britain and Spain, the former country yielding some 75,000 tons per annum, and the latter probably an equal supply. Nearly a fourth of the total British produce is procured from the Northumberland and Durham district, where there exists, at Allenheads, one of the largest mining establishments in the world. Scotland and Ireland furnish only a very small quantity. With the exception of a little from the carbonate of lead, all the supplies of this metal are obtained from the sulphide of lead or galena. The lead ore, when taken from the mine, is broken up into small pieces, "hotched," and washed, to separate impurities. Sulphide of lead, when tolerably pure, is smelted with comparative ease. It is first roasted in a reverberatory furnace. From 20 to 40 cwts. of galena are put into the furnace at a time, either with or without lime. In about two hours the charge becomes sufficiently roasted. During the process, the larger portion of the ore (PbS) takes up four equivalents of oxygen, and becomes sulphate of lead (PbO,SO_3), a little oxide of lead (PbO) is also formed, while another portion remains unaltered as sulphide of lead. After it is roasted the ore is thoroughly mixed together, and the heat of the furnace suddenly raised. This causes a reaction between the unchanged and the oxidized portion of the ore, and reduces much of the lead, sulphurous acid being at the same time evolved. In the third stage, lime is thrown in and mixed with slag and unreduced ore. When this becomes acted on, the whole of the lead is practically separated from the ore, and is then run off at a tap-hole.

In some districts, the roasted ore is smelted on a separate ore-hearth called the Scotch furnace, where the heat is urged by bellows. Peat and coal are used as the fuel. This is a slower mode of smelting than the last, but yields a purer lead. During the operation of smelting, a considerable quantity of lead is volatilized, and carried off as *fume* or *smoke*, which, when allowed to escape into the atmosphere, not only involves a loss of lead, but destroys all vegetation for some distance around the works, and poisons cattle and other animals feeding near them. Much attention has of late been paid to the obviating of these evils, and several plans are in use for the purpose. Where it can be done no method is more effective than simply conducting the smoke from the furnaces through a long horizontal flue—say a mile in length—to a vertical stack. The fume condenses on the sides, certain openings being left for the purpose of collecting it. About 33 per cent. of the fume thus recovered consists of metallic lead. When lead contains antimony and tin as impurities, they are separated by fusing the metal in shallow pans, and allowing it to oxidize at the surface. In this way the antimony and tin form oxides, and as such are skimmed off.

Lead is an important metal in the arts. Rolled out into sheets, it is largely used for roofing houses, for water-cisterns, and for water-pipes. It is also of great service in the construction of large chambers for the manufacture of sulphuric acid. Its value for the manufacture of shot is well known. Alloyed with antimony, etc., it is largely consumed for type-metal, and with tin, for solder. Much lead is also required for the manufacture of pewter, Britannia Metal, etc.

Of the compounds of lead, other than alloys, which occur largely in commerce, the following are the principal: *White Lead* or *Carbonate of Lead*, a substance very extensively used as white paint, and also to form a body for other colors in painting. As much as 16,000 tons of it are annually made in England. White lead is still largely made by the old Dutch process which consists in treating metallic lead, cast in the form of stars or gratings, in such a way as to greatly facilitate the absorption of carbonic acid. These stars of lead placed in earthenware vessels, somewhat like flower-pots, and containing a little weak acetic acid, are built up in tiers in the form of a stack, and surrounded with spent tan or horse-dung. The heat given out from the dung volatilizes the acid, which, along with the air, oxidizes the lead. The acetic acid changes the oxide into the acetate of lead, and this is, in turn, converted into the carbonate by the carbonic acid given off from the hotbed. By this process, metallic lead requires from 6 to 8 weeks for its conversion into white lead. Several less tedious processes for the manufacture of a white paint from lead have been tried at various times, but the only one now practiced is that for the production of an oxychloride of lead, by acting on raw galena with hydrochloric acid. *Minium, Red Lead, or Red Oxide of Lead*, is much consumed in the manufacture of flint-glass and porcelain, and to some extent as a pigment. It requires to be made of very pure lead, as a slight trace of copper would impart a color to glass. Minium is prepared by heating *Massicot*, or protoxide of lead, to a temperature of 600° F. in iron trays, in a reverberatory furnace, carefully avoiding fusion. More oxygen is thus gradually absorbed; and a compound of the protoxide and the peroxide of lead is formed, having a bright red color, which is the red lead of commerce.—*Litharge* has been already noticed.

LEAD COATING PROCESS.—The process of lead-coating projectiles, chemically, as adopted by Ordnance Officers, is as follows: 1. The projectiles must be turned off smoothly and brightly. 2. Keep them in a pickle or solution of zinc and vitriol (proportion three pounds of zinc to each pound of vitriol,) until they show a metallic appearance; about 20 pounds of vitriol to 100 shells of nine pounds, and enough water to cover the surface to be coated; the projectiles being set upright in a wooden box lined with lead. The zinc prevents the acid from acting too violently on the iron. 3. After the pickle, immerse them in clear water, and then in a bath of one pound of lime to 2¾ gallons of water. 4. Rub the surface with rags and sand until a clear metallic appearance shows itself; wipe dry with rags and saw-dust; brush off the saw-dust. 5. Heat the projectiles to that degree that a drop of water thrown on them will boil at once. 6. Dip them in a solution of one part of sal-ammoniac to four parts of water (hot.) 7. Then cover them with a thick layer of powdered sal-ammoniac. 8. Being perfectly dry, dip them into the molten zinc until they have the same temperature as the zinc. 9. Wipe off the dripping zinc with gloves previously saturated with the solution of sal-ammoniac (6). The gloves must have dried without being wrung. 10. Cover them again with powdered sal-ammoniac. 11. Dip them into molten pewter for about half a minute. (For projectiles of hardened iron the coating with zinc is dispensed with.) 12. Wipe off the dripping pewter with the sal-ammoniac gloves. 13. Cover them again with the powdered sal-ammoniac. 14. Put them in the mold and pour the molten lead in. The process to the zinc coating (8) is the same or similar to the galvanizing, only more caution is taken to have very smooth surfaces. The process from the tin coating to the casting must be done quickly. The mold for the final casting is of cast iron, made of two halves, working on a heavy hinge, and connected to a heavy bottom plate, and opened and shut by a pair of long handles. The inside must be polished. Its interior diameter must be a little longer than the diameter of the finished coated projectile. The mold, prior to casting, is warmed so that drops thrown on will boil at once, and receives a coating of grease, which should be allowed to dry before casting. The casting is tested by making incisions which will show whether it adheres firmly to the iron or will peel off. The projectile is finished by turning off in the lathe the lead coating to the desired dimensions; prove them, and screw in the bottom or head-screws. See *Coated Projectiles*.

LEADERS.—Long paper tubes of small diameters inclosing a strand of quick-match. They are used to communicate fire rapidly from one point to another. The velocity of combustion is from 1 to 2 yards per second, depending upon the size of the tube, being more rapid as the tube is smaller.

Leaders are made by rolling a strip of thin paper, 25 inches wide, as obliquely as possible, on a ramrod, or cut the paper into trapezoids 4 inches wide at one base and 2¼ at the other; paste the edges of the strips 0.25 inch, and roll them on a ramrod so that one end shall be enlarged, funnel-shape. When dry, pass a strand of quick-match through, and let it project about an inch at each end.

To unite them into a long line, insert the end of one into another a distance of .75 inch, and tie them with a thread. If the line be long, first stretch a piece of twine, and attach the leader to it every few feet. See *Fireworks*.

LEADING.—The clogging of the grooves of a rifle with lead from the bullet; one of the principal obstacles against continuous accurate shooting. It is obviated by covering the bullet with a paper patch or by using a lubricant in the canellures.

LEADING COLUMN.—The first column that advances from the right, left, or center of any army or battalion.

LEADING FILE.—The first two men of a battalion or company that marches from right, left, or center, by files. See *File-leader*.

LEADING FLANK.—When a line breaks into column in order to attack an enemy, the Leading Flank is that which must always preserve the line of *appui* in all movements in front. The first battalion, or company of every column which conducts, is called the head or leading flank of that column.

LEADING QUESTION.—In the proceedings of Military Tribunals, a question to a witness which suggests the desired answer. Such questions are objectionable except under certain conditions.

LEAD OUT.—A command in the mounted service to cause the horses to be taken from the stable or picket line preparatory to mounting or harnessing.

LEAF SIGHT.—A form of elevating rear sights, consisting of several hinged leaves of different heights. It is usually attached to the tangent sight, and is often called a *Sliding Leaf-head*. See *Sight*.

LEAGUE.—1. A measure of length of great antiquity. It was used by the Romans, who derived it from the Gauls, and estimated it as equivalent to 1500 Roman paces, or 1.376 modern English miles. The League was introduced into England by the Normans, probably before the battle of Hastings (1066), and had been by this time lengthened to 2 English miles of that time, or $2\frac{3}{10}$ modern English miles. At the present day, the League is a nautical measure, and signifies the 20th part of a degree—i. e., 3 geographical miles, or 3.456 statute miles. The French and other nations use the same nautical league, but the former nation had (until the introduction of the metrical system) two land-measures of the same name, the legal posting-league = 2.42 Eng. miles, and the league of 25 to the degree, which is = 2.76 statute English miles.

2. The term generally employed in the 16th and 17th centuries to designate a political alliance or coalition. The most famous Leagues were those of Cambray, Schmalkald, Nürnberg, etc. But the name has a peculiar importance in the history of France,

as applied to the opposition organized by the Duke of Guise to the granting of the free exercise of their religion and political rights to the Huguenots. This League, known as the Holy League, was formed at Péronne, in 1576, for the maintenance of the Roman Catholic Religion in its predominance; but the object of the Guises was rather to exclude the Protestant Princes of the Blood from the succession to the throne. For an account of the civil war that ensued, see *Histoire de la Ligue* (5 vols., Par. 1829).

LEAGUE OF MARBACH.—Under the rule of Count Frederick of Hohenstaufen and his successors, Suabia became the most rich, civilized, and powerful country of Germany, and the Ducal Court was the resort of the Minnesingers; but the wars of the Guelphs and Ghibellines, and the quarrel with the French respecting Naples, put an end to the Dynasty in 1268. The Ducal Vassals in Suabia rendered themselves almost independent, and professed to acknowledge no lord but the Emperor. During these dissensions arose the Lordships of Würtemberg and Baden, with numerous lesser States, holding direct of the Crown, and opposed to them the Cities, which strove also for an equal independence, and at last, in reward of important service, obtained in 1347 great additional privileges. A number of them united to make common cause against the neighboring Feudal Lords in 1376 (known as the *First Suabian League*); an opposite league was formed between Würtemberg, Baden, and 17 towns in 1405, called the League of Marbach; and both took part in the war of Swiss Independence, the former in support of the Swiss, the latter of the Austrians. At last, the towns, which had been rapidly increasing in wealth and power, decided at Ulm, in 1449, to form a standing army, and a permanent military commission, for the forcible preservation, if necessary, of peace and order; and the Count of Würtemberg, the most powerful of the opposite party, having joined them, was appointed Military Chief of the League, which ultimately grew up into the *Great Suabian League*, and exercised both administrative and judicial authority over the whole country, effectively repressing feudal quarrels. In 1512, Suabia became one of the ten circles into which Germany was now divided, received its complete organization in 1563, and retained it almost without change till the dissolution of the Empire in 1806. But during this period, the wars of the towns with Würtemberg, the Peasants' War, of which Suabia was one of the foci, the Thirty Years' War, and those between France and the Empire, destroyed the democratic constitution of the towns, and with it their energy, and then their prosperity disappeared, leaving now no relic which could suggest their former great political importance.

LEAGUER.—1. The camp of a besieging army; less often a camp in general; a siege or beleaguering. 2. A confederate, or one who unites in a league.

LEAST SQUARES.—The method of Least Squares, in astronomy and problems of motion, is the best mode hitherto discovered of obtaining the most correct result from the number of observations upon any phenomenon. These observations are assumed to differ slightly from each other, and to be all of equal value, that is, taken under equally favorable conditions, and with equal instruments. The ordinary and long established mode of approximating to the truth in such cases, is by finding the arithmetic mean, and accepting it as the correct result; but in all cases where the result required does not come directly from observation, but requires to be discovered by calculation, this simple and useful method is inapplicable, and that of 'Least Squares,' which gives more probable corrections, is adopted. The method is founded on a theorem which was first propounded by Legendre in 1806, more for the sake of insuring uniformity among calculators than from any belief in its intrinsic value; but it was afterwards thoroughly discussed and proved by Gauss and Laplace, that "if the mean of a number of distinct observations be so taken, that the sum of the squares of its differences from the actual observations (generally designated *errors*) shall be a minimum, this mean will be, under these circumstances, the correctest obtainable value." The process by which the mean thus obtained is shown to be the most trustworthy approximation is too long for insertion here; but it may not be undesirable to give an example of the most common form of the method as occurring in astronomy. Let there be a series of equations—

$$\begin{aligned} X &= x + y + 2z \\ X_1 &= 3x + 2y + 5z \\ X_2 &= 4x + y + 4z \\ X_3 &= -x + 3y + 3z \end{aligned}$$

where the unknown quantities are x, y, and z, connected by various (the more the better) equations with X, X_1, etc., quantities which must be determined by actual observation. Suppose the value of the quantities thus found to be 3, 5, 21, and 14, then since by hypothesis all these four observations are erroneous, the errors are $3 - X$, $5 - X_1$, $21 - X_2$, $14 - X_3$, or

$$\begin{aligned} &3 - x - y - 2z, \\ &5 - 3x - 2y - 5z, \\ &21 - 4x - y - 4z, \\ &14 + x - 3y - 3z. \end{aligned}$$

The squares of these four errors are now added together; and, to find the values of x, y, and z, which will render this sum (call it S) a minimum, we must differentiate S with respect to x, y, and z in turn, and putting each of these partial differential coefficients equal to zero, we obtain the three equations, $-88 + 27x + 8y + 30z = 0$; $-76 + 8x + 15y + 25z = 0$, and $-157 + 30x + 25y + 54z = 0$; from which the most trustworthy values of x, y, and z can be found by common algebra.

LEATHER.—The skins of animals chemically altered by the vegetable principle called tannin, or tannic acid, so as to arrest that proneness to decompose which is characteristic of soft animal substances. Its invention reaches beyond the dawn of history and was probably among the earliest germs of civilization; for as the skins of animals would naturally be among the first articles of clothing, any means of preserving them more effectually than by drying would be highly prized. The discovery that bark had this effect was doubtless the result of accident. The principle of its action was unknown up to the present century; and the same unvarying method has been employed from the earliest times until the last few years, when the invention of new processes has much faciliated the manufacture.

The skin of all animals used in the production of leather consist chiefly of gelatine, a substance which easily enters into chemical combination with the tannic acid found in the bark of most kinds of trees, and forms what may be termed an insoluble *tanno-gelatin*. This is the whole theory of tanning, or converting the skins of animals into leather. Formerly, oak-bark was supposed to be the only tanning material of any value; but lately very numerous additions have been made to this branch of economic botany.

In addition to the process of tanning in making leather, there are other modes, one of which is *tawing*, another *dressing in oil*. The following are the skins which form the staple of our leather manufacture: ox, cow, calf and kip, buffalo, horse, sheep, lamb, goat, kid, deer, dog, seal, and hog. These are consumed, in a great degree, in the construction of military equipments and appliances. The term *pelt* is applied to all skins before they are converted into leather. When simply made into leather in the state we find in shoe-soles, it is called, "Rough Leather;" but if, in addition, it is submitted to the process called currying, it is termed "Dressed Leather." The following trade-terms are in general use: hides or crop-hides, butts and backs, bends, offal, and skins. The complete hide when rounded, with the cheeks, shanks, and belly-pieces, etc., pared off, is called a *butt;* the pieces cut off constitute the *offal;* and *skins* are all the lighter forms of leather, such as sheep, goat, deer, etc.

Sheep and lamb skins are imported (in the wool) in large quantities from Australia and the Cape of Good Hope. The latter with the cape skin, are used for book-binding, gloves, etc. Lamb-skins are imported also from Italy, Sicily, and Spain, and tewed and dyed for making gloves, in imitation of kid. A great portion of all sorts of lambs and sheep are tawed and used for aprons, sewing harness, plaster-skins, tying up bottles, lining shoes, and other jobbing and inferior purposes. *Deer-skins* are dressed by the oil process, and form a great portion of the so-called *shamoy* leather, which derives it name from the chamois of the Alps, from the skin of which it was formerly made. *Dog-skins* are tanned or tawed for gloves, and for thin shoes and boots. *Seal-skins* are manufactured into the so-called "patent leather," by varnishing their upper surface. The manufacture of this kind of leather has of late become of great importance to the London, Edinburgh, and Newcastle tanners. *Hog* or *pig skins* are imported from Russia and other countries, and many are supplied by Scotland; their use is chiefly in the manufacture of saddles, etc. *Walrus* and *Hippopotamus hides* are tanned in considerable numbers for the use of cutlers and other workers in steel goods, "buffing-wheels" being made of them often an inch thick, which are of great importance in giving the polish to metal. Lately, belts for driving machinery have successfully been made from them. *Kangaroo-skins* of various species are tanned or tawed in Australia, and form a kind of leather in great favor for dress-boots.

The first process in making *tanned sole leather* is to soak the skins or hides in water for a greater or less time, to wash and soften them; they are then laid in heaps for a short time, and afterwards hung in heated rooms, by which means a slight putrefactive decomposition is started, and the hair becomes so loose as to be easily detached. This process of "unhairing" is mostly followed in America; but in Great Britain milk of lime is used for soaking the hide till the hair loosens. Hides or skins intended for dressing purposes, such as shoe, coach, harness, or book-binding, after the hair is taken off by the lime, have to be submitted to a process called "bating," for the purpose of reducing the thickening or swelling occasioned by the introduction of the lime, and for cleansing the skin from grease and other impurities. This is effected by working the skins in a decoction of pigeons' or dogs' dung and warm water, and no dressing-leather is ever submitted to bark or shumac without undergoing this process.

The first attempts at improvement in tanning were the method invented by Mr. Spilsbury in 1823, and the improvement on this method by Mr. Drake, of Bedminster, in 1831. The principle consisted in causing the *ooze* or *tan-liquor* to filter through the hides under pressure. For this purpose, in Drake's process, the edges of the hides were sewed up so as to form a bag. The bags being suspended, were filled with cold tan-liquor, which gradually filtered through the pores of the hides, and impregnated them with the tannin. The processes by infiltration, however, have been entirely abandoned for heavy leather, as they have the effect of rendering the leather porous and deficient in firmness.

Various patents for improvements in tanning have been in operation of late years. Herepath and Cox, of Bristol, tied hides to each other to form a long belt, and pressed them between rollers, to squeeze out the partially exhausted tan-liquor from the pores, so that a stronger liquor might be absorbed. Messrs. J. and G. Cox, of Gorgie Mills, near Edinburgh, made an improvement on this mode by attaching the hides to a revolving drum, so that the hides press on each other on the top of the drum, but hang suspended in the tan-liquor from the lower part; and thus, by the hides being alternately in and out of the liquor, the tanning is quickly effected.

Tawing consists in dressing the skins with antiseptic materials, so as to preserve them from decay; but by this operation no chemical change is effected in the gelatine of the skins; hence, tawed leather can be used in the manufacture of glue. In tawing, the first process is careful washing, next dressing them with lime, then removing the hair or wool, and lastly, steeping them in some one or more of the various mixtures which are used for converting skins into leather by this method.

Besides *tanning* and *tawing*, many kinds of leather require the currier's art to bring them to the state of completion required for military purposes. The currier receives the newly tanned skins, and finds them harsh to the feel, and rough on the flesh-side. He removes all the roughness by carefully shaving with a peculiar knife. After soaking in clean water, he then scrapes the skin with considerable pressure upon a scraping-tool or *slicker*, and thus removes any irregularities. The moisture is then removed as much as possible, and oil, usually cod oil and tallow, are rubbed over the leather, which is laid aside to dry completely, and as the moisture leaves it, the oil penetrates. When quite dried and saturated with the oil, the skin is rubbed on a board with rounded ridges, by which a peculiar grained appearance is given, and the leather is rendered very pliable. In currying, almost every variety of leather requires some variation in the processes employed, but the currier's object is in all cases to give a suppleness and fine finish to the skins.

Morocco Leather, formerly an article of import from the Barbary coast, is now prepared in large quantities in this country from goat-skins; sheep-skins are also used for imitation. It is always dyed on the outer or grain side with some color, and the leather-dresser in finishing gives a peculiar ribbed or a roughly granulated surfaace to it, by means of engraved boxwood balls which he works over the surface.

Russia Leather is much valued for its aromatic odor, which it derives from the peculiar oil of the birch-bark used in tanning it. The fact that this odor repels moths and other insects, renders this leatber particularly valuable for binding documents; a few books in a library, bound in Russia Leather, being effective safeguards against insect enemies. It is also said to destroy or prevent the vegetable evil called mildew, to which books are so very liable.

The drawing represents a side of leather, and is made to the scale of one inch to the foot; the marks show the size and shape of the specimens tested, and the figures give the strain in pounds at which each piece broke, the permanent elongation in fractions of an inch, and weight in ounces and drachms. The pieces were each 11¼ inches long by 2 inches wide, and were taken out of the exact portion of the hide on which they are marked.

These test were made by Messrs. Riehlé Brothers, at the testing department of their works, for the obvious reasons of determining by actual experiment, the tensile strength of the different portions of a side of leather.

These tests have been the means of awakening new interest in important investigations, as to the comparative value of sides of leather for special military purposes, and as to the best means of producing the best results. Until comparatively lately the testing of iron and other metals, excepting by the crudest methods, was almost entirely neglected, but now testing has become a necessity, and the value of metals is determined between buyer and seller by their endurance under certain tests that are brought to bear upon them, and that correspond to the special use that they may be required for. This, no doubt, will also be the method of determining the value of leather, especially that used for belting, etc., and the comparison of tests made with patented and rubber belting is interesting and useful. See *Testing Machines*.

LEATHER CANNON.—A variety of cannon introduced by Gustavus Adolphus into the army on account of their mobility. Undeniable evidence, however, of their earlier existence, though of a smaller size, is found in the "Landeshuter Harnisch-Kammer-Inventarium" of 1562, in which mention is made of a "Lange lederne Buchse mit Kugel-Modell." Although Gustavus Adolphus improved and perfected the leather cannon which he introduced into his army in 1626, and used in the siege of Wormditt, yet neither he nor the German Freiherr Melchior von Wurmbrandt, nor the North British Baron Robert Scot, can be regarded as the inventor. The invention is evidently of much earlier date. A leather mortar for firing shells, on exhibition in the Arsenal at Venice, was, the Venetians assert, made in 1349; it is very likely, however, that its origin is somewhat earlier. One is here reminded of the many substitutes for metal ordnance, especially of the wooden cannon (entirely bound with iron hoops), which are frequently mentioned in the period from 1525 to 1530.

The leather cannon varied from a 1-pr. to a 4-pr. The bore consisted of a copper cylinder, of the thickness of three-fourths of the diameter of the ball used. The length of the cylinder was sixteen calibers; cascable and breech were screwed into the cylinder. The vent, of copper, was screwed into the breech. The entire length of the bore was covered with iron hoops, over which a number of ropes were wound, which, in turn, were covered with several layers of varnish. Over these layers another round of ropes was wound, and over this was spread a layer of cement. This process was repeated until the coat was of the thickness of two calibers; the last coating consisted of tarred leather, which gave the cannon its name. The charge amounted to one-fourth, rarely one-third, of the weight of the ball; the cannon was loaded only with canister. Canister-shot, until that time only used in sieges, was introduced by Gustavus Adolphus into the field service, and consisted mostly of musket bullets, though old pieces of iron were very often used. The shot were put into wooden and tin boxes, linen bags, and sometimes only in rude wicker baskets. The leather cannon, of 90 lbs. weight, with its light carriage, was easily drawn by two men. This cannon, however, by no means met the high expectations entertained of it. Already in 1631 the Swedes ceased using this nature of gun, because at the battle of Breitenfeld it not only became so overheated that the charges ignited of themselves, but it also gave a very short and unreliable range. In 1629, a certain Lieutenant Wolf Muller, of Chemnitz, circulated the report that he was in possession of a secret for the construction of leather cannon which had many and decided advantages over metal ordnance. The Elector of Saxony ordered Colonel von Schwalbach to investigate and to report as to its worth. The report of the Colonel was found to be favorable, and expressed in these words:—"Owing to their light weight, easy transportation, and saving of powder, as well as the advantagos they offer in the field against the enemy, and in mountainous and swampy regions, in which latter places heavy cannon can seldom be used at all, such pieces cannot be too highly regarded," etc. The Elector ordered the construction of two leather cannon, for which were given "fifty-seven florins three groschen ready money; seventeen florins three groschen for sixty pounds pewter; fifty-one florins three groschen for two and one-fourth hundred-weight refined copper. Of the copper, the coppersmith received two hundred-weight, with which he made a tube four and one-half ells long, weighing ninety pounds, and used twelve pounds for muzzle and vent. The waste in melting twice amounted to sixteen pounds, the remainder was left to the smith as pay for his work." The trial with these leather guns could not have been very satisfactory, if we may judge from the following item in a record of weights of the Armory at Dresden, June 14, 1630: "Inventory of the weights of copper and pewter of the *burst leather pieces* in the Elector's Armory at Dresden:—Copper, one-half hundred-weight, twenty-six pounds; pewter, thirty-four pounds." No mention being made of these guns at a later period, it is taken for granted that this one failure was thought sufficient to cool all enthusiasm for leather cannon.

LEAVE OF ABSENCE.—The permission which officers and soldiers of an army obtain to absent themselves from duty. In the British service, in applying for leave, the War Office form is used. The General Commanding has the power to grant leave within monthly returns. For special duties, the officer who is to perform the work in the interim is to be named in the application for leave. The application of a Medical Officer goes first to the principal Medical Officer in the division or garrison; that of a Paymaster to the War Office, accompanied by a certificate from a Board that his accounts are satisfactory, cash balance correct, acting Paymaster engaged, and declaration made that the real Paymaster is answerable for substitute. The application of an officer proceeding on *sick leave* must be accompanied by a medical certificate. If the officer is not likely to rejoin soon, it is usual for the Medical Board to ask the General to assemble the Board, or to get him to apply to the Horse Guards, should the regulations point out this to be the course to be pursued. In the Indian military service, leave of absence includes three kinds:—1. Furlough in or out of India on sick or general leave; 2. General leave on private business, or on sick certificate in India, or short leave to sea; 3. Privilege leave. In the rules which govern an officer's *furlough in* or *out of* India, there is no distinction between *sick* and *general leave* with respect to allowances, hitherto drawn, both being included under the general term, furlough; provision, however, is made for the obtainment of leave under medical certificate without all the restrictions applicable to furlough when taken without it. In the rules under the head of furlough, it is shown that an officer of the Indian Army must serve six years after his return from England or elsewhere, after taking furlough, before he is entitled to any more leave counting as service: but should the officer in question have accumulated leave, so that after two years' absence he has still one or two years leave due him, he will be permitted three years after his return to proceed again on leave without loss or appointment. *Short leave*, not exceeding three months, may be taken to sea on certain conditions; but absence from India for any longer period is treated as furlough. *Privilege leave* for sixty or ninety days (depending upon the part of the country an officer is cantoned in), in each year, is granted to all officers in military employ without loss of allowances; should this time be exceeded, it must be converted into general leave, unless sickness has been the cause of detention.

In the United States service leaves of absence are not granted so that a company will be left without one of its *commissioned officers*, or a garrisoned post without two commissioned officers and competent medical attendance; nor is such leave granted to an officer during the season of active operations except on urgent necessity.

No leave of absence exceeding seven days, except on extraordinary occasions, when the circumstances must be particularly stated, is granted to any officer until he has joined his regiment or corps, and served therewith at least two years. In giving permission to apply for the extension of a leave of absence, the term of the extension is stated. The term of the extension approved by the Department Commander is regulated by the season and the usual opportunities for reaching the officer's station, so that he may not be absent during the time for active operations. Leaves of absence are granted for periods specified as "one month," "one month and ten days," "two months," etc., instead of so many days, and commences on the day the officer departs from his proper station. The expiration of his leave must find him at his post. Leave for one month, beginning on the first day of a calendar month, expires with the last day of the month, whatever may be its number of days. Commencing on an intermediate day of a month, the leave will expire with the day preceding the same day in the next month. The day of departure, whatever the hour, is counted as a day of absence; the day of return, whatever its hour, as a day of duty. The Commander of a post way take leave of absence not to exceed seven days at one time, or in the same month, reporting the fact to his next Superior Commander; and in time of peace the Commander of a post may grant leaves of absence not to exceed seven days at one time, or in the same month. A Department Commander may grant leaves for one month, or extend to that period those granted by Post Commanders: a Military Division Commander, for two months, or extend one month a leave granted by a Department Commander under him; the General of the Army, four months, or extend to that period a leave already granted. Applications for leaves of absence for more than four months, or to officers of Engineers and Ordnance, or officers of the General Staff or serving on it (Aides-de-Camp excepted), for more than one month, are referred to the Adjutant General for the decision and orders of the Secretary of War. Officers are not permitted to leave the United States, to go beyond sea, without a special permission from the War Department. Officers of the army traveling or stopping in foreign countries, whether on duty or leave of absence, are expected to avail themselves of all opportunities, properly within their reach, for obtaining information of value to the military service of the United States, especially that pertaining to their own arm or branch of service. Verbal permits for less than twenty-four hours are not counted as leaves of absence. But for every other absence of whatever duration, the date of departure and return is noted on Post, Regimental, Department, and Division Returns against each officer borne thereon. Permission to hunt is not considered as a leave of absence or charged as such if the officer, on his return to his station, files with his Commanding Officer a certificate that his absence has been solely employed in hunting, and furnishes as complete a description of the country passed over as circumstances permit. Officers when absent on account of sickness or wounds, or lawfully absent from duty and waiting orders, receive full pay; when absent with leave for other causes, full pay during such absence, not exceeding in the aggregate thirty days in one year, and half-pay during such absence exceeding thirty days in one year. When absent without leave, they forfeit all pay during such absence, unless the absence is excused as unavoidable.

By an Act of Congress approved in 1876, an officer may permit his leave to accumulate for a period not exceeding four years. He may, moreover, enjoy five months' continuous leave on full pay, if the fifth month of such leave is wholly distinct from the four year period. An officer on leave over this time receives half-pay only. When an officer is absent under certificate of disability duly accepted, on account of sickness or wounds, he is entitled to the same pay as if an order had been issued granting him a sick-leave. Officers absent on certificate of disability should so arrange that the certificates may cover entire calendar months, and not monthly periods commencing with intermediate days. The pay-account of every officer on leave should, throughout the period of his absence, exhibit the date of commencement of leave, the authority for his absence, and in case the account is for the month in which the absence terminates, the date of return to duty. In all cases the day of departure or relief from duty is counted as a day of absence, and the day of return as a day of duty. In determining the portion of a leave of absence for which an officer is entitled to full pay, no time is considered outside of a period of four successive leave years, including the leave year or years in which the absence is taken. The leave year is reckoned from June 20th to the following June 19th inclusive. In estimating the period of absence during any one leave year, each and every day's absence is included. Every officer who is dropped by the President from the rolls of the Army for absence from duty three months without leave, forfeits all pay due or to become due. See *Furlough* and *Sick-leave*.

LE BOULENGE CHRONOGRAPH.—In this instrument the time between two events is ascertained by noting the distance of the *free* fall of a heavy body during the interval, the beginning and end of this distance being made to accord with the occurrence of the events by means of the galvanic current. It can be used not only as a micro-chronometer, but directly as a velocimeter. The drawing shows the instrument ready for use, for taking velocities, and for measuring minute intervals of time To obtain velocities at once, two electric circuits are established, a fixed distance, say fifty meters, apart, in such a manner as to be successively broken by the projectile in its flight. The first current circulates through the electro-magnet A, whose armature is a long cylindrical rod C, called the *chronometer*, furnished with two enveloping zinc tubes, D and E, called *recorders*. The second current passes by the electro-magnet, B, whose armature, the shorter rod, F, is called the *registrar*. The third active element of the instrument is the *indenter*, consisting of a circular knife, fixed in a mainspring, which can be cocked by means of a catch on a lever.

On the breaking of the first circuit, the chronometer falls vertically; on the rupture of the second the registrar falls in its turn, depresses the free end of the lever, and thus releases the mainspring; the knife juts forward, strikes the falling chronometer, and indents the upper recorder. As shown below, a very simple relation holds between the dent thus obtained and the velocity of the projectile which caused it. Even with this brief description, a moment's thought will show that the lower the velocity the higher up shall the recorder be indented.

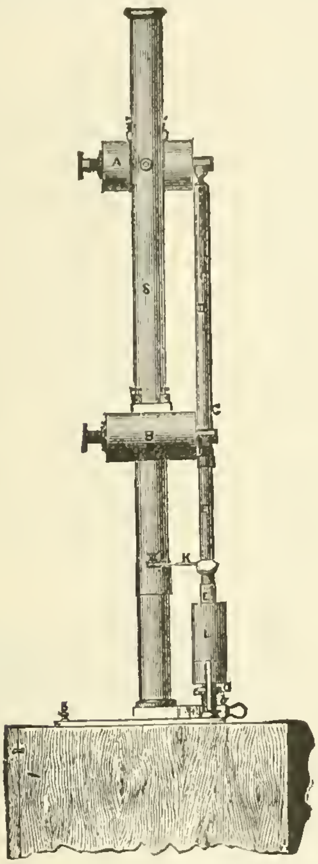
The above succint account of the action of the instrument is sufficient for a comprehension of its theory. As an *origin* of reference for the falls of the chronometer, we take the dent imprinted on the lower recorder, when the knife is "let off," while the chronometer is suspended. Let h be the height above the origin of the dent due to the shot; then, as the chronometer followed the law of falling bodies from the beginning of its movement up to the time it was struck by the knife, we have $T' = \sqrt{\frac{2h}{g}}$ as the time corresponding to this fall. It would also be the time of the trajectory between the targets (giving a velocity of $\frac{50}{T'}$ meters to the projectile), provided the chronometer began its fall at the precise instant the first, and the knife struck it at the precise instant the second current was broken. But this is, in reality, not so; for, after the breaking of the first current, a certain interval, ϕ, elapses before the electro-magnate is sufficiently demagnetized to permit the fall of the chronometer, which will accordingly be retarded by this time, and the observed duration of trajectory will be too small by the same quantity.

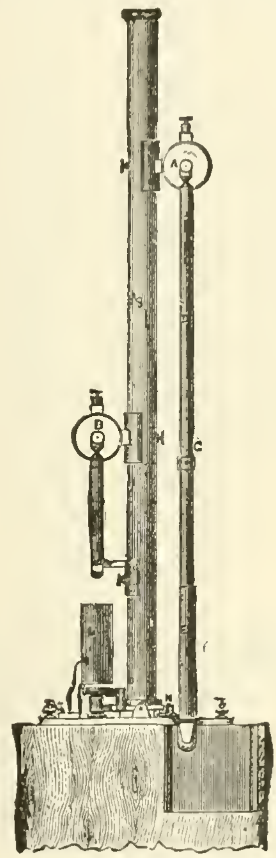
On the other hand, from the breaking of the second current up to the instant of the knife striking the chronometer, the following intervals elapse: o' for the sufficient demagnetization of the electro-magnet, B. t' for the fall of the registrar to the disk of the indenter. t'' for the release of the catch. t''' for the knife to clear the horizontal distance to the falling chronometer. The observed time T' is then too great by the quantity $(o' + t' + t'' + t''')$, and too small by ϕ. For the true time of flight, T, we have, therefore, $T' - (o' + t' + t'' + t''' - \phi) = T' - t$. For $T = \phi$, we have $T' = t$, whence to obtain the value of t we have only to break both circuits simultaneously, and note the resulting time of fall; since after this common rupture, there passes the time ϕ before the chronometer falls, and $(o' + t' + t'' + t''')$ before it struck; until it is dented there elapses then the time $(o' + t' + t'' + t''' - \phi)$ or t. As will be shown presently, the instrument can be so adjusted as to give t a constant value, say $0''.15$. Whenever desirable, we can very readily ascertain whether the apparatus is thus adjusted or not, by using the *disjunctor*, which is in both circuits. If the resulting dent is 110.29mm above the origin (the height corresponding to 0″.15 at Watertown Arsenal), then the instrument is properly set. Dependent upon this condition, we can fix in advance the height corresponding to any given velocity of projectile. For example, with an initial velocity of 500 meters, the projectile will pass over the 50 meters' interval between the circuits in 0″.1, and the instrument will record 0″.15+0″.1, or 0″.25, and the height will therefore be

$$H = \frac{9.8037 \times 0''.25^2}{2} = 306.36^{mm}.$$

Reciprocally, if the shot gives a dent 306.36mm above the origin, we conclude that the projectile was moving with a velocity of 500 meters. The heights corresponding to all velocities within the ordinary limits of experiments have been calculated and inscribed

also serves as a stand for mounting it. After unpacking the box screw on the sectional iron tripod, then stand it independently of the floor, so that it may be subject to as little vibration as possible, and fasten securely in its place the triangular plate that carries the indenter and column. The electro-magnets are commonly attached by passing the threaded stems through the column, and then tightening with the milled nuts. The disjunctor should be placed very near the instrument, within easy reach of the operator. Ordinarily one seven-inch chromic potash cup will be found sufficient for the registrar circuit, and three cups for the chronometer. As so little power is required, we would recommend, if easily attainable, that Daniell's or Hill's batteries be used as giving most constant action. Two recorders are put on the chronometer. These tubes should be lightly tapped, before being slipped on, to insure a snug fit. Care must be taken that the lower recorder rests closely against the bob.





on a metal rule, furnished with a sliding index, which thus affords a simple means for *directly* measuring the velocity of the projectile fired. The shot having given the indent, we adjust the rule to the chronometer, slide the beak of the index into the notch, and read off the velocity.

As has already been stated, when it is desired to measure velocities directly, two targets must be set up 50 meters apart. The chronometer circuit passes through the first, and the registrar through the second, the disjunctor being in both. Should local difficulties intervene to prevent the targets being set up exactly 50 meters apart, multiply the velocity read from the scale by the constant ratio $\frac{D}{50}$ where D is the actual space in meters. For transport, the different parts of the instrument are packed in a box, which

The currents being properly established and sufficiently strong to enable the magnets to maintain the rod-armatures, the next step is the adjustment of the apparatus, which comprises these three operations: 1. Leveling the instrument. 2. Regulating the power of the electro-magnets. 3. Fixing the height of the disjunctor-reading. The instrument is set up for firing in the same manner as for taking a disjunctor reading. To avoid confusion, numbered ink-marks, about one-sixteenth of an inch apart, are made around the bases of the two recorders, and each mark is successively brought in line with the cut on the ring as the firing progresses, by which means the dents are made on equidistant straight-line elements. The zincs can thus receive about twenty dents, and then be turned end for end and receive twenty more. The shot having given a dent, apply the rule to the chronometer in the manner described for tracing the disjunction circle, bring the vernier-knife against the edge of the notch, clamp it, and read off the velocity. The experiments for the day being over, the date is inscribed on the proper recorder, and, if deemed necessary, it may be filed for future reference. If the foregoing directions as to the setting-up and adjustment of the instrument are carefully followed, not only will there be no appreciable variation in the disjunctor-readings before any shot, but they will, remain constant from round to round. See *Breger Chronograph*, *Chronoscope*, *Disjunctor*, *Indenter*, and *Micro-chronometer*.

LEE.—A term employed in target practice to denote the quarter to which the wind is directed, as distinguished from *windward*, or the part *whence* the wind comes. Also written *Leeward*.

LEEK.—The Welsh emblem, in consequence of a command from Dewi, or David, afterwards Archbishop of St. Davids', in 519. On the day that King Arthur won a great victory over the Saxons, Dewi is said to have ordered the soldiers to place leeks in their caps.

LEE MAGAZINE-GUN.—This gun, patented in 1879 in Europe and America, is entirely novel in principle and not only obviates all the objections found in tubular magazine systems, but has numerous and marked advantages peculiar to itself. The arm is of the bolt class, which years of use in the armies of Russia, France, Italy, Prussia, and other great powers, has proved to possess all the essential qualities of a military weapon. The drawing gives a sectional view of this gun with the magazine in place, and it will be noticed that the parts are few in number. The resistance in this gun is direct, and is taken on both sides of the receiver; a lug being constructed on the lower side of the bolt and opposite the shoulder on the bolt handle, which locks itself firmly into a recess made for that purpose in the receiver, thereby affording an equal bearing on each side instead of on one side only, as in most other bolt systems. The extractor, also, is of new design, having direct action and great power.

notch cut on the extractor-spring next the shoulder of the bolt handle, the extractor-spring, Q, is pressed forward, releasing the hook on its under side, from the pin with which it engages when in place. This releases the extractor-spring and the extractor, and the bolt may then be drawn out of the receiver. By pressing forward and downward on the lug of the key-sleeve, F, it is released from the bolt, together with the thumb-piece, E, the firing-pin, C, and the mainspring, D. To assemble the bolt and its parts, the pieces, E, C, and D, are placed in their proper position, and the lug of the key-sleeve, F, is pressed upward into its locking-notch in the bolt. Returning the assembled bolt into its place in the receiver, lay the extractor in its notch on the bolt and place the extractor-spring in position, giving the bolt a sharp push forward, and the hook will engage itself on the pin on the bolt-rib created for the purpose, and the arm is ready for use. For simplicity, strength, ease of manipulation, rapidity and certainty of fire, this system is not excelled as a single fire breech-loader by any other in use.

To change this single fire breech-loader to a magazine arm, consists simply in introducing through a slot or opening cut through the stock and receiver, forward of the trigger guard, a magazine made to contain five (more or less) cartridges, which insertion or removal can be effected more quickly than a single cartridge can be loaded into or ejected from any ordinary single breech-loader. The magazine is held in place by the magazine catch, K, which engages into a notch or depression in the rear of the magazine, as shown in the drawing, and can be released in a moment by an upward pressure on the magazine catch, K, at its lower end, where it projects downward into the trigger guard. The magazine is retained so firmly and secure in position that it is impossible for it to become accidentally released, no matter how roughly the arm is used or how severe a shock it may receive. These magazines are pressed into shape from one piece of metal, and are strengthened by a rib made on their rear and bottom interior, which renders them, although weighing but about three ounces, strong and rigid enough to endure without injury any shock or blow liable to be received in rough service. They may be adapted to cartridges of any length. The cartridges are held

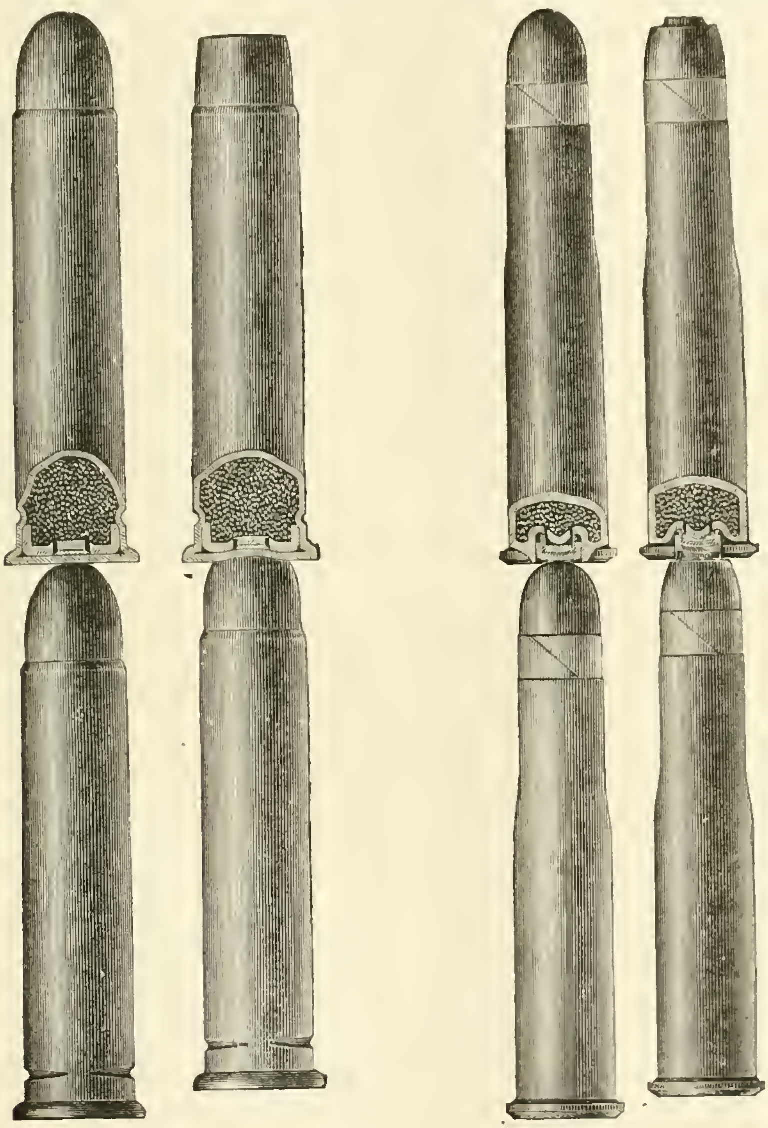
The arm can be carried while loaded with perfect safety by withdrawing the thumb-piece, E, to the half-cock notch, which operation fixes the bolt firmly to its closed position, and locks the firing-pin backward clear from the cartridge until the thumb-piece is drawn back to full-cock, when the piece may be fired. The ease and rapidity with which this arm can be dismounted and assembled is noticeable. By inserting the point of a knife or screw-driver into the

in a nearly horizontal position, the flange or head of each being in advance of the one below it, as shown, rendering it impossible for anything to impinge upon the primer of either cartridge, and thus obviating every possible danger of premature discharge in the magazine. The cartridges are fed upward into the system by the magazine spring, N, as required, and being held strongly in position, no deformation of the bullet is possible. By actual experiment, the bullet of cartridges so held, and exposed to the recoil received from one hundred shots fired in the arm, showed no diminution in length.

The simplicity of the magazine mechanism proper of this arm is unequalled and remarkable, consisting only of three pieces — the magazine, M, the magazine-spring, N, and the magazine-catch, K, and *incidentally*, a small spring which operates in a slot in the side of the receiver, and projects over the opening through which the cartridges pass upward from the magazine, forming a bottom to the receiver, while the arm is being used as a single loader. The complexity of the magazine mechanism in most repeating arms, with the consequent liability to breakage or derangement, has been one of the objections offered to their adoption for military purposes. When the magazine is put into place (accomplished either by pressure or by a sharp tap of the hand), the head of the upper cartridge is relieved of its tension against the inclined flanges on the rear and upper part of the magazine, by its pressure against the under side of the bolt, B (the upper edge of the rear wall of the magazine being slightly hollowed to the shape of the bolt). The rearward motion of the bolt in opening the breech draws back the upper cartridge, relieving its front end from the hemispherical depression in which it rested; the spring, N, lifts the bullet end of the cartridge upward, and free from the magazine, the bolt moving backward just far enough to allow its front end to pass in rear of the head of the cartridge, which head, thus relieved, rises by the pressure of the spring, N, sufficiently to engage the end of the bolt. The forward movement of the bolt then carries this cartridge into the chamber of the barrel. On opening the system and withdrawing the bolt, the extractor ejects with certainty the exploded shell, and the same operations apply until the magazine is exhausted.

It is intended that two or more magazines shall be furnished with each arm, which are to be carried, charged, in the cartridge box or pocket of the soldier. The magazines can be charged with cartridges (five is the number recommended that they shall contain), each in less than five seconds. It is quite practicable that all ammunition issued to troops be contained in these magazines, which may be made, if required, very light, of skeleton form, and of such cheap construction as will admit in action of their



A B C D

being dropped and left on the field, as are the exhausted shells of expended cartridges. The arm can be used as a single loader until the need of rapid firing becomes apparent, when at the word of command, the charged magazines may be inserted and used. The least intelligent soldier can obey this order without looking at the arm. While removing or inserting the magazine, the arm should be held firmly at the grip by the soldier's RIGHT hand, in a vertical position. It is believed that the feature of *detachability*, as arranged in the Lee system, will particularly commend itself to the minds of military authorities. The ease, rapidity, and certainty, with which the charged magazines can be inserted into, or removed from the arm, places it in the power of the officers of disciplined troops to positively control the expenditure of ammunition. The soldier may use his arm as a single loader until the vital moment when a rapid fire is needed. At the order a loaded magazine can in an instant be inserted, and a volley of five, to be immediately succeeded by five, ten, or fifteen more shots (if as many as four magazines be supplied), rapidly delivered. It will require but little drill to teach the ordinary soldier to deliver twenty-one well directed shots from this gun in forty seconds. Experts at the Armory fire that number easily in *thirty* seconds. Using the *detachable magazines*, the necessity of all *cut-off* appliances is obviated, and the danger of the soldiers becoming so confused in the heat and excitement of action as to err in the proper adjustment of the cut-off, need not be feared.

This arm possesses evident advantages over all magazine-guns having tubular magazines, placed under or above the barrel, or in the butt-stock. In such magazines the cartridges ride lengthwise, one following another; the bullet of one coming directly in contact with and resting on the primer of the cartridge next it. All of the cartridges are forced toward the breech mechanism by a spiral spring, which must be of sufficient strength to support the weight of the column of cartridges, and force them into the receiver or breech of the arm as fast as required, and of necessity it must have very considerable stiffness or strength. A French army cartridge, which is about the average weight of military cartridges in use, weighs more than $1\frac{4}{10}$ ounces. The weight of a column of five such cartridges would be seven ounces, four-fifths of which weight would in a tubular magazine, rest upon the point of the bullet of the last cartridge, and which bullet comes directly in contact with the primer of the cartridge in advance of it. Add to this compressive force the possibility of the cartridge having extra sensitive primers, and the soldier or marksman may reasonably shrink from the possibility of an accident which would probably kill, or maim for life. It is hardly necessary to allude to the demoralizing effect a single instance of premature explosion of a cartridge contained in the tubular magazine of a military weapon would have upon the soldiers of a command armed therewith. Such an accident would probably at least seriously wound the operator, and the knowledge that such casualties are possible would cause the men to shrink from bringing their arms to the shoulder, and if fired at all, their guns would be held at arm's length, as far as possible from the person, without aim or probable effect.

Another serious disadvantage pertaining to all tubular magazine systems, is the unavoidable deformation of all cartridge bullets carried therein. In the drawing, A, shows perfect cartridges (with inside primers), as in position while contained in a tubular magazine-rifle, at "Order Arms"; B, shows one of the cartridges with its head depressed, the fulminate of the inside primer compressed, and the bullet flattened. C, shows perfect cartridges (with outside primers) as in position while contained in a tubular magazine-rifle at "Order Arms"; and D, shows one of the cartridges with its bullet flattened and compressed ($\frac{12}{100}$ of an inch), and the primers deformed; the deformity in each case being due to the recoil of 100 rounds. Even the ordinary jolting incident to an infantry march, greatly aggravated in the case of cavalry, will in a short time so batter and deface the point of the lead bullet—thus increasing its diameter—as to materially impair its accuracy in flight, besides rendering it difficult to force it into place in the chamber of the barrel, and with the possibility of wedging the enlarged bullet so tightly into the chamber—the cartridge being only part way home—that any attempt to withdraw the charge may separate the bullet from the cartridge case, leaving the lead jammed into the chamber, removable only by use of a rammer introduced through the muzzle. The soldier, baffled and confused by any failure of his arm—which failure is liable to occur at the supreme moment which decides the fate of battle—will be less efficient than if armed with the obsolete muzzle-loader, which, although slow, is supposed to be tolerably sure. A final objection to all tubular magazine systems is that the balance of the arm is constantly being changed. Each cartridge expended from the magazine alters the relative weight which one extremity of the arm bears to the other, and must radically affect the accuracy of the soldier's him. See *Magazine gun.*

LEFAUCHEUX GUN.—A breech-loading gun of peculiar merit. The under-guard of the barrel formed of two pieces of iron having a joint, is maintained in a right line by a rigid plate which supports it. This plate may be made to revolve on its axis with a horizontal backward and forward movement, by the action of the hand, when it withdraws its support from the under-guard, which forthwith yields and severs the breech from the rest of the barrel. The chamber which is to receive the cartridge thus is exposed and the piece is loaded. The cartridge itself at its base is provided with a large cap, from which projects a pin or small nail; this fits an opening in the breech of the gun, and the hammer strikes it and so fires the piece. To breech-loading military rifles constructed on the Lefaucheux system it would be impossible, or at least impracticable, to add the bayonet; for the use of the bayonet in actual conflict would be almost certain to lead to a complete separation of the two parts of the piece.

LEGATE—LEGATION.—As commonly used in modern times the word Legate is applied to the person charged by the Pope of Rome to represent him, or the Roman Church, at the seat of Government of a foreign country, or at the seat of a bishopric of the Church. But the word need have no such restricted use. It was employed by the Romans under the Republic, before the Church controlled Rome, to indicate any person sent by the Government on a special mission of importance to another Government, or even to a Conquered Province; when a Legate frequently became acting Governor by virtue of such commission. *Legatus* among the Romans was a synonym of Ambassador. Envoy Extraordinary, Legate, Ambassador, are three words signifying nearly the same thing: the first two indicating a fresh or special appointment for a specific object, and the last a more permanent mission. The term Legation includes all that appertains officially to the position of a Legate, an Ambassador, or an Envoy Extraordinary, viz., his Secretaries, Attaches, Family, and Residence. We speak of the Residence of the American Legation, but by "A call at the Legation" one may mean a call on any officer or any of the families of the officers of the Legation, meaning then by Legation the seat of residence of its members.

LEGION.—A legion in the Roman military system, corresponded in force and organization to what in modern times we should call a *corps d'armée*. It differed in constitution at different periods of Roman history. In the time of the Republic, a legion composed 4,500 men, thus divided: 1,200 *hastati*, or inexperienced troops; 1,200 *principes*, or well-trained soldiers; 1,200 *velites*, or skirmishers; 600 *triarii*, or *pila-*

ni, veterans forming a reserve; and 300 *equites*, knights who acted as cavalry, and belonged to families of rank. During this period the legions were formed for the season, standing armies being of later growth. The hastati, principes, and triarii, formed three separate lines, each divided into 10 *maniples* or companies, 120 men each in the case of the two front lines, and 60 men in the triarii. A maniple was commanded by a Centurion or Captain, who had a Second Centurion, or Lieutenant, and two Sub-officers, or Sergeants, under him: as non-commissioned officers, there was a *Decanus*, or Corporal, to every squad or tent of ten men. The senior Centurion of each line commanded that line, and had therefore functions corresponding to a modern Lieutenant-colonel. The *primipilus*, or senior Centurion of the triarii, was the most important regimental officer, and commanded the legion in the absence of the Tribunes. The 300 cavalry formed a regiment of ten *turmæ*, or troops of 30 horsemen, each under three *Decurions*, of whom the senior had the command. The velites were light troops, not forming part of the line of battle; had apparently no officers of their own; and were attached to the 30 maniples in equal proportions. The Staff of the legion consisted of six Tribunes, who managed the paying, quartering, provisioning, etc. of the troops, and who commanded the legion in turns for a period each of two months. This command, although inconvenient, lasted till the times of the civil wars, when a *Legatus*, or Lieutenant-general, was appointed a permanent Commandant of the legion. The offensive weapons of the hastati and principes were two barbed iron-headed javelins, one of which was hurled at the enemy on the first onslaught, while the other was retained as a defense against cavalry. The triarii had long pikes. In addition to these arms, every soldier bore a very short, strong, cut-and thrust, two-edged sword. The legionaries' defensive armor consisted of a plumed hemlet, breastplate, iron-bound boot for the right leg, and a semi-cylindrical shield 4 feet long by 2½ broad. The velites had no defensive armor, were lightly armed, and in action usually operated for flanking purposes. Each maniple bore an ensign aloft, and each legion had its distinguishing eagle. Up to the time of Marius, service in a legion was sought as honorable occupation, and men of some means were alone eligible; but Marius enlisted slaves, and turned the legions into corps of a purely mercenary army. At the same period, the manipular formation was abolished, the three lines were assimilated, and the legion was divided into 10 cohorts, each of three maniples. Soon the cohorts were raised to 600 men, making the legion 6,000 infantry, besides cavalry and velites. It was ranged in 2 lines of 5 cohorts each; but Cæsar altered the formation to 3 lines, of respectively 4, 3, and 3 cohorts. During the latter Empire, the legion became complex and unmanageable; many sorts of arms being thrown together, and balistæ, catapults, and onagers added by way of artillery. Having so degenerated from its pristine simplicity and completeness, the legionary formation was soon overthrown amid the incursions of the victorious barbarians. See *Thundering Legion*.

LEGIONARII.—The second of three classes of soldiers in the Roman Army; the soldiers of the legions.

LEGION OF HONOR.—An Order of merit instituted under the French Republic in 1802 by the First Consul, as a recompense for military and civil services. It was ostensibly founded for the protection of republican principles and the laws of equality, and for the abolition of differences of rank in society, every social grade being equally eligible; but its real aim doubtless was, by popularizing the idea of personal distinction, to pave the way for establishment of the Empire and of the more exclusive titles of nobility that were to accompany it. The proposal for its institution was at first violently opposed by the legislative body and the tribunate, on democratic grounds, and carried eventually by a very narrow majority. The Order originally comprised three classes—Grand Officers, Commanders, and Legionaries. The class of Grand Officers was, on the coronation of Napoleon I., divided into Knights of the Grand Eagle (the highest class), and Grand Officers. On the restoration of the Bourbons, the legion was retained, but remodeled so as to lose much of its original character. The eagle was called a cross, and the effigy of Henry IV. replaced that of Napoleon. The Knights of the Grand Eagle became Grand Crosses, the Legionaries were transformed into knights, and the numerous educational institutions, founded by Napoleon for the children and relatives of the members of the Order, were much reduced in scale. In 1837 a new military class called Officers was admitted. Under the presidentship of Louis Napoleon, part of the property of Louis Phillippe, which had been restored to the State, was set apart as an endowment for the legion, and new regulations were made regarding the pensions of the different classes. The original form of decoration was reintroduced, which under the Second Empire was somewhat modified. As worn then, it consisted of a cross of ten points of white enamel edged with gold, the points connected with a wreath of laurel proper, and in the center, with an azure circle charged with the words "Napoléon III., Empereur des Français," was a head of the Emperor. The cross is ensigned by the imperial crown of France, and worn attached to a red ribbon. The Grand Officers also, as a general thing, wore on the right breast a silver star charged with the imperial eagle. The same star was generally worn on the left breast by the Knights Grand Cross, and their cross was attached to a broad red ribbon which passes over the right shoulder. The vast numbers of this Order, and the insignificance of many of the persons on whom it has been conferred, have detracted much from its value. The number of members in 1872 was 69,179; but the law passed in that year, that only one new member should be added for every two vacancies, reduced the membership in the next five years (1877) to 59,208. The revenue of the College of the legion has been augmented by the addition of property belonging to Louis Philippe. Out of this fund pensions are paid to those members of the Order who have served in the Army or Navy; the civilian members receive no pension. By the existing statutes, candidates in times of peace must have served in some military or civil capacity for 20 years; exploits in the field or severe wounds constitute a claim in time of war. Two distributions take place in the year. The nomination of military persons takes place on parade, and of civil in the Courts of Justice. No ignoble punishment can be inflicted on a member of the Order so long as he belongs to it. To rise to a superior rank, it is indispensable, at least for natives of France, to have passed through the inferior grades.

LEGS.—Human legs are not unfrequently borne as charges in Heraldry, sometimes naked, sometimes booted, and they may be coupled, *i. e.*, cut evenly off, or erased, cut with a jagged edge, and that either at the thigh or below the knee. The knee when represented is always embowed. A remarkable device of three legs in armor, conjoined at the thighs, and flexed in triangle, forms the insignia of the ancient Kingdom of Man, with the appropriate motto, *Quocunque jeceris stabit*. The classical symbol of the Island of Sicily (Trinacria) was formed of three naked legs similarly conjoined, and the triple-mountained Isle of Man might have awakened in its Norman Sovereigns some recollections of their Mediterranean conquests.

LELEGES.—An ancient and warlike people which peopled the Islands of Ægean, and is supposed to have been of Pelasgic origin. Authorities differ as to its exact identity, some having confused the Leléges with the Carians, with whom they are said to have united in support of the Trojans. Homer represents Altes, King of the Leléges, as having been the father-in-law of Priam. Pausanias considers Lelex, the founder of this race, to have been a foreigner from Egypt, and that he became King of Megara. According to this authority, the grandson of Lelex, Pylus by name, founded the city of Pylus in Messenia with a colony of Megarian Leléges. The last that is recorded of the Leléges is that they joined the Carians in colonizing the west coast of Asia Minor.

LENGTH OF BORE.—The *slow rate* of burning of mealed powder, which was originally used in cannon, led to the belief that the longest pieces gave the greatest ranges. In spite of much experience to the contrary, this belief was entertained, even after gunpowder received its granular form; and several pieces were made of enormous length, with the expectation of realizing corresponding ranges. A culverin was cast during the reign of Charles V. which was 58 calibers long, and fired a ball weighing 36 lbs.; but on trial, this piece was found to have actually less range than an ordinary 12-pdr. gun. The experiment of reducing its length, by successively cutting it off to 50, 44, and 43 calibers, was tried, and it was found that the range increased at each reduction until it gained 2,000 paces.

That the length of the bore has an important effect on the velocity of the projectile, will be readily seen by a consideration of the forces which accelerate and retard its movement in the piece. The *accelerating* force is due to the expansive effort of the inflamed powder, which reaches its maximum when the grains of the charge are completely converted into vapor and gas. This event depends on the size of the charge, and the size and velocity of combustion of the grains. With the same or constant accelerating force, the point at which a projectile reaches its maximum velocity depends on its density, or the time necessary to overcome its inertia. The *retarding* forces in action, are—1st. The friction of the projectile against the sides of the bore: this is the same for all velocities, but is very different for all the different metals; 2d. The shocks of the projectile striking against the sides of the bore: these will vary with the angle of incidence, which depends on the windage, and the extent of the injury due to the lodgment and balloting of the projectile; 3d. The resistance offered by the column of air in front of the projectile: this force will increase in a certain ratio to the velocity of the projectile and length of the bore. As the accelerating force of the charge increases up to a certain point, after which it rapidly diminishes, as the space in the rear of the projectile increases, and as the retarding forces are constantly opposed to its motion it follows, that there is a point where these forces are equal, and the projectile moves with its greatest velocity; it also follows that, after the projectile passes this point, its velocity decreases until it is finally brought to a state of rest, which would be the case in a gun of great length. The length of bore which corresponds to a maximum velocity depends upon the projectile, charge of powder, and material of which the piece is made; and taking the caliber as the unit of measure, it is found that this length is greater for small-arms which fire leaden projectiles than for guns which fire solid iron shot, and greater for guns than for howitzers and mortars, which fire hollow projectiles. It may be broadly stated that with suitable powders, the following relations should exist between the charge and the length of bore, in order that there may be a profitable use of the charge:—

Charge.	*Length of bore.*
$\frac{1}{3}$ the weight of shot.	About 26 calibers.
$\frac{1}{2}$ " " " " . . .	" 30 "
$\frac{2}{3}$ " " " "	" 35 "

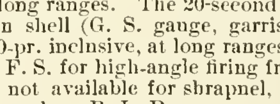
In each case a greater length of bore would give increased velocity, but it would be obtained at the expense of additional weight, which can be better utilized elsewhere in the gun. See *Cannon.*

LENGTH OF CANNON.—In smooth-bore guns, the distance between the rear of the base ring and face of the muzzle, measured in a line parallel to the axis. The length of B. L. R. guns is measured from behind the breech to the face of the muzzle, the breech screw not being included, and the length of M. L. R. guns from the neck of the cascable to the face of the muzzle. The length of a mortar is the whole distance from face to breech, measured along the axis. The length of guns is sometimes expressed by their calibers; but this, except with smooth-bore guns, is a very inaccurate method of comparing the lengths of rifled guns. To say with smooth-bore guns that they were so many calibers long, was sufficiently accurate, because the weight of charge and shot was always in proportion; but with rifled guns, which not only differ in this respect very greatly from smooth-bore guns, but even among themselves, to speak in this manner is very misleading. A 68-pr. gun has about the same length of bore as the 8-inch rifled gun, and is consequently the same length in caliber; but, as the charge of the latter is double that of the former, the number of expansions with an 8-inch gun is only half of what it is with a 68-pr. The more scientific way, is to designate the length of bores by the number of expansions of the charge.

LENGTH OF FUSE.—This expression has reference to the period a fuse is required to burn, the time being determined by the range. Fuses (time), such as are used with M.L.R. English guns, burn a certain number of seconds, viz., 5, 9, and 20 seconds respectively. The use and object of these different fuses are as follows: The 5-second fuse is used with shrapnel shell (G. S. gauge), up to the 80-pr. inclusive. This fuse is very necessary for F. S. shrapnel shell, which must be burst with great accuracy to develop its power. The 9-second fuse is used with common and shrapnel shell (G. S. gauge), up to 80-pr. inclusive, at long ranges. The 20-second fuse is used for common shell (G. S. gauge, garrison service), up to the 80-pr. inclusive, at long ranges. It is only used in the F. S. for high-angle firing from the 7-pr. gun. It is not available for shrapnel, as it has no powder-channels. B. L. R guns use fuses of the same lengths as above. The following will be found, as a general rule, nearly correct for getting the length of fuse with muzzle-loading rifled guns. Divide the number of hundreds of yards in the range by 2, and add 1 up to 1,000 yards, 2 up to 2,000 yards, and so on, for length of fuse in tenths of inches.

LENGTH OF PROJECTILES.—This length necessarily varies in the different descriptions of projectiles for the same gun, inasmuch as it is to some extent subordinate to the consideration of bringing them all (with certain exceptions) to the same weight, but it has been decided that a length of two calibers at least is necessary for very accurate shooting, and it is desirable for good *vis viva*, or destructive effect on impact, at any but very short ranges, to have the weight great in proportion to the caliber, or in fact to the surface of resistance, and of course this is favored by an increased length of projectile.

LENS.—A circular section of any transparent substance, having its surfaces either both spherical, or



one of them plane and the other spherical. A ray of light in passing through a lens is bent towards its thickest part; hence lenses are either convex (thickest in the middle) or concave (thickest at edges). The former make the rays more convergent than before, the latter make them more divergent. The point to which the rays converge, or from which they diverge, is called a focus—principal focus when the rays are parallel. The focus for a convex lens is real, i.e., the rays actually pass through it, and form an inverted image smaller or larger than the object according as the object is at a distance greater or less than twice the principal focal length; but the image is erect and magnified if the object be within the principal focal length. For a concave lens the focus is virtual—the rays seem to come from it and form an erect image smaller than the object.

The lenses in the drawing, though they may be of the same focal length, have peculiar properties which render them suitable for particular optical instruments; thus, the convexo-plane lens has only one-fourth of the aberration of a plano-convex, or two-thirds of an equi-convex or equi-concave of the same focal length; but, in general, the equi-convex is the most desirable form. Aberration has been to opticians what refraction is to the astronomer, an unwelcome intruder, which spoils his finest theories, and limits the accuracy of his results. This aberration has, indeed, been destroyed by combining lenses of equal and opposite aberrations, as for instance, uniting, by means of Canada balsam, a double convex with a double concave. A still better method would be the formation of lenses having one side spherical, and the other of an ellipsoidal or a hyperboloidal form; but this has not yet been successfully accomplished. Convex lenses of glass, rock-salt, ice, etc., may be used as "burning-glasses," since radiant heat is refracted according to the same laws as light—the hot focus being nearly coincident with the luminous one. Platinum, gold, etc., have been fused in three or four seconds by this means.

LEOPARD.—The leopard has been described by some Heralds as the issue of the pard and lioness; and the circumstance that such hybrids are unproductive, is assigned as a reason for appropriating that animal to the armorial ensigns of Abbots and Abbesses. However, the representations of leopards, at least in English Heraldry, are so exactly like those of the lion passant gardant, that it has been made a question whether there is any difference between the two, and it has more especially been a keenly-contested point whether the three animals in the royal escutcheon of England were lions or leopards. In early times we find them blazoned in both ways, and the true solution of the *quæstio vexata* seems to be, that at one period the heraldic leopard came to be considered as a mere synonym for the lion passant gardant, though the two animals were originally regarded as distinct. In the infancy of Heraldry, before distinctive appellations were invented for the different attitudes of animals, it was customary to draw a lion in the attitude since called rampant, and a leopard as passant gardant. This difference of position sufficiently indicating which animal was meant, they were otherwise similarly represented, and no attempt was made to exhibit the spots of the leopard. By and by, as coats of armor were multiplied, it became necessary to difference them by varying the position of the animals depicted; and the blazoners of those days, thinking more of attitude than of zoology, had recourse to a compromise in their nomenclature. The lion was naturally supposed to be rampant and in profile, the leopard passant gardant. When the conventional animal that might stand for either was passant and in profile, he was designed a *lion-leopardé*; and when rampant gardant he was a *leopard-lionné*. The king of beasts was very early assumed as his appropriate insignia by the Sovereign of England, as well as by the Sovereigns of other countries in western Europe. The lion was at first borne singly, and his natural attitude, like that of other lions, was considered to be rampant. But when a second and third lion were added, it became less convenient to draw them in the rampant attitude, and the lions became lions-leopardé or passant, as seen in the seal of King John; a further change of position to passant gardant made them heraldically leopards. Edward III., Edward the Black Prince, and Richard II., speak of their crest of the leopard. Nicholas Serby was designated Leopard Herald in the reign of Henry IV.; and it was not till the middle of the 15th century that the lions of England regained their original name. Though leopards, properly so called, hardly occur in English Heraldry, having passed into lions passant gardant, their heads or faces are occasionally borne. If no part of the neck is shown, the proper blazon is a leopard's face; if a portion of the neck is drawn, it is a leopard's head, erased or couped, according as it is cut off evenly or with a jagged edge.

LESGHIANS. A body of 300,000 people, inhabiting the mountains of western Daghestan in the Caucasus (Asiatic Russia), and speaking various languages. For many years they made a brave resistance to Russian aggression. Since 1859 they have been peaceable. Their religion, a modification of Islamism, is called Muradism, and was founded about 1830 by a native Prophet.

LESSE. A machine covered with rawhides, used as a mantelet by the ancient Greeks for different purposes.

LETTER BOOK.—A book containing the entry of all official letters written by the Commanding Officer, or under his direction, to the public departments, and to individuals, on regimental business. It contains an alphabetical index, and a separate index for the public departments. It need not be preserved beyond three years, after it is completed, care being taken to keep copies of such letters as may be likely to be required for reference.

LETTER OF MARQUE.—The commission authorizing a Privateer to make war upon, or seize the property of another nation. It must be granted by the Lords Commissioners of the Admiralty, or by the Vice Admiral of a distant Province. Vessels sailing under such commissions are commonly spoken of as *Letters of Marque*. Making war without Letters of Marque by a private vessel, is piracy. Letters of Marque were abolished among European nations at the Treaty of Paris, in 1856.

LETTRE DE PASSE.—A paper which was formerly signed by the Kings of France, authorizing an officer to exchange from one regiment to another.

LETTRES DE CACHET.—The name given to the famous warrants of imprisonment issued by the Kings of France before the Revolution. All Royal Letters (*Lettres Royaux*) were either *Lettres Patentes* or *Lettres de Cachet*. The former were open, signed by the King, and countersigned by a Minister, and had the great Seal of State appended. Of this kind were all ordinances, grants of privilege, etc. All Letters Patent were registered, or *enterinated* by the Parliaments. These checks on arbitrary power did not exist with regard to Lettres de Cachet, also called *Lettres Closes*, or sealed letters, which were folded up and sealed with the King's little seal (*cachet*), and by which the Royal pleasure was made known to individuals or to corporations, and the admistration of justice was often interfered with. The use of Lettres de Cachet became much more frequent after the accession of Louis XIV. than it had been before, and it was very common for persons to be arrested upon such a warrant, and confined in the Bastile, or some other State Prison, where some of them remained for a very long time, and some for life, either because it was so intended, or, in other cases, because they were forgotten. The Lieutenant General of the Police kept forms of Lettres de Cachet ready, in which it was only necessary to insert the name of the individual to be arrested. Sometimes an arrestment on Lettres de Cachet was a resource to shield criminals from justice.

