MATHEMATICS.—The science which has for its subject-matter the properties of magnitude and number. It is usually divided into *Pure* and *Mixed;* the first including all deductions from the abstract, self-evident relations of magnitude and number; the second, the results arrived at by applying the principle so established to certain relations found by observation to exist among the phenomena of nature. The branches of Pure Mathematics which were first developed were, naturally, *Arithmetic*, or the science of number, and *Geometry*, or the science of quantity (in extension). The latter of these was the only branch of mathematics cultivated by the Greeks, their cumbrous notation opposing a barrier to any effective progress in the former science. Algebra, or the science of numbers in its most general form, is of much later growth, and was at first merely a kind of universal arithmetic, general symbols taking the place of numbers; but its extraordinary development within the last two centuries has established for it a right to be considered as a distinct science, the *Science of Operations*. Combinations of these three have given rise to *Trigonometry* and *Analytical Geometry*. The Differential and Integral Calculus makes use of the operations or processes of geometry, algebra, and analysis indifferently; the *Calculus of Finite Differences* is in part included under algebra, and may be considered as an extension of that science; and the *Calculus of Variations* is based upon the Differential Calculus. The term "Mixed Mathematics" is calculated to lead to error; "Applied Mathematics" is a more appropriate name. This portion of mathematics includes all those sciences in which a few simple axioms are mathematically shown to be sufficient for the deduction of the most important natural phenomena. This definition includes those sciences which treat of pressure, motion, light heat, sound, electricity and magnetism—usually called *Physics*—and excludes chemistry, geology, political economy, and the other branches of science which, however, receive more or less aid from mathematics.

MATRAS.—An ancient bolt or arrow with a round disk or head, which killed without piercing. It was oftener used for the chase than in war, and was especially useful in bringing down such beasts as the hunter might wish to preserve with the skin uninjured.

MATRON.—A woman, generally the wife of some well-behaved soldier, who is employed to assist in the hospital, do the washing, etc. The matrons are under the direction of the Surgeon and are originally appointed by this officer.

MATROSS.—A name formerly given to an artilleryman. In the early organization of the British artillery, there were only two-trained artillerymen per gun; they consisted of a gunner and his *mate* or *matross*. It was in the year 1783 that the term *gunner* was substituted for that of *matross*. It would appear from this that the mate, or matross, was in fact a gunner. Another explanation of the word is as follows: A man whose business it is to be in the train of artillery, next the gunners, to assist them in loading, firing, and sponging the guns.

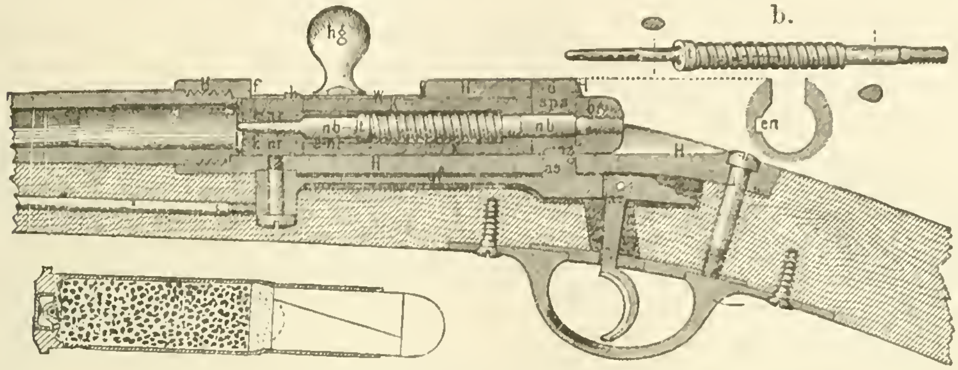
MATTER.—From a physical point of view, matter is anything that can affect the senses, or that can exert, or be acted on by force. The existence of matter, in the sense of *substance*, has been doubted by many Philosophers, including some of the greatest of Experimenters. Indeed, as we can know matter only by the forces it exerts, it is obvious that the supposition of mere geometric points, capable of exerting force (technically called *centers of force*), will as satisfactorily account for all observed phenomena as any other idea of the ultimate nature of matter. Here, however, we are dealing with a question confessedly beyond the reach of experiment, and belonging to the domain with which metaphysics professes to deal. Although experiment cannot lead to a knowledge of the ultimate nature of matter, it may lead to important discoveries as to the arrangement of the molecules of different bodies, and their similarity or dissimilarity. Some of the questions to which we may expect an answer, though not a speedy one, have already been mentioned in the article Force; but in order to render intelligible the short account which we intend to give of some very interesting ideas recently propounded by Graham, it will be necessary to repeat some of them. The old idea of the transmutation of metals implicitly contains the assumption that all kinds of matter are ultimately one. Far from being a startling assumption, this is the simplest and most easily conceived notion we can entertain on the subject; and it offers a remarkably simple explanation of that extraordinary property of matter which Newton proved by careful experiments, that the weight of a body depends only on the quantity, not on the quality of the matter that composes it. One idea, then, of matter is, that the atoms (or smallest parts, whatever these may be) of all bodies are identical, but that the molecules (each of which is a single atom, or a definitely arranged group of atoms) differ from one body to another. Thus (to take an instance merely for *explanation*, not as at all likely to be correct), if hydrogen be supposed to consist of the simple atoms of matter; oxygen, each molecule of which is 8 times as heavy as one of hydrogen, may have each molecule formed of 8 elementary atoms, arranged in a group such as the corners of a die; carbon, 6 times as heavy per molecule, might be composed of 6 simple atoms grouped as at the corners of an octohedron; and so on. It is obvious that here each atom must be supposed capable of exerting force on every other. This leads us naturally to speculations as to the medium through which this force, if it be exerted at a distance, is propagated; and then we have introduced matter of a more refined character than our supposed elementary atoms. This difficulty has suggested to various Philosophers the idea that there is no *actio in distans*, that all pressure, for instance, in a gas is due to incessant impacts of its particles upon each other and upon the containing vessel. But from various experimental results, we know that *this* species of motion is capable of being transferred from one body to another, of being increased or diminished by change of temperature, and is, in fact, *heat* itself, one form of kinetic energy. This, if there be no ultimate difference between kinds of matter, could never be the cause of their apparent difference. Hence, in Graham's view, though all ultimate atoms are identical in substance, they have special motions of their own, by which one is distinguished from another, these motions not being capable of transfer from one atom or group of atoms to another. It is difficult to conceive energy in such a form as not to be transferable, so that we refer the reader to Graham's own papers for the further development of his theory—remarking, in conclusion, that no theory of the nature of matter can be considered as at all complete till it account for the mutual action of separate atoms; for this the existence of a *continuous* material medium in space would seem to be necessary; and this, in its turn, would, if accepted, enable us to dispense with the idea of atoms. In connection with this, we may mention that Sir William Thomson has shown that mere heterogeneity (which we know exists in matter), together with gravitation, is sufficient to explain all the apparently discordant laws of molecular action; matter being supposed, in this theory, to be continuous but of varying density from point to point.

MATTOCK. A pioneer tool, resembling a pick-axe, but having two broad, sharp edges instead of points.

MATTUCASHLASH—An ancient Scotch weapon, sometimes called *Armpit Dagger*, which was worn under the armpit, ready to be used on coming to close quarters. This, with a broad-sword and shield, completely armed the Highlanders.

MAUL.—A heavy beater, or hammer, usually shod with iron, used in driving stakes, etc. That furnished from arsenals has a cylindrical head of wood, 6 inches in diameter and 8 inches long, with an iron band around each end. The handle is 24 inches long and 1.5 inch in diameter. Weight 10 lbs. This maul, as issued, owing to poor material and faulty construction, is of but little value. Where much service is required, it is better to make the head of tough, hard wood, with a handle considerably larger than the one of regulation pattern.

MAUSER RIFLE.—The Mauser is a modification of the Chassepôt system, by which it is adapted to the use of the metallic gas-check cartridge, and has been adopted by the Prussian Government as a substitute for the needle-gun. In the drawing, H represents the housing or receiver attached to the barrel by the usual form of screw at its forward end, and to the stock at its rear end by a tang-screw, which penetrates through the stock to the trigger-guard. The general form of the receiver is a tube cut away at different points for the reception of the parts that work in and are attached to it. The breech is closed by a bolt called the breech-bolt, which contains the firing-pin, and other parts necessary to the operation of locking and cocking. The principal part of the breech-bolt is the tube, K. The rib, *w*, on the exterior of this tube, known as the locking-tube, is for the purpose of locking into the space cut away in the receiver between *f* and *f*, to enable the breech-bolt to sustain the force of the discharge. The ends of this rib being made quite oblique to the axis of the bore, or rather of spiral form, and the ends of the cut being moreover made to correspond, the breech-bolt is screwed forward against the cartridge when it is locked in loading. By this arrangement the cartridge is not only forced into its place in the chamber, should there be undue resistance, but accidental explosions which might arise from striking the head of the cartridge directly when the bolt is shoved forward, are avoided. The thumb-piece, *h g*, is attached to this rib for the purpose of working the breech-bolt. The breech-bolt is terminated in the separate piece, *k n r*. By way of designation, this piece is called the bolt-head. The forward portion has a small round hole for the point of the firing-pin; the tennon which enters the locking-tube, has an oval hole, that being the shape of the cross-section of the firing-pin which passes through it. The extractor-hook is attached to the side of the bolt-head by means of a dovetail-tennon and works in a over the flange of the cartridge into its recess in the barrel. The screw motion of the locking-tube gives power to start the cartridge case should it adhere to the chamber. When withdrawn, the case falls out by slightly tipping over the barrel to the right. The following are some of the principal weights, dimensions, etc., of the Mauser rifle and cartridge as adopted for the Prussian military service: The bore is .433 inch (11 millimeters) diameter, and rifled with 4 flat grooves equal to the lands in width; the depth of the grooves is .01 inch and the twist is from right to left and one



corresponding groove cut in the left side of the well of the receiver. The stud, *h*, fits into the notch of the rib, and is the means of uniting these two parts longitudinally, at the same time their motions around their common axis are independent of each other.

The lower front corner of the cocking-piece, *s p s*, catches against the nose of the sear, *a s*, and holds the firing-pin at full-cock when the bolt is shoved forward and the breech is closed. It has also a groove, into which the nose of the sear projects when the firing-pin is pushed forward. The projection, *d*, works in a cut in the receiver, H, and thereby prevents the firing-pin from turning. A projection fits into a correspondingly shaped cut, in the locking-tube, K, and by the pressure produced by the firing-pin spring keeps the breech-bolt in the locked position.

The firing-pin nut, *b s*, secures the cocking-piece to the firing-pin. The projection, *g*, fits into a groove, and is thereby prevented from unscrewing. The parts marked, *a f*, and *a s*, are the sear-spring and sear combined in one piece. This piece is attached to the lower side of the receiver by a screw; the portion through which the screw passes serves as the ramrod-stop. The trigger, *a z*, is pivoted to the sear, and is composed of an arm and finger-piece. Fig. b, shows the firing-pin, and its spiral spring, made of square instead of round wire. The portions in front and rear of the spring are made oval in cross-section to prevent the pin from turning in locking. The re-enforce, *t*, forms a shoulder for the spring to press against. The main drawing represents the firing-pin in the position of resting on the head of the cartridge after firing. As the piece is brought to the position of full-cock in loading, an improvement has lately been introduced into this arm for locking the firing-pin in case it is not to be fired immediately, and thereby preventing accidental explosions. The motion of the breech-bolt to the rear is limited by the sear, *a s*, which works in a groove on the under side of the locking-tube, K. To remove the bolt entirely from the receiver it is only necessary to press on the trigger at the same time that the breech-bolt is pressed back. A recess serves to relieve the strain on the sear-spring by allowing the nose of the sear to penetrate it. The firing-pin screw, *b s*, is removed with the fingers (having a milled head) by pushing back the firing-pin and slipping forward the cocking-piece so as to free the projection, *g*, from its recess. The spring of the extractor allows the hook to pass turn in 33 inches. The length of the barrel is 33.65 inches; the total length of the rifle without bayonet is 53.15 inches; with bayonet, 71.65 inches; weight, without bayonet, 10 pounds; with bayonet, 11.6 pounds. The sight is arranged for a natural point-blank of 300 meters. The movable part is graduated up to 1,600 meters, some 500 yards farther than most military rifles. The initial velocity is about 1,400 feet. The cartridge-shell is drawn out in the usual way from a disk of sheet-brass, and is shown natural size. The head is solid, and has an exterior primer of the Berdan pattern. This distribution of the metal in the head is somewhat different from that in ordinary solid-head shells, and is such as to give it great strength to resist rupture under the pressure of the powder. The interior of the cartridge-shell is covered with a coating of varnish to prevent the metal from acting injuriously on the powder-charge. This varnish is applied by means of very ingenious machines devised and made by the Pratt and Whitney Company, of Hartford, Conn. The bullet is patched with bank-note paper, thin and strong, and there is a lubricating-wad between the powder and bullet. The powder-charge is 77 grains. The powder for the Mauser rifle differs from all other Prussian powder, inasmuch as red charcoal instead of black is employed in its manufacture, which is thought to give it greater strength. The size and shape of the grain are similar to that of the English musket-powder, known as Curtis and Harvey's No. 6. The bullet weighs 386 grains. See *Chassepôt Rifle*, and *Small-arms*.

MAXIMILIAN TOWERS.—Circular buildings 33 feet high, with a mean thickness of wall of $6\frac{1}{2}$ feet; the diameter of the base is 118 feet, and that of the top 110 feet. They are surrounded by a ditch 8 yards wide towards the exterior, and gradually becoming narrower towards the interior, where it is only four yards wide at the entrance gate. The deblais of the ditches have been employed to construct a glacis, that covers the masonry on the exterior, and gradually falls to the level of the ground in rear. 32 of these towers, from 500 to 600 yards apart, have been placed around Lintz. They are to be connected at the moment of need by a curtain, a ditch, and a palisaded covered-way the whole being flanked by the towers.

MAXIMILIENNE.—A German fluted armor of the Sixteenth century. Often written *Maximilian*. See *Milanaise*.

MAXIM MACHINE-GUN.—In other machine-guns, the feeding and firing and the traversing have to be performed by manual power, and, however beautifully carried out, the operator in any competition for speed is pretty severely tried; and one operator alone can hardly manipulate the machine at high speed, and in his breathless condition alter its direction to any purpose. Of course, the assistance of another man must be had when the particular magazine from which the rounds are entering the gun is exhausted. The inventor of this gun claims to have achieved a remarkable advance in making the recoil of his barrels work the feeding and firing gear; the operator kneels down quietly behind the breech and directs the barrel at his leisure exactly as he likes. There are clearly more advantages in this than appear at once. First, as noticed above, the heavy work of manipulation is saved; secondly, the danger of a jamb from a delay or hang fire is obviated, for the obvious reason that as it is the shock of discharge of each round that loads and fires the succeeding one, when a cartridge hangs fire the gun must wait for it, as without it there is no motive power to load the next round. This is clearly a very different condition of things from that in other machine-guns, when a man is driving the loading and firing-gear as hard as his strength permits, and when a jamb may be produced by delay; thirdly, a much greater rate of firing may be attained than by hand-driving gear, viz., 600 rounds per minute, instead of about 200; fourthly, the machine may be much lighter, and need not be clamped rigidly, as must be the case when a level handle has to be violently worked on one side of it.

The gun may be described as follows: It has a single barrel, arranged in such a way as to recoil slightly in its bearings, the force of recoil of each round acting on the feeding and firing-gear, so as to load and discharge the next round, and so on, round after round, in succession. That is, the force of recoil extracts and ejects the empty case, brings the next round into position, pushes it home, and cocks and liberates the striker. The barrel recoils 9-16 inch, with its breech held firmly closed. This gives the bullet time to escape and fly about a hundred feet, so that the gases have also abundant time to escape after it has left the muzzle. Then a locking-hook, which has held it close, is opened, and the barrel is stopped, while the breech and extractor run on, carrying the empty case with them. This is ejected, and the succeeding round brought into position by a feed-wheel, when the return stroke, given by a connecting rod, sends the charge home, closing the breech, pushing the barrel forward into a firing position, and finally releasing the striker which fires the round. The recoil of this round repeats the above movements, and so on, as long as filled cartridges are supplied and fired. The inventor has made his gun with a 0.45 inch bore to fire the service cartridges. He has a pattern of cartridge case which enables him to have a much simpler gun, because he is able to dispense with the recoil of the barrel proper, and work with the breech recoil alone; but he thinks it wiser to sacrifice what is necessary to enable him to meet all existing conditions. The gun without stand weighs about 60 pounds, a tripod for a man-of-war about 130 pounds, and a carriage for field service from about 60 pounds to 200 pounds, according to the requirements of the case. This tripod is about three feet high, and the piece from muzzle to rear of firing mechanism measures about 4 feet 9 inches. The gun can be left to move freely by hand for rapid change of position, as in the case of torpedo boats or cavalry at short distances; or it may be clamped and traversed or elevated by slow or quick movement screws. The cartridges are fed either from a belt or a drum. The belt is preferred by many. Each band or belt is about 7 feet long, and carries 333 cartridges, and one belt can be joined on to another, so that a stream of indefinite length can be used with care and attention in placing the boxes containing each belt in position. The drum fits on to the top, and is, we think, a more ordinary and less complete arrangement; it only holds 96 cartridges, also, and a man would be much more likely to be exposed in changing drums than in arranging the belts, and he would be kept constantly employed; in fact, one man does not appear to be at all sufficient for the work in rapid firing. When at full speed—600 per minute—allowing the bullets a velocity of 1,200 feet per second, it will be seen that a stream of bullets is formed, 150 feet from bullet to bullet. Should all the men near the piece be killed, the gun will go on firing as long as the supply of ammunition lasts. Under these conditions, the barrel must become very violently heated. Some of our readers are perhaps familiar with the spectacle of machine-gun barrels firing at a much lower rate of speed passing through the different tempering colors of steel. Mr. Maxim endeavors to provide for this by enclosing the barrel in an outer gun-metal case, which allows a large space between barrel and case to be filled with water. Finally he has devised a plan for carrying the smoke of from the muzzle.

The natural objections that appear to suggest themselves are—(1) That the opening of the breech by recoil is difficult to manage safely at so great a rate. It is thought, however, if it is clearly understood that the breech must remain completely closed—indeed no more opening than any breech-loading cannon during recoil—until it has reached a point when the bullet is 100 feet away, it will be seen that there is no danger of escape of gas. It would be interesting to see what would happen if a bullet lodged in the bore; but this is an awkward contingency for any machine-gun. (2) It may be objected that a miss-fire stops the firing for the moment, while in many machine-guns it merely involves the failure of one bullet, the cartridge being ejected and the firing going on without interruption. Perhaps the machine can be sent on by hand instantly; but we think cartridges for this gun ought to be as free from miss-fires as possible, as the loss of a number of rounds delivered in quick firing must be serious. Altogether, the gun is a wonderful design, and one which naturally attracts much greater interest than almost any piece in the same stage of development. The speed of firing, the ease of working, and saving of exposure of men promise great practical advantages, and the extreme neatness of the idea of the automatic system, by which each round fires itself and works the gear at exactly the speed that suits its own behavior, is very attractive. See *Machine-gun*.

MAXIMUM.—A term variously employed in Ordnance and Gunnery. In Mathematics, *maximum* is the greatest value of a variable quantity or magnitude, in opposition to *minimum*, the least. More strictly, a maximum is such a value as is greater than those immediately preceding and following it in a series; and a minimum is a value which is less than those immediately preceding and following it, so that a function may have many maxima and minima unequal among themselves, as in the case of a curve alternately approaching and receding from an axis. Traces of the doctrine of maxima and minima are to be found in the works of Apollonius on conic sections. The thorough investigation of them requires the aid of the differential calculus, and even of the calculus of variations. The brothers Bernouilli, Newton, Maclaurin, Euler, and Lagrange, have greatly distinguished themselves in this department of Mathematics. The Hindus have displayed great ingenuity in solving, by ordinary algebra, problems of maxima and minima, for which, in Europe, the calculus was considered to be necessary.

MAXIMUM CHARGE.—By increasing the charge of powder of a fire-arm, the greater and (in consequence of the wedging of the unburned grains among each other) the more difficult will be the mass to be set in motion; the space between the front of the charge and the muzzle will be diminished; and a larger number of grains will be thrown out unconsumed. It is evident, therefore, that the effect of a charge of powder on a projectile should not increase with the size of the charge; and experiment shows that beyond a certain point, an increase of charge is actually accompanied with a loss of velocity. The charge corresponding to this point is called the maximum charge. All experience proves that the longer a piece is, in terms of its caliber, the greater will be the maximum charge in proportion to the weight of the projectile. For heavy cannon, 19 to 20 calibers long, the maximum charge may be stated to be $\frac{1}{2}$ the weight of the projectile; and for light cannon of the same length, $\frac{1}{2}$ to $\frac{2}{3}$ of this weight; the increase of range for charges above the weight of the projectile, being very small. A charge of $\frac{1}{4}$ the weight of the projectile, and a bore of 18 calibers, is the most favorable combination that can be made in smooth-bored cannon, to obtain the greatest range with the least strain to the carriage. In the early days of artillery, when *dust* instead of grained powder was used in cannon, the weight of the charge was equal to that of the projectile; after the introduction of grained powder, it was reduced to $\frac{2}{3}$, and in 1740 to $\frac{1}{2}$, this weight.

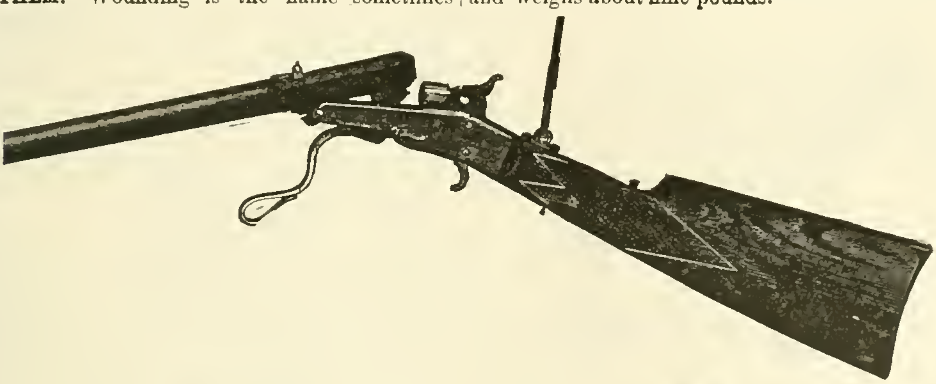
MAXIMUM RANGE.—In gunnery, the very extreme range of a projectile either *in vacuo* or in the air. In the former (were it possible), with a given velocity, the extreme range of a spherical projectile would be obtained at an angle of 45°; in the latter, with a velocity of 1600 feet per second, the maximum range would be obtained at an angle of about 32°; a 56-lb shot would, under these circumstances, at 32° elevation, range 5720 yards in the air, and 23,946 yards *in vacuo*, and at 45°, 26,666 yards *in vacuo*. The maximum range of rifled ordnance is much in excess of that of smooth-bore guns, the 9-inch gun having ranged over 11,000 yards.

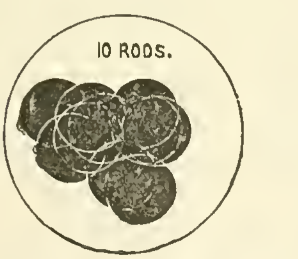
MAYHEM.—Wounding is the name sometimes found in law books for the offense of inflicting on another some dangerous hurt or wound; and it has been otherwise described as an aggravated species of battery. A still more aggravated and atrocious offense of this kind used to appear in the list of offenses against the criminal law of England under the term of MAYHEM, which was a violently depriving another of the use of a member proper for his defense, such as an arm, a leg, a finger, an eye, a fore-tooth, and some others; but it was laid down quaintly enough, that the loss of one of the jaw-teeth, the ear, or the nose, was no Mayhem in common law, because these members can be of no use in fighting.

MAYNARD PRIMER.—A primer made by indenting a sheet of paper at regular intervals, filling each indentation with a small charge of percussion powder, and covering the whole with another sheet of paper firmly pasted on. The sheet is then cut into strips, each strip containing 60 primers in a single row, and, to protect it from the moisture, it is covered with a thick coat of shellac varnish.—See *Friction Primers*.

MAYNARD RIFLE.—While special attention has been paid to the manufacture of superior sporting rifles, the interest in rifle shooting at long range, has led to the invention and introduction of what is known as the "New Creedmoor Rifle," in which the acknowledged and superior merits of the Maynard system are introduced, securing convenience, safety, accuracy, and efficiency, all made applicable to meet the present demand for long range practice. The Creedmoor rifle is a 32-inch, 44 caliber, specially adapted to the requirements of the Creedmoor range, and to which has been applied every facility and appendage which has been found by trial and experience best adapted to secure the most satisfactory results, including ammunition, vernier, and wind-gauge sights, spirit level, and all of superior models and workmanship. All the advantages comprised in the Creedmoor rifle, have also been applied to a new model mid-range target rifle, 32-inch, 40 caliber, designed and especially adapted for target practice and ordinary field-service.

This rifle is represented in the drawing, together with two models of targets selected from the large number in possession of the Massachusetts Arms Company, and representing a fair average result for the distance named. The rifle has an elevating peep, adjustable rear-leaf, and Black's combination-sights, and weighs about nine pounds.



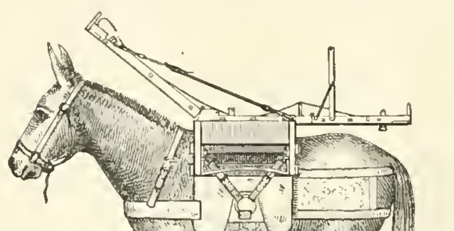


One valuable and special feature of the Maynard system is, that it admits of an interchange of barrels of any length or caliber. The manner of attaching the barrel to the stock is very simple and as follows: Push the arm of the lever axis-pin down and forward until it stops against the screw which holds it in place, then withdraw it as far as possible; hold the barrel in the left hand, pass the lever down through the breech-piece, hook the barrel on to the axis-screw at the front end, insert the lever axis-pin through the lever, then turn its arm back to its fastening position. No screw-driver required. To detach the barrel, place the barrel in position as for inserting the cartridge, then reverse the motions for attaching.

This is a capital gun in the field, and especially on marches through a game country, when it may be desirable to use the weapon either as a rifle or shot gun. Either barrel can be slipped into the same stock in a moment. The ammunition is peculiar. The strong brass cartridges are loaded at leisure, costing nothing but for the powder and lead, and may be used over and over again for any number of times. One can carry cartridges in his pocket, loaded with different sizes of shot, and slip in and fire any size wanted, for large or small game. The rifle in itself is confined to the central-fire ammunition in each and all of the calibers, excepting the .22, in which the rim-fire ammunition is used; but, by the application of a simple device rim-fire cartridges may also be used. See *Hadley Firing-pin.*

McCLELLAN SADDLE.—A saddle used by the United States cavalry prior to the advent of the *Whitman* saddle. This saddle was a great step in advance in its time, and was received with much favor. Its greatest faults were bad bearing surface, too wide in front, like the Mexican, allowing it to slip forward and embrace the tender points of the shoulder-blades; too short in the seat and too wide in front of seat, forcing the rider to an upright position, or the extreme "forked seat," throwing the weight of the rider too much over the fore-legs of the horse; a high, sharp, dangerous pommel, and heavy. See *Saddle.*

McELDERRY MULE-LITTER.—In the operations against the Modoc Indians, in the lava-beds of Oregon, the ordinary methods of transport were found unsuitable, and a form of mule-litter, devised by Assistant Surgeon H. McElderry, U. S. Army, proved serviceable and well adapted to the exigencies encountered.



The drawing shows the construction of the litter and the manner of using it. When not in use it can be folded compactly together, so as to permit a load of grain, provisions, etc., to be packed upon it. When the animal arrives at its destination, the load may be removed, the litter unfolded, and made available for the transportation of the wounded back to the base of supplies. By the use of the adjustable iron support, which raises up over the lower end of the litter, a wounded lower extremity can be suspended in the anterior or other splint, and the patient thus carried with much greater ease and comfort than when the wounded member is simply laid upon or fixed to the litter. It is used upon the *aparejo*, is well-balanced, and has no tendency to make the animal's back sore. It is firmly fixed in position by means of an extra-broad horse-hair girth, as shown in the drawing. The litter weighs, without a mattress, 54 pounds, and like the *Thistle* litter, has the advantage that its width does not much exceed the outer limits of the flanks of the pack-animal; a condition adapting it to the passage of narrow defiles or canyons, or of roads encumbered by vehicles. See *Litter.*

McINTYRE-FUSES.—The time-fuse, shown in Fig. 1, and inserted in the rear of the shell, consists of the brass stock, A; time-fuse B; a brass screw-plug, C; and a lead igniting cap, D. The fuse composition driven in a paper case is first inserted in the

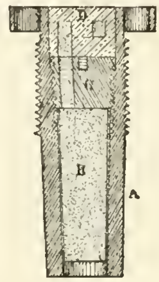


Fig. 1.

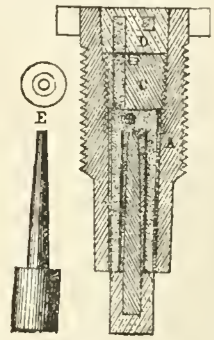

Fig. 2.

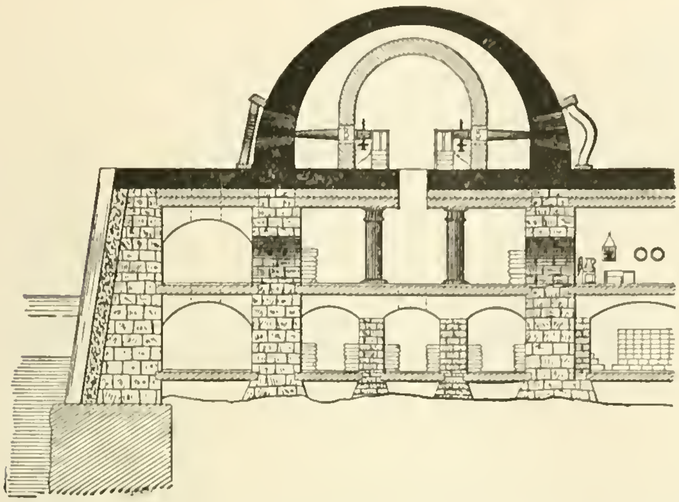
stock, the screw-plug with a vertical hole, to one side of its center is screwed to touch the top of the fuse. The igniting cap with its channel of pressed powder composition is then inserted so that the under opening of the channel shall communicate directly with the hole through the screw-cap, which is also filled with the composition. Directly under the projection which rises above the top of the igniting cap is the upper opening to the channel. Before firing, this projection is removed with a sharp knife and the composition thus exposed. The combination-fuse, shown in Fig. 2, is identical with the time-fuse, except that there is inserted in the fuse composition a plunger, whose head is of lead, and whose tapering stem is of brass; immediately surrounding the stem of the plunger is a column of plaster of Paris, between which and the composition is a tube of fusible metal. Should the projectile in which the fuse is inserted strike a resisting object before the fuse composition has burned out, the plunger is thrown forward into the shell, giving the flame from the burning composition direct access to powder in shell. See *Fuse.*

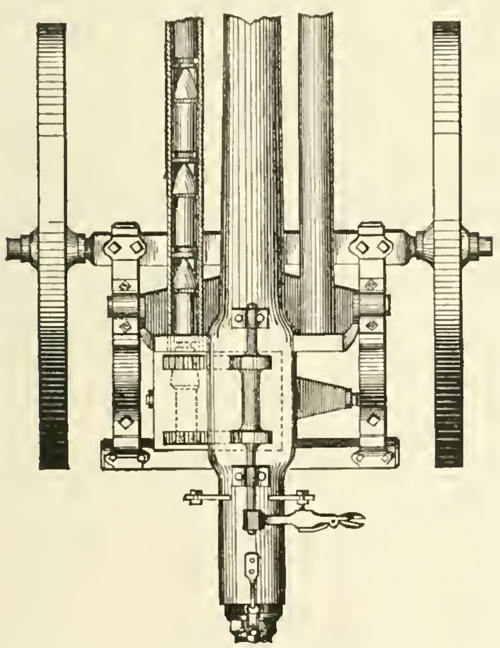
McKEEVER CARTRIDGE-BOX.—This box, invented by Captain Samuel McKeever, of the U.S. Army possesses all the requirements and advantages necessary for the military service, and is at present used by the United States troops. It is made of leather, is 6¾ inches long, 3¼ inches wide, and 1½ inches thick. It is carried on the waist-belt by two loops, opens from the top, the outside half working on a hinge formed by a brass rod running under the box and holding it together. The cartridges are held in webbing loops, ten in each section of the box, and are readily extracted from the box, a bellows arrangement allowing the tops of the cartridges to incline forward when the box is open. It has been improved by the addition of a brass escutcheon, and by making the bellows of russet leather, which is not so liable to corrode the cartridge. This box possesses all the merits of the thimble, or service belt, which has been highly recommended by many officers of the Army, with the additional advantages of protecting the cartridges from the danger of loss, or exposure to dust or moisture. No provision has been made in this box for a screw-driver, but, whenever necessary to carry one, a cartridge may be taken out and the screw-driver inserted in its place.

McLEAN FORTRESS.—This fortress, a section of which is shown in the drawing, is designed to be a permanent structure, or it may be a huge raft, with interior compartments for supplies of all kinds found necessary. The raft is to be towed from place to place, and when in position in shallow water will rest on the bottom, being held by ballast or piles, or by anchors. The fort or raft is to bear two turrets,



one within the other, the outside one being stationary, the inner one rotating, the guns firing through port-holes in the outer turret. The surface of the fort is to be heavily armored, and have quarters and storerooms below the armor.

McLEAN MACHINE-GUN.—This gun, illustrated in the drawing, is one in which every detail is made subordinate to the one of extreme rapidity of fire. The cartridges are in magazines at each side of the barrel, and are forced back by their spring followers into a sidewise reciprocating breech slide containing chambers for two cartridges. When one of the chambers is in line with the barrel the other is in line with



the magazine, and the loaded cartridge pushes out the old shell, the bullet being too large to pass into the slide further than its seat. The cartridge is fired in the slide, the force of the recoil serving to cock the firing-pin so that it is in position for the next shot. The same system is intended to be used with a magazine small arm. Dr. McLean has made more varieties of machine-guns than any other maker, but, in the opinion of the writer, he has sacrificed too much in other directions in order to secure rapidity of fire, and up to this time none of his working guns have met with more than a moderate degree of success. He has a number of improvements now in progress which are expected to overcome the difficulties hitherto experienced. See *Machine-guns*.

MEALED POWDER. Gunpowder pulverized by treating with alcohol. It causes compositions to burn readily and quickly. See *Gunpowder*.

MEAN. As a general term, the medium between two extremes, and is ordinarily understood to be what is known in mathematics as an arithmetic mean. An *arithmetic mean* between two numbers is found by adding them together and dividing by two. A *geometric mean* is found by dividing the larger number by the smaller, and taking the square root, which gives the common ratio; the smaller number multiplied by this ratio, or the greater number divided by it, gives the mean. A *harmonic mean* is found by adding the reciprocals of the numbers and dividing by two; the reciprocal of the result is the mean.

MEAN DEVIATION.—For the same trajectory, the *mean deviation* of a projectile, at a given distance, may be taken as an indirect measure of its accuracy at that distance. To obtain the mean deviation; let the piece be pointed at the center of a target stationed at the required distance, and fire a certain number of shots, say ten; and let the position of each shot-hole be measured in a horizontal and vertical direction from the origin of co-ordinates, taken at the lower left hand corner of the target. The sum of the distances in each direction divided by the number of shots, gives the corresponding co-ordinate of the *center of impact*, or the center of the cluster of shots fired. Multiply the horizontal co-ordinate thus obtained by the number of shots whose corresponding co-ordinates exceed that of the center of impact; take the difference between this product and the sum of the horizontal co-ordinates that exceed that of the center of impact; this difference divided by one-half the number of shots fired, will give the *mean horizontal deviation*. The *mean vertical deviation* is determined in a similar manner. Each of these results may be verified by making the same calculations upon the shots whose co-ordinates are less than the corresponding one of the center of impact. The *mean absolute deviation*, which is the average distance of the shots from the center of impact, will be the hypothenuse of a triangle whose sides are the mean horizontal and mean vertical deviations. The successive steps are explained by the following tabulated example:

The + signs are prefixed after the determination of the center of impact. The foregoing furnishes a measure for the accuracy of fire of the piece and projectile, but it does not afford a measure for marksmanship, the object of which is to direct a projectile so as to strike a given point or surface. In the U. S. Military Service ordinary target practice is recorded by the number of projectiles striking a target of a given size; and when firing for prizes, by the "string" or sum of the distances of the shots from the point aimed at, each miss counting twenty inches on the string. The shortest string is the one selected. The measure of "marksmanship" now most generally adopted is the "score," or sum of the numbers representing the value of shots placed within certain circles described about the center of a given target. The size of the target and the radii of the circles depend upon the distance, the number assigned to corresponding circles being the same for all distances.

SHOTS,	Co-ordinates.	
	Horizontal.	Vertical.
	Feet.	Feet.
1	+5.60	+5.80
2	+5.40	4.95
3	5.05	4.45
4	4.85	+5.25
5	+5.20	+6.00
6	4.75	+5.45
7	+5.35	4.50
8	4.65	+5.20
9	+5.18	4.30
10	+5.50	4.00
Sum	51.53	49.90
Sum divided by 10 gives center of impact	5.153	4.99
Preceding, multiplied; horizontal by 6; vertical by 5	30.918	24.95
Sum of the greater co-ordinates	32.23	27.70
Difference of two preceding lines	1.312	2.75
Divide by 5 for mean deviations	.262	.55
Center of impact; horizontal multiplied by 4; vertical by 5	20.612	24.95
Sum of lesser co-ordinates	19.30	22.20
Difference of two preceding lines	1.312	2.75
Divide by 5 for mean deviations	.262	.55
Mean absolute deviation	.609 feet.	

MEAN IMPACT.—The point of mean impact on a horizontal target is the intersection of the lines of mean range and mean lateral deviation; and on a vertical target, it is the intersection of the lines of mean vertical and lateral deviation.

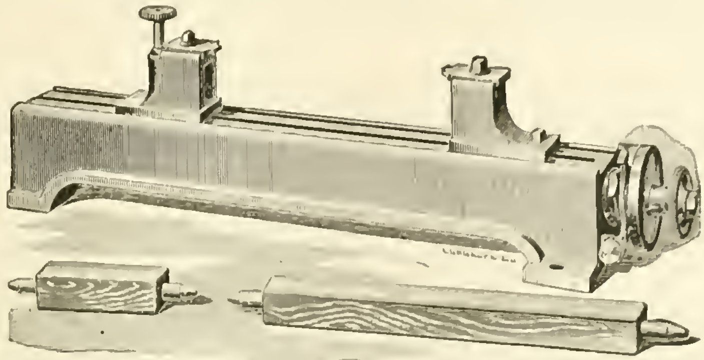
MEAN RADIAL DISTANCE.—The relative precision of small arms is decided by what is termed the *mean radial distance* of the shots from the center of the group on the target. To determine it, find the *point of mean impact*, and measure the absolute distance of each shot from it. Divide the sum of these distances by the number of shots on the target.

MEASURE OF UNIFORMITY.—In gunnery, the regularity in the velocity given by a number of consecutive rounds. It is calculated as follows: Take the mean observed velocity, and from this deduct the difference of each round, and divide the sum of the differences by the number of rounds fired.

MEASURING MACHINE.—The need of an instrument for the purpose of determining dimensions by difference from verified standards has been felt in all well-regulated engineering, tool, and machine shops. The screw operated by a wheel with graduated periphery, has been in use for many years, and was brought to a high degree of perfection by Whiteworth in England, and others. It may be said that, with proper safeguards in its use, it is sufficiently accurate for all practical purposes. It is doubtful if a screw of perfectly uniform pitch throughout any considerable length can be made. The attempt to compensate for this variability of pitch is frequently made by various devices.

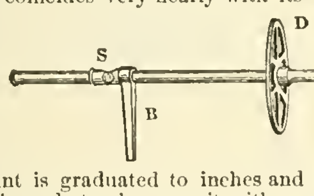
An interesting means of doing so is shown in the dividing engine at the Frankford Arsenal. A new screw having been made with great care by Wm. Sellers & Co., of Philadelphia, it was put into the engine and was found to give, for a certain number of turns, a greater length than the nominal pitch of its thread indicated. To counteract this an inclined plane was attached to the engine, upon which a weighted lever secured to the nut runs up or down as the nut traverses the screw in opposite directions. The effect, as it runs up the plane, is to back the nut a small fraction of the distance it would otherwise travel, and thereby compensate for the error of the pitch, and *vice versa*. If the pitch were absolutely uniform throughout the length of the screw this would leave nothing to be desired from a mechanical point of view, but when the pitch varies from inch to inch, as is nearly always the case, instead of an inclined plane, the corrective element of the engine would have to be a surface having a series of elevations and depressions to correspond to the variations of the pitch, a result only to be attained by a "cut and try" process, alike tedious and expensive, and of only approximate accuracy. It could not be depended upon for small fractional parts of the inch, say 0.0002 inch, or more or less, such as are daily brought into use. Short screws, or portions thereof, may be quite uniform, or so nearly so that the error can be safely disregarded, or an allowance made for it.

These considerations have led to the adoption at arsenals of the plan of obtaining certified standards of length, diameter, etc., in suitable forms and measuring, by difference from them, the object under examination as proposed by Mr. Richards. These standards differ by convenient fractions of an inch from one another, and by using the nearest one to the object whose dimensions are required, only a very short screw is necessary. The drawing shows the form of a Measuring Machine much used in arsenals. These machines are made of various sizes, are adjusted for absolute measurement of dimensions within their range, and are correct within a limit of one ten-thousandth of an inch. This is the usual limit of accuracy for cylindrical guages, and sufficiently precise for all practical purposes. These



machines will *indicate*, by means of vernier attachment, variations to one twenty-five-thousandth of an inch, or even less: but *measuring* and *indicating* are very different things, although generally confounded. See *Guage*.

MEASURING-STAFF.—An instrument employed in the inspection of cannon. It consists of a staff of steel or iron, in joints of suitable lengths, connected together by screws. Each joint is provided with a light brass disk, D, the diameter of which is .05 inches less than that of the bore. Through the center of the disk there is a hole which fits upon the shoulder at the joint; the whole is so arranged that when the joints are screwed together the disks between them are held firmly in place, while the length of the staff is not affected by them. A steel point is screwed on to the end. When pushed to the bottom of the bore, the staff coincides very nearly with its axis. The



outer joint is graduated to inches and tenths. A slide, S, is made to play upon it with a vernier scale, graduated to hundredths of an inch. On the inner end of the slide, a branch, B, projects at a right angle, sufficiently long to reach across the muzzle-face, and, when in contact with it, to indicate the precise length obtained from that point to the end of the measuring-point on the other end of the staff. The instrument is introduced until the point reaches the bottom of the bore, and the branch placed so that it takes across the muzzle-face, and the reading shows the length of the bore of the gun. See *Inspection of Ordnance*.

MEAT BISCUIT.—A preparation of the substance of meat combined with a certain quantity of flour, and made into the form of biscuits, by which process the nutritive qualities of the meat are preserved for any length of time. One way of preparing these biscuits is as follows: Large pieces of beef are placed in a quantity of water sufficient to cover them, and are subjected to slow ebullition. The fat being skimmed off, evaporation is allowed to take place, until the liquid is about the consistency of syrup, when it is mixed with fine wheaten flour, rolled out to the thickness of ordinary ship-biscuit, cut into any shape required, baked, and dried in the ordinary manner. One pound of biscuit usually contains the soluble parts of 5 lbs. of meat and half pound of flour. The meat biscuits can be eaten like ordinary biscuits; but boiled in about twenty times their own weight of water for half an hour, with the usual condiments, they make an excellent soup, and for this they are chiefly intended. Meat biscuits were first introduced into Britain from America by Mr. Borden, in the year 1851. They have been spoken highly of by medical men as food, and are still made to a limited extent; but one purpose they were first intended to serve—that of preserving the animal food of South America and Australia—has since been more effectually done by other and simple means.

MECHANICAL GUN-CARRIAGES.—The first of all considerations as to the mounting of a battery is, that it should admit of the utmost possible rapidity of fire, united with accuracy of aim. It is important to secure the greatest possible efficiency of the weapon under the conditions in which it is required to be employed. The duty of providing the most perfect means of working guns seems to be second only in importance to that of adopting the best material, form, and construction for the gun itself. Of two similar guns, that which can fire the greatest number of rounds in a given time is certainly more effective, and rapidity of fire depends more on the gun-carriage and conveniences for loading, than upon any peculiarity attaching only to the gun. Owing to the increase in the size and power of ordnance since the introduction of armor, gun-carriages have gradually become elaborate machines; and mechanical science, in the hands of experts, has produced carriages and slides which enable the heaviest guns to be easily, accurately, and safely worked in cramped positions. The great superiority of wrought-iron to timber as a material for gun-carriages is now universally acknowledged. The principal requirements of mechanical carriages are powerful moving-machinery so contrived as to be unaffected by the concussion of firing; self-acting controlling gear, almost independent of human carelessness; the gradual absorption of, rather than rigid resistance to shocks; the dispersion of concussions over large surfaces; and smoothness and ease of motion in every direction, and safety under all conditions. Guns mounted on the disappearing principle, are arranged to drop when fired into a position in which they can be loaded under cover, and from which they are only raised when required again to deliver their fire. In this system the gun must not only be loaded while lowered and under cover, but it is usually fitted to be trained and aimed while there, by indirect methods, such as by telescopic apparatus adapted to the gun's axis, and so arranged that it can enable an observer to look over and above the cover.

MECHANICAL MANEUVERS.—The mechanical maneuvers are the application of machines and of mechanical powers for mounting, dismounting, moving, and transporting artillery. The implements and machines required for the various operations depend upon the kind and weight of the piece and the nature of the maneuver to be performed. In every case the minimum number of each is used. When much work is to be done, due allowance must be made for wear and tear, which, with heavy material, is very considerable. Sound discretion should be exercised not to allow the wearing to go beyond the limit of safety. Those now used for siege-pieces are such as can be found in most localities; the rollers, chocks, and, if necessary, the hand-spikes being readily shaped from sections of trees. The following is a list of the implements generally used when maneuvering siege-pieces:

Implements.	Length.	Width.	Thickness.	Weight.		Remarks.
	Inch.	Inch.	Inch.	Lb.	Oz.	
Handspike	84	......	......	12	0	
Long roller.....	42	6	r'nd	25	0	Grooved ¼ inch deep in the middle.
Short roller.....	12	7	r'nd	12	0	
Gun-chock.....	3.6	2.75	3.5	0	6	Wedge-shape.
Wheel-chock...	7	6	3	2	4	Section a triangle. Top rounded ¼ of an inch.
Roller-chock...	7	5	2	1	0	
Shifting-plank.	67	12	2.25	48	0	Ends beveled on opposite sides.
Trace-rope......	360	r'nd	1.25	8	8	
Hammer wr'nch	......	......	......	2	4	Sometimes called monkey-wrench.
Sling-chain.....	156	......	......	55	0	Made of round iron 0.75 in. in diameter, with a stout hook at each end; length of links 5 inches.

In every case the wooden handspike is required, and the following general directions for its use are given. Six are the number generally used. When men on opposite sides of a piece apply themselves to a handspike, the handspike used is that of one of the even numbers; the man to whom it belongs is at the smaller end, the corresponding odd number at the butt end; those who assist place themselves inside of these two numbers; the lowest numbers nearest the ends. When two or more men work at the same end of a handspike, the man to whom it belongs is at the end, and the other men in the ascending order of their numbers from him. When several handspikes are crossed at the muzzle in order to raise or lower it, they are applied in the order of the numbers of the men to whom they belong, those of the highest numbers nearest to the trunnions. The handspikes used in the mechanical maneuvers are beveled on one side, as these will enter into places or under bodies where square handspikes could not be used. When a handspike rests on a fulcrum, and the weight on one end is to be raised by bearing down on the other, the weight should never rest on the beveled side, as the handspike would not then give a good hold, and would be liable to split. In this case the beveled side should be down. But if used for lifting, as when two handspikes are crossed under the breech or chase of a gun to heave it upward, their ends resting on the ground or platform, the beveled side should be up. Two or more men, lifting or hauling together, must wait for the command before exerting their strength. The gunner sees that all are ready before giving the command *heave*. Then all move with a prompt but steady effort, and apply their power increasingly until the weight responds to their effort. The gunner will repeat the command *heave* as often as it may be necessary. When the movement has been sufficiently made, the gunner commands: Ease Away. Those making the effort will then desist; but in doing so will be careful to avoid all sudden shocks or strains. Every operation should be done with spirit and animation, but without bustle or confusion. Vigilance should be constantly exercised to have the piece or rollers securely chocked. The limber of a siege-piece makes a powerful lever, and may be advantageously used in many cases. The pole is raised and the pintle engaged in a sling around the weight to be raised. The pole is hauled down by a trace-rope attached to the eye.

The machines and appliances usually employed for moving heavy artillery: Ropes, blocks and tackle, gins, hydraulic-jacks, sling-carts, casemate truck, truck-wagon, railway truck, cradle, gun-lift, capstan, derrick, shears, blocks and skids, hand-cart, blocks (whole, half, and quarter), way-planks, pinch-bars, mortar-wagon, collar. These, with the implements used in the mechanical maneuvers with siege pieces are sufficient to manage the heaviest pieces of artillery in all cases which ordinarily present themselves in service. All implements and machines, before being used, should be most carefully examined in every detail, to see that they are serviceable and suitable for the operation to be performed. None should be put to uses for which they are not intended, nor subjected to strains they are not constructed to bear. It must be borne in mind that the giving way of one part breaks and destroys other parts, frequently to an extent not readily repaired, and, furthermore, endangers those working at the maneuver. Heavy weights must never be allowed to *drop*, even for the

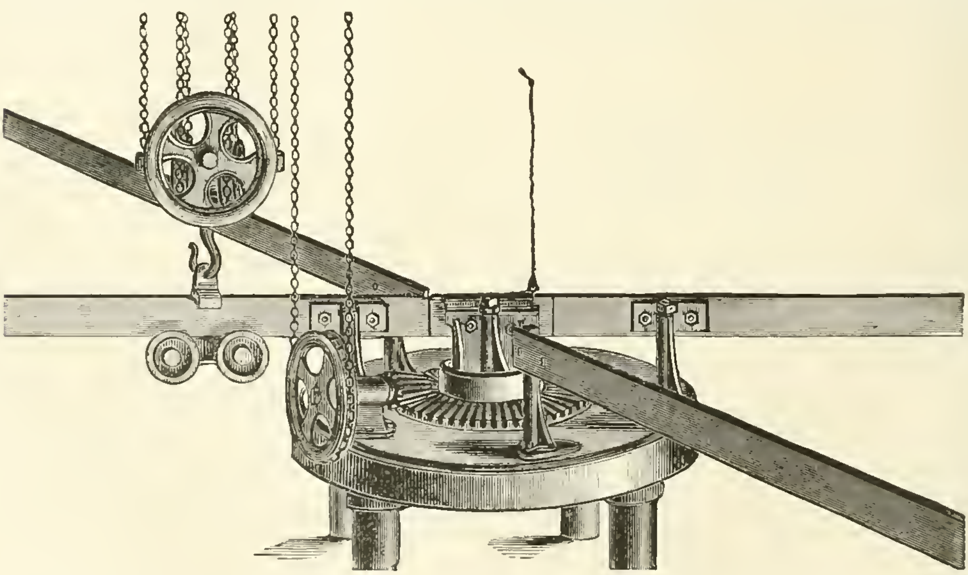


Fig. 1.

shortest distances; they must be lowered to rest with a gentle motion, and at the same time chocked to prevent rolling or sliding. In hoisting, they must, when practicable, be closely followed up with blocks and chocks to guard against any possible giving way. All motions with heavy bodies must be slow, so as not to generate momentum. Supports must have a firm base, and scaffolding a level foundation, and be built up vertically. All holdfasts must be secure beyond possibility of giving way.

The maneuver of the various service pieces are detailed in the Tactics. Within the limits of this article we will confine our descriptions to some general maneuvers and appliances, the details of which will cover the ground of the whole subject. 1. *To move a gun by rolling it.*—Place a skid under the rear of the trunnions, and another under the middle of the chase, and roll the gun over. By inclining the skids and cutting the muzzle it may be moved in different directions. In rolling heavy guns it is most

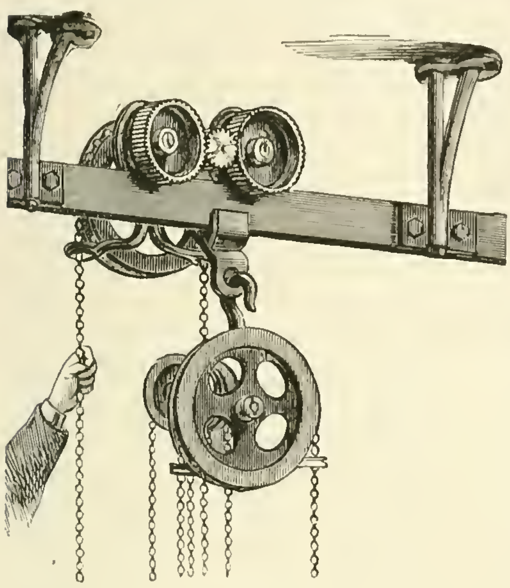

Fig. 2.

convenient to use two collars of wood or cast-iron of equal diameters (one on the breech, the other on the muzzle), large enough to allow the trunnions to turn without striking the ground. A rope used as a parbuckle is the best method of rolling a gun. To do this, place the gun on skids, and attach the rope by a bowline to one of the trunnions, passing it under and around up over the gun, and hauling on the end. If the gun is to be rolled up a slope, two ropes, of size suitable to the weight of the gun, are used. An end of each rope is made fast to some fixed object at the upper part of the slope; the other ends are carried under the chase and body respectively, and up over the gun; these ends are hauled upon by means of a capstan, or by attaching to them a fall and tackle. The muzzle is slued forward by pinching with bars, or by means of a rope and tackle attached to a roller or skid thrust into the muzzle. The piece is lowered by inverse means.

2. *To shift a gun from the trunnion-holes to its travelling-bed.*—Limber up; remove the cap-squares and chock the wheels front and rear; place the short roller under the reinforce; attach the trace-rope at its middle to the cascabel by two half-hitches; cross two handspikes under the one in the bore; lift and push at the muzzle, and haul on the rope until the trunnions are over their travelling position; raise the chase, bring forward the roller to the head of the stock and lower the chase upon it; raise the chase again; remove the roller, and lower the chase upon the stock; take off the rope; replace the cap-squares; insert the elevating screw from below, and lash it. If a lifting-jack can be used, place it under the swell of the muzzle; raise the chase; place a half-block on the head of the stock; take a second lift, and place two rollers on the stock, one just in rear of the trunnion, the other under the reinforce; chock the latter toward the muzzle, and remove the half-block; haul on the rope attached to the cascabel, and bring the breech over the bolster; chock the rear roller; place the jack under the muzzle, and remove the rollers. To shift the gun from its travelling-bed to the trunnion-holes, chock the wheels front and rear; remove the cap-squares; raise the chase and insert the short roller under the trunnions; attach the rope by its middle to the cascabel; bear down the muzzle, and, as the piece rolls forward, guide the trunnions into their holes by means of the rope; remove the short roller. A howitzer is shifted to and from its travelling-bed by the same means, except that the handspike in the bore is chocked above and below for raising the chase, the lower chock being placed about 18 inches in the bore. The vertical diameter of the short roller should be just forward of the rimbases.

3. *To move and handle heavy guns with a truck and tramway.*—The ease with which heavy loads are moved when loaded on an ordinary railway-car, on a smooth, rigid, unyielding track, as compared with other means of conveyance, has led to the adoption of this mode of transportation whenever the work to be done will justify the expense of preparing the roadway and laying down the track. It is thought that this means of transportation might be made available for the transportation of 15-inch guns and other heavy loads in and about our permanent works; that a temporary portable track might be provided capable of supporting as great a weight as that of a 15-inch gun, and could be laid down readily without much preparation of the road-bed, in many places none at all, and furnished at a small expense. A four-wheeled truck of simple construction, strong enough to sustain a weight of twenty-five tons, could be constructed at a cost not much greater than that of a cradle, but could be moved with far greater ease and much greater celerity. This idea elaborated, and proposed as the best, for transporting 15-inch guns over moderately even ground. For this purpose, under the above mentioned conditions, it will commend itself for its simplicity, efficiency, and economy.

In foundries, and special locations in permanent works, there are positive advantages attending the use of *overhead* tramways, within certain limits of weight and strain. The excellent machinery in this line made by Edwin Harrington & Son, and adopted by the United States Government, has demonstrated that there is an actual saving of 50 per cent. in the cost of labor, and little liability to accident, by the use of such a system. Two men can handle a large casting of 2,500 lbs. with great ease, and raising it clear of other heavier articles in the path or on the floor, avoid the necessity of moving or handling the latter. Fig. 1 shows a simple form of turn-table for an overhead track. The load is revolved by means of a hand-gear and pinion operated by a wheel and chain; the table can be adjusted to any required number of tracks that will allow the load, when once raised, to be transported to any desired point with safety and dispatch. The carrier truck cannot be run off from any track, except on to the turn-table, and when on the turn-table it cannot be run off except on to some one of the tracks. When connection is made with any track, the table is securely locked in position, thereby preventing all possibility of accident. Fig. 2 shows the construction of the most approved geared truck. The ordinary truck, when constructed of one or more wheels, and run by pushing or pulling the load at the lower end of the cage or sling, is very liable to lurch or jump, especially if running around a curve, often causing breakage of the chain or rope, as may be in use, besides being a source of great annoyance to persons that may be on the floor over the truck. The geared truck obviates all this, and one man can run the heaviest load required with ease on a straight rail or round a curve, stopping and starting at any desired point, the truck running with perfect smoothness and disturbing no one.

To mount a gun on the surface car, raise it by hydraulic jacks high enough to get the track and car under it; support it by blocks built up under the muzzle and breech; lay the track between the blocks, and place the truck on the track under the gun, the trunnions midway between the wheels; lower the gun on the truck; or place skidding, one end on blocks built up to the required height to reach the bolster, the other on the ground, and roll the gun up the inclined plane thus formed to its place on the truck. The bolsters are just high enough to permit the gun to be rolled into its place. Four men can lay down the track a distance of eighty yards in thirty minutes where no grading is required. Four men can transport a 15″ gun over level ground, using a capstan, twenty yards in five minutes after it has been mounted, the track has been laid down, and the capstan in position, or they can lay down the track and transport the gun twenty yards in fifteen minutes, all of the preparations having been first made. A horse with one double and one single block will move a 15″ gun as fast as the track can be laid and the tackle shifted, or a pair of oxen will pull a 15″ gun, a dead pull, without the intervention of pulley-blocks, the road being level. An increased force will be required if the track, instead of being in a level, is on an ascending grade, and proportionately greater as the angle of the slope increases. Horse-power is the only one recommended, except in very extraordinary cases, where there is a great amount of work to be done and done quickly.

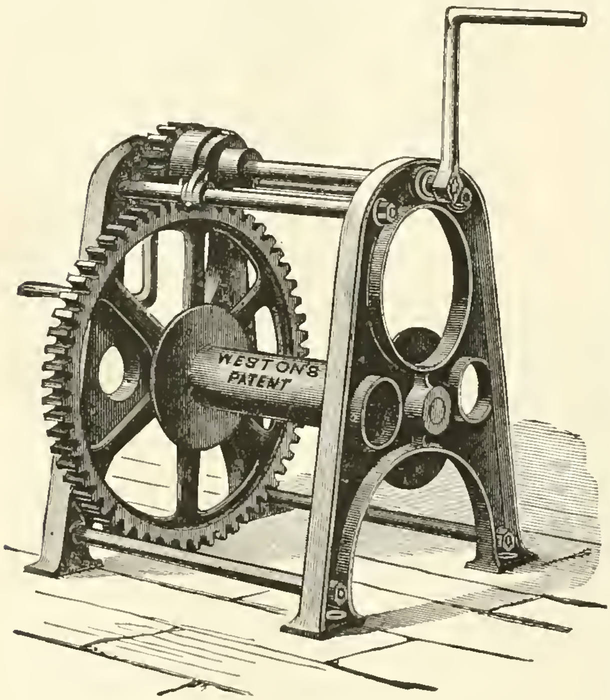

Fig. 3.

4. *To move and mount heavy guns, etc., with blocks, hydraulic jacks, capstan, or crab, cradles, etc.*—To move a heavy gun a short distance, raise it on skids, so that the trunnions will not touch the ground, roll it over by the pinch-bars, chocking the breech and cutting the muzzle when necessary. For longer distances, and through narrow entrances, mount it on the cradle, with rollers and shifting-plank underneath, and if on level ground move it along with pinch-bars or handspikes; if up a ramp, rig the fall and blocks to cradle, crab, and some fixed or well-secured object on top of ramp, and then work it up with the crab, changing the shifting-plank and rollers as required. Weston's hoisting crab, with automatic safety brake, should be used on every possible occasion. This excellent machine is shown in Fig. 3, and consists of the usual winding barrel, for common rope or chain, driven by manual power, applied to cranks, through two or more spur wheels, the ratio of the gearing being varied in the several sizes of machines, according to the load to be lifted. The lifting is accomplished in the usual manner. The lowering is done with the least possible exertion, by winding the handles backwards, and as long as this motion is continued the load will descend. The construction of the safety ratchet or brake is such that the load is always self-sustained and cannot run down. The handles cannot recoil on the operator, and if suddenly "let go" at any time, either in hoisting or lowering, the load will quietly come to rest and remain suspended. The smaller size has only a single speed or power; the larger size, two changes of speed. The capacity of either may be increased by the use of a running block in the usual manner.

For the purpose of thorough illustration, we will notice the process of mounting a fifteen-inch gun. The gun is supposed to be in its cradle, the cradle being blocked up to a level with the skidding that rests one end on the chassis-rail. Each skid is supported near the rail by a crib of heavy blocks piled one on top of the other, three in a crib, and brought to a level with the rail. The cribs, if placed obliquely to the skidding, will still be stable and support the skidding more in the direction of its length. The ends of the skidding remote from the chassis-rail are supported by two double cribs. Each crib is built of three tiers of blocks, alternate ends resting on the lower tier, each pair of blocks parallel to each other and 1′ 6″ apart. The cribs are brought to a level with a chassis-rail. To move the gun from the cradle on the skidding, a man with a chock stands by muzzle and breech, the rest of the men work at the bars. The muzzle is first cut and chocked from the cradle to the skidding; after the muzzle rests on the skidding the breech is cut on the skidding the same way as the muzzle. This operation is continued alternately with breech and muzzle as before, except the men with the chocks now chock on the side toward the chassis-rail until the gun rests on the skidding on the chassis-rail, under its position when mounted on the carriage. The gin or pumps are now set over the muzzle and breech or under them, as the case may be. The cribs to support the muzzle and breech are now respectively placed 3′ from the muzzle, and at the greater swell of the breech. In raising the gun, the breech is raised first by pump or gin 6″ full, a man standing on each side with chock, in case of slip, to prevent rolling. Care is taken to set the gin or pump vertical over or under the breech, and when lowering to ease up, without jerking, gradually. The muzzle can now be raised 12″ full, blocked and chocked in that position. The skidding is now removed. The breech 6″ additional, always having the men with chocks on either side ready, and following up the gun with the blocks, so that it cannot have a fall in case of accident. The blocks used come from the cribs for the skidding that are no longer required. The operation of alternate blocking at breech and muzzle is continued until the gun stands above the height of the trunnion-beds with the axis through the trunnion horizontal. The top-carriage is now put on the chassis and assembled with the trunnion-beds under the trunnions. The gun is then lowered in the trunnions, and the blocks and gin or pumps removed.

Another plan, when the top-carriage has not been taken apart, is as follows: Mount the chassis on platform and top-carriage on the chassis with gin, and then run the top-carriage into battery. Bring the gun upon cradle or skidding until it is parallel to a convenient position of chassis. Roll the gun over the chassis, having the breech projecting beyond the rear end of the chassis, raise it by blocking under the breech beyond the rails, and under the muzzle by blocks outside rails, with a skidding laid across them, until the muzzle is high enough for the top-carriage to be moved back under the trunnions; the muzzle is raised by gin and the breech by hydraulic pump. Run the top-carriage back under the trunnions, lower the gun into the trunnions, remove scaffolding. In building scaffolding of blocks, put the thickest at bottom, and as you gain in height in raising a gun, replace thin blocks by thicker ones. Derricks for raising and mounting ordnance as heavy as 15″ are to be avoided, if possible, as they are heavy and troublesome to move and set up—more difficult to handle than guns, and can only be used under favorable conditions of space; in other words, they consume labor and time that ought to be expended only on the guns. These objections apply to any machine of much weight and size beyond two or three cubic feet. Forts are often at comparatively inaccessible places, and are often in themselves very limited, and possess platforms for guns in angles and confined places hard to approach with guns as large as 15″, and, consequently, the *means* of handling—moving and mounting—must be small and powerful.

We will close this article with a description of the unloading and mounting of the 20-inch gun at the United States Centennial Exhibition. This gun, with a 13-inch sea-coast mortar of about 18,000 pounds, a cradle of about 4,000, with heavy yellow-pine skidding and a deck-load of lumber, in all about 80 tons, were shipped from Fort Monroe on a vessel rated at 94 tons. She nearly foundered in a gale on Chesapeake Bay on her way to the canal at Baltimore, but arrived at Philadelphia afloat but leaking badly, with her deck only about eight inches above the water-line and about four feet below the level of the wharf at high tide. The steam-crane on the wharf had been found by analysis to be insufficiently strong to lift the gun entire; it was consequently simply used as an auxiliary. A 14-inch spar was wedged very tightly into the muzzle of the gun, and served also as a fastening-point for the 11-inch hawser by which the gun was raised. The gun having been blocked up about 2 feet from the cascabel, the crane began to lift. It lifted the muzzle about 15 inches, besides stretching the hawser about 8 feet. Blocking was then placed just back of the center of gravity of the gun, and the muzzle lowered on this pile as a fulcrum until the breech was high enough to take a fresh pile of blocking beneath it. By this lift the gun was raised about 3 inches. The position of the three supports was as follows: 1st, 5 feet from the muzzle; 2d, immediately back of the trunnions; 3d, 2 feet from the breech. Owing to the position of the third point the crane was strained about 13 tons by this lift. Double piles of blocking were used at each bearing-point for safety, so as to limit any accidental fall in raising or lowering the gun to an inch or two at the utmost. Chocking-quoins were also used to follow up the gun closely in its movements. About 15 men were used throughout the maneuvers. One of these men, as ship-carpenter, with his adze and crosscut-saw, was particularly valuable, and also a rigger from the United States Navy-yard. Heavy 18-inch yellow-pine skidding was placed from under the gun to the wharf, inclining slightly upwards, and the hawser parbuckled around the gun and fastened to the crane. A purchase was taken from the muzzle by a locomotive standing on a neighboring track. The crane began to hoist at 6.44, the gun immediately rolling toward the wharf as the hawser uncoiled. The muzzle was cut meanwhile by the locomotive. At 7.04 p.m. the gun was landed, in 11 hours 6 minutes working-time.

As the vessel was relieved of the weight of the gun it rose, converting the inclined way of skidding into a declivity leading to the wharf. This feature permitted the pile of blocking on deck to be much lower than would otherwise have been necessary. On the second day the gun was rolled by the crane and locomotive together to a position parallel with the railroad track across which it had been necessarily landed. Toward the latter part of this operation the locomotive was dispensed with, it being found that by placing the crane in a favorable position, taking hold of the muzzle, and then topping the boom, the muzzle could be cut almost as well as with the locomotive. After about 4 hours of effective hoisting, the gun was placed on the car, on which it was transported safely the next morning to the exhibition grounds, and unloaded the same day. The advantages in this operation were as follows: I. The proximity of William C. Allison & Son's wharf and their large car-works, from which were obtained, readily, supplies of blocking, flat iron bars, heavy tools, men, and notably the use of their steam-crane and railroad-plant, and the 6-inch oak car-bolsters, especially valuable for blocking. II. The use of an extra heavy flat car procured from the Pennsylvania Railroad Company. The disadvantages were: I. The small size of the vessel, its breadth of 23 feet giving only 8 or 9 feet on each side of the bare gun to work in. The gun also occupied all the space between the masts. With the additional weight of the blocking upon her decks, used in raising the gun, the danger of breaking them in or of starting fresh leaks was greatly increased. II. The Captain of the schooner refused to permit hydraulic jacks to be used, for fear of breaking in his deck. III. The gun had to be raised so high, in order to roll it off upon the dock, that the stability of the vessel was considerably endangered. IV. The Captain of the schooner refused to lie alongside of the wharf, fearing, as he represented, shoal water; consequently the gun had to be rolled off from end of the wharf in a direction at right angles to the railroad track. V. Much of the work was done after dark, in the hope of getting the gun on the car by Sunday, the Pennsylvania Railroad wishing to move it to the grounds on that day, for fear of obstruction to the track and to avoid car-demurrage. VI. The men were unaccustomed to moving heavy weights, and shirked all they could, especially at night. In mounting the 20-inch gun, the Laidley gun-lift was used, assisted by blocking. The other guns were mounted with blocking only. The light auxiliary shears, provided with the gun-lift, proved of considerable value in placing in position heavy articles, such as the field-cannon, raising the ways of the drop-hammer, etc. A casemate-gin, mounted on three rollers, was also used. This was very useful in picking up heavy pieces, such as lumps of ore, drop-anvils, etc., and moving them to the pedestal or the foundation on which they were to be placed. Two of the rollers on the windlass-legs were joined together by a sleeve of heavy steam-pipe, fitting over the projecting limbs of the axles, to prevent the rollers from assuming their natural position at right angles to the line of the leg. See *Blocks, Capstan, Casemate-gin, Casemate-truck, Cordage, Crab, Cradle, Derrick, Gin, Gin-derrick, Knots, Lever-jack, Lifting-jack, Mounting Cannon, Piper Gin, Rope, Shears, Sling-cart, Sling-wagon,* and *Tackles.*

MECHANICAL MOTION.—Colonel A. R. Buffing ton, United States Army, has recently designed an interesting machine, which is serviceable as a practical illustration of the resolution of forces into components, and of the principle of mechanics that action and reaction are equal, simultaneous, and contrary. For a full description of this machine, reference is made to the Report of the Chief of Ordnance for 1882. In this connection we will be confined to an investigation of the theory of the contrivance. Suppose, in Fig. 1, the two circles *A* and *B* represent the pitch-lines of two gear-wheels, one, the larger, geared inside—a ring-gear— and twice the diameter of the other, each fixed at, but free to revolve on, its center. Any point, *d*, of the smaller will mark on the face and through the center of the other a right line, *a b*. Suppose a point *over* the point *d* be fixed to a slide on the face of smaller *A* [which slide can move only in the line *d e*], and compelled to move in a groove, *a b*, across the face and center of larger *B*. If a force whose direction is the same as in the direction of *e d* (Fig. 1). As it was shown above how the perpendicular component of the applied force is destroyed, it remains to show in what manner the parallel one is neutralized.

In Fig. 3 let *a b* represent the groove across the face and center of *B*, *d* the point of a slide on the face of *A*, and also of a block free to move in the groove *a b*, and the arrow *e d* represent the applied force and direction of it. It has been seen that under the action of this force the gear *A* would start to roll around inside of *B*, as indicated by the arrow, carrying the arm *h i* as indicated, which in its turn would carry the gear *C* and give it by means of fixed gear *D* the motion indicated by the arrow. But the two small gears engage at *c*, and examining them at this point it is seen that they have motion or, strictly, tendencies to motion, in opposite directions, consequently no motion can take place, although the system is free to move either by application of force to the arm or the *free* ring-gear. Thus the teeth of a

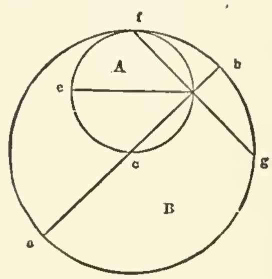

Fig. 1.

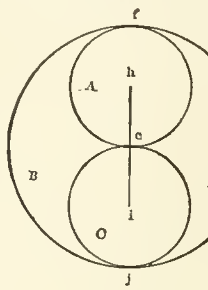

Fig. 2.

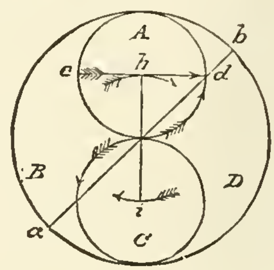

Fig. 3.

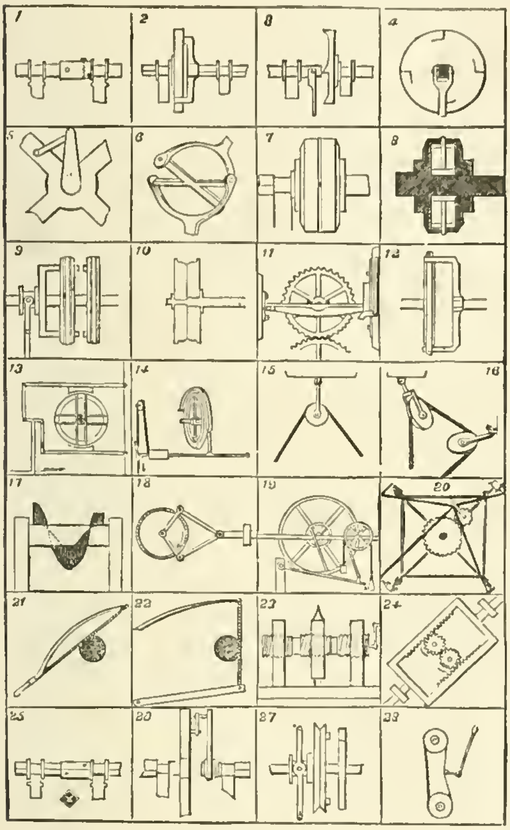
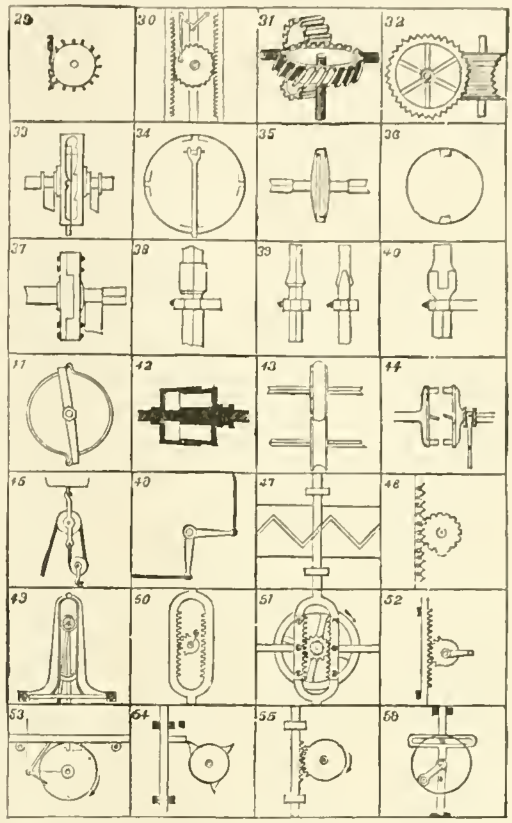
the line *d e* be applied to this point no motion of the system can take place; for the action against the larger would be in the line *f d g*, perpendicular to *a b* at *d*, and passing through *f*, the point of engagement of the two gears, and the *reaction* on smaller would be in the same line; these, action and reaction, being equal, no motion could take place. But suppose the center of smaller gear be free to move, motion would then take place—the smaller would roll around inside the other, the point referred to moving in the groove *a b*, the larger gear, although free to move around its center, remaining stationary—that is, the force applied would be resolved into two components, one perpendicular to and the other parallel with line *a b*, the former destroyed by action and reaction, the latter passing through the center of larger, producing motion only of smaller gear.

Suppose, now, two more gears precisely the same in size and gearing and having the same relation to each other be placed so that the small ones shall engage over the centers of large ones—these latter having no *direct* connection with each other—and that the centers of small ones be connected by an *arm* fixed so as to revolve at *c*, (Fig. 2); the two systems differing only in that the ring-gear (D, Fig. 2) shall be fixed—unable to move in any way. *A* and *B* of Fig. 2 being the two gears explained in Fig. 1, engaging at *f*; *C* and *D* (*D* and *B* coincident, showing but one circle), engaging at *j*, being the equal pair of last supposition; the smaller gears engaging at *c* and united by the arm *h i*, each free to revolve on journals of arm at *h* and *i*. If motion be given to the arm the small gear *C* will roll around inside the fixed ring-gear *D*, and revolve the other *A* about its center *h*, as it is carried around by the arm, and *A* will carry with it the movable ring-gear *B*, or if motion be given to this latter (*B*) it will carry *A* with it, which in turn will roll *C* around inside the fixed gear *D*. During this motion any point of *A* will describe a right line across the face and center of *B* as previously noted. But if *A* and *B* be arranged with slide and groove and a force applied, as above supposed, the system cannot be moved as long as the direction of this force crosses the center of *A* fixed ring-gear are interposed at every point of revolution to neutralize the parallel component. To always practically have the force applied, as described, to a crank arm whose center is at *c*, a link is attached and connects with the slide and block. To carry over the centers, the system of four gears above explained is doubled, the crank-arms being placed at right angles on the shaft to which they are attached. The point *d* describes during a revolution a double cusp.

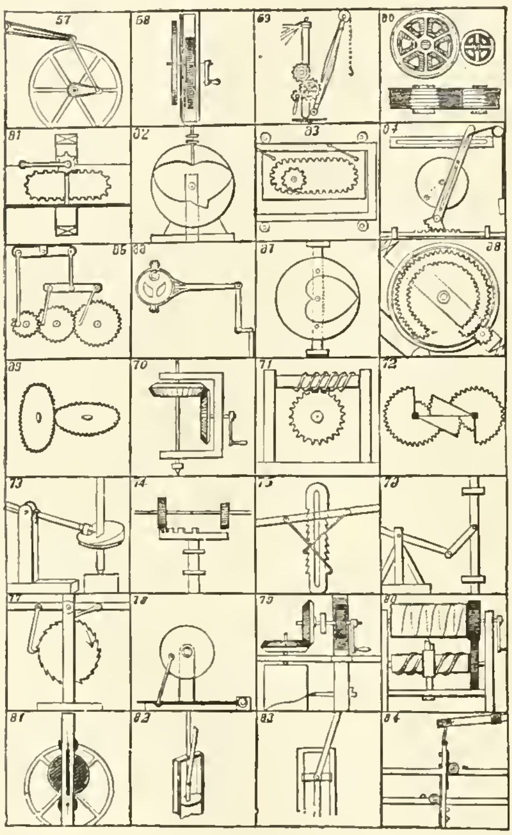
MECHANICAL MOVEMENTS.—In the construction of models or machinery, the skillful inventor and mechanic will study to avoid clumsiness in the arrangement of the parts, and will naturally select the simplest and best forms of mechanical movements. By the kind assistance of the proprietors of the *Scientific American* we are enabled to present a series of such movements, from among which the inventor may select at once that movement best suited for his purpose, and see at a glance the separate parts best adapted to any special combination of mechanism. The following is a brief description of the various movements as numbered: 1. Shaft coupling. 2. Claw coupling. 3, 4. Lever couplings. On the driving shaft, a disk with spurs is mounted, and to the shaft to be driven a lever is securely hinged. By causing this lever to catch in the spurs of the disk the coupling is readily effected, as in the figure 5. Knee or rose coupling, of which 26 gives a side view. 6. Universal joint. 7, 8. Disk and spur coupling. 9. Prong and spur lever coupling. 10. Fast and loose pulley. 11. Sliding gear, the journal-boxes of one of the wheels being movable. 12. Friction clutch. By tightening or releasing a steel band, encircling a pulley on the shaft, the machinery is thrown in or out of gear. 13, 14. Shoe and lever brakes. 15, 16. Change of motion by sheaves. 17. Spiral flanged shaft. 18. Connected with the rod are pawl links, catching into ratchet teeth in the wheel to which rotary motion is to be imparted. When the rod moves in one direction, one of the pawls acts; and when the rod moves in the opposite direction, the other pawl acts in the same direction as the first. 19. The reciprocating motion of a rod is converted into rotary motion of the fly-wheel by a weight suspended from a cord, which passes over a small pulley that connects with a treadle, from which the motion is transmitted to the fly-wheel. 20. "Flying horse." By pulling the cords radiating from the crank, the persons occupying the seats or horses on the ends of the arms are enabled to keep the apparatus in motion. 21, 22. Bow-string arrangements to convert reciprocating into rotary motion. 23. Same purpose by differential screw. 24. The same by double rack and wheels. 25. Coupling for square shafts. 26. Side view of Fig. 5. 27, Sliding-spur pulley coupling. 28. Lever with bearing roller to tighten pulley bands. 29. Chain wheel. 30. Reciprocating rectilinear into reciprocating rotary motion by two racks and cog-wheel, as shown. 31. Oblique-toothed wheels. 32. Worm and worm-wheel. 33, 34. Claw coupling with hinged lever.



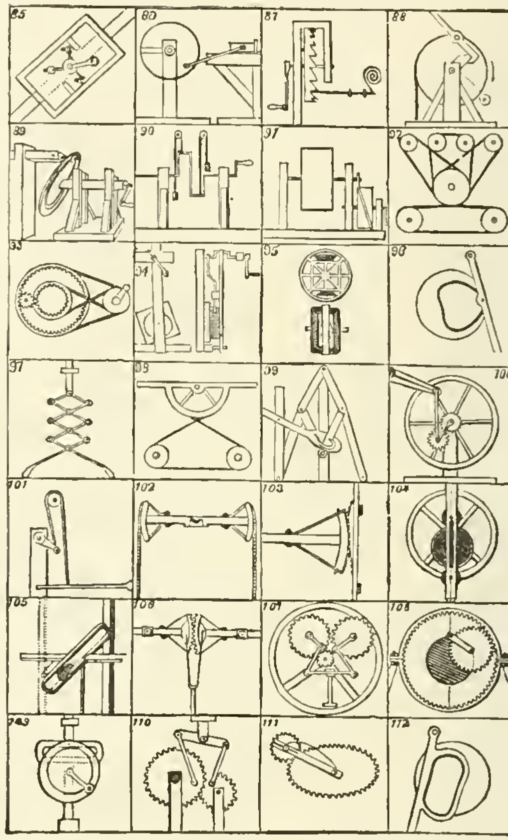
35, 36. Disk couplings with lugs and cavities. 37. Disk coupling with screw bolts. 38, 39, 40. Shaft couplings. 41. Face view of Fig. 12. 42. Friction cones. 43 Friction pulleys. 44. Self-releasing coupling. Disks with oblique teeth. If the resistance to the driven shaft increases beyond a certain point, the disks separate. 45. Hoisting blocks. 46. Elbow crank, for changing motion. 47. Reciprocating into rotary motion by zigzag groove on cylinder. 48 Another form of Fig. 29. 49. Reciprocating into rotary motion. 50. Same purpose. 51. Same purpose, by double rack and two ratchet pinions. When the double rack moves in one direction, one pinion is rigid with the shaft; when the rack moves in the opposite direction, the other pinion is rigid, and a continuous rotary motion is imparted to the fly-wheel shaft. 52. Reciprocating into oscillating. 53. Rotary into reciprocating. By the action of the wheel-pins the carriage is moved in one direction, and by the action of the same pins on an elbow-lever it is moved in the opposite direction. 54. Stamp rod and lifting cam. 55. For giving reciprocating motion to rack 56. Same motion to a bar, with slot, by means of an eccentric pin projecting from a revolving disk and catching in the slot. 57. Walking-beam and fly-wheel. 58. Reciprocating motion to pump or other rod by means of eccentric disk and friction rollers. (See 81 and 104). 59. Hoisting crane. 60. Friction gears. (See 43). 61. Rotary into reciprocating by rising and falling pinion acting on endless rack. 62. By the revolving cam a rising and falling or a reciprocating rectilinear motion is readily imparted to a drum. 63. Reciprocating mo-



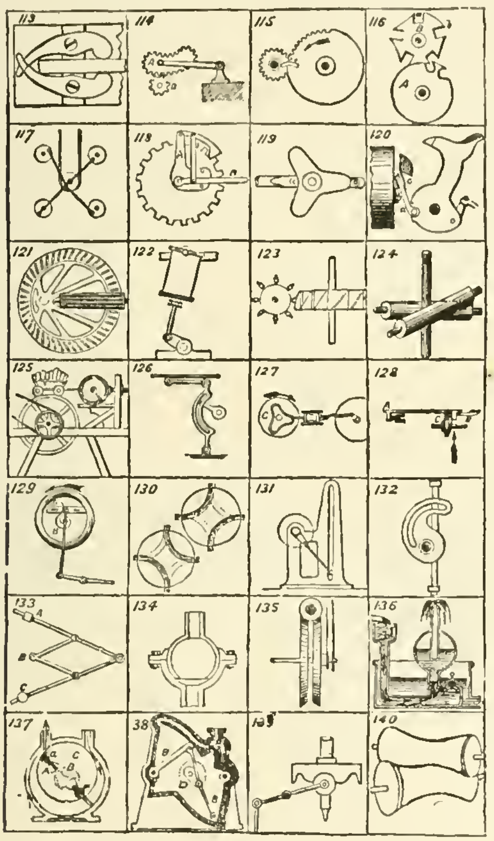
tion is communicated to a frame by means of the endless rack and pinion. 64. Reciprocating rectilinear motion to a toothed rack by a toothed segment on a lever-arm, which is subjected to the action of a weight, and of an eccentric wrist-pin, projecting from a revolving disk. 65. Reciprocating motion to a rod. The wheels are of different diameters, and consequently the rod has to rise and fall as the wheels revolve. (See 110). 66. Cam and elbow-lever. 67. Rod reciprocates by means of cam. 68. Revolving into reciprocating motion, by an endless segmental rack and pinion, the axle of which revolves and slides in a slot toward and from the rack. This rack is secured to a disk, and a rope round the disk extends to the body to which a reciprocating motion is to be imparted. 69. Elliptic gears. 70. Bevel gear. 71. Worm and worm-wheel. 72. Transmitting motion from one axle to another, with three different velocities, by means of toothed segments of unequal diameters. 73. Continuous revolving into reciprocating, by a cam-disc acting on an oscillating lever. 74. Intermittent revolving motion to a shaft with two pinions, and segment gear-wheel on end of shaft. 75. Oscillating lever, carrying pawls which engage teeth in the edges of a bar to which rectilinear motion is imparted. 76. Oscillating lever, connecting by a link with a rod to which a rectilinear motion is imparted. 77. Oscillating lever and pawls, which gear in the ratchet-wheel. 78. Common treadle. 79. Describing on a revolving cylinder a spiral line of a certain given pitch which depends upon the comparative sizes of the pinion and bevel-wheels. 80. Marking a spiral line, the graver moved by a screw. 81. (See Fig. 58). 82. Plunger and rods. 83. Cross-head and rods. 84. Reciprocating rod guided by friction rollers. 85. Revolving into reciprocating motion, by means of roller-arms extending from a revolving shaft and acting on lugs projecting from a reciprocating frame. 86. Crank motion. 87 Reciprocating motion communicated by toothed wheel and spring-bar. 88. The shaft carries a taper, which readily catches against a hook securely hinged to the drum,so as to carry the drum along and raise the weight on the rope. When the tappet has reached its highest position, the hook strikes a pin, the hook disengages from the tappet, and the weight drops. 89. Reciprocating motion to a rod by means of a groove in an oblique ring secured to a revolving shaft. 90. Double crank. 91. Cam groove in a drum. to produce reciprocating motion. 92. Belts and pulleys. 93. Pulleys, belts and internal gear. 94. As the rod moves up and down, the teeth of the cog-wheels come in contact with a pawl, and an intermittent rotary motion is imparted to said wheel. 95. By turning the horizontal axles with different velocities, the middle wheel is caused to revolve with the mean velocity. 96. Oscillating lever and cam groove in a disk. 97. Lazy tongs. 98l. Oscillating segment and belt over pulleys. 99. Converting oscillating into a reciprocating motion by a cam-slot in the end of the oscillating lever which catches over a pin projecting from one of the sides of a parallelogram which is connected to the rod to which reciprocating motion is imparted. 100. Oscillating motion of a beam into rotary motion. 101. Motion of a treadle into rotary motion.