LEVEE.—This term originally meant visits of ceremony paid in the morning among persons of rank. It is now understood to mean an assembly at Court, on state occasions, of those of Her Majesty's subjects who are entitled to the privilege of presenting themselves before the Sovereign. The privilege of holding levées is also accorded to Her Majesty's representatives at home and abroad, to the Field Marshal Commanding in Chief, and other high Functionaries.

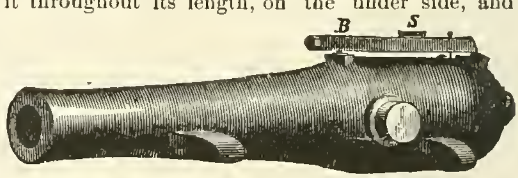
LEVEE EN MASSE.—A general rising of the people of any country, either for the purpose of self-defense, or to answer the intention of its governing powers. See *Levy*.

LEVELERS.—A party which arose in the army of the Long Parliament, when it overawed that body, and sent the King to Hampton Court in 1647. They determined to level all ranks, and establish an equality of titles and estates througout the Kingdom. Several of the officers belonging to this party were cashiered in 1649, and on the departure of Cromwell for Ireland, at the close of that year, they raised mutinies in various quarters, and were put down by Fairfax with bloodshed. They were not only treated as traitors by the King, but persecuted by Cromwell as dangerous to the State. In politics their fundamental principles included: 1. The impartial authority of the law; 2. The legislative power of Parliament; 3. Absolute equality before the law; 4. The arming of the people for securing the enforcement of the laws, and the protection of their liberties.

LEVELING.—Level is a term applied to surfaces that are parallel to that of still water, or perpendicular to the direction of the plum-line; it is also applied to the instrument employed in determining the amount of variation from perfect levelness. The instrument ordinarily is a cylindrical glass tube very slightly convex on one side, and so nearly filled with water, or what is better, with alcohol, that only a small bubble of air remains inside. The level is then mounted on a three or four legged stand, with its convex side upwards, and by means of a pivot and elevating screws, is made capable of assuming any required position. If the level be properly constructed, the bubble should lie *exactly* in the middle of the tube when the instrument is properly adjusted, and, at the same time, the line of sight of the telescope attached to the level should be accurately parallel to the surface of still water. In ordinary levels, this first condition is seldom seen, and, instead, two notches are made on the glass to mark the position of the two extremities of the bubble when the instrument is level. The tube and bubble should be of considerable length to insure accuracy. A very handsome level of precision, constructed by Fauth and Company, United States, for the Coast and Geodetic Survey, is employed for the most exact work. It can also be used as a gradienter, the micrometer screw for raising or depressing the telescope being made with the utmost exactness, and being provided with a graduated head. The telescope has an aperture of 1½ inches, and 16 inches focus, with two astronomical eye-pieces, magnifying 40 and 60 times respectively. The pivot-rings are of phosphor-bronze, and rest on agate. The striding level is chambered, and one division equals 3 seconds of arc. The horizontal circle, of five inches diameter, divided on silver, reads to 30 seconds; the center is of steel; clamp and spring tangent motion.

Custom has established the measurement of absolute levels from the average surface of the ocean—the mean between high and low water—as the zero level; when reckoned from any other zero level, they are relative levels. Leveling, or finding the difference between the levels of two or more points, is designated by the term hypsometry in geodesy. There are three principal and independent methods of leveling. The first depends upon the fact that the surfaces of fluids at rest are perpendicular to the direction of the force of gravity; upon this is based the common level. In the second method, trigonometrical leveling, we must know, first, the zenith distance, or the angle between the zenith of the station and the object whose height we wish to find (making a correction for the effect of refraction,) and, second, we must know or accurately determine the horizontal distance from the station to the object determined usually by triangulation. In accurate work a careful adjustment of the theodolite, the instrument used in this method, is necessary. Local attraction sometimes causes a deflection of the plumb-line, thus affecting measurements of zenith distance. Atmospheric refraction is a more important element of uncertainty, for which reason the horizontal distance should not exceed 12 or 15 miles. The coefficient of refraction is irregular, and varies with the temperature and pressure of the atmosphere; it is most steady and nearest its minimum between 10 A. M. and 2 P. M. From the above data, the difference in level is easily calculated. The weight of the atmosphere bearing upon a unit of surface diminishes in a geometrical progression as the heights increase in an arithmetical progression; therefore, by the third method, heights are determined with the barometer. Physicists have constructed numerous formulæ embodying the law of Mariotte, and introducing corrections for temperature, expansion of air, and the effect of latitude and height upon the action of gravity. It is believed that considerable accuracy can be attained by this method, particularly if the annual means of temperature and pressure for the stations whose difference in level it is desired to find are substituted in the formulæ. Aneroid barometers have been graduated to indicate heights up to 12,000 or 16,000 feet; they give only approximate results. If a delicate apparatus for determining the boiling point of water be used, the corresponding heights taken from a table will give the reading of the barometer at that point, so that the instrument itself can be dispensed with. This depends upon the fact that the boiling-point of water decreases as the pressure of the atmosphere becomes less. Ses *Theodolite* and *Y Level*.

LEVELING BAR.—A square steel bar with parallel faces, somewhat longer than the distance between the sights on the largest gun. The rear end is bevelled at an angle of 60°, the angle at which the sight is placed. It has a central line marked on it throughout its length, on the under side, and



along the bevelled end. It has also marked on its sides, near the forward end, the distance at which the sights should be placed for each class of gun. It is also fitted with screws for bringing it to a level. The leveling-bar being laid on the front sight, and its bevelled end taking against the rear sight-bar, bring it to a level with the spirit-level and screws. This will give the true guide for angle of rear sight-bar, and the latter's proper plane. As soon as rear sight-box is fitted, bore hole for same through rear sight-mass. The hole is bored with the rear sight-box *on*, and the latter is kept down in its place by a sling around cascabel set up by a handspike. The rear sight being fitted true as to the leveling-bar, again level the arm of sighting-tompion, and stretch the thread back over the gun, this time bringing the thread to the exact middle of the rear sight-notch. Now, in theory, the thread ought to come directly over the inital point of the base-ring, and over the mark already accurately laid off on the front sight-mass; but practically this is never the case, as it is *almost impossible* to fit a rear sight-box so true as to bring the middle of the sight-notch in the exact line of sight already laid off. It will be found, upon stretching the thread the second time, that it will fall a trifle one side or other of the initial point on base-ring. So, virtually, it is necessary again to lay off a line of sight. With a measure take the distance that the thread falls to one side of the initial point on base-ring. Take this same distance that the thread is out, and lay it off horizontally on the cross-bar of the vertical sighting-arm. Of course, when the thread is also moved this distance on the sighting-arm, the thread will fall the same distance to one side on the front sight-mass; therefore mark this last point where the thread falls over the front sight-mass, and thus is established the second and final line of sight. Also mark the point where the thread now crosses the base-ring, and this is the final initial point to be marked for a full due on the base-ring. Where the thread crosses the front sight-mass, hold the front sight itself directly under the thread. When the front sight mass was lined out, at the same time with the rear sight-mass a regulation distance was given from base-ring to center of front sight-mass, and from this central point the mass was marked out and cut. See *Cannon Sights*.

LEVELING RODS.—The various leveling-rods used by American engineers are made in two or more parts, which slide from each other as they are extended in use.

these depressed surfaces are painted white, divided into feet, tenths and hundredths of a foot, and the feet and tenths figured. The front piece reads from the bottom upward to seven feet, the foot figures being red and an inch long, the tenth figures black, and eight-tenths of an inch long. When the rod is extended to full length the front surface of the rear half reads from seven to thirteen feet, and the whole front of the rod is figured continuously and becomes a self-reading rod thirteen feet long. The back surface of the rear half is figured from seven to thirteen feet, reading from the top down; it has a scale also by which the rod is read to two-hundredths of a foot as it is extended. The target is round and made of sheet-brass raised on the perimeter to increase its strength, and is painted in white and red quadrants; it has also a scale on its chamfered edge, reading to two-hundredths of a foot. When a level of less than seven feet is desired the target is moved up or down the front surface, the rod being closed together and

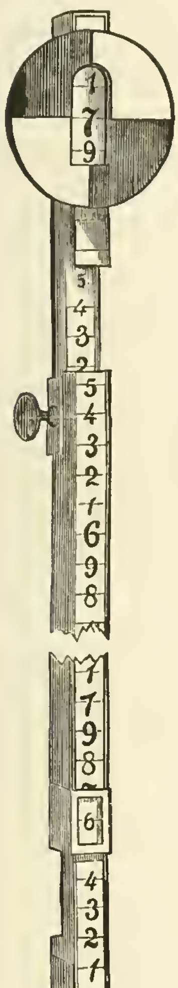


Fig. 1.

Fig. 2.

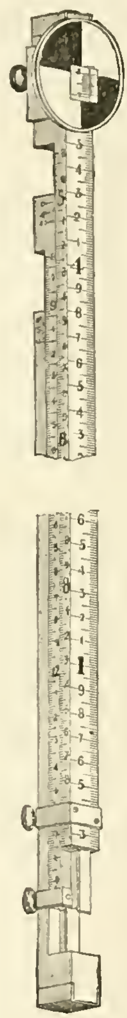

Fig. 3.

Fig. 4.

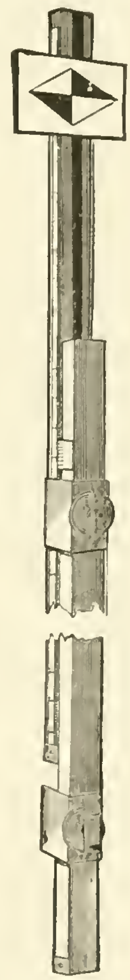

Fig. 5.

The *Philadelphia rod*, shown in Fig. 1, is made of two strips of cherry, each about three-fourths of an inch thick by one and a half inches wide and seven feet long, connected together by two metal sleeves, the upper one of which has a clamping-screw for fastening the two parts together when the rod is raised for a higher reading than seven feet. Both sides of the back strip and one side of the front one are planed out one-sixteenth of an inch below the edges; clamped; but when a greater height is required the target is fixed at seven feet and the rear half slid out, the scale on the back giving the readings like those of the target to two-hundredths of a foot.

The *Troy rod* shown in Fig 2. is a self reading rod up to six feet, or can be read by a vernier on the rear piece to thousandths of a foot as usual. It has two targets as shown, both fastened to the front half of the rod, the lower one having its center line just three-tenths above the end, and the target exactly six feet above the lower. There is a clamping piece with screw on the back of the rod below the target, by which the two parts are clamped together when desired. The face of the front piece is recessed like that of the Philadelphia Rod, painted white, divided to feet and hundredths, and figured as represented. The side of the front half is divided to feet and hundredths, read by a vernier on the top of the rear half to thousandths, and figured from the top downwards, beginning with three-tenths, that being the height of the center line of the lower target. When a level of less than six feet is taken on the rod the observation is made by the lower target, and the reading is direct as given on the side ; but when a greater height is taken the upper target is sighted upon, and six feet added to the reading on the side in every instance, and thus a reading up to twelve feet readily obtained.

The *New York rod* is made of maple, in two pieces, sliding one from the other, the same end being always held on the ground, and the graduations starting from that point. The graduations are made to tenths and hundredths of a foot, the tenth figures being black, and the feet marked with a large red figure. The front surface, on which the target moves, reads to about six and a half feet; when a greater height is required, the horizontal line of the target is fixed at the highest graduation, and the upper half of the rod, carrying the target, is moved out of the lower, the reading being now obtained by a vernier on the graduated side, up to an elevation of twelve feet. The mountings of this rod are differently made by different manufacturers. We shall give those which are mostly used. The target is round, made of thick sheet brass, having, to strengthen it still more, a raised rim, which also protects the paint from being defaced. The target moves very easily on the rod, being kept in any desired position by the friction of the two flat plates of brass which are pressed firmly against the two alternate sides, by small spiral springs, working in little thimbles attached to the band which surrounds the rod. There is also a clamp-screw on the back, by which it may be securely fastened to any part of the rod. The face of the target is divided into quadrants, by horizontal and vertical diameters, which are also the boundaries of the alternate colors with which it is painted. The colors usually preferred are white and red ; sometimes white and black. The opening in the face of the target is a little more than a tenth of a foot long, so that in any position a tenth, or a foot figure, can be seen on the surface of the rod. The right edge of the opening is chamfered, and divided into ten equal spaces, corresponding with nine-hundredths on the rod ; the divisions start from the horizontal line which separates the colors of the face. The vernier, like that on the other side of the rod, reads to thousandths of a foot. The clamp, which is screwed fast to the lower end of the upper sliding-piece, has a movable part which can be brought by the clamp-screw firmly against the front surface of the lower half of the rod, and thus the two parts immovably fastened to each other without marring the divided face of the rod.

Fig. 3 represents another form of this favorite rod, introduced by the Messrs. Gurley, United States. In this rod, a third or fourth piece is added to the two of the old rod, giving thus a rod of greater length, and at the same time making it more compact and portable. The divisions, the verniers, readings, and target are the same as those of the old rod. There are two varieties of the three-parted rod, one sliding to allow a reading of thirteen feet and the other extending to fourteen feet; the first when closed is only five feet long, the last but a little over five and a half feet. The four-parted rod is, when closed, but five feet in length, but can be extended to sixteen feet.

The *Architects' rod* is a very light and simple sliding rod made of maple, in two parts, each seven-eighths of an inch square, and when closed, about five feet six inches long. As shown in Fig. 4, the front half is divided on two sides to feet, tenths, and hundredths, reading by verniers on the target and side to thousandths of a foot. The target is smaller than those of the rods already described, but of sufficient size, and moves on the closed rod when levels of less than five feet and four-tenths are to be taken. When a greater height is needed the target is fixed at the highest division, the front half carried above the rear part and clamped at any point desired, by the clamp-screw, as shown, the height being now read off by the vernier on the lower half up to ten feet. This rod is adapted for use with any level, and is so light and efficient that we believe it will come into general use ; when it is to be used by an architect, the divisions are made in feet, inches and sixteenths, and no verniers are then required.

The *Boston rod*, shown in Fig. 5, is formed of two pieces of light mahogany or baywood, each about six feet long, and sliding easily by each other in either direction. One side is furnished with a clamping piece and screw, and a small vernier at each end, the other or front piece carries the target and has on each side a strip of satinwood inlaid upon which divisions of feet, tenths and hundredths are marked and figured. The target is a rectangle of wood fastened on the front half, is painted black and white, and has its middle line just three-tenths above the end of the rod. Each tenth of the rod is figured decimally in three figures or to hundredths of a foot, and by the verniers is read to thousandths. The target being fixed, when any hieght is taken above six feet, the rod is changed end for end, and the divisions read by the other verniers ; the height to which the rod can be extended being a little over eleven feet. This kind of rod is very convenient from its great lightness, but the parts are made too frail to endure the rough usage of this country, and therefore American engineers have generally given the preference to others, made heavier and more substantial.

In addition to the above, there is what is termed a *Telemeter rod*, formed of two pieces of pine, each three and a half inches in width, seven-eighths of an inch thick, and six feet long. Both sides of the rods are painted white, the inner surfaces being also recessed to protect the divided surface, with divisions in black of feet, tenths, and hundredths, and figured, the feet in red, the tenths in black. The two pieces are connected by a strong iron hinge, and folded in transportation; when in use, they are opened, laid flat, and joined firmly in line by a wooden bar, about eighteen inches long, held to each piece by two strong brass screws, which enter into metal sockets secured in each part of the rod. This is a self-reading rod, and is often used in connection with the micrometer wires to ascertain distances by a simple observation in the same manner as the Philadelphia rod.

A rod of English make is sometimes used, in which the two smaller upper parts slide out of a larger and lower one which answers as a case ; when closed the rod is five feet long, and extends to fourteen feet. It is divided on a recessed face to feet, tenths, and hundredths, the divisions being painted and figured like those of the Philadelphia and Telemeter rods. This is also furnished with divisions in meters, decimeters, and in centimeters ; length when closed one and a half meters, and sliding out to four meters. See *Y Level*.

LEVER.—This, the most simple and common, but, at the same time, most important of the seven mechanical powers, consists of an inflexible rod—straight or bent, as the case may be—supported at some point of its length on a prop which is called the *fulcrum*, and having the *weight* to be moved and *power* to move it applied at other two points. In the accompanying illustrations, AB is the lever, F the fulcrum, A and B the points of application of P and W, the power (or pressure) and weight respectively. If the arms AF and BF be equal, the power P and the weight W must also be equal to produce equilibrium; if the arm of the power, A F, be longer than the arm of the weight, BF, then, to produce equilibrium, the power P must be less than the weight W, and *vice versâ*; if AF be double the length of BF, then P, to produce equilibrium, must be half of W; and, generally, as is shown in the elementary treatises on mechanics, *the power and weight are in the inverse ratio of their distances from the fulcrum.* This is equally true for straight or bent levers; but the distance of the power and weight from the fulcrum is not, in all cases, the actual length of the arms, but the lengths of perpendiculars from the fulcrum upon the directions of the power and weight. The principle holds good, whatever be the relative positions of the power, weight and fulcrum; and as there can be three different arrangements of these, we thus obtain what are called "the three kinds of levers." *The first kind* (Fig. 1) is where the fulcrum is placed between the power and the weight; the balance, spade (when used for raising earth), the see-saw, etc., are examples of this; and scissors and pincers are examples of double levers

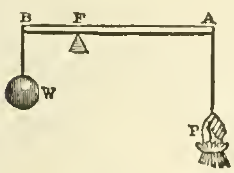

Fig. 1.

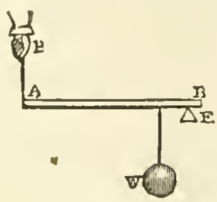

Fig. 2.

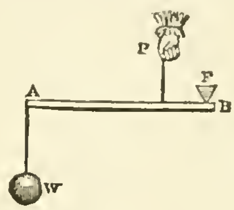

Fig. 3.

of the same kind. Levers of *the second kind* (Fig. 2) are those in which the weight is between the power and the fulcrum; examples of this are the crowbar, when used for pushing weights forward, the oar—the water being the fulcrum, and the row-lock the point of application of the weight—and the wheelbarrow; and of double-levers of this kind we have the nut-crackers as an ordinary example. In levers of *the third kind* (Fig. 3), the power is always between the weight and the fulcrum. Fishing-rods, whips, umbrellas, and most of the instruments used with the hand alone, are levers of the third kind; and shears, tongs, etc., are examples of double levers of this class. It is evident that, to produce equilibrium in levers of the first kind, the power may, according to the ratio of the lengths of the arm, be either greater or less than the weight; in the second kind it must always be less; and in the third kind, always greater. This is expressed in technical phrase by saying that the first kind of lever gives a *mechanical advantage* or *disadvantage*, the second always gives a mechanical advantage, and the third always a mechanical disadvantage. Levers of the second kind, having the same mechanical advantage, are, when

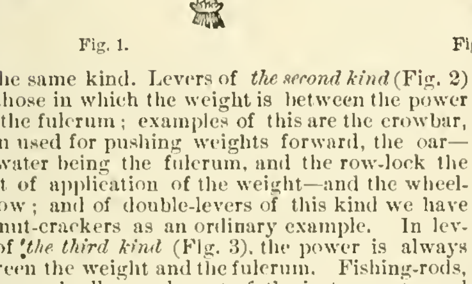

Fig. 4.

worked by man, twice as powerful as those of the first kind, because in one case he uses his muscular force as the power, in the other case only his weight. Levers of the third kind are used when velocity, or a large extent of motion, is required at the expense of power, and we consequently find this form much used in the structure of the limbs of animals. The structure of the human arm (Fig. 4), is a very good example of this; the fulcrum is the socket (C) of the elbow-joint, the power is the strong muscle (the *biceps*), which passes down the front of the *humerus*, and is attached at A to the *radius* (as shown); the weight is the weight of the forearm, together with anything held in the hand, the two being supposed to be combined into one weight acting at B. By this arrangement, a large extent of motion is gained, by a slight contraction or extension of the muscle.

When a large mechanical advantage is required, this may be obtained, without an inordinate lengthening of the lever, by means of a very simple combination of them. Here the levers have their arms in the ratio of 3 to 1, and a little consideration will make it plain that a power (P) of 1 lb. will balance a weight of 27 lbs.; but in this instance the particular defect of the lever as a mechanical power shows itself prominently; for if the weight has to be lifted 2 inches, the power requires to be depressed (2×27 or) 54 inches; and, as the extent of the power cannot be largely increased without inconvenience, the advantages of this machine are confined within narrow limits. See *Mechanical Powers.*

LEVER HITCH.—A knot similar to the drag-rope knot or woolding-stick hitch. It is used for tightening ropes, but instead of turning the woolding-stick round, it is applied on the principle of the lever.

LEVER-JACK.—An adjustable fulcrum with a lever fifteen feet long, used chiefly for greasing the axles of traveling carriages. It consists of a wooden stand, made of two uprights and framed into one bed. Two lever-plates (cast brass) are fastened to the large end of the lever by screws, and prevent the lever from slipping on the fulcrum-pin. See *Mechanical Maneuvers.*

LEVER-RING.—A wrought-iron ring, fitting on the circular part of the breech-screw of the Armstrong gun. It is kept in place by two split keep-pins which work in a groove round the breech-screws. The object of the lever and tappet arrangement is to give a powerful momentum in tightening up and releasing the vent-piece from its seat in the gun.

LEVER SHEARING-MACHINE.—It is evident that in all punching or shearing-machines, driven by a belt, there must be a conversion of the rotary motion of the driving pulley into a reciprocating motion of the punch or shear blade. To obtain the requisite power, many revolutions of the driving pulley must occur to one stroke of the punch. In crank machines, the whole pressure of the cut comes directly on the crank pin, which must perform a good portion of its revolution under this heavy strain at whatever speed the crank shaft may be running. This limits the power of such machines to the practical pressure sustainable on a given surface at a given velocity. When the vertical slide which carries the punch is operated by a lever, the sliding motion of the part of the lever in contact with the vertical slide is almost inappreciable: the pressure extends over large surface with little motion; so with the fulcrum pins over which the lever works; with very little and very slow motion of these parts much pressure is admissible, while the long end of the lever is operated upon by the lifting cam acting under comparatively light pressure. Added to this economical use of power, with the very greatly diminished frictional resistance, comes the possibility of so shaping the cam which is designed to lift the lever as to cause the motion of the punch to be about uniform through the whole length of the stroke, to return quickly, and then to dwell during any required portion of the revolution of the cam-shaft at the top of its stroke. Therefore, in comparing machines using the crank or eccentric with those employing the level and cam, if in both cases the same pulley, belt, and gearing is used, running at the same rate of speed, and making the same length of stroke at the punch or shear blade, it will be found that there is a capability of punching larger holes or of shearing thicker plates when the cam and lever are used than when the crank or eccentric is employed. On the lever punch and shears is arranged a four-toothed clutch on the main shaft, to be used in stopping and starting the plunger. This admits of quicker work than when the cam is shifted on the main shaft. The tail end of the lever is made to drop on a block of wood held in a box at the back of the machine, and the adjustment of the length of block to limit the fall of the lever enables the stroke to be controlled, and in thin metal to carry the punch close to the plate with less drop than when thicker iron is being punched, so obtaining a longer dwell for setting the plate.

In the Seller's machine, the heavy wrought iron lever in the housing easily raises the blade by its own gravity, and the cam which moves the lever is so shaped as to cause the motion of the blade in cutting to be at a uniform rate of speed. Returning quickly it dwells for some time at the top of its stroke, thus giving ample time to shift the plate for the next cut. In the earlier machines, the lifting-cam was moved sideways from under the lever when it was desired to stop the machine. This could only be done when the cam was free from pressure at the end of the stroke, and in starting again the cam could only be pushed in when in proper position in regard to the lever. The cam is now kept in position under the lever and is attached to or detached from the shaft by means of a four-toothed clutch, which, while it can only be withdrawn at the completion of the stroke, yet at the same time will permit the starting again to be effected in any one of four positions of the driving wheel in relation to the cam, thus saving much time, and also preventing the damage to the machine likely to arise from working the cam only partly under the lever.

The shear blades are placed so as to be right for trimming edges of plates, not for cutting bar iron. Operated by a heavy wrought iron lever within the housing. Independent stop motion by means of a four-toothed clutch in the housing. Blades rest open when clutch is out of gear. Vertical motion of blades $1\frac{1}{4}$ inches. Can be used to shear plates of iron $\frac{1}{16}$ inch thick. Fast and loose pulleys on the machine 36 inches diameter, 7 inches face, which should make 114 revolutions per minute. See *Angle Shearing-machine*, *Power Shears*, and *Shearing-machine*.

LEVER SHEERS.—A contrivance consisting of a long, heavy spar, with one end resting on the ground, and the other supported on two short spars, crossed and securely lashed together. The butt-end of the spar is heavily weighted, and is usually sunk a little in the ground, resting against a board or slab of wood, to prevent the earth from yielding to the pressure of the force acting in a direction parallel to the spar, and tending to force the end of it into the ground. A rear guy is also employed, to prevent short cross spars, or sheers, from falling to the front. The pressure of the spar or lever at the point where the short spars cross prevents them from inclining to the rear.

LEVET.—A blast of a trumpet probably that by which soldiers are called in the morning. This term is now obsolete.

LEVIGATION.—A process of the laboratory for converting different substances to a smooth, uniform powder by grinding them between two flat surfaces. The same process essentially is used in grinding paints, printing inks, and drugs.

LEVY.—The compulsory raising of a lot of troops from any specified class in the community for purposes of general defense or offense. When a country is in danger of instant invasion, a *levée en masse* is sometimes made—i. e., every man capable of bearing arms is required to contribute in person towards the common defense. On less urgent occasions, the levy may be restricted to a class, as to men between 18 and 40 years of age. At other times, a levy of so many thousand men of a certain age is decreed, and the districts concerned draw them by lot from among their eligible male population. In armies sustained by volunteering, the levy, which is a remnant of barbarous times, is unnecessray; but the system was frequently resorted to in France before the enactment of the Conscription Laws: 1862 has shown great levies in the United States of America; and in any country where great danger is apparent, and volunteers are not sufficiently numerous, recourse must at all times, be had to a levy of the people.

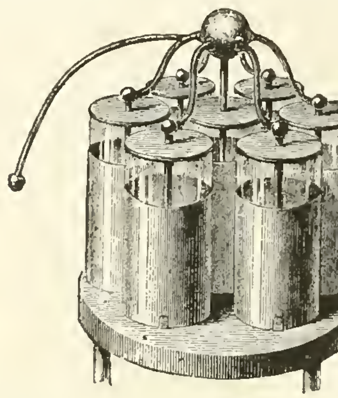
LEWIS.—An ingenious mode of lifting heavy weights. It consists of three pieces of iron, two of them wedge-shaped, and the third straight, which, when placed together with the straight piece in the center, form a dove-tailed wedge. The wedge is inserted in a hole of similar shape, cut either in stone or in metal. To the end of each of the pieces a ring is attached, throughw hich a horse-shoe ring is passed, and to this the rope or chain is securely fastened.

LEWIS HOLES.—The holes, in which the shell-hooks work in the 10-inch and 13-inch, mortar shells. They take the place of the early *lugs*, which are objectionable because of being knoced off in transport or piling.

LEWIS-RICE MAGAZINE-GUN.—This gun belongs to that system in which a fixed chamber is closed by a moveable breech-block rotating about a horizontal axis at right angles to and below the axis of the barrel; in front, the lock is conaled. The breech-block is operated by a lever, and is locked by a cam. The cam is held in position by a spring, one branch of which serves as a trigger-spring. The breech-block is simply a box containing the firing-pin, a bell crank lever, one arm of which controls the motion of the firing-pin, the mainspring, trigger-spring, etc. The box is closed by a cover, in a slot in which is situated the extractor. In operating the lever, so as to open the block, a point bears against the surface of the cam, presses it forward, and unlocks the piece. During the unlocking, the lower arm of the firing-pin lever is so moved by the nose of the cocking-lever as to cause the upper arm to retract the firing-pin. When the lever has been rotated sufficiently, the trigger-spring causes the nose of the trigger to enter the full-cock notch; at the same time the shoulder of the cam rides over the point of the trigger. The piece cannot then be fired until the cam is in its seat. The extractor is a flat blade, turning on the same axis as the lever, and operated by the shoulders of the slot in the cover of the breech-block in which it lies. The magazine is in the butt-stock. It is loaded at the side, near the rear, by first withdrawing the magazine-tube nearly its full length. When the breech-block is opened, a cartridge is forced by the magazine spring against the cartridge-stop As the block is closed, the stop descends, due to its arm working in a slot on the inner surface of the receiver, and the cartridge enters the chamber. A fork on the upper surface of the receiver prevents the cartridge being thrown out when the block is closed, and also guides it into the chamber. A cut-off is situated on the left side of the receiver. It may be so set as to prevent the breech-block opening far enough to allow cartridges to feed from the magazine. The piece may then be used as a single-loader. As a magazine gun, 3 motions are necessary to operate it, viz.: opened, closed, fired. As a single-loader, 4 motions are necessary, viz.: opened, loaded, closed, fired. This gun carries 5 cartridges in the magazine and one in the chamber. If the breech-block be opened, the six cartridges may be loaded directly in the magazine. See *Magazine-gun*.

LEYDEN JAR.—The principle of the Leyden jar was discovered by Muschenbroeck at Leyden in 1745, hence its name. Gralath, in Germany, 1746, continued the electric battery by combining a series of jars; and finally Drs. Watson and Bevis, by covering the outside of the jar with tinfoil, brought it to the complete state in which we now have it. The mouth of the jar is generally closed by a wooden stopper, through which passes the stalk of a brass knob or ball, surmounting the whole. The connection between the inside coating and the ball is completed by a chain extending from the stalk to the bottom of the jar. If this jar be put on an insulating stool, so that sparks can pass from the prime conductor of a machine to the knob, when the jar is thus insulated, one or two sparks pass, and then the charge seems complete, for no more sparks will follow, though the action of the machine is continued; or if they do, they are immediately dissipated from the knob in a brush discharge. If then, however, the knuckle of the experimenter be brought near the outer coating, sparks begin again to pass freely; and for every spark of + electricity that passes between the machine and the knob, a corresponding spark of the same name at once passes between the knuckle and the outer coating. This continues for some appreciable time, and then the jar appears to be again completely saturated. It is now said to be fully charged. The outside of the jar can, in this state, be handled freely, and if it be still on the insulating stool, so may also the knob, although when the hand first approaches, it receives a slight spark. But if, when the experimenter has one hand on the outer coating, he bring the other hand to the knob, before it can reach it, a straight, highly brilliant spark passes between the knob and his hand, and he experiences a shock of great violence. If he try the same thing again, a feeble spark and shock again ensue, and the jar is now thoroughly discharged. As it is highly inconvenient, if not dangerous, to discharge the jar through the body, *discharging tongs* are used for that purpose, which consist of two brass arms ending in balls, and moved on a hinge by glass handles.

A very instructive experiment may be made when the coatings are fitted to the jar so as to be removed at pleasure. After the jar is charged, it is put on an insulating stand. The inside coating is lifted out by the knob, and a slight spark is got by the hand in doing so. The jar is now taken up by one hand, and the outside coating is removed by the other, and, as before, another feeble spark is got. The whole is now built up in inverse order and discharged, when the spark is nearly as brilliant as when it is discharged at once without such dissection. From this it may be positively argued that the charge of the jar lies in the glass and not in the coatings, and that it is very likely that in all cases it is in the dielectric the charge resides; that the conductors, which are usually looked upon as the seat of the charge, are merely the limiting surfaces or exponents of it. A portion of the total charge may reside in them, but no more than is found on two similar contiguous dielectric surfaces. Taking this for granted, it is easy to explain the action of the Leyden jar. The electrifying power of the charging machine is exerted on two dielectrics—the glass of the jar and the air—the external limit in both cases being the surrounding objects which constitute the ground. The action on the air through the inside coating or the knob is quite similar to what we find in the case of any body to be charged. The action through the glass is peculiar, because we are shut out from it. The limits of this action are the inside surfaces of the inside and outside coatings. The air charge we participate in as we move in it. We are, however, quite external to the action on the glass; but if we could move about in it between the coatings, we should find things there exactly similar, so far, at least, as kind of action is concerned, to what we find in charged air. Seeing that the glass of the jar is a thin and good dielectric, and the air much thicker and more difficult to polarify, the charging power of the machine is exerted for the most part in the glass, the polarification in the air being comparatively slight. Assuming electricity to be a polarification of molecules, the electricity of the jar resides thus in glass, and to a much less extent in the air. The potential at the inner coating is the same as that at the knob, for any connected system of good conductors must be at the same potential. We judge of potential by the air charge, and thus we take the potential at the knob as the potential at the inner coating. The spark got from the knob of the insulated jar is small compared with that of the charging machine, and as sparking distance is, generally speaking, proportional to potential, the potential of the jar is much below that of the charging machine. Thus, a *Leyden jar is a contrivance for accumulating large quantities of electricity at a low potential.* The thinner the glass, the greater will be the accumulation of electricity, but the feebler will be the potential of the jar. When the electric field is limited, as in the glass of the Leyden jar, it is sometimes said to be *bound*, as distinguished from the *free* charge of an ordinary air field. When the knob of the insulated jar is touched, a spark is got, and if the finger be then removed to the outer coating, another spark, but of the opposite name, is obtained, and the knob is again prepared to give a spark, and this alternating process may be continued till the jar is emptied. When the inner coating is touched, the outer coating becomes insulated, and thus the potential always shifts to the insulated coating with an opposite name to what it had before. Each spark obtained by the finger in going from one to the other consumes so much of the energy of the charge, and so the potential is gradually lowered. When the jar is discharged by the tongs, the charge of the dielectric glass is thrown into the dielectric air. The particles of the glass, though more easily electrified than those of air, having a higher specific inductive capacity, offer a much greater resistance to discharge than those of air. At the same stage of polarification, the air gives way, while the glass still keeps polarified. Hence a jar with glass only a fraction of an inch in thickness can give rise to an air-spark of several inches; besides this, the charge in the glass is somewhat uniformly distributed. In the air, with the tongs, the force of the charge is concentrated on a certain region of it, and the breaking down of the conductive resistance of the air is more easily effected. The feeble *residual* spark from the jar, after the first main discharge, is due to what is called *electric absorption*. Somehow, the electricity given to a dielectric is not immediately available when a circuit is offered, the dielectric taking some time to recover itself. This is observable in all solid dielectrics, but no trace of such action is found in air. The sparking or *striking distance* of the jar indicates the potential of the charge. The quantity may be measured by the turns of the charging machine. It is found that when the same quantity is given to two jars, one double the other in point of covered surface, the striking distance of the large jar is only half that of the small jar; and that to charge the large one so as to obtain the same length of spark, twice the quantity must be given. If two jars be taken of the same size, and one of them be charged, we find that, on connecting their outside coatings, a spark passes when their knobs are brought together, and that, when now the double jar is discharged, the spark is only half as long as was got from the single jar discharged directly. The quantity discharged finally in the double jar was the same as in the single jar, but the potential was half. The spark occurring at the participation of the charge accounts for the loss of potential For great power, large surfaces are necessary. This can be obtained either by constructing a large jar, or by uniting several small jars together so as to act as one. The latter method is preferable, as we can vary the surface according to the number of jars employed.



A combination of small jars united together as one is called an *electric battery*. A very convenient form of electric battery is shown in the drawing. The knobs of each jar communicate with a large central one by arms of brass moving on hinges, and the outer coatings are put in a conducting connection, by being placed on an insulated stool covered with tinfoil. The interior coatings are conveniently charged by a long projecting arm from the central knob, and the exterior ones by connecting the stool with the knob of the unit jar, or by a wire with the ground. Any jar can be thrown out of action by throwing back its arm. See *Electricity*.

LIBERTY, EQUALITY, FRATERNITY.—For nearly a century, these three words have been accepted as embodying the creed of those who maintain the rightful supremacy of the numerical majority; and they have been sounded as the watchword of that formidable movement known on the Continent of Europe as "The Revolution," of which the object was to assert this supremacy by overturning the existing fabric of society. When contrasted with the democratic creed of antiquity, the only novelty which the modern symbol exhibits consists in the proclamation of "Equality;" for "Liberty," in the widest sense—meaning thereby the ultimate extension of political power to the whole body of the citizens—has been the object of the most enlightened politicians of all ages; whilst the protest in favor of "Fraternity" is a mere sentimental commonplace, about the speculative soundness of which there never was any real difference of opinions.

The first state document of importance in which the doctrine of "Equality" is set forth is the American Declaration of Independence of July 4, 1776. This celebrated document proceeds thus: "We hold these truths to be self-evident: *that all men are created equal;* that they are endowed by their Creator with certain unalienable rights; that among these are life, liberty, and the pursuit of happiness," etc. This, as we have said, was in 1776. But as a speculative opinion, the doctrine of "Equality" had been proclaimed by Hobbes more than a century before, and from his time down to the period at which it thus received practical recognition, it had never been lost sight of by the class of speculators to which Hobbes belonged. Under different forms and from various points of view, it had been reasserted by Spinosa, Rousseau, Helvetius, and ultimately by the class of political declaimers whose works were simultaneous with the American, and immediately proceeded the French Revolution.

LIBRARIES—Military Libraries are either garrison or regimental. The former comprise large collections of books, with newspapers, games, lectures, etc., in commodious rooms, and are intended to win soldiers from the gin-shops and vicious haunts which are ever prevalent in garrison towns. Attempts have been made to provide the soldiers with books, both for instruction and amusement; but statistics prove that the men patronize few besides fiction and travels, and religious books, not at all. Regimental Libraries are smaller collections of books, which accompany regiments in their various movements. The charge for Military Libraries in the British Army was, for 1876-77, the sum of £4,085.

LICORNE—An improved howitzer introduced by the Russians in 1777. Short, light cannon intented to throw large projectiles with comparative small charges were used by the Dutch in the early part of the 17th century and came into almost general use during that century, prior to the introduction of the *licorne*. See *Howitzer*.

LICTORS.—Among the Romans, the official attendants of Magistrates of the highest rank. They carried the *fasces* before the Magistrates, clearing the way, and enforcing the use of the appropriate marks of respect. It was their duty to execute the punishments ordered by the Magistrates, such as scourging with rods and beheading. They were originally free men of the plebeian order, and not till the time of Tacitus could the office be held by freedmen. Slaves were never appointed Lictors.

LIDE.—A warlike machine which was formerly used to throw large stones against a fortified place, or upon an enemy.

LIEUTENANT.—A term applied to a variety of offices of a representative kind. Thus, in military matters, a *Lieutenant-general* personates with each division of an army the General-in-Chief. A *Lieutenant-colonel* commands a battalion for a Colonel in the latter's absence. But the title Lieutenant, without qualification, denotes the second officer and deputy, or *locum-tenens*, of the Captain in each company of cavalry or infantry. A Lieutenant in the British Foot-Guards ranks as Captain in the Army, and exchanges with a Captain in another regiment. *Captain-lieutenant*, an obsolete rank, was the subaltern who commanded the "Colonel's Company" in each regiment. —A *Second Lieutenant* is the junior subaltern of a company, and corresponds to what formerly was an Ensign. In the United States Army and Marine Service, the Lieutenant ranks next after the Captain and there are two grades, First and Second Lieutenant, the latter being the lowest commissioned officer. These grades rank with those of Master and Ensign in the United States Navy.

In the British Navy, Lieutenant is a misnomer in the case of the officer bearing that title. His functions in all respects correspond to those of a Captain in the Army, with whom he ranks, and with whom he also nearly matches in regard to pay. A Lieutenant's full pay is 10s. a day; and his half-pay ranges, according to length of services, from 4s. to 7s. a day. Six years' service afloat are requisite to qualify an officer for the rank of Lieutenant, and the candidate has also to pass a satisfactory examination in seamanship and general professional knowledge. As leaders in all minor enterprises, such as boat expeditions, cutting out, etc, Lieutenants in war time carry off most of the laurels awarded to actions of singular personal daring.

LIEUTENANT COLONEL.—The rank in the United States Army next above Major and next below Colonel, and answering to that of Commander in the Navy. In the British Army it is nominally the second officer in a regiment; but virtually a Lieutenant-colonel commands every battalion of infantry and regiment of cavalry, the post of Colonel being merely an honorable sinecure, with usually £1,000 a year attached, awarded to some General Officer. The Lieutenant-colonel is responsible for the discipline of his battalion, the comfort of his men, and ultimately for every detail connected with their organization. He is assisted by the Major and Adjutant. In the artillery and engineers, where the rank of Colonel is a substantive rank, with tangible regimental duties, all the functions of Lieutenant-Colonel are more limited, one having charge of every two batteries of artillery, or two companies of engineers. The pay of a Lieutenant-colonel varies £1. 9s. 2d. per diem in the Household Cavalry to 17s, in the Infantry of the Line. Five years' regimental service as Lieutenant-colonel entitles an officer to brevet rank as Colonel, which, while improving his position in the Army, does not, however, affect his status in his regiment.

LIEUTENANT-GENERAL.—In the United States army the rank next beneath that of General; the latter under the President, being Commander-in-Chief. It was first authorized by Congress in 1798, and bestowed upon General Washington, in view of the then anticipated war with France. After Washington's death the rank remained in abeyance until 1855, when it was revived (in brevet) by Congress for General Winfield Scott, at whose death it again lapsed. In 1864 it was again revived by special Act, and conferred on General U. S. Grant, on whose promotion by the creation of the grade of General in his behalf, Major General William T. Sherman became Lieutenant General; and, on his succession to the rank of General, Major General Philip H. Sheridan was promoted to be Lieutenant General, and so remains until the present time, 1884. See *General Officer.*

LIEUTENANT DE LA COLONELLE.—The Second Officer, or what was formerly styled the *Captain-lieutenant* of the Colonel's Company of every infantry regiment in France. See *Lieutenant.*

LIEUTENANT DU ROI.—During the Monarchy of France there was a Deputy Governor in every fortified place, or strong town, who commanded in the absence of the Governor, and who was a check upon his conduct when present. This same person was called *Lieutenant du Roi. Lieutenants des Gardes Françaises et Suisses* bore the rank of Lieutenant-colonel, and took precedence of all Captains. *Lieutenants Provinciaux d'Artillerie* were certain officers belonging to the old Erench service, and immediately attached to the artillery, who bore the title or name of the particular Province in which they were stationed. Several of these Lientenants, who had military employment under the Board of Ordnance received the rank of Lieutenant-general in the Army from the King, and could rise to the most exalted stations.

LIFE GUARDS.—The mounted body-guard of the Sovereign. In the British Army there are two corps so designated. They never leave the country except in a very great emergency. These regiments were engaged in the Peninsula, and were present at the battle of Waterloo, where they greatly distinguished themselves. The two regiments of Life Guards wear a cuirass over a scarlet tunic. Their headpiece is a steel helmet. The remainder of their dress consists of leather breeches, long gauntlets, and jack-boots. Their weapons are the sword and the carbine. See *Guards.*

LIFE OF PIECE.—An expression denoting the length or time or the number of rounds a piece of ordnance will stand before it becomes unserviceable. This is estimated in smooth-bore ordnance at from 1,000 to 1,200 rounds with service charge and one shot. Experience, however, has shown that it is not so much the number of rounds fired which destroys a gun as the high elevation given to it to obtain extensive range. Guns fired horizontally, or at no greater elevation than 5° or 6°, do not experience the great strain which a gun fired at 30° would, and the reason is obvious, as guns fired at a low elevation recoil in proportion to the relative weight and friction of the projectile; whereas, when elevated to 30°, the gun cannot recoil, the force, therefore, is exerted downwards, and the gun impinges on its support, which is comparatively immovable; thus the force which displaced the gun in the first instance is now exerted on the sides of the gun. The initial velocity is also increased with the angle of projection, which causes the shot to press more upon the charge and thus to increase the resistance of the expansion of the gases. This increased resistance also adds to the strain upon the gun. Sufficient experience has not yet been had of rifled guns to state what number of rounds the different classes of such ordnance can bear, but it may be inferred that their endurance will be considerable.

LIFE ROCKET DEPARTMENT.—That branch of the Marine Department of the Board of Trade which has the management of life-rockets, mortars, lines, buoys, and belts, divides with the National Life-boat Institution the labors connected with the prevention of shipwreck, and the rescue of shipwrecked persons. This has been the arrangement since 1855. Until that year the life-mortars in use were partly under the control of the Admiralty, sometimes under the Board of Customs, partly under the Institution just named, and partly belonging to private individuals. The Merchant Shipping Act, passed in 1854, and put in force the following year, placed the whole under a different organization. To work out properly the rocket and life-saving system, a topographical organization is in the first instance adopted. The coasts of the United Kingdom are classified into 59 coast-guard divisions or wreck-registrars' districts; and the coast-guard Inspector of each division or district has control over all the rockets, mortars, buoys, belts, and lines kept at the various seaside stations in his district. There were in 1874 about 300 such stations; some supplied with mortars, some with rockets as well as mortars, but the greater number with rockets only. Most of the mortars are Boxer's improvement on Manby's; and most of the rockets are Boxer's improvement on Dennett's. Boxer's rockets, found more effective than mortars, are made at the Royal Labratory, at Woolwich, and are supplied by the War Department to the stations, on requisition from the Board of Trade; as are likewise mortar-shot and shell, fuses, portfires, signal-lights, gunpowder, etc. At each station is kept a cart, expressly made to contain all the requisites for the rocket apparatus, ready packed. Eighteen rockets are supplied with each apparatus; and a new supply is obtained before these are exhausted. Between 1874 and 1880, the system has extended year by year in the number of stations and of men; but while the details of organization have changed, no new principle has been introduced. Simlper apparatus, consisting of life-belts and life-lines, is kept at a much greater number of stations. The system is worked by the coast-guard, the men being paid for periodical drilling, and for regular service. Special services are rewarded with gifts of money, medals, etc.

LIFE-SAVING ROCKETS.—When a life-boat is not at hand, or a raging sea and a shoal coast renders its use impracticable, a distressed ship may often receive help from shore, provided the distance be not too great for the throwing of a rope. A small rope may draw a thicker, and that a hawser, and the hawser may sustain a slinging apparatus for bringing the crew on shore. For short distances, Captain Ward's *heaving-stick* has been found useful; it is simply a piece of stout cane about 2 ft. long, loaded at one end with 2 pounds of lead, and at the other end is securely attached to a thin line. It is whirled round vertically some 2 or 3 times, and then let go; but it cannot be relied on for more than 50 yards. Kites of various kinds have been employed, but are not found to be certain enough in action. The firing by gunpowder of some kind of missile, with a line of rope attached to it, is the method which has been attended with most success. In 1791 Sergeant Bell, of the Royal Artillery devised a mode of firing a shot and line from a distressed ship to the shore. It was afterwards found to be more practically useful to fire from the shore to the ship. In 1807 Captain Manby invented his *life-mortar*, an ordinary 5½ in. 24-pounder coehorn, fixed at a certain angle in a thick block of wood. The missile discharged from it was a shot with curved barbs, something like the flukes of an anchor, to catch hold of the rigging or bulwarks of a ship. How to fasten the shot to the rope was at first a difficulty: chains were not found to answer; but at length strips of raw-hide were found suitable. To assist in descrying the exact position of a distressed ship on a dark night, in order to aim the mortar-rope correctly, Manby used a chemical composition as a firework, which would shine out in brilliant stars when it had risen to a certain height. A third contrivance of his for replacing the shot by a shell filled with combustibles, in order to produce a bright light which would render the rope visible to the crew, was not so successful.

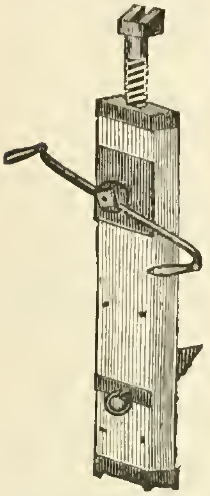
Many variations have been made in the line-throwing apparatus. Colonel Boxer has recently substituted a *bolt* for the shot, with four holes at the end; fuses thrust into these holes shed a light which marks the passage of the bolt through the air. Trengrove's rocket-apparatus, invented in 1821, consisted of an ordinary 8-oz. sky-rocket. Certain practical difficulties, however, affected it, and it did not come much into use. In 1832 Dennett's apparatus was invented. It nearly resembled the old sky-rocket, but with an iron case instead of a paper one, and a pole 8ft. long instead of a mere stick; it weighed 23 lbs., was propelled by 9 lbs. of composition, and had a range of 250 yards. A ship's crew having been saved by the aid of this rocket at Bembridge, in the Isle of Wight, the Board of Customs caused many of the coast guard stations to be supplied with the apparatus in 1834. Carte's apparatus, brought forward in 1842, depended on the use of a Congreve rocket instead of an ordinary sky-rocket. It does not appear that this apparatus was ever adopted by the authorities. Mr. Dennett next sought to improve the power of his apparatus by placing two rockets side by side, attached to the same stick; and it certainly did increase the range to 400 yards; but as the simultaneous and equal action of the rockets could not be always insured, the scheme was abandoned. Colonel Delvigne, of the French army, invented a *life-arrow*, to be fired from an ordinary musket. It is a stick of mahogany, shaped like a billiard-cue; the thicker end presses on the powder; while the thinner end, loaded with lead, is fitted with loops of string; a line or thin rope is attached to the loops, and the thin end of the stick projects beyond the barrel. The jerk, when the arrow or stick is fired, causes the loops to run down the stick to the thick end; this action has an effect like that of a spring, preventing the stick from darting forward so suddenly as to snap the line. The apparatus will send an arrow of 18 oz. to a distance of 80 yards, with a mackerel line attached. Another French contrivance, Tremblay's rocket with a barbed head, was soon adopted for the Emperor's yacht; but as it is to be fired from the ship to the shore, it partakes of the same defects as Sergeant Bell's original invention. The most effective apparatus yet invented is Colonel Boxer's. Finding that Dennett's parallel rockets on one stick do not work well, he succeeded after many trials in a mode of placing two rockets in one tube, one behind the other. The head is of hard wood; there is a wrought-iron case, with a partition between the two rockets. When fired, the foremost rocket carries the case and the attached line to its maximum distance, and the rearmost rocket then gives these a further impetus. The effect is found to be greater than if the two rockets were placed side by side, and also greater than if the quantity of composition for the two rockets were made up into one of larger size. The rocket is fired from a triangular stand, and is lighted by fuse, port-fire, or percussion-tube; the elevation is determined by a quadrant or some similar instrument.

The lines used with these several projectiles have varied greatly; but the best is found to be Italian hemp, spun loosely. It is very elastic, and when thick enough for the purpose, 500 yds. weigh 46 lbs. In Boxer's rocket, the line passes through the tail of the stick, then through the head, where it is tied in a knot, with India-rubber washers or buffers to lessen the jerk. The line is carefully wound on a reel, or coiled in a tub, or faked in a box provided with pins ranged round the interior—to enable the line to run out quickly without kinking or entangling. Dennet's faking-box for this purpose is the one now generally adopted.

Life-belts, jackets, and buoys of various kinds are used, made of cork, inflated India-rubber, etc.; but one apparatus now employed in conjunction with the life-rockets is known by the curious name of *petticoat-breeches*, or more simply, *sling life-buoy*. It is not strictly either a belt or a buoy, but a garment in which a man may be slung clear out of the water. When a rocket has been fired, and a line has reached the distressed ship, signals are exchanged between the ship and the shore; a thicker rope is pulled over the ship by means of the line, and a hawser by means of the rope. When all is stretched taut by fastening to the masts, etc., any articles can be readily slung and drawn to and fro. The petticoat-breeches, was originally invented by Lieutenant Kisbee, and consists of a circular cork life-buoy forming the top ring of a pair of canvas breeches; one of these is hauled over from the shore to the ship; a man gets into it, his legs protruding below the breeches, and his armpits resting on the buoy; and he is hauled ashore by block-tackle. The crew of a wrecked ship can thus one by one be relieved. To prevent losing the hawser and other apparatus, when the last man has left the ship, an apparatus called a hawser-cutter is used working *in* the ship, but worked *from* the shore.

After the destruction of the *Northfleet* in 1873, off Dungeness, an exhibition was organized at the London Tavern, to which the inventors of new life-saving appliances were invited to contribute. Among the apparatus were Hurst's *life-raft*, consisting of a double pontoon, bridged over, stowed outside a ship, and lowered by simply cutting the lashings; Christie's *life-raft*, a large, rectangular framework, rendered buoyant by numerous air-tight spaces, some of which are available for stowing water and provisions; and Parrott's *tubular life-raft*, composed of cylindrical air-bags made of painted canvas, supporting a flooring of sail-cloth and netting, and rendered rigid by poles fixed in various directions. Many other novelties were displayed at the London Tavern, and also at a similar collection in the annual International Exhibition, in the forms of life-boats, rafts, garments, belts, buoys, etc. See *Anchor-rocket, Boxer Life-saving Rocket, Chandler Anchor-shot, Delvigne Life-saving Gun, German Life-saving Rocket, Hooper Life-saving Rocket, Hunt Life-saving Rockets, Lyle-Emery Grapple-shot, Manby Shot, Parrott Life-saving Mortar, Rockets, Russian Life-saving Rocket, Shot-lines*, and *Signal Rocket*.

LIFTING JACK.—A geared screw, with a projecting foot or hook at its lower end, for lifting heavy weights. This jack, as used at military posts, consists of the following detailed parts: 1 *bed*; 1 *handle*; 2 *rivet-bolts* No. 2 A, to strengthen the bed; 4 *washers*; 2 *nuts*; 2 eye-plates for the braces, let into the ends of the bed, and fastened by 4 *screws*, 2 inch, and 1 *screw*, 1 inch, No. 16; 1 *stand* (cast-iron); 4 *steadying-points*, screwed into the bottom of the stand; 2 *braces*, fastened to the stand at the upper end by 2 *bolts* No. 2; 1 *screw*, same size and pitch as the elevating screw for casemate carriages; 1 *foot;* 1 *plate*, fastened to the foot by 3 *screws*, 1½-inch, No. 14; 1 *nut;* 1 *pinion* for the hoisting-screw (brass), like those for the casemate elevating screw; 1 *shaft* for pinion, kept in place by one *screw-pin* let in the stand; 1 *crank*, held to the shaft by 1 *nut* No. 4; 1 wooden *handle*, fastened by 1 *washer;* 1 *nut* No. 2; and 1 *cap-plate*, let into the head of the stand one-eighth of an inch and fastened by 4 *bolt-screws* No. 1. This jack is now quite superseded by the hydraulic-jack. The jack represented in the drawing is used for general purposes, is simple, compact and powerful. A good substitute for a jack are two handspikes placed under the axle-tree, when, with the aid of two robust gunners, the carriage can be raised to take off the wheel. The jack known as *Clerk's* is the common screw-jack of the service, in a cast-iron conical box, with metal top and triangular base. This jack is of great power, and used for heavy carriages in lieu of the "tooth and pinion" and "screw-jack." There are other jacks in the service, such as the *rack and pinion*, lifting 3 tons; *Haley's*, which varies in power from 2 to 20 tons; and *Tangye's hydraulic*, capable of lifting from 4 to 20 tons. See *Jack-screw*, and *Mechanical Maneuvers*.



LIGHT.—Optics ranks next to dynamics in the category of nearly *exact* sciences—that is, of sciences whose fundamental principles are so well known, that the result of almost any new experimental combination can be predicted mathematically. Given the forces acting on a body, the laws of motion enables us, by purely mathematical processes, to determine the consequent motion. Though we have not as yet arrived at equal perfection in optics, we are certainly far on the way, and probably have now attained nearly all the progress (independent of improvements in our mathematical methods) which will be made until the next great step in molecular physics shall give us the clue to the nature of the minute motions on which light, heat, electric currents, and magnetism depend. The most extraordinary and almost incredible predictions of theory have been verified by experiment, and at present the differences between theory and experiment may be divided into two classes, corresponding to the above exceptions. The first are those depending on the imperfections of mathematical processes, where, because, for example, as we are yet unable to obtain the exact solution of a certain differential equation, we have to content ourselves with an approximate one. But every improvement in our means of approximation is found to introduce a closer agreement between theory and experiment. This difficulty may safely be left to mathematicians. It is otherwise with the second difficulty. This depends on our ignorance of the ultimate nature of matter, and our consequent inability to apply mathematical reasoning in a perfectly correct and sufficiently comprehensive manner. Here, the experimenter's work is still required, and it is in this direction that we must in all probability now look for important extensions of our knowledge. Optics is divided into two parts *physical* and *geometrical*. Of these, the latter contents itself with assuming certain obvious experimental truths, such as the fact, that light in a uniform medium moves in straight lines, the ordinary laws of reflection and refraction, etc., and making these its basis, employs mathematics to develop their further consequences. It is thus that theory has shown how to carry to their utmost perfection such exquisite specimens of art as the best telescopes and microscopes of the present day. But these investigations, and their practical application, are wholly independent of the *nature* of light, and cannot be affected by discoveries in that direction. It is otherwise when we come to physical optics. This commences with the question: "*What is light?*" and then endeavors to deduce from the nature of light the experimental laws which, as we have seen, are assumed as the basis of geometrical optics. By two perfectly distinct classes of astronomical observations—aberration and the eclipses of Jupiter's satellites—we know that light takes *time* to pass from one body to another—the velocity being enormous—about 200,000 miles per second. Hence it follows, that either *matter* or *energy* must be transferred from a body to the eye before we can see it. Here we have at once the rival physical theories of light, which have alternately had the advantage of one another in explaining observed phenomena. It is only of late years that an *experimentum crucis* has finally decided between them—by showing one of them to be utterly incompatible with a result of observation. Newton adopted the corpuscular theory, in which light is supposed to consist of material particles—i. e., he adopted the first of the two possible hypotheses; and he gave the first instance of the solution of a problem involving molecular forces, by deducing from this theory the laws of reflection and single refraction. We shall see immediately that this beautiful investigation led to the destruction of the theory from which it was deduced. But, independent of this, there are many grave and obvious objections to the corpuscular theory; for it involves essentially the supposition of material particles impinging on the eye with the astounding velocity of 200,000 miles per second. If such particles weighed but the millionth of a pound, each would have something like ten times the momentum (*i, e.*, the battering power), and *six million* times the vis viva or kinetic energy (*i. e.*, the penetrating power), of a rifle-bullet. Suppose them a million times smaller—yet as millions of millions of them must ever be supposed to enter the eye at once, coming from every point of the surface of every visible object, it seems impossible to reconcile such a hypothesis with the excessive delicacy of the organs of vision.

It is not pretended by the advocates of the rival hypothesis, undulatory theory of light, that they understand exactly the nature of the transference of energy on which they suppose light to depend; but they take from the analogy of sound in air, and of waves in water, the idea of the existence in all space of a highly elastic fluid (or quasisolid), provisionally named the *ether*, and they suppose light to consist in the propagation of waves in this fluid. Huygens has the credit of having propounded, and ably developed and illustrated, this theory. As we have seen above, no third hypothesis as to the nature of light is admissible. Many strong arguments against the truth of the corpuscular theory had been furnished by experiment, especially in the early part of the present century; and as they were always met by further and more extraordinary properties which had to be attributed to the luminous corpuscles, the theory had become complicated in the most fearful manner; and this of itself was an almost complete disproof. Still, it held its ground, for Newton's old objection to the rival theory, viz., that on the undulatory hypothesis there should be no shadows at all (witness the analogy of sounds heard round a corner), was as yet unanswered. This difficulty was overcome by Young, to whose sagacity we are indebted for the idea of *interference*, which completely explained the apparent discrepancy. But the question between the rival theories was finally settled by Fizeau and Foucault, who, by processes entirely different, but agreeing in their results, determined the velocity of light in air and in water. Now, Newton had shown that refraction, such as that of light by water, if predicated of moving *particles*, requires that they should move faster in water than in air. Huygens, again, had clearly shown, that if such refraction be predicated of *waves*, they must move much slower in water than in air. Fizeau and Foucault found, by direct measurement, that light moves slower in water than in air. Hence, it is certain that *light consists in the transference of energy, not of*

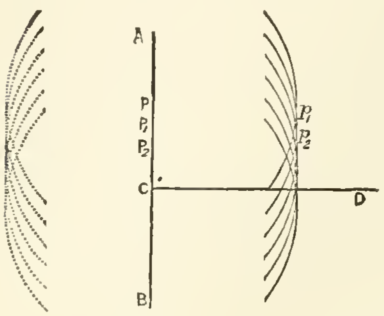


Fig. 1.

matter and the undulatory theory is based upon this fact. But, as to the manner in which energy is thus transferred, we are entirely ignorant. The common assumption is, that waves of distortion are propagated in the ether. The nature of this motion will be described under Wave. But many other modes have been suggested, one of the most notable of which is that of Rankine. Here the particles of ether are not supposed to be *displaced*, but each is merely made to turn an axis as the wave of light passes it; the particles having polarity by virtue of which they arrange themselves in similar positions when no light is passing, and by which, also, any rotation of one particle produces a consequent rotation of those in its neighborhood. For the explanation of most of the common phenomena of optics, it is quite indifferent which of these assumptions we make, and, indeed, theory has not yet been carried far enough to enable us to devise experimental methods of testing which is the more likely to be the case in nature. It cannot be too strongly insisted on that all we know at present is, that light certainly depends on the transference of energy from one part of the luminiferous medium to another; what kind of energy is transferred, vibratory or oscillatory motion, or rotation, etc., is a problem which may possibly forever remain unsolved. But vibratory wave-motion being that with which we are most familiar, as in earthquakes, sound, waves in water, etc., we naturally choose this as the most easily intelligible basis of explanation and illustration. And we shall now briefly show how the laws of linear propagation, reflection, single refraction, interference, diffraction, dispersion, polarization, and double refraction may be accounted for.

We assume, then, that light consists in a succession of waves, and for our earlier inquiries it does not matter whether they be (like those of sound) waves of condensation and rarefaction, in which the vibrations take place *in* the direction of the ray, or (like those in water) waves of distortion or displacement without condensation, in which case the luminous vibrations must be assumed to take place in some direction *perpendicular* to the ray. The phenomena of polarization and double refraction show us that the former of these hypotheses is very untenable.

Propagation of Light in a Uniform Isotropic Medium (An isotropic medium is such that if a cubical portion be taken, it possesses precisely the same properties whatever be the directions of its sides. Glass and water are isotropic, rock-salt and ice are not.)—Suppose AB (Fig. 1) to represent at any time the *front* of a plane wave which is passing in the direction CD; *i. e.*, suppose all particles of the ether in the plane AB (perpendicular to the plane of the paper) to be similarly and equally displaced. According to Huygens, we must suppose every particle, P, to be itself the source of a wave, which, from the uniformity of the medium, will spread with the same velocity in all directions. With center P, and radius

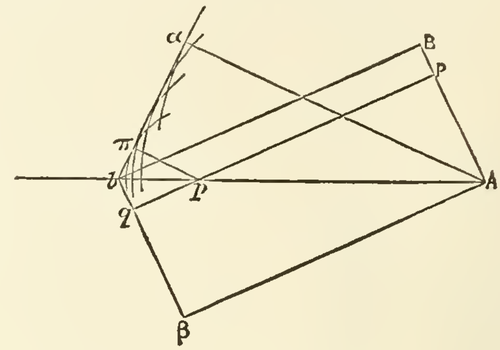

Fig. 2.

the space which light passes over in any assigned interval, t, describe a sphere represented in section by a circle in the figure Do the same for adjacent points, P_1, P_2, etc. Let p_1 be the intersection of the circles whose centers are P and P_1, p_2 that of the circles whose centers are P_1 and P_2, and so on. Then, as p_1 is *equidistant* from P and P_1, and (approximately) from all points of a small circular space between P and P_1 on the wave-front AB, all the separate wave-disturbances coming from these points to p_1 will be in the same *phase*, and will therefore combine so as to strengthen each other; while in other directions they will be in different phases and combine to destroy each other. The locus of all such points as p_1, p_2, etc., will therefore, at the end of the time t, contain all particles of the ether equally and similarly disturbed, and will thus be the new wave-front. But it is obviously a plane parallel to AB. Also the disturbance at P has passed to p_1; and, when the distance PP_1 is taken as very small, Pp_1 is perpendicular to the wave-front AB. Hence, in such a medium, it is readily seen that a plane wave remains plane, and always moves with uniform velocity in a direction perpendicular to its front. [There is a difficulty as to what becomes of the disturbance, which, according to Huygen's assumption, ought to travel *back* into the dotted portions of the spheres; and it is not easy to account for the absence of this on mechanical principles. But we are content here to take for granted that no

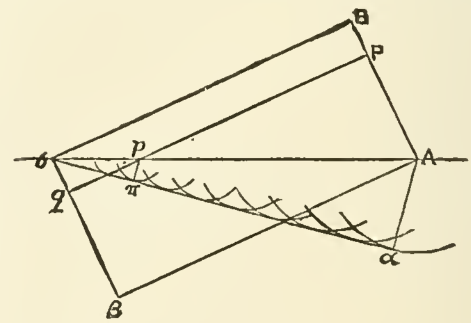

Fig. 3.

waves are propagated backward from the main wave, as a fact clearly proved by experiment.] Since a small portion of the surface of any curved wave may be considered as plane, we now see how any such wave will be propagated in an isotropic medium. Erecting perpendiculars at every point of the surface of the curved wave, and laying off along these lines the space which light passes over in a given interval, and the extremities form a new surface, which is the wave-front after the lapse of that interval. *Reflection at a Plane Surface.* Suppose AB (Fig. 2) to be a plane wave-front, moving in the direction of B*b* perpendicular to AB. Let A*b* be the reflecting surface, and let the intersection of the plane of the wave-front with the reflecting surface be a line through A perpendicular to the paper. When B has arrived at *b*, A would have arrived at *B*, and P at *q* (where *bB* is parallel to BA, and P*q* and A*B* to B*b*), had it not been for the reflecting surface. Hence, when B is at *b*, A has diverged into a sphere of radius A*B*, P from *p* into a sphere of radius, *pq;* and so for each point of the wave-front. Now, the spheres so described about A and *p* as centers obviously touch the plane *bB;* consequently they touch the other plane *ba*, which makes the angle A*ba* equal to A*bB*. Now, *bπa* is the front of the reflected wave, and A*a* is the direction in which it is proceeding. Hence, obviously, the ordinary laws of reflection. See *Catoptrics.*

Refraction at a Plane Surface into an Isotropic Medium—Here we take account of the change of velocity which light suffers in passing from one medium to another. In Fig. 3, A, P, B, *b*, *p*, *q*, and *B* represent the same as before—but suppose A*a* now to represent the space through which the wave travels in the second medium, while it would travel from B to *b* in the first. With center A, and radius A*a*, describe a sphere. Let *ba* touch this sphere in *a*. Then *ba* is the front of the refracted wave. For, if *pπ* be drawn perpendicular to *ba*, we have *pπ*: A*a*:: *bp*: *b*A:: *pq*: A*B*. Hence, while A travels to *a*, and B travels to *b*, P travels to *p*, and thence to *π*. And the sines of the angles BA*b* and A*ba*, which are the angles of incidence and refraction, are to each other as B*b* to A*a*, *i. e.*, as the velocity in the first medium is to that in the second. See *Dioptrics.*

It is quite obvious from the above figure that the *less* the velocity in the second medium the more nearly does the refracted ray enter it at right angles to its surface. As a contrast we may introduce here a sketch of Newton's admirable investigation of the same problem on the corpuscular hypothesis. Let U and V be the velocities in the two media, *a* and *B* the angles of incidence and refraction. Then the forces which act on the corpuscle being entirely perpendicular to the refracting surface, the velocity *parallel* to that surface is not altered. This gives

$$U \sin. a = V \sin. B.$$

Also the kinetic energy is increased by the loss of potential energy in passing from the one medium to the other. Hence, the square of V exceeds that of U by a quantity which depends only on the nature of the two media and of the corpuscle. This shows that V is the same whatever be the direction of the ray, and then the first relation proves that the sines of the angles of incidence and reflection are *inversely* as the velocities in the two media, *i. e.*, the refracting ray is more nearly perpendicular to the refracting surface the *greater* is the velocity in the second medium. It is very singular that two theories so widely dissimilar should each give the true *law* of refraction: and in connection with what has just been said, it may be mentioned that on the corpuscular theory a corpuscle passes from one point to another with the least *action*, while on the undulatory theory it passes in the least *time*. Hamilton's grand principle of *varying action* includes both of these. *Interference*—Fresnel's mode of exhibiting this phenomenon (whose discovery, as before said, is due to Young) is very simple and striking. An isosceles prism of glass, with an angle very nearly 180°, is placed (Fig. 4) in front of a brilliant point (the image of the sun formed by a lens of very short focus, for instance). The effect of the prism is that light which passes from O through the portion QR appears to have come from some point such as A (the image of O as seen through the upper half of the prism). Similarly the light which has passed through PQ appears to come from some point B. The light which has passed through the prism is to be received on a white screen ST. At the point T, which is in the prolongation of the line OQ, the distances TA and TB are equal; but for no other point, as U in the line ST, are UA and UB equal. Suppose U and V to be such that UA and UB differ in length by half a wave-length of some particular color, VA and VB by a whole wave-length of the same; then waves arriving at T, as if from A and B, have of necessity passed over equal spaces, and consequently their crests must truly coincide, so that at T they reenforce each other. But at U a hollow from A is met by a crest from B, so that darkness is the result. At V, again, crest and crest coincide. And so on. Hence, if we are experimenting with one definite color of light, the effect on the screen is to produce at T, V, etc., bright bands of that color, all parallel to the edges of the prism PQR. At points like U there are dark bands. And the length of a wave can easily be calculated from this experiment; for the lengths of OQ and QT can be measured, and knowing the angles of the prism and its refractive index for the particular color employed, we can calculate the positions of A and B. We have then only to measure the distance TV between the centers of the two adjoining bright bars, and then geometry enables us to calculate the difference of the lengths of VA and VB, which, as we have seen, is the length of a wave. The results of this experiment show how very minute are these wave-lengths for visible rays. Thus for

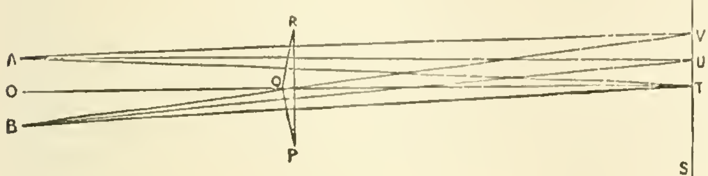

Fig. 4.

	Inch.
Extreme Red, the wave-length in air is ...	0.0000266
" Violet, " " "	0.0000167

These are, roughly, the $\frac{1}{40000}$ and the $\frac{1}{60000}$ of an inch. Seeing, then, that light describes 200,000 m. per second, the number of waves which enter the eye per second are:

Extreme Red.........460 millions of millions.
" Violet......730 " "

These numbers, compared with those of sonorous waves show the extraordinary difference in delicacy between the optic and auditory nerves. But whereas the range of the ear is somewhere about 12 octaves, that of the eye is less than one.