102. Double-acting beam. 103. Single-acting beam. 104. (See Figures 58 and 81). 105. Device to steady a piston by a slotted guide-piece, operated by an eccentric on the driving shaft. 106. Rod operated by two toothed segments. 107. Two cog-wheels of equal diameter, provided with a crank of the same length, and connected by links with a cross-bar to which the piston-rod is secured. 108. Device for a rectilinear motion of a piston-rod based on the hypocycloidal motion of a pinion in a stationary wheel with internal gear. If the diameter of the pinion is exactly equal to one half the diameter of the internal gear, the hypocycloid becomes a sight line. 109. Same purpose as 56. 110. Action similar to 65. 111. Revolving motion by a circular sliding pinion gearing in an elliptical cog-wheel. 112. Similar to 96. 113. Carpenter's clamp. The jaws turn on the pivot-screws, and clamp the board. 114. An irregular vibratory motion is given to the arm carrying the wheel A by the rotation of the pinion B. as shown. 115. Intermittent rotary motion of the pinion-shaft, by the continuous rotary motion of the large wheel. The part of the pinion shown next the wheel is cut on the same curve as the plain portion of the circumference, and therefore serves as a lock whilst the wheel makes part of a revolution, and until the pin upon the wheel strikes the guide-piece upon the pinion, when the pinion-shaft commences another revolution. 116. Stop-motion used in watches to limit the number of revolutions in winding up. The convex curved part, *a b*, of the wheel B serving as the stop. 117. Several wheels, by connecting-rods, driven from one pulley. 118. Intermittent circular motion is imparted to the toothed wheel by vibrating the arm B. When the arm B is lifted, the pawl is raised from between the teeth of the wheel, and traveling backward over the circumference again, drops between two teeth on lowering the arm, and draws



with it the wheel. 119. Reciprocating rectilinear motion is given to the bar by the continuous motion of the cam. The cam is of equal diameter in every direction measured across the center. 120. Mechanism for revolving the cylinder in Colt's firearms. When the hammer is drawn back, the dog, *a*, attached to the tumbler acts on the ratchet, *b*, on the back of the cylinder, and is held up to the ratchet by a spring, *c*. 121. Alternate increasing and diminishing motion, by means of eccentric toothed wheel and toothed cylinder. 122. Oscillating or pendulum engine. The cylinder swings between trunnions like a pendulum. The piston-rod connects directly with crank. 123. Intermittent rotary motion. The small wheel is driven, and the friction rollers on its studs move the larger wheel by working against the faces of oblique grooves or projections across the face thereof. 124. Longitudinal and rotary motion of the rod is produced by its arrangement between two rotating rollers, the axles of which are oblique to each other. 125. Friction indicator of Roberts. Upon the periphery of the belt-pulley a loaded carriage is placed, its tongue connected with an indicator.



tor. With a given load the indicating pointer remains in a given position, no matter what velocity is imparted to the pulley. When the load is changed the indicator changes, thus proving that the friction of wheels is in proportion to load, not velocity. 126. Circular intermittent rectilinear reciprocating motion. Used on sewing-machines for driving the shuttle; also on three-revolution cylinder printing-presses. 127. Continuous circular into intermittent circular motion. The cam is the driver. 128. Sewing-machine, four-motion feed. The bar, B, carries the feeding-points or spurs, and is pivoted to slide, A. B is lifted by a radial projection on cam, C, which at the same time also carries A and B forward. A spring produces the return stroke, and the bar, B, drops by gravity. 129. Patent crank motion to obviate dead centers. Pressure on the treadle moves the slotted slide, A, forward until the wrist passes the center, when the spring, B, forces the slide against the stops until next forward movement. 130. Four-way cock. 131. One stroke of the piston gives a complete revolution to the crank. 132. Rectilinear motion of variable velocity is given to the vertical bar by rotation of the shaft of the curved arm. 133. Pantagraph for copying, enlarging and reducing plans, etc. C, fixed point. B, ivory tracing point. A, pencil. Trace the lines to be copied with B, and the pencil will reproduce them double size. Shift the slide to which C is attached, also the pencil slide, and size of the copy will be varied. 134. Ball-and-socket joint for tubing. 135. Numerical registering device. The teeth of the worm-shaft gear with a pair of worm-wheels of equal diameter, one having one tooth more than the other. If the first wheel has 100 teeth and the second 101, the pointers will indicate respectively 101 and 10,100 revolutions. 136. Montgolfier's hydraulic ram. The right-hand valve being kept open by a weight or spring, the current flowing through the pipe in the direction of the arrow escapes thereby. When the pressure of the water current overcomes the weight of the right valve, the momentum of the water opens the other valve, and the water passes into the air-chamber. One equilibrium taking place, the left valve shuts and the right valve opens. By this alternate action of the valves, water is raised into the air-chamber at every stroke. 137. Rotary engine. Shaft B and hub, C are arranged eccentric to the case. Sliding radial pistons, *a*, *a*, move in and out of hub C. The pistons slide through rolling packings in the hub C. 138. Quadrant engine. Two single-acting pistons, B, B, connect with crank D. Steam is admitted to act on the outer sides of the pistons alternately through valve *a*, and the exhaust is between the pistons. 139. Circular into rectilinear motion. The scalloped wheel communicates motion to the horizontal oscillating rod, and imparts rectilinear movement to the upright bar. 140. Rotary motion transmitted by rolling contact between two obliquely arranged shafts.

MECHANICAL POWERS. — Machines are instruments interposed between the moving power and the resistance, with a view of changing the direction of the force, or otherwise modifying it. Machines are of various degrees of complexity; but the simple parts, or elements of which they are all composed, are reducible to a very few. These elementary machines are called the Mechanical Powers, and are usually reckoned as six in number, three being primary—viz., the *lever*, *inclined plane*, and *pulley;* and three secondary, or derived from the others—viz., the *wheel-and-axle* (derived from the lever), the *wedge*, and the *screw* (both derived from the inclined plane). To these some add toothed wheels. What is special to each machine will be found under its name; a few observations applicable to all may appropriately be made here. 1. In treating of the theory of the lever and other mechanical powers, the question really examined is, not what power is necessary to move a certain weight, but what power is necessary to balance it. This once done, it is obvious that the least additional force to P will suffice to begin motion. 2. In pure theoretical mechanics, it is assumed that the machines are without weight. A lever, for instance, is supposed to be a mere rigid line; it is also supposed to be *perfectly* rigid, not bending or altering its form under any pressure. The motion of the machine is also supposed to be without friction. In practical mechanics, the weight of the machine, the yielding of its parts, and the resistance of friction, have to be taken into account. 3. When the effect of a machine is to make a force overcome a resistance greater than itself, it is said to give a *mechanical advantage*. A machine, however, never actually increases power—for that would be to create work or energy, a thing now known to be as impossible as to create matter. What is gained in one way by a machine is always lost in another. One pound at the long end of a lever will lift 10 pounds at the short end, if the arms are rightly proportioned; but to lift the 10 pounds through one foot, it must descend 10 feet. The two weights, when thus in motion, have equal momenta; the moving mass multiplied into its velocity, is equal to the resisting mass multiplied into its velocity. When the lever seems to multiply force, it only concentrates or accumulates the exertions of the force. The descending one pound weight, in the case above supposed, may be conceived as making 10 distinct exertions of its force, each through a space of a foot; and all these are concentrated in the raising of the 10 pound weight through one foot. The principle thus illustrated in the case of the lever holds good of all the mechanical powers. 4. The object of a machine is not always to increase force or pressure; it is as often to gain velocity at the expense of force. In a spinning factory, e. g., the object of the train of machinery is to distribute the slowly working force of a powerful water-wheel or other prime mover, among a multitude of terminal parts moving rapidly, but having little resistance to overcome. 5. The mechanical advantage of a compound machine is theoretically equal to the product of the separate mechanical advantages of the simple machines composing it; but in applying machines to do work, allowance must be made for the inertia of the materials composing them, the flexure of parts subjected to strains, and the friction, which increases rapidly with the complexity of the parts; and these considerations make it desirable that a machine should consist of as few parts as are consistent with the work it has to do. 6. The forces, or "moving powers," by which machines are driven are the muscular strength of men and animals, wind, water, electrical and magnetic attractions, steam, etc.; and the grand object in the construction of machines is, how, with a given amount of impelling power, to get the greatest amount of work of the kind required. This gives rise to a multitude of problems, some more or less general, others relating more especially to particular cases—problems, the investigation of which constitutes the science of applied mechanics. One of the questions of most general application is the following: If the resistance to a machine were gradually reduced to zero, its velocity would be constantly accelerated until it attained a maximum, which would be when the point to which the impelling force is applied was moving at the same rate as the impelling force itself would move if unresisted. If, on the other hand, the resistance were increased to a certain point, the machine would come to a stand. Now, the problem is, between these two extremes to find the rate at which the greatest effect or amount of work is got from the same amount of driving power. The investigation would be out of place here, but the result is that the greatest effect is produced when the velocity of the point of application is one-third of the maximum velocity above spoken of. The moving force and the resistance should therefore be so adjusted as to produce this velocity.

It will be our endeavor in this article to find the relation between the power and the weight when they balance each other in each of the simple machines; friction and the weight of the machine not being taken into account. For the sake of convenience, the power will be denoted by P, and the weight by W. A *lever* is an inflexible rod, straight or bent, turning on a point called the *fulcrum*. It is much used in the form of an iron bar for moving heavy bodies, through small distances. Fig. 1 shows a lever used for that purpose, in which F is the fulcrum, P is the power exerted by the hand, and W is the weight to be moved. Take a straight inflexible bar, A B, Fig. 2,and place it on a prop, F. On the end, B, hang a weight, W, and balance it with the power, P, hung on the end, A; F A is the power-arm, and F B the weight-arm. Now if F A is equal to F B, then W is equal to P; if F A is three times the length of the arm, F B, then W is double the length of F B,then W is double of P; if F A is three times P;and so on. The *weight* always bears

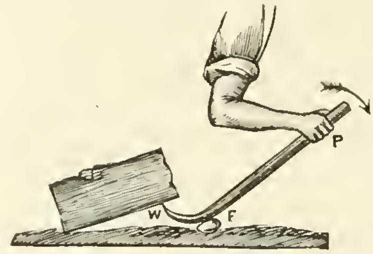


Fig. 1.

the same proportion to the *power* as the *power-arm* bears to the *weight-arm*. The same thing may be expressed by saying that the power multiplied by the length of the power-arm is always equal to the

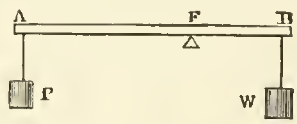

Fig 2.

weight multiplied by the length of the weight-arm. This rule holds for all levers; but if the lever be bent as in Fig. 3 we must not take the bent arms of the lever, E M and F N, for the power and weight arms; but for the power-arm we must take, F A the perpendicular drawn from the fulcrum to the direction

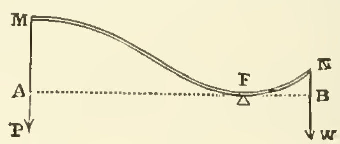

Fig. 3.

in which the power acts, and for the weight-arm we must take F B, the perpendicular drawn from the fulcrum to the direction in which the weight acts. The same precaution must be observed if the power and weight do not act in directions parallel to each other, as shown in Fig. 4.

In Figs. 2, 3, 4, the power multiplied by the length

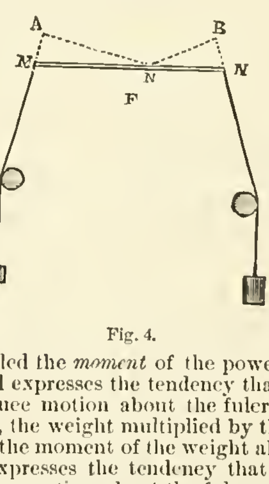

Fig. 4.

of F A is called the *moment* of the power about the fulcrum, and expresses the tendency that the power has to produce motion about the fulcrum; in the same figures, the weight multiplied by the length of F B is called the moment of the weight about the fulcrum, and expresses the tendency that the weight has to produce motion about the fulcrum in the opposite direction. We see that when a lever is at rest the moments of the power and weight about the fulcrum are equal. Levers are generally divided into three kinds, according to the position of the power and weight with regard to the fulcrum. In levers of the first kind the power and weight act on different sides of the fulcrum, as shown in Fig. 5. It is evi-

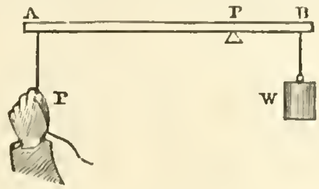

Fig. 5.

dent that with levers of this kind we may either have a *mechanical advantage* or a *mechanical disadvantage*, according as the fulcrum is placed nearer the weight or the power. Examples of this kind of lever are numerous: the crowbar, used as seen in Fig. 1; the poker used in stirring the fire; and the claw-hammer used in drawing a nail, are familiar illustrations. In these, as well as in the examples to be given of the other two kinds of levers, the reader should satisfy himself as to what constitutes the *fulcrum*, *power*, and *weight* in each case. In levers of the second kind, the power and weight act on the

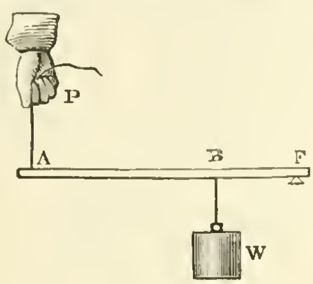

Fig. 6.

same side of the fulcrum, the weight being nearer the fulcrum, as shown in Fig. 6. Here, it is evident, that we have always a *mechanical advantage*, whether great or small, for the power-arm must be always somewhat longer than the weight-arm. Nut-crackers, a chipping-knife, an oar used in propelling a boat, and a door taken by the handle and opened on its hinges, are levers of the second kind. In levers of the third kind, the power and weight also act upon the same side of the fulcrum, the power being nearer the ful-

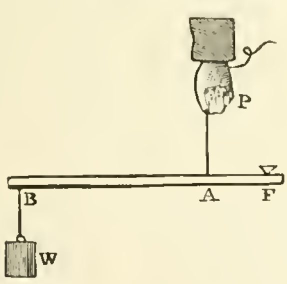

Fig. 7.

crum, as in Fig. 7. In this kind of lever there is always a *mechanical disadvantage*, for in it the power-arm is always shorter than the weight-arm, so that to support a weight with it a greater power is required than if the power were applied directly and without the intervention of a machine at all. This kind of lever is only used when velocity rather than power is wanted: the human arm, Fig. 8, is an example. The fulcrum is at the elbow, the weight is the body resting on the hand, and the contractile

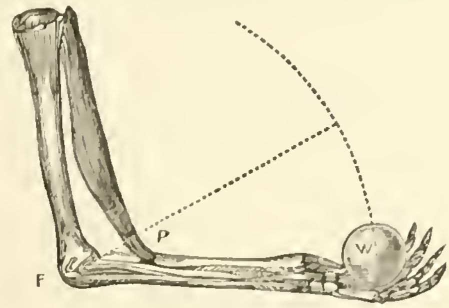

Fig. 8.

force of the muscle furnishes the power which acts at P. When the muscle contracts, the hand describes a much longer curve than P does, and this

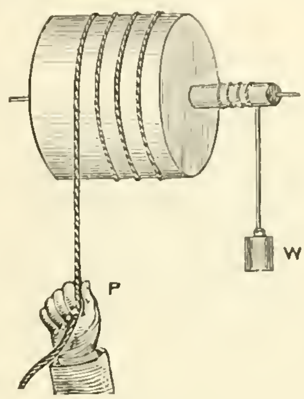

Fig. 9.

is convenient. The *Wheel-and-Axle*, as represented in Fig. 9, consists of two cylinders of different sizes, having a common axis to which they are rigidly attached: the larger cylinder is called the wheel, because a wheel having a groove in its circumference for carrying a rope is sometimes used instead of it; the smaller cylinder is called the axle; their common axis is firmly supported on a strong frame. The weight is attached to the end of a long rope which is coiled round the axle, and the power acts at the end of another rope which is coiled round the wheel in an opposite direction, so that when the

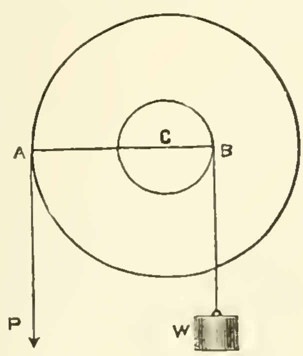

Fig. 10.

rope is pulled down the weight is raised. Fig. 10 represents a vertical section of the wheel-and-axle, from which it is manifest that it is merely a modification of the lever, in which C, the center of the axle, is the fulcrum. C A, the radius of the wheel, is the power-arm. and C B, the radius of the axle is the weight-arm.

It clearly follows, from the law of the lever, that the wheel-and-axle is in equilibrium when the power multiplied by the radius of the wheel equals the weight multiplied by the radius of the axle; so that if the radius of the wheel were eighteen inches and the radius of the axle two inches, then a power of

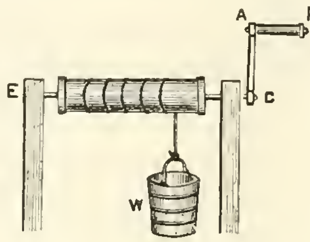

Fig. 11.

one pound would balance a weight of nine pounds. In the windlass, shown in Fig. 11, the arm, A C, is used instead of a wheel. Examples of the practical application of the wheel-and-axle are seen in the capstan. crane, water-wheel, and toothed wheels.

Fig 12 shows a *Pulley* in use. It is a small disk or wheel, of wood or metal, having a groove in its circumference for carrying a string, and turns on an axis passing through the center of its faces, the axis being supported by a frame called a block. Pulleys are designated as either fixed or movable; a pulley is said to be *fixed* when it does not ascend or descend according as the weight is raised or lowered. It is manifest from Fig. 12 that a fixed pulley has no mechanical advantage, for the power, P, must be equal to the weight, W, in order to support it. This machine is only used to change the direction in which a force acts. When force is transmitted through a string, as it is in the case of pulleys, it gets the name of *tension*, and a string possesses the property of transmitting a force without changing its amount; thus the tension at every point of the string in Fig.

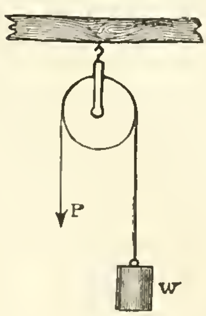

Fig. 12.

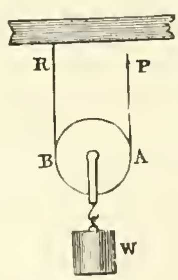

Fig 13.

12 is the weight, W. Pulleys are called *movable* when they ascend or descend according as the weight is raised or lowered. We have a movable pulley in Fig.13. When one movable pulley is used, the strings being parallel, the weight is equal to twice the power. For W is supported by the tension in B R and the tension in A P; and since the tension in each of these is the power, P, acting upward, these two tensions would support a weight of 2 P: therefore W must be equal to 2 P. It is generally found to be convenient to use a fixed pulley along with a movable one when we wish to change the direction of the force, as in Fig. 14. There are three systems of arranging pulleys—or reeving them, as it is called. In the first system, which is shown in Fig. 15, each pulley hangs by a separate string, and all the strings are parallel. When three movable pulleys are ar-

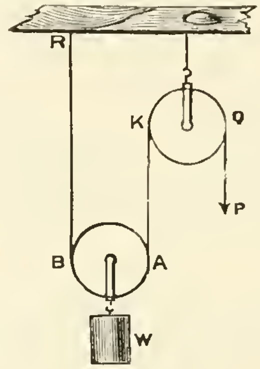

Fig. 14.

ranged thus, the weight is equal to eight times the power; for the tension in the string passing under the first movable pulley at the top is the power, P;

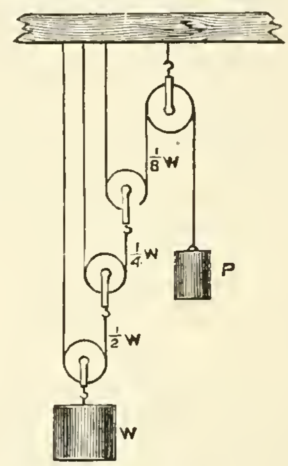

Fig. 15.

the tension in the string passing under the second movable pulley is 2 P; the tension in the string passing under the third movable pulley is 4 P; and the tension in the string hanging from this pulley is 8 P. But this last tension supports the weight, W, therefore W = 8 P. It will be observed that in this system each movable pulley that is added doubles the mechanical advantage. In the second system the string passes round all the pulleys, and the folds of this string are parallel, as represented in Fig. 16. Here the weight, W, is supported by the tensions in the folds of the string; and as there are four folds, each having the tension of the power, P, the weight must be four times the power. In this system the weight is always as many times the power as there are folds in the string, the folds being counted between the two blocks. In the third system Fig. 17, each pulley hangs by a separate string, and the end of each string is attached to the weight, the whole being suspended from a fixed support. The tension in the string passing over the first pulley at the bottom is the power, P; the tension in the string passing over the next pulley is 2 P; the tension in the string passing over the third pulley from the bottom is 4 P; and so on. Thus it is when three pulleys are arranged in this manner, W is supported by P + 2 P + 4 P, that is, by 7 P, and therefore the weight is exactly equal to seven times the power. The effect of any other number may be calculated similarly. The first thing that strikes one on experimenting with the pulleys is the

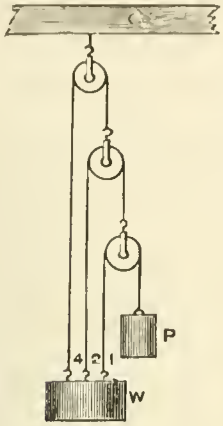

Fig. 16.

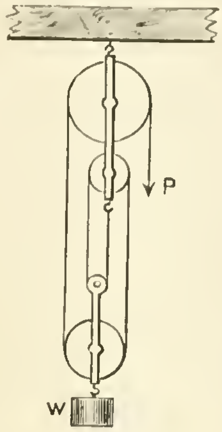

Fig. 17.

principle of virtual velocities. Let us make an experiment with the first system, shown in Fig. 15. Here we have three movable pulleys, and we find that a power of 1 oz. balances a weight of 8 oz. True: but on putting the machine in action, we also find that when the weight is raised 1 ft. the power has to move through 8 ft., so that what is gained in power is lost in speed, and, as we said before, this is true of every machine.

We now come to consider the inclined plane. Here

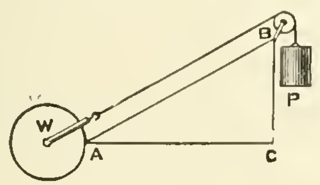

Fig. 18.

is one in Fig. 18. We shall perform an experiment on it, and then draw a conclusion. Let the weight, W, be drawn from the bottom to the top of the inclined plane by the power, P, which acts on the

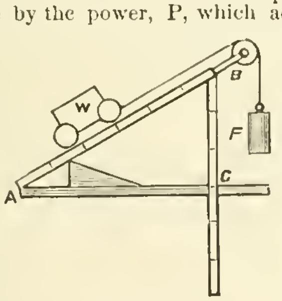

Fig. 19.

weight in a direction parallel to the length of the plane A B; W will be thus raised through a vertical distance equal to B C, the height of the plane; but during this time P will have descended through a vertical distance equal to A B, the length of the plane. Now, from the principle of virtual velocities it follows at once that there is equilibrium here, when P multiplied by A B is equal to W multiplied by B C; that is, on the inclined plane, when the power acts parallel to the length of the plane, there is equilibrium when the power multiplied by the length is equal to the weight multiplied by the height. In Fig. 19, an experiment is shown which verifies the rule we have just drawn from the principle of virtual velocities. A B and A C are two boards, hinged together at A. A C rests for convenience on a table, and A B can be made to rise from it at any angle by inserting a wedge, properly prepared as seen in the figure. From B hangs a bar graduated in inches, by which the height of the plane can be at once measured. The carriage, W, constitutes the weight, and the power, P, acts on it in a direction parallel to the length of the plane. Now make P balance W, and then measure the height and length of the plane; it will be found that P is to W as the height of the plane is to its length; that is, the power multiplied by the number of inches in the length will be equal to the weight multiplied by the number of inches in the height. By varying the experiment, so that the power might act in a direction parallel to the base, we would find that there would be equilibrium when the power multiplied by the base equals the weight multiplied by the height. Two inclined planes placed base to base form a *Wedge*. It is much used in splitting wood, as in Fig. 20; it is also used for raising great

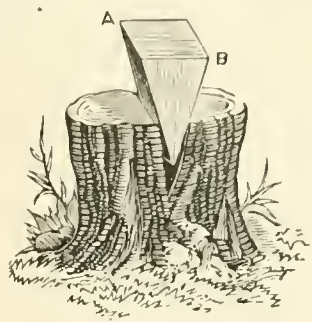

Fig. 20.

weights through small distances. In dockyards, ships are raised on the stocks by wedges driven under their keels. Theoretically considered, the mechanical advantage of the isosceles wedge is the side of the wedge divided by half the back. But this gives us no idea of the real advantage of the machine: this arises from its enormous friction, and also because the force which urges it is derived from the blow of a hammer or a mallet, etc.; a force so very different in its nature from the resistance that it has to overcome, which is the pressure of some weight or the cohesion of the particles of a body, that it admits of no numerical comparison. One part of the theory is true: that the smaller the back the greater is the advantage of the wedge. If a flexible inclined plane, A—one made of paper, for example—be wrapped round a cylinder, B, as in Fig. 21, a *screw* is formed. By means of the apparatus in Fig. 22 we can determine the mechanical advantage of the screw. The resistance here is the bar, W, which is to be moved forward; the power acts at the handle A P. When

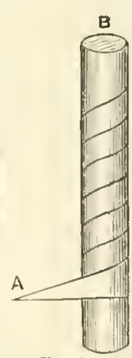

Fig. 21.

the machine is put in action by turning the handle, the power moves through the circumference of the circle described by the handle, while the weight is only moved from *a* to *b*, the distance between two threads; so that in the screw the power is to the weight as the distance between two threads is to the circumference of the circle described by the power. Thus, suppose A P sweeps a circle of 30 in., and that the distance between two threads is ½ in.: then the mechanical advantage of the machine is 30 divided by ½, that is 60; so that if a power of 50 lbs. is exerted on the handle, A P, the bar, W, is urged forward with a force of 60 times 50 lbs., that is 3,000 lbs.

The screw is much used to exert a great pressure through small distances. Fig. 23 shows a common screw-press. To apply the screw here, in an expeditious way, a hollow screw is cut in the nut, N,

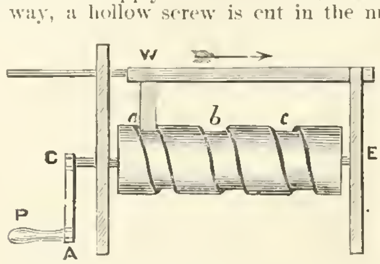

Fig. 22.

into the groves of which the threads of the solid screw fit exactly. The solid screw, S, is fixed to the press-board, B B, so that it cannot turn round, but can be made to move up and down; on the other hand, the nut, N, is fixed, so that it cannot be moved up and down, but can be made to turn round by means of the bar, P, which is inserted in a hole in its side. When the power makes one revolution, the solid screw, with the press-board attached to it, is raised through the distance between two threads; so that if the power, P, sweeps a circle of 20 ft., that is, 240 in., and the

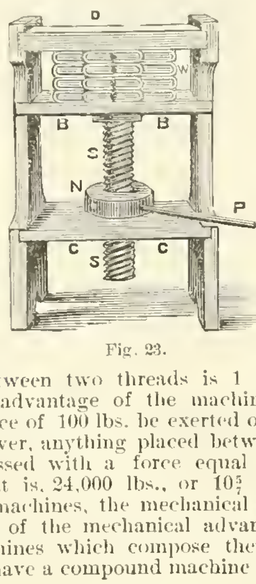

Fig. 23.

distance between two threads is 1 in., then the mechanical advantage of the machine is 240; so that if a force of 100 lbs. be exerted on the extremity of the lever, anything placed between B and D will be pressed with a force equal to 240 times 100 lbs., that is, 24,000 lbs., or $10\frac{5}{7}$ tons. In the compound machines, the mechanical advantage is the product of the mechanical advantages of the simple machines which compose them. Thus, in Fig. 24 we have a compound machine consisting of

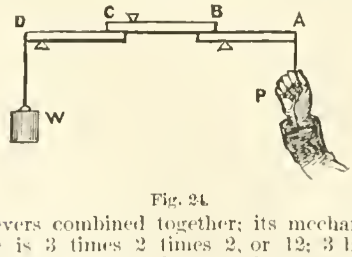

Fig. 24.

three levers combined together; its mechanical advantage is 3 times 2 times 2, or 12; 3 being the mechanical advantage of the first lever, 2 that of the second, and 2 that of the third. A power of 1 lb. applied at A. would balance a weight of 12 lbs. at D.

MECHANICS.—The science which treats of the nature of forces and of their action on bodies, either directly or by the agency of machinery. The nature of force will be found treated of under FORCE. The action of forces on bodies may be in the form of pressure or of impulse, and may or may not produce motion. When the forces are so balanced as to preserve the body affected by them in a state of equilibrium, their actions are investigated in that branch of mechanics called STATICS; when motion is produced, they are considered under the head of DYNAMICS, or *Kynetics*. The equilibrium and motion of fluids (including liquids and gases) is treated in the subordinate branches of HYDROSTATICS and HYDRODYNAMICS; though the special terms AEROSTATICS and AERODYNAMICS (for which the comprehensive term PNEUMATICS is often used) are sometimes employed to designate those portions of the science of mechanics in which the action of gaseous bodies is treated of. The science of mechanics owes very little to the ancient philosophers. They were acquainted with the conditions of equilibrium on the lever—discovered by Archimedes—and had reduced the theory of all the mechanical powers, except the pulley and the inclined plane and its derivatives, to that of the lever, but this was nearly all. Archimedes, starting from the principle of equilibrium on the lever, struck out the idea of a center of gravity for every body, and investigated the position of that point for the triangle, parabola, and paraboloid. Till the 16th century, the science remained stationary. Cardan, the Marquis Ubaldi, and Stevinus—the first to give the correct theory of equilibrium on the inclined plane—then gave it a slight impetus, and the labors of Galileo, who introduced the expression of mechanical propositions in mathematical formulas, discovered the laws regulating the motion of falling bodies, and originated investigations concerning the strength of materials, placed the science on a broad and substantial basis. Torricelli, Descartes, Pascal, Fermat, Roberval, and Huyghens, on the continent, and Wallis and Wren in England—the last three of whom simultaneously discovered the laws which regulate the collision of bodies—added each his quota to the *New Science*, as Mechanics was then called. In 1687, appeared Newton's *Principia*, in which the complete experimental basis of the subject was first laid down in a satisfactory manner, and the mechanical principles which had before been considered to act only at the surface of the earth, were shown to rule and direct the motions of the planets. Contemporary with Newton were Leibnitz, and the two elder Bernouillis, James and John, who, besides contributing greatly to the advancement of the science, applied to it the newly-invented differential calculus, which was found to be a weapon of immense power. From this time, a constant succession of illustrious men have prosecuted the study of theoretical mechanics, or of subjects connected with it. The chief names are Daniel Bernouilli, Euler, D'Alembert, Clairaut, Lagrange, Laplace. Lagrange's *Mécanique Analytique* not only systematised the subject, but enormously increased its power and the range of its applications. The last great additions to the science are those made by Sir W. R. Hamilton, under the name of the principle of *Varying Action*. The developments which this has received from Jacobi, Boole, Cayley, Liouville, Donkin, Bour, etc., form an extensive and difficult branch of applied mathematics, chiefly of the theory of simultaneous differential equations.

MEDAL.—A piece of metal in the form of a coin, not issued or circulated as money, but stamped with a figure or device to preserve the portrait of some eminent person, or the memory of some illustrious action or event. The study of medals, interesting in an historical and antiquarian point of view, is also important as illustrating the contemporary state of art. Like coins, medals belong to two periods, ancient and modern, separated by a wide interval. To the former belong those pieces issuing from the mint of ancient Rome, known as *Medallions*, of the size of the aureus in gold, of the denarius in silver, and of the first or large brass in copper. They are generally supposed to have been struck on occasions similar to those on which medals are coined in modern times, on the accession of an Emperor, on the achievement of an important victory, or as specimens of workmanship; but there are circumstances which countenance the belief that they were circulated as money. Medallions prior to the time of Hadrian are rare and of great value; one of the most beautiful and most famous being a gold medallion of Augustus Cæsar; from Hadrian to the close of the Empire they are comparatively common. Of the Roman medallions, some were struck by order of the Emperors, some by the Senate; the latter may be known by being inscribed with the letters S. C. The larger bronze medallions are of admirable workmanship. In some of them a ring of bronze surrounds a center of copper, and the inscription extends over both metals. No portrait of a person not princely occurs on any ancient medal, a remarkable circumstance, considering the numerous contemporary statues of poets, historians, and philosophers. The *Contorniati* are bronze medals marked with furrows *(contorni)*, distributed at the public games and apparently also in use as money, Numerous medals and medallions were struck in the Greek provinces of the Roman Empire, of less substance and thickness, for the most part, than those of Rome. The Sicilian medals are of very fine workmanship, particularly one with a head of Ceres, and on the reverse a Victory crowning a figure in a car.

Medals in the present day are conferred by the Sovereign as marks of distinction for eminent worth or noble conduct, more particularly for naval and military services. Such medals of honor are seldom of great intrinsic value, their worth depending merely on the associations connected with them. They have ribbons attached, with clasps or small bars, each of which bears the name of a particular action. The Waterloo medal is of silver, with the head of George IV (Prince Regent), a winged Victory, and the words "Waterloo," "Wellington;" it hangs from a crimson ribbon, with a narrow stripe of blue near each edge. The Crimean medal, also of silver, is attached to a blue ribbon with yellow edges when worn for service in the Crimea, and to a yellow ribbon with blue edges when for service in the Baltic. Good-service medals of silver were instituted in 1830 and 1831, and rules formed for their distribution among meritorious sailors, soldiers, and marines. The Naval medal is worn suspended from a blue, and the Military from a crimson ribbon. There are also various British medals which have been conferred for services in the Peninsula, India, etc. On every medal is engraved the name, rank, etc., regiment or ship of the recipient of it. Medals and decorations do not seem to have been ever conferred as rewards in the Army or Navy prior to the Commonwealth. The French military medal and the Sardinian War Medal were some time ago bestowed to a large extent on British officers, soldiers, seamen, and marines. The former exhibits the effigy of Napoleon III., surmounted by an eagle, and is worn from a yellow ribbon with green borders; the latter is charged with the Cross of Savoy, and suspended from a sky-blue ribbon.

MEDAILLE MILITAIRE.—A French military medal instituted by Napoleon III. It is conferred principally on privates and non-commissioned officers for gallantry in the field, and carries with it a pension of £5 a year. The *médaille militaire* is, however, also conferred on Field Marshals and Generals when they have attained to the highest rank of military honors, that of Grand-Croix of the Legion of Honor. It exhibits the effigy of the founder, surmounted by an eagle, and is attached to a yellow ribbon with a green border. It was, after the Crimean War, bestowed, to a large extent, on British soldiers.

MEDICAL BOARD.—A Board consisting of three or more officers of the Medical Department, convened by an order through the Secretary of War, for the inspection of wounded officers in order to secure them a provision for life, in accordance with the regulations regarding pensions, etc.

MEDICAL DEPARTMENT.—This Department of an army, next to the Commissariat, is the most important of all the non-combatant sections. The surgical treatment of the wounded in actual fighting, and still more the combat with disease engendered by crowding, unhealthy stations, and the reckless habits of the soldiery, necessitate a large Medical Staff; for, on an average of the whole army, it is found that the rate of sickness is at least triple that for the civil population.

In the British army every battalion, when at home or in the temperate zone, has a Surgeon and an Assistant Surgeon; when in India or the tropics, another Assistant Surgeon is added. In addition to these officers, there are numerous Staff Medical Officers at all stations, who have charge of detachments, hospitals, etc. The active list of the Medical Officers comprised, in 1879-80, 530 Surgeons-General, Deputy Surgeons General, Surgeons Major, and Surgeons. Besides these, there are between 400 and 500 Medical Officers employed with the army in India. The total estimate for medical establishments and services in 1879-80 was £266,200. The Medical Department is governed by a Director-General, who is a member of the War Office, and has charge of the surgical, medical, and sanitary arrangements of the army.

In the United States, the Surgeon General is charged, under the Secretary of War, with the administrative duties of the Medical Department. The Chief Medical Purveyor is the chief purchasing and disbursing officer of the Medical Department. He has, under the direction of the Surgeon General, the supervision of the purchase and distribution of all medical and hospital supplies. Every military post has at least one medical officer and sometimes two, as the nature of the climate or the strength of the garrison demands; all of whom are under the command of the Surgeon General.

The Medical Department is, at present, organized as follows:—One Surgeon General, with the rank of Brigadier General; one Assistant Surgeon General, with the rank of Colonel; one Chief Medical Purveyor, with the rank of Colonel; four Surgeons, with the rank of Colonel; eight Surgeons, with the rank of Lieutenant-colonel; two Assistant Medical Purveyors, with the rank of Lieutenant-colonel; fifty Surgeons, with the rank of Major; eighty-eight Assistant Surgeons, with the rank of Captain; and thirty-seven Assistant Surgeons, with the rank of First Lieutenant. There are also in the Medical Department, four Medical Storekeepers, and one hundred and fifty Hospital Stewards. Assistant Surgeons have the rank, pay, and emoluments of First Lieutenant of Cavalry for the first *five* years' service, and the rank, pay, and emoluments of the grade of Captain after *five* years' service.

MEDICAL DIRECTOR.—In the United States service, an officer who is assigned to duty at the Headquarters of a Military Geographical Division or Department, and who, under the supervision of the Surgeon General, has control of the Medical Department within the limits of the command in which he is serving. Medical Directors are assigned by order of the Secretary of War, and are required to make such special reports to the Surgeon General as shall at all times keep him fully informed as to the sanitary condition of his Department.

MEDICAL SCHOOL.—An establishment for the technical education of medical officers for the British and Indian military service. Candidates are examined competitively in the ordinary subjects of professional knowledge; and, passing satisfactorily through that ordeal, are then required to attend, for six months, at the Military Medical School, where they go through practical courses of military hygiene, military and clinical-military surgery and medicine, and pathology with morbid anatomy. As the School is attached to the Royal Victoria Hospital, which is the great invalid depot for the whole army, the students have ample opportunity of seeing theory exemplified in practice. The School comprises 4 Professors with £850 a year each, 4 Assistant Professors having £450 each, and usually about 40 medical candidates, who receive each 5 shillings a day and lodging-money. The annual cost of the whole establishment is about £7,900.

MEDICAL STAFF.—A branch of the British Army, under the control of some experienced officer, stationed at headquarters and denominated Director General. Immediately under his command are a number of Inspectors General, Deputy Inspectors General, and a Corps of Staff Surgeons. The locality of all the officers subordinate to the Director General is determined by the force to which they may be attached. All the Regimental Surgeons and Assistant Surgeons make their reports to and consult the Staff Officer who is placed in their district. The Director General is paid from the civil department of the Government. A Deputy Inspector General of Hospitals must have served five years at home, or three years abroad in this rank, before he shall be eligible to the highest rank of Inspector General.

MEDICAL STOREKEEPERS.—Medical Storekeepers are charged, under the direction of the Surgeon General and the Chief and Assistant Medical Purveyors, with the storing and safe-keeping of Medical supplies, and with the duties of receiving, issuing, and accounting for the same, according to regulations. If a Medical Storekeeper be assigned to the same depot with an Assistant Medical Purveyor, he prepares all requisitions under his direction and subject to his approval. Medical supplies transferred to Medical Storekeepers by the Chief or Assistant Medical Purveyors are receipted for as invoiced, without breaking packages, provided that the number of packages corresponds with the invoice, that they be in good shipping condition, and that there be no reason to suppose the contents broken or defective. Medical Storekeepers cause the Medical supplies issued or transferred by them to be well packed, each article designated by the name of the maker or vender, and each package legibly and correctly marked with the address of the officer for whom it may be intended, and with its weight and contents, whether medicines, hospital stores, instruments, dressings, books and stationery, bedding, clothing, or furniture and appliances. There are four Medical Storekeepers in the United States army, with the rank, pay and emoluments of a Captain of Cavalry.

MEDICAL SUPPLIES.—The Medical supplies for an army are prescribed in the Standard Supply Tables furnished by the Surgeons General, and issues are governed by it, except as to the size of packages, which may be regulated by circumstances and quantities required. When any requisition is not according to the Supply Table, the reason therefore is explained, as in the prevalence of epidemics, unhealthy location of troops, or other cause making a deviation desirable. In the United States service, Acting Assistant Medical Purveyors at field depots, and the senior Medical Officer of every hospital, regiment, post, or detached command, forward their requisitions for Medical supplies to the Medical Director under whom they may be serving. The Medical Director approves or modifies the requisition at his discretion and transmits them to the nearest purveying depot for issue. If the Assistant Medical Purveyor or officer in charge of the depot deems necessary, on account of the character of the supplies, he forwards the requisition through the Chief Medical Purveyor to the Surgeon General for instructions. If the quantity required be large, and there is time, the Medical Director transmits the requisitions, with his recommendations indorsed thereon, to the Surgeon General.

Requisitions to replenish Medical supplies are made in detail, in duplicate, and transmitted by different mails, on the 30th June and 31st December They are made only for articles that are, or probably will be, deficient. They exhibit the quantity of every article on hand, whether more be wanted or not. At remote posts, requisitions are made at such times and for such periods as may be specially authorized by the Surgeon General. Special requisitions are only permissible in cases of emergency. A duplicate of every special requisition, giving the name of the officer upon whom it is made, is immediately forwarded to the Surgeon General for his information. Requisitions for articles not on the Standard Supply Table is, in all cases, forwarded to the Surgeon General for his action. When it is necessary to obtain Medical supplies, and recourse cannot be had to a purveying depot, they may be purchased by the Medical Officer, and bills in duplicate therefor sent through the Medical Director to the Surgeon General for examination and payment. The purchasing officer shall prepare, in triplicate, an invoice of all the articles bought—one copy to be forwarded to the Surgeon General, with the bill; one, as a voucher, to accompany his next property return, on which he accounts for the articles purchased; and one to be filed with his retained set of vouchers. In all official lists of Medical supplies the nomenclature, order, and classification of the Standard Supply Table is strictly followed. The whole table is not transcribed in all instances, but the names of the articles mentioned follow the official arrangement.

I.—REGULAR LIST

MEDICINES.

Acid, acetic.
Acid, carbolic, for disinfection.
Acid, carbolic, pure, crystallized.
Acid, citric.
Acid, muriatic.
Acid, nitric.
Acid, sulphuric.
Acid, sulphuric, aromatic.
Acid, tannic.
Acid, tartaric, powdered.
Alcohol.
Aloes, powdered.
Alumina and potassa, sulphate of.
Ammonia, aromatic spirits of.
Ammonia, carbonate of.
Ammonia, muriate of.
Ammonia, solution of.
Antimony and potassa, tartrate of.
Arsenic, pills of.
Arsenite of potassa, solution of.
Belladonna, alcoholic extract of.
Bismuth, subnitrate of.
Borax, powdered.
Camphor.
Castor oil.
Cerate, blistering.
Cerate, resin.
Cerate, simple.
Chalk, prepared.
Chloral, hydrate of.
Chloroform, purified.
Cinchona, fluid extract of.
Cinnamon, oil of.
Cod liver oil.
Colchicum seed, fluid extract of.
Colocynth, compound extract of.
Copper, sulphate of.
Croton oil.
Digitalis, tincture of.
Ergot, fluid extract of.
Ether, compound spirits of.
Ether, stronger, for anæsthesia.
Ether, spirits of nitrous.
Flaxseed.
Flaxseed meal.
Ginger, fluid extract of.
Glycerine, pure.
Gum arabic, powdered.
Hyoscyamus, alcoholic extract of.
Iodine.
Ipecacuanha, powdered.
Iron, solution of the sulphate of.
Iron, sulphate of.
Iron, tincture of the chloride of.
Iron and quinia, citrate of.
Jalap, powdered.
Lavender, compound spirits of.
Lead, acetate of.
Liquorice, extract of.
Liquorice root, powdered.
Magnesia, heavy calcined.
Magnesia, sulphate of.
Mercurial ointment.
Mercury, corrosive chloride of.

Mercury with chalk.
Mercury, mild chloride of.
Mercury, ointment of the nitrate of.
Mercury, pill of.
Mercury, red oxide of.
Morphia, sulphate of.
Mustard seed, black, ground.
Nux vomica, alcoholic extract of.
Olive oil.
Opium, camphorated tincture of.
Opium, compound powder of.
Opium, deodorized tincture of.
Opium, powdered.
Opium, tincture of.
Pepper, Cayenne, ground.
Peppermint, spirits of.
Pills, camphor and opium, in bottles.
Pills, compound cathartic, in bottles.
Pills, opium, in bottles.
Podophyllum, resin of.
Potassa, caustic.
Potassa, acetate of.
Potassa, bicarbonate of.
Potassa, bitartrate of.
Potassa, chlorate of.
Potassa, nitrate of.
Potassa, permanganate of.
Potassium, bromide of.
Potassium, iodide of.
Quinia, sulphate of.
Rhubarb, powdered.
Rochelle salt.
Santonin.
Seneka, fluid extract of.
Silver, nitrate of, in crystals.
Silver, nitrate of, fused.
Soap, castile.
Soap, common.
Soda, bicarbonate of.
Soda, chlorinated solution of.
Squill, powdered.
Squill, syrup of.
Strychnia.
Sulphur, washed.
Turpentine, oil of.
Vaccine virus.
Wax, white.
Zinc, acetate of.
Zinc, oxide of.
Zinc, solution of chloride of.
Zinc, sulphate of.

II.—SUPPLEMENTARY LIST.

MEDICINES.

Acid, arsenious.
Acid, benzoic.
Acid, chromic.
Acid, gallic.
Acid phosphoric, diluted.
Acid, hydrocyanic, diluted.
Aconite root, fluid extract of.
Aconite root, tincture of.
Ammonia, phosphate of
Anise, oil of.
Arnica, fluid extract of
Arsenic and mercury, solution of iodide of.
Assafetida.
Atropia, sulphate of.
Bismuth, subcarbonate of.
Bismuth, tannate of.
Blistering, liquid.
Bromine.
Buchu, fluid extract of.
Cacao, butter of.
Calabar bean, extract of.
Cantharides, tincture of.
Cantharides, cerate of the extract of.
Catechu.
Chamomile flowers.
Cinchona bark, powdered,
Cloves, oil of.
Collodion.
Copabia.
Creosote.
Cubeb, oleo-resin of.
Gentian, fluid extract of.
Gum arabic.
Guaiac, resin of.
Indian hemp, purified extract of.
Ipecacuanha, fluid extract of.
Iron, dried sulphate of.
Iron, by hydrogen.
Iron, hypophosphate of.
Iron, syrup of the iodide of.
Iron, oxalate of.
Iron and potassa, tartrate of.
Iron, pyrophosphate of.
Mercury, green iodide of.
Mercury, yellow subsulphate of.
Morphia, acetate of.
Myrrh.
Origanum, oil of.
Potassium, cyanide of.
Sarsaparilla, fluid extract of.
Senna, confection of.
Sinapism paper.
Soda, phosphate of, exsiccated.
Soda, sulphite of, exsiccated.
Sulphur, in roll.
Tar, wood.
Taraxacum, fluid extract of.
Tolu, balsam of.
Valerian, fluid extract of.
Veratrum viride, fluid extract of.
Veratrum viride, tincture of.
Wax, yellow.
Wild-cherry bark, fluid extract of.

HOSPITAL STORES.

Arrow-root.
Barley.
Beef, extract of, Liebigs.
Brandy.
Candles.
Candles, wax.
Cinnamon,
Cocoa or chocolate.
Corn starch.
Farina.
Gelatin, shred.
Ginger.
Milk, concentrated.
Nutmegs.
Pepper, black.
Sugar, white.
Tapioca.
Tea, black.
Whiskey.
Wine.

III.—ARTICLES EXPENDABLE.

Pillow ticks.
Sheets.

The above Table is ample and sufficiently varied for ordinary practice, but in order to provide for the necessities of unusual emergencies, and to indulge, as far as practicable, individual preference and treatment, special requisitions for numerous miscellaneous articles, not on the Table.may be made to the Surgeon General at any time.

MEDICINE CHEST.—A pannier filled with a variety of medicines necessary for a campaign, together with such chirurgical instruments as are useful. These chests are usually provided by the Government, and are fitted up with a view to being transported on pack animals. Before taking the field for a long or indefinite period, Commanding Officers, or Surgeons-in-Charge, should provide a sufficient number of *Medicine Chests*, each supplied with the following articles: A case of pocket surgical instruments, consisting of, at least, a lancet, scalpel, small knife, forceps, and scissors; a few rolls of sticking and adhesive plaster; some silk, needles and waxed thread; an assortment of bandages, splints, sponges and some red flannel; some lint, oil-silk and tow; a flask of wine or brandy; a hypodermic injection syringe; a tourniquet and small cup; blue mass, quinine, opium and cathartic, put up in usual doses; a little chloroform, laudanum, hartshorn, camphor, solution of morphia, iodine, tincture of chloride of iron, chloride of lime, tincture of myrrh and aloes, tincture of arnica (excellent for strains and contusions), spirits of nitre, ammonia and turpentine; sulphates of iron, zinc and copper; pulverized indigo, carron oil, saltpeter, tartar emetic, nitrate of potash, prepared chalk, tincture of opium and catechu, cantharides (in powder), sugar of lead, acetic acid, and powdered mustard; emetics and aperients (mild and powerful); nitrate of silver, in a holder; cold cream or glycerine (cooling for irritated surfaces); a cordial for diarrhœa, a sudorific (Dover's powders excellent), and some simple cerate or a mixture of wax and lard; some alum, Jamaica ginger, castor oil, linseed oil and meal, flaxseed, and an assortment of cathartic, diuretic, sedative, febrifuge and alterative "balls"; also some astringent ointment (one part acetate of lead and three parts of lard), hoof ointment (equal parts of tar and lard), and a strong liniment. See *Field Remedies*, *Medical Supplies* and *Military Surgery*.

MEDJIDIE.—A Turkish Order, instituted in 1852, and conferred after the Crimean Campaign, to a considerable extent, on British officers. It has five classes; and the decoration, which differs in size for the different classes, is a silver sun of seven triple rays, with the device of the crescent and star alternating with the rays. On a circle of red enamel, in the center of the decoration, is the legend in Turkish, whose signification is "Zeal, Honor, and Loyalty," and the date 1268, the Mohammedan year corresponding to 1852; the Sultan's name is inscribed on a gold field within this circle. The first three classes suspend the badge around the neck from a red ribbon having green borders, and the fourth and fifth classes wear it attached to a similar ribbon on the left breast. A star, in design closely resembling the badge, is worn on the left breast by the first class, and on the right breast by the second class.

MEDIUM CAVALRY.—An appellation given to some of the regiments of the British army which are neither *heavy* nor *light*. There are 11 regiments of medium cavalry, 5 of which are Lancers (5th, 9th, 12th, 16th, and 17th), five Dragoon Guards (1st, 2d, 3d, 6th, 7th), and one (6th) Dragoons. The latter 6 regiments wear brass helmets. The average weight carried by the horses of the medium cavalry is about 18 stone 10 lbs.

MEER BUKSHY.—A Chief Paymaster in the East Indies.

MEER TOZUK.—In the East Indies, a Marshal whose business is to preserve order in a procession or line of march, and to report absentees.

MEGGHETERIARQUE.—The Commanding Officer of a body of men called *Heteriennes*, who formerly did duty at Constantinople. They were composed of soldiers who were enlisted in the Allied Nations.

MEGRIMS.—Megrims and vertigo are the terms usually applied when a horse at work reels, and then either stands for a minute dull and stupid, or falls to the ground, lying for a time partially insensible. These attacks come on suddenly, are often periodical, are most frequent during hot weather, and when the animal is drawing up a hill, or exposed during heavy work to the full rays of a hot sun. Liability to megrims constitutes unsoundness, and usually depends upon the circulation through the brain being temporarily disturbed by the presence of tumors. Horses subject to megrims are always dangerous; if driven at all, they should be used with a breastplate or pipe-collar, so as to prevent, as much as possible, pressure on the veins carrying the blood from the head. They should be moderately and carefully fed, and during hot weather have an occasional laxative.

MEIGS GUN.—An early magazine-gun carrying a great number of cartridges. Some patterns carried as many as forty or fifty rounds. This system, like many of its contemporaries, did not meet with any considerable success. See *Magazine-gun*.

MELDER SYSTEM OF FORTIFICATION.—This system very much resembles that of Freytag, but there is an absence of ravelins on the salients of bastions.

MELEE.—A military term which is used among the French to express the hurry and confusion of a battle. Melée corresponds with the English expression "Thick of the fight."

MEMBERED.—A term in Heraldry; when a bird has its legs of a different color from its body, it is said to be membered of that color.

MEMBERS.—Officers are so called who are detailed by orders to sit on General or Garrison Courts-Martial. In case supernumerary members are detailed for a court-martial, they are sworn, and it is right that they should sit and be present at all deliberations even when the court is cleared, in order to be prepared to take the place of any absent member. Until then they have no voice.

MEMOIR.—The title given by military officers to those plans which they offer to their government or commanders on subjects relating to war or Military economy. *Memoirs* is a species of history, written by persons who had some share in the transactions they relate, answering in some measure to what the Romans' call Commentarii. Cæsar's Commentaries are the Memoirs of his Campaigns.

MEMORIAL.—An address in the form of a petition to a Sovereign or other authority, able to redress the grievance of the memorialist. Memorials or petitions of the nature above adverted to may be addressed by officers to government; they must be written, not printed, and signed by the writer.

MENACE.—A hostile threat. A Court-Martial may punish, at discretion, any person who uses any menacing words, signs or gestures in its presence, or who disturbs its proceedings by any riot or disorder.

MENAGE.—All military men should have a thorough knowledge of the structure and powers of endurance of horses; should be familiar with the rules for their management under all circumstances; should understand in detail the method of shoeing them, and be able to treat all ordinary cases of injury or disease. In the field, or on the march, an ignorant or careless commander will always have many broken down and unserviceable animals, while the animals of other commands, performing the same duties, but judiciously handled, remain in good condition.

To make the horse tractable and steady in mounting. - Go up to the horse, and pat him on the neck, and speak to him; then take the reins from the horse's neck, and hold them at a few inches from the rings of the bit with the left hand; take such position as to offer as much resistance as possible to the horse, should he attempt to break away; hold the whip in the right hand, with the point down; raise the whip quietly and tap the horse on the breast; the horse naturally tries to move back to avoid the whip, follow the horse, pulling at the same time against him, and continuing the use of the whip; be careful to show no sign of anger nor any symptom of yielding. The horse, tired of trying ineffectually to avoid the whip, soon ceases to pull, and moves forward; then drop the point of the whip and make much of him. This repeated once or twice, usually proves sufficient; the horse having found how to avoid the punishment, no longer waits for the application of the whip, but anticipates it, by moving up at the slightest gesture; this is of great assistance in the bending-lessons, as also in mounting and dismounting, and accelerates the training of the horse.

To bend the horse's neck and to rein in, dismounted.—The balance of the horse's body, and his lightness in hand, depend on the proper carriage of his head and neck. A young horse usually tries to resist the bit, either by bending his neck to one side, by setting his jaw against the bit, or by carrying his nose too high or too low. The bending-lessons serve to make a horse manageable by teaching him to conform to the movements of the reins and to yield to the pressure of the bit. During the lessons the horse must never be hurried. *To bend the neck to the right* for instance, take a position on the near side of the horse, in front of his shoulder and facing toward his neck; take the off rein close up to the bit with the right hand, the near rein in the same way with the left hand, the thumbs toward each other, the little fingers outward, bring the right hand toward the body, and at the same time extend the left arm so as to turn the horse's head to the right. The force employed must be gradual, and proportioned to the resistance met with, and care must be taken not to bring the horse's nose too close to his chest. If the horse back, continue the pressure until, finding it impossible to avoid the restraint imposed by the bit, he stands still and yields to it. When the bend is complete, the horse holds his head there without any restraint, and champs the bit; then make much of him, and let him resume his natural position by degrees, without throwing his head round hurriedly. A horse, as a rule, champs the bit when he ceases to resist. The horse's neck is bent to the *left* in a similar manner, the man standing on the off side. *To rein in*, cross the reins behind the horse's jaw, taking the near rein in the right hand, and the off rein in the left, at about six inches from the rings; draw them across each other till the horse gives way to the pressure and brings his nose in. Prevent the horse from raising his head by lowering the hands. When the horse gives way to the cross-pressure of the reins, ease the hand, and make much of him.

To bend the horse's neck and to rein in, mounted.—The horse should be equipped with the curb-bridle. *To bend the neck to the right*, for instance, adjust the reins in the left hand; seize the right rein with the right hand well down; draw it quietly toward you until the horse's head is brought completely around to the right, in the same position as in the bend dismounted. When the horse champs the bit, make much of him, and allow him to resume his natural position. *To rein in*, lower the bridle-hand as much as possible, turning the back uppermost; with the right hand, nails down, take hold of the curb-reins above and close to the left hand and shorten them by degrees, drawing them through the left hand, which closes on the reins each time they are shortened. When the horse resists much, and holds his nose up, keep the reins steady; do not shorten or lengthen them; close the legs to prevent the horse from backing; after remaining perhaps a minute or more with his nose up, and his jaw set against the bit, he will yeld, bring his nose in, and champ the bit; make much of him, loosen the reins, and, after a few seconds, *rein in* again. This exercise gives the horse confidence, and teaches him to arch his neck, and bring his head in proper position whenever he feels the bit. Most young horses are afraid of the bit, and they must never be frightened by sudden jerks on the reins, lest they should afterward refuse to stand the requisite pressure of the bit. A certain amount of bearing is necessary to induce the horse to work boldly and well, as well as to apprise the rider of what the horse is going to do. In reining in, some horses rest the lower jaw against the breast: to counteract this press both legs equally and force the horse forward to the bit. Some horses will not work up to the hand, that is, will not bear on the bit at all. Such horses are unfit for the service.

To teach the horse to obey the pressure of the leg.—If it is desired to *turn to the right on the fore-feet*, for instance, apply the right leg well behind the girth, very quietly, and without touching the horse's side with the spur; press against him till he makes a step to the left with his hind-legs; then cease the pressure of the leg and make much of him; then repeat the same until the horse takes another step, and so on until he has turned about, always pausing when he takes a step in turning. The horse should not be reined back; his fore-legs remain in place, and his hind-quarters move around in a circle. Both legs are kept close to the horse, the pressure of either leg being increased as the occasion requires. *Turning to the left on the fore-feet* is executed in a similar manner.

To break the horse of bad habits.—Should the horse *rear*, the rider must yield the hand when the horse is up, and urge him vigorously forward when he is coming down; if the horse be punished while up, he may spring and fall backward. *Kicking* can be prevented by holding the horse's head well up, and closing the legs; if necessary, they are closed so much as to force the horse forward. *Shying* sometimes results from defect of sight, and sometimes from fear. If from fear, the horse must be taken up to the object with great patience and gentleness, and be allowed to touch the object with his nose. *In no case should a horse be punished for timidity.* The dread of chastisement will increase his restiveness.

To accustom horses to firing. Station a few men at a little distance from, and on both sides of, the stable-door, and cause them to fire pistols as the horses are led into the stable to be fed; for the same object, a gun may be fired during the hour of feeding.

To teach horses to jump—Horses should be first taught to leap the ditch and then the bar. They are equipped with the watering-bridle, and follow a steady horse who is accustomed to jumping. The horses are taken in the open field and practiced at jumping shallow ditches, fallen logs, very low fences, etc. Great discretion must be used in applying the whip, and the horses will not be required to leap repeatedly over the same thing or at the same place. See *Horse* and *Horsemanship*.

MEN'S HARNESS.—An arrangement by which men are attached to a gun-carriage which is to be moved but a short distance, or where animal power cannot be employed. It consists of a rope 18 feet long and 4 inches in circumference, having a thimble at one end and a thimble and hook at the other. Ten leather loops are fixed in pairs to the rope, 5 on each side. These are of sufficient size to allow a man to pass his body through them, the strain of the draft coming on the chest.

MENSURATION.—That branch of the application of arithmetic to geometry which teaches, from the actual measurement of certain lines of a figure, how to find, by calculation, the length of other lines, the area of surfaces, and the volume of solids. The determination of lines is, however, generally treated of under trigonometry, and surfaces and solids are now understood to form the sole subjects of mensuration. As the length of a line is expressed by comparing it with some well-known *unit* of length, such as a yard, a foot, an inch, and saying how many such units it contains, so the extent of a surface is expressed by saying how often it contains a corresponding superficial unit, that is, a square whose side is a yard, a foot, an inch; and the contents of solid bodies are similarly expressed in cubes or rectangular solids having their length, breadth and depth a yard, a foot, an inch. To find the length of a line (except in cases where the length may be calculated from other known lines, as in trigonometry) we have to apply the unit (in the shape of a foot-rule, a yard measure, a chain), and discover by actual trial how many units it contains. But in measuring a surface or a solid we do not require to apply an actual square board, or a cubic block, or even to divide it into such squares or blocks; we have only to measure certain of its boundary-lines or *dimensions;* and from them we can calculate or infer the contents. To illustrate how this is done, suppose that it is required to determine the area of a rectangular figure ABCD, of which the side AB is 7 inches, and the side AC 3 inches. If AC be divided at the points F and E into 3 portions, each 1 inch long, and parallels be drawn from F and E to AB or CD; and if AB be similarly divided into 7 parts, of 1 inch each, and parallels be drawn to AC or BD through the points of section, then the figure will be divided into a number of equal squares or rectangular figures, whose length and breadth are each 1 inch; and as there are 3 rows of squares, and 7 squares in each row, there must be in all 7×3, or 21 squares. In general terms, if a and b be the lengths of two adjacent sides, there are a rows of little squares, and b squares in each row. Hence the *area of a rectangle = the product of two adjacent sides.*

The areas of other figures are found from this, by the aid of certain relations or properties of those figures demonstrated by pure geometry; for instance, the area of a parallelogram is the same as the area of a rectangle having the same base and altitude, and is therefore equal to the base multiplied by the height. As a triangle is half of a parallelogram, the rule for its area can be at once deduced. Irregular quadrilaterals and polygons are measured by dividing them into triangles, the area of each of which is separately calculated. By reasoning similar to what has been employed in the case of areas, it is shown that the volume of a rectangular parallelopiped or prism is found in cubic inches by multiplying together the length, breadth, and depth in inches; and the oblique paralellopiped, prism, or cylinder, by multiplying the area of the base by the height.

MENTONIERE.—The bearer of a helmet, sometimes called *Baviere.* Also written *Mentonniere.*

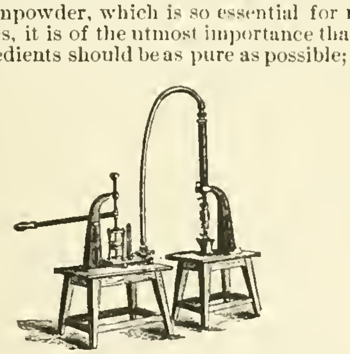
MERCENARIES.—Soldiers serving for pay in any foreign service.

MERCURY.—One of the so-called noble metals, remarkable as being the only metal that is fluid at ordinary temperatures. It is of a silvery white color, with a striking metallic luster. When pure, it runs in small spherical drops over smooth surfaces; but when not perfectly pure, the drops assume an elongated or *tailed* form, and often leave a gray stain on the surface of glass or porcelain. Moreover, the pure metal, when shaken with air, presents no change upon its surface; while, if impure, it becomes covered with a gray film. It is slightly volatile at ordinary temperatures, and at 662° it boils, and forms a colorless vapor of specific gravity 6.976. Hence it is capable of being distilled; and the fact of its being somewhat volatile at ordinary temperatures, helps to explain its pernicious effects upon those whose trades require them to come much in contact with it—as, for example, the makers of barometers, looking-glasses, etc. At a temperature of —39°, it freezes, when it contracts considerably, and becomes malleable. In consequence of the uniform rate at which it expands when heated, from considerably below 0° to above 300°, it is employed in the construction of the mercurial thermometer. All mercurial compounds are either volatilized or decomposed by heat; and when heated with carbonate of soda, they yield metallic mercury. Native or virgin quicksilver only occurs in small quantity, usually in cavities of mercurial ores. Of these ores, by far the most important is *cinnabar.* There are two means of obtaining the metal from the cinnabar: the ore may be burned in a furnace, in which case the sulphur is given off as sulphurous acid, and the mercury is collected in a condensing chamber; or the ore may be distilled with some substance capable of combining with the sulphur—as, for example, with slaked lime or iron filings. The mercury imported into this country is usually almost chemically pure. If the presence of other metals is suspected, it may be pressed through leather, re-distilled, and then digested for a few days in dilute cold nitric acid, which exerts little action on the mercury, if more oxidizable metals are present. The mercury, after being freed from the nitric acid by washing with water, is chemically pure.

There are two oxides of mercury, the black suboxide (Hg_2O) and the red oxide (HgO). Both of these lose all their oxygen when heated, and form salts with acids. The *black suboxide,* although a powerful base, is very unstable when isolated, being readily converted by gentle warmth, or even by mere exposure to light, into red oxide and the metal ($Hg_2O=HgO+Hg$). The most important of its salts is the nitrate (Hg_2O,NO_5+2Aq), from whose watery solution ammonia throws down a black precipitate known in pharmacy as *mercurius solubilis Hahnemanni*, from its discoverer, and consisting essentially of the black suboxide with some ammonia and nitric acid, which are apparently in combination. Of the *red oxide*, the most important salts are the nitrate (HgO,NO_5+8Aq); the sulphate (HgO,SO_3), which is employed in the manufacture of corrosive sublimate; and the basic sulphate ($3HgO,SO_3$) which is of a yellow color,and is known as *turpeth mineral*. Sulphur forms two compounds with mercury—viz., a sulphide (Hg_2S), a black powder of little importance and a sulphide (HgS), which occurs naturally as cinnabar. *Sulphide of mercury* is thrown down as a black precipitate by passing sulphureted hydrogen through a solution of a persalt of mercury (corrosive sublimate, for example). When dried and sublimed in vessels from which air is excluded, it assumes its ordinary red color. The well-known pigment *vermillion* is sulphide of mercury, and is sometimes obtained from pure cinnabar, but is more frequently an artificial product. Mercury unites with most metals to form amalgams, several of which are employed in the laboratory.

Of the numerous organic compounds of mercury, it is unnecessary to mention more than the fulminate and the cyanide ($HgCy$), which may be prepared by dissolving the red oxide of mercury in hydrocyanic acid, and is the best source from which to obtain cyanogen. The uses of mercury are so numerous that a very brief allusion to the most important of these must suffice. It is employed extensively in the extraction of gold and silver from their ores by the process of amalgamation. Its amalgams are largely employed in the processes of silvering and gilding, and some (as those of copper and cadmium) are employed by the dentist for stopping teeth. It is indispensable in the construction of philosophical instruments, and in the laboratory in the form of the mercurial bath, etc. It is the source of the valuable pigment vermillion. It is constantly used for percussion caps, and in taking the density of gunpowder. Spherical projectiles are floated in mercury to ascertain whether they are homogeneous.

MERCURY DENSIMETER.—In order to secure a first-class gunpowder, which is so essential for military purposes, it is of the utmost importance that the several ingredients should be as pure as possible; this

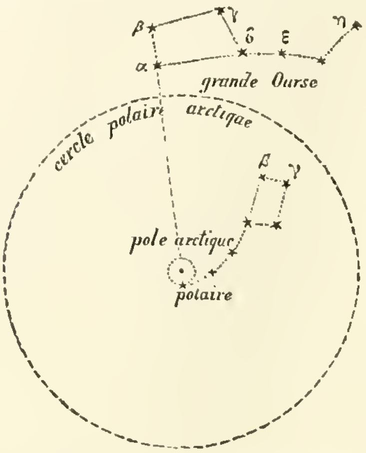


being secured,it then becomes very necessary that the density or specific gravity of the powder should at all times be as nearly as possible the same,as any variation however slight, affects its quality and force to an immense extent. To ascertain its density,therefore, is a matter of considerable importance and for this delicate operation a very ingenious instrument has been devised called a "densimeter"; it may be described as follows: On a small table a kind of barometer is fitted, but instead of the glass tube being closed at the upper end and all in one piece, as is usual, it is in this case made in two pieces and open at the top. The upper part is about 24 inches in length, and is connected to the lower, which is 10 inches in length, by means of a closely fitting and perfectly air-tight screwed metal joint; the lower part, instead of being a plain parallel tube of the same diameter throughout as the upper, is made in the form of a globe or bulb, and on the neck at each end of it a metal union and stop-cock are secured, both of which are made perfectly air-tight. By means of one of these unions this glass globe or lower half of the instrument is attached to the upper, while the other union, into which is screwed an open nozzle or metal tube, dips into a cup fastened to the table filled with mercury. On another table standing by the side of the first one an ordinary air-pump is fixed, with vacuum gauge, etc. It will readily be seen that if the upper part of the glass tube of the densimeter be connected with the air-pump, and the air be extracted from the glass tube whilst the lower tap is closed, a vacuum will be formed, and that upon opening the lower tap so as to afford a free passage for the mercury in the cup, it will rise and fill the glass globe and upper portion of the tube to such a height as will balance the pressure of the atmosphere, thus giving a column of mercury of precisely the same total height as that in an ordinary barometer.

To use the instrument, two tables are placed side by side, the open upper end of the glass tube of the densimeter is connected with the air-pump by means of a flexible tube, the tap on the upper union of the densimeter is opened, the lower one is closed. The air-pump is worked; as soon as all the air is exhausted, shown by a vacuum gauge attached to the air-pump, the lower tap on the glass tube immediately below the globe is opened, and the mercury rushes into the tube; when it ceases to rise, the two metal taps are closed, and the globe part,with the mercury contained therein,is removed and carefully weighed. All the mercury is now emptied back again into the cup,and the globe, nearly filled with a known weight of gunpowder, say 100 grammes, is then reconnected to the densimeter under the same conditions as before, and the air again exhausted until a vacuum is formed. The lower tap is now opened, and the mercury allowed to find its way in and rise in the tube; the mercury rises to precisely the same height in the tube as before; but the globe having been nearly filled with gunpowder will contain less mercury. The taps on the lower portion of the instrument are closed, the globe part removed and again weighed. This weight, as well as that previously ascertained when the globe was entirely filled with mercury,is recorded, and from these two ascertained weights the density of the powder can readily be obtained by the following rule: *To find the density of the gunpowder, we have only to multiply the specific gravity of the mercury by the weight of the gunpowder placed in the globe of the densimeter, and divide by the difference in weight of the globe when filled with mercury only and when filled with gunpowder and mercury, plus the weight of the powder placed in the globe*; the result will show the density of the gunpowder under test. See *Densimeter, Dupont de Nemour's Densimeter, Inspection of Powder*, and *Mercury Densimeter.*

MERIDIAN.—The name given to the great circle of the celestial sphere which passes through both poles of the heavens, and also through the zenith and nadir of any place on the earth's surface. Every place on the earth's surface has consequently its own meridian. The meridian is divided by the polar axis into two equal portions, which stretch from pole to pole, one on each side of the earth. It is midday at any place on the earth's surface, when the centre of the sun comes upon the meridian of that place; at the same instant it is midday at all places under the same half of that meridian, and midnight at all places under the opposite half. All places under the same meridian have, therefore, the same longitude. Stars attain their greatest altitude when they come upon the meridian; the same thing is true approximately of the sun and planets; and, as at this point the effect of refraction upon these bodies is at a minimum, and their apparent motion is also more uniform, astronomers prefer to make their observations when the body is on the meridian. The instruments used for this purpose are called *meridian circles*.

The meridian may be determined at night by passing a plane through a plumb-line and the north star. The trace of this plane on a horizontal plane will be the projection of the meridian sought, the north star



being only $\frac{1}{12}°$ from the true pole. It is easy to recognize the north star—it is the seventh star of the little bear and is found precisely in the prolongation of the two first stars of the great bear (*grande ourse*), a constellation disposed in symmetrical order as in the drawing.

To practically determine the variation of the compass, erect a pole, and at a distance of 200 yards set up another, so that the two are in a line with the true north; the variation of the compass may be ascertained the next morning by taking the bearing of one pole from the other.

MERIDIAN MEASUREMENT.—The determination of the form and size of the earth from the measurement of an arc of a meridian has been a favorite problem with mathematicians from the earliest times, but up to the middle of last century their operations were not carried on with exactness sufficient to render their conclusions of much value. Since that time, however, geodesy has so rapidly progressed, owing to the invention of more accurate instruments and the discovery of new methods, that the measurement of the meridian can now be performed with the utmost accuracy imaginable. The *modus operandi* is as follows: Two stations, having nearly the same longitude, are chosen; their latitude and longitude are accurately determined (the error of a second in latitude introduces a considerable error into the result), and the direction of the meridian to be measured ascertained; then a base line is measured with the greatest accuracy, as an error here generally becomes increased at every subsequent step; and then, by the method known as triangulation, the length of the arc of the meridian contained between the parallels of latitude of the two stations is ascertained. As the previously found latitudes of its two extremities give the number of degrees it contains, the average length of a degree of this arc can be at once determined; and also—on the supposition that the length of a degree is uniform—the length of the whole meridional circumference of the earth. This operation of meridian measurement has been performed at different times on a great many arcs lying between 68° north latitude and 38° south latitude., and the results show a steady though irregular increase in the length of the degree of latitude as the latitude increases. On the supposition that this law of increase holds good to the poles, the length of every tenth degree of latitude in English feet is as in the following table:

Degree of Latitude.	Length of Degree in English feet.	Degree of Latitude.	Length of Degree in English feet.
0°	362,732	50°	364,862
10°	362,843	60°	365,454
20°	363,158	70°	365,937
30°	363,641	80°	366,252
40°	364,233	90°	366,361

This result shows that the earth is not spherical, as in that case the length of all degrees of latitude would be alike, but of a more or less spheroidal form—that is having its curvature becoming less and less as we go from the extremity of its greater or equatorial diameter to the lesser or polar axis. It was by the measurement of a meridional arc that, in 1792–99, the length of a quadrant of the earth's circumference was determined, in order to form the basis of the French metrical system. See *Metrical Measures*.

MERIT ROLLS.—Rolls prepared by the Academic Board, at each examination, in which the merit of each Cadet (at the United States Military Academy) in each branch of study upon which he has been examined, is denoted by a number proportional to his proficiency and to the importance of the subject; and in which the names of the Cadets are arranged, in their respective classes, in the order of aggregate merit, as determined for each, by the addition of the numbers expressing his merit in each particular branch, and in discipline. The table on page 315 shows the manner of forming the general *Merit Roll*.

MERKIN.—A mop used for cleaning cannon. Also written *Malkin*.

MERLON—In fortification, the position of the parapet between two embrasures. Its length is usually from fifteen to eighteen feet. The term is also applied to the projection on the top of a crenellated wall.

MERRILL BAYONET HANDLE—The essential feature of this device is a slide in the side of the handle, which being withdrawn, allows the bayonet-stud to pass aside into the square notch prepared for it at the farther extremity of its L-shaped groove. It is securely kept there by pushing back the slide into its former position. In a modification of this invention, the bayonet is held on the gun by the engaging of the bayonet-stud with a corresponding notch in the spring-catch swinging in a slot in the end of the handle. By pressing down the outer end of the spring-catch the shoulder on its forward extremity is passed above the bayonet-stud, and the bayonet is still further secured on the gun by the muzzle passing through a corresponding hole formed in the guard.

MERRILL GUN.—A breech-loading rifle having a fixed chamber closed by a movable breech-block, which slides in the line of the barrel by direct action. It is opened by raising the handle of the breech-bolt to a vertical position and drawing it back to its full extent. In raising the handle, the firing-pin is retracted by a lug near its head engaging with a spiral cam-recess in the receiver; it is held back by the lug entering a circumferential groove in the bolt. In withdrawing the bolt, it passes over the hammer and presses it back to the full-cock. The piece is closed by reversing the movement of the bolt. At the end of the forward stroke, the point of the extractor engages with a recess in a ring which sur-

See *United States Military Academy.*

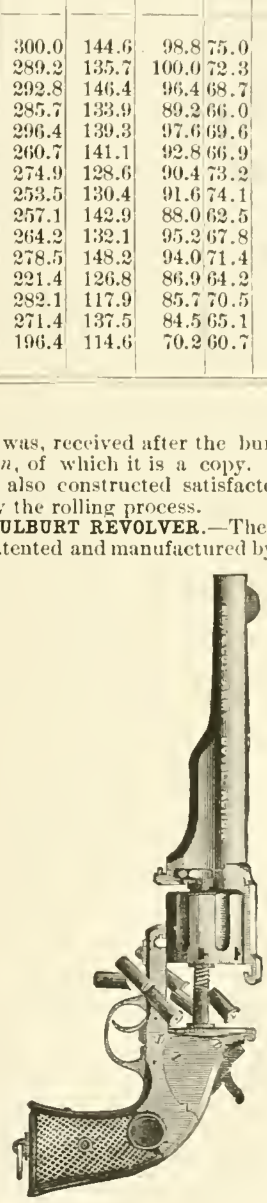
rounds the mouth of the chamber, and against which the bolt is pressed, and turns the ring with it; so that the rotation of the bolt in locking will not cause it to grind against the head of the cartridge. In turning down the handle, the piece is locked by the engaging of a sectional collar on the bolt with a corresponding groove in the receiver. When this is accomplished, the lug on the firing-pin is opposite the deepest part of the spiral recess and is free to move forward when the piece is fired (by means of a center-lock moved by a double mainspring.) Extraction is accomplished by a spring-hook lying on top of the breech-bolt; and in drawing back the bolt, the natural spring of the extractor presses down the rim of the cartridge upon the bottom of the receiver, until it is checked by striking against a notch left there for that purpose, and is thereby thrown upward around the hook of the extractor and clear of the gun.

MERRILL LOCK.—A lock intended to dispense with the tumbler and adjacent parts, and to be hermetically imbedded in the stock. In a modification of the lock the motion of the mainspring is arrested by a stop-pin after the hammer, in falling, has passed the half-cock notch. When applied to the Springfield system the act of raising the firing-pin guard in turning the cam-latch to open the block would be sufficient to easily overcome the friction and weight of the hammer and to bring it to the half-cock. In this lock there is no swivel, the mainspring pressing directly on the hammer.

MERRILL MAGAZINE.—In this device, the comb of the butt-stock is cut out in a groove deep enough to receive one cartridge, on end, and long enough to accomodate four or five of them side by side. A movable back for this groove is formed by a follower-block, which is pressed forward by a spiral-spring, carrying the cartridges ahead of it to the mouth of the magazine, from which they are to be picked out one by one. The magazine has a sliding cover by which, in traveling, the cartridges are to be kept from falling out.

MERSEY GUN.—The 12-inch wrought-iron gun, in the Brooklyn Navy Yard, was forged like the *Horsfall Gun*, by the Mersey Iron Works, in 1845. Its dimensions are: total length, 169 inches; diameter over the chamber, 28 inches; length of bore, 144 inches; diameter of bore, 12 inches; weight, 16,700 pounds. It was received after the bursting of the *Stockton Gun*, of which it is a copy. The Mersey Works have also constructed satisfactory wrought-iron guns by the rolling process.

MERWIN HULBURT REVOLVER.—The new Army Revolver, patented and manufactured by the Messrs.



Merwin, Hulbert and Company, is rapidly becoming a favorite with the military organizations throughout the United States. The details of its construction may be readily understood by a reference to the illustration which we present herewith. This revolver makes the following claims for superiority :—Compactness, symmetrical, easy outline, and general neat appearance; no salient points to prevent its ready and easy insertion into or withdrawal from the holster. In handling, not liable to injure the hand; all the projecting parts being rounded and smooth; cleaning being thereby facilitated. The circular form of cylinder front gives a continuous cover to breech of barrel; prevents sand or dirt entering therein. Accidental unlocking of the parts prevented, as hammer must first be set at half-cock. The front sight forged solid with the barrel; not liable to be separated therefrom or injured. The extractor ring prevents the interior of the lock and ratchet from fouling by escape of gas about the primer when using outside primed ammunition. The hood and collar at front of cylinder covering base-pin and base-pin hole prevents fouling. The flanged recoil plate here covers and protects the heads of the cartridges; prevents sand or dirt entering between face of recoil plate and cylinder, which might clog it and prevent rotation. The cylinder and barrel can be dismounted from the frame and re-assembled thereto without the use of screw-driver or any tool. The construction is not intricate nor fragile, and the extractor is a solid part of the base pin. Strength, durability and endurance. Simultaneous, positive, and easy extraction of shells; great power obtained for starting the shells before final extraction by the incline screw action on the base-pin. Less lateral escape gas is deflected downward into the works, as no top strap is used. The face of the collar on cylinder takes against the bracket, prevents forward movement of cylinder when pressed by the ball in rotating; gives a central bearing; prevents abrasion of cylinder face against rear of barrel; gives easy rotation; permits a close joint without friction, reducing the escape of gas; the cylinder is not forced backward on firing, but is held forward by the hood-clutch taking into the recess of the cylinder collars. The lines of recoil and resistance are close together, lessening upward inclination of barrel when fired.

The following are the directions for manipulating the arm:

To load—Place the hammer at half-cock, press the gate downward and insert the cartridges.

To eject the shells—Push back the thumb-bolt under the frame, turn the barrel outward, and draw forward, when the shells will fall out.

To take the arm apart—When the barrel and cylinder are drawn forward, press the small pin in the barrel-catch even with the frame, *then* press the catch down and draw forward.

Complimentary letters have been received as regards these arms from all parts of the world. Col. George T. Denison, author of the Russian Imperial Report on Arms and Cavalry Tactics, for which he received the government reward of five thousand dollars and gold medals, as well as medals from other governments, says: "This army revolver is, in my opinion, the most perfect cavalry pistol in the world."

MESAIL.—That portion of a helmet which closes on the open front, more generally known in England as the *Ventaill.* Also written *Mezail.*

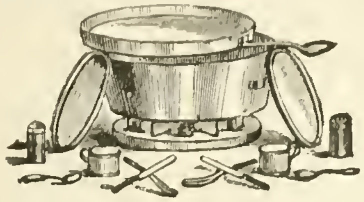
MESNE PROCESS.—Any writ issued in the course of a suit between the original process and execution. By this term is also meant the writ of proceedings in an action to summon or bring the Defendant into court, or compel him to appear or put in bail, and then to hear and answer the plaintiff's claim.

MESS.—A term at present used in the sense of a number or association of officers or of men taking their meals together. In societies consisting entirely of the male sex, and of one set of men continually thrown together, it is a very important social point that the Mess should be well regulated. There are consequently stringent rules—both of the service and of mutual etiquette—laid down for its government. One officer acts as caterer, receives subscriptions from the several members, charges the wine to those who drink it, etc.; a steward has charge of the more menial department, arranging for the cooking, purchase of viands, servants, rations, etc. In the British army, the Mess is a regimental institution for the maintenance of a common table for all the officers in a regiment, who are bound to subscribe an annual subscription, whether present or absent. Married men pay one half if they do not regularly attend the mess, but they pay all contributions to the mess fund. The introduction of messes into the British Army has been attended with the happiest results. Officers of all ranks meet together on an equal social footing, and the youngest officer in the regiment is able to enjoy the society of his senior and brother officers without reserve. The advantages of a mess are manifold, and are seen not only in its social value, but also in the means it offers to all ranks of living well and comfortably. A small government allowance is granted in aid of the expenses of the officer's mess. Messes are extended also to the non-commissioned officers and men of a regiment, who have their several messes under the superintendence of the officer commanding the regiment and the captains of companies. In France, the several grades mess separately; lieutenants and sub-lieutenants forming two tables; captains another, and field officers of different grades generally eating separately also.

MESSAGES. — Communications passing between officials whether in peace or war time. In the former, messages are generally sent by dismounted orderlies, except the communication is urgent, when it is sent by a mounted orderly. In the latter, mounted orderlies are sent between the general and his staff, on subjects relating to the army and requiring expedition. Important messages forwarded to a distance, and where the bearers may fall into the enemy's hands, should be sent in duplicate, one real, the other false; the former to be concealed in a quill about his person, in such a way as is not likely to be discovered, and which way will in peril suggest itself; the latter in the form of a letter. One orderly is not considered safe; one or two more should be sent at certain intervals of time, say two or three hours between each. Emissaries sent from besieged cities with messages to relieving forces or to friends should use great wariness to avoid falling into the hands of the enemy; but if they do, they should be able to conceal the message, which in all probability would be in cipher and in only a few words, about their person. The modes resorted to in warfare, to avoid written communications being seized, are numerous. During the siege of Metz, Marshal Bazaine, desirous of communicating with the government at Tours, sent two emissaries disguised as peasants, who both managed to pass through the German lines; one carried his despatch in cipher inside a hollow tooth, and the other had his message woven in one of his socks. Carrier pigeons very often play an important part in the transmission of messages during hostilities, as they did during the siege of Paris in 1870-71.

MESSENGERS.—Officers employed by Secretaries of State to convey dispatches at home and abroad. In former days their occupation consisted, to a considerable extent, in serving the Secretaries' warrants for the apprehension of persons accused of high treason and other grave offenses against the State, nor was it unusual for them to keep the prisoners whom they apprehended at their own houses. They are now principally employed in foreign service.

MESS-KIT.—That portion of camp equipage consisting of cooking utensils. The cooking implements and table necessaries should be so selected as to nest compactly. The camp kettles may enclose the dishpans, and these the skillets and smaller articles. It is best with a view to packing to have the skillets, fryingpans, etc., so constructed that a spoon



may be applied as a handle, and removed when not in use or when packed. The drawing shows the idea.

MESTRE DE CAMP GENERAL.—The next officer in rank, in the old French cavalry service, to the Colonel-General. This appointment was created under Henry II. in 1552. *Mestre de Camp Général des Dragoons*, was an appointment which first took place under Louis XIV., in 1684.

METAL.—1. A term in Heraldry. The field of the escutcheon and the charges which it bears may be of metal as well as of color; and the two metals in use among heralds are gold and silver, known as or and argent. It is a rule of blazon that metal should not be placed on metal, or color on color. 2. Broken stone, etc., used as a road cover.

METAL CASTING.—The art of obtaining casts of any desired object by means of pouring melted metal into molds prepared for the purpose. It has risen to great importance in recent times, on account of the many new applications of iron. Iron-founding, brass-founding, type-founding, as well as casting in bronze and zinc. are the principal divisions of the art. The casting of the finer metal and alloys, as gold, silver, and German silver, is necessarily conducted on a smaller scale. When the casting of an object is required, it is necessary, in the first place, to make a pattern. Suppose it to be a plain round iron pillar, such as is used for hanging a gate upon. A pattern of this is turned in some wood which can be readily made smooth on the surface, such as pine, and then varnished or painted so as to come freely out of the mold. This wooden pillar, or any similar pattern, is always made in at least two pieces, the division being lengthwise, for a reason which we shall presently see. The next step is to prepare the mold. The molds used by the iron-founder are either of sand or loam, but more generally of fine sand. Proceeding with the preparation of the mold, the founder takes a molding-box, which is composed of two open iron frames with cross bars, the one fitting exactly on the other, by means of pins in the upper dropping into holes in the lower frame. One half of the box is first filled with damp sand, and the pattern laid upon it a little dry *parting sand* being sprinkled on the surface. The upper half of the box is then put on and sand firmly rammed all around the pattern. The box is then carefully opened, and when the pattern is removed, its impression is left in the sand. The mold at this stage, however, is generally rough and broken. It is necessary, therefore, to give it a better finish, which is done by taking each half of the mold separately, repairing it with a small trowel, and reintroducing the corresponding half of the pattern till the impression is firm and perfect. Finally, the surface of the mold is coated with charcoal-dust, which gives a smooth surface to the future casting. These columns being made hollow, there is yet another matter to arrange before the casting can be made—namely, the *core*. In the instance before us, it would simply be a rod of iron, covered with straw and loam to whatever thickness the internal diameter of the column happened to require. The core of course occupies the center of the mold.

The cast iron is melted with coke in a round fire-brick furnace, called a *cupola*, the heat being urged by means of a powerful blast, created by fanners revolving at high speed. The molten metal is run from a tap at the bottom of the furnace into a malleable iron ladle, lined with clay, from which it is poured into the mold through holes called *runners* or *gates*. When the mold is newly filled, numerous jets of blue flame issue from as many small holes pierced in the sand. These perforations are necessary for the escape of air and other gases produced by the action of the hot metal on the mold. Care must also be taken not to have the mold too damp, otherwise steam is generated, which may cause holes in the casting, and even force part of the metal out of the mold. The casting remains covered up for a time, in order to cool slowly, and is then removed by breaking away the sand, and drawing out the core. In the case of a fluted or otherwise ornamented pillar, the pattern would require to be in at least four pieces instead of two, because it is only a plain pattern that will come out of the mold in halves without tearing away the sand. When a pattern is necessarily made in several pieces, it is drawn out of the mold bit by bit, to the right or left, as the case may be, and so parts from the sand without breaking it. Suppose that a small ornamental vase was to surmount the pillar, the founder would prepare the pattern of this in a more elaborate manner. He would first mold it in wax or clay, from which a cast in plaster of Paris is made; from that, again, a cast is taken in an alloy of tin and lead, which, after being sharply chased, and divided into the required number of pieces, is used as a pattern to cast from. All ornamental patterns, such as figures, scrolls, leaves, enriched moldings, and the like, are made in this way, whatever metal the ultimate casting is to be produced in. Very large engine cylinders, pans, and such vessels, are cast in loam-molds, which are built of brick, plastered with loam, then coated with coal-dust, and finally dried by means of a fire. This method is adopted with large plain objects, where a pattern would be expensive, and when very few castings of one kind are required. Iron molds, coated with black lead or plumbago, have recently been introduced for casting pipes into; they are greatly more expensive than any other kind, but they enable a founder to dispense with a pattern, as, when once made into the required form, they are not destroyed like molds of sand or loam at each casting. Bronze and brass are cast in molds prepared with finer sand than that used for iron. Pewter and similar soft metallic alloys are cast in brass molds. The type-founder, on the other hand, uses molds of steel, which are now worked to a great extent by a machine. The variety of articles produced by casting are very numerous, among others we may mention cylinders, cisterns, paper-engines, beams, boilers, pumps, and the heavy parts of machinery generally, gates, railings, lamps, grates, fenders, cooking-vessels, and the like, in iron; cannon, many portions of machinery, and numerous ornamental objects, in brass; sculpture and other works of art in bronze and the more costly metals. One of the most remarkable castings yet executed for the requirements of modern engineering, was the cylinder of the hydraulic press used for raising the tubes of the Britannia bridge. It measured 9 ft. x 3 ft. 6 in., the metal being 10 in. thick, and weighed upwards of 20 tons. It remained red hot for three days, and it was seven days more before men could approach it to remove the sand. Sole plates of steam-hammers, and for other purposes, have been cast more than double this weight, but the same care was not required in their execution. In regard to sculpture, perhaps, the most wonderful casting known is the colossal statute of Bavaria at Munich, finished in 1850, which stands 54 ft. high, the face being equal to the height of a man. It took eight years to cast, and the cost of the bronze used was about £10,000. See *Foundry*.

METALLIC AMMUNITION FOR SMALL-ARMS.—For the manufacture of metallic ammunition for small-arms and friction and electric primers for cannon on a large scale, the following buildings are required: No. 1. *Fire-proof factory* with L; basement being provided with machinery adapted to the manufacture of primers, etc., with a separate room containing grindstones, emery-wheels, etc., and tumbling barrels. The first story being fitted up with all the machines, tools, and benches of a first-class machine-shop, for manufacture and repair of the machines and tools employed in the works, with necessary office and engine rooms, and well furnished with presses and cabinets for surplus tools, standard gauges, specimens, etc. A room in L, with all appliances for washing cases, and a large and conveniently arranged drying-room over the engine boiler. The second story contains all the machinery necessary for drawing, trimming, heading, and forming cartridge-cases, with a separate room in L provided with machines and tables for making paper packing boxes; printing-presses, type-fonts, etc., for printing. No. 2. *Fire-proof factory* for manufacture of bullets, with separate rooms for charging cases and inspecting and packing finished ammunition. No. 3 *Blacksmiths' shop* and stacks for forgings and small castings, and annealing furnaces for tools, etc., with a separate room for annealing and pickling cases. No. 4. *Carpenter-shop*, for making boxes, tools, implements, etc.

No. 5. *Paint-shop*. No. 6. *Retort-house*, for manufacture of fulminate of mercury. No. 7. *Magazine*, for powder. No. 8. *Small Magazine*, for fulminate of mercury and friction-powder. No. 9. *Storehouse*, for storing cartridges, primers, etc.

The modern center-fire metallic cartridges may be divided into three classes: the solid attached head, the solid head, and the folded head. There are two varieties of folded-head cartridges the reinforced and non-reinforced. As regards priming, the above-named classes are divided into outside and inside primed cartridges, and may be designated respectively as re-loading and non-reloading cartridges. They are generally made from sheet-copper or brass, the latter material having more elasticity, and the former more uniformity and durability.