Dispersion.—We have just seen that, by Fresnel's interference experiment, waves of different length are separated (for in the last figure the position of the bright line, V, depends on the length of the waves which produce it). But the different colors are also separated by common refraction, as in Newton's celebrated experiment. This shows, of course, that in refracting media, waves of different colors move with different velocities; and, as the violet are more refracted than the red, it appears that the shorter waves move more slowly in glass or water than the longer ones. In free space, waves of all lengths travel with equal speed, else all stars ought to appear drawn out into spectra, in consequence of the earth's annual motion. Also, a star suddenly breaking out, or suddenly vanishing (a phenomenon several times observed), should flash out in the first instance red, and gradually become white, or it should gradually decay from white to violet, which is not, however, observed to be the case. These facts are, indeed, the most difficult to explain of any to which the undulatory theory has as yet been applied. Fresnel, indeed, appears to have been in possession of a solution of the difficulty, but the appendix to one of his papers, to which he more than once refers as containing this explanation, was not found among his MSS. Cauchy and others have, however, by very delicate investigations, shown that, *if the forces exerted by the molecules of a refracting body on the ether are exerted through distances comparable with the length of a wave*, the velocity of light will then depend on the wave-length. The velocity is, in fact, shown to be represented by a formula such as this:

$$A - \frac{B}{\lambda^2}$$

where A and B are constant quantities for a given medium, and λ is the length of a wave. The larger λ is, the less will be the second term of the formula, and therefore the velocity will be the greater. A very singular result follows from this same formula—viz., that the velocity will become more and more nearly equal to A as the wave length is greater. Hence, waves of low radiant heat, which are merely waves of light which are incapable of producing vision, must be crowded together toward a limit, not very far beyond the red end of the spectrum. *Polarization*—We now come to a set of phenomena which give us some further information as to the nature of luminiferous waves. When two beams of light, such as those in Fresnel's experiment, are polarized in planes perpendicular to each other before they meet, *they do not interfere*. This is in accordance with the assumption required for the explanation of the existence of polarization itself—viz., that the vibrations of the ether take place *transversely* to the direction of the ray. *Double Refraction*—Our assumptions, forced upon us by experimental results, are now so far complete that we may proceed, after Fresnel, to apply them to the explanation of double refraction. This explanation is extremely beautiful, and when published, was justly hailed as the greatest step in physical science which had been made since Newton deduced the facts of physical astronomy from the law of gravitation. As we have seen above, in treating of simple reflection and refraction, that the form and velocity in and with which a disturbance spreads from any point of a wave is all that is required for the determination of the course of a ray, we must endeavor to find the form in which a disturbance spreads in a double-refracting crystal; and this should lead us to a construction for each of the two rays. Huygens had already pointed out that one of the two rays produced by Iceland spar folows the ordinary law of refraction. Hence the disturbances which give rise to this ray are propagated in spherical waves in the crystal. He showed also that the other ray could be accounted for, if the disturbances to which it is due were propagated in the form of an oblate spheroid touching the sphere with the extremities of its axis, that axis being parallel to the crystallographic axis of the mineral. The following diagram (Fig. 5) when carefully examined will make this apparent:—P is the point where the ether is disturbed. Two waves spread from P in the form shown in the cut, the line ABP being the axis of rotation of the spheroid, and parallel to the axis of the crystal. Thus, let rays *a*A, etc. (Fig. 6), of which AB is the wave-front, fall upon the surface A*b* of such a crystal; and let AC be the direction of its axis. Draw, about A as a center, the sphere and spheroid into which the disturbance at A spreads in the crystal while light in air passes from B to *b*. Then if planes be drawn through the line *b* (perpendicular to the paper) so as to touch the sphere in B_1 and the spheroid in B_2, these planes will touch respectively all the intermediate spheres and spheroids produced by disturbances at points between A and *b*. Thus, bB_1 and bB_2 are the new wave-fronts and the ray *a*A, falling on the crystal, is divided into the two AB_1 and AB^2. Of these AB_1 is the ordinary ray, and being produced by spherical waves, has all the properties to be looked for in the case of a ray ordinarily refracted. It obviously moves forward perpendicularly to its front, as AB_1 is perpendicular to B_1b. But it is otherwise with AB_2, which is, in general, *not perpendicular to its front*, B_2b. Again, if AC, the axis of the crystal be not in the plane of incidence, the ray AB_2 is not in that plane; so that here we have *refraction out of the plane of incidence*. The exact accordance of this construction with observation was proved by the careful experiments of Wollaston. We have only to add, that the two rays AB_1 and AB_2 are, in all cases, completely polarized in planes at right angles to each other. The experiments of Brewster showed that in by far the greater number of minerals and artificial crystals, *both* rays are extraordinary—*i.e.*, neither of them can be accounted for by disturbances propagated spherically in the crystal. But no tentative process could lead to the form of the wave-surafce in this most general case. Here Fresnel's genius supplied the necessary construction. He assumes that the ether in a crystallized body is possessed of different rigidity, or different inertia, in different directions; a supposition in itself extremely probable, from the mechanical and other properties of crystals. In the general case there are shown to be three principal directions in a crystal, in any one of which, if the ether be displaced, the resulting elastic force is in the direction of the displacement. Each of these is, in all cases, perpendicular to the others. Any given displacement of the ether corresponds to partial calculable displacements parallel to each of these lines, and thus the elastic force consequent on any displacement whatever is known if we know those for the three rectangular directions. All the calculations are

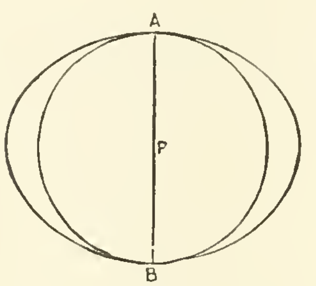

Fig. 5.

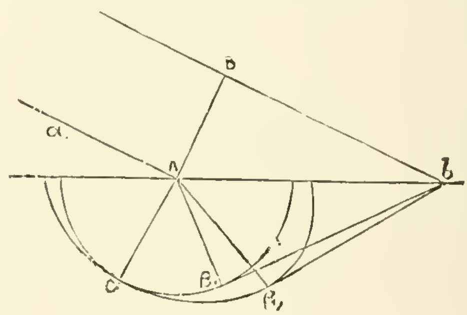

Fig. 6.

thus dependent on *three* numbers only, for each substance. It would unduly lengthen this article, and besides would lead us into discussions far too recondite for a work like this, to enter upon the question whether the vibrations in polarized light are *perpendicular to* or *in* the plane of polarization, a subject which has recently been well investigated by Stokes; or to consider the production of elliptically polarized light by reflection at the surface of metals, diamond, etc.; and various other most important points of the theory. We can only mention that Green, Cauchy, Stokes, and others, who have entered deeply into the mechanical question of luminiferous vibrations, have found themselves obliged to take into account the *normal* wave, which, as we have seen, Fresnel neglected. Fluorescence, spectrum analysis, and various other important recent additions to the theory, must be merely mentioned; as also the very remarkable observation of Maxwell, which appears to connect light and electricity, and was derived from a theory which assumes the ether to be the vehicle of electricity and magnetism as well as of light and heat, and by which it appears that the velocity of light is expressible in terms of the static and kinetic units of electricity.

LIGHT ARTILLERY BATTERY.—A mounted Battery of field-guns. In the United States army, for the purpose of diffusing instruction, the Lieutenants of the five artillery regiments are passed through the School of Light Artillery in their respective regiments, so that no Lieutenant will be in that School more than two years at any one tour. From this rule may be excepted Lieutenants in command of companies the Captains of which are indefinitely absent, Adjutants, Regimental Quartermasters, together with such others as from accidental causes may be unable to ride. If a vacancy happen in the grade of Captain of a Battery designated as a Light Battery, it will be filled by the order of the Secretary of War, on the recommendation of the Colonel, who usually names the Captain best qualified for the service. Every Battery of Artillery actually armed and equipped as a Battery of Horse-artillery or a Light Battery, and serving as such, is allowed, for annual practice, as many blank cartridges and friction-primers for instruction and drill as may be deemed necessary by the Battery Commander, and approved by the Post Commander. Such Batteries are also permitted to expend in target practice, annually, twenty-five projectiles for each gun of the command.

LIGHT-BALLS.—Preparations in pyrotechny, made in the same manner as fire-balls, except that there is no shell in them, as they are used for lighting up our own works.

They continue alight from 9 to 16 minutes, according to the caliber. Light-balls are of four different natures, viz: 10-inch, 8-inch, 5½-inch, and 4⅖-inch. Their form is oblong, and about 1½ caliber. The skeleton frame is made of wrought iron, and is partially covered with canvas, and filled with composition which burns with a brilliant light.

The proportion of composition is as follows:—

	lbs.	oz	drs.
Saltpeter, ground	6	4	0
Sulphur, ground	2	8	0
Rosin, pounded	1	14	0
Linseed oil, boiled	0	7	8

See *Fire-Balls* and *Fireworks*.

LIGHL-BARREL.—A common powder-barrel pierced with numerous holes, and filled with shavings that have been soaked in a composition of pitch and rosin; it serves to light up a breach, or a bottom of a ditch. See *Fireworks*.

LIGHT BOBS.—In the British service, the familiar term used for the light infantry.

LIGHT CAVALRY.—Regiments of mounted soldiers who, from their light equipment and active horses, are especially adapted for making long marches, performing outpost duties, skirmishing, etc. The experience of the wars of 1866 and 1870-71 has shown, clearly and convincingly, that the splendid charges, which in the days of Frederick and Napoleon frequently decided the fate of battles, have passed away, and that, in the future, it is before an action that the main *role* of the cavalry will be found to lie. Since the introduction of arms of precision, the duties of this branch may well be considered purely strategical, as cavalry can seldom be employed to take a decisive part in a battle. Upon this branch now devolves the task of preparing the way for an engagement, by *reconnoitering* the positions of the enemy, and giving, as to his movements, as much valuable information as possible. Light cavalry can therefore be used as a screen to mask the movements of the advancing or retreating army, and like a swarm of spies, to search the country of the enemy, gather information from all quarters, facilitate and often render unnecessary an armed attack, and, finally, bewilder, by harassing the foe. Employed as *éclaireurs* or feelers in every direction, they make a ring of mystery around their own army. The enemy does not know their whereabouts, while they carry back valuable information to their chiefs. The duties now thrown upon the light cavalry soldier demand much increased intelligence, and a knowledge of the operations of war. The value of good information is so important, and the evil of bad so great, that it would never be safe to trust anybody of ordinary trained men to fulfil these duties. Light cavalry form an important branch of the Intelligence Department, and it may be well said that 'They are the eyes and ears of an army." The hussar regiments form the light cavalry of the British army; but the lancers and the dragoons, although classed as medium cavalry, are often employed in the same duties.

LIGHT HORSE.—All mounted soldiers that are lightly armed and accoutered for active and desultory service: such as dragoons, hussars, mounted riflemen, etc. See *Light Cavalry*.

LIGHT-HOUSE BOARD.—A body organized in the United States, in accordance with an Act of Congress approved Aug. 31, 1852, and having the control and management of all lights, buoys, beacons, etc., on the coasts of the United States. It consists of eight persons, viz., two officers of high rank in the Navy, two officers of the Corps of Engineers, two civilians of high scientific attainments, an officer of the Navy, and an officer of the Corps of Engineers—the two latter serving as Secretaries. The Board as thus constituted is attached to the office of the Secretary of the Treasury, who is *Ex-officio* President of the same. A chairman, elected by the members from their own number, is chosen to preside in the absence of the President *Ex-officio*. The Board is required to meet four times a year, and the Secretary of the Treasury is empowered to call it together whenever, in his judgment, the exigencies of the service may require a meeting. It actually meets almost every week in the year. The coast and the waters of the country are divided into districts, each of which is served by an officer of the Army or the Navy in the capacity of Light-House Inspector, and other officers are employed from time to time, according to the exigencies of the service. The different subjects requiring attention are first referred to standing committees, whose duty it is to investigate and report to the Board what action, if any, is required. The two Secretaries perform all routine and general administrative duties under the orders and regulations of the Board.

LIGHT INFANTRY.—A body of armed men selected and trained for rapid evolutions. The service of Light Infantry often demands great individual address, intelligence, and quite well developed physical powers; a combination of qualities not easily found, and seldom, indeed, without careful, habitual training. Whereas, in Infantry of the Line, the qualities of the individual are of less importance, as results here depend almost solely upon the action of the mass.

The habitual order of battle of Light Infantry is the *dispersed order;* and whether acting offensively or defensively, it depends for its results upon the effect of its fire, resorting to the close order, and using the bayonet, only exceptionally. As each individual, although immediately supported by his own file-closer, and those on his right and left, is still often thrown upon his own resources, being obliged to take cover where he can most conveniently find it, he must be a good marksman, cool, deliberate, and circumspect; since it may become necessary to keep an enemy occupied hours, and even days together, pressing on him at one moment and yielding to him the next, or holding with tenacity, and disputing inch by inch some particular point, as it may suit the views of the General in command. In Infantry of the Line, as success depends upon the action of the mass, *ensemble*, judgement, coolness, and, determinaion should always characterize all its movements whether it delivers its fire in line, forms in column to attack with the bayonet, or throws itself into a square, to await the charge of the enemy's cavalry. The duties of Light Infantry are to open an engagement, and, after it is fairly under way, to keep it going; turning it to advantage if successful, otherwise breaking it off. In its relations to the Infantry of the Line it should cover the flanks of the latter: clear the way for its advance by rooting the enemy out of all covers, and then holding them if requisite. Upon it devolves all advanced-post, detachment, and advanced and rear-guard service.

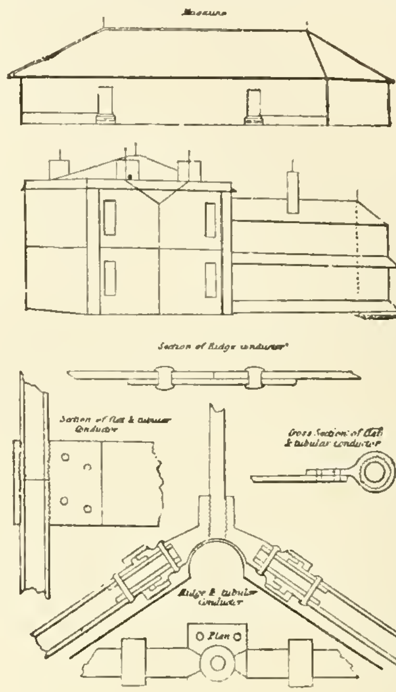
LIGHT INFANTRY COMPANY.—In the British service, a company of active, strong men carefully selected from the rest of the regiment. It always occupies its place on the left of the battalion until called for. When the call sounds, the Light Company orders arms and unfixes bayonets without word of command, and remains in readiness to move.

LIGHT MARCHING ORDER.—A term applied to troops lightly accoutered for detached service—usually paraded with arms, ammunition, canteen, and haversack.

LIGHTNING CONDUCTORS.—The following points and precautions should be carefully observed in the construction of powder-magazines and factories, in localities visited by lightning: experience shows that metal in a building, whether disposed of in the form of a conductor or otherwise, never *attracts* lightning. That, provided the surfaces of metals are not interrupted by bodies possessing a less conducting-power, a building entirely of metal will be the safest of all, and that such buildings require no further lightning-conductors than connection with the earth over the masonry foundations on which they are often laid. That, with regard to a building of brick or stone, the object must be to establish a sufficient number of lines of electrical conductors, extending from its most elevated and prominent points to the ground; and, further, bring the building into a condition similar to that of a metal building by means of other conductors generally attached to more prominent lines of the building itself, such as the ridges, angles, and eaves. There is no advantage, but the contrary, in endeavoring to insulate the conductors from the building.

The best material for conductors is copper, either in tubes 1½ to 2 inches diameter and .125 inch to .2 inch thick, or a wire rope. All metal surfaces, whether lead, copper, or iron, on ridges, roofs, gutters, or coverings to doors or windows, to be connected by plates of copper with the conducting system. Lead, on account of its low conducting power, cannot be altogether depended upon. One or more solid copper rods to project freely into the air, about 5 feet above the highest points of the building to which the main conductors are applied. The summit of the rod to be pointed; but gold, gilt or platinum tops are unnecessary. The termination of the conductors below to be led into damp or porous soil, when the building happens to stand upon it; but, when the soil is dry, two or three trenches to be cut, radiating from the foot of the conductor to a depth of 18 inches or two feet, and 30 feet in length, and either the conductor carried along the bottom of the trenches or old iron chain laid in them, carefully connected with the foot of the conductor. The trenches to be then filled up to one foot in depth with coal-ashes or other carbonaceous substance, and afterwards with earth or gravel.

If it be possible, in regulating the surface drainage to lead a flow of water, during the rain which gen-



erally accompanies thunder-storms, over the site of the trenches, it will be an additional precaution. Tanks are useless, except where the water flows freely into them from the surrounding soil, and even then they are superfluous as appendages to the conductors.

The conductors for brick or stone magazines with slate roofs should consist of a sheet-copper strip 4 inches wide, and .125 inches thick, covering the ridge, and securely fixed to it by wrought-copper nails. At each end of the ridge a solid copper rod .5 inch in diameter is securely fixed to the conductor on the ridge; and projects about 5 feet above the highest point of the building. Upper end of this rod is carefully pointed. Copper strips about 3 inches wide, or copper tubes nearly one inch in diameter, pass down the angles of the hip, and are firmly secured to the copper eaves-gutter. The descending water-pipes, made also of copper, and fastened to the face of the building by copper holdfasts, are connected at their lower end to the underground conductor by a piece of copper, 3 inches wide, wrapped around the lower end of the water-pipes and riveted to the underground conductor. The underground conduetor runs out from the building 4 feet, and then branches into two parts, each 8 feet long, 2 inches wide, and .125 inch thick. These conductors are about 2.5 feet from the surface of the ground at the lower end, and are covered with coal ashes and earth. The copper sheathings on the doors and windows are connected with the lower end of the water-pipes by flat copper strips, 2 inches wide, fixed to the water-table by copper nails driven into wooden plugs about 10 feet apart. When tubular conductors cannot be had of sufficient length in one piece, they are connected by a union joint, and strengthened by a small pipe or ferrule, about 4 inches long, inside the tube, and riveted to each end. Buildings which have the eaves-gutters and down-pipes made of tin or zinc should have a main conductor communicating directly with the ground; it should also be connected with the eaves-gutters, and the down-pipe should connect by a metallic communication with the ground, running out some distance from the building. In case of buildings situated on a dry or rocky soil, especial pains must always be taken to lay down old chains or other conductors in various directions, to at least a distance of 10 to 15 yards, and from 1 foot to 1.5 feet below the surface of the ground; and, if possible, lead a flow of rain over the surface of the ground about or near the conductor. Let the conductor terminate in a large surface of moist earth whenever it can be effected.

If copper be not used for conductors, zinc is the next best material of which they can be made. If iron be used, it should be in the shape of galvanized wrought-iron pipe, not less than 2 inches in diameter, firmly screwed together in joints of extra thickness.

Copper tube, of a thickness of from .125 to .2 inch is always to be preferred: it has more than five times the capacity for conducting electricity that iron has, and more than three times that of zinc. See *Powder Depots.*

LIGHTNING MAGAZINE-GUN.—The inventors of this rifle, the Colt's Patent Fire-arms Manufacturing Co., have adopted the left-handed method of handling, which enables the breech-action to be much simplified and lightened without detracting from its strength. The cartridge used is the same as that of the 44 caliber Colt revolver; it contains 40 grain of powder, and the bullet weighs 200 grains. The drawing shows the arm and its parts in position ready for firing.

To load and fire, bring the piece to the shoulder in the usual way; grasp the handle of the slide *A*, with the left hand and draw it to the rear. The first part of this movement raises the locking brace, *B*, from the abutment, *C*, acts upon the firing-pin-lever, *D*, withdraws the firing-pin, *E*, and releases the magazine-gate, *F*, causing it to hold back the cartridge in the magazine. Continuing the movement, the bolt, *G*, moves to the rear, ejects the cartridge-shell, cocks the hammer, *H*, and raises the carrier, *I*, so that when the movement is finished, the cartridge is in proper position to enter the chamber. The slide is then drawn forward. This movement carries the bolt forward, drives the cartridge into the chamber, throws down the carrier into position to receive another cartridge, and the rifle is ready for firing.

A feature peculiar to this rifle is, the lock is brought clear forward and the extractor is hooked over the cartridge-head *before* the magazine-gate will allow another cartridge to be fed to the carrier, thus preventing blocking of the breech-action. The firing-pin is held back positively until the cartridge has entered the chamber, when the bolt is locked so that premature explosion is impossible. The hammer is automatically locked and unlocked by the hook on the rear end of the magazine-gate. By this arrangement the rifle may be loaded and discharged by the reciprocating motion of the slide, keeping the trigger constantly pressed back during the motion by the forefinger of the right hand. The magazine can only be charged when the slide is drawn to the rear.

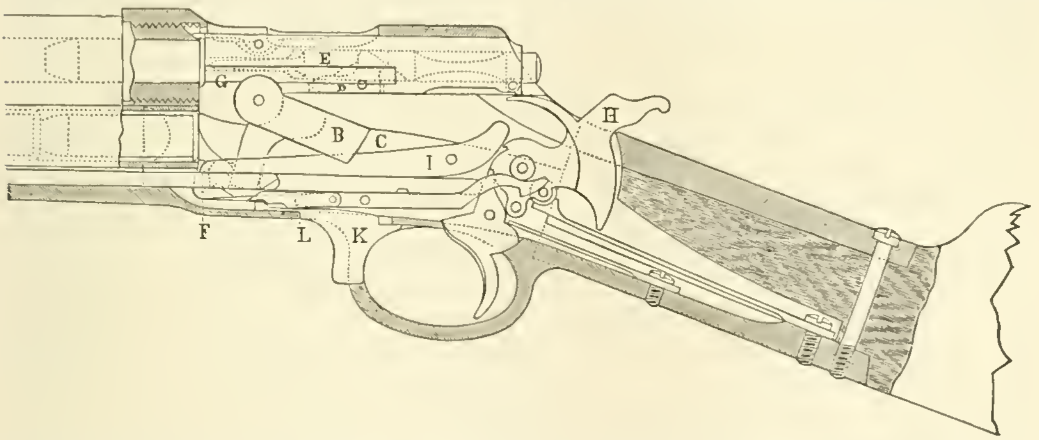
To take apart the rifle, take out the tang-screw. Draw off the butt-stock. Take out the magazine-screw at the front end and remove the magazine. Take out the two side screws, cock the piece, draw the slide about half way to the rear, and withdraw the trigger-plate. Slide the bolt clear back, insert a punch in the small hole on the left hand side, and push out the locking-brace pin, and slide out the lock. The other parts can be removed without special directions. To assemble the rifle, replace the parts in the reverse order from that given for taking the rifle apart See *Colt Magazine-rifle.*

LIGHTS.—In pyrotechny, lights are made by pressing lance or similar composition in shallow vessels, or in cases of large diameter. The burning surface being large, the light attains a great intensity.

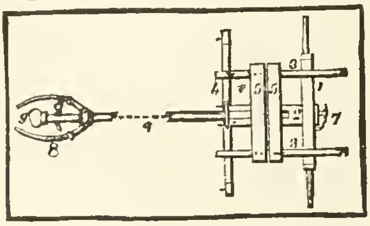
Shallow earthern, wooden, or metal vases or paper cases are used. The vase or case is filled with dry composition, slightly pressed in; or composition, moistened with gummed water may be used and pressed in the case more compactly. It is primed by powdering the surface first with a mixture of equal parts of the composition and mealed powder, and then with powder alone. Cover the top over with paper, pasted on the sides of the case. Through the center of the cover pass several strands of quick-match, spreading them over the suface and uniting them on the exterior in a single strand.

When the light is made with dry composition, the case must be placed in a vertical position. It may be placed horizontally if moistened composition be used and firmly packed.

Torch-lights for funeral ceremonies are made by impregnating large strands of cotton with a thin alcoholic pap, the whole arranged in vases like an oil-lamp, the pap replacing the oil. See *Fireworks.*



LIMBER.—To suit a gun-carriage to the easy and rapid transportation of its load, it must be converted into a *four*-wheel carriage, which is done by attaching it to another *two*-wheel carriage, called a *limber.* The field-limber is composed of an *axletree* (1), a *fork* (2), two *hounds* (3 3), a *splinter-bar* (4), two *foot-boards* (5 5), a *pole* (6), a *pintle-hook* and *key* (7), two *pole-yokes* (8), and a *pole-pad* (9). A side view of the limber is shown in the article CAISSON, with the manner of attaching the rear carriage to the pintle-hook. The limber axle-tree is made of iron, imbedded in a body of wood, as in the case of the gun-carriage. The fork constitutes the middle portion of the limber, and is the portion to which the pole is attached.



It is formed of a single piece of wood one end of which is mortised into the axle-body, and secured by the pintle-hook bolts, and the other is cut into the shape of a fork, to receive the tenon of the pole. The hounds are two wooden rails which are bolted to the axle-body and splinter-bar. They serve to support the ends of the limber-chest and foot-boards, and also for the purpose of transmitting the draught of the horses to the axle-tree. The chest is firmly secured by a stay-plate which is situated at the bottom of the cut in the fork, and two stay-pins, which pass through holes near the rear ends of the hounds. The splinter-bar is a piece of wood placed cross-wise with the pole, and is firmly secured to the fork and hounds. It has four hooks, to which the traces of the wheel horses are attached. The pole, or tongue, is employed to regulate the motion, and give direction to the carriage. The point of attachment of the rear carriage being near the axle-tree, and there being no sweep-bar, the weight of the pole is mostly supported by the collars of the rear horses; it should therefore be made of strong, light wood—ash is generally used for this purpose. As the pole is liable to be broken in ordinary service, the method of attaching it to the fork should always be such that all of the fragments can be promptly removed, and a new pole inserted. The foot-boards are secured to the fork and hounds in a proper position for the feet of the cannoneers to rest upon, while riding upon the limber-chest. The pintle-hook is a stout iron hook firmly fastened to the rear of the axle-tree, for the purpose of attaching the rear carriage. This mode of attachment is *simple*, *strong*, and *flexible*—qualities which are essential to rapid movements and great endurance. The point of the hook is perforated with a hole for the *pintle-key*, which prevents the carriages from separating while in motion. In the old system of field-carriages, the operation of limbering and of unlimbering was so difficult, that a rope, called a "prolonge," was used to connect the gun-carriage and limber in action. This implement is still retained, but the same necessity does not exist for using it. All field-carriages should admit of being turned in the shortest possible space. This depends upon the size of the front wheels, the distance between the front and rear axle-trees, the position of the pintle, and the thickness of the stock at the point where the front wheel strikes it. Notwithstanding that the front wheels are made higher in the present system of field-carriages than the Gribeauval system, which preceded it, the carriages of the former have greater facility of turning in consequence of the diminished thickness of the stock. See *Gun-carriages*.

LIMBER CHAIN.—A keep-chain which goes round the pintle and confines the trail to the limber, preventing its flying off the limber-hook.

LIMBER CHEST.—The ammunition or tool-chest belonging to the limber of an artillery carriage of any description. Those of the gun-carriage and caisson are fitted up as ammunition-chests, while those of the forge and battery wagon contain respectively tools and stores for blacksmiths, and for carriage-makers' and saddlers' use.

LIMBER HOOK.—The hook on the limber to which the trail of the gun is attached.

LIMBERING-UP HOOP.—A stirrup-handle on the trail of a gun by which the piece is moved in limbering and unlimbering.

LIMBER PITS.—Artificial cover provided in warfare for the limbers of guns. They are usually 12 feet long, $5\frac{1}{2}$ feet wide at bottom, 7 feet at top, 3 feet deep, and provided with ramps at each end. A pit of this size can be executed in two hours by eight men. Each pit should cover a limber and two horses.

LIMENARQUE.—An office of distinction, which existed in the Roman Empire. The persons invested with it were directed to watch the frontiers of the Empire, and they commanded the troops that were employed upon that service.

LIMITARY.—The guard or superintendent placed at the confines or boundaries of any Kingdom or State.

LIMITATION OF TIME OF PROSECUTION.—In the United States Army, no person is liable to be tried and punished by a General Court-Martial for any offense which appears to have been committed more than two years before the issuing of the order for such trial, unless, by reason of having absented himself, or of some other manifest impediment, he shall not have been amenable to justice within that period.

LIMITES ROMANI.—The name of a continuous series of fortifications, consisting of castles, walls, earthen ramparts, and the like, which the Romans erected along the Rhine and the Danube, to protect their possessions from the numerous attacks of the Germans.

LIMITS.—The importance of the notion of a *limit* in gunnery cannot be over-estimated, since many branches of mathematics, including the differential calculus and its adjuncts consist of nothing else than tracing the consequences which flow from this notion. The following are simple illustrations of the idea: The sum of the series $1 + \frac{1}{2} + \frac{1}{4} + \frac{1}{8} +$ etc., approaches nearer and nearer to 2 as the number of terms is increased; thus, the several sums are $1\frac{1}{2}$, $1\frac{3}{4}$, $1\frac{7}{8}$, $1\frac{15}{16}$, etc., each sum always differing from 2 by a fraction equal to the last of the terms which have been added; and since each denominator is double of the preceding one, the further the series is extended, the less the difference between its sum and 2 becomes; also this difference may be made smaller than any assignable quantity—say, $\frac{1}{100000}$—by merely extending the series till the last denominator becomes greater than 100,000 (for this, we need only take 18 terms; 3 terms more will give a difference less than $\frac{1}{1000000}$; and so on); again, the sum of the series can never be greater than 2, for the difference, though steadily diminishing, still subsists; under these circumstances, 2 is said to be the limit of the sum of the series. We see, then, that the criteria of a limit are, that the series, when extended, shall approach nearer and nearer to it in value and so that the difference can be made as small as we please. Again, the area of a circle is greater than that of an inscribed hexagon, and less than that of a circumscribed hexagon; but if these polygons be converted into figures of 12 sides, the area of the interior one will be increased, and that of the exterior one diminished, the area of the circle always continuing intermediate in position and in value; and as the number of sides is increased, each polygon approaches nearer and nearer to the circle in size; and since, when the sides are equal, this difference can be made as small as we please, the circle is said to be the limit of an equilateral polygon the number of whose sides is increased indefinitely; or, in another form of words commonly used. "The polygon approaches the circle as its limit, when its sides increase without limit," or again, "When the number of sides is infinite, the polygon becomes a circle." When we use the terms "infinite" and "zero" in mathematics, nothing more is meant than that the quantity to which the term is applied is *increasing without limit* or *diminishing indefinitely;* and, if this were kept in mind, there would be much less confusion in the ideas connected with these terms; from the same cause has arisen the discussion concerning the possibility of what are called vanishing fractions (*i. e.*, fractions, whose numerator and denominator become zero simultaneously) having *real* values; thus $\frac{x^2-1}{x-1} = \frac{0}{0}$ when $x = 1$; but by division we find that the fraction is equal to $x + 1$, which $= 2$, when $x = 1$. Now, this discussion could never have arisen had the question been interpreted rightly, as follows: $\frac{x^2-1}{x-1}$ approaches to 2 as its limit, when x continually approaches 1 as its limit, a proposition which can be proved true by substituting successively 3, 2, $1\frac{1}{2}$, $1\frac{1}{4}$, $1\frac{1}{10}$, $1\frac{1}{100}$, etc., when the corresponding values of the fraction are 4, 3, $2\frac{1}{2}$, $2\frac{1}{4}$, $2\frac{1}{10}$, $2\frac{1}{100}$, etc. The doctrine of limits is employed in the differential calculus. The best and most complete illustrations of it are found in Newton's *Principia*, and in the chapters on maxima and minima, curves, summation of series, and integration generally, in the ordinary works on the calculus.

LIMITS OF FIRE.—Within the limits of the zones of danger, positions are found for front, for reverse, and for enfilading fire. If the two faces, for example, of a work be prolonged to intersect the extreme limit of dangerous ground, the sector which they embrace is termed *the limits of direct* or *front fire;* since, from every position that can be taken up within this sector, a direct fire alone can be brought to bear upon the two faces. The two sectors which lie adjacent to this are termed *the limits of lateral*, or *reverse fire*, since they afford positions from which a reverse fire can be obtained against one of the faces, and a front fire upon the other. It is also only within these last limits that positions for enfilading the terre-pleins of the faces can be obtained. See *Defilement*.

LINCH-PIN.—A pin through the end of an axle-arm of an artillery carriage to keep the wheel on. A hook attached to the head of the pin and embracing the axle-arm prevents the pin from being jolted out. A ring against which the linch-pin rubs is called the *Linch-pin Washer*.

LINE.—1. In fencing, an imaginary line opposite to the fencer, wherein the shoulders, right arm, and the sword should always be found, and wherein are also to be placed the two feet at the distance of 18 inches apart. 2. In tactics, a body of men in either one or two ranks; generally a body of troops drawn up with an extended front. 3. An expression used in the British Army to distinguish ordinary Cavalry and Infantry from the Guards, Artillery, and Engineers. It obviously takes its origin from the fact that the troops in question constituted the usual "Line of Battle." 4. The Line Officers of the Navy and Army in the United States are divided into eleven grades, and their comparative rank on the active or retired list is as follows:

The Admiral of the Navy ranks with a General of the Army.

The Vice Admiral of the Navy ranks with a Lieutenant General of the Army.

10 Rear Admirals of the Navy rank with Major Generals of the Army.

25 Commodores of the Navy rank with Brigadier Generals of the Army.

50 Captains of the Navy rank with Colonels of the Army.

90 Commanders of the Navy rank with Lieutenant Colonels of the Army.

80 Lieutenant Commanders of the Navy rank with Majors of the Army.

280 Lieutenants of the Navy rank with Captains of the Army.

100 Masters of the Navy rank with First Lieutenants of the Army.

100 Ensigns of the Navy rank with Second Lieutenants of the Army.

Midshipmen of the Navy.

All Staff Officers are appointed by the President with the sanction of the Senate. He also appoints for vessels in actual service all Warrant Officers, such as boatswains, gunners, sail-makers, and carpenters, that may be required. All officers not entitled to hold warrants are called Petty Officers. All officers of the Army above the grade of Sergeant hold their authority by commissions, and are therefore termed Commissioned Officers, to distinguish them from Non-commissioned Officers.

President Fillmore in General Orders, No. 51, of 1851, has given the following satisfactory exposition of the use of the word *Line* in our Statute Book: The 122d Article of War provides that "If, upon marches, guards, or in quarters, different corps of the Army shall happen to join, or do duty together, the officer highest in rank of the Line of the Army, Marine Corps or Militia, by commission there, on duty, or in quarters, shall command the whole, and give orders for what is needful to the service, unless otherwise specially directed by the President of the United States, according to the nature of the case." The interpretation of this Act has long been a subject of controversy. The difficulty arises from the vague and uncertain meaning of the words "Line of the Army," which, neither in the English service, (from which most of our military terms are borrowed), nor in our own, have a well-defined and invariable meaning. By some they are understood to designate the Regular Army as distinguished from the Militia; by others, as meant to discriminate between officers by ordinary commissions and those by brevet; and, finally, by others, to designate all officers not belonging to the Staff. The question is certainly not without very great difficulty, and it is certainly surprising that Congress should not long since have settled, by some explanatory law, a question which has been so fruitful a source of controversy and embarassment in the service. The President has maturely considered the question, and finds himself compelled to differ from some for whose opinions he entertains a very high respect. His opinion is, that, although these words may sometimes be used in a different sense, (to be determined by the context and subject-matter,) in the 122d Article of War, they are used to designate those officers of the Army who do *not* belong to the Staff, in contradistinction to those who do, and that the article intended, in the case contemplated by it, to confer the command exclusively on the former. The reasons which have brought him to this conclusion are briefly these: 1st. It is a well-settled rule of interpretation that in the construction of *statutes*, words of doubtful or ambiguous meaning are to be understood in their usual acceptation. Now it must be admitted that, in common parlance, both in and out of the Army, the words "Line" and "Staff" are generally used as correlative terms. 2d. Another rule of construction is, that the same word ought not to be understood, when it can be avoided, in two different senses in different laws, on the same subject, and, especially, in different parts of the same law. Now in another article of this same law, the words "Line and Staff of the Army" are clearly and beyond question used as correlative and contradistinctive terms. The same remark applies equally well to almost every case in which the words "Line" and "Staff" occur in the numerous Acts of Congress. On the other hand, there is but one Act of Congress in which the words "Line of the Army" have been purposely employed to designate the Regular Army in contradistinction to the Militia, and none in which they have been manifestly used as contradistinctive of brevet. 3d. If Congress had meant by these words to discriminate between officers of the Regular Army and those of the Militia, or between officers by brevet and by ordinary commission, it is to be presumed that they would have employed those terms, respectively, which are unequivocal, and are usually employed to express those ideas. 4th. If we look at the policy of the law, we can discover no reasons of expediency which compel us to depart from the plain and ordinary import of the terms: on the contrary, we may suppose strong reasons why it may have been deemed proper, in the case referred to by the Article, to exclude officers of the Staff from command. In the first place, the command of troops might frequently interfere with their appropriate duties, and thereby occasion serious embarrassment to the service. In the next place, the officers of some of the Staff Corps are not qualified by their habits and education for the command of troops, and although others are so qualified, it arises from the fact that (by laws passed long subsequently to the Article in question) the officers of the Corps to which they belong, are required to be appointed from the Line of the Army. Lastly, officers of the Staff Corps seldom have troops of their own Corps serving under their command, and if the words "Officers of the Line" are understood to apply to them, the effect would often be to give them command over the officers and men of all the other Corps, when not a man of their own was present—an anomaly always to be most scrupulously avoided where it is is in any manner possible to do so. 5th. It is worthy of observation that Article 25, of the first "Rules and Articles," enacted by Congress for the government of the Army, corresponds with Article 122 of the present Rules and Articles, except that the words "of the Line of the Army" are not contained in it. It is evident, therefore, that these words were inserted intentionally with a view to a change in the law, and it is probable that some inconvenience had arisen from conferring command indiscriminately on officers of the Line or the Staff, and had suggested the necessity of this change. It is contended, however, that Sec. 10, of the Act of 1795, enumerates the Major General and Brigadier General as among the Staff Officers, and that this construction of the Article would exclude them from command, which would be an absurdity. No such consequence would, however, follow. The Article in question was obviously designed to meet the case (of not unfrequent occurrence) where officers of different Corps of the Army meet together with no officer among them who does not belong exclusively to a Corps. In such a case, *there being no common Superior*, in the absence of some express provision conferring the power, no officer, merely of a Corps, would have the right to command any Corps but his own; to obviate this difficulty, the Article in effect provides that, in such an event, the Officer *of the Line*, highest in rank, shall command the rest. But if there be a Major General or Brigadier General present, the case contemplated by the Article does not exist. No question can arise as to the right of command, because the General Officer, not belonging to any particular Corps, takes the command by virtue of the general rule which assigns the command to the officer highest in rank. See *Brevet*, *Command*, and *Rank*.

LINEAL RANK.—The rank of a Line-officer in his particular arm of the service. The *lineal promotion* of a Line-officer is his promotion according to seniority in the arm of service, as opposed to promotion in the regiment.

LINE OF BATTLE.—The formation of an army for battle. In all actions it is necessary to place troops in such a formation previous to making the assault, or in showing front to the adversary, as shall expose them as little as possible, and yet place them in the readiest mode to carry out the orders of the Commander. It has been the custom from a very ancient date, coming to us from the Romans, and an accepted principle by most nations, that an army, when drawn up for battle, should be formed in three distinct lines; the *first line*, to commence the battle; the *second*, to support it, and to fill up the gaps; the *third* which is in rear of all, as a reserve.

This triple formation, though modified, remains much the same at the present day; but instead of deployed lines or lines of heavy columns, the troops are placed in lines of half-column formation. This has been rendered necessary from the withering fire and long range of the present arms of precision, which necessitate the reduction of the front of battalions. It has also become necessary, whether taking the offensive or standing on the defensive, that shelter, either artificial (such as shelter-trenches) or natural, should be taken advantage of to screen the men as much as possible, and so not to expose them (in the case of an attacking party) more than can be helped before the moment of formation previous to the final rush in upon the enemy's position.

LINE OF CIRCUMVALLATION.—The front and the rear of camps around a besieged place are secured by lines of field works. The exterior line of works, termed the *Line of Circumvallation*, should form an unbroken line of intrenchments composed of the most simple elementary parts, as tenailles, redans, etc., with a slight profile; its chief object being to prevent succors of small detachments from slipping into the place. The interior line, termed the *Line of Countervallation*, is composed of detached works, which, if the garrison is strong, should be in defensive relations. The main points which should be occupied by these works are the principal avenues to the defenses, and the positions selected for the parks of the siege-train: to secure these points from the attempts of the garrison, and to render the entrance of large convoys into the defenses impracticable. The lines are so placed as to leave a space of about 200 yards between them and the front and rear of the camps.

When the great extent of ground that must be taken up by a besieging force, in the investment of any considerable position, which requires to be entirely surrounded to cut off all communication between it and the exterior, is taken into consideration, particularly now when rifled guns have acquired such long ranges, it will be seen that complete lines of circumvallation will be seldom practicable, and in most cases must be of too weak a character to serve as an intrenched defensive position for the besieging force to receive battle within them. Accordingly, in the later sieges in Europe, continuous lines of circumvallation have been seldom resorted to; the besiegers contenting themselves with occupying only the main points of their position by field works, and giving the intervening space such protection as could be afforded by strong patrols and posts This departure from former practice arose, in most cases, from the want of strength of the besieging force, and was frequently attended by the very events against which lines are chiefly effectual in guarding. As a field of battle against a succoring force of sufficient strength to cope with the besieging army, a position taken behind a line of circumvallation is but in rare exceptions eligible, a maxim that applies to all extended and weak lines; and in almost every case, where a serious effort has been made against such positions it has proved successful, and has entailed heavy loss on the besiegers. But, it must be repeated, as this is not the object of these lines, they are not open to this objection; and, as they have been found serviceable for the sole purpose to which they should be applied, they ought to be thrown up in all cases where the means of the besiegers will admit of it. See *Intrenched Camps*.

LINE OF COUNTERMARCH.—A sort of a trench which the besieged make, and push forward from the glacis, for the purpose of counteracting the enemy's works.

LINE OF COUNTERVALLATION.—The line of field works constructed in front of the camps, and on the side next to the besieged position, to defend the camps, parks, and trains against any attacks which might be made by the besieged. See *Line of Circumvallation.*

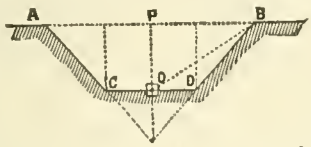
LINE OF DEFENSE.—A line representing the flight of a rifle-ball from the place where the soldiers stand, to scour the face of the bastion. The line of defense should never exceed the range of the rifle. It is either *fichant* or *rayant*. The first is when it is drawn from the angle; the last, when it is drawn from a point in a curtain, ranging the face of the bastion in fortification.

LINE OF DIRECTION.—In gunnery, the line formerly marked upon guns by a short point upon the muzzle, and a cavity on the base-ring, to direct the eye in pointing the gun.

LINE OF FIRE.—1. In gunnery, the production of the axis of the gun directed upon a point which is at a vertical distance above the object to be struck, corresponding to the time of flight required for the range, and at the end of which time the shot will be brought to the object by the force of gravity.

2. In fortification, this term admits of two distinct acceptations: *first*, when it is found necessary to give an idea of the manner in which a rampart or an intrenchment covers any space of ground by the discharge of ordnance or musketry, lines must be drawn to represent the distances traversed by the shot, etc.—these lines are called *lines of fire*, being representations of the actual ranges; *second*, all that extent of a rampart or intrenchment from which the projectile of ordnance or musketry are discharged.

LINE OF LEAST RESISTANCE.—The shortest distance from the center of the charge of a mine to the open air. Assuming the crater to be of the form of a truncated cone, as is usual, the radius O D, of the lower circle, being also assumed at one-half the radius P B, of the upper circle, then the radius P B, of the upper circle, is termed the *crater radius*, and the line O P, drawn from the center of the powder



perpendicular to the surface where the explosion takes place, the *line of least resistance*. The line O B, drawn from the same center to any point in the circumference of the upper circle, *the radius of explosion*. A mine with a line of least resistance not greater than nine feet, formed by sinking a shaft from the surface of the ground and placing the charge at the bottom of it, is termed a fougasse.—See *Crater.*

LINE OF MARCH.—The arrangement of troops for marching; also, the course or direction taken by an army or smaller command.

LINE OF METAL.—The profile cut from the upper surface of the piece by a vertical plane passing through the axis of the bore. When pointing a piece, the *line of metal* is accurately determined, and the piece is so maneuvered as to bring the line of metal into the plane of fire.

LINE OF METAL ELEVATION.—In gunnery, the visual line connecting the front and back sight when the latter is at its lowest point, *i. e.*, connecting the notch on the swell of the muzzle, or dispart sight, when the trunnions are perfectly horizontal.

LINE OF OPERATIONS.—All lines of communication leading towards an enemy's base do not offer equal advantages to an army acting on the offensive. Some lead more directly and offer more security than others in an advance on the enemy; some may offer greater advantages than others when our superiority lies either in infantry or in cavalry; some are more favorable as to subsisting an army, or afford ing it more convenient transportion, or in enabling us to turn the enemy's position; others again receive better support from the base of operations, etc. The talent of a Commanding General is chiefly shown in weighing the advantages and defects of each of these circumstances, and selecting from them the best. A line of operations is said to be *simple* when the army corps moving against the enemy are kept together, or at least are not so far separated as to be beyond mutual supporting distances. These corps consequently must all move on roads nearly parallel, and not too far apart, and without any impassable obstructions between them. A line of operations is said to be *double* when an army divided into two parts follows two sensibly parallel roads which are so far asunder that the two portions cannot be reunited upon the same day on the same field of battle.

Unless we are superior to the enemy on each line, both in numbers and the moral qualities of our troops, a double line of operations is purely disadvantageous to us; and particularly so if the two lines diverge as we advance; for the enemy, by throwing himself between the two fractions of our army, may beat each of them separately, and find himself in an attitude to intercept our communications. The more rapidly the double lines diverge, the greater will be danger and the certainty of success to the enemy.

Here we find a marked difference between what may be termed a strategical and a tactical operation. In the latter the greatest danger that an army can run is to be surrounded on the field of battle; whereas an army that throws itself, by a strategical movement, between several fractions of an enemy's army beyond supporting distance of each other, may, by superior activity, defeat them all in succession.

The only case in which—the armies on the two sides being sensibly of equal strength, and controlling reasons calling for it—a double line can be followed, in the face of a General of respectable abilities, is when the latter has also adopted double divergent lines, or lines very far asunder. But in this case our double line must be an *interior* one, or lie between those of the enemy, so that the two fractions may, in case of need, support each other if attacked; or be suddenly concentrated so as to attack one of the fractions on the enemy's exterior line, the other in this case being beyond supporting distance of the one attacked. This principle of interior lines, particularly when they converge as we advance, as a matter of fact, is only a modification of the one of a single line. It only amounts to keeping the fractions of our army in such distances from each other that they are nearer together than those of the enemy, and can be concentrated on any one of his before it can be reinforced by the others. Still, it must be observed, that it is always safer to maneuver on a single line than upon two, although they may be interior.

It is important not to confound double, or multiple lines, with the various lines of communication over which fractions of an army are necessarily marched, in order to concentrate on a particular point. In this case the movements of all concur to the same end; the army corps are momentarily separated only to march with greater convenience and rapidity; to reconnoiter the ground more thoroughly over which they move; and to live more comfortably. This momentary separation of our forces, to be again united at the moment of battle, when well executed, is the very acmé of good generalship. It is one of the best means of keeping the enemy for a long time uncertain of our real intentions as to the point of attack. To know when, in turn, to scatter our forces to embrace a greater extent of country, when circumstances permit or call for it, and then to concentrate them, in order to strike a decisive blow, is one of the most marked features in the qualities of a great Captain. No General of modern times has shown this trait in as high a degree as Napoleon.

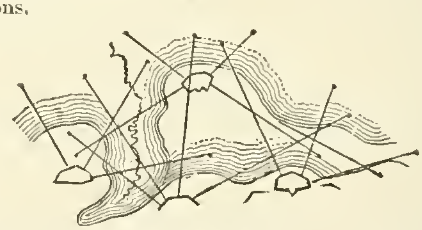
When, by the eventualities of a campaign, we find ourselves rather forced to abandon our primitive line of operations and take up some new one, the latter generally receives the appellation of an *accidental line of operations*. This term is not properly applicable to a line voluntarily taken up, to march upon a point which the enemy may have weakened by withdrawing from it troops, under the apprehension that he was threatened on some other. This change of line, so far from being an accident, is the legitimate fruit of profound combinations, and may be the cause of important successes. The primitive line was, to some extent, a feint; and the line apparently but secondary the true one; it cannot therefore be termed accidental; it will be thus simply the *new line of operations*

In like manner in a retrogade movement an army may abandon its natural line of retreat and take up another,leading off laterally from it, for the purpose of enticing the enemy into a district of country less favorable to him, and at the same time to throw him further off from his main object. The line of retreat in this special case will be sensibly parallel to our own frontier instead of being, as it is generally, perpendicular to it. This new line of retreat also cannot be classed under the head of accidental lines, since it is one voluntarily adopted, and presents advantages over the natural line of retreat. It has received the name of the *parallel retreat*, a term sufficiently expressive of the thing itself. To be successfully executed the retreating army should not be too inferior in force to the enemy, and should run no risk in being cut off from its own frontier by moving too far from it. The local features are particularly to be taken into consideration in such operations. If they are of a broken character, the movement will be the less perilous; if, on the contrary, the country is open, and without strong natural points of defence, the safest plan will be to regain our frontier by the shortest line.

When a choice between several lines of operation is offered, it will be best to adopt the one where the army can be most easily subsisted, and in which, according to the kind of troops of which it is composed, the army will be most secure from the enemy's enterprises If the army is superior to the enemy in cavalry, it will naturally prefer to move over an open district and country; if, on the contrary, its main strength lies in its infantry, it will prefer to skirt along the foot of a mountainous range, or to march through a broken country. A line of operations parallel and near to a river presents the advantage of having its wing nearest the water course perfectly secure from attack, whilst the river itself furnishes an excellent communication for bringing forward men and the supplies. The defensive position taken up by the enemy also has great weight in determining the direction of the line of of operations. If he occupies cantonments extending over a considerable line, the most natural line will be the one by which the army can throw itself into the center of the enemy's isolated corps, and thus separate them and beat them in detail. By attacking one wing of a position of this kind we should, in all likelihood, force back one corps after another upon the neighboring one, until in the end the whole would, in this way, be concentrated in their natural order of retreat. If, on the contrary, the enemy's corps are in proper supporting distance of each other, the natural point of attack is certainly one of his wings, provided that, in making the said movement, the line of operations of our own army is not left exposed; for the first of all necessities is never to place either our base or our line of operations in jeopardy. The choice to be made will also depend upon the characters and military talents of the enemy's Generals, the quality of the forces, their moral condition, etc., etc.; these are points which carry such great weight with able Commanders that they have often been known to have adopted plans the very reverse of what they would have done under contrary circumstances, according to their being in front of one or another General. Turenne,having for his opponent Condé, did not allow himself to do things which seemed to him as easy and a matter of course before the Archduke. On one occasion, in 1654, he lost some men while passing within the range of grape in front of the Spanish lines, which called forth remarks from some of the officers accompanying him. To these he replied: "The march we are making would be very imprudent before Condé's position; but it is very important that I should examine thoroughly this position; and I am so well acquainted with the Spanish service, that I feel assured that before the Archduke has been informed of it, has sent word to Condé, and called together his council, I shall have completed it and returned to camp." "See," said that Captain who more than the other was capable of pronouncing a judgment on such points, "here is something that pertains to the divine portion of the art." In truth, military genius manifests itself in just such subtle distinctions and delicate shades. See *Base of Operations*, and *Objective Point*.

LINE OF SIGHT.—In gunnery, the right line passing through the notch of the tangent-scale and tip of the trunnion-sight (at any elevation), and the object. See *Pointing*.

LINE OF WORKS.—When it is necessary to hold for a time a line of considerable extent by a force inferior to that which may be brought against it, the line should be fortified by intrenchments, consisting of a series of works laid out according to the approved principles. The kind of work for any particular position on the line will depend upon the nature of the locality it is to occupy and the manner in which it will combine with those adjacent in securing mutual support throughout. Such lines are frequently from fifteen to twenty, or even thirty miles in length, extending over every variety of country, and in their construction call for the highest skill in military engineering. They are constructed, usually, either for the protection of important towns, cities, and depots; or to make secure the base of operations and lines of communications of any army maneuvering in the field; or, by stretching across peninsular regions, to restrict the theater of operations of the enemy; or for surrounding and besieging a place; or for the purpose of holding the enemy in position with a part of an army while the remainder makes a flank or other strategic movement. The civil war of 1861-65 afforded numerous instances of each of these conditions.



The same general principles apply to lines as to other field-works; but, from their great extent, they usually receive only a slight relief, and the simplest angular figures are adopted for their plan. In laying them out, advantage should be taken of all the natural features presented by the position, so as to diminish the labor of erecting artificial ones. The flanks of a line or position are generally weak points. When possible, one or both should rest on natural points of support. A flank not so supported must be secured by strong works especially well garnished with artillery. A point that has not a clear field of fire is a weak point, and should be strongly intrenched, so that the enemy may not have advantage of hills, ravines, or other shelters in approaching the line. Care should be exercised in determining the kind of artillery for such positions. The field of fire being contracted, long range is not of so much importance as ability to search behind the enemy's shelter, or to throw a great mass of projectiles in a limited time. Mortars, howitzers, and machine-guns will be found serviceable. In establishing a line of works, the most important object should be to cover every portion of the front within fair range with direct or cross fire. To accomplish this, all prominent points along the line are fortified, each with a work having a trace most suited to the conformation of that particular site. The most important of these should be inclosed works upon the bastion-front principle, and of considerable size, capable of enduring an independent attack. Smaller inclosed works, such as redoubts and star forts, occupy the secondary points. Between the works thus located extend *rifle-trenches*, capable of sheltering infantry. The line is therefore composed of a series of works mutually supporting each other and covering every avenue of approach.

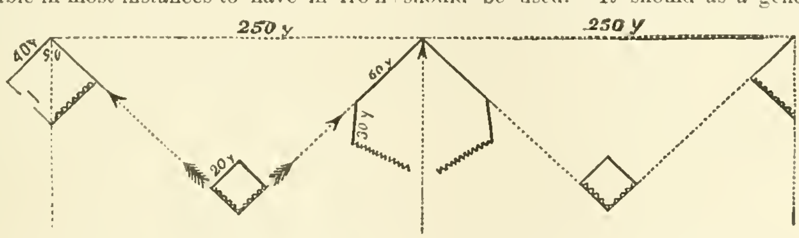
The artillery, of which there should be an abundance, will naturally be placed in the works occupying the most commanding and salient positions. These works should never be so far apart as to be out of mutual flanking range of the artillery with which they are armed. It is the duty of officers of artillery to co-operate with those of engineers in selecting the positions of the works that are to be armed with artillery, and to determine the kind and quantity to be placed in each. As infantry troops constitute the chief garrison of works of this nature, they will be required to construct them, leaving to the artillery the construction of magazines, embrasures, and the other accessories pertaining to their special arm. Generally these works are thrown up very hastily, and often when an immediate attack is apprehended; this, to a considerable extent, decides not only the nature of the works, but the parts of them that require the first attention. Subsequently, if time permits, they are strengthened, improved, and worked into better shape. As far as practicable, the line should be composed of inclosed works, for the reason that should the enemy concentrate and break through at any point, he will not be able to sweep the line to the right and left by taking it in flank and rear. To storm and capture each work in succession would be an operation too costly for him to undertake.

It is advisable in most instances to have in fro n of the line, within easy musket range, a line of small redans or lunettes at intervals of about 1,500 yards. Each of these should be capable of holding from one to two hundred infantry and four to six field-pieces. This line of outworks would form, as it were, a species of picket-line, keeping the enemy from closely observing and harassing the main line, and would constitute an advanced line of battle, against which the first shock of the enemy is partially thrown away, and he dare not attempt to neglect them; for an endeavor to penetrate through the intervals would expose his flanks to a close and deadly flank and cross fire. The redans being open towards the main line, could not be held if captured by the enemy. A somewhat similar line of works should be established in rear of the main line. They should, however, have their gorges stockaded or otherwise closed to prevent the enemy, should he succeed in forcing his way through the main line, from obtaining easy possession of them by the rear. Sites for them should be selected with a view of obtaining from them a searching fire of the front line in reverse. This line of works, although apparently inert in rear, must be kept fully armed and manned, ready to drive the enemy from any part of the main line that he may succeed in obtaining possession of. Prominent salients in the main line are especially inviting to the enemy; behind these a second line should be prepared, so placed, if possible, that should the enemy obtain the main line he will be within musketry range of the second, and be forced with wearied troops to undertake the capture of it. See *Field Fortification*.

LINES. The field-works known as lines are divided into several classes, according to the object for which they are constructed; or, according to some peculiar arrangement of their parts, or some other characteristic quality. They are most generally classified as *continued lines* and *lines with intervals*. There are no openings in a continued line, except those made for the use of the defense. Continued lines have been much used in past military operations, and will, in all probability, be used in the operations of the future. They may be usefully employed where a passive defense only is to be made, and where the position to be defended is limited in extent, and not exposed to flank attacks. They are not fitted for an active defense, and they have the serious disadvantage of being untenable, when any part of the line has been taken by the enemy. They require a large amount of labor to construct; and it is a very doubtful question, whether the advantages they give compensate for the time and labor employed in their construction.

Lines with intervals differ from the continued lines, by leaving intervals along the front of the position, which intervals present no obstructions to an enemy moving through them, excepting so far as they may be defended by the fire of the works, or may be obstructed by natural obstacles, or by artificial ones, placed along the front. The works forming the line may be placed so close to each other as to be in defensive relations; or they may be so far apart, as to admit only of their defending the intervals between them.

If an obstinate defense is to be made, a second line should be used. It should as a general rule be placed behind the first, and distant from it, about one-fourth, and certainly not greater than one-half, of the distance between the works in the first line. When artillery is used in the second line, a good position would be about six hundred yards distant from the first. This places the second line just out of range of aimed musketry fire, but in close range of artillery fire. A third line of field-works is sometimes built. The general arrangement of the works of this third line with the works of the first and second, conforms to the principles employed in arranging the work in the second line. A third line might be useful, in case of an active defense, since the works placed along this line can be utilized as screens for the reserves and for bodies of cavalry. A fourth line would evidently be of no practical service in the defence of a position. A force, unable to retain possession of outer lines, could not hold the fourth.



Plan of a Line with Intervals of Lunettes, or Square Redoubts flanked by Retired Redans.

The number of lines, whether a single one, or two, or three in number; the kinds of works to be used on each line; the distance apart of the works on each line; the distance apart of the lines; and the details of their construction, depend upon the natural features of the ground, the numbers and kinds of troops which are to occupy them, the range of the arm used in their defense, and the time disposable in which to construct them.

Certain advantages are claimed for lines with intervals. These advantages may be briefly stated to be as follows 1. The lines with intervals admit of either passive or active defense. They are peculiarly fitted for the latter. 2. Lines with intervals are more easily adapted to the natural features of the ground than continued lines. 3. For the same extent of front, they require fewer men to defend them, and the works require less labor to construct, than other kinds of lines. 4. They admit of a better use being made of raw and inexperienced troops. 5. A line with intervals may still be defended, even after a part of the line has been captured, or after the enemy has broken through the line.

The main defect inherent in lines of this class, is the sub-division of the defenders into several independent commands, by which unity of action of the whole command is impaired. This defect is reduced somewhat by a proper disposition of the works. A few capacious and strong works are better than a large number of small ones. Experience has shown that a body of one thousand men, in a single, well-constructed work will offer a more effective resistance to the attacks of an enemy than the same number would, when scattered among three, four, or more, smaller works. The difficulty which a General would meet, in obtaining experienced officers fit for these independent commands, and in having these officers to act in unison with each other, gives sufficient grounds for such a result to be expected under ordinary circumstances. See *Bastioned Line, Crémaillère Line, Multiple Lines, Redan Line, Rogniat Line, Serrated Line*, and *Tennaille Line*.

LINESMEN.—A term frequently applied in the British service to the infantrymen of the Regular Army.

LINES OF COMMUNICATION.—A term applied to all the practicable routes and roads connecting the different parts of an army occupying the theater of war. Therefore, as the army moves from its base, the *lines of operations* become *lines of communication*, and since these *lines of operations* are generally the longest and most important *lines of communication*, it is to them that the simple term *communications* generally refers. All the routes used by the trains employed in provisioning an army, form a part of the communications. The most important, safest, and most convenient of these routes, all other things being equal, will be the central one, or the one leading from the center of the army back to its base. This particular route is sometimes designated as the *line of supplies*.

LINES OF RETREAT.—The roads passed over by an army when advancing are ordinarily the roads taken when the army retires or is driven back. In the latter case they are known as Lines of Retreat, and are *Single, double diverging*, etc, according to their number and position. See *Retreat*.

LINES OF TORRES VEDRAS.—Famous lines of defense within which Wellington took refuge in 1810, when he found it impossible to defend the frontier of Portugal against the French armies; and from which, in the year following, he issued on that career of slow and hard-won victory, which ended in the expulsion of the French from the Peninsula. The *first*, or outermost of these lines, extending from Alhandra, on the Tagus, to the mouth of the Sizandro, on the sea-coast, and following the windings of the hills., was 29 miles long; the *second* (and by far the most formidable) from 6 to 10 miles behind the first, stretching from Quintella, on the Tagus, to the mouth of the St. Lorenza, a distance of 24 miles; the *third*, situated to the southwest of Lisbon, at the very mouth of the Tagus, was very short, being intended to cover a forced embarkation, if that had become necessary. The entire ground thus fortified was equal to 500 square miles.

LINES WITH INTERVALS.—When the front to be defended is covered by a number of field-works, scattered along this front, and placed near enough together to sweep the intervals with their fire, the whole arrangement forms a disposition called a Line with Intervals. Field-works placed so near to each other, that each one can bring its fire to bear upon the ground in front of those adjacent, are said to be in defensive relations with each other. See *Lines*.

LINGERER.—One who pretends to be indisposed, in order to avoid his tour of duty. Hence the expression malingerer, or a soldier who avoids duty in a disreputable manner.

LINKED REGIMENTS.—In localizing the forces of the British Army, it is laid down that in each of the sub-districts of the country two regiments shall be permanently selected (whether absent or present) to be so localized, and the mode of selection is of regiments having any connection with the county. These regiments are termed *linked*, and in the case of one of the regiments going or being on foreign service requiring men to make up its numbers, soldiers are drafted from the regiment remaining at home.

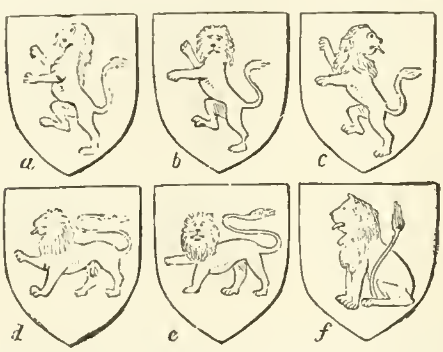
LINKED SHELLS.—Admiral the Hon. Arthur A. Cochrane has recently devised a novel method of marine attack and defense. Its very novelty may tend to prejudice against it those who are saturated with the conviction that nothing new which is also good can be devised in warfare; but the whole scheme is at once so simple, so ingenious, and so easily and cheaply tested, that it commends itself to impartial minds. He proposes to strew the line of approach of a hostile ironclad preparing to ram, or the wake of a ship when retreating, or the course of an enemy engaging on the broadside, with floating or partly submerged torpedoes, through which the pursuer dare not attempt to pass. These torpedoes could be thrown to some distance from the ship by means of mortars, which would fire very small charges of powder. Thus the 13-inch service mortar, at an elevation of 45 degrees, has a range of 850 yards with 3 pounds of powder, and with half a pound of powder a range of 180 yards when projecting a shell of about 180 pounds weight. The shells would have a charge of high-class explosive, say, of 35 pounds weight, surrounded by an envelope, whether of thin metal or other material, of sufficient capacity to buoy the bursting charge and of strength to resist the projecting charge of, say, 1½ pounds of powder. The shells would be connected by a floating line 100 feet or 200 feet in length, of small diameter, but of great strength; such coupled shells could be very readily fired from two mortars simultaneously by electricity; they could be placed quite close together; or the mortars, of which there would likely be six or eight on a large ship's deck, might be placed at a distance apart of 50 or 80 feet on the line of keel or otherwise, the rope still connecting the shells. The action of the air on the connecting line when the shells were fired would be to draw the shells together; but it is not anticipated that this would be a practical difficulty over the ranges expected, viz., from 200 to 1,200 yards as the mortars would be slightly deflected from each other. It is proposed to use such shells against ships on their near approach by firing them across and just ahead of the ship. It is clear that if the hostile ship still proceeded, she would, by fouling the rope, draw the shells alongside and be blown up, and as the shells would be concussive and fitted with time-fuses, they would doubtless not fail to act. Should the ship stop in time to avoid the shells, others could be thrown astern of or over her, so as to hamper her movements. Under any circumstances, the hostile ship could not ram her enemy, and by stopping would offer a good target for mortar shells to be thrown on her decks, and for artillery fire.

It is proposed to employ shells of several classes: "A" shells charged with explosives, capable of floating on water, cased in metal or other material, and united by a floating rope; to be fired across the bows of ships, or dropped across ships or ports in a tideway. "B" shells, charged with explosives, of slightly greater specific gravity than water; such to be regulated as to the depth they shall sink in water by means of an India-rubber tube or other material; such tube to be securely attached to the shell when it is fired, or by a line to the shell when it is necessary, filled with air and attached to the shell. In the case of land service, such a tube could be easily filled with explosive, and such tube could be attached to a second shell, for clearing parapets, trenches, etc., under special circumstances. "A" shells would be useful to clear hostile ships out of rivers, tideways, and to blow up buttresses of bridges floating-bridges, such as those lately used in the Danube, preventing ships entering the Dardanelles, etc. "B" shells, on being thrown near the ships and buoyed by a practically invisible tube, at a depth of say, 15 feet, would be very fatal on exploding. "B" shells could be thrown on the line of advance of a torpedo; and when entering a hostile port, defended by submerged torpedoes, they could be thrown in advance of ships entering, and regulated by means of the buoy line, to explode at any depth, or on the bottom, thus clearing the channel. The shells could be cased in metal and made in sections, or could be made of paper suitably prepared. Shells from mortars are now considered to be efficient in proportion to their falling weight. The shells suggested would be efficient in proportion, not to their weight, but to the charge of explosive carried. From the small weight of the mortars, very small charge and small recoil, they could be most readily fitted to any ship almost without strengthening fitments, and in the case of numerous river steamers would add but little to the draught of water. It will be seen that the success or failure of the whole scheme depends on the possibility of firing linked shells, so that their line of flight would be nearly parallel, and on the construction of the shells. Nothing but direct experiment can decide the first point; but it might be settled in a day for an outlay of a few pounds. The construction of the shells obviously presents some difficulties. Admiral Cochrane has proposed several designs for shells intended to overcome these difficulties. It may be fairly assumed that fire from mortars, whose shells would be, or might be, connected by a slight line, would be very inaccurate, particularly in high and cross winds. But if one is driven to make comparison of efficiency, the accuracy of artillary fire in ships in high cross winds may be seriously questioned, and the accuracy of action and aim of torpedoes fired from or at ships in motion may be very much more seriously questioned, particularly if fired at more than 500 yards distance. The bows and the sterns of ships are, as a rule, now the favored points for projecting the torpedoes, and compressed air, steam, steam pistons, and gunpowder, are being tried to endeavor to obtain a satisfactory means of projecting them into the water, after which they have to find some yet undiscovered process of making them go straight to the object to be struck, a result which, when there is any sea on, or the boat or vessel is in motion, will never be accomplished in any degree to be relied on. A comparison may be made between the effect of, say, a 100-ton gun, 30 feet long, burning 400 or 500 pounds of powder, and projecting a shot of three-quarters of a ton, against a 26-inch armor plate, and that of one of the shells proposed by Admiral Cochrane, falling when charged with 20 pounds or 30 pounds of gun cotton, on the deck or into the barbette battery of a 10,000 tons ironclad. Further, when the cost of the 100-ton gun, the powder and shot fitments, and complication of hydraulic gear required to work such a gun, are considered, as against a 13-inch mortar, weighing perhaps 12 hundred-weight, and requiring, so to say, no science to work it whatever, the advantage seems notably in favor of mortars as the principal arm. It may be observed that a sea-service 13-inch mortar weighs about 5 tons; its shell, loaded, about 200 pounds, carrying a bursting charge of some 10 pounds, and when fired at an angle of 45 degrees, with 3 pounds of powder, ranges 850 yards; but, as at present, Admiral Cochrane only suggests shells of a weight of, say, 100 pounds, and that to be projected to a distance of, say, 1,200 yards, and that as the mortars should be made of phosphor-bronze, 12 cwt. might, it is assumed, suffice for the weight of the mortar. The S. S. mortars have to face the firing of 200-pound shells up to a range of 4,000 or 5,000 yards. Mortar firing and sustained efforts to improve mortars have been but little considered. Rifled mortars are hardly known; and the suspended mortars—Roberts' patent, on turntables for sea service and used in the Baltic in 1854—have dropped out of sight, though they were stated to offer many advantages in principle, while faulty metal and construction were quoted against them.

LINOLEUM.—A peculiar preparation of linseed-oil, which is variously employed for military purposes. In 1849 Nicles and Rochelder independently discovered that chloride of sulphur will solidify oil, and render it usable in many new ways. In 1859 M. Perra communicated to the Académie des Sciences the details of a mode of effecting this by mixing and melting the ingredients, and pouring the mixture out in a thin layer. By varying the proportions the resulting substance assumes varying degrees of consistency. Thus, 100 linseed oil +25 chloride of sulphur produces a hard and tough substance; 100 oil +15 chloride a supple substance like India-rubber; and 100 oil + 5 chloride, a thick pasty mass. This third kind dissolves well in oil of turpentine. Mr. Walton afterwards found that, by the application of heat, linseed oil will become hard without the addition of chloride of sulphur. He conceives that it is not a mere drying, but a real oxidizing. Linseed-oil, first boiled, is applied as a layer to a surface of wood or glass, then dried; then another layer; and so on till the required thickness is produced. The sheet is then removed, and is found to be very much like India-rubber in elasticity; in fact, the production of a layer by this means is analogous to the smearing of clay-molds with caoutchouc juice to produce India-rubber, as practiced in South America. The drying is a little expedited by adding a small portion of oxide of lead. The solid oil is crushed, and worked thoroughly between heated rollers; and when treated either with shellac or with naphtha, it becomes applicable in various manufacturing forms. The term *Linoleum* properly applies to the hardened or the oxidized oil itself, but is cheifly used as a designation for one of the substances made from or with it, a kind of floor-cloth. When the oxidized oil is rolled into sheets it becomes a substitute for India-rubber or gutta-percha. When dissolved as a varnish or mastic and applied to cloth it is useful for water-proof textiles, felt-carpets, carriage-aprons, wagon and cart-sheets, nursing-aprons, water-beds, tank-linings, table-covers, etc., according to the mode of treatment. When used as a paint, it is useful for iron, for wood, and for ships' bottoms. When used as cement, it possesses some of the useful properties of marine glue. When vulcanized or rendered quite hard by heat it may be filed, planed, turned, carved, and polished like wood, and used for knife and fork handles, moldings, etc. When brought by certain treatment to the consistency of dough or putty, it may be pressed into embossed molds for ornamental articles. When used as a grinding-wheel, touched with emery, it becomes a good cutter. Lastly when mixed with ground cork, pressed on canvas by rollers, the canvas coated at the back with a layer of the same oil in the state of paint, and the upper or principal surface painted and printed, it becomes the *Linoleum* floor-cloth, for the production of which a factory has been established at Staines. Dunn's patented fabric for similar purposes has no oil in it; it is a mixture of cork-shavings, cotton, or wool fibers, and coutchouc, spread upon a cotton or canvas back, and embossed with patterns; it is a kind of kamptulicon.

LINSTOCK.—An iron-shod wooden-staff used in gunnery, for holding the lighted linstock in readiness to be applied to the touch-hole of the cannon. In old pictures, the linstock is seen planted in the ground to the right rear of each piece, with a match smoking at each of the ends of the fork in which it terminates.

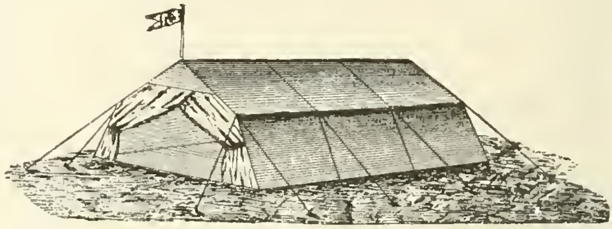
LION.—The lion holds an important place among the animals borne in coat-armor. As early as the 12th century, the king of beasts was assumed as an appropriate emblem by the Sovereigns of England, Scotland, Norway, Denmark, the native Princes of Wales, the Counts of Flanders and Holland, and various other European potentates. Lions occur in different positions. 1. The earliest attitude of the heraldic lion is *rampant (a)*, erect on his hind legs, and looking before him, the head being shown in profile, as he appears in the Arms of Scotland, and originally did in those of England. This was the normal position of a lion; but as the royal animal came to be more generally used by all who claimed to have any kindred with royalty, and to be granted to favorite followers by way of augmentation, some diversity of attitude was adopted for distinction's sake. 2. *Rampant gardant*



(*b*), erect on the hind legs, and affronté or full-faced. 3. *Rampant regardant* (*c*), erect on the hind legs, and looking backwards. 4. *Passant* (*d*), in a walking position, with the head seen in profile. 5. *Passant gardant* (*e*), walking, and with the head affronté. 6. *Passant regardant*, walking, and with head looking behind. 7. *Statant*, with all four legs on the ground. 8. *Saliant*, in the act of springing forward on his prey. 9. *Sejant (f)*, rising to prepare for action. 10. *Sejant affronté*, as seen in the crest of Scotland. 11. *Couchant*, lying down, but with his head held well erect, and his tail beneath him. 12. *Dormant*, asleep, with his head resting on his fore-paws. 13. *Coward* or *Coué*, with his tail hanging between his legs. The lion passant gardant is often blazoned as the *lion of England;* and at a time when terms of blazonry were comparatively few, it was confounded with the leopard, and hence the lion passant and rampant gardant came to be called respectively the *lion-leopardé*, and *leopard-lionné*. Two lions may be depicted *rampant combatant*—*i. e.*, face to face—or *rampant addossé*, placed back to back. Among leonine monsters, we have two-headed lions, bicorporate and tricorporate lions, lion-dragons and lion-poissons. There is also the Bohemian lion, with two tails, and the more celebrated winged lion of St. Mark, adopted by the Republic of Venice. The Island Republic bore, azure, a lion winged or sejant, holding between his fore-paws a book open argent, in which are the words, *Pax tibi Marce Evangelista meus.* Two or more lions borne on one shield are sometimes (though never when on a royal coat) blazoned *Lioncels*. See *Heraldry*.