Manufacture—Sheet metal of the required thickness, from .025″ to .09″, is used for the various kinds of cartridges. This is fed to a double-acting die and punch, which cuts out a disk and forms it into a cylindrical cup at one operation. The cup is reduced to a cylinder of the required length in from four to six operations by dies and punches, and is called drawing or reducing. The cylindrical shell is trimmed to a standard length in a machine called the case-trimmer. After washing, the shells or cases have a flange formed at the closed end by pressure in a special machine called the header. The headed case is tapered to a standard size. The open end is made cylindrical for the length the bullet enters it, so as to inclose the latter snugly; and if it be inside-primed, like the present service cup-anvil cartridge, the anvil is inserted and fastened at the same time by crimping the case around its edge.

Priming is done in a machine called the primer. For outside priming a percussion-cap is used, made in the ordinary way. Priming of fulminate of mercury should not under any circumstances, be deposited on brass, as it forms an amalgam, and rapidly deteriorates the metal and priming. Shellac varnish is used to protect the surface of brass. No injurious deterioration from this cause has been noticed in the use of copper. *Bullets* are made in a bullet-machine from a cast slug or rolled bar; the last is considered the best; they are trimmed by a machine called the bullet-trimmer. The diameter is required to be up to standard with no minimum allowance, and they are sized at the lubricating machine by passing through a die. The form, width, and depth of grooves must conform to the standard with very little variation. The weights should not vary more than two grains from the standard of 405 grains. The lubricant should be free from acid reaction, and of vegetable origin as bayberry or Japan wax, and filled into the grooves by a machine. Loading, or assembling the case, powder, and bullet, is done in a machine called the loader, by one operation (as in the Frankford arsenal loader), or by several operations known as plate-charging. The bullet should be perfectly concentric with the case at the time of insertion. The charge of powder should be as uniform as possible, with not more than two grains variation from the standard weight of 70 grains. All cartridges should be wiped clean and gauged as to diameter, length, and diameter and thickness of head. Those should be rejected showing any defects in material, or bad workmanship. Each cartridge should be weighed to detect loss of parts or deficiency in weight of powder. A special automatic weighing machine is used at Frankford arsenal.

That the present degree of perfection in the manufacture of these several classes of metal cartridges has been the result of gradual and careful develop-

 METALLIC AMMUNITION FOR SMALL-ARMS.

ment, is evident from a cursory examination and comparison of the earlier, intermediate, and more recent best forms.

Among the first of metal cartridges of American invention is the Morse, which was brought out a short time before the war of the rebellion, but not thoroughly experimented with at the time or introduced into service. Its objectionable features are apparent in the light of progress made. Its merits over paper or similar ammunition are apparent, the chief, perhaps, being that it was designed as a self-primed cartridge, had a flanged-head for extracting the case, and that it reduced the operations of loading.

About the same time the Burnside, Maynard, and a few others, were produced, some of which were good in their day, and for the arms for which they were designed, but were fired by means of a cap, through a vent, at some distance from the cartridge, and were extracted by the fingers. With them there was not that necessary nicety of fit to the chamber of the gun, the joint was not absolutely closed, and the failures to explode were as frequent as with the old-fashioned paper cartridge and percussion-cap. Such failures would, now-a-days, be considered a most unwarranted percentage in any metallic ammunition laying claim to excellence, and, in the best known varieties, do not occur to the extent of one in one thousand rounds; in fact, many attain a much higher standard of surety than indicated by this figure. The records of the testing-rounds show long-continued firing and consumption of thousands of rounds without failure at all from any cause, and the summation of a year's practice and test, in proof of manufacture, exhibits but an exceedingly small percentage of such failures.

For some time the idea of combining the primer and cartridge did not assert itself, but some inventions were pushed in this direction, and the rim-primed cartridge was produced. In this the fulminate composition was placed in the folded head of the case. This mode of priming requires a large charge of the priming composition, which, being thrown into the fold by swiveling, the entire circumference of the head was not always primed thoroughly, and as the cartridge is exploded by striking the rim at a part of the head under the hammer, it not infrequently happened that it failed from the point struck not having any priming. The large charge required, also (about 5 grains against ½ grain for the center-fire), was a further objection to rim-priming; the exploding of so large a quantity of quick-powder in the folded head, the weak part of the cartridge, tending to strain and open the fold to bursting, as it frequently did. Another objection to rim primed cartridges is that they are more liable to accident in handling, and in shock of transportation, and in those incident to service; in fact, a number of instances of explosion in the magazine of repeating-arms, and in patent cartridge-boxes for service of such, have been reported, by which serious injury resulted to the soldier.

Hence, efforts to produce a still more reliable and satisfactory cartridge, and the development, production, and general adoption for service of what is now so well known as *center-primed metallic ammunition*, its advantages being sure explosion when struck by the point of the firing-pin; less of fulminate and less strain on the head of the cartridge; greater security in handling and using under all exigencies of service. These cartridges have been subjected to the severest tests to demonstrate their capability to resist all accidents, such as mashing up boxes of ammunition, and even firing into them with bullets. Only the cartridges actually impinged upon exploded under such tests, their neighbors being only blackened and not otherwise damaged. The safety of handling and transporting this ammunition in comparison with that of the old-fashioned kind is vastly in its favor, and the risk attending its carriage is almost nothing. Its greatly superior quality to resist exposure of climate, moisture, etc., has also been proven by such exceedingly severe tests that it may be asserted to be practically water-proof. A central and direct blow on the point primed is an essential and highly important feature of the center-primed cartridge; its general adoption, and adaptation of all breech-loading service small-arms to its use, is the best proof of its acknowledged superiority. Simple modifications of the form of the head adapt it to safe use in magazine arms, even though the front of one bullet rests on the head of the preceding cartridge, while with all varieties of repriming ammunition the central fire is a *sine qua non*. Other reasons in its favor might be given, but it is believed sufficient have already been adduced to warrant the statement that whatever may be claimed as the particular merit of any one variety of metalic ammunition, by ardent inventors and admirers of special forms, all are agreed that, for military purposes at least, the palm to center-priming must be yielded. The service-cartridge, made of a copper case with a folded-head and copper fulminate primed cup anvil, crimped in position, has been so long used and tested on the experimental ground and in the field, and by various boards of experts on small-arms, and its excellence in all these fields of trial so well demonstrated, that no particular description of its construction and performance is here necessary. Some of the varying modifications of the folded-flange cartridge are noted in the drawings. It is of rare occurrence that the fold is sometimes slightly opened or burst in firing, probably from a defect or thinness of the metal, but this is not attended with the least inconvenience or risk to the person or arm, and, in most cases, would escape notice altogether outside the carefully scrutinized cases at the experimental and testing grounds.

So far this has not been deemed of any consequence in the service, and none of the best model breech-loading arms take the least notice of it. If necessary, however, the folded-head cartridge is abundantly susceptible of improvement, in an easy and practicable manner, as is evident from an examination of the various forms of re-enforcement of cartridges of this construction, experimentally tested and herein described.

The Berdan, made in large numbers for the Russian government, for use in the Berdan breech-loading rifle, has been most strictly and severly tested during manufacture, and has proved of great excellence. It is exceedingly ingenious; its re-enforcement simple and effective; its capacity as a reloader fully tested and demonstrated by prolonged and repeated trial, daily, during production of millions of rounds; a number of the shells being reloaded, primed, and fired ten times, and much more extended trials have been had for special test of the endurance of the cases in this particular. Its chief distinguishing feature is that its anvil is of the same continuous piece of metal as that of which the case is made. Herein there is no possible displacement or misplacement of the anvil, and it has a fixed position with respect to the primer. The cartridge is singular in this respect, and superior to its rivals that require a separate anvil. In it was a happy idea hit upon by the inventor of making his anvil by a simple return of the metal of the pocket for the primer. All other anvils are its inferiors in that they have to be handled in assembling the parts of the shell. Another advantage is, it presents a point to the primer inside, rendering it sensitive to the blow of the hammer. The use of the special Hobbs' primer is most excellent in this combination. Other varieties of an excellent re-enforcement may be referred to, as exhibited in the drawings and notes under this class.

These re-enforcements may be accomplished in various ways, as by a ring of expanding metal, a ring of solder, felt or *papier-maché* wads, etc. When the ring of this metal is used as a re-enforcement it is best applied, and perhaps only effectually, in those cartridges having a pocket or return of the head for the priming. In these cases it should be so formed as to act by expansion against the walls of the case and of the pocket, to cut off the escape of gas to the folded head in both directions. The solder ring has been found to be a good re-enforce also, and in the wrapped-metal and some other varities of cartridges it serves also to attach the flanged-head to the body of the case. It was first used here for this purpose, and that it acted also as a re-enforce was a resulting discovery. The felt or *papier-maché* wad is not believed to be as good or to hold the head as securely, although it is extensively used in the various forms of Boxer ammunition. It is not believed that a simple ring of any soft metal of any shape, as lead or its alloys, forced into the case at the head, will act as a re-enforce, as has been claimed. No matter how closely the metallic surfaces are in contact, if the re-enforcement does not expand more promptly and as fully as the case itself under all the pressure of the gas, it does not strengthen or re-enforce the point to which it is applied. A re-enforcing ring works well, applied to a Martin cartridge, as well, in fact, as to a Berdan, and in the same manner. An objection to the Martin is its small anvil for small-headed cartridges, and their liability to burn the priming composition inclosing the pocket on the anvil, a difficulty met with in their manufacture, with the bar-anvil, and which can only be wholly eliminated by careful inspection of primed cases.

A very notable cartridge is the Boxer, as made at the Royal Arsenal, Woolwich, for the Snider and Martini-Henry rifles. A perusal of the English reports of their small-arm ordnance board will show the most casual reader that the failures of these cartridges, from all causes, have been what would be considered in our trials of the best American cartridges as a very large percentage, sufficient to warrant the abandonment of a cartridge that failed so often. Unlike its American prototype, from which it was originally taken, its parts are more numerous, and the steps of operations in its production more than double those in that simple cartridge. Its cost, hence, is also large, considering the low prices of labor and materials, and the very large numbers fabricated in the country of its adoption; a cost very much in excess, it is believed, of that of any other of the most approved American varieties of metal cartridges fabricated under similar advantages of cheap labor, low-priced materials, and large production. It does not appear to be well adapted to stand the shocks of transportatin or exigencies of service, is easily indented and disfigured, so much so as seriously to interfere, with ease of loading. Per contra, it is beautifully expanded and brought into shape of the exact walls of the chamber in firing, and extracts readily if the head holds, which, from the reports, seems not always to be the case. It is not suitable in its present state and form for use as a reloader, whatever may be claimed for it in this respect, and it is doubtful if it could be made so. The idea of such a use does not seem to receive encouragement from recent reports. Its attachable heads, from the peculiar and awkward mode of fixing them, are not exact or even, and may not always be firmly put on. Made of iron, it is believed they never should be for cartridges subjected to all varieties of climate. The use of this metal for a cartridge, otherwise so costly, is the poorest kind of economy.

There are several varieties of solid heads, as the Hotchkiss, the Dutch, the United States Cartridge Company's &c. The head, here, is re-enforced by using a thick sheet-metal strip to form the case, and leaving sufficient stock in the head, in drawing the case, to flow out and form the flange solidly. That this is effective in making a very strong case is unquestionable; its manufacture requires some heavier plant for special operations; its cost in metal and production is somewhat greater; and it is believed that the head is unnecessarily strong for the present work required by well-constructed breech-loading small-arms.

Experience, it is believed, has fully demonstrated that, in order to insure the best results in service, our small Army should be furnished with the most approved arms and material practicable. To effect this, the careful selection of an excellent (the best if it can be determined upon, for the chief trouble of such a selection seems to be from *embarras de richesse* in this branch of invention) system of breech-loading rifle small-arm, and suitably working efficient ammunition for the service of the same, is preeminently desirable. Supposing the first part of the proposition accomplished, and such a breech-loading system selected, approved and adopted, their production in such numbers as may be required by the Government for the Army, the uniform equipment of the militia, and the necessary reserve-stores for future emergencies, can unquestionably be accomplished at the National Armory, and no danger need be apprehended of any serious difficulty in the way of adaptation of its present machinery and plant, to the manufacture of any breech-loading system of small-arms, perfectly interchangeable, in these days of advanced scientific manufacture, when the production of the most complete and intricate machinery, interchanging in all their parts, is a problem of an easy, sure, and daily accomplishment.

If, from the abundance of good things to be chosen from, the difficulty of selection can be overcome, the rest, with adequate appropriations, is comparatively easy. A prime essential of such manufacture should be the institution of a rigorous standard from which there should not be the slightest departure, except by competent authority. *Especially should this apply to the chamber of the gun or seat of the cartridge*, the dimensions of which should be invariably fixed, and the greatest nicety of finish and adjustment of breech-mechanism insisted upon. In other words, the chambers should, within the limits of mechanical construction, be of the same dimensions, to the thousandth of an inch, both for the body of the cartridge and its flange or head. *The seat of the extractor should not occupy any part whatever* of the body of the chamber, and its surface should be as smooth as it is possible to make it. The depth of the flange recess of the chamber should only be sufficiently deeper than the thickness of the head of the cartridge to be employed in it to allow for the easy closing of the breech-block, the small variations of thickness of metal from which the case is made, and of necessary manufacture. A difference of 0".01 is believed to be ample for all purposes; its diameter may be at least 0".03 larger than that of the cartridge-head, which should itself be great enough to allow a secure hold to the extractor. *All the angles of the chamber should be slightly rounded.* The length of the chamber should be but a few hundredths of an inch longer than that of the case of the cartridge, and its throat, or seat of the projecting part of the bullet, should be accurately attended to, so that, with the cartridge *in situ*, the breech-block being closed, it should always occupy the same relative position with respect to its bearings in the chamber, and the bullet have the smallest necessary distance to move before engaging the grooves of the barrel, which engagement should be well advanced before the bullet is free from the case, to insure that it will start with its axis in the direction of the axis of the barrel. The expansion of the case in firing should immediately shut off escape of gas around its body to the rear—the only limits in difference of diameter of chamber and case allowable being those necessary to insure the required case in loading, and there should be no fouling of the chamber in firing ball-cartridges.

A little reflection will convince all that *an invariable chamber is the prime essential to the proper performance of the cartridge,* assuming, of course, that the latter is also as carefully made. This once obtained, let us insist on the case of the cartridge fitting as closely as practicable—the limit of variation allowable being only the very small unavoidable range of thickness in metal strips, and a reasonable life or wear of dies and punches necessary to the production of ammunition by the quantity. These degrees of perfection *can* be obtained only *by the adoption and preservation of exact standard gauges,* by frequent and every-day careful inspection of material and work, and keeping the attention of mechanics directed to the necessity of constant watchfulness over and frequent verification of their tools dies, and punches, in current use to insure the desired nicety Without this constant care in keeping up to the standard, work, however satisfactorily and successfully inaugurated, will soon become indifferent.

All experience shows that the fulminate composition for priming should not be in contact with any easily corroding metal, or so deposited in the primer or in assembling the parts as to render any galvanic action possible for its deterioration and eventual destruction. It is not believed that the service fulminate composition for priming in contact with pure copper undergoes any such deleterious change, as our percussion-caps of twenty years ago are now prompt and perfectly reliable. It should not be in immediate contact with brass, however, where brass is used in construction. This is not necessary, as in the Hobbs' primer, for instance, it is efficiently protected by being between two coats of varnish, one applied to the botom of the cap before the priming is dropped in, the other to one side of a tin-foil varnished disk pressed over the priming, which also holds it securely in place. Similar means of protection are used in other primers, or an equivalent. The United States Cartridge Company's primers, the Millbank, etc., are well protected from moisture, deterioration, and injury. See *Ammunition.*

METAL-LINED CASES.—Powder barrels lined with sheet copper, for the purpose of holding prepared cartridges. Metal-lined cases are used as portable magazines. When tested.they should be water-tight.

METALLURGY.—The art of extracting metals from their ores. The operations are partly mechanical and partly chemical. Those processes which depend principally on chemical reactions for their results have reference chiefly to the roasting and smelting of ores, and are described under the heads of the different metals. But there are certain preliminary operations of a mechanical kind which metallic ores undergo, such as crushing, jigging, washing, etc., which we shall describe here, as they are essentially the same for the ores of lead, copper, tin, zinc, and indeed most of the metals. Ores are first broken up with hammers. into pieces of a convenient size for crushing or stamping. Waste material, such as pieces of rock, spar, etc., which always accompany ore, are as far as possible picked out by hand, and the ore itself is arranged in sorts according to its purity. Various kinds of apparatus, such as riddles, sieves, etc., are then used for separating it into different sizes, in order to secure a uniform strain on the crushing machinery. In one of the most approved forms of crushing-mills the ore is raised by means of small wagons to a platform, where it is ready to be supplied to the crushing-rollers through an opening. These rollers are mounted in a strong iron frame, held together by wrought-iron bars, and bolted to strong beams. Their distance apart is regulated by means of a lever to which a weight is attached. The bearings of the rollers slide in grooves, so that when any extra pressure is put upon them by a large or hard piece of ore, the lever rises, and allows the space between the rollers to widen. The crushed ore falls upon a series of sieves, which are made to vibrate. These have meshes increasing in fineness as they descend; and the upper two are so wide that pieces of ore too large to pass through them are conducted into the lower part of the bucket-wheel and raised again to the platform to be recrushed. The lower four sieves separate the remaining portion of the crushed ore into different degrees of fineness, which is collected in pits.

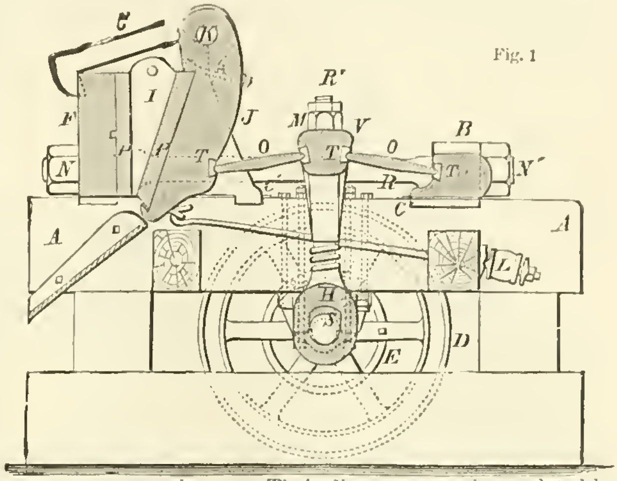


Fig. 1

A sectional view of the Blake Ore Crusher, standard in the United States and abroad, is shown in Fig. 1. A three-sided framework of cast-iron,with broad flanged base, holding the movable jaw, J, in suspension, from the front part of the machine,between the upright convergent jaws of which the stone is crushed. The jaw shaft, K, is held in place by wrought iron or steel clamps, C, which serve to take part of the strain due to crushing in the upper part of the jaw space, and also serve as walls thereof. In the lower part of the three-sided frame or front part of the crusher, and on each side of it, are holes in the casting to receive the main tension rods which connect the front and rear part of the machine. The rear part B, is called the main toggle block, and is also provided with holes for the tension rods R. R., corresponding to those in the front casting. These two parts of the machine are connected by the main steel tension rods, R R., each provided with screw-thread and nuts, N. N., by which their lengths and the jaw opening are readily adjusted to crush coarse or fine, as may be desired. The front and rear castings are supported on parallel timbers, to the under side of which are bolted the boxes carrying the main eccentric shaft, S, provided with fly wheels and pulley, D and E. The timbers are thus made component parts of the machine, and take the transverse strain which comes upon the pitman connecting the main shaft and the toggle joint placed to the rear of the movable jaw, and between it and the main toggle block.

Between the broad flanged bases of the front and rear castings and the timber on which they rest, are placed flat rubber cushions, C C, one-quarter to three eighths of an inch thick. Every revolution of the shaft brings the toggles, O, O, more nearly into line, and throws the swing jaw forward; it is withdrawn by the rod provided with rubber spring L. In this way a short reciprocating or vibratory movement is communicated to the movable jaw.

The rigidity inseparable from machines with cast iron frames, and which is the cause of frequent breakages is completely overcome in this machine, and the longitudinal as well as the transverse strains are brought upon materials which are strong and elastic as compared with cast iron. The rubber cushions.

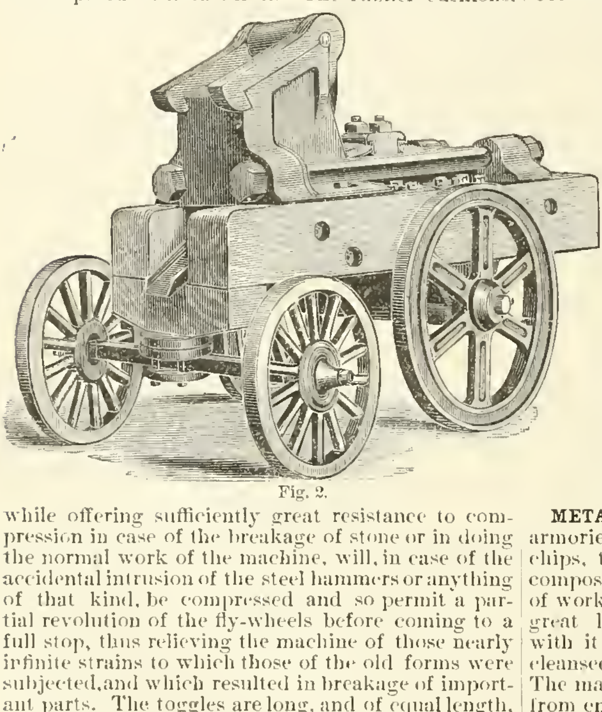

Fig. 2.

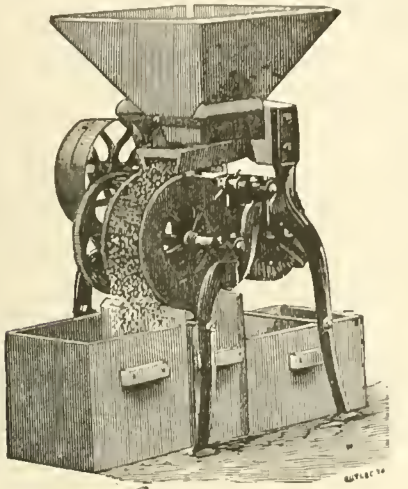
while offering sufficiently great resistance to compression in case of the breakage of stone or in doing the normal work of the machine, will, in case of the accidental intrusion of the steel hammers or anything of that kind, be compressed and so permit a partial revolution of the fly-wheels before coming to a full stop, thus relieving the machine of those nearly infinite strains to which those of the old forms were subjected, and which resulted in breakage of important parts. The toggles are long, and of equal length, and may be worn indefinitely as compared with those in the old machines. The construction of the pitman, R' H, is such as to admit of change of inclination of the toggles, and consequently of adjustment of the length of stroke of the movable jaw. The jaw opening can be varied between any working limits by means of the nuts, M, on the tension rods, and the machine be set to *crush coarse or fine* as may be desired. This Breaker can be run at a higher rate of speed with safety than any of the old forms of crusher with cast iron frames, and will consequently do a greater amount of work. It is very much lighter than the old forms, and has at least double their strength. It has been repeatedly subjected to the test of a steel hammer being thrown between its jaws, when going at as high a rate of speed as 300 revolutions per minute without the slightest injury to or any breakage of the machine. The manner of mounting the Crusher, so that it may be readily hauled from place to place, is illustrated in Fig. 2. It will be seen how peculiarily well adapted this style of Breaker is for mounting. The fly wheels themselves serve as the rear pair of wheels. The keys of the main fly wheels are withdrawn, and the main shaft is provided with a collar and set screw to hold the wheels in place when the machine is being hauled about. After being crushed, the ore is washed and sifted on a jigging sieve. In one of its simplest forms the ore is placed on a table from which a sieve is filled. It is then immersed in a tub of water and a jigging motion communicated to it by a workman alternately raising and lowering a handle. This effects two purposes—it washes the ore, and separates the material into two layers: the upper consists of the lighter spar and other impurities, which are raked off; and the lower consists of the heavier and purer portions of the ore, which are now ready for the roasting furnace. It will be apparent that in the bottom of the tub there must be a quantity of more or less valuable ore, which, from its fineness, has fallen through the sieve. This is called sludge or slime; and the minute particles of ore it contains are recovered either by simply forming an incline on the ground, and washing it with a current of water, or by using an inclined table called a *sleeping-table*. Ore which has been reduced to powder at the stamping-mill, as well as slime, is washed by this apparatus. The material is put into a chest which is placed in a sloping position, and is supplied with water on turning a stopcock. The current carries the contents of the chest through an opening at the bottom, and spreads it, with the aid of a series of stops, or small bits of wood, over the surface of the table. A stream of water is then kept flowing over the table till the earthy impurities are all carried down into a trough, the pure particles of the ore remaining, by reason of their greater specific gravity, near the top of the table, whence they are removed to be smelted. Sometimes the table is suspended by chains and receives a succession of blows at the top from a *buffer*, moved by cams on the same principle as the stamping-mill. The variety of machinery and apparatus used in dressing ores is very great, and they pass under different names in different districts, but they are all very similar in principle to those we have described. See *Iron*.

METAL SEPARATOR.—A machine much used in armories and arsenals for separating iron and steel chips, turnings filings etc., from those of brass or composition. Its capacity and utility for this kind of work are very great. The machine is not only a great labor-saving device, but brass-stock treated with it is much improved, as it is so thoroughly cleansed that it may be used for the best of work. The machine may also be used for separating iron from emery. The driving shaft should run 90 to 100 turns per minute. There are two things absolutely necessary in using the machine: 1st, Whenever the machine is not running, raise the brush and cover the wheel with iron. 2d, The tray under the hopper should strike equally on each side, so as to distribute the stock evenly on the wheel. If you wish it to feed faster, draw the hopper forward. The boxes should be placed as shown in the drawing.

METCALFE CARTRIDGE-BLOCK.—This consists of a wooden block, 5 inches by 1 3-4 inches by 11-16 inch, bored on its edge with eight holes to receive the same number of rifle cartridges. It is provided with a carrier or metallic hook, sliding upon the belt, in which it is proposed to carry the block full of cartridges. The rifle and the block are so arranged that, at pleasure, they can be secured together in a very convenient position for loading. It is intended that the blocks, when exhausted, shall be thrown away; but they can, if necessary, be refilled and used many ines. It is proposed that as many of these carriers and blocks be worn upon the belt as may be necessary, due regard being had to the size of the men and to the character of the service requiring their use. The advantages of this invention are manifold. The block in itself is a good package for the cartridges. It is nearly indestructible in transportation or by wet; it keeps the cartridges from jostling together, and



Metal Separator.

thereby, as has been shown by experience, endangering their surety of fire. It also protects them from dust and sand, quite as injurious to the gun as moisture would be to the cartridge. It is a convenient package in shape and size, if an extra supply of ammunition had to be carried in the men's pockets.

When combined with the gun, a considerable increase in the possible rapidity of fire is attained and a very marked advantage is found in firing lying down. In this position it seems probable that much of the firing of the future is to be conducted. The only portion of a man so firing which it is at all necessary to move is his right arm. If an isolated skirmisher, he need not twist or roll over to get at his back or side for ammunition, and thereby attract attention. The cartridges are immediately in front of the firer, under his eye. He sees just where they are, and how many are left him. We have frequently heard of troops engaged in intrenchments spreading, for convenience, their cartridges on the parapet in front of them. In a similar case, a man provided with the block has all this facility of manipulation, with this additional advantage, that, if obliged to change his position hurriedly, he does not have to leave his ammunition behind him, but carries it with the gun to which it belongs. Pickets or other troops exposed to surprise may sleep with their belts off if they have their blocks fixed. In case of a surprise, they have but one thing to look for—the gun.

Moreover, the block protects the hand from burning on the barrel. After a few shots have been fired from the new Springfield rifle, especially on a hot day, the barrel becomes so hot that it can hardly be touched. The block, when fixed, prevents the hand from touching it if the thumb be properly laid along the stock. The English War Department has consequently been obliged to issue leather pads to buckle over the barrel at the grip. With the cartridge-block *it is never so much needed as when it is used.*

METEOROLOGICAL REGISTER.—A monthly report prepared and transmitted by the Senior Surgeon on duty at each military post. It embraces the following items, as noted in the forms on pages 324 and 325.

METHYLATED SPIRIT.—Alcohol(C^4H_5OHO), of specific gravity of ·83, mixed with 10 per cent. of wood spirit, or methylic alcohol (C^2H_3O,HO), which is one of the products of the destructive distillation of wood. Methylated spirit is used for damping detonating compositions, so as to form them into paste, when they can be handled. It dissolves shellac.

METIER.—A term applicable to those nations which keep up large standing armies, and make war their principal object and pursuit. Chevalier Folard gives the following definition relative to the question which is often discussed on the subject of war, namely whether war be a trade or a science. The English call it a profession. Folard, however, distinguishes it in this manner: *La guerre est une métier pour les ignorants, et une science pour les habiles gens.*

METRICAL MEASURES. The frequently recurring necessity for changing tables expressing the dimensions, weights, and power of foreign guns (other than British) into their equivalents in our own system has suggested the preparation and compilation of the tables on pages 326 and 327. Some of the tables have been published in part, or in another form, but such have been generally based upon values for the *meter* and *kilogram*, which the latest accurate investigations have rendered obsolete; other of the tables, if ever published, are not generally accessible. All (except table M) are based upon the value of the meter in *inches* and of the kilogram in *grains*. The standard inch and grain of the United States are copies of the British; the tables, therefore, also express the equivalents of metrical in British measures.

MEASURES OF LENGTH, SQUARES, AND CUBIC MEASURES. —(Tables A., B., and C.) The international bureau of weights and measures at Paris is now engaged in determining, with the utmost exactness, the relations of the French standard to those of other nations. Since 1868 the United States Coast Survey Office has used a value for the meter equal to 39.370432 inches, as determined by an extensive series of comparisons, the results of which are published in a volume entitled "Comparisons of the Standard of Lengths of England, France, Belgium, Prussia, Russia, India, and Australia, made at the Ordnance Survey Office, Southampton, 1866." Pending the result of the investigation at Paris, this value of the meter is generally accepted by scientific men. The fact that the meter is standard at 0° C. (32° F.) and the yard at 62° F. has been taken into account, and the value given is that of the meter in inches of the standard yard. Tables A, B, and C, like all the remaining ones, consist of the values of each denomination, from 1 to 9 inclusive, which can be applied to all numbers, by decimal multiplication and division.

WEIGHTS.—(Table D.) The standard troy pound of the United States, at Philadelphia, is our only standard of weight; it is an exact copy of the imperial troy pound of Great Britain, obtained in 1827. Elaborate comparisons, since 1855, of this troy pound, weighing 5,760 grains, and of the commercial or avoirdupois pound of 7,000 grains, derived from the former, with copies of similar weights from the standard pound of Great Britain, have shown that there is less than $\frac{1}{1000}$ of a grain difference between the money standards (troy weights) of the two countries. The British *standard pound avoirdupois* is the weight, in the latitude of London, of a certain piece of platinum kept in the exchequer office. In the Philosophical Transactions for 1856, is published Prof. W. H. Miller's determination of the weight of the kilogram equal to 15.432.34874 grains, which is accepted as authoritative. This value has been used in the preparation of Table D.

AIR SPACE PER UNIT OF WEIGHT OF POWDER-CHARGE. —(Table E.) In the metrical system, the volume of the chamber and bore of the gun is expressed in decimeter cubes (d. c.) or liters. The space in the bore (or chamber), in rear of the projectile in place, in which the combustion of the charge takes place, constitutes the *initial volume*, and the *final volume* results when the projectile leaves the piece and the in

N.	Units of heat in a Calorie	3.96831835	0.5986065	1.4013935	0.25199593	Calorie in a unit of heat.

flamed gasses have expanded to completely fill the whole of the bore. The definite relation between the powder-charge and the initial and final volumes, which we express by "— —cubic inches of air-space to the pound of powder," is in that system expressed by "———decimeter cubes of air-space to the kilogram of powder." Table E enables us to convert these expressions.

Pressure of an Atmosphere.—(Table F.) The value of the *unit atmosphere* (or atmo.) which has been adopted in the metrical system, and used by Regnault in his investigations to determine the relations between the temperature and pressure of gases, is the pressure of 760 millimeters(29.922 inches) of the mercurial column at 0° C. (32° F.) at Paris; which amounts, in that latitude, to 1.0333 kilograms on the square centimeter, or 14.6967 pounds on the square inch. In consulting this table it is therefore necessary to remember that it deals with an arbitrary *unit atmosphere.*

The Encyclopædia Britannica, gives as *an atmosphere*, in the English system, the pressure due to 29.905 inches of the mercurial column at 32° F. at London, which atmosphere thus becomes 0.99968 of that of the metrical system. Under this pressure (29.905) distilled water boils at 212° F.

Rankine assumes as the value of an English *atmosphere* the pressure due to 29,922 inches of the mercurial column at 32° F., which in the latitude of London corresponds to a pressure of 14.704 pounds per square inch. This, it will be observed is the *height* used in the metrical system, which is thus indicated as the universal standard.

There are two ways of taking such a standard. 1st. If the *absolute pressure at Paris*, due to 76 centimeters of the mercurial column at 0° C., be assumed, then if we would have the same absolute pressure in taking readings of the barometer for *pressures*, in a different latitude, allowance must be made for a difference of height of the mercurial column, corresponding to the difference between the latitude of the place of observation and that of Paris. The height of the mercurial column at 0° C. giving a pressure equivalent to that of *this* metrical atmosphere, can be computed in centimeters by the following expression:

$$76 \times \frac{1 + .00531 \sin^2 48° 50'}{1 + .00531 \sin^2 l.}$$

for any latitude l. (48° 50′ being the latitude of Paris.) Thus we have for New York City, taking l=40° 42′ 43″, a value for the expression, of 76.06314 centimeters=29.946 inches, which height of the mercurial column at 32° F. at New York City would indicate a pressure equivalent to the metrical atmosphere of *constant pressure.*

2d. On the other hand, assuming the universal standard to be the pressure (wherever taken) due to 29.922 inches of the mercurial column at 32° F., then the absolute pressure of *this unit atmosphere* at New York would equal but 14.686 pounds on the square inch, which is 0.999272 of the metrical atmosphere *at Paris.* It may be added that 29.922 inches of the mercurial column at 32° F. corresponds to 30 inches at 57°.8 F.; the reduction to 32° for this reading being—0.078 of an inch for an observed reading of the attached thermometer of 57°.8 F.

Bending-Stress per Unit of Length.—(Table G.)—In the case of a uniformly distributed load, or of a pressure tending to bend or burst open a structure, this table enables us to pass from "kilogrammes to the centimeter" to "pounds to the inch," etc., and *vice versa.*

Stress per Unit of Square and Cubic Measures.—(Tables H and I.) The first of these tables finds its application especially in the conversion of expressions giving the tensile strength of materials, wherein we change the metrical expression in "kilogrammes to the square millimeter" into "pounds to the square inch," otherwise stated simply as "—— pounds tensile strength." The two tables apply to the conversion of values of forces of compression; the word *stress* being used to indicate either a force of extension or compression.

Units of Work or Energy.—(Table K.)—This table gives simply the equivalent values of "kilogrammeters" in "foot-pounds," and "tonnes-metres" (sometimes written *dynamodes*) in "foot-tons." It will be used in the translation of abstract quantities of work or energy.

Energy of Projectiles.—(Table L.)—The translation of expressions for total energies will be made by Table K, while in this series (L) we pass readily to expressions for energies of projectiles in terms of the "units of the shot's circumference" and "units of the shot's cross section." This series also enables us to translate the proportion of the total energy due to each kilogram of the powder-charge, each kilogram of the piece, or each kilogram of the projectile, into equivalent denominations in our own system, and *vice versa.* Further, it includes a translation of the proportion of the total energy due to each unit of the terms in which the pressure upon the bore is expressed; as, for example, "tonnes-mètres (of energy) per atmosphere of pressure" in "foot-tons per pound of pressure."

In Ordnance Notes, No. XLV, Maj. George W. McKee, United States Army, has already called attention to the influence of the *local* value of the force of gravity (g) in using the formula $E=\frac{Wv^2}{2g}$, which is employed for determining the energy of a projectile. In connection with these tables, it may be remarked that while they translate the value given in the foreign tables, yet the values thus deduced may not always be strictly comparable with each other or with our own. The practice of the United States Ordnance Department is to use a value for g=32.2, which is the same as that used in Great Britain; this makes the published tables of energy directly comparable for the two countries, but slightly underrates the local power of our own guns.

The French use the value of g at Paris, where it is equal to 9.81 meters=32.185 feet, which, it will be seen, gives slightly greater energies for one of their guns than we publish for one of ours, supposing all the values entering in the formula (except g) to be identically the same for the two guns under comparison. Small changes introduced in the value of g will, however, make little practical difference in the published results, which, for energies, are usually given in foot-tons to tenths only.

Thermometers.—(Table M.) This table presents merely a tabulated solution of the formula

$$F° = \frac{C° \times 9}{5} + 32 = \frac{R° \times 9}{4} + 32.$$

By decimal multiplication and division it can be applied to all numbers, as the others. In passing from centigrade or Reaumur to Fahrenheit we first take out the tabular numbers and then add 32; in the reverse operation we first subtract 32 from the Fahrenheit degrees, to be converted into centigrade or Reaumur, and then take out the tabular numbers corresponding to this remainder.

Units of Heat—(Table N.)—The thermal unit centigrade is the amount of heat required to raise unit mass of water from 0 to 1° C.

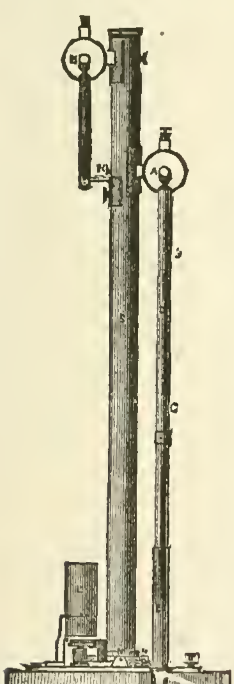
This table expresses the relation between the amount of heat required to raise *one kilogram* (2.2046 pounds) of water from 0 to 1° C. (1°.8. F), and the amount of heat required to raise *one pound* of water 1° F, (from 32° to 33° F). The mechanical equivalents of the "unit of heat" in the two systems bear a like relation to each other. This mechanical equivalent, in the English system, is the number of foot-pounds of mechanical energy which must be expended in order to raise the temperature of one pound of water one degree. For Farenheit's degree that quantity (Joule's equivalent) is 772 foot pounds; for the Centigrade degree $\frac{9}{5}$ of 772 = 1389.6 foot-pounds. If we replace the pound by a kilogram (2.2046+ pounds), that quantity becomes for the Centigrade degree 2.2046 of $\frac{9}{5}$ of 772 = 3063.54 foot-pounds, which is the mechanical equivalent of the metrical unit of heat, and is equal to 423.55 kilogrameters.

METRONOME.—A valuable machine for indicating the correct time or cadence. It was invented in 1815 by Mälzel, the inventor also of the automaton trumpeter. The test of a correct metronome is, that when set at 60 it shall beat seconds.

MEURTRIERES.—Small loop-holes, sufficiently large to admit the barrel of a rifle or musket, through which soldiers may fire, under cover, against an enemy. Likewise the cavities made in the walls of a fortified town or place.

MEXICAN SADDLE.—The Mexican, or California saddles as sometimes called, are extensively used throughout the Western States of America; and, in proportion to their excessive cost, are considered by the traders and Indians far superior to any other saddles manufactured. They are furnished with wool-lined bastos, llama skin anqueras, sudaderos, tapaderos and stirrup-leathers handsomely cut-stamped. These saddles, direct descendants of the Moorish-Spanish, brought over by Cortez 300 years ago, have hardly improved in the changes. The convenience and safety of the rider are alone considered. The shape of the bearing surface running through all the many varieties is invariably *bad*. They can never be used without a great thickness of saddle cloth or blankets, and even then cut, gouge, and lacerate the back of the horse. They are always *heavy* and *awkward*.

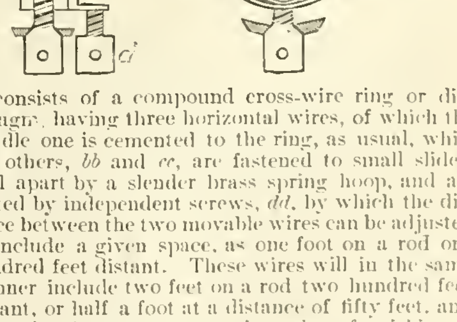
MICRO CHRONOMETER.—When the chronograph is used, with an interval of 50 meters or more between the targets, the chronometer receives the dents near the top, when of course it is moving with its greatest speed, and, consequently, small differences in time give proportionately large differences in height. But when the interval to be measured becomes small this no longer obtains, for then the dent of the shot is imprinted on the *lower* recorder near the disjunction circle before the chronometer has acquired much acceleration. To obviate this difficulty the arrangement shown in the drawing is adopted. The electro-magnet of the registrar with its stop is removed to the upper part of the column, and *introduced in the circuit that is broken first*. By this arrangement we obtain a disjunction dent near the *upper* end of the chronometer and thus regain the advantage, even when the interval is very small, of recording very minute times where the representative scale is greatest. This disjunctor-reading is about 0″.3, at least double what it was before, hence the representative dents of small times are readily marked on the chronometer



when it has double its former velocity. We may remark here that for diminishing velocities and in measuring small times for decreasing intervals, the units of the scale in the one case and the corresponding spaces on the chronometer in the other increase —most desirable attributes of instruments of this class. The fall corresponding to the time to be measured is recorded *negatively*, as the firing dent is below the disjunctor-reading, and the duration of this fall is found by subtracting that of the former from the latter. These heights are measured to tenths of a millimeter by means of the scale engraved on the rule and by its vernier and the corresponding times may be calculated from the formula $T = \sqrt{\frac{2H}{g}}$, or taken directly from a table, which is formed analogously to the ordinary logarithmic tables. When the interval becomes so great as to give a dent below the upper recorder, the ring on the rod must be removed, and two of the larger tubes applied to the chronometer, one above the other. The largest interval that can be recorded by the instrument thus arranged is that which corresponds to the disjunctor-reading, a little over 0″.3. When the time between the rupture of the two circuits exceeds this reading, the chronometer is struck before it has commenced to fall, and the dent of the origin is obtained. See *Le Boulengé Chronograph*.

MICROMETER.—An instrument used with a telescope or microscope to measure small distances, or the apparent diameters of objects which subtend very small angles. The micrometer with a graduated scale is used for measuring distances by direct comparison. The application of the micrometer to the telescope is credited by Whewell to Huyghens, Malvasia and Azout. It was a great advance in the attempt to do by accuracy of measurement what had previously been attempted, and in part accomplished, by enlarging the instrument so as to enable the measurements of smaller arcs. The first micrometer on record is that of Gascoigne, of England, constructed about 1640, and used by him in measuring the diameters of the moon and some of the planets. The instrument had nicely-ground parallel edges of brass-plate, and parallel hairs were substituted by the renowned Dr. Hooke.

The drawing shows the micrometer used with the Engineer's Transit and other standard instruments.



It consists of a compound cross-wire ring or diaphragm, having three horizontal wires, of which the middle one is cemented to the ring, as usual, while the others, *bb* and *cc*, are fastened to small slides, held apart by a slender brass spring hoop, and actuated by independent screws, *dd*, by which the distance between the two movable wires can be adjusted to include a given space, as one foot on a rod one hundred feet distant. These wires will in the same manner include two feet on a rod two hundred feet distant, or half a foot at a distance of fifty feet, and so on in the same proportion, thus furnishing a means of measuring distances, especially over broken ground, much more easily and even more accurately than with a tape or chain.—See *Engineer's Transit*, *Gradienter* and *Stadia*.

MICROPHONE.—This instrument, invented in 18 by Prof. Hughes, does for faint sounds what the microscope does for matter too small for sight; the fall of a bit of tissue-paper or the tread of a fly being rendered audible at many miles distance. In principle the microphone illustrates the action of sonorous vibrations on the strength of an electric current. One of the most sensitive substances for microphonic action is willow-charcoal, plunged in a state of white heat into mercury. The theory is that in a homogeneous conductor the compressions and dilatations of the molecules balance each other, and no variation of current ensues while under minute subdivision, with electrical continuity, sonorous waves affect the strength of an electric current, and variations in the current reproduce sonorous waves. One form of microphone consists of a piece of mercury-tempered carbon an inch long, placed vertically between two carbon-blocks hollowed to receive its ends, wires connecting the blocks with the battery and the receiver by which the sounds are to be heard. "A piece of willow-charcoal," says the inventor, "the size of a pin's head is sufficient to produce articulate speech." Two nails laid parallel, with wire connections, and a third nail laid across them, make a simple form of microphone. A few cells of any form of battery may be used. A continuous sound has been made by the mutual interaction of the microphone and telephone, each instrument in turn repeating the sound made by the other. Many useful applications of the microphone have been made or suggested.

MICROSCOPE.—An optical instrument by which objects too small to be viewed by the naked eye may be seen and examined. A *single* or simple microscope is one by which the object is seen directly; it may consist of a single lens or more than one. In a *compound* microscope two or more lenses are so arranged that the image formed by one is magnified by the others, and viewed as if it were the object itself. In a *solar* microscope a reflector and condensor are employed to direct the sun's rays on the object. In a *lucernal* microscope the rays of a lamp are similarly directed. The microscope is used for a variety of military purposes in arsenals, and also for detecting adulterations in the ration and fabrics. Another use to which it may be applied was disclosed during the late Franco-Prussian war. Copies of newspapers, reduced many-fold in size by photography, were fastened in large numbers to carrier-pigeons and introduced into besieged cities. These were easily read by the microscope.

The United States Army microscope, made by Zentmayer, is thus described: It has a brass body, 16 inches high, on a brass stand, with a joint to incline it to any angle, double-milled head-rack and pinion for coarse adjustment, micrometer-screw for fine adjustment, and a movable glass stage; under the stage a tube is fitted for carrying the accessory illuminating apparatus, concave and plane mirrors, arranged for direct or oblique illumination, two eye-pieces, one achromatic object-glass $\frac{8}{10}$ of an inch focus, of 24 degrees angular aperture, one achromatic object-glass $\frac{1}{5}$ of an inch focus, of 80 degrees angular aperture (not adjustable for glass-cover), giving power of 50, 100, 250, and 450 diameters; camera lucida, stage micrometer ruled $\frac{1}{100}$ and $\frac{1}{1000}$ of an inch, and a condensing lens two inches diameter on a separate stand.

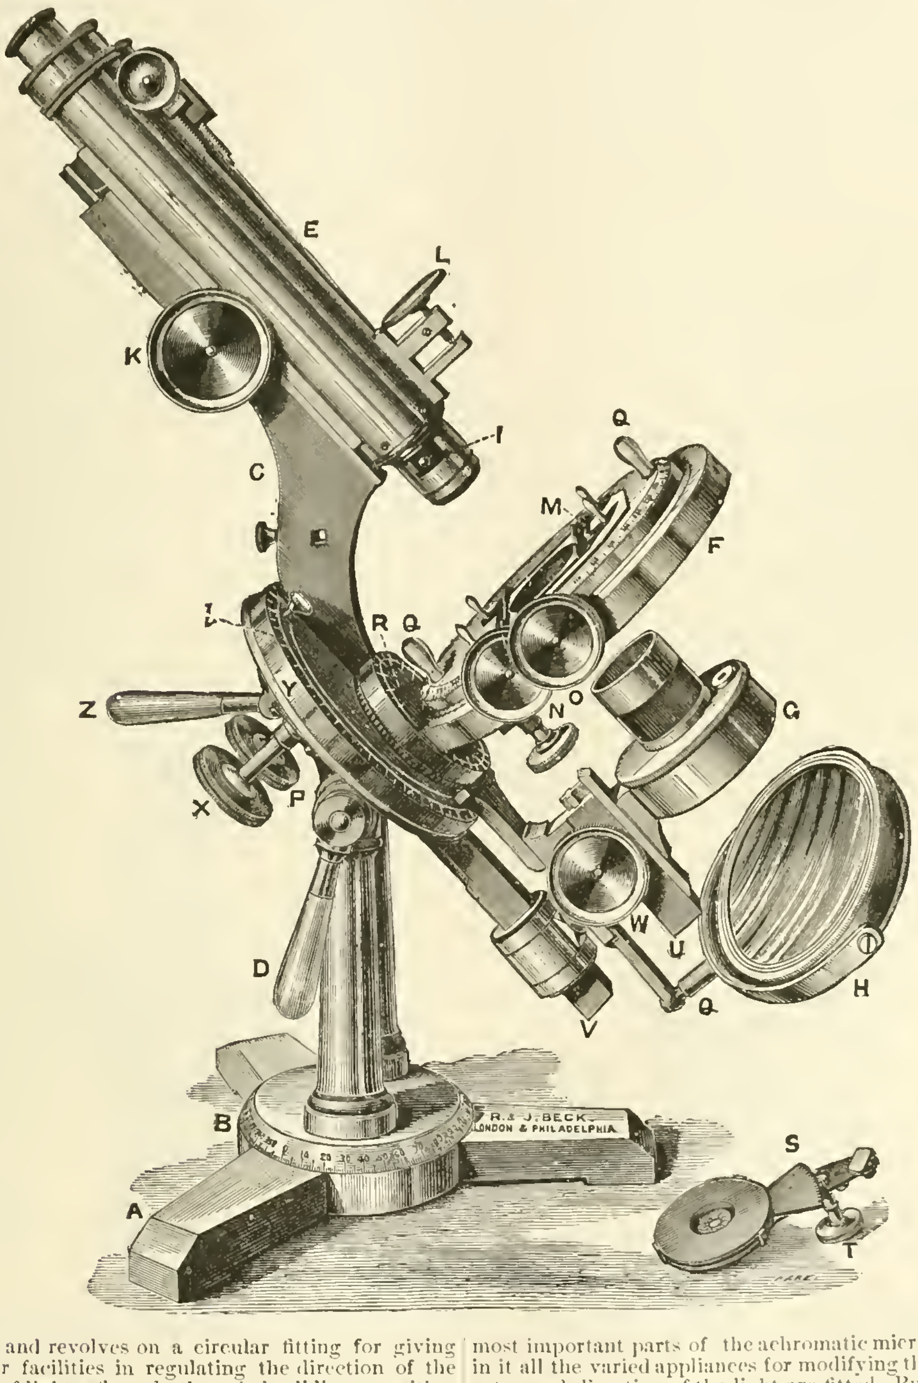
The drawing shows one of the latest improved microscopes and stands. The stand has a tripod (A) for its base, upon which is placed a revolving fitting (B), graduated to degrees, by which means the microscope can be turned around without its being lifted from the table, and the amount of such rotation registered; upon this fitting two pillars are firmly fixed, and between them the limb (C) can be elevated or depressed to any angle, and tightened in its position by the lever (D). The limb carries at one end the body (E) (binocular or monocular), with eye-pieces and object-glasses; in its center the compound stage (F), beneath which is the circular plate, sliding on a dove-tailed fitting, and moved up and down by the lever (Z), and carrying the supplementary body or sub-stage (G); and at the lower end a triangular bar carrying the mirror (H). Each of these parts requires a separate description.

The binocular body consists of two tubes, the one fitted in the optical axis of the microscope, and the other oblique. At their lower end and immediately above the object-glass there is an opening, into which a small brass box or fitting (I) slides; this box holds a prism so constructed that when slid in it intercepts half the rays from the object-glass, diverts them from their direct course, and reflects them into the additional or oblique tube. To the prism-box is attached a spring-catch, which, when pressed in, permits of the removal of the prism-box; but this is only needed for cleaning, as, when the box is drawn back to the distance properly allowd by this spring, the prism in no way whatever interferes with the field of view, and all the rays pass up the direct body and the microscope is converted into a monocular one. The upper or eye-piece ends of the tubes are fitted with racks and pinion for varying the distances between the eyes of various persons; and arrangements are made for racking out one tube more than the other, to suit irregularities or inequalities between the eyes of the observer. This body is moved up and down with a quick movement by means of the mill-heads (K), and with a very delicate and a fine adjustment by the milled head (L). This milled head works against a lever, which moves a slide independent of the rack-movement, and gives an adjustment at once certain and decided.

The compound stage is of an entirely new construction: the object is most frequently merely placed upon it, but, if necessary, it can be clamped by carefully bringing down the spring-piece (M); the ledge will slide up or down, and the object may be pushed sideways; this arrangement forms the coarse adjustment. Finer movements in vertical and horizontal directions are effected by means of two milled heads (N and O), the screws attached to which are kept up to their work by opposing springs, so as to avoid all strain or loss of time. The whole stage revolves in a circular ring by the milled head (P), or this can be drawn out, and then it turns rapidly by merely applying the fingers to the two ivory studs (Q, Q) fastened on the top plate, which is divided into degrees to register the amount of revolution. The stage is attached to the limb on a pivot, and can be rotated to any angle, which angle is recorded on the divided plate (R), or can be turned completely over, so that the object can be viewed by light of any obliquity without any interference from the thickness of the stage. Beneath and attached to the stage is an iris diaphram (S), which can be easily and altogether removed, as shown in the illustration, from its dove-tailed fitting, so as not to interfere in the slightest degree during the rotation of the stage. The variations in the aperture of this diaphragm are made by a pinion working into a racked arc and adjusted by the milled head (T).

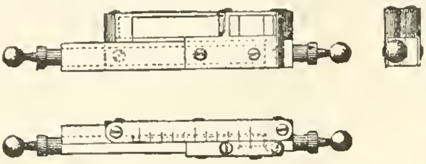
Beneath the stage are two triangular bars (U, V), the one revolving around and the other rigid in the optical axis of the instrument. On the former the sub-stage (G), carrying all the apparatus hereafter described for illumination and polarization, fits, and is racked up and down by the milled head (W): the mirror also, if desired, slides on the same bar: the revolving motion to this bar is given by the milled head (X), and the amount of angular movement is recorded on the circle (Y), whilst the whole of this part of the stand is raised and lowered concentric with the optical axis of the instrument by the lever (Z), and the amount of such elevation or depression registered on a scale attached to the limb. This bar can be carried around and above the stage, and be thus used for opaque illumination. The lower triangular bar (V) carries the mirror H, or a right-angle prism, when the illumination is required to be concentric with the optical axis of the instrument, and independent of the movements of other illuminating apparatus. The mirror-box contains two mirrors, one flat and the other concave; it swings in a rotating semicircle attached to a lengthening-bar, which enables it to be turned from one side to the other, and revolves on a circular fitting for giving greater facilities in regulating the direction of the beam of light reflected, the whole sliding on either of the triangular bars, previously referred to, and made to reverse in the socket (a) so as to bring the center of the mirror concentric with the axis of the microscope in either case.

As the mirror alone is insufficient for many kinds of illumination, some provision has to be made for holding various pieces of apparatus between the object and the mirror. For this purpose a supplementary body, or sub-stage, is mounted perfectly true with the body, and is moved up and down in its fitting by rack and pinion connected with the milled heads (W). This sub-stage, to which reference has already been made, is now regarded as one of the most important parts of the achromatic microscope; in it all the varied appliances for modifying the character and direction of the light are fitted. But a few years since it was considered sufficient for this part of the stand to be constructed so as to move up and down perfectly coincident with the optical axis of the instrument, and for that purpose it was racked in a groove planed out on the same limb as that on the



upper end of which the optical portions were carried. But lately microscopists have shown the desirability of affording every facility for lateral angular adjustments; and this has led to the sub-stage being attached to an arc (*b*) working in the circular plate (Y), and moved by a rack and pinion (X), whilst the amount of such angular movement is recorded on the upper surface of the plate (Y). Having once fixed the angular direction of the light, the focusing of it depends upon the lever (Z), which moves the circle up and down, and with it the arm carrying the illuminating apparatus, *in the optical axis of the instrument.*

MICROSCOPIC-GAUGE.—An instrument used in connection with the testing machine. It consists of a pair of glass sides, which are connected with the specimen by collars in the manner shown. One of the



glass sides is graduated to thousandths of an inch, and the other to hundredths of an inch. A microscope using a one-inch objection is employed in reading these scales, and by means of it the scale of thousandths may be readily subdivided into ten thousandths of an inch by the eye alone. The microscope is supported by an adjustable arm attached to one of the posts or the testing machine, or to a post expressly provided for this purpose, and detached from the machine. See *Taper-rule* and *Vernier gauge*

MICRO-SPECTROSCOPE.—A spectroscope placed in connection with a microscope, in order that the absorption lines may be readily produced. The instrument is employed in various testings; but notably, by Surgeons in viewing the absorption bands of blood in toxicological research. The micro-spectroscope designed by Walmsley and Co., and shown in figures 1 and 2, consists of a series of prisms, (A), arranged for direct vision, fitted into an eye-piece, and supplied with various appliances—namely, a slit, (B), a supplementary spectrum arrangement, consisting of a small right-angle prism, D, a stage, for placing an object upon, and a mirror, for reflecting the light and all the necessary adjustments. In the focus of the top lens of an eye-piece especially constructed is placed what is technically termed a slit, B; this consists of two shutters meeting in the center of the field, the one sliding up to the center of the field of view, and the other adjusting by means of a delicate milled head. Upon the delicacy of the edge of this slit the value of the Spectroscope largely depends, any irregularity or piece of dust appearing a dark band at right angles to the spectrum under examination, and greatly interfering with the definition. In the same part of the instrument is inserted a small right-angle prism, (D), which can be pushed forward or drawn back out of the field of view by a milled head. In the former position it reflects the rays passing through any object placed upon the supplementary stage to the eye placed at the eye-end of the instrument, and enables the observer to compare two spectra with one another, or to measure and record the position of the absorption bands. Placed on the flat surface of the eye-piece are a couple of levers, moving two shutters, placed immediately over the slit, for regulating the length of the spectrum under examination. Above the top lens of the eye-piece the most important portion of the instrument slides; this consists of a series of prisms, (A), so arranged as to give a direct-vision spectrum, and upon the amount of the dispersion of which prisms much of the value of the instrument depends. At the side of the main tube is a supplementary stage, upon which a standard scale, or a second object is placed, supplied with a mirror, for reflecting the light through the object, the rays then being totally reflected by the right-angle prism, (D), before alluded to, and thrown up the tube to the observer. To use the instrument, remove the ordinary eye-piece of the microscope, and slide the spectroscope eye-piece (Figs. 1 and 2) into the body in its place. Remove the upper tube, containing the series of prisms, and draw back the sliding slit by a milled head, so that one-half of the field of view is clear. Focus the microscope to the object to be examined,

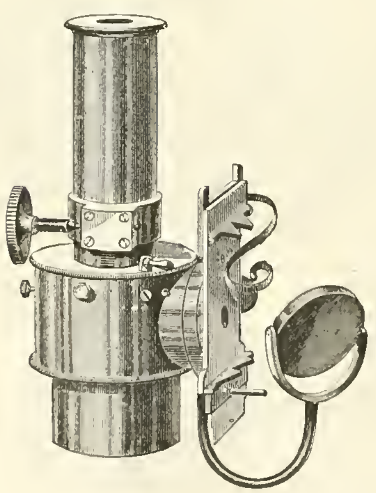


Fig. 1.

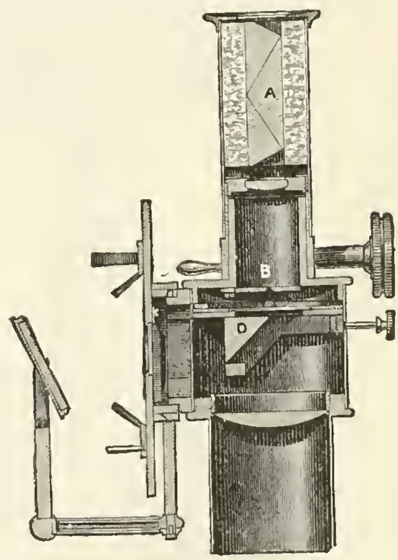

Fig. 2.

which is placed upon the stage, pass it up to the edge of the slit, move the side shutters by the levers, so as to shut off all side light, save that passing through the object, and push back the sliding side of the slit by the milled head. Focus the top lens of the eye-piece to the slit by means of the rack-and-pinion, place the tube, containing the compound prism, (A), over the eye-piece, remove the object from the stage, adjust the slit by means of an adjusting milled head, so as to obtain clear vision, if by daylight, so that the Fraunhofer lines are faintly seen, replace the object to be examined upon the stage, and the absorption-bands will be readily seen. The character of these bands and their position varies in every object; and if any practical use is to be made of the investigations, it is necessary not only to observe, but to record their position, by means of a standard scale provided for the purpose.

MICROTASIMETER.—An instrument invented by Mr. Thomas A. Edison for the purpose of measuring very minute variations of pressure caused by the expansion or contraction of any given body, from whatever causes, heat, moisture, etc. A part of the apparatus is constructed upon the principle of the pyrometer, and when the expansion is caused by moisture, upon that of some forms of hygrometer. But the novel and unique part of the invention consists in the effect which the pressure of the expanding rod has upon the electric resistance of a piece of carbon placed in the circuit of a galvanic battery. A rod of vulcanite is used as the expanding element when it is desired to use the instrument to ascertain slight variations in the heat vibrations coming from any object, as the sun, or a gas, or electric light. This rod is adjusted in a strong frame kept at an equable temperature, so that no expansions or contractions shall exert any influence, except those which take place in the vulcanite rod itself. In the chamber which receives one end of this rod, or plate, there is placed under a follower, or slide, a piece of carbon, which becomes compressed with great force upon the expansion of the vulcanite rod. If radiant heat is to be measured, a large funnel is placed in front of the apparatus to gather the rays and throw them upon the rod or plate. When the rays increase in intensity the rod expands, compresses the button, and changes its conducting capacity, which at every moment is indicated by a galvanometer. The instrument has been used successfully to ascertain the variations in the radiation from the sun during an eclipse. It may also be used to note the variations taking place on a day when clouds are passing across the sun's disk, or when the transmission of his rays differs from increase or decrease of moisture. It may be used as a delicate hygrometer by substituting in place of the vulcanite rod a body containing gelatine, which expands under the influence of moisture.

MIDDLE AGES.—The designation applied to the great historic period between the times of classic antiquity and modern times. The beginning and close of this period are not very definite. It is usual, however, to regard the Middle Ages as beginning with the overthrow of the Western Roman Empire in the year 476; and there is a pretty general concurrence in fixing on the Reformation as the great event which brought this period to a close. It began with the rise of the Frankish upon the ruins of the ancient Roman Empire, and with the commencement of civilization among the barbarous tribes which had taken possession of what were formerly Roman Provinces. In course of it the different nations of Modern Europe were formed, and their political and social systems developed. It was a period of much superstition, in connection with which much religious enthusiasm very extensively prevailed, manifested in many great religious endowments, in magnificent ecclesiastical buildings, in pilgrimages, and, above all, in the Crusades. In the earlier parts of this period the Church was much occupied in the extension of its bounds in the north of Europe, where heathenism still subsisted, and the means employed were not always consistent with the spirit of Christianity. During the Middle Ages the Hierarchy acquired enormous power and wealth, and the Papacy rose from comparatively small beginnings to its utmost greatness. During the Middle Ages chivalry had its rise and decline, modifying and, in many respects, tending to refine the feelings and usages of society. Towards the close of the Middle Ages the revival of letters, the increase of knowledge, and the formation of a wealthy and influential class in society, distinct alike from the aristocracy and the peasantry, tended, even before the Reformation, both to the diminution of the power of the Hierarchy and the decay of the feudal system.

MIDDLE ASSEMBLINO BAR. A component part of the caisson. It is made of iron, has two ears in the middle to serve as stay-plates for the middle-chests, and a slot for the axe on the right of the middle-rail.

MIDDLE CHEST.—The front ammunition-chest on the body of the caisson; so called because it is between the hind chest and the limber-chest when the caisson is limbered.

MIDDLE-CULVERIN. A cannon of the French artillery, under Henry II., carrying a projectile weighing two pounds.

MIGNON.—The former French term for a *picked soldier*—at present called *Elite*.

MIKADO. The popular title of the Emperor of Japan, though in official documents the term Tenno (Heavenly King) or Tenshi (Child of Heaven) is most frequently used. Other titles used in the native parlance or literature are Nin-ó (King of men), O-ó or Dai-o (Great King), Ko-tei (Ruler of Nations). Other terms arising from the application of the name of the Mikado's place of residence to his person, are Dai-ri (Imperial Palace), Chó-tei, (Hall of Audience), Kinri (the Forbidden Interior), Go-sho (Palace), which names occur frequently in old European works on Japan. The term Mikado means Honorable Gate, like the Turkish "Sublime Porte," and the Egyptian "Pharoah." The Dynasty of Mikados is the oldest in the world, the present ruler, Mutsuhito, being the 123d of the Imperial Line. The first Mikado was Jimmu Tennó, who began to reign 660 B. C., the professed starting-point of Japanese chronology. The first seventeen Mikados in the official list are said to have died at ages ranging from 100 to 141 years. The Mikados have each a personal name, but no family name, and the name of any one Mikado is never repeated; though in two instances in the list, two Mikados reigned each twice, and have each two posthumous titles. Seven of these Sovereigns of Japan were females. The average duration of each reign is nearly 21 years. The Mikados claim descent from the heavenly gods, and their regalia of sovereignity are a mirror, crystal ball, and sword. The possession of these palladia is the test of legitimacy during civil or dynastic war, of which but one is known in Japanese history—the period 1336-92, when a compromise was made by the rival in possession of the regalia receiving the title of Ex-Emperor, and handing over the sacred emblems to the other. After death, the Mikado receives a posthumous title by which he is known in history. The Mikado is allowed twelve *miogo* or concubines, besides the Empress; and in addition, there are four noble families called Shinno from whom heirs may be chosen for adoption. Succession is not always to the oldest son, but usually to the Mikado's nominee. The Imperial Household forms a distinct department of the government, called the Kunaishó.

MILANAISE.—A German fluted armor of the beginning of the sixteenth century. The cuirass is rounded, the breast-plate does not possess the central ridge or *tapul*, and the shoulder pieces are large with *passe-gardes*. The cuishes and upper arm pieces are fluted like the rest of the armor but, the lower arm pieces and the greaves are plain. The *solerets* are paw-shaped and indicate the time to which this armor belongs.

MILBANK GUN.—A breech-loading small-arm, having a fixed chamber closed by a movable breech-block, which slides in the line of the barrel by direct action. The piece is opened by raising the handle of the breech-bolt from its recoil-bearing in the receiver, and then drawing back the bolt. It is closed by reversing the action of the bolt; the hammer-bolt striking a sear-bolt in closing, and thereby compressing the spiral mainspring which surrounds its rear portion. It is locked by the support afforded the base of the handle by its bearing on the recoil-shoulder of the receiver when the piece is closed. The piece is fired by the action of a spiral mainspring surrounding the hammer-bolt. The hammer-bolt is kept from accidentally discharging the cartridge by striking the firing-pin before the breech is fully closed, by means of a transverse stop-pin, which, when the handle is up, passes through the firing-pin and keeps it forced back with its point flush with the face of the bolt. When the breech is fully locked by turning down the handle into place, the transverse pin is drawn back by an inclined surface in the hole of the firing-pin through which it passes, and it leaves the firing-pin free to be driven forward, at pleasure, in the usual way. The rear end of the firing-bolt when drawn back passes through the base of the rear section of the breech-bolt, and indicates the position if cocked. Extraction is accomplished by a hook swinging on a pin passing transversely through the recoil-block near its face. Ejection is caused by the action of a spiral spring, set in the face of the bolt and pressing against the lower edge of the cartridge-head until the shell is clear of the chamber. The shell being then free to turn, is rotated around the hook by which it is held and is thrown clear of the gun. A safety-lever is connected with this arm and serves to dispense with the necessity of a half-cock notch. The accidental opening of the breech may be prevented by turning up the handle part way and pressing down its stop-pin ; the point of this passes into a hole in the side of the recoil-block, and thus prevents the revolution of the entire bolt.

MILD STEEL.—The statistics of iron and steel are very suggestive of the condition of the times. In the middle of the last century the amount made in England was about one five-hundredth part of what it is at present; the amount imported was more than that manufactured at home, whilst now the English annually export millions of tons; the last few years have shown a striking increase in the world's annual production, though great fluctuations have occurred; the amount produced has risen from some 10½ million tons in 1869 to about twenty-one millions in 1882 —an enormous increase due to the vast development in the use of iron and steel for ships, railways, bridges, buildings, machines, etc. Apart, however, from the increase in the total quantities we notice (Fig. 1) that cast iron, wrought iron, and steel have not increased uniformly, but the last has far surpassed the others in the rate of its growth, having multiplied some twelve times in the thirteen years under consideration.

Although steel has been made from remote ages, it was only about twenty-five years ago employed on a comparatively small scale for such articles as tools, knives, swords, springs, etc., and from the expenditure of time and fuel on its manufacture, it was necessarily an expensive article: but the inventions of Bessemer, Siemens, and others have resulted in the production of a class of "mild" steel in large quantities, moderate in price, suitable for various purposes of construction, and surpassing wrought iron in all, or almost all, of its good qualities. Of late years competition in the trade has led to numberless improvements, and great economy in manufacture, especially in the amount of fuel consumed. It may be interesting to notice the proportion of iron and steel annually produced (in 1882, for example) in each country. We are at once struck by the salient feature that Great Britain is far ahead of all others in *quantity;* in fact, excluding the United States, her production probably exceeds that of all the rest of the world put together; but other nations are also now making good progress. With regard to *quality*, the reputation of English iron and steel is deservedly very high: the great majority of modern improvements in manufacture are due to English inventors, practically developed by English makers, and many foreign firms are glad of English assistance. Iron ores and good coal, as well as materials for fire-bricks and fluxes, are found abundantly all over England, while the great carrying trade gives facilities for the plentiful supply of good ores from Spain, and pig iron from Sweden for modern steel making, as well as for the export of manufactured iron and steel to foreign customers. The resources of other countries are, however, being largely developed.

Second on the list comes the United States, whose rate of increase of manufacture is unexampled. The demand has been hitherto so great, to meet the wonderful development of the railway system, and other large works, that millions of tons have been sent from across the Atlantic, but the time has now come when the United States produces sufficient for its own wants. Its natural resources are very great, and it has excellent ores of great richness and abundance, vast coal-fields, calculated to last for centuries, and a people full of energy. At first sight it may seem strange that at the present moment steel for only an 8-in. gun can be produced, but this is simply because until lately there has been no demand for it. The colossal plant needed for heavy gun manufacture does not exist in America, where the heaviest hammer is one of 17 tons, while France has one of 100 tons, and Krupp is said to be making one of 150 tons. Whitworth is now supplying the Government of the States with steel for 10 in. guns. The United States have lately sent a Gun Foundry Board to make inquiries in Europe concerning the manufacture of steel for military purposes; their report has been published, and contains most valuable information: a supplement submitted to the Senate 22d December last, gives plans of two proposed gun factories, one for the Army and the other for the Navy. Besides certain annual expenses, it is estimated that a sum of £7,000,000 will last for six and a half years, in-two years will be required.

Next on the list of producers comes Germany, which possesses the largest manufactory in the world —that of Krupp—remarkable for its excellent steel which soon attained a wide reputation, as shown by the fact that in 1865 England ordered from this firm, for her own use and that of her colonies, no less than 11,396 tyres and 564 axles for railway purposes. Krupp early applied his steel to the manufacture of ordnance, and he has supplied several nations with guns. Germany depends greatly on this maker for her ordnance, but the American officers do not consider this a wise arrangement, as the Government may find it difficult to deal with a single private firm in times of great emergency.

Fourth in magnitude comes France; with her well known Le Creusôt, Terre Noire, and other works. The first, with its massive plant and 100-ton hammer has produced steel armor plates of excellent quality; while the second has, after many difficulties, attained great success in steel castings, and in the manufacture of steel projectiles. Although the loss of Alsace has told heavily on the production of iron and steel by France, and though half her ores are imported, her progress is certainly very good, especially in the steel required for warlike purposes, as after the war of 1870 the French Government encouraged private companies to such an extent that several can produce the largest steel ingots, others have the plant of a gun factory, and others again are able to produce armor-plates of excellent quality. The American officers consider that France has made better arrangements than other nations between the Government and the steel makers.

Belgium has good supplies of coal, but having exhausted her own ores, has to import for the manufacture of steel; nevertheless she has made good progress, especially considering the means at her disposal, and she enters keenly into competition with England in certain departments of the trade.

Austria, though formerly celebrated for metallurgical manufactures, and possessing excellent ones, has been unable to keep pace with other countries in the production of iron and steel. The want of coal, and of easy communications, and perhaps the lack of organization and capital, have proved hindrances to development.

Russia possesses excellent ores in the mountains of Siberia and the Ural, but the want of good means of transport and of coal prevents a large manufacture; but mild steel has been made since 1876, and the production for military purposes is now considerable. The Russian Government seems anxious to supply itself with steel; armor and guns up to 50 tons are now made in Russia. Formerly Krupp supplied ordnance.

The best Swedish pig iron is of capital quality, as the ores from which it is produced are very pure, and the charcoal employed as the fuel in smelting being free from sulphur, does not contaminate the cast iron: but the want of coal limits the supply.

Fig. 1.

The production of iron and steel by the countries of the world in 1882.

Increase of the world's annual production of iron and steel during 13 years—1869 to 1882.

Great Britain. United States. Germany. France. Belgium. Austria, Russia, Sweden, and the rest of the world approximately. Quantities of steel produced by the different methods in 1882.

Figs. 1 and 2:—A, steel; B, wrought iron; C, cast-iron. Fig. 3:—B, Bessemer; C, crucible; O. H., open hearth.

Spain cannot be called a manufacturing country; but the Bilbao ore has lately been very largely used in steel making; twenty years ago hardly any foreign ore was used in England; now she annually imports about 3,000,000 tons from Spain, and other nations also supply themselves largely. This country is consequently important to the steel makers.

Italy has hardly any iron or steel works; the Elba ore has long been famous, but is not so important as formerly. The huge armor-clad ships of Italy, with their very heavy guns, have, however, called for large supplies of mild steel for warlike purposes from abroad, and they have contributed not a little to the development of some private firms for producing heavy war material. According to the *Standard* of recent date the firm of Sir W. Armstrong and Co. has obtained a concession for establishing large factories for making guns and armor plates in the neighborhood of Naples.

The other nations of Europe produce but little iron and steel, and they are chiefly supplied from those already named. In the other countries of the world considerable progress has been made, as also in some of the colonies—the establishment of a gun foundry at Quebec is under consideration; and in many places large supplies of ore are available.

Steel is by no means easy to define, since it is a complex body, and as all persons are not exactly agreed concerning the difference between it and iron, lawsuits have consequently arisen; but the definition of mild steel given by Holley, quoted in the Royal Gun Factory Treatise, that it is "an alloy of iron, cast, while in a fluid state, into a malleable ingot," has, at any rate, the advantage of simplicity, if not of perfect exactness. This definition serves to distinguish it from cast iron on the one hand, and from wrought iron on the other: as cast iron is not malleable, but crumbles to pieces if heated and struck by the hammer, and wrought iron, though malleable, is produced, not as a fluid, but as a pasty mass, the temperature of the ordinary furnace being insufficient to melt it.

Wrought iron is more fibrous than mild steel, and it contains, from the method of its manufacture, an average of 3 per cent by weight, or 7½ per cent by volume of slag, dispersed through its mass in fine filaments, which detracts from its strength; on the other hand, the process of fusion in the manufacture of mild steel gets rid of all traces of slag; and this is a great advantage. Old definitions of steel stated that the proportion of carbon in it was more than in wrought iron, but less than in cast iron; but this hardly holds good at the present time, when some mild steel has no more carbon than some wrought iron. Sir W. Armstrong states that "steel is iron produced by a process of fusion instead of by one of adhesion, and in that sense it is independent of any particular sense of carbonization. Using the term in this sense, steel has the advantage over iron in being free from defects in welding. It generally contains more carbon than wrought iron, which renders it stronger. It is also tougher under some tests, but more prone to fracture under others. . . . The manufacture of steel continues to improve, while that of iron is stationary, and the time is probably near when the manufacture of iron, as now practiced, will entirely merge into that of steel, as produced by the process of fusion."

Taking Holley's definition, carbon is the essential substance which alloys with iron to form steel; it increases the hardness, elasticity, and tenacity, although it decreases the elongation before fracture: it also gives rise to the important property of tempering by rapid cooling, by which these advantages can be increased, though with a further loss of power to elongate. Annealing, or softening by slow cooling, may be called the reverse of tempering. The presence of carbon, however, greatly adds to the difficulty of forging, which must be done at a lower temperature as the proportion of carbon increases; if too hot, the mass will crumble to pieces under the hammer, or if this does not actually take place, the result will be to give brittleness instead of strength in the operation of forging—producing what is technically called "burnt steel," : in explanation of this remarkable fact it can only be stated that some physical and (possibly) chemical change takes place in steel at a certain temperature depending on the proportion of carbon present, which causes it to assume a coarsely crystalline structure, greatly decreasing its strength and reliability: the forging of steel is consequently generally more tedious than that of wrought iron, which can often be heated to a white heat when it becomes soft, and can then be quickly hammered into the required shape. At the beginning of modern steel making, the necessity for care about the temperature for forging was not fully recognized, and "burnt steel" was often produced, accounting probably for many of the mysterious fractures which happened, and which gave reason for so much distrust. At Terre Noire especially, the men who had been accustomed to deal with wrought iron could not understand for a long time that steel must be treated differently, and experience was only gained at the cost of a good many failures. On one occasion, the ordinary workmen were turned away, and carpenters who had to learn the work, but who would do what they were told, were engaged instead

So great, however, is the progress in some departments of steel-making, that notwithstanding these difficulties of working we find Mr. Denny writing that "steel for ships' plates has become so uniform as to have lost interest, while iron attracts attention from its deterioration and want of uniformity, and the men complain if they are put to work upon it on account of the amount of spoilt work involved;" and this is not an isolated opinion. It cannot be said, however, that the large masses of steel for guns are as yet produced with such uniformity.

Mild steel can be welded like wrought iron, but the operation becomes more and more difficult as the carbon increases; the 13-pr. steel axletree is consequently made in one piece without any weld, but wrought iron axletrees are most conveniently made in two pieces, which are afterwards welded together. On the other hand, large quantities of excellent tubular steel are now produced by the process of lap welding.

It is more difficult to cast mild steel than cast iron, because a more uniform result is required, and since the temperature of fusion is so much higher (from the smaller proportion of carbon), much greater contraction takes place on cooling, giving rise to a variety of intense molecular strains, which are sometimes sufficient to tear the metal apart in the mold, and often cause surface cracks, telling of a state of strain which must be allowed for and counteracted as far as possible by suitable methods of cooling and reheating Krupp takes the greatest care on this point, making the cooling of his ingots very slow indeed, keeping them warm with hot ashes sometimes for weeks, and they are said to be remarkably free from cracks or flaws. Annealing for several days is often resorted to in the case of steel castings.

As small differences in the proportion of carbon make very great differences in the elasticity, tenacity, hardness, elongation, etc., it is most important to use every effort to control the quantity admitted into steel in manufacture, and it is one of the greatest aims in making steel for ordnance, to obtain, as nearly as possible, the desired proportion of carbon: for this purpose it ranges from about 0.25 to 0.5. For the hard steel face of compound armor plates it may be as high as 0.8 per cent.

In all modern steel there is a considerable proportion of manganese; this is supposed to act in the same way as carbon in hardening, but its effect is not so marked. It is always added to melted steel in manufacture, in order (it is supposed) to take away ferrous oxide, which forms at a high temperature, and also to a certain extent, it may take away other impurities which would impart red shortness or brittleness at the forging temperature; as manganese has an extraordinary affinity for oxygen, it is prepared for use as an alloy with carbon and iron, termed spiegeleisen or ferro-manganese, according as the proportion of iron or manganese predominates; both of these alloys are now important articles of commerce. When the manganese mixture is put into the liquid steel, some of it immediately attacks the ferrous oxide, deprives it of its oxygen, and becoming itself oxidized, runs harmlessly into the slag, leaving a certain small quantity of metallic manganese to alloy with the steel; this is the last operation before pouring out, in the Bessemer and "open hearth" processes, so that no time may be given for the formation of any more ferrous oxide. Mild steel should not have more than about 1.0 per cent. of manganese, or it will be brittle, but it is generally best to have less than this quantity. Messrs. Hadfield and Co., however, have lately produced steel having as much as 12 per cent. of manganese which has shown remarkable qualities, and may perhaps become of practical utility in various ways. This alloy is very hard, but not brittle, and is scarcely affected if heated and plunged into water; but considerable variations have occurred in its properties.

Silicon has the property of rendering cast-steel ingots sound and free from blow-holes; small quantities of pig iron rich in silicon are often added for this purpose. It is supposed to de-oxidize, the carbonic oxide gas which forms the bubbles, and thus silica is produced which enters the slag. Not more than about 0.3 per cent. of silicon should be present, and much less if the steel is to be of very mild quality (or brittleness will be produced.)

Sulphur and phosphorus (especially the latter) are the enemies of the steel maker, for if present beyond a very small amount (say 0.04 and 0.06 respectively) they produce brittleness: as a very large proportion of the ore-deposits in the world contain too much phosphorus to allow them to be used in the manufacture of steel as it is generally carried on, it has long been a great problem to invent some process by which it could be eliminated, and it appears that this has at last been practically accomplished by the basic process, invented by Messrs. Thomas and Gilchrist, in which freshly calcined magnesian limestone (dolomite) absorbs the phosphorus almost entirely when the metal is melted, and by this process good steel has been produced from highly phosphoric ores. The averages of analyses made in the North Eastern Railway Company's laboratory by Mr. Routledge, of twenty steel rails made from hæmatite iron, and of twenty others made from phosphoric Cleveland iron by the basic process, give very nearly the same results.

	Carbon	Silicon.	Sulphur.	Phosphorus.	Manganese.	Iron.
Hæmatite steel.	0·452	0·105	0·121	0·052	1·178	98·092
Cleveland steel.	0·450	0·065	0·095	0·054	1·201	98·134

As far as present experience goes, the physical qualities of the two steels are said to be similar: basic steel has not yet, however been employed for ordnance.

Although this plan was invented by Englishmen, it has been more widely adopted in some parts of the Continent (where phosphoric ores abound) than in England, where good ores are generally procurable from abroad if not close at hand; and the practical question now seems to be generally one of economy, whether it is better according to local conditions, cost of carriage, etc., to employ an expensive ore and a comparatively cheap method of production, or a cheap ore and a somewhat more expensive process: as further experience, however, is obtained, the additional labor and expense of the basic lining plan may possibly be reduced. The results have been so good that it seems as if a new departure has occurred in the progress of steel making; already about a million tons of steel are manufactured annually in Europe from phosphoric pig, and the highest honors have been given to the inventors. It must, however, be stated that ores rich in silicon present some difficulty with this process, as the furnace lining is much corroded, and care must be taken to use freshly calcined limestone, as it soon absorbs moisture from the atmosphere.

The power to resist abrasion and rubbing possessed by mild steel, is greater than that of wrought iron; this is apparently due, not only to greater hardness imparted by more carbon, but it also results from the greater uniformity of its structure: wrought iron, on the other hand, flakes off, from the presence of filaments of slag. The advantage of mild steel over wrought iron in this respect has been shown in a marked manner by the superior endurance and uniformity of steel rails: as, for instance, when the London and Northwestern Railway Company some years ago made a careful experiment at Chalk Farm Station at a spot where the traffic was specially heavy, the top side only of steel rails lasted eleven times as long as both sides of wrought iron ones on the other side of the same line. Steel has consequently been widely adopted for rails, though it cannot be said that all now manufactured are of nearly such good quality as those made for that experiment. This same property was long ago recognized in gun making, when the bores of ordnance, which have to resist the abrasion of studs, etc., and the erosive action of fired gunpowder, were made of steel.

The process of drawing into wire increases the elasticity, tenacity, and elongation of steel to a degree unattainable in any other way. Advantage has of late years been taken of this fact in the manufacture of ordnance, as this method also allows of the initial tensions being very accurately adjusted, and no extensive flaws can remain undetected. Many other physical and chemical properties of steel might be considered, but those just mentioned are probably the most important for the purposes under consideration.

Excluding the older processes for the manufacture of hard tool steels, we find that mild steel for constructional purposes is produced by the three following methods:

1. Crucible. 2. Open hearth. 3. Bessemer.

In each of these plans a very high temperature must be obtained in order to melt the steel, which must not be in contact with the solid fuel, because if it were so, the proportion of carbon in the steel would be too large; and means are always taken to render the product as uniform as possible.

1. The crucible plan is by far the oldest, but it is now the least employed; it has long been known that wrought iron enclosed in a crucible with carbonaceous matter is capable of combining with the carbon, and melting, to form steel, at a temperature insufficient to melt wrought iron alone. At the present time, carefully weighed proportions of wrought iron, with sometimes a little steel, or even good cast iron of known composition, powdered charcoal, and spiegeleisen are put into a crucible capable of holding some 60 to 100 pounds, this being about the limit which its strength will enable it to bear without risk of cracking. A number of such crucibles are placed in a furnace specially constructed for their reception; a very high temperature is obtained, and after some two and a half to three hours, according to the degree of carbonization required, the contents are melted, the carbon has alloyed with the iron to form steel, and the manganese in the spiegeleisen has reduced any ferrous oxide which may be present. A liquid slag formed at the top, and a fire-clay cover prevent oxidation, which might otherwise occur at the high temperature attained; the contents of several crucibles are then poured into the same ingot mold as rapidly as possible. Krupp has greatly developed this method, and he has poured from as many as 1,800 crucibles into one mold: great care and arrangement in the large numbers of men employed being necessary.

The advantages claimed for this plan are that the flame is not in contact with the steel, and, therefore, cannot contaminate it; and uniformity of quality is gained if the temperature and time of heating are the same, otherwise the reactions may differ in different crucibles if the heat varies in duration and intensity. The disadvantages are, the expense and the great care and arrangement necessary for very large ingots, when great numbers of men must be carefully trained to work together; the length of time taken in casting is also a drawback, but the product is often excellent if all necessary conditions are observed, and it has been largely employed for gun tubes, where Firth's crucible steel has been much used.

2. The open hearth plan is perhaps the most recent method of steel making, and it owes its success to the invention of Siemens and others, who have constructed furnaces of the regenerating type, capable of producing very high temperatures. This so-called hearth is somewhat spoon-shaped, sloping down to one point, and the bed is covered with partly fused sand; good cast iron is first thrust in, and the flame beating down or reverberating from the low roof, soon melts it, as the metal is readily fusible from the large quantity of carbon which it contains, and thus the so-called "bath" is formed. Sometimes only one kind of pig iron is used, but generally it is more economical to make a mixture; for instance, a very pure Swedish pig iron combined with a cheaper iron from English haematite ore, which has a good deal of sulphur, but not enough to make an injurious amount in the mixture, and sometimes steel mixed at first with the cast iron. When the bath is sufficiently fluid, steel scrap, crop ends of rails or wrought iron are thrown in, after being warmed by the waste heat, the object being to obtain a mixture having less and less carbon; when these have been well melted down, a further reduction of carbon is effected by the addition of known quantities of good Spanish haematite ore—an oxide of iron. When this is added, a violent ebullition ensues, due to the combination of the carbon in the melted charge with the oxygen in the haematite, and the consequent production of carbonic oxide gas; this is technically called "boiling." The whole operation *might* be done by the use of pig iron and ore without any wrought iron or steel. This was a good deal practiced at one time, but it was found to be very expensive, as more fuel was required, and the wear and tear of the furnace lining was considerable, from the corrosive action of the large quantities of slag produced. During the latter part of the process the steel maker is constantly testing the composition of the molten mass, by inserting a large iron rod with a spoon at the end of it, and taking out a little of the steel; this is judiciously cooled, hammered on an anvil, bent over and broken, and the fracture and general appearance are compared with the samples previously obtained which have given good results, and which have been chemically analysed. If it is judged that the carbon is not low enough, more ore must be added if no "boil" is going on; but if, on the other hand, it is too low already, some good pig iron must be put in, and on leaving off the operation the steel should be as quiet and free from bubbles as possible, to avoid blow holes in the casting.

Great practical skill is required on the part of the steel maker; his tests must be taken rapidly, and a judgment must soon be made from the scanty and apparently rough data furnished by the comparison of the test pieces with the standards but, nevertheless, the same results may be repeatedly attained by the same operator within comparatively narrow limits.

Just before the pouring out, comes the addition of the proper quantity of spiegeleisen or ferro-manganese: both of these necessarily contain carbon, and consequently the melted mass should previously be more decarbonized than the finished steel. The manganese is previously heated, carefully scattered over and stirred up in the steel, and allowed to remain a short time to become thoroughly incorporated and to ensure uniformity of composition; at the last moment two spoon tests are taken, one for chemical analysis of the carbon and the other for physical trial; the tapping hole at the bottom is knocked through by means of hammers and a long rod, and the liquid steel flows out along a gutter into a large iron ladle lined with fire-clay and previously heated; if not heated, or if the temperature of the liquid steel is too low, a good deal of waste occurs from the formation of a considerable "skull," or metallic lining, caused by the solidifying of the outer part of the steel in the ladle. When all the steel has been poured out, two spoon samples are very generally taken for chemical and physical tests, the ladle is carried by a powerful crane to the ingot mold it is desired to fill, and a plug is raised at the bottom, worked by a rod passing through rings of fire-clay in the liquid mass; the steel then runs out of the bottom of the ladle and fills the ingot mold; the slag being lighter remains at the top and is not mixed up with the steel, unless indeed any difficulty occurs with the bottom plug, when the steel must be poured from the top of the ladle, as water is from a jug: in this case, small quantities of slag may become entangled in the steel, and the ingot will probably be spoilt.

Sometimes the metal is run direct into the ingot mold without the use of a ladle, but this is not generally considered a convenient plan. The whole operation lasts from 7 to 11 hours, or longer, according to the size of the furnace and the weight of charge; the largest furnace yet made will melt over 30 tons at a time; the furnace bottom needs repair after each charge. The advantages of this process are that it is cheaper than the last, the composition of the steel can be very carefully controlled, but it requires very great attention and skill on the part of one or two responsible persons. It is very largely employed in making steel for ordnance, carriages, and other military constructions, where uniformity and high qualities are more desirable than economy.

3. By far the largest proportion of mild steel (nearly 80 per cent.) is manufactured by the Bessemer process, but it is not applied to military purposes to anything like that degree; the rapidity and economy of this plan are considerable, and the whole operation is startling and impressive. A large egg-shaped iron vessel called a "converter," can revolve on trunnions, one of which is provided with teeth which gear with rack-work, by means of which it can be turned up or down. The other trunnion is hollow, and through it comes a pipe communicating with a great number of small holes or "tuyéres" fitted in the fire-bricks situated in the bottom of the vessel; a blast of air can thus be sent from an engine through the tuyéres. The top of the converter is provided with a short chimney, and the interior is lined with a very refractory material called ganister. The operation is as follows: The converter being heated, it is turned down and melted cast-iron is poured in by a gutter, either from a reheating furnace, or in some cases, as first practiced at Terre Noire, direct from the blast furnace, where it is reduced from the ore; when a sufficient charge has been poured in—only about ⅕ of the total capacity, so that the iron may not rise to the tuyéres on pouring in—the blast is turned on, and when it is fully on, the converter is turned up; the liquid iron cannot run down the small tuyére holes through which the blast comes, but on the contrary, the pressure is sufficient to cause a continuous stream of bubbles of air to rise up through the molten mass, thus oxidizing the carbon in it with the formation of carbonic oxide gas, which burns with a strong flame some 20 feet in length at the top of the chimney.

The temperature of the iron is considerably raised by the combustion of the carbon in it, and, although it becomes decarbonized and consequently more infusible, it still remains liquid; after some 20 minutes the flame becomes much shorter and alters its character, signifying that the carbon is becoming very low, and that the operation is nearly completed; it is essential that the exact time of leaving off should be chosen, as if the "blow" is stopped too soon, sufficient carbon is not extracted; if, on the other hand, it is continued too long, the iron becomes oxidized, when not only is some of it wasted but the quality of the rest is spoilt, for the iron itself burns, and excess of oxide is formed. The appearance of certain lines in the spectroscopic appearance of the flame is employed to find the proper time for leaving off, but it is often determined by eye alone. Before pouring out, however, comes the addition of manganese, which is absolutely necessary in this plan; as from the method of manufacture a good deal of ferrous oxide must necessarily be formed; the "blow" is continued for rather less than a minute, after which the steel is poured out into the ladle, when it is sometimes stirred by means of an "agitator" to distribute the manganese and produce uniformity. The ingot casting is the same as in the "open hearth" system. The rapidity of this plan enables an enormous output to be made with a moderate plant, as each "blow" lasts less than half an hour to produce 6 to 12 tons of steel, but this very rapidity prevents the careful control over the results which can be exercised in the last method; in a large firm this can be allowed for by sorting the ingots produced, and applying each to the purpose for which it is most suited; but it is most difficult to know what will be the exact proportions of carbon and the other qualities of any particular "blow." It does not appear at present to be well suited for the manufacture of ordnance; and the following extract from the "Proceedings of the American Society of Civil Engineers" about the Monongahela Bridge, Pittsburg, seems to represent the facts concerning the employment of this steel for work of the higher qualities: "The difficulty seemed to consist in controlling the uniformity of the steel within close limits for quality and strength with the Bessemer process. After a while, the attempt was given up, and the 'open hearth' was substituted—no trouble was then experienced in getting a uniform grade of steel of prescribed quality." Some 42,000 tons of "open hearth" steel will be used in the construction of the Forth Bridge. Bessemer steel is very much used for rails, and also for a great variety of other purposes, including compound armor.

When steel is to be forged, it is cast into an ingot mold of a very simple form, efforts being made, by the use of silicon, either in the pig or in a special mixture, or by fluid pressure as used by Whitworth, to get rid of blow-holes; the ingot is taken out, reheated, carefully inspected, cracks cut out, and it is then either hammered, rolled, or pressed to the required shape, great care being taken about the temperature. In order that the blows may be well transmitted through the mass, it appears that very heavy hammers are now generally preferred, probably because mild steel is not in as soft a condition as wrought iron when forged. As large masses of steel are now worked, it is probable that the numbers of already existing very heavy hammers may be increased, unless Whitworth's method of hydraulic pressure be employed instead; and this now appears to be very generally preferred; great progress has been made in some of the leading factories abroad; and this seems an important matter for English manufacturers to consider, with reference to the large masses required for ordnance. Larger ingots have been produced in France and Germany than in England.

Increase of tenacity can be obtained by the important operation of tempering, but this is at the expense of elongation before fracture. The temper obtained varies with the amount of carbon in the steel, the temperature and the nature of the cooling material—rape oil—being generally considered the best for large masses, as it has a less conducting power than water, and cools the metal more slowly. Krupp is said to temper his steel at a uniform heat; while our plan for ordnance is to temper a test piece at 1,450 deg. F., and if this does not give good results, the temperature is varied within certain limits, and then the whole mass is treated in the same way as nearly as possible, as the test piece which gave the best results. Tempering lowers the specific gravity slightly, consequently warping and surface cracks are often produced by this operation, when large masses are acted upon. The Schneider steel plate at the Spezzia experiment in 1882 was tempered on the face to gain hardness, and it consequently warped so much that it had to be planed off at the corners to make it fit the frame it was placed in. Gun tubes often develop surface cracks after tempering, but sufficient thickness of metal is allowed so that they may afterwards be cut out in the lathe.

With steel castings, every effort is made to get rid of blow-holes; this generally involves (for all good work) a very considerable deadhead, which adds to the expense, and has to be cut off. Annealing for several days is resorted to by some, while others are content with slow cooling in hot ashes; tempering is sometimes used for special purposes, such as the head of an armor-piercing projectile, though it cannot be said that cast-steel projectiles are as yet very successful for armor-piercing purposes against steel or compound armor. Great progress has recently been made in steel castings; and they are now used for a great variety of purposes; some cast trucks have been subjected to very rough treatment, and yet they have not shown any signs of fracture,but have simply bent out of shape. Swedish castings now being exhibited by Mr. Nordenfeldt have attracted very great

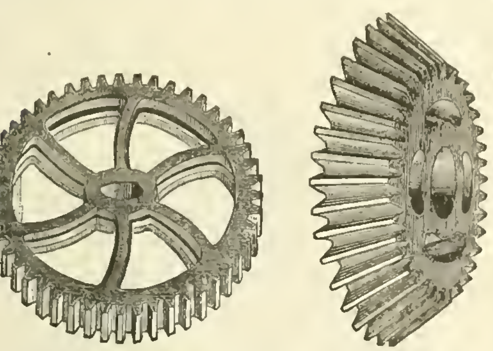

Fig. 2.
Examples of steel castings of complicated forms. Messrs. Hadfield & Co.

attention on account of their soundness and excellence; a very high temperature is obtained when melting the steel, and liquid fuel is employed. In designing the shape of a casting, sharp corners and great differences of thickness must, if possible, be avoided on account of the difficulties of preventing unequal strains tending to produce rupture in contracting on cooling down.

A great variety of tests are applied to steel in different places, according to the purpose for which it is required; latterly there has been a growing tendency towards uniformity; the workmen's rough tests of bending, breaking, and observing the fracture has been systematized in various pulling machines, actuated by a dead weight or by levers, or by hydraulic pressure, by all of which the limits of elasticity and tenacity are indicated; bending and torsional tests are also often applied, and in other cases dynamical trials are made, as by dropping heavy weights on to rails, or by exploding gun-cotton, as is sometimes done with boiler plates, which are made of very mild steel, having but little carbon.

For ordnance, the tension and bending tests are generally sufficient; the elasticity, tenacity, and elongation are carefully recorded, and the area of the fracture and its general appearance are also noticed both before and after tempering. In gun manufacture the behavior of the tempered test piece serves as a guide for the treatment of the mass from which it came; but it appears now to be generally acknowledged, that the same heat will cause a different temper in a small test piece, and in the large mass, as the latter will cool so much more slowly,and will not, therefore, be so much affected as the smaller piece. It seems a sound method to proceed (as it is believed the French do) to cut a piece off the tempered mass and then test it, and the result will be a more certain knowledge of the tenacity etc., really attained—more particularly as with all the care at present used, it is not possible to be quite sure that the large mass is brought to the same heat as the test piece was. The elongation on fracture has of late attracted attention, as it is a well recognized fact that a short test piece will elongate much more per cent. of its length than a longer one of the same material; this is explained by the circumstance that as the elongation is only considerable just immediately at the point where rupture takes place, the *total* elongation of the long piece is not actually

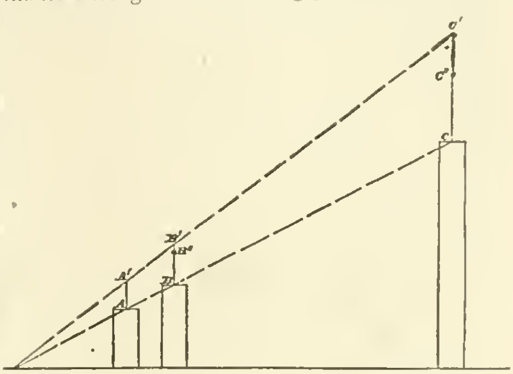

Fig. 3.
Showing loss of elongation per cent. in test pieces of thin proportions, but of the same material.

The dotted lines A B C, A'B'C" are drawn to indicate similar elongations A A', B B', C C".)

much more than that of the short piece, and is consequently less in proportion to its length—or the elongation per cent. of its length is less—(*vide* Fig. 3, where a test piece of Whitworth's dimensions is supposed to elongate an amount A A; if the same material is made according to Royal Arsenal pattern, it will only elongate BB", instead of BB' which would be in the same proportion as the last, while if the test pieces are still longer, the elongation CC" is even less per cent;) thus if a test is taken according to the Woolwich plan, it will not give such a favorable result as by the Whitworth method unless the differences in the proportions of the test pieces are taken into account. It is usual to say that the elongation is so much in a test piece of so many inches, but this is not really correct, as a thick piece will elongate more than a thin one: it is now proposed that all test pieces shall be of the same proportion of length to thickness.

It is important that the tests imposed should be reasonable and possible, but this apparently has not always been the case, as, for instance, when iron was first employed in the construction of ships,the test employed by Lloyd's was the single one of good tenacity, irrespective of elongation, before fracture; the consequence was that much inferior brittle iron was built into many a vessel, accounting, doubtless, for numbers of casualities. On the other hand, to show the advantage of good elongation before fracture, many instances have occurred of steel vessels grounding on rocky places, when the bottom plates have been bent and crumpled, but not fractured, as they doubtless would have been if they had been brittle, although with a high tenacity. Going to the other extreme, the demands for tenacity *and* elongation, within certain limits of temperature for tempering, have been so high in some specifications that it has not been found possible to come up to the standard when large masses have been supplied; the steel has in some cases been rejected wholesale, whilst at other times it has been passed, when the tests being set aside became useless.

Not only are mechanical tests employed, but the chemical composition of steel is found by quantitative analysis in a most systematic manner; and each large factory has a regular laboratory, with one or more analysts, a class of men created by the requirements of the steel trade, in which sound scientific training in those concerned is a *sine quâ non* for successful manufacture.

The tests imposed by the Ordnance Committee on large masses of steel appear to have been very stringent, and manufacturers have found a difficulty in complying with the conditions, but the making of steel in the Royal Arsenal has given a decided impetus to gun steel, which differs somewhat from that required for most other purposes. The French Government, intent upon progress, have insisted on rigorous tests for steel which their own makers at first declined, but afterwards agreed to comply with; in the meantime, however, a large contract was given to a foreign firm. It would appear to be the wisest course to insist on obtaining the very best material for gun steel.

The amount of steel used for naval and military purposes bears only a small proportion to that which is used for ordinary industries, and this ratio varies greatly in different countries, being probably highest in Russia and lowest in the United States. A great part of the steel for warlike uses can only be produced by special plant on a colossal scale—thus we hear of 100-ton hammers, immense rolling mills for armor, 160-ton cranes, a tank containing 100 tons of oil for tempering, railway trucks for taking immense weights, and tools for machining enormous masses of metal. The number of factories in the world where the heaviest guns and armor can be produced is thus necessarily limited.

About two years ago a most important decision was made that English ordnance, of all calibers, was in future to be constructed entirely of steel, and wrought iron coils were abandoned, as there was no longer a doubt that steel is much superior to wrought iron for this purpose, from its greater strength. This has been especially noticed with guns firing the modern large charges of slow-burning powder. The steel for ordnance should be of such a quality as to possess a considerable elastic limit, so that permanent deformation or enlargement of the bore may not take place to any appreciable extent, its *uncertainty* being always urged as a reason for its non-adoption in the service as long as wrought iron was used in manufacture. It appears, however, that reliability and uniformity are now being attained, though only by most unceasing and intelligent care in all processes of manufacture. Especially is this recognized to be the case where very large masses are forged, as the difficulties in obtaining uniformity in the mass become greatly increased. The percentage of carbon is about 0.4 to 0.45 with crucible steel when the manganese is low; but with the "open hearth" steel the percentage is a good deal less (0.28 to 0.31) when more manganese is present.

A modern heavy steel gun is constructed as follows: The tube is made from the ingot by repeatedly and alternately heating and drawing out under the hammer, and a core is then cut out or trepanned and thus most of the material cut to pieces in the ordinary process of boring is available for other purposes; the process is also quicker. Whitworth proposes, however, to proceed in a different manner, suggesting the plan adopted with such success by his firm in forging hollow propeller shafts, which are made thus: An ingot is bored, and the shavings remelted; the interior containing a higher percentage of carbon and other constituents, is not considered of sufficiently good quality for further use without remelting. The hollowed ingot or cylinder is then heated, a hollow steel mandrel of smaller diameter than the interior is passed through it, and both are

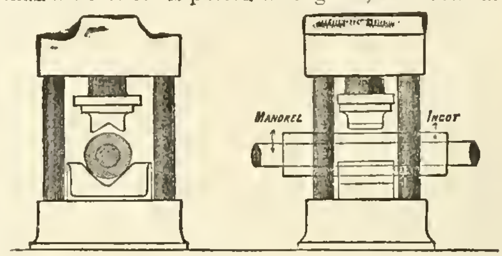

Fig. 4.
Whitworth's Hydraulic Forging Press. Drawing out a Tube.

placed in the powerful hydraulic pressing machine, which presses the metal of the cylinder against the mandrel by repeated pressings while the cylinder and mandrel are turned round into fresh positions (Fig. 4); the consequence is the hollow cylinder becomes gradually less in diameter, but increases in length. this process is repeated with thinner mandrels and repeated heats until the cylinder assumes the desired proportions of the propeller shaft; the mandrels are kept cool by water circulating through them. No service gun tubes, except those supplied through the Elswick Company, have yet been made in this manner, though it may possibly be adopted for some of the largest.

The hoops for service guns are also made from the ingot, which is trepanned, the ends cut off and remelted, and the rest is cut into thick rings, each of

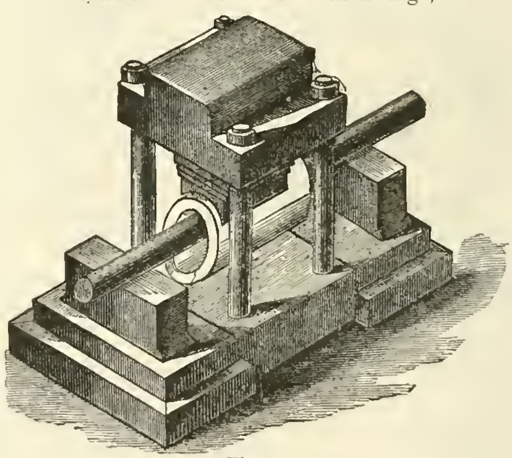

Fig. 5.
Whitworth's Hydraulic Forging Press. Enlarging a Hoop.

which is afterwards heated and made thinner by hammering on a mandrel placed through it and supported at each end (the hoop is thus suspended on the mandrel). This operation naturally increases the diameter, and the manufacture resembles that of the weldless tires of railway wheels. Whitworth makes some hoops in this way, substituting the press for the hammer (see Fig. 5), but he proposes to construct others in the same way as the tube, in the form of long, thin cylinders, and thus the heaviest guns could be made of fewer parts than those at present designed. For instance, the 110-ton gun is intended to be made of forty-three parts, but one of Whitworth design would consist of only eleven pieces. The new English heavy guns are now required in large numbers for the Navy, and also for the coast defenses of England and the Colonies, and every effort should be made to supply them with all the rapidity consistent with efficiency. The steel for the 110-ton guns is being made by Whitworth and Cammell, and the forgings will be handed over to the Elswick Ordnance Company, who will machine them and build up the guns. In a few months time Whitworth's fine establishment will have all the tools necessary for completing the heaviest guns, and Elswick will probably have the plant for casting and forging the heaviest ingots; the country will then possess two complete establishments to supplement the Royal Gun Factories, and there are of course several other firms which can produce excellent steel in large masses, and who are accustomed to the working of heavy steel forgings. Care should be taken that thoroughly reliable guns are produced, and close inspection should be insisted on during manufacture, as well as rigorous proofs, before the guns are admitted in the service. Military *matériel* has before now been neglected in our country for years during peace time, from indifference or on the score of economy; then suddenly, when the need for it has been felt, on the outbreak of war, a hurried order has been given for large quantities; this is an expensive plan, as a high price is necessarily charged under such circumstances, and it is difficult to make proper inspection: it is far the wisest plan to proceed methodically and diligently while there is time.

The barrels for small arms are made of mild steel from the bar, in an ingenious machine with a series of vertical and horizontal rolls, which in one heat draws out the barrel to the required length with accuracy. This has been in use some six years at Enfield, and copies have since been supplied by an English firm to several foreign governments. The bayonet is made of a hard steel welded by the aid of borax to a socket of softer steel; great care being taken not to overheat the end of the bar, which will form the blade, while the socket being milder, is made much hotter; the tests to which bayonets are subjected before being passed into the Service have lately been made a good deal more severe than before the late war in the Eastern Soudan.

The increased strains which the large charges of modern guns impose on gun-carriages have necessitated the employment of steel in their construction, in order to obtain the necessary strength; and steel plates and axles are now freely used, as in the 13-pr., but wrought iron is still preferred for some parts, as for instance the trail eye of a field gun-carriage, which is subject to constant jars. Steel castings are much used for heavy gun carriages; some of 55 cwt. each have been made in considerable numbers for the sides of 43-ton gun-carriages; and steel castings on a grand scale are contemplated for the proof carriage of the 110-ton gun. Steel racers have long been introduced for use with some of the heavier garrison guns, as they well resist the blow caused by the jump of the platform on firing, which indented the older and softer wrought-iron racers, and rendered subsequent traversing a difficult operation; the path and twenty-eight rollers of cast iron on which the turrets of the *Inflexible* revolve have not been found hard enough; in future they will probably be of steel. Tubular steel linings are employed for the cylinders of Vavasseur mountings; and corrugated steel plate has been tried for field artillery ammunition boxes and appears to succeed.

Steel has been applied to shells with great success, but at present the expense is considerable. Shrapnel are made for the 7-pr. and 12-pr. of Delmard's tubes, with thin walls and bursting charge in the head; the proportion of useful weight in the former being 45.4 per cent., while in other natures it is 25 per cent., and often much less. Steel has been tried for common shells, as they do not break up so often on striking earth as cast-iron shells. An example of the advantage of their use was furnished by an experiment, when a parapet was more readily breached by a 12-pr. with steel shells, than by a 5-in. gun with 50 lb. cast-iron ones, the velocities being about the same in each case: the walls of steel shells being made thinner than those of cast-iron a larger bursting charge can be inserted. By lengthening shells and compressing the powder, it has been found possible to more than double the bursting charge; thus with the 6-inch gun the bursting charge in the ordinary common shell is under 7 lbs., but long steel ones have been made holding 16 lbs. of compressed powder; this increase is most important when destroying earthworks, etc. Krupp has done a good deal in this direction. It is doubtful which is the best way to apply steel for these purposes, whether to cast it at once to the required shape or to forge it; the first is the simplest and cheapest way: but at present difficulties are apt to appear with blow-holes which may lead to fracture in the bore when the walls of the shell are thin; however, with recent improvements in casting steel, this objection may very possibly be overcome.

Another plan is to cut off lengths of tubular steel heat it, bend in one end for the head, and turn in and close up the other end for the base, or else weld in a base disk; another device has been ingeniously employed of cutting off a piece of thick bar steel stamping it into a hollow, and drawing up the sides gradually when heated to form a shell. With regard to armor-piercing projectiles, some few years ago experiments were made at Shoeburyness with 9-inch projectiles, with striking velocity about 1,500 f. s., to determine the best material of which they should be made, and also the form of head, etc. The general result was that forged steel (from Sir J. Whitworth and Co.) was decidedly the best, but at the same time it was very expensive; since then, however, conditions have altered, and not only is the striking velocity of modern projectiles often considerably above 1,500 f. s., but the steel and compound armor of ships now being made is harder than the wrought iron plates which were formerly employed. Consequently, the projectiles break up, and it cannot be said that the present shells are quite satisfactory. Careful experiment is needed to find out the best methods to pursue. It is to be hoped that the subjects of steel armor piercing projectiles for the heaviest guns may be thoroughly gone into, and the best material for the purpose employed.

At the present time the Service Palliser cast iron chilled shells do very great damage to the targets, but they break up in doing so. Krupp has produced a good armor-piercing projectile, and the French Navy has for some years past been provided with steel armor-piercing shells for 32 and 19 cm. guns, all supplied by contract under severe tests for reception. The following conditions were imposed some time ago when the French Government invited their steel makers to supply a large number (2,100) of armor-piercing projectiles for 32 and 27 cm. guns: the conditions imposed appear to be somewhat severe, and show that a high standard of excellence is desired. The total number is divided into four for each caliber, and the behavior of two shells tested out of each lot will determine the acceptance or rejection of the others. The heavier projectiles are to be fired almost at right angles against a 30 cm. Creusôt steel plate with wood backing with striking velocity of 435 to 445 meters per second, while the lighter ones will strike a 25 cm. steel plate with a velocity of 455 to 465 meters per second. If the first projectile perforates the target unbroken and uncracked, the lot to which it belongs is to be at once accepted; but if it breaks up in perforating, the second projectile will be fired, and only if it gets through uninjured will the lot be accepted. If the first round does not perforate the target, the lot will at once be rejected. Facilities were given to allow the makers to fire trial shots against steel plates before submitting their finished shells.

Nordenfeldt bullets for penetrating the sides of torpedo-boats are forged from steel bars by drawing down a part to form two heads; pieces are then cut off, stamped to true shape in a die, and oil tempered. Compound armor is constructed on two plans by the only two firms which at present manufacture it in England.

The Atlas Works (Sir J. Brown & Co.) make it on Ellis's patent; a considerable thickness of wrought iron and a thin steel face plate are kept at a few inches distance from each other, with wedge plates round three sides, and small steel studs at several points keep them from coming too close to each other in the furnace; the whole mass is then strongly heated with the plates horizontal; when hot enough it is taken out and lifted by a crane, swung vertical, placed in a pit, and melted steel is poured from a large ladle into a trough which distributes little streams into the cavity between the two plates and joins them together; in a short time the whole plate is taken up and put back again into the furnace; when reheated, it is taken out, and the whole is passed through the large rolling mill.

In Wilson's plan, adopted by Cammell and Co., a large wrought iron plate built up of many thicknesses is passed through the rolls, and is then pushed horizontally into a huge iron chamber which can revolve on trunnions; when the plate is secured, the whole is turned up and becomes vertical, and liquid steel is poured in from a ladle and trough, between one side of the wrought iron and the side of the box, precautions being taken to prevent it from flowing elsewhere. In Wilson's plan the steel was formerly poured on to a wrought iron plate provided with a rim and placed horizontally; but this was given up, as the scum, etc., tended to remain on the face of the plate. The whole is afterwards rolled.

The steel constitutes about one-third of the weight in both systems, its object being to break up the projectile on impact; it consequently has a considerable amount of carbon in order to give it the necessary hardness, while the wrought iron at the back of the plate is intended to hold the plate together, and to prevent the formation of cracks and splits as far as possible. This class of armor has achieved good results: the experiments at St. Petersburg and at Spezzia during the last two or three years, as well as some made at Shoeburyness, having been favorable. Ellis's plan has the advantage of a very good front surface, but the results attained by each are generally considered to be about the same as far as present experience has shown. The resisting power of compound armor is greater than that of wrought iron, and consequently a less weight will give as great protection under ordinary circumstances, and it is coming into use on board ships; on land, however, it will probably be little used, except, perhaps, in some very confined situations. Wrought iron of equal resisting power, but of greater weight is cheaper.

The injury sustained by wrought iron when it is struck is generally local; but compound armor tends to split over a considerable area, and is not well calculated to resist blows falling close together. Very good estimates can be formed beforehand by calculation of the probable penetration of wrought iron, if the plate be of ordinary quality, but the resisting power of compound armor is at present difficult to foretell; it depends more, perhaps, on the total weight than on the thickness of the plate, and the nature of the backing has a most important influence on the resistance offered. It has been suggested that a considerable number of experiments might profitably be made on a small scale in order to endeavor to determine the value of various alterations in its arrangement. Compound armor is now made in large quantities in Russia, Germany, and France on the Wilson system; in the latter country there are three factories busily engaged and in Germany the Dillengen works have been in operation for two years producing compound armor for the three ships *Oldenburg*, *Bremse*, and *Bremmer*. The Russian works at Kolpino, 16 miles from St. Petersburg, are just completed, and the first of their compound armor-plates, under an English director, are now being manufactured. The works will probably be well employed, as the Russians are rapidly developing their navy, and six large armor-clads are fast approaching completion. Excellent steel armor has been made at Le Creusot, of a milder quality than the face plates of compound armor, and it has given good results when tested at Spezzia, in competition with compound armor. Thin shields are used for the protection from musketry fire of men working machine-guns; they are $\frac{1}{4}$ inch thick, and oil tempered; the resisting power is considerably better than that of wrought iron.

Steel enters into the construction of a variety of warlike stores, notably in torpedoes; the beautiful air receiver before us is a good example of the finest work, forged from a bored-out ingot, oil tempered, and accurately turned down till the metal is very thin. It is most carefully tested to make sure that it will sustain the pressure of the compressed air which drives the engine in the Whitehead torpedo; and the hollow torpedo propeller shaft also presents a good example of a weldless steel tube of great strength. Tubular steel also comes into use in rocket cases and in sockets for tent poles, in which strength and lightness are combined. Large quantities of compressed hay have been sent out to Egypt bound round with Bessemer steel wire. A very interesting and recent example of the use of welded steel tubes is furnished by the gas vessels which contain compressed hydrogen for military balloons. These have only been developed during the last few months, and 150 are now in South Africa with Major Elsdale, R. E., who hopes to make good use of them under Sir Charles Warren. It was considered difficult to make hydrogen in the field, and therefore the plan was adopted to carry it in strong receivers. Various makers were asked to produce this rather novel work, and many responded, with the result that the pattern shown by Mr. Delmard was considered far the best, as it holds more than any other with due regard to weight and safety. Each vessel is proved before use, and it must not show signs of any permanent enlargement when charged with a test pressure very considerably in excess of that which it will have to stand when the hydrogen is stored in it. Some said that under such high pressure the gas would get through the thin metal; but as a matter of fact it does not do so, and some vessels have remained fully charged for months. It will be most interesting to hear how this contrivance will answer on active service. The receivers can easily be transported; the weight of gas in them is only 12 ozs. when fully charged, and they will float in water. In fact some fully charged have been formed into a raft. Somewhat similar vessels are also employed for carrying oxygen and hydrogen under great pressure for use with the lime light when signalling. See *Steel*.

MILEAGE.—An allowance of eight cents per mile paid to officers for travel. To entitle an officer to mileage the travel must be performed *without troops*, and be covered by a specific order in the case issued by a superior officer previous to commencement of the journey. Suco orders are issued only where the journey is on account of and necessary to the public service. Distances must "be calculated by the shortest usually traveled route," no matter by what route the travel was performed. Exception to this rule may be made only when the terms of the order, or impracticability of the "shortest usually traveled route," compel the officer to proceed by a longer route. In such cases mileage may be paid for "each mile actually traveled." Lists of distances are furnished by the Paymaster General. Mileage cannot be allowed for such part of a distance as lies over that portion of a "railroad on which the troops and supplies of the United States are entitled to be transported free." Officers whose orders entitle them to mileage may exercise the option of "mileage" for the entire journey (free railroads excluded); or of "transportation in kind" for the entire journey; or of "mileage" and "transportation in kind" for different parts of the same journey. But mileage cannot be allowed for any distance for which transportation in any other form has been furnished by the United States. Advance mileage may by paid, without special authority, when the distance to be traveled, exclusive of any part which may by embraced in the list of free roads, is not less than two thousand miles. This will not apply, however, to journeys in which the order contemplates delays at intermediate points affording opportunity to collect mileage for completed travel. In the following cases no expense of travel is allowed: In joining for duty upon first appointment to the military service; or under first order after reinstatement, reappointment, or revocation of an order of dismissal; or to effect an exchange of station, or a transfer from one company or regiment to another when the same is made at the request of the parties. Excepting only in the following cases: Assistant Surgeons, approved by an examining board and commissioned, joining for duty under the first order; graduates of the Military Academy, from West Point to their stations; enlisted men journeying under first order after appointment or commission.

MILES.—A soldier of the Middle Ages, usually of noble or knightly rank. He went to the wars, mounted on a good war-horse and followed by an escort, more or less numerous in accordance with his own rank and means, composed of vassals and serfs, who were equipped with slings, bows and arrows, cutlasses, and spears.

MILITARY ART.—Military art may be divided into two principal branches. The first relates to the order and arrangement which must be observed in the management of an army,—when it is to fight, to march, or to be encamped. This branch is generally known under the name of *tactics*, which signifies order. The second belongs to the other branch of military art, and includes the composition and application of warlike machines.

MILITARY ASYLUM, ROYAL.—An educational Government Institution at Chelsea, near, but wholly distinct from, the Royal Hospital for Pensioned Soldiers. Its object is the suitable education for trade, etc., of 500 male children—generally orphans—of British soldiers. For these, there are a Model School and an Infant School, and the boys have a completely military organization, with scarlet uniform, band, etc. As a result of their training, a large proportion of the pupils ultimately volunteer into the army. This school was originally established in 1803 by the late Duke of York, whence it is still commonly known as the "Duke of York's School." Originally a similar school for soldiers' daughters was included, but was not found to answer, and has been discontinued. Attached to the school is a training establishment for military schoolmasters, known as the Normal School. The total cost of the whole Institution is about £11,500 per annum.

MILITARY BRIDGE.—A temporary construction, to facilitate the passage of rivers by troops, cannon, and military wagons. The most efficient are described under PONTOON; but there are many other kinds. A *bridge of boats* is formed of small-craft, especially cargo-boats, collected from various places up and down the river; trestles are placed in them to bring their tops to one common level: the boats are anchored across the river, and baulks of timber, resting on the trestles, form a continuous road from boat to boat across the whole breadth of the river; the boats ought to be of such size that, when fully laden, the gunwales or upper edges shall not be less than one foot above the water. *Rope-bridges* are sometimes, but not frequently, used by military engineers. A *boat-and-rope bridge* consists of cables resting on boats, and supporting a platform or road of stout timber. A *cask-bridge* consists of a series of timber-rafts resting on casks; the casks are grouped together in quadrangular masses; at certain intervals timbers are laid upon them to form rafts, and several such rafts form a bridge; it is an inferior kind of pontoon-bridge. A *trestle-bridge* is sometimes made for crossing a small stream in a hilly country; it consists of trestles hastily made up in any rough materials that may be at hand, with planking or fascines to form a flooring, cables to keep the trestles in a straight line, and heavy stones to prevent them from floating. *Raft-bridges*, consisting of planks lashed together, are easily made of any rough materials that may be found on the spot; but they have little buoyancy, and are not very manageable. A *swing-flying bridge* consists of a bridge of boats, of which one end is moored in the center of the river, and the other end left loose; this loose end is brought to the proper side of the river, the boats are laden, and they make a semicircular sweep across the river, by means of rudders and oars, until the loose end of the bridge reaches the other bank. A *trail-flying bridge* is a boat or raft, or a string of boats or rafts, which is drawn across a river by ropes, in a line marked out and limited by other ropes.

History has many examples of the use of military bridges. The first of magnitude, of which we have detailed accounts, was the one built of boats, over the Hellespont, by Xerxes, when he invaded Greece, nearly two thousand four hundred years ago. This bridge was about one and one half miles long, and was composed of two roadways. One was used by the troops; the other by the baggage train and camp followers. It is said that the number with him was 5,283,220, and that they were seven days and nights in crossing. Bridges across the Tigris resting on boats are mentioned by Xenophon. Alexander the Great used skins of animals inflated, or filled with hay, as floats in crossing streams, as shown in his passage of the Oxus. The Romans carried with their armies small boats and bridge material, when rivers intersected their lines of march. An example of a military bridge resting upon fixed points of support is described in the fourth book of "Cæsar's Commentaries." This bridge was across the Rhine, and was of sufficient strength to meet all the demands made upon it. We find many descriptions of military operations along the Rhine, and of the means used to pass this river, by armies operating along its banks. The same may be said with reference to the Danube. History records, in many cases, the failures arising from a want of a military equipage, and the disasters averted by the use of such equipage, or by the construction of an improvised bridge from the materials found in the neighborhood. The want of a bridge equipage was particularly felt by Bonaparte in his campaign in Italy, in 1796. The presence of such an equipment would have enabled him to cross the Po in time to place his forces in the rear of the Austrians, and would have avoided the forcing of a passage over the Adda, at Lodi. The importance of bridge equipages was particularly felt by the armies of the United States in the war of 1861–5. The delay in the arrival of the bridge material was, on more than one occasion, a cause of disaster. No better example of the importance of a bridge equipage and the value of skilled pontoniers can be given than the single instance of Napoleon's crossing of the Beresina, in 1812, in his retreat from Moscow. See *Bridges* and *Pontoon*.

MILITARY COLLEGES.—The great improvements made in the art of war in late years, in weapons and discipline, makes a demand for a body of trained officers capable of moving, directing, and bringing into effective operation the modern appliances of war. As this special training cannot be obtained at the few Government Institutions and ordinary educational establishments, it has become the policy of most governments to encourage a study of military science by establishing military departments in the various State and private Colleges. In the United States, officers of the army are detailed as professors at Colleges and Universities as follows:— The details are apportioned throughout the United States as nearly as may be practicable according to population; such States as do not contain sufficient population to entitle them to one officer are grouped with one or more contiguous States or Territories, so that the combined population of the group will allow the detail of one or more officers, to the extent of thirty officers in all. As a rule Captains of Companies, Regimental Staff Officers, or officers who have served less than three years with their regiments or corps, or who have recently completed a tour of detached duty, are not eligible. No details are made that will leave a battery, troop, or company without two officers for duty with it. The period for detail is not longer than three years. Retired officers, if acceptable to any Institution, may, on their own request, be detailed on this duty among the thirty authorized. Besides this number, any retired officer may arrange to serve at a College or University without detail from or reference to the War Department; but unless *detailed* under section 1225, Revised Statutes, such service will not entitle the institution to the arms, etc., provided by that section. No detail is made for any Institution except upon an application from its proper representatives, nor is any other so detailed, unless acceptable to the authorities of the Institution, who should make their selection from the officers available for this duty. Applications for officers should be addressed to the Secretary of War, and should duly certify the number of male students the College or University has the capacity to educate, and should also be accompanied by the last printed catalogue. Officers of the army desiring a detail at Colleges or Universities may make application to the Adjutant General, through the usual military channels; their applications and the recommendations forwarded therewith will, if the officers are available, be furnished to such Institutions as may desire to make a selection.

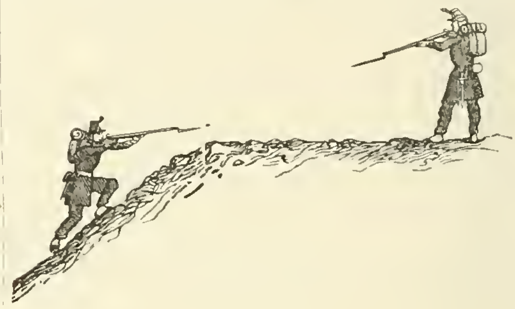
Issue of stores, limited to the following, will be made, under section 1225, Revised Statutes, by the Chief of Ordnance to any selected Institution upon its filing a bond in the penal sum of double the value of the property, conditioned that it will take good care of and safely keep account for the same, and will, when required by the Secretary of War, duly return the same, within thirty days, in good order, to the Chief of Ordnance United States Army, or to such officer or person as the Secretary of War may designate to receive it.

2 3-inch rifled guns, wrought-iron, model 1861, at $450,	$900 00
2 carriages and limbers, 3-inch gun, at $325,	650 00
2 gunners' haversacks, at $3,35,	6 70
4 lanyards, at 10 cents,	40
2 priming wires, at 10 cents,	20
2 handspikes, trail, at $1,	2 00
4 sponges and rammers, 3-inch, at $1,	4 00
4 sponge covers, 3-inch, at 30 cents,	1 20
2 tube-pouches at $1.50,	3 00
4 thumbstalls, at 20 cents,	80
2 tompions, 3-inch, at 30 cents,	60
2 vent-covers, at 40 cents,	80
1 pendulum hausse, 3-inch,	2 50
1 pendulum hausse seat,	60
1 pendulum hausse pouch,	75
2 paulins, 12 by 15 feet, at $11,75,	23 50
150 Springfield "cadet" rifles, cal. .45, with appendages, etc., at $18,	2,700 00
150 bayonet scabbards, steel, "cadet," at 91 cents,	136 50
150 waist belts and plates, at 50 cents,	75 00
150 cartridge-boxes, cal. 45, at $1.25,	187 50

For practice-firing the following allowances of ammunition will be made annually to each of the various institutions, viz: 1,000 carbine metallic ball-cartridges, cal. .45; 1,000 metallic blank cartridges, cal. .45; 100 rounds blank cartridges for 3-inch gun; 300 friction primers. This ammunition is issued upon requisitions, which should be forwarded to the Chief of Ordnance by the presidents or superintendents of the institutions. See *Military Schools*, and *Post Schools*.

MILITARY COLUMN.—Among the Romans a column on which was engraven a list of the forces in the Roman Army, ranged by legions in their proper order. They had another kind of *Military Column* called *Columna Bell'ca*, standing before the Temple of Janus, at the foot of which the Consul declared war by throwing a javelin towards the enemy's country.

MILITARY CREST.—A common expression for the top line of a slope. The drawing shows how the defender (who, while standing near the military crest, uncovers only his shoulders and observes



the whole body of the assailant as he climbs the ascent) will, on receding from the crest, place himself below the prolongation of the slope and lose sight of his climbing adversary. At the same time, he will receive the enemy's grazing fire as the latter ascends to the crest. See *Interior Crest*.

MILITARY DECORATION.—A medal, cross of honor, etc., bestowed for distinguished services.

MILITARY DEPARTMENT.—A military sub-division of a country. The whole territory of the United States is divided into Military Departments, each being under the command of a general officer. See *Geographical Departments and Divisions*.

MILITARY DISCIPLINE.—The obedience to and exercise of all orders and regulations which have for their object the good government and management of a regiment or army. In fact, discipline may be defined as the perfection of order and regulation in an army. To it may be attributed in the day of battle much of the success which has attended the arms of a nation. Without it, an army becomes a rabble; and though bravery will do much towards achieving success, it is by discipline mainly that the object of a war can be ultimately attained. In the United States service, the following regulations in this connection are observed: All inferiors are required to obey strictly, and to execute with alacrity and good faith the lawful orders of the superiors appointed over them. Military authority is to be exercised with firmness, but with kindness and justice to inferiors. Punishments shall be strictly conformable to military law. Superiors of every grade are forbidden to injure those under them by tyrannical or capricious conduct, or by abusive language. Courtesy among military men is indispensable to discipline; respect to superiors will not be confined to obedience on duty, but will be extended on all occasions. Deliberations or discussions among any class of military men having the object of conveying praise or censure, or any mark of approbation toward their superiors or others in the military service, and all publications relative to transactions between officers of a private or personal nature, whether newspaper, pamphlet, or hand-bill, are strictly prohibited. See *Discipline*.

MILITARY EXECUTION. The punishment inflicted by the sentence of a Court-Martial; also the ravaging or destroying of a country or town that refuses to pay the contribution inflicted upon them.

MILITARY FIRST PRINCIPLES. The bodily training for a soldier, to make him hardy, robust, and capable of preserving health amidst fatigue, bad weather, and change of climate; to march at such possible pace, for such length of time, and with such burden, as without training he would not be able to do.

MILITARY FRONTIER. The former name of a narrow strip of land along the Turkish frontier of the Austro-Hungarian Empire. It had a special military constitution and formed a separate "Crown-land." Of late, however, the peculiar institutions of the Military Frontier have been abolished; portions of the territory have been incorporated with adjoining provinces; and since 1873 the remainder of the Military Frontier, now officially termed the Croato-Slavonic Border-land, forms, along with Slavonia and Croatia, a dependence of the Hungarian Crown. The Constitution, civil and military, is now accordingly similiar to that of the other Provinces of the Hungarian part of the Empire. The area of the Military Frontier was about 7,500 square miles, and its population in 1869 was 690,300. The breadth of the territory once known under this name is considerable towards the western extremity, but diminishes to only a few miles at the eastern. The surface has an average elevation of upwards of 2,000 feet. All the important rivers flow eastward. The climate is severe in the highlands of the west, but mild in the lower districts toward Slavonia. Maize, wheat, oats, fruits, and vegetables are the principal productions. The Military Frontier owes its origin as a Crown-land to the necessity of having a permanent body of defenders on the borders during former wars, and especially during wars with the Turks. In the 15th century the Austrians had gained from the Turks certain tracts of territory on the banks of the Save and Danube. These tracts they colonized, making it, however, a condition that the Colonists must render military service against the Turks. Thus originated the Capitanate of Zengg, during the reign of Mathias Corvinus. The Warasdin Frontier originated in the same manner in the 16th, and the Banat Frontier in the 17th century. The Constitution of the Military Frontier, as it existed till 1873, has been thus described: The military stations along the frontier serve a threefold purpose—the defense of the country, the prevention of smuggling, and the prevention of the spread of contagious disease into the territories of the Austrian Empire. The inhabitants of this Crown-land enjoy peculiar privileges. Their immigrant ancestors received only the temporary use of lands consigned to them; but in 1850 a law was passed making over the land to the occupiers as their own property. This right of property does not belong, however, to individuals, but to the family in a united sense. The oldest member of a family (called the *Hausvater*) is intrusted with the management of the land; his partner (the *Hausmutter*) ranks equal with him, and they each receive a double share of the profits for the year as recompense for the management of the estate. A family of this sort is called a border-house (*Grenzhaus*). All who are able to bear arms are sworn to the service from their 20th year. The soldier of the frontier, who is clothed as well as armed and supplied with ammunition by Government, finds it his duty not only to watch and protect the frontier, but to preserve peace and order in the interior, and to go on foreign service when required. Only the smaller portion of the forces of the Military Frontier is retained in readiness for active service, while the remainder pursue their ordinary employments. To facilitate the accomplishment of the purposes aimed at by the Military Frontier, the *cordon*, a series of guard-houses along the frontier, affording accommodation to from four to eight men, as well as larger ones accommodating twelve men and a junior officer, has been instituted. Within this line are the officers' posts. Without announcing himself at the posts, no one is allowed to pass the boundary; and, after permission is given, the passenger must remain a longer or shorter time at the quarantine establishment, in order that all introduction of disease may be prevented.

MILITARY INDICATIONS. There are many indications which, if reported to a General and his Staff, enable them to judge of what they wish to know, as clearly as if a detailed picture of the enemy were spread before them. It is necessary, therefore, that every officer and soldier should know how to mark and collect these signs. They consist, when a camp, bivouac, or cantonment is observed, in the color of coats and pantaloons; other distinctive marks, the numbers of videttes, sentinels, fires, and tents of the enemy; the frequency and direction of rounds, patrols, and reconnoissances; the nature and time of signals by trumpet or drum; the placing of signal posts; measures of straw; boughs broken off; the arrival of reinforcements; new uniforms; collections of fascines, beams, joists, ladders, boats. When a corps is watched on the march, the signs to observe are the depth and front of columns; the number of subdivisions; the sort of troops, infantry, cavalry, artillery, trains; the quickness and direction of the march; the height of the dust; the reflection of arms; the number of the flankers and the eclaireurs. When an army ready for battle is observed, we should particularly note the number of its lines, their extent, the composition of the troops in column or in line of battle; the caliber of pieces; their position relative to cavalry and infantry; the number of skirmishers; their maneuvers; the concentration of forces or artillery on such a point, flank marches of one or many corps. If troops are followed on their march, we note the tracks of men and horses, those made by wheels, cattle, and beasts of burden; the relative positions of these tracks; whether they are regular and preserve an invariable order; whether the places where they stop have little or much space between them; whether the route passed over is covered with remains of animals; whether the skletons of the horses are lean and sore; whether the ground is bloody; if graves have been freshly made, whether some indications may not show them to be for superior officers; whether the country has been devastated; whether the entrails of beef, mutton, or horses are seen; whether the fires are recent; whether they are numerous, and show much or little ashes; whether bridges are broken, and in what parts; whether the inhabitants of the country are anxious, sad, humble, animated, or satisfied. See *Signs*.

MILITARY JURISDICTION.—Military jurisdiction is of two kinds: first, that which is conferred and defined by statute; second, that which is derived from the common law of war. Military offenses under the statute law must be tried in the manner therein directed; but military offenses which do not come within the statute must be tried and punished under the common law of war. The character of the courts which exercise these jurisdictions depends upon the local laws of each particular country. In the armies of the United States the first is exercised by Courts-Martial: while cases which do not come within the "Rules and Articles of War," or the jurisdiction conferred by statute on Courts-Martial, are tried by military commissions. See *Jurisdiction*.

MILITARY JUSTICE.—That species of justice which prevails in the army, and which is administered by military tribunals in accordance with the Articles of

War. In Russia justice is frequently obtained through what is known as the Court of Honor. In the United States the Articles of War provide that any officer who thinks himself wronged by the Commanding Officer of his regiment, and upon due application to such Commander, is refused redress, may complain to the General commanding in the State or Territory where such regiment is stationed. The General shall examine into said complaint and take proper measures for redressing the wrong complained of; and he shall, as soon as possible, transmit to the Department of War a true statement of such complaint with the proceedings had thereon. Any soldier who thinks himself wronged by any officer may complain to the Commanding Officer of his regiment, who shall summon a Regimental Court-Martial for the doing of justice to the complainant. Either party may appeal from such Regimental Court-Martial to a General Court-Martial; but if, upon such second hearing, the appeal appears to be groundless and vexatious, the party appealing shall be punished at the discretion of said General Court-Martial., See *Articles of War*, 72 to 105, *Court of Honor*, and *Courts-Martial*.

MILITARY KNIGHTS.— An Institution of Military Knights at Windsor, England, formerly called "Poor Knights," which owes its origin to Edward III., and is a provision for a limited number of old officers. These officers consist of a Governor and 12 Knights on the upper foundation, and 5 on the lower, together 18, and are composed of officers selected from every grade, from a Colonel to a Subaltern, chiefly veterans, or on half-pay. They are allowed three rooms each in Windsor Palace, and 2 shillings per diem for their sustenance, besides other small allowances. See *Knights*.

MILITARY LAW.—Under the Constitution of the United States, Congress is intrusted with the creation, government, regulation and support of armies; and all laws passed by Congress for those purposes are military laws. Congress, being also invested with power "to make all laws which shall be necessary and proper for carrying into execution the foregoing powers, and all other powers vested by this Constitution in the Government of the United States, or in any department or officer thereof," is supreme in all military matters. The office of Commander-in-Chief, intrusted by the Constitution to the President, must have its functions first defined by Congress. Such military powers only as Congress confers upon him can be exercised. Excepting that, being the Commander-in-Chief under the Constitution, he of course exercises all authority that Congress may delegate to any military commander whatever, by reason of the axiom that the power of the greater includes that of the less. Many of the functions, thus devolved by the Constitution on Congress, in most governments belong to the Executive. The King of Great Britain makes rules and articles for the government of armies raised by him with the consent of Parliament. Congress, with us, both raises and governs armies. An army raised in Great Britain is the King's army; with us it is the Army of the United States. These most essential distinctions should cause Congress to give more of its attention to the army. It should be borne in mind that our rules for the government of the army have been borrowed almost entirely from Great Britain; that the relation of the army to the people is in the two countries entirely distinct; therefore, that rules adapted to an aristocratic government may not be entirely suited to democratic forms.

Martial law must be distinguished from both military law and military government. The last denotes the rule of a conquered or insurrectionary district by military authority, while military law is that branch of the law which regards military discipline and the government of persons employed in the military service. Martial law, says Kent, supersedes and suspends the civil law, but military law is superadded and subordinate to the civil law. It will be seen that martial law is in the highest degree arbitrary and capable of abuse. It may be decreed at will by competent military authority, and the only rule as to the propriety of its being established is the test of necessity. The Duke of Wellington, from his place in the English House of Lords, deprecated its employment, except under the most urgent pressure, and then only with great modifications. In a celebrated Ceylon case the late Lord Chief-Justice Cockburn was very reluctant to admit that civil law could be superseded by Court-Martial, *except* where, as in India, the military government was absolute; but in the same case Blackburn, J., laid down the dictum universally accepted in the United States, that martial law is derived from statutory provisions and founded on paramount necessity. Thus the question as to its *nature* is closely connected with the *manner* of its exercise, and this again with the *responsibility* for such exercise. As to its extent, we may refer to a decision of the U. S. Supreme Court in the case of *Neal Dow* v. *Bradish Johnson*, October term, 1879. It was *held:* that an officer of the United States, while in service in an enemy's country, was not liable to an action in Civil Courts for acts done in pursuance of a Superior's orders; and when any portion of an enemy's country was in the military possession of the United States, the municipal laws were to be continued in force and administered through the ordinary channels for the protection and benefit of the inhabitants and others not in military service, but not for the protection and control of army officers or soldiers. In the Supreme Court of Missouri it has been held that the Act of Congress making the order or authority of the President a good defense for acts done or left undone during the Rebellion, is unconstitutional. The whole subject of the relations of the civil and military authorities in time of war, and especially the constitutionality of Acts passed distinctly as war measures, is of great interest, and, while much may be *res judicata*, there are many points not yet clearly determined. See *Martial Law*.

MILITARY NECESSITY.—Military necessity, as understood by modern civilized nations, consists in the necessity of those measures which are indispensible for securing the ends of the war, and which are lawful according to the modern law and usages of war.

It admits of all direct destruction of life and limb of *armed* enemies, and of other persons whose destruction is incidentally *unavoidable* in the armed contests of the war; it allows of the capturing of every armed enemy, and every enemy of importance to the hostile government, or of peculiar danger to the captor; it allows of all destruction of property, and obstruction of the ways and channels of traffic, travel, or communication, and of all withholding of sustenance or means of life from the enemy; of the appropriation of whatever an enemy's country affords necessary for the subsistence and safety of the Army, and of such deception as does not involve the breaking of good faith, either positively pledged, regarding agreements entered into during the war, or supposed by the modern law of war to exist. Men who take up arms against one another in public war do not cease on this account to be moral beings, responsible to one another, and to God.

Military necessity does not admit of cruelty, that is, the infliction of suffering for the sake of suffering or for revenge, nor of maiming or wounding, except in fight, nor of torture to extort confessions. It does not admit of the use of poison in any way, nor of the wanton devastation of a district. It admits of deception, but disclaims acts of perfidy; and, in general, military necessity does not include any act of hostility which makes the return to peace unnecessarily difficult.

MILITARY ORDERS.—Religious Associations which arose from a mixture of the religious enthusiasm and the chivalrous love of arms which almost equally formed the characteristics of medieval society. The first origin of such Associations may be traced to the necessities of the Christian residents of the Holy Land, in which the monks, whose first duty had been to serve the pilgrims in the hospital at Jerusalem, were compelled, by the necessity of self-defense, to assume the character of soldiers as well as of monks. The Order of the Templars was of similar origin. Those of Alcantara and Calatrava in Spain had for their immediate object the defense of their country against the Moors. These Orders, as well as that of Avis in Portugal, which was instituted with a similar view, followed the Cistercian rule, and all three differed from the Templars and the Knights of St. John in being permitted by their institute to marry once. The same privilege was enjoyed in the Savoyard Order of Knights of St. Maurice and the Flemish Order of St. Hubert. On the contrary, the Teutonic Knights, who had their origin in the Crusades, were bound by an absolute vow of chastity. With the varying conditions of society, these Religious Associations have at various times been abolished or fallen into disuse; but most of them still subsist in the form of Orders of Knighthood, and in some of them, attempts have recently been made to revive, with certain modifications, the monastic character which they originally possessed. See *Order*.

MILITARY PITS. Rows of pits in the form of inverted cones or pyramids made before a work, and having a strong palisade or stake in the center of each. To prevent the enemy's riflemen from making use of them, they should be made either too deep or too shallow, that is, either 8 feet or 2½ feet deep. The diameter of the pits at the top is 6 feet, and 1 foot at the bottom; that of the shallow pits, 3 feet square at the top, and not more than 2½ feet deep. The usual position for military pits is beyond the counterscarp, and principally opposite the salient angles. They would form an obstacle to cavalry. One man can construct two deep pits per day in easy soil, and ten shallow pits under the same circumstances.

MILITARY POLICE.—A few steady soldiers who are chosen from a regiment or regiments to maintain order and regularity within the lines of a camp or garrison. They are under the superintendence of the Provost-Sergeant, and their number varies according to circumstances. When on duty, they wear a badge round their right arm marked M. P.

When an army is in the field, it is recommended that a troop of police should be attached to each division, and one to the head-quarters of each army corps, to preserve civil order as distinct from military discipline. This body of men to be under the Provost-Marshal, who, during war time, is vested with exceptional powers.

MILITARY POSITION.—An officer, to be able to select a suitable position for an army, should know the distances taken up by troops in order of battle; the tactical combinations of the different arms, and their placing for mutual support to derive the greatest advantages from their respective action in battle, the qualifications of each for the defensive and offensive, and the nature of the ground best adapted to their maneuvers. In selecting a position for an army, regard must be had not only to the ground in the immediate vicinity of the field of battle; but also to the nature of the surrounding country in its relation to the position to be chosen; whether the latter lends itself in every respect to advantage to the particular ground in question.

The following are the principal points to be held in view in selecting a position:

1st. The extent should be in proportion to the number of troops in hand to occupy it; its general direction being such as to present an unbroken front throughout, from which a strong direct fire may be brought to bear upon all the approaches leading to it. If too extended, weak points will have to be left in the line; if too contracted, all the troops available cannot be placed to bring their fire to bear upon the enemy. An allowance of one thousand yards for every five thousand to six thousand men of all arms will generally be made. This provides for two lines and a reserve. Cavalry in line requires one yard to each file, infantry two feet, and artillery from eighty to one hundred and ten yards for each battery of six pieces, depending upon the intervals. Every position should have a depth of at least five hundred to one thousand yards, to permit the free movements of troops of all arms. No position should be taken up which does not present ample means for retreat, allowing the troops to be marched off the field without confusion from crowding.

2d. Good communications should exist throughout the whole extent of the position, permitting the troops to move freely from point to point to re-enforce the line where necessary; good *débouches* to the front, to allow the offensive to be promptly assumed; good roads leading to the rear, to facilitate the safe withdrawal of the troops in case of disaster. As a passive defense will never lead to any decisive results, a position should always present every facility necessary for the army to assume the offensive at any favorable period of the battle.

3d. Good command over the ground by which the enemy must approach, thus providing for a strong, direct fire, and facilitating shelter for the troops, which, if not afforded by the natural features of the ground, should be supplied by the construction of the best protections possible under the circumstances.

4th. There should be natural obstructions along the front of the position within effective rifle range, as a marsh or a stream. These serve to break the enemy's line and delay him in his advance at a time when the most damage may be inflicted. If these obstacles do not exist, the weak points of the line should be strengthened by abattis, slashed timber, entanglements, etc. The obstacles should not, however, be of a nature to afford shelter to the enemy, but simply cause a delay in his advance. A pond, marsh, or a narrow, deep stream, are good examples of what is most favorable to fulfill this condition. An obstruction parallel to the front, and between one hundred and three hundred yards from it, is very favorable and adds to the strength of a position, provided always, that it does not afford shelter to the enemy's troops. Any position with obstacles perpendicular to the front, as hills, wooded ground, etc., should be avoided, as they afford shelter for the enemy and conceal his movements. If, however, these obstructions cease some distance in advance of the line, they are not so unfavorable. Any position along a small stream flowing into the sea or a large river, would be a desirable one, as it presents the features of an obstruction in the front, and at the same time a strong support for one flank.

5th. Strength on the flanks is particularly important at the present time, as, with the improved weapons, a front attack will not offer many chances of success without severe losses. Measures must then be taken to turn a flank and thus render the position untenable, at the same time having a strong force in front to prevent the enemy from re-enforcing the flank attacked, or extending his line to meet the turning movement. If the flanks do not rest on some natural obstacles, as a village, extended marsh, an unfordable river, etc., they must be strengthened by all the means at hand, as fortifications, accumulations of troops, etc. The flanks should not be commanded by any ground in the vicinity, nor should there be facilities of any kind in the neighborhood which would allow the enemy to approach unseen.

6th. The location should be healthy, and the requisite wood and water should be near at hand and easy of access.

7th. Conditions two and four cannot be satisfied at one and the same time. In case an active defense is intended, condition too will govern, in order to have good *débouches* by which to fall upon the enemy at the proper time. For a passive defense, which is generally imposed when the forces are much inferior to the enemy in numbers or discipline, the third condition should be fulfilled.

In a defensive position, if the flanks are well protected, the concave front is the strongest; for the enemy while moving forward to the attack exposes both his flanks to a strong fire of artillery posted at the extremities of the line. If, however, the flanks are not strong naturally, or are liable to be turned, a convex front is desirable; for it gives short lines of communications, allowing supports to be moved quickly to either wing when threatened. The general case will be a combination of the two above mentioned, presenting alternately salients, re-entering angles, and straight lines joining them.

MILITARY POSITIONS.—Isolated positions, occupied by small detachments, for the purpose of guarding particular points which are of importance during the operations of a campaign, or for the longer or shorter period. These positions are frequently villages, farm houses, etc. The officer charged with placing a village in a defensive attitude, should first proceed to a careful examination of its environs, for the purpose of ascertaining what natural obstacles, and what facilities, they present to the approach of the enemy. Very slight accidents of ground may be greatly improved by trenches of trifling depth, to place troops speedily under cover. When the surface is undulating it should be particularly examined with this view, the officer taking a position at different points and directing men to approach him, and occasionally stooping to observe how much they will be masked from a fire at various heights above the surface. The side slope of a ridge from the enemy will be the best position for the trench to obtain speedy cover, provided the ground in advance of it can be well swept from its crest. The next points to be considered are the walls, hedges, etc., of enclosures, which may be turned to a useful account for the defense, or which might serve as a shelter to the enemy. After having finished this examination, he will next proceed to lay out his works; arranging their plan so as to draw every possible advantage from the natural and artificial obstacles at hand, to render certain points inaccessible, and to procure a shelter for troops snd flanking arrangements by means of the walls, hedges, etc. If there should be danger of an attack before these works can be completed, the roads leading to the village, by which the enemy might approach, should be broken up; and cannon should be placed in the best position to guard the most accessible points. The streets of the village should by barricaded, and the houses and walls, in the vicinity of tbe barricades, should be placed in a defensive attitude. In taking these preparatory measures against a sudden attack, any means that will afford the troops a cover from the enemy's fire should be resorted to; bales of cotton or wool, casks set side by side, and filled with earth, piles of timber, etc., have been used with great success under such circumstances. As the various arrangements called for under such circumstances will demand great activity on the part of the garrison, care should be taken to distribute the work among the men most conversant with it, placing the men who have any skill in the handling of tools at preparing the wooden and stone defenses, and common laborers at throwing up the earthen works, etc. The works that surround the village should be placed so far from the houses that the troops shall not be incommoded either by the splinters occasioned by the enemy's artillery, or by the flames and smoke, should the houses be set on fire. The communications from all the exterior defenses to some central rallying point should be carefully arranged, to avoid confusion in retreat, and check the pursuit of the enemy. The garrison should be made perfectly familiar with them and with the resources they may afford, in case of need. Short-cuts should be made for this purpose by breaking through garden walls, the party walls of houses, etc., and by the erection of barricades at all suitable points to make a stand.

MILITARY POST.—A Military "Station" is synonymous with Military "Post." In each case it means not an ordinary residence, having nothing military about it except that one of its occupants holds a military commission, but a place where military duty is performed or stores are kept or distributed, or something connected with war or arms is kept or done. The interchange of official compliments and visits between foreign Military or Naval Officers and the authorities of a Military Post are international in character. In all cases it is the duty of the commandant of a Military Post, without regard to his rank, to send a suitable officer to offer civilities and assistance to a vessel-of-war (foreign or otherwise) recent-arrived. After such offer it is the duty of the Commanding Officer of the vessel to send a suitable officer to acknowledge such civilities, and request that a time be specified for his reception by the Commanding Officer of the Post. The Commanding Officer of a Military Post, after the usual offer of civilities, is always to receive the first visit without regard to rank. The return visit by the Commanding Officer of the Military Post is made the following day, or as soon thereafter as practicable. Whan a Military Commander officially visits a vessel-of-war he gives notice

of his visit to the vessel previously thereto, or sends an officer to the gangway to announce his presence, if such notice has not been given. He is then received at the gangway by the Commander of the vessel, and is accompanied there on leaving by the same officer. The officer who is sent with the customary offer of civilities is met at the gangway of a vessel-of-war by the Officer-of-the-Deck; through the latter he is presented to the Commander of the vessel, with whom it is his duty to communicate. A vessel-of-war is approached and boarded by Commissioned Officers by the starboard side and gangway, when there are gangways on each side. In entering a boat the *junior* goes first and other officers according to rank; in leaving a boat, the *senior* goes first. The latter is to acknowledge the salutes which are given at the gangway of naval vessels. Naval vessels fire personal salutes to officers entitled to them when the boat containing the officer to be saluted has cleared the ship. It is an acknowledgment for his boat to "lie on her oars" from the first until the last gun of the salute, and for the officer saluted to uncover, then at the conclusion to "give way." The exchange of official visits between the Commanding Officers of a Post and vessel opens the door to both official and social courtesies among the other officers.

The foregoing list comprises the Military Posts occupied by troops of the United States on the 1st of January, 1884. Those not garrisoned are marked *.

MILITARY PUNISHMENT.—In a military sense, the execution of a sentence pronounced by a Court-Martial upon any delinquent. The Romans punished crimes committed by the soldiery with the utmost rigor. On the occurrence of a mutiny, every tenth, twentieth, or hundredth man was sometimes chosen by lot, but generally only the ringleaders were selected for punishment. Deserters and seditious persons were frequently, after being scourged, sold for slaves, and occasionally the offender was made to lose his right hand, or was bled nearly to death. Among the nations of Western Europe, the punishments for military offenses were, till lately, no less severe than they were among the Romans. Besides the infliction of a certain number of lashes with cords, soldiers convicted of theft, marauding, or any other breach of discipline which was not punishable with death, were sentenced to run the gantlope. In Russia the knout was extensively used. (See KNOUT.) It is often necessary to punish to maintain discipline, and the Rules and Articles of War provide ample means of punishment, but not sufficient rewards and guards against errors of judgment. In the French Army degrading punishments are illegal, but soldiers may be confined to quarters or deprived of the liberty of leaving the garrison; confined in the guard-room, in prison, or in dungeon; required to walk or to perform hard labor; and officers may be subjected to simple or rigorous arrests. Every officer who inflicts a punishment must account for it to his superior, who approves or disapproves, confirms, augments, or diminishes it. If an inferior is confined to the guard-room, he cannot be liberated except upon application to a superior. Any officer who has been subjected to punishment must, when relieved, make a visit to him who ordered it. The French Code has, in a word, been careful to provide for both the security of its citizens and the strength of authority. The punishments established by law or custom for U. S. soldiers by sentence of Court-Martial, are embodied in the Articles of War. (See Articles of War.) It is regarded as inhuman to punish by solitary confinement or confinement on bread and water exceeding fourteen days at a time, or for more than eighty-four days in a year, at intervals of fourteen days.

MILITARY REGULATIONS.—The rules and regulations observed in one uniform system, and by which the discipline, formations, field-exercises, and movements of the whole army are directed. See *Army Regulations* and *Articles of War*.

MILITARY SCHOOLS.—Establishments for the education of officers, non-commissioned officers, and men of the army. In the United States, schools are established at all posts, garrisons, and permanent camps at which troops are stationed, in which the enlisted men are instructed in the common English branches of education, and especially in the history of the United States. The Secretary of War details such officers and enlisted men as may be necessary to conduct them. It is the duty of every post and garrison commander to set apart a suitable room or building for school and religious purposes. The United States Military Academy, the Artillery School, and the School of Application for Cavalry and Infantry are discussed in detail under the appropriate heads.

The military schools of foreign countries deserve considerable attention, especially those of France, where a military commission is one of the best scholastic prizes looked forward to. In France no attempt is made to impart general education at the military seminaries; a boy is required to have a thorough general knowledge before he can be admitted to these institutions. Being open to universal competition, and being the only channel—or nearly so—to the best employment under the state the great military schools by the high standard required for them, give great impetus to general education throughout the empire and the lycées, or public schools, adapt their course of instruction to the anticipated competition. In the army, two-thirds of the line commissions and one-third of those for the scientific corps are given to non-commissioned officers, but very few of these rise beyond the rank of Captain; the remaining commissions in the line and scientific corps, and all appointments to the Staff, are given by competion after a careful course of professional education. The candidates in open competition are placed according to merit either in the Infantry School of St. Cyr or the celebrated Polytechnique; at both colleges they have the right, if they need it, to partial or entire state support. From the School of St. Cyr the more promising pupils pass to the Staff School, and thence, after a thorough course, to the État Majeur of the army; the remaining students pass as subalterns in to the Line. The pupils of the Polytechnique, which is entered after the age of 17 years, have annually about 160 valuable prizes open to them. The first 30 to 40 candidates usually select civil employment under the state, such as the "ponts et chausées;" those next in merit choose the artillery and engineers, and pass through a technical course at the School of Application. The remaining students either fail to qualify and leave the school, or have to content themselves with commissions in the line, subordinate situations in the government, civil or colonial service, or they retire into civil life altogether. In actual service there are schools for the men, who are also taught trades and singing. The standard of education among French soldiers is far higher than among their English brethren, as the conscription draws the men from all classes of society.

The Prussian system of military education differs from that of France in that competition is but sparingly resorted to; and the object is to give a good general and professional education to all the officers, rather than a specially excellent training to a selected few. Aspirants for commissions must enter in the ranks, and within six months pass a good examination in general and liberal knowledge; if however, the candidate has been educated in Cadet House—which is a semi-military school for youths—and has passed properly out of it, this examination is dispensed with. After some further service, the aspirant goes for nine months to one of three "Division Schools", where he completes his professional education. If he pass the standard here required, he is eligible for the next vacancy, but cannot be commissioned unless the officers of the corps are willing to accept him as a comrade. The Artillery and Engineer Schools do for those services what the Division Schools do for the line. The culmination of Prussian military education is the Staff School, open to competition for all the officers of the army, and presenting the highest prizes in the profession. In all the schools, the candidates study at the expense of the state, or receive great auxiliary grants.

The Austrian system is very elaborate, and commences at an early age; boys intended for military service beginning their professional almost contemporaneously with their general education. There are schools for training for non-commissioned officers and for officers, and senior departments for imparting more extended instruction to both classes. Candidates for appointment as non-commissioned officers pass by competition through the lower houses, where they remain till 11 years old; the upper houses, which detain them till 15; and the school companies, whence, after actual apprenticeship to service, a few pupils pass to the academies for aspirants for commissions, and the others are drafted into the service as non-commissioned officers. For officers, boys are pledged to the service by their parents at the age of 11, when they are placed in Cadet Schools; after which the state takes charge of them. At about 16 the boys pass, according to qualification, to the line or scientific corps academies, and four years later into those services themselves. The young officer's chance of entering the Staff School—and therefore the Staff—depends upon his place at the final academic examination. The competition observed throughout the course of military education is said to impart great vigor to the tuition.

In the Italian army the system so nearly approaches that of France that a separate description is unnecessary. It need only be stated that the educational status of the Italian officers is considered high. In the British army the schools are of several varieties. 1. Those for the education of the officers already in the service, as the *Staff College* and the establishment at Chatham for training engineer officers. 2. Professional schools common to officers and men, as the SCHOOL OF GUNNERY and the SCHOOL OF MUSKETRY. 3. Schools for the professional education of candidates for commissions; as SAND HURST MILITARY COLLEGE and the ROYAL MILITARY ACADEMY. 4. The schools for men in the ranks and for their children, or the REGIMENTAL SCHOOLS; and the instruction provided for their sons or orphans, as at the ROYAL MILITARY ASYLUM. See *Military Colleges*.

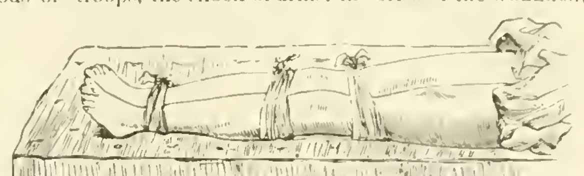
MILITARY SCIENCE.—War is both a *science* and an *art*. All investigations which have for their object the determination of the great principles which should govern a General in conducting his military operations; all analyses which are made to show the important and essential features which characterize a campaign or battle, and comparisons made with other campaigns and battles; all deductions and formations of rules which are to be used in military operations; all these belong to the "*Science of War*." The practical application of these great principles and rules belong to the "*Art of War*."

In the science of war as in the other physical sciences, the facts must precede theory; and although the number of known facts is steadily increasing the number of general principles upon which the theories of the science are based, is constant, if not decreasing. These general principles are deduced by a close and critical examination of such methods of waging war as have been adopted by those great Generals who are known as eminent in their profession. It is evident then that an intimate connection exists between military history and the science of war. Napoleon said, "Alexander made eight campaigns: Hannibal, seventeen, one in Spain, fifteen in Italy, and one in Africa; Cæsar, thirteen, of which eight were against the Gauls and five against the legions of Pompey; Gustavus Adolphus, three; Turenne, eighteen; Prince Eugene of Savoy, thirteen; Frederick, eleven, in Bohemia, Silesia, and on the banks of the Elbe. The history of these eighty-four campaigns, written with care, would be a complete treatise on the art of war. From this source, the principles which ought to be followed, in offensive as well as defensive warfare, could at once be obtained." To these campaigns, are to be added the battles and campaigns of Napoleon. Jomini, an eminent writer on military art, says: "Correct theories, founded upon right principles, sustained by actual events of wars, and added to accurate military history will form a true school of instruction for generals. If these means do not produce great men, they will at least produce generals of sufficient skill to take rank next after the natural masters of the art of war." The sources of all treatises on *Military Science* are to be found in the military histories narrating the events and results of the battles and campaigns just enumerated.

MILITARY STORES.—The arms, ammunition, clothing, provisions, etc., pertaining to an army. In the United States all public stores taken in the enemy's camp, towns, forts, or magazines, is secured for the service of the United States. The clothes, arms, military outfits, and accouterments furnished by the United States to any soldier can not be sold, bartered, exchanged, pledged, loaned, or given away; and no person not a soldier, or duly authorized officer of the United States, who has possession of any such clothes, arms, military outfits, or accouterments, so furnished, and which have been the subject of any such sale, barter, exchange, pledge, loan, or gift, can have any right, title, or interest therein; but the same may be seized and taken wherever found by any officer of the United States, civil or military, and thereupon be delivered to any Quartermaster, or other officer authorized to receive the same. The possession of any such clothes, arms, military outfits, or accouterments by any person not a soldier or officer of the United States is presumptive evidence of such a sale, barter, exchange, pledge, loan, or gift.

MILITARY SURGERY. Restricted to its rigorous signification, *Military Surgery* is the surgical practice in armies; but in its broad and ordinary acceptation embraces many other branches of art comprehending the practice of medicine, sanitary precautions, hospital administration, ambulances, etc.

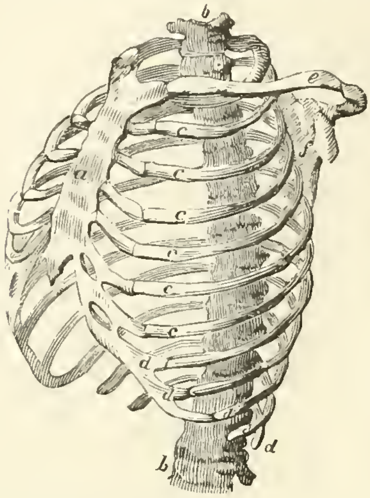
The military surgeon must not only be a skillful physician and surgeon, but he must have a constitution sufficiently strong to resist the fatigues of war, and all inclemencies of weather; a solid judgment and a generous activity in giving prompt assistance to the wounded without distinction of rank or grade, and without even excluding enemies. He must have the courage to face dangers without the power, in all cases, of combating them; he must have great coolness in order to act and operate in the most difficult positions, whether amidst the movement of troops, the shock of arms, the cries of the wounded,



in a charge, in a retreat, in intrenchments, under the ramparts of a besieged place, or at a breach. He must have inventive ingenuity which will supply the wants of the wounded in extreme cases, and must be prepared for all emergencies.

Frequently the surgeon is not immediately available. In anticipation of such an event, it is incumbent upon all who take the field to possess a sufficient knowledge of medicine and practical surgery to enable them to relieve the sick and wounded (both men and horses) until professional aid can be secured.

The fracture or dislocation of a limb is the most frequent of all accidents attending a campaign in a rough or mountainous country. A mis-step of the soldier, or a fall of the horse, often results in this mishap. When fractures occur and there are no splints at hand, they must be improvised from such materials as may be found. If the thigh be fractured, a rifle may be used for a splint, placing its butt in the axilla, and allowing it to pass along the outside of the limb, being secured by bandages around the trunk and ankle. A fractured leg may be secured with a splint of any description placed along its outside and the whole then wrapped in a coat or blanket and made fast by straps, or strings of soft material. It is a good plan to tie the fractured leg, at the ankles and convenient points, to the uninjured leg, and rest them on coats, blankets, or a mattress. In this manner the two legs will move as one, and the broken bone will not injure the flesh. A fracture may be "put up" with a gun stock or sword scabbard—even a roll of straw or grass makes a good temporary splint. A fracture of the arm may be "put up" with a bayonet scabbard, or with thin bundles of straw or grass. Light pieces of board, bark, or even the soles of shoes or boots are often useful for splints. The fore-arm should be carefully supported in a sling. Often a severe shock or collapse from pain or nervous fear follows the fracture, in



which case a stimulant (whisky and water) should be administered.

Dislocated and broken ribs are frequently the results of falls and other accidents. The drawing shows the normal position of the ribs and adjacent bones—*a* is the breast-bone; *c. c. c.* the ribs, which are fastened at one end to the spine *b. b.*, and at the other end are attached to the breast-bone by means of strips of cartilage, *d. d. d.*; *e* is the collar-bone. There are twelve (12) ribs on each side, all of different lengths—the shortest are at the top and have the smallest curves; descending they increase in lengt to the seventh, which is the longest, then decrease. The last two have no cartilages, are very short, and are attached to the spine only.

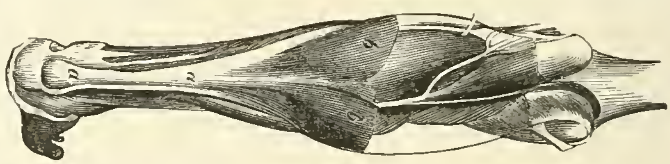
In this connection it would be well to carefully note the formation of the pelvis, and the sacrum which supports the spine. The pelvis is frequently

injured by thrusts and gun-shots, all of which wounds demand the most careful and cautious treatment. The drawing shows its form, with the location of the iliac fossae, *a. a.*, and the anterior surface of the promontory of the sacrum, *b*. To know how to arrest bleeding is all important, as life may often be saved by promptly adopting simple means. Bleeding may be from veins or from arteries. In the first case the blood is of a dark color, and flows slowly in a stream towards the heart; in the second case it is of a bright red color, forcibly issues in jets, and is in a direction from the heart. In ordinary venous hemorrhage, such as the bursting of a varicose vein, the bleeding may be stopped by pressure or elevation of the limb. Should there be any difficulty in checking it, ligatures should be applied. When the bleeding is arterial, the limb should be firmly grasped by both hands above the wound, so as to cut off the current from the heart by firmly compressing the wounded vessel against the bone, until a tourniquet may be applied.

A temporary tourniquet may be adjusted by placing a flat or roundish stone over the course of the artery and above the wound, between it and the center of circulation, holding it *in situ* by means of a band, handkerchief, string, or thong, the ends of which are securely tied. A stick or bayonet is then passed through the band or thong and twisted round and round several times, until the band is so tightened as to press the stone forcibly on the artery, which, being compressed against the main bone of the limb, will cut off the passage of blood through the vessel. If the bleeding be from the hand, fore-arm, or arm, apply the tourniquet or bandage near the shoulder. If from the foot, leg, or thigh, apply it between the knee and hip.

As a rule the main arteries are so placed that they are not likely to be reached and injured; they are deep in the flesh, and follow the courses of the inner seams of the coat sleeves and pants. Thus the main artery of the arm runs from the axilla down the inner side of the arm, at the lower edge of the biceps muscle, to the end of the elbow; that of the thigh runs from midway the groin, down the inner side of the thigh, under the deeper muscles to the back of the thigh near the ham.

Ice, if convenient, may be applied to wounds of small vessels, with good results, causing a rapid congelation of the blood. Hot water will accomplish the



same, and is far preferable if the patient be feeble. When the patient becomes faint and insensible from loss of blood, he should be placed flat on his back, with his head low. Cautery may be resorted to when the tourniquet fails to do its work. The accompanying drawing shows the manner of the attachment of the muscles, a, b, to the bone, the functions of ligaments about the joints, and the manner in which the arteries are covered and protected by the muscles, etc. In reseting a strong and muscular limb it is often necessary to keep up a great strain on the muscles in order to weary them and cause them to relax, when the bone may be set with less difficulty. See *Field Remedies*, *Medical Supplies*, *Medicine Chest*, and *Wounds*.

MILITARY TENURE.—In England, an accompaniment or immediate consequence of the Feudal System established during the Middle Ages throughout the greater part of Europe. Feuds were introduced by the barbarous tribes who poured themselves into the Roman Empire during the 4th, 5th, and 6th centuries. The chief feature of feuds was, that the lands of the conquered country were parceled out to the leaders, on the condition of bearing arms whenever the Sovereign required them. The relation thus created between Sovereign and Vassal was called a feud. The Grantee held his lands at first for life only, but gradually it was developed into a hereditary character, and also into one which admitted of subinfeudation, i. e., the parceling out of the feudal land among Vassals of the head Vassal, who was the Lord of his own Vassals This kind of relation between Lord and Vassal gradually was extended to all kinds of land, for the owners of allodial land voluntarily surrendered their land to some Lord, so as to have the same advantages. The Vassal did homage to the Lord, and took the oath of fealty. Besides these characteristics, the holding came to be attended with the following incidents. 1. An aid, which was a payment granted to help the Lord in his necessities. 2. A relief was a tribute paid by a new Tenant on succeeding to his predecessor. 3. A fine was paid by a Tenant to the Lord on alienating the lands to a purchaser. 4. An escheat or forfeiture was the reverting of the estate to the Lord when there was a failure of heirs or some violation of duty on the part of the Vassal. The Feudal System was extended to England by the Norman Barons soon after the Conquest, with the concurrence of William I., much to the dislike of the Saxons, whose grievances grew until they found vent in Magna Charta, which was in fact an attempt to restore their earlier Constitution.—The chief fiction, however, of a relation between the Crown and the holders of land was not got rid of. The Crown was nominally the Lord Paramount, and there were intermediate Lords called Mesne Lords, of whom the Tenants held. Gradually, the kinds of tenure were classed under free and base services—the former being those which a freeman might perform, as serving in war, or paying a sum of money; the latter, such as a Peasant might perform, such as ploughing the Lord's land, etc.

MILITARY TRAIN.—Formerly a highly important corps of the army, of which the function was to transport the provisions, ammunition and all other matériel, together with the wounded in time of battle. It was formed after the Crimean war, on the dissolution of the Land-Transport Corps. It comprised six battalions, in all 1840 officers and men; and its annual cost for pay, etc., was about £71,000. The corps ranked after the Royal Engineers, and was classed as Mounted Infantry, the officers receiving infantry rates, and the men cavalry rates of pay. The commissions were purchasable, as in the line. The men were armed with carbine and sword, but rather for defensive than aggressive purposes. Attached to each battalion were 166 horses, with proportionate wagons and ambulances.

It is proper to observe that the Military Train constituted only the nucleus of a transport service for a large army, and that in time of war it would be expanded by the addition of thousands of horses or mules, and the incorporation of many hundred drivers, etc. The advantage of possessing even a few men ready trained, and capable of directing the movements of others, was amply demonstrated by the failures of the Crimea in 1854-1856; so that Parliament voted ungrudgingly the expense of this corps, although in time of peace it was comparatively without employment. The Military Train was disbanded in 1870, as being too military in its formation. Its functions were transferred to the Transport section of the Army Service Corps, a purely non-combatant organization.

MILITARY WAYS.—The large Roman roads which Agrippa caused to be made through the empire in the reign of Augustus for the marching of troops and conveying of carriages. They were paved from the gates of Rome to the utmost limits of the Empire. The British have constructed a military road throughout India, with wells and other accommodations at certain distances.

MILITIA.—The purpose and opinion of the founders of our government is unequivocally expressed in the second amendment to the Constitution, which declares, "A well-regulated militia being necessary to the security of a free State." The unvaried agreement of all subsequent writers and statesmen with this assertion might well cause us to view with some alarm the fact that all attempts to secure an efficient militia have hitherto signally failed. While all agree that the perpetuity of a republican form of government depends on maintaining a well-regulated militia, the fact has been demonstrated that under no other form of government is it so difficult, owing to the indisposition of the people to submit to the enforcement of military duty in time of peace. Washington, in his annual message to Congress in 1794, said: "The devising and establishing of a well-regulated militia would be a genuine source of legislative honor, and a perfect title to public gratitude." The wisdom of this assertion has been proven by the subsequent failure of all attempts at legislation. Nevertheless, we are certainly convinced that the solution of the difficulties is now easy, not through any superior wisdom of our own, but because time and experience have solved the difficulties for us. This solution we conceive to be to substitute a volunteer militia in place of enforced militia duty, believing that our population has reached such a number that the volunteer militia of the States will be sufficiently large and efficient for all the purposes for which militia can or ever should be used.

No subject, unless it be that of finance, has so long and so often engaged the attention of Congress as that of the militia, and on none have more able and exhaustive reports been written by those whose slightest utterances we have been taught to honor and respect. The records of Congress are filled with messages from Presidents, reports of Executive Officers, reports of Committees of both Houses of Congress, and with plans and bills for the improvement and organization of the militia, to attempt even a brief outline of which would far exceed the proper limits of this article. We cannot, therefore, do more than give a brief outline of the most salient features in the history of the subject.

On July 18, 1775, the Continental Congress passed a series of resolutions recommending "to the inhabitants of all the United English Colonies in North America that all able-bodied effective men between sixteen and fifty years of age in each colony immediately form themselves into regular companies of militia." One of these resolutions is particularly suggestive, as it contains the germ of the volunteer system which has now grown to such proportions. It is as follows:

That one-fourth part of the militia in every Colony be selected for minute men, of such persons as are willing to enter into the necessary service, . . . and as these minute men may eventually be called to action before the whole body of the militia are sufficiently trained, it is recommended that a more particular and diligent attention be paid to their instruction in military discipline.

On the formation of the Federal Government one of the earliest acts of the first House of Representatives, in 1789, was the appointment of a Committee to prepare a bill to organize the militia. The session adjourned before the Committee made a report, but at the following session, in 1790, General Knox, Secretary of War, submitted his celebrated plan for organizing the militia, accompanying it by a letter of transmittal which is remarkable for its terse, striking, and strong arguments. His plan, in brief, was that every boy on arriving at the age of eighteen years should be enrolled in the cadet corps of militia and be obliged to serve in camp of instruction thirty days in each of first two years and ten days in the third year, and that no person arriving at the age of twenty-one years should be entitled to exercise the rights of a citizen unless he could produce his certificate of having so served; all citizens between twenty-one and forty-five years of age were to be enrolled in the main corps of militia and be obliged to drill four days in each year; and between forty-five and sixty years of age to be enrolled in the reserve corps, which should be assembled twice in each year for inspection of arms. Under his plan the general government was to furnish uniform, arms, equipments, and bear all the expenses of the camps of instruction. The features of General Knox's plan were clearly embodied in a bill prepared by a Committee of the House of Representatives, and the subject was discussed in detail on many occasions through the two succeeding sessions until all of its original features were changed or modified, and the Act of May 8, 1792, finally agreed upon and enacted. As this is the law still in force, we reserve a detailed explanation of its provisions, and simply state here that its main feature is that every citizen, between eighteen and forty-five years of age, shall be enrolled in the militia and shall arm and equip himself at his individual expense. This law was found to be so crude and inadequate that it became the subject of criticism immediately after its passage, and of efforts to amend it which have continued to the present time. As well expressed by Washington, after the attempt was made to put it in practical operation it "exhibited such striking defects, as could not have been supplied but by the zeal of our citizens"; and in his annual messages to each succeeding session of Congress, during his two terms of office, he urged that the evident defects of the law be remedied. In the session succeeding the enactment of the law an effort was made to repeal the provision requiring every citizen to arm himself. In the next following session, in 1794, a bill was reported by a Committee of the House of Representatives to organize a "*select corps*" of militia, to be armed and equipped by the general government, and paid for service in annual camps of instruction. Different propositions, having in view these two changes in the militia system, were discussed in successive sessions until 1798, when the threatening condition of our relations with France culminated in the formation of a provisional army and other warlike preparations that temporarily suspended consideration of the militia system.

Our troubles with France having been amicably settled, the militia question again assumed prominence, and Jefferson, in his annual message to Congress, importuned them to take some action. It was chiefly through his earnest efforts that the law of April 23, 1808 (section 1661 Revised Statutes), was passed, making a permanent appropriation of $200,000 a year to provide arms and equipments for the militia. Somewhat curiously, however, the requirement of the old law that every citizen should arm and equip himself was not repealed, and still remains the statute. As the country was rapidly increasing in population the uselessness of requiring active military duty from the whole body of citizens became more apparent, and was felt to be an unnecessary burden. Jefferson in his annual message in 1805, recommended that the militia be classined according to ages, and thought that those from eighteen to twenty-six years of age would form a sufficiently large body to be subjected to any duty in time of peace. This proposition was taken up by Congress, and in various forms was the subject of debate in successive sessions, until the war of 1812 put an end to the discussion without any result having been reached.

Madison was almost as urgent in his appeals to Congress to amend the militia law as Jefferson had been. In his annual message in 1810 he advanced a new proposition in the suggestion that the commissioned and non-commissioned officers of the militia should be assembled in annual camps of instruction at the expense of the general government; and in his last annual message, in 1816, he earnestly recommended a reorganization of the militia, and classifying them according to age. Prompted by the recommendations of Madison, the Fourteenth Congress, in 1816, directed the Secretary of War to prepare and report a plan for the organization of the militia. Secretary of War Graham reported to the following Session, recommending very forcibly that the militia be divided into three classes according to age, and that the two younger classes be detailed and required to assemble annually in large camps of instruction and be armed, equipped, and subsisted at the expense of the general government. This report was referred to a committee of which General Harrison (then a Representative from Ohio) was chairman. Harrison took a deep interest in the subject, and presented a careful report. He deemed it essential that the whole body of the people should be instructed in military matters, and for this purpose recommended that military instruction be made a branch of education in every school in the country. Believing that it would entail too great an expenditure of time and money to subject the whole enrolled militia to drill and military training, he revived the old propositions first made by President Madison, and recommended that the Officers and Sergeants be assembled annually in camps of instruction, be paid for their time, and be thoroughly drilled and instructed at the expense of the general government, which he estimated would amount to about one and a half million dollars a year. Harrison continued the agitation of the subject while he remained in Congress, and made reports in 1818 and 1819 urging action.

In 1825 Secretary of War Barbour addressed a circular letter to the Governors of all the States and to many citizens most prominent in military and civil life, setting forth that it had long been apparent that some change in the militia law was necessary, and asking their views on the subject. He then convened a Board composed of some of the most distinguished officers of the army and militia for the purpose of considering the question, and submitted to them the voluminous correspondence that had resulted from his circular letter. It is worthy of note that the president of this Board was Winfield Scott, then a Major General in the Army, and that Zachary Taylor, then a Lieutenant-colonel of Artillery, was one of the members. The militia were represented on the Board by General Cadwalader of Pennsylvania, General Sumner, of Massachusetts, and General Daniel of North Carolina. The report of this Board, together with all the papers and correspondence connected with it, was transmitted to Congress by the President. The Board reported that they considered the primary defect of the militia law to be in the excess of numbers which it held to service. They recommended that a select corps of militia be formed, to consist in each State of one brigade for every Congressional Representative, and that the officers of this select militia be assembled in camps of instruction ten days in each year, and be paid by the general government for their time and traveling expenses. They also recommended that the office of Adjutant General of militia be created, and that, on the application of State Executives, the United States should furnish officers to instruct the annual camps.

In 1835 President Jackson, in his annual message urged Congress, in his usual forcible style, to give their attention to the subject, and among other things recommended that volunteer organizations be encouraged and inducements held out for their formation. The Secretary of War (General Cass), in his annual report, gave his views on the subject, and represented the necessity of some legislation. Urgent effort was made in Congress to secure agreement to some plan, but without success.

In 1840 Secretary of War Poinsett submitted a plan to Congress. Apparently despairing of securing agreement to any plan that simply changed and perpetuated the existing system, he proposed a radical reform that stretched the constitutional powers of the general government to such an extent as to cause opposition to it on that ground. His plan was to divide the militia into three classes—the active, reserve, and mass. The active militia to consist of 100,000 men, apportioned to the respective States, and each State to be required to keep its quota filled at all times, either by voluntary enlistment or draft. One-fourth of the active militia to go out of service annually and be enrolled in the reserve corps. The mass of the militia not to be subject to any duty in time of peace. He proposed that Congress should by law authorize the President to order the active militia into the service and pay of the United States for thirty days in each year for the purpose of placing them in camps of instruction. This appears to have been the last decided attempt to save the decaying system from dissolution, with the exception of an effort in 1846, when a bill was reported to remedy the excess of number of the militia by limiting the enrollment in time of peace to those between twenty-one and thirty years of age, who should be formed into a legion of active militia in each State, the officers of which should serve annually in camps of instruction at the expense of the general government.