LIP-STRAP.—A small strap with a buckle passing from one cheek of the bit through a ring in the center of the curb chain to the other cheek, for the purpose of preventing the horse from seizing the cheek of the bit in his mouth.

LIS.—A warlike machine used by the Ancients. It consisted of a piece of wood or a stake, about the size of the human body, which was made smaller at the top than at the bottom, and resembled a lily not yet blown. Several of these were tied together with ozier or willow twigs, and were used for the security of a camp. They were not unlike the palisades of the present day.



LISCHINE TENT.—A Russian hospital tent of peculiar construction, and well endorsed by military men. The frame is of iron, and is covered with thin pieces of board 10 feet long and 1 foot wide, overlapping each other like Venetian blinds. The ridge is of canvas. The iron frames are four in number. It has the advantage of being cheaper, more durable, warmer, and capable of better ventilation than the canvas tent. See *Tents*.

LISSBERGER FUSES.—The Lissberger percussion fuse, shown in Fig. 1, consists of a copper tapering body, A, with enlarged head, but closed at the rear by a brass screw-plug, which is hollow nearly its entire length. Fitting this screw-plug is a brass hollow cylinder filled with a friction composition; the

Fig. 1.

Fig. 2.

lower part of the cylinder is closed. A wire, whose lower end is serrated and twisted, passes through central holes in the screw-plug and the solid cylindrical plunger; it has its upper end looped to form a shoulder against the plunger. Between the plunger and the end of the screw-plug is a disk of leather.

The lower end of the screw-plug is closed by a small quantity of rifle-powder, and a disk of leather pressed in. The fuse-body has about the same taper rearward, and is inserted in the shell the same as the ordinary paper time-fuse; when inserted in a shell whose flight is suddenly arrested, the serrated wire is drawn forward by the plunger, igniting the friction composition, and setting fire to the charge.

The time-fuse is an ordinary paper fuse, A, shown in Fig. 2, which is ignited by means of an inertia igniter. The igniter, B, consists of four parts: A brass solid-headed shell, slightly tapering on the exterior, having holes in the head and side-openings for the escape of gas; through the head of the body, A, is introduced a hollow brass cylinder, whose lower end is cut and closed; within this cylinder is a lead plunger and a friction-pellet. At the instant of discharge, the friction-pellet is forced back and through the rough-closed end of the cylinder by the plunger and the time-fuse is thus ignited. See *Fuse.*

LIST.—1. A line inclosing or forming the extremity of a piece of ground, or field of combat; hence, in the plural, the ground or field enclosed for a race or combat. *To enter the Lists*, is to accept a challenge, or engage in a contest. 2. To engage in the public service by enrolling one's name, as soldiers; to inclose for combat. 3. A roll or a catalogue; as the *Army List*, the *Pay List*, etc.

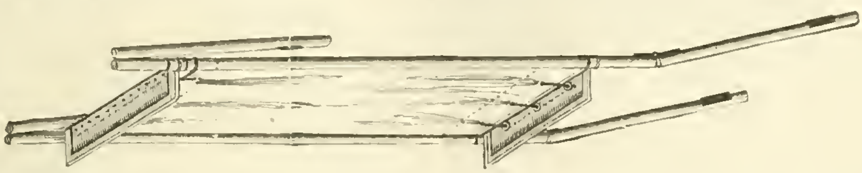
LISTENING GALLERIES.—The galleries of a fortification, leading outwards from the counter-scarp gallery. See *Gallery*.

LITHOFRACTEUR.—An explosive mixture having the following composition:

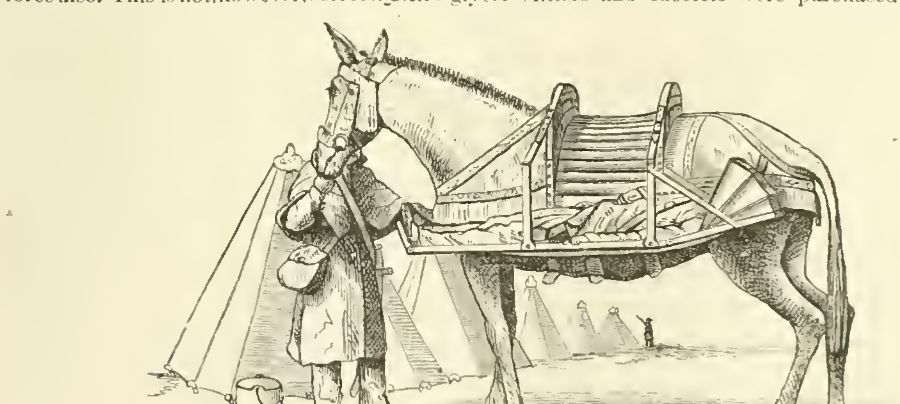
Nitro-glycerine	52.10	per cent.
Kieselguhr	30.00	"
Coal	12.00	"
Soda-saltpeter	4.00	"
Sulphur	2.00	"
	———	"
	100.00	"

Sometimes, instead of the sodium nitrate, the potassium of barium salt is used, and variations made in the quantity of nitro-glycerine contained in it. Like all the nitro-glycerine preparations, it has no necessarily definite composition, it being merely a mixture made according to the caprice of the manufacturers. This preparation is made by Krebs Bros. & Co. in Cologne, and has been used to some extent in Europe. It is claimed by the makers that the other substances (coal, saltpeter, and sulphur) mixed with the nitro-glycerine increase the quantity of gas delivered, and, therefore, the explosive force also. This is not, however, correct. Nitro-glycerine is so sudden in its explosion that nothing can be added to it from the slower burning of any of the other combustible ingredients, which are present in comparatively small amount and in bad proportions. Neither does the presence of these substances add any thing to the safety of the mixture. They tend to lower its firing-point, and render it more easily exploded. Its characteristics, as compared with dynamite, are: 1. Greater sensitiveness to temperature, exploding at 120°, while dynamite explodes at 190°; 2. Greater sensitiveness to moisture from the presence of the hygroscopic nitrate of soda; 3. The gases from the explosion always contain carbonic oxide from the carbon in the compound; 4. For equal volumes it has the lesser explosive power. See *Dynamite*, *Explosive Agents*, and *Nitro-glycerine*.

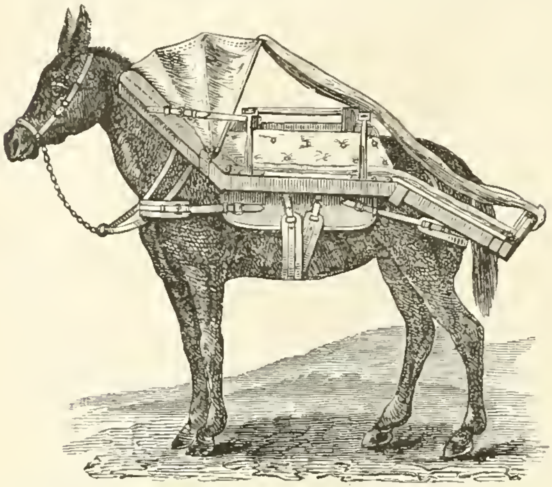
LITTER—A sort of a stretcher or hurdle-bed on which the wounded are carried off the field of battle. It is especially used for the badly wounded, who can only be carried lying down. In 1859 a Medical Board was convened to examine the subject of hospital transport. Besides various recommendations regarding the kind of vehicles suitable for the conveyance of patients and of supplies, the Board advised that *two-horse litters* should be constructed and issued to the frontier posts. This recommendation



was approved, and the specifications for the construction of such litters were incorporated in the Regulations for the Army. The form of litter recommended appears to have been derived from experiences in Florida and Mexico. The drawing shows the manner of its construction and its different parts. It weighs 88 pounds: the poles are $2\frac{3}{4}$ inches in diameter and 16 feet long; the sections are $4\frac{1}{2}$, 8 and $3\frac{1}{2}$ feet respectively from front to rear. Numerous improvised litters, constructed on the same general plan, have been extensively employed in Indian Campaigns and in travel over very rough country. During the late war in this country, a number of persons, actuated by motives of patriotism, humanity, or interest, devised and brought to the notice of the War Department forms of conveyance for the sick and wounded, in localities impracticable for wheeled vehicles. Several of these were apparently suggested by the descriptions of Delafield and McClellan of the horse-litters and cacolets they had observed in the Crimea. A number of sets of these litters and cacolets were purchased by the United

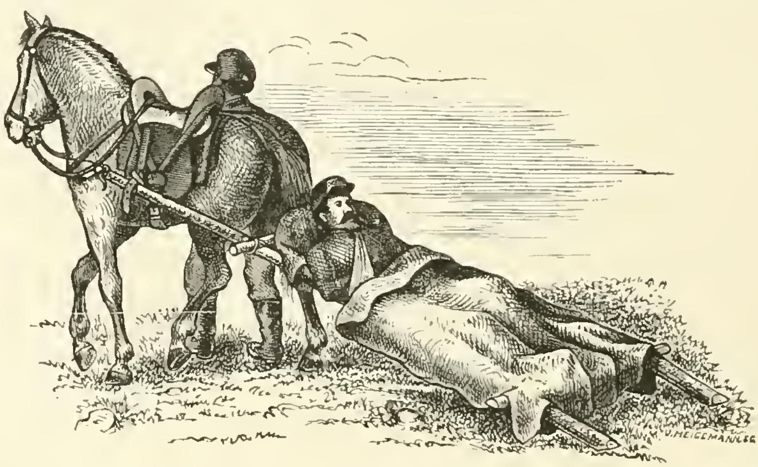


States Government, but were never used with success. The drawing shows the British Crimean mule-litter, also the very easy position of the wounded soldier when ready for transport, and the equipment. In the litters and cacolets now issued in the French Army there are improvements providing for making



the sections of the litter rigid, so that it can be used temporarily as a stretcher, for reduction in weight, and for greater compactness in packing. The mule-chairs and litters now issued by the British Royal Carriage Department are lighter and more conven-

A mode of transporting sick and wounded by litters that at one end rest on the ground, so that the patient is drawn, but only partially sustained, by the pack-animals, is mentioned by early travelers among the North American Indians. Parkman indicates that in the war with Pontiac, in 1763, the Colonists carried their wounded by this contrivance, and, in a later work, refers to the *travée* used by the Oregon Indians; and Lewis and Clark resorted to it in 1805, to carry a wounded hunter of their party. Latterly, this method of transport has received much attention from medical officers, as well adapted to the exigencies of frontier service. Assistant Surgeon McGillycuddy, United States Army, has made the accompanying drawing of such an appliance attached to a horse. A sacking bottom is lashed to two poles that are separated by traverses, and secured to the stirrup-leathers of a cavalry horse equipped with the regulation saddle. The soldier's pack makes a pillow, and a blanket is thrown over him. In this contrivance the utmost limit of simplicity has been attained. This form of litter is *drawn*, while the *two-horse* litter is *carried*, it being substantially a stretcher, either horses or mules being substituted for the men who act as stretcher-bearers. In the latter, one animal is harnessed between the poles before, and the second between the poles behind; the patient being



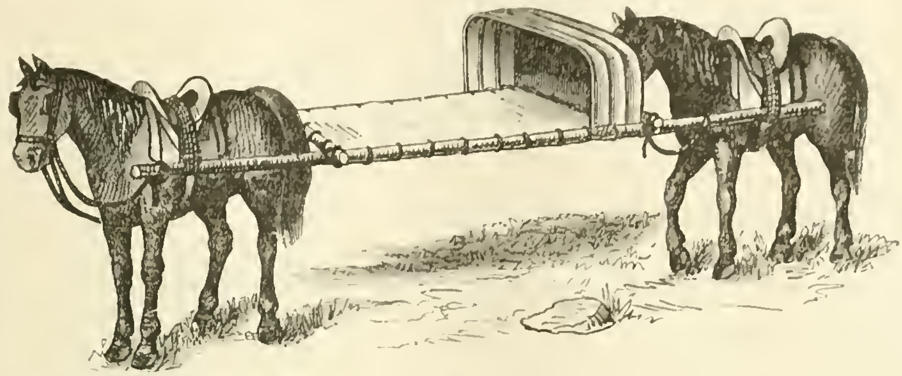
ient than those used in the Crimea. The drawing shows the British Army mule litter attached to its pack-saddle. It weighs 84 pounds, without bedding or pack-saddle. With the paillasses and pack-saddle, the weight is 167 pounds. The weight of a pair of English litters, used in the Crimea, was 138 pounds and 12 ounces, without the pack-saddle. So far as experience has gone, every form of litter and cacolet has been disapproved for one cause or another by the United States War Department. Although used in European services and in Algeria, with satisfaction and under favorable circumstances either on plains or on open rolling country, in our mountainous country, they are only a troublesome and barbarous encumbrance, cruel alike to the wounded and the pack-animals. This aversion to sick-transport by cacolets and double litters is doubtless due to defects in administration rather than to any demerits of the system, without efficient animals and packers it is vain to anticipate useful results from the best-contrived appliances. Used with the greatest advantage in Algeria, and in the Crimea, the French cacolets and litters were adopted by the British Army Medical Department with satisfactory results.

placed on a piece of canvas or other material, stretched between the poles in the intermediate space. Such a litter was extemporized by Assistant Surgeon A. Hartsuff, United States Army, as shown in the drawing.

This litter possesses the disadvantage of accident in case the two animals do not work well together; also, if the animals keep step, the litter begins to vibrate, from the regularity of the motion, and increases to such a degree as to almost throw the patient out. Again, the litter cutting off the sight of the ground from the rear animal, makes him particularly liable to stumble. All things considered, it would appear that the one-horse litter is far superior to this form, and the experience of all having had occasion to use both contrivances, confirms this opinion. The aparejo is the favorite pack-saddle for general purposes in America, and it is believed that ambulance-chairs and litters can be adjusted with facility to these saddles; what is essential is that there should be trained animals and skilled packers. Until these indispensable adjuncts are provided the contrivances found useful in European armies cannot be advantageously employed in our service, and medical officers will be compelled to resort in emergencies to the travée or to the two-horse litter. See *Ambulance*, *Cacolet*, *Stretcher* and *Travée*; also *Cleary*, *Doane*, *Greenleaf*, *McElderry*, and *Thistle Litters*.

and till the Reform Bill in 1832, they had the exclusive privilege of voting for Members of Parliament for the city.

LIVE SHELLS.—Shells loaded with their bursting charges ready for service.



LITTLE FORTIFICATION.—The name given to the first division of the first system of Vauban, when the exterior side of the fortification does not exceed 350 yards. It is used in the construction of citadels, small forts, crown-works, and horn-works. See *Fortification*.

LIVE HEAD.—The *head-stock* of a lathe, which contains the *live-spindle*; in contradistinction to the *dead-head* or *tail-stock*, which contains the *dead spindle*.

LIVERY.—A word applied in its origin to the custom which prevailed under the Merovingian and Carlovingian Kings, of delivering splendid habits to the members of their households on great festivals. In the days of chivalry, the wearing of livery was not, as now, confined to domestic servants. The Duke's son, as page to the Prince, wore the Prince's livery, the Earl's son bore the Duke's colors and badge, the son of the Esquire wore the livery of the Knight, and the son of the gentleman that of the Esquire. Cavaliers wore the livery of their mistresses. There was also a large class of armed retainers in livery attached to many of the more powerful nobles, who were engaged expressly to use the strong hand in their master's quarrels. By the colors and badge of the retainer was known the master under whom he served. The livery colors of a family are taken from their armorial bearings, being generally the tincture of the field and that of the principal charge, or the two tinctures of the field are taken instead, where it has two. They are taken from the first quarter in case of a quartered shield. These same colors are alternated in the wreath on which the crest stands The royal family of England have sometimes adopted colors varying quite widely from the tinctures of the arms. The Plantagnets, for instance, had scarlet and white colors, the House of York, murrey and blue; white and blue were adopted by the House of Lancaster; white and green by the Tudors; yellow and red by the Stuarts, and by William III.; and scarlet and blue by the House of Hanover. An indispensable part of the livery in former times was the badge. The Church of Rome has its liveries for Apostles, Confessors, Martyrs, Virgins, and Penitents. The Freemen of the 91 guilds or corporations which embrace the different trades of London, are called Liverymen, because entitled to wear the livery of their respective companies. In former times the Wardens of the companies were in use yearly to deliver to the Lord Mayor certain sums, 20 shillings of which was given to individuals who petitioned for the money, to enable them to procure sufficient cloth for a suit, and the companies prided themselves on the splendid appearance which their liveries made in the civic train. The Common Councilmen, Sheriffs, Aldermen, and some other superior officers of the city are elected by the Liverymen of London;

LIVING FORCE.—That force of a body in motion which determines the work of which it is capable. It is measured by the product of the mass and the square of the velocity. See *Force*, and *Work*.

LIZIERE.—The berme or narrow path round fortifications between the parapet and the ditch, to prevent the earth from falling in.

LLAMA.—This animal was in general use as a beast of burden on the Peruvian Andes at the time of the Spanish conquest, and was the only beast of burden used by the natives of America before the horse and ass were introduced by Europeans. It is still much used in this capacity on the Andes, the peculiar conformation of its feet enabling it to walk securely on slopes too rough and steep for any other animal. The working of many of the silver mines of the Andes could scarcely be carried on but for the assistance of llamas. The burden carried by the llama should not exceed 125 pounds. When too heavily loaded the animal lies down and refuses to move, nor will either coaxing or severity overcome its resolution. It is generally very patient and docile. Its rate of traveling is about 12 or 15 miles per day. See *Pack Animals*.

LOAD.—1. A word of command in the Manual of Arms, executed as follows: The Instructor commands—1. *Squad*, 2. LOAD. Execute the first motion of *about face*, the left knee slightly bent: at the same time drop the piece into the left hand at the lower band, elbow against the body, the small of the stock two inches below the right breast, the barrel sloping downward at an angle of about twenty-five degrees, the right hand at the small of the stock. (Two.) Look toward the chamber, open it, remove the cartridge-case if necessary, take a cartridge from the cartridge-box, and hold it near the chamber, between the thumb and first two fingers. (Three.) Place the cartridge in the bore, pressing it home with the thumb, close the chamber, cast the eyes to the front; carry the right hand to the small of the stock, and raise the muzzle to the height of the chin. 1. *Carry*, 2. ARMS. Resume the carry with the right hand, at the same time face to the front. (Two.) Drop the left hand by the side. With cartridges, the commands for loading, previous to the first are: 1. *With ball* (or *blank*) *cartridge*, 2. LOAD. 2. The term "load" is also applied to to the charge of a fire-arm. See *Loading* and *Manual of Arms*, *Fig.* 14.

LOADER.—An instrument used with smooth-bore siege howitzers to steady the shell in the passage down the bore. The fixed iron band which crosses the hollow hemisphere of the loader has a hole in it which embraces the fuse, and which on reaching the bottom of the bore can be easily disengaged.

LOADING.—In loading guns and howitzers, the powder is carefully put up in a cartridge-bag of woolen cloth, which is either attached to or carried separate from the projectile, depending on the weight of the projectile. In ramming a charge, only a sufficient force should be used to send it home, as the space which the powder occupies affects the initial velocity. In loading mortars, the powder is poured from the cartridge-bag into the chamber, and leveled with the hand; the shell is then carefully lowered upon it with the hooks. After a piece has been discharged the bore should be well sponged, to extinguish any burning fragments of the cartridge that may remain; and to prevent the current of air from fanning any burning fragments that may collect in the vent, it should be kept firmly closed with a thumb-stall in the operation of sponging. Experience shows that the use of a wet sponge is dangerous, as it contributes to form, from the fragments of the cartridge-bag, a substance which retains fire. It may be sometimes necessary to fire projectiles that are either very much smaller or larger than the bore. If it be desired to use a gun-shell, or solid shot, which is very much smaller than the bore, it should be very securely strapped to a stout sabot which fits the bore; if a mortar-shell, it is placed in the center of the bore by means of wedges, and the surrounding space is filled up with earth. Mortar-shells are fired from guns and howitzers, by digging a hole in the ground about 20 inches deep, and placing in it two pieces of stout plank inclined at an angle of 45°, for the support of the breech; the chase is supported on a moveable wedge, which rests on skids firmly secured with platform stakes; the charge of powder is then inserted in the bore, and the projectile is placed on the muzzle and secured by passing strings over it, and tying their ends to a rope, which encircles the neck of the chase. Pieces fired in this way should be elevated 40° or 45°; thus situated, the fuse of the 8-inch mortar-shell takes fire from very small charges; but the 10-inch fuse should be primed with strands of quick-match, which are allowed to hang over the sides of the shell.

LOADING-BAR.—A more convenient implement than the shell-hooks for carrying and loading the shell. It is simply a bar of round iron about two feet long, fashioned into a ring at one end for a handle, and having a screw cut on the other end, which screws into a shallow hole tapped in the shell at a short distance from the fuse-hole. When the shell is lowered into the bore and adjusted, the bar is unscrewed and removed.

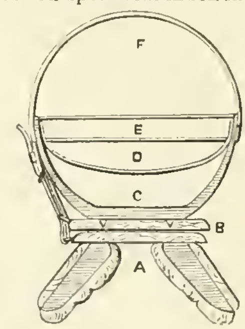
LOADING SIDE OF A GUN.—The side of the grooves of a gun, by which a projectile passes down the bore of a rifled gun from the muzzle. The studs of the shot press against this side when being loaded, but on being forced out by the explosion of the charge, they press against the other side, termed the *driving* side.

LOADING-TONGS.—Tongs for placing in the charges and shells of siege howitzers. They are formed of two arms, so hinged together that the bent ends of the short arms will enter the ears of the shell, and the grooved and widened ends of the long ones will clasp between them the cartridge. The implement is made of such a length that the cartridge can be thrust into the chamber by reaching in one hand, holding the tongs with the cartridge in position.

LOCALIZATION. The act of establishing troops, depots, magazines, etc., in any appointed place, dividing them into a number of small centers independent of each other. In case of mobilization of an army, each appointed town forms a place of rendezvous, where men on furlough and those belonging to the reserve meet to obtain their arms and equipment, and to be drilled until they are draughted into the regiments in the field, or join the army of reserve.

LOCAL RANK. The rank given to an officer in Her Majesty's service serving in a foreign land with other troops, whereby he is placed in his proper position, as regards equality of rank, with those officers whose first commissions are of the same date, but who have been more fortunate in promotion. For instance, a British officer located in India, with his regiment and with troops belonging to the Indian Army, may find himself junior in rank to an Indian officer, though his first commission is of the same date; to equalize their standing in the country, what is termed *local* rank is conferred by the Commander in-Chief in India.

LOCATI LITTER.—A single mule-litter designed by M. Locati, of Turin, for the passage of the narrowest defiles, avoiding as far as possible obstructions from tree-branches overhead or impediments on either side. It is looked upon with much favor in Europe.



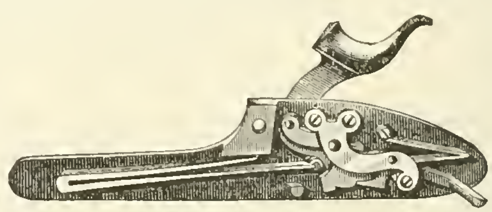
The drawing shows a cross-section of this litter, with its frame, braces, and cover, C. D. E. F., attached to its saddle, A. See *Litter*.

LOCHABER AXE.—An axe with a curved handle and very broad blade. It was the ancient weapon of the Highlanders, and was carried by the Old City Guard of Edinburgh.

LOCHAGE.—In Greek antiquity, the title of an officer who commanded a cohort.

LOCHOI.—The designation for a *file* in the elementary tactical formations of the Greeks. The composition of the grand phalanx was as follows: Tetraphalangarchia = 4 *Phalanxes* = 16 *Chiliarchiæ* = 64 *Syntagmata* = 256 *Tetrarchiæ* = 1024 *Lochoi* or files = 4 096 *Enomitiæ* of 4 men each. It is thus seen that, in the various formations, one division of the whole could be made by the powers of 2 or 4.

LOCK—1. In fencing, to seize, as the sword-arm of an antagonist, by turning the left arm around it, in order to disarm him. 2. That part of a fire-arm by which the powder is fired. Muskets, in their earliest use, were fired by the hand applying a slow match to the touch-hole. Towards the end of the



14th century, the first improvement appeared in the *matchlock*. This consisted of a crooked iron lever, in the end of which the match was fixed. By a pin-gear of a simple nature, pressure on the trigger brought the match accurately down on the powder pan, of which the lid had previously been thrown forward by the hand. This mode of firing involved the carrying of several yards of slow match, usually wound round the body and the piece; rain extinguished the match, and wind dispersed the powder in the pan, so that the match-lock, clumsy withal, was but an uncertain apparatus.

Superior to the match-lock was the *wheel-lock*, introduced at Nuremberg in 1517, in which fire was produced by friction between a piece of flint or iron pyrites and a toothed wheel. The mechanism which generated the sparks simultaneously uncovered the pan, so that the dangers from wind and rain were averted; but before firing, the apparatus required to be wound up like a clock, and therefore the charges could not be frequent.

The wheel-lock continued for a long period to be used in Germany, and partially in France. In the Spanish dominions, however, its place was supplied by the simpler contrivance called the snaphaunce, snapphahn, or the asnaphan lock, of nearly contemporaneous invention, which, acting by means of a spring outside of the lock-plate, produced fire through the concussion of a flint against the ribbed top of the powder-pan. Its positions of half and full-cock were obtained by the insertion of a pin to stay the operation of the mainspring. In the middle of the 17th century the *flint-lock* was invented, combining the action of the wheel-lock and the snaphaunce, while it was incontestably superior to either. After combating much prejudice, it was universally adopted in the armies of western Europe by the commencement of the 18th century. Muskets embracing it obtained the name of "fusils," a French adaptation of the Italian word *focile*, a flint. With successive improvements, the flint-lock continued in general use until the introduction of the *percussion-lock* almost in our own day; and among eastern and barbaric nations the flint-lock is still extant. Its great superiority over the snaphaunce consisted in the "tumbler" (of which presently) and also the "scear," appliances still retained in the percussion-lock, which enabled the positions of half and full cock to be taken up without the intervention of pins, always uncertain in their action.

The principle of the percussion-lock is the production of fire by the falling of a hammer upon some detonating powder, the explosion of which penetrates well into the charge in the barrel of the gun. The first practical application of this principle to fire-arms is due to the Rev. Mr. Forsyth, of Belhelvie, in Aberdeenshire. Various forms in which to ignite the detonating powder have been devised, but that generally accepted until within the last few years was the copper cap, fitting tightly on the nipple of the gun, charged with a detonating compound, and exploded by the hammer falling upon it. The mainspring communicates through the swivel with the tumbler, which concentrically with the hammer moves on the tumbler-nail. After the hammer has delivered its stroke, its further progress in the direction required by the spring is barred by the nipple. On pulling back the hammer to the position of half-cock the tumbler turns with it, and the pointed end of the scear (which moves on the scear-nail as center), influenced by the scear-spring falls into a notch in the tumbler. On forcing back the hammer to full-cock, however, the scear will move down to a shallower notch; and on the lever end of the scear being raised by the trigger, it brings down the hammer with a heavy blow on the cap. To keep the works firmly in their several places, a "bridle" is screwed over them which includes the pin through the tumbler in its width. Since the adoption of breech-loading arms, the action of the lock is so far varied that the hammer usually falls on a movable pin, which is impelled against a detonating charge placed in the body of the cartridge itself. A spiral spring around the pin brings it back to the position necessary for another blow. The advantage of this arrangement is that one operation of loading is substituted for the double process of loading and capping.

The conditions to be fulfilled in the construction of a military lock, are—1st. The production of fire, and its communication with the charge, should be certain, and under the perfect control of the soldier. 2d. The cap should be placed upon the cone with facility, and it should not be displaced in handling the piece. 3d. Fragments of the cap should not incommode persons near by, nor should the gas generated by the explosion of the cap corrode or injure the cone, barrel, or stock. 4th. There should be no danger of accidental explosions. The ordinary percussion lock as commonly constructed is composed of the *lock-plate*, to which the several parts are attached, and by which the lock is fastened to the stock; the *hammer*, which strikes upon the cap, and explodes the composition; the *mainspring*, which sets the hammer in motion; the *tumbler*, or axle, by which the power of the mainspring is communicated to the hammer; the *sear*, or lever, the point of which fits into the notches of the tumbler, and holds the hammer in the required position; the notches are designated as the *full-cock notch*, and *safety-notch*; the *sear-spring*, which presses the point of the sear well into the tumbler notch; the *bridle*, which is pierced with two holes for the inner pivots of the sear and tumbler; the *swivel*, which joins the mainspring and tumbler. The foregoing constitute the essential parts of an ordinary percussion-lock; in addition to these, the new service lock is supplied with Maynard's self-priming apparatus. The primer used in this apparatus, is a long strip of paper containing about 60 charges of percussion-powder, distributed at uniform intervals. The strip is wound up in the form of a coil, and inserted in a cavity cut into the exterior surface of the lock-plate, called the magazine. One end of the coil protrudes through an opening in the *magazine*, so that the center of the first charge of percussion-powder is directly over, but not in contact with, the top of the cone. When the lock is sprung, the primer is accurately cut off by a knife-edge located on the lower side of the face of the hammer, carried forward and promptly exploded on the top of the cone. A *feeding-finger*, connected with the tumbler, pushes out another primer, when the hammer is brought to the position of "full-cock." Other methods are used for self-priming, in some of which the primer is enclosed in the cartridge itself; but few are found, under all circumstances, to be as reliable as the common percussion lock. In the back-action lock, the mainspring is placed in rear of the tumbler, and the sear-spring, as a separate part, is dispensed with. The mortise, which forms a bed for this lock, seriously affects the strength of the stock at the handle; and, for this reason, the front-action lock is generally preferred for military arms. The drawing shows the Parker lock at full-cock. See *Springfield Rifle*.

LOCK CYLINDER.—A component part of most machine-guns. Behind the *carrier-block* the shaft carries another cylinder, called the *lock-cylinder*, in whose surface guide-grooves are formed, which are in line with the barrels, and in which slide long breech-plugs or locks, called *lock-tubes* or *plungers*, by which the cartridges are thrust into the barrels, and which close the barrels and resist the reaction of the charges when they are fired. This cylinder is called the *lock-cylinder*, because each plug or lock contains a spiral mainspring acting on a firing-pin or hammer, by which the charge is fired, so that the plug performs all the functions of a gun-lock, as well as of a breech-plug. See *Gatling Gun*.

LOCKET.—A name sometimes applied to the chape of a sword-scabbard; the metallic part put on the end to prevent the point of the sword from piercing through it.

LOCKING ANGLE.—The turning angle of carriages, or the angle formed between the gun-carriage and limber, when the wheel of the latter comes in contact with the trail.

LOCKING-CHAIN.—The work of holding back a carriage, on descending ground, devolves on the pole-horses. When the descent is very steep and the load large, they are relieved of a portion of this work by attaching a chain to one of the rear wheels, in such a manner as to prevent it from turning, and thereby changing the friction on the axle-arm to friction on the ground. In field-carriages, one end of the locking-chain is secured to the stock by an assembling-bolt, and the other is passed around the felloe, and secured to itself by a key. In siege-carriages, where the load is much heavier, a shoe is attached to the chain, upon which the wheel rides. This prevents the tire from being worn and the wheel from being strained; at the same time, the operation of locking and unlocking can be performed without stopping the carriages. The lock-chains on caissons are fastened to *lock-chain bridles* under the front ends of the side-rails, and are held up by *lock-chain hooks* fastened to the outside of the side-rails.

LOCKING PLATE.—A plate of metal fixed on each side of the trail of a wooden field carriage, at that point where the wheel of the limber, when it is turned round, comes in contact with the trail, called the locking angle. The plate being thus placed, the trail can receive no damage, as the plate acts as a fender.

LOCK-NAIL.—One of the pins by which the parts of a gun-lock are secured to the *lock-plate*. In the old form of lock, they are the *tumbler-pin, mainspring-screw, sear-pin, bridle-screw, hammer-nail*, and *hammer-spring screw*.

LOCK-NUT.—A nut placed in contact with the main nut, on the same shaft, to keep the main nut from turning. It is of frequent occurrence in the construction of artillery carriages, the elevating gears, etc. It is also called *jam-nut* or *check-nut*.

LOCK-PIECE.—A block of metal at the outer opening of the vent for the attachment of the lock. As friction-tubes are now used for firing cannon in the land service, this part is omitted.

LOCK PLATE.—The plate in a small-arm which covers the lock, and to which the mechanism is attached.

LOCKSPIT.—In field fortification, the small cut or trench made with a spade, about a foot wide, to mark out the first lines of a work.

LOCK-STEP.—A mode of marching by a body of men going one after another as closely as possible, in which the leg of each moves at the same time with, and closely follows, the corresponding leg of the person directly before him.

LOCOMOTIVE CRANE.—Cranes of this type consist of a rotary crane, usually of the pillar variety, mounted upon a suitable car or truck, and provided with an independent boiler and engine, the power of which is utilized for hoisting, lowering and rotating the load, and also for propelling the car upon its tracks. Locomotive cranes are of a great convenience in large works of all kinds where the buildings cover much ground and are connected by means of railroad tracks. By means of these tracks the crane can be transferred from one place to another, to suit the requirements of the work, and can be utilized also for transferring heavy loads from one building to another. They are useful also upon freight wharves, where, by means of a track laid near the edge of the wharf, they can be utilized for unloading vessels, and also for transferring heavy loads from one vessel to another. The construction of cranes of this type is varied according to the requirements of the work to be done. See *Cranes*.

LOCOMOTIVE TORPEDOES.—During the war between Great Britain and the United States in 1812-14, this name was applied to certain mysterious boats invented by Fulton and other Americans for the purpose of navigating beneath the surface of the water, and injuring the bottoms of hostile vessels. In those days of hand-to-hand naval war, all these designs (which, by the way, were failures) were looked upon as little less than diabolical. The progress of destructive weapons during half a century has removed this aversion. The modern torpedo is of two kinds—first, the locomotive torpedo, which is in various ways projected against the side of a hostile vessel; secondly, the fixed torpedo, a kind of stationary bomb-shell intended to explode under the bottom of the enemy's ship. To these fixed torpedos it is now more usual to give the appropriate name of submarine mines.

Of locomotive torpedoes there are three classes: (1.) The Whitehead 'fish torpedo,' which has a fish-shaped case, and is propelled in a straight line under water by means of a small screw-propeller driven by compressed air. It is discharged from a carriage on the deck of a man-of-war, and explodes on impact against the object aimed at. The secret of the construction has been sold by the inventor to the Austrian, Russian, and English Navies. (2.) The Harvey 'towing torpedo,' which is towed out at an angle from the side of the attacking ship, and maneuvered so as to come in contact with the bottom of the ship attacked. It is exploded either mechanically on contact, or by means of an electric fuse, the wire being inserted in the towing line. (3.) Boom, or outrigger torpedoes, which are carried on long booms in the bows of boats or steam-launches, and thus driven against the side of a hostile ship and exploded. Torpedo boats are becoming a special feature of European Navies: they are swift steamers not more than 60 feet long, lying low in the water, and steaming up to 19 knots an hour. The *Polyphemus*, added to the English Navy in 1881, is an armored ram, expressly and cunningly designed for torpedo warfare (carrying Whitehead torpedoes) and is a formidable vessel, 240 feet long. See *Torpedoes*.

LODGE ARMS.—An old word of command, which was used on guards and pickets for the men to place their arms in front of the guard-house or quarter-guard.

LODGED.—A term in Heraldry. A beast of chase, as a stag, is said to be lodged when lying down with its head erect; a beast of prey in the same position is said to be couchant.

LODGING-MONEY.—An allowance in the British Army, granted to officers and others, for whom suitable quarters cannot be provided in barracks. Married Sergeants and private soldiers who are married "with permission," are entitled to lodging-money at various rates up to 8s. a week, when separate rooms in barracks cannot be spared for the accommodation of each couple. The total charge for lodging-money in the Army Estimates amounts to about £100,000.

LODGMENT.—1. In gunnery, the hollow or cavity in the under part of the bore, where the shot rests when rammed home; it is formed in smooth-bore ordnance, after much firing, from the elastic force of the powder acting upon the upper surface of the projectile, and forcing it down, so as to occasion an elliptical indentation. 2. In fortification, an intrenchment hastily thrown up on a captured breach or outwork, in order to maintain the position against recapture. See *Siege*.

LOGARITHMS.—A series of numbers having a certain relation to the series of natural numbers, by means of which many arithmetical operations are made comparatively easy. The nature of the relation will be understood by considering two simple series such as the following, one proceeding from unity in geometrical progression, the other from 0 in arithmetical progression:

Geometrical series—1, 2, 4, 8, 16, 32, 64, 128, 256, 512, etc.
Arithmetical series—0, 1, 2, 3, 4, 5, 6, 7, 8, 9, etc.

Here the ratio of the geometrical series is 2, and any term in the arithmetical series expresses how often 2 has been multiplied into 1 to produce the corresponding term of the geometrical series; thus, in proceeding from 1 to 32, there have been 5 steps or multiplications by the ratio 2; in other words, the ratio of 32 to 1 is compounded five times of the ratio of 2 to 1. It was this conception of the relation that led to giving the name of *logarithms* to the arithmetical series, the word *logarithm* meaning "the number of the ratios." As to the use that may be made of such series, it will be observed that the sum of any two logarithms (as we shall now call the lower series) is the logarithm of their product; e.g., 9 ($=3+6$) is the logarithm of 512 ($=8\times 64$). Similarly, the difference of any two logarithms is the logarithm of the quotient of the numbers; a multple of any logarithm is the logarithm of the corresponding number raised to the power of the multiple; e.g., 8 (= 4 × 2) is the logarithm of 256 (= 16^2), and a submultiple of a logarithm is the logarithm of the corresponding root of its number. In this way: with complete tables of numbers and their corresponding logarithms, addition is made to take the place of multiplication, subtraction of division, multiplication of involution, and division of evolution. In order to make the series above given of practical use, it would be necessary to complete them by interpolating a set of means between the several terms, as will be explained below. We have chosen 2 as the fundamental ratio or base, as being most convenient for illustration; but any other number (integral or fractional) might be taken; and every different base or *radix*, gives a different system of logarithms. The system now in use has 10 for its base; in other words, 10 is the number whose logarithm is 1. The idea of making use of series in this way would seem, upon inquiry, to have been known to Archimedes and Euclid, without, however, resulting in any practical scheme; but by the end of the 16th century, trigonometrical operations had become so complicated that the wits of several mathematicians were at work to devise means of shortening them. The real invention of logarithms is now universally ascribed to John Napier, Baron of Merchistoun, who in 1614 printed his *Canon Mirabilis Logarithmorum*. His tables only give logarithms of sines, cosines, and the other functions of angles: they also labor under the three defects of being sometimes + and sometimes —, of decreasing as the corresponding natural numbers increase, and of having for their *radix* (the number of which the logarithm is 1) the number which is the sum of

$$1 + 1 + \frac{1}{1.2} + \frac{1}{1.2.3} +, \text{ etc.}$$

These defects were, however, soon remedied: John Speidell, in 1619, amended the tables in such a manner that the logarithms became all positive, and increased along with their corresponding natural numbers. He also, in the sixth edition of his Work (1624), constructed a table of Napier's logarithms for the integer numbers, 1, 2, 3, etc., up to and including 1000, with their differences and arithmetical complements, besides the numerous other improvements. Speidell's tables are now known as *hyperbolic logarithms*. But the greatest improvement was made in 1615 by Professor Henry Briggs, of London, who substituted for Napier's inconvenient "radix" the number 10, and succeeded before his death in calculating the logarithms of 30,000 natural numbers to the new radix. Brigg's exertions were doubly seconded; and before 1628 the logarithms of all the natural numbers up to 100,000 had been computed. Computers have since chiefly occupied themselves rather in repeatedly revising the tables already calculated than in extending them.

The following is the simplest method of constructing a table of logarithms on Brigg's system. The log of 10 = 1; the log. of 100 (which is twice compounded of 10) = 2·; the log. of 1000 = 3·, etc.; and the logarithms of all powers of 10 can be found in the same manner. The intermediate logarithms are found by continually computing geometric means between two numbers, one greater and the other less than the number required. Thus, to find the log. of 5, take the geometric mean between 1 and 10, or 3·162..., the corresponding arithmetic mean (the log. of one being 0, and that of 10 being 1·) being ·5; the geometric mean between 3·162... and 10, or 5·163..., corresponds to the arithmetic mean between ·5 and 1·, or ·75; in a similar manner the geometric mean between 3·162... and 5·623..., or 4·216..., has its logarithm = ½ (·75 + ·5), or ·625; this operation is continued till the result is obtained to the necessary degree of accuracy. In this example, the twenty-first result gives the geometric mean = 5·000,003, and the corresponding arithmetic mean = ·698,970, which is in ordinary calculations used as the logarithm of 5. Since division of numbers corresponds to subtraction of logarithms, and since $2 = \frac{10}{5}$, the log. of 2 = log. 10 − log. 5 = 1· − ·698970 = ·301030. The logarithms of all prime numbers are found in the same way as that of 5; those of composite numbers are obtained by the addition of the logarithms of their factors; thus, the log. of 6 = log. 2 + log. 3 = ·301030 + ·477121 = ·778151. This method, though simple in principle, involves an enormous amount of calculation; and the following method, which depends on the modern algebraic analysis, is much to be preferred. According to this method, logarithms are considered as indices or powers of the radix; thus, $10^0 = 1$, $10^{\cdot 301030} = 2$, $10^{\cdot 477121} = 3$, $10^2 = 100$, etc.; and the laws of logarithms then become the same as those of indices. Let r represent the radix y the natural number, x its logarithm: then $y = r^x$, or, putting $1 + a$ for r, $y = (1+a)^x$; and it is shown by the binomial and exponential theorems (see the ordinary works on algebra) that $y = 1 + Ax + \frac{A^2x^2}{1.2} + \frac{A^3x^3}{1.2.3} +$, etc., where $A = r - 1 - \frac{1}{2}(r-1)^2 + \frac{1}{3}(r-1)^3 -$, etc., the former equation expressing a number as the sum of different multiples of its logarithm and the radix.

If $\frac{1}{A}$ be now substituted for x, then, $y = r^{\frac{1}{A}} = 1 + \frac{1}{1.2} + \frac{1}{1.2.3} +$, etc. = 2·71828182.... which, as before mentioned, is Napier's radix, and is generally called e; then $r^{\frac{1}{A}} = e$, or $r = e^A$, or A is the logarithm of r to the base of radix e. Then, referring to the above-mentioned value of A, we have log. $_e r$ (*i.e.*, log. of r to the base of e) $= r - 1 - \frac{1}{2}(r-1)^2 + \frac{1}{3}(r-1)^3 -$, etc., or, as before, putting $1 + a$ for r,

$$\log._e(1+a) = a - \frac{a^2}{2} + \frac{a^3}{3} -, \text{ etc.};$$

a series from which log. $_e(1+a)$ cannot be found, unless a be fractional. However, if we put $-a$ for a, log.

$$_e(1-a) = -a - \frac{a^2}{2} - \frac{a^3}{3} -, \text{ etc.};$$

and subtracting this expression from the former, log. $_e(1+a)$ − log. $_e(1-a)$ or

$$\log._e\left(\frac{1+a}{1-a}\right) = 2\left(a + \frac{a^3}{3} + \frac{a^5}{5} +, \text{ etc.}\right),$$

and, for the sake of convenience, putting $\frac{u+1}{u}$ for $\frac{1+a}{1-a}$, in which case $a = \frac{1}{2u+1}$, we finally obtain

$$\log.\frac{u+1}{u} = 2\left(\frac{1}{2u+1} + \frac{1}{3(2u+1)^3} + \frac{1}{5(2u+1)^5} +, \text{ etc.}\right),$$

or

$$\log._e(u+1) = \log._e u + 2\left(\frac{1}{2u+1} + \frac{1}{3(2u+1)^3} + \frac{1}{5(2u+1)^5}\right) +, \text{ etc.}$$

If 1 be substituted for u in this formula, the Napierian logarithm of 2. is at once very readily obtained to any degree of accuracy required; if 2 be put for u, the Napierian logarithm of 3 can be calculated, etc. Now, as logarithms of any system have always the same ratio to one another as the corresponding logarithms of any other system, no matter what its base, if a number can be found which, when multiplied into the logarithm of a certain number to one base, gives the logarithm of the same number to another base, this multiplier will, when multiplied into *any* logarithm to the first base, produce the corresponding logarithm to the other base. The multiplier is called the modulus, and, for the conversion of Napierian into common or Brigg's logarithms, is equal to ·4342944...; so that *to find the common logarithm of any number, first find the Napierian logarithm, and multiply it by* ·4342944... As in Brigg's system the logarithm of 10 is 1, and that of 100 is 2, it follows that all numbers between 10 and 100 have, for their logarithms, unity + a proper fraction, in other words, the integer portion of the logarithms of all numbers of two figures is unity; similarly, the integer portion of the logarithms of all numbers between 100 and 1000 is 2, and, in general, the integer portion of the logarithm of any number expresses a number less by unity than the number of figures in that number. This integer is called the *characteristic*, the decimal portion being designated as the *mantissa*.

As the logarithm of $1 = 0$, the logarithms of quantities less than unity would naturally be negative; thus, the logarithm of $\frac{1}{2}$ would be—·30103, but, for convenience in working, the mantissa is kept always positive, and the negative sign thus only applies to the characteristic: the logarithm of $\frac{1}{2}$ or ·5 would thus be $\bar{1}\cdot69897$, the characteristic in this and similar cases expressing, when the fraction is reduced to a decimal, the number of places the first figure is removed from the decimal point; thus, the logarthm of ·0005 is $\bar{4}\cdot69897$. Logarithms are of frequent application in the solution of problems of gunnery, etc.

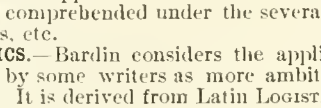
LOGEMENT.—Any place occupied by military men, for the time being, whether they are quartered upon the inhabitants of a town, or are distributed in barracks. When applied to soldiers that have taken the field, it is comprehended under the several heads of huts, tents, etc.

LOGISTICS.—Bardin considers the application of this word by some writers as more ambitious than accurate. It is derived from Latin LOGISTA, the Administrator or Intendant of the Roman armies. It is properly that branch of the military art embracing all details for moving and supplying armies. It includes the operations of the ordnance, quartermaster's, subsistence, medical, and pay departments. It also embraces the preparation and regulation of magazines, for opening a campaign, and all orders of march and other orders from the General-in-Chief relative to moving and supplying armies. Some writers have, however, extended its signification to also embrace STRATEGY.

LOG LINE.—The cordage used for lashing to gun-aprons, sponge and muzzle caps, etc. There is also a log-line made in India which is used for choking rockets; for handles for case-shot, etc.

LOG PAPER.—A thin drawing paper used in the manufacture of paper fuses, etc.

LOG REVETMENT.—A revetment made of trunks of small trees or saplings laid horizontally one on the other, and supported by posts sets into the banquette. At frequent intervals tie beams are dovetailed between the logs, and, extending six or eight feet into



the parapet, are secured to horizontal anchoring logs. For intrenchments hastily thrown up, this is the most usual form, rails or timber of any kind being used. See *Revetment*.

LOMBARDS.—A German people of the Suevic family, not very numerous, but of distinguished valor, who played an important part in the early history of Europe. The name is derived from *Longobardi*, or *Langobardi*, a Latinized form in use since the 12th century, and was formerly supposed to have been given with reference to the long beards of this people; but is now derived rather from a word *parta*, or *barte*, which signifies a battle-axe. About the 4th century they seem to have begun to leave their original seats (on the Lower Elbe, where the Romans seem to have come first in contact with them about the beginning of the Christian era), and to have fought their way southward and eastward, till they came into close contact with the Eastern Roman Empire on the Danube, adopted an Arian form of Christianity, and having been for some time tributary to the Heruli, raised themselves upon the ruins of their power, and of that of the Gepidæ, shortly after the middle of the 6th century, to the position of Masters of Pannonia, and became one of the most wealthy and powerful nations in that part of the world. Under their King Alboin, they invaded and conquered the north and center of Italy (568—569). The more complete triumph of the Lombards was promoted by the accession of strength which they received from other tribes following them over the Alps—Bulgarians, Sarmatians, Pannonians, Norici, Alemanni, Suevi, Gepidæ, and Saxons—for the numbers of the Lombards themselves were never very great. 2. Cannon of peculiar form in former use, and originally employed by the Lombards. See *Bombard*.

LONG-BOW.—A bow of the height of the archer, formerly used in England for war and sport. The term is now synonymous with *bow*, and used in contradistinction to *Cross-bow*. See *Bow*.

LONGE.—The training ground for the instruction of a young horse, to render him quiet, tractable, and supple; to give him free and proper use of his limbs, to form his paces, and to prepare him in all respects for the cavalry service.

LONGEVITY PAY.—An extra rate of pay for long service. It has recently been decided by the Supreme Court that service as Cadets must be taken into account in computing Longevity Pay. The service performed as enlisted men of Regulars or Volunteers is also to be counted.

Under secton 1284, Revised Statutes, a soldier who completes a term of five years' continuous service, and re-enlists within thirty days thereafter, is entitled to an additional allowance of $2 per month; and for each successive and continuous re-enlistment under the same conditions he is entitled to a further addition of $1 per month. See *Pay*.

LONG ROLL.—When the troops should form suddenly to meet the enemy, the signal "*to arms*," is sounded or the "*long roll*" is beaten. The troops after assembling on their company parades, form rapidly in front of their camps. In the cavalry, if the troops are to form mounted, the signal "*to horse*" is sounded.

LONG-ROLLER.—A round piece of wood, 6 inches in diameter, and $3\frac{1}{2}$ feet long, having a groove cut round it in the middle, for the reception of the gun when placed upon it. It is used to move a gun in the direction of its axis, on skids, on a hard smooth surface, such as a platform, etc. Two of them are used at once, and the gun moving upon them, gains twice the distance passed over by the roller.

LOOKING-GLASS SIGNALING.—A method of signaling invented and extensively used by the North American Indians, both on the Plains and in the regions west of the Rocky Mountains. The reflection of the sun is flashed from a small piece of a mirror held in the hand, and in this manner a Chief is frequently enabled to direct the movements of his warriors with the greatest ease and certainly from a distant point overlooking the field. This method of signaling, modified by the resources of science, has been lately introduced into the English service, and used both in India and Southern Africa. A great advantage of this method over the ordinary signal system is that the apparatus is more portable, but it can be succesfully used only in regions where the atmosphere is clear of clouds through considerable periods of time. Anybody who has any idea of the ordinary method of telegraphing by electricity with the ear alphabet, will understand how spaces of time may be employed to indicate letters and words by means of the eye. There are two methods: the reflector may be obscured except when the screen is temporarily removed to produce a flash or letter; or the reflector may be kept exposed except when it is obscured to produce a letter. The first method is said to be the easier for the beginner, but the second less fatiguing to the eye. The distance through which this mode of communication may be carried on varies with the size of the mirrors and the clearness of the atmosphere. From the Himalayas a 5-inch mirror has communicated distinct signals 60 miles. The instrument could be used with good success on the Andes. When the signaling station forms an angle greater than a right angle between the sun and the receiving station, two mirrors are used to prevent too great a loss of rays by oblique reflection. The mirrors are mounted on tripods, and are held by a socket, or a universal joint. Besides its use as a signaling instrument, the heliograph has served to define distant points in a survey, and for this purpose was employed in the triangulation of India. It was also used by the late Astronomer-Royal of England at the Cape of Good Hope in verifying the arc of the meridian. See *Heliography*.

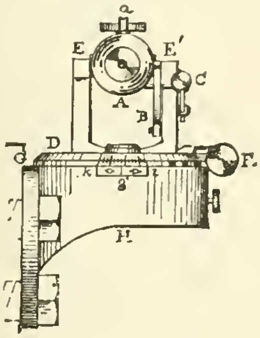
LOOPHOLED GALLERIES.—Vaulted passages or casemates, usually placed behind the counterscarp revetment, and behind the gorges of detached works, having holes pierced through the walls, to enable the defenders to bring a musketry fire from unseen positions, upon the assailants in the ditch. Loopholes, however, are not confined to galleries. In modern fortifications, the revetments, both scarp and counterscarp, are very generally pierced for a musketry fire.

LOOP HOLES.—In fortification, loop-holes are small apertures in the walls, through which sharp-shooters may fire. The loop-hole should widen towards the outside, that the shooter may have a sweep with his rifle; and it is of importance, on that account, so to fashion the sides that a bullet may not penetrate, unless fired straight into the center. For this purpose, the stones are generally laid stepwise, although other forms are frequently resorted to. Walls are readily made available for purposes of defense by loopholing them, the mode of doing it varying with their height and situation. It is a general rule that loopholes must be so placed that an enemy, if he succeeds in rushing up, shall not be able to make use of them. To prevent this they should be 8 or 9 feet above the ground on the outside; but on the inside the banquette from which the defenders are to fire should not be more than about 4 feet 6 inches below them. A portion of the wall not less than 18 inches high should be left above the loop-holes to screen the men's heads when firing. These points are attainable in several ways; if the walls are high, the loopholes may be made near the top, and a temporary stage or earthen banquette might be placed inside; if the wall is not over 6 feet high, the loop-holes may be made at 4 feet 6 inches above the inside level, and a ditch made outside. The quickest way of making a loop-hole is to break the wall down from the top for about 2 feet, and then to fill it up at the top with a stone or sand bag. If the wall should be low, a piece of timber supported on a couple of stones would be a ready expedient. If exposed to the fire of artillery, a wall will not afford good cover, but it may be improved by sinking a trench in rear and throwing the earth against the wall, or by digging a ditch in front and throwing the earth over the wall.

LOOSEN.—To open ranks or files from close order. To loosen is, in fact, to lose that firm continuity of line or perpendicular adherence, which constitutes the true basis of military operations. The lock-step was introduced for the purpose of counteracting the mischievous effects of loose marching, but it produced a greater inconvenience, and has therefore been laid aside. The equal pace and marked time correct both.

LOOTEES. An East Indian term for a body of irregular horsemen, who plunder and lay waste the country, and harass the enemy in their march. The word is derived from *loot*, plunder or pillage, and is frequently written *Looties* and *Looty Wallars*.

LORAIN SIGHT.—Owing to the great range at which rifled guns are used, and of the accuracy of fire demanded of them, it is important that they should be provided with aiming apparatus more perfect than the coarse and clumsy sights heretofore supposed to be sufficient for artillery purposes. The Lorain sight, of which the following is a brief description, combines the properties most desirable in a sight for heavy rifled guns. This instrument is essentially a transit with a vertical and horizontal limb, the former to give the required elevation or depression, and the latter to give proper allowance for drift. The telescope (A) has a top, a front and rear open sight (*a*), used to bring the object aimed at within the field of view. The vertical limb (B) is graduated to degrees. The least count of the vernier is six minutes. The tangent screw (C) elevates or depresses the telescope. The horizontal limb (D) has a scale of 20° on each side of the zero, which is graduated to degrees. The standards (E E') are supported by the horizontal limb. The tangent screw (F) moves the horizontal limb to right or left. The base of the



instrument (G) has on it the vernier (*g*) of horizontal limb, the least count of which is six minutes. When in use, this instrument sits in a seat (H) which is screwed on to the right trunnion of the gun. This seat is so placed that the plane of its top is parallel to the horizontal plane through the axis of the bore. When the vertical limb is at zero, the axis of the telescope will be parallel to the axis of the bore, if the zero of the horizontal limb coincides with the mark (*i*) on the seat. The mark (*i*) is on a movable piece (*k*) and attached to the seat, and its position is easily determined. The elevations given with this sight and with a quadrant do not agree, the latter being measured from the horizontal and the former from the line from sight to object. In firing from above an object, the telescopic sight requires more elevation than the quadrant. If from below an object, it requires less elevation than the quadrant. When the piece is to be fired, the instrument is lifted out of its seat. One instrument suffices for three or four guns, it being carried from piece to piece as they are prepared for firing. For short range and rapid firing, the pieces should, in addition, have the ordinary sighting arrangements. The proper place for the sight is on the left trunnion; but as, with carriages now constructed, it would be interfered with by the crane, it is placed on the right trunnion.

LORARII.—Among the Romans, officers whose business it was, with whips and scourges, to compel the gladiators to engage. The Lorarii also punished slaves who disobeyed their masters.

LORD.—A title given in Great Britain to persons noble by birth or by creation. Peers of the Realm are so styled, including such Archbishops or Bishops as are members of the House of Lords, who are Lords Spiritual. By courtesy, the title Lord is given to the eldest sons of Dukes, Marquises, and Earls, prefixed to an inferior title of the Peerage, and to the younger sons of Dukes and Marquises, prefixed to their Christain name and surname. The following persons bear the title Lord in virtue of their employments: the Lord-Lieutenant of Ireland and Lords-Lieutenant of Counties, Lord Privy Seal, Lords of the Treasury and of the Admiralty, the Lord High Admiral, Lord Great Chamberlain, and Lord Chamberlain, Lord High Constable, Lord High Almoner, Lord High Steward, Lord Steward of the Household, Lords in Waiting, Lords of the Bedchamber, Lords Justices, the Lord Chief Baron of Exchequer, the Lord Chief Justice, the Lord Lyon, the Lord Mayor of London, York, and Dublin, and the Lords Provost of Edinburgh and Glasgow. The Committee of the Scottish Parliament by whom the laws to be proposed were prepared, were called Lords of the Articles. The favored beneficiaries, who, after the Scottish Reformation, obtained in Temporal Lordship the benefices formerly held by Bishops and Abbots, were called Lords of Erection. Persons to whom rights of regality were granted in Scotland, were termed Lords of Regality. The representative of the Sovereign in the General Assembly of the Church of Scotland is called the Lord High Commissioner. The Judges of the Courts of Session and Justiciary in Scotland have the title "Lord" prefixed to their surname, or some territorial designation assumed by them; and throughout the three kingdoms Judges are addressed "My Lord," when presiding in Court.

LORD LIEUTENANT.—In Great Britain, the Lord Lieutenant of a county is a permanent Provincial Governor appointed by the Sovereign by patent under the Great Seal. The office, in England, arose from the occasional Commissions of Array issued by the Crown in times of danger or disturbance, requiring experienced persons to muster the inhabitants of the counties to which the Commissioners were sent, and set them in military order. The right of the Crown to issue such Commissions was denied by the Long Parliament, this question proving the immediate cause of the breach between Charles I. and his subjects. Their legality was established at the restoration by a Declaratory Act. The Lord Lieutenant is now the permanent local Representative of the Crown, who, on the occasion of an invasion or rebellion, has power to raise the militia, form regiments, troops, and companies, and give Commissions to officers. The history of the office seems to have been somewhat similar in Scotland. The "Lieutenant" is commanded to "raise the County" whenever it may be necessary to bring the rebellious and unruly possessors of castles and fortalices into subjection; and though his powers were executive rather than judicial, he seems sometimes to have had authority to exercise the functions of the Sheriff, or overrule his decisions. The Lord Lieutenant of a county is at the head of the Magistracy, the Militia, and the Yeomanry; he nominates officers of militia and volunteers, and is the Chief Executive Anthority, forming the settled channel of communication between the Government and the Magistracy for the preservation of public tranquility. Under him are permanent Deputy-Lieutenants appointed by him.

LORD LIEUTENANT OF IRELAND—The Viceroy or Deputy of the Sovereign to whom the Government of Ireland is committed. The office has existed from a remote period, the appointment having been made under different designations. His powers were in early times very extensive, almost regal. For the last half century following the Revolution the Lord Lieutenant resided little in Ireland, visiting it only once in two years to hold the session of Parliament. Some Lords Lieutenant never went to Ireland at all, and occasionally, instead of a Viceroy, Lords Justices were appointed. The Lord-Lieutenant is appointed under the Great Seal of the United Kingdom, and bears the Sword of State as the symbol of his vice-regal office. He has the assistance of a Privy-Council of 58 members, appointed by the Sovereign, and of Officers of State. He is commissioned to keep the peace and the laws and customs of Ireland, and to see that justice is impartially administered. He has the control of the police, and may issue orders to the General commanding the troops for the support of the Civil Authority, the protection of the public, the defense of the Kingdom, and the suppression of Insurrection. He may confer knighthood, and, previous to its disestablishment, had the disposal of church preferment, as well as all the other patronage of the country. The granting of money, and lands, and pensions, of all titles of honor except simple knighthood, the appointment of Privy-Councilors, Judges, Law Officers, and Governors of Forts, and the appointment to military commissions, as a common thing, are reserved to the Sovereign, acting, however, on the Lord Lieutenant's advice and recommendation. No complaint of injustice or oppression in Ireland is entertained by the Sovereign until first made to the Lord Lieutenant, who is in no case required to execute the royal instructions in a matter of which he may disapprove until he can communicate with the Sovereign and receive further orders. Yet, notwithstanding the dignity and responsibility of his office, the Lord Lieutenant acts in every matter of importance under the direct control of the Cabinet of Great Britain. The views and opinions of the Cabinet on all the more important questions connected with his government are communicated to him by the Home Secretary, who is held responsible for the Government of Ireland, and with whom it is the duty of the Lord Lieutenant to be in close correspondence; on matters of revenue he must be in constant communication with the Treasury. On his occasional or temporary absence from Ireland, Lord-Justices are appointed, who are usually the Lord-Primate, the Lord Chancellor, and the Commander of the Forces. His salary is £20,000, with a residence in Dublin Castle, as well as one in Phœnix Park. His tenure of office depends on that of the Ministry, of which he is a member. A Roman Catholic is ineligible for the Lieutenancy of Ireland.

LORICA—A curiass, or coat of mail worn by the Roman soldiers, made of various materials. The ordinary kind consisted of a skin, or a piece of strong linen covered with small plates of iron, which resembled, both in their shape and in their manner of overlapping each other, the scales of a serpent or fish. Sometimes cuirasses or hauberks, composed entirely of iron rings linked together, were worn by the Roman *Hastati*. A less flexible but more impervious defense was the cuirass made of hard leather or of metal, and consisting of two parts (the one covering the breast and abdomen, and the other the back), united by hinges and leather thongs.

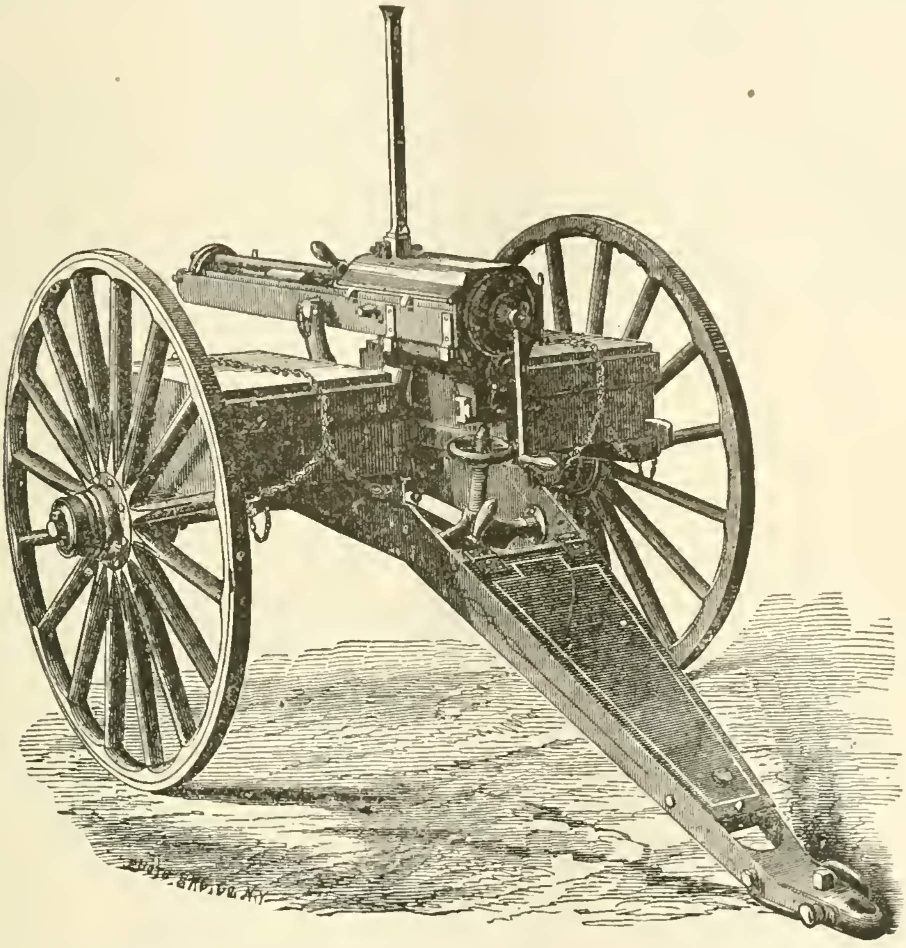
LORIMER.—A maker of bits, spurs, stirrup irons, all metal mountings for saddles and bridles, and generally of all articles of horse-furniture. In London, the lorimers, who had previously formed part of another guild, were incorporated by letters patent in 1712; in the Scottish burghs they have been comprehended as a branch of the corporation of hammermen. Cutlers, locksmiths, and brass-founders have been considered as in the exercise of branches of the lorimer art, and therefore bound to enter with the corporation. The Court of Sessions in 1830 held it to be a gross violation of the exclusive privileges of the lorimer craft to manufacture bits, stirrup-irons, and other metallic articles of horse-furniture, with a view to silver-plating them before selling.

LOSSES.—1. Killed, wounded, and captured persons, or captured property. 2. In the British Army there is a regular provision made for indemnification for losses by fire; by shipwreck; in action with the enemy; by capture at sea; by destruction or capture of a public store-house; by the destruction of articles or horses, to prevent their falling into the hands of the enemy, or to prevent the spreading of an infectious disorder. In the United States it would seem just that Congress should establish some general rules regulating such matters. The principle of settling all such claims by special legislation cannot but bear hardly on a number of individuals, and also probably in the end imposes greater burdens upon the treasury.

LOUP DES ANCIENS.—An iron instrument, made in the shape of a tenaille, by means of which the ancients grappled the battering-rams, and broke them in the middle.

mounted with four barrels arranged in a circle. After firing from one barrel until it may become heated, it is moved aside by a simple movement, and another brought into action, and so on. The first barrel becomes cooled before it is again brought into use, so that a continuous fire can be maintained for any length of time. The barrels being hung upon trunnions may be disconnected from the machine or tilted upwards, allowing them to be readily inspected or cleaned, also facilitating the extraction of any obstruction.

The working parts are exceedingly simple and strong, requiring but a few seconds for their removal or replacement, and can be manipulated by any man of ordinary capacity. The firing is from the center of the machine, and therefore is not diverted from its aim by the recoil. The lock has two extract-



LOUIS.—The name of a Military Order in France, instituted by Louis XIV., in 1693. Their collars were of a flame color, and passed from left to right. The King was always Grand Master. Commonly written *Knights of St. Louis.*

LOVER'S WAR.—In French history a name given to a civil war in the year 1580, during the reign of Henry IV. It was so called because it arose from the jealousies and rivalries of the leaders, who were invited to meet at the Palace of the Queen-Mother.

LOW-BLAST FURNACE.—A metallurgic furnace in which the air of the blast is delivered at moderate pressure.

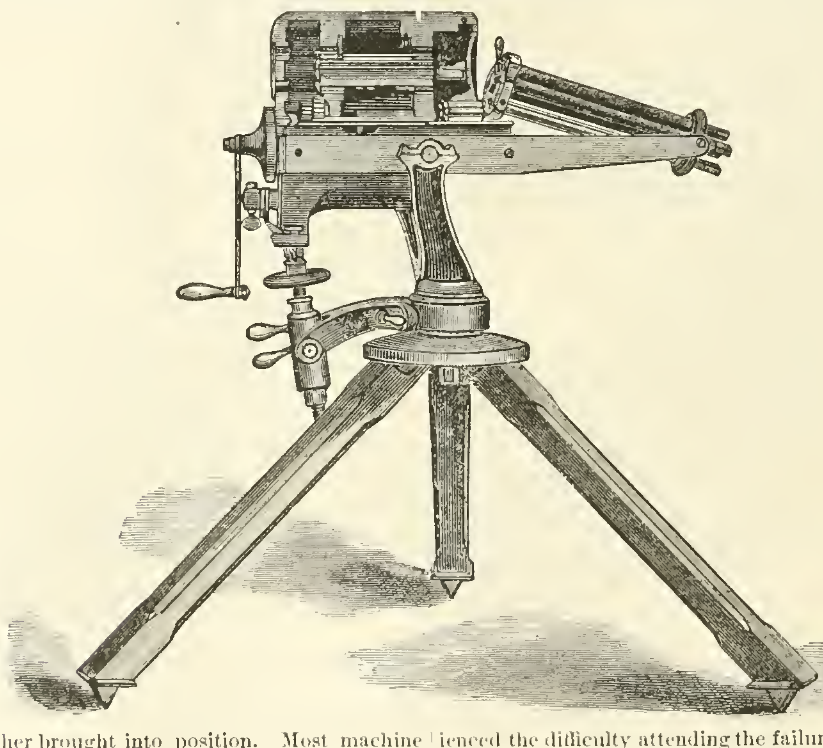
LOWELL BATTERY-GUN. This gun is of the Mitrailleur order. It may be mounted with one or any number of barrels, but the firing is confined to one at a time, and requires but one lock. It is generally

ors, which are not dependent upon springs, but operating positively, insure the extraction of the empty shells under all circumstances. The cartridges are fed into a hopper from which they are taken by two carrier-rolls and deposited one by one between the plunger and opening in the barrel. The plunger then forces them into the chamber of the barrel, fires them and extracts the empty shell, leaving it in the position which it occupied before firing. The next motion of the carrier-rolls throws out the shell and brings another loaded cartridge into position to be forced into the barrel. It is impossible for the empty shell to be carried around a second time, by which the gun might be clogged.

The drawing shows the gun mounted upon its improved gun-carriage. The mechanism of this carriage is so arranged that the gun can be leveled, adjusted or trained to be effective in any position, either at elevation or depression. When operating upon rough or uneven ground and when frequent changes of position are necessary, this arrangement is of much value, as it enables the gunner to bring the gun into any desired position in a very short time. Attached to the carriage are two skeleton cages or crates, where four thousand cartridges can be deposited and carried with the gun, and at the same time be within easy reach of the operator and fed directly to the magazine, requiring no transfer of the ammunition after it is packed at the place of manufacture. Three men can work the gun steadily and continuously when the carriage is used.

The following points should be noticed in connection with this gun: The firing being from the center of the machine, the barrel is not diverted from its aim by the recoil, whereas in most machine-guns the firing-barrel is located some distance from the center of the machine, and the barrel is consequently soon diverted by the continued recoil. The firing being confined to one barrel at a time, other cool and clean barrels are kept in reserve, so that a continuous fire may be maintained. It is well known that the barrels of a rapid firing machine gun become overheated after a few hundred shots, and thereby become practically inoperative until cooled. As the firing is confined to one barrel at a time the gun is not rendered inoperative by the bursting of a cartridge shell or other obstruction in the chamber, as the obstructed barrel may be instantly moved aside, occupying but little space, and requiring but a few seconds for its removal and replacement. it can all be taken from the gun and packed in a close box: by which it can be kept in condition for use at all times. In making long marches over dusty roads the mechanism of some guns is liable to be clogged by dust and found inoperative when called into action. The Lowell Battery Gun requires no feed case or any preparation or transfer of the ammunition whatever, but the cartridges are fed directly from the packages as they are prepared at the factory into a trough which conveys them one by one to the carrier rolls. By this arrangement two men can keep up a continuous fire for any length of time. It is well-known that when feed cases are required for working machine-guns, a large force is required to fill and apply them. Frequent jams also occur in transferring the cartridges from the feed-cases; to the hopper, and the feed cases being necessarily of delicate construction they are liable to injury.

The plunger of this gun is provided with two strong extractors, operating positively and not depending on springs. These extractors are arranged to grasp the cartridge shell at opposite sides and remain locked until the shell is fully withdrawn. Extractors operated by springs are liable to slip over the flange of the shell when it sticks in the chamber of the barrel, preventing the further operation of the gun until removed. The ejection of the empty shells does not depend upon gravity, but is absolutely forced out by the positive movement of the carrier rolls. This feature will be appreciated by those who have exper-

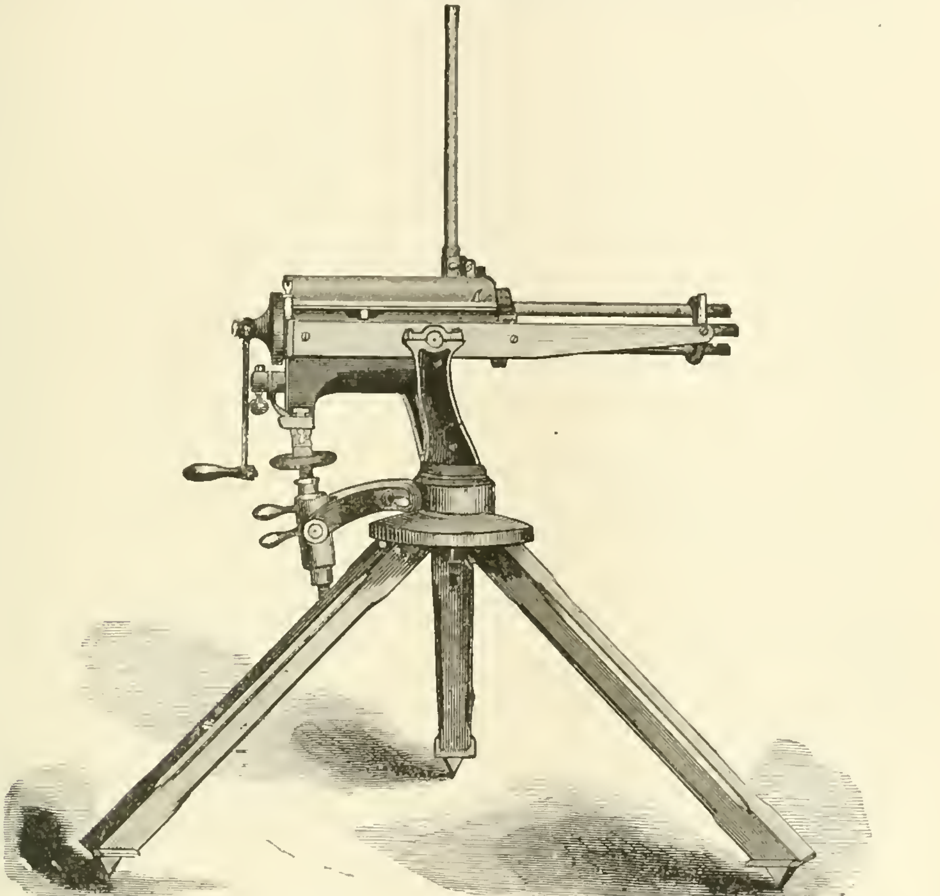


ienced the difficulty attending the failure of the ejection of a shell. The barrels are firmly fixed in the breech plate and require no adjustment after the firing has begun, But few tools are required to dissect the machinery, all of which and a spare plunger are packed with the gun, requiring no spare article or tool box to be carried with it. The lateral, oscillating or traverse motion is very simple, and can be operated by the gunner while firing, and be made to cover any desired space at any distance and returned to a fixed position without cessation of firing. This gun can be worked and fired by two men steadily and continuously 400 shots per minute; and, by the

and another brought into position. Most machine guns become more or less disabled when one barrel is obstructed by the non-extraction of the empty shell, and in some cases entirely so until the obstruction is removed. The barrel and working parts may be removed and replaced in a few seconds, allowing them to be readily inspected and cleaned or removed for protection or other purposes.

In most machine guns, the barrels are made fast to the frame work, rendering inspection and cleaning quite difficult, and, the working parts being encased, considerable time, and services of an expert are required to extract any obstruction. The mechanism assistance of a third man to feed, it can be worked at the rate of 600 per minute, taking the cartridges from the boxes as they come from the factory. By the addition of a second plunger the number of shots per minute can be doubled. The lock is constructed upon a new principal, is very simple, and not liable to be injured or disabled by wear.

The drawing shows the gun mounted on a tripod and ready for firing. Russia, after thorough investigation by its naval officers, bought twenty Lowell Battery Guns. The United States Navy has adopted it. California has purchased three for its State prisons. Ohio has one, and other States are in negotiation for them for use by militia companies stationed in cities.



A comparison of this gun with rival guns detracts nothing from the Lowell. While the Gatling gun has ten locks and ten barrels, all revolving at each shot, the Lowell Battery gun has but one lock and uses but one barrel at a time. The disabling of one lock or barrel of the Gatling renders it useless until repaired by a skillful mechanic. A disarrangement of the Lowell can be remedied by the renewal of a lock or change of the barrel, which can be done in five seconds by any person of ordinary capacity. See *Machine Gun* and *Battery Guns*.

LOW STEEL.—This variety of steel is often known as "mild steel," "soft steel," "homogeneous metal," and "homogeneous iron," and is made by fusing wrought-iron with carbon in a crucible, after which it is cast into an ingot and worked under a hammer. As it contains less carbon than high steel, it has a greater specific gravity. It can be welded without difficulty, although overheating injures it. It more nearly resembles wrought-iron in all its properties, although it has much greater hardness and ultimate tenacity, and a lower range of ductility depending on its proportion of carbon. It has less extensibility within the elastic limit than high steel, but greater beyond it; or, in other words, greater ductility. Its great advantage over wrought-iron for general purposes is that it can be melted at a practicable heat and run into large masses, possessing soundness and tenacity. Its advantages for cannon are greater elasticity, tenacity, and hardness. Its tenacity when suitable for cannon is about 90,000 lbs., or three times as much as cast gun-iron, and 50 per cent. more than the best wrought-iron. The difficulty in the use of steel for large, homogeneous guns is the great size of the hammers required to work the blocks into which it is cast. See *Steel*.

LOYALIST.—A person who adheres to his Sovereign, or to the constituted authority; especially one who maintains his allegiance to his Prince or Government, and defends his cause in times of revolt.

LOZENGE.—In Heraldry, a charge generally enumerated among the sub-ordinaries, in the shape of a rhombus placed with the acute angles at top and bottom. The horizontal diameter must be at least equal to the sides, otherwise it is not a lozenge, but a fusil. The term *lozengy* is applied to a field divided by digaonal lines crossing one another at regular intervals so as to form a diamond pattern, the compartments being of alternate tinctures. See *Heraldry*.

LUBRICATION.—The application of a substance to a surface for the purpose of making it smooth. This substance, which is called a lubricant, may be either a liquid, a semi-liquid, or a solid. Plumbago, or black-lead, is in most common use as a solid lubricant, but powdered soap-stone, or talc, is used for many purposes, as, for instance, by shoemakers upon the inside of the heels of boots and shoes to facilitate the pulling on. When it is desired to have a rope or cord slip over a bearing, as a pin, or a pulley which refuses to turn, it is usual to smear it with lard. Grease is the common lubricant, but for machinery, or the bearing of axles generally, other substances may be added which will materially reduce the friction. Mineral oils, particularly the thicker portions of petroleum, have valuable lubricating properties, and may be used either alone or added to lard, tallow, or animal oils, according to the size, weight and velocity of the revolving shaft. Oils are used for high speed; pasty lubricants for large and heavy bearings. There are a great variety of lubricants used for the axles of artillery carriages, many of them patented. Perhaps the most favorite lubricant fo rlight, fine road carriages, which are furnished with tight boxes, is castor oil. When the box is not tight,a mixture of lard and rye flour is used to advantage.

It has the property of lasting, when mixed in the proportion of about 4 parts of grease to one of flour. Black-lead may be used in combination with lard and flour, or it may alone be mixed with lard or oil. Some vehicles are made with wooden axles, and for these common pine tar is an economical, lasting, preservative, and efficient lubricant. Its application may be alternated with lard, or a mixture of lard and tallow, or lard, tallow and flour; but it is well to have some tar always present. Wherever great delicacy of motion is required, as in watches and other time-pieces, the lubricant must be very fluid. The lubrication may be performed by manual application, or mechanical devices may be employed. There are many kinds of lubricators. They are in the form of reservoirs, which discharge their contents, the lubricants, as fast as they are consumed by the revolving shaft or piece of moving machinery. A simple and often a very efficient lubricator is an inverted oil-can suspended over the bearing or place which requires lubrication. When a pasty lubricant is used, it may be applied on a sponge or brush, if the situation favor such application. The ingenuity of the operator is often advantageously exercised as well as that of the inventor.

LUGS.—The ears of the ordinary bomb-shell, to which the hooks are applied when lifting it.

LUNETTE.—1. An iron ring at the end of the trail of a field-piece, which is placed over the pintle-hook of the limber in limbering up the gun. The term is also applied to the hole through an iron plate on the under side of the stock of a siege-piece, into which the pintle of the limber passes when the piece is limbered. 2. A field work consisting of two faces forming a salient angle, or one projecting towards the enemy, and two flanks, parallel, or nearly so, to the capital or imaginary line bisecting the salient angle. In shape, it is like the gable end of a house. It is intended for the defense of avenues, farm-houses, bridges, and the curtains of field-works. The term is specially applied to a small work beyond the ditch of the ravelin, to supply its deficiency of saliency, and formed at the re-entering angle made by the ravelin and bastion. The lunette has one face perpendicular to the ravelin, andthe other is nearly perpendicular to the bastion. The term *lunettons* is applied to a smaller sort of lunettes. See *Field Works*.

LUNETTES D'ARCON.—In order to bring the lunettes further off the place and diminish the defect of their gorge, General D'Arcon has constructed lunettes which bear his name, and which are supposed to be capable of defending themselves. This work has the same dimensions as an ordinary lunette, except that the salient angle may be made as open as deemed necessary. The gorge is closed by a loop-holed wall 18 feet high, and a round tower 15 feet in diameter separated from a terreplein by a ditch 12 feet wide.

LUNGE.—An extended thrust in fencing and bayonet exercise. The lunges are used the same as the thrusts, and differ from them only in advancing the left foot, so that the left leg, from the foot to the knee, shall be vertical. In both the thrust and the lunge, the body must be covered on the side of the adversary's piece. See *Bayonet Excercise* and *Thrust*.

LUNT.—The match-cord formerly used for firing cannon.

LUSTRATION.—In antiquity, purification by sacrifices and various ceremonies. The Greeks and Romans purified the people, cities, fields, armies, etc., defiled by crime or impurity. This was done in several ways,,viz.: by fire, water, sulphur, and air, the last by fanning or agitating the air around the thing purified. When Servius Tullius had numbered the Roman people, he purified them as they were assembled in the Campus Martius; and afterwards a lustration of the whole people was performed every fifth year before the Censors went out of office. On that occasion the people assembled in the Campus Martius, when the sacrifices termed *Suovetaurilia*, consisting of a sow, sheep, and ox, after being carried thrice around the people, were offered up, and a great quantity of perfumes was burned. This ceremony was called *Lustrum*. It was instituted by Servius Tillius, 566 B.C., and performed for the last time in the reign of Vespasian. The term *Lustrum* was given also to the period of five years between the lustra. The army was purified before a battle by causing the soldiers to defile before the two quivering halves of a victim, while the Priest was engaged in offering certain prayers. The establishment of a new Colony was preceded by a lustration with sacrifices. Rome itself, and in fact all the towns within its dominion, always underwent a lustration after being visited by some great calamity. The lustration of fields were performed after sowing was finished, and before reaping began. The lustrations of flocks, designed to keep them from disease, was performed every year at the festival of the Palilia, when the shepherd sprinkled them with pure water, thrice surrounding the fold with savin, laurel, and brimstone set on fire, and afterwards offering incense and sacrifices to Pales, the tutelary goddess of shepherds. Private houses were purified with water, a fumigation of laurel, juniper, olive-tree, and the like, a pig being offered as a victim. Infants were purified, girls on the third, boys on the ninth, day after birth, then named and placed under the protection of the god of the family. The lustration of a funeral pile was by having the spectators march round it before a fire was kindled. Whatever was used at a lustration was cast into a river, or some other inaccessible place, as to tread upon it was considered ominous of some great disaster.

LUTE.—A term employed in the laboratory to denote a substance used for effectually closing the joint of apparatus, so as to prevent the escape of vapor or gases,or for coating glass vessels so as to render them more capable of sustainging a high temperature, or for repairing fractures. For ordinary purposes, lutes made of common plastic clay or pipe-clay with an admixture of linseed-meal or almond-powder, or,for common stills,linseed-meal and water made into a paste, are quite sufficient; for more delicate experiments, *fat lute*, covered over with moistened bladder, is used. Lutes for coating glass vessels are generally composed of Stourbridge clay or Windsor loam, mixed with water; but the most simple method is to brush the glass retort over with a paste of pipe-clay and water, dry it quickly and repeat the operation till a sufficient thickness of coating is obtained. Other lutes in frequent use are *Willis's lute* (a paste composed of a solution of borax in boiling water with slaked lime), various mixtures of borax and clay, of lime and white of egg, *iron cement*, moistened bladder, paper prepared with wax and turpentine, and caoutchouc. The use of the last named lute has on account of its flexibility and consequent non-liability to accident, been rapidly extending.

LUZERNER.—A name given to the *pole-hammer* in Germany and Switzerland, it being a favorite arm of the people of Lucerne.

LYCANIENS.—A term applied by the French to the Hungarian light infantry.

LYING OUT OF QUARTERS.—In the United States army, any officer or soldier who lies out of his quarters, garrison, or camp, without leave from his Superior Officer, is punished as a Court-Martial may direct.

LYLE EMERY GRAPPLE SHOT.—This projectile was devised by Lieutenant D. A. Lyle, United States Army, and Mr. C. E. Emery, draughtsman at the National Armory. It is intended for use in connection with the 2½-inch Lyle gun for life-saving purposes. It is an elongated, solid, cast-iron, smooth-bore projectile, with a wrought-iron base and shank. In form the shot is cylindro-ogival. The radius of the ogival head is equal to the diameter of the projectile. An axial cavity, 1.25 inchs (3.175 centimeters) deep is bored in the rear end of the shot, upon whose interior cylindrical surface is cut a female screw-thread to engage the screw on the wrought-iron base. The base has a cylindrical axial cavity drilled through it, with a rounded groove on one side to accommodate the stop and stop-spring. The front end of this cavity is enlarged by counter-boring, to allow the necessary longitudinal play of the shank-head in opening and closing the flukes. The screw on this end fits accurately that in the body of the shot. At the rear end of the base are formed five sectoral slots, equidistant circumferentially. These slots receive the heads of the flukes, which are fastened to the base at these points by rivets. Circular grooves are milled out between the slots to allow the insertion of the rivets. The shank is of forged wrought iron. The front end of this bolt has a screw-thread, upon which, after insertion in the axial cavity of the base, a nut is placed. This end of the bolt is riveted after screwing on the nut. A rectangular groove on one side of the shank receives the stop and spring. Five lugs, placed equidistantly around the shank near the forward end, serve as points of attachment for the links that extend the flukes. The rear end of the shank contains an eye-hole for attaching the line in firing. Each link is composed of two flat pieces of Troy steel, with holes at each end to receive the rivets that connect them with the shank and fluke. The flukes, five in number, are also made of Troy steel. Each fluke has a rounded notch near its upper or forward end to accommodate the corresponding lug on the shank when closed. All edges or angles are carefully rounded. The details of form and construction permit the use of the projectile in the 2½-inch gun already in the service, and prevent the entanglement of the line as much as possible in firing. The projectile is inserted in the gun point first, with the flukes closed, as shown in the drawing, and the line tied in the eye-hole of the shank. In this position the base of the shot is toward the muzzle of the gun; the flukes partially enter the bore while the shank extends beyond the muzzle. In firing, the projectile describes the first part of its trajectory base foremost; the strain upon the shank being toward the rear, the flukes are kept closed; but, as soon as the projectile reverses, the tension on the line draws out the shank to the limit of its *play* in the base, spreading the flukes to their full extent. When the head of the shank reaches the bottom of the counter-bore in the base of the shot, the stop is thrown out by the action of the stop-spring, and a square shoulder catches on the base and prevents the closing of the flukes. The latter may be opened and closed readily by hand. To close the flukes press the thumb upon the stop until the shoulder is disengaged, and then push in the shank gently till its head strikes the front end of the counter-bore.

When vessels are stranded the crews sometimes fasten a line or rope to a cask, spar, buoy, or raft, and heave it overboard, hoping that the wind and waves will throw it on the shore to be seized by persons there, thus establishing communication between the wreck and beach. It frequently occurs, however, that there is an inshore current that carries the floating object along parallel to the coast, in which case the object desired fails to be attained. This projectile was devised for the purpose of firing over the line thus paid out from the stranded vessel, so as to pass above that line at some desired point between the cask or buoy and the vessel, and then by hauling in the attached shot-line, the flukes grapple the ship's line, and enable the life-saving crew on shore to land the buoy and secure the line from the vessel. There are other uses to which it may be put that will readily suggest themselves to those familiar with the service.

The following are the principal dimensions of the shot:

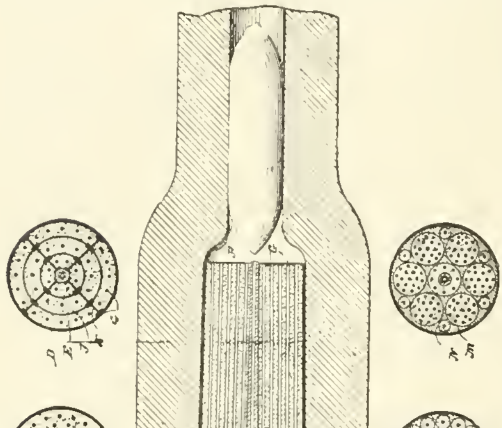
	Inches.	Cent.
Total length of body and base	13.50	34.289
Length of ogival head	2.17	5.5118
Radius of head	2.50	6.350
Length of cylindrical part	9.83	24.967
Diameter of cylindrical part	2.50	6.350
Axial cavity—Length	1.25	3.175
Base—Total length	2.75	6.985
Shank—Total length	13.25	33.654
Total length of shot and shank flukes closed	23.50	59.689
Total length of shot and shank, flukes extended	24.60	62·483
Distance of center of gravity from base	5.00	12.700

The weight of the shot is 18.218 + lbs. = 8.264 kilos. See *Anchor-rocket*, *Chandler Anchor-shot*, and *Life-saving Rockets*.

LYON KING-OF-ARMS.—The title borne since the first half of the 15th century by the chief heraldic officer for Scotland. He is the Presiding Judge in the Lyon Court, and appoints the Heralds, Pursuivants, and Messengers-at-Arms. Unlike the English Kings-of-Arms, he has always exercised jurisdiction independently of the Constable and Marshal, holding office directly from the Sovereign by Commission under the Great Seal. In Scotland he takes precedence "of all Knights and Gentlemen not being officers of state, or Senators of the College of Justice." In England he ranks after Garter, and before the Provincial King-of-Arms. Since the revival of the Order of the Thistle, he has been King-of-Arms of that Order. So sacred has his person been held that, in 1515, Lord Drummond was declared guilty of treason, attainted, and imprisoned in Blackness Castle, for striking Lyon. Prior to the Revolution, Lyon was solemnly crowned at Holyrood on entering on office by the Sovereign or his Commissioner, his crown being of the form of the royal crown of Scotland, but enameled instead of being set with jewels. The crown is now only worn at coronations; and that actually supplied on occasion of the last four appointments has been similar to the crowns of the English King-of-Arms. Lyon's badge or medal, suspended by a triple row of gold chains, or on common occasions by a broad green ribbon, exhibits the Arms of Scotland, and on the reverse, St. Andrew on his cross; and his baton is of gold enameled green, powdered with the badges of the Kingdom and with gold ferrules at each end. Besides the velvet tabard of a King-of-Arms, he has an embroidered crimson velvet robe; and as King-of-Arms of the Thistle, a blue satin mantle, lined with white, with at St. Andrew's cross on he left shoulder.

LYMAN CARTRIDGE.—The object of Mr. Lyman is to supply a cartridge which shall burn with a constantly increasing fire-surface so that nearly uniform pressure shall be exerted upon the projectile until the powder is about all consumed. When the cartridge is suited to the length of the barrel, the strain will be distributed equally throughout the principal part of the barrel, whatever may be its length. It consists in forming powder into a solid cake within the cartridge shell, which cake, if for small-arms, is pierced by a central perforation from end to end, and is protected from the fire by the shell on its outer surface and rear end, so that only the small surface of the perforation and the front end of the cake can be exposed to the igniting flame. After this small surface is ignited the burning proceeds in a radial direction toward the surface of the cake, thereby continuously enlarging the burning surface in a constantly increasing ratio and increasing the development and heat of the gases, and exerting a nearly uniform pressure upon the projectile throughout the principal part of the length of the barrel.

The character of this powder cake is very important: it should be solid and compact, none of it granular; it should have a uniform density so that it will be burned evenly on all sides. To make it, powder meal which is reduced very fine may be moistened until it becomes somewhat plastic or of a consistency adapting it to to be molded and compressed into a solid mass, and while in this soft or plastic condition it is properly compressed in the cartridge shell. When dried the rapidity with which the powder burns depends upon the porosity of the cake, and this depends upon the amount of water contained in it when being compressed as well as upon the pressure.



The drawings show a longitudinal section of the breech of the gun containing a cartridge in position for firing, also cross sections of modified forms of the cartridge. In the chamber of the gun B is the breech-block which holds the cartridge in place, C is a wedge for securing the breech-block, which part may be of any suitable construction, D is the cartridge shell or case, and E is the powder cake packed in the shell which protects its outer cylindrical and rear end surfaces from the action of the fire, G represents holes running through the powder cake and through the head F of the cartridge, H is a firing tube passing centrally through the powder cake, and is designed to direct the igniting flame to the front end of the cake. This tube projects rearwardly from the cartridge head, and bears against the breech-block, leaving a space I between them. The cartridge head is also located somewhat within the shell, so that the shell may bear upon the breech-block, as shown. To fire the cartridge a flame is forced through the firing tube and ignites the front end of the powder cake and flashes back down the perforations in the powder cake, igniting the surfaces of all the holes at the same instant.

The particular object of the chamber I behind the cartridge head is to permit the perforations through the powder cake to communicate with one another to insure their being instantly and simultaneously ignited throughout their whole extent. If these holes were closed at their rear ends some of them might possibly become more or less filled with air and gases upon the first of ignition which would prevent their entire surfaces from being instantly ignited and thereby prevent the intended uniformity of the radial burning and increase of the burning surface along the whole length of the hole; but when these channels open into a common space as shown they cannot become so filled or obstructed and their entire surfaces are instantly ignited and the progress of the radial burning is practically the same in all parts of the powder cake. The distance of the perforations in the powder cake from each other determines the time of the burning of the cartridge and this distance should be proportionate to the length of the gun. The holes should meet some time before the projectile reaches the end of the bore. When the walls of the powder cake are burned through, the burning and caving of their remaining fragments may raise the pressure slightly; but the space into which the burning gases expand has now become so large and the rapid onward movement of the shot increases it so rapidly that such increase in pressure is not material.

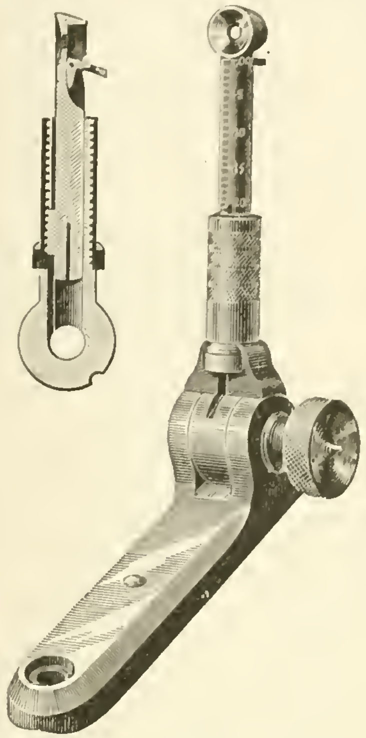
Trials of the cartridge in a $\frac{3}{8}$ inch rifle show initial velocities of 2080, 2247, and 2312, f. s., although these experiments are the first, and naturally do not show its capabilities when everything is perfect. The shot thrown at these velocities was *seven* calibers long, and with a twist of $4\frac{1}{2}$ inches. The cartridge as adapted for cannon has the following specifications: 1. A cartridge consisting of a shell charged with a solid cake of powder or other material having longitudinal holes running through from end to end, and protected by said shell from the action of the fire upon its outer surface. 2. A cartridge consisting of a shell charged with solid cakes of powder or other explosive material packed in the shell and extending from end to end of the shell, and each provided with one or more holes piercing them longitudinally, and being protected from the action of the fire upon their outer surfaces. 3. A cartridge consisting of a shell charged with a solid cake of powder, which is protected from the action of the fire upon its outer surface by said shell, and at its rear end by the head of the shell, said cake and the head of the shell being pierced by longitudinal holes. 4. A cartridge consisting of a shell charged with a solid cake of powder pierced from end to end by holes extending also through the head of the cartridge, the cartridge being provided with a projection extending rearwardly and adapted to bear against the gun, and thereby form an open space back of the head of the cartridge. 5. A cartridge consisting of a shell charged with a solid cake of powder pierced from end to end with holes extending also through the cartridge head, and provided with a firing tube arranged to direct the igniting-flame to the front end of the powder-cake.

LYMAN HASKELL MULTI CHARGE CANNON.—The theory of this curiosity of ordnance is the gradual accumulation of velocity or power by a succession of charges of powder exploded behind the projectile as it passes along the bore of the gun. The inertia of the shot is first overcome by a moderate charge of coarse-grained, slow-burning powder, and then repeated charges of quick-burning powder are applied in succession until a greatly increased velocity is attained. General Newton, United States Army, says the penetrative power of this gun is not inferior to that of the Armstrong 81-ton and 100-ton guns. He thinks the 10-inch accelerating gun would be as efficient as the 81-ton gun, and nearly as much so as the 100-ton gun, and that the 12-inch accelerating gun would be more powerful than the 100-ton gun. No doubts are entertained by experts that the gas check can be made perfectly efficient, and it is believed that early experiments will show that these guns, at comparatively moderate cost are at least as efficient as the best in Europe. See *Haskell Multi-charge Cannon.*

LYMAN SIGHT.—The optical principle involved in this most excellent sight is entirely new in its application. When aiming it has the appearance of a ring or hoop, which shows the front sight and the object aimed at, without intercepting any part of the view. The drawing shows the manner of its construction. The aperture of the sight, being very near the eyes, is greatly magnified as compared with the notch in the common open sight. This feature gives many the impression that an aperture which looks so large cannot allow of accurate aim; whereas, the larger this small aperture looks, the more accurate the aim. Furthermore, the distance from the Lyman sight to the front sight is nearly twice as much as from the ordinary open sight to the front sight which, in itself, doubles the accuracy.

The rim of the sight can be instantly changed to give it a large aperture with a narrow rim, or a small aperture with a wider rim. For all quick shooting the large aperture should be used. The sight cannot shut out the view of the front sight, nor the object to be aimed at; while with any other rear sight the chief difficulty in aiming is to bring the sights and objects quickly into line without interfering with the view of the front sight or the object. It possesses the following additional advantages, viz., it allows an instantaneous aim to be taken—the object being sighted as quickly as if only the front sight were used; it readily permits one to shoot moving objects, with both the eyes in use; it is also very accurate, simple, and strong. Any kind of front sight may be used with it, and it may be put on any rifle in the same way that a peep sight is attached, and adjusted for shooting any distance up to 1,000 yards.

To apply the sight to any rifle, screw the base firmly on the tang of the piece. See that the *spring* notch



in the sight-joint is filed so that the sight stands perpendicular when in use. Remove the middle sight, *i. e.*, the rear open sight from the gun. A blank piece can be put in the slot on the barrel, if desired. It is recommended to use the Beach *front sight*, in conjunction with the sight, and for most shooting, use the large aperture of the rear sight; and for very quick shooting, aim with both eyes open.

M

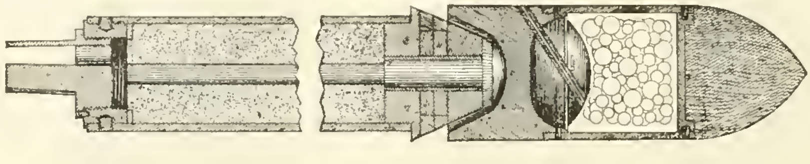
MACADAMIZED.—A term applied to roads covered with broken stone. The principles of the Macadam system of road-making are as follows: For the foundation of a road, it is not necessary to lay a substratum of large stones, pavement, etc., as it is a matter of indifference whether the substratum be hard or soft; and if any preference is due, it is to the latter. The metal for roads must consist of *broken stones* (granite, flint, or whinstone is by far the best); these must in no case exceed 6 oz. each in weight, and stones of from 1 to 2 oz. are to be preferred. The large stones in the road are to be loosened, and removed to the side, where they are to be broken into pieces of the regulation weight; and the road is then to be smoothed with a rake, so that the earth may settle down into the holes from which the large stones were removed. The broken metal is then to carefully spread over it; and as this operation is of great importance to the future quality of the road, the metal is not to be *laid* on in shovelfuls to the requisite depth, but to be *scattered* in shovelful after shovelful, till a depth of from 6 to 10 inches, according to the quality of the road, has been obtained. The road is to have a fall from the middle to the sides of about 1 in 60, and ditches are to be dug on the field side of the fences to a depth of a few inches below the level of the road. This system, which at one time threatened to supercede every other, is calculated to form a hard and impermeable crust on the surface, thus protecting the soft earth below from the action of water, and so preventing it from working up through the metal in the form of mud. Strange to say, it has succeeded admirably in cases where a road had to be constructed over a bog or morass, but in some other circumstances, it has been found deficient.

MACANA.—The war-club of the South American Indians.

MACCONNELL CARTRIDGE-BOX.—This box, invented by Captain C. C. MacConnell of the U.S. Army.

is square-shaped, made of leather lined with tin, and has compartments to hold 40 cartridges. There is an opening at the bottom, working by means of a spring, and by which one cartridge can be taken out at a time. The cartridges are placed in the box on top by raising the flap. The box is worn on the waist-belt.

MACDONALD'S HALE ROCKET.—The case of this improved rocket is of steel of great strength, at the end of which is soldered a collar, to the center of which is screwed a wrought-iron tube; this tube unites the head to the body of the rocket and allows the gas to escape through the upper vents. The head has a cavity, communicating with the exterior by five openings directed toward the rear. These vents or openings, as in the Hale rocket, have semi-cylindrical flanges; the gas escaping acts against



the concave face of the flanges and imparts a motion of rotation to the rocket. The lower end of the case is closed by a disc, also pierced with five vents corresponding to those in the head, and furnished with similar flanges. This construction applies the motion of rotation to the head as well as to the rear part of the rocket, and remedies the considerable deviation of the Hale rocket due to the motion of rotation being applied to the base only; as its center of gravity is quite considerably in front, the head describes very large and irregular spirals. The rocket composition consists of 70 parts of niter, 16 parts of sulphur, and 23 parts of charcoal. It is pressed into the tube with a pressure of 90 tons. As it is bored throughout its whole length by the channel, the surface of inflammation is much more considerable than in the Hale rocket, and its velocity much greater. The head has at its front part, in front of the cavity, a shell with a bursting charge, which is ignited by means of a fuse, either percussion or time. The rocket thus perfected has given results very superior to those obtained by war-rockets of other systems. Five 12-pounder rockets thrown under an angle of 8° 15′ had a mean range of 1,870 meters, with a lateral deviation of 2.74 meters only, while Hale rockets of the same caliber, under the same angle of elevation, had a range of only 1,200 meters with a lateral deviation of 34 meters. See *Rockets*.

MACE.—A strong, short wooden staff, with a spiked metal ball for a head. It was a favorite weapon with knights, with the cavalry immediately succeeding them, and at all times with fighting priests, whom a canon of the church forbade to wield the sword. No armor could resist a well-delivered blow from the mace. The mace is now borne before magistrates as an ensign of authority. The variety known as *Morgenstern*, or *Morning-star*, had generally a long handle, and its head bristled with wooden or iron points or spikes.

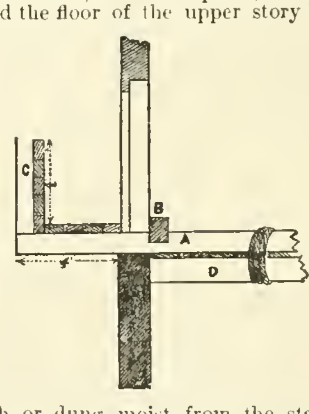
MACEDONIAN PIKE.—A spear or lance of great length used in warfare by the Greeks. It is commonly called *Sarissa*.

MACHETE.—A large, heavy knife resembling a broadsword, often 2 or three feet in length, used by the inhabitants of Spanish America as a hatchet, to cut their way through thickets, and for various other purposes.

MACHICOLATION.—The act of hurling missiles, or pouring various burning or melted substances upon assailants through *Machicolations*.

MACHICOLATIONS.—The apertures between the corbels supporting a projecting parapet. The machicolations are for the purpose of allowing projectiles to be hurled at an enemy when he approaches near the wall, as in scaling, undermining, etc. Such defenses are very common in castellated architecture, especially over gateways, towers, etc. For the purpose of attaining, by musketry, the foot of a scarp wall without flank defenses, resort must be had to a machicoulated arrangement at the top of the scarp. The usual mode adopted for this purpose, is to form a parapet wall which rests upon a solid horizontal band of stone, near the top of the scarp, which is supported on corbels or projecting blocks, firmly built into the wall. The back of the parapet wall is placed a few inches in advance of the scarp, leaving room for the slanting loop-holes pierced in the horizontal band through which the fire is to be delivered on the foot of the scarp. The top of the parapet wall is also arranged to admit of firing on more distant points. Where, from the irregularity of the site, the ordinary machicoulis cannot be made efficient, resort may be had to small polygonal chambers of stone, open at top, and having the sides and bottom pierced with loop-holes and machicoulis. These constructions may be made just of sufficient size to hold a single sentinel. They are placed at the angles of the works where they will not be exposed to artillery, and are supported on a corbel work projecting from the top of the scarp wall.

MACHICOULIS GALLERY.—To place a house in a defensive attitude, the doors and windows of the lowest story should be firmly barricaded, and loop-holes be made as in the case of a wall. A tambour should be placed before the doors, both for their protection and to procure flanking arrangements if required. The windows of the upper stories should be partly barricaded, to cover the troops within, and loop-holes should be arranged as in the lower stories. The roof, if not fire-proof, should be torn down, and the floor of the upper story be covered



with earth or dung, moist from the stable, to the depth of about two feet. If it is intended to defend the upper stories, should the enemy succeed in forcing the lower, the stairs should be torn down, and slight ladders be used in their stead; holes should be made through the floor to fire on the enemy in the lower story, or to throw heavy articles, or boiling water, etc., on him. If there are balconies to the windows of the upper stories, or an upper gallery, they can readily be placed in a defensive state by placing thick boards as a shelter on the outside, and cutting suitable holes through the floor to defend the doors and windows of the lower story. If there should be no conveniences of this nature, a temporary structure, termed a Ma-

Trial No. 1. For Accuracy. Range 500 meters; 2 targets, 20 meters apart.

Name of Gun on Trial.	No. of barrels.	Caliber in inches.	No. sighting shots.	No. shots fired.	No. hits on both targets.	Remarks.
Hotchkiss	5	1.45	4	10	10	Gun sighted after each shot.

Trial No. 4, one mile. Time 30 seconds. Range, 800 meters; two rows of targets.

Name of Gun.	Time loads.	Sighting shots.	Shots fired.	Nelson Park target.	Remarks.
Hotchkiss	30	1	485	888	
Nordenfeldt	30	12	52	20	
Gardner	30	4	84	44	
Pratt & Whitney	30	4	170	27	Most of shots went over. It being late this
Gardner	30	2	160	120	trial was made in a hurry. It was the first
Nordenfeldt	30	20	251	121	trial made with the Gatling. A large party
Gatling	30	13	413	29	were present, who wanted to see the gun,
Gatling	30	8	195	82	or it would not have been fired.

Pratt and Whitney gun fired 3,266 shots in $9\frac{1}{4}$ minutes, with four changes at the crank; two barreled Gardner, 1,446 in $4\frac{1}{4}$ minutes; 100 shots fired at 70° elevation in $3\frac{1}{4}$ seconds by the Gatling.

chicoulis Gallery, may be formed by placing stout pieces of scantling through holes made in the wall, on a level with the floor; these pieces being confined to the floor on the inside, either by nailing them to it or by tying them with rope to the joists; they should project from three to four feet beyond the wall on the exterior, and vertical pieces of smaller scantling, about four feet long, should be nailed to them, on which boards are nailed to cover the troops from the enemy's fire; these boards should be at least three inches thick. The flooring of the gallery is laid on the horizontal pieces, and holes are made through it to fire on the enemy, or to throw grenades, stones, etc., on him. Any similar arrangement which will shelter a man, in the act of firing from a window on the foot of the wall, or in throwing over stones, etc., will serve the same purpose as a Machicoulis gallery. A table might easily be arranged to answer the end in view. The drawing shows a section of a Machicoulis. D is a flooring joist: A is a horizontal support; B is a cross timber; and C is an upright in front. See *Tambour.*

MACHINE-GUN.—A gun designed to deliver against animate objects a strong, rapid, continuous and accurate fire of small projectiles at all ranges suited to infantry; to be served by the fewest possible number of men, and also to give a fire that may, in many cases, be as effective as the discharge of canister from artillery. The conditions to be fulfilled in the construction of such guns are: simplicity and strength of mechanism; lightness; freedom from sensible recoil; endurance; and interchangeability of ammunition with that used by the troops generally. A variety of machine guns, having merits, will be found noticed under Battery Guns. Prominent among the American battery or machine guns are the *Gatling*, the *Lowell*, the *Gardner*, and the *Hotchkiss Revolving Cannon.*

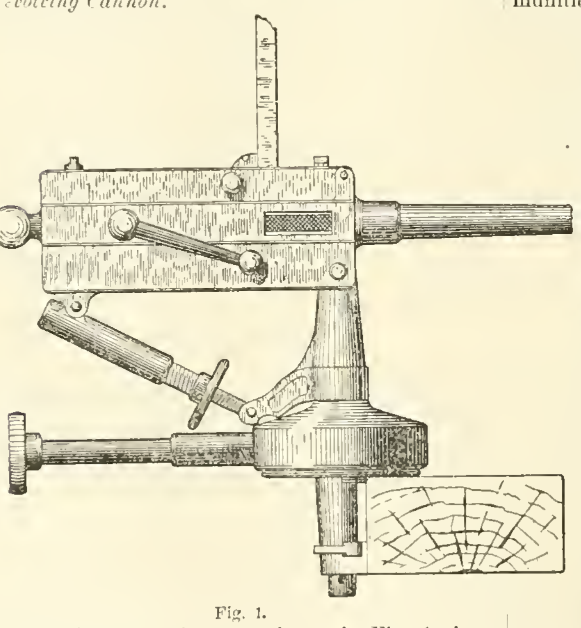

Fig. 1.

The Gardner machine-gun, shown in Fig. 1., is an exceedingly simple machine, with a capacity for rapid fire probably as great as is consistent with the economical expenditure of ammunition, and its extreme lightness of construction makes it very easy to handle. Several forms of cartridge-holders and feed-cases to feed cartridges to the Gardner gun have been devised by Mr. Parkhurst. In one of these the cartridges are held by the bullet end in a block, leaving the flanges exposed. The feed tube or guide of the gun receives all the flanges in a block. The block is then pulled off. The Lowell machine-gun, manufactured at Lowell, Mass., fires a single barrel. but is provided with two, three, or more barrels which can be rapidly turned into position for firing as one or another becomes heated. The cartridges are held in feeding-tubes above the gun, and pass down the tubes into the carrier-rolls. These are two cogged wheels placed side by side behind the barrel and on axes parallel with the barrel, the cogs abutting instead of intermeshing, and the space between the cogs being just large enough to receive a cartridge. A plunger carries the cartridge forward from this receptacle while the wheels are at rest, fires, and then withdraws the shell, when a further rotation of the cog-wheels ejects the spent shell and brings another into line with the barrel. The gun is made with an automatic traversing mechanism which may be thrown into or out of gear, so that the direction of fire may change slowly or rapidly over a sector of considerable extent in front of the gun, or the fire may be confined to a single line of direction. The rapidity of fire for the 45 caliber is about 300 shots per minute.

The carriage, usually employed in the United States, for the machine-gun is at wo-wheeled vehicle, drawn by two horses placed abreast; the off horse works in shafts situated so as to occupy the proper position; the carriage is guided by this horse, and he supports the portion of the weight that is not borne by the axletree. The near horse is ridden by the driver. When firing, the horses being detached, the shafts serve as a trail. The gun is mounted over the center of the axletree on an iron *bed* formed of two plates, one of which moves over the other about a vertical axis, to give the desired horizontal training to the gun. On each side of the gun is a box opening to the rear; the enterior is divided into spaces, each of which carries a feed-case. These boxes serve also as seats for the gunners. Boxes of additional ammunition and tools and spare parts are carried in a compartment beneath the gun bed in rear of the axletree. Fig. 2. on the opposite page, shows the form of light gun-carriage used with the Lowell Battery-gun when making long marches over very rough country. It is a suitable pattern for all machine-guns, and is, of very simple construction.

The trials of machine-guns at Turin, Italy, commencing October 10, 1883, and tabulated on page 241, will serve to show the wonderful powers of these weapons.

MACKAY GUN.—A wrought iron gun distinguished from the Whitworth and Lancaster guns by the following characteristics: The Whitworth has a hexagonal bore in a tube of homogeneous iron, strengthened with hoops forced on by hydraulic pressure; the Lancaster is without grooves, but the bore is oval; the Mackay has numerous grooves, but the projectile does not, as in other guns, fit into them, its rotation being imparted by the rush of gases through the spiral grooves around it. In every case the groove or oval takes one turn, or portion of a turn, within the gun.

MACKAY PROJECTILE.—The distinguishing feature of this projectile consists in the application and use of several diagonal grooves formed in the interior surface of the gun at a great angle, which are to act as windage grooves so that the powder and gas passing down such grooves, encircling the projectile, shall have a longer distance to travel than the projectile, and also cause the projectile to revolve round its longest axis at a high rotation as it passes down the gun. The projectiles are not allowed to enter or fit these grooves as in rifles, but simply to pass down the smooth surface in which the grooves are formed.

MACKENZIE CUPOLA FURNACE.—This pattern of furnace is extensively used in working cannon metals, and in the fabrication of projectiles. The body of the cupola, which is oval in shape, consists of a lining of fire-brick inclosed in a wrought-iron caisson, contracted at the top to form the stack, and resting on a cast-iron bottom plate, which is supported on iron pillars. The peculiarity of this cupola, as compared with others of the many varieties in use, exists only in the shape of the tuyere, or in the method employed for introducing the blast, a continuous air-chamber inclosed between the caisson and a wrought-iron apron, which projects inward, and is braced by a cast-iron ring, which can easily be replaced when worn out. The tuyere itself is the slot beneath, through which the air, admitted to the chamber from the blast-pipes, passes into the cupola. The bottom is a cast-iron drop-door made in two hinged parts, and supported, when closed, by a prop. This bottom is covered with a layer of sand, arranged with a gentle slope towards the spout; the latter, through which the melted iron runs to the ladle, is of iron coated with loam, and painted with coke-wash. *The charging-door* is situated at the rear of the furnace, and the stock is generally lifted to it on an elevator. To charge the furnace most expeditiously shavings are placed in the bottom, then light wood, and cord-wood sawed into lengths of from ten to eighteen inches, a part of it being stood on end around the sides to protect them, and the whole bed being built up level. In this last respect care is used through all the subsequent stages of the charging. On the top of the wood is placed the "stock," which, for a No. 8 furnace, consists of about 2,100 pounds of (Lehigh) lump coal. The fire is then lighted, and when the flames are seen to be working well through the mass about five tons of iron are

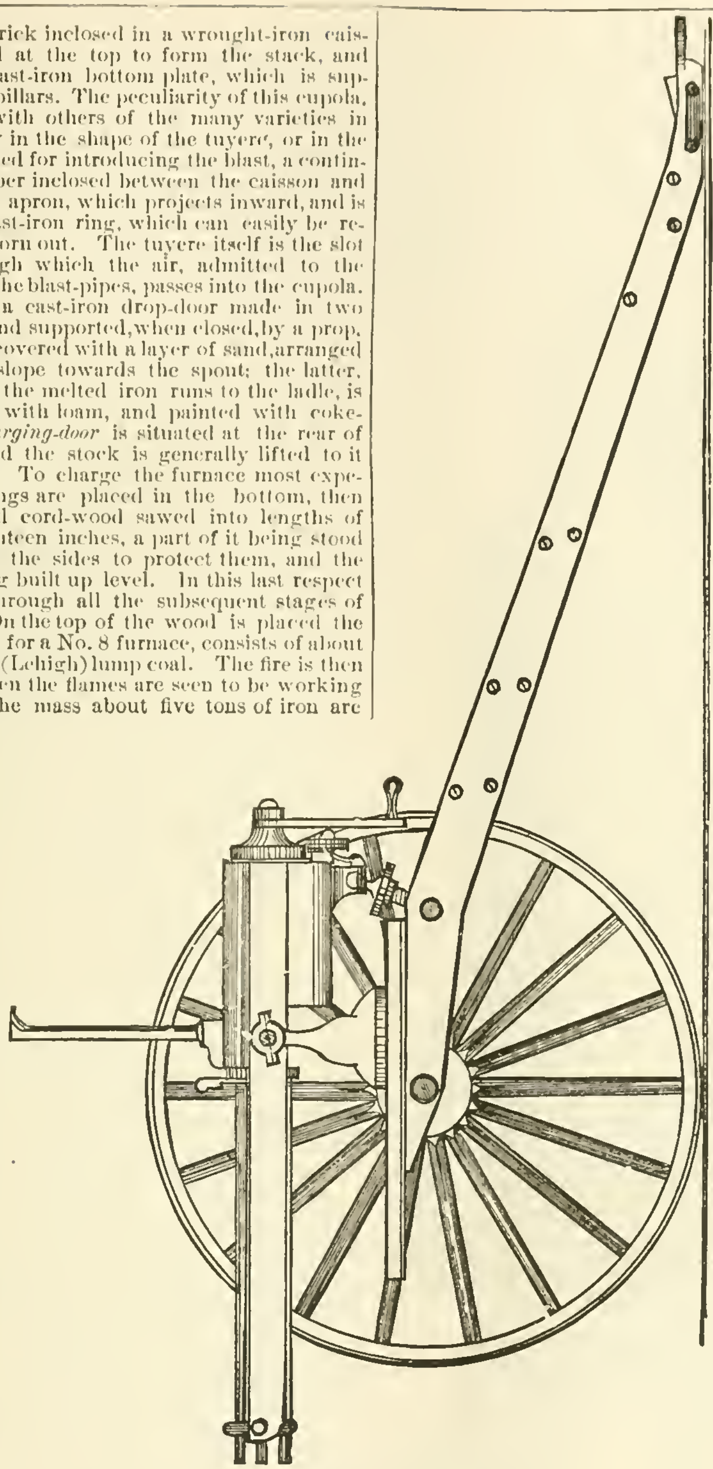

Fig. 2.

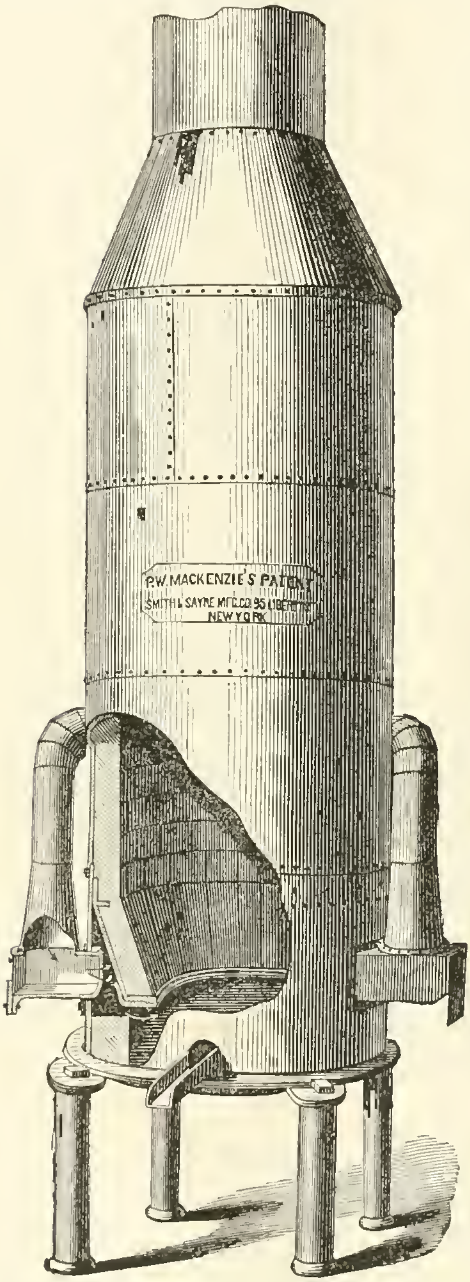
placed evenly on top; then about 900 pounds of egg or grate coal, followed by five tons of iron. This "building up" of the charge can be continued as long as the material can be handled through the charging-door, the ordinary capacity of such a furnace as described being about fifteen tons. In charging the iron, it is usual to first put in pieces of plate and light scrap iron to protect the lump coal from being broken as the heavier portions of the charge are added. As soon as the cupola is "charged" the blast is put on, and in about twenty minutes the iron is "down," and ready to be drawn off. Warned of this by the melted metal "blowing" through the "tap-hole," the melter closes it securely with a "*bod*" made of sand mixed with clay-wash; he has prepared in advance also a number of other "bods," which he uses for the same purpose whenever it may be necessary while drawing the metal. The "bod" is lightly attached to the end of an iron or wooden rod, and being shoved into the tapping-hole, sticks to it and closes it up. To "tap" the cupola, the melter shoves into the "bod" an iron bar with a square point, and enlarges the hole by turning the bar around. The ladles into which the metal is run are lined with a mixture of molding sand and clay-wash, or with loam, and thoroughly dried before being used. When all the metal is drawn off, the cupola is "dumped" by removing the prop and allowing the doors to fall. The "dump" is then extinguished, and the pieces of iron and fuel picked and sifted out. After each day's casting, the furnace has to be repaired by picking



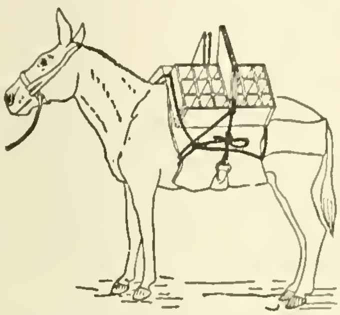
out the slag which has formed within, and by daubing with a mixture of clay and fire-sand the parts of the lining where the fire-brick has been burned out. About once in six months the entire fire-brick lining has to be replaced. See *Cupola Furnace*, *Foundry*, and *Iron*.

MACLED ARMOR.—Armor of the Middle Ages, composed of small lozenge-shaped plates of metal, sewed on a foundation of cloth or leather, and sometimes overlapping each other half way.

MACOMBER GUN.—A gun, the peculiarity of which consists in its stated extraordinary strength. The chamber for holding the powder and the breech of the gun are formed of discs of wrought iron, composed of three different qualities of the iron, the softest forming the center and the hardest the outer circumference of the disc, which are thoroughly welded together, leaving a hole in the center. After a sufficient number of these are prepared to form the gun, they are roughly engine-turned to bring them to a uniform thickness. These discs are then submitted to a process of "setting" by steel punches (each disc separately), by powerful blows of a steam-hammer, beginning lightly, and increasing gradually until the soft and hard metal have been forced (in a cold state) from center to circumference to the point of enlargement of the latter which *commencement* of the enlargement is *proof* that every portion of the disc *will* bear its equal proportion of a future strain or concussion which it may be subjected to and which, in the use of gunpowder, cannot exceed the test thus supplied. After the discs are set, they are welded one at a time upon a mandrel; by the process known to smiths as "jump welding." Subsequently, the mandrel upon which the discs were forged will be entirely taken out by the process of boring the gun, leaving only the metal which has been subjected to the steam-hammer and punch. The breech of the gun is surrounded with steel rings, which are forced over it, in a cold state, by a powerful hydraulic press. The gas-check is Mr. Macomber's own invention. He uses Dyer and Sons' friction-primers, and makes use of the strongest powder and of a fine grain; but he states that he would have no objection to use gun-cotton. The weight of the gun is 12 cwt., caliber $1\frac{3}{4}$ inch, weight of shot 3 lbs., initial velocity about 2000 feet per second. The inventor states that at an elevation of 38° the shot attains the very remarkable range of $9\frac{1}{4}$ miles.

MACROMETER.—An instrument by means of which the ranges of distant objects can be determined with rapidity and accuracy. It consists of two mirrors, disposed somewhat similarly to the mirrors of a marine sextant, the observations being taken much in the same way. One of the mirrors is movable, and is fixed to an arm on which the several distances, from 20 to 2,000 yards, are marked. The arm moves over a peculiar curve placed on a part of the instrument called the "fan," and indicating the distances answering to any given inclination of the mirror. The arm, moreover, is fitted with a slide so as to be capable of being set to any length of base, and this base may either be measured by a chain or may be paced, the slide being set to the line marked "yards" or "paces," as the case may be. The result is always given in yards. When it is required to make an observation, two men take up a position so as to form a triangle with the object, the distance of which it is desired to ascertain. One of the two observers, by means of an optical square, places himself so as to be at right angles with the distant object and the second observer, by whom the macrometer is used. From experiments made with this instrument, the distance of moving objects has been ascertained with very great accuracy, and in the case of stationary objects the error has been found to be less than 1 per cent. The notation of the instrument admits of the units being taken to represent chains and links; thus 835 would be 8 chains and 35 links.

MADIGAN AMMUNITION-BOX.—These boxes, also adapted for use as a medicine or mess chests, are packed in pairs on either an aparejo or ordinary pack-saddle. They meet all the requirements of active service and by means of them, troops in line of battle or skirmishing may be quickly supplied, and are not obliged to lose valuable moments of time, while unpacking, unscrewing covers, etc. The drawing shows the boxes packed on an aparejo, and the manner of using them. Their construction is such that *all* or *any part* of the contents may be removed, whenever desired for immediate use, without unloading, slacking the lash-rope, or even halting the animal carrying them. These are certainly important advantages in case of a surprise or sudden attack upon the pack-train, or the unexpected discovery of the enemy; or, if used for medical or subsistence stores, and in case of sudden illness, or the



necessity of eating a meal under the various circumstances forbidding a halt. Many instances will doubtless recur to every officer or soldier of experience in field service, where disasters have resulted from not having been able to quickly replenish the supply of ammunition.

The devices by which this box is made available for sudden emergencies, are essentially three in number, viz: FIRST, and most important:—The angle castings or corner-bands in the center of each side of the top of the box, each of which has a diagonal circular opening, or socket, for the lash rope. SECOND:—The center partition, $1\frac{3}{8}$ inches thick, on the top of which is screwed a center strip, $2\frac{1}{2}$ inches in width, with two lids hinged thereto, opening from the ends. THIRD:—The sub-division of the interior of the box, by adjustable partitions, into compartments, adapted in number and arrangement, to the nature of the contents, and shape and size of the packages. These compartments prevent the shaking or damaging of the packages by the motion of the animal, which would occur with an ordinary box after being partially emptied: and permit the load to be kept practically balanced by taking out of each box, alternately all or part of the contents of one or more compartments--thus obviating any necessity for unloading, or touching a rope during the march other than the usual adjustment of the lash rope. By filling only a portion of the compartments, when the packages are unusually heavy, or when the animal is not in good condition, the weight of the load may be adapted to the circumstances of the case, without danger of rattling, shaking, or breaking the packages; for hard bread or other stores of light weight, the boxes may be made larger, if desired: or if *necessary*, four boxes of the usual size *can* be packed on one animal.

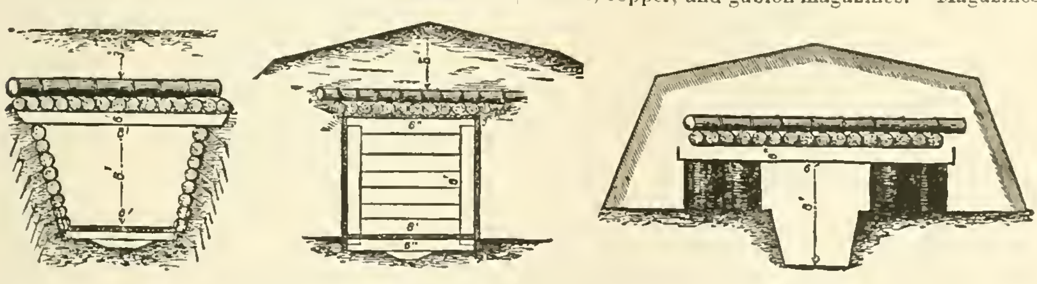
No special fittings or attachments to the ordinary aparejo or pack-saddle, are required; the boxes are complete in themselves and in case of emergency may be packed with very little in the way of outfit — a few old sacks filled with hay or straw, a couple of cinches and a piece of rope will answer. The ammunition boxes in present use in the United States are very unsuitable for packing; two being too light for a proper load, while three are awkward to handle, very difficult to lash so as to be kept in place on an aparejo or pack-saddle, and are liable to chafe and strain the animal's back.

MADRIERS.—Long planks of broad wood, used for supporting the earth in mining, carrying on a sap, making coffers, caponiers, galleries, and for various other purposes at a siege; also to cover the mouth of petards after they are loaded, and are fixed with the petards to the gates or other places designed to be forced open. When the planks are not strong enough they are doubled with plates of iron.

MADRINA.—The animal preceding a troop of mules, usually an old mare, in South America, to the neck of which a little bell is attached, the sound of which the mules follow with the greatest docility.

If several large troops are turned into one field to graze, in the morning the muleteer has only to lead the madrinas a little apart, and tinkle their bells, and although there may be 200 or 300 mules together, each immediately knows its own bell, and separates itself from the rest. The affection of these animals for their madrina saves infinite trouble. It is nearly impossible to lose an old mule; for, if detained several hours by force, she will, by the power of smell, like a dog, track out her companions, or rather the madrina; for, according to the muleteer, she is the chief object of affection. The feeling, however, is not of an individual nature; for any animal with a bell will serve as a madrina.

MAGAZINE.—In a literal sense, any place where stores are kept; but as a military expression, a magazine always means a *powder-magazine*, although arms may at times be kept in it. A magazine may be a depot where vast quantities of gunpowder are held in reserve, an entrepot for the supply of several advanced works, a battery magazine for the wants of a fortress during a siege, or merely an expense magazine for the daily requirements of the special battery in which it may be situated. The last is usually temporary, and hollowed out in the back of the rampart; but the other forms require most careful structure. They must be bomb-proof, and therefore necessitate very thick walls; they must be quite free from damp; and they should admit sufficient daylight to render the use of lanterns within generally unnecessary. The drawing shows cross sections of fascine, copper, and gabion magazines. Magazines



are commonly built of brick, the solid masonry being arched over within, and a thickness of earth sometimes added above the brick-work to insure impermeability to shells. The entrance is protected by shot-proof traverses, lest an opening should be forced by ricochet shots. Within, the magazine is divided into bins or compartments, and one of these should always be kept empty in order that the barrels of powder may frequently be moved from one place to another, a process necessary to keep it in good condition. The battery magazine commonl contains 500 rounds for the guns dependent on it. Depot magazines should, when possible, be limited to 1000 barrels of powder.

In 1870–71, the German Army Corps had supply trains generally attached to the divisions of each corps; these distributed food to the troops—they carried 4 days' rations for men. Then they had a certain number of supply wagons, containing food for men and horses for six days; these kept in rear of the corps, and could communicate with the magazines. When traveling by rail, the troops were fed at certain stations, or took in their food at these stations. The whole management of supply appears to have been admirably carried out, and, when so performed, it considerably facilitates operations. The subject of the formation and position of magazines is one of such vast importance that military men will do well to study the history of past campaigns, when they will observe—to take only one example—how Napoleon, in the Wars of the Republic, was careful to accumulate vast magazines and to keep his communications open, notwithstanding that his troops helped themselves pretty freely off the country they invaded; nevertheless, no General ever realized more than he did the necessity of having accumulated supplies ready to fall back upon, and to keep his communication to the rear carefully guarded. See *Lightning Conductors*, *Powder Depots*, and *Powder Magazines*.

MAGAZINE-GUN.—A breech-loading small-arm, having a magazine capable of holding a number of cartridges which may be fired in quick succession—the empty shell being ejected and another cartridge conveyed to the chamber from the magazine by working the mechanism of the piece. There are several types. 1. Those in which the magazine is a tube below the barrel, as in the Winchester, the Ward-Burton, etc. 2. Those in which the magazine is in the stock, as in the Spencer, Meigs, and others. 3. Those in which the magazine is a separate piece attachable to the gun when required, as in the Lee, Elliot, and Gatling gun. The following is a general classification of magazine-arms, founded on the method by which cartridges are fed from the magazine:

sity of providing troops with arms that will give every possible superiority of fire in battle. Rapidity of discharge is certainly an essential element under all circumstances. Should equal detachments be opposed, there can be no doubt but that the one able to fire ten effective shots per minute, each man, more than the other, would have a great advantage. Rapidity of fire alone can compensate for an inferiority in number of men engaged. In magazine or repeating arms, the cartridges are fed automatically into the chamber of the barrel, by the manipulation of the breech mechanism. It is only necessary to close the breech when the arm is ready to fire. This obviates the necessity of handling and charging each cartridge, besides preventing the considerable loss of ammunition, occasioned by soldiers dropping cartridges while transferring from the cartridge-box to the arm, which, in the excitement of battle and rapid firing, are seldom recovered or saved. The principal objection offered to magazine guns, is that their use causes a wasteful and unnecessary expenditure of ammunition. The same argument was largely used, when only a few years ago, the merits of breech versus muzzle-loaders, were being discussed, *and is as weak now as then.* With officers and non-commissioned officers thoroughly impressed with the necessity of an economical and judicious use of ammunition, the question becomes one only of discipline and drill.

No valid reason can be given why, other essentials being equal, the same men should not aim as well, firing rapidly, as slowly sighting requires the same time whatever may be the time used in loading; and if increasing the time expended between the firing of one shot and sighting for the next, increases the effectiveness of the man, it follows, that to shoot accurately, a certain amount of time must be wasted in operations other than aiming the weapon—a theory that could hardly be sustained.

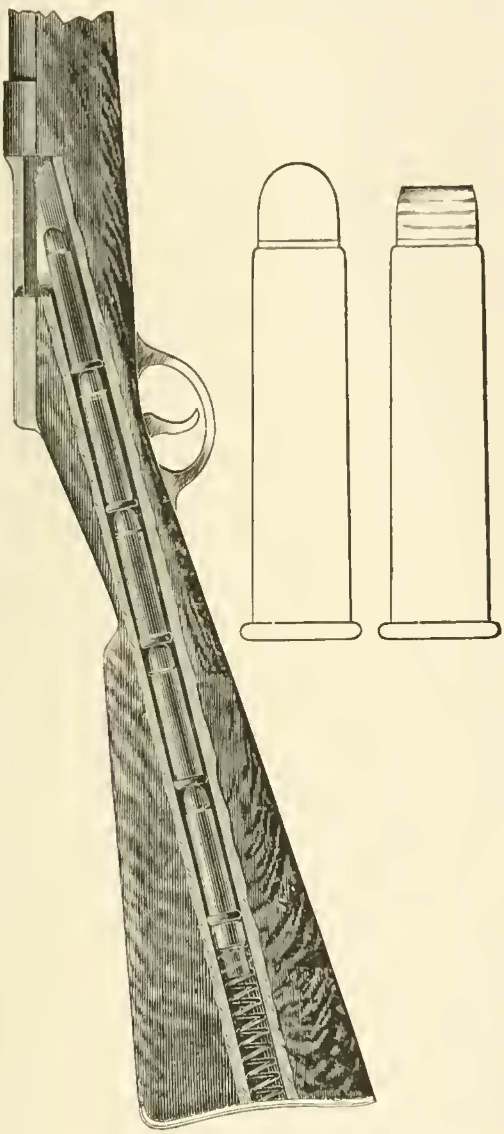
The drawings show the positions at "order arms," of cartridges contained in tubular magazine-guns, constructed with magazines under the barrel and in the butt-stock. All the cartridges are forced toward the breech mechanism by a spiral spring (as partly

Magazine-arms supply chamber with cartridges from:

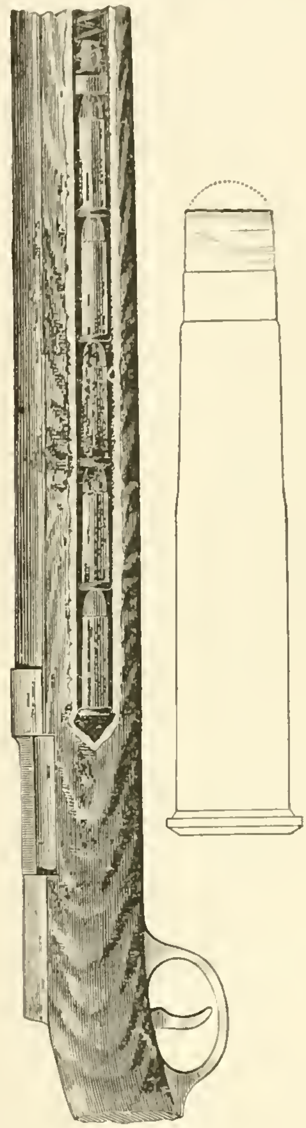
- 1st, butt stock
  - 1st, by a spring.
    - 1st, direct
    - 2d, indirect...
      - 1st, by rotating barrel about axis parallel to it into line with magazine.
      - 2d, to position opposite receiver
  - 2d, by a ratchet, which is—
    - 1st, automatic
    - 2d, operated by hand.
  - 3d, by a spiral cam (screw-motion).
- 2d, tip stock.. by a spring— on a carrier which is—
  - 1st, sliding, at right angles to axis of bore
  - 2d, rotating—
    - 1st, to position oblique to axis of bore.
    - 2d, to position parallel with axis.
  - 3d, sliding and rotating—
- 3d, magazine on top of barrel — by a spring— to position parallel to axis of bore and above receiver— and by gravity into line with axis of bore.
- 4th, magazine below bolt — by a spring (vertically)— to position opposite center of chamber.
- 5th, revolving chambers

The question of the comparative merits of magazine guns and single breech-loaders, for military purposes, has been so exhaustively discussed by the military authorities of the world, that there would seem to be no longer any doubt regarding the neces-

shown in A), which spring must be of sufficient strength to support the weight of the column of cartridges, and force them into the receiver of the arm as fast as required, and of necessity it must have very considerable stiffness or strength. The weight of a column of five ordinary service cartridges would be about seven ounces, at least four-fifths of which weight would in a tubular magazine, rest fairly upon the point of the bullet of the last cartridge and which bullet comes directly in contact with the primer itself of the cartridge in advance of it. All ordnance officers and ammunition manufacturers realize the difficulty experienced in preparing fulminate of mercury (used for primers), that will, in practical use, always have a uniform degree of sensitiveness. It can be made so sensitive that the slightest scratch will ignite it, and many fulminate mixers have lost their lives by a moment's inattention or relaxation of caution while compounding it. While it is generally possible to produce fulminate of nearly equal quality, still different batches do vary: and whether it be from difference in this quality, or from the different position or placement of the fulminate in the primer as regards the cartridge-anvil, or otherwise, still it is certainly true that cartridges are to be found in use that will explode with one half the concussion ordinarily required. It is a fact that cartridges have exploded by dropping a few inches from the machine in which they are loaded into the receptacle below. It is readily seen, then, that the use of such a spiral spring makes premature explosion not only *possible*, but *very probable*, and there is no way to prevent it, except by discarding it, as in the Lee or Chaffee-Reece guns. During the War of the Rebellion, guns using the spiral spring have been known to explode when the cavalry were on a march. Of course such arms were discarded; but the same thing may happen to any arm of recent invention which is so constructed as to require a spiral spring in feeding the cartridge into the chamber.



A



B

Where the cartridges are fed from the butt-stock by a spiral spring the bullet is liable to strike the counter-bore of the barrel, making a notch in the bullet and rendering it useless for accurate work. When the cartridges are brought up by a carrier on an angle the same thing will happen—the counter-bore of the barrel either stops the bullet or cuts off a piece sufficiently large to make it impossible that its flight be accurate and make a good target, because of its irregular shape made by such contact. It is well understood that a good shot, when using any of the magazine-guns in which the cartridges are fed up by a spiral spring, uses it as a single-loader;

and the reason is, that the bullet is generally so mutilated by striking the counter-bore, that its flight is not to be depended upon for accuracy.

MAGISTRAL GALLERY.—A name frequently applied to the gallery immediately behind the counterscarp wall, in contradistinction to the *Enveloping Gallery*, which is parallel to the counterscarp gallery, and at some thirty or forty yards in advance of it. See *Gallery*.

MAGISTRAL LINE.—The trace or outline of a work as the plan of its guiding or *magistral* line. In field fortifications, this line is the interior crest line. In permanent fortifications, it is usually the line of the top of the escarp of each work.

MAGNA CHARTA.—The great Charter which was granted by King John of England to the Barons, and has been viewed by after-ages as the basis of English liberties. The oppressions and exactions of a tyrannical and dastardly Sovereign called into existence a Confederacy of the Barons or Tenants-in-Chief of the Crown, who took up arms for the redress of their grievances. Their demand was for the restoration of the laws of Henry I., laws which might probably be characterized as an engrafting of Norman Feudalism on the "ancient custom of England," or previously existing Saxon and Danish Free Institutions, in which "ancient custom" were comprehended the laws of Edward the Confessor. A conference between the Sovereign and the Barons was held at Runnymede, near Windsor, a place where treaties regarding the peace of the kingdom had often before been made. King and Barons encamped opposite each other; and after several days of debate, John signed and sealed the Charter with great solemnity, on June 15, 1215.