The militia system, by this time, was virtually dead; during the many years devoted to debating a remedy for its defects it had gradually sunk, until it no longer existed except on the Statute-book. In the mean time, in all the States, by a process of "natural selection," there had sprung up volunteer organizations of militia, and the States, by fostering and encouraging them, had supplied the deficiencies of the general law. These volunteer organizations made possible and gave efficiency to that splendid body of volunteers whose soldierly qualities and deeds of valor in the Mexican War gave such renown to our arms. After that war still greater interest was manifested in the volunteer militia; the States devoted to them the meager supply of arms and equipments obtained annually from the general government, which in many instances they supplemented by large appropriations of their own, and the volunteer militia continued to increase in numbers and efficiency until the breaking out of the "War of the Rebellion." Of that fearful struggle it is safe to say that the magnificent armies which were so quickly formed on both sides were only made possible by the facts that the efforts of regularly educated officers in drilling and disciplining them were supplemented by those who had received a partial military training in the volunteer militia.

Just before the war, in 1860, an earnest effort was made in the House of Representatives to increase the annual appropriation for furnishing arms and equipments to the militia. In urging the measure, Mr. Vallandigham reviewed the militia system and spoke of the volunteer system replacing it, asserting that they would "in time become the National Guard of America."

After the close of the War of the Rebellion, another most decided effort was made, both in the House and Senate, to reorganize the militia, or rather to create a new militia system, and several bills for that purpose were introduced in the Thirty-ninth Congress. Although none of these bills were passed, they contained provisions that are interesting and suggestive, and some that went to the extreme limit, if they did not go beyond the constitutional power of Congress in the premises. It was, however, a purpose common to all the bills to form an active volunteer militia, and that seemed to be accepted as the true solution of the militia question.

This closes the history of the efforts to achieve a satisfactory militia system, with the exception of an interesting report by the Chief of Ordnance, and a report by the Senate Committee on Military Affairs (S. Report 56, second session Forty-fifth Congress), both recommending that the permanent appropriation for providing arms and equipments for the militia be increased to $1,000,000 a year.

The three following points are at present urged as the proper remedy for the defects in the Militia system:

First. To substitute a volunteer militia, limited in number in time of peace, for the existing compulsory system that applies to the whole body of the people, and which has become so inapplicable as to be utterly disregarded.

Second. To make such provisions as will aid and encourage the formation of volunteer organizations, remove the disparity in their numbers and discipline that exists between different States, and promote their efficiency to a common standard that will make them available for all the purposes for which a militia is required.

Third. To abolish the present system of a permanent appropriation to provide arms and equipments for the militia, and substitute provisions prescribing with what arms and equipments the militia shall be furnished, and on what conditions—leaving it to the discretion of Congress to regulate the annual appropriations for that purpose.

In relation to the first feature, the substitution of the volunteer system, the brief sketch we have given of the history of the militia law will have made it apparent that the chief defect of the existing system was early recognized to be in the excess of numbers held to militia duty by it. As the country increased in population this excess of numbers correspondingly increased, until the law has now become a practical absurdity by requiring to-day actual militia service from six and one-half millions of men. We have seen that for more than half a century the best and wisest statesmen of our country endeavored to procure agreement to some plan that would limit the militia to a practicable number, in order that it might be made an effective body. The more the country increased in population, and the more the population became absorbed in the pursuit of wealth and material prosperity, the more impracticable became the provisions of the militia law, until finally it sank into such utter contempt that all pretense of regarding it ceased. The "cornstalk militia" and the annual "trainings," with all their accompanying parodies on military efficiency, remain only as recollections of our boyhood days. Volunteer organizations gradually increased as regard of existing law decreased, and, though unrecognized by the general law, and without any of the aids or requirements necessary to secure efficiency, they have managed to maintain a precarious existence, and have unquestionably been of great and essential service to the country. We think it good policy and true statesmanship to acknowledge the changes and avail ourselves of the results which time and the force of circumstances have brought about, and we therefore assent to the proposition that the volunteer militia of the State—the militia in fact—should be recognized as the militia of the law, and provided for accordingly. On the second feature, the provisions made for promoting the efficiency of the volunteer militia and securing a uniformly high standard in all the States, we believe there can be no disagreement. The unorganized levies which, under the name of militia, have been called into service in all the great wars of the country, while they occasionally performed some brilliant service, have not only shown the inefficiency of existing law, but have also served to make the term "militia" one of contempt and derision. It is not denied that great disparity exists in the character and efficiency of the existing volunteer organizations between the States and even within the States. During the "Labor Riots of 1877" some volunteer organizations proved utterly undisciplined and unreliable, while others performed conspicuous and valuable service. Congress has never exercised its constitutional power "to provide for organizing, arming, and disciplining" the volunteer militia. On the contrary, the volunteer organizations have maintained themselves at their own expense, with such aid as by unwearied exertions they may have been able to procure from their respective States. It is due solely to the want of support and of uniform requirements as to drill and discipline that the volunteer organizations have not all reached the same efficiency that characterize a part of them. The men who constitute the volunteer organizations are naturally those who have some love or aptitude for military affairs, and we therefore see no reason why, under the proper regulations for their discipline and training, they cannot attain a high and uniform efficiency. That they have been or are in any particular inefficient is not an argument against the possibility of making them all that we desire. We therefore consider the suggestions made, to aid and encourage the volunteer system and to exact certain requirements of them, as both politic and wise. We deem them politic, for the reason that the aid they offer is conditioned on the volunteers complying with the provisions which are deemed essential to their efficiency. We deem them wise, for the reason that we believe that under their operations a volunteer militia will be created, which, although remaining under the exclusive control of the States, will, when its services are required by the general government, be found ready and equipped for instantaneous service and fully efficient to perform the duties of militia, which Jefferson defined to be "not only to meet the first attack, but, if it threatens to be permanent, to maintain the defense until regulars can be engaged to relieve them." It is also worthy of consideration that in encouraging the volunteer system you provide for disseminating military knowledge and a partial military training among those who would be most likely to respond to a call for volunteers in time of war. It has been agreed by all who have preceded us in considering the subject that, whatever might be the expense of securing an efficient militia, it would be so small, as compared with the benefits to be derived from it, that it should not be considered, and would, in fact, be covered by indirect savings of expense which it would render practicable in other directions. While the States have applied all the existing permanent appropriation for the militia to providing the volunteer militia, the issue of property under that appropriation is limited to arms and equipments. This has been not only the greatest obstacle to the advancement of the volunteer militia, but has also prevented them from being useful on the occasions when their services have been required, Tents and camp equipage are absolutely necessary to enable the volunteers to go into camps of instruction and learn the elementary duties of soldiers. A plain, serviceable, and unostentatious uniform, over-

coats, blankets, haversacks, canteens, etc., are essential to the outfit of the volunteer, that he may be called into service at a moment's warning, and that his services may be effective when called for.

On page 356 is an abstract of the militia force of the United States (organized and unorganized), according to the latest returns received at the office of the Adjutant General, United States Army, furnished for the information of the Congress of the United States in compliance with section 232 of the Revised Statutes.

The existing volunteer militia are provided with what is essential. Some of the States have made very large appropriations to supplement the amount heretofore allowed by the General Government, and many of the States, as we have before mentioned, have now in possession considerable amounts of arms and equipments that have been issued to them by the general government. It is therefore difficult to estimate what would be the cost of making up deficiencies, and of completing the arming and equipment and of providing uniforms and camp equipage for the volunteer militia in the manner contemplated, but we judge that three million dollars would be ample for that purpose, and that its appropriation might be distributed into the budget of three successive years. After the volunteer militia should be once completely armed and equipped, we judge that an annual expenditure of $750,000 would maintain it in proper condition. These sums are comparatively very small, scarcely large enough to excite either opposition or comment, being smaller than was frequently contemplated and advocated in the early days of the Republic. The annual expenditure would be less than is required to sustain a regiment of cavalry in the regular service, and it cannot for a moment be questioned that a standing force of 150,000 thoroughly armed, equipped, and well-drilled volunteers, ready to take the field at the first moment of danger, would be as effective in the national defense as one regiment of regulars, and that the existence of such a force would be seriously considered by any Nation contemplating an attack on us. In this connection it is not improper for us to observe that the Senate Committee on Military Affairs in the Forty-fifth Congress recommended that the annual appropriation for the militia be increased to $1,000,000, very pertinently observing that "if $200,000 was none too much in 1808, certainly $1,000,000 is none too much now"

There is no feature in our form of government in which the powers of the general government and the rights of the States are so intimately interwoven as in the jurisdiction over the militia. One of the stated primary causes for forming the Union was to "provide for the common defense." In the opinion of the framers of the Constitution, a well-regulated militia was the essential means of providing for the common defense, and they accordingly framed the clause to provide that Congress shall have power—to provide for organizing, arming, and disciplining the militia, and for governing such part of them as may be employed in the service of the United States, reserving to the States respectively the appointment of the officers and the authority of training the militia according to the discipline prescribed by Congress.

The purposes and provisions of this clause are clearly and distinctly stated and scarcely admit of misinterpretation. The States are expressly limited to the appointment of the officers and to training the militia, and in training it, it will be observed, according to the discipline prescribed by Congress If the certain power conveyed to Congress by the words "organizing, arming, and disciplining" could be doubted, the debates of the Federal Convention are sufficiently clear to remove them. The Committee that reported the clause, on being asked the scope of the powers that they intended to convey, replied that they meant by "organizing" proportioning the officers to the men; by "arming," not only to provide for uniformity of arms, but the authority to regulate the modes of furnishing them, either by the militia themselves, the State governments, or the national Treasury; and by "disciplining," to prescribe the manual exercise, evolutions, etc., and that laws for disciplining must involve penalties and everything necessary for enforcing penalties.

The debates of the Federal Convention on adopting the clause, though short, are pertinent. Mr. Mason, who introduced the subject, thought that all powers over the militia should be vested in the general government, which he subsequently modified by suggesting that this absolute power should be limited to a portion of the militia at a time, so that by serving in rotation the whole body would finally be disciplined. Mr. Madison thought that the regulation of the militia naturally appertained to the authority charged with the public defense, that it did not seem in its nature divisible between two distinct authorities, and that the discipline of the militia is evidently a national concern, and ought to be provided for in the national Constitution. The clause as reported by the Committee had but little opposition, it being conceded, as stated by Mr. Randolph, that reserving to the States the appointment of the officers was all the security they needed. Mr. Dayton and Mr. Ellsworth expressed themselves in favor of placing greater limitation on the power of Congress, but a motion made for that purpose received only one vote, that of Mr. Ellsworth, who moved it, and the clause, as it now stands, was therefore adopted with a marked unanimity in sentiment and vote.

We have only adverted to the question of the constitutional power of Congress as a matter of historical interest in connection with the general subject, for whatever question there may be as to the constitutionality of the existing law, or of some of the plans heretofore suggested for reorganizing the militia, none can possibly arise on the proposed reorganization, for it is a happy solution of all the constitutional questions involved. There is not a compulsory feature presented. It simply says to the States that if they will by their own laws provide for and enforce such requirements as Congress deems necessary to secure an efficient militia, Congress will exercise its unquestioned constitutional power, and provide for arming such militia out of the national Treasury.

From this review of the subject we are satisfied that time has solved those difficulties of the militia system for which the wisdom of our predecessors could find no acceptable remedy, and that the great increase in the population of the country now makes it not only practicable but desirable to substitute the volunteer system for enforced militia duty in time of peace. The subject is one on which there never have been any political differences, and on which none should exist. Washington, as the exponent of the Federalists, was unceasing in his efforts to procure legislation, and Jefferson, as the leader of the Anti-Federalists, was even more importunate in urging it. In view of these facts, and of the fact that we now have practically no militia system, and that the strength and perpetuity of our republican form of government largely depend on the existence of a well-regulated militia, we indulge the hope that the subject will receive the earnest consideration which it deserves, and that some decisive action will be taken on it. See *State Troops*.

MILITIA ADJUTANT.—An officer appointed to each regiment of militia to superintend the drill and instruction of the regiment. He is taken from the regular army. The following are the regulations recently issued relative to the duties of Adjutants of Militia:

"1. The Militia Adjutant will be, during the non-training period, the representative at the brigade depot of the officer commanding the militia battalion or battalions.

"2. He will raise and enroll all recruits for the militia battalion or battalions, and superintend the out-station recruiting for the army and the militia as required.

"3. He will have military charge of the militia staff during the non-training period, and the military charge and supervision of the drill of the militia recruits when they are trained in large bodies; militia recruits, when they come up singly or in small numbers, will be attached to squads of line recruits, and they will in that case be under the supervision of the officer of the brigade depot.

4. The duties specified in the foregoing paragraph will have priority over all others, but when Militia Adjutants are not employed upon them, they will be liable to perform such other depot and sub-district duties as the officer commanding the brigade depot or sub-district may direct.

MILITIA ARTILLERY.—Forms a large body of artillery in addition to that of the regular forces of Great Britain. Formerly the militia artillery was called upon to exercise with all kinds of ordnance, but since 1873 they only practice with garrison and coast guns. Each regiment, however, has some Armstrong guns for the drill of recruits; but, from the absence of horses, its organization into batteries remains incomplete. The places of meeting chosen for the yearly drills (two months for recruits, and one for a regiment) are some fortified points of the coast, where the men are taught to exercise with garrison and field pieces. There are 30 regiments of artillery, composed of 796 officers, 66 surgeons, 15,978 men.

MILITIA RESERVE.—A force created by the Act of 1867; its numbers not to exceed one-fourth of militia quota; the men to be enlisted for 5 years, during which time they remain on the strength of militia regiments, but are liable to be drafted into the army in time of war.

MILLAR GUNS.—Guns introduced into the English service by General Millar in 1827. The thickness of metal at the breech is considerable, and comparatively slight in the chase. Two of his 8-inch guns are still in the service. Besides these guns, General Millar also introduced the 10-inch and 8-inch iron howitzers and the present L. S. S. B. iron mortars.

MILLAR HIND SIGHT.—A sight consisting of a block of gun-metal, with a thumb-screw, lead packing, a brass scale, and two screws. The blocks are of five different patterns. The scale differs for each nature. It is tightened by a thumb-screw working against a brass spring in the block, and is in every case graduated to $\frac{1}{4}$ degrees. It is attached to the rear of the base ring at an angle of 76°.

MILLBANK.—A large prison, situated on the banks of the Thames, Chelsea. All soldiers under sentence of Courts-Martial for lengthened terms of imprisonment in England are committed to the military division of this prison. Soldiers also sent from abroad under punishment for lengthened periods are generally sent to Millbank, or to the military prison in the district in which they disembark.

MILL-CAKE. The incorporated materials for gunpowder, in the form of a dense mass or cake, ready to be subjected to the process of granulation. As the process of incorporation approaches completion, the charge requires to be carefully watched, in order to insure each finished charge leaving the mill in as nearly as possible the same state as regards moisture. The appearance of the powder when finished depends mainly on the state in which the charges leave the mill. The finished charge usually has from two to three per cent. of moisture. If too much moisture be present as the incorporation draws to a close, the charge must be repeatedly pushed up with a *shover*; if too little, some more must be added from the watering-pot. The color of the charge gives a very good indication of the amount of moisture present. When the process is finished, the charge, now known as *mill-cake*—being partly in the state of soft cake, and partly of dust—is scraped and swept up from the mill-bed, placed in wooden tubs, and transferred to the charge-house to await inspection. If the charges are found to be of a proper color and consistency, samples from each are taken, which, after being roughly granulated by hand and dried, are flashed on a glass-plate to ascertain the thoroughness of the incorporation they have undergone. This flashing is more a matter of form than anything else, for the mill-cake seldom fails to give satisfactory results. See *Gunpowder*.

MILLER MAGAZINE-GUN.—This gun is an adaptation of a magazine to the United States service Springfield rifle. The alterations are as follows: The original receiver and breech-pin are replaced by a receiver alone the tang being solid with it. The upper rear part of the receiver gives the bearing for the cam, while the space ordinarily filled by the breech-pin if utilized as a channel through which the cartridges are fed from the magazine in the butt-stock. The ejector-stud is replaced by one beveled on its rear as well as its front, in order that the cartridges may slip easily over it into the chamber. The magazine, is a tube slotted through its whole length. To the upper side of the side of the tube flat springs are screwed. At the end of each spring and riveted to it is a lug, beveled on its rear service; all these lugs pass through holes cut in the magazine and serve to separate the cartridges. A ratchet works in the slot in the magazine-tube. It is operated by a slide attached to the guard-plate. When the slide is drawn back the teeth of the ratchet pass in the rear of the heads of the cartridges. On being returned to position each tooth moves a cartridge forward, the lugs on the springs being pressed out of the way by the cartridges themselves. At the front of the ratchet is a cartridge-stop, held up by a spring. The stop is prevented from rising too far by a pin. When the ratchet is withdrawn the stop-spring yields—since the cartridge cannot move backward on account of the shoulders of the lugs on the springs—the stop descends and is drawn under the first cartridge, which is then free to leave the magazine and enter the chamber, gravity being the motive force, the gun being held muzzle downward. When the ratchet is moved forward the 2d cartridge occupies the place of the 1st, the 3d of the 2d, and so on. The ratchet is prevented from entering the tube by two pins which bear against the outer surface of the tube along the edges of the slot. It is held in contact with the tube by a spring, which is kept from slipping off the bottom of the ratchet by two forks. The magazine is loaded through a gate in the butt-plate. A projection on the breech-block hooks over a pin and prevents motion of the ratchet when the piece is locked. As a magazine-gun, five motions are necessary to operate it, viz: cocked, opened, loaded (by operating the ratchet by the slide), closed, fired. The same number of motions is necessary as a single-loader. This gun carries six cartridges in the magazine and one in the chamber. The last cartridge will not feed from the magazine, however, until forced down by others when the magazine is reloaded. See *Magazine-gun*, and *Springfield Rifle*.

MILLING.—The term "milling" as generally understood, means the cutting of metals by aid of serrated revolving cutters, each having a suitable number of cutting-teeth. Milling cutters have been used in this country for many years, but until recently with only a limited amount of success, owing to the expense and difficulty of producing their cutting edges and keeping them in order. This was next to impossible before the introduction of a small emery-wheel and compound slides, etc., for carrying the milling cutter while being re-sharpened. Hence in the old system of milling, which did not permit of the re-sharpening of the hard teeth, the results were, that after much expense and time had been bestowed on a cutter (including a quantity of hand-labor spent upon it while in its unsharpened state), the whole was as it were upset by the process of tempering; the accuracy which had previously been imparted to it being usually quite destroyed by the action of the fire and sudden cooling. In some cases the cutter would be found slightly warped or twisted; in others it would be oval or eccentric; and most frequently, when set to work on a truly-running mandrel in the milling machine, not more than one-third of the number of its teeth were found to be cutting at all, the others not coming in contact with the work. This really meant that not more than one-third of the proper feed per revolution could be applied, and not more than one-third of the proper work produced. Nor was this the only drawback: the quality of the workmanship produced by such a milling cutter was not of the best, and deteriorated hourly from blunting and wear. Such a cutter would probably not work for more than two whole days before it would require to be again softened by being heated red-hot and allowed to cool gradually. The expensive and unreliable process of re-sharpening by hand-filing had to be gone through once more; then the re-tempering, which caused the cutter again to become warped, swelled, or eccentric; and each time it was subjected to the heat of the fire, it ran the risk of being destroyed by cracking when plunged into a cold bath.

We represent in Fig. 1 the Brown and Sharpe universal milling machine, which has all the movements of a plain milling machine, and the following in addition:—the carriage moves and is fed automatically, not only at right angles to the spindle, but at any angle, and can be stopped at any required point. On the carriage, centers are arranged in which reamers, drills and mills can be cut either straight or spiral. The head which holds one center can be raised to any angle, and conical blanks placed on an arbor in it, cut straight or spiralling. The

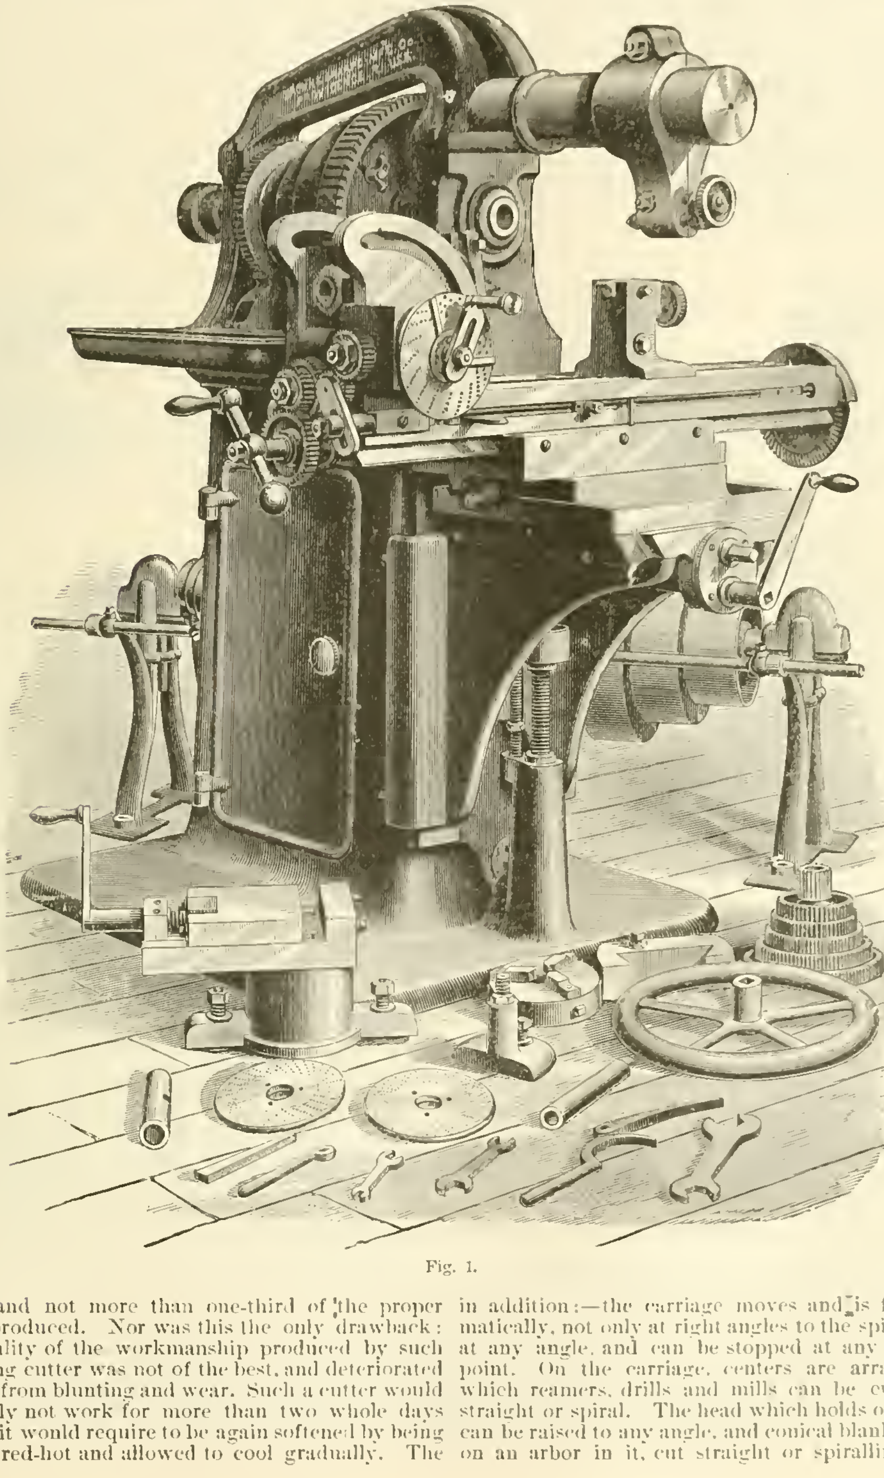

Fig. 1.

cone has three diameters, each $3\frac{1}{2}$ inches face. In addition, the cone is strongly geared, thus making six changes of speed. There are, also, the same number of changes of feed. The spindle boxes are of hardened cast steel, and, together with the spindle bearings, are carefully ground, and are provided with means of compensation for wear. The spindle will carry a cutter arbor projecting 15 inches, which is supported by an adjustable center at the outer end. Cutters of eight inches or less diameter can be used. The horizontal movement of the spiral clamp bed upon the knee, in a line with the spindle of the machine, is $6\frac{1}{2}$ inches, and the vertical movement of the spiral bed centers below the spindle centers is 11 inches. The spiral bed can be set at angles of 35° each way from center line of spindle, and can be fed automatically 22 inches, taking also 22 inches between the centers, and will swing $11\frac{1}{2}$ inches. The hole through the chuck and spiral head is $1\frac{1}{2}$ inches. In addition to all the more common kinds of plain surface milling, this machine is applicable to a great variety of work, among which may be mentioned the following: cutting of bevel and spur wheels, worm wheels and racks; milling of circular arcs and slots; squaring of bolt heads and nuts; fluting of tops, reamers, &c., cutting the teeth of mills, either straight or spiral; slotting of screw-heads; making of twist drills; drilling of holes on the periphery or face of plates; die-sinking, milling key-ways in spindles, &c., &c.; proving as its name indicates, a machine adapted for universal application to milling purposes.

It is proper now to describe the modern system of making and maintaining the improved milling cutters. A cast-steel forging, or blank as it is usually styled, is bored, and then turned to its proper shape in a lathe. The teeth are then machined out of the solid to the required forms, in a universal milling or other machine. The work is so accurately produced, direct from the machine, that no costly hand-labor need be expended upon the milled cutter, which is taken direct from the milling machine to the hardening furnace, and tempered. The hole in the center of the cutter is then carefully ground out to standard size, so that it may fit accurately and without shake on the mandrels both of the grinding machine and of its own milling machine. The cutter or mill is now placed on a mandrel of the small cutter-grinding machine; the mandrel itself is adjusted vertically and horizontally by ordinary slides, and by means of a worm and worm-wheel, to its required angular position; and each tooth is ground or re-sharpened by passing at once rapidly forward and backward under a small revolving emery-wheel. The mandrel fits easily into the cutter which is being ground, so that the latter may be readily turned round by the thumb and finger of the operator. Milling cutters are made of the required form to suit the various shapes they are intended to produce; and all the ordinary forms can be used in any milling machine either of the horizontal or vertical class. The face-milling cutters, Fig. 2, are of disk form, and are among the most useful. They are constructed to cut on one face and on the periphery; and they produce very perfect finish, especially on cast-iron. This form is also very useful for all kinds of stepped work, which even when not of the simplest form, can be readily and reliably finished to standard breadths and depths; so that the pieces may be interchangeable, and fit together without the slightest shake or play, just as they leave the machine, and without any hand-labor bestowed on them. Another ordinary and useful form is the cylindrical cutter, with teeth cut spirally over its circumference. This is largely employed for cutting flat, vertical, or horizontal surfaces, for finishing concave and convex curves, and for complicated forms made up of straight lines and curves. With this spiral arrangement of the teeth, and with reliable means of re-grinding or re-sharpening them, very high-class machine work can be produced. Some experiments have been made by cutting a spiral groove or thread into the outer surface of one of this class of mills, and thus reducing the aggregate length of its cutting surface. Other mills again are made in the form of small circular saws, varying from $\frac{1}{4}$ to $1\frac{1}{2}$ in. or more in thickness. The teeth in some of these are simply cut around the circumference; others have these teeth extending some distance down each side, their edges radiating from the center of the mill. Toward the center they are reduced in thickness so as to clear themselves. These cutters are useful for a great variety of work; for instance the cutting of key-ways, parting off or cutting through pieces of metal, and making parallel slots of various widths, for the broad-

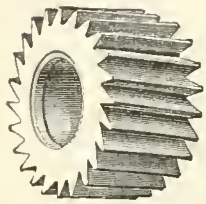

Fig. 2.

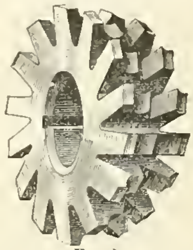

Fig. 3.

Fig 4.

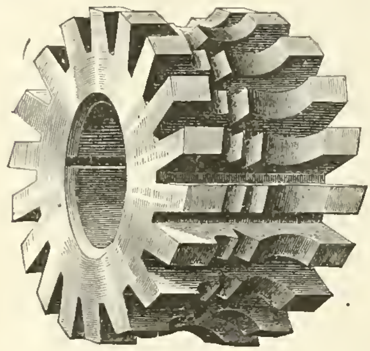

Fig 5.

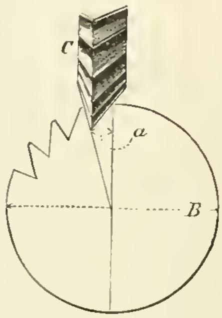

Fig. 6.

er of which two or more cutters may be used side by side. Conical and angular milling cutters are much employed for a great variety of work, such as the cutting of rimers, the making of milling cutters themselves, beveling, cutting the serrated part of hand and thumb-screws, nuts, etc. Any complex forms, such as the spaces between the teeth of spur, miter, and other wheels, can be machined by using what are known as the patent cutters, which can be re-sharpened as often as required by simply grinding the face of each tooth. They are so constructed that, however often they are re-ground, they never lose their original curved forms, and always produce the same depth of cut. One of these cutters, for instance, will cut the same standard shapes of teeth in a spur-wheel, after it has been used for years, as it did the first day it was started. Figures, 3, 4, and 5 illustrate some forms to which these cutters are adapted. There is risk of fracture in making large milling cutters out of one solid cast steel blank, the principal difficulty being in the tempering. In practice it is found that if they are required of larger diameter than about 8 ins. they are better made of wrought-iron or mild-steel disks, with hardened cast-steel so securely fitted into them that they do not require to be removed. The cutting-edges can then be re-sharpened in their own places, as in the case of the ordinary milling cutters; thus insuring that each shall have the same angle of cutting and clearance, run perfectly concentric, and therefore do a maximum amount of cutting in a given time. It must however be borne in mind that the smaller the diameter of the milling cutter, the better finish it will produce; and cutters of large diameters should only be used to reach into depths where one of smaller diameter could not, or to do the heavier classes of work. Again, the smaller the cutter, the less does it cost to make and maintain.

Fig. 6 represents a cutter in connection with the work, showing the position required in cutting the teeth of a spiral cutter. The distance a=one tenth of B. The hole in the cutter is ⅞ inch. Fig. 7 shows Garvin's spiral attachment, designed for use with the milling machine, and which will cut with the proper charge gears, spirals with pitch varying from one turn in 1.66 inches to one turn in 60 inches. Fig. 8 shows the swivel vise, mounted upon a graduated base 2½ inches high. This vise is useful for a variety of work, is quickly adjusted, and may be securely fastened at any angle, by two square head screws, one of which is shown in the drawing. Fig. 9 shows a *dividing head and tail* Stock, well adapted to the uses for which it is designed. It has a compensating wedge for adjusting the halves of the spacing worm gear, and an alteration of the usual tail stock pattern so that milling cutters, adjusted close to the center, pass clear across. With it gears can be accurately spaced, mills cut of straight, conical or irregular forms, taps and reamers fluted and worm wheels gashed. The slots in the stock allow the head to be elevated from a horizontal to a vertical position, and by supplemental slots in the elevated head, in which the T heads of clamp bolts slide, the head can be depressed to 30 degrees below a horizontal line, and 5 degrees beyond a vertical, making 125 degrees of change, all determined by graduations on stock. The spacing worm gear is made in halves, and all points liable to wear are provided with means of compensation for wear. Three index dials go with the head, dividing all numbers up to 50, and as many others as an every day machine shop practice may demand.

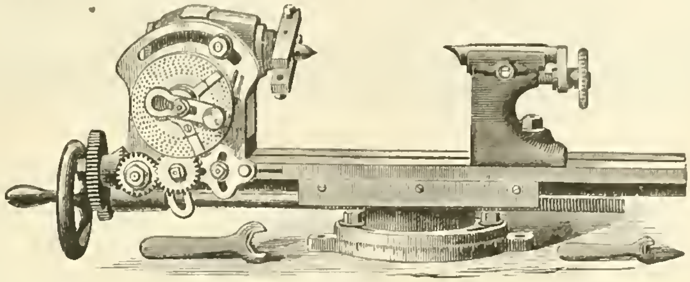

Fig. 7.

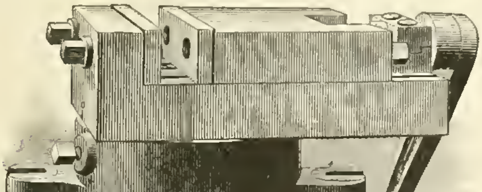

Fig. 8.

The spindle of the elevating head has a taper hole clear through, and the end of the spindle is threaded to receive the chuck, allowing pieces of any length less than 1 and 1-16 inch diameter to be milled. The tongues under the base of the head and tail stock are of steel, and can be removed to allow swivelling of the head, so that work held in the chuck, such as hollow mills, etc., can be cut under or hooking. The tail stock has a milled head adjusting screw, and screw to bind the spindle central in any position. These centers are designed to be used on milling, shaping and planing machines.

The cutting speed which can be employed in milling is much greater than that which can be used in any of the ordinary operations of turning in the lathe, or of planing, shaping, or slotting. A milling cutter with a plentiful supply of oil, or soap and water, can be run at from 80 to 100 ft. per minute when cutting wrought iron. The same metal can only be turned in a lathe, with a tool-holder having a good cutter, at the rate of 30 ft. per minute, or about one-third the speed of milling. Again, a milling cutter will cut cast-steel at the rate of 25 to 30 ft. per minute. The increased cutting speed is due to the fact that a milling cutter, having some thirty points, has rarely more than three of these cutting at the same time. Each cutting point therefore is only in contact with the metal during one-tenth of each revolution. Thus, if we suppose it is cutting for one second, it is out of contact, and therefore cooling, for the succeeding nine seconds, before it has made a complete revolution and commences to cut again. On the other hand, a turning tool while cutting is constantly in contact with the metal: and there is no time for it to cool down and loose the heat imparted to it by the cutting. Hence, if the cutting speed exceeds 30 ft. per minute, so much heat will be produced that the temper will be drawn from the tool. The same difficulty to a great extent applies to the cutting tools in planing, shaping, and slotting machines. The speed of cutting is governed also by the thickness of the shaving and by the hardness and tenacity of the metal which is being cut: for instance, in cutting mild steel with a traverse of 3-8 in. per revolution or stroke, and with a shaving about 5-8 in. thick, the speed of cutting, must be reduced to about 8 ft. per minute. A good average cutting speed for wrought or cast-iron is 20 ft. per minute, whether for the lathe, planing, shaping, or slotting machine.

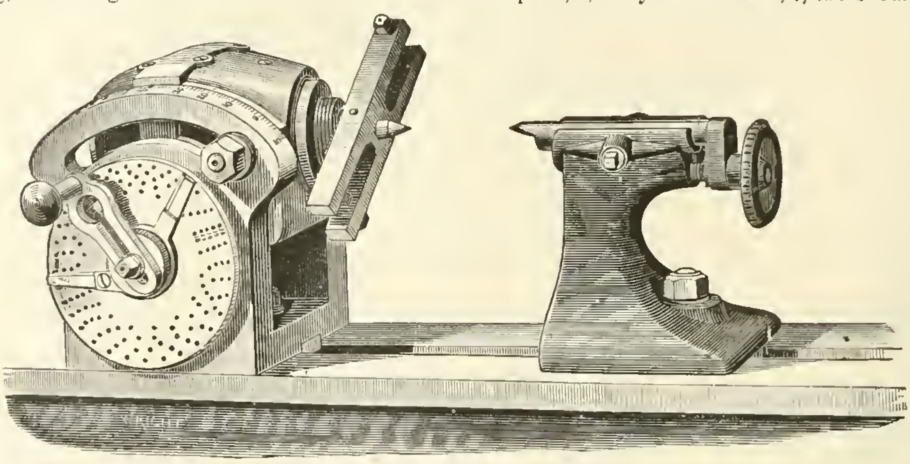

Fig. 9.

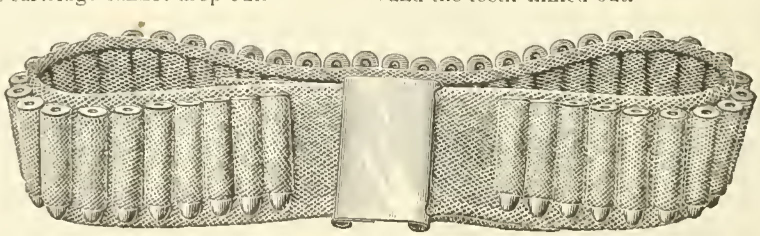
Millrind.

MILLRIND.—MILLRIND, or FER DE MOULIN in Heraldry; a charge meant to represent a mill-iron originally a mere variety in designating the cross moline, but accounted a distinct charge by some heralds. See *Heraldry*.

MILLS CARTRIDGE-BELT. This belt in its main features is not unlike what has been for a long time known as the "Prairie Belt," its distinguishing characteristic being that it is not only made entirely of heavy cotton fabric, but that the whole belt—the main fabric or body of the belt, as well as the loops or thimbles which hold the cartridges—are woven in one solid piece, at one and the same time, in the same loom, there being no sewing whatever in the entire belt. The cylindrical loops are taken from and returned to the main web at the same point, so the cartridge is held in place by friction produced by contact with its whole circumference, and are of such accurate form that, aided by the cord at the top of the belt, the cartridge cannot drop out.



As seen in the drawing, the belt has a suitable margin above and below the cartridge and loop which prevents the wearing of the former by rubbing against the clothes of the wearer. Handsome and durable buckles are furnished, so formed that the wearer may adjust the length of the belt to his person without sewing or cutting, and can also adjust the buckle midway between the cartridge loops. This belt was recommended by the Equipment Board of 1879, was very fully approved by the General of the Army, and adopted by the Secretary of War, and is now the Regulation Belt for the United States Army. See *Pooler-Jones Belt*.

MILLS SPUR.—This spur, the invention of Colonel Anson Mills, United States Army, and shown in the drawing, is composed of a heel-strap, *a*, or "main leather band," as it is called by the inventor, to which the rowel-plate, *b*, is riveted, a lower strap, or under strap, *c*, passing under the boot; and a spur-strap, *d*. The metallic parts of the spur are the rowel-plate, *b*, the yoke or frame, *e*, the shoulder, *h* (all of brass in one piece), the rowel, *f*, of steel, the rowel-pin of steel, the buckle, *k*, of brass, eyelet, *l*, and the brass rivets and burs, marked 1, 2, and 3. The buckle is fastened to the understrap by means of a small projection, which is twined over the bar of the buckle and riveted, the tongue passing through the slot. The eyelet, *l*, is intended for the insertion of a button attached to a steel wire double loop for strapping down the trowsers.

The different steps in the process of manufacture of the rowel-plate and yoke are very simple. The plate and yoke are first punched out flat in a rotary press. The middle slot and the holes for the rivets and rowel-pin are then punched. The branches of the yoke are next rounded and bent up by means of a punch and die of proper shape. The shoulder is then formed and by the next operation set firmly down on the rowel-plate. The holes are then drilled, and the finished rowel-plate and yoke are pickled and polished. The hole for the rivet is drilled or punched, and the rowels are strung on a wire passing through the hole, placed in the milling machine, and the teeth milled out.

The rowel is riveted in the yoke with a rotary press. The rivet is increased in diameter throughout its entire length by this operation, and the hole in the rowel is made $\frac{1}{16}''$ larger than the rivet to allow for this increase. The rowel-plate is riveted to the heel-strap by the same press, as it is not easy to do the riveting by hand without the plate. The leather parts are assembled after the rowel-plate has been riveted. The spur-strap and heel-strap are placed together and the eyelet inserted; the heel-strap and under-strap on the other side are assembled in the same manner; the end of the under-strap with the slot in it is then carefully inserted between the heel-strap and the spur-strap, and the whole securely riveted.

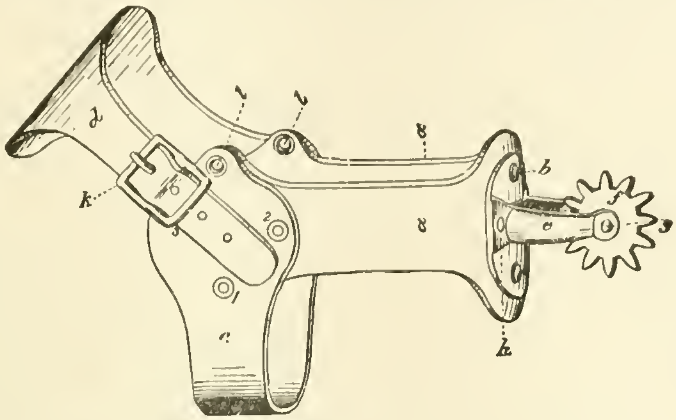
MIM BASHY.—In the East Indies, a commander of one thousand horse.

MINER'S TRUCK.—In low galleries and branches, where wheelbarrows cannot be used, small wagons or *miner's trucks*, resting on short cast-iron wheels, answer the same purpose, a man pushing behind, assisted by another pulling with a rope in front, when the gallery is descending.



Mills Spur.

MINES.—Military mines constitute at once one of the most important departments in military engineering, and a very formidable accessory both in the attack and defense of fortresses. A military mine consists of a gallery of greater or less length, run from some point of safety under an opposing work, or under an area over which an attacking force must pass, and terminating in a chamber which, being stored with gunpowder, can be exploded at the critical moment. Mines are of great use to the besiegers in the overthrow of ramparts and formation of a breach; the *countermines* of the besieged in undermining the glacis over which the assaulting column must charge, and blowing them into the air, or in destroying batteries erected for breaching, are equally serviceable. But far above the actual mischief wrought by the mine often very great is its moral influence on the troops, and especially on the assailants. The bravest soldiers, who advance without flinching to the very mouth of the cannon *which they see*, will hesitate to cross ground which they suppose to be undermined, and on which they may be dashed to destruction in a moment, without the power of averting the *unseen* danger. The first employment of mines was very ancient, and merely consisted in obtaining an entrance to the interior of towns by passing beneath the defenses; but this soon fell into disuse, the chances of success being merely those of introducing a body of men before the besieged discovered the mine. The next use occured during the Middle Ages, and was more destructive. The miners went no further than beneath the wall, then diverged to either side, and undermined the wall, say for about 100 feet. During the process, the wall was sustained by timber props; and these being ultimately set on fire, the wall fell; and the besiegers, who had awaited the opportunity, rushed in at the breach. This use of mines of *attack* necessitated those of *defense* which obtained in mediæval times and have ever since kept the name of "*counter-*

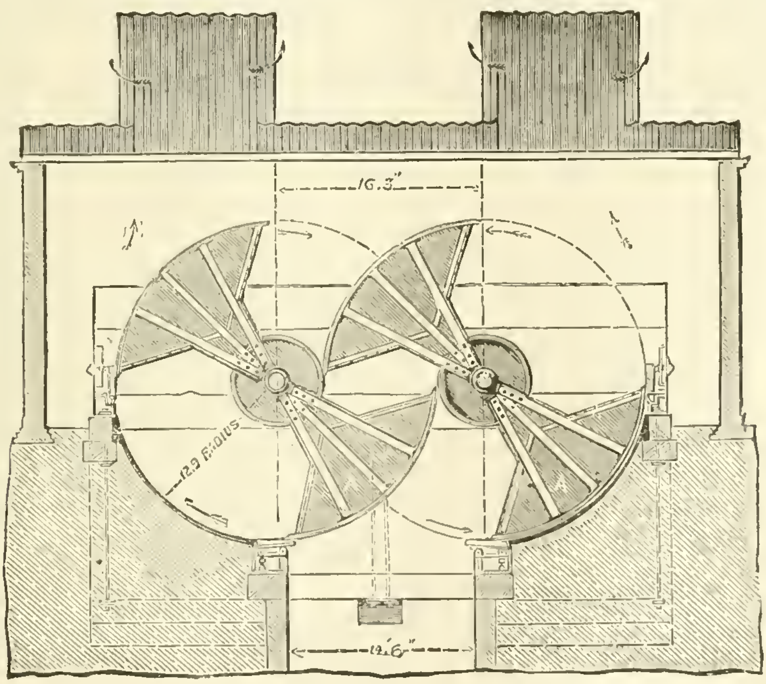


Fig. 1.

mines." The earliest subterranean defense consisted of a gallery surrounding the fort in advance of the foot of the wall, and termed an enveloping gallery. From this the garrison would push forward small branches of tributary galleries, whence they could obtain warning of the approach of hostile miners, and by which they succeeded, at times, in overthrowing the battering-rams or towers of the besiegers.

Two centuries appear to have elapsed between the introduction of gunpowder into European warfare and its application to subterranean operations. The first instance of this occurred in 1503, at the siege of the Castello del' Uovo, in the bay of Naples, which a French garrison had succeeded in holding for three years against the combined Spanish and Neapolitan forces. At length a Spanish Captain, Pedro Navarro, devised a gallery into the rock, which he stored with powder, whereof the explosion, hurling portions of the rock and many of the besieged into the sea, caused the immediate capture of the place. At once the use of mines of attack spread throughout Europe; and so irresistible were they soon considered by all military engineers, that it was not at all unusual for the besieger, after preparing his mine, to invite the besieged to inspect it, with the view of inducing the latter at once to surrender. Defense soon availed itself of the new power, and, retaining the enveloping gallery as a base, ran small countermines in many directions, to ascertain, by hearing, the approach of the enemy's sappers—his work being audible, to a practiced ear, at a horizontal distance of 60 feet. Small charges were then exploded, which, without creating surface disturbance, blew in the approaching gallery, and buried the sappers in its ruins. Thus commenced a system of subterranean warfare, requiring the greatest risk and courage, in which the operator was in constant danger of being suffocated. Of course, in such a system, the balance of advantage lay with the besieged, who had ample opportunities, before the siege commenced, of completing his ramifications in every direction, and, if desirable, of revetting them with masonry, which much diminished the chance of being blown in; while the assailant, no longer able to cross the glacis by an open zigzag trench, was compelled to engage in a most uncertain subterranean advance. The French engineer, Belidor, in the 18th century restored the advantage to the attack, by demonstrating that the explosion of a very large mass of powder in a mine which had not yet entered the labyrinth of defensive mines, effected the destruction of the latter for a great space round, clearing the way with certainty for the hostile advance. Although the primary purpose of a mine is the explosion of a charge of powder, they are often used as a means of communication between different works, or between different parts of the same work, some being constructed of size sufficient to permit the passage of four men abreast, of horses, and of artillery.

It is, of course, impossible, in such a work as this to give even an outline of the professional part of military mining; but the article would be incomplete without some allusion to the main principles. Mines are either vertical (*shafts*), horizontal, or inclined, in either of which latter cases, they are *galleries*, the word "ascending" or "descending" being added if there be inclination. The dimensions range from the *great gallery*, 6 ft. 6 in. by 7 ft., to the *small branch*—the last diminutive of the gallery—which has but 2 ft. 6 in. height, with a breadth of 2 feet. The most frequent work is the *common gallery*, 4 ft. 6 in. by 3 ft., which is considered the easiest for the miner. The sapper's tools are numerous, but most in request are his shovel, pickaxe, and, above all, his push-pick, he has, besides, a barrow, a small wagon, a lamp, and other accessories. As he advances, it is necessary to line his gallery, always at the top, and almost always at the sides. This he does either by frames—which resemble door-frames, and serve to retain horizontal planks or sheeting in position against the earth—or by cases somewhat resembling packing-cases, of little depth, which are used to form the sides and top. With cases, galleries are supposed to advance one foot and a half per hour; while with frames, the progress is barely more than half that amount. When a mine is exploded, the circular opening on the surface is called the *crater;* the *line of least resistance* is the perpendicular from the charge to the surface; the half diameter of the crater is its radius; and the *radius of explosion* is a line from the charge to the edge of the crater, on the hypothenuse of the triangle, the revolution of which would form the cone. When the diameter equals the line of least resistance, the crater is called a one-lined crater; when it doubles that line, a two-lined crater; and so on. The common mine for ordinary operations is the two-lined crater; and for this the charge of powder should—in ground of average weight and tenacity—be in pounds a number equal to one-tenth of the cube of the line of least resistance in feet, for example, at a depth of 18 feet, the charge should consist of 583 pounds. In surcharged mines, or globes of compression, as introduced by Belidor, vastly greater charges are employed, and craters of six lines are sometimes produced. The rules, in these cases, for computing the charges vary exceedingly, according to different engineers, and in every case are very complicated. Previous to the explosion, the gallery is filled up behind the charge, or *tamped*, with earth, sand-bags, etc., to prevent the force of the powder wasting itself in the mine. This tamping must extend backwards for one and a half or twice the length of the line of least resistance. The mine is commonly fired by means of a powder-hose, composed of strong linen, inclosed in a wooden pipe laid carefully through the tamping, or by wires from a voltaic battery.

One of the most important subjects engaging the attention of the engineer is the proper ventilation of the mines. With the progress of civilization, this subject is assuming, every day, aspects of more and more importance, not only in relation to safety and health, but in a great measure from its vital connection with some of the great enterprises of the day. The entire inadequacy of any of the present arrangements or systems to give any thing like a thorough and perfect ventilation becomes more and more apparent as they proceed to greater depths and distances under ground; which, taken in connection with the unhealthiness, great risk and fearful loss of life from explosions, now of such common occurrence, suggest the alarming contingency of being compelled to abandon them at no very distant day. The consequences of even a slight interference with the mining interests of Europe are dreadful to contemplate. And in some parts of our own country the subject is one of great importance. Sometimes, in connection with high chimneys above ground, additional shafts have been sunk. Fires have been kept in the mines and chimneys, in order to rarefy the air and thus produce draught. This is not only dangerous, but to a great degree ineffectual. And further, it has been demonstrated that the power resulting from the combustion of one pound of coal will give more ventilation than thirty to fifty pounds consumed in the way spoken of. May we not, therefore, on the whole, pronounce this system a failure? The only remaining plan of note to be considered is the fan. Of late they have received considerable attention. Enormous fans of from twenty to fifty feet in diameter, have been constructed at great expense, and requiring a vast amount of power to run them. But these considerations would not be of so much consequence, if they accomplished the purpose; but this, in mines of any considerable depth and extent, they do not and can not. Within a certain range, fans would undoubtedly be beneficial, but fans do not have a positive action either for pressure or exhaustion. Their capabilities are thus limited. The deeper and more extensive the mine, the greater the necessities for thorough ventilation. Here they must always fail.

The Root's positive blower appears to be the most satisfactory machine ever used by the mining engineer. With this apparatus placed at the mouth of the shaft we can exhaust the damps and foul air in any required quantity, and discharge it entirely out of and away from the mine, where it can do no harm whatever. The foul air thus displaced will be replaced by pure air, which will rush in from the surface in a volume equal to the air displaced. Thus the most distant parts of the mine will be equally as well ventilated as any other part and the mine throughout its entire extent may be said to be washed out with pure air. By this method, the foul air resulting from blasting in mines and tunnels is exhausted at the point where the gases are formed, and entirely removed from the tunnel and replaced with pure air. This ventilator is shown in section in Fig. 1. It consists of two rotary pistons, which are each 25 ft. diameter and 13 ft. wide, and are built upon steel shafts. Upon each of the shafts are keyed five cast iron disc plates, having flanges at their circumference which are all turned to exactly the same diameter. In each disc plate there are three wrought iron bars fixed on each side of the center, and reaching to the outside of the rotary piston; planed recesses are provided in the disc plates to receive the bars, which are also secured to the disc plates by bolts turned to fit. The outer ends of the bars are widened, and marked off and slotted to the radius of the outer circle. Angle irons bent to the radius of the outer circle are riveted to the extremities of the bars, and are covered with $\frac{1}{4}$ in. sheet iron plate; the center circles are also covered with $\frac{1}{4}$ in. sheet iron plates on the turned flanges of the disc plates. The sides of the pistons are covered with wood, and the ends with sheet iron. These rotary pistons revolve in bearings fixed upon deep cast iron girders, which form the framework of the ventilator pit, and are connected together at each end of the ventilator by cross girders. The girders and the cast iron side plates above them are planed on their inside surfaces, and the stonework of the ventilator pit is dressed off level with the planed girders. The engines to drive the ventilator are a pair of 28 inch cylinders with 4 ft. stroke, and provided with adjustable cut-off valves. They are placed at right angles to the ventilator, and are connected to it with bevel wheels 9 ft. $2\frac{3}{4}$ in. diameter, two bevel wheels being fixed upon the crank shaft, each gearing into a bevel wheel keyed upon the end of the ventilator shafts. The engine beds are carried along and fixed upon a stay girder, securely keyed and bolted to the main girder. The main girders are fixed 13 ft. $\frac{1}{4}$ in. apart, therefore, the clearance between the rotary pistons of 13 ft. and the sides of the ventilator pit is only $\frac{1}{8}$ in. on each side. At each end of the ventilator pit, and at the bottom on each side of the inlet from the upcast shaft, adjustable packing blocks of timber are fixed upon hinged iron frames, and can be adjusted with screws and nut; these blocks are set up quite close to the periphery of the rotary pistons within $\frac{1}{8}$ inch. The clearance between the periphery of one of the rotary pistons and the center circle of the other is also the same, and thus in any part of the ventilator the clearance for loss by the returning of the air is not much more than $\frac{1}{8}$ inch.

The arrangement of the engine-house and ventilator building is shown in the engraving; the discharged air escapes through perforated openings in the roof, and, owing to the very large area of outlet from the ventilator—the top of the ventilator casing being left entirely open—the air that is being exhausted from the pit must necessarily be delivered into the atmosphere at a lower velocity than is usual with other ventilating machines. The range of this blower, when employed as an exhauster, is certainly in advance of any of the previous mechanical ventilators; and in the writer's opinion this would be a decided advantage in the case of an explosion. When the air-doors become disarranged, the ventilation of the mine is interfered with at the moment when it would be of the greatest service, and this owing to the limited power of fan ventilation, which can only be depended upon up to about 3 in. water gauge; but in a case of emergency, with a Root's ventilator similar to the one described, the machine could be instantly driven at its maximum power, and would speedily clear the workings of the choke-damp, fire-damp, or after-damp. Since explosions cannot always be prevented, it is of importance that the deadly gases should be drawn out in the shortest possible space of time, and replaced with pure air; and from present experience this ventilator appears to be well fitted to suit these requirements.

Fig 2. shows the adaptation of the Cameron mining pump for sinking and recovering shafts. It frequently happens in sinking a shaft that it makes water so rapidly that it is very difficult to remove it as fast as necessary, and for the same reason great trouble is experienced in lowering an ordinary horizontal pump from one level to another; and in attempting to recover old mines that have been "drowned out," the difficulty is the more serious, because of the large surface below to make water. This machine is held in suspension in the shaft, and being vertical, requires but little room, and can be raised and lowered as required. There is no danger of its being submerged. Being compact and strongly made, without any of the working parts exposed to injury, they are well adapted for the rough usage incidental to the work for which they were designed. Adjustable wrought-iron dogs are provided to fasten the pump to the shaft timbering, although they will work equally as well when hanging by the tackle, or will operate perfectly when placed at an angle or horizontally. The general features are exactly the same as in an ordinary horizontal machine, except that they are arranged to work vertically. Iron pipes or flexible hose may be employed as best suits the situation.

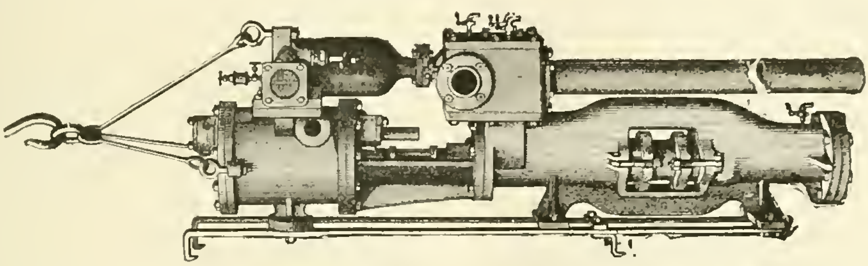

Fig. 2.

It is but rare that, in the defensive arrrangements of a field work, any combination for a war of mining is provided for; although in many, and those but recent cases of a stubborn and protracted defense of field works against regular siege operations, mines have been employed with great success, although not made before the works of the assailant were under way. As the end to be attained is the same in conducting the defense of a work by mines, whether it be a temporary or a permanent one, the same principles in the arrangement of a combination of mines for this purpose are equally applicable to the two cases; the most essential of which are as follows: As the galleries of a system of mines serve the purpose of underground communication, they should be subjected to the same conditions as other communications. A condition of primary importance is, that no combination shall be made which might compromise the safety of the work. To this end, no gallery beyond the ditch should lead to the interior of the work; for should the enemy get possession of such a gallery he might either penetrate into the work, or else barricade the gallery and hold possession of it long enough to blow up the works under which it leads. The galleries should not offer any facilities to the besiegers for carrying on their works. Those galleries, therefore, which, communicating with the ditches, might serve the besiegers for their descent of the ditch; also a continued counterscarp gallery, which may not only facilitate the descent of the ditch to the besiegers, but also, when in their possession, give them that of the whole system of mines, and, besides, serve to protect their passage of the ditch, and to prevent sorties in it, should be rejected. A gallery behind a portion of the counterscarp not favorable to the enemy's works, is very useful as a depot for the implements of the miners, and also as a communication. A complex system of mines should not be used for works that can be carried by storm; for the reason that the besiegers might easily get possession of the system before it could be brought into play. The entrance to a sytsem from the ditch must be revetted, to offer a sufficient obstacle to prevent the enemy from getting possession of the system by surprise; hence, a revetted counterscarp is a necessary condition in the establishment of the system. The galleries should not be run out to any considerable distance beyond the covered-ways, both on account of procuring a good circulation of air, and because very advanced galleries are easily destroyed by the besiegers. The distance to which the galleries may extend should be so much the less as the ground above them is well protected by the collateral defenses. The soil must be suitable for the establishment of a system; wet, marshy ground, shifting sand, and hard rock, present almost insuperable obstacles; whereas a dry, firm soil, soft rock, or ordinary earth, under a thin superstratum of hard rock, are very favorable circumstances. If the sub-soil is wet, but presents a firm and dry superstratum 12 ft. thick above the level at which the water collects, mines may still be placed with advantage.

Besides the above general conditions, there are certain special ones to be attended to in arranging the galleries and chambers. The galleries should be placed as far below the surface as practicable, to withdraw them from the effect of the globes of compression of the besiegers. To drain the galleries they should have a slight inclination, about $\frac{1}{50}$, towards the ditches; or, if the ground descends towards a hollow, the inclination may be given in that direction. The chambers, on the contrary, should be near the surface; by this arrangement the powder is economized, and all danger to the galleries from the explosion avoided, whilst the object of the mines, which is to destroy the enemy's works, can be as fully attained by small mines as large ones. The galleries should not be placed nearer to each other than twice the line of least resistance of the heaviest charged mines, and not much less than four times the line of least resistance of the smallest charges. This arrangement will readily admit of a combination of mines in two tiers, the line of least resistance of the lower being at least double that of the upper, the chambers of which may be so arranged that the explosions of one tier shall not affect either the galleries or the mines of the other. Twice the line of least resistance of the largest mines is the least distance that can be allowed between the galleries, in order that the mines of the lowest tier, which, being placed near one gallery to destroy a part of it, shall not injure those parallel to it. By placing the galleries at this least distance apart, the branches for the service of the upper tier will be as short as possible, effecting thus a saving of time and labor; and for the same reason, the galleries on any one point being as many as can be placed, there will be less chance of all being destroyed by an explosion, but that some one of the galleries will be found serviceable. The galleries and branches for the service of the different groups of mines should be independent of each other, so that there may be no confusion in the service, and that no group may be rendered unserviceable by the destruction of the communications to another. The same principle should be attended to in combining the different groups of mine chambers. The galleries and branches should never present their flanks or sides to the globes of compression of the besiegers. This rule leads to the rejection of enveloping galleries. See *Blower*, *Countermines*, *Firing-battery*, *Gallery*, and *Shaft*.

MINIE BALL.—A ball or bullet of peculiar construction. It is cast hollow for nearly two-thirds of its length, and into the opening of the internal cylinder there is introduced a small concave piece of iron, which the powder at the moment of firing forces into the slug, spreading it open, and causing it to fit perfectly to the barrel. Hence, a great increase in the precision of aim and the extent of range. See *Bullet*.

MINIE RIFLE.—A rifle introduced some years ago and adapted for firing the Minie bullet, the peculiarity of which bullet was that it had an iron cup placed in a cavity at the base, which, on the rifle being fired, expanded the lead into the grooves of the barrel. In 1851 a rifle musket of the Minie pattern was supplied to the English Army, but only to a limited extent; it was used in the Crimea, at the battles of the Alma and Inkerman. Notwithstanding its many advantages, it was found to be defective in practice, and was superseded by the Enfield rifle in 1853.

MINION.—An ancient form of ordnance of small size, the caliber of which was about three inches.

MINISTER.—I. Functionary Diplomatic. By the American system Ministers to exercise diplomatic functions near Foreign Courts are appointed by the President and confirmed by the Senate of the United States. They are accredited by letter to the Sovereign of the country to which they are appointed, and are permitted certain immunities and privileges, being entitled to be addressed as "Excellency," and conceded exemption from the operation of municipal law. The United States send no Envoys of the rank of Embassadors, permanently accredited to Foreign Courts; but have not infrequently conferred the rank and authority in the case of special missions. II, Functionary Executive, In the United States Government, the executive officers are under the immediate official direction and control of Heads of Departments, including those of State, Treasury, Interior, War, Post-Office, Navy, Justice, and Agriculture. Seven of these Officials have seats in the Cabinet or Council of Advisers of the President, and are termed "The Cabinet." They are the Secretaries of State, War, the Treasury, the Navy, and the Interior; the Postmaster-General, and the Attorney-General, or the Head of the Department of Justice. These Officials are appointed by the President, and confirmed by the Senate; their duty is to administer or execute the functions of their respective offices under the direction of the President; to whom they are immediately responsible and to whom they report annually; and from time to time on special subjects if so desired by him. They hold their offices at the will of the President, who may request their resignations if the good of the public service shall seem to require it. As an Advisory Council, they assemble at the call of the President, or at stated times, for conference, to enunciate opinions or to answer questions. There is nothing, however, in the Constitution or elsewhere in American law which renders it obligatory on the President to employ them in this manner, though custom has made it usual and convenient so to do. Excepting to the President for the proper performance of their official duties, they have no responsibilities; and in no particular except in the nature of these duties do they resemble the Ministers of Great Britain or those of the European Powers

MINOR BARONS.—The word baron, in the earliest period of Feudalism, signified one who held lands of a superior by military tenure. The superior might be the Sovereign, or he might be an Earl or other eminent person, who held of the Sovereign. According as he was the one or the other, the Baron was, in the earliest sense of the distinction, a Greater or Lesser Baron. At the Conquest a large part of the soil of England was parceled by William the Norman among his military retainers, who were bound in return to perform services, to do homage, and to assist in administering justice, and in transacting the other business done in the Court of the King. 400 of these Tenants-in-Chief of the Crown are enumerated in Domesday, including among them "Vice-comites" and "comites", who together constituted the body of men called the Barons of England. As the Sovereign was entitled to demand from the Baron's military service, homage, and attendance in the Courts, so, many of the principal Barons, particularly, such of them as were Earls, had Military Tenants, from whom they in turn received homage and assistance in administering justice in their Baronial Courts. These Tenants were Barons of the Barons, or, in the earliest sense, Minor Barons; but by the usage of England, from the Conquest downwards, they were seldom called Barons, that term having been generally restricted to the former class, the holders of land direct from the Crown, who were next to the King in dignity, formed his army and his legislative assembly, and obtained the great Charter from King John. The subinfeudation which produced the Minor Barons was checked by a statute of Edward I., directing that all persons acquiring lands from a subject, should hold not of that subject, but of his superior.

MINUTE GUNS. Guns fired on the interment of an officer of rank, or of some high personage of the realm. The officer to whom these honors are paid must have been above the rank of Colonel in the Army, or of Commodore in the Navy, and have died on service. Minute guns are also fired as signals of distress.

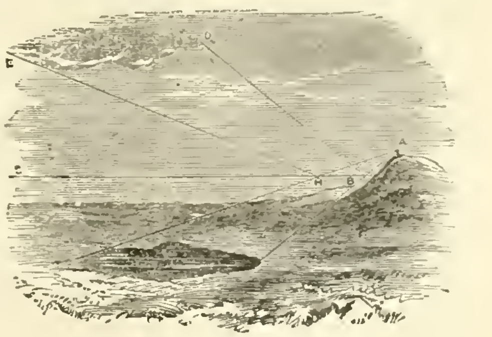
MINUTE MAN.—A man enlisted for service wherever required, and ready to march at a moment's notice. The term was first used in the American Revolution.

MINUTES.—A brief or rough report of the proceedings of a Society or Council drawn up by the Secretary or Recorder. They are so called from being taken down shortly, and in *minute* or small writing, to be afterwards engrossed.

MINUTES OF COUNCILS IN THE MILITARY DEPARTMENT.—The notification of orders and regulations, which are directed to be observed by the British Army in India. These minutes receive the sanction of the Governor-General in Council, and are the results of previous communications from the Court of Directors in Europe. The answer to the French word, *Resultat*, which was prefixed to all orders and regulations that were occasionally issued by the Military Boards, or *Conseils de Guerre*, for the government of the Army. The term, *Jugement d'un Conseil de Guerre*, corresponded with minutes of a General or Garrison Court-Martial, and expressed not only the minutes, but the sentence of the Court.

MIQUELETTI.—A small body of mountain fusiliers, who formerly belonged to the Neapolitan Army. The term *Miquelets* is applied to Bandits, who have infested the Pyrenean Mountains; the name is also borne by the Captain-General's Guard. In 1808, Napoleon organized a corps of *Miquelets Francais*, who rendered good services.

MIRAGE.—A phenomenon extremely common in certain localities, and as simple in its origin as astonishing in its effects. Under it are classed the appearance of distant objects as double, or as if suspended in the air erect or inverted, etc. One cause of the mirage is a diminution of the density of the air near the surface of the earth, produced by the transmission of heat from the earth, or in some other way; the denser stratum being thus placed *above*, instead of, as is usually the case, *below* the rarer. Now, rays of light from a distant object situated in the denser medium (i. e., a little above the earth's level), coming in a direction nearly parallel to the earth's surface, meet the rarer medium at a very obtuse angle, and instead of passing into it, are reflected back to the dense medium, the common surface of the two media acting as a mirror. Suppose, then, a spectator to be situated on an eminence, and looking at an object situated like himself in the denser stratum of air, he will see the object by means of directly transmitted rays; but besides this, rays from the object will be reflected from the upper surface of the rarer stratum of air beneath to his eye. The image produced by the reflected rays will appear inverted, and below the real object, just as an image reflected in water appears when observed from a distance. If the object is a cloud or portion of sky, it will appear by the reflected rays as lying on the surface of the earth, and bearing a strong resemblance to a sheet of water; also, as the reflecting surface is irregular, and constantly varies its position, owing to the constant communication of heat to the upper stratum, the reflected image will be constantly varying, and will present the appearance of a water surface ruffled by the wind. This form of mirage, which even experienced travelers have found to be completely deceptive, is of common occurrence in the arid deserts of lower Egypt, Persia, Tartary, etc.



In particular states of the atmosphere, reflection of a portion only of the rays takes place at the surface of the dense medium, and thus double images are formed, one by reflection, and the other by refraction—the first inverted, and the second erect. The phenomena of mirage are frequently much more strange and complicated, the images being often much distorted and magnified, and in some instances occurring at a considerable distance from the object, as in the case of a tower or church seen over the sea, or a vessel over dry land, etc. The particular form of mirage known as *looming* is very frequently observed at sea, and consists in an excessive apparent elevation of the object. A most remarkable case of this sort occurred on July 26, 1798, at Hastings. From this place the French coast is fifty miles distant; yet, from the sea-side the whole coast of France, from Calais to near Dieppe, was distinctly visible, and continued so for three hours. In the Artic regions it is no uncommon occurrence for whale-fishers to discover the proximity of other ships by means of thier images seen elevated in the air, though the ships themselves may be below the horizon. Generally, when the ship is above the horizon, only one image, and that inverted, is found; but when it is wholly, or in great part below the horizon, double images, one erect and the other inverted, are frequently seen. The faithfulness and distinctness of these images at times may be imagined from the fact, that Captain Scoresby, while cruising off the coast of Greenland in 1822, discovered the propinquity of his father's ship from its inverted image in the sky. Another remarkable instance of mirage occurred in May, 1854, when, from the deck of H. M. screw-steamer Archer, then cruising of Oesel, in the Baltic, the whole English fleet of nineteen sail, then nearly thirty miles distant, was seen as if suspended in the air upside down. Besides such phenomena as these the celebrated *Fata Morgana* of the Straits of Messina sinks into insignificance. The *Specter of the Brocken* in Hanover, is another celebrated instance of mirage. Its varieties are indeed numberless, and we refer those who wish for further information to Brewster's *Optics*, Biot's *Traite de Physique*, and for the mathematical theory of the mirage to the works of Biot, Monge, and Wollaston.

MIRE.—In the French artillery, a piece of wood about 4 inches thick, 1 foot high, and 2½ feet long, which is used in pointing cannon.

MIREUR.—An instrument employed in coast batteries for ascertaining whether the enemy's ships are within the range of the guns, and thus to prevent the gunners from expending their shot unnecessarily.

MIRMILLONES.—A variety of Roman gladiators, said to have been so called from their having the image of a fish on their helmets. Their arms were like those of the Gauls; hence we find that they were also called Galli. They were usually matched with the Retiarii.

MIRROR.—An instrument used in the inspection of cannon. The interior of the bore is examined by reflecting the rays of the sun into it from the mirror or mirrors; or, if the sun is obscured, and there can be no delay, by means of a spirit-lamp or of a wax taper on the end of a rod, taking care not to smoke the surface of the bore. See *Inspection of Ordnance*.

MISBEHAVIOR BEFORE THE ENEMY.—The Articles of War declare that any officer or soldier who misbehaves himself before the enemy, runs away, or shamefully abandons any fort, post, or a guard which he is commanded to defend, or speaks words inducing others to do the like, or casts away his arms or ammunition, or quits his post or colors to plunder or pillage, shall suffer death, or such other punishment as a Court-Martial may direct.

MISCELLANEOUS.—An item or charge in the Estimates of the British Army, and so distinguished as *Miscellaneous Services;* the same as our *Contingent Expenditures.*

MISCONDUCT AT DIVINE SERVICE.—In the Articles of War, it is earnestly recommended to all Officers and Soldiers diligently to attend divine service. Any officer who behaves indecently or irreverently at any place of divine worship is brought before a General Court-Martial, there to be publicly and severely reprimanded by the President thereof. Any soldier who so offends, for his first offense, forfeits one-sixth of a dollar; for each further offense he forfeits a like sum, and is confined twenty-four hours. The money so forfeited is deducted from his next pay, and is applied, by the Captain or Senior Officer of his troop, battery, or company, to the use of the sick soldiers of the same.

MISCONDUCT IN TIME OF WAR.—All Officers and Soldiers are to behave themselves orderly in quarters and on the march; and whoever commits any waste or spoil, either in walks or trees, parks, warrens, fish-ponds, houses, gardens, grain-fields, inclosures, or meadows, or maliciously destroys any property whatsoever belonging to inhabitants of the United States (unless by order of a General Officer commanding a separate army in the field), shall, besides such penalties as he may be liable to by law, be punished as a Court-Martial may direct.

In time of war, insurrection, or rebellion, larceny, robbery, burglary, arson, mayhem, manslaughter, murder, assault and battery with an intent to kill, wounding, by shooting or stabbing, with an intent to commit murder, rape, or assault and battery with and intent to commit rape, shall be punishable by the sentence of a General Court-Martial, when committed by persons in the military service of the United States, and the punishment in any such case shall not be less than the punishment provided, for the like offense, by the laws of the State, Territory, or District in which such offense may have been committed.

MISERICORDE.—A very short sword, in early times, attached to the right side, corresponding with the position of the regular sword on the left side. This weapon is so called because it was habitually used to stab the fallen and vanquished foe, when in such extremity either that mercy would be sought, or that it would be a merciful deed to put an end to the sufferer's agonies.

MISNOMER.—The mistaking of the true name of a person. If any prisoner plead a *misnomer* before a Court-Martial, the Court may ask the prisoner his real name, and call upon him to plead to the amended charge.

MISSILE.—A weapon thrown, or intended to be thrown, for doing execution; as, a lance, an arrow, or a bullet.

MITER.—The miter, as an ornament, seems to have descended in the earliest times from Bishop to Bishop. Among the Cottonian MSS. is an order dated July 1, 4 Henry VI., for the delivery to Archbishop Chichely of the miter which had been worn by his predecessor. It was in some cases a very costly ornament. Archbishop Pecheham's new miter, in 1288, cost £173 4s. 1d. In England, since the Reformation, the miter is no longer a part of the Episcopal costume, but it is placed over the shield of an Archbishop or Bishop, instead of a crest. The miter of a Bishop has its lower rim surrounded with a fillet of gold; but the Archbishops of Canterbury and York are in the practice of encircling theirs with a ducal coronet, a usage of late date and doubtful propriety. The Bishop of Durham surrounds his miter with an Earl's coronet, in consequence of being titular count palatine of Durham and Earl of Sedburgh. Before the custom was introducod of Bishops impaling the insignia of their sees with their family arms, they sometimes differenced their paternal coat by the addition of a miter. Miters are rare as a charge in Heraldry, but are sometimes borne as a crest, particularly in Germany, to indicate that the bearers were feudatories, or dependencies of ancient Abbeys.

MITFORD PERCUSSION BULLET.—An ordinary Enfield bullet, having a chamber, down its longer axis, to within ⅛ inch of the hollow; this chamber contains 4½ grains of detonating composition; and the bottom is closed with wax. It is intended to explode ammunition wagons.

MITIGATE.—To diminish the severity of punishment. Every officer who is authorized to order a General Court-Martial has power to pardon or mitigate any punishment adjudged by it, except the punishment of death or of dismissal of an officer. Every officer commanding a regiment or garrison in which a Regimental or Garrison Court-Martial may be held, has power to pardon or mitigate any punishment which such Court may adjudge.

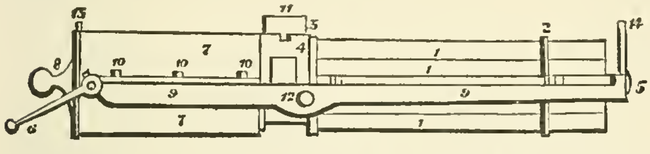
MITRAILLE.—Small pieces of old iron, such as heads of nails, etc., with which pieces of ordnance are sometimes loaded.

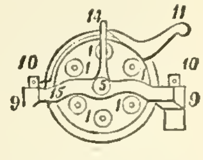
MITRAILLEUR.—A machine-gun in which numerous large bored rifles are combined with breech action, by means of which a shower of bullets may be rapidly projected by one man. It was invented in Belgium, and adopted by the French Emperor soon after the Prussian-Austrian war of 1866. It was the chief cannon of the French artillery during the Franco-German war of 1870. The mitrailleuse existed in a primitive form as early as the 14th century, and well-preserved specimens may be found in the arsenals and museums of Vienna, Rome, Berlin, Moscow and Constantinople. A late form of the weapon, used by the French, has 37 barrels, and ammunition chests alongside the gun on the same axle. The 37 cartridges, intended for the charge, are contained in a small box. A steel plate with corresponding holes is placed on the open box, which is then reversed, and the cartridges fall, points foremost into their respective holes. They are prevented from falling through by the rims at their bases. The loaded plate is then introduced into the breech-slot, and when the breech is closed by a lever, a number of steel pins, pressed by spiral springs, are only prevented from striking the percussion arrangement in the cartridges by a plate in front of them. When this case is moved slowly by a handle, the cartridges are fired one by one. If the plate be withdrawn rapidly, they follow each other so quickly that their discharge is almost simultaneous. The projectile weighs 37 grammes, or a little over an ounce. The charge of powder is from 6 to 8 grammes. The last amount is that counseled by the inventors. This mitrailleur weighs 180 kilogrammes, or 400 pounds without the carriage, and it can be worked by two men. It was found, however, at Vienna, in December 1869, that to obtain the most rapid firing, or 48 balls per minute, five men were necessary to work the piece. The front carriage contains from 48 to 56 boxes for loading, and the two caissons hold 16 breech-plates furnished with cartridges. The piece is, therefore, provided with 2368 cartridges; and a battery of 8 mitrailleurs can hurl on an attacking column 3848 effective projectiles per minute.

The description and nomenclature of the one-inch mitrailleur (Gatlin Gun), a piece much used in the United States Army, is as follows: The breech loading rifled *barrels* (1) are fastened together by a *front barrel-plate* (2) and a *rear barrel-plate* (3). The *carrier-block* (4),a hollow cylinder which carries the cartridges, is directly behind the barrels. The *lock-cylinder*, another cylinder behind the carrier-block, contains the *locks* (one to each barrel). The barrels, carrier-block, and lock-cylinder, revolve around a common axis called the *mainshaft* (5), which is turn by the *hand-crank* (6). The lock-cylinder revolves within a *breech-casing* (7), forming the body of the gun and closed in rear by the *cascabel plate* (8) The breech-casing is fastened to the *frame* (9) by the *casing-screws* (10). The cartridges are inserted in the *hopper* (11), and pass successively into the *channels* of the carrier-block, whence they are thrust into the barrels by the *lock-tubes* or *plungers*, and held there until exploded by the *firing-pins*. The *cartridge-shell stop* is attached to the hopper. The other parts are the *trunnions* (12); *rear-sight* (13); *front-sight* (14); *face* (15); *socket*, for head of elevating-screw; *socket guide-plate* and *screw*; *locking-block* for locking bolt; *plug* for removing locks; *traversing-screw*; *regulating nut*, on traversing-screw; *thumb-spring* for regulating nut; *crank-stop*; *hinges*; *hopper-spindle*; *hopper-grooves*; *hopper-spring*. See the drawing below The following parts are within the breech-casing *lock-cylinder*; *rear-guide nut*; *cocking-ring*; *cocking knob*; *cocking-device*; *cocking-ring clamps*; *spiral cam*; *diaphragm*; *diaphragm-plug*; *gear-wheel*; *pinion*; *rear cam screw*; *crank-shaft*; *worm*; *worm-gear*. Each lock consists of a *lock-butt*, *lock-tube* or *plunger*, *lock-hammer*, *lock-spring*, *firing-pin*, and *extractor*.

To take the mitrailleur apart Block up frame and barrels; take off hopper; take off cascabel plate; take pin out of pinion, turn crank downward, and then remove crank-shaft; take out rear-sight, and then remove large gear-wheel; take out rear plug in diaphragm, and gently revolve the piece until a lock presents itself on a line with the hole in the diaphragm, through which the locks are successively removed; take out large screws on sides of breech-casing, and remove casing to the rear. Be careful to have the lock-cylinder and piece supported so as to keep the center-line of main-shaft parallel to top of frame; this is necessary to prevent the inner breech or rear of the piece from dropping when the casing is removed. The large rear nut, on the shaft in rear of the lock-cylinder, and which serves as a guide for the rear-ends of the locks, is made fast by a tapered pin and a *left-handed screw*; to remove this nut, the pin is taken out and the *nut turned to the right*. The lock-cylinder and carrier-block are then taken off. The spiral cam need not come out of the casing in taking the mitrailleur apart.

To put the mitrailleur together—Put main-shaft in place, through the plates which hold the barrels, and then replace carrier-block, lock-cylinder, and large rear nut; screw up this nut tightly,and put tapered pin through the nut and shaft; place the mitrailleur in the frame, and let front end of main shaft rest in the hole designed for it, in the front of frame; take care to keep the center of main-shaft in the plane of top of frame. When the piece is in this position, push the cocking-ring over the lock-cylinder and let it hang loosely round the carrier-block; raise the breech slightly, and push the breech-casing over the lock-cylinder, etc., to its place; screw casing to frame and put cocking-ring in its proper place: revolve the piece to the right or left, so that the places for the locks will come on a line with the hole in the diaphragm, through which the locks are successively inserted and placed in a proper position; then insert screw-plug to close the hole through diaphragm; put on cog-wheel; replace crank-shaft, pinion, and tapered pin; then put on rear-sight, and screw on butt-plate and hopper.





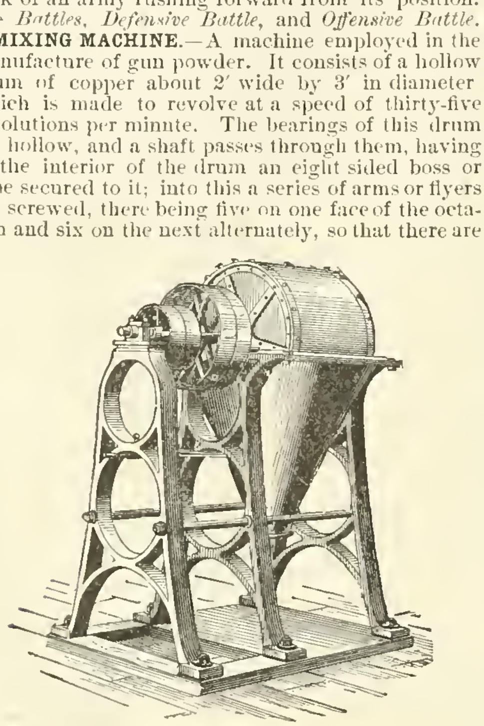
The following is the nomenciature of the gun-carriage for the mitrailleur: *Stock*; *head*; *groove*; *trail*; *rounding of trail*; *trail-plate*; *lunette*; *pointing-ring*; *pointing-socket*; *trail-handles*; *wheel-guard plate*; *elevating-screw*; *elevating-screw box*; *elevating-screw bed*; *rondelles*; *cheeks*; *washer-hooks* for handspike; *under-straps*; *handspike-rings*; *cap-squares*; *cap-square chains*; *key-chains and keys*; *trunnion-beds*; *trunnion swivel*; *trunnion-swivel friction-bed*; *frame for traversing-apparatus* or *traversing-arm*; *traversing-fork*; *traversing-fork spring*; (spiral); *traversing-fork handle*; *traversing-fork clamp-screw*; *traversing-fork case*, with slot for handle; *locking-bolt* connected with traversing-fork by a *locking-lever*; *locking-bolt case*; *stock-seat*, with *hinge* and *prop*; *drag-hooks*; *elevating-screw nut*; *elevating-nut handle*; *elevating-clamp screw*; *rod-case* and *keys*; *axle*; *wheels*. See *Gatling Gun*, *Machine-gun*, and *Piece*.

MITTEN.—A hand-covering which superseded the gauntlet in the 15th century. It was made of thin plates of steel, with joints, to enable the hand to move freely. It is of this mitten that Bayard says,—"Ce que gantelet gagne, gorgerin le mange."

MITTLERER.—One of the three parts of which the enciente is formed, in the German system of fortification.

MIXED BATTLE.—A combination of defensive and offensive battles. The most common case of this class is that in which a position is selected before hand where the army awaits the attack of the enemy, and at a suitable moment moves from it and attacks the assaulting columns. This case is sometimes known as a "defensive-offensive" battle. Where the ground is favorable and the troops are in good condition, these battles offer peculiar advantages, since the assaulting columns, being exhausted by their first efforts are not in the best condition to repel the attack of an army rushing forward from its position. See *Battles*, *Defensive Battle*, and *Offensive Battle*.

MIXING MACHINE.—A machine employed in the manufacture of gun powder. It consists of a hollow drum of copper about 2′ wide by 3′ in diameter which is made to revolve at a speed of thirty-five revolutions per minute. The bearings of this drum are hollow, and a shaft passes through them, having in the interior of the drum an eight sided boss or tube secured to it; into this a series of arms or flyers are screwed, there being five on one face of the octagon and six on the next alternately, so that there are



forty-four flyers altogether. They are made of a flat section, but forked at the ends, and provided with holes through their flat sides, and each one is set at a different angle to the next: their points just clear the inside of the drum, and they revolve in the opposite direction to it at the rate of seventy revolutions per minute. The three bags of ingredients (50 lb. in all) are emptied one at a time through a door into the copper drum, and after the machine has been five minutes at work they will be found to be thoroughly mixed. The door in the drum is now opened, and the composition falls down a shoot into a tub, and after being spread out, is carefully examined, and then placed in the receiving bags. When the bags are filled, they are tightly tied up, and it is very essential that this operation be carefully performed, for should the composition be allowed to remain loose in the bags (the ingredients having very different specific gravities), the saltpeter would fall to the bottom, the charcoal rise to the top, and the sulphur occupy the center, thereby undoing the mixing; and as any vibration caused by the working of adjacent machinery would be much against the composition retaining the thorough mixture given to it by the machine, the bags are put into small magazines separate from all buildings containing machinery, and there laid on their sides, so that the weight of the saltpeter may affect the mixture as little as possible. The composition is now ready for the next operation, and this is performed in the incorporating mill. See *Gunpowder*.

MOAT.—The ditch round the ramparts of a fortress, may be either wet—i. e., full of water—or dry. In the latter, which is the commoner case, the depth should not be less than 12 feet nor the width under 24. The more perpendicular the walls, so much the greater will be the obstruction to the enemy. In regular works the walls are usually revêted with masonry, that at the foot of the rampart being the scarp or escarp, and that below the covered way the counterscarp. See *Ditch* and *Fortification*.

MOBILISATION—MOBILIZATION.—The act of preparing troops for war. The process consists in augmenting a regiment from its peace to its war complement, in calling in men on furlough, in organizing the staff of divisions and brigades, constituting the commissariat, medical, artillery, and transport services, and in accumulating provisions and munitions. As the work of mobilizing an army causes great and inevitable expense, it is only resorted to when hostilities appear imminent. The rapidity with which armies can be mobilized has been of late years great. In 1859, it took thirty-seven days for France to collect on the river Po, a force of 104,000 men, with 12,000 more in Italy. In 1866, the Prussian armies (220,000 in number) were placed on the Frontiers of Saxony and Silesia in a fortnight; and in 1870, Germany was able to mobilize her forces in nine days, and to send in eight days more to the French frontier an army of 400,000 soldiers and 1200 guns. The mobilization of the British army has been provided for under orders issued by the War Office and Horse Guards. By this scheme, which is not only based upon defensive requirements, but also adapted for offensive warfare as well, 300,000 men will be available within a few days for the defense of the country, and if necessary, a certain portion of the force can be embarked for a war in foreign countries.

MOBILITY.—Lightness, facility in moving. In warfare it is of the highest importance that the artillery and transport of the army should be as light and movable as is consistent with efficiency. Not only does this term apply to the particular branches above adverted to, but mobility expresses also the facility and rapidity with which an army can traverse a country, when called upon to do battle with the enemy, which, combined with concentration of force, is likely to bring matters to a successful issue.

MODEL.—A pattern or imitation of anything on a small scale, in wood, stone, wax, or any other convenient substance. Models are not only made for the reduction in size of articles of all sorts, and for possession of fac-similes of all such works as are either too large to be moved or too expensive to be bought, but they are valuable in a military point of view in giving, in a handy and instructive form, the elevation of ground sketched out in topographical maps, and which is also applicable to fortifications, etc. Under the name of *model* an apparatus has been lately invented by Captain E. Padmore Clark (Instructor of Musketry, Herefordshire Militia), for the purpose of instructing officers and men in the cavalry and infantry drill. The infantry model consists of a miniature regiment of infantry, in metal, and is so formed that the ranks can be simultaneously turned in any direction, and the position of officers and markers is clearly defined. This apparatus, which is called "Drill Model Apparatus," consists of a battalion of six companies, with mounted and other officers, color-party, band, and pioneers, complete. Two of the companies are divisible into half-companies, for the purpose of showing the movement of the side-face companies in the formation of a two-deep square in a battalion of *four* companies. There are six small stands to attach to the right or left, or the center, of each company, for the leading guide in formations of fours to a flank, or for the right guide in retiring in line. This apparatus will, doubtless, prove very useful in imparting to young officers practical knowledge in this important branch of their profession, and will assist them in clearly understanding the different movements which companies and battalions are called upon to perform on the drill-ground or in the field. The drill model for cavalry is similar, and represents a whole regiment, and the troops and squadrons are divisible on the plan of the infantry model.

MODULUS. A constant coefficient or multiplier, by means of which one series or system of quantities can be reduced to another similar series or system. Thus we have the modulus of elasticity, of friction, and of systems of logarithms. The system of logarithms which is universally accepted as the primary is Napier's, and from it all other systems are deduced in the following manner: Let N be a number of which the Napierian logarithm is b, e being the Napierian base, it is required to find the logarithm of N to some other base a. Let x be this logarithm, then, we will find

$$x = \frac{b}{\log._e a}; \text{ i. e., } \log._a N = \frac{\log._e N}{\log._e a} = \frac{1}{\log._e a} \times \log._e N.$$

This multiplier or "modulus," $\frac{1}{\log._e a}$, is independent of N, and is therefore constant for the reduction of all Napierian logarithms to the system whose base is a. If $a=10$, the multiplier becomes $\frac{1}{\log._e 10}$, the modulus of Briggs', or the common system of logarithms, and is equal to $\frac{1}{2.30258509} = .4342944\ldots$

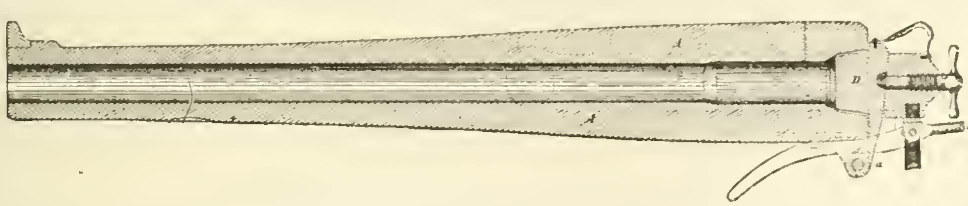
MOENCHS BUCHSE.—A small hand-cannon 11 inches long and 4¾ inches in diameter. It preceded the invention of the wheel-lock, and gave the first idea of it.

MOFFATT GUN.—A breech-loading rifled field-gun. The body A is of steel, and bored through from end to end. The breech-mechanism consists of a conical breech-plug, accurately fitted to the bottom of the bore, and efficiently closing the same through the support afforded by the breech-strap. This strap is attached to the trunnions as an axis of motion, but is enabled to withstand the strain of discharge by locking into lugs on either side of the breech of the gun. The breech-strap rests in rear upon the top of the elevating-screw, to which it is attached by a suitable coupling, to admit of the free movement of the screw. The breech-block is hinged in a fork attached to the under side of the breech. The operation of the mechanism is as follows: The breech is opened by tilting up the breech of the gun, through the medium of a lever E, which has its axis in a stirrup underneath the breech-strap. By this operation the block is raised out of the breech-strap, and falls back by its own weight upon the latter, thus exposing the chamber. To close the breech again the lever is raised, and the gun, owing to its preponderance, falls back into the position for firing; the wedge-shaped back of the breech-block, at the same time, enters a correspondingly beveled recess in the breech-strap, and draws the latter firmly against the lugs, the loops of the strap over the trunnions admitting of a slight play for that purpose.

In the preliminary firings had with the gun, to test the working of the parts, the breech was thrown open by the shock of discharge, closing again during the recoil. To obviate this a locking device was added, consisting of a bolt and key, passing through the breech-strap and into a recess in the breech-block. A half-turn of the handle is sufficient to press the block firmly down into place, and there retain it. A half-turn in a contrary direction disengages the key from the recess in the block, and the breech can be thrown open. Should the breech-block not always fall back on tilting up the breech, a leather strap is provided, which pulls back the block after the breech has been sufficiently raised to disengage it from the strap. The trunnions are screwed into the gun-body, and are furnished with shoulders, by which the loops of the breech-straps are confined to the rimbases.

The rifling of the gun consists of twelve grooves and lands each, the width of the lands being 0″.25, and the depth of the grooves 0″.05. The twist is uniform, and makes one turn in 12 feet. The chamber is concentric with the bore, but of larger diameter, measuring 3″.19, the diameter of the bore through grooves being but 3″.17. Its capacity is such as to accommodate a charge of 1¼ pounds of powder and a lead-coated or a double-bearing Butler projectile of about 10 pounds weight, the projectile being inserted in the rifled portion of the bore as far as the front rib or band. The vent is in the normal position on top of the gun. When the gun was originally finished it was provided with a cup-shaped gas-check of copper; but having failed to give satisfaction under heavy charges, a number of Broadwell rings, of steel, brass, and composition, were tried, several of which gave excellent results. The use of a loose internal Rodman pressure-gauge being precluded in a small breech-loader, and it not being wished to mar the gun by boring for the external gauge, the inner face of the breech-block was bored and tapped for the reception of an interior plug.

The gun-body was manufactured by Messrs. Firth & Sons, Sheffield, England, of the best quality of crucible cast-steel, and forged from a single ingot. As received at the South Boston foundry, it was rough-bored and turned. The steel for the breech-block, strap, etc., were forgings from the Nashua Works, New Hampshire. The final work of fitting, finishing, and assembling, was accomplished at the South Boston foundry, under the supervision of the Inventor.



The following are the dimensions of its principal parts, to wit:

Diameter of bore across lands	3.07 inches
Diameter of bore through grooves	3.17 inches
Diameter of chamber	3.19 inches
Diameter of breech-block cavity at seat of gas-check	3.90 inches
Diameter of breech-block cavity, outer edge	5.23 inches
Diameter of piece at muzzle	5.90 inches
Diameter of piece at trunnions	8.00 inches
Diameter of breech	9.57 inches
Diameter of trunnions	3.67 inches
Length of rifle portion of bore	55.00 inches

Length of beveled junction of chamber and bore	1.00 inches
Length of chamber	9.50 inches
Total length of gun	72.65 inches
Pitch of rifling uniform; one turn in	144.00 inches
Number of grooves and lands	12
Width of lands	0.25 inch.
Weight of gun	1,000 lbs,
Weight of gun-carriage without implements	900 lbs.

The preponderance of the gun at the elevating-screw is such as to render the gun easily operated. The gun is mounted on a United States 6-pounder carriage; the only modifications required being to change the housing for the elevating-screw, and to slightly increase the space between the cheek-pieces. See *Rifled Howitzers*, and *Ordnance*.

MOGRABIAN.—A soldier of a branch of the Turkish infantry composed of the peasants of the northern part of Africa, who sought to better their condition by entering foreign service.

MOGUL.- The popular designation of the Emperor of Delhi, as the impersonation of the powerful Empire established in Hindustan by the Mongols, who were called *Moguls* by the Persians. The first Great Mogul was Baber, the great-grandson of Timur, who founded the Mongol Empire in Hindustan in 1526. In 1803 the Great Mogul was deprived of his throne; in 1827, of even the appearance of authority, becoming a mere pensioner of the British; and in 1858, Mohammed Bahadur, the last of the Dynasty, was condemned, and transported for complicity in the Indian Mutiny.

MOIENNE.-A piece of ordnance, which is now called a 4-pounder, and which is ten feet long. It was formerly used by the French.

MOINEAU.—A small, flat bastion, raised in front of an indented fortification, to defend it against attacks from small-arms.

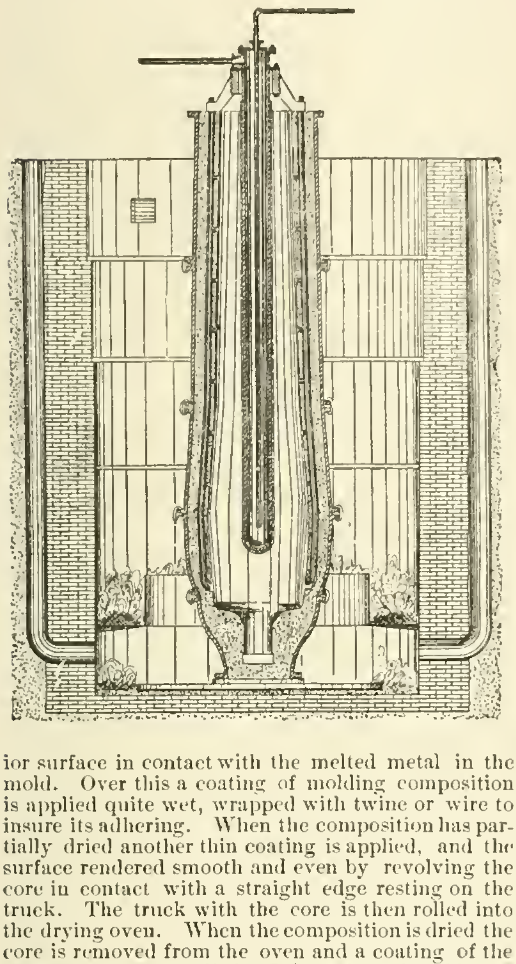
MOLDED POWDER.—A powder having the same ingredients as those of ordinary gunpowder, but each grain is separately molded. Gen. Rodman was the first to propose this variety of powder; the object being to cause the powder to burn on an increasing surface, thus lessening the strain on the gun in the first moments of combustion. See *Gunpowder*.

MOLDING.—The process by which a cavity of the form of the gun is obtained by imbedding a model in sand and then withdrawing it. The model of a gun, technically termed the *pattern*, is usually constructed of wood made in as many sections and parts as may be necessary to admit of its being easily withdrawn from the mold. The sections of the pattern for the breech and reinforce are made with diameters exceeding very slightly those of the finished gun, while the diameters of the sections for the chase are largely in excess. The breech section is provided with a cascabel for supporting the gun in the lathe while being turned and bored. The patterns of the trunnions are attached in their places by wooden pins, which can be easily withdrawn when it becomes necessary to detach the patterns. The several sections of the pattern for the body of the gun are made with a slight taper to facilitate their withdrawal. The pattern for the chase of the gun is made considerably longer than the required length of that part, to provide a "sinking-head" which, when the gun is cast, receives the scoria of the melted metal as it rises to the surface, and also furnishes the metal required to feed the shrinkage caused by the cooling of the casting. The *sand* used for the molding composition should be principally of silex, very refractory, commonly called sharp-sand. When not sufficiently refractory it is vitrified by the high temperature of the melted metal, and protuberances are formed upon the casting which are removed with great difficulty. To prepare the composition for use the sand is carefully sifted, then properly mixed and moistened with water in which clay has been stirred, or with the refuse of distillery wash called "returns." Great care is required in securing the proper degree of cohesiveness in the composition, as it must be sufficient to enable the mold to preserve its form in handling, and not so much as to cause it to be injured by contraction in drying. It is considered sufficiently cohesive when it will retain its form when taken in a moist state and squeezed in the hand. The same composition may be repeatedly used in molding, but as its cohesive property is destroyed by the heat to which it is exposed, it must be reprepared in the same manner as when first formed.

The mold is formed in a cast-iron case called a *flask*, which is usually made in sections corresponding in number and length to those of the pattern. These sections consist of two pieces which, when united, are circular in cross-section, excepting two slight enlargements opposite each other for the formation of the channels or "side gates" for the metal to pass down. The pieces are flanged at the edges, fastened by bolts, and additionally secured by clamps over the flanges. The trunnion sections of the flask are fitted with trunnion boxes which have movable plates at their ends for the purpose of introducing the trunnion patterns and facilitating the formation of that part of the mold. The several sections are so constructed as to be united to each other in their regular order by means of clamps over the flanges at the top and bottom. To form the mold the lower or breech section of the flask is placed upon an iron plate in an upright position, the corresponding section of the pattern introduced and centered: the space between the pattern and the flask filled with molding composition, which is rammed down in thin layers around the pattern until the section is completed. The patterns for the side gates and their branches for conveying the metal into the mold are introduced as the work progresses. After the mold for the lower section is finished the next section of the flask is placed upon it and secured, the corresponding section of the pattern introduced, fitted with dowels, which enter the breech section and hold it accurately in place. The molding is continued with this section as with the first, and when completed it is lifted off, the pattern being left in the mold. The third section of the flask, which is usually the trunnion section, is then placed upon the second and secured, and the pattern adjusted in the same way as before. The trunnion patterns are attached and the molding is continued. When this section is completed the pins attaching the trunnion patterns are removed and the patterns withdrawn. The formation of the remaining sections is continued until the whole is completed, thus insuring a perfect mold throughout, free from irregularities at the junction of the sections.

Care is taken to sprinkle dry sand upon the surface of each section of the mold before continuing the work to prevent adhesion and to admit of the sections being separated without injury. As the work upon the respective sections is finished the patterns are withdrawn. If any portions of the mold are injured in the withdrawal they are repaired. The several sections are placed in the drying oven, where a moderate heat is kept up, until thoroughly dried. They are then removed from the oven, and a wash, composed of German graphite, pulverized anthracite coal, and distillery returns, applied to the interior surface of the mold. The sections are replaced in the oven, and when dried removed, and a second coating of the wash applied while the mold is still warm. This wash is to produce a smooth, hard surface. It prevents the melted metal from mixing with the sand of the mold and forming protuberances on the surface of the casting.

The *core-barrel* or *arbor* consists of a water-tight cast-iron tube, made sufficiently thick to withstand the pressure of the metal in the mold. Its length and diameter are such as to leave a sufficient surplus of metal in the bore of the gun to secure a good finish. It is constructed with a slight taper to facilitate its withdrawal after the casting. The lower end is rounded off and is fitted with several iron pins for securing the extremity of the rope, which is used as wrapping material in the preparation of the core; the exterior of the barrel is fluted from top to bottom to allow the escape of the gases generated by its combustion. Before being used the core-barrel is always subjected to a powerful water pressure to test its soundnes. To prepare the core for casting, journals are fitted at its extremities. It is then placed in a horizontal position upon an iron truck, supported by the journals resting in bearings, and turned by a crank attached to one of the journals. It is first wrapped with white hemp rope so as to cover all of the exter-



ior surface in contact with the melted metal in the mold. Over this a coating of molding composition is applied quite wet, wrapped with twine or wire to insure its adhering. When the composition has partially dried another thin coating is applied, and the surface rendered smooth and even by revolving the core in contact with a straight edge resting on the truck. The truck with the core is then rolled into the drying oven. When the composition is dried the core is removed from the oven and a coating of the same wash again applied. It is again replaced in the oven until thoroughly dry, when it is removed and the journals taken out. The one at the bottom is replaced by a tight fitting screw-plug covered over with molding composition. The top is fitted with a water-tight cap so constructed as to receive the conducting-pipes for the water, and is ready for use.

The *pit* as usually constructed for the casting of guns on the Rodman plan, is cylindrical in form and is surrounded with a brick wall, built in offsets, affording supports for braces to steady the mold in position; grates are arranged around the circumference of the bottom for fires lighted immediately after the casting to retard the radiation of heat from the exterior of the mold. To retain the heat of the fires in the grates the month of the pit is covered with a close-fitting cover of boiler iron. For furnishing air to the fires, flues are made opening into the pit below the grates, while near the top another flue, making suitable connection with a chimney, produces the necessary draught. If the pit has been out of use for any very great length of time, it is thoroughly dried by fires in the grates before placing the molds in position. To prepare the pit to receive the mold, the bottom is covered with a layer of sand. A heavy cast-iron plate is then laid down and carefully leveled. Upon this section the breech section of the mold is placed in an upright position. The other sections are successively lowered and secured in their places, the whole being braced from the sides of the pit to keep it in a vertical position. The core is then lowered into the mold of the gun. To center and secure it in position, a cast-iron frame, usually termed a "spider," is employed. The spider consists of a heavy ring supported upon three legs, each having a projection at the bottom fitted with an adjustable screw resting upon the upper flange of the flask. The core passes through the ring of the spider, is secured to it by bolts through the flange at the top of the barrel, and held firmly, so that any movement of the spider will produce a change in the position of the core. To center the core, a long wooden rod is used, to the end of which a piece of board is fixed to hold a light. The length of this projecting board, previously determined, is the distance which the core should be, when in the center, from the mold at its maximum diameter. Having adjusted the core in the mold by means of the screws in the legs of the spider, it is firmly secured in its position by clamps made to fit under the flange at the top of the flask and over the projections at the end of the legs of the spider. The fuel for the fires in the pit is arranged on the grates in readiness to be kindled. See *Rodman Gun*.

MOLDING COMPOSITION.—The sand most used for this purpose is a kind of loam, which contains a sufficient quantity of clay to render it moderately cohesive when damp. Sand, possessing all the qualities required for molding, is seldom, if ever, found in a state of nature; but when the requisite qualities are known the materials may be selected, and an artificial composition produced without difficulty. The sand should be principally of silex, very refractory, and of the kind commonly called *sharp-sand*. When not sufficiently refractory, the sand is vitrified by the high temperature of the melted metal, and protuberances are found upon the casting which are not easily removed.

The method of preparing the molding-composition artificially, varies according to the kind of casting for which it is to be used. In preparing it for cannon, great care is taken to introduce the exact quantity of clay required. When too litle is used, the composition is not sufficiently adhesive; when too much is used, the mold is injured by contraction in drying. The sand is first carefutly sifted, then properly mixed and moistened with water in which clay has been stirred; the composition is considered sufficiently adhesive when it will retain its form after having been taken in a moist state and squeezed in the hand.

The same composition may be repeatedly used for molding, but as the adhesive property of the clay is destroyed by the heat to which it is exposed in casting, more clay must be added every time, in the same manner as when the composition is first formed. See *Molding*.

MOLLY MAGUIRES.—A secret Order which existed in 1854-77, and probably still exists, in the anthracite coal mining region of north-eastern Pennsylvania. Here 400 collieries employed 60,000 men: Americans, Germans, Welshmen, Englishmen, and Swedes comprising one-half the number, the remainder being Irish. Among the latter half originated, in the locality named, the Order of Molly Maguires, a branch of the "Ribbonmen" of Ireland. The Order, however, had a much wider existence, and is alleged to have been affiliated with the "Ancient Order of Hibernians," elsewhere a peaceable and reputable organization. Until 1865 and '66 the Order of Molly Maguires had not become generally known for the murders and other brutalities which then distinguished it. In 1875, having gained control of a combination which forced a general strike in the coal regions, it succeeded in obtaining an ascendency in the councils of the miners, and from that period was prominent in assassinations and other outrages, committed usually on the persons and against the property of Justices of the Peace, Police Officers, and Mining Bosses. The number of murders increased between 1869 and '71, and fell off after the latter year, and until that of the great strike of 1875. According to some of those who made an investigation into the antecedents of the Molly Maguires, they originated in the trade-unions, and not in the A. O. H. or among the Ribbonmen. None but Catholic Irishmen or their descendants were admitted to membership: the Order was organized in divisions, each having a chief official known as a "Body-Master"; and there were signs and passwords to enable members to distinguish each other. These signs and passwords were given to the members by the Body-Masters, who received them from the County Delegate, who got them from the State Delegate, to whom they were furnished by the National Delegate or National Board in New York City; to the latter they came quarterly from Ireland, by the hands of the Steward of one of the transatlantic steamships. A central and governing organization known as "The Board of Erin" was said to be the origination of the Order, and this held quarterly meetings in England, Scotland, or Ireland. So extended were the ramifications of this Order in Pennsylvania, that it was made known during the trials of the Molly Maguires in 1877 that one of their Body-Masters in the Pottsville district held the high office of County Commissioner. The final exposure, capture, and punishment of the Molly Maguires was largely due to the energy and determination of Franklin B. Gowen, President of the Philadelphia and Reading Railroad Company; through the immediate instrumentality of James McParlan, a detective, who joined the Molly Maguires, he became acquainted with their members and the secrets of organization, and was at length enabled to afford information which disclosed the names of criminals connected with a majority of the murders committed by the Order. A large number were apprehended, tried, and condemned, and their execution—that of a number of them occurring on the same day—so alarmed the members of the Order that it ceased to possess any extended influence.

MOMENT.—The moment of any physical agency is its importance with reference to some special application. Thus the moment of a force applied (perpendicularly) to a lever, is the importance of the force as regards turning the lever about its fulcrum. It is, as we know (see LEVER), proportional to the product of the force by the distance of its point of application from the fulcrum. The moment of a force about any axis (to which its direction is perpendicular) is the product of the force by its least distance from the axis; and a similar definition is laid down for moment of velocity and moment of momentum. It is easy to see (see MOMENTUM) that in any system of mutually acting bodies the moment of momentum about any axis remains constant, since the equal mutual forces measure the momentum transferred from one body to another, and the moments of these forces are in pairs equal and opposite. A particular case of this is Kepler's law, that each planet describes equal areas in equal times about the sun.

In the rotation of bodies round an axis, the moment of inertia is the sum of the products of each particle of the body into the square of its distance from the axis; or if M be the body, m_1, m_2, m_3, etc., the particles composing it, and r_1, r_2, r_3, etc., their corresponding distances from the axis, then the moment of inertia of $M = m_1 r_1^2 + m_2 r_2^2 + m_3 r_3^2 +$ etc., and if a quantity, K, be found such that $MK^2 = m_1 r_1^2 + m_2 r_2^2 + m_3 r_3^2 +$, etc. then K is called the *radius of gyration*. See *Center of Gyration*.

MOMENTUM.—Momentum may be defined as proportional to the mass moving, and its velocity, conjointly. If we assume unit of momentum to be that unit of mass moving with unit of velocity, we shall evidently have, for the momentum of a mass M, moving with velocity V, the expression MV. And such is the unit generally adopted. It is shown by experiment that, when force produces motion in any body, the momentum produced in one second is proportional to the force—and, in fact, *force is measured by the momentum it is capable of producing in unit of time.* Thus, the same force, if acting for one second on each of a number of bodies, produces in them velocities which are *inversely* as their masses. Also when, as in the case of falling bodies, the velocities produced in one second are the same in all, we conclude that the forces are *proportional* to the masses; and, in fact, this is the physical proof that the weight of a body is proportional to its mass. Again, if different forces act, each for a second, on the *same* mass, the velocities produced are proportional to the forces. All these are but different modes of statement of the experimental fact that force is proportional to the momentum it produces in unit of time; which forms a part of Newton's second law of motion. When two masses act on each other, Newton's third law of motion shows that the forces they mutually exert are equal and opposite. The momenta produced by these must therefore be equal and opposite. Thus in attraction or impact of two masses, *no momentum is lost;* since what is lost by one is gained by the other. The momentum of a system of bodies can be resolved (as velocity is resolved) into components in any assigned directions, and the mutual forces of the system may be thus likewise resolved. Applying the previous result, we see at once that in any system of mutually acting bodies (such, for instance, as the solar system), no momentum is, on the whole, either gained or lost in any particular direction; it is merely transferred from one part of the system to another. This fact, called the conservation of momentum, has caused great confusion in the minds of pseudo-physicists, who constantly confound it with conservation of work or energy, a totally different thing. The momentum produced by a force in any period of time is measured by the product of the force and the *time during which it has acted*—the energy or work done by a force is measured by the product of the force and the *space through which it has acted.* Momentum is proportional to the simple velocity of a body, and *can never, by any known process, be transformed into anything else.* Energy, when depending on velocity, is proportional to the *square* of the velocity, and is in the natural world *constantly being transformed from its actual or kinetic form to its potential form, and back again, or to some other kinetic form, such as heat, and finally must become heat.* Momentum, on the contrary, is never altered, either in kind or in amount. In *knocking down* a wall, or in staving in the whole side of a ship, the battering-ram of the ancients (when constructed of sufficient mass, and worked by the proper number of men or animals) was probably nearly as effective as the best modern artillery. But in making a *breach* in a wall, or in punching a hole in the armor of an iron-clad, mere massive shot with low velocities (such as those of the Dahlgren guns), are comparatively ineffective, however great their momentum; while an Armstrong or Whitworth projectile, with a fraction of the momentum, but with greater velocity, and, for its size, much greater kinetic energy, effects the object with ease. In many every-day phenomena, we see most distinctly the difference between these two affections of matter. Thus, a blow delivered from the shoulder by a *heavy* pugilist, even if it be sluggishly given, generally floors its man, without doing much other injury; but a sharp stroke administered by a light weight, while hardly disturbing the adversary's equilibrium, inflicts serious punishment.

MONARCHY.—That form of government in a community by which one person exercises the sovereign authority. It is only when the King, or Chief Magistrate of the community, possesses the entire ruling power that he is, in the proper acceptation of the term, a Monarch. Most of the Oriental Governments past and present, Russia at present, and Spain and France as they were in the last century, are in this strict sense Monarchies. The degenerate form of Monarchy is tyranny, or Government for the exclusive benefit of the Ruler. When the Head of the State, still possessing the status and dignity of royalty, shares the supreme power with a class of Nobles, with a popular body, or with both, as in our own country, the Government, though no longer in strictness monarchical, is called in popular language a Mixed or Limited Monarchy, the term Absolute Monarchy being applied to a Government properly monarchical. The highest ideal of Government would perhaps be attained by an Absolute Monarchy, if there were any security for always possessing a thoroughly wise and good Monarch; but this condition is obviously unattainable, and a bad Despot has it in his power to inflict infinite evil. It therefor becomes desirable that a governing class, composed, if possible, of the wisest and most enlightened in the country, should share the supreme power with the Sovereign. A Limited Monarchy has this advantage over an Aristocratic Republic that, in difficult crises of the nation's existance, Royalty becomes a neutral and guiding power, raised above the accidents and struggles of political life. Monarchy, most usually hereditary, has sometimes been elective, a condition generally attended with feuds and distractions, as was the case in Poland. The elective system is still followed in the choice of the Pope. Constitutional Monarchy may be in its origin elective, or combine both systems, as when one family is disinherited, and the scepter declared hereditary in the hands of another under certain conditions.

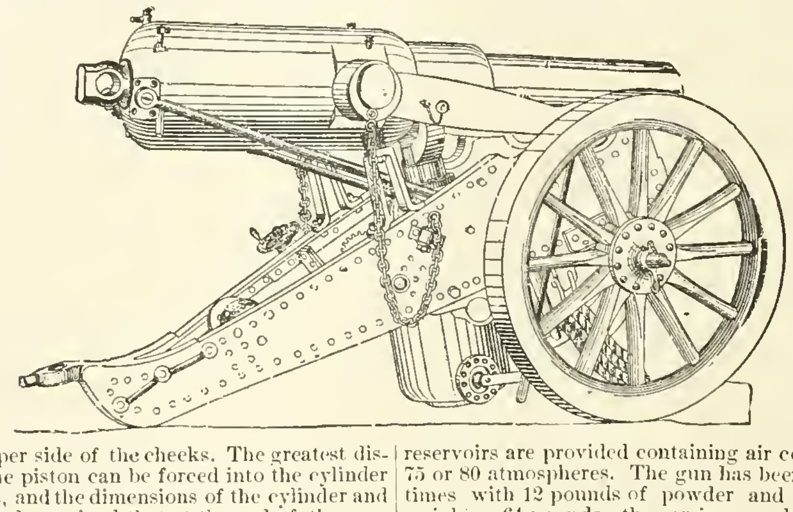
MONCRIEFF DEPRESSION CARRIAGES.—The depressing garrison-carriages have been made to mount guns of 6.3-inch, 7-inch, and 9-inch calibers, the latter being as large as it is thought practicable to work on this kind of carriage. The cheeks are made like those of the heavy carriages, of two ½-inch plates riveted together, with wrought-iron frames 3½ inches wide between them. The cheeks are connected by two transoms of plate-iron. The elevator is made in the same way as the cheeks. The chassis-rails are of girder-iron, 19¾ feet long, 6¾ inches wide on the flange, and 12 inches deep for the 9-inch gun. Six traverse-wheels are used. The carriage has been tested at Shoeburyness by repeated firings, some of which with the 6.3-inch and 9-inch gun we witnessed. The smaller gun comes down to the loading position after firing more smoothly and with less shock than the larger gun, the charge for which was 50 pounds of powder and a projectile weighing 250 pounds. The 6.3-inch gun is designed to fire over a parapet 9 feet 4 inches high, and the 9-inch gun over one 12½ feet high. In the 9-inch hydro-pneumatic carriage the force of the recoil is utilized to compress a certain volume of air contained within a close vessel, and is afterward employed to raise the gun from under cover to the firing position. The gun is supported on two strong lever supports. One end of each embraces the trunnion of the gun, and the other is keyed to a heavy shaft which turns in journals near the foundation-plate. This shaft has two strong cranks which operate pistons fitted to two cylinders. A third lever support is hinged at one end to the breech of the gun,, and the other to a support attached to the elevating-apparatus. The cylinders communicate by means of strong pipes with air-vessels, and a valve is arranged to permit the water to pass from the cylinders to the air-vessels, but does not allow it to return. A sufficient quantity of water is used to assure the valves being always immersed in it. The air in the vessels is compressed by means of the air-pump until it is under sufficient pressure to raise the gun from the loading to the firing position. When the gun is fired, the recoil forces the pistons in the cylinders, and compresses the air in the vessels, which hold it in store until required to raise the gun for the next fire. By turning the valve which allows the water to flow back from the vessels to the cylinders, the water at once presses against the piston-heads, and forcing them back raises the gun to the firing position. The carriage is the same in principle as the hydro-pneumatic siege-carriage, which will be noticed in detail.

Major Moncrieff urges with much force that by the adoption of a depressing carriage for siege-guns, embrazures for earthworks, which are entirely unsuited to modern warfare, may be dispensed with, and a better and safer battery can be used; namely, that in which the guns are planted in pits or trenches where the gunners are entirely protected from the fire of sharpshooters and the direct fire of canister and shrapnel. In his siege-carriage, instead of using the recoil of the gun to raise a counterpoise weight which shall in turn elevate the gun from the loading to the firing position as in his sea-coast carriage, he utilizes the recoil to compress a volume of air, which being brought to act upon the gun shall raise it to the firing position. The same idea, was proposed several years ago by Mr. James Eads, civil engineer of St. Louis, and a carriage made to operate on this principle was patented by him. Moncrieff's carriage is built for a 64-pounder rifled gun. It resembles in its general appearance an ordinary wrought-iron siege-carriage, and differs from it only in the addition of the hydro-pneumatic cylinder and piston, the elevating arms or supports, and a modification of the apparatus for pointing the gun. Between the cheeks of the carriage is placed a cast-iron cylinder with trunnions, which are supported in trunnion-beds in the cheeks. The cylinder hangs in a vertical position, and comes down to within 15 inches of the ground. This cylinder is a compound one, having an inner cylinder in its axis, there being two channels of communication between them, closed by valves. The first is intended to permit the passage of the liquid from the inner to the outer cylinder, and is closed on one side by a valve which works out automatically, and on the other by a regulating-valve for moderating the motion of the piece at the last part of the recoil, and also acting automatically; the other channel allows the liquid in the outer cylinder to pass into the inner one, and is closed by a valve which is operated by means of a lever attached to the left trunnion of the cylinder. A piston fits the inner cylinder closely. Its head is divided into two branches and serves as a transom to the two lever arms, to which it is secured by hinge-bolts. The two lever-arms are strong wrought-iron bars, the lower ends of which are formed in the shape of trunnions, and fit in the trunnion-beds of the carriage, being held in place by the cap-squares. The upper ends have holes bored in them to receive the trunnions of the gun. In the firing position these arms are nearly vertical, and raise the axis of the piece 8 feet above the platform; the recoil brings them nearly horizontal, lowering the trunnions of the gun to about 3¼ feet. Two long iron rods are fastened to one end to the breech of the gun by a hinge-bolt, and the other end to the elevating apparatus.

The inner cylinder is filled with liquid, which also occupies the lower part of the outer cylinder, but only for a short distance, so as to cover the passages between the two cylinders. The liquid is a mixture of one part of glycerine to two of water. The air is the outer cylinder is compressed ,by means of an air-pump before it is put in position. The exact degree of pressure must be determined by experiment. The carriage is held in place behind the epaulement by means of a chain or rope, which is made fast at one end to a hook on the axle at its middle point, and the other to an anchor in the ground in front of the gun. The recoil of the carriage must be prevented in order that the hydraulic apparatus may be made to operate. The regulating-valve of the cylinder is worked by a crank, which is moved by a connecting-rod attached at its upper end by a hinge-bolt to the right lever-arm. The connecting-rod has a slot in its lower end, in which the pin of the crank plays. Supposing the gun to be in the firing position, the regulating-valve is wide open. When the gun is discharged the recoil presses the lever-arms down to the rear, forcing the piston in the cylinder, which turns around its trunions. The pressure on the liquid opens the valve and allows it to pass into the outer cylinder, compressing the air contained therein. The regulating-valve is open during the great part of the motion downward, the length of the slot being so regulated that the pin of the crank will not reach its upper end until the gun is almost down, when it will turn the crank and close the passage between the two cylinders. The trunions strike on India-rubber buffers bolted to the upper side of the cheeks. The greatest distance that the piston can be forced into the cylinder is 28½ inches, and the dimensions of the cylinder and piston are so determined that at the end of the motion this air will have been compressed to about one-third of its original volume. When the piece is loaded, in order to bring it to the firing position, it is only necessary to open the passage between the outer and inner cylinders. To effect this, the gunner on the left turns the key in the left trunnion of the cylinder, and opens the valve which allows the liquid to return to the inner cylinder; the pressure of air drives back the liquid, which raises the piston and the gun. Two chains fastened on the right and left of the piece, one end to the lever-arms and the other to the cheeks, stop the gun when it has reached the firing position. During the upward motion the connecting-rod attached to the right lever turns the regulating-valve and opens it ready for the discharge of the piece. A windlass between the sides of the trail affords the means of bringing down the gun by the aid of ropes to the loading position without firing, or when the trunnions are not brought in contact with the rubber buffers, as will happen when firing with small charges at high angles.

The elevating apparatus consists of two circular racks placed on the inside of the cheeks, and operated by means of an endless screw, which turns a pinion engaging in the teeth of the rack. The two long iron rods attached to the breech are hinged to the upper end of the racks. By turning the handle of the endless screw, the circular racks are raised or lowered, and also the breech of the gun. The circular rack has its center at the point around which the rod is pivoted on the breech of the gun when it is in the loading position, so that the angle that its axis makes with the horizon in this position is the same, no matter at what angle it may be fired. Reflecting sights are arranged on the carriage, so that the gun may be aimed by the gunner without exposing himself to the enemy's fire.

The carriage is mounted on an ordinary siege-platform, and the parapet should be an overhanging one, in order that there should be the necessary space for loading, and to insure the muzzle of the gun when in the firing position being well beyond the crest. If the hydro-pneumatic arrangement be disabled, the gun may be then mounted on the carriage as an ordinary siege-gun. The hydro-pneumatic cylinder should be charged in the park and not in the battery. Air-pumps are provided for this purpose. The mean pressure in the cylinder during the experiments has been 400 pounds per square inch, about 27.2 atmospheres, the piece being in the firing position and corresponds to 500 pounds when it is in the loading position. If it should be necessary for any reason to increase the pressure in the cylinder, portable air-reservoirs are provided containing air compressed to 75 or 80 atmospheres. The gun has been fired many times with 12 pounds of powder and a projectile weighing 64 pounds; the carriage worked well. It has been found that it can be fired at the rate of one round per minute at low angles of elevation. The weight of the carriage complete is 62¼ cwt., the service-carriage being 32¼ cwt. Major Moncrieff believes the weight may be reduced (by making the cylinder of bronze instead of iron, the plunger a hollow cylinder of wrought iron, and the lever-arms of built beams instead of solid) to 50¼ cwt. The great weight of the carriage is still regarded as a serious objection to it. Besides, the complex and delicate nature of the machinery, and the complication of stores required to go with it, induce the belief that it would prove too cumbrous for use in sieges generally. See *Seacoast and Garrison Carriages*, and *Siege Carriages*.



MONGOLIAN CASQUE.—An ancient helmet with peak crest and socket for plume. It was very beautiful, and richly ornamented with damascened work.

MONK. The most common methods of firing mines are by the use of the *monk* and the *box-trap* These two methods require a powder-hose. The monk is a bit of agaric 1½ inches in length. The train to be fired by it, is arranged as follows. Stretch the extremity of the hose upon a sheet of paper and sprinkle some dry, fine powder upon it; cover this powder over with another sheet of paper, secured at its four corners with dry earth or stones; pass the monk through a hole in the upper sheet, and let it project half its length above it, its base being plunged in the powder on the bottom sheet; set fire to the monk at top with another piece of agaric, termed an *informer* of the same dimensions and form as the first, and retire quickly.

Both the use of the box-trap and monk have the inconvenience of requiring a powder-hose, which, from its own explosion, poisons the galleries. They have also, and more particularly the monk, the defect of not producing the explosion always at the instant desired. To avoid these inconveniences a galvanic current has of late been applied to fire mines, and with complete success. This method has been found particularly serviceable in firing charges under water. See *Box-trap*, and *Rocket-trough*.

MONOMACHY.—A single combat or the fighting of two, hand to hand. It is derived from the Greek. A duel may properly be called a Monomachy.

MONTALEMBERT SYSTEM OF FORTIFICATION.—Among the writers on permanent fortification whose works have had an important bearing on the progress of the art, Montalembert holds a conspicuous place, although not educated as an engineer. Struck by the evident defects of the methods of his predecessors, particularly the want of casemates, both for defensive dispositions for artillery and musketry, and the shelter of the garrison and munitions, Montalembert devoted his time, talents, and fortune to bringing about a change in the direction in which it seemed to him called for. His efforts, however, led to no modifications of consequence during his life, which was principally spent in angry controversies with his opponents, except the extension of casemated defenses for sea-coast works; and it is only within a comparatively recent period, in the present century, that a new school of engineers has grown up principally in Germany, based upon the views put forth mainly by Montalembert. The principal propositions of Montalembert consist: 1. In the entire rejection of the bastioned system, as, according to his views, unsuitable to a good defensive disposition; and in its stead he proposed to use either the *tenailled system*, or else the *polygonal system*. 2. In basing the strength of these last systems upon an overwhelming force of artillery fire in defensive casemates. 3. In organizing strong permanent works within, and independent of the body of the place, which are to serve as a secure retreat for the garrison when forced to give up its defense. Montalembert first gave the name polygonal system to a tracé of the enceinte in which all of the angles are either salient, or where the re-enterings are very slight. A description of the polygonal system in its most simple form, the one in which Montalembert presented it for the fortifications at Cherbourg, one of the most important naval stations in France, will be given here as an example. The body of the place consists of the scarp wall, arranged with casemates for artillery and musketry; of a corridor, between these casemates and the earthen rampart and parapet. In rear of the rampart is a high wall, arranged with loop-holes, within which the garrison retired when driven from the defense of the rampart. Casemated caponnières, which are secure from a *coup-de-main*, are placed along the rampart, and so arranged that a fire can be thrown from them over the parapet and also along the terre-plein. The corridor is also swept by a casemated caponnière for musketry; and the front of the wall by a like arrangement. The principal caponnière for flanking the main ditch is in the form of a lunette, and placed at the middle of the exterior side, its flanks joining the casemated gallery of the enceinte. The flanks and the faces of this work, are arranged with two tiers of artillery and musketry fire; each flank carrying ten and each face twelve guns. A wet ditch separates the faces and flanks; a loop-holed wall encloses the portion between the flanks, from which the opposite portion between the faces is swept by musketry. The caponnière is covered in front by a face cover of earth, in the shape of a redan. The scarp of the enceinte is covered in like manner by the continuous face cover of earth, in the re-entering angles of which casemated batteries of two stories, for artillery and musketry, are placed to flank the ditches and sweep the positions for counter batteries around the salients of the covered-way. These batteries are masked in front by earthen works. The whole is covered by the glacis of the covered way, arranged in the usual manner. The better to flank the main caponnière, the portion of the casemated gallery joining it is arranged with two tiers of artillery fire, the remaining portion having but one tier of guns. The communications between the different works are by bridges across the wet ditches. See *Polygonal System of Fortification*, and *System of Fortification*.

MONTER.—A term signifying to rise from one rank to another in the way of promotion, as from Lieutenant to Captain, etc., or from having the command of the youngest company to be promoted to that of the oldest.

MONTERO.—A military cap and hood formerly worn in camp.

MONTIGNY MITRAILLEUR.—A machine gun consisting of 37 rifled steel barrels, hexagonally formed exteriorly, and fitted and soldered into a wrought-iron tube, somewhat in the form of an ordinary piece of artillery. This has a movable breech-piece worked by means of a lever, and containing a spring and striker, corresponding with each barrel. The whole of the barrels can be charged simultaneously by the introduction of a steel plate containing the thirty-seven cartridges; they can be fired independently, and at any interval of time, or the whole may be fired in one second; reloading takes five seconds, and a continuous fire at the rate of ten discharges per minute can be maintained. The gun is provided with both vertical and horizontal adjustments, and may be made to sweep horizontally along a line of adjustment between each discharge, or during the discharge itself. As there is no recoil, the gun once laid will continue to throw 28 lbs. weight of projectiles per minute on the same spot, or at various points of any line requiring the same elevation without any further labor than that involved in the working of the lateral adjustment. It appears from Major Fosbery's account, who was sent to Belgium by the English government to report on this mitrailleur, that at 866 yards the hits were 32·12 per cent. From the report of the Special Committee appointed to carry out comparative experiments with the Montigny and Gatling mitrailleurs, it would seem that the result is in favor of the latter. In the special competition between this gun and the Montigny mitrailleur of thirty-seven barrels, the former made 618 hits in 3 minutes 31 seconds, in 720 rounds at 600 yards; the Montigny, at the same range and with the same number of rounds, scoring 538 in 4 mintutes. With 558 rounds at 800 yards, the result was even more favorable to the Gatling, which made 439 hits in 2 minutes 26 seconds, against the Montigny's 292 in 3 minutes 3 seconds.

MONT-PAGNOTE. In fortification, an eminence where persons post themselves out of reach of cannon, to see a camp, siege, battle, etc., without being exposed to danger. It is also called the *Post of the Invulnerables*.

MOORING.—This is the most difficult operation connected with submarine mines. It is a problem containing so many conditions that it is impossible to give more than general suggestions concerning its solution. In order to possess a maximum of efficiency, no indication of the position of a mine should appear on the surface of the water, and yet the spot, to within a few feet of where it is deposited, must be known to the defenders of the channel in which it is used. In certain cases—as when there is considerable rise and fall of the tide—it is impossible to totally conceal the position of a system of mines. When such is the case, the very smallest indication possible should be allowed to appear on the surface of the water. It has been found that the least current, or so much roughness as only a moderate breeze would cause, renders the placing of even a single mine in a definite position a matter of very considerable difficulty. When a series of mines are to be moored in proper relative position, this difficulty is much increased, and it is, furthermore, augmented in proportion to the depth of the water.

The objects to be obtained in mooring are as follows: 1st. That the charge should be kept as nearly as possible stationary at the point where it is required to act. This is particularly necessary where there is a tide which, flowing first in one direction and then in another, tends to cause the mine to shift its position, and is indispensable in the case of mines intended to be fired by judgment. 2d. The moorings should be so arranged that there shall be as little twisting as possible, which might break or injure the insulation of the electrical cables. 3d. The anchors or heavy weights used should be suited to the nature of the holding ground or bottom. 4th. Mooring cables should be so arranged that they may not be likely to become twisted together or entangled. The best special mooring appartus for general purposes is the *mushroom anchor*. It is decidedly so for a soft, muddy bottom. On a hard, rocky bottom the deadweight of the mooring must be depended upon to keep a mine stationary, and if a heavy mushroom anchor is used, its edges should be furnished with toes or points to catch in the crevices of the rocks. The weight of the anchor would depend on the buoyancy to be overcome, and would usually be from 500 pounds upwards. Ordinary mooring chains and hemp cables may generally be employed in connecting the charges or circuit-closers with the anchors. Where there is any tendency to twist, a wire cable is the best to counteract it. Any considerable amount of twisting must be checked, as it is liable to entangle the moorings and to rub and injure the electric cables.

Next to the mushroom sinker the ordinary anchor is the best. For make-shifts, any heavy-weights—as large stones, pigs of metal, or bars of iron—may be used. These must necessarily be sufficiently heavy to hold a mine in position simply by their deadweight. The material just mentioned can be fastened to frames of wood, and the whole sunk as one mass.

The weight necessary for a mooring, whether anchor, sinker, or other apparatus, will depend upon the buoyant force of the mine, the nature of the bottom, and the currents.

The buoyancy of a mine is in excess of flotation over its weight. This would be measured by the number of pounds required to sink it, and no more. When wooden casks are used the buoyancy may be roughly taken as equal to the weight of the charge of powder. With heavy metallic cases their weight must, in all cases, be taken into consideration. In water free from currents twice its buoyancy is considered necessary to keep the mine in a vertical position over the mooring; this, therefore, would be the weight required for the mooring. Where there is a current, additional weight to keep it from swinging off with it is required, and this increases with the strength of the latter. When the mine is moored by a single cable, a convenient rule, approximating closely to results from experiments, is to allow one additional buoyancy for each mile per hour of current; *i. e.*, two buoyancies being allowed for still water, three would be allowed for a current of one mile; four for two miles; five for three miles, and so on. These represent the weights for the mooring in each instance. In a tide-way where there is a current of more than five miles an hour, two anchors may be advantageously used, placed up and down stream at a considerable distance apart, depending upon the force of the current and the distance from the bottom at which the mine is to float. It is extremely difficult to moor mines in proper lines and depths by this means. When the mine is small, say one containing a charge not greater than 200 pounds, a single large barge may suffice for placing it. The anchors can be let down at a suitable distance apart from the extremities of two out-riggers, one from each end of the barge. The mine, attached to the middle of the cable connecting the anchors, is weighted down by a heavy saddle, which after the anchors are down, is hoisted in and the mine permitted to rise to the proper depth from the surface.

In order to place a large buoyant charge of, say, 1000 pounds and upwards, three of these large boats are required to carry it and its anchors, one for each anchor or mooring sinker, and one for the charge itself. They are connected by a rope, which, if kept stretched, would insure the anchors being placed at the proper distance apart. The sinkers and mine are carried out and lowered from the davits at the stern of each boat. Skillful boatmen and sailors are required for all operations connected with the placing of mines, and a handy steam-tug is the most convenient craft to use. The floating mine is used where the depth of water is so great that, if placed on the bottom, the mine would require for efficiency an excessively large charge. In this case it is held to the bottom by moorings in such position as not to rise to the surface at low tide, nor at high tide be so deep as to be beyond effective range of over-passing vessels. To arrive at this exact point, it is best to haul the mine down towards the sinker. For this purpose there are various contrivances, some one of which would be supplied with the rigging furnished with the mine. When the mines are to rest upon the bottom, they are lashed to some heavy object sufficient to sink and hold them in position, and then lowered to their places. See *Submarine Mines*.

MOORS.—A people who form the great majority of the population of Barbary. Their appearance indicates their origin, which is a mixture of the Mauri, (from whom they derive their name), Numidians, Phenicians, Romans, and Arabs, who have successively held possession of the country. In consequence, they are found to vary considerably in appearance and character in different parts of Barbary, but all show much more or less strongly the symptoms of a considerable infusion of Arabian blood. They are a well-formed race, with fine oriental features, and a mild and melancholy expression of countenance. They are more friendly and sociable than the Bedouins and Berbers, who inhabit the deserts and mountains; but are inferior to them in mental ability, besides being voluptuous and cruel.

As the Arab conquerors of Spain invaded that country from Africa, where they had largely recruited their forces, they were naturally enough called Moors, and in Spanish history the terms Moors, Saracens, and Arabs are synonymous. From this mixed Moorish-Arab race sprang the *Moriscoes* who were permitted by Ferdinand the Catholic to remain in Spain after the expulsion of their countrymen, on condition of their embracing Christianity. A cruel persecution, which was originated by Philip II., drove them to rebellion (1567-70), and in 1571 many of them emigrated to Africa; those who remained being, to the number of 500,000, expelled in 1610 by Philip III.

The Moors first appear in modern history as the Allies of the Vandals in their invasion of Africa, and were continually rebelling against the Byzantine Emperor. They were next, after a severe struggle, conquered and converted by the Arabs in 707. In 1091 they were summoned by the latter into Spain, to aid in stemming the tide of Christian Conquest; and after faithfully supporting the Arab Calif of Cordova, etc., till his dominions fell into the hands of the King of Leon and Castile, they retired in 1238 to Granada, where they founded their kingdom. The Kings of Granada carried on a vigorous, and, at the same time, chivalrous warfare with the Kings of Castile; but at length, weakened by internal discord, were compelled to succumb to Ferdinand the Catholic in 1492. The Moors, or at least that portion of them who refused to adopt Christianity, were then expelled from Spain, and in revenge, founded in 1518 the piratical States of Algiers Tunis, and Morocco.

MOORSOM FUSE.—The body of this fuse is made of bronze, and is screwed into the eye of the shell by means of a key fitted into two mortises made in the head. The lower part is not threaded, and projects into the chamber of the shell. In the body of the fuse two cylindrical chambers are placed, one above the other, with their axes perpendicular to each other. These chambers are both alike, with similar percussion apparatus. In each chamber is placed a solid cylinder of bronze, terminated at each end by a small projection, or piston One head of the chamber is movable, and when screwed into its place, its exterior is flush with the convex surface of the fuse. Holes are left on the exterior for the use of a key, and the head is screwed in, after the hammer is placed in the chamber and suspended. In each end of the chamber is a small recess, a vent being bored through to it from the exterior of the fuse. These are both filled with fulminating powder. A hole is drilled through the hammer at its middle point, and perpendicular to its axis, and is used to suspend the hammer, by means of a copper wire, in the center of the chamber. The wire passes through corresponding holes in the body of the fuse, and is soldered at the ends in the curved positions of the holes near the surface of the fuse. In the lower end of the fuse a third chamber is placed with a percussion apparatus similar to the preceding, acting, however, in the direction of the axis of the fuse, and having but one end of the chamber provided with percussion-powder, the vent leading from which communicates with a cross-chamber, having at each end a small chamber filled with powder. The hammer, a cylinder of bronze, with a piston like the others, on its upper end, is suspended in the same way, and has below it a copper-wire passing through holes in the fuse, and soldered like the rest. At the bottom of this last chamber stands a cylinder of lead, fixed in its position by its base, which is pressed in a little offset, between the bottom end of the fuse and the cap which closes the chamber. When the shell strikes, the suspension wire of that hammer whose axis coincides with diameter of the shell passing through the point of impact, or, is parallel to it, is torn loose, releasing the hammer, and allowing it to plunge forward and explode the fulminate, by striking it with the piston on its end. From the construction of this fuse it will be seen that there are six points on the surface of the shell, the striking of which will produce the working of the apparatus with certainty. See *Fuse.*

MOOTIANA.—In the East Indies, a term applied to the soldiers who are employed to collect the revenue.

MOPPAT.—A very early name for a cannon sponge.

MORGENSTERN.—A mace with a long handle and spiked head. See *Morning Star.*

MORGENSTERN GUN.—A breech-loading rifle having a fixed chamber closed by a movable breechblock, which rotates about a horizontal at 90° to the axis of the barrel, lying above the axis of the barrel, and in front. It is opened by drawing back the handle of the firing-bolt until the ribs on its sides are clear of the grooves in the receiver in which they slide. This cocks the piece by compressing the spiral mainspring which surrounds the firing-bolt, until it is caught and held by a sear lying well in the bottom of the breech-block. The breech-block may then be thrown upward and forward until it is stopped by striking the front part of the receiver. It is held open there by the head of the ejector-spindle, which changes its bearing on the extractor so as, through it, to support the block. The piece is closed by reversing the movement of the breech-block, and is locked by the side ribs of the firing-bolt engaging with the undercut grooves in the rear portion of the receiver. The piece is fired by a concealed spiral-spring lock the firing-bolt being released by the action of the trigger within the receiver upon the sear within the block. Extraction is accomplished by the breech-block striking the lug on the extractor above its centre of motion, and ejection is caused by the acceleration impressed on the extractor by the action of the ejector spring on the ejector-spindle, when, by the motion of opening, the direction of this latter passes below the axis of the extractor. The ejector-spring is then released from the tension caused by its compression in opening, and causes the extractor to rapidly rotate about its axis, carrying the empty cartridge against the beveled shoulders of the receiver, by which it is deflected upward and thrown clear of the gun.

MORGLAY.—An ancient and very deadly weapon, in the form of a great sword.

MORION.—Originally a Spanish helmet. It had neither vizor, nose-piece, gorget, nor neck-guard; but was surmounted by a high crest sometimes half the height of the helmet. Its edge turned up in a point in front and behind, so as to form a crescent when seen in profile. The *Morion* was worn by Arquebusiers and Men-at-Arms.

MORNE.—The head of the lance used in tilting or other peaceful encounters. It was curved so that an adversary might be unhorsed, but not wounded, by a stroke. Also written *Mortne.*

MORNING GUN.—The gun fired at the first note of reveille, at all military posts, forts, etc.

MORNING PARADE.—The daily parade at *troop*, sometimes called Troop Parade. In every garrisoned town, fortified place and camp, as well as in every town through which soldiers pass, or occasionally halt, a certain hour in the morning is fixed for the assembling of the different corps, troops, or companies, in regular order. See *Dress Parade.*

MORNING REPORT.—A report of troops, their service, condition, etc., rendered every morning to superior authority. The Morning Reports of Companies and Detachments are combined and form the *Consolidated Morning Report.* The form of Morning Report, given on page 380, used at West Point, will illustrate its purpose.

MORNING STAR.—A mace having a long handle and a head with projecting spikes. It received its name from the ominous jest of wishing the enemy good morning with the *Morning-star*, when they had been surprised in camp or city. This weapon became very popular on account of the facility and quickness with which it could be manufactured. The peasant made it easily with the trunk of a small shrub and a handful of large nails. *Morning-stars*, short in the handle, like hammers, were made especially for the Cavalry, Some were supplemented with small hand-cannon in the 15th century.

MORRIS-PIKE.—An ancient pike much used by the Moors. See *Pike.*

MORTAR.—A short and comparatively light cannon, employed to throw hollow projectiles at great angles of elevation. It is intended to produce effect by the force with which these explode. The great curvature of their fire gives them power of reaching objects behind works which would be secure from direct fire. As the projectile has a large diameter, and, except in rare instances, a very great range is necessary, a comparatively small charge of powder is requisite. To give this its utmost power and concentration, it is confined in a hemispherical chamber at the lower end of the bore, but of less diameter. The shell completely closes this chamber; and when the explosion ensues receives its full force on its center. Ordinary mortars range in diameter of bore from 5 to 13 inches. Large mortars have, however, been tried at times, as at the siege of Antwerp citadel

NOTE. On the monthly return of absentees and men on special duty to be accounted for by name, after "Explanations of Alterations."

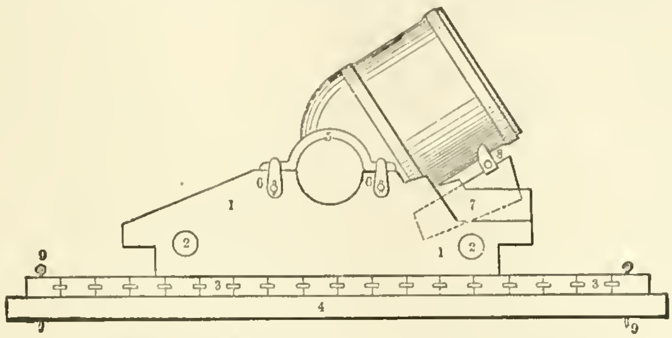
Cadet (First Sergeant) Company ——
Corps of Cadets

Station, ————
Date, ————

Cadet (Captain) Corps of Cadets,
Commanding Company.

in 1832, when the French brought one of 24 inches bore to the attack. This monster, owing to its unwieldiness and other causes, was a failure. Larger still than this, though perhaps more manageable, is Mr. Mallet's great 36-inch mortar, constructed in 1855, of iron parts welded together, and now at Woolwich, rather as a curiosity than for use. As loaded shells are of immense weight, so heavy, indeed, as in larger calibers to involve the apparatus to deposit them in their places, and the mortar is fired at high elevations, the recoil is so great and so nearly vertical that no carriage could withstand the shock; it is necessary, therefore, that the mortar should be mounted on a solid iron or timber bed, by the trunnions, which are placed behind the breech, and supported in front by massive blocks of wood. This arrangement renders the apparatus so heavy provided with complete pointing apparatus, are capable of following the course of a moving vessel with the same facility as a gun.

Mortars, like other cannon, are aimed by first giving the direction and then the elevation. The elevation, which is usually that of the greatest range of projectiles in *vacuo*, viz., 45°, is determined by applying the quadrant to the face of the piece, and raising and lowering the breech until that number of degrees is indicated. The charge of powder is varied to suit the required range. To give the shell, for the same range, a greater velocity in the descending branch of its trajectory, the mortar is sometimes fired at an angle of 60°, in which case the charge of powder must be increased accordingly. As mortars are usually masked from the object to be bombarded by an epaulment or parapet, different means from those



1. Cheeks. 2. Maneuvering bolt. 3. Deck plank. 4. Sleeper. 5. Cap square. 6. Cap straps. 7. Bolster. 8. Quoin. 9. Eye bolts.

that mortars of large size are rarely used in field operations, their ordinary positions being in defensive or siege works, and in mortar-vessels. More wieldy, however, are the Coehorn mortars, invented by the Dutch engineer of that name, for clearing the covert-way or ditch of a fortress. This mortar is sufficiently small to be managed by one man, and is accounted useful in siege or defense operations. The French use a similar Lilliputian ordnance under the denomination of pierriers, or stone-throwers. Small mortars are likewise constructed for mountain warfare; a mule carries the mortar, another the bed, and a third is laden with the projectiles. The use of mortars is diminishing at the present time, elongated shells of great weight being now thrown from rifled cannon.

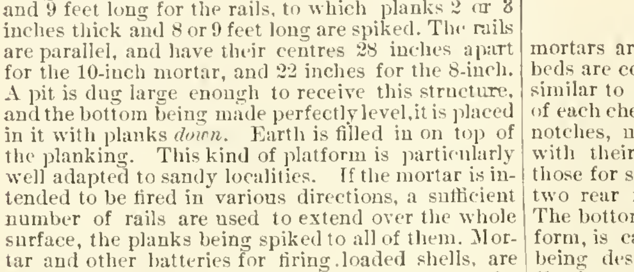
Vertical fire is effective when it is desirable to prevent an enemy from occupying certain anchorage. The deck of a ship is as completely vulnerable to falling shells as the bottom is to submarine mines and torpedoes. Judiciously-placed batteries, if armed with a sufficient number of mortars throwing shells, would make it perilous for an enemy to remain within their reach. But mortar-firing from smooth-bore mortars is at best somewhat wild, and depends on quantity for its effectiveness. It is, however, safe to say that no fleet nor vessel can remain under well-directed fire from heavy mortars. A battery of one hundred heavy mortars will keep at bay all the iron-clads that can maneuver or anchor within their range. The moral effect of mortar-firing is appalling, and increases vastly with the numbers of mortars used. The armor that a vessel is capable of carrying on her deck, in addition to that upon other parts, is not sufficient to resist the crushing power of a 13-inch shell with maximum velocity —419 feet per second. The 10-inch mortar is serviceable only against unarmored decks, or those very slightly protected. In firing at iron-clads the shells should not burst before striking; in fact, it is best to fill the shells with sand instead of powder. Solid shot would be preferable to either. Mortars mounted on the center-pintle traversing chassis, and used with guns become necessary for giving them their direction. There are several processes employed, all of which, however, are reduced to determining practically two fixed points which shall be in line with the piece and the object, and sufficiently near to be readily distinguished by the person pointing the mortar. These points determine a vertical plane which when including the line of metal becomes the plane of fire. See *Bob*, *Coehorn Mortar*, *Dyer Pointing Apparatus*, *Ordnance*, *Paddock Interpolater*, *Plummet*, *Sea-coast Mortar*, and *Siege Mortar*.

MORTAR BATTERIES.—Mortar batteries have principal features of batteries for guns. It is desirable that they should be located where good views of the enemy's position may be had: this, in order that the gunner may himself see the effect of his shot, and not, as is too frequently the case, have to depend upon the imperfect report of a distant observer. For siege mortars, the platforms are placed the same distance apart as for siege guns, viz., 16 feet; for sea-coast mortars, the distance is the same as for sea-coast guns, viz., 18 to 22 feet. They are usually placed in pairs, with traverses between each set of pairs. Embrasures are not required, and as the platform must be at such distance from the parapet that the blast will not injure the interior crest, it is not necessary to revet the interior slope, the earth being allowed to assume its natural slope.

There are two kinds of mortar batteries used in the attack: those for mortars throwing shells; and those for mortars throwing baskets of stones, or other like projectiles. Besides these, there is the Coehorn mortar, which, from its small size, may be placed in any unoccupied corner of the trenches within their range from the besieged works. The first kind of batteries may be in front of the first and second parallels, or any other points farther back. The positions chosen for them should be such as to bring as great a portion of the defences under the direction of their fire as practicable, to increase the chances of destructibility of each shell thrown. The second kind are usually placed in front of the third parallel, mainly with a view to annoy the covered-ways and parts adjacent. These batteries are usually sunk below the natural surface, since even several feet difference of level in the position of a mortar will have but little effect on the range, or the trajectory. The profile suitable for such positions, under the ordinary circumstances, is the following. Width of trench at bottom, 13 feet 6 inches. Depth in front, 3 feet 6 inches. Depth in rear, 4 feet. Reverse slope, $\frac{1}{3}$. Front slope, 2 feet base. Height of parapet, 4 feet. Thickness of parapet, 18 feet. Berm, 1 foot. The earth for the epaulement is taken from an exterior ditch; and, when splinter-proof traverses are required, portions of ditches are made opposite to their position to furnish the requisite earth.

The siege-mortar platform furnished for field-purposes is too light to sustain much firing. For fixed batteries, they should be constructed of heavy timbers, and to insure anything like accuracy in firing, must be both level and stable. The sea-coast platforms when properly laid, are in every respect efficient. A good kind of rail platform may be made by using two pieces of timber, 12 to 15 inches square and 9 feet long for the rails, to which planks 2 or 3 inches thick and 8 or 9 feet long are spiked. The rails are parallel, and have their centres 28 inches apart for the 10-inch mortar, and 22 inches for the 8-inch. A pit is dug large enough to receive this structure, and the bottom being made perfectly level, it is placed in it with planks *down*. Earth is filled in on top of the planking. This kind of platform is particularly well adapted to sandy localities. If the mortar is intended to be fired in various directions, a sufficient number of rails are used to extend over the whole surface, the planks being spiked to all of them. Mortar and other batteries for firing loaded shells, are provided with bomb-proof shelters for the men who load the shells, and others also for the loaded shells These shelters may be placed in the epaulements of the batteries, under thick traverses, or in any position most convenient for the service of the battery.

When the site of the battery is marshy, the construction of the parapet and the laying of the platforms require great care to give them the requisite strength and firmness. Each of these parts should receive a firm bottoming of two layers of long fascines, 12 inches in diameter, the border for a breadth of 2 or 3 feet receiving a thickness of 3 or 4 layers, the first well covered with sand or rammed clay, if they can be obtained, before placing the second

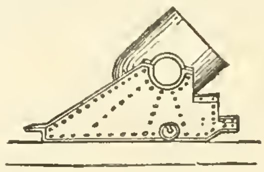


layer, which should cross the first at right angles, and be well picketed to it. On this bed the parapet is raised, and, if the adjacent soil of which it is formed is very wet, layers of smaller fascines may be advantageously used at different heights to prevent the wet soil from running. The site of the guns should be covered, to a depth of at least 6 inches, with moist sand, or good loam well rammed, to receive the platforms; which, like those at the sieges of Forts Pulaski and Wagner, should rest on a bed of plank, over which the weight of the guns should be well distributed by the under timbers of the platform.

On a site of solid rock the only means that can be well employed for constructing the parapet is sandbags. If the surface of the rock on which the platforms are to rest, is too uneven or too much inclined to be easily leveled by hammers, it will be necessary to fill in the space required for the service of the guns with earth or sand, and to use a cribwork if necessary around the border of the interior to confine the soil, which, as in the case of a marshy soil, should be well rammed and levelled before laying the platforms.

The drawing shows a plan of an indented sunken battery on a causeway from 50 to 60 feet wide. A.B. is the line of direction of fire; C, contraction of rear of battery; D D, enlargement of rear of battery; E, ramp.

MORTAR BEDS.—Mortar beds serve the same purpose as gun-carriages. The beds for the smaller

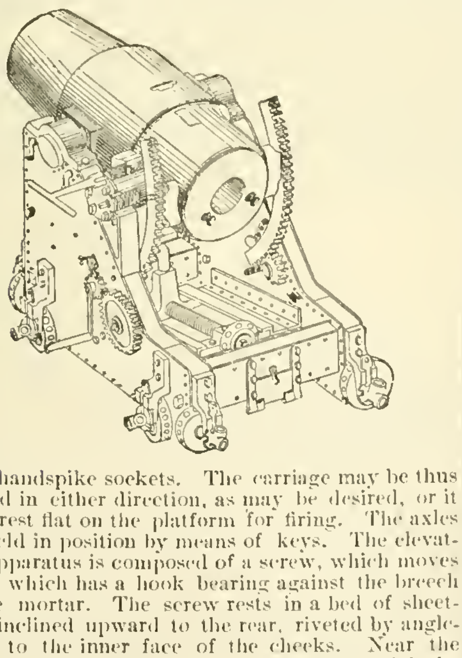


mortars are made of one solid block. The larger beds are constructed and put together in a manner similar to the top-carriages for guns. At the ends of each cheek are projections, called front and rear notches, underneath which the cannoneers embar with their handspikes to move the carriage. On those for siege mortars there are also two front and two rear maneuvering bolts for the same purpose. The bottom part of each cheek, resting on the platform, is called the shoe; the front and rear ends being designated the toe and heel, respectively. Carriages for siege mortars are without truck-wheels, and rest directly on the platform. Sea-coast mortars have two truck-wheels on an eccentric axle, for maneuvering the carriage on the platform, and maneuvering bolts are omitted. See *Mortar Carriages* and *Thirteen-inch Mortar*.

MORTAR CARRIAGES.—The application of the principle of rifling to mortars, in common with guns of all kinds, has had the effect to obliterate to a great degree the sharply-defined lines of distinction which formerly divided the different classes of cannon, and to reduce them more closely to a common model, adapted more nearly to a common use. The rifled mortar, to give it the desired efficiency, has been increased in length until it differs in no respect from a howitzer or short gun, and is no longer confined as formerly to a vertical fire exclusively, but may be used with effect for direct or curved fire, with solid or hollow shot, as well as shell. The carriages for the different guns have had to undergo necessarily corresponding changes to adapt them to the new conditions of service; and as the guns have been modified till they bear a resemblance to each other, so the carriages on which mounted are less distinctive in appearance and more nearly approach the same pattern. The mortar, in place of being mounted as formerly on its bed, must in its changed condition be provided with a carriage constructed so as to enable it to deliver its fire at any angle from 0° to 60°, and be turned with promptness on any object within a wide field of fire.

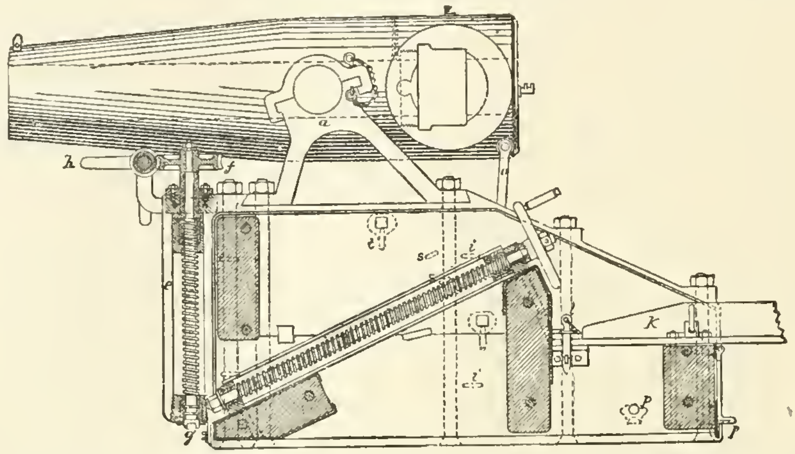
United States.—The Coehorn mortar carriage is simply a block of wood, weighing 132 pounds; the total weight of piece, equipments, and carriage being 311 pounds. The carriage or block upon which the mortar is mounted, is provided with two handles on each side, by means of which the mortar is readily carried by four men from one part of the work to another. They accompany troops in the field for use against an enemy covered by intrenchments. The ground, when firm, is sufficient for the carriage to rest upon; if it is not firm, a platform can readily be extemporized from such material as may be at hand. The carriage should be level when the mortar is fired. The siege mortars are fired from wooden platforms. The carriages are of wrought-iron, and, being without chasses, rest directly upon the platforms. The 13-inch mortar is fired from a wooden platform. The carriage is of wrought-iron, and, being without chassis, rests directly upon the platform. An axle, carrying at each extremity a truck-wheel, passes through the carriage near the front end; this axle is eccentric, and when thrown in gear the truck-wheels rest upon the platform; only the rear part of the shoe then rests on the platform and moves with sliding friction. Two steps are placed on the front part of the carriage for convenience in loading. The carriage of the 10-inch sea-coast mortar is of wrought-iron, and is provided with an eccentric axle and truck-wheels similar to the carriage for the 13-inch mortar.

Austria.—The Austrian carriage is composed of two cheeks, each formed of two plates of boiler-iron riveted together around their outer edges, with a wrought iron frame between them. The cheeks are 47 inches high in front and 18½ inches in rear. Trunnion-beds formed in the upper face are provided with trunnion-plates and cap squares: the latter are held each by two keys. The two cheeks are joined together front and rear by two transoms, each formed of two plates of iron and angle-irons. These transoms pass through cuts made in the inner plate and are riveted to the outer plate of the cheek; they are also secured to the inner plate by angle-irons riveted to each. Two bolts pass through these transoms and join the cheeks, besides a bolt, about a third of the height from the top in front. The part of the bolts embraced between the cheeks has a wrought-iron pipe over it. A square hole is cut in the cheek near the front edge, intended for the wrought-iron axle used in transportation. The axle is composed of a body, square in cross-section, and two cylindrical arms for the wooden wheels. The cheeks are provided with four pairs of truck-wheels, two for moving the carriage to the front or rear, and two others for moving it laterally. They are all mounted on eccentric axles, which have cast-



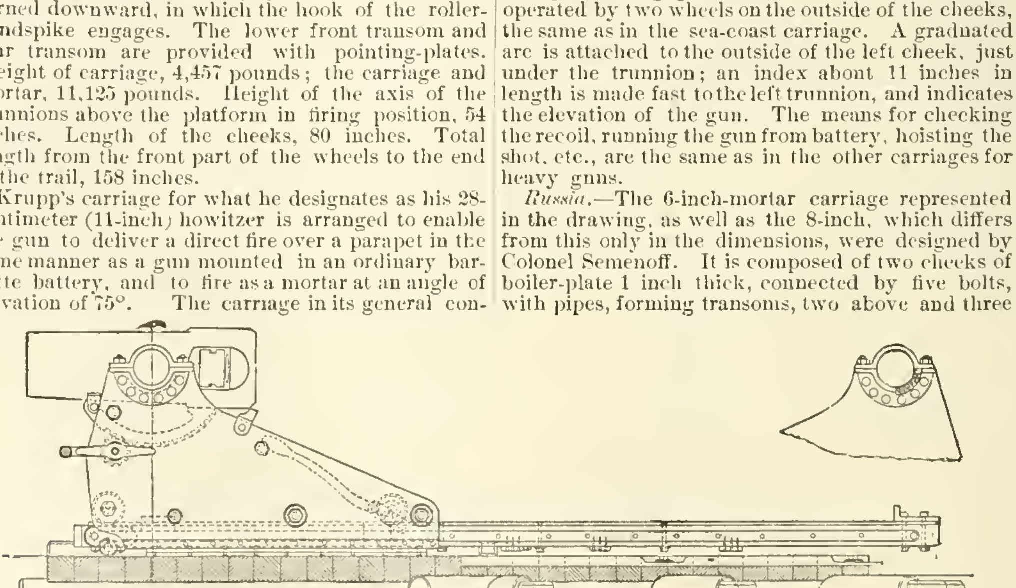
iron handspike sockets. The carriage may be thus moved in either direction, as may be desired, or it may rest flat on the platform for firing. The axles are held in position by means of keys. The elevating apparatus is composed of a screw, which moves a nut which has a hook bearing against the breech of the mortar. The screw rests in a bed of sheet-iron inclined upward to the rear, riveted by angle-irons to the inner face of the cheeks. Near the rear end of the bed there is a collar, in which the screw turns. The head of the screw has in it holes in which is inserted a crank-handle to give rotation to the screw. The nut is guided in its motion by two projections which move in corresponding grooves in the bed. For firing at low angles of elevation a block is placed on the hook, fitting over it and increasing its height. In order to bring the mortar quickly from the firing position to that for loading, there are fastened to either side of the breech of the mortar two circular steel arcs with teeth which engage each with a pinion on the inner face of the cheeks. A wheel and pinion on the outside of the cheeks are used to give motion to the inner pinion. To transport the mortar an axle is inserted in the cheeks of the carriage and ordinary wheels are put on, raising the carriage with jacks. A trail is provided which has a lunette for hooking on to an ordinary siege-limber; it is secured to the carriage by passing one end under the front transom and engaging it in two hooks under the pointing-bed, and held by a cross-piece. Weight of the carriage, 5,140 pounds; of the axle, 231 pounds; the trail, 192 pounds; with the lock-chain and shoe, 286 pounds; the two wheels, 476 pounds; the limber with wheels, 838 pounds; the total weight of the carriage ready for traveling, 6,973 pounds; with the mortar, 17,826 pounds. Width of track of rear wheels, 72 inches; front wheels, 48.5. Angle for turning, 42°. The elevating screw with the ordinary hook will give elevation of 20° to 60°; by putting on the block, angles from 10° to 20°.

Germany—This carriage is composed of two wooden cheeks, the greater portion of the border re-enforced by iron straps and joined together by four wooden transoms and eight transom-bolts. A trunnion-piece, *a*, of wrought-iron is bolted to the upper side of each cheek, and is provided with a cap-square, key, and chain. The elevating apparatus is composed of a long iron screw with a square double thread, turning from right to left, inclined at about 25°. It is terminated at the upper end by a wheel and handle, and turns in two collars fastened one to the front side of the lower transom and the other to the middle transom. The nut *c* travels along the screw throughout its length. The ends of the female screw are provided with rollers, which play in the grooves of channel-beams secured on the inner face of the cheeks. Two iron rods, *o*, connect the female screw to the breech of the mortar, which has a horizontal hole drilled into it to receive a bolt, forming an axle around which the rods, *o o*, move. By this arrangement angles of elevation from 0° to 75° may be given. The carriage is provided with two siege-wheels and a wrought-iron axle, which may be raised vertically by means of a hoisting apparatus and made to move in two slots formed by an iron bar fastened to the front face of the cheeks. This axle has near each arm a square re-enforce, with a vertical hole in it, in which is placed a bronze female screw with a double thread; one nut is right-handed, the other left. The hoisting apparatus is composed of two vertical screws in the slots, *e*, passing through the nuts in the axle. The screws have on their upper end the spur-wheel, *f*, engaging in the threads of the endless screws, one of which is right-handed, the other left, and mounted on the same horizontal shaft, which is turned in journal-boxes in the upper part of the grooves by means of a capstan-handle, *h*, on each end. The axle is guided in its motion in the grooves by a plate of iron, screwed to the inner face of the axle, between the two shoulders, and terminating in square hooks, which form guides, and slide in the grooves. The hoisting apparatus is used either to lower the carriage on the platform by raising the wheels so that they do not touch, or to raise the carriage by bringing the wheels on the ground. Four men at the handles of the screw are sufficient to do this work. To lower the mortar on the platform, it is necessary to raise the wheels only from ½ to ¾ of an inch, whereas for the transportation of the mortar the carriage must be raised sufficiently to attach it to the limber. This is done by means of a trail, *k*, of T-iron. This has a lunette at one end, and is made fast to the middle transom by means of a strong bolt, *l*, and to the rear transom by two iron ears, between which it is firmly held. A 15-centimeter gun-limber is used. The wear on the female screws in the axle is diminished by means of stirrups with screw ends; the axle is lowered to its lowest point in the groove, the ends of the stirrups are passed through holes drilled in the axle to the right and left of the shoulders, and the threaded ends are screwed into double nuts, which are jammed hard. The middle part of the stirrup fits in a notch, *q*, cut in the lower end of the screw, and prevents it from turning. There are several other irons on the cheeks; two priming-wire eye-bolts, four equipment-



rings, *i i*, two hooks, *t*, four plates, *p p*, at the rear, two of which are on the outer face of the cheeks and two on the rear face: they present a kind of cup turned downward, in which the hook of the roller-handspike engages. The lower front transom and rear transom are provided with pointing-plates. Weight of carriage, 4,457 pounds; the carriage and mortar, 11,125 pounds. Height of the axis of the trunnions above the platform in firing position, 54 inches. Length of the cheeks, 80 inches. Total length from the front part of the wheels to the end of the trail, 158 inches.

Krupp's carriage for what he designates as his 28-centimeter (11-inch) howitzer is arranged to enable the gun to deliver a direct fire over a parapet in the same manner as a gun mounted in an ordinary barbette battery, and to fire as a mortar at an angle of elevation of 75°. The carriage in its general con-

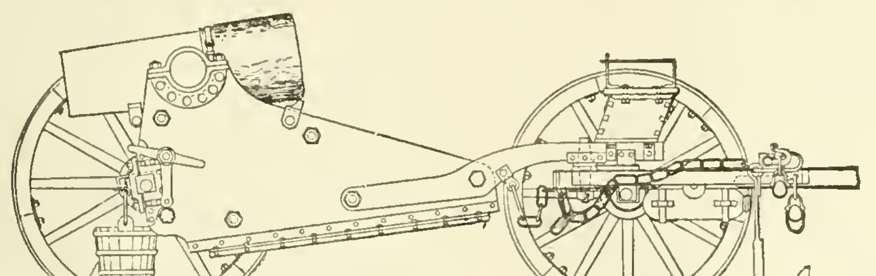


struction is quite similar to that made for the sea-coast guns, with such modifications only as became necessary to fit it for the special service required of it. To enable the chassis to resist the strain brought upon it in firing at elevations of 75°, the rails are made to bear evenly on four traverse-circles laid in the platform, placed at equal distances from each other. The rear traverse-wheels are mounted on eccentric axles, and when the gun is to be traversed these wheels are thrown in gear, and when the proper horizontal direction has been given to the gun they are thrown out of gear, and receive none of the shock of the recoil. The means for traversing the chassis are the same as in the sea-coast carriages, namely, a windlass and chain made fast to the platform near either end of the outer traverse-circle. The pintle is in the front transom. In order to preserve the axis of the gun at the proper height above the platform to enable the gun to fire over parapets of the usual construction, it is necessary to make the top carriage as much higher as the top of the chassis has been lowered. To give the different elevations ranging from 0 to 75°, a circular rack is fixed to the under side of the gun, the center of the rack being at the intersection of the axis of the trunnions with that of the gun. A cog-wheel engages in the teeth of the rack, and is operated by two wheels on the outside of the cheeks, the same as in the sea-coast carriage. A graduated arc is attached to the outside of the left cheek, just under the trunnion; an index about 11 inches in length is made fast to the left trunnion, and indicates the elevation of the gun. The means for checking the recoil, running the gun from battery, hoisting the shot, etc., are the same as in the other carriages for heavy guns.

Russia.—The 6-inch-mortar carriage represented in the drawing, as well as the 8-inch, which differs from this only in the dimensions, were designed by Colonel Semenoff. It is composed of two cheeks of boiler-plate 1 inch thick, connected by five bolts, with pipes, forming transoms, two above and three below. The trunnion-bed is formed by re-enforcing the hole cut in the plate with a flat piece of iron on the outside and an angle-iron on the inside. The trunnion-bed is secured to this by means of rivets with countersunk heads, and inside of the angle-irons are battens, with screws on the end for holding the cap-squares. The lower edge of the cheek is re-enforced both on the inside and outside by angle-irons, and shod with a flat bar fastened by rivets with countersunk heads. Two guides are fastened to the angle-irons in front and rear, and serve to guide the carriage in its motion by pressing against the directrix, which will be mentioned hereafter. The elevating apparatus is composed of an arc fastened at each end to the mortar, having teeth which engage in a pinion mounted on an axle turned by two handles outside of the cheeks. Two cannoneers, one on the right and the other on the left, give the elevation by turning the two handles at the same time. The angles of fire are embraced between 5° depression and 73° of elevation. A clamp-screw on the left end of the shaft prevents the gun from moving after it has been pointed. To load the mortar, it must be brought after firing to nearly a horizontal position. The use of a gunner's level each time is avoided by having a graduated bronze arc fastened on the outside of the cheeks, just under the right trunnion, and an index marked on the face of the trunnion.

In firing, the carriage slides on the platform; or, for the facility of running it into battery and moving it laterally, it may be mounted by means of four truck-wheels on a kind of low chassis or directrix. The two front wheels, mounted on the same axle, are just over the top of the chassis, but do not touch it; the rear wheels are mounted each on a crank-axle; a forked lever, which can be brought down between the cheeks, serves to bring the wheels in contact with the tops of the directrix. To cause the carriage to run on its four wheels, it is sufficient for a cannoneer to force the forked lever down to the rear; the rear end of the carriage is thus raised, and the front wheels are made to bear. The directrix is composed of two wooden beams, covered on top and sides by plates of iron, and joined by two wooden transoms and three bolts. Near the front end is an iron axle, with a vertical hole in its middle for the pintle, and provided with two traverse-wheels which rest on the front traverse-circle of the platform. Two hurters, attached to the front end of the directrix, stop the carriage in its motion into battery, and two counter-hurters, placed in rear, limit the recoil when firing at low angles. Near the middle, between the two beams, is placed a traverse-wheel, which travels on the rear traverse-circle. The directrix is provided underneath with four cross-sleepers, which prevent its bending under the weight of the carriage. The length of the directrix will allow a recoil of 9 feet, which is sufficient for the maximum charges with a dry platform at angles greater than 20°, and with a damp platform at angles greater than 45°. For less angles it is necessary to throw some sand or similar material under the carriage. To give lateral motion to the mortar, if only a slight motion is required, insert the end of the lever in the holes in the rear traverse-circle and press against the carriage. If, on the contrary, it is desired to move the carriage through a great angle, the directrix is traversed on its wheels by three or four men pulling on a rope fastened to its rear end. The platform, as originally adopted, is fan-shaped; nine sleepers, semi-circular in cross-section, are placed crosswise, four toward the front, three in the middle, and two in rear; eleven round sleepers are laid on and slightly let into them; nine of the round sleepers are laid down in the shape of a fan, and the other two halved into the others form the rear oblique sides of the platform. On top of the eleven sleepers, and slightly let into them, are laid thirty-two 6-inch square scantling of variable length, according to their position, the ends cut off obliquely. The last sixteen scantling are secured at their ends by two hurter-planks let into the scantling and held by bolts. The front scantlings are secured in the same way, only the hurter-plank is not let into the scantling. In rear of each sleeper a large picket is driven. Near the front end of the platform the pintle-plate and friction-circle are placed and screwed fast, and near the middle of the platform a second traverse-circle with oblong holes in it. The length of the platform is 16 feet, its slope to the rear 1½°, and the lateral field of fire 90°. This platform, which is still provisionally used in sea-coast batteries, has been recently replaced in siege and garrison batteries by a simpler one, which has been tested with much satisfaction since 1873. This last is formed of two rectangular parts of unequal width. It is composed of nine sleepers, 6 inches square, and covered with twenty planks 3 inches thick and 9 inches wide; seven sleepers, five in the middle and two at the edge of the platform, are 15 feet long, and extend from one end to the other; the remaining two are 7 feet 9 inches long, and support only the rear plank. The sleepers rest on the heads of fifty-eight pickets 2 inches in diameter and 3 feet long, driven into the earth. Two cross-pieces are placed under the front ends and middle of the seven long sleepers; that under the middle supports the front ends of the short sleepers, also the traverse-circle and the rear end of the carriage.

For transporting the mortar and its carriage an axle has been fitted to the latter for two wheels, and a movable trail intended to hitch on to the siege-limber is used. The axle is held in the boxes cut in the front edge of the cheeks by means of cap-squares and bolts. The movable trail is represented in the drawing, with its lunette, its friction-plate, and lashing-ring. It is put in place by unscrewing the two rear bolts of the carriage, bringing the trail in position, replacing the bolts, and securing them by the nuts. The mortar being in battery, to put it in traveling position it is run back to the rear of the platform; the axle and trail are put in place. The front of the carriage is raised by means of a jack put under the middle of the axle, blocking up with blocks till it is high enough. The rear end of the carriage is raised with two jacks, or by means of a lever-bar passed under the carriage crosswise. The wheels are put on and the limber hooked. A seat for the driver is placed on the forward end of the trail, in front of the pintle; in the box under this seat the handles of the elevating-screw are carried; they have to be removed to admit the wheels being put on. The axle is provided with a bucket-hook. The siege-limber is arranged so as to be drawn by ten horses.



In rear of the fixed splinter-bar, with its two swingle-trees, a longer splinter-bar is made fast, and provided with two swingle-trees. The pole has a movable double-tree at its end with three swingle-trees: the front horses are hitched to the traces of the three middle ones. Two lock-shoes for the rear wheels are carried on the body of the limber. The directrices of the mortar carriages are carried by themselves in siege-wagons; four can be carried in one wagon, with great ease.

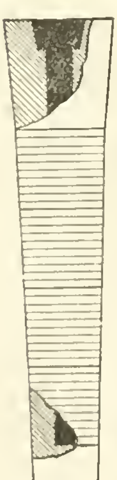
The following are the principal weights and dimensions:

	Pounds.
Weight of the carriage with mortar and limber	8,893
Weight of the mortar	3,461
Weight of the carriage without trail, axle or wheels	2,692
Weight of the trail and seat	3,373
Weight of the axle with two wheels	1,030
Weight of the siege-limber	1,373
Number of horses to draw the carriage	10
Whole length of the carriage to the end of the pole	23 feet.
Width of the carriage	76 inches.
Diameter of the front wheels	56 inches.
Diameter of the rear wheels	62½ inches.

See *Gun-carriages* and *Siege-mortar*.

MORTAR CASEMATES.—These are usually placed in rear of the parapet, by which it is covered from direct fire. The arch is covered by earth, to break the shock of shells. It rises towards the front to give ample room for the shell in its flight. The casemates are covered on their flanks from enfilading fire by an embankment, and are partly closed by a wall in the rear. A small ditch is made in front of the chamber, and a slight wall built within it, to give cover from the splinters of shells falling between the parapet and the casemate. Arched chambers are in some cases made beneath the mortar chambers which serve as store-rooms and temporary magazines. When these casemates are placed in rear of a portion of the parapet but little exposed to direct fire, the thickness of the parapet in front of them may be reduced, and the interior slope be replaced by a breast-height wall along the front of the casemates, in order to give better cover in flank and from slant fire, by throwing forward the casemates more under cover of the parapet. See *Casemates*.

MORTAR FUSE.—The mortar-fuse now used is a paper-case time-fuse, similar in general appearance to the ordinary paper-case fuse, of long time of burning. They are made up in packages and marked with the kind and length of fuse. For any shorter time the fuse is cut with a sharp knife or fine saw. With this fuse is used a wooden fuse-plug, having a conical opening, which is reamed out to fit the paper case. When the shell is loaded, and the fuse cut to the required length, it is pressed in the plug and the plug firmly set in the fuse-hole. The head of the fuse having been covered with tow or something to prevent breaking the composition, the fuse-setter is placed on the plug, and it is driven with the mallet until the head is about ¼ of an inch above the surface of the shell.



The old form of mortar-fuse consists of a case made of beech-wood, turned in a lathe to a conical shape, and bored out nearly to the bottom to receive the composition. The composition is driven with fifteen blows of the mallet. The bore is enlarged at the top to receive a priming of mealed powder moistened with alcohol. To protect priming from moisture, the top of the fuse is covered with a cap of water-proof paper, on which is marked the rate of burning of the composition. The exterior is divided into inches and tenths, to guide the gunner in regulating the time of burning. This operation is generally performed before the fuse is driven into the fuse-hole of the shell, by cutting it off with a saw, or boring into the composition with a gimlet. If the fuse be driven, the column of composition may be shortened by taking a portion from the top with the fuse-auger.

The great disadvantage of this fuse is its irregularity, it being very difficult to press such a large column of composition so that equal lengths will burn in equal times. See *Fuse* and *Time-fuse*.

MORTAR PLATFORM.—A platform similar to that used with siege guns, but of smaller dimensions and without a slope. See *Platform*.

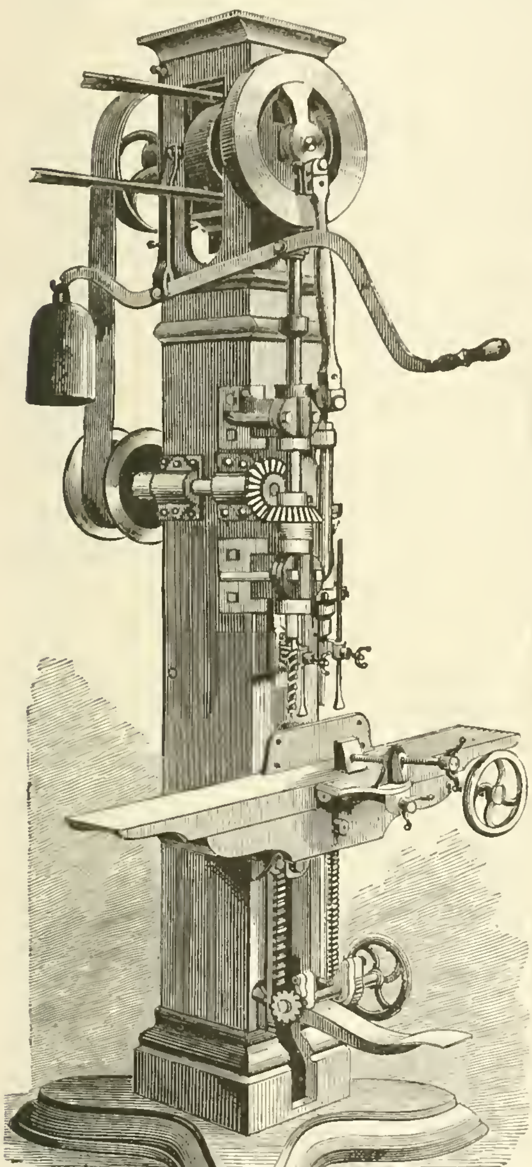
MORTAR SCRAPER.—A slender piece of iron with a spoon at one end and a scraper at the other, used for cleaning the chambers of mortars.

MORTAR SHELL.—A hollow projectile of dimensions to fit the pieces shown under the head of Mortar. Mortar shells are issued loose, but are filled with a charge of bursting-powder at the time they are required. They are fired from mortars at high angles; the larger natures, with the object of setting fire to buildings, ships, or other combustible constructions (and in the attack of a place they would be especially directed on the gunpowder magazines); the smaller natures, to annoy or drive out troops behind parapets or any particular cover.

MORTAR VESSEL.—A class of gun-boat for mounting sea-service mortars, and in some cases provided with steam-power. The mortars are usually of the largest caliber—13 inch. To enable the mortar to be properly maneuvered, and to resist the recoil from the nearly perpendicular explosion of so great a piece of ordnance, the vessel has considerable breadth in proportion to her length. The mortar is slung amidships in a massive bed. The ancient form of mortar-vessel was the "bomb-ketch," convenient because of the length of deck without a mast. The present vessels originated during the Russian war, and were found serviceable at the bombardment of Sveaborg.

MORTAR WAGON.—A wagon used for the transportation of siege mortars, siege guns, and heavy projectiles. The limber and wheels are the same as those for the siege-gun carriage. The body consists of a platform of rails and transoms, resting on the rear axle-tree, the two middle rails being prolonged to the front to form the stock. The side rails are prolonged to the rear, and furnish supports for the roller of a windlass; which is used for loading the wagon, the guns, mortars, etc., being drawn up the stock, which rests on the ground, forming an inclined plane. Each end of the roller is provided with pawl and ratchet, operated by a handspike, fitting into a socket after the manner of the windlass of a gin. Over good and firm roads, the mortar-wagon is capable of carrying the 100-pounder Parrott, or any other piece not exceeding in weight 10,000 pounds.

MORTISING-MACHINE. A machine much used in arsenals in the construction of gun-carriages, etc. The self-acting mortising-machine was invented by General Bentham, and described in his specification of 1793. He made them for the British Admiralty previous to 1800. His description includes the operation by means of a hole previously bored and then elongated by a vertically reciprocating chisel; and also the making of a mortise by a rotary cutter during the traveling of the work. One form included a pivoted table. Brunel's mortising-machine, made by Maudslay for the British Admiralty, about 1804, with improvements, is employed at this time for mortising the shells of blocks. The drawing shows the C. B. Rogers medium-power mortising-machine, as employed in most of the arsenals of construction. This machine is provided with boring apparatus and is especially adapted for ordinary work in hard wood and the heavier classes of building. The chisel has a rapid perpendicular motion, and is brought down to the work by the treadle, and carried up by the balance-weight on back end of treadle. It is self-reversing, turning the chisel when the treadle is let up, at each end of the mortise. The bed can be set at any angle required. The machine has the boring apparatus, which is set on the same line with the chisel, so that the work can be bored and then run under the chisel and mortised without unclamping it from the bed. The bit-shaft is run by a belt from the chisel-shaft, and so arranged, that



when the chisel is working the bit stops, and, as the chisel is let up by the treadle, the bit starts, ready for boring. The driving pulley is 10 inch diameter. 3 inch face, and should make 300 revolutions per minute. The machine may be driven from a main line, if it is level with the pulley in top of machine. If not, a counter will be needed, to set on a level with the pulley, and 8 or 10 feet distant. The weight of the machine is 1,450 pounds. See *Double Boring and Mortising-machine*, and *Hub Mortising-machine*.