MAGNESIUM.—Although the discovery of the metal magnesium was made by Sir H. Davy in 1808, it was looked upon as little more than a chemical curiosity for about half a century. In 1830 a French chemist, Bussy, obtained globules of the metal by fusing globules of potassium, in a glass tube, with anhydrous chloride of magnesium. Bussy's labors were followed by somewhat improved methods, adopted by Bunsen, and subsequently by Matthiessen, who succeeded in pressing some grains of the metal into wire. The first great advance was in 1856, when Deville and Caron effected the reduction of the pure chloride of magnesium by mixing it with fused chloride of sodium in clay crucibles, using fluoride of calcium as a flux, and throwing in fragments of sodium; they thus obtained magnesium on a larger scale than any of their predecessors. The most important part of their investigations was the discovery of the volatility of the metal. All these were, however, mere laboratory experiments. In 1859 Bunsen, of Heidelberg, and Roscoe (now of Manchester), published a memoir on the great importance of magnesium for photographic purposes, owing to the high refrangibility and the great actinic power of the light emitted by burning magnesium-wire. The study of this memoir led Mr. Sonstadt to consider whether, the magnesian salts being so abundant, the metal might not be obtained, on a comparatively large scale, at a moderate price. After a prolonged series of expensive experiments he succeeded, in 1862, in producing very satisfactory specimens of the metal varying from about the size of a pin's head to that of a hen's egg. Although it burned freely enough, it was still wanting in ductility and malleability, in consequence of the presence of certain impurities; but by May, 1863, these difficulties were overcome by a process of purification by distillation; and by the close of that year he considered it safe to begin manufacturing. The Magnesium Metal Company was consequently organized, and soon operations commenced at Manchester, where magnesium is now made on a very considerable scale, as well as by an American Magnesium Company at Boston. One great advantage of Sonstadt's method is its simplicity; it can be accomplished by the hands of ordinary workmen ignorant of all chemical knowledge. The process of manufacture may be thus described: 1. An anhydrous chloride of magnesium is prepared by saturating lumps of rock-magnesia (carbonate of magnesia) with hydrochloric acid, and then evaporating the solution to dryness. 2. One part of metallic sodium cut in small pieces is placed in a iron crucible, and covered with five parts of the chloride. The crucible is covered, and heated to redness, when the chlorine leaves the magnesium and unites with the sodium, for which it has a stronger affinity. When the crucible has cooled, and its contents are removed *en masse*, and broken, the magnesium—in that state known as crude magnesium—is seen in nuggets of various sizes, varying from granules to masses as large as a hen's egg. 3. The distillation of the crude metal is effected in a crucible through which a tube ascends to within an inch of the lid. The tube opens at the bottom into an iron box, placed beneath the bars of the furnace, where, on the completion of the operation, magnesium is found in the form of a heap of drippings, which may be melted and cast into ingots or any desired form. The difficulty of obtaining a metal with so little ductility in the form of wire—the only form that was originally used for yielding light—had still to be overcome; and after various partially successful attempts to press small quantities into wire by Matthiessen and some other chemists, Mr. Mather, of Salford, devised a piece of machinery by which the metal is pressed into wire of various thickness. Mr. Mather also was the first who obtained the metal in ribbons, in which form, from the larger exposed surface, combustion takes place more completely. The apparatus for making the wire and ribbon is very ingenious. The chief feature of it is a small hollow cylinder, adapted to receive a ram at one end, and covered at the other by an iron screen perforated with two or more holes opposite the chamber. This press, as the cylinder is called, is subjected to the action of gas from a blow-pipe, and the heat employed is only sufficient to soften the metal in the press. The pieces of magnesium are thrust into the chamber, the ram is placed in the mouth of the press, and a pressure of between two and three tons—obtained by hydraulic apparatus or by steam—forces the ram against the softened metal, and the latter oozes in continuous strings of wire through the perforations already named. To make ribbon, the wire thus obtained is passed between two hollow heated rollers, and is received in a flattened state upon a reel. To Mr. Mather is also due the credit of having constructed the first magnesium lamp, in which the end of the wire or ribbon is presented to the flame of a spirit-lamp. A concave reflector sent the light forward, and protected the eyes of the operator.

The first time that a photograph was taken by this light was at Manchester in the spring of 1864, by Mr. Brothers and Dr. Roscoe. That the magnesium light, in a more or less modified form, must prove of extreme value to photography, cannot be called in question. Besides overcoming the obstacle of unsuitable weather for the employment of sunlight, it may be applied both for the exploration and the photography of various dim structures, underground regions, etc., such as the interior of the pyramids, of catacombs, natural caverns, etc., which could not otherwise be examined or photographed.

Its color approaches very much nearer daylight than that of the light from oils, candles, or coal-gas. As compared with the sun, its luminous intensity is $\frac{1}{525}$, but its chemical intensity is $\frac{1}{36}$, and this high actinic power makes it specially valuable for photographic purposes. Although it does not nearly equal the electric light as an illuminating agent, like it the magnesium light gives off no noxious vapors. But while it burns, white clouds of the vapor of magnesium are formed which would be more or less

troublesome in private rooms. This objection is said to be to some extent removed, without diminishing the brilliancy of the light, by alloying with zinc; and at any rate it would scarcely at all interfere with its use in large public buildings. Still less would it do so when the light is burned in the open air. There is, however, not much hope of the magnesium light successfully competing with the electric light for the illumination of large buildings, streets, or even of ocean steamers. Recent trials with the electric light at the British Museum and other places have now proved conclusively that wherever a great deal of light is required, gas is beaten out of the field on the score of economy. As respects the maintenance of an equal amount of light, gas is twenty times more costly, a difference which will speedily cover the original expense of the necessary electrical apparatus. The magnesium light, on the other hand, is much more costly than gas; and although the ores which could be used as a source of magnesium are very abundant, yet any probable cheapening of the process of extracting the metal from these is not likely to make the light a very economical one. Still, for any purpose where, for a comparatively brief time, a very intense light is required, magnesium wire or ribbon has about it almost the simplicity of a wax taper; nor are the lamps at all complex by which the metal may be burned for hours continuously.

Two kinds of magnesium lamps are made. In one of these kinds, wire or thin ribbon of the metal is coiled about a reel or bobbin. From this reel the ribbon is drawn by means of two small rollers and projected through a tube to the focus of a metallic reflector, where it passes through the flame of a spirit-lamp to insure its continuous combustion. These rollers are kept in motion either by an operator turning a small wheel, or in the more expensive forms by clock-work. In the other kind of lamp the magnesium is used in the form of dust, which is mixed with fine dry sand in the proportion of one of the former to two of the latter. This mixture is placed in a funnel-shaped reservoir, and conducted, by means of a narrow tube provided with a stop-cock, to the flame of a spirit-lamp which serves to ignite and maintain the flame of the powdered magnesium. If nitrate of strontia be substituted for sand, a splendid red light is produced, and in this way, by using other chemicals, various colors can be obtained. It was about the year 1864 that magnesium was first made on a commercial scale, and it is found that the demand for it, although not decreasing, is scarcely at all extending. It is almost wholly used for burning in photographic lamps, for flash lights, and for fire-works. It has been attempted to make magnesium useful for other purposes. Various alloys have been made with it and other metals such as lead, tin, zinc, cadmium, and silver; but they are all brittle and liable to change. It is very doubtful, therefore, if any of these alloys will become useful in the arts, and the metal itself is scarcely likely to be available in the construction of objects of ornament or utility, since, when exposed to damp, it soon becomes coated with a film of hydrate of magnesium.

MAGNETISM.—The power which the magnet has to attract iron. Magnets are of two kinds, *natural* and *artificial*. Natural magnets consist of the ore of iron called magnetic, familiarly known as loadstone. Artificial magnets are, for the most part, straight or bent bars of tempered steel, which have been magnetized by the action of other magnets, or of the galvanic current. The power of the magnet to attract iron is by no means equal throughout its length. If a small iron ball be suspended by a thread, and a magnet be passed along in front of it from one end to the other, it is powerfully attracted at the ends, but not at all in the middle, the magnetic force increasing with the distance from the middle of the bar. The ends of the magnet where the attractive power is greatest are called its poles. By causing a magnetic needle moving horizontally to vibrate in front of the different parts of a magnet placed vertically, and counting the number of vibrations, the rate of increase of the magnetic intensity may be exactly found.

A magnet has two poles or centers of magnetic force, each having an equal power of attracting iron. This is the only property, however, which they possess in common, for when the poles of one magnet are made to act on those of another, a striking dissimilarity is brought to light. It might be thought that, by dividing a magnet at its center, the two poles could be insulated, the one half containing all the north polar magnetism, and the other the south. When this is done, however, both halves become separate magnets, with two poles in each—the original north and south poles standing in the same relation to the other two poles called into existence by the separation. *We can therefore certainly never have one kind of magnetism without having it associated in the same magnet with the same amount of the opposite magnetism.* It is this double manifestation of force which constitutes the polarity of the magnet. The fact of a freely suspended magnet taking up a fixed position has led to the theory that the earth itself is a huge magnet, having its north and south magnetic poles in the neighborhood of the poles of the axis of rotation, and that the magnetic needle or suspended magnet turns to them as it does to those of a neighboring magnet. All the manifestations of terrestrial magnetism give decided confirmation of this theory. It is on this view that the French call the north pole of the magnet the south pole *(pôle austral)*, and the south the north pole *(pôle boréal)*; for if the earth be taken as the standard, its north magnetic pole must attract the south pole of other magnets, and *vice versa*. In England and Germany the north pole of a magnet is the one which, when freely suspended, points to the north, and no reference is made to its relation to the magnetism of the earth. All artificial magnets are either bar magnets or else horse-shoe magnets, (See Fig. 1.) When powerful magnets are to be made, several thin bars are placed side by side, with their poles lying in the same way. They end in a piece of iron, to which they are bound by a brass screw or frame. Three or four of these may be put into the bundle, and all these again into bundles of three and four. Such a collection of magnets is called a *magnetic magazine* or *battery*. A magnet of this kind is more powerful than a solid one of the same weight and size, because thin bars can be more strongly and regularly magnetized than thick ones. A good form of magnet is a parallelopiped of magnetic iron ore, with pieces of soft iron, bound to its poles by a brass frame encircling the whole. The lower ends of the soft iron bars act as the poles, and support the armature. The magnetic needle is a small magnet nicely balanced on a fine point. When a short bar of soft iron is suspended from one end of a magnet it becomes for the time powerfully magnetic. It assumes a north and south pole, like a regular magnet, as may be seen by using a small magnetic needle; and if its lower end be dipped into iron filings, it attracts them as a magnet would do. When it is taken away from the magnet the filings fall off, and all trace of magnetism disappears. It need not be in actual contact to show magnetic properties; when it is simply brought near, the same thing is seen, though to a less extent. If the inducing magnet be strong enough, the induced magnet, when in contact, can induce a bar like itself, placed at its extremity, to become a strong magnet; and this second induced magnet may also transmit the magnetism to a third, and so on, the action being, however, weaker each time. If a steel bar

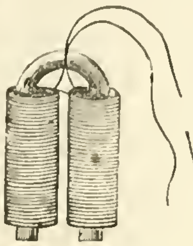

Fig. 1.

be used for this experiment, a singular difference is observed in its action; it is only after some time that it begins to exhibit magnetic properties, and, when exhibited, they are feebler than in the soft iron bar. When the steel bar is removed, it does not part instantly with its magnetism, as the soft iron bar, but retains it permanently. Steel, therefore, has a force which, in the first instance, resists the assumption of magnetism; and, when assumed, resists its withdrawal. This is called the *coercitive force*. The harder the temper of the steel, the more is the coercitive force developed in it. It is this force, also, in the loadstone, which enables it to retain its magnetism. The inductive action of terrestrial magnetism is a striking proof of the truth of the theory already referred to, that the earth itself is a very large magnet. When a steel rod is held in a position parallel to the dipping-needle, it becomes in the course of some time permanently magnetic. The result is reached sooner when the bar is rubbed with a piece of soft iron. A bar of soft iron held in the same position is more powerfully but only temporarily affected, and when reversed, the poles are not reversed with the bar, but remain as before. If when so held it receive at its end a few sharp blows of a hammer, the magnetism is rendered permanent, and now the poles are reversed when the bar is reversed. The torsion caused by the blows of the hammer appears to communicate to the bar a coercitive force. We may understand from this how the tools in work-shops are generally magnetic. Whenever large masses of iron are stationary for any length of time they are sure to give evidence of magnetization, and it is to the inductive action of the earth's poles acting through ages that the magnetism of the loadstone is to be attributed. Magnets, when freshly magnetized, are sometimes more powerful than they afterwards become. In that case they gradually fall off in strength till they reach a point at which their strength remains constant. This is called the *point of saturation*. If the magnet has not been raised to this point, it will lose nothing after magnetization. We may ascertain whether a magnet is at saturation by magnetizing it with a more powerful magnet, and seeing whether it retains more magnetism than before. The saturation point depends on the coercitive force of the magnet, and not on the power of the magnet with which it is rubbed. When a magnet is above saturation, it is soon reduced to it by repeatedly drawing away the armature from it. After reaching this point, magnets will keep the same strength for years together if not subjected to rough usage. It is favorable for the preservation of magnets that they be provided with an armature or keeper. The power of a horse-shoe magnet is usually tested by the weight its armature can bear without breaking away from the magnet. Häcker gives the following formula for this weight: $W=a\sqrt[3]{m^2}$; W is the charge expressed in pounds; a, a constant to be ascertained for a particular quality of steel; and m is the weight in pounds of the magnet. Small magnets, therefore, are stronger for their size than the large ones. The reason of this may be thus explained: Two magnets of the same size and power, acting separately, support twice the weight that one of them does; but if the two be joined, so as to form one magnet, they do not sustain the double, for the two magnets being in close proximity, act inductively on each other, and so lessen the conjoint power. Similarly, several magnets made up into a battery have not a force proportionate to their number. Coulomb discovered, by the oscillation of the magnetic needle in the presence of magnets, that *when magnets are so placed that two adjoining poles may act on each other without the interference of the opposite poles*, that is, when the magnets are large compared with the distance between their centers, *their attractive or repulsive force varies inversely as the square of the distance*. Gauss proved from this theoretically, and exhibited experimentally, that when the distance between the centers of two magnets is large compared with the size of the magnets, that is, *when the action of both poles comes into play, their action on each other varies inversely as the cube of the distance*. When a magnet is heated to redness it loses permanently every trace of magnetism; iron, also, at a red heat, ceases to be attracted by the magnet. At temperatures below red heat the magnet parts with some of its power, the loss increasing with the temperature. The temperatures at which other substances affected by the magnet lose their magnetism differ from that of iron. Cobalt remains magnetic at the highest temperatures, and nickel loses this property at 662° F.

Electro-magnetism includes all phenomena in which an electric current produces magnetism. The most important result of this power of the current is the electro-magnet. This consists (Fig. 1) generally of a round bar of soft iron bent into the horse-shoe form, with an insulated wire coiled round its extremities. When a current passes through the coil, the soft iron bar becomes instantly magnetic, and attracts the armature with a sharp click. When the current is stopped, this power disapears as suddenly as it came. Electro-magnets far outrival permanent magnets in strength. Small electro-magnets have been made by Joule which support 3,500 times their own weight, a feat immeasurably superior to anything performed by steel magnets. When the current is of moderate strength, and the iron core more than a third of an inch in diameter, *the magnetism induced is in proportion to the strength of the current and of the number of turns in the coil*. When the bar is much thinner than one-third of an inch, a maximum is very soon reached beyond which any additional turns of the wire give no additional magnetism; and even when the core is thick, these turns must not be heaped on each other, so as to place them beyond influencing the core. It follows from the above principle, that, in the horse-shoe magnet, where the inductive action in the armature must be taken into account, *the weight which the magnet sustains is in proportion to the squares of the strengths of the currents and to the squares of the number of turns of the wire*. This maximum is in different magnets proportional to the area of section or to the square of the diameter of the core. The electro-magnet, from the ease with which it is made to assume or lay aside its magnetism, or to reverse its poles, is of the utmost value in electrical and mechanical contrivances. The action of the electro-magnet is quite in keeping with Ampere's theory, as the current of the coil, acting on the various currents of the individual molecules, places them parallel to itself, in which condition the soft iron bar acts powerfully as a magnet. The direction of the current and the nature of the coil being known, the poles are easily determined by Ampere's rule. Builders of magnetic engines take advantage of the facility with which the poles of an electro-magnet may be reversed, by which attractions and repulsions may be so arranged with another magnet as to produce a constant rotation. The forms in which they occur are exceedingly various. Fig. 2, shows a simple and common construction, whereby a double-beam engine of much power is obtained. Powerful machines of this kind have been made with a view to supplant the steam-engine; but such attempts, both in respect of economy and constancy, have proved utter failures.

Magneto-electricity includes all phenomena where magnetism gives rise to electricity. Under *Induction of Electric Currents* it was stated that when a coil, in which a current circulates, is quickly placed within another coil unconnected with it, a contrary induced current in the outer coil marks its entrance, and when it is withdrawn, a direct induced current attends its withdrawal. While the primary coil remains stationary in the secondary coil, though the current continues to flow steadily in the primary, no current is induced in the secondary coil. It is also shown, that if, while the primary coil is stationary,

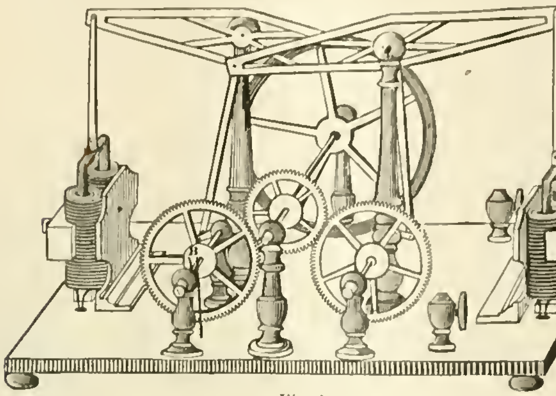

Fig. 2.

the strength of its current be increased or diminished, each increase and diminution induce opposite currents in the secondary coil. Change, in fact, whether in the position or current strength of the primary coil, induces currents in the secondary coil, and the intensity of the induced current is in proportion to the amount and suddenness of the change. In singular confirmation of Ampere's theory, a permanent bar-magnet may be substituted for the primary coil in these experiments, and the same results obtained with greater intensity. When a bar-magnet is introduced into the secondary coil, a current is indicated, and when it is withdrawn, a current in a contrary direction is observed, and these currents take place in the directions required by Ampere's theory. A change of position of the magnet is marked by a current, as in the former case. If we had the means of increasing or lessening the magnetism of the bar, currents would be induced the same as those obtained by strengthening or weakening the current in the primary coil. It is this inductive power of iron at the moment that a change takes place in its magnetism, that forms the basis of magneto-electric machines. Of late years quite a new era has arisen in the construction of magneto-electric machines. The compactness, simplicity of construction, and marvelous power which the new machines possess, give them quite a novel importance in practical electricity. The names chiefly associated with the new improvements are Wilde of Manchester, Siemens and Wheatstone, and Gramme of Paris. Mr. H. Wilde, in 1866, patented a magneto-electric machine, founded on the principle that *a current or a magnet indefinitely weak can be made to induce a current or a megnet of indefinite strength.* A Wilde's machine 1½ ton in weight, measuring about 5 feet in length and height, and 20 inches in width, driven by a steam-engine, produces a most brilliant electric light, and exhibits the most astonishing of heating powers. Wheatstone and Siemens gave a new interpretation to Wilde's principle.

The great drawback of all the forms of the machine is the enormous velocity at which they rotate some 2,000 or more revolutions in the minute. At this speed a machine soon wears itself out. Another disadvantage is the heating of the armatures in Wilde and Ladd's machine. Ferguson's has never been tried on a large scale. It is found necessary to keep the armatures cool by a flow of cold water. This heat, however removed, is manifestly a mere squandering of the energy of motion, and a loss to the current given off. A third objection is the loss that always takes place when the side-springs change from the one ring to the other, sparks more or less bright accompanying the change. For the electric light, however, the alternate currents are used, and this source of loss is not experienced. These defects are removed in the latest form of the electro-magnetic machine by Gramme, of Paris. In it, instead of a solid armature of iron, a ring is employed on which a great number of bobbins of wire are set. Astonishing as were the effects produced by Wilde's machine, those obtained from Gramme's seen quite to eclipse them. In comparing two magneto-electric machines, we must take into account the kind of wire used for the revolving armature. For tension purposes, a thin and long wire gives the best results; for quantity or heating purposes, a short and thick wire does best. To compare a tension with a quantity armature, the same test even in the same machine would give most contradictory results. But comparing, so far as possible, machines intended for the same purpose Gramme seems to have the advantage of all others. In the first place, the speed of revolution seldom exceeds 800 revolutions per minute; 300 is sufficient for most purposes. A Gramme machine driven by the hand will melt 10 inches of an iron wire $\frac{1}{25}$ of an inch in diameter, a feat not accomplished by any other arrangement. The electric light got by a 3-horse-power engine working a machine a ton in weight is equal to upwards of 8,000 sperm candles. A signal-light of this kind has been constructed for the House of Lords, under the superintendence of the eminent engineer Conrad W. Cooke, who has rendered no small service in perfecting the machine. The carbons consumed last four hours, and when burned out are instantaneously replaced. A Gramme machine adapted for electro-plating, and worked by a 1-horse-power engine, deposits nearly 27 oz. of silver per hour, an achievement far transcending the similar performance of other machines. Among the heating wonders of the Gramme machine we are told of a file half an inch in diameter being burned up in 5 minutes, of 15 feet of No. 18 platinum wire being brought to a glowing heat, and of 8 feet of iron wire .051. See *Electricity* and *Galvanism*.

MAHRATTA HELMET.—An Indian casque, having a long movable nose-piece of a singular shape; a large mail hood which protects all the head, and a neck-guard which descends to the loins.

MAIDEN.—A name given to a machine for beheading criminals, which was in use in Scotland from about the middle of the 16th century to nearly the end of the 17th century. It is said to have been introduced into Scotland by the Regent Morton, who had seen it at Halifax, in Yorkshire, and was himself the first to suffer by it, whence the proverb, "He that invented the maiden first handselled it." Morton, for anything that is known to the contrary, may have introduced the maiden; but he certainly was not its first victim. Fifteen years before he was put to death by it (1581 A. D.) it was employed to behead Thomas Scott, of Cambusmichael, one of the murderers of Rizzio (1566 A. D). It would seem at first to have been called indifferently "The Maiden" and "The Widow"—both names, it may be conjectured, having their origin in some such pleasantry as was glanced at by one of the maiden's last victims, the Earl of Argyle (1681 A. D.), when he protested that it was "The sweetest maiden he had ever kissed." A frightful instrument of punishment used in Germany in the Middle Ages was called "The Virgin." But it had no resemblance to the maiden, which was exactly like the French guillotine, except that it had no turning-plank on which to bind the criminal. The maiden which was used in the Scottish capital is now in the Museum of the Antiquaries of Scotland at Edinburgh. The term *maiden* is also applied to a fortress which has never been taken.

MAIL.—A term signifying a metal net-work, and ordinarily applied to such when used as body defensive armor. Well-made mail formed an admirable defense against all weapons except fire-arms, and its pliability and comparative lightness gave it favor over the more cumbrous plate-armor.

MAILLET.—A kind of mallet formerly used by the French in their engagements. The maillet was used at the famous battle "Des Trente" in 1351. Under the reign of Charles VI. a Parisian mob forced the arsenal, and took out a large quantity of mallets, with which they armed themselves for the purpose of murdering the custom-house officers. The persons who assembled on this occasion were afterwards called *Maillotins*. In the days of Louis XII. the English archers carried mallets as offensive weapons.

MAILLOTIN.—An old French term which signified an ancient weapon that was used to attack men who wore helmets and cuirasses. A faction in France was also distinguished by this appellation. See *Maillet*.

MAIN.—A term signifying first in size, rank, or importance. It has many useful compounds attached to it, such as: *Main body* of an Army, the body of troops, other than those forming the advanced or rear guard. *Main guard*, a body of men generally of the strength sufficient to guard a person or place from injury or attack. It remains on duty 24 hours before being relieved. Large forts or fortresses have a main guard chosen from the troops garrisoning them, under which guard all disturbers of peace, drunkards, etc., are placed, as well as all people who cannot by night give an account of themselves, or who do not know the parole. *Main magazine*, the principal magazine in a work or battery, in which there is more than one magazine. *Main work*, in fortification, the principal work as distinguished from the outworks.

MAINADE.—The French term for a body of marauders commanded by a chief.

MAIN-GAUCHE.—A dagger of Spanish origin especially used in duels in the 16th century. On one side of the hilt it has a guard, which is curved and carried up to the pommel in the form of a half shell; from the *talon*, or heel of the blade, on the opposite side, is a hollow indent, intended to hold the thumb. The weapon was held in the left hand, with the thumb above and the guard below; and it was used, while making an attack, with the sword held in the right hand to ward off the blows or thrusts that the adversary might make with his sword. See *Pennated Dagger*.

MAIN PIN.—A strong cylindrical bar passing vertically through a hole in the front bolster of the wagon body, and through one in a corresponding bolster in the fore carriage. The pull of the traces is conveyed from the fore carriage to the body solely through the *main-pin*. This means of connection between fore carriage and body allows the former to turn horizontally independently of the latter.

MAIN-SPRING.—The spring in a gunlock which drives the hammer. See *Lock*.

MAINTENANCE.—The Cap of Maintenance, sometimes called *Cap of Dignity*, a cap of crimson velvet lined with ermine, with two points turned to the back, originally only worn by Dukes, but afterwards assigned to various families of distinction. Those families who are entitled to a cap of maintenance place their crests on it instead of on a wreath. According to Sir John Fearne, "the wearing of the cap had a beginning from the Duke or General of an army, who, having gotten victory, caused the chiefest of the subdued enemies whom he led to follow him in his triumph, bearing his hat or cap after him, in token of subjection and captivity." Most of the reigning Dukes of Germany, and various families belonging to the peerage both of England and of Scotland, bear their crests on a cap of maintenance.

MAISON DU ROI.—The King's Household. Certain select bodies of troops were so called during the Monarchy of France, and consisted of the *Gardes-du-Corps*, the *Gendarmes*, the *Chevaux-legers*, the *Mousquetaires*, the *Gendarmerie*, the *Grenadiers à Cheval*, the regiments belonging to the French and the Swiss Guards, and the *Cent Suisses*. The Maison-du-Roi was not considered a separate establishment from the rest of the Army until the reign of Louis IV. This establishment was successively formed by different kings out of militia companies, which they took into their body-guard.

MAITRE D'ARMES.—A term in general use among the French, signifying a Fencing Master. Every regiment has a Maitre d'Armes attached to it.

MAJESTY.—A title of honor now usually bestowed on Sovereigns. Among the Romans, *Majestas* was used to signify the power and dignity of the people; and the Senatorial, Consular, or Dictatorial Majesty was spoken of, in consequence of these functionaries deriving their power from the people. After the overthrow of the Republic, *Majestas* became exclusively the attribute of the Emperors, *Dignitas* being thenceforth that of the Majestrates. The *Majestas* of the Emperors of Rome was supposed to descend to those of Germany as their successors; but the adoption of the attribute by other European Sovereigns is of comparatively late date. Its use began in England in the latter part of the reign of Henry VIII., up to which time, "Your Grace" or "Your "Highness" had been the appropriate mode of addressing the Sovereign. Henry II. was the first King of France who was similarly styled, and Louis XI. and his successors became entitled, in virtue of a papal bull, to call themselves by the title of "Most Christian Majesty." Ferdinand and Isabella of Spain similarly obtained for themselves and their successors the title of "Most Catholic Majesty;" and Stephen, Duke of Hungary, and Maria Theresa, of "Apostolic Majesty." The Emperor of Austria is now styled His Imperial Royal Majesty; in German, "K.K. (abbreviated for Kaiserliche Konigliche) Majestat" Emperors, Kings, and Queens are now generally addressed as "Your Majesty," not including the Sultan of Turkey, whose proper style is "Your Highness." The Sovereign of the United Kingdom is personally addressed as "Your Majesty," and letters are addressed to "The King's" or "Queen's" "Most Excellent Majesty." In Heraldry, an eagle crowned and holding a scepter, is blazoned as an "Eagle in his Majesty."

MAJOR.—1. An officer next in rank above a Captain and below a Lieutenant-colonel. He is the lowest Field Officer. Since the reorganization of the English army, the Major is a selected man, and his term of service in this rank is for five years, after which, if not re-employed, he is put on half-pay. This does not relate to Majors of the artillery and engineers. The duties of a Major depend upon the nature of the service on which he is employed. In the line, whilst with his regiment, he has to see to the drill and equipment of the men in conjunction with the Adjutant. Being a Field Officer, he is mounted on all parades and in action. In the artillery and engineers, the rank of Major has been recently reintroduced, and single batteries of artillery are now commanded by officers of this rank, instead of by a Captain, as hitherto. It was in the year 1827 that the rank of Major in the artillery was abolished, its holders being made Lieutenant-colonels. It appears that this class of Field Officer did not exist in the army until the seventeenth century. 2. Used adjectively, the word *Major*, in the army signifies a superior class in a certain rank, as Sergeants-Major, who are superior Sergeants; except in the case of General Officers, in which its signification is arbitrarily limited to Major-general, the third of the four classes of Generals.

MAJOR GENERAL.—The rank next below that of Lieutenant-general, and above Brigadier-general. He usually Commands a Division. A Major's command in peace time in England is that of a District; in India, a Division of the Army. A Brigade of the army is properly a Major-general's command, Thus, on service with a large army, a General would command a *Corps d'Armée*, a Lieutenant-general a Division, and a Major-general a Brigade.

MALABAR GUNS.—Heavy pieces of ordnance, which were made in the Malabar country, and were formed by means of iron bars joined together with hoops. They were very long and extremely unwieldy.

MALCHUS.—A short sword of Italian origin, used in the fifteenth century, and very much like the *Anelace*.

MALINGERER.—A soldier who feigns himself sick. Any soldier convicted of malingering, feigning or producing disease, or of intentionally protracting his cure or aggravating his disease, is liable to be tried by a Court-Martial for "Conduct prejudicial to good order and military discipline," and to suffer the punishment attached to that offense. See *Feigning of Disease*.

MALKIN.—A sponge with a jointed staff for cannons.

MALLEABILITY.—The property which certain metals possess of being reducible to thin leaves, either by hammering (hence the corresponding German word *hämmerbarkeit*) or by lamination between rollers. The order in which the malleable metals exhibit this property is as follows: gold, silver, copper, platinum, palladium, iron, aluminium, tin, zinc, lead, cadmium, nickel, cobalt. Gold far surpasses all other metals in malleability, being capable of reduction into films not exceeding the 200,000th of an inch in thickness; and silver and copper may be reduced to leaves of great tenuity. Although gold and silver also present the property of *ductility* in the highest degree, there is no constant relation between the two properties; for example, iron, although it may be reduced to extremely thin wire, is not nearly so malleable as gold, silver, or copper.

MALLET.—A wooden hammer. It is used for a variety of purposes in the field, such as driving pickets, tent-pins, etc. The head is made of elm, and the helve of ash. Mallets vary in size and shape, and are made in India of babool or soondry wood. Mallets are also very generally used by mechanics, such as joiners and carpenters, coopers, tinmen, etc.

MALLET'S MORTAR.—A monster mortar manufactured some years ago by Mr. Mallett. It consisted at the lower end of a solid cast-iron breech, abutting on which were a series of wrought-iron hoops, following each other in succession up to the muzzle; these were inserted into each other by rebates, and were firmly secured by six iron staves, at equal intervals, about its surface, extending longitudinally the whole length of the mortar. The total weight of the mortar was 50 tons 13¼ cwt.; the diameter of the shell 3 feet, and its weight, when unfilled, 26¼ cwt. From the experiments made with this mortar, it appears that there was a tendency to separation between the trunnions and the cascable, and consequently there was reason to think that it never could be employed on service. This piece of ordnance is not in the service, but a model of it may be seen in the Royal United Service Institution, Whitehall, London.

MALTA.—The most ancient and celebrated of Military Orders is that of *Saint John of Jerusalem*, which owes its origin to the Hospital of St. John, founded in Jerusalem in the year 1048. It became in 1118 a Religious Order of Knighthood, and from 1309 the Knights were called *Knights Hospitallers of Rhodes*, and from 1530 *Knights of Malta*. The representative of this Order in England was the Prior of Clerkenwell, who had a seat in Parliament, and was styled the First Baron of England. This Order is now almost extinct, no Grand Master having been elected since 1805. The badge worn by all the Knights is a Maltese cross, enamelled white and edged with gold, suspended to a black ribbon. Some members of this Order did duty during the war of 1870-71 with the sick and wounded, the order thus appropriately ending, as it had begun, in hospitals.

MALTESE CART.—A cart which can be used with either single or double draught. The two side pieces of the cart form the shafts, and are bolted across an axle-tree bed, and connected also by a hind ear-bed, splinter-bar, and axis slats. The cart is formed of wood, and is adapted for man draught. Its weight is under 7 cwt.

MALTESE CROSS.—A cross of eight points, of the form worn as a decoration by the Hospitallers and other Orders of Knighthood.

MAMELIERE—Armor for the breast, from which depended two chains, one attached to the pommel, and the other to the scabbard of the sword.

MAMELUKES—MAMLOUKS—MEMLOOKS.—An Arabic word signifying *slaves*, the name given in Egypt to the slaves of the Beys, brought from the Caucasus, and who formed their armed force. When Genghis Khan desolated great part of Asia in the 13th Century, and carried away a multitude of the inhabitants for slaves, the Sultan of Egypt bought 12,000 of them, partly Mingrelians and Tcherkesses, but mostly Turks, and formed them into a body of troops. But they soon found their own power so great that, in 1254, they made one of their own number Sultan of Egypt, founding the Dynasty of the Baharites, which gave place to another Mameluke Dynasty, that of the Borjites, in 1382. The Caucasian element predominated in the first Dynasty, the Tartar element in the second. In general, they formed able and energetic rulers, and Egypt under their sway arrived at a degree of prosperity and power to which she had been a stranger from the days of Sesostris. Selim I., who overthrew the Mameluke Kingdom in 1517, was compelled to permit the continuance of the 24 Mameluke Beys as Governors of the Provinces. This arrangement subsisted till the middle of the 18th Century, when the number and wealth of the Mamelukes gave them such a preponderance of power in Egypt that the Pasha named by the Porte was reduced to a merely nominal ruler. The number of them scattered throughout all Egypt was between 10,000 and 12,000 men. Their number was kept up chiefly by slaves brought from the Caucasus, from among whom the Beys and other Officers of State were exclusively chosen. Their last brilliant achievements were on the occasion of the French Invasion of Egypt, and during the time immediately following the retirement of the French. At this time Murad Bey stood at their head. But in 1811 they were foully massacred by Mohammed Ali, afterwards Viceroy of Egypt.

MAMMOTH POWDER.—A variety of powder formed by breaking up mill cake. Exact uniformity of size and shape of grains does not therefore exist. The average granulation is 85 to the pound. The diameters of the holes in the testing sieves are .75 inches and .90 inches. See *Gunpowder*.

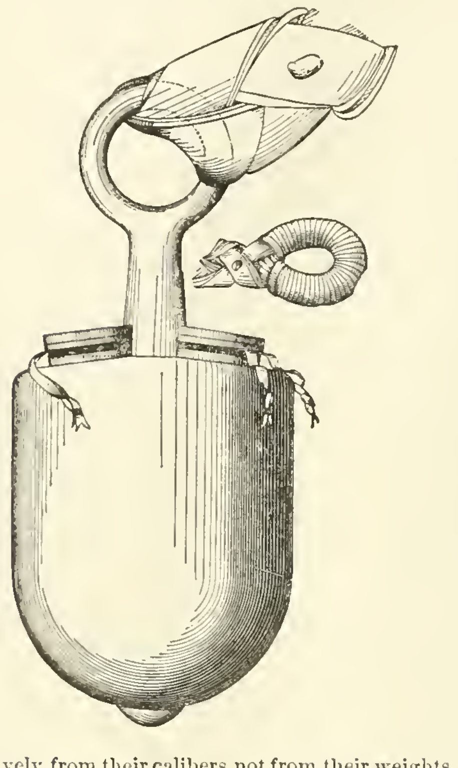
MANACLES.—Handcuffs or *nippers* for prisoners. The two pieces of metal are hinged together, the upper portion of which is curved so as to fit the wrist, and the lower portion is straight except at a point near its outer end, where it is slightly bent.

MANBY SHOT.—Without entering upon a detailed description of the different plans proposed, from time to time, for establishing communication between a stranded vessel and the shore, it will, perhaps, be well to mention that Manby's apparatus is not the only one which has been used for this purpose. Kites have also been suggested as a simple means of carrying a line from a wreck to the shore, and are manufactured for this purpose by the "Shipwrecked Mariners' Society, London Bridge." The board of trade employed, to a great extent, until 1865, Dennett's rockets, in preference to Manby's shot; and there can be no question that the balance of advantages inclines strongly to the side of the rockets.

In 1865 a rocket proposed by Colonel Boxer, R. A., was adopted by the board of trade to supersede Dennett's rocket, to which it is preferred because.—1st.

The range of Colonel Boxer's rocket is little, if at all, inferior, and in every other respect it is much superior; 2d. The combination of Mr. Dennett's two rockets is very objectionable, and from their velocity they frequently carry away the line, and sometimes both do not ignite. They are also double the expense. These rockets are fast superseding Manby's shot at all stations, and the latter may shortly be expected to become entirely obsolete.

There are two natures of Manby's shot in the service, the 24-pounder oblong or "cylindrical," shown in the drawing, and the 6-pounder spherical shot. They are designated 24-pounder and 6-pounder, re-



spectively, from their calibers, not from their weights. The 24-pounder oblong, or "cylindrical" Manby's shot, is a cast-iron cylindro-conoidal projectile, with a slightly rounded base, and about $1\frac{1}{4}$ calibers in length. The shot is drilled down its longer axis for the reception of a wrought-iron bolt, which passes completely through the projectile from end to end, and projects about five inches beyond the base, terminating in an eye, to which is attached a plaited hide thong 2 feet in length. Four holes, for the reception of "fuses," are drilled into the shot at the base, equidistant from one another and from the center of the base, and slightly inclining inwards. These holes are conical in form, and are about the same diameter as the fuse-holes of the 13 and 10 inch mortar shells. They are about $3\frac{1}{2}$ inches in length and are roughed in the interior to afford a better hold to the fuses. The hide thong, or "strop," which is fastened to the eye-bolt, is made of four strips of raw horse-hide, doubled through the eye and tightly plaited, the plait being further secured by being stitched in several places with hide. The end of the thong is formed into a loop which is tightly woolded with fine tarred spun-yarn. These projectiles weigh (with thong) about $30\frac{1}{2}$ pounds.

The 6-pounder spherical Manby's shot is rarely demanded, and is scarcely to be considered as a service projectile. It consists of a diaphragm shell filled with lead, and having an iron loop fixed into it, to which is attached a thong similar to that of the oblong projectile. This shot is without fuse-holes. It weighs about 8 pounds.

The action of a oblong shot is as follows: The end of the line is made fast to the loop-hole of the thong, the rest of the line being carefully coiled either in a basket or upon the ground or deck, and a fuse is placed in each of the four holes made for the purpose. The fuses being uncapped, the projectile is carefully placed in the piece with its base toward the muzzle, and upon the discharge of the piece carries out the line, one end of which being retained, a good communication is thus established between the vessel and the shore. The use of the hide thong is to remove the line from the immediate flash of the discharge, and so prevent it from being burned. The fuses serve, by the bright light which they give forth, to indicate the path of the shot and guide the firing party in laying the piece. The strength and direction of the wind must be considered in determining the direction to be given, the trajectory being affected by them to a very great extent, owing to the influence which the wind has upon the line. With deep-sea line, and with the ordinary charge of 12 ounces, the range varies from 400 yards downward, according to the strength and direction of the wind. The 6-pounder is used in the same way, with the exception that, having no fuses, the operation of fixing and uncapping them is dispensed with. These projectiles are mainly used to establish a communication between the shore and a stranded vessel, but the principle is applicable to a variety of other purposes, etc.

The maximum charge for the 24-pounder oblong Manby's shot is only 12 ounces, giving, with 45° of elevation, a range from 400 yards downward, according to the strength and direction of the wind. If a higher charge is used, the line is generally broken. See *Life-saving Rockets*.

MANCH MAUNCH.—A frequent charge in English Heraldry, meant to represent a sleeve with long pendant ends, of the form worn by ladies in the reign of Henry I. Or, a manch gules, has been for a long time the arms of the Hastings family, one of whom was steward of the household to Henry I.

MANDARIN.—A term applied to Chinese officers of every grade by foreigners. It is derived from the Portuguese *mandar*, to command; the Chinese equivalent is *Kwan*. There are nine ranks, each distinguished by a different-colored ball or button placed on the apex of the cap, by a peculiar emblazonry on the breast, and a different clasp of the girdle. The balls are ruby, coral, sapphire, a blue opaque stone, crystal, opaque white shell, worked gold, plain gold, and silver. Theoretically, these grades are indicative of relative merit, but as office and titles are sold to a great extent, the competitive examinations, which are the only legitimate road to distinction, have lost much of their value. A Mandarin is not allowed to hold office in his Native Province; the intention being to prevent intrigue, and to draw to Pekin the ambition and talent of the country, where temporary employment is given in subordinate offices, prior to appointments to the Provinces. He is not allowed to marry in the jurisdiction under his control, nor own land in it, nor have a near relative holding office under him; and he is seldom continued in office in the Station or Province for more than three years—a system of espionage which serves further to strengthen the Imperial Government. It is incumbent on every Provincial Officer to report on the character and qualifications of all under him, which he periodically transmits to the Board of Civil Service; the points of character are arranged under six different heads. viz., to those who are not diligent, the inefficient, the superficial, the untalented, superannuated, and diseased. According to the opinions given in this report, officers are elevated or degraded so many step in the scale of merit, like boys in a class. They are required to accuse themselves when remiss or guilty of crime.

MANDILION.—A soldier's loose coat—usually an outer garment without sleeves.

MANDREL.—An arbor or axis on which work is temporarily placed to be turned. The arbor which revolves in the headstock of a lathe and carries the upper pulley and also the chuck or face-plate, if one be used. Traversing mandrels are used in connection with lathes, and are driven by gearing from a countershaft overhead. The term is also employed in forging, to denote a rod used to preserve the interior form of hollow-work.

MANEGE.—The art of horsemanship or of training horses; also, a school for teaching horsemanship, and for training horses. See *Horsemanship*, and *Menage*.

MANEUVER.—A term from the French, commonly written *manœuvre*, and signifying 'handy-work,' is somewhat vaguely used in English dimilitary and naval language to denote collateral movements, not openly apparent, of bodies of men or squadrons of ships, by which an enemy is coerced, or by which it is sought to compel him to take some course adverse to his interests.

MANEUVERING WHEELS.—The eccentric truck-wheels used on Sea-coast Carriages for regulating the motion to and from battery. When it becomes necessary to check the recoil of the gun-carriage, the wheels are thrown out of gear by means of a handspike inserted in the socket attached to the end of the axle-tree, and the carriage moved on sliding friction. When the gun is to be moved into battery, the wheels are thrown into gear in a similar manner, and the front of the carriage moves on rolling friction. In the 15-inch carriage there are two pairs of maneuvering wheels, one pair being placed in front and the other pair near the rear end of the carriage. See *Sea-coast* and *Garrison Carriages*.

MANEUVER MARCHES.—Marches made to gain a position, the possession of which compels the enemy to leave the position he is occupying. When such marches are under the observation of the enemy, they are termed *Manoeuvres*. An example of manoeuvre marches is seen in the movements of the different corps of the French Army in 1805, from the time they crossed the Rhine until they crossed the Danube, since by their execution, the Austrian position at Ulm was turned and was no longer tenable by the Austrian army. See *Concentration Marches*, *Marches* and *Tactical Marches*.

MANEUVER OF HEAVY GUNS.—The introduction of iron-clad vessels of war, and of larger cannon using projectiles of greatly increased power, has rendered it necessary that more complete protection for the gun and for the cannoniers should be provided than that furnished in the batteries of the present day. This want has brought forth a system of Depressing Carriages, by which the gun, after being fired, is drawn below the parapet and there loaded. Of these carriages the "Moncrieff" in Europe, and those known as the "King" and "Buffington," invented in the United States, have met with the most favor, but the general adaptability for service of no one of them has yet been established. The only plan proposed, with the view of offering increased protection in maneuvering heavy cannon on the carriages now in our service, is that of the late Colonel Benton, of the Ordnance Department. In this system the movements are effected by *two chains* or *ropes*, worked by a *windlass* placed within a casemate in the parapet or in a traverse, between two guns.

The power being situated to the right of the gun, "rope No. 1" passes from the windlass to a pulley in the axis of the platform, thence to a pulley at the left of the platform, back over a pulley attached to the fork of the left rear traverse wheel, up over a pulley on the rear transom of the chassis, thence forward under a pulley at the front transom of the top carriage, and the end of the rope is attached to a staple on the under side of the gun in front of the trunnions. "Rope No. 2" goes from the windlass over a pulley attached to the fork of the right rear traverse wheel, thence up over a pulley on the rear transom of the chassis, then to a pulley at the rear transom of the top carriage; the end of this rope is fastened to a pin in the base of the breech of the gun. The ropes passing loosely over the pulleys, the application of force to "No. 1" will depress the muzzle and to "No. 2" will depress the breech. The gun is drawn "*from battery*" by force bing applied to both ropes at once, or to one rope alone, the traverse wheels being choked. A rope attached to a handspike and passing over a pulley at the upper part of the cheek enables a gunner protected by the parapet to place the rear truck wheels "in gear" and allows the gun to run "*into battery*" by the force of gravity, the windlass being out of gear.

To *traverse* the gun, "rope No. 1" must be locked to the pulley at the front of the top carriage. Movement to the *left* will then be accomplished by "No. 1," the force being exerted at the pulley at the left fork, and to the right by "No. 2," which will exert its force at the right fork. To *load* the gun, the muzzle is depressed below the parapet; the projectiles are on a shelf along the face of the parapet, and are conveniently transferred to the piece on a *carriage*, which is worked by a *rope* and *pulley* running on a movable inclined tramway. A *sectional* or *telescopic* sponge and rammer must be used, and the carriage may be employed to force the projectile home. The gunners, whilst loading, are protected from shot and shell by a piece of boiler plate set in the face of the parapet. The sights are placed on the under side of the gun as near as convenient to the cheek. The elevation may be given by an arc, a pointer being on the trunnion. The gun is mounted with the *vent down*, which enables it to be fired with the least exposure to the cannoniers. Each windlass is capable of maneuvering two guns. See *Mechanical Maneuvers*.

MANEUVERS.—In all changes of position that demand a disturbance of the fundamental order of battle of the unit, it is broken into its subdivisions, which are placed in certain relative positions with respect to each other, according to the object in view. These combinations are termed *maneuvers*, and their chief object usually is to change the direction of the front of the unit, according to the particular exigency. Maneuvers, like all the rest of the mechanism pertaining to the unit, should be stamped with simplicity and uniformity. The tactics of the present day present, in this respect, a remarkable contrast to those of the period anterior to it; which is owing, in no small measure, to the little scope left for individual fancy; every proposal being submitted to the formal examination of an enlightened board. Stage spectacles alone now occasionally furnish some notions of those whimsies of olden times; so happily hit off in the well-known article of Salmagundi, where the street-pump figures as an almost impassable obstacle to the show soldier of that day. See *Evolutions*.

MANGAN.—An ancient war machine. The term *Mangan* was generally adopted to signify any species of warlike machine; but it more particularly meant the largest and most powerful machine that could be used for warlike purposes—whether it was practiced to throw enormous stones against besieged places, or to cast javelins, etc. This machine answered the double purpose of defending or attacking fortified places, and it was sometimes used at sea. Also written *Mangon*, and *Mangonel*. The Mangonel proper was a very strong and powerful *cross-bar*, from 15 to 20 feet long, used for throwing arrows, darts or stones. The *Trebucket*, *Ribaudequin*, etc., were only a variety of the above.

MANGANESE.—A metal resembling iron in its chemical properties, and seldom if ever absent from cast-iron. It is commonly found in iron ores, and the same operation which reduces the iron in the blast-furnace also reduces the manganese, and this metal becomes alloyed or closely mixed with the melted iron. The influence exerted by the manganese upon the character of the cast-iron is very decided, tending to the production of the white variety, the manganese diminishing the tendency of the carbon to separate in the form of graphite. White cast-iron, therefore, is found to contain the largest proportion of manganese. The spathic iron ores yield a cast-iron containing a particularly large quantity of manganese, sometimes exceeding one-tenth of the weight of the cast-iron. Such an iron is capable of containing upwards of one twenty-fifth of its weight of carbon in combination with it, and the compound thus formed chrystallizes in large and shining plates, whence it is named by the Germans *Spiegeleisen*, or *mirror-iron*. It is largely employed in the manufacture of Bessemer steel. The presence of manganese in iron increases the fluidity of the slag, and encourages the passage of phosphorus, sulphur and silicon into the slag, thus reducing the proportion of those injurious impurities in the metal. Its most important property, however, consists in its affinity for oxygen, preventing the formation of oxides of iron. See *Cast-iron.*

MANGE.—An infectious disease which attacks horses when neglected. It results from the attacks of minute mites, or *acari*, which burrow in the skin, especially if it be dirty or scurfy, cause much irritation, heat, and itching, and the eruption of minute pimples, with dryness, scurfiness, baldness, and even bleaching of the skin. The treatment consists in destroying the *acari* and insuring the cleanliness and health of the skin, both of which objects are effected by washing the parts thoroughly every second day with soft soap and water, and dressing daily with sulphur or mild mercurial ointments, or with a solution containing four grains either of corrosive sublimate or arsenic to the ounce of water. Castor-oil seeds, bruised and steeped for twelve hours in buttermilk, are very successfully used by the native Indian farriers. Where the heat and itching are great, a few drops of tincture of belladonna may be added to the usual dressing, or applied along with a little glycerine. Where the general health is indifferent, as in chronic cases, the patient should be liberally fed, kept clean and comfortable, have an occasional alterative dose of any simple saline medicine, such as niter or common salt, and a course of such tonics as iron or arsenic. Cleanliness and occasional washing and brushing maintain the skin in a healthy state, and thus prevent its becoming a suitable nidus for the *acari*.

MANIFAIRE.—Armor covering the mane and neck of a horse.

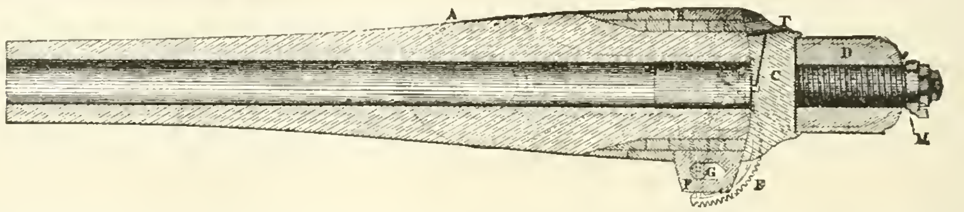
MANIFESTO.—A public declaration issued by a Sovereign Prince, or by a Government on some state emergency, expressive of intentions, opinions, or of motives. Immediately before entering on a war, a Manifesto is issued containing a statement of the reasons which have been held to justify the Sovereign or Government in taking up arms. In case of a revolt, a Manifesto is sometimes issued to recall subjects to their allegiance.

MANIGLIONS.—The two handles on the back of a piece of ordnance.

MANIPULARIS.—The chief office in a *Manipulus* of the Roman infantry. This office was likewise ordinary.

MANIPULUS.—In the tactics of the Romans, each class of the infantry of the line was subdivided into ten persons, each termed a *Manipulus*. The velites were attached to these by equal portions. The cavalry were divided into ten troops, termed *Turma*. To each manipulus there were assigned two centurions, and two file-closers; and to each turma two decurions. The velites, although forming a part of the manipuli, had centurions assigned to them, to lead them in battle. The normal order of battle of the Romans, prior to the time of Marius, was in three lines; the hastati in the first; the principes in the second; the triarii in the third; and the cavalry on the wings. The manipulus, which was the unit of force, was drawn up in 12 files, with a depth of 10 ranks, in the line of hastati and principes; in the line of triarii there were only 6 files. The right and left files of the manipulus were led by a centurion, and closed by an officer file-closer. The manipuli of the three lines were disposed in quincunx order; the manipulus of one line opposite to the interval between the manipuli in the one in front, this being the same as the manipulus front. The intervals between the lines were the same as the depth of each line. An interval of about 3 feet was left between the ranks and the files of the manipulus. The same order of battle was followed for the social troops on the wings. The two legions occupied the center; but what interval was left between them, or between the center and wings, or how far the cavalry was posted from the infantry, is not well ascertained.

MANN GUN.—The breech mechanism of this gun belongs to that system in which the breech-block remaining stationary, the body of the gun is made to revolve upon its trunnions the necessary degree to open and close the breech. It may be generally described as consisting of a breech-block attached by straps to the trunnions, with suitable devices for securing, first, the requisite closeness of contact with the breech of the gun to produce the necessary revolution about the trunnions. To describe more particularly: In the drawing, A represents the cast-iron body of the gun, re-inforced about the breech with forged-rings, B, of wrought iron, shrunk on. The mass of metal C D, closing the bottom of the bore, consists of two pieces. The piece C, in front, constituting the breech-block proper, is loosely recessed upon the piece D in rear, and has a slight play back and forth, so as to admit of being pushed up in close contact with the breech when the gun is prepared for firing. The means of producing this movement in the block is furnished by the screw N, which, passing centrally through the fixed breech-piece D—the latter being bored and threaded to receive it—abuts against the rear face of the movable block. The outer extremity of the screw is fitted with a weighted lever or handle, having "lost motion" checked by a lug, M, attached to the circumference of the screw shoulder. A point of support for the breech-apparatus is supplied by the elevating device. This consists of two screws of the same pitch, one on either side on the breech, connected by a worm-gearing and operated by cranks which extend beyond the carriage. The rimbases are concentric with the trunnions, but project sufficiently beyond the surface of the gun to accomodate the loops of the breech-straps. In order to open or close the breech, the raising or lowering of the breech of the gun is effected by means of a crank and pinion, centered upon the side of each breech-strap and working in a large-toothed segment, E, the crank-



shaped axle G of which passes under the gun and through a slotted lug, F, and thus communicates the motion produced by the crank to the breech of the gun. The fixed breech-piece D and the straps are of wrought iron; the movable block C is of cast-iron.

The gun is rifled with eleven lands and grooves, each of equal width, and of a uniform pitch of one turn in 60 feet.

Width of lands and grooves, ...	1''.18524
Depth of grooves, ...	0''.125

The chamber is concentric with the bore, and of a diameter slightly greater than that of the bore between grooves; its capacity is sufficient to contain a charge of 30 pounds of powder and a shot of 170 pounds, the latter being inserted in the bore as far as its front band. The top of each land is connected with the cylindrical surface of the chamber by a suitable ramp or bevel. The gun is center-fire through a vent in the breech-block. This vent makes a turn at nearly right angles, so as to make its exit on top of the gun. Its interior opening is through a steel disc. The gas-check (designed by the inventor) used in this gun is cup-shaped, and is pierced with a hole to admit the flame from the vent. It is necessary to remove this check before and replace it after loading. Gas-checks of this pattern, but of different alloys of copper, tin, zinc, and lead, were prepared with the view of determining the most suitable material. The projectile for this gun consists of a cast-iron body, having a front and rear band of soft metal—lead and antimony—encircling it. The iron body of the projectile allows the usual windage, but the lead bands exceed slightly the diameter of the bore, including grooves. The weight is from 150 to 170 pounds.

The gun is loaded as follows: The breech-screw is loosened, and the crank-handles turned until the gun, revolving on its trunnions, assumes a position in which the chamber is sufficiently exposed above the breech-block for the insertion of the charge. The gas-check is then removed, and the projectile inserted by sliding it along the trough T in the top of the breech-block, and pushing it forward until the front band stops against the rifling. The charge then follows, the gas-check is replaced, and the crank reversed until the gun is restored in line with the breech-block; finally, the breech-screw is tightened by means of a two-handled lever. The gun is mounted on a 10-inch carriage, widened to accommodate the increased length of the rimbases, with such other alterations as are required by the nature of the elevating-devices. The recoil-check is of the Parrott friction clamp-pattern. The following are the principal dimensions:—

Exterior diameter of gun at muzzle,	15.00	inches.
Maximum diameter, ...	28.50	"
Diameter of trunnions, ...	10.00	"
Diameter of rimbases, ...	17.00	"
Diameter of breech-screw, including threads, ...	8.50	"
Diameter of bore, ...	8.40	"
Diameter of chamber, ...	8.60	"
Radius of breech,(trunnions to breech)	51.25	"
Distance from trunnions to muzzle,	92.75	"
Total length of gun, ...	144.00	"
Length of breech-screw, including nut, ...	28.00	"
Thickness of breech-straps, . . .	4.50	"
Depth of breech-straps at trunnions,	25.00	"
Depth of breech-straps at breech-block, ...	16.00	"
Depth of breech-straps at middle point, ...	11.00	"
Length of chamber, including ramp,	24.00	"
Total length of bore.	144.00	"
Number of grooves, ...	11	
Depth of grooves, ...	0.125	inch.
Width of grooves and lands, . .	1.18524	inches
Pitch uniform; one turn in, . . .	60	feet.
Total length of gun over all, . .	178.50	inches.
Total weight of gun, ...	20,000	pounds.

See *Ordnance*.

MANOMETER. Properly an instrument for measuring the rarity of the air or of other gases; but the name is most frequently applied to instruments for indicating the elastic force of gases which is always inversely proportional to their rarity. The several kinds of barometers are really manometers, and so is the steam-gauge of a steam-engine.

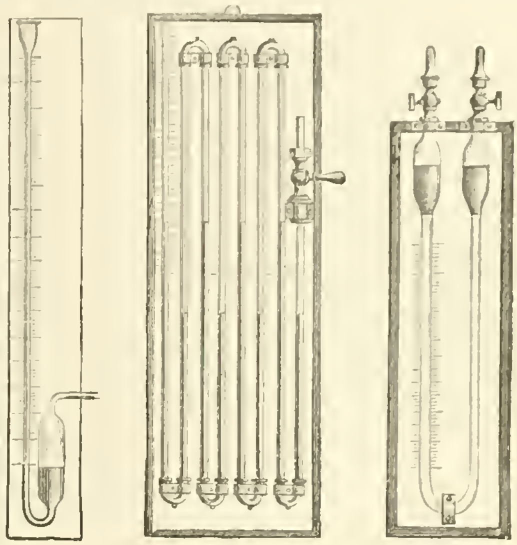


Fig. 1. Fig. 2. Fig. 3.

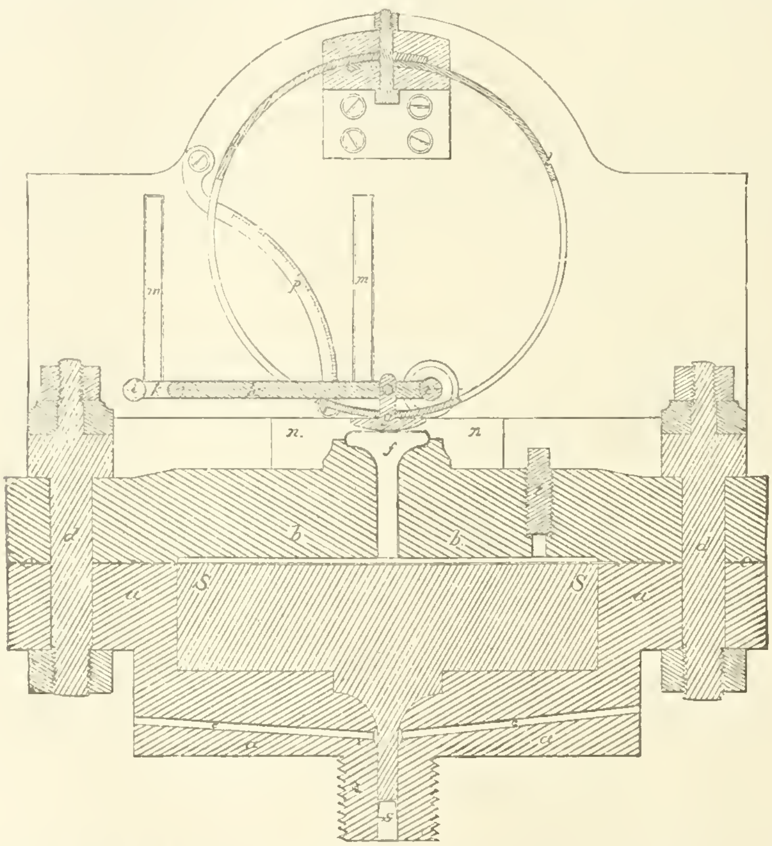
The various forms of manometer may be classified under three heads: 1, the open-air manometer, on the principal of the barometer; 2, the confined-air manometer,on the principle of Mariotte's instrument; and 3,the metallic-spring manometer. A simple open-air manometer consists of a glass tube, open at both ends, placed upright in a strong bottle of glass or iron the bottom of which contains mercury. The tube passes through a tight packing box in the neck. In the upper part of the bottle there is an orifice which admits compressed air, acted upon by steam or vapor, whose tension it is desired to measure. But this form cannot be used for high pressures. The multiple-branch manometer is a modification of the simple open instrument, and is constructed by bending a long tube, open at both ends, in a series of V-shaped flexures of from 20 to 40 inches in height, the number of flexures depending upon the pressure the instrument is liable to be subjected to. Columns of mercury, of equal height, being placed in the lower halves of the V-shaped legs, will indicate the pressure excited at one end of the tube, by the sum of the excess of height of the mercurial columns in alternate legs, or by multiplying the excess of height in one leg by the number of legs containing such excess. The system is fastened to a board or metallic plate, which at one side, near the last branch, is furnished with a graduated scale. The compressed-air manometer is simply a strong V-shaped tube closed at one end, while at the other is attached the pipe communicating with the gas or vapor whose tension it is desired to measure or ascertain. A portion of the flexure of the V contains mercury, and the space between it and the closed end is filled with common air. Now, according to Boyle's or Mariotte's law, a pressure exerted on the column of mercury sufficient to force the air into half the space it occupies at the normal atmospheric pressure, must become doubled, or 15 lbs. to the square inch must be added. Again, to compress the air into half the remaining space, 30 lbs., or double the pressure required for the reduction to the first half, must be added, making in all a pressure of four atmospheres for the reduction to one-fourth the original volume. It is evident, therefore, that a graduated scale, to exhibit the degrees of pressure, must have its spaces decrease from below upwards. The graduation is accomplished by means of an open-air multiple manometer. The metallic-spring manometer consists of an index traversing a graduated arc, and having applied to a spring connected with it—which may be in the form of a spiral—a piston actuated by the force of the gas or vapor in the boiler or steam-chamber. Fig. 1 represents the common open manometer; Fig. 2 is a compound open manometer: and Fig. 3 the differential manometer. The latter is used to register very small differences in pressure. It consists of a bent glass tube, placed upright and having a cylindrical bulb and a stop-cock on each arm. One bulb and both tubes, as far as zero of the scale, are filled with a mixture of alcohol and water. The other bulb and the remaining part of the corresponding tube are filled with a colored oil, of exactly the same specific gravity as the former mixture. A very slight difference in pressure is thus strikingly shown.

MANOMETRE A POUDRE.—An apparatus, designed by M. N. Korshunoff, of Paris, and embodying an application of the reversed hydraulic press to the measurement of powder pressures in gunnery. For the conversion of unwieldy weights and strains into amounts conveniently measurable, the inversion of the principle of the hydraulic press possesses the same advantages of compactness and simplicity that characterize that press in its normal applications. It meets with elegant illustrations in some forms of heavy weighing machines, in the Edward's instrument for registering "proof strains," etc., but certain practical difficulties have heretofore precluded its use in registering powder pressures. In the "manometre" under consideration, however, not only is this object claimed to have been attained, but a graphic record of the pressures, during the passage of the projectile through the bore, is traced in a moving band of paper. The apparatus is suitable for resolving the following problems: 1. To determine the force of expansion of powder, thus permitting the comparision of powders differing in their chemical composition and form. 2. To determine what is the best charge for a given caliber, according to the nature and quality of the powder. 3. To determine the different pressures of the gases in the bore during the departure of the projectile, and thus to decide upon the best dimensions for a cannon according to its charge and the nature and weight of its projectiles.

Referring to the drawing, we may make the following description of parts; *a*—A cylinder carrying a screw plug, which serves to attach the apparatus to the breech of the gun. *b*—Cover of the cylinder. *c*—Sheet of platinum forming the cylinder at its upper portion. *d*—Nuts securing the cover of the cylinder. *e*—Tubes for the escape of the gases which may be above the fitting S. *f*—Very thin capsule of platinum, inserted in a central aperture of the cylinder, fitting into the annular *cannelures* with which the wall of the aperture is furnished, and clinched upon the lower face of the cover. *g*—A small button resting on the capsule, actuating the spring *l*, and having a fork for the support of the lever *h*. *h*—Steel lever hinged at the point *v*, and carrying at its extremity *y*, a pin for raising another



lever *k*. *h*—Steel lever hinged at the point *i*, and carrying at its farther end a style or pencil *z*, limited in its movements by a curved guide *p*. *l*—Steel spring fixed to the plate *r*, perforated by a slot for the admission of the lever *h*, and by a second slot symmetrical therewith. This spring is traversed by the stem of the button *g*, and presses vertically upon the head of this same button. *m*—Brass rollers fixed in the plate *r*, and guiding the band of paper. *n*—Clock-work giving motion to the large toothed-wheel which transmits it to the roller *o*, against which is arranged a compressing cylinder, which effects the unrolling of the paper carried by the reel *ó*. *p* Circular guide for style or pencil. *r*— Brass plate fixed to the cover of the cylinder. *t* Screw closing the orifice which serves to introduce the mercury, oil, or alcohol into the capsule *f*, as well as between the cover and the sheet of platinum *e*.

Calling P the pressure upon a unit of surface exercised by the gases of the powder; *s* the surface of the piston receiving direct pressure of the gases; S the surface transmitting the pressure to the liquid; *p* the resulting pressure upon a unit of surface of the liquid, we shall have:

$$p = \frac{Ps}{S}$$

It is evident from this formula that the value of *p* can be reduced to any desirable amount by varying the ratio of the surfaces; that is to say, by increasing S or diminishing *s*.

Let us assume *s* equal to a circle of $0^{m}.005$ diameter $= 0^{cm}.19635$. S equal to a circle of $0^{m}.100$ diameter $= 78^{cm}.54$. P equal to 6500 kilogrammes to the square centimetre.

$$p = \frac{6500^{k} \times 0.19635}{78.54}$$, or $16^{k}.25$ per square centimetre. It becomes evident that the immense pressure of the gases of the powder thus manifests itself by a greatly reduced and perfectly measurable pressure: moreover, the space traversed by the piston is, in effect, almost nothing; the volume of liquid which penetrates into the capsule, supposing that the point in contact with the button rises one millimetre, will be equivalent in volume to a cone having for base a circle of about 20^{mm} diameter and 1^{mm} in height; so that

$$\frac{\pi D^2}{4} \times \frac{h}{3} = \frac{3.1416 \times 20^2}{4} \times \frac{1}{3} = 104^{mm}.75.$$

The surface S of the piston under the sheet of platinum being 7854^{mm} the elevation of this piston for the above displacement of volume will be $\frac{104.72}{78.54}$ or $0.^{mm}013$; that is to say, a trifle over one hundredth of a millimetre.

The apparatus is fixed upon the breech of the cannon, in a hole tapped for the purpose, communicating with the interior of the piece by an aperture of the same diameter as the piston *s*. The pressure of the powder gases acts upon the piston *s*, and distributes itself by the surface S upon the sheet of platinum, which transmits it to the liquid contained in the capsule *f*. This pressure causes the upper portion of the capsule to rise in a spherical form, raises, by this movement, the button *g*, which raises in its turn the lever *h*, thus making it describe an arc of a circle about the point *r*. In order to verify the pressures of the curve, it is necessary that, for reference, horizontal lines be previously traced by the pencil under different pressures, each maintained constant for a determinate time. For this purpose it is necessary, at a previous experiment, to arrange a recurved tube fixed by one of its arms to the screw plug of the cylinder. This tube, filled with liquid, should terminate at its other extremity in a stuffing box, traversed by a stem, upon which graduated pressures can be maintained by means of a lever, which should be hinged by one end to some fixed point, should press upon the stem, and should be capable of being loaded at its other end with successive weights corresponding to the pressures which it is desired to exercise upon the piston.

Each pressure being maintained for an instant, the pencil traces during that time a horizontal line indicating the height which corresponds to that pressure. These different heights, when compared, with the curve, indicate exactly the pressures existing during the departure of the projectile. It is contemplated that in all the above mentioned experiments the cannon be mounted on some mechanical device which shall neutralize the effect of recoil; such, for instance, as that of M. l'Admiral Labrouse. This apparatus may, however, be employed for the following uses; 1. To measure hydraulic pressures. 2. To measure the pressures required to liquefy gases. In these applications it will be desirable to increase the diameter of the piston *s*, and to diminish that of the piston S. The sheet of platinum may be replaced by a diaphragm of gutta-percha, thus reducing the cost of the machine, and, in fact, the clockwork. The paper and the pencil may be omitted, their place being supplied by an index moving upon a dial-plate, as is represented in the drawing of the hydraulic manomètre.

MANTA.—A water-proof canvas, five feet square used as a pack-cover. It serves to protect the loads in transit, during damp and rainy weather; and is used for the shelter of the stores and the packers, when in camp.

MANTEAU.—A term, literally signifying a cloak, but frequently used among the French to express the covering that Hussars or Light Infantry carry for the double purpose of shielding their bodies from the inclemencies of the weather in outposts, etc., and for spreading over their heads, by means of poles, when they occasionally halt, and take a position. The *Manteau d'Armes* was a round shield much used during the fifteenth and sixteenth centuries.

MANTILLIS.—A kind of shield, anciently fixed upon the tops of ships as a cover for archers.

MANTLE.—A long flowing robe, worn in the Middle Ages over the armor, and fastened by a fibula in front, or at the right shoulder. The mantle is an important part of the official insignia of the various orders of knighthood. Ladies of rank wore similar mantles, in many instances decorated with heraldic charges, in which case the mantle bore either the impaled arms of the lady and her husband or her husband's arms only. A number of examples may be seen in monumental effigies.

MANTLET.—A shield placed over the mouth of an embrasure to prevent musketry bullets and fragments of shells from flying through and injuring those serving the piece. A hole in the lower part allows the muzzle of the piece to pass through into the embrasure when it is to be fired. The size of

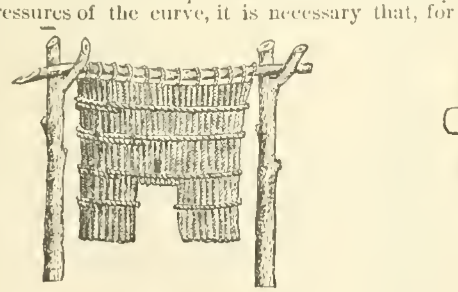


Fig. 1.

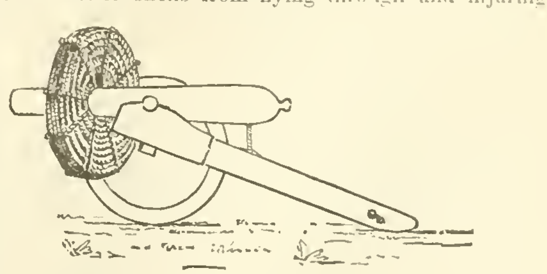

Fig. 2.

these openings will depend upon the dimensions of the piece. Rope is the best material for constructing mantlets. The usual size of a mantlet is 5 feet high, 4.5 feet across, and 4 inches thick. For siege guns the opening is 1.6 feet high by 1.3 feet across. Three-inch rope is a suitable size, it is laid in three or five thicknesses, each of the two outer layers being in one piece bent vertically.

The inner layers are bent and laid horizontally, and the whole well tied together. The mantlet is hung on a horizontal pole supported by forked uprights set in the ground, on each side of the embrasure, at the foot of the interior slope, as shown in Fig. 1.

The elasticity thus afforded by the supports greatly increases the resistance of the mantlet. A small hole or slit is pierced in the mantlet to allow the piece to be aimed.

Mantlets of this size weigh about 400 pounds.

A small ring mantlet of rope, shown in Fig. 2, placed upon the chase of the gun is sometimes used.

When rope cannot be obtained, one of similar shape may be made of wood.

Mantlets may be made of wood or of iron, or of wood and iron combined. Those of the latter kind furnished for the siege of Yorktown were made of two thicknesses of $\frac{1}{4}$-inch wrought-iron spiked to 3-inch oak plank. On the head was a 2-inch square iron bar riveted to the edge of the iron plates, against which the oak planks abutted. The ends of this bar projected 6 inches, and were rounded, serving as supports to rest upon upright stakes or timbers standing against the interior slope of the parapet. See *Gun-shelters*.

MANTLING.—A heraldic ornament depicted as hanging down from the helmet, and behind the escutcheon. It is considered to represent either the cointise, an ornamental scarf which passed round the body, and over the shoulder; or the military mantle, or robe of estate. When intended for the cointise, it is cut into irregular strips and curls of the most capricious forms, whose contortions are supposed to indicate that it has been torn into that ragged condition in the field of battle. When the mantling is treated as a robe of estate, the bearings of the shield are sometimes embroidered on it. A mantling adjusted so as to form a background for the shield and its accessories, constitutes an *Achievement of Arms*. It is not till the latter end of the 14th century that the mantling appears as a heraldic ornament on seals. In British Heraldry, the mantling of the Sovereign is of gold lined with ermine; that of Peers, of crimson velvet lined with ermine. Knights and gentlemen have generally crimson velvet lined with white satin; but sometimes the livery colors are adopted instead, as is generally the practice in Continental Heraldry. See *Lambrequin*.