MOSS TROOPERS. Marauders; free-booters; plunderers. They were confined to the districts which divided the Scotch and English territories before the Union. They were banded together in clans, and lived by rapine, and received this denomination from the character of the country over which they traveled in their adventurous mode of life. In Fuller's *Worthies of England* it is stated that, at one time, they numbered several thousands, and that their great enemies were "The laws of the land and the Lord William Naworth," who finally reduced them to legal obedience. Scott mentions them in *The Lay of the Last Minstrel*.

MOTHIR AL MOOLK.—In the East Indies, a term applied to fortifications, barricades, intrenchments, or breast works.

MOTION. 1. A division of a movement in the manual of arms to facilitate the instruction of recruits. 2. The laws of motion are the fundamental principles connecting force and motion in the physical universe; and are obviously to be derived from *experiment* alone, since intuitive reasoning cannot possibly give us any information as to what may or may not be a law of nature. Though these laws are derived from experiment, it cannot be said that we have any very *direct* experimental proofs of their truth—our most satisfactory verifications of them are derived from the exact accordance of the results of calculation with those of observation in the case of such gigantic combinations of mutually influencing bodies as that of the solar system; and it is by such proofs that they must be considered to have been finally established. They seem first to have been given systematically and completely by Newton, at the opening of the *Principia;* but the first two were known to Galileo, and some of the many forms of a *part* of the third were known to Hooke, Huyghens, Wren, and others. We shall give them here in order, with a few brief comments, showing their *necessity* and their *use* First, then, we naturally inquire, what matter would do if left to itself; and, by considering cases in which less and less external force is applied to a body, we are led to the statement called the *first law of motion*.

1. *Every body continues in its state of rest or of uniform motion in a straight line, except in so far as it may be compelled by impressed forces to change that state.* This expresses simply the *inertia* of matter—i. e., a body cannot alter its *state* of rest or motion; for any such alteration external *force* is required. Hence the definition of force as that which changes or tends to change a body's state of rest or motion. Now, how does the change of state depend on the force which produces it? This is obviously a new question, to be resolved by experiment; and the answer is the *second law of motion:*

2. *Change of motion is proportional to the impressed force, and takes place in the direction of the straight line in which the force acts.* Newton's silence is as expressive as his speech. Nothing is here said about the previous motion of the body, or about the number of forces which may be at work simultaneously. Hence, a force produces its full effect in the form of change of motion, whether it act singularly, or be associated with others; and whatever, moreover, be the original motion of the body to which it is applied. Hence, there is no such thing as equilibrium of *forces;* every force produces motion—and what we call equilibrium is *not* the balancing of forces, but the balancing of their *effects*. Hence, the absurdity of attempting to found the science of Statics on any other basis than is to be derived from the second law of motion; which, in fact, leads us at once (by the *parallelogram of velocities*, which is a purely geometrical conception) to the *parallelogram of forces*, and thence, with the help of the third law, to the whole subject of Statics. The second law also supplies the means of measuring *force* and *mass;* and of solving any prob-

lem whatever concerning the motion of *one* particle. But more is required before we can study the motion of a *system* of particles—as a rigid body, or a liquid, for instance; or a system of connected bodies. Here there are mutual actions and reactions of the nature of pressure or of transference of *energy* between the parts—and these are regulated by the *third law of motion.*

3. *To every motion there is always an equal and contrary reaction; or, the mutual actions of any two bodies are always equal and oppositely directed in the same straight line.* Thus, the mutual pressure between two bodies has equal, but *opposite,* values for the two. The tension of a rope is the same throughout, and tends as much to pull *back* the horse at one end as to pull *forward* the canal-boat at the other. The earth exerts as much attractive force on the sun as the sun exerts on the earth—and the same law applies to the other attractive and repulsive forces, as those of electricity and magnetism. But Newton goes much further than this: he shows, in fact, that action and reaction (subject to the third law) may consist in *work done by a force,* instead of the mere force or pressure itself. From this form of the third law we derive at once the principle of virtual velocities, which in its application to machines is familiar as "*What is gained in power is lost in speed.*" But we also derive the grand principle of the indestructibility of work or energy; at all events in the case of the ordinary mechanical forces—and this must be regarded as one of the grandest discoveries which Science owes to Newton. It is trne that he merely *mentions* it, and then abruptly passes to another subject; yet we can hardly exaggerate the value of this single remark. Experimenters, mainly Davy and Joule, have since shown that all the physical energies, as heat, light, electricity, etc., are subject in their transformations to the third law of motion, and thus the system constructed by Newton for ordinary dynamical purposes, is now found to rnle the most mysterious of the affections of matter. See *Force*, and *Mutipliers.*

MOTON.—In ancient armor, a small plate covering the armpits of a knight, used when plate armor was worn.

MOTTLED CAST-IRON.—A mixture of the white and the gray varieties in varying proportions, the gray iron sometimes appearing in specks, like minute flowers upon a white ground; whilst in other specimens the mass is composed of gray iron, and the white iron appears in spots. Fine gray mottled iron from its great tenacity is known to be the best fitted for large castings where great strength is required, and is employed for gun-founding. It may be made by mixing white and gray iron, or by continuing gray iron in fusion for some time, until it gets the proper color. The kind of mottle will depend much upon the size of the castings. See *Cast-iron.*

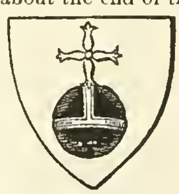
MOTTO.—In Heraldry, a word or short sentence which forms an accompaniment to a coat-of-arms, crest, or household badge. Mottoes were originally attached to the badge when the family had one, or to the crest where there was no badge. In later Heraldry, the practice is to place the motto in an escrol either over the crest or below the shield. A motto is sometimes a religious or moral sentiment, as "Gardez la foi," "Humanitate;" it is not unfrequently a heroic exclamation or war-cry, "Courage sans peur," "Forward." In a great many cases it bears reference to the crest, badge, or some bearing of the escutcheon; thus, Stuart, Earl of Moray, has for crest a pelican wounding herself, and for motto, "Salus per Christum Redemptorem;" and not a few mottoes are punning allusions to the family name—as Scudamore. "Scuto amoris Divini;" Vernon, "Ver non semper viret;" "Fare, fac," for Fairfax; and "Time Deum, cole regem," for Coleridge. Two mottoes are sometimes used by the same family—one above the crest, the other below the shield. The motto, "Dieu et mon Droit," which accompanies the royal arms of Great Britain, is supposed to have been a war-cry, and was used in England at least as early as the time of Henry VI. Its origin has been assigned to a saying of Richard I., "Not we, but God and our right have vanquished France."

MOULINETS.—1. Circular swings of the sword or saber, performed as follows: *Left Moulinet.* Being at guard, extend the arm obliquely to the left and front to its full length, the hand in tierce and as high as the eyes, the point of the saber to the front, and a little higher than the hilt. (Two). Lower the blade, edge to the front, and make rapidly a circle around the hand, to the left of and near the horse's neck, the blade passing close to the left elbow; return to the first position. (Three). Resume the guard.

Right Moulinet. Being at guard, extend the arm to the front to its full length, the hand in quarte, and as high as the eyes, the point to the front, and a little higher than the hilt. (Two). Lower the blade, edge to the front, make rapidly a circle around the hand, to the right of and near the horse's neck, the blade passing close to the right elbow; return to the first position. (Three). Resume the guard.

Rear Moulinet. Being at guard, raise the arm to the right and rear to its full extent, the point of the saber upward, the edge to the right, the body slightly turned to the right. (Two.) Begin by moving the point of the saber toward the left, and describe a circle in rear. (Three.) Resume the guard. In executing the moulinets, the right arm is kept as steady as possible in position, the saber being controlled by motions of the wrist and hand. See *Saber Exercise.*

2. Mechanical appliances employed to draw up the cords of the cross-bows, while the bows were held down by the feet. They were in common use about the end of the 13th century.



Mound.

MOUND.—A bulwark for offense or defense. 2. In Heraldry, a representation of a globe, surmounted with a cross (generally) pattée. As a device, it is said to have been used by the Emperor Justinian, and to have been intended to represent the ascendancy of Christianity over the world. The royal crown of England is surmounted by a mound, which first appears on the seal of William the Conqueror, though the globe without the cross was used earlier.

MOUNT.—The means or opportunity for mounting, especially a horse: and the equipments essential to a mounted horseman. 2. To place one's self on, as a horse, or anything that one bestrides or sits upon. Hence, to put on horseback; to furnish with animals for riding. 3. To put anything that sustains and fits, for use; as, to mount a gun on its carriage, to prepare for being worn or otherwise used; as, a sword-blade by adding the hilt and scabbard. A ship or a fort is said to *mount* cannon when they are arranged for use in and about it. 4. A term in Heraldry. When the lower part of the shield is occupied with a representation of ground slightly raised, and covered with grass, this is called a mount in base; e. g., argent, on a mount in base, a grove of trees ppr.—Walkinshaw, of that ilk, Scotland. 5. A word of command in cavalry exercise for the men to mount their horses. It is executed as follows: The men standing to horse, the Instructor commands: Prepare to mount, whereupon the odd numbers lead out. All the men then face to the right, dropping the right rein from the hand, take two side steps to the right, sliding the hand along the left rein, make

Mount.

a half face to the left so as to bring the right side toward the horse's flank; carry the right foot three inches to the rear; take the reins with the right hand aided by the left, and place the right hand on the pommel, the reins coming into the hand between the thumb and fore-finger, and held so as to feel lightly the horse's mouth. (Two.) Each recruit places a third of the left foot in the stirrup, with the assistance of the left hand if necessary, and supports it against the forearm of the horse; rests upon the ball of the right foot; places the left hand on top of the neck, well forward, and grasps a lock of the mane, the lock coming out between the thumb and fore-finger. The Instructor then commands: 2. MOUNT. At this command, spring from the right foot, holding firmly to the mane, and keeping the right hand on the pommel; bring the heels together, the knees straightened and resting against the saddle, the body erect. (Two.) Pass the right leg extended over the croup of the horse without touching him; let the body come gently down into the saddle; let go the mane, insert the right foot in the stirrup, pass the reins into the left hand and adjust them. At the commands, 3. *Form*, 4. RANK, the even numbers move up upon reaching the saddle, a position should be assumed with the buttocks bearing equally upon the saddle, and as far forward as possible; the reins coming into the left hand on the side of the little finger, and leaving it between the thumb and fore-finger; the little finger between the reins, the other fingers closed, the thumb pressing the reins firmly on the second joint of the fore-finger; the left fore-arm horizontal, the fingers six inches from the body and turned toward it; the little finger a little nearer the body than the upper part of the hand; the right hand behind the thigh, the arm falling naturally, the feet inserted one-third of their length in the stirrups, the heels slightly lower than the toes.

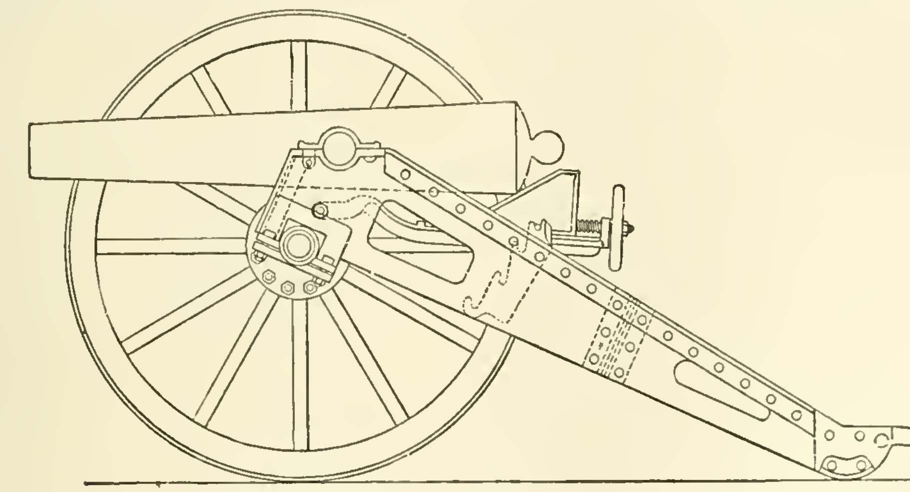
MOUNTAIN ARTILLERY.—Mountain artillery is designed to operate in a country destitute of carriage-roads, and inaccessible to field artillery. It must, therefore, be light enough to be carried on pack-animals. The piece used for mountain service in the United States is a short, light 12-pdr. howitzer, weighing 220 lbs. The form of the chamber is cylindrical, and suited to a charge of ½ lb. of powder. The projectiles are shells and case-shot. It is discharged from a low, two-wheel carriage, which serves for transportation whenever the ground will permit. When the piece is packed, the carriage is packed on a separate animal The mountain howitzer is also employed for prairie service, and in defending camps and frontier forts against Indians, in which case it is mounted on a light, four-wheel carriage, called "the prairie carriage." In the Mexican war, the mountain howitzer was found useful, from the facility with which it could be carried up steep ascents, and to the tops of flat-roofed houses, in street-fighting. See *Field Artillery*.

MOUNTAIN ARTILLERY CARRIAGE.—The carriage for the mountain-rifle is similar in material and general construction to that of the field-gun, and combines strength, simplicity, and lightness. The axle is without an axle-body, and the wheels have metal naves.

The mountain-howitzer carriage should be light enough to be carried on the back of a pack animal, and the axle-tree should be short enough to permit it to pass through very narrow defiles. It differs in construction from the field-carriage, inasmuch as the stock and cheeks are formed of the same piece, by hollowing out the head of the stock. The wheels are thirty-eight inches in diameter, and the axle-tree is made of wood, the arms being protected from wear by *skeans*, or strips of iron. The distance between the wheels is about equal to their diameter. It is arranged for draught by attaching a pair of shafts to the trail. The pack-saddle and its harness are constructed to carry severally, the howitzer and shaft, the carriage, or two ammunition chests, or it enables an animal to draw the carriage, with the howitzer mounted upon it. A portable forge accompanies each mountain battery, and is so constructed that it can be enclosed in two chests, and carried, with a bag of coal, upon the pack-saddle.

The Russian carriage has very short cheeks, the front ends of which are cut off obliquely instead of vertically; the trunnion-beds are let into this oblique face, and the trunnions are held by cap-squares and keys. Krupp makes two sizes of carriages for the 8-centimeter and 6-centimeter guns, respectively. The elevating-screw admits of 18° of elevation and 10° depression. The ammunition-chests are made of wood, with iron angle-pieces.

The English have two carriages, as shown in the drawing, for the two 7-pounder guns, one of which weighs 150 pounds when made of steel, and 200 pounds if made of brass; the other weighs 200 pounds when made of steel, and 224 if made of bronze. The wheels are 30 inches and 36 inches in diameter, respectively, and have a track of 27 inches. The elevating apparatus consists of a movable bed, which hooks on a cross-bar between the cheeks over the axle, and has two studs, one on each side, to rest in racks riveted to the inside of the trail-pieces. A sliding-quoin rests on the bed, and is worked by a screw which passes through a collar in the end of the bed and enters a nut in the quoin. A light iron limber is made for the heavier carriage, and carries two ammunition-chests, which contain ten rounds of ammunition each.



In transportation the gun is carried in Russia and

Germany over the horse's spine, the breech in front, this being deemed the more favorable position for passing narrow passes and the roads through which mountain artillery has frequently to make its way. The objection to having any part of the load cross-ways has induced the Russians to detach the axles for transportation, believing that the delays which may occur on the march from the axle-arms interfering with a free passage through woods, etc., would be greater than would result from having to adjust the axle to the carriage when it was required to commence firing. The carriage pack-saddle is provided with a rear pad to protect the animal's rump from blows from the end of the trail.

The following are the principal weights and dimensions of Krupps carriages :—

	8-centimeter,	6-centimeter.
Weight of carriage with wheels.	322 pounds.	178½ pounds.
Weight of gun with wedge.....	227 pounds.	198 pounds.
Weight of ammunition-chest, packed.................... ..	103.6 pounds.	105½ pounds.
Number of rounds in each chest.	8	16
Weight of pack-saddle.........	46¼ pounds.	46¼ pounds.
Weight of powder-charge......	14 ounces.	7 ounces.
Weight of shell, loaded..	8 lbs. 13 oz.	4 lbs. 6½ oz.
Initial velocity of shell........	952 feet	919 feet.

The following are the principal weights of the English carriages :—

	Pounds.
Weight of light carriage without wheels....................	161
Weight of light carriage with wheels........................	287
Weight of heavier carriage without wheels.........	192
Weight of heavier carriage with wheels.....................	328
Weight of limber.........	333

MOUNTAINOUS SITES.—The crests and gorges are the most important military features of a prominently marked mountainous position. It is through the latter that the roads are made, and the former, from their elevation, command the latter. The crests should therefore never be abandoned to the enemy, although from their position, or distance, they may not directly overlook the gorges; for, independently of the real advantage of position, which the enemy would thus acquire, he would possess a relative advantage in the moral effect produced on troops when they find themselves in a commanded position. If the base of the mountain does not stretch out too far from the summit to admit of a sure retreat on the latter, works may be thrown up for the defense of the base, with intermediate works between the base and the summit placed on the secondary ridges, or other commanding points. But if the distance between the summit and the base is great, and particularly if it is decided beforehand to retreat upon the summits, in case of disaster, then the base should be disregarded.

The works thrown up for the defense of the summit should be laid out on the brow of the height, for the purpose of overlooking and guarding its sides. As has already been stated, the plan and relief of the defenses will be subordinated to the features of the ground. Where the surface along the crests is undulating, presenting salient and re-entering parts, consisting of spurs and ravines more or less prominent, the salient points should be occupied by works with a good relief, and otherwise strengthened by passive obstructions to the assailant's advance, as from their position a broad flanking sweep of the surface for artillery can be obtained for the defense of the approaches upon the collateral salients. The re-entering portions may be occupied with defenses of a weaker profile, as their position is stronger and it is from them that a strong fire of musketry and of the lighter field guns can be brought to bear upon the ground directly in front of the salients adjacent to them. The cremaillère line and the redan line with long curtains broken forward, so as to form a tenailled combination with alternate long and short branches, both lend themselves better than most other combinations to a configuration of ground of this description.

Very steep slopes will not admit of a defense with artillery, because the gun cannot be fired under a much greater depression than one-sixth, and unless the shot take effect the enemy will be inspirited to advance, confiding in the safety of his position. In slopes of this character the works may consist simply of a parapet, in the form of a glacis, without any ditch, the earth for the parapet being taken from an interior trench; in some cases a dry stone wall may be substituted for an earthen parapet. An abattis may be formed in front of the parapet within close musket range; and heavy round logs, or large masses of rock, be arranged along the parapet, ready to be rolled over on the enemy should he break through the abattis. Steep escarpments of rock are generally considered as inaccessible; but those points should never be left to their own strength. It is always prudent to post a small detachment to frustrate an attempt of the enemy to surprise them. A steep natural slope maybe made inaccessible by cutting away the face of the eminence.

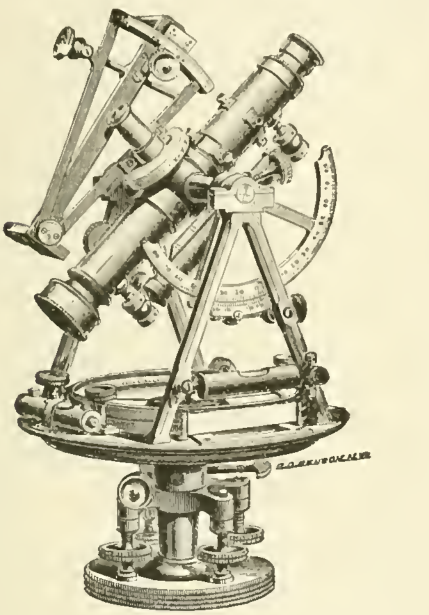
It may, in some cases, be indispensably necessary to guard certain points at the base of a mountain, as, for example, where the base is washed by a river, over which there is an important ferry. Under such circumstances the point to be guarded should be most thoroughly protected by some strong work; moreover, a number of posts, placed at intervals on the most commanding points between the summit and the base, should connect the two. These posts should, when practicable, be placed in defensive relations, and in all cases their fire should sweep all the ground between the two principal points. The interior of the posts most advanced should be exposed to the fire of those in their rear, in order that the enemy may be driven out, should he succeed in forcing his way into any one. As these posts will require a considerable detachment for their defense, care should be taken not to multiply their number unnecessarily, and never at the expense of the main defense. All communications, leading through the mountains, should be carefully guarded, both at their outlets and at the most suitable intermediate points for defense; otherwise the most respectable positions will be liable to be turned by the enemy. If the communications are not of use to the assailed, they must be barred by a line of abattis, or by an artificial inundation, etc.; and they should be watched by a detachment of light troops, whose retreat on the main works should be secured in case of an attack by superior forces. If the communications are of use to the assailed they should be defended by intrenchments, which should command and enfilade them in the most effectual manner.

MOUNTAIN TRANSIT.—This instrument is a modification of the Engineer's Transit, made for mountain and mine surveys, but applicable as well to all the other work of the Engineer. It is made exceedingly light and portable, its needle being 4 inches long; and its telescope 8 inches long, having a power of 20 diameters. Its sockets with the leveling head, remain attached to the instrument; and its compass circle is movable about its center, so as to lay off the variation of the needle. In this instrument the limb is divided on solid silver to half degrees, with verniers reading to single minutes: sometimes the limb is divided to twenty minutes with verniers reading to half minutes. There are also cylindrical caps above the leveling screws to exclude the dust, etc. The drawing shows one of the celluloid reflectors, which are placed over the two opposite verniers of the limb, and are of service especially in the surveys of mines, to throw light upon the divisions below.

Like the Engineer's Transit, this instrument is sometimes used with a plain telescope; but oftener with one or more of the extras, as level, clamp and tangent, and vertical circle. More frequently, however, the Mountain Transit is furnished as shown, with vertical arc, level, clamp and tangent, and the solar attachment,' which is essentially the solar apparatus of Burt placed upon the cross-bar of the ordinary transit, the polar axis being directed above instead of below, as is the case in the solar compass. A little circular disk of about an inch and a half diameter, and having a very short, round pivot, projecting above its upper surface, is first securely screwed to the telescope axis. Upon this pivot rests the enlarged base of the polar axis, which is also firmly connected with the disk by four capstan-head screws passing from the under side of the disk into the base already named. These screws serve to adjust the polar axis.

The hour circle surrounding the base of the polar axis is easily movable about it, and can be fastened at any point desired by two flat-head screws above. It is divided to five minutes of time; is figured from I. to XII., and is read by a small index fixed to the declination arc, and moving with it. A hollow cone, or socket, fitting closely to the polar axis and made to move snugly upon it, or clamped at any point desired by a milled-head screw on top, furnishes by its two expanded arms below, a firm support for the declination arc, which is securely fastened to it by two large screws, as shown.

The declination arc is of about five inches radius, is divided to quarter degrees, and reads by its vernier to single minutes of arc, the divisions of both vernier and limb being in the same plane. The declination arm has the usual lenses and silver plates



on the two opposite blocks, made precisely like those of the ordinary solar compass, but its vernier is outside the block, and more easily read. The declination arm has also a clamp and tangent movement, as shown in the drawing. The arc of the declination limb is turned on its axis and one or the other solar lens used, as the sun is north or south of the equator; the drawing shows its position when it is north. The latitude is set off by means of a large vertical limb having a radius of two and a half inches; the arc is divided to thirty minutes, is figured from the center, each way, in two rows, viz., from 0 to 80°, and from 90° to 10°, the first series being intended for reading vertical angles; the last series for setting off the latitude, and is read by its vernier to single minutes. When desired, an arc of three inches radius is prepared reading by its vernier to half minutes of a degree. It has also a clamp-screw inserted near its center, by which it can be set fast to the telescope axis in any desired position. The vernier of the vertical limb is made movable by the tangent-screw attached, so that its zero and that of the limb are readily made to coincide when, in adjusting the limb to the level of the telescope, the arc is clamped to the axis. The usual tangent movement to the telescope axis serves, of course, to bring the vertical limb to the proper elevation. A level on the under side of the telescope, with ground vial and scale, is indispensable in the use of the solar attachment. The divided arcs, verniers, and hour circle are all on silver plate, and are thus easily read and preserved from tarnishing.

To determine latitude, first level the instrument very carefully, using, as before, the level of the telescope until the bubble will remain in the center during a complete revolution of the instrument, the tangent movement of the telescope being used in connection with the leveling screws of the parallel plates, and the axis of the telescope firmly clamped. Next clamp the vertical arc, so that its zero and that of its vernier coincide as near as may be, and then bring them into exact line by the tangent-screw of the vernier. Then, having the declination of the sun for 12 o'clock of the given day as affected by the meridional refraction carefully set off upon the declination arc, note also the equation of time and fifteen or twenty minutes before noon, the telescope being directed to the north, and the object-end lowered until, by moving the instrument upon its spindle and the declination arc from side to side, the sun's image is brought nearly into position between the equatorial lines. Now bring the declination arc directly in line with the telescope, clamp the axis firmly, and with the tangent-screw bring the image precisely between the lines and keep it there with the tangent-screw, raising it just as long as it will run below the lower equatorial line, or in other words, as long as the sun continues to rise in the heavens. When the sun reaches the meridian the image will remain stationary for an instant, and then begin to rise on the plate. The moment the image ceases to run below is of course apparent noon, when the index of the hour arc should indicate XII, and the latitude be determined by the reading of the vertical arc. It must be remembered, however, that the angle through which the polar axis has moved in the operation just described is measured from the zenith instead of the horizon as in the ordinary solar, so that the angle read on the vertical limb is the complement of the latitude.

The Mountain Transit is usually placed upon an extension tripod, in which all the legs can be shortened or lengthened at will. It is thus adapted for use in mountain surveys, where one or more legs must be shortened; or for mines, where in many places a short tripod is indispensable. If desired, the sliding pieces can be easily turned end for end, the points being thus put out of the way, and the tripod more safely transported. The tripod when closed is only three feet long, and is carried by an ordinary shawl-strap. The weight of this instrument, as made by the Messrs. Gurley, United States, with plain telescope is 8½ pounds; with the solar attachment, arc, level, and clamp, 9½ pounds. The extension tripod weighs about 8 pounds. See *Engineer's Transit*.

MOUNTAIN WARFARE.—In warfare, mountains offer a considerable obstacle to an invading army, and, if properly defended, may either stay the advance of an enemy or prevent ingress into the country. The difficulty to be overcome will be still greater if there be other obstacles, such as rivers and a succession of mountain ranges. In such warfare the invading General should use every precaution in examining each step of the way, and gleaning all information in his power from maps, guides, and reconnoissances. Further, he should be careful that he does not fall into a trap, which the enemy may lay for him in feigning retreat, when he is endeavoring to outflank him and get in his rear, thus rendering the position of the invader very precarious. It should therefore be laid down as a maxim that, in mountain operations, especially, the flanks and rear of the invading army must be secured, to prevent being surrounded. One of the great difficulties in this nature of warfare is keeping the communication open with the rear, and bringing up food for the army, as mountain ranges, passes, etc., do not afford facility for using wheeled carriages; and the transport, therefore, resolves itself into men and pack animals. Such transport forms but a slow and precarious means of carrying forward supplies, if not well guarded. History affords examples of the difficulty of mountain warfare in transporting the *matériel* of war; thus, for instance, that of Napoleon, the First Consul, whilst effecting the passage of the Alps, with the French army, in that part called the Great and the Little St. Bernard. The carriage of his artillery and stores was a source of great anxiety and difficulty. The exertion of a whole battalion was requisite for the conveyance of one field-piece, with its proportion of ammunition; one-half of the regiment could only draw the load, while the other half was obliged to carry the knapsacks, firelocks, camp kettles, and five days' rations.

MOUNTED PAY.—A grade of pay allowed mounted officers, or to other officers serving under conditions which entitle them to the same pay. The following officers, in addition to those whose pay is fixed by law, are entitled to pay as mounted officers: officers of the Staff Corps below the rank of Major, officers of troops of cavalry, officers of one light battery for each regiment of artillery, officers announced in orders from the Adjutant General's Office as Acting Signal Officers, and authorized Aides-de-Camp duly appointed as such. Other light batteries of artillery which may be designated by the President, and equipped as such, will each have the organization of a light battery, except the additional 2d Lieutenant and the officers thereof actually serving with the light batteries will be mounted. Officers actually serving with companies of infantry mounted by authority of the War Department, and not in excess of the legal organization of infantry, are mounted while so serving. A company of infantry mounted retains the same organization as on foot. Other officers on duty which, in the opinion of the Department Commander, requires them to be mounted, are entitled to be so considered, on the certificate of their Department Commanders that they have been on duty in the service of the United States which required them to be mounted during the time. See *Pay*.

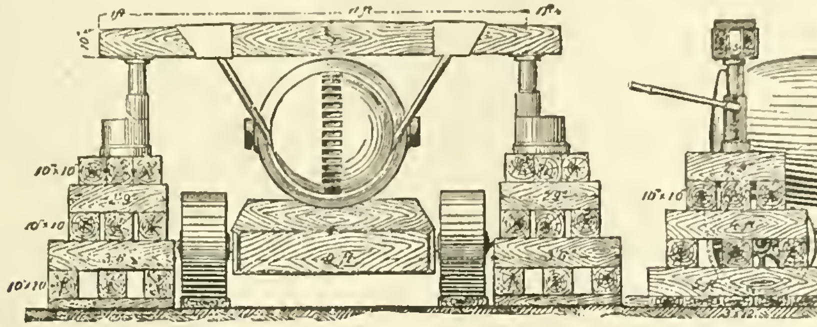
MOUNTED RIFLEMEN.—Mounted infantry, the designation of riflemen being given to them from the arm they were equipped with. Mounted riflemen are soldiers trained to act as foot and cavalry soldiers. This arm is but little known at the present time in the British service, but since the war of 1870–71, which has confirmed the opinion held by many soldiers, that mounted riflemen are now essential to every enterprising army, the subject of reintroducing it in the army has been often discussed. The first mention in military history of mounted riflemen is that of the dragoons created by Maréchal de Brissac in 1600. They were foot soldiers mounted on horses, who on emergencies carried a comrade *en croupe*. The first official record of such troops in the British service dates from a royal warrant of 1672, which regulates the matchlock as one of the arms. The Scots Greys, who were raised in 1683, carried also fire-arms, as well as the British dragoons of the seventeenth century; both were instructed to act as infantry on horses, to enable them to make more rapid movements. Dragoons, acting as such, were eventually changed into cavalry; and the last corps bearing the name of mounted riflemen was that at the Cape, which was disbanded a few years ago. This nature of mounted infantry has been reintroduced in the volunteer forces of the country, there being four small bodies of mounted riflemen. Mounted riflemen were considerably used and appreciated by Napoleon I. and his Generals. Jomini writes on the subject as follows: "It is certainly an advantage to have several battalions of mounted infantry, who can anticipate an enemy at a defile, defend it in retreat, or scour a wood." Sir G. Wolseley, in writing on the subject of outposts, gives it as his opinion that, whenever mounted infantry is introduced into the service, and its employment properly understood, these outpost duties will devolve to a very considerable extent on it. Such men are invaluable in covering retreats; to seize, destroy, and hold bridges; for works of destruction, such as removing rails and telegraphs, etc. For these duties they were frequently employed in the American and the last Continental wars, most foreign armies having adhered to that system. Colonel Hamley says, in his "Operations of War," second edition: "As cavalry alone could effect nothing in an intersected country, or against a body of mixed troops, or a force sheltered by obstacles, it is indispensable that the troops thus employed, while mounted for the sake of celerity, should be able to meet infantry on good terms. Their chief action must therefore be as infantry, the horses of the dismounted men being held by their comrades. . . . Mounted infantry is altogether a different thing from dismounted cavalry, and the two kinds of force should be kept carefully distinct. All experience has shown that cavalry who are habituated to rely on their fire-arms are apt to lose their distinctive characteristics of promptitude, impulsion, and resolution in attack; and it would be impossible, by any amount of training, to combine such opposite functions in the same troops. By establishing mounted riflemen as a separate arm of the service, men and horses of a size which, though admirably suited for rapid and sustained movements, is deficient in the power and weight that tell so formidably in the charge, might be turned to excellent account." Colonel Hamley further states that on this kind of troops might properly devolve the business of reconnoitring or heading the advanced guards, of seizing defiles, etc. On the other hand, the regular cavalry, spared in great measure the harassing duties which fritter away its strength, would be preserved intact for the day of battle. In a country like India, infantry can be mounted on camels, and has been so utilized when it was desirable to send troops on a forced march to take a place by surprise, or to scatter a collecting force. Each camel carries two men. It would be necessary on such service to dismount; and rest the men during the journey. But except for the expense there is no reason why there should not be a permanent Corps.

MOUNTING CANNON.—If the platform is much above the general level of the ground, as in casemated batteries and on ramparts, the cannon have to be raised by strong *derricks* to the level of the platform, or they may be drawn up ramps of earth or of scaffolding.

1st. The chassis being on the platform, the top carriage not in position.

There will be required to mount the gun one or two *hydraulic* or two or three *screw jacks*, depending on their power, and *blocks* of different lengths and widths, varying in thickness from one to twelve in., also a few skids and chocks. The gun is brought parallel and near the chassis, a jack is placed under the breech and one under the muzzle; the extremities of the gun are raised alternately and supported by blocks till they are at such a height that skids placed on the rails of the chassis will pass under it. The gun is rolled till it occupies a proper position under that for the top carriage. It is then raised as before, being supported by cribs of blocks built one under the swell of the breech, another under the chase, three feet from the muzzle, till it is brought to a height above that for the trunnion beds, the trunnions being level. The top carriage is taken to pieces and assembled in position under the gun, which is then let down into place.

2d. The chassis and top carriage being in position.—The gun is brought parallel to the chassis, and is raised and rolled as before on to skids placed on the rails in rear of the top carriage, the breech projecting to the rear. It is then lifted by jacks and supported on a crib of blocks built in rear of the chassis under the breech, and by a skid bearing under the muzzle laid across and resting on two cribs, one on each side of the muzzle without the chassis. The gun being sufficiently high, the top carriage is moved to the rear and the gun lowered into the trunnion beds. In raising heavy cannon an ordinary gin can sometimes be used for the muzzle, the jack being required for elevating the breech only. In building the cribs the thickest blocks, as a rule, should be



placed at the bottom, and thin blocks should be replaced by thicker ones as the gun rises.

3d. The cannon being on or by the platform, the chassis and the top carriage in position or not.

In many instances the position of the platform is such that the mounting may be facilitated by the jacks being placed above the gun. In this case a special device is used. The jacks, two in number, are supported each upon a heavy timber or *bolster* resting on blocks, or on high, strong trestles. On top of the jack rests one end of a *lever*, the other end bearing on a *fulcrum*. A strong iron *hoisting-bar* also through one made in the lever. This bar is passes through a mortise prepared in the bolster and pierced with a number of holes, into which iron pins may be placed. The extremities of the gun are slung to the lower ends of the hoisting-bars; pins being placed in the bars immediately above the levers, the jacks acting on the levers raise the gun; pins are then passed through the bars above the bolsters and the weight sustained by them till a new lift is taken with the jacks; by transferring the pins the gun is brought to any desired height, the jacks being worked together. The bolsters should be of sufficient length to embrace the chassis, and the gun placed by the side of it. If the chassis and top carriage are in position the gun is raised to the necessary height, the carriage traversed till it is brought beneath it, and the gun then lowered into place. If the gun alone is on the platform it can be raised, and the chassis and top carriage be brought in succession on a truck and placed in position beneath it. The appliances to be employed in mounting heavy cannon, and the order in which the different parts should be placed on the platform, must vary with the position and nature of the work and the construction and the arrangement of each particular platform. Any device or arrangement that may expedite or facilitate the work should be resorted to. The circumstances may be such as to render advisable slight variations in the steps taken in mounting each gun in a battery. See *Mechanical Maneuvers*.

MOURNE.—That part of a lance or halbert to which the steel or blade is fixed.

MOUSER.—In the British Army, a sobriquet which was sometimes used in sport to distinguish the battalion men from the flank companies. It was indeed generally applied to them by the Grenadiers and Light Bobs, meaning that while the latter are detached, the former remain in quarters, like cats to watch the mice, etc.

MOUSING A HOOK.—A mode of passing a piece of spun yarn round the point and back of the hook of a block, in order to prevent it disengaging itself from anything to which it may be hooked.

MOUSQUETAIRES.—A body of horse-soldiers under the old French *Régime*, raised by Louis XIII, in 1622. This Corps was considered a Military School for the French nobility. It was disbanded in 1646, but was restored in 1657. A second company was created in 1660, and formed Cardinal Mazarin's Guard. Also written *Musketeers*.

MOUSQUET FUSIL.—A *flint-lock* gun which was invented by Marshal Vauban, about 1640, and which was so contrived that in case the flint did not strike fire, the powder might be inflamed by means of a small match which was fixed to the breech. Most authors of Encyclopedias, from the habit of copying one another, have repeated that the bayonet was invented and manufactured at Bayonne by Puységur, who died in 1682. Nevertheless this sort of dagger or sword had been adapted to the arquebusc, and even perhaps to the earliest portable fire-arms. The bayonet was already known in France in 1570, but was not universally adopted until 1640, when it replaced the pike in certain regiments. Subsequently the bayonet was fixed at the end of the gun by means of the socket. This was the side-arm joined to the fire-arm, called *musket-gun*, and attributed to Vauban.

MOUTH.—1. The opening of a piece of ordnance at which the charge is introduced, and from which, when fired, it issues. 2. The interior opening of an embrasure, from eighteen inches to two feet wide, according to the caliber of the gun, and of a rectangular or trapezoidal form. See *Embrasure*.

MOVABLE BATTERY.—A battery usually consisting of field guns and small mortars which can take up, temporarily, any favorable position for damaging the enemy's defences. The movable gun batteries will consist of 10, in some cases, 20-pounder rifled guns; and the Napoleon gun for throwing hollow projectiles. These guns will take advantage of any temporary covers, as undulations of the ground, woods, fences, etc., from which they can bring a damaging fire on the defences, and which they will maintain until the fire of the besieged becomes too heavy for them. In this way, a very important auxiliary to the fixed batteries will be called into play; sometimes forcing the besieged to establish new positions to drive off these light guns. In like manner the smaller mortars that can be readily moved by hand, or on sleds, may be placed in good temporary positions to increase the amount of fire delivered on any given point. See *Batteries* and *Fixed Batteries*.

MOVABLE PIVOT.—The arc described by the soldier or guide on that flank of a line of troops toward which a wheel is made. See *Pivot*.

MOVEMENT.—The regular and orderly motion of an army for some particular purpose. It is also described as the changes made by an army from place to place, either to take up new camping ground, to engage the enemy, or to avoid him. Under this term are comprehended all the different evolutions, marches, countermarches, and maneuvers, which are made in Tactics, for the purpose of retreating from or of approaching towards an enemy. The science of military movements forms one of the principal features in the character of a great Commander. If he be full of resource in this important branch, he may oftentimes defeat an enemy without even coming to blows, for to conceal one's movements requires great art and much ingenuity.

MOYENNE.—An ancient 4-pounder, 10 feet long, weighing 1,300 pounds. In the time of Charles IX. (1572) it was a $2\frac{3}{4}$ pounder.

MOYENNE VILLE.—A term formerly given by the French to any town in which the garrison was equal to one-third of the inhabitants, and which was not deemed sufficiently important to bear the expense of a citadel; more especially so because it was not in the power of the inhabitants to form seditious meetings without the knowledge of the soldiers who were quartered on them.

MOYENS COTES.—In a fortification, all those sides which contain from 80 to 120 toises in extent. They are always fortified with bastions on their angles. The *moyens cotés* are generally found along the extent of irregular places, and each one of these is individually subdivided into small, mean, and great sides.

MUFTI.—A term in the army for plain clothes, the opposite of regimental clothing. In the British army, an officer in England is permitted to appear in *mufti* when off duty.

MUHLAGIS.—Turkish Cavalry composed of expert horsemen, who generally attend the beglierbeys. They are not very numerous.

MUIRKIRK IRON.—A variety of iron well suited for the purposes of gun construction. It is made with charcoal at Muirkirk, Prince George's County, Maryland The ore used is a nodular carbonate of iron from the tertiary sands of the western shore of Chesapeake Bay. It is more or less altered into sesquioxide of iron by the action of surface water, and is cleaned and roasted before charging the furnace. The yield of iron from the raw ore is from 40 to 45 per cent., and from the roasted about 50 per cent. This iron has been used at the South Boston foundry for a number of years and with excellent results, but has not until recently been employed for ordnance purposes. See *Dover Iron* and *Iron*.

MUIR-MONTSTORM RIFLE.—A breech-loading small-arm having a fixed chamber closed by a movable breech-block, which rotates about a horizontal axis at 90° to the axis of the barrel, lying below the axis of the barrel and in front, being moved from above by a thumb-piece. The breech-block of this arm is moved by an outside lever, the interior shaft connected with which is cam-shaped, so that the first motion of opening draws down the breech-block, until a lip on its upper surface is clear of a hook or jaw formed on the under side of a projection of the frame overhanging the mouth of the chamber. By continuing the motion of the lever, the breech is fully exposed by the rotation of the block, the hammer at the same time being brought to the full-cock. By reversing the movement of the lever the breech is closed. The breech-block is locked by the abutment of the frame upon its back. Extraction and ejection are accomplished by a sliding extractor in the lower side of the barrel. Its under side is notched for the upper end of a lever, which is pivoted on the same pin as the hammer. This lever has two horizontal arms, which are struck by corresponding prongs on the lower side of the block, in opening the piece.

MULCT.—A soldier is said to be *mulcted* of his pay when put under fine or stoppages for necessaries, or to make good some dilapidations committed by him on the property of the people or the government.

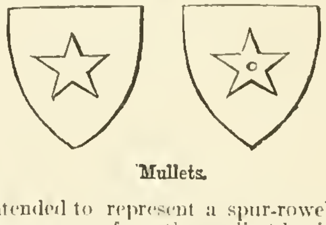
MULE.—A hybrid animal, the offspring of the male ass and the mare, much used and valued in many parts of the world as a beast of burden. The ears are long; the head, croup, and tail resemble those of the ass rather than those of the horse; but in bulk and stature the mule approaches more nearly to the horse. The mule seems to excel both the ass and the horse in intelligence; it is remarkable for its powers of muscular endurance; and its sure-footedness particularly adapts it to mountainous countries. It has been common from very ancient times in many parts of the East; and is much used also in most of the countries around the Mediterranean Sea, and in the mountainous parts of South America. Great care is bestowed on the breeding of mules in Spain and Italy, and those of particular districts are highly esteemed. In ancient times the sons of Kings rode on mules, and they were yoked in chariots. They are still used to draw the carriages of Italian Cardinals and other ecclesiastical dignitaries. Both in Spain and in South America mules employed to carry burdens are driven in troops, each preceded by an animal—in South America usually an old mare—called the *madrina*, or godmother, to the neck of which a little bell is attached, and the mules follow with the greatest docility. When troops mingle in their halting-places or elsewhere, they are readily separated, as they recognize at once the sound of their own bell. Mules are comparatively little used in Britain.

Pack mules should not be too large or high on their legs. The Spanish-Mexican mules, for endurance, are superior to all others. These mules are small, but can stand a great amount of abuse and starvation, and will suffer but little from the effects of a hard drive. Being smaller than the American mules, they can fill up in a much less time, and it will be found that in three hours on thin grass they will fill up and recuperate better than American mules on the same pasture in six hours. This is the secret of small mules outlasting the large ones in the mountains and on the prairies. The time spent in camp is not sufficiently long, when the grass is scarce, to allow a large one to find enough to eat. The small mule finds sufficient in a short while and has some time left for rest and recuperation.

As in other hybrid animals generally, males are more numerous among mules than females, in the proportion, it is said, of two or three to one. There is no instance on record of offspring produced by two mules: but instances occur, although rarely, of their producing offspring with the horse and with the ass. The mule is very superior in size, strength, and beauty to the hinny, the offspring of the male horse and the female ass. See *Pack Animals*.

MULLER.—A hand instrument made of wood and covered with leather; it is used in the laboratory for reducing powder to great fineness. The term is also applied to the painter's stone for mixing paint.

MULLET.—Mullet, or Mollét, in Heraldry, is a charge in the form of a star having generally five



Mullets.

points, intended to represent a spur-rowel, and of frequent occurrence from the earliest beginnings of coat-armor. Gwillim, Sir George Mackenzie, and Nisbet lay it down that mullets should always be pierced to represent the round hole in which the spur-rowel turns, but this has been by no means uniformly attended to in practice. Much confusion exists in blazonry between mullets and stars; in England the rule most generally adopted is that the mullet has five points, whereas the star has six, unless any other number be specified. Nisbet lays down a rule nearly the converse of this, which has never been adhered to; and in Scottish Heraldry the same figure seems to be often blazoned as a mullet or a star, according as it accompanies military or celestial figures. The mullet is the mark of cadency assigned to the third son, "To incite him to chivalry." The mullet is occasionally used in Heraldry for the fish so called. See *Heraldry*.

MULTIBALL CARTRIDGE.—A cartridge in which two or more bullets or pieces of lead are substituted for the ordinary bullet, with the idea of doing more execution at short ranges. The following advantages are claimed for the encased multiball cartridge as manufactured by Merwin, Hulbert & Co:—1. No leading of barrel by any number of discharges. 2. At each discharge the casing acts as the cleaner and lubricates the barrel. 3. The lubricated case taking the rifling gives an easy transit of balls and accuracy of flight. 4. The lubricant is preserved under the different ordinary degrees of temperature. 5. By the centrifugal force given to the casing and balls by the rifling, the casing is thrown off after leaving the barrel, the balls diverge or separate nearly equal to the front of three men at about one hundred yards distance. 6. The multi (or 3-ball) cartridge in its effective (or destructive) results at each discharge at short range is nearly equal to three separate discharges by a breech-loader throwing one ball. 7. The cartridge is firmly constructed and will withstand rough usage of actual service and preserve its uniformity of shape. 8. Continuous (and rapid) firing without requiring the barrel to be cleaned. 9. Preservation of powder. The casing as an insulator prevents galvanic action between the metallic shell and balls which chemical action in time would deteriorate the powder. 10. The casings are made, the balls placed and secured firmly therein, separate from the metallic shells and can be transported in bulk or otherwise without injury and attached to the loaded metallic powder case when desirable (or at reloading of shells)

The multiball cartridge for the service rifle is shown in Fig. 1, and has the following particulars:

Weight of powder charge. . . .	grains.	52
Number of balls.		3
Diameter of balls (each)		0″.424
Weight of balls	grains.	108.66
Total weight of lead.	grains.	326

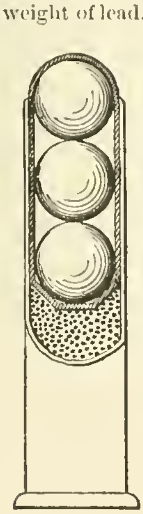


Fig. 1.

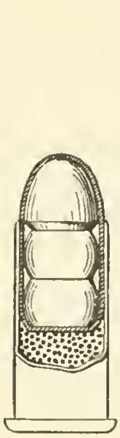

Fig. 2.

The charge is inclosed in a copper cartridge case of service dimensions. The three balls are inclosed in a strong casing of paper lubricated with a mixture of paraffine and beeswax, making of them a single piece. The paper is saturated with the lubricant. The case is crimped at the base to hold the balls in place; longitudinal cuts are made through the case to facilitate rupture after it has left the piece. (A light coating of shellac covers the portion of the case that projects from the shell in some of the cartridges with a view to protection of the cartridges from atmospheric influences). The lubricant is placed in the recesses (corresponding to cannelures), where the balls come in contact.

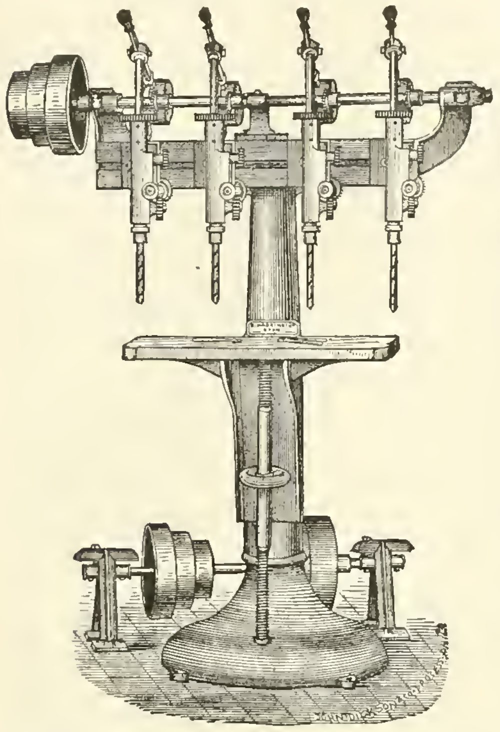
The multiball cartridge for the service revolver is shown in Fig. 2, and has the following particulars:

Weight of powder charge . . .	grains	22
Number of balls (1 ogival and 2 spherical segments)		3
Diameter of balls		0″.424
Length of ogival bullet		0″.39
Altitude of segments -		0″.236
Weight of ogival bullet	grains	111
Weight of segments (each) . . .	grains.	82
Total weight of lead	grains.	275

The charge is inclosed in a copper cartridge case, of service dimensions. The paper casing for the bullets is like that for the rifle. The ogival has a flat base, and the bases of the segments fit to this and to each other. The lubricant is placed in the recesses and about their junctions. Assuming that $1\frac{1}{4}$ inches penetration in soft pine boards with these balls would inflict a dangerous wound, it has been found by experiment that the effective range of the rifle-bullet multiball is limited to about 160 yards; and with the pistol even at 25 yards, but one of the bullets in the cartridge has a penetration of $1\frac{1}{2}$ inches. The question naturally arises whether it would be advisable to encumber men in action with cartridges which, as revolver cartridges, are not at any range superior to the uniball to inflict a dangerous wound, and in any case could not be used with effect beyond 75 yards; and as rifle cartridges could not be used with effect beyond 175 yards, while their superiority to the uniball is limited between 30 and 160 yards. See *Buckshot Cartridge* and *Wright Multiball Cartridge*.

MULTI-CHARGE GUN.—Many attempts have been made by inventors to utilize the accelerating effect on the projectile of several charges successively fired in a gun. Bessemer proposed to use a very long gun, placing the charges separately in holes at the breech, to be fired in succession by electricity. In the Lyman-Haskell multi-charge cannon, the inertia of the shot is first overcome by a moderate charge of very coarse-grained, slow-burning powder, and then repeated charges of quick-burning powder are applied in succession until a great increased velocity is attained. In recent experiments with an acce e-ating or multi-charge gun the average penetration in laminated armor composed of one-half inch boiler-plates was $4\frac{7}{16}$ inches. No doubts are entertained by experts that early experiments will show that these guns, at comparatvely moderate cost, will be at least as efficient as the best in Europe. See *Lyman Haskell Multi-charge Cannon*.

MULTIPLE DRILL.—A tool designed more especially for drilling side frames and steel armor plates, but well adapted to a wide range of other general work in the armory. The large size machine is fitte l with two or any required number of sliding heads; these heads, carrying drill spindles, with a lateral range of 17 feet from center to center of spindles, and a forward and back movement, at right angles, on a sliding horizontal arm, of 10 inches (or more if desired), thus enabling holes to be drilled in *line or otherwise*. Capacity on top of table under drill spindle, 32 inches; from floor to top of table, 32 inches; fsom column to center of drill spindle, 22 inches, or more, according to length of the sliding arm; from column to front of table 18 inches; top surface of table, 14 inches wide by 18 feet 4 inches in length; table has a front or vertical surface, 25 inches deep by 18 feet 4 inches in length; T-slots on both top and vertical surfaces for clamping work; vertical traverse of spindles, 12 inches; spindles balanced by weight attached direct to top of spindle; has quick return by wheel and rack; has automatic gear feed suitable for drilling or boring; driving cone $22 \times 4\frac{1}{4}$ inches in diameter, to run 225 turns per minute, four or more sections; each head has perfectly independent universal movement and an independent feed, also an independent friction for stopping and starting; spindles are steel; pinions and rack gearing are of steel; steel shafts and screws; all cut gearing; floor space occupied, 48 inches wide by 18 feet 8 inches long; total height to top of spindles, 9 feet; weight, 18,000 pounds. The drawing shows a smaller tool which is used for general work. The spindles have hand and power feed; balanced, quick return by lever; lateral adjustment, can be run one or more at same time, and at any desired speed, by arrangement of gearing; table has vertical adjustment by right and left screw; distance from spindle to column, $7\frac{1}{2}$ inches; and with counter-shaft and pulleys, 12 by $3\frac{1}{2}$ inches, to run 350 turns per minute. Weight, 850 pounds. See *Drill Press* and *Gang Drills*.



MULTIPLE LINES.—It has been proposed, by some writers, to throw up several lines of detached works for the defence of a position; so that the troops in the first line may retreat under cover of the second, and so on. This arrangement, in the first place, can seldom be made, without *weakening the order of battle*, and therefore weakening the defence, by too great a dissemination of the troops. Moreover, in works of great extent there never can be that concert which is so essential to a vigorous defence, from the impracticability to direct it properly. The troops destined to act offensively against the enemy if repulsed, are too far in the rear to be brought up in time; and the ground being greatly cut up, by such a multiplication of works, will render the maneuvers slow and difficult. Besides, *a very capital objection in war*, the time and labor required to throw up so many works are altogether beyond what can be disposed of in the ordinary circumstances of an army. See *Lines*.

MULTIPLIERS.—It would exceed the limits of this work to enter into a discusion of the formulas from which the values of the multipliers used in the equations of motion in air are calculated; it will be sufficient to explain how these tables are used in practice.

The reader will find this subject, as well as all others relating to Ballistics, ably and fully treated in Dinion's *Traité de Balistique*.

Multiplier B. The decimals are carried out to three places, which is sufficient for ordinary purposes. The valnes of $\frac{x}{c}$ are given in the first horizontal line, the value of $\frac{V_,}{r}$ in the first vertical column, and the values of the corresponding multipliers are set opposite to them.

To find the multiplier B for two intermediate values of $\frac{x}{c}$ and $\frac{V_,}{r}$, not given in the tables, we seek, in the absence of the proper numbers, the corresponding values of the nearest tabular numbers. We add to these, parts proportional to the differences, as though each part were to be considered separately.

Multiplier I. The values of I are given in the same table as those of B; except that it is necessary to commence in the lower horizontal line, and subtract from them the product of $\frac{V_,}{r}\left(1+\frac{V_,}{r}\right)$, by the corresponding number of the line called "Correction."

Values of U and D. This table is calculated for differences of 0.10 in case of $\frac{x}{c}$, in the upper line, and for differences of .05 in case of $\frac{V_,}{r}$. For U, the values of $\frac{x}{c}$ are found in the upper horizontal line, and for D, in the lower line.

Values of $\frac{x}{c}B$ for calculation of Ranges. This table gives the value of $\frac{x}{c}$ and $\frac{V_,}{r}$, for differences of 0.05 and 0.05; the unknown quantity to be determined is $\frac{x}{c}$ when $\frac{V_,}{r}$ and $\frac{x}{c}B=p$, are given.

Arrange the calculations as in the preceding cases. Only one of the proportional parts is unknown, and this is determined by the condition, that if it be added to the other proportional part, and to the number in the table, the sum is equal to the required number.

Values of $\frac{V_,/r}{\sqrt{B}}$ for initial velocities. This table gives the result arising by dividing $\frac{V_,}{r}$ by $\sqrt{B}$ for values of $\frac{x}{c}$ and $\frac{V_,}{r}$; the quantity to be determined is $\frac{V_,}{r}$. The method is the same as in the preceding table; the sign of the difference should invariably be changed if the value of the quotient q is found to diminish as

x
-increases. See *Didion's Formulas.*
c

MUNCHEEL.—A kind of litter which is used on the Madras and Bombay side of India. It is simply a hammock suspended from a horizontal pole, and is carried by two men. It weighs about 20 lbs. To keep the canvas of the cot or hammock at full length, there is a cross piece of wood at the top and bottom. On service it would be used for the same purpose as the doolie of Bengal. Under another name, the muncheel is largely used to carry people about in the Himalaya Mountains. A large umbrella is used to keep off the sun, and a waterproof piece of cloth, or a blanket, is thrown over the supporting pole to keep off the rain. See *Litter.*

MUNIFICE.—A Roman soldier who was subjected to every kind of drudgery-work in camp.

MUNIMELL.—A stronghold, fortification, breastwork, etc.

MUNITIONS OF WAR.—Ammunition and military stores of every description.

MURAGE.—An ancient term for money appropriated to the repair of military works.

MURAL CIRCLE.—An astronomical instrument for taking declinations; consisting of a large circle built against the wall (whence its name), movable on its axis in the plane of the meridian, and with a telescope attached, also in the plane of the meridian, which turns about an axis. The circle is graduated, the whole instrument counterweighted and furnished with an illuminating apparatus for night readings. Readings are made accurate by set-screws and microscopic micrometers. The plane of the limb and the optical axis of the telescope are made parallel to the meridian by leveling and sweeping-screws, and the cross lines of the eye-piece should follow a star near the equator their whole length. The instrument being rectified, the height of a star above the horizon is measured by a cup of mercury; the star is observed directly and then by reflexion, the half sum of the readings being the correct angle. The co-latitude of the place is obtained as with the theodolite. As the tube is movable about the circle, reading should always be checked by reiteration: with more than one limb of the circle.

MURAL CROWN.—In Heraldry, a crown in the form of the top of a circular tower, masoned and embattled. It is meant to represent the crown which was given by the Romans as a mark of distinction to the soldier who first mounted the walls of a besieged town, and fixed there the standard of the army. A mural crown supporting the crest, in place of a wreath, occurs in the achievements of several of the English Nobility, and in various grants of arms made in the early part of the present century to officers who had distinguished themselves in war. Viscount Beresford, in consequence of his gallantry at the battle of Albuera, obtained as crest, issuing out of a mural crown, a dragon's head with its neck pierced through by a broken spear, the head of the spear, point downwards, being held in the mouth of the dragon.

MURDER.—The crime of killing a human being of malice aforethought, and is punishable with death. It is immaterial what means are employed to effect the object. Blackstone says that the name of murder, as a crime, was anciently applied only to the secret killing of another, which the word *moërda* signifies in the Teutonic language. And among the ancient Goths in Sweden and Denmark the whole vill or neighborhood was punished for the crime, if the murderer was not discovered. Murder is defined by Coke thus: "When a person of sound memory and discretion unlawfully killeth any reasonable creature in being, and under the King's peace, with malice aforethought, either express or implied." Almost every word in this definition has been the subject of discussion in the numerous cases that have occurred in the law courts. The murderer must be of sound memory or discretion; i. e., he must be at least 14 years of age, and not a lunatic or idiot. The act must be done unlawfully, i. e., it must not be in self-defense, or from other justifiable cause. The person killed must be a reasonable creature, and hence killing a child in the womb is not murder, but is punishable in another way. The essential thing in murder is that it be done maliciously and deliberately, and hence in cases of hot blood and sculling, the offense is generally manslaughter only. Killing by duelling is thus murder, for it is deliberate. It is not necessary, in order to constitute murder, that the murderer kill the man he intended, provided he had a deliberate design to murder some one. Thus if one shoots at A, and misses him, but kills B, this is murder, because of the previous felonious intent which the law transfers from one to the other. So if one lays poison for A, and B, against whom the poisoner had no felonious intent, takes it, and is killed, this is murder. The only sentence on murderers is now death, which is carried out by hanging. Formerly the murderer was directed after death to be hung on a gibbet in chains near the place of the crime. Formerly, also, dissection was added as part of the sentence, and the execution was to take place on the day next but one after sentence. But now an interval of a fortnight usually takes place and the body is buried in the precincts of the prison. Attempts to murder were until recently punishable in England like capital felony; but now all attempts to murder are punishable only with penal servitude for life, or for a term not less than three years.

MURDERER.—A great piece of artillery. Among the ordnance given up to Monk with Edinburgh Castle in 1650 is mentioned "The great iron murderer, Muckle Meg."

MURDRESSES.—In ancient fortification, a sort of battlement with interstices raised on the tops of towers in order to fire through.

MURSAIL.—That portion of the helmet made so as to lower or turn down in order to protect the face. So called from the resemblance it bore to the muzzle of an animal. It is the same as *Mesail* and *Ventail.*

MUSCHITE.—A local designation applied to the early hand-culverins, and which gave its form to the word *mousquet* or musket.

MUSCULE.—In ancient times, a machine of war; a low, long, and sharp-roofed shed, which enabled the besiegers to advance to and sap the wall of the besieged. See *Testudo.*

MUSICIANS.—The men enlisted and detailed to furnish music for troops. Regiments are supplied with field music on the requsitions of the Commanders, made, from time to time, direct on the Adjutant General; and, when requested by Regimental Commanders, the Adjutant General will endeavor to have suitable men selected from the recruits, or enlisted, for the regimental bands. See *Band, Drummer, Fifer,* and *Trumpeter.*

MUSKET—MUSQUET.—The fire-arm for infantry soldiers, which succeeded the clumsy arquebuse, and in 1851 gave way before the Enfield rifle, which, in its turn, was converted into Snider's patent breech-loading rifle, now known as the Snider-Enfield; the latter arm, so far as the regular infantry is concerned, has been replaced by the Martini-Henry breech-loader, but the English navy, cavalry, and the auxilliary forces still retain the Snider. The first muskets were match-locks; after which came wheel-locks asnaphans or snap-hance and flint muskets; and lastly, percussion muskets, which were a vast improvement, both for accuracy and lightness, on all which had gone before. Compared, however, to either the Enfield or Martini Henry rifle, the musket familiarly known as Brown Bess, was a heavy, ugly, and ineffective weapon. The following is a table of the ranges attained, on an average, by the musket, the Enfield, and the Martini-Henry :

	Musket	Enfield Rifle.	Martini-Henry Rifle.
Accurate fire	100	600	1200
Effective against detached parties	150	800	1500
Effective against troops in column	200	1000	1800

MUSKET BASKETS.—Small baskets about a foot or a foot and a half high, 8 or 10 inches diameter at bottom, and a foot at the top, so that being filled with earth there is room to lay a musket between them at the bottom. They are set on low breastworks, or parapets, or on such as are beaten down.

MUSKETEER.—A soldier armed with a musket. See *Mousquetaires.*

MUSKETOON.—An obsolete weapon, a short musket with a very wide bore, carrying a ball of 5 oz., and sometimes bell-mouthed like a blunderbuss. The arm was mostly used toward the close of the seventeenth century. Also written *Musquetoon.*

MUSKETRY INSTRUCTION.—The knowledge imparted to the officers and soldiers of a regiment, to perfect them in the theory and practice of small-arms. The following is the course pursued in all Line Regiments. Every year, in the infantry and cavalry, each company and troop in a regiment is struck off duty in turn, to go through the annual course of musketry, under the Regimental Instructor. This is divided into preliminary drill and practice. The former lasts four days, and consists of position (standing and kneeling), aiming, the judging distance drill, and the teaching of theory; the latter is divided into three periods, and consists in firing a number of rounds at different distances, from 150 to 800 yards—standing, kneeling, or in any position. Volley and independent firing, skirmishing, etc. form part of the course, during which each man fires 90 rounds. The result of each man's firing is consigned to carefully drawn up tables, and classified by regiments according to the figure of merit. These tables are published yearly in a blue-book. See *Schools of Musketry.*

MUSKETRY INSTRUCTOR.—In England, an officer attached to each regiment of the regular and auxiliary forces, to carry out the instruction and practice of the musket. He is one of the Permanent Staff of a regiment.

MUSTER.—A review of troops under arms and fullly equipped, in order to take an account of their numbers, inspect their arms and accoutrements, and examine their condition.

In the British army, muster is a calling over of the names of all the men composing a regiment. Each man present answers to his name, those not answering being returned as absent. The muster-roll from which the names are called is the Paymaster's voucher for the pay he issues, and must be signed by the Commanding Officer, the Adjutant, and himself. The crime of signing a false muster-roll, or of personating another individual at a muster, is held most severely punishable—by imprisonment and flogging for a common soldier, by immediate cashiering in the case of an officer. In regiments of the Line a muster is taken on the 24th of each month. The muster after a battle is a melancholy proceeding, intended to show the casualties death has wrought. In early times, before the army was a standing force, and when each Captain was a sort of contractor to the Crown for so many men, the muster was most important as the only security the Sovereign had that he really obtained the services of the number of men for whom he paid. Accordingly, any fraud, as making a false return, or as mustering with his troop men not actually serving in it was by the Articles of War of Henry V. made punishable with death for the second offense, and by Charles I. with death "without mercy" for even the first such crime; while any person abetting in any way in the fraud shared the penalty.

In the United States, troops are mustered for pay on the last day of February, April, June, August, October, and December. The musters are made by an Inspector General, if present, otherwise by an officer specially designated by the Commander of the Army, Division, or Department; and in absence of either an Inspector General or officer specially designated, the muster is made by the Commander of the Post. All stated musters of the troops, when practicable, are preceded by a minute and careful *Inspection* in the prescribed mode; and if the command be of more than a company, by a *Review*, before inspection. The Mustering Officer having inspected the companies in succession, beginning at the head of the column, returns to the first company to muster it; each Captain, as the Mustering Officer approaches, brings his company to rear open order, supports arms, and commands: *Attention to muster.* The Mustering Officer then calls over the names on the roll; each man, as his name is called, distinctly answers *Here!* and brings his piece to a *carry* and then to an *order arms.* The Adjutant, at muster, provides himself with the muster-roll of the Field and Staff; and each Captain with a roll of his company, and a list of absentees alphabetically arranged. After muster, the presence of the men reported in the hospital and on guard is verified by the Mustering Officer, who is accompanied by the Company Commanders.

MUSTER-BOOK.—A book in which military forces are registered.

MUSTER-MASTER.—The *Mustering* or *Inspecting* officer who takes an account of troops, and of their arms and other military apparatus. This title is not known in the United States Army. See *Muster.*

MUSTER-ROLL.—A return or list of all troops and establishments, actually present on parade or otherwise accounted for, which is taken on the day of muster. The presence at muster of all concerned is peremptorily necessary, otherwise an officer or soldier subjects himself to forfeiture of pay, unless leave by competent authority has been obtained Sometimes written *Muster-file*. See *Pay-roll.*

MUTILATED.—Wounded in such a manner as to lose the use of a limb. A battalion is said to be *mutilated* when its divisions, etc., stand unequal.

MUTINY.—Behavior either by word or deed subversive of discipline, or tending to undermine superior authority. Till recently mutiny comprised speaking disrespectfully of the Sovereign, Royal Family, or General Commanding, quarrelling, and resisting arrest while quarrelling; but these offenses have now been reduced to the lesser crime of "Mutinous Conduct." The acts now constituting mutiny proper are exciting, causing, or joining in any mutiny or sedition; or when present thereat, failing to use the utmost effort to suppress it; when, knowing of a mutiny or intended mutiny, failing to give notice of it to the Commanding Officer; striking a Superior Officer; or in using or offering any violence against him while in the execution of his duty; disobeying the lawful command of a Superior Officer. The punishment awarded by the Mutiny Act to these crimes is, if the culprit be an officer, death or such other punishment as a General Court-Martial shall award; if a soldier, death, penal servitude for not less than four years, or such other punishment as a General Court-Martial shall award. As the crime of mutiny has a tendency to immediately destroy all authority and all cohesion in the naval or military body, Commanding Officers have strong powers to stop it summarily. A Drum-head Court-Martial may sentence an offender, and if the case be urgent, and the spread of the mutiny apprehended, the immediate execution of the mutineer may follow within a few minutes of the detection of his crime. It, however, behooves Commanding Officers to exercise this extraordinary power with great caution, as the use of so absolute an authority is narrowly and jealously watched. To prevent mutiny among men the officers should be strict without harshness, kind without familiarity, attentive to all the just rights of their subordinates, and above all things most particular in the carrying out to the very letter of any promise they may have made.

MUTINY ACT.—An Act of the British Parliament passed from year to year, investing the Crown with powers to regulate the government of the Army and to frame Articles of War. The Navy stands under Navy Discipline Acts, 1861 and 1866, the successors of Articles of War first enacted under Charles II., which, unlike the Mutiny Act, remained in force for an indefinite time. By the Bill of Rights, the maintenance of a Standing Army in time of peace, unless by consent of Parliament, was declared illegal, and from that time the number of troops to be maintained, and the cost of the different branches of the service, have been regulated by an annual vote of the House of Commons. But Parliament possesses a further control over the Army. Soldiers, in time of war or rebellion, being subject to martial law, may be punished for mutiny or desertion; but the occurrence of a mutiny in certain Scotch regiments soon after the Revolution, raised the question whether military discipline could be maintained in time of peace; and the courts of law decided that, in the absence of any statute to enforce discipline, a soldier was only amenable to the common law; if he deserted, he was only liable for breach of contract; or if he struck his officer, to an indictment for assault. The authority of the Legislature became indispensable to the maintenance of discipline; and Parliament, from 1689 till 1879, at the beginning of every Session, conferred this and other powers in the Mutiny Act, limited in its duration at one time to six months, but latterly to a year. Although it was greatly changed from the form in which it first passed, 190 years ago, the annual alterations were slight, and substantially it had a fixed form. The preamble quoting the above declaration from the Bill of Rights, added that it was judged necessary that a force of such a number should be continued, while it gave authority to the Sovereign to enact Articles of War for the government of the force. The Act had 107 clauses, the first five specified the persons liable to its provisions—namely, all enlisted soldiers or commissioned officers on full pay, those of the Militia or Yeomanry employed on active service, and to recruits for the Militia under training. Clauses 6-14 treated of Courts-Martial; clauses 15-28 related to crimes and their punishment; for mutiny, desertion, cowardice, treason, insubordination, death might be the penalty; for frauds, embezzlement, etc., penal servitude was awarded. Clauses 29-33 provided for military prisons, the reception of soldiers in civil jails under the sentences of Courts-Martial. Clauses 34-37 enacted rules for deserters. Clause 38 referred to furlough; 39-41 enacted that no person acquitted or convicted by a Civil Magistrate or Jury be tried by Court-Martial for the same offense, and similar matters. Clauses 42-59 referred to Enlistment; 60-74 to stoppages, billets, carriages, and ferries, and the conveyance and entertainment of troops. The remaining 24 clauses adverted to miscellaneous matters. By clauses 105 and 106, the Militia, Yeomanry and Volunteers might on emergency be attached to the regular forces. For years prior to 1878, attention had been drawn in Parliament and elsewhere to the shortcomings of the Act, as well as to its cumbrousness, and the Articles of War by which it was accompanied, explained and amplified. These representations culminated in the appointment of a Parliamentary Committee, which, in 1879, presented a Bill to supersede the Mutiny Act, and, like it, to be passed annually as the "Army Discipline and Regulation Act." The Marine Mutiny Act, applying to the Marine Forces when serving on shore, was almost identical in its provisions with the Mutiny Act. Passed annually up to 1878, it was in 1879 merged with the Mutiny Act in the "Army Discipline and Regulation Act."

MUZZLE-LOADER.—The name given to all guns, smooth-bore or rifled, which are loaded at the mouth or muzzle, to distinguish them from those loaded at the breech. All the newly-made ordnance used in the service are rifled, and loaded at the muzzle, but the first rifled guns (Armstrong's) were breech-loaders. The change from breech-loading to muzzle-loading was brought about, chiefly, from the instability of the system in heavy guns, a want of a reliable breech-closer, and the want also of a suitable percussion-fuse. Moreover, the nature of the powder used when heavy breech-loaders were in the service was such as to render the breech apparatus unsafe. A muzzle-loading gun has a simpler, less costly, and stronger construction: the ammunition is less costly, and a simple fuse, without percussion arrangement, can be used.

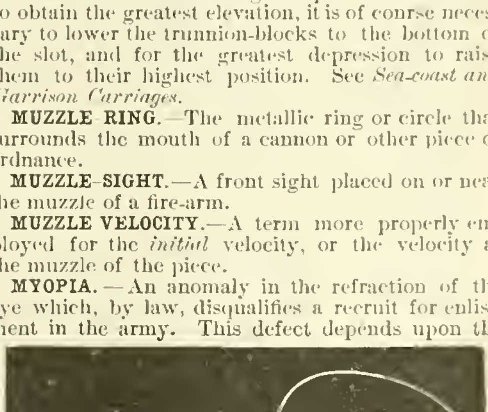
MUZZLE-PIVOTING CARRIAGE.—The vertical field of fire of guns mounted in casemates is so much restricted by the embrasure that the want has long been felt of a carriage which will allow the gun to be used at high angles of elevation, and also at a depression, without a great enlargement of the embrasure. With the view of solving this problem, a new carriage for casemates has been constructed recently, by which the gun can be fired through an embrasure of the usual dimensions at 15° elevation and 7° depression. The principle adopted in its construction is to vary the height of the trunnion-beds instead of always preserving them in the same fixed positions as in the ordinary carriages. To effect this, each cheek of the carriage is cut with a wide vertical slot, in which plays up and down a rectangular block of iron bored with a hole to receive the trunnion of the gun. Under this block is placed a strong screw to support the weight of the gun. By means of a hydraulic jack placed under each trunnion-block the gun is raised or lowered to any desired height, and the motion is immediately followed up by the two screws, to which the weight of the gun is at once transferred. Two minutes are required to raise the gun from the lowest to the highest position. In order to obtain the greatest elevation, it is of course necessary to lower the trunnion-blocks to the bottom of the slot, and for the greatest depression to raise them to their highest position. See *Sea-coast and Garrison Carriages*.

MUZZLE RING.—The metallic ring or circle that surrounds the mouth of a cannon or other piece of ordnance.

MUZZLE-SIGHT.—A front sight placed on or near the muzzle of a fire-arm.

MUZZLE VELOCITY.—A term more properly employed for the *initial* velocity, or the velocity at the muzzle of the piece.

MYOPIA.—An anomaly in the refraction of the eye which, by law, disqualifies a recruit for enlistment in the army. This defect depends upon the



refractive condition of the eye; it is that condition in which the rays from distant objects come to a focus *in front* of the retina, and consequently the latter receives but the blurred and indistinct image of external objects. A glance at the drawing will explain this. Myopia is usually due to an abnormal lengthening of the eyeball, thus causing the retina to recede from the point where the rays come to an accurate focus. It is a disease which often exists from birth, and is frequently hereditary; but, although frequently this condition is present from birth, and manifests itself in later life, no doubt, many cases are developed by excessive use of the eyes at fine "near work," such as reading or sewing, before the coats of the eye have become fully developed and hardened. Statistics show that the percentage of Myopia increases in proportion to intellectual development, and, that while it may be quite small in the lowest grades of Schools, it steadily gains in numbers as the course of study becomes higher, until, in the Colleges and Universities it reaches a very large percentage.

Among the prolific causes of the development of this disease, is the habit of reading with the head bent forward and over the book, thus preventing the free circulation of the blood, and causing a congestion of the eyes, which tends still further to stretch the coats of the perhaps already weakened organ. The habit of reading with insufficient illumination, or in a reclining posture, is also most injurious. The popular belief that near-sighted eyes are strong ones is not only absolutely incorrect, but also most mischievous, since there is no state of the eye which more urgently demands the use of a proper glass, than does Myopia. Such eyes instead of being strong, are not only absolutely weak, but they are sick eyes, and, if the defect be of a high degree, liable to the most serious accidents, which may result in loss of sight. The danger lies not in the imperfect vision, but in the interocular changes which accompany the defect in its higher grades, and which often are progressive.

The treatment of near-sightedness is the use of the proper *concave* glasses. By this, there is an endeavor to attain two objects. The rays are brought to a focus on the retina, and thus distinct vision is insured; and, by wearing the proper glasses, the disease may usually be arrested. In cases where the defect is slight, the correcting-glasses can be given by a good optician, care being taken to select the *weakest* concave lens with which vision is normal; where, however, the defect is high, the advice of an oculist should be sought. Messrs. Walmsley & Co. make a specialty of glasses for myopic eyes, and supply most hospitals with same. See *Recruits*.

MYRIARCH.—A Captain or Commander of 10,000 men.

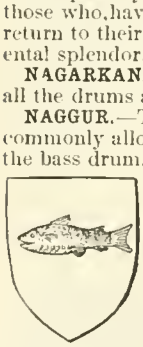
MYRMIDONS.—Those soldiers who accompanied Achilles in the expedition against Troy. Rough, desperate characters banded under a leader, are frequently called Myrmidons.

N

NABOB.—A corruption of the word *nawâb* (deputy), was the title belonging to the administrators, under the Mogul Empire, of the separate Provinces into which the district of a *Subahdar* was divided. The title was continued under the British rule, but it gradually came to be applied generally to natives who were men of wealth and consideration. In Europe, and especially in Britain, it is applied derisively to those who, having made great fortunes in the Indies, return to their native country, where they live in oriental splendor. Also written *Na'ab*.

NAGARKANA.—In the East Indies, the place where all the drums and war-music are kept.

NAGGUR.—The principal drum in Asiatic armies, commonly allowed only to persons of high dignity; the bass drum.



Naiant.

NAIANT—NATANT.—A heraldic term applied to a fish when borne horizontally across the shield in a swimming position.

NAIGUE.—A native subaltern officer among Indian and Anglo-Asiatic troops, whose functions are rather somewhat analogous to those performed among European troops by the Drill-sergeant. Also written *Naick* and *Naik*.

NAIL BALL.—A round projectile with an iron pin protruding from it, to prevent its turning in the bore of the piece.

NAILS. Pointed pieces of metal, generally having flattened or rounded heads, used for driving into wood-work, for the purpose of holding the pieces together. A variety, in which the head is very large, and the spike portion small, used by shoemakers for protecting the soles of boots and shoes from wear, is called the *hob-nail*; another, which is made by cutting thin plate-iron into thin pointed pieces of various lengths, is called *brads;* these sometimes are without heads, but are usually made with a slight projection by way of a head. When made small, with flat heads, for attaching cloth or hangings in upholstery work, they are called *tacks;* and when very large for heavy carpentry, *spikes*. Formerly, all nails were hand-made, by forging on an anvil; and in Britain and the north of Europe vast quantities are still made in this manner, being preferable, for many kinds of carpenters' work, to those made by machinery. In France, the greater part of the nails used for light carpentry-work are made of soft iron wire, pointed with the hammer; and in order to head them they are pinched in a toothed-vise; which leaves the portion for the head projecting, and makes below it three or four grooves in the nail, which increase its hold on the wood when driven home. The head is beaten into a counter-sinking on the vise, which regulates the size. The iron used for hand nail-making in Britain is sold in bundles, and is called *nail-rods;* it is either prepared by rolling the malleable iron into rods or small bars of the required thickness—which process is only employed for very fine qualities—or by cutting plate-iron into strips by means of rolling-shears; these shears consist of two powerful revolving shafts, upon which are fixed discs of hard steel with squared edges. The discs of one shaft alternate with those of the other; they are of the thickness of the plate to be cut, and the shafts are so placed that a small portion of one set of the discs are inserted between those of the other set. When the shafts are revolving a plate of iron is pressed between the discs, and it is forcibly drawn through, the steel discs cutting the plates into strips with great rapidity. The quantity produced in this way is enormous, some mills turning out at the rate of ten miles per hour of nail-rods. Several inventions in which America took the lead, have been introduced, and are successfully worked, for making nails direct from plate-iron, either by cutting them out cold or hot; and a very large proportion of the nails in use are made in this way. Nail-making by machinery was originated in Massachusetts in 1810.

NAIRS.—A native military tribe of the Malabar Coast. They affirm that they are the oldest nobility in the world. Their pride on this supposition is greater than that of the Rajpoots. In 1755, the King of Travancore, with the assistance of a French officer called Lannoy, disciplined 10,000 Nairs in the method of European Infantry.

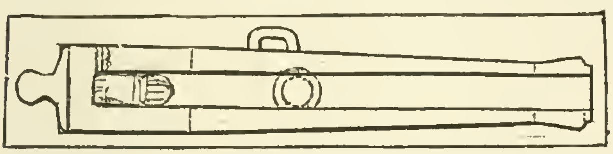
Naissant.

NAISSANT.—A term applied in heraldric blazon to an animal depicted as coming forth out of the middle—not like *issuant* or *jessant* out of the boundary line—of an ordinary.

NAKED BULLET.—A grooved or cannelured bullet as distinguished from the patched bullet. See *Bullet.*

NANA.—In the East Indies, the title which is given to a Chief of the Mahrattas. It more properly signifies the acting head of the Government, and General of the forces.

NAPOLEON GUN. In 1856 it was proposed to increase the power of the light and diminish the weight of the heavy field artillery, by the introduction of a single piece of medium weight and caliber. The form of the new piece is shown in the drawing. It has no chamber and should therefore be classed as a gun. Its exterior is characterized by the entire absence of molding and ornament; and in this respect it may be at once distinguished from the old field cannon. The first reinforce is cylindrical; and it has no second reinforce, as the exterior tapers uniformly with the chase from the extremity of the first reinforce. The size of the trunnions and the distance between the rimbases are the same as in the 24-pdr. howitzer, in order that both pieces may be transported on the same kind of carriage. The *diameter of the bore* is that of a 12-pdr. The *length of bore* is just $13\frac{3}{4}$ calibers. The *weight* is one hundred times the projectile, or 1,200 lbs. The *charge of powder* is exactly the same as that for the heavy 12-pdrs. (pattern of 1840), or $2\frac{1}{2}$ lbs. for solid and case shot, and 2lbs. for canister shot. It has, therefore, as great range and accuracy as the heaviest gun of the old system; and, at the same time, the recoil and strain on the carriage are not so severe. The new gun and carriage weigh about 500 lbs. more than the 6pdr. and carriage; still it has been found to possess sufficient mobility for the general purposes of light artillery. The effect of this change is to simplify the *matériel* of field artillery, and to increase its ability to cope with the rifle-musket, principally by the use of larger and more spherical case-shot. The principal objection to an increased caliber for light field-guns is the increased weight of the ammunition, and the reduction of the number of rounds that can be carried in the ammunition chests. See *Field Artillery.*



NASAL.—A kind of peak or visor, on ancient helms for the protection of the nose.

NASIR-JUNG.—An Indian term expressing victorious or triumphant in war.

NATION.—A word used in two distinct senses. 1. A State or Independent Society united by common Political Institutions. 2. An aggregate mass of persons connected by ties of blood and lineage, and sometimes of language. The modern dogma of nationalism, as maintained by a class of Continental Politicians, starts from an assumption that a nation in the latter sense ought necessarily to be also a Nation in the former, and endeavors to assign limits to the several races of Europe, with the view of erecting each into a distinct State, separated from other States or Nationalities. The extreme Politicians of the National School seem to consider the supposed rights of Nationalities as paramount even to the obligations of treaties, and the political conjunction of one Nationality with another is looked on by them as an adequate ground for a revolt or separation, apart altogether from the question whether the Nationality is well or ill governed. In point of fact, the different races in Europe are so commingled, that any reconstruction of the political map of Europe, on ethnological principles, would be impossible, even if desirable. The blood of nine-tenths of Europe has been mixed within the historical period. The test of language, on which Nationality has sometimes been based, is a deceptive one, in so far as it is indefinite and perpetually fluctuating. The people on the frontier between two races, as in the South Tyrol, generally speak two languages. Then we have dialects, like the Walloon, the Grödnerisch of the Tyrol, and the Romansch of the Grisons—as also the Breton, Welsh, Gaelic, and Irish languages, which could hardly be made the basis of independent communities. The well-being of the people governed is properly the end of all government, and it has practically not been always found that a State is better governed when it consists of one race only, than when it includes an aggregate of races. Highly diversified Nationalities may be united in one political system, provided only that the Government respects and consults the peculiarities of the several races and does not attempt to force the usages, habits, or language of one on the rest.

NATIONAL ANTHEM.—A selection of music set to words, and common to all nations. In England the national anthem is "God save the Queen," which is played when troops pay the prescribed honors to the Sovereign and members of the Royal Family; in the latter case only six bars of the anthem are played. The first part of the national anthem may also be played at the salute of a Viceroy, at state ceremonials, and at the trooping of colors. The playing of the national anthem is only due to those personages who are entitled, under the regulations, to a royal salute.

NATIONAL ARMORY.—A national establishment for the manufacture of small-arms, etc. The manufacture of United States small-arms and small-arm ammunition for the present armies and militia, and for the reserve supply, is one of the greatest importance, and the Springfield Armory is a model one of the world in the perfection of its fabrications, the extent and completeness of its arrangements and the facilties for the production of this class of war-ike stores.

NATIONAL ARMORY CIRCULAR CUTTER.—A modification of the Adams cutter, from which it differs only in the details of its form and dimensions. The diameter of the circle which forms the cutting-edge is 3″; the angle formed by the elements of the two right cones whose intersection forms that edge is 60° instead of 61° 20′. The altitudes of these cones are the same, and are equal to 0″.866. The thickness of the disk is 0″.25 The angle of 60° was adopted for the edge as being an angle which could be accurately formed in a turning-lathe without difficulty, as almost every machinist possesses an equilateral triangular gauge by which he can verify at any instant the angle included between the legs of the striding-gauge that he uses to guide him in turning the bevels. The diameter and thickness of the disk-plate were chosen with reference to retaining the angle of 60°, and with reference to ease of exact measurement by practical mechanics. By assuming these dimensions the strength of the cutter is not impaired; it is rendered a little more sensitive to small differences of pressure than the Adams cutter; and its dimensions, both linear and angular, are easily preserved in fabrication by any one of ordinary mechanical skill. The limits of these linear dimensions, whether expressed in hundredths or thousandths of an inch, can always be made to fall upon the larger and more common divisions of almost any English scale of inches. The special advantage of the circular cutting or indenting edge is that it can be readily pressed into the indentation, previously made in the copper block or disk while in the piece, upon its removal to the dynamometer or testing-machine. In the case of the pyramidal cutter, it is, and always will be, a matter of considerable difficulty to make the apex of the pyramid coincide with its former position, in adjusting it in a dynamometer for the purpose of getting the reading of the estimator or the setting of the limit-gauge, in order to govern the operator in making the similar secondary cut or cuts from or by means of which the pressures are determined. The more accurately the cutter is inserted into the indentation made by the force of discharge, and the greater the precision of the adjustment of the limit-gauge, the more nearly will be the approximation to the true pressure as determined by the dynamometer. With the circular cutter, no difficulty is experienced in adjusting its edge to the bottom of the indentation in the copper. The steel disks for the National Armory circular cutters were made in September, 1876. See *Adams Cutter*, *Benton Dynamometer*, *Circular Cutter*, and *Pressure Gauge*.

NATIONAL CEMETERIES.—In the United States, these are the burial-places for soldiers, provided by the general government. The Quartermaster General of the army has charge of all the National Cemeteries, and the records pertaining thereto. There are, at present, (1884) 26 National Cemeteries of the *First Class;* 20 of the *Second Class;* 11 of the *Third Class*, and some 23 of the *Fourth Class*. The Superintendents of these classes are paid $75, $70, $65, and $60 per month respectively. Military Commanders exercise the same supervision over National Military Cemeteries within the Geographical limits of their commands as over other military posts or establishments under them, only excepting the Military Cemeteries in the District of Columbia and at Arlington and Alexandria, Virginia, which are attached to the Quartermaster's Principal Depot of Washington, D. C.—

A copy of the following law is kept posted at the entrance, and in several other conspicuous places, in each Cemetery :

Every person who willfully destroys, mutilates, defaces, injures, or removes any monument, gravestone, or other structure, or who willfully destroys, cuts, breaks, injures, or removes any tree, shrub, or plant within the limits of any National Cemetery, shall be deemed guilty of a misdemeanor, punishable by a fine of not less than twenty-five dollars and not more than one hundred, or by imprisonment for not less than fifteen days and not more than sixty. The Superintendent in charge of any National Cemetery is authorized to arrest forthwith any person engaged in committing any misdemeanor herein prohibited, and to bring such person before any United States commissioner or judge of any district or circuit court of the United States within any State or district where any of the cemeteries are situated, for the purpose of holding such person to answer for such misdemeanor, and then and there shall make the complaint in due form. See *Battle-ground Cemeteries*, *Post Cemeteries*, and *Superintendent of National Cemeteries*.

NATIONAL DEFENSE.—The defense of a State or a Nation against invasion. The national defenses of a country consist, besides her armies and reserves, of the navy ; of the fortifications, forts, and fortresses built along the coasts, and on some important strategical points, either inland or on the frontier line; of torpedoes laid down for the protection of harbors, arsenals, etc. When these have been found insufficient, an appeal is made to all men able to carry arms to stand up for the defense of the country, and to repulse the invasion. This is called a *levée en masse*. In England, in the event of a threatened invasion, the volunteers would be called out and mobilised with the different army corps to which they belong.

NATIONAL GUARD.—A body of militia composed ncipally of the Bourgeoisie, first formed by the Committee of safety in 1789, and mustering at one time 300,000 men under the command of Lafayette. Napoleon dissolved them in 1795, and reorganized them in 1814. They were again dissolved in 1827, by Charles X., were reorganized in 1830, deserted Louis Philippe in 1848, were reorganized in 1852, and took part in the Franco-Prussian war and the Insurrection of the Commune.—The same term is applied to the State Militia of New York and New Jersey.

In England the National Guard is an organization for local defense, differing from the British militia and volunteers, in being at the disposal of the Municipalities, not of the Crown. Italy, Greece, and other nations have maintained this civic force; but the country whence it derives historic fame is France. The French National Guard was instituted in Paris in 1789, when the Government had an army of 30,000 at the gates. The Municipality armed 48,000 men, and their example was followed by the chief towns of France. These corps obtained the name of National Guard and assumed the famous tricolor as their ensign. In 1795, 30,000 of the Paris National Guards attacked the Tuileries and were repulsed by Napoleon Bonaparte with 6,000 regular troops. In 1830 they were reorganized under the command of Lafayette, their original chief; and between 1848 and 1851 a law was passed by which all males above 20 not otherwise employed under Government were included in the National Guard. After the *Coup d'Etat* in December, 1851, they were reduced to the condition of an armed police. In the war of 1870-1871 they showed some signs of vitality in sympathy with the Commune, but effected nothing for France. After the fall of the Commune they were disbanded. See *Militia*.