MANSLAUGHTER.—The unlawful killing of another without malice, express or implied. Manslaughter is either voluntary, i. e., where there was an intent to commit the injury; or involuntary, where there was no such intent. It differs from murder in its absence of malice, and, as it is supposed to be committed in hot blood, no person can be an accessory before the fact. Among cases of homicide which constitute a manslaughter may be mentioned killing a person by gross negligence, though in the discharge of a lawful act; killing a person who has given great provocation; and killing an officer acting without or beyond his authority, though this may also be excusable homicide. The killing of an officer acting within his legal authority is murder. The provocation above-mentioned must be immediate, not remote; and though proof of provocation sufficiently repels the presumption of malice which the law attaches to every case of homicide, it is not sufficient to lower an offense from murder to manslaughter, if express malice be made out. In most of the United States manslaughter is divided into different degrees, punished with longer or shorter terms of imprisonment.

MANUAL.—A prescribed exercise by means of which soldiers are taught to handle and use their weapons. The *Manual of Arms*, the *Manual of the Piece*, the *Manual of the Sword*, etc., are explained in detail in the Tactics and Regulations of an army.

MANUAL OF ARMS.—An exercise with the musket

or rifle, through which recruits are drilled, to give them a free use of their limbs, and of the weapon regarded merely as a pike. It comprises the first course of instruction after the rifle has been placed in the learner's hands.

In the United States service, the piece is in the right hand: the barrel nearly vertical, and resting in the hollow of the shoulder, the guard to the front: the arm hanging nearly at its full length, near the body, the thumb and forefinger embracing the guard, the remaining fingers closed together and grasping the stock just under the hammer, which rests on the little finger. This is the position of *carry arms*, the position is represented in Fig. 1.

Recruits often have defects in the conformation of the shoulders, breast, and hips. On first bearing arms they are liable to derange their positions, by lowering the right shoulder and the right hand, or by sinking the hip and spreading the elbows. The Instructor endeavors to correct these faults, so that the position of the pieces in the same line may be uniform, without constraint to the men.

The Instructor sees that the piece at a carry is neither too high nor too low; if, too high, the right elbow will spread out, the soldier will occupy too much space in his rank and the piece be unsteady; if too low, the files will be too much closed, the soldier will not have room enough to handle his piece with ease, the right arm will become fatigued, and will draw down the shoulder.

cruits progressively, after becoming familiar with handling the piece. As the motions relative to the cartridge, the fixing and unfixing of the bayonet, cannot be executed at the rate prescribed, nor even with a uniform swiftness, they are not subjected to the cadence. The Instructor, however, causes these motions to be executed with promptness and with regularity. As soon as the recruits thoroughly understand the several motions, they execute them alternately with and without the numbers, in order to attain the proper cadence, and to become perfect in the mechanism. The piece is habitually carried at half-cock.

To avoid repetition the following rules in the Manual of Arms are *general:*

1. In resuming the "carry" from any position in the manual, the motion next to the last concludes with the left hand at the height of the shoulder, fingers extended and joined, the thumb close to the forefinger, back of the hand to the front, the elbow close to the body, the right hand embracing the guard with the thumb and forefinger.

2. In all positions of the left hand at the lower band, except *charge bayonet* and *arms port*, the thumb is extended along the barrel, the end of it touching the lower band. In *charge bayonet* and *arms port* the thumb clasps the piece immediately below the lower band.

3. In all positions of the piece in front of the center of the body, the barrel is to the rear, and vertical.

16

The Manual of Arms is taught to four men, placed at first in one rank, elbow to elbow, and afterwards in two ranks. To make the mechanism better known, the execution of each command is divided into motions. The rate or swiftness of each motion in the manual of arms, with the exceptions herein indicated, is fixed at the ninetieth part of a minute. The same interval of time should separate the command of execution from the preparatory command. The Instructor at first looks more particularly to the execution of the motions without requiring a nice observance of the cadence, to which he brings the re-

The drawings show the various positions of the soldier and piece in executing the Manual of Arms, authorized for the United States Army. See *Aim, Arms Port, Carry Arms, Charge Bayonet, Fix Bayonet, Load, Order Arms, Parade Rest, Present Arms, Rest on Arms, Reverse Arms, Right Shoulder Arms, Secure Arms, Support Arms, Trail Arms*, and *Unfix Bayonet*.

MANUAL OF THE PIECE.—The term piece, as here used, applies to cannon, whether gun, howitzer, or mortar. As a matter of convenience, it is also used to designate both cannon and carriage when the cannon is mounted. The men employed in the service of artillery are called artillerymen. Those for a single piece constitute a *gun-detachment*, and vary in number with the size and kind of piece. The *detachment* is composed of two non-commissioned officers, and from two to ten privates. The senior non-commissioned officer is called *chief-of-detachment*; the other *gunner*. The privates are called *cannoneers*. The detachment is formed in double rank, and told off from the right as follows: No. 1 is on the right of the rear rank; No. 2 in front of No. 1; No. 3 on the left of No. 1; No. 4 on the left of No. 2; the other numbers follow in the same order, even numbers in the front, odd in the rear rank. When, by facing about, the front becomes the rear rank, the numbers of the cannoneers do not change.

The service of the piece consists of all the operations required in loading, pointing, and discharging it.

To avoid repetitions, the following general rules are noted collectively:

1. The implements and equipments required for a piece are taken to it by the detachment when going to the exercises, or they may be placed there previous to that time. They are removed, at the conclusion of the exercises, by the same means, and returned to their proper places in the store-house. It is the especial duty of the chief-of-detachment to see that all that appertains to his piece is complete and in good order.

2. When the equipments are distributed, the gunner buckles the strap of his pouch around his waist, wearing the pouch in such position as to interfere as little as possible with his movements. The cannoneer who wears it, buckles on the primer-pouch in like manner. The gunner removes the vent-cover, and clears the vent with the priming-wire. Cartridge-pouches are carried suspended from the left shoulder to the right side.

3 In sponging or in ramming, the knee on the side toward which the effort is made is always bent, the other straightened. The weight of the body is added, as much as possible, to the effort exerted by the arms. When the sponge fits so tightly as to be difficult to move in the bore, Nos. 1 and 2 may use both hands in inserting and withdrawing it. Cartridges are inserted into the bore, bottom foremost and seams to the sides. All projectiles having fuses are inserted into the bore so that the fuse shall be towards the muzzle.

4. A primer is prepared for insertion in the vent by holding it between the thumb and forefinger of the left hand: the lanyard, wound upon its handle, is held in the right hand, the hook by the thumb and forefinger: the hook is attached by passing it upward through the eye of the primer; the hook and primer, thus attached, are held by the thumb and forefinger of the right hand; the primer is pushed into the vent by the thumb. After the primer has been inserted in the vent, the cannoneer who fires the piece drops the handle, allowing the lanyard to uncoil as he steps back to the position from which he is to fire; holds the handle, with the cord slightly stretched, passing between the middle fingers of his right hand, back up, and breaks to his left and rear a full pace with the left foot, the left hand hanging naturally by his side.

5. In aiming guns and howitzers, the gunner places the breech sight in its seat or socket, and aims through it; gives the proper direction by causing the trail to be moved, commanding *left* or *right*, tapping, at the same time, on the right side of the breech for the trail to be moved to the left, and on the left side for it to be moved to the right. The cannoneers at the trail will closely observe the motions of the gunner. With mortars, the gunner signals, with his hands, the direction in which he wishes the carriage moved. When the piece is pointed, the gunner raises both hands as a signal; the cannoneers moving the piece then unbar and resume their posts.

6. At the command *fire*, the cannoneer who discharges the piece turns his face from it, pulls the lanyard quickly, but steadily, and fires. Immediately after the discharge he resumes the erect position, rewinds the lanyard upon its handle, returns it to his pouch, and resumes his post. The gunner, after pointing, goes where he can observe the effect of the shot; when he resumes his post. At the command, *cease firing*, pieces that are loaded remain so until further orders; those that are partly loaded—if with the cartridge only—the cartridge is rammed home; if the projectile has been inserted, it likewise is rammed home. In both cases the priming-wire is left in the vent, as an indication that the piece is loaded. If the piece is not loaded it is sponged out. All the cannoneers resume their posts.

7. The habitual post of the chief-of-detachment is facing the piece and two yards in rear of the platform or rearmost part of the carriage. He has, under the instructor, or officer immediately over him, general supervision of all duties performed by his detachment. During firings he looks after the supply of ammunition, and sees that those engaged in preparing and serving it to the piece perform their duties properly. All ammunition must be prepared for firing at the service magazine. Projectiles should be carefully cleaned of all rust, dirt, or protuberances liable to cause them to stick, or injure the bore.

8. In the service of a battery of several pieces, the pieces are designated Nos. 1, 2, 3, etc., from right to left: these numbers are independent of the *permanent* numbers assigned to pieces in a work. In directing the pieces to be fired, they are always designated by their *battery* numbers; as, *Number one*—FIRE; *Number two*—FIRE, etc. When the wind comes from the right, the firing should commence on the left, and reciprocally. Under the fire of the enemy, the men are directed to cover themselves by the parapet or traverses as much as may be consistent with the execution of their duties.

9. Previous to proceeding with any exercise with the pieces, and frequently at other times during the exercises, the instructor, assisted by the other officers, will explain to the men the nomenclature of everything appertaining thereto; the application and use of the various parts, machines and implements used; the names and use of the different parts of the work adjacent to the piece: the kinds of ammunition used; charges of powder; kinds of fire; and, generally, all matters that assist in making the men efficient artillerists.

10. In aiming, first get a clear view of the object, and see that the piece is approximately in the line of fire before looking through the sights, and if the object be not in the line, instantly give the command to move the trail to the right or left. Always aim quickly, as the eye will not then become wearied. The prop upon which the sponge and rammer are supported is a low trestle, or simply a block of wood sufficiently high to prevent the sponge taking up dirt from the ground. The rammer is always laid on the side nearest the piece. To prevent the projectile from starting forward, guns should be given at least five degrees elevation previous to being run into battery, and running into battery should be done so as to prevent sudden jar against the hurters.

11. In all exercises for instruction, duties should be performed as nearly as possible as in actual service, and not by pretense only. To do this, in the service of the piece a dummy cartridge should be used, together with actual projectiles. The cartridge may be made of canvas or stout gunny-sacking, filled to the proper weight with coal broken to the size of the powder used for the piece. A worm serves for withdrawing the cartridge. A strong lanyard attached to the fuse-plug will serve to withdraw the projectile. The free end of the lanyard remains out of the muzzle as the projectile is pushed home. See *Artillery*.

MANUAL OF THE PISTOL.—To draw the pistol the Instructor commands: 1. DRAW; 2. PISTOL. At the command *draw*, unbutton the flap of the holster with the right hand, and grasp the stock, the back of the hand to the body. At the command *pistol*, draw and raise the pistol, the hand holding the stock with the thumb and last three fingers, the forefinger over the guard, guard to the front, barrel vertical, elbow near the body, the wrist as high as the right shoulder and six inches in front of it.

To LOAD the pistol, lower into the left hand, the barrel pointing to the left and front, and downward at an angle of forty-five degrees, half-cock the pistol (cock it if necessary); grasp the stock with the right hand. (Two) Open the chamber, if necessary eject the cartridge-cases, take a cartridge from the cartridge-box with the right hand, and hold it near the chamber between the thumb and first two fingers. (THREE.) Place the cartridge in the chamber, pressing it home with the thumb; continue to insert cartridges until the chambers are loaded: close the chamber, carry the right hand to the stock, and resume the position of *raise pistol*.

At the command READY, cock the pistol with the thumb of the right hand. To AIM, lower the pistol to the front, the arm about three-fourths extended, forefinger upon the trigger; close the left eye and sight with the right. To FIRE, press the forefinger against the trigger, fire, and take the position of *raise pistol*. To return pistol, the instructor commands: 1. *Return*, 2. PISTOL. Drop the muzzle, insert the pistol in the holster, back of the hand to the body, button the flap, and drop the hand by the side.

The squad being in the position of *raise pistol*, the instructor commands: 1. *Inspection*, 2. PISTOL, passes along the rank, and examines the pistols. To inspect the pistol minutely, he takes it in his hands, and then returns it to the recruit, who grasps it at the stock and takes the position of *raise pistol*.

MANUAL OF THE SABER. The manual of the saber is taught in the following order, and by the following commands: 1. *Draw*, 2. SABER. At the command *draw*, unhook the saber with the thumb and first two fingers of the left hand, thumb on the end of the hook, fingers lifting the upper ring: pass the right hand through the saber-knot, and push the sliding loop up to the wrist with the left hand: grasp the scabbard with the left hand at the upper band, bring the hilt a little forward, seize the gripe with the right hand, and draw the blade six inches out of the scabbard, pressing the scabbard against the thigh with the left hand, Fig. 1. At the command *saber*, draw the saber quickly, raising the arm to its full extent, at an angle of about forty-five degrees, the saber in a straight line with the arm, and make a slight

Fig. 1.

Fig. 2.

Fig. 3.

pause: hook up the scabbard with the thumb and first two fingers of the left hand, thumb through the upper ring, fingers supporting it: and drop the left hand by the side; at the same time, bring the back of the blade against the hollow of the shoulder, the blade vertical, the arm nearly extended, the left side of the gripe with the thumb against the thigh, the little finger on the back of the gripe. *This is the position of carry saber dismounted*, and is represented in Fig. 2. 1. *Present*, 2. SABER. Carry the saber vertically to the front, raising the hand as high as the neck, and six inches in front of it, edge to the left, the thumb extended on the back of the gripe, little finger by the side of the others, Fig. 3. 1. *Inspection*, 2. SABER. Take the position of *present saber*. (Two.) Turn the wrist outward to show the other side of the blade, the edge to the right; make a slight pause, and then turn the wrist back. (Three.) Resume the carry. 1. *Return* 2. SABER. At the command *return*, take the position of *present saber*; at the same time unhook and lower the scabbard with the left hand, and grasp it at the upper band. At the command *saber*, carry the right hand opposite and six inches from the left shoulder; lower the blade and pass it across and along the left arm, the point to the rear; turn the hand slightly to the left, fixing the eyes on the opening of the scabbard, and insert the blade six inches in the scabbard. (Two.) Return the blade, and free the wrist from the saber-knot; turn the head to the front and drop the right hand by the side; at the same time hook up the saber with the left hand, turning the saber toward the body, guard to the rear, and drop the left hand by the side.

MANUAL OF THE SWORD.—The Manual of the Sword in the United States Army, is as follows: 1. DRAW, 2. SWORDS. At the command *draw*, unhook the sword with the thumb and first two fingers of the left hand, thumb on the end of the hook, fingers lifting the upper ring; grasp the scabbard with the left hand at the upper band, bring the hilt a little forward, seize the gripe with the right hand, and draw the blade six inches out of the scabbard, pressing the scabbard against the thigh with the left hand. At the command *sword*, draw the sword quickly, raising the arm to its full extent, at an angle of about forty-five degrees, the sword in a straight line with the arm, and make a slight pause: hook up the scabbard quickly with the thumb and first two fingers of the left hand, thumb through the upper ring, fingers supporting it, and drop the left hand by the side: at the same time bring the back of the blade against the shoulder, the blade vertical, back of the gripe to the rear, the arm nearly extended, the thumb and forefinger embracing the gripe, the left side of the gripe with the thumb against the thigh, the other fingers extended and joined in rear of the gripe. *This is the position of carry sword.* Officers mounted unhook the sword before mounting, and, in the first motion of *draw sword*, reach with the right hand over the bridle-hand, and without the aid of the bridle-hand draw the sword as before; the right hand in the *carry* rests on the right thigh. When the sword-knot is worn, the right wrist may be placed in it in the first motion, before grasping the gripe. 1. *Present*, 2. Sword. At the command *present*, carry the sword vertically, and promptly to the front, raising the hand as high as the neck and six inches in front of it, the thumb on the back of the gripe, back of the gripe to the right, elbow close to the body. At the command *sword*, drop the point of the sword by extending the arm, so that the right hand may be brought to the side of the right thigh, the back of the hand down, the blade inclining downward and to the front.

In rendering honors with troops, officers execute the first motion of the salute at the command *present*, the second motion at the command *arms*. The sword is returned to the *carry* at the command, 1. *Carry*, 2. ARMS. When arms are *ordered*, the officers and non-commissioned staff drop the point of their swords, the back of the hand invariably up. At *parade rest*, they clasp the hands directly in front of the centre of the body, the left hand uppermost, the point of the sword between the feet.

In marching in double time, the sword is carried diagonally across the breast, edge to the front, the point in front of and at the height of the left shoulder; the left hand steadies the scabbard. At funeral ceremonies, the sword is reversed under the right arm, the left hand clasping the blade behind the back. When the escort *rests on arms*, the officers stand at *parade rest*, inclining the head. Officers on all duties under arms, draw and return sword without waiting for any command. All commands to soldiers under arms are given with the sword drawn. In route marches the sword is carried in the scabbard. The non-commissioned staff and sergeants with swords drawn salute by the first motion of *present sword*, as explained for officers. This position is taken at inspection, and the wrist turned outward to show the flat of the sword toward the face. 1. *Return*, 2. Sword. At the command *return*, take the position of the first motion of *present sword;* at the same time unhook and lower the scabbard with the left hand, and grasp it at the upper band. At the command *sword*, carry the right hand opposite and six inches from the left shoulder; lower the blade and pass it across and along the left arm, the point to the rear; turn the head slightly to the left, fixing the eyes on the opening of the scabbard, and insert the blade six inches in the scabbard, (Two.) Return the blade, free the wrist from the saber-knot (if inserted in it), turn the head to the front, and drop the right hand by the side; at the same time hook up the sword with the left hand, turning the sword toward the body, the guard to the rear, and drop the left hand by the side. Officers mounted return swords without using the left hand; the sword is hooked up on dismounting

MANUBALLISTE.—A cross-bow. There were two kinds used in the reign of Henry VIII. viz., the *latch* which was used for quarrels and the *prodd* for bullets.

MAP.—A map is a delineation, on a plane, of some portion of the surface of a sphere, celestial or terrestrial, on which the objects intended to be shown are traced, whether stars or towns, mountains, etc. Terrestrial maps are termed *geographical*, when they refer to the land; and *hydrographical* maps, or *charts*, when they delineate the shores of the sea. A perfect representation of a country, with all its parts in true proportions and relative positions, may be made on a globe; but since the surface of the earth is spherical, it is not possible so to delineate any large portion of it on a plane as to retain these properties. Hence geographers resort to different methods of representation called projections, which are of two kinds—either real perspectives from different points of view, or approximate developments. The five principal projections are—the orthographic, the stereographic, the globular, the conical, and the cylindrical, or Mercator's In the first of these, the flat surface on which the map is drawn is supposed to pass through the center of the earth, and according to the distance of the eye, the projection is either of the first, second, or third kind. In the *orthographic*, the eye is assumed to be at an infinite distance from the center of the earth, so that all rays of light proceeding from every point in its surface are parallel and perpendicular. From the nature of this projection, it is evident that while the central parts of the hemisphere are almost accurately represented, towards the circumference the countries are crowded together and diminished in size. On this account it is of little use for geographical, though of considerable value for astronomical purposes. In the *stereographic*, the eye or point of projection is assumed to be placed on the surface of the sphere opposite the one to be delineated. If the globe were transparent, the eye would then see the opposite concave surface. Contrary to the orthographic, this method contracts the center of the map, and enlarges it towards the circumference. Owing to the unequal area of the divisions, and the difficulty of finding the true latitude and longitude of places, this projection is not much employed. In order to rectify the opposite effects of the two preceding, the globular projection, a modification of the two, is generally adopted. If we suppose the eye to be removed from the surface to a distance equal to the sine of 45° of the circumscribing circle, the projection is called globular. In other words, if the diameter of the sphere be 200 parts, it must be produced 70 of these parts in order to give the point of projection. All meridians and parallels in this projection are in reality elliptical curves, but as they approach so nearly to being circular arcs they are very rarely shown otherwise.

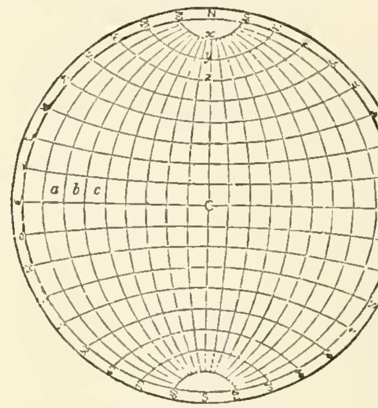

Fig. 1.—Globular, or Equidistant Projection of a Hemisphere.

The construction of the globular or equidistant projection is as follows (Fig. 1). Describe a circle NESW, to represent a meridian, and draw two diameters, NCS and WCE, perpendicular to each other, the one for a central meridian, the other for the equator. Then N and S will represent the north and south poles. Divide each of the quadrants into 9 equal parts, and each of the radii CN, CE, and C also in 9 equal parts. Produce NS both ways, and find on it the centers of circles which will pass through the three points 80 *x* 80, 70 *y* 70, etc., and these arcs described on both sides of the equator will be the parallels of latitude. In like manner, find on WE produced, the centers of circles which must pass through *a*, *b*, *c*, and the poles. Having selected the first meridian, number the others successfully to the east and west of it. A map in this way may be constructed on the rational horizon of any place. The impossibility of getting a perfect representation of special parts of the sphere by any of the previous methods, led to the desire for others less defective. Of all solid bodies whose surfaces can be accurately developed or rolled out upon a plane without alteration, the cone and cylinder approach nearest to the character of the sphere. A portion of the sphere between two parallels not far distant from each other, corresponds very exactly with a like conical zone; whence it is that conical developments make the best projections for special geographical maps, and even with some modifications for large portions of the globe.

Since all meridians on the globe are great circles passing through the poles, the north and south points at any places correspond with the poles of the earth. The east and west points, however, are indicated by a line at right angles to the meridian, and do not, except at the equator, correspond with those of the earth. In all the projections hitherto described, the direction either of the north and south, or of the east and west points, is represented by a curved line, so that on such a map the course of a vessel would almost always be laid down in a curve, which could only be described by continually laying off from the meridian a line at an angle equal to that made with the meridian by the point of the compass at which the ship was sailing. If the vessel were to steer in a direct N. E. course by one of the previous projections, she would, if land did not intervene, describe a spiral round, and ultimately arrive at the north pole; therefore, the mariner requires a chart which will enable him to steer his course by compass in straight lines only. This valuable instrument is supplied by Mercator's chart, in which all the meridians are straight lines *perpendicular* to the equator, and all the parallels straight lines *parallel*

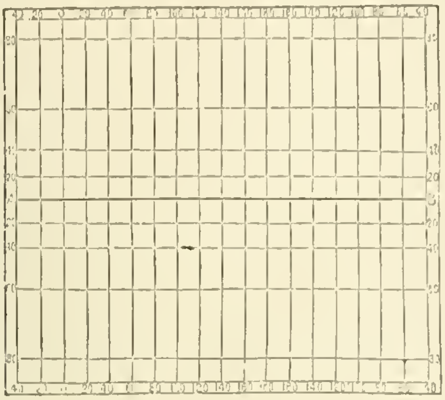

Fig. 2.—Mercator's Projection.

to the equator. It is constructed as follows (Fig. 2): A line AB is drawn of the required length for the equator. This line is divided into 36, 24, or 18 equal parts, for meridians at 10°, 15°, or 20° apart, and the meridians are then successively drawn through these points perpendicular to AB. From a table of meridional parts (a table of the number of minutes of a degree of longitude at the equator comprised between that and every parallel of latitude up to 89°), take the distances of the parallels and of the tropics and arctic circles from the equator, and mark them off to the north and south of it. Join these points, and the projection is made. This projection, of course, does not and is not intended to give a natural representation of the earth, its effect being to exaggerate the polar regions immensely. The distortion in the form of countries and relative direction of places, is rectified by the degrees of latitude being made to increase proportionably to those of longitude. This is the only map which gives an unbroken view of the whole surface of the earth. The term *map* is specially applied to representations of land, or land and water together; while that of *chart* is limited to the coast and water surface only, showing currents, rocks, anchorage, light-houses, harbors, soundings, and other objects of importance.

A geographical map proper is a general map of the world, or of a large extent of country. A topographical map differs from it in being limited in area, and much more detailed. The ordnance survey of Britain is a good example of a topographical map. Besides purely geographical and topographical maps, others are constructed for special purposes, which may be physical, political or civil, military, statistical, historical, etc. In order to construct a map and to determine accurately the positions of places on it, a knowledge of two elements is essential—viz., latitude or distance from the equator, and longitude or distance east or west of the meridian adopted. Every map, whatever its dimensions, is in some definite relation to the actual size of the globe. This relation is indicated by a scale—a graduated line showing, by its divisions, the number of miles corresponding to any space measured on the map. The scales of geographical maps range from about 800 m. to an inch (for maps of quarters of the globe) to 10 miles to an inch; those of topographical maps range from 1 inch to 25 inches to a mile, the largest topographical maps we have, admitting of the most minute details. The ordnance survey of Great Britain is on the scale of $\frac{1}{63360}$ of nature, or 1 inch of paper to one mile of surface. A recent improvement introduced into our best maps is that of printing the water-courses in blue ink, making the orography and skeleton of every country stand out in clear relief, thus avoiding the confusion resulting from all the lines being black.

MARAUDING.—This word common, under orthographic variations, to most of the European languages, and, probably, of identical root with the verb "to mar" means irregular plunder or violence offered to the inhabitants of a country by the individuals of an army. In all armies where discipline is maintained, marauding is, at least professedly, punished by death; the Provost Marshal having power to inflict that penalty summarily on all offenders taken in in the act.

MARCASITE.—Sulphurous pyrites, which superseded the *match*, in discharging fire-arms. The pyrites when struck, ignited, and fired the charge.

MARCEL-DEPREZ REGISTER.—In order to replace the induction-spark as means of registration, Mr. Marcel-Deprez had recourse to electro-magnets whose armature, retracted by a counteracting spring, was furnished with a pen which rested on the surface of the cylinder of the chronograph, this pen being so arranged as to be displaced in the direction of a generatrix during the movement of the armature. As a result of this arrangement, the pen traced on the

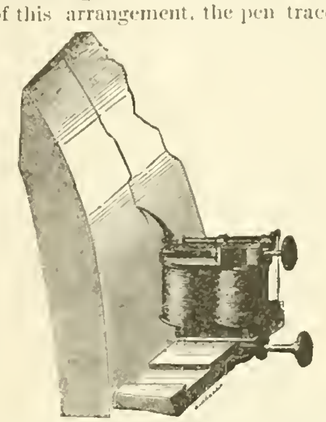

Fig. 1.

cylinder in motion a given circumference so long as the current passing in the electro-magnet of the register kept the armature attracted; when the current was broken, the pen, drawn laterally by the armature, traced a hook, and connected with the preceding circumference by a curve, the form of which depended on the relative velocities of the cylinder and the pen, and finally, the armature being arrested by a catch which limits its course, the pen traced a new circumference a little distant from the preceding, Fig. 1. If the current was re-established at the end of a certain time, the armature was attracted anew, the pen traced a second hook, and was replaced on the original circumference of which it continued the trace. The two hooks obtained indicate the instants when the breaking and the closing were produced. The employment of electro-magnets as registers was not new; these devices had been applied since 1844 to the Wheatstone and Breguet chronographs, and Regnault employed them also with the chronograph that he used in his celebrated experiments on the measure of the velocity of sound. If we were limited to the reproduction of the arrangements adopted by these different experiments, it would be impossible to obtain a precision susceptible of competing with the employment of the induction-spark. The usual electro-magnets, similar to those used in telegraphy, have, in fact, a functional retardation which is far from unimportant. If we seek for these apparatus, employing, for example, the time that elapses between the moment when the current which animates an electro-magnet is broken and that when its armature is set in motion under the action of the counteracting spring which retracts it, we find that this time, which may be called retardation of disconnection, attains and often exceeds a hundredth of a second. The time that elapses between the moment when the current is re-established, and the armature returned to its original place is greater still; it may be called retardation of connection. The sum of these two retardations forms the time lost between two successive signals, and limits the number of signals to be required in a second by a given electro-magnetic register. Hence, we see that an ordinary electro-magnet could scarcely give more than 40 signals in a second.

In order that we might count on the precision of these signals, it would be necessary, besides, that the functional retardations, or at least the retardations of disconnection, should be absolutely constant for the same register. If this condition was fulfilled, we could, in fact, notwithstanding their slow action, obtain a great precision of measure in the valuation of a difference of durations; we could also measure, with equal precision, portions of time smaller than the time lost by the apparatus, by using two electro-magnets for registering the two signals which determine the time to be measured, provided that we had the means of determining exactly the supposed constant retardation of each apparatus. This means exists, as we shall see further on; but the retardation of disconnection is unfortunately not constant in the ordinary electro-magnets. This retardation, is composed of two parts: a retardation in the cessation of the magnetic attraction, which retardation is owing to the phenomenon usually designated by the name of remaining magnetism, and a retardation owing to the setting in operation the mechanical organs of registration: this latter retardation can be made constant, but it is not the same with the retardation of demagnetization, which depends on several various circumstances, and especially on the intensity of the current, which may vary with the resistance of the

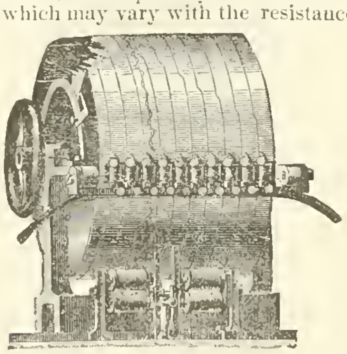

Fig. 2.

circuit or the activity of the battery; the retardation depends also on the manner in which the current is broken. The variations of the retardation or demagnetization, although very trifling in themselves, would, by using the usual electro-magnets, have attained limits greater than the degree of precision sought would allow; it was necessary, then, to find the means of regulating the working of the devices. The course to pursue naturally presented itself: it was necessary first of all to seek to reduce, in absolute value, the retardation of demagnetization, because thus the variations of this retardation must be reduced in the same proportion, while at the same time the apparatus could be made sufficiently rapid in its operation to follow, in most cases, the succession of the phenomena to be observed. The employment of these small registers, formed of diminutive electro-magnets, like those which are now used in some special apparatus, such as the electric toys of Mr. Trouve, must, after what is known of the working of these toys, secure the first improvement. Another motive led to the employment of very small apparatus, or at least of very small movable pieces; it was the necessity for accelerating as much as possible the movements of the tracing-pen.

In ordinary electro-magnets, where the counteracting force applied to the armature, as well as the attractive force which is opposed to it, are comparable to the weight of this armature, the latter moves with only a very feeble acceleration, at the disconnection as well as the connection. The result is that if the rotatory movement of the cylinder on which the pen, guided by this armature, makes its trace is a little fast, the traces obtained unite tangentially by a lengthened curve with the circumferences described by the pen in its two extreme positions, so that it is very difficult to catch the line at the precise moment when the pen is set in motion. If, on the contrary, the pen is animated by a rapid movement, so that its velocity is promptly comparable to that of the cylinder, the lines that it leaves are cleanly detached from the extreme circumferences and give signals easy to distinguish with precision. Now, this result can be obtained by employing very small armatures, so constructed that the inertia of the movable pieces develops only a very feeble resistance to the movement, and so arranged that the energy exerted on them by the counteracting spring that impels them may be considerable in proportion to the masses set in motion. These considerations induced Mr. Marcel-Deprez to establish very small electro-magnetic registers, furnished with still smaller armatures, that the magnetic attraction might be relatively great in proportion to the mass of these armatures, and to employ long and light pens, placed, as well as the movable masses, as near as possible, or practicable, to the axis of rotation, in order to reduce to a very minimum the moment of inertia of the system. Moreover, in order to diminish the retardation of disconnection, Mr. Marcel-Deprez provided his registers with a means of regulating the counteracting force applied to the armature in such a manner as to cause this force to form nearly an equilibrium with the magnetic attraction, so that disconnection takes place as soon as the attraction becomes slightly reduced and instantly after the rupture of the electric current. The forms given to the Marcel-Deprez registers, in departing from these principles, were very variable, and we will content ourselves with describing some especially applicable to the chronograph and other ballistic apparatus.

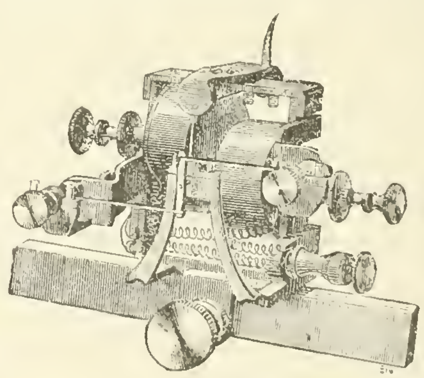

Fig. 3.

Fig. 1, represents one of the registers placed against the cylinder of a modified Schultz chronograph, and Fig. 2, represents the registers arranged side by side 10 in number, on a horizontal form fixed in front of the revolving cylinder: they are mounted each on a little screw-slide on which a counteracting spring acts, and which allows each pen to come into contact with the cylinder or to withdraw from it at will. A general lever movement of the form removes at will all the pens at the same time, or, on the contrary, brings them together in contact with the cylinder. Each electro-magnet, Fig. 1, is composed of two helices of about 12mm (0.4724 inch) diameter, placed vertically in a plane normal to the cylinder, and furnished with polar masses, relatively strong; between them is fixed a small armature of prismatic form, which weighs only a few milligrammes, and which, being thus immersed in the magnetic field, is subjected to an attractive force which can be raised to 10 000 and 20,000 times its weight. The supporting power of the electro-magnets may amount to 200 grammes (6.4303 oz. troy). This armature is secured to a very light horizontal axis of steel, placed as near as possible, and which has at one extremity a small, very slender steel pen, and at the other a small lever, directed from the side opposite to the armature, and whose extremity, bent into a hook, hooks into the ring of a double thread of extended caoutchouc. The tension of this caoutchouc thread can be regulated with precision to any degree desired; the lower part of the double thread passes through a small clasp, where it is held by a tension-screw; by loosening this screw a determined weight can be suspended at the extremity of the thread; the tension is allowed to be produced, and when equilibrium is established the clasp is tightened and the weight (become useless) is removed. Thus the thread is a repository of a tension exactly measured by the weight, and which accordingly can be reproduced at any instant.

In order to establish an equilibrium between the tension thus produced and the attractive force of the electro-magnet, a small additional piece of soft iron is employed, placed on the electro-magnet in contact with the polar mass, in proximity to the armature, and on the side opposite to the axis of rotation, Fig. 1. This mass can be displaced gradually by means of an adjusting screw; by setting it nearer to or farther from the armature the attractive force is diminished or augmented, and this force may thus be sufficiently reduced to cause the spontaneous disconnection of the electro-magnet; if the mass is then removed a little farther off by a very slight movement of the screw, the attraction is augmented in a measure just sufficient to maintain the armature, so that the least reduction in intensity of the current suffices to liberate it, and consequently it is set in motion as soon as the current is broken, or at least with a retardation exceedingly small and very constant. The arrangement represented by Fig. 2, and which shows the working of 10 registers placed side by side against the chronograph cylinder, is especially applied to the measuring of the durations of phenomena following each other in too rapid succession to permit the connection of a register between each signal. In this case, in fact, it is necessary to employ as many registers and distinct circuits as there are signals to observe, requiring for each register only one signal, for the necessity is thus dispensed with of making the registers connectors, that is to say, of regulating the course of the armatures in such a manner that they might be recalled by the magnetic attraction at the time of the re-establishment of the current. This latitude facilitates in a singular manner the employment of the apparatus, because it allows of giving to the pens a course large enough to make the traces easy to read, and of regulating the position of the additional mass so as to render the electro-magnets very sensitive, which could not be done to the same degree if an excess of force must be left to the attractive force, in order to restore the armature from a distance. This is the arrangement which it would be most proper to adopt for the electro-magnet almost exclusively, if the fact of employing different electric circuits did not, on the other hand, introduce causes of uncertainty and difficulties in their use often very great.

The employement of electro-magnets, also, simply as disconnecters, has been reserved in practice for the case where the intervals of the successive signals are so short that it is not possible to find registers sufficiently rapid in their course to follow the production of these signals. The limit is now very much extended by the recent improvements which Mr. Marcel-Deprez has made in his registers, which can execute as many as 2,000 movements per second.

At the time when his first investigations were executed, in concert with the marine artillery service, he had already produced registers whose retardation of disconnection was reduced to less than one two-thousandth of a second, and which, placed in the circuit of a fork sustained by electricity and giving 1,000 simple vibrations per second (500 periods), could follow the movement of this fork, and thus produce 500 rupture signals and 500 closing signals per second, by leaving on the revolving cylinder of a chronograph traces which indicated that the register remained still at rest for an appreciable time in the interval between the two signals.

But however rapid the registers might be, they would not have given the 10 signals which it was the object to obtain in case of need during the development of the pressures in the bore of a gun from the moment of the inflammation of the charge to the moment of the maximum pressure which, it is known, can scarcely be two or three thousandths of a second in duration, so that the successive signals could only be two ten-thousandths of a second apart, and even less. It would also be necessary to adopt for these special researches the employment of many independent registers, each giving but a single signal, as Fig. 2 shows.

For other researches, such as the studies of exterior ballistics, or even that of the law of the movement of the projectile in the bore, reconnecting registers could be employed.

Fig. 3 shows a register with large, wide helices arranged with regard to each other in such a manner as to cause the oscillation of a small armature mounted symmetrically on a horizontal axis, which is terminated at one end by a small lever, to the extremities of which can be fixed the threads of extended caoutchouc, two in number. The armature can only receive a very slight oscillatory movement, which is regulated in case of need by displacing the cores of the helices, and a great force of attraction is thus obtained to induce the reconnection. The movement of the armature is communicated to the pen which is on the extremity of a small parallel axis, placed on the upper part, by means of a very light lever, secured in a small fork, and which produces a notable amplification. In another mode of construction much used, two registers mounted side by side so as to be simultaneously utilized, are arranged

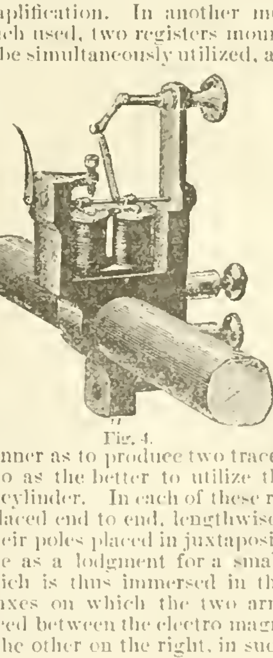

Fig. 4.

in such a manner as to produce two traces very near each other, so as the better to utilize the available space on the cylinder. In each of these registers the helices are placed end to end, lengthwise to one another, and their poles placed in juxtaposition are cut so as to serve as a lodgment for a small prismatic armature which is thus immersed in the magnetic field. The axes on which the two armatures are fixed are placed between the electro magnets, one on the left and the other on the right, in such a manner as to bring the pens near to each other; these axes have each a pen at one of the extremtiies and support, in their middle, a small plate of spring-steel placed vertically, against the extremity of which rests a horizontal screw, that can be worked with a key, so as to produce a counteracting effort adjustable at will. A vertical supporting screw, whose position can be regulated with the same key, serves to limit the course of the armature, so as to make the connection possible, allowing at the same time a sufficient course for the pens. In order to obtain the connection in these registers, it is necessary always to give to the magnetic attraction an excess of force over the tension of the counteracting spring, which does not permit the retardation of demagnetization to be reduced to the minimum which it would be possible to attain without this necessity; but the excessive reduction of the dimensions of the helices, which in the last apparatus figured did not exceed 5 millimetres (0.1968 inch) each in diameter and 7 millimetres 0.2756 inch) in length, permits the reduction of the retardation to a value extremely small and makes the variations in it altogether insignificant. We are assured, in fact, by the arrangement which will be described farther on, that the retardation of disconnection of these registers can be reduced to one three-thousandths of a second, and that the variations of this retardation, from one disconnection to another do not attain to one fifty-thousandth of a second.

In the apparatus sketched, which was arranged for mounting by means of a collar with a clamp screw, on a cylindrical shaft placed before the chronograph cylinder, one of the registers was mounted stationary on the common support, the other was sustained by a small movable slide which a square-headed screw permitted to move backwards or forwards, by means of the key already used for the other adjusting screws; this regulated the two pens so that they might rest equally on the surface of the cylinder of the chronograph. Fig. 4 represents another type of register, frequently employed. It is adapted to a number of mechanical arrangements, especially when it is desiered to combine side by side, as we shall see upon investigation, several indedependent registers. The helices, which in this case measure 7 millimetres (0.2756 inch) in diameter and 9 millimetres (0.3543 inch) in length, are placed vertically as in the apparatus, Fig. 1. The employment of a prismatic armature lodged between two polar masses is abandoned on account of the difficulties in construction and adjusting which it involved, and a flat armature is substituted which acts directly on the poles and approximates the arrangement of the ordinary electro-magnets; this armature is hollowed out, however, outside of the poles, in order, thereby, to diminish the mass, and it is made movable around an axis parallel to its length, and as near as possible to diminish the movement of inertia. The resistance due to the inertia of the lever on which the counteracting spring in the register (Fig. 1,) is applied is also avoided by applying directly on the armature the effort which is here produced by a small spiral spring. This spring can be extended at will by a mill-headed button, fitted very tightly, and which acts upon a crank to the extremity of which it is fastened. An adjusting screw, whose point touches against the armature, limits at will the course of the pen which is soldered on a small pipe fitted on the extremity of the shaft. By loosening this screw the course can be made so great that the register cannot naturally connect; in this case, a tension may be given to the counteracting spring slightly inferior to the attractive force so as to reduce as much as possible the retardation of disconnection. On the contrary, by revolving and tightening the screw so as to diminish the course, and by reducing also the tension of the counteracting spring, a preponderance may be restored to the attractive force, great enough to produce the connection of the apparatus which is then in a condition to give numerous successive signals, but the retardation of disconnection is, in this case, slightly augmented, according to the intensity of the current.

These registers are each secured to a ring-shaped mounting with its under part open. By these rings they are fitted side by side on a cylindrical shaft; they constitute so many clasps susceptible of being each tightened on this shaft, in any position whatever, by means of a mill-headed screw. To each of these registers may thus be given an individual movement of rotation around this shaft, by which movement the pens are brought on the same line, and a general rotary movement of the shaft afterwards removes them altogether, or makes them bear equally and at the same time on the surface designed to receive the registry. By what precedes, we see that the property of connecting automatically can be given to a register only on the important condition of limiting the course of the pen and in also reducing the counteracting force which determines the rapidity of its movement of disconnection; the magnetic attraction, exerted on the armature, diminishing according to the square of the distance, we imagine that, in practice, in order to preserve a course sufficiently rapid, we may be led to reduce, to a very small quantity, the amplitude of the displacement of the pen, which renders the readings difficult. A remedy was sought for this defect by the employment of organs for multiplying the movement like those represented by Fig. 3. Mr. Napoli also constructed registers such as that represented by Fig. 5, in which the amplification of the movement was produced by

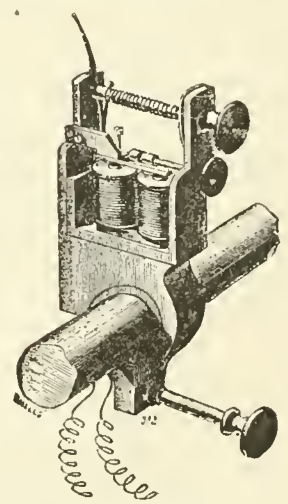

Fig. 5.

the medium of two cams resting one on the other, with surfaces arranged in such a manner as to vary, at each instant, according to a proper law, the relation of the arms of the lever and consequently the action of the counteracting spring acting then directly on the shaft which contains the pen; this is the, arrangement known by the name of "distributer of Robert Houdin." Mr. Marcel-Deprez also sought to overcome this difficulty by using electro-magnets, combined in pairs and of different forces, working successively by the same action of the disconnection; the attraction of the armature, in ordinary circumstances, was produced by a very small and very sensitive electro-magnet, whose retardation of disconnection could be made small, and, at this time of the disconnection, the armature established contact which introduced in the circuit a larger electro-magnet susceptible of acting with force on the armature in order to return it to its place. When the current was reestablished, it was this second electro-magnet which caused the connection, and when the armature was thus brought into contact all things were restored automatically to their place: the current was then sent again into the small electro-magnet. See *Sebert and Marcel-Deprez Chronograph.*

MARCH.—A term applied to a piece of music composed chiefly for military bands, to accompany the marching of troops, to help them to preserve time and to act as a preventive against fatigue. Marches are played on wind instruments or by the fifes and drums, and are generally some simple popular air. Each regiment in the British service has its special march for marching past; the Fusiliers are allowed to play on that occasion the "British Grenadier."

MARCHANDS.—Petty sutlers who follow an army on its march. As they generally deal in articles which are required by the officers and soldiers, it is the business of every General to see them properly treated, to insure their safety, and to permit them, under certain regulations, to have access to the camp.

MARCHES. 1. The boundaries between England and Scotland, also between England and Wales. The term signified primarily the *mark* of a country's limits (the *march*); and hence was applied as a designation of the border countries or districts of the German Empire, conquered from neighbouring nations. Thus, we read of the *marks* of Austria, of Northern Saxony or Brandenburg, Lausatia, Moravia, Steiermark, etc. The governors intrusted with the charge of these border districts, or *marks*, were called *markgrafs*, corresponding to the English and Scottish *Wardens of the Marches.* 2. The movements by which a body of troops is conducted from one place to another. They should be well directed and should be ordered so as to conduct the troops to their destination with the least amount of privation and fatigue compatible with the object to be attained. The art of directing properly a march belongs to "Strategy", while the art of arranging the details of its execution is a part of "Logistics." As the success of many military operations depends almost entirely upon their execution marches form a most important element in the Art of War. Marches when made at a distance from the enemy and where it is not necessary to take precautions to guard against an attack are known as *route* marches: those made in the theater of operations and where the enemy may at any moment make his sudden appearance, are called *strategical* marches; those made in the immediate vicinity of the enemy and so near, that they may be observed by him, are called *tactical* marches. Besides these three classes of marches which are based upon the position of the enemy, writers use various other classifications, based upon the object to be attained, or upon some other characteristic feature. These are known as *marches of concentration, maneuver marches, retreats, flank-marches,* etc.

Although the object of the movement and the nature of the ground determine the order of march, the kind of troops in each column, and the number of columns, the Commander must so act as to present his men in fighting order at any moment. With this in view, it will be necessary to observe the following points: 1. All things to be arranged in the same order in which they are likely to be required. 2. The cheerfulness and efficiency of the men to be secured, carefully considering the proper indulgences, the weather, the physical features of the country, and important hygienic principles. 3. The animals to be herded, loaded, driven and guarded with the greatest care. When distant from the enemy, or when in broken or dusty country, certain considerations of the first order may very properly give way to ease and comfort, but, as a general rule, the transportation (kept well closed up) should follow closely in the rear of the main command.

The simple movements of the troops, like that of forming into line of battle from a column formation, or the converse, or a change of position in the actual presence of the enemy, form a part of tactics; but the following general rules are applicable at most times and places:—Batteries of artillery and their caissons move with the corps to which they are attached; the field train and ambulances march at the rear of the column, and the baggage with the rear guard. Cavalry and infantry do not march together, unless the proximity of the enemy makes it necessary. In cavalry marches, when distant from the enemy, each regiment, and, if possible, each squadron, forms a separate column, in order to keep up the same gait from front to rear, and to trot, when desirable, on good ground. In such cases, the cavalry may leave camp later, and can give more rest to the horses, and more attention to the shoeing and harness. Horses are not bridled until the time to start. The officers and non-commissioned officers of cavalry companies attend personally to the packs and girths. When necessary, the orders specify the rations the men are to carry in their haversacks. The Field Officers and Captains make frequent inspections during the march; at halts they examine the knapsacks, valises, and haversacks, and throw away all articles not authorized. When it can be avoided, troops should not be assembled on high-roads or other places where they interrupt the communication. Generals of divisions and Commanders of detached corps send a Staff Officer to the rendezvous, in advance, to receive the troops, who, upon arriving, take their place in the order of battle, and then form in close column, unless otherwise ordered. Artillery, or trains halted on the roads, form in file on one side. The execution of marching orders must not be delayed. If the Commander is not at the head of his troops when they are to march, the next in rank puts the column in motion. If possible, each column is preceded by a detachment of pioneers to remove obstacles to the march, aided, when necessary, by infantry. The detachment is divided into two sections; one stops to remove the first obstacle, the other moves on to the next.

In night marches, and at bad places on the line of march, when practicable, and at cross-roads, if necessary, intelligent non-commissioned officers will be posted to show the way, and are relieved by successive details from the regiments as they come up. The Sergeant-major of each regiment remains at the rear with a trumpeter or a drummer, to give notice when darkness or difficulty stops the march. In cavalry, a trumpeter is placed in rear of each squadron, and the signal is repeated to the head of the regiment. The General and Field Officers frequently stop, or send officers to the rear, to see that the troops march in the prescribed order, and keep their distances. To quicken the march, the General warns the Colonels, and may order a signal to be sounded, which is repeated in all the regiments. In approaching a defile, the Colonels are warned; each regiment passes separately in column of fours in the order designated by the Commanding Officer, two battalions, when possible, marching abreast; on emerging from the defile, the battalions form line under the immediate direction of the General, the flank battalions being so posted as to prevent the enemy from passing between them and the entrance to the defile. Halts to rest and reform the troops are frequent during the day, depending on the object and length of the march. They are made in preference after the passage of defiles. Led horses of officers, and the horses of dismounted men, follow their regiments. The baggage wagons never march in the column. When the General orders the field train and ambulances to take place in the column, he designates the position they shall take. If two corps meet on the same road, they pass to the right, and both continue their march, if the road is wide enough; if it is not, the first in the order of battle takes the road, the other halts. A corps in march must not be cut by another. If two corps meet at cross-roads, that which arrives last halts if the other is in motion. A corps in march passes a corps at a halt, if it has precedence in the order of battle, or if the halted corps is not ready to move at once.

A column that halts to let another column pass resumes the march in advance of the train of this column. If a column has to pass a train, the train must halt, if necessary, till the column passes. The column which has precedence must yield it if the Commander, on seeing the orders of the other, finds it for the interest of the service.

The rate of march ordinarily for different troops is as follows:—Infantry, $2\frac{3}{4}$ miles an hour; field-artillery $3\frac{1}{2}$ miles an hour; horse-artillery or cavalry, 4 to 5 miles an hour. These rates only apply to small bodies marching independently. Practically, infantry in large bodies can only march at the rate of 2 miles an hour. Infantry, being the slowest marchers, necessarily regulate the pace of mixed columns. It is computed that a division of infantry of 12 battalions, of 800 men, marching in fours, will occupy about 7,680 yards. Its artillery (two batteries), without wagons, and marching by divisions, occupies about 400 yards. A division *complete*, including the advanced and rear guard, will cover about 7 miles. To determine the time of march (T) of a column: Let D = the distance (in feet) to be passed over; L = the length of the column in feet; D′ = the distance (in feet) passed over in one minute by the column, including halts; and T′ = the time of delay (in minutes) due to the elongation of the column in passing defiles, the physical condition of the command and all the irregularities of the route; then, $\frac{L}{D'}$ = the time (in minutes) for the column to pass over a distance equal to its length, and T (in minutes) =

$$T' + \frac{L}{D'} + \frac{D}{D'} = \frac{D'\,T' + L + D}{D'}$$

Thus, for a column of troops 860 feet in depth, moving at the rate of 100 yards per minute (including halts) and delayed eleven minutes, to pass over six miles.

$$T = \frac{300 \times 11 + 860 + 31680}{300} = 119\tfrac{14}{30} \text{ minutes.}$$

The average march for infantry is from fifteen to twenty miles per day. When troops move in large bodies, and particularly in the vicinity of the enemy, the march should be conducted in several columns, in order to diminish the depth of the columns, and to expedite the deployment into line of battle. The order of march should state the time for each division to commence its movement, so as not to interfere with the march of the division preceding or following, and to prevent fatigue from keeping men longer under arms than is necessary. In route marches, regiments usually alternate in leading the brigade; in like manner brigades alternate in divisions, and divisions in corps. In large commands, the roads, if possible, are left to the artillery and trains. The order of march should state whether the troops or trains should have the right of way. Each brigade is provided with a corps of pioneers under charge of a commissioned officer. The pioneers precede the column for the purpose of removing obstacles and preparing the way for the troops. Whenever fences, hedges, walls, ditches, or small streams, are encountered, a passage-way is made wide enough for four men, or eight men if in double column of fours, to march abreast without obstruction. This will prevent the column from lengthening out, and also prevent the fatigue and delay of regaining distances. On long marches, a halt of half or three-quarters of an hour should be made for the regular meals. The halt, if practicable, should be made in the vicinity of wood and water. When long distances have to be overcome rapidly, it is done by changing the gaits; the double time is used for ten or fifteen minutes, and the quick time for five minutes; the most favorable ground is selected for the double time; special care should be taken not to exhaust the troops immediately before engaging the enemy. Whenever delays occur in front, the brigades may form in column of battalions, and stack arms. It is the duty of all Commanders, within their commands, to investigate, personally or by means of staff-officers, every cause of delay, and staff-officers should be frequently sent ahead for the purpose of gaining any information that might shorten the march, and lessen the fatigue of the troops.

When cavalry and artillery form part of the column, Commanding Officers must bear in mind that their efficiency depends almost entirely upon the *condition of the horses*, which alone makes them able to get over long distances in short spaces of time. The horses must, therefore, be nursed with great care, in order that they may endure the utmost fatigue when emergencies demand it. When near the enemy, the artillery always marches with the bulk of the troops, its place being near the center or rear of the infantry or cavalry, never at the head of the column. In campaign, if a battery does not march with troops of the other arms, a sufficient escort must always be provided.

When an accident happens to a carriage, it is pulled out of the column, if possible, so as not to interrupt the march; otherwise, the carriages in rear pass it by the most convenient flank and close to proper distance. The disabled carriage resumes its place as soon as the damage is repaired; if the road be narrow, it must fall into the first interval it finds, and regain its proper place as soon as the ground permits. The caisson of a disabled piece remains with it; a piece, however, does not remain with its disabled caisson, the caisson corporal, and men to assist him, if necessary, being left behind.

When a piece and its carriage are overturned, it is better to disengage the piece by letting the breech rest on the ground, or on a block of wood, and by then raising the muzzle with a handspike, while the cap-squares are taken off; the carriage is then righted and the piece mounted. To right the carriage without disengaging the piece, detach the limber, secure the cap-squares, and lash the knob of the cascabel to the stock; place the middle of a rope over the nave of one wheel, pass the ends of it downward between the lower spokes of that wheel, then under the carriage, through the corresponding spokes of the other wheel, and then upward over the wheel and across the top of the carriage to the side where it was first attached; the ends of the rope and the wheel to be raised are then manned, and the carriage pulled over, two men being required to steady the trail. If necessary, the ends of the rope may be fastened to the limber, and horses used to assist in righting the carriage. A piece and its carriage may also be righted without disengaging the piece as follows: detach the limber; fasten two prolonges, or the middle part of a picket-rope, to the trail; chock the wheels; and dig an oblong hole under the muzzle about two and a half feet deep; pass one of the prolonges, or one end of the picket-rope, over the carriage to the front; man the ends of the prolonges, or picket-rope; then raise the trail and pass it over the axle to the opposite side. Other methods may be resorted to, depending upon the circumstances of the case, and the appliances at hand. Light carriages may be righted by hand without using a rope.

After pulling up a short, steep hill, the horses should be halted to recover their wind; when this cannot be done, they will move very slowly. In going up a difficult hill, the carriages may be halted to rest the horses, by bringing them across the declivity and locking the limbers or chocking the wheels; for this purpose, it may be expedient to start the sections, or platoons, from the bottom in succession, leaving a distance of twenty or thirty yards between the different portions of the column. If the draught be so difficult that the teams are liable to stall, some of the carriages in the rear are halted and their leaders hitched to the teams in front; on completing the ascent, these leaders are sent back to the carriages which have halted, with as many additional pairs as may be required. As it is very hard to make the horses pull together, not more than five pairs can be hitched with effect to a single carriage. The drivers never dismount in going down hill; the wheel-driver holds his near horse well in hand, and his off horse very short; the other drivers barely stretch their traces. If the hill be steep, the wheels may be locked; if very steep, the prolonge may be used by the cannoneers to hold back; in this case the wheel-horses only remain hitched to the carriage, the others being led in rear. In mounted batteries, the cannoneers usually attend to the locking; in horse batteries, the swing-driver, or with a team of but two pairs, the lead-driver, dismounts for this purpose; should there be a ditch or other dangerous place on the road-side, the wheel toward that side is locked in preference to the other. If a carriage have to move along a declivity so steep that a slight jolt may overturn it, a prolonge is fastened to the lower side of the carriage, and held by two or three cannoneers who march on the upper side of the slope; the rope passes over the carriage. When crossing a ditch, if it be wide and deep, the prolonge is fixed and the handspike taken out; the team is halted on the edge, and the piece run by hand close to the limber, which then moves slowly until the piece reaches the bottom of the ditch, when it moves quickly until the piece is out. If the ditch be deep and narrow, it may be necessary to cut down the edges, and hold back with prolonges; should the trail sink into the ground in passing over, it is disengaged with a handspike, or by fastening a prolonge to it. In passing shallow ditches, drains, or deep furrows, the carriage must cross them obliquely. When moving over marshy ground, each carriage moves at a distance of ten or twelve yards from the one preceding it, to avoid having to halt; officers, or non-commissioned officers, are posted at the worst places to instruct the drivers how to conduct their teams. The horses must pull freely and quicken the gait; if the ground be very miry, it may be necessary to assist with prolonges, or even to use them alone, the teams crossing separately.

When about to cross a ford, if it be not well known, it must be examined, and the dangerous places marked, before the carriages attempt to cross. If the water be deep and the current strong, great care is necessary. The men are instructed to keep their eyes fixed on some object on the opposite bank which marks the place of exit; they must not look at the stream, and move rather against the current, so as to better resist its power. If the ford have a bad bottom, and the banks be difficult, the teams are strengthened by adding pairs; an officer or non-commissioned officer, is posted at the entrance to regulate the distance between carriages, and to instruct the drivers how to proceed; a second officer, or non-commissioned officer is posted at the exit to direct the drivers how to leave the ford. The management of the team is the same as in crossing marshy ground; the horses must not be allowed to halt, or trot, either in passing the ford or in leaving it, unless the stream be neither deep nor very rapid; in this case, the carriages may be halted to let the horses drink, or at least to give them a mouthful of water. Upon reaching the opposite bank, the leading carriages are halted after they have moved far enough forward to leave room for the carriages in rear. If the chests be not water-tight, and are at the usual height of two feet ten inches above the ground, a ford deeper than two feet four inches cannot be crossed without danger of wetting the ammunition. If the chests be water-tight, or means have been taken to raise them high enough, a depth of three and one-third feet may be safely attempted. When the ford is deeper than this, the cannoneers must carry over the cartridges, fuses, and primers, in pouches which they hold above the water. The chests are sometimes removed and taken over in boats. In crossing rivers which cannot be forded, when there are no bridges, the horses are swum, and the carriages and harness crossed on rafts, etc., if the rivers be broad and swift, it is too hazardous for horses to be ridden; in this case a horse, known to be a good swimmer, is ridden without a saddle, as a leader, the other horses following without riders; the horses are led or driven to the bank, and can generally be made to take the water without much trouble. The bridle-reins must be secured to prevent the horses from getting their legs entangled. A horse swims easily and safely with a man floating and holding to the mane or tail. In the passage of a military bridge, when at the entrance of the bridge, the lead and swing drivers dismount and lead their pairs. A distance of twelve yards is taken between the carriages, and the gait is free and decided; the drivers keep the carriages as near the middle of the flooring as possible, and must not halt; if the bridge crack under a carriage, it must increase its gait and get over as fast as possible. If the flooring be wet, battens should be nailed across it to keep the horses from falling. If the bridge begins to rock, the passage of the column is suspended. In passing over a flying bridge, all the drivers dismount and hold their horses; it may be occasionally advisable to take the horses out; and in boisterous weather, or at night, the wheels may be locked.

The disposal of the troops for a march and the manner of executing it and overcoming the difficulties attending the same belong, as we have already observed, to the practical details of the profession, for which specific rules are laid down in every service; and with which it is presumed that every man who accepts the resposibility of a General's position has made himself acquainted. All of this may be summed up in a few words. First, the trains of every description must be covered by the troops, for which purpose they must, in an advance movement, be either in the rear, or on that flank where they will be least exposed to the enemy. In a retreat they must be in advance. When an army moves in several nearly parallel columns, the combination must be such that an imposing force can soon be concentrated on any point threatened. The divisions of each column must, in like manner, be in supporting distance of each other, but, for convenience, not crowded on the march. As to advanced guards, flankers, and rear guards, both their strength and composition must depend on the General's judgment, founded on the force, character and position of the enemy, and of the nature of the country through which the march is made. Just in proportion as he has read, has reflected, has had opportunities for action, will his judgment lead him to take right measures; whilst still more certainly, if he has wanted these aids to forming an enlightened judgement, will he take wrong one. See *Concentration Marches, Flank Marches, Maneuver Marches, Route Marches, Strategical Marches*, and *Tactical Marches*.

MARCHING.—One of the first necessities to distinguish a body of disciplined troops from a mere crowd of men, is a regular cadenced step, taken by every individual at the same time and with the same foot. The necessity of this for harmonious action is obvious. The ancient Roman legions had military music to beat the time for their march. In the feudal ages, when infantry fell into disrepute, cadenced marching was unattended to, and seems only to have been thoroughly revived by Marshal Saxe. The best music for a march is found to be some simple tune, such as can readily be performed by drums and fifes. The music, besides preserving the time, acts as a preventative of fatigue.

In the British service there are the slow march of 75 paces, each of 30 inches, in a minute—only used on parade; the quick march, of 110 paces, in which all evolutions are performed; and the double-quick, of 150 running paces, with the knees raised high. This last cannot be sustained for any great distance, and is employed in a charge, or in suddenly occupying a hill or some commanding position, and in a few short internal movements of regiments.

In the United States service, the length of the step in common and quick time is 28 inches, and the cadence is at the rate of 90 steps per minute for common time and 110 for quick time; in double time, the length of the step is 33 inches, and the cadence at the rate of 165 steps per minute, but it may be increased to 180. When troops are to march a long distance, the *route* step is employed, the men keeping their proper places in the ranks. See *Marches.*

MARCHING MONEY.—The additional pay which officers and soldiers receive for the purpose of covering the expense necessarily incurred when marching from one place to another.

MARCHING ORDER.—A soldier is said to be in *marching order* when he is fully equipped with arms, ammunition, and a portion of his kit. In the English service this equipment weighs from 30 to 35 pounds. In *service marching order*, by the addition of provisions and some campaigning necessaries, he carrys nearly 50 pounds. The *heavy marching order*, which was yet heavier, is now happily abolished.

MARCHING ORDERS.—The orders issued preparatory to troops marching. In these orders, the routes, the orders of march, and detailed instructions for the different arms of the service are clearly set forth; and in the British service the marching orders are intended to cover at least six days.

MARCHING REGIMENTS.—A term given in England to those regiments having no permanent quarters, but liable to be sent to any part of Great Britain or to any part of her possessions abroad. Although the word *marching* is insensibly confounded with those of *line* and *regulars*, it was originally meant to convey something more than a mere liability to be ordered upon any service; for by marching the regular troops from one town to another, the inhabitants, who from time immemorial have been jealous of a standing army, lost their antipathy to real soldiers, by the occasional absence of regular troops. At present the English guards, infantry, etc., may be considered more or less as *Marching Regiments.* The marines and volunteers have stationary quarters.

MARCH PAST.—An expression made use of when a regiment or any larger body of men pass in review order before the Sovereign or Reviewing Officer. It is usually performed in column or quarter-column at quick march or at the double, and with the mounted branch, when so ordered, at a quick trot, canter, or gallop. In England, the "march past" of large bodies of troops is carried out after the completion of the autumn maneuvers or summer drills.

MARCOMANNI.—An ancient German people who, in the time of Cæsar, lived along the banks of the Rhine, but afterwards, as appears from Tacitus and Strabo, settled in Bohemia, from which they expelled the Boii. Their King, Maroboduus, entered into an alliance with the tribes living around them to defend Germany against the Romans. The combined forces of the alliance numbered 70,000 men, and the Emperor Tiberius signed a treaty with them 6 A. D.; but the Marcomannic Alliance was beaten 11 years later by the Cherusci and their allies, and in 19 the Gothic Catualda drove Maroboduus from the throne, and himself usurped the sovereignty. But he was soon overthrown, and the native dynasty established, under whose rule the Marcomanni extended their territory up to the Danube, till their encroachments alarmed the Romans, who attacked them in the time of Domitian. This war, which subsided for a time in the reigns of Trajan and Hadrian, broke out again under Marcus Aurelius, and was carried on with bitterness from 166 to 180, when it was ended by the peace of Commodus. The Marcomanni continued to make raids into the Provinces of Noricum and Rhætia, and in 270 invaded Italy as far as Ancona. From this time they are little heard of; and their identity finally disappears among the followers of Attila.

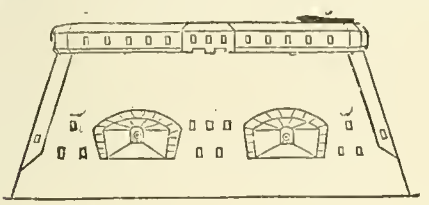
MARDI GRAS.—The French designation for what is known as Shrove Tuesday in the calendar of the English Church, the Festival held upon the Tuesday preceding Ash Wednesday, the first day of Lent; with the exception of Mi-Carême or Mid-Lent Thursday, the last of the prolonged festivities known as the Carnival. It is most extensively celebrated in Rome and Paris. In the latter it has been the custom for many centuries to lead in procession a fat or prize ox (*Bœuf Gras* whence *Mardi Gras*), followed in a triumphal car by a child called the Butchers' King. The entire day and night is spent in the wildest revelry, sometimes degenerating into unrestrained license. In the United States the only celebration of Mardi Gras worthy of note is that of New Orleans, where the first display was given in 1857, and since the end of the war the observance has been carried out with great pomp and splendor. For the preceding week the gayety has been universal, and on Mardi Gras the whole city is turned over to the rule of King Rex, who enters the gates on the previous day. On Tuesday the mimic monarch passes through the streets, escorted by his body-guard, the "Mystic Krewe of Comus," Knights of Momus, and various military and visiting organizations. To him are confided the gates of the city; minor police regulations are suspended, and until the dawn of Ash Wednesday the air is filled with music; in every street are dense throngs of merry-makers, and the glare of illuminations. In the evening occurs the great street pageant of the Mystic Krewe of Comus, in which are displayed elaborate tableaux, placed on moving platforms and brilliantly illuminated. These represent noted scenes of history, poetry, or fiction, and are constructed at great expense and with artistic elegance. All the arrangements of the parades and accompanying balls are under the control of societies composed of the most noted professional and business men of the city. The observance is gaining ground also in Memphis.

MARECHAL.—A Major General. This word is variously compounded in forming military terms. *Maréchal de Bataille* is a military rank which once existed in France, but was suppressed before the Revolution, or rather confined to the Body-Guards. An officer belonging to that corps received it as an honorary title. Its original functions, etc., with respect to general service, sank in the appointment of *Maréchal de Camp* and Major General. It was first created by Louis XIII. *Maréchal-Général des Logis de la Cavalerie* took place under Charles IX. in 1594. He had the chief direction of everything which related to the French cavalry. *Maréchal des Logis pour les Vivres* was a person belonging to the Quartermaster General's Department in the old French service. The person invested with the rank of *Maréchal de Camp* was a General Officer and ranked next to a Lieutenant General. It was his duty to see the army properly disposed of in camp or quarters, to be present at all the movements, to be the first to mount his charger and the last to quit him. He commanded the left in all attacks. The appointment under this distinction was first created by Henry IV. in 1598. *Maréchal-Général des Camps et Armées du Roi* was a post of high dignity and trust, which during the French Monarchy was annexed to the rank of *Maréchal de France.* Military writers differ with respect to the privileges, etc., which belonged to this appointment; it is, however, generally acknowledged that the General Officer who held it was intrusted with the whole management of a siege, being subordinate only to the Constable, or to any other *Maréchal de France*, who was his senior in appointment. *Maréchal-Général des Logis de l'Armée* was an appointment which existed during the old French government, and has since been replaced by the *Chef de l'Etat-Major*, which corresponds with that of Quartermaster-General in the British service.

MARECHAUSSEES DE FRANCE.—A species of military police which formerly existed in France. During the French Monarchy there were 31 companies of Maréchaussées à Cheval, or mounted policemen. These companies were formed for the purpose of preserving public tranquility, and were distributed in the different Provinces of the Kingdom. This useful body of men was first formed under Philip I. in 1060; they were afterwards suppressed, and again re-established in 1720, as constituting a part of the Gendarmerie of France. There were other companies of Maréchaussées, who were particularly distinguished from the 31 above mentioned; such, for instance, as that of the Constables, called the Gendarmerie.

MARGRAVE. A German Nobleman corresponding in rank to the English Marquis. *Margravine* is the wife of a *Margrave.* See *Marquess.*

MARINE FORTIFICATION.—Marine fortification differs from land fortification in that the approaches of the enemy which are to be resisted take place on the level of the sea, so that he can come near without having to overcome the dangerous slope of the glacis. The combat is simply one between two powerful batteries, and the question to be decided is whether the ship or the fort will first be placed *hors de combat;* the ship having ordinarily the largest number of guns, while the fort has more solid battlements, and its fewer guns of great caliber can be fired with a steadiness unattainable on so shifting a base as the ocean. Under these circumstances, the less relief a sea-fortress has the better, as by so much the less is it likely to be hit from the shipping. Its walls are usually built perpendicular, or nearly so. The magazines and quarters for the men are bomb-proof, as also are the casemates, from which the guns are usually fired, although sometimes, as in the martello-tower, the gun is worked on the top of the structure. Sea-fortifications may be of various importance, the simplest being the battery consisting



of a mere parapet formed in a cliff or on a hill, and mounted with guns to command the sea; these are generally built in such concealed situations that it is hoped the hostile ships will not perceive them until they actually open fire. They are numerous all around the British coast. Next greater in importance is the martello-tower. More powerful still are the beach-forts, such as those which on either shore defend the entrance to Portsmouth harbor; these are constructed of the most solid masonry, faced with massive iron plates, and armed with guns of the heaviest caliber, sweeping the very surface of the sea, so as to strike an approaching ship between wind and water. The guns are usually in bomb-proof casemates, and the fort is often defended on the land side if the coast be level; if, however, higher ground be behind, this would be useless, and then the sea-front alone is defensible. Most terrible of all sea-forts, however, are the completely isolated forts, with perpendicular faces and two or three tiers of heavy guns. Such are the tremendous batteries which render Cronstadt almost inapproachable, and by which Spithead and Plymouth Sound are now fortified. These forts are generally large, with all the requisites for a garrison to maintain itself; against them wooden ships stand no chance, and in the American Civil War fort Sumter, at Charleston, showed itself no mean antagonist for ironsides. In such forts iron is employed as the facing, in plates of such vast thickness and weight that it is supposed no ship can ever possess any comparable resisting power; and, as they are armed with guns the smallest of which will probably be 300-pounders, it is expected that they will be able to destroy any fleet that could be sent against them. At the present day the value of sea-fortifications is disputed, as iron-plated vessels may pass them with impunity unless the artillery in the fort be so heavy as to destroy the armor of the ships. In the long run, however, it is apparent that the fort can command the greater power, for its armor may be of any thickness, while that of the ship must be limited by her floating powers, and, on the other hand, the limit to the size of artillery must be sooner reached in a ship than in a solid and stationary fortress.

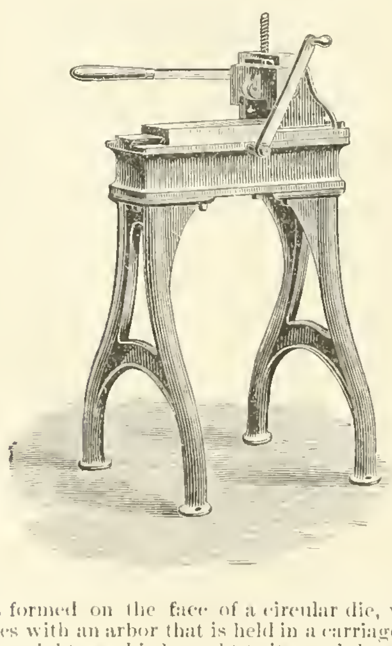
MARINES.—Troops who serve at naval stations, and on board ships of war. The men are drilled in all respects as soldiers (light infantry), and therefore on shore are simply ordinary land-forces. On board ship they are trained to seaman's duties, but still preserving their military organization. Their ordinary functions are as sharpshooters in time of action and at other times to furnish sentries for guarding the stores, gangways, etc. They are useful as exercising a good control over the less rigidly disciplined sailors, and having always fire-arms and bayonets ready, they have often been instrumental in suppressing the first outbreaks of mutiny. The introduction of Marines into the American Army took place by Act of Congress, passed Nov. 10, 1775, by which two battalions of this arm were directed to be organized. Again, by Act of July 11, 1798, "establishing and organizing a Marine Corps," this body became an established element in the naval force of the United States, liable to do duty either on board vessels of war at sea, in forts or otherwise upon shore as might be directed by the President. The Commandant of the Corps has the rank and pay of Colonel. It has no regimental organization, however, but may be formed into as many companies or detachments as the President may direct. When employed on naval service the Marines are subject to the laws and regulations which govern the Navy; but if engaged on shore duty, they are amenable to the authority of the Articles of War. The United States Marine Corps consisted in 1880 of 86 officers and 1,500 enlisted men. Marines were first established in England, as a nursery from whence to obtain seamen to man the fleet, by Order in Council of Oct. 16, 1664. Their utility becoming conspicuous, other regiments of Marine Forces were raised, so that by 1741 there were 10,000 men, and in 1759 as many as 18,000. During the great French war the number rose above 30,000, but a great reduction took place after peace was concluded. By recent Navy Estimates, 14,000 Marines were provided, including 2,900 artillery, at a yearly cost of £940,417. Their government rests solely with the Admiralty. The Royal Marines are divided into three divisions of light infantry and one of artillery. Promotion goes by seniority throughout the artillery and infantry respectively. In rank, Marine Officers correspond with Army Officers of similar grades according to seniority: as a corps the Marines take place between the 49th and 50th regiments of Infantry of the Line. Every ship, on being commissioned, has her complement of Marines drafted into her. The uniform is red, with blue facings and white belts. On their colors the men proudly bear the word "Gibraltar," in the famous defense of which fortress they bore an heroic part.

MARIOTTE'S LAW.—An empirical law deduced by Boyle and Mariotte from two independent series of experiments, though, strangely enough, reached by both at about the same time. It is generally expressed as follows: *The temperature remaining the same, the volume of a given mass of gas is in inverse ratio to the pressure which it sustains.* This law may be held to be substantially correct within a considerable range of pressure. But the labors of Regnault have made it evident that atmospheric air and most other gases, especially under very high pressures, are really more compressed than if they followed the law. This deviation is most marked in the case of gases capable of being liquefied, as they approach the point of liquefaction.

MARK 1. A German geographical term, which signified primarily the *mark* of a country's limits (the *march*); and hence was applied as a designation of the border countries or districts of the German Empire, conquered from neighboring nations. Thus, we read of the marks of Austria, of Northern Saxony or Brandenburg, Lausatia, Moravia, Steiermark, etc. The Governors intrusted with the charge of these border districts, or the *marks*, were called *Mark-grafs*, corresponding to the English and Scottish *Wardens of the marches*. See *Marquess*. 2. That toward which a missile is sent; the part of a target aimed at.

MARKER.—1. The soldier who forms the pivot of a wheeling column. 2. A person, whose duty it is to record the number of hits and misses made by soldiers at target-practice. 3. In maneuvers, for the purpose of indicating the direction of lines of battle, the battalion is provided with four markers, who are habitually posted in the line of file-closers, one near each flank of the right and left companies when in line, and the leading and rear subdivisions when in column. At parades and inspections, two markers are required, who retire, after the line is formed, behind the flanks of the color-company. At inspection they accompany the color-guard to the front and are inspected with it, taking post two yards from the rear rank, in rear of the right and left files.

MARKING MACHINE.—A tool for impressing textual or emblematic designs into finished work at the armory or foundry. The drawing shows a handy machine of this class, which is much used. The de-



sign is formed on the face of a circular die, which revolves with an arbor that is held in a carriage sliding in uprights, and is brought to its work by a foot-lever (not shown in the drawing), the device being impressed on the piece to be marked, as it is moved, with the table to which it is secured, by hand-lever under the die. Pieces of varying diameters may be marked in the same machine. The machine is mounted on legs of convenient height, and weighs about 300 pounds All cannon are required to be marked with the weight in pounds, the number of the piece, the initials of the Inspector's name the initials or name of foundry and year of fabrication. All pieces manufactured in the United States, since 1861 have these marks on the face: those of previous date have them distributed on the ends of the trunnions, the face, the breech, and the top. The numbers for each kind and caliber at each foundry are in separate series. Cannon that have been inspected and condemned are marked on the face X C. See *Inspection of Ordnance*.

MARKSMANSHIP.—To become skilled in *marksmanship*, one must possess a thorough knowledge of the rifle, the principles of its construction, its capabilities, and the care required to preserve it always in a condition of greatest efficiency, the laws governing the flight of the bullet, and the causes which tend to impress upon its motion certain irregularities; an understanding of the best positions for firing; a readiness for estimating distances; and the experience required to make allowance for the force of the wind, or the motion of the object aimed at. The acquirement of the requisite skill to fire accurately is one of the most important duties of the soldier; not only his own safety but that of his companions may often depend upon his ability to deliver his fire with effect, and the greatest proficiency in the manual of arms cannot atone for a want of dexterity in this particular. Any man having perfect vision can, through perseverance, become a fair marksman. Long practice with cartridges is not necessary; but a strict compliance with the rules for pointing and aiming, and a careful study of the causes modifying the accuracy of fire, will be sure to lead to more than average skill in firing.

When firing *in vacuo*, the trajectory is easily traced and its properties simply discussed. Considering its position with reference to the line of sight it will be seen that near the muzzle it is below the line of sight for some distance, then it cuts it; beyond this point it rises above the line of sight for some distance, then falls and cuts it again. This second point of intersection is the point-blank and determines the point-blank-range. With a rifle, up to 175 or 200 yards, the line of fire will not cut the line of sight; or, in other words, will not shoot high. Now, as it is necessary, in order to hit an object within or beyond the point-blank, to aim below or above it certain distances, it is readily seen how indispensable are the contrivances (sights) which will so alter the point-blank as to make it coincide with any object directly aimed at. The range in vacuo equals $\frac{2xy}{g}$ in which x and y are the horizontal and vertical components of the impulsive force, and g the acceleration due to the force of gravity. From this we see that (velocity being constant) the range will be the same when the angles of fire are equally distant from 45°; thus, angles of fire 36° and 54° will give the same range. It is also seen that the range will be a maximum when xy is a maximum, or when $x=y$, or when the angle of fire is 45°

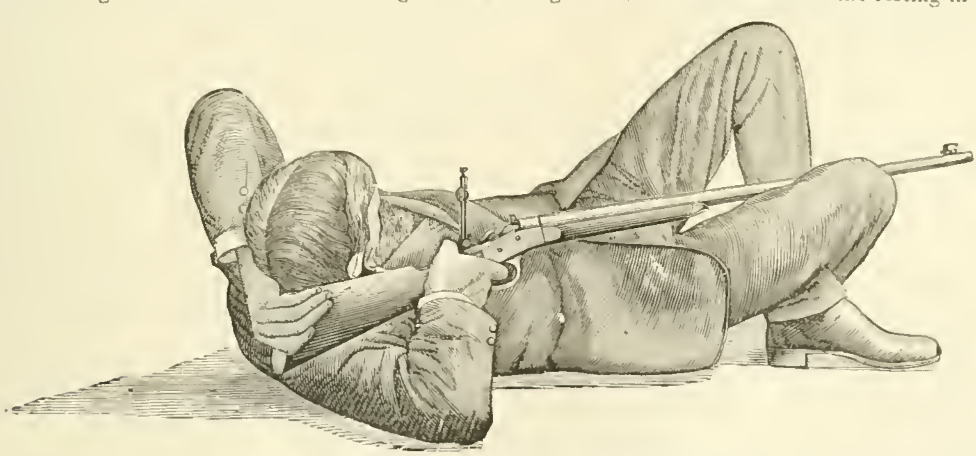
The motion of a bullet is greatly modified when the movement is through the air. The progressive velocity of fall of the bullet being so much less than its initial velocity, the air resistance opposed to its descent will be inappreciably small in comparison with that in the direction of its motion of translation (the resistances being proportional to the squares of the velocities). Hence, when the bullet would have been at certain points, in vacuo, it will in reality be at points below and in rear of them, by distances increasing from the point of departure (since the resistance of air causes the spaces passed over in equal times to become progressively smaller and smaller), thus causing the trajectory in air to be constantly below and in rear of its place in vacuo and changing its curvature, so that the left branch presents a flattened form while the right branch approaches the vertical. From thus destroying the symmetry of this curve, there results that the angle of fall is greater than the angle of ascent, and more considerably so as it is distant from the origin, that the point of culmination is lowered, and that the range is greatly diminished. To make proper allowances, the sights must be carefully manipulated, and when firing at long range a delicate estimation of distance is necessary to obtain accuracy of fire, even when using the best and most accurately graduated sights. Any ordinary man can be drilled to estimate distances up to 600 yards with great accuracy and dispatch, by the eye alone. Instruments may be used for greater distances, but their use is of no practical value in the field before an enemy, and can only be resorted to on the drill ground as an aid where time is an important element.

Having thoroughly mastered the principles of aiming, experience only can teach the best positions under various conditions and circumstances. The when the fire is in two ranks, the front rank kneel, not only to obtain a steadier position, but to get them out of the way of the rear rank, and thus secure a more rapid and accurate fire.

The favorite position for long-range firing, particularly with a military rifle, is that of the *Skirmisher Lying.* In taking this position, the legs should be well separated, the toes being turned outward, so as to cause the body to hug the ground as closely as possible. The left elbow should be kept almost straight under the rifle (if placed too far to the left, it strains the wrist), and the barrel grasped *firmly* with the left hand. The right elbow should be placed a little to the right. To prevent the elbows separating, as they are naturally inclined to do on hard ground, a depression may be made in the ground with the heel of the boot, or something soft placed under them.

regulation position, "firing standing," is generally preferred. Many find an easier and firmer position by bringing the left shoulder well to the front, and resting the rifle over the lower part of the left thumb. The advantage of this position is that it brings the left elbow directly under the barrel without any strain on the muscles. Its disadvantage is that, in a side wind, the body is too apt to sway sideways, which must be avoided by placing the feet further apart. The Hythe School directs that the rifle be pressed against the shoulder with the *left* hand, the right holding the stock lightly; but most marksmen prefer, while grasping the barrel firmly with the left hand, so as to keep it steady, to hold it well against the shoulder with the right. In The hips should be twisted to the left, and the right shoulder well raised, to keep the collar-bone out of the way and afford a firm seat for the rifle-butt, which must be held closely against it. Many of the best shots at Creedmoor and Wimbledon shoot, lying on their backs. Some lie slightly on the right side resting the rifle-barrel over the left leg, the left hand grasping the piece at the small of the stock, and pressing it against the shoulder. In this position, the distance of the rear sight from the eye requires a larger aperture than usual. The following is a favorite back position:—

The marksman lies on his back, his legs crossed, the left leg under the right knee, and firmly held by the right calf, the muzzle of the rifle resting in the



all cases, it will be found that the pull-off of the trigger will be lightened by a firm grip with the right thumb. The standing position depends so much on the personal equation of the marksman as to prevent that extreme nicety of aim required in long-range firing. It also renders the rifleman liable to be swerved by the wind, and offers the enemy a better target. It is seldom used before the enemy or at long-range. Kneeling is open to the same objections, but to a less extent. In the English army, crotch between the knees. The left arm is placed behind the head, the hand firmly grasping the butt of the rifle, the back of the head resting on the left forearm, and the right cheek touching the side of the butt. The right hand holds the small of the stock with a firm grasp, the elbow resting on the ground. In this position, not only the piece, but the entire person of the shooter is perfectly supported, and absolute steadiness is secured. Gildersleeve, Coleman, and other Americans have adopted this position, and

Sir Henry Halford and others at Wimbledon concede its advantages. It is doubtful whether any advantage is gained by lying on the back, in shooting with military rifles. The position, *Face Downwards*, is certainly preferable for military reasons, enabling the soldier to rapidly advance or retreat, to shelter himself behind cover or to entrench himself. Whether the-rifleman shoots standing, kneeling, sitting, or lying, after having once tested and become satisfied as to the position best suited to himself, he should practice it until it becomes perfectly natural and easy.

With a steady aim and position, the circumstances which cause the bullet to deviate from the spot at which it is aimed are so numerous, that it is rather the exception than the rule when a man can aim directly at the object to be struck. It is, therefore, necessary that the soldier should know how to make allowances for these causes of deviation; to know where he should aim in order to strike the object. A frequent cause of deviation of the bullet is a false or defective barrel, short swells and long depressions being often found on its interior. These swells or ridges, by increasing the friction, may so affect the recoil as to have an injurious effect on the fire, or so affect the exterior form of the bullet as to produce an irregularity in its motion. The swells and depressions, moreover, change the interior lines of the piece and give the bullet a false direction. Another cause of deviation of the bullet is the vibration of the barrel when firing caused by the want of a homogeneous distribution of metal about its axis, and often to binding bands. These vibrations tend to alter the direction of the bullet as it leaves the muzzle. Recoil causes the firer to turn to the side from which he fires, and produces deviation in that direction. It is supported by pressing the butt firmly against the shoulder, and is differently felt according as the position of the rifle, relatively to the horizontal, changes. The shock of the recoil against the shoulder is diminished by the bend in the stock, serving to decompose the force into two components, one acting through the stock against the shoulder, the other in the direction of the axis of the barrel, tending to raise it. Whatever lessens the recoil, theoretically, increases the range. The recoil is only 95 lbs. for the Remington rifle (70 grains powder and bullet of 450 grains), while in our service rifle, caliber 45, it is 175 lbs.

When the bullet reaches the muzzle of the rifle, it will revolve about its axis nearly 800 times in a second, and a point on its exterior side surface will have an axial velocity of about ninety feet per second. This, in connection with the resistance of the air produces a lateral drifting of the bullet in the direction in which the grooves have a turn. This is known as drift, and is greater in the descending than in the ascending branch of the trajectory. It increases as the diameter of the bullet, the angle of fire, the velocity of rotation and the range *increase*, and as the velocity of translation decreases. The drift in our service rifle, at 500 yards, is two feet. The pull of the trigger should not be too great, a *three-pound* pull being the minimum. It should be pressed by a steadily increasing pressure of the finger in the direction of the axis of the barrel, without communicating motion to the rifle, the breath being held until the hammer falls. If the trigger is too hard and is pulled convulsively, the muzzle will be turned to the right. There should be a quick and decided connection between the mind and finger. Few men can pull off the trigger of the service rifle with the first joint of a single finger. A defective position of the line of sight or incorrect graduation of the rear sight will cause a deviation of the bullet. If the front sight be to the right of its proper place, the bullet will go to the left, and *vice versa*. The bullet will also be raised (range increased), since the top of the sight is lower than it is when in its proper position. If the rear sight be to the right or left of its true place, the bullet will go to the right or left, and will be lowered (range diminished), since the top of the sight will be lower than when in its true position.

A serious cause of inaccuracy, originating with the firer, is the faulty position that he gives to the musket in firing, by inclining to the right or left, which tends to carry the bullet to the side to which the rifle is inclined, and to diminish the range. When firing at long ranges a trifling inclination to the right or left will throw the bullet very wide of the target. The condition of the atmosphere noticeably affects the course of the bullet. The more moisture there is in the air, the greater the elevation required; hence it is that the bullet is frequently noticed to fall immediately after a rain. Warm air offers much less resistance to the motion of the bullet than cold air does, even a fall of 20° in temperature causing the bullet, ordinarily, to lower ten or eleven inches at 300 yards range. In firing over water, the elevation must be increased, in consequence of the lower temperature of the air over the water. In ascending a mountain, the air becomes more and more rare, and consequently the resistance to the bullet is less on the mountain than at its base. Mirage, an optical illusion, occurring in level districts on very warm days, causes the target to apparently raise in the air and become distorted in shape. This materially affects such objects as are near the ground, and engenders a tendency to shoot too high.

The influence of light and shade on the effect of firing is remarkable. On a bright day the target is refracted so as to apparently stand higher, and will, theoretically, require a lower elevation than on a very dull day. When the light shines directly on the target, when the target is against a light background (so that the details are better brought out); when the sun shines on the firer's back, when the atmosphere is clear, when the ground is level and uniform in appearance or when it gradually rises toward the target, the same will appear much nearer, and will theoretically require a higher elevation. The best shooting is invariably done on cloudy days when the sun's light is evenly diffused. It is very difficult to shoot well when passing clouds intercept portions of the sun's light and heat. It is readily seen how this disturbance might set up currents in the air which would tend to carry the bullet from its course, and how the rays of light deflected from their course before reaching the eye would cause the target to apparently occupy a false position. It will be well to diminish the elevation should the sun suddenly appear and light up the target while the firer still remains in the shade, and to increase it should the target remain in the shade while the sun shines on the firer. Bright sights and barrels are obviously objectionable. The reflection of the sun's light on the sights causes them to appear as brilliant points and precludes the possibility of an accurate aim. If the sun's rays come laterally, the trouble will be still greater inasmuch as they will brighten the rear side of the front-sight and the opposite side of the notch of the rear-sight, and cause a tendency to shoot away from the sun. The refraction of the sun's rays from a polished barrel causes the target to become indistinct and to assume the appearance of motion. The sights and barrel about the muzzle should be blackened with smoke if nothing better is at hand.

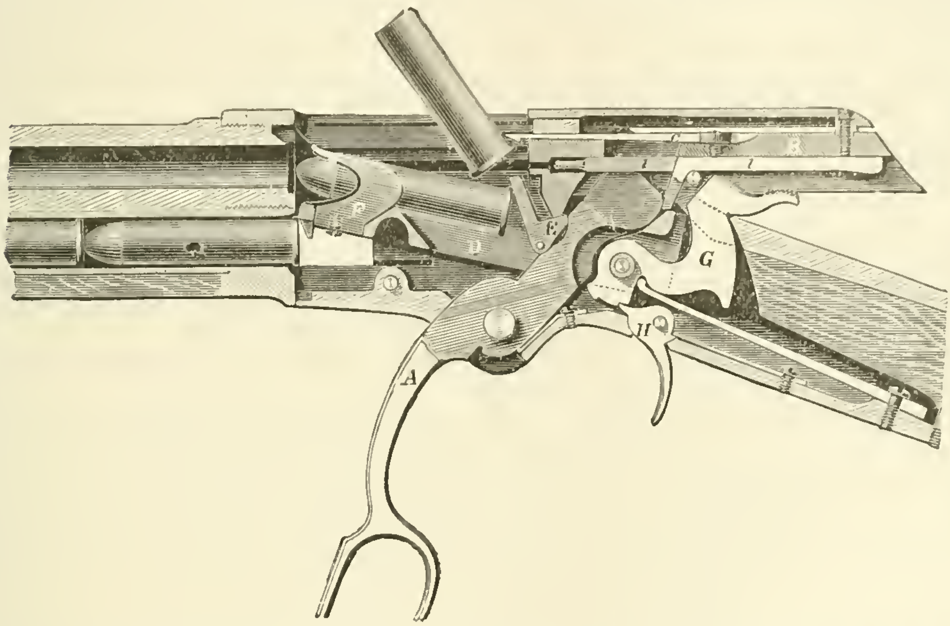
The effect of wind on the trajectory and the allowance to be made for it are most troublesome questions for the marksman. His best skill and judgment must be taxed when firing in windy weather, or in mountainous districts where there are many cross-currents with which to contend. All winds, except toward the target, retard the bullet and render a higher elevation necessary. A wind from the rear helps the bullet and tends to high shooting. Experience has shown it necessary to alter the wind-gauge twelve or more feet between two consecutive shots over a range of 1,000 yards, in order to make a bull's eye each time, when the wind was very high or variable. In Busk's 'Hand-book for Hythe' it is stated that "One hour a day of private practice in aiming-drill will, in a few weeks, make a man a first-class shot." This is true, for the position and aiming drills constitute the very foundation of any system of practice. It is an absurd mistake in any service to have recruits fire off-hand at a target one hundred yards distant, when they scarcely know the difference between a rifle and a shotgun, and cannot hit a barn-door when thirty paces distant with either. See *Rifle Practice.*

MARK TIME.—A command in the School of the Soldier. It is executed by moving each leg alternately in quick or ordinary time, without gaining ground. This movement is frequently practiced when a front line or column has opened too much, in order to afford the rear an opportunity of getting up; and sometimes to let the head of a column disengage itself, or a body of troops file by, etc.

MARLINE SPIKE.—A ponderous iron pin, with a large head and a taper point, used for separating the strands of rope preparatory to splicing or knotting; also employed as a lever in tightening rigging, etc.

MARLIN REPEATING RIFLE. An American rifle having notable advantages over most repeating arms. It belongs to the *bolt* class, so long used by many of the European Governments; but instead of operating the bolt by a cumbersome and ungainly handle projecting from the side, it is operated by a strong and powerful lever, on the under side of the arm, thus making a handsome model, easy of manipulation. The bolt comes solidly up to the base of the cartridge, covering it entirely; in this way all danger is avoided, even though a defective cartridge should happen to be used. A premature explosion cannot occur, and the greater the recoil, the more firmly the bolt is held in its place. The operation of the gun is of the simplest kind, and yet the action is the strongest that can be made. The drawing shows the rifle with all the operative parts in open position. Throwing forward the lever, A, withdraws the firing-pin, I, unlocks the bolt, B, and causes it to recede, carrying with it the extractor, C, which extracts the shell of the cartridge just fired, while the ejector E, attached to the lower section of the bolt, ejects the same from the receiver. By the same motion, the carrier-block, D, is raised from its natural position, in a simple manner, brings the cartridge with it, and places the same in line with tha chamber of the barrel, while the spring F firmly holds cartridge in place. The hammer, G, is brought to full-cock by the same motion, and held there by the action of the trigger, H, entering its full-cock notch. Bringing the lever back to its natural position causes the bolt to move forward, pushes the cartridge into the chamber, lowers the carrier-block to receive a fresh cartridge, securely locks the breech mechanism, and leaves the arm ready to fire.

The magazine is loaded through an opening in the side of the receiver, which opening is closed by a cover. It holds nine cartridges and one can be placed in the barrel. The cartridges can be inserted in the magazine either with the block open or closed. When the bolt is withdrawn the cartridge at the bottom of the magazine enters the carrier-block *gradually*, avoiding the concussion produced in many guns by the sudden jump of the whole column of cartridges with a momentum, in some cases, sufficient to explode a sensitive primer. All the advantages of a single breech-loader are also contained in this rifle; it can be used with great rapidity, the cartridge being inserted in the barrel instead of in the magazine, and cartridges specially loaded with patched bullets for target shooting can be used in this way. The rifle is made for two sizes of cartridges: 40 cal., 60 grains powder, 260 grains lead, straight shell; and 45 cal., 70 grains powder, 420 grains lead, being the regulation Government cartridge. In the 40 caliber we find a heavy charge of powder behind a comparatively light bullet, thus attaining a high initial velocity and very flat trajectory; with excellent results up to 800 yards. The barrel is octagonal in cross section, is 28 inches long, and the weight of the arm is 9½ pounds. See *Rifle.*



MARLINS.—Tarred white skeins or long wreaths or lines of untwisted hemp dipped in pitch or tar, with which cables and other ropes are wrapped round, to prevent their fretting and rubbing in the blocks or pulleys through which they pass. The same serves in artillery upon ropes used for rigging gins, usually put up in small parcels called skeins.

MAROLAIS SYSTEM OF FORTIFICATION.—This system adopts the fausse-braye, and the flanks are retired and casemated. It is a very fair sample of the *Dutch School.* See *Fortification.*

MARON.—A piece of brass or copper, about the size of a crown, on which all the hours for going the rounds were marked in the old French service. Several of these were put into a small bag, and deposited in the hands of the Major of the regiment, out of which they were regularly drawn by the Sergeants of Companies, for the officers belonging to them. The hours and half hours were engraved on each *Maron*. These pieces were numbered one, two, etc., to correspond with the several periods of the night; so that the officer, for instance, who was to go to the 10 o'clock rounds, had as many *Marons* marked ten as there were posts or guard-houses which he was directed to visit. Thus on reaching the first, after having given the *mot* or watch-word, to the Corporal, he delivers into his hands the *Maroon* marked one. These *Marons* being pierced in the middle are successively strung by the different Corporals upon a piece of wire, from which they slide into a box called *Boite aux Rondes*. This box is carried next morning to the Major, who keeps the key; and who on opening it can easily ascertain whether the rounds have been regularly gone by counting the different *Marons*, and seeing them successively strung.

MAROONS..—A name given in Jamaica and Dutch Guiana to runaway negro slaves. The term was first applied to those slaves who were deserted by their Masters, the Spaniards, when the British conquered Jamaica (1655), and who took refuge in the Uplands, where for 140 years they maintained a constant warfare with the British Colonists; but in 1795 they were subdued, and a portion of them removed to Nova Scotia, and afterwards to Sierra Leone. The remnant fraternized with their manumitted brethren in 1834-35. The Maroons of Dutch Guiana form a number of small independent communities.

MARQUEE.—An awning or cover of canvas forming an officer's tent; a tent complete. Marquees are of two kinds, viz., *Dining and Sleeping Marquees*: the former being used as officers' mess tents. Also written *Markee*.

MARQUESS—MARQUIS.—The degree of nobility which in the peerage of England ranks next to Duke. Marquises were originally Commanders on the borders or frontiers of countries, or on the sea-coast, which they were bound to protect. In England, the title of Marquis was used in this sense as early as the reign of Henry the III., when there were Marquises or Lords-marchers of the borders of Scotland and Wales: and the foreign equivalent of *Markgraf* was common on the Continent. The first English Marquis in the modern sense was Robert de Vere, Earl of Oxford, who was created Marquis of Dublin by Richard II., to the no small offense of the Earls who had to yield him precedence. The oldest existing Marquisate is that of Winchester, created by Edward VI. in 1551. The title was first introduced into Scotland in1599, when the Marquises of Huntly and Hamilton were created.

The Coronet of a Marquis, as worn in the United Kingdom, is a circle of gold, with four strawberry leaves (or oak leaves), and as many pearls alternating with them, and placed on pyramidal points of the same height with the leaves. The mantle is scarlet, with three and a half doublings of ermine. A Marquis is styled "The Most Honorable;" his wife is a Marchioness; his eldest son takes by courtesy the next lower title in the peerage, except where that is identical with the title of the Marquisate, in which case he must take the next lower still, as in the case of the Marquis and Earl of Salisbury, whose eldest son bears the courtesy-title of Viscount Cranborne. The younger sons of a Marquis are styled 'Lord,' and daughters 'Lady,' with the addition of Christian name and surname.

MARRIED ROLL.—A register kept in each regiment, troop, battery, or establishment, in the English Army, and in which are inserted the names of all non-commissioned officers and soldiers who are married with permission. All non-commissioned officers holding the rank of Staff Sergeants of certain grades are permitted to marry, and also Sergeants of troops, batteries, or companies, &c., in a certain proportion, as laid down in the Regulations. Of the rank and file, 7 per cent. in England and 10 per cent. in India are allowed to marry, and are entered on the married roll; these numbers are calculated upon the establishment of the corps, except in the royal artillery, in which the calculation is made upon the establishment of each battery. No non-commissioned officer or soldier is entitled to have his name placed on the married roll without having obtained the consent of his Commanding Officer before marriage. In the case of a soldier below the rank of Sergeant wishing to marry, he must have completed 7 years' service and be in possession of at least one G. C. badge. If he has a balance in the savings-bank of £5 or upwards, it will be considered a desirable qualification. The fact of the name of a non-commissioned officer or soldier appearing on the married roll ensures him and his family certain privileges which are not accorded to men marrying without the consent of their Commanding Officer.

MARRONS.—Small cubic boxes, made of pasteboard, filled with powder, and wrapped with strong twine. They are used to give a loud report, or the effect of cannonading. To make a marron, cut the pasteboard into rectangles, whose sides shall be 3 and and 5 times, respectively, the length of the side of the marron required. Divide the rectangle into 15 equal squares; cut out the squares forming the four corners of the rectangle, and divide the three remaining squares on the long side from each other by a cut the length of their side and perpendicular to the long side of the rectangle. Form a small cubic box with the pasteboard thus cut out; paste the squares together which cover each other, and paste a band of paper around the box, leaving the cover open. When dry, fill the box with powder, paste down the cover, and envelop it with two or three layers of strong twine. Cover the marron with glue or kit, and prime it with quick-match inserted in a hole punched into the powder at the middle of one of the faces. See *Compositions* and *Fireworks*.

MARRUCINI.—An ancient people in central Italy, on a narrow tract of land along the right bank of the river Aternus. Their territory extended from the Apennines to the Adriatic: between the Vestini on the north and the Frentani on the south; and between the Peligni and the Adriatic on the east and west. They were an independent nation, said to be descended from the Sabines, and generally were in alliance with their neighbors, the Marsi and Peligni. They entered into alliance with the Romans in 304 B. C, but rebelled at the beginning of the Social War. Their only place of importance was Teste, now Chieti, on the right bank of the Aternus, now the Pescara.

MARS.—The Roman Mars, who as a war-god is surnamed *Gradivus* (=*grandis divus*, the great god), also bore the surname of *Silvanus*, and appears to have been originally an agricultural deity; the propitiatory offerings were presented to him as the guardian of fields and flocks; but as the fierce shepherds who founded the city of Rome were even more addicted to martial than to pastoral pursuits, one can easily understand how *Mars Silvanus* should have, in the course of time, become the "God of War." Mars, who was a perfect personification of the stern, relentless, and even cruel valor of the old Romans, was held in the highest honor. He ranked next to Jupiter; like him he bore the venerable epithet of *Father* (Mars-*piter*); he was one of the three Tutelary Divinities of the City, to each of whom Numa appointed a flamen; nay, he was said to be the father of Romulus himself (by Rhea Silvia, the Priestess of Vesta), and was thus believed to be the real progenitor of the Roman people. He had a sanctuary on the Quirinal; and the hill received its name from his surname, *Quirinus*, the most probable meaning of which is *the spear-armed*. It was under this designation that he was invoked as the protector of the *Quirites* (citizens) in other words, of the State. The principal animals sacred to him were the wolf and the horse. He had many Temples at Rome, the most celebrated of which was that outside the *Porta Capena*, on the Appian Road. The *Campus Martius*, where the Romans practiced athletic and military exercises, was named after him; so was the month of March (*Martius*), the first month of the Roman year. The *Ludi Martiales* (games held in his honor) were celebrated every year in the circus.

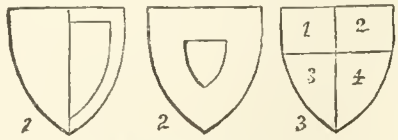
Ares, the Greek god of war, was the son of Zeus and Hera, and the favorite of Aphrodite, who bore him several children. He is represented in Greek poetry as a most sanguinary divinity, delighting in war for its own sake, and in the destruction of men. Before him into battle goes his sister *Eris* (Strife); along with him are his sons and companions, *Deimos* (Horror) and *Phobos* (Fear). He does not always adhere to the same side, like the great *Athena*, but inspires now the one, now the other. He is not always victorious. Diomede wounded him, and in his fall, says Homer, "he roared like nine or ten thousand warriors together." Such a representation would have been deemed blasphemous by the ancient Roman mind, imbued as it was with a solemn Hebrew-like reverence for its gods. The worship of Ares was never very prevalent in Greece; it is believed to have been imported from Thrace. There, and in Scythia, were its great seats, and there Ares was believed to have his chief home. He had, however, Temples or Shrines at Athens, Sparta, Olympia, and other places. On statues and reliefs, he is represented as a person of great muscular power, and either naked or clothed with the chlamys.

MARSEILLAISE.—The name by which the grand song of the first French Revolution is known. The circumstances which led to its composition are as follows: In the beginning of 1792, when a column of volunteers was about to leave Strasbourg, the Mayor of the city, who gave a banquet on the occasion, asked an officer of artillery named Rouget de Lisle, to compose a song in their honor. His request was complied with, and the result was the *Marseillaise*—both verse and music being the work of a single night. De Lisle entitled the piece *Chant de Guerre de l'Armée du Rhin*. Next day it was sung with rapturous enthusiasm that only Frenchmen can exhibit, and instead of 600 volunteers, 1000 marched out of Strasbourg. Soon from the whole army of the north resounded the thrilling and fiery words *aux armes aux armes*; nevertheless the song was still unknown at Paris, and was first introduced there by Barbaroux when he summoned the youth of Marseilles to the Capital in July, 1792. It was received with transports by the Parisians, who—ignorant of its real authorship—named it *Hymne des Marseillaise*, which name it has ever since borne.

MARSHAL.—A term which originally meant a groom or manager of the horse, though eventually the King's Marshal became one of the principal Officers of State in England. The Royal Farrier rose in dignity with the increasing importance of the *Chevalerie*, till he became, conjointly with the Constable, the judge in the *Curiæ Martiales*, or Courts of Chivalry. An Earldom is attached to the dignity, and the office of Earl-Marshal is now hereditary in the family of the Duke of Norfolk. When the King headed his army in feudal times, the assembled troops were inspected by the Constable and Marshal, who fixed the spot for the encampment of each noble, and examined the number, arms, and condition of his retainers. With these duties was naturally combined the regulation of all matters connected with armorial bearings, standards, and ensigns. The Constable's functions were virtually abolished in the time of Henry VIII., and the Marshal became thenceforth the sole judge in questions of honor and arms. The Earl-Marshal is president of the English college of arms, and appoints the Kings-at-Arms, Heralds, and Pursuivants. The Marshal's functions were formerly exercised in time of peace in the *Aula Regis* or King's Great Court, and on the division of the *Aula Regis*, he appointed deputies in the new courts; hence arose the offices of Marshal of the King's (Queen's) Bench, and of Exchequer, whose principal duty is to take charge of persons committed to their custody by the court. Besides the Earl-Marshal there is a Knight-Marshal, or Marshal of the King's (Queen's) household. The Marshal of the King's Bench held two different courts, which have been altogether discontinued since 1849. The Marshal, or Provost-Marshal, of the admiralty is an officer whose duty it is to act ministerially under the orders of the court of admiralty in securing prizes, executing warrants, arresting criminals, and attending their execution.

The dignity of Marshal existed formerly in Scotland, where a different orthography was adopted, and the office of Marischal was hereditary in the family of Keith. Sir Robert Keith, the Marischal, was one of the most distinguished warriors in the army of Robert the Bruce; and his descendant, the Marischal in 1456, had the dignity of Earl conferred on him with no other title but that of Earl-Marischal. There is little doubt that the Lyon King-at-Arms was, like the English Kings-at-Arms, originally subject to the Marischal, but his dependence ceased at a very early period, and the heraldic functions discharged by the Earl-Marshal in England devolved in Scotland on the Lord Lyon, who held office directly from the crown. Scotland had no Knight-Marischal till 1633, when Charles I., at his coronation, created the office. In 1716 George, tenth Earl-Marischal, was attainted in consequence of his share in the rebellion of the previous year, and the office has since been in abeyance. In France the highest military officer is called a Marshal, a dignity which originated early in the 13th century. There was at first only one *Maréchal de France*, and there were but two till the time of Francis I. Their number afterwards became unlimited. Originally the Marshal was the Esquire of the King, and commanded the vanguard in war; in later times the command became supreme, and the rank of the highest military importance. From the title of this class of general officers the Germans have borrowed their Feld-Marschall, and we our Field-Marshal, a dignity bestowed on commanders distinguished either by elevated rank or superior talents. In the United States the word is used in three significations: 1. To denote the Ministerial Officer of the United States Courts, there being one appointed to each judicial district. The duties of this officer resemble those of a Sheriff in the State Courts; he opens and closes the sessions of the District and Circuit Courts, serves warrants, and with his deputies enforces the execution of the internal revenue and other U. S. Statutes. 2. To denote a leader or director of ceremonies, festivities, or processions. 3. In many states of the south and west the Marshal is the head of the municipal police force, and is to be distinguished from the officers of the county called Sheriffs, and from the officers of the justice courts called Constables. In a few northern cities, formerly the name was applied with doubtful propriety to special police officers.

MARSHALLING OF ARMS.—The combining of different coats-of-arms in one escutcheon, for the purpose of indicating family alliance or office. In the earlier heraldry, it was not the practice to exhibit more than one coat in a shield, but the arms of husband and wife were sometimes placed *accollée*, or side by side, in separate escutcheons; or the principal shield was surrounded by smaller ones, containing the arms of maternal ancestors; and we not unfrequently find maternal descent or marriage indicated by the addition of some bearing from the wife's or mother's shield. Then followed *dimidiation*, where the shield was parted per pale, and the two coats placed side by side, half of each being shown. By the more modern custom of impaling (Fig. 1), the whole of each coat is exhibited, a reminiscence of the older practice being retained in the omission of bordures, orels, and tressures on the side bounded by the line of impalement. The most common case of impalement



Marshalling of Arms.

ment is where the coats of husband and wife are conjoined, the husband's arms occupying the dexter side of the shield, or place of honor, and the wife's the sinister side. Bishops, Deans, Heads of Colleges, and Kings-of-Arms, impale their arms of office with their family coat, giving the dexter side to the former. A man who marries an heiress (in heraldic sense) is entitled to place her arms on a small shield called an *escutcheon of pretence*, in the center of his achievement, instead of impaling (Fig. 2.). *Quartering* (Fig. 3), or the exhibiting different *coats* on a shield divided at once perpendicularly and horizontally, is the most common mode of marshalling arms, a practice which, however, was unknown till the middle of the 14th century. The divisions of the shield are called quarters, and are numbered horizontally, beginning at the dexter chief. The most common object of quartering is to indicate descent. The coats quartered in an escutcheon must all have been brought in by successive heiresses, who have intermarried into the family. In the case of a single quartering the paternal arms are placed in the first and fourth quarters, and the maternal in the second and third. The third and fourth quarters may, in after generations, be occupied by the arms of a second and third heiress. Sometimes an already quartered coat is placed in one of the four quarters of the escutcheon, then termed a grand quarter. We occasionally find the shield divided by perpendicular and horizontal lines into six, nine, or even more parts, each occupied by a coat brought in by an heiress; and in case of an odd number of coats, the last division is filled by a repetition of the first. In the course of generations, a shield may thus be inconveniently crowded by the accumulation of coats, including the several coats to which each heiress may, in a similar way, have become entitled, and in Germany, sometimes twenty or thirty coats are found marshalled in one escutcheon; but in British Heraldry, families entitled to a number of quarterings, generally select some of the most important. Quarterings, at least in Scotland, are not allowed to be added to the paternal coat without the sanction of the heraldic authorities. Sovereigns quarter the ensigns of their several States, giving precedence to the most ancient, unless it be inferior to the others in importance. In the royal escutcheon of the United Kingdom, England is placed in the first and fourth quarters, Scotland in the second, and Ireland in the third; the relative positions of Scotland and England being, however, reversed on the official seals of Scotland. Spain bears the arms of Leon in the first and fourth quarters, and Castile in the second and third. An elected King generally places his arms surtout on an escutcheon of pretence.

MARSI.—An ancient tribe of central Italy, inhabiting the district around the lake Fucinus (*Lago di Celano*). Their origin, like that of other Italian tribes, is involved in obscurity and fiction. They were probably of Sabine origin. They are worthy of notice chiefly on account of their warlike spirit. The Marsians were at one time allies of the Romans, but, in 308 B. C., they revolted and joined the Samnites. After being subdued they again, 301 B.C., shook off the alliance of Rome, but were beaten in the field, and lost several of their fortresses. From this time they continued the firm allies of Rome, contributing by their valor to her triumphs until the Italians were aroused in 91 B.C., to demand a redress of their wrongs and a share in the privileges of Roman citizens. A war ensued, generally known as the Social War, but frequently called the Marsic War, because the Marsi were prominent among the malcontents. Their leader was Silus Pompædius. Though often defeated, their perseverance gained the object for which they had taken up arms in 87 B.C. The Marsians, inhabiting a mountainous district were simple and temperate in their habits, but hardy, brave, and unyielding. So marked was their valor that there was a proverbial saying recorded by Appian, "That Rome had achieved no triumph *over* the Marsi, or *without* the Marsi." The ancient Marsi were represented as enchanters, able to tame serpents and to heal their bites; and it is worthy of note that the jugglers who now amuse the people by handling serpents are natives of the region in the vicinity of *Lago di Celano*. Their only important town was *Marruvium* (San Benedetto), the ruins of which are visible on the east shore of the lake.

MARTEAU D'ARMES.—An offensive weapon, so-called from its resemblance to a hammer.

MARTEL DE FER.—An offensive weapon in use at the beginning of the 13th century. It was in the shape of a pointed hammer or small pickaxe. It is stated to have made sad havoc in mail or armor, and left fatal openings for the passage of the sword or lance.

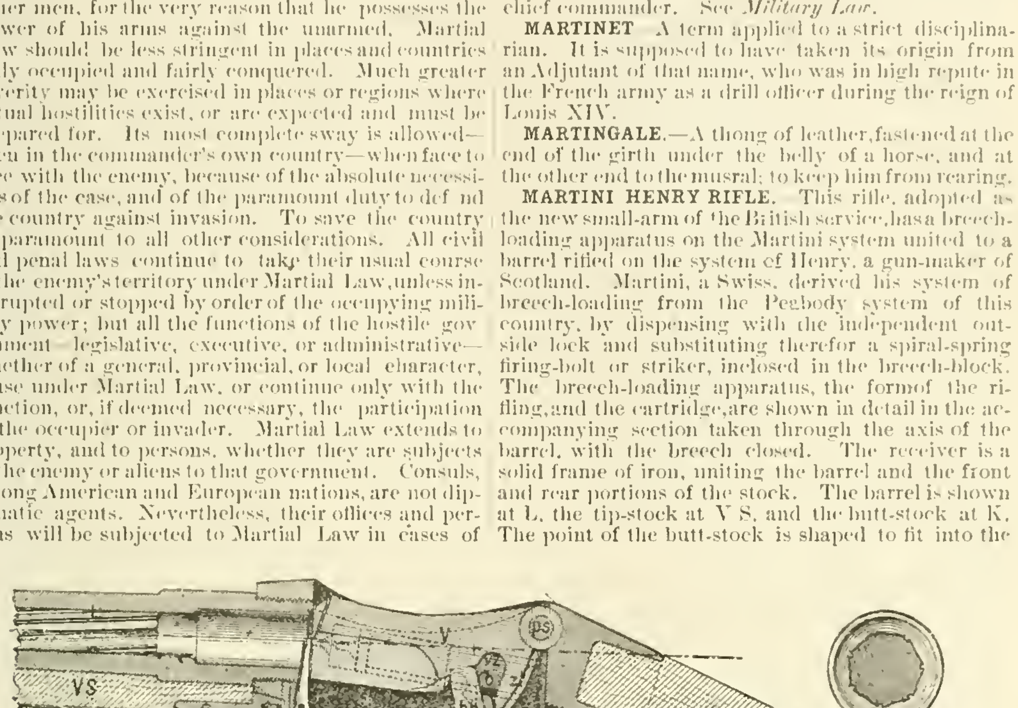
MARTELLO TOWERS—are round towers for coast defense, about 40 feet high, built most solidly, and situated on the beach. They occur in several places round the coast of the United Kingdom; but principally opposite to the French coast, along the southern shore of Kent and Sussex, where, for many miles, they are within easy range of each other. They were mostly erected during the French war as a defense against invasion. Each had walls of 5½ feet thickness, and was supposed to be bomb-proof. The base formed the magazine; above were two rooms for the garrison, and over the upper of these the flat roof, with a 4½ feet brick parapet all round. On this roof a swivel heavy gun was to be placed to command shipping, while howitzers on each side were to form a flanking defense in connection with the neighboring towers. Although the cost of these little forts was very great, they are generally considered to have been a failure; their armaments have mostly been removed. The name is said to be taken from Italian towers built near the sea, during the period when piracy was common in the Mediterranean, for the purpose of keeping watch and giving warning if a pirate-ship was seen approaching. This warning was given by striking on a bell with a hammer (Italian *Martello*), and hence these towers were called *torri da martello*.

MARTIAL LAW.—An arbitrary law, proceeding directly from the military power, and having no immediate constitutional or legislative sanction. A place, district, or country occupied by an enemy stands, in consequence of the occupation, under the Martial Law of the invading or occupying Army, whether any proclamation declaring Martial Law, or any public warning to the inhabitants, has been issued or not. Martial Law is the immediate and direct effect and consequence of occupation or conquest. The presence of a hostile army proclaims its Martial Law. Martial Law does not cease during the hostile occupation, except by special proclamation, ordered by the commander-in-chief; or by special mention in the treaty of peace concluding the war, when the occupation of a place or territory continues beyond the conclusion of peace as one of the conditions of the same. Martial Law in a hostile country consists in the suspension, by the occupying military authority, of the criminal and civil law, and of the domestic administration and government in the occupied place or territory, and in the substitution of military rule and force for the same, as well as in the dictation of general laws, as far as military necessity requires this suspension, substitution, or dictation. The commander of the forces may proclaim that the administration of all civil and penal law shall continue, either wholly or in part, as in times of peace, unless otherwise ordered by the military authority. Martial Law is simply military authority exercised in accordance with the laws and usages of war. Military oppression is not Martial Law; it is the abuse of the power which that law confers. As Martial Law is executed by military force, it is incumbent upon those who administer it to be strictly guided by the principles of justice, honor, and humanity—virtues adorning a soldier even more than other men, for the very reason that he possesses the power of his arms against the unarmed. Martial Law should be less stringent in places and countries fully occupied and fairly conquered. Much greater severity may be exercised in places or regions where actual hostilities exist, or are expected and must be prepared for. Its most complete sway is allowed—even in the commander's own country—when face to face with the enemy, because of the absolute necessities of the case, and of the paramount duty to defend the country against invasion. To save the country is paramount to all other considerations. All civil and penal laws continue to take their usual course in the enemy's territory under Martial Law, unless interrupted or stopped by order of the occupying military power; but all the functions of the hostile government—legislative, executive, or administrative—whether of a general, provincial, or local character, cease under Martial Law, or continue only with the sanction, or, if deemed necessary, the participation of the occupier or invader. Martial Law extends to property, and to persons, whether they are subjects of the enemy or aliens to that government. Consuls, among American and European nations, are not diplomatic agents. Nevertheless, their offices and persons will be subjected to Martial Law in cases of mainly to the support and efficiency of the Army, its safety, and the safety of its operations. The law of war does not only disclaim all cruelty and bad faith concerning engagements concluded with the enemy during the war, but also the breaking of stipulations solemnly contracted by the belligerents in time of peace, and avowedly intended to remain in force in case of war between the contracting powers. It disclaims all extortions and other transactions for individual gain; all acts of private revenge, or connivance at such acts. Offenses to the contrary shall be severely punished, and especially so if committed by officers. Whenever feasible, Martial Law is carried out in cases of individual offenders by Military Courts; but sentences of death shall be executed only with the approval of the chief executive, provided the urgency of the case does not require a speedier execution, and then only with the approval of the chief commander. See *Military Law*.

MARTINET A term applied to a strict disciplinarian. It is supposed to have taken its origin from an Adjutant of that name, who was in high repute in the French army as a drill officer during the reign of Louis XIV.

MARTINGALE.—A thong of leather, fastened at the end of the girth under the belly of a horse, and at the other end to the musrol; to keep him from rearing.

MARTINI HENRY RIFLE. This rifle, adopted as the new small-arm of the British service, has a breech-loading apparatus on the Martini system united to a barrel rifled on the system of Henry, a gun-maker of Scotland. Martini, a Swiss, derived his system of breech-loading from the Peabody system of this country, by dispensing with the independent outside lock and substituting therefor a spiral-spring firing-bolt or striker, inclosed in the breech-block. The breech-loading apparatus, the form of the rifling, and the cartridge, are shown in detail in the accompanying section taken through the axis of the barrel, with the breech closed. The receiver is a solid frame of iron, uniting the barrel and the front and rear portions of the stock. The barrel is shown at L, the tip-stock at V S, and the butt-stock at K. The point of the butt-stock is shaped to fit into the



urgent necessity only; their property and business are not exempted. Any delinquency they commit against the established military rule may be punished as in the case of any other inhabitant, and such punishment furnishes no reasonable ground for international complaint. The functions of Ambassadors, Ministers, or other diplomatic agents, accredited by neutral powers to the hostile government, cease, so far as regards the displaced government; but the conquering or occupying power usually recognizes them as temporarily accredited to itself. Martial Law affects chiefly the police and collection of public revenue and taxes, whether imposed by the expelled government or by the invader, and refers rear end of the receiver, which is cupped to receive it; it is fastened to the receiver by the longitudinal screw-bolt, K S, in the manner shown in the drawing. The several parts of the breech system may be divided into two groups, viz: 1. The falling breech-block and the firing apparatus contained in it; 2. The trigger and other parts attached to the trigger-plate, and the extractor. The breech-block is pivoted at its rear and upper portion, and in uncovering the chamber of the barrel for the purpose of loading, its front portion falls. The axis-pin, *p s*, around which the block turns is made of hard bronze. The portion of the collar surrounding this pin is embedded in the receiver and constitutes the principal recoil-bearing surface of the block. As this surface is above the axis of the bore, prolonged to the rear, there is a downward pressure of the block at the moment of explosion. This pressure is resisted by the short arm of the lever, *b h*, and the block thereby secured in its place. This lever, called the block-lever, is composed of two arms, and turns round the pin, *n w*. The short arm of the block-lever is divided into two branches. The long arm serves as a handle by which the block is worked, and when closed its point enters a countersink, and is held in place by a small catch-pin. The short arm of the block-lever works in a cut on the lower side of the breech-block. This cut is so shaped that the points of the branches of the short arm working against its sides raise and lower the block and lock it. The drawing shows the block in the locked position. The lever-pin passes through both cheeks of the receiver, and is secured to the left cheek by a small screw, the head of which enters a groove in the point of the pin.

The firing-bolt, or striker, lies in a hole extending nearly through the center of the breech-block. It is composed of its point, which projects through a corresponding opening in the head of the block; a collar, which serves as a shoulder for the spiral mainspring to press against, and the body enveloped by this spiral spring. The rear portion of the striker has a vertical slot, in which works the point of a lever to draw back the striker to the position of full cock. This lever is called the tumbler. The rear end of the striker has a slot in it, that it may be adjusted by a screw-driver to receive the point of the tumbler. The striker is kept in place by a nut screwed into the rear end of the breech-block. The tumbler is pivoted on the same axis-pin as the locking-lever, *n w*, and is placed between its two branches. To show when the striker is at full cock, the end of the lever-pin, *n w*, has an index-arm, which lies on the right side of the receiver and turns with the tumbler. It is for this purpose that the portion of the pin on which the tumbler fits is made square. The tumbler, when at full cock, is supported on a rocker, called the tumbler-rest. The nose of the trigger, in turn supports the tumbler-rest at *r*. The tail-piece of the tumbler-rest bears against the back of the trigger when the latter is pulled. The trigger-spring is shown in, *d f*. To prevent accidents when the piece is carried loaded, the trigger is secured in place by the trigger-bolt, which is slid back and forth by pressing on the finger-piece. When locked, the bolt fits into a notch, and is kept in place by a spring.

The extractor, *e*, is a bent lever pivoted at *e s*. Its vertical arm is composed of two branches with points which hook under the rim of the cartridge to extract the shell. The horizontal arm is shaped to receive the downward pressure of the breech-block on its point and start the shell from the chamber. As soon as the shell has moved slightly the point of the breech-block strikes the arm near the fulcrum, and ejects the shell with force from the piece. The form of the rifling is shown in the drawing. The number of grooves is seven; in shape they are flat at the bottom; the lands are narrow, having the appearance of sharp ribs, which are designed to take a firm hold of the bullet. It is understood that these grooves are made somewhat deeper at the breech than at the muzzle. Twist is one turn in 22 inches. There is a brass collar around the head of the ramrod to prevent injury to the bore in wiping out. The triangular bayonet is issued with all arms to private soldiers. The sword-bayonet is issued to non-commissioned officers.

The weight of the Martini-Henry rifle is 8½ pounds; of the present bayonet 13½ ounces; of the new bayonet, 14 ounces; of the old scabbard, 6 ounces; of the new scabbard, 4½ ounces. The weight of the rifle with a new bayonet attached is 9 pounds 11 ounces; with the old bayonet, 9 pounds 11½ ounces.

The cartridge adopted for the Martini-Henry rifle is made of wrapped metal, after what is known in England as the Boxer system. Each cartridge is composed of some fourteen distinct pieces, as shown in section. The body of the shell is made by wrapping a trapezoidal piece of thin sheet-brass around a cylindrical former, making a tube. One end of this tube is turned inward to form an interior flange for securing the shell to its head, the other end is reduced in diameter to fit the cylindrical portion of the bullet. A piece of thin paper is rolled up with the brass sheet for a lining to the shell to protect it against the action of the powder. The head of the shell is made of a perforated sheet-iron disk, *t*, two re-enforcing cups of thin sheet-brass, *k*, the anvil-pocket, *g*, made of copper, and a paper wad, *c*. The relative positions of these pieces are shown in the sectional figure, and they are held together by the anvil-pocket and the paper wad, which is pressed into its place with great force under the head of the anvil-pocket, while the open end of the pocket is riveted to the disk.

The shell is primed by inserting into the anvil-pocket from the outside a primer composed of a percussion-cap of copper, *z*, and containing an anvil, *a*, also of copper. The bottom of the anvil-pocket has a small hole for the passage of the flame from the fulminate of the primer when it is exploded.

The bullet, *c*, is of cylindro-conoidal form, made of lead hardened by an admixture of one-thirteenth part of tin. The bullet is slightly cupped at the base, and has around it a slight groove, *r*, *r*, or cannelure, into which the cartridge-shell is choked to hold the bullet in place. The bullet is enveloped in a patch of thin paper, similar to that used for bank-notes. The lubricating material is a bee's-wax wad, *w d*, lying between the powder and bullet. This wad is separated from the powder by a stout paper disk (jute), and from the bullet by two disks of the same material. The weight of the bullet is 480 grains, and the powder is similar in quantity to that known as No. 6, Curtis and Harvey's make, and weighs 85 grains. These cartridges can be reprimed and reloaded.

Since the Martini-Henry rifles have been placed in the hands of the troops certain defects have been developed, and the necessary alterations have been made to correct them. The most serious defect appears to have been the recoil, or "kick," of the arm, extending, according to the newspaper accounts, so far as to disable soldiers after firing a series of not more than one hundred shots. The cause of this severe recoil is attributed to the great weight of the charge (powder and bullet) in proportion to the weight of the arm. The prominence of the stock in rear of the breech-frame contributes to the inconvenience of the recoil by striking against the face of the firer, if care be not taken to hold the piece properly. The injurious effect of the recoil is found to be the greatest with soldiers not accustomed to the use of the new arm, and diminishes as they become more accustomed to it. To remedy the evil as far as practicable, it has been decided to lengthen the butt of the stock. Originally the distance from the trigger to the middle point of the butt-plate was 13 and 14 inches, and the two kinds of rifles were issued to the troops in the proportion of two of the former to one of the latter length. The corresponding distances now are about 14 inches and 14½ inches, and the change is said to have gone quite far toward remedying the evil. To protect the left hand from the heat of the barrel in rapid firing the portion of the barrel embraced by the hand is covered with a leather shield strapped and buckled on. The butt-plates were formerly roughed by cross-hatching with a file to give a firmer hold against the shoulder. This has been dispensed with as unnecessary, and the surface is now left smooth. The locking-bolt has also been dispensed with as unnecessary, and the block axis-pin is countersunk and made of steel instead of hard bronze. The strikers having been found to break, have been materially strengthened. The plan of screwing in the point of the ramrod to hold it in its place has been changed to a shoulder resting against a stop, which is strongly secured to the stock below the tip, somewhat after the American plan.

The carbines of the cavalry and artillery patterns have the same caliber as the Martini-Henry rifle, and have also the same twist and form of rifling, but the barrels are only 19 inches in length. The weight of the cavalry carbine is 7 pounds, 8 ounces, and that of the artillery carbine is 7 pounds, 10¾ ounces. Total length, 3 feet, 1¼ inches. See *Boxer Cartridge*, *Peabody-Martini Rifle*, and *Royal Small arms*.

MARTIN SHELL.—A very ingenious substitute for a red-hot shot, to which, as far as experience has gone, it is much superior. It is an ordinary shell furnished with an iron screw stopper. Molten iron is poured into the shell, the stopper screwed in, and the missile discharged for incendiary purposes.

Martlet.

MARTLET.—In Heraldry, a bird resembling a swallow, with long wings, very short beak and thighs, and no visible legs, given as a mark of cadency to the fourth son. It is also otherwise used as a charge. The martlet was originally meant for the martin, and in the earliest Heraldry, it is not deprived of its feet.

MASCLE.—In Heraldry, a lozenge-shaped figure perforated and showing a very narrow border. The term *mascally* is as a general thing applied to any field that is divided by diagonal lines into lozenge-shaped compartments of alternate tinctures, each having its center voided of the opposite tincture. *Lozengy-mascally* is a field composed of lozenges and mascles alternately. In the earlier Heraldry, mascally was used for what was afterwards callen lozengy. Crosses and other ordinaries may be formed of mascles, in which case they should begin with half a mascle. See *Heraldry*.

Mascle.

MASCLED ARMOR.—A kind of armor sometimes worn by the Norman soldiers, composed of small lozenge-shaped plates of metal fastened on a leathern or quilted under-coat.

MASK.—1. In a permanent fortification, a casemated redoubt, one or two stories high and 12 yards in

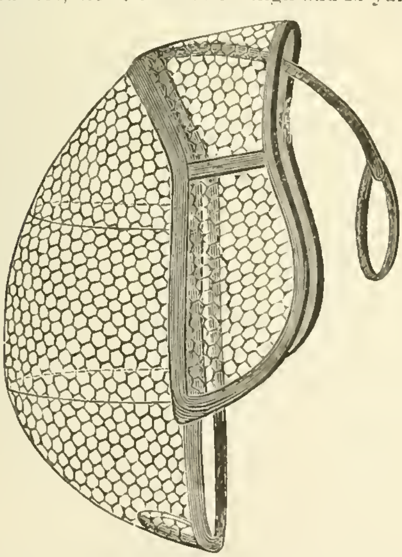


Fig. 1.

width at the capital, which is sometimes added in front of the caponier; a ditch 10 yards wide may be formed in front and rear of it. Its salients being made circular and loop holed, a close and powerful fire can be brought to bear upon the enemy if he succeeds in establishing himself in the ravelin. The name *mask* is given to this redoubt, as it acts as an efficient mask or counter-guard to the caponier. 2. A wire cage to protect the face in fencing. Fig. 1 represents the ordinary *fencing mask*, furnished with ears and fronts. Fig. 2, represents the *hau rapier mask* padded. 3. As a military expression, *mask*, is used in several senses. A *masked battery* is one so constructed, with a grassy glacis, etc., as to be hidden from the view of the enemy until, to his surprise, it suddenly opens fire upon him—on his flank, perhaps. The fire of a battery is *masked* when some

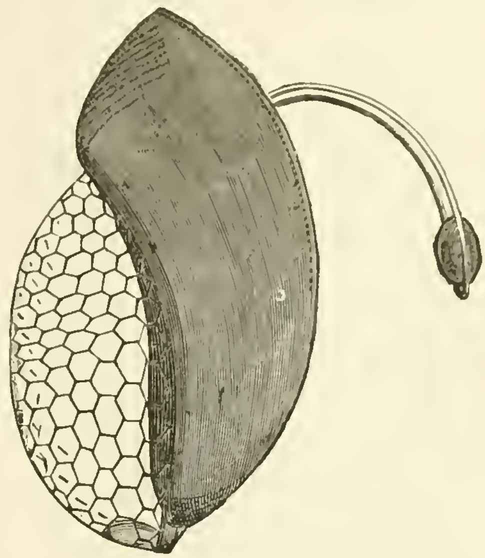

Fig. 2.

other work, or a body of friendly troops, intervenes in the line of fire, and precludes the use of the guns. A fortress or an army is *masked* when a superior force of the enemy holds it in check, while some hostile evolution is being carried out

MASON AND DIXON'S LINE.—This line originated in the difficulties which occurred in tracing the boundary line of a tract of land granted to William Penn in 1681. This land lay west of the Delaware and north of Maryland, and a part of its southern boundary was defined to be "a circle drawn at 12 miles distant from Newcastle northwards and westwards into the beginning of the 40° of northern latitude." Later, Penn received another grant, and, his agent being unable to agree with the authorities in America as to the just boundary, he came to this country himself in 1682 to establish his claim and take possession of his land. He was opposed by Lord Baltimore, the matter was referred to the Committee of Trade and Plantations, a change in the reigning monarch of England took place, and it was not until 1760 that the final deed was issued to the heirs of Penn, closing the controversy. But even then the question of surveying the disputed territory with a view of defining the boundary-line opened new disagreement; and it was to arrange this that Charles Mason and James Dixon, "Mathematicians and Surveyors," were mutually agreed upon by the contestants, Thomas and Richard Penn, on the one part, and Lord Baltimore, the great grand-son of Cecilius, the first patentee, on the other, "To mark, run out, settle, fix and determine all such parts of the circle, marks, lines, and boundaries as were mentioned in the several articles or commissions, and were not completed." The two surveyors commenced their work in 1764, and did not finish it until 1767; the delay being partly owing to Indian troubles, involving negotiations with the Six Nations in their settlement. The line as finally drawn, has been popularly supposed to have been the dividing line between the Free and the Slave States; but this is an error, as slavery existed throughout Delaware, which is both east and north of the line, until abolished by the 14th Amendment to the Constitution. To this line is owing the peculiar tract of land known as the Pan-handle," where a part of Virginia runs up between Pennsylvania and the Ohio River. Very little is known of the two "Surveyors of London," as they were styled. Mason was an assistant of Dr. Bradley at the Royal Observatory at Greenwich; both were members of the American Philosophical Society; both were sent by the Royal Society to the Cape of Good Hope to observe the transit of Venus in 1769. Dixon died in Durham, England, in 1777; and Mason died in Pennsylvania in 1787.

MASONED.—In Heraldry, a term used to describe the lines formed by the junction of the stones in building.

MASS.—1. In *Statics*, the amount of matter contained in a body. In *Dynamics*, that measure of the matter in a body which determines its relation to force. The accepted measure is the weight divided by the force of gravity. 2 The formation of troops in column at less than half distance. To *mass troops*, is to concentrate them by this arrangement on a certain point. A column is *closed in* mass when the sub-divisions have less than half distance.

MASSACRE.—The killing of human beings by indiscriminate slaughter, murder of numbers with cruelty or atrocity, or contrary to the usages of civilized people. As an example, we may cite the Mountain Meadows Massacre, an atrocity committed by the Indians in 1857, in Mountain Meadows, Santa Clara Co., Utah; as is supposed, under the instigation and direction of the Mormon leaders. A party of 120 emigrant settlers, on their way through Utah to California, had in some way aroused the suspicions of the Mormons, and at the place named were surrounded by Indians under Mormon control, and brutally massacred: only a few children of the party survived. In 1874 an investigation into the affair was ordered by the U. S. Government, and John D. Lee, a Mormon Bishop, and others, were indicted, tried, and condemned. Lee was executed on March 22, 1877, by being shot on the very spot where the massacre took place.

MASSAGETAE.—A nomadic people who inhabited the broad steppes on the northeast of the Caspian sea, to the northward of the river Araxes or Jaxartes. Herodotus says that they had a community of wives; that they sacrificed and devoured their aged people; that they worshipped the sun, and offered horses to him; that they lived on the milk and flesh of their herds, and on fish; and fought on horseback and on foot with the lance, bow, and double-edged axe. Cyrus is said to have lost his life in fighting against them, 530 B.C. Niebuhr and Böockh are of opinion that they belonged to the Mongolian, but Humboldt and others to the Indo-Germanic or Aryan family.

MASSE.—A species of stock-purse, which, during the French monarchy, was lodged in the hands of the Regimental Treasurer or Paymaster, for every Sergeant, Corporal, Drummer, and Soldier. The amount retained for each Sergeant was *vingt deniers* per day, and *dix deniers* for each of the other ranks, according to the establishment, not the effective number, of each battalion. Out of these stoppages a settled and regular *masse*, or stock-purse, was made up, and at the end of every month it was paid into the hands of the Major or Officer intrusted with the interior management of the corps, and was then appropriated to defray the expense of clothing the different regiments, and lodged in the hands of the Directors or Inspector-General of Clothing.

MASSE D'ARMES.—A warlike weapon, which was formerly used in France. It consisted of a long pole with a large iron head.

MASSELOTTE.—A French term used in the foundry to signify that superfluous metal which remains after a cannon or mortar has been cast, and which is sawed or filed off to give the piece its proper form.

MASSIE.—A short stick or rod, used by artificers in making cartridges.

MASSING GUNS.—The best mode of successfully silencing the enemy's artillery, or of destroying some special position of his, is by means of a number of guns brought to bear on that point. This system was first introduced by Napoleon at the battles of Wagram, the Moskwa, and Lützen, and subsequently was employed with great effect by the Germans during the war of 1870-71.

In the concentration of artillery in action it is not necessary that all the guns should be formed up into one gigantic battery. With pieces commanding a range of 3,000 yards, a hundred guns might generally direct their fire on to one spot, without being crowded together, and it is hardly likely so many guns would be required to concentrate their fire. It is further shown that it is important in massing guns, especially under the fire of an enemy, that the guns should come into action as nearly simultaneously as possible; otherwise each battery may be crushed in its turn as it comes up, from the enemy having got the exact range of the battery which first got into position.

MASTER GENERAL OF THE ORDNANCE.—An officer formerly at the head of the Board of Ordnance. Before the present regimental organization of the artillery, all details of the regiment came under the care and superintendence of the Master-General. The position of Master-General was introduced into the English Army as early as 1483; at all events, that seems to be the earliest date that the name of such a functionary can be traced. This officer was at the head of the Board of Ordnance, to which most important duties were assigned; and if any one would wish to learn what the Master-General had to do in the 17th century, let him go to the Tower and examine the correspondence of Lord Dartmouth, the faithful friend and servant of Charles II., a professional artilleryman, and James II., a skilled Master-General to the last. The last Master-General of the Ordnance was Lord Raglan, who died while in command of the British Army in the Crimea.

MASTER-GUNNER.—Formerly an ancient office under the crown, as far back as the reign of Henry VIII. The appointment is now filled by pensioned sergeants of artillery. A Master-Gunner, as understood nowadays, is a warrant officer selected from the Non-commissioned officers of artillery, whose duty is to take charge of guns, ammunition, stores etc., in a fortress. The Coast Brigade is composed of Master Gunners (pensioners), and there are 3 classes, 1st, 2d, and 3d, containing 16, 26, and 83 respectively.

MASTER OF THE BUCKHOUNDS.—An officer in the Master of the Horse Department of the Royal Household, who has the control of all matters relating to the royal hunts. A salary of £1,500 is attached to the office, which is regarded as one of considerable political importance. The Master of the Buckhounds goes out of office on a change of ministry.

MASTER OF THE CEREMONIES.—An office instituted at the Court of England in 1603, for the more honorable reception of Ambassadors and persons of distinction. The same term was afterwards extended beyond the Court, by being applied first to Beau Nash, the famous "Master of the Ceremonies," or President of the amusements at Bath, and then to other persons exercising the same function in ordinary assemblies.

MASTER OF THE HORSE.—The third great officer of the Court, who has the superintendence of the Royal Stables, and of all horses and breeds of horses belonging to the Queen. He exercises authority over all the Equerries and Pages, Grooms, Coachmen, Saddlers, and Farriers, and has the appointment and control of all artificers working for the Queen's stables. He is answerable for the disbursement of all revenues appropriated to defray the expenses of his Department; but his accounts are audited and examined by the Board of Green Cloth. He has the privilege of making use of the royal horses, pages, and servants, and rides next to her Majesty on all state occasions. The office is one of great antiquity, and is considered to be a position of great honor. The Master of the Horse is appointed during pleasure, by letter-patent; but his tenure of office depends on the existence of the political party in power. The salary is £2,500 a year.

MASTER OF THE SWORD. A citizen employed to instruct in the use of the small-sword, broad-sword, and bayonet, at the U. S. Military Academy. He is without rank, but wears a uniform of the following pattern:

Coat—Double-breasted frock, two rows of buttons of the General Staff of the Army, seven in each row. *Overcoat*.—Same as prescribed for a Second Lieutenant, dismounted. *Pantaloons*—Dark blue, plain. *Cap*—Chasseur pattern, with letters M. A. in silver, encircled by a wreath in gold on the front. *Sword and Sword-belt*—Same as prescribed for Lieutenants of Infantry. He is permitted to wear the dark-blue sack-coat prescribed for Army officers, with the buttons of the General Staff.

MASTER TAILOR.—A competent tailor, attached to each regiment, who has been, if a soldier, pronounced by a Board of Sergeant Master Tailors to be efficient and well up to his work, or who has been instructed in the art of tailoring at the Government Clothing Establishment, Pimlico. A civilian tailor may volunteer for the situation; and if so, he will have to pass an examination at the Royal Army Clothing Depot, and be enlisted as a Sergeant Master Tailor

MASTIC.—A species of gum-resin yielded by the mastic or lentisk tree (*pistacia lentiscus*, natural order *terebinthaceæ*). It oozes from cuts made in the bark, and hardens on the stem in small round tear-like lumps of a straw-color, or if not collected in time, it falls on the ground; in the latter state it acquires some impurities, and is consequently less valuable. The chief use of this gum-resin is in making the almost colorless varnish for varnishing prints, maps, drawings, etc. It is also used by dentists for stopping hollow teeth, and was formerly used in medicine. It is imported in small quantities, chiefly from the Morocco coast, but some is occasionally brought from the south of Europe. The name of mastic is also given to oleaginous cements, composed of about 7 parts of litharge and 93 of burned clay, reduced to fine powder, made into a paste with linseed oil.

MATADOR.—A long, narrow sword with a cross-bar. The toreador, on foot, fights with this sword and kills the bull.

MATAFUNDA.—An ancient machine of war, which was used for throwing stones, probably by means of a sling.

MATCH.—The name given to a material, such as cotton, hemp, tow, etc., which is rendered combustible by being dipped or soaked in some ignitible solution: There are two kinds of match familiar to the artilleryman, *quick-match* and *slow-match*. Quick-match is made of different-sized threads—vis: four-, six- and ten-thread—soaked in a solution of gunpowder, mixed with gum arabic and water in a boiling state, and of such consistency that the thread shall be thoroughly coated with it; it is then wound on reels, and gunpowder sifted on it. If it be stiff, and has the coating of powder perfect over the surface, it is serviceable. If it has been bruised or twisted and the coating of powder removed, it is unserviceable. It is largely used for priming fuses, etc. Slow-match is made of slightly twisted hempen rope, soaked in lime-water and saltpeter, and then dried, or it can be prepared by washing the hemp in a lye of water and wood ashes. It burns at the rate of one yard in eight hours, and is used for lighting port-fires, etc.

MATCHLOCK.—The name formerly given to a small-arm or musket. The earliest muskets were fired by means of a piece of slow-match applied by the hand to the touch-hole. An improvement on this mode of ignition was made at the end of the fourteenth century by a lock being attached to the musket which held the match, and by pressure applied to the trigger of the lock, it brought the lighted match down on the powder-pan and thus ignited the priming powder. This mode of ignition caused the musket to be called the *matchlock*. See *Lock*.

MATE-GRIFFON.—An ancient machine, the destroyer and terror of the Greeks, which projected both stones and darts.

MATERIEL.—The expression, "matériel of artillery," embraces all cannon, carriages, implements, ammunition, etc., necessary for artillery purposes, and is used in contradistinction to "*personnel of artillery*," which refers to the officers and men. The expression, "*system of artillery*," refers to the character and arrangement of the matériel of artillery, as adopted by a nation at any particular epoch. In the United States' service, the term "ordnance and ordnance stores," embraces not only all the *matériel* of artillery, but the swords, small-arms, and accoutrements used by infantry and mounted troops.

MATHEMATICAL INSTRUMEMTS.—Those instruments employed in the determination of the length of lines or the size of angles. Pairs of compasses, surveying-chains, etc., are examples of the former class; while the compass, sextant, theodolite, and the numerous list of astronomical instruments generally denominated telescopes, including the equatorial transit instrument, mural circle, etc., form the latter class. The more important of these instruments will be treated of under separate heads.