NATIONAL HYMNS.—Popular airs which are peculiar to and characteristic of a particular nation. It is a singular fact that the composers of national hymns are seldom known. The Germans call their national music *volk's musik*, a designation which is very appropriate, as a people collectively may not improperly be considered as the actual composer of its national tunes. A short melody extemporized by some one in a moment of patriotic emotion, is often taken up by others and traditionally preserved. In the course of time it generally undergoes modifications, until it has attained those conditions which insure it a general acceptance. This fully explains what W. Grimm means in his laconic saying, "A national song composes itself" (*Ein Volkslied dichtet sich selbst*), for the attempts of celebrated musicians to invest a tune with universal and permanent popularity have been successful in a few instances only. Among the most popular European national hymns, is *God save the King*, but the authorship of the tune has not hitherto been satisfactorily ascertained. In Prussia it is called *Heil Dir im Sieger Kranz*, and in the United States the melody is sung with the words "*My country 'tis of thee*," etc. Although there is no satisfactory evidence of its having been in existence before the reign of George II., there are several tunes known of an earlier date in some degree resembling it. The Austrian national hymn, *Gotte erhalte* [*Franz*] *den Kaiser*, is a composition by Joseph Haydn. Having during his visit to England witnessed the effect of *God save the King*, on public occasions, Haydn resolved after his return to Vienna, to present his country with a similar composition. Baron Swieten and Count Saurau procured the poetry for him, and the hymn was sung for the first time on the birthday of the Emperor Franz, Feb. 12, 1797. The poetry was written by L. Leopold Haschka. The Russian hymn dates from the year 1830, when the Emperor Nicholas ordered it to be performed in concerts and representations on the stage. Its composer was Alexis Lwoff, and the air appears to have been suggested by the *Sicilian Mariner's Hymn*, which is also a favorite melody of the Gondoliers in Venice. The poetry of the patriotic song of the Danes, *Kong Christian stod ved hoien Mast*, was written by Ewald, and the music is by a German composer, Johann Hartmann. The French national hymn, the *Marseillaise*, dates from the year 1792. It was composed by Rouget de l'Isle, during the French Revolution. The national hymn of the Germans, *Die Wacht am Rhein*, came into great popularity during the Franco-German war of 1870. *Was ist des Deutschen Vaterland* was written by Ernst Moritz Arndt, a German patriot, during the wars of Napoleon I. There have been many attempts to manufacture national songs in the United States, but the great national hymn of America will probably be a spontaneous production. The *Star-Spangled Banner* was written by F. S. Key, in 1814, and the words were adapted by F. Durang to an old French air, long known in England as *Anacreon in Heaven*, and in America as *Adams and Liberty*. It grew in favor in the Loyal States during the Rebellion, and was played continually by all military and orchestral bands. But as a patriotic song for the people at large it is almost useless, as the range of the air, an octave and a half, places it out of the compass of ordinary voices. *Yankee Doodle* has the claim of long association, and will probably always retain a certain degree of favor. Its words are mere childish burlesque, and it is reported to have been a popular tune in England during the Commonwealth. Some state that its doggerel words originated at that time, Oliver Cromwell being designated as Nankee Doodle. Others state that it was the tune originally set to the old English song, *Lydia Locket lost her Pocket*, and that the present words were written by a British Sergeant in Boston in 1775. *Hail Columbia* was written by Joseph Hopkinson in 1798, and was set to the music of the *President's March*, which was composed by one Phylas or Fayles, a German leader of orchestra in New York. *Columbia the Gem of the Ocean*, and Harrison Millard's *Viva l'America* have also attained considerable popularity.

NATIONAL RIFLE ASSOCIATION.—Although the introduction of the rifle as a military weapon was owing to the lessons of our Revolution, and although our success in the earlier contests of our history depended upon the skill in its use displayed by our ancestors, no recognition, until lately, was given by our citizens of the fact that the change which has taken place in the habits of the American people was rapidly depriving them of that personal skill in arms and marksmanship, which hitherto formed one of the greatest elements of our national strength. Other nations have long since instituted a thorough system in rifle practice. France, Germany, Switzerland, and, above all, England and Canada, unite in giving to rifle practice a leading position in their system of military training. 150,000 trained riflemen are a standing proof of the Wimbleton contests in England. So, on our Northern border, Canada boasts her 40,000 skilled shots, and has her annual Local, Provincial, and Dominion matches, by which their skill is maintained. In this country, on the other hand, the matter was entirely neglected, although our entire system of defense is based upon the levying of volunteers in cases of emergency, who, to be valuable, or even available, must understand the use of arms, and supply by their skill as individuals the confidence which discipline gives to regular troops.

While England had a system of rifle practice which was required to be annually and thoroughly performed by every soldier in the army, whether stationed in India, Australia, or Europe, our war Department for a long time sent raw recruits against the Indian sharp-shooters of the plains. In the National Guards a similar apathy prevailed; and it was the rule, not the exception, for a man to serve out his full term of enlistment in their ranks without firing a shot.

This anomalous condition of affairs having excited on siderable discussion among military men through the press, finally, on November 24, 1871, led to the formation in the city of New York of the *National Rifle Association*, which was designed to be the parent of many similar Associations throughout the country, and of uniform practice in the Army. This Association was incorporated under the laws of the state of New York, and included among its incorporators many prominent officers and ex-officers of the Army and National guard.

The main aim of the Association is the encouragement of rifle practice throughout the United States, and the success thus far attained surpasses the most sanguine anticipations. The present scope and condition of the Association will be best comprehended by carefully reviewing the Regulations:

I.—Management.—*A.—Annual Meetings.* 1. Annual meetings for competition will be conducted by an Executive Officer, wearing a *tri-colored* badge, aided by a Statistical Officer, wearing a *blue* badge, a Financial Officer, wearing a *white* badge, a Range Officer, wearing a *red* badge, and assistants, wearing badges corresponding in color to those worn by the chiefs of their respective Departments. 2. The Executive Officer shall have control of the range for the conduct of matches, and shall appoint an Adjutant to assist him. 3. The Statistical Officer shall have charge of all statistics. 4. The Financial Officer shall have charge of all finances connected with these meetings. 5. The Range Officer shall have charge of all Firing Points, and of the shooting thereat. *B.—Other Competitions.* 1. All other association competitions will be conducted by an Officer or Director of the Association, or other competent person previously designated as the Executive Officer. In the absence of the Officer, Director, or other person previously designated, the Assistant-Secretary or Superintendent of Range shall act as the Executive Officer.

II.—General Regulations.— 1. During the progress of a match, no one, except, the Officers, Directors and Employees of the Association, the competitors and the Scorekeepers, will be permitted within the ropes, without special permission of the Range Officer. 2. The squads of competitors will be stationed not less than four yards in the rear of the firing points, where each competitor must remain until called by the Scorekeeper to take his position at the firing point, and until he has completed his score. The Scorekeepers will be seated close to and in rear of the firing point stakes. 3. Scorekeepers shall, as each shot is signaled, call in a loud voice the name of the competitor and the value of the shot, and at the conclusion of the score of each competitor, announce in like manner his name and total score. Competitors must pay attention to the scores as announced and recorded, so that any error may be promptly investigated. 4. All competitors will be allowed to examine the records of the Scorekeeper during the progress of any match. 5. All protests and objections must be made to the Executive Officer, or, in his absence, to the Range Officer in charge. In case a competitor is dissatisfied with the decison of the latter, he may appeal to the Executive Officer. 6. Any competitor feeling himself aggrieved by the ruling of an Executive Officer, may make to the Secretary a statement of his grievance in writing, giving the names of two or more witnesses in the case, which shall be handed to the Executive Committee at its first meeting thereafter for its consideration. The decision of the Executive Committee shall be final, subject, however, to the discretion of said Committee, or any two members of it, to refer the matter to the Board of Directors for its decision. 7. All practice upon the Range is subordinate and must give way to matches of the Association. 8. These regulations, and such special rules or directions as the Executive Officer may give, must be rigidly complied with by competitors and all other persons upon the Range grounds.

III.—Rifles.—The rifles or carbines allowed to be used in the competitions are—1st. Military rifles;

2d. Any rifles; and must comply with the following conditions, viz.: 1. *Military Rifles*, weight (without bayonet) not to exceed 9 pounds, 4 ounces. Stock sufficiently strong for military purposes, and such as to admit the use of a sling; minimum pull of trigger six pounds. Sights to be of *bona fide* military pattern, to be attached to the barrel; the front sight to be immovable. The rear sight may be used as a wind gauge, by the sliding bar or the leaf being moved laterally, either by sliding, or by a screw, or by any similar device suitable for military purposes. Filing or altering the sights of such rifles, or of the rifles used by the National Guard, or Regular forces (except as authorized by the military authorities thereof) is prohibited. The sliding bar of the rear sight may be inverted, and lines drawn to mark the center. Any pad or shoe attached to the butt is prohibited. 2. *Any Rifle*, maximum weight 10 pounds, minimum pull of trigger three pounds; sights of any description, except telescope, magnifying and such front aperture sights as solid disks or bushes pierced in the center, which cover the target so as to conceal the danger signal when displayed. No stirrup constructed of metal or other substance, connected to the rifle by straps of any kind, for the purpose of taking up or lessening its recoil, will be allowed. 3. Competitors shall submit their rifles and ammunition for inspection whenever required. 4. No hair or set trigger will be allowed. 5. No fixed or artificial rests will be allowed.

IV.—Ammunition.—1. In competitions restricted to the use of breech-loaders, the gun shall be loaded at the breech with fixed ammunition. 2. In all other competitions any ammunition may be used.

V.—Targets.—The targets are divided into three classes, and shall be of the following sizes:

1. *Third Class*, to be used at all distances up to, and including 300 yards—Target 4×6 feet.
   Bull's-eye circular, 8 inches in diameter.
   Center " 26 " "
   Inner " 46 " "
   Outer, remainder of target.

2. *Second Class*, to be used at all distances over 300, to, and including 600 yards—Target 6×6 feet.
   Bull's-eye, circular, 22 inches in diameter.
   Center " 38 " " "
   Inner " 54 " " "
   Outer, remainder of target.

3. *First Class*, to be used at all distances over 600 yards—Target 6×12 feet.
   Bull's-eye, circular, 36 inches in diameter,
   Center " 54 " " "
   Inner, square, 6×6 feet.
   Outer, remainder of the target.

VI. Marking, scoring and signaling.—

1. Bull's-eye, counts 5; signal, white circular disk.
   Center, " 4; " red "
   Inner, " 3; " white and black "
   Outer, " 2; " black "
   Ricochet, scored R; " red flag waved quickly twice right and left in front of the target. Ricochet hits will be marked out after the flag signal. 2. When a shot strikes the angle iron upon which the target stands, the marker will open the trap and raise and lower his flag three times in front of the target. 3. Any objection to the record of a shot as signaled or to one not signaled, must be made before another shot is fired. Any competitor challenging the marking of a shot shall first deposit with the Executive Officer, or his representative, the sum of $1.00. If his challenge is sustained the money shall be returned. In case the challenge is not sustained the money shall be forfeited to the Association. The challenger shall be permitted to inspect the target in company with the proper officer. 4 Any alteration of a scoring ticket must be witnessed by the officer in charge of the firing point, and endorsed with his initials.

VII. Running Deer. 1. Will be run only by a signal from the firing point. Any rifle may be used, provided the sights are without traverse adjustment. Position, standing; distance, 100 yards, unless otherwise prescribed. A fine of ten cents will be imposed for firing when out of bounds, not firing, or for hitting the haunch.

Scoring and Signalling.

Bull's-eye, white disk, counts 4,
Center, red " " 3.
Outer black " " 2.
Haunch, white disk, with black cross, scoring H.

VIII.—Bull's-Eye Targets.—1. Bull's-eye targets will be open all the time during the Annual Meetings. 2. Tickets (entitling the holder to one shot at any Bull's-eye target) will be sold at the office of the Financial Officer, upon the Range, at 10 cents each, or twelve for $1.00. 3. Each competitor making a Bull's-eye will receive a Bull's-eye ticket. 4. At the close of the firing each evening, the pool receipts (less one-half retained for expenses) will be divided *pro rata* among those making Bull's-eyes, on presentation of their tickets. 5. No person will be allowed to fire more than three shots consecutively at any Bull's-eye target, provided others are waiting to fire.

IX.—Matches.—1. The commencement of the Annual Meetings will be signaled by the firing of two guns, 15 minutes apart. The first will be the signal for competitors and scorekeepers to assemble at the firing points, and the second to commence firing. 2. The matches will take place, if possible, at the hour previously named. Any deviation from the programmes will be posted upon the Bulletin board as long before hand as practicable. *The posting upon such bulletin board will be considered sufficient notice to all competitors of everything so posted.* It should be examined by all competitors daily, both morning and afternoon, before the shooting commences. 3. In team matches, at Annual Meetings, an officer will be assigned to each of the firing posts as Supervisor, and he will, in connection with the Scorekeeper, keep a record of the firing; and any disagreement between such officer and Scorekeeper, will be decided by the Executive Officer, subject to appeal, as provided for in the Regulations. 4 Each Team may appoint a responsible person to act as Supervisor, whose duty it shall be to see that the rules of the N. R. A. are strictly adhered to by the team at whose target he may be assigned. 5. No practice will be allowed upon the range on any of the days of the Annual Meetings, unless specially authorized by the Executive Officer. This does not apply to days upon which special matches of the Association, or of affiliating associations or clubs take place.

X.—Entries.—*A. Annual Meetings.*—1. For all competitions open to military organizations, the teams shall (unless otherwise specified) consist of twelve from each Regiment, Battalion, Company, or Troop. 2. In all cases competitors for prizes offered to military organizations must be either officers or regularly enlisted members in good standing of the Regiment, Battalion, Company, or Troop which they represent, and shall have been such for at least three months prior to the match for which they are entered. All entries must be made for full teams. 3. Entries must be made at the office of the Association, in New York City, at least *one week* preceding the commencement of the meetings, when the entry books will be closed at the office of the Association, and all subsequent entries shall be called Post Entries, and a charge of 50 per cent. additional will be imposed upon all such Post Entries. 4. Competitors who are prevented from being present at any meeting shall have the entrance fees they have paid returned after the meeting, provided that they send their tickets and give written notice to the Secretary before the day on which the prize for which they have entered has been announced for competition. 5. Competitors prevented from competing by illness will receive back their entrance fee in full, on production of a medical certificate and their entry tickets. 6. The holders of post entry tickets may be ordered to fire whenever target accommodation can be provided, but should they be precluded from competing by deficiency of target accommodation, their entrance fees will be returned to them, the Executive Officer not being able to guarantee accommodation for all such entries. 7. All entries are received upon the express condition that the competitor is to appear at the firing point at the exact time named upon his score card, and complete his score within the limitation of time prescribed, regardless of weather or any other unforeseen cause. 8. The same person shall not be a member of more than one team in the same match. 9. Competitors selected to shoot in team matches, or who are detailed to shoot off a tie at a particular hour, and who find that such engagements will interfere with their shooting in other competitions, must at once communicate with the Executive Officer. These cases will be provided for, *when possible*, by altering the hour; and when that cannot be done, the entry will be cancelled and the entrance fee refunded.

B.—General Regulations.—1. A member of the Association entering for or shooting in a match on the range must exhibit his badge. 2. A register ticket may be transferred at any time before the firing for the match has commenced, by exchanging it at the office of the Statistical Officer for one having the name of the new holder. It is available only for the hour and target for which it was originally issued. Any erasure or alteration not initialed by the Executive Officer will render the ticket invalid. 3. No post entries shall be received for any competition after the firing in such competition has commenced, unless expressly permitted by the terms of a match.

XI.—Shooting.—1. Competitors must be present at the firing points punctually at the time stated upon their tickets, or forfeit their right to shoot. 2. After a competitor has joined a squad he shall not quit it until he has completed his firing, or retired. 3. No two competitors shall shoot in any match with the same rifle, nor shall a competitor change his rifle during a competition, unless expressly permitted by the terms of a match, or unless his first rifle has become unserviceable through an accident, which must be verified by the officer in charge of his firing point. 4. In all competitions confined to members of military organizations, competitors shall shoot in the authorized uniform of their corps, including waist belts. 5. In each match of the Annual Meetings, except where otherwise stated, the squad or team assigned to each target will be required to commence firing at the time named on the score card, and to continue firing at the rate of one shot per minute until the completion of the score. 6 The time for each squad to commence and close will be signaled by firing a gun every thirty minutes, from 9 A. M. to 5.30 P. M., and no firing by any of its members will be permitted except between those signals. In case a competitor, without fault on his part, has been prevented from finishing his score within that time, he may apply to the Executive Officer for further assignment, the granting of which will be in the discretion of that officer. 7. Competitors retiring from matches forfeit all claims therein. 8. *No sighting shots will be allowed in any match*, but targets will be assigned as *Bull's-eye Targets* at which competitors may practice at any time, provided such practice does not in any manner interfere with their presence at the designated time at the firing point to which they may have been previously assigned. 9. In all competitions restricted to military rifles the competitors shall place themselves at the firing point by twos, and shall fire alternately until they have fired all their shots. 10. In other competitions the competitors shall fire their shots alternately throughout the squad. 11. Competitors may wipe or clean their rifles during any competition, except those restricted to the use of military rifles. In competitions at more than one distance, restricted to military rifles, cleaning will be permitted between distances. 12. Whenever the danger flag is displayed, competitors about to fire will be required to open the breech block of their rifles (if breech-loaders). If they leave the firing point they must withdraw the cartridge. 13. Any competitor delaying his squad will be passed by. In no case will the firing be delayed to enable a competitor to procure a rifle. 14. Competitors must shoot their scores at different distances in the order named in the conditions of the competition.

XII.—Position.—1. In all matches (except those specially for carbines), the position up to and including 300 yards, shall be standing. The left elbow may be rested against the body, provided the little finger of the left hand is in front of the trigger guard. 2. In carbine matches, the position at 200 yards shall be standing; at 300 yards, kneeling; over that distance, in any position (as prescribed for infantry). 3. In all other matches, at distances above 300 yards, any position may be taken without artificial rest to the rifle or body. 4. One-armed competitors will be allowed to use false arms, without extra support, in the standing and kneeling positions, and to assume any position in the use of military rifles, at distances above 200 yards. 5. Shots at Bull's-eye targets, at all distances, beyond 300 yards may be fired in any position without artificial rest. 6. In all cases the rifle shall be held clear of the ground.

XIII —Ties.—1. Ties shall be decided as follows:

A.—In Individual Shooting. 1. When the firing takes place at more than one distance, by the total score made at the longest distance; and if still a tie, and there be three distances in the competition by the total score at the second distance. 2. By the fewest misses in the entire score. 3. By the fewest outers in the entire score. 4. By the fewest inners in the entire score. 5. In handicap matches (after the preceding), by the fewest centers in the entire score. 6. If still a tie, by inverse order of shots, counting singly from the last to the first. 7. In matches where two or more scores added together count, if still a tie, by adding together the last shots of each single score, and if still a tie, by adding together the next to the last and so on. 8. By firing single shots at the longest range.

B.—In Team Shooting. 1. By the aggregate total score made at the different distances in inverse order. 2. By the fewest misses in the entire score. 3. By the fewest outers in the entire score. 4. By the fewest inners in the entire score. 5. By the total of each round in inverse order. 6. By the competitor on each side who has made the highest score, firing five rounds at the longest distance. II. The names of competitors who have to shoot off ties will be posted on the Bulletin-board as soon after each match as practicable. III. When the ties are shot off, one sighting shot shall be allowed without charge IV. Competitors not present at the firing points at the hour named for shooting off ties, loose their right to shoot. V. If, having forfeited their right to compete, they shall still be within the number of prize winners, they shall take any prize that may be allotted to them by the Executive Committee.

XIV.—Prizes. 1. Prize winners, upon application to Statistical Officer on the range, will receive certificates, which must be given up on receiving the prizes. 2. Prizes will be delivered on the range at the close of the meeting, under the direction of the Prize Committee, unless otherwise specified. 3. All prizes and Bull's-eye money not claimed within thirty days after the day on which same was won, shall be forfeited to the Association.

XV.—Penalties.—Competitors must make themselves acquainted with the regulations, as well as with the conditions of any match for which they may have entered, as the plea of ignorance of either of them will not be entertained. *Disqualification*: Any competitor (*a*) who shall fire in a name other than his own, or who shall fire twice for the same prize, unless permitted by the conditions of the competition to do so, or (*b*) who shall be guilty of any conduct considered by the Board of Directors or the Executive Committee as discreditable; or (*c*) who shall be guilty of falsifying his score or being accessory thereto; or (*d*) who shall offer a bribe of any kind to an employee—shall, upon the occurrence being proved to the satisfaction of the Board of Directors or the Executive Committee, forfeit all his entrance fees, be forever disqualified from competing at any time upon the range of the association, and shall not be entitled to have any prize won by him at the time or meeting awarded to him.

Exclusion from all further Competition. 1. Any competitor who shall be detected in an invasion of the conditions prescribed for the conduct of any match, shall be ruled out of such competition. 2. Any competitor, in any meeting or match, refusing to obey any instructions of the Executive Officer, or his assistants, or violating any of these regulations, or being guilty of unruly or disorderly conduct, or being intoxicated, will be immediately ruled out of all further competition, during such meeting or match, and forfeit his entrance fees; and may also be reported to the Board of Directors or the Executive Committee, and be by them disqualified from the use of the Range. 3. Any competitor firing when the danger flag or trap disc is shown at the target or firing point, or knowingly discharging his rifle except at a target to which he has been assigned or into the blowing-off pits, or as may be directed by an Officer, shall be debarred from all further competitions during the meeting, and shall forfeit his entrance fees. This shall not apply to a competitor accidentally firing at the wrong target, when no danger disc is up. 4. Any person discharging a rifle or snapping a cap within the inclosure, except in accordance with the regulations for shooting may, at the discretion of the Executive Officer, be required to leave the ground. 5. Any competitor or other person found with a loaded rifle except at the firing points and when about to shoot, shall be debarred from further competition during the whole of that meeting or competition. 6. Any person, whether a competitor or not, interfering with any of the firing squads, or annoying them in any way will be at once expelled from the ground. 7. Any competitor discharging his rifle accidentally, either by his own want of care or by reason of any defect in the rifle, shall be disqualified from further competition in the match. 8. Should a competitor lose his register ticket, omit to take it to the firing point, fail to attend at the prescribed hour, or give a wrong ticket, and so by his own neglect miss the opportunity given to him of competing for the prize for which his ticket was issued, his claim in regard to such competition shall be cancelled. 9. Any person firing on a wrong target will be reported by the scorer to the Executive or Range Officers present and will be fined $1.00 or be debarred from further competition; or both, in the discretion of the Executive Officer. 10. Any person ruled out of any meeting or competition shall forfeit all entrance fees.

NATIONAL SALUTE.—A salute of one gun for each State in the Union. This salute is fired at noon on the anniversary of the Independence of the United States at each military post or camp provided with artillery. See *Salutes*.

NATIONAL TROOPS.—Troops raised under the authority of Congress, in contradistinction to the Militia, which may be called State troops, being organized by the several States.

NATURAL ANGLE OF SIGHT.—The angle which the *natural line of sight* makes with the axis of the piece.

NATURAL FORTIFICATION.—A fortification consisting of those obstacles which nature affords to retard the progress of an enemy; such as woods, deep ravines, rocks, marshes, etc. The term is employed in contradistinction to *Artificial Fortification*, or that which is raised by human ingenuity to aid the natural advantages of the ground, or supply its deficiencies. See *Fortification.*

NATURAL LINE OF SIGHT.—The right line passing through the highest point of the line of metal at the muzzle, and the highest point of the same line in rear of the trunnions. See *Line of Metal.*

NATURAL POINT-BLANK.—The point-blank is the point at which the line of sight intersects the trajectory the second time; or, more practically speaking, it is that point which, being aimed at, is struck by the projectile. The *natural point-blank* corresponds to the natural line of sight when this line is horizontal, and the distance of this point from the muzzle is called the *point-blank range*.

NATURAL STEEL.—A variety of steel which is obtained by reducing the rich and pure kinds of iron ore with charcoal, and refining the cast-iron, so as to bring it to a malleable state. It is made principally in Germany, and is used for making files and other tools. The India steel, called *wootz*, is said to be a natural steel, containing a small portion of other metals. See *Shear Steel* and *Steel.*

NAVAL CAMP.—In military antiquities, a fortification, consisting of a ditch and parapet on the land side, or a wall built in the form of a semi-circle, and extended from one point of the sea to the other. This was beautified with gates, and sometimes defended with towers, through which the defenders issued forth to attack their enemies. Towards the sea, or within it, they fixed great piles of wood, like those in their artificial harbors; before these, the vessels of burden were placed in such order, that they might serve instead of a wall, and give protection to those without; in this manner, Nicias is reported by Thucydides to have encamped himself. When their fortifications were thought strong enough to defend them from the assaults of enemies, the ancients frequently dragged their ships on shore. Around these ships the soldiers disposed their tents, as appears everywhere in Homer But this seems only to have been practiced in winter, when their enemy's fleet was laid up, and could not assault them; or in long sieges, and when they lay in no danger from their enemies by sea, as in the Trojan war, where the defenders of Troy never once attempted to encounter the Grecians in a sea-fight.

NAVAL CROWN.—In Heraldry, a rim of gold round which are placed alternately prows of galleys and square sails. The device is said to have originated with the Roman Emperor Claudius, who, after the conquest of Britain instituted it as a reward for maritime services. He who first boarded the enemy's ship, and was the occasion of its being captured, was entitled to a naval crown. A naval crown supporting the crest in place of a wreath occurs in various grants of arms in the early part of the present century, to the naval heroes of the late war. The crest of the Earl of St. Vincent, bestowed on him after his victory over the Spanish fleet in 1797, is issuing out of a naval crown or, enwrapped by a wreath of laurel vert, a demi-pegasus argent maned and hoofed of the first and winged azure, charged in the wing with a fleur-de-lis or.

Naval Crown.

NAVAL HOWITZER.—A bronze shell-gun, adapted to field and boat service. They are made of bronze on account of their comparative lightness for the same strength, and from their being less liable to burst than iron guns of the same caliber. They are both smooth-bore and rifled, and are alike in the principle of construction and general appearance, and differ only in weight and dimensions. Around the charge the metal is distributed in the form of a cylinder, extending sufficiently in front of the seat of the projectile; thence to the muzzle it is continued as a truncated cone.

NAVE.—The central portion of a wheel; it is generally composed of a cylindrical block of wood in which the spokes are firmly fixed, and in which the axle-arm works. This has hitherto been the nave of all artillery carriages in the British service, but in the newly constructed wrought-iron carriages the Madras pattern nave, made of metal, with some slight modification, has been adopted. In the Madras wheel, as originally formed, the nave-box is made of gun-metal, and cast in one piece with one of the plates, but the principle of construction is the same whether it be so united or cast separately. Between the two plates, 12 spokes are placed, so formed that the parts which enter the nave are in close contact with each other, and with their ends forming an arch completely round, but not quite touching, the nave box. The whole construction is then firmly bolted together, with 12 triangular bolts passing through holes in the discs, and fitting into the triangular spaces formed between each spoke by their radiation from each other. These bolts have circular heads, and when driven into their places, their ends are secured outside by nuts. The naves are in two or three parts. The great advantage in the latter is that the top and bottom, as two of its parts are termed, are almost rendered perpetual, whereas in the nave in two parts, if the box wears and therefore becomes unserviceable, the box with bottom, altogether nearly three-fourths of the nave, is rendered useless, and must be renewed; but with the nave in three parts, the box alone is renewable if it wears away. In the late Madras artillery, the *gun-metal nave* had been in use for the last sixty or seventy years, and no failure of its strength or want of durability had ever been reported. For many reasons it was a great improvement on the *block nave*. Its durability was apparent after the occupation of Burmah in 1852, and subsequent years. In that country, for a long period after it was annexed to the British possessions, gun carriages, Bengal and Madras, had for want of cover to stand out exposed to sun and rain. During that period not a Madras wheel was the worse for exposure, whereas the majority of the Bengal wheels had large deep slits in the wooden naves, which necessitated their being replaced and the wheels set up afresh. Side thrusts on the wheel tend to shear the material of the nave (if it be of wood), and to bend the flanges when of metal. The amount of material and its disposition in the nave, must be fixed with special reference to these side thrusts. The strains in the planes of traction are but slight, on account of the small inertia of the nave about its axis. See *Archibald Wheel*.

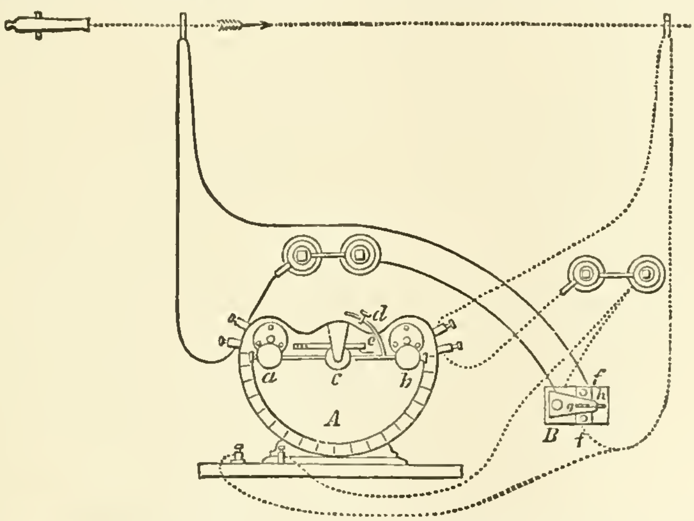
NAVE-BOXES. Boxes which are placed in the naves; they were formerly made of brass, but experience has shown that those of cast-iron cause less friction, and are much cheaper. There are two, one at each end, to diminish the friction of the axletree against the nave.

NAVE-BRAKE. A contrivance for skidding the weeels of gun carriages in order to increase the frictional resistance, at the time of recoil. The two halves of the brake clasp the nave with more or less tightness. The attachment between the brake and the nave is only a frictional one, and a certain amount of slipping round occurs if there is a very violent recoil.

NAVE HOOPS.—Flat iron rings used to bind the nave; there are generally three on each nave.

NAVEL.—A lug with a hole through it on the under side of a carronade, used to connect it with its carriage.

NAVEZ-LEURS CHRONOSCOPE.—This is probably the most successful of all the pendulum instruments, where the value of the time is expressed in arc. It may be said to consist of two separate instruments, the *pendulum* and the *disjunctor*. The pendulum is an upright plate of vulcanite with a graduated arc, *A*, mounted on a stand, and supporting two pendulums, two electro-magnets, a pair of springs, and the pivot upon which the escapement system works. One of the pendulums, *a*, is termed the *chronometer pendulum*, and the other, *b*, the *register pendulum;* and the magnets are so adjusted, one behind each pendulum, that when magnetized by a current of electricity they will just sustain the bobs of their respective pendulums, into both of which a piece of soft iron is inserted. An index-needle, having a vernier at the end to slide along the graduated arc, is riveted to a steel disc, *c*, working in the same axis as the chronometer pendulum, with which it oscillates, simply by friction, until clamped by the action of the escapement. The springs are attached to the vertical plate, and pass one on each side of the steel disc, *c;* near the ends of the springs are two cleats, one on each spring, between which a wedge-lever, *e*, can be adjusted to keep the springs apart: two other cleats close on the disc of the index-needle, which is between the springs, when the wedge-lever, *e*, is displaced by the face of the stirrup, *d*.



____________Circuit from battery which magnetizes the chronometer electro-magnet.
..........................Circuit from the battery which magnetizes the register electro-magnet.
- - - - - - - - - - - - - - -Arrangement of the second circuit to investigate the value of the coefficient x.

The rod of the register pendulum is provided with an arc carrying a stirrup, *d*, which in its descent when the pendulum is released, knocks away the wedge-lever, *e*, from between the springs, and so closes them upon the disc, *c*, of the index-needle, thus clamping it. The disjunctor consists of a small stand, *B*, on which are two pieces of brass, *ff*, each provided with a pressure-screw, a brass spring, *g*, fastened by another pressure-screw, and a cam, *h*, to work the spring: the brass pieces have platinum points, separated from each other by a very short interval, and the spring has also a platinum point below it, which, when pressed down by the action of the cam, connects the two other points; thus connecting, when requisite, the circuits through the apparatus.

The electric currents are obtained by means of Bunsen's voltaic batteries, there being two circuits for an ordinary experiment, one passing through the magnet of the chronometer pendulum on the first screw, the other through the magnet of the register pendulum and the second screw; as both pass through the disjunctor, the simultaneous disjunction of both circuits can be effected by turning the cam, releasing the spring, and so disconnecting the platinum points. The apparatus is placed in a small house at a distance of about 130 yards from the gun, so that it may not be effected by the firing, and the arrangement of the gun and targets is as follows: The first target is placed at a distance of 10 yards in front of the muzzle of the piece, and the second target 40 yards beyond the former; both targets are of the same construction and dimensions; each consisting of a wooden frame having copper wires stretched across in parallel rows by means of pins in the sides of the frame, and these wires are broken by the passage of the projectile through them. In order to protect the wires of the first target from the action of the gas, a wooden screen is placed about 40 inches from this target, between it and the gun; the screen has a circular hole, about 1½ calibers in diameter, through which the projectile passes. When the gun is fired, the projectile passes through the first target, breaks the first circuit, and demagnetizes the magnet of the chronometer pendulum; the bob begins to fall, carrying with it the index-needle. When the projectile cuts the wires of the second target, the circuit is broken, and the magnet of the register pendulum is demagnetized; the bob falls, carrying with it the arc and stirrup, which in its descent knocks away the wedge-lever and clamps the index-needle. The time due to this arc of vibration can, by the theory of the pendulum, be readily ascertained, but it must be greater than the time taken by the projectile to pass from one target to the other; for a certain small interval of time elapses between the rupture of the second circuit and the clamping of the index-needle. This small portion of time is found by means of the disjunctor, before the gun is fired, by breaking both circuits at once, and the small arc so found must be deducted from the arc determined by firing the gun. See *Chronoscope*.

NAVICULAR DISEASE.—A disease in the horse, consisting in strain of the strong flexor tendon of the foot, at the point within the hollow of the fetlock, where it passes over the navicular bone. It is most common amongst the lighter sorts of horses, and especially where they have upright pasterns, outturned toes, and early severe work on hard roads. It soon gives rise to a short, tripping, yet cautious gait, undue wear of the toe of the shoe, wasting of the muscles of the shoulder, and projecting or "pointing" of the affected limb whilst standing. When early noticed, and in horses with well-formed legs, it is often curable; but when of several weeks standing, it leads to so much inflammation and destruction of the tendon and adjoining parts, that soundness and fitness for fast work are again impossible. Rest should at once be given, the shoe removed, the toe shortened, and the foot placed in a large, soft, hot poultice, changed every few hours. Laxative medicine and bran mashes should be ordered, and a soft bed made with old short litter. After a few days, and when the heat and tenderness abate, cold applications should supersede the hot; and, after another week, a blister may be applied round the coronet, and the animal placed for two months in a good yard or in a grass field, if the ground be soft and moist; or, if sufficiently strong, at slow farm-work on soft land. Division of the nerve going to the foot removes sensation, and consequently lameness; and hence is useful in relieving animals intended for breeding purposes or for slow work. The operation, however, is not to be recommended where fast work is required; for the animal, insensible to pain, uses the limb as if nothing were amiss, and the disease rapidly becomes worse.

NEBULY.—One of the partition lines in Heraldry, which runs out and in, in a form supposed to represent the uneven edges of clouds.

NECESSARIES.—The articles issued to the British soldier, such as boots, shirts, stockings; razor, etc., which are requisite for his comfort and cleanliness. These are technically termed *regimental necessaries*. Non-commissioned officers are not allowed to sell regimental necessaries to the soldiers. Every article is directed by the Regulations to be marked with the owner's name, the letter of his company, and the number of his regiment; and the sale or injury of them renders him liable to be tried by Court-Martial and punished.

NECK.—The elbow or part connecting the blade and socket of a bayonet. See *Bayonet*.

NECK COLLAR.—A piece of armor which supported the whole of the rest of the harness. This must not be confounded with the *gorget*, underneath which it was placed, and which, like it, was formed of several plates.

NECK LINE.—An old term in fortification signifying the gorge.

NECK OF A CASCABEL.—The part joining the knob to the base of the breech. See *Cascabel*.

NECK OF A GUN.—The small part of the piece in front of the chase.

NEEDFIRE.—Fire obtained by the friction of wood upon wood, or the friction of a rope on a stake of wood, to which a wide-spread superstition assigns peculiar virtues. With varieties of detail, the practice of raising needfire in cases of calamity, particularly of disease among cattle, has been found to exist among most nations of the Indo-European race. It has been supposed effectual to defeat the sorcery to which the disease is assigned. When the incantation is taking place, all the fires in the neighborhood must be extinguished and they have all to be relighted from the sacred spark. In various parts of the Scottish highlands the raising of needfire was practiced not long ago, and it is perhaps still had recourse to in some very remote localities. The sacrifice of a heifer was thought necessary to insure its efficiency. The ways of obtaining fire from wood have been various; one is by an apparatus which has been called the "fire-churn," a cylinder turning on a pivot, and furnished with spokes, by means of which it is made to revolve very rapidly, and fire is generated by the friction. Fire struck from metal has been supposed not to possess the same virtue, and in some instances the persons who performed the ceremony were required to divest themselves of any metal which might be about them. In its origin the fire-churn was considered a model of the apparatus by which the fires of heaven were daily rekindled. It is still in daily use in the temples of the Hindus. The same superstition was doubtless the origin of the story of Prometheus.

NEEDLE.—An instrument of metal, or other material, for the purpose of carrying the thread in sewing, embroidery, knitting, netting, and other similar operations. Needles are generally made of metal, but bone, ivory, and wood are also used; for ordinary needlework, called sewing, they are made of fine steel, and are too well known to need description; for other kinds of work they are often much larger and differently formed, according to the requirements of the work to be done. The *magnetic needle* is a slender bar, usually pointed and resting on a pivot, in a compass, so as to turn freely towards the magnetic poles of the earth by virtue of the magnetic polarity with which it has been artificially endued.

NEEDLE GUNS. To be loaded at the breech, and to be fired by the penetration of a needle into, or the impinging of a piston on, a detonating cap within the cartridge, are distinct attributes in a weapon; and although it is only within the last fifty years that the system has been carried out with success, breech-loading arms have been tried, accepted, and abandoned without number during the last three centuries. Indeed, a sort of instinct dictates that loading at the breech is the preferable course; and all the earliest muskets were so made, the system being doubtless abandoned from the difficulty of accurately closing the breech, in those days of rough workmanship. The extraordinary efficacy of breech-loading arms for military purposes was brought prominently forward during the wars of the last few years, and notably in the Prussian campaigns of 1864 against Denmark, and of 1866 against Austria. The successes of the Prussian arms were attributed in no small degree to the rapidity with which their troops could fire as compared with the enemy. They had, in greater or less numbers, borne these same rifles since 1835, but these were the first opportunities of using them in warfare. To all the other powers, whose men still carried muzzle-loading rifles and who had debated, without practical result, for years past the question of armament with breech-loaders, soldiers thus armed appeared irresistible. From July, 1866, to the present moment, the hammer and the anvil have been busy night and day throughout the civilized world in making the weapons of death yet more deadly. Scarcely two countries seem to have adopted the same plan; each nation has elaborated a system from among its own inventors. Those possessing no great reserve of rifles have prepared new arms; but the majority of Governments have been content, in the first instance, to convert their existing stock into breech-loaders of as good a construction as circumstances would permit. Thus, Britain, after offering a handsome prize for the best design, selected one said (subject to some controversy) to be the invention of the late Mr. Snider. It is to be borne in mind that the British Government only regarded the Snider arm as a make-shift for the conversion of the enormous stock of Enfield rifles then in hand, reserving to itself the ultimate selection of a suitable pattern on which to manufacture new weapons. It is not to be understood from what is said above that Britain adopted a breech-loading arm in a sort of panic *after* the battle of Sadowa. It was after the Danish Campaign, on the 11th July, 1864, that it was decided as an abstract question to arm the British infantry with breech-loaders; a portion of the cavalry having for a number of years previously been armed with Sharp and Westley Richards carbines, loading at the breech. The selection of an arm took longer; but by the beginning of 1865 it had been decided to convert the great stock of rifles on the "Snider" system. In 1869 it was determined that new arms should be on the Martini-Henry system—i. e , with the Henry barrel, and the Martini breech action. The advantage of breech-loading is obvious; to be able to insert the charge at the breech end instead of the muzzle, is to save time, and to avoid exposure to hostile fire during the operation of loading and ramming home, which involves considerable outstretching of the limbs. The great condition of success is, that the bullet shall be propelled with equal force and accuracy, and with equal safety to the rifleman, as from the muzzle-loader. When a charge is ignited, the constituents of the gunpowder, assuming a gaseous condition under the heat engendered, expand into a volume of light gas many times greater in bulk than the powder before occupied. On the amount of this expansion and its sudden action on the projectile, the force of the shot depends. Any joint in the breech-piece through which a portion of this gas can escape, without having imparted its thrust to the ball, tends, therefore, to lessen the range and penetration; while the shock of the explosion falling more severely on this than on any other part of the barrel, tends yet more to dislocate the breech-piece, and diminish the closeness of the joint's fit. In weapons which do not call for a long range, as revolver pistols, a perceptible interval is left between the chamber and barrel, through which much gas escapes; but in rifles, which have range and penetration as principal objects, there is *prima facie* ground for preferring a muzzle-loader. The gas, however, is far from pure, as generated in the barrel, for much water is produced and held in suspension, while there is also a solid residuum consisting of unburned materials of the powder. In the muzzle-loader, these clog (or, technically, foul) the barrel, filling the grooves, and rendering the ramming home of succeeding charges more and more difficult. The effect is, that a solid mass of unburned matter is gradually forced by ramming into the head of the barrel, destroying the accuracy and usefulness of the weapon. In the breech-loader, this solid deposit must be provided against both ways. The backward throw on firing (for, of course, the charge explodes with equal power in every direction) tends to force it into the mechanism of the joints, preventing their proper fit, and continually augmenting the escape of gas; and, on the other hand, the deposit in front is most detrimental to accuracy of fire. This protection of the breech apparatus, the prevention of fouling, and the retaining, and, if possible, improving the force and accuracy of fire, were the problems which inventors have had to solve.

A moderate escape of gas in front of the first position of the ball, is not under any circumstance, found to be of any material disadvantage. If, then, the barrel could have an opening where the cartridge could be inserted, and then pushed backwards, an escape of gas through the joints by which the opening might be subsequently closed would be comparatively immaterial; but this formation would be impracticable, because the explosion of each cartridge would drive the fouling more and more backwards, till ultimately the chamber at the breech would be unable to contain the cartridge. It is clear, therefore, that the charge must be inserted either at the barrel's head, or, if the barrel be opened, in a space close to the barrel's head. In either of these cases, the breech must be solidly closed to resist the explosion. A third case, as in the Snider, is where the cartridge is inserted and then pushed forward, the aperture being closed by a solid breech-piece which completely fills that portion of the barrel, and forms, with the barrel's head, a massive foot to resist the backward pressure of the fired powder. No breech action can be made to fit so accurately, as to prevent a backward escape of gas unless a properly-constructed cartridge-case is used. A perpendicular moving joint is found in practice to be the one which is best adapted for preventing a serious escape of gas. In the Prussian needle-gun, the end of the barrel is the frustum of a cone, which fits into a corresponding cavity in the fore-end of the breech-piece, but in practice this joint is not sufficiently tight to prevent an escape of gas from the self-consuming cartridge used with this gun, which becomes inconveniently great after long use of the weapon, and it is only available when the breech-piece is pushed up from the rear. In the Snider and several other breech-loading weapons, the cartridge is made itself to close hermetically the aperture between the barrel and the fore-end of the breech-piece. This is effected by the expansion of the cartridge-case which, being composed of metal, or a combination of metal and paper, is driven out by the force of the explosion till it completely fills the chamber and prevents any escape backwards between the sides of the case and the chamber. The cartridge has a portion of its case at the base flattened out into a rim which fits into a corresponding recess in the end of the barrel; and to prevent expansion backwards, which would fracture the cartridge-case, and injure the breech or the firer, the breech-piece is made to fit as closely as possible against this base. This rim is on the Snider cartridge.

The Prussian gun, although it may be said to be now obsolete (having been superseded by the Mauser, a bolt gun on much the same principle, but using a metallic cartridge-case), was first in the field. As regards its breech-apparatus and needle-lock, it consists of three concentric hollow cylinders, with a solid cylindrical bolt inside the last (Figs. 1 and 2).

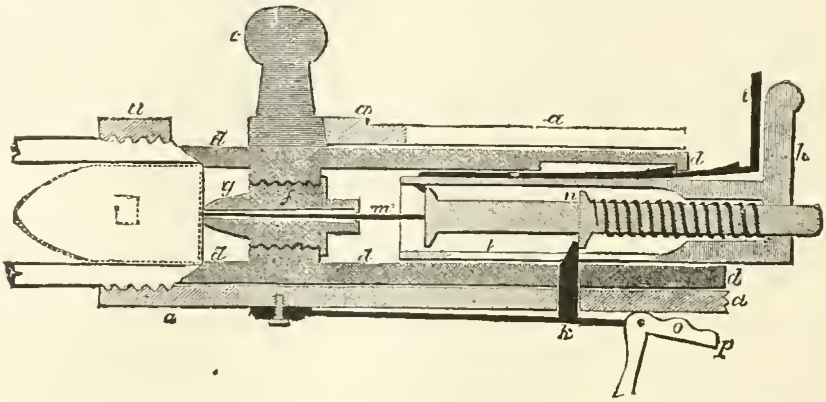


Fig. 1.

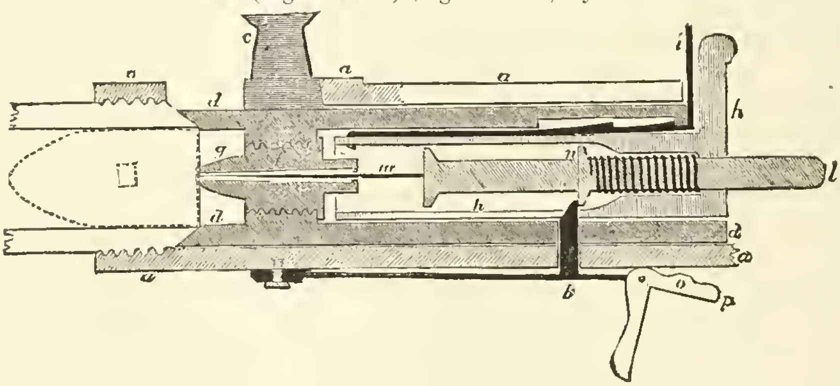

Fig. 2.

The rear-end of the barrel is firmly screwed into the head of the chamber, *a*, which is fixed to the stock of the piece, and is open at the rear-end. The upper half of the cylinder is cut away at the front end for rather more than the length of the cartridge; this constitutes the opening in which the musketeer inserts the cartridge. From the rear of this opening to the back, a groove is cut, sufficiently wide to allow the square pillar of the breech-handle, *c*, to pass along it. In the middle of this groove is a right-angled shunt, offering a stop to the breech-handle when drawn backwards, unless it be likewise turned downwards when it may be passed completely out at the rear end. Next within the chamber is the breech-piece, which, to admit the cartridge, is drawn back for a sufficient distance by the breech-handle along the groove. When the cartridge is deposited in the recess in the chamber, this breech-piece is closed against the heel of the barrel by moving up the handle to the front end of the groove, and then turning it down to prevent it from being driven back on the explosion of the charge; representing, indeed, the resistance offered by the heel of an ordinary muzzle-loading barrel. Firmly screwed within the breech-piece, at a short distance from its front, is a solid block of metal, on which impinges the first force of the explosion. Projecting from this block to the base of the cartridge is a strong *tige*, or pillar, around which a suitable space containing air is left. Through this same pillar is the channel for the needle to work. Fitting within the rear-end of the breech-piece is a smaller cylinder, *h*, constituting the lock of the gun. It slides within the breech-piece, and is retained from falling out backwards by the spring, *i*, which catches in a notch, *d*. Along the bottom of this cylinder is a groove to admit the passage of the trigger, *k*, and at the back is a short, upright handle, by means of which the weapon is cocked. Lastly, within the lock is a bolt, *l*, pressed forward by a spiral spring, and having the needle, *m*, rigidly fastened to its front end. Having now described the several parts of the rifle, it is easy to follow it from the moment of a shot being fired until the next is ready for discharge. The soldier first presses down the spring, *i*, with his finger, releasing the catch below it, and enabling him to draw back the lock to the next catch on the spring (Fig. 1.) Having done so, he raises the breech-handle to the perpendicular, and passes it along the groove to open the breech. This done, he places the cartridge in the opening thus made in the chamber, and again moving up the breech-piece to close the breech, the tige in it pushes the cartridge forward into the barrel, and the rifle is at once at "half-cock;" for in drawing back the lock, the front point of the spring, *i*, forced the bolt, *l* (including the needle *m*), with it, and the projection, *n*, on it, having passed over the head of the trigger, *k*, is caught by the latter in a way which can only be released by the falling of the trigger.

It will be observed that at half-cock the needle is ready to penetrate the cartridge, but that the spiral spring is loose and without power. To "full-cock," no more is necessary than to push *h* back to its original position. It cannot take the bolt, *l*, with it, as the trigger retains it to the rear. The position (Fig.2) is now obtained, in which the bolt, *l*, projects at the back, and the spiral spring is compressed into a state of passive strength. All that is now needed to fire the gun is to press upon the trigger, until the point *o* bears, when the bolt, *l*, being released by the depression of *k*, the spiral spring asserts its power, and drives the needle into the heart of the cartridge, the parts all resuming their original positions. At first sight, one cannot help exclaiming: "What a complicated apparatus with the four cylinders and the springs"; but, in reality, it is as simple as almost any other gun, for the whole mechanism of the lock is dispensed with. If it be desired to take the needle-gun to pieces, press the trigger till the point, *p*, bears. If the breech-handle be then in the hinder part of its groove, the breech-piece with its contents will slip out of the chamber. Pressing down, next, the spring *i*, until the second catch is passed, there is nothing to retain the lock, *h*, in the breech-piece; and the lock being free, the needle, with its attached bolt and spring, falls readily out of its fore-end. The gun is thus taken to pieces in a few seconds, and as many suffice to put it again in fighting order. The most delicate portions are the needle and the spiral spring; but in case of accident to these, there is a spare one in a small cavity opening by a spring in the butt-end of the stock. The worst feature about this celebrated gun is its weight, 12 lbs., or 33 per cent. heavier than the Enfield or Snider rifle. See *Prussian Needle Carbine* and *Prussian Needle-gun*.

NEESHUNGPAT.—An Indian term expressing a violent assault without bloodshed.

NEGATIVE.—1. A term used to express the result of measures or enterprises which, though not entirely successful, are not productive of serious or mischievous consequences. Hence the British expeditions to Spain and Walcheren may be considered as having had negative success. 2. In photography, that kind of photographic picture in which the lights and shadows of the natural object are transposed; the high lights being black, and the deep shadows transparent, or nearly so. Negatives are taken on glass and paper by various processes, and should indicate with extreme delicacy, and in reverse order, the various gradations of light and shade which occur in a landscape or portrait. A negative differs from a positive inasmuch as in the latter case it is required to produce a deposit of pure metallic silver to be viewed by *reflected* light; while in the latter, density to *transmitted* light is the chief desideratum; accordingly inorganic reducing and retarding agents are employed in the development of a positive, while those of organic origin are used in the production of a negative.

NEGATIVE HAUSSE.—In order to strike an object at a distance less than point-blank range, it will be necessary to diminish the angle that the axis of the piece makes with the natural line of sight. This will be accomplished by diminishing the difference between the radii of the muzzle and base-ring. This amount, required to be taken from the radius of the base-ring, is generally called the *negative hausse*.

NEGATIVE PENALTY.—The term applied to such punishments as removal from command, bars to indulgence, reprimands, etc.

NEGLECT OF DUTY.—Total omission or disregard of any prescribed service, or unsoldier-like execution. All crimes not capital, and all disorders and neglects, which officers and soldiers may be guilty of, to the prejudice of good order and military discipline, though not mentioned in the Articles of War, are to be taken cognizance of by a General, or a Regimental, Garrison, or Field Officers' Court-Martial, according to the nature and degree of the offense, and punished at the discretion of such Court.

NESHAUMBURDAR.—The Indian name of an Ensign.

NETLEY HOSPITAL.—The Royal Victoria Hospital, at Netley, is a superb building, on the shore of Southampton water, for the reception of invalids from the army on foreign service, and from among the troops serving in the adjacent military districts. In times of peace, it is only necessary to use a portion of the vast structure; but in the event of a European war, in which the British army should take part, the exigencies of the service would probably tax its accommodation to the utmost. There is provision for 1,000 patients with power to increase the number if necessary. The Medical Staff of course varies in proportion to the work to be done; but at present it consists of a Governor, an Adjutant, a Paymaster, an Assistant-Commandant, and Medical Officers, and Officers of Orderlies of various ranks. The total cost of the construction of this hospital, which was commenced in 1855, has been about £350,000. Attached is the Medical School for candidates for the army Medical Department, the students having the best means of practical instruction in the wards of the hospital. Netley is also the head-quarters of the female nurses of the army, who are under the control of a lady stationed there as Superintendent. Complete arrangements have been made for the landing of wounded men in front of the hospital and for conveying them thither with the least disturbance. There is no doubt as to the convenience of this great hospital for its purposes; but some questions have been raised, under high sanitary authority, as to the salubrity of the site, adjacent as it is to the wide banks of mud which Southampton water uncovers at low tide.

NETTOYER LES MAGAZINS.—In artillery, a term which means to remove the different pieces of ordnance, for the purpose of having them carefully examined, etc., and to have the stores and ammunition so arranged as not to receive damage.

NETTOYER LES TRANCHEES.—A term meaning to scour or clean the trenches. This is effected by means of a vigorous sally which the garrison of a besieged place make upon the besiegers; when they beat in the guard, drive off the workmen, level the parapet, break up and choke the line of circumvallation, and spike or nail the cannon.

NEUTRAL AXIS.—The name given to an imaginary line to any body which is being subjected to a transverse strain, and separating the forces of extension from those of compression. If the ratio of the resistances to extension and compression were the same for all substances, and depended merely on the form of the body, then in all bodies of the same form the neutrals axis would have a definite geometrical position; but it has been satisfactorily proved by Mr. Eaton Hodgkinson, that this ratio has a separate value for each substance. In wood, where the ratio is one of equality, the neutral axis in a beam supported at both ends, whose section is rectangular, passes lengthwise through the center of the beam: while in cast-iron, in which the resistance to compression is greater than that to extension, it is a little above, and in wrought-iron, in which the contrary is the case, it is a little below, the center.

NEUTRALS.—Nations who, when a war is being carried on, take no part in the contest, and evince no particular friendship for or hostility to any of the belligerents. As a general rule Neutrals should conduct themselves with perfect impartiality, and do nothing which can be considered as favoring one belligerent more than another. The duties and obligations of Neutrals at sea have given rise to many complicated questions. It is allowed on all hands that a Neutral State forfeits her character of neutrality by furnishing to either belligerent any of the articles that come under the denomination of contraband of war. If she does so, the other belligerent is warranted in intercepting the succors, and confiscating them as lawful prize. Contraband of war, besides warlike stores, has sometimes been held to include various other articles, a supply of which is necessary for the prosecution of the war; and it has been doubted how far, in some circumstances, corn, hay, and coal may not come under that category.

An important question regarding the rights of Neutrals is, whether enemies' goods not contraband of war may be lawfully conveyed in neutral bottoms. The principle that free ships make free goods was long resisted by England and other maritime countries; and the general understanding has been that belligerents have a right of visiting and searching neutral vessels for the purpose of ascertaining—First, whether the ship is really neutral, as the hoisting of a neutral flag affords no absolute security that it is so; Second, whether it has contraband of war or enemies' property on board. Neutral ships have therefore been held bound to provide themselves with passports from their Government, and such papers as are necessary to prove the property of the ship and cargo; and it is their duty to heave to when summoned by the cruisers of either belligerent. It has been considered that a neutral ship which seeks to avoid search by crowding sail, or by open force, may be captured and confiscated. When a merchant-ship is sailing under convoy of a vessel of war it has been said that the declaration of the officer in command of the convoy that there is no contraband of war or belligerent property on board is sufficient to bar the exercise of the right of search.

A declaration having important bearings on the rights of Neutrals was adopted by the Plenipotentiaries of Great Britain, Austria, France, Prussia, Russia, Sardinia, and Turkey, assembled in Congress at Paris on April 16, 1856. By its provisions, 1. Privateering is abolished. 2. A neutral flag covers enemies' goods, with the exception of contraband of war. 3. Neutral goods, with the exception of contraband of war, are not liable to capture under the enemy's flag. 4. Blockades, in order to be binding, must be effective—that is, maintained by a force sufficient really to prevent access to the coast of the enemy. It has sometimes been proposed to exempt private property at sea from attack during war. Such a project, however, seems inexpedient. There may be a propriety in respecting the property of individuals on land in a time of war, because its destruction, however injurious to the persons immediately concerned, can have little influence on the decision of the contest. But at sea private property is destroyed, because those from whom it is taken, being purveyors or carriers for the community at large, its loss must seriously affect the public, and have no small influence in bringing the contest to an end. See *Blockade*, and *C'ntraband of War*.

NEUBAUER SYSTEM OF FORTIFICATION.—This system is distinguished by a reduit in the re-entering places of armes, imitated by Cormontaingne. It also proposes six fold flanks.

NEW MATTER.—It is not proper that the Prosecutor should be allowed to introduce *new matter*, neither should it be admitted on the defense. There is a great difference between new matter of accusation and facts proved by evidence to mitigate the sentence. The latter are not new matter in its strict sense. Should either party, in the course of their examination of witnesses, or by bringing forward new ones for that purpose, introduce new matter, the opposite one has the right of calling other witnesses to rebut such new matter. The Court-Martial should be very circumspect to see and prevent new matter from being introduced, either in the prosecution or defense. But the Accused may urge in his defense mitigating circumstances, or examine witnesses as to character or service, and produce testimonials of such facts, without its being considered new matter; and if any point of law be raised, or any matter requiring explanation, the Judge-Advocate may explain ; no other reply is admitted.

NEW MODEL.—In the United States, all cannon made since 1861 are on the *New Model*. This is characterized by the absence of all ornament on the exterior,—the outline is made up of gentle curves as far as possible,—and on the inside the bottom of the bore is a semi-ellipsoid.

NEW TRIAL.—In Court-Martial, the privilege of a new trial is not denied. The provisions therefore are borrowed from common law, and are not held, in either civil or military tribunals, to preclude the accused from having a second trial on his own motion. Officers who sat on the first trial should not be detailed for the new trial; they have formed and expressed opinions. New, or second trial, can only be authorized where the sentence adjudged upon the first trial has been disapproved. After a sentence has been duly approved and has taken effect, the granting of a new trial is beyond the power of a Military Commander, or the President.

NEW ZEALAND CROSS.—A decoration instituted in the year 1869. The New Zealand Cross was provided in the year 1869, by the Government of the Colony, with the sanction of the Crown, as a reward for acts of distinguished valor similar to those recognized by the Victoria Cross. The fourth clause of the Order in Council, which subsequently received her Majesty's special sanction, as "Fountain of Honor," provides that "The distinction shall only be conferred upon those officers or men who, when serving in the presence of the enemy, shall have performed some signal act of valor or devotion to their duty, or who shall have performed any very intrepid action in the public service; and neither rank nor long service, nor wounds, nor any other circumstance or condition whatever, save merit or conspicuous bravery, shall be held to establish a sufficient claim to the honor."

NIELLO-WORK.—A method of ornamenting metal plates by engraving the surface, and rubbing a black or colored composition, so as to fill the incised lines, and give effect to the intaglio picture. It is by no means quite certain when this art was originated ; Byzantine works of the 12th century still exist to attest its early employment. The finest works of this kind belong to the former half of the 15th century, when remarkable excellence in drawing and grouping minute figures in these metal pictures was attained by Maso di Finiguerra, an eminent painter, and student of Ghiberti and Massacio. In his hands it gave rise to copper-plate engraving, and hence much interest attaches to the art of niello-cutting. Genuine specimens of this art are rare, some of those by Finiguerra are very beautiful and effective, the black pigment in the lines giving a pleasing effect to the surface of the metal, which is usually silver. Those of his works best known are some elaborately beautiful pattines wrought by him for the church of San Giovanni at Florence, one of which is in the Uffizia, and some are in various private collections. In the collection of ornamental art at South Kensington, there are no less than 17 specimens of this art.

NIGHER.—An Indian term for any fortified city measuring at least 8 coss, or 8 English miles, in length and breadth.

NIGHT-FIRING.—Cannon are pointed at night by means of certain marks, or measurements, on the carriage and platform, which are accurately determined during the day. In the case of guns and

howitzers, the elevation may be determined by marking the elevating screw where it enters the nut, or by measuring the distance between the head of the screw and stock. In the case of mortars, the position of the quoin may be determined by marking, or by nailing a cleat on the bolster. The direction of a carriage or mortar-bed is determined by nailing strips of boards along the platform, as guides to the trail and wheels; to prevent the strips from being injured by the recoil, they should be nailed at a certain distance from the carriage, or bed, and the space filled up with a stick of proper width, which should be removed before firing. The chassis of a sea-coast carriage can be secured in a particular direction by firmly chocking the traverse wheels. See *Pointing.*

NIGHTLY CORDON.—In the operation of a siege, the investment of the position is usually performed by a strong body of troops detached from the attacking force, which body moves quickly and suddenly, surrounding the position, and seizing all the avenues of approach. A chain of outposts and sentinels placed just outside of the range of fire of the defence, but close enough to watch all the avenues leading to the position, is established by the investing force. This chain is drawn in nearer to the position at night, and moved back a short distance in day time. The terms nightly cordon and daily cordon are frequently used to designate this chain. See *Cordon.*

NIGHT-SIGNALLING.—An important branch of signalling. It may be effected in various ways. In ordinary service two torches are used,—one on the ground and the other attached to a staff, which is used precisely as the flag for day signals. Lanterns held in the hands can also be used. For long distances and when stations cannot be seen on account of intervening obstacles, such as woods, signal-rockets, candle-bombs, and other pyrotechnic devices are used.

NIHILISTS.—A revolutionary organization in Russia, aiming at the destruction of all existing laws, religions, and political and social systems, while preparing to replace them with nothing. It is stated that the term was first employed by the Rnssian novelist, Ivan Turgenieff, in his stories of Russian society. It was, however accepted by the organization itself, as will appear in the following quotation from a speech by a member, and which may be accepted as fairly significant of the doctrines with which the minds of the advanced Radicals of Russia have become imbued. "Nothing, in the present state of social organization can be worth much, for the simple reason that our ancestors instituted it. If we are still obliged to confess ourselves ignorant of the exact medium between good and evil, how could our ancestors, less enlightened than we, know it? A German Philosopher has said: 'Every law is of use. It rules the conduct of individuals who feel for one another and appreciate their respective wants. Every religion, on the other hand, is useless; for ruling, as it does, our relations with an incommensurable and indefinite Being, it can be the result only of a great terror or else of a fantastic imagination.' Now, we Nihilists say, no law, no religion—Nihil! The very men who instituted these laws ruling their fellow-creatures have lived and died in complete ignorance of the value of their own acts, and without knowing in the least how they had accomplished the mission traced for them by destiny at the moment of their birth. Even taking it for granted that our ancestors were competent to order the acts of their fellow-creatures, does it necessarily follow that the requirements of their time are similar to those of to-day? Evidently not. Let us, then, cast off this garment of law, for it has not been made according to our measure, and it impedes our free movements. Hither with the axe and let us demolish everything. Those who come after us will know how to rebuild an edifice quite as solid as that which we now feel trembling over our heads." Two points will be observed in this manifesto: the one being its positive antagonism to all existing things—because they exist; the other the sophistry with which the accepted position is reasoned out to a logical conclusion. And this brings us naturally to the starting points of Russian Nihilism: in the influence of the Russian history; in the nature of the Russian people; and in the exceptional character of the Russian Political System.

NIP.—A term used in artillery, meaning to stop ropes with a gasket, or with several turns of spun yarn round each, and the ends made fast.

NIPPLE.—The passage of communication in percussion arms between the cap and the charge; the percussion cap is placed on the nipple when the fire lock is primed, and by the action of the lock the piece is discharged. In breech-loading arms, except in the Snider, there is a different arrangement for igniting the charge, which renders the nipple unnecessary; these are fired by means of a needle or some similar method.

NIPPLE WRENCH.—The spanner with sides which fit the square of the nipple, and which is used for screwing it to and unscrewing it from the barrel.

NIQUIBS.—An Indian term for men whose military functions among the Sepoys, correspond with those of Corporals in other services.

NITER—NITRE.—Niter occurs as a natural product in the East Indies, Egypt Persia, where it is found sometimes as an efflorescence upon the soil, and sometimes disseminated through its upper stratum. The crude salt is obtained by lixiviating the soil, and allowing the solution to crystallize. A large quantity of niter is artificially formed in many countries of Europe, by imitating the conditions under which it is naturally produced. The most essential of these conditions seems to be the presence of decaying organic matter whose nitrogen is oxidized by the action of the atmosphere into nitric acid, which combines with the bases (potash and lime) contained in the soil. The method employed in the artificial production of niter consists in placing animal matters, mingled with ashes and lime rubbish, in loosely aggregated heaps, exposed to the air, but sheltered from rain. The heaps are watered from time to time with urine or stable runnings; at suitable intervals the earth is lixiviated, and the salt crystallized. Three years usually elapse before the niter bed is washed; after this interval a cubic foot of the debris should yield between 4 and 5 ounces of niter. As there is always a considerable quantity of the nitrates of lime and magnesia present, which will not crystallize, carbonate of potash, in the shape of wood-ashes, is added so long as any precipitate occurs. The nitrate of lime is decomposed, and the insoluble carbonate of lime separated:

Carbonate of Potash.	Nitrate of Lime.	Carbonate of Lime.	Nitrate of Potash.

$$KO,CO_2 + CaO,NO_5 = CaO,CO_2 + KO,NO_5$$

The clear liquor is then evaporated and crystallized. It has been found that the earth in which niter has once been formed furnishes fresh niter more readily than on the first occasion. Care is taken that the *niter plantations*, as they are termed, shall rest upon an impervious flooring of clay, so that the liquid which drains away from them may be collected and preserved. See *Nitrates* and *Saltpeter.*

NITHING.—An old term for coward or poltroon. Also written *Niding.*

NITRATE OF SODA.—An extensive deposit in the soils of some portions of Peru and northern Mexico. It is cheaper than nitrate of potassa, and for the same weight affords a greater amount of nitric acid, or oxygen. Its affinity for moisture constitutes a serious objection to its use in the manufacture of a gunpowder for war purposes, or one that is to be preserved for any length of time. The nitrate of soda may be used in obtaining the nitrate of potassa by decomposing it with carbonate of potassa—the potash of commerce. See *Chlorate of Potassa* and *Niter.*

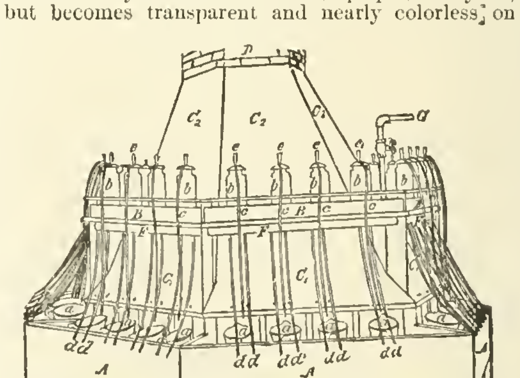
NITRATES.—Salts formed by the union of nitric acid with bases. Some are found in a natural mineral condition, as saltpeter and cubic niter. They are distinguished for their solubility in water. On being heated, they undergo decomposition, being converted either into free nitric acid and a base, or into oxygen and a nitrite. In many respects one of the most important nitrates is the nitrate of silver, or lunar caustic. It is of great use in surgery and the arts. As a caustic it acts powerfully, but rather superficially, producing a white slough, which blackens soon on exposure to the light. It is used in a solid state, or in solutions of all strengths. If dissolved in pure water, it remains colorless; but the smallest particle of organic matter will cause the solution to turn dark. On this account it is employed for making marking-fluids for linen. Indelible ink is usually made by dissolving 1 part of nitrate of silver and 4 parts of gum-arabic in 4 parts of water, and adding a little India ink to give it color, so that it may be seen when the mixture is applied. The place which is to receive the impression is first moistened with a solution of carbonate of soda and dried. After the application of the ink, the writing is exposed to the sunlight. Lunar caustic markings may be readily removed by applying a few drops of tincture of iodine, and dissolving out the iodide of silver thus formed by a solution of hyposulphite of soda, or a dilute solution of caustic potash. Nitrate of silver is used in photography. Nitrate of ammonia, or ammonic nitrate (according to modern nomenclature, ammonium nitrate), NH_4O,NO_5, or, according to later views, NO_3NH_4, may be formed by the action of the galvanic current on a mixture of nitrogen and oxygen with an excess of hydrogen; but the common method is to add a slight excess of aqua ammonia to nitric acid. If crystallization is conducted slowly, six-sided prisms, like those of nitrate of potash, will be formed, having a specific gravity of 1.635. It melts at 226° F., and at 482° decomposes into water and nitrous oxide, or laughing-gas. Nitrate of baryta, or baryta saltpeter, is made by treating the native carbonate of baryta with nitric acid. It crystallizes in anhydrous regular octahedrons, having a specific gravity of 3.184. When heated strongly it is converted into baryta, or baric oxide, with evolution of oxygen and nitrogen. Nitrate of bismuth and also sub-nitrate are important salts in the arts and medicine. Nitrate of cobalt, prepared by the action of nitric acid on the oxide, crystallizes from solutions in beautiful pink-red deliquescent crystals, having a specific gravity of 1.83. It is much used in the chemical laboratory, particularly as a blow-pipe reagent. With magnesium compounds, it yields a pink color; with those of zinc, green; and with aluminum compounds a beautiful blue; for this reason it is much used in coloring porcelain and earthenware. Nitrate of copper is made by the action of diluted nitric acid on copper turnings. Nitric oxide gas is given off during the operation. It crystallizes from cold solutions in beautiful blue, deliquescent, rhomboidal prisms, containing four molecules of water. From solutions above 59° it crystallizes with three molecules of water in needles, having a specific gravity of 2.047, soluble in alcohol. Nitrate of copper is converted, by moderate heat, into an insoluble basic nitrate. By raising the heat, the acid is completely driven off, leaving only the black oxide of the metal. Nitrate of copper is sometimes useful in surgery, as an application to certain ill-conditioned ulcers. The nitrates of iron are important salts. The protonitrate or ferrous nitrate, is formed by digesting iron-turnings in very dilute nitric acid. It crystallizes in pale green rhombohedrons, having the formula $Fe(NO_3)_2$, $6H_2O$. It is much used in dyeing. The pernitrate, or ferric nitrate, is made by dissolving iron-turnings in nitric acid of sp. gr. between 1.2 and 1.3. It is used in surgery. Nitric acid forms several salts with lead, the principal of which is the common nitrate, or plumbi nitrate, $Pb(NO_3)_2$. It crystallizes in anhydrous regular octahedrons, usually milk-white and opaque. It dissolves in 7½ parts of cold water. Is is decomposed by heat, with evolution of peroxide of nitrogen. Nitric acid forms a greater number of salts with mercury than with any other metal, one of which is used in medicine, and the other for the manufacture of corrosive sublimate. See *Niter*.

NITRO-CELLULOSE.—During the last few years great improvements have been effected in the manufacture and application of this material, and in consequence, its use is rapidly extending, especially in Great Britain, where it is found of great advantage in mining operations, owing to its not producing smoke when exploded. For the improvements as well as the invention of gun-cotton, we are indebted to Germany and Austria, the most important improvement being that of Baron Lenk, consisting chiefly in the following precautions in the manufacture: 1. A perfect cleansing and drying of the cotton. 2. The use of the most concentrated and purest acids procurable commercially. 3. Steeping the cotton a second time in a mixture of the strong acids. 4. Continuance of this steep for 48 hours. 5. A thorough purification of the gun-cotton from free acid by washing in a running stream for several weeks. This may be supplemented by washing in a weak solution of potash, but is not absolutely necessary. The following are the important advantages insured by the new method of making nitro-cellulose: 1. The same initial velocity of the projectile can be obtained by a charge of nitro-cellulose one-fourth of the weight of gunpowder. 2. There is no smoke from the explosion of nitro-cellulose. 3. Nitro-cellulose does not foul the gun. 4. Nitro-cellulose does not heat the gun to the injurious degree of gunpowder. 5. Nitro-cellulose gives the same velocity to the projectile with much smaller recoil of the gun. 6. Nitro-cellulose will produce the same initial velocity of projectile with a shorter length of barrel. 7. In projectiles of the nature of explosive shells, nitro-cellulose has the advantage of breaking the shell more equally into much more numerous pieces than gunpowder. 8. When nitro-cellulose is used in shells instead of gunpowder, a quantity equal in weight to one-third of the latter produces double the explosive force.

NITRO-GLYCERINE.—An explosive agent formed by the action of nitric acid upon glycerine at a low temperature. The following reaction occurs:

$$C_3H_3O_8+3HNO_3=C_3H_5(NO_2)_3O_3+3H_2O.$$

When freshly made it is a white, opaque, heavy oil, but becomes transparent and nearly colorless on



standing for a sufficient time. Above 5° (41° F.) it has a specific gravity of 1.6, is odorless and of a sweet taste. It is poisonous, and if placed in contact with the skin, even in small quantities, before the system has become accustomed to its action, produces violent headache. If incompletely freed from acids, it undergoes spontaneous decomposition, is dangerous to handle, and ultimately may lose its explosive properties; when pure it congeals below 5° (41° F.) into a white, crystalline solid, which is nearly incapable of explosion; it may readily be thawed by introducing the vessel containing it into warm water, which restores its full explosive power. Nitro-glycerine, ignited in small quantities by a flame, and unconfined, burns with difficulty; at 217.2° (423° F.) it deflagrates violently; if ignited confined, or if subjected to the explosion of 15 grains of fulminating mercury, it detonates with tremendous force; fully exploded it gives off no injurious gases. It is not ordinarily sensitive to friction or moderate percussion, but is very much so when in a state of decomposition.

In the manufacture, nitric acid is mixed with twice its weight of strong sulphuric acid to take up the water formed during the reaction, and prevent the dilution of the nitric acid. The process consists essentially in the conversion of glycerine into nitro-glycerine, and the separation and washing of the nitro-glycerine. The apparatus is shown in the drawing. *A*, *A*, are wooden troughs placed around the brick chimney, *D*, *D*. In these troughs are the earthenware pitchers, *a*, *a*, which contain the acid mixture. On the shelf, *B*, above the pitcher, are the bottles, *b*, *b*, which contain the glycerine. The bottles are loosely closed by wooden stoppers with broad, rounded tops. Through holes in these stoppers pass loosely the rubber tubes, *c*, *c*, which reach to the bottom of the bottles and carry small glass jets at their outer ends. Conical wooden plugs, *e*, *e*, are placed in the holes through the stoppers alongside the rubber tubes. The steam-pipe, *G*, passes along the shelves, *B*, *B*, just behind the glycerine bottles. The air-main, *F*, passes under the shelf, *B*, and carries on its under side a number of small, short pipes or jets (two for each pitcher), to which are attached the rubber tubes, *d*, *d*, which hang over the pitchers. In these rubber tubes are inserted glass tubes, long enough to extend to the bottom of the acid pitchers. The troughs are made tight to hold the ice-water with which the pitchers are surrounded Partitions, with openings at the bottoms, cut off the corners of the troughs forming clear spaces. These spaces contain water only, as the partitions keep out the ice. These water spaces are convenient as affording opportunities for quickly emptying a pitcher into water if it becomes necessary. In one corner of each trough is placed a pipe, through which the water may be drawn off into the escape, *E*, when the operation is finished. The pitchers stand on narrow strips, which raise them off the bottom about two inches, thus giving the cold water free and perfect access all about them, and when set in proper position are well under the overhanging hoods, C_1, C_2. These hoods are flat wooden boxes, wide at the bottoms and drawn in at the tops, where they fit against openings in the chimneys, *DD*. In the lower part of the chimney, on the floor below, is placed a grate and fire-door. Each pitcher receives 18 to 20 lbs. of the acid mixture according to the strength of the latter. All are then set in place in the troughs, covered with glass plates, surrounded with ice and water, and allowed to stand until completely cooled. Into each bottle is put 2 lbs. of glycerine. When the acid in the pitchers has fallen to the temperature of the surrounding ice water, the covers are removed from the pitchers, and the air-tubes passed through holes in the hoods down into them. Through these air-tubes a strong current of air is forced by means of a pump driven by steam. This current of air keeps the contents of the pitchers in continual agitation. The air for the pump is drawn through sulphuric acid to render it perfectly dry, and just before it enters the air-main over the troughs it is thoroughly cooled. The cooling arrangement is made of 10 coils of small tin pipe, which are surrounded by ice. These coils are so arranged as to give an extensive cooling surface without impeding the current. As soon as the air current has been turned on, the flow of glycerine is begun. Each rubber tube, *c*, is a syphon which is started by suction through a glass tube inserted in the outer end. As soon as the glycerine runs freely, the suction tube is withdrawn and a fine-pointed glass jet put in its place. The glycerine runs from this jet in a fine stream directly into the pitcher under it. In cold weather the glycerine may become too thick to flow easily. To overcome this the bottles of glycerine are warmed by passing steam through the pipe behind them until the glycerine is sufficiently thin. The glycerine dropping into the acid mixture is rapidly acted on and converted into nitro-glycerine. The reaction is accompanied by a considerable evolution of heat. This heat must be removed, for if the temperature be allowed to rise too high the glycerine is not converted into nitro-glycerine, but is oxydized or burned, with formation of other substances. The limits of temperature are very narrow. Starting at 32°, the temperature must never go beyond 48°; at 50° to 55°, there is great danger of "firing" taking place. The liquid in the pitchers is kept cold by surrounding them with ice-cold water and by the stream of cold air passing into the acid. The most important work of the air-current is to keep the acid mixture in constant agitation. In this way the heat generated is quickly diffused through the whole, preventing any sudden local rise of temperature. The glycerine is much lighter than the acid mixture, and would be apt to collect in little pools above it, and when these were broken up and a quantity of glycerine suddenly brought into contact with the acid, the action would be so rapid that it could not be controlled. While the glycerine is running into the pitchers, observations with the thermometer are constantly made of the temperature attained in them. If in a pitcher the temperature is found to be rising too rapidly and to be approaching the higher limit, the glycerine is evidently running in too fast, and its flow must be checked, which is done by pressing down the conical wooden plug in the stopper of the glycerine bottle. This plug passes through the same opening as the rubber glycerine tube; therefore, when it is pressed down, it compresses the latter so that less liquid can pass through. If the temperature is too high or continues to rise, the plug is forced hard down, closing the glycerine tube altogether. The flow of glycerine being checked or stopped, the pitcher rapidly cools down again. As soon as the thermometer shows this to be the case, the plug is loosened and the flow again set up. Constant care is therefore necessary, but the operation is a simple one, easily learned and performed by ordinary workmen. If the limit of temperature is exceeded, "firing" takes place, indicated by the copious evolution of red, nitrous fumes, and in extreme cases by flame. Usually when this occurs it is easily controlled by stopping the glycerine stream and stirring vigorously the contents of the pitcher, but if it is violent the pitcher must be emptied as quickly as possible. During the operation of conversion, acid and irritating fumes are given off in large quantities, greatly to the injury of those compelled to breathe them. In the apparatus here described these are entirely removed through the hoods and chimney. A fire in the grate at the bottom of the chimney causes a powerful draught in the hoods, which overhang the pitchers, drawing upwards all the fumes and discharging them into the open air. Generally a small fire at first is found to be sufficient, and quite frequently no fire at all is necessary.

It does not mix with and is unaffected by water. It has a sweet, pungent, aromatic taste, and produces a violent headache if placed on the tongue, or even if allowed to touch the skin at any point. Those constantly using it soon loose their susceptibility to this action. Freshly made, opaque nitro-glycerine does not freeze until the temperature is lowered to 3°-5° below 0° Fah., but the transparent or cleared nitro-glycerine freezes at 39°-40° F. Nitro-glycerine freezes to a white crystalline mass. When frozen it can be thawed by placing the vessel containing it in water at a temperature not over 100° Fah. Pure nitro-glycerine does not spontaneously decompose at an ordinary temperature; but if it contains free acid, decomposition is apt to occur. It is, therefore, very important that all acid should be removed by thorough washing when it is made. No instance has yet been noticed of the spontaneous decomposition of properly made and purified nitro-glycerine. Pure nitro-glycerine is not sensitive to friction or moderate percussion. If placed upon an anvil and struck with a hammer, only the particle receiving the blow explodes, scattering the remainder. Nitro-glycerine in a state of decomposition becomes very sensitive, exploding violently when it is struck, even when unconfined.

Nitro-glycerine may be conveniently kept in large earthen jars, with a layer of water over the explosive. If it is to be transported, the liquid form is very inconvenient, especially from the danger of leakage. It is therefore advisable to freeze it, and carry it in a frozen state, when it is perfectly safe. For transportation it should be put in strong tin cans holding about 45 or 50 lbs. Each can should be paraffined on the inside, and have passing vertically through its center a tin tube, so that freezing or thawing may be more easily accomplished. All vessels in which nitro-glycerine has been kept should be destroyed when not wanted for the same use, as the nitro-glycerine cannot be easily washed off.

Nitro-glycerine is the most powerful explosive in use. In difficult blasting, where very violent effects are required, it surpasses all others. In spite of the many accidents that have occurred with it, it has been found to be so valuable that its use has steadily and largely increased. Its liquid form is a disadvantage except under favorable circumstances, as when made at the place where it is to be employed. It, however, forms the essential ingredient in a number of solid mixtures. When used in blasting-work it is usually put in tin cans or cartridge-cases. If the bore-holes are tight, it may be poured directly in; but it is rarely safe to do this, as there is great danger that some of it will escape through seams in the rock, and not be exploded, remaining to cause accident at a future time. Since nitro-glycerine is so readily detonated, it has the advantage of not requiring strong confinement. Even when freely exposed it will exert violent effects, such as breaking masses of rock or blocks of iron. So, in blasting, it requires but little tamping. Loose sand or water is entirely sufficient. The relative force of nitro-glycerine is not easily estimated, since the effect produced depends greatly on the circumstances. Thus, a charge of nitro-glycerine in wet sand or any soft material will exercise but a slight effect, while the same charge will shatter many tons of the hardest rock. In the former case much more sand would be thrown out by a slower explosion, which would gradually move it, than by the sudden, violent shock of the nitro-glycerine, which would only compress the material immediately about it. But in the hard rock the sudden explosion is much more effective than the same amount of force more slowly applied. Roughly, it may be said that nitro-glycerine is eight times as powerful as gunpowder, when taken weight for weight.

On explosion, nitro-glycerine is resolved entirely into the gases carbonic, anhydride, water, nitrogen, and oxygen (Nobel), the last named appearing only in small quantity. If explosion is imperfectly accomplished, oxides of nitrogen are formed, and the total quantity of gas is lessened. If fully exploded, no disagreeable or poisonous gases are given off. See *Dualin*, *Dynamite*, *Gun-cotton*, *Gunpowder*, and *Lithofracteur*.

NITRO-MANNITE.—A high explosive resembling nitro-glycerine in its properties, and made in an analogous manner by the action of nitric and sulphuric acids upon Mannite; a peculier saccharine matter which forms the principal constituent of manna; it is also found in several kinds of fungi, in asparagus, celery, onions, etc, It is most readily obtained by digesting manna in hot alcohol. On cooling the filtered solution, the mannite is deposited in crystals, which are very soluble in water, and possess a sweet taste.

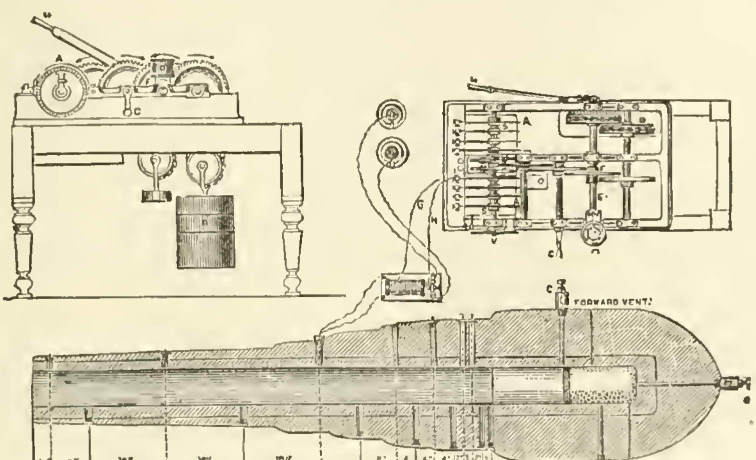
NOBILITY.—That distinction of rank in civil society which raises a man above the condition of the mass of the people. Society has a tendency to inequality of condition, arising from the natural inequality, physical, moral, and intellectual, of those who compose it, aided by the diversity of external advantages, and of the principles and habits imbibed at an early age. This inequality is apt to increase; the son, inheriting the faculties of his father, is more favorably situated than his father was for making use of them; and hence, in almost every nation, in even the very early stages of civilization, we find something like a hereditary nobility. Privileges originally acquired by wealth or political power are secured to the family of the possessor of them; and the privileged class come to constitute an Order, admission into which requires the consent of society or of the order itself. The military tenant who held but a portion of a knight's fee participated in all the privileges of nobility, and an impassable barrier existed between his Order and the people. Over Continental Europe in general, the Nobles, greater and lesser, were in use, after the 10th century, to assume a territorial name from their castles or the principal town or village on their demesne; hence, the prefix "De," or its German equivalent "Von," still considered over a great part of the continent as the criterion of nobility or gentility. Britain was, to a great extent, an exception to this rule, many of the most distinguished family names of the aristocracy not having a territorial origin.

After the introduction of Heraldry, and its reduction to a system, the possession of a coat of arms was a recognized distinction between the Noble and the Plebeian. In the words of Sir James Lawrence: "Any individual who distinguishes himself may be said to ennoble himself. A Prince judging an individual worthy of notice gave him patent letters of nobility. In these letters were blazoned the arms that were to distinguish his shield. By this shield he was to be known or *nobilis*. A Plebeian had no blazonry on his shield because he was *ignobilis*, or unworthy of notice. Hence arms are the criterion of nobility. Every Nobleman must have a shield of arms. Whoever has a shield of arms is a Nobleman. In every country in Europe, without exception, a grant of arms, or letters of nobility, is conferred on all the descendants." On the Continent the term Noble is still generally used in this sense; in England it is now more common to restrict the words noble and nobility to the five ranks of the peerage constituting the greater nobility, and to the head of the family, to whom alone the title belongs. Gentility, in its more strict sense, corresponds to the nobility of Sir J. Lawrence and of Continental Countries. This difference of usage is a frequent source of misapprehension on both sides of the channel; at some of the minor German Courts the untitled member of an English family of ancient distinguished blood and lineage has sometimes been postponed to a recently created Baron or "Herr Von," who has received that title, and the gentility accompanying it along with his commission in the army. It has been taken for granted that the latter belongs to the "Adel" or nobility, and not the former.

The nobility of Spain boasts of a special antiquity and purity of blood, a descent from warriors and conquerors alone, without the infusion of any of the elements derived from the church, law, and commerce that are to be found in other countries. "Hidalgo" (*hijo d'algo*, son of somebody, not *filius nullius*) is a term which implies gentility or nobility. The Hidalgo alone has in strictness a right to the title "Don," which, like "Sir" of English Knights and Baronets, requires the adjunct of the Christian name. When the Christian name is omitted, the title "Senor" instead is prefixed with the addition of "De." "Don" has latterly been used by persons who have no proper claim to it about as extensively as "Esquire" in England. Hidalguia, till recently, conferred important privileges and immunities. The higher nobility are styled Grandees; formerly the title was "Ricohombre," and the ceremonial of creation consisted in granting the right of assuming the pennon and caldron (*penon y caldera*)—the one the rallying ensign of command, the other of maintenance of followers. In contradistinction from the Grandees, the class of nobility below them are called "Los Titulados de Castilla." Red blood is said to flow in the veins of the Hidalgo, blue in that of the Grandee. Formerly there were three classes of Grandees, whose mark of distinction was this—that a Grandee of the first class was entitled to put on his hat in the royal presence before the King spoke to him; the second, after the King spoke to him; the third, after the King had spoken and he had replied. The second and third classes are now absorbed into the first.

of this shaft can be recorded with accuracy to the one-tenth part of a second. The speed usually attained in working this instrument is about 1,000 inches per second, linear velocity, at the circumference of the revolving discs so that each inch travelled at that speed represents the one-thousandth part of a second; and as the inch is subdivided by the vernier, V., into a thousand parts, a linear representation at the circumference is thus obtained of intervals of time as minute as the one-millionth part of a second.

As a small variation in speed would affect the relation between the several records obtained, the uniformity of rotation is ascertained on each occasion of experiment by three observations: one immediately before, one during, and one immediately after the experiment, the mean of the three observations being taken for the average speed. With a little practice there is no difficulty in arranging the instrument so that the discs may rotate either uniformly or at a rate very slowly increasing or decreasing. The arrangements for obtaining the *electrical records* are as follows: the revolving discs are covered on the edge with a strip of white caper, and are connected with one of the secondary wires, G, of an induction coil. The other secondary wire, H, carefully insulated, is brought to a discharger, I, opposite the edge of its corresponding disc, and is fixed so as to be just clear of the latter. When a spark passes from the discharger to the disc, a minute hole



NOBLE CHRONOSCOPE.—The principle of action of this instrument consists in registering, by means of electric currents upon a recording surface, traveling at a uniform and very high speed, the precise instant at which a projectile passes certain defined points in the bore. It consists of two portions: first, the *mechanical arrangement* for obtaining the necessary speed, and keeping that speed uniform; secondly, the *electrical recording arrangement*. The first part of the instrument consists of a series of thin metal discs, A, A, each 36 inches in circumference, fixed at intervals upon a horizontal shaft, SS, which is driven at a high speed by a heavy descending weight, B, through a train of gearing, multplying 625 times. The driving-weight is, during the experiment continually moved up by means of the handle H. If the requisite speed of rotation were got up by the action of the falling weight alone, a considerable waste of time would ensue. To obviate this inconvenience, the required velocity can be obtained with great rapidity by means of the handle C. The precise rate of the discs is obtained by means of the stop-clock D, which can at pleasure be connected or disconnected with the revolving shaft, E; and the time of making any number of revolutions

is perforated in the paper covering upon that part of the disc which was opposite the discharger at the instant of the passage of the spark; but, as the situation of this hole in the paper would be very difficult to find, on account of its extreme minuteness, the paper is previously coated with lamp-black, and the position of the hole is thus readily seen: a distinct white spot is left on the blackened paper, the lamp-black at that point having been burnt away by the spark, so that the white paper is shown beneath. By means of the micrometer the distance between the sparks on the disc is read off.

In order to connect the primary wires of the induction coils with the bore of the gun, so that they may be cut by the projectile in its passage, the gun is tapped in a number of places for the reception of hollow steel plugs carrying at the end next the bore a cutter which projects slightly into the bore. This cutter is held in position by the primary wire, which is carefully insulated and passed down the plug, through the cutter, and back out of the plug, the ends being connected to the main wires leading to the induction coils. When the projectile reaches the point where the plug is screwed in, it presses the cutter in flush with the bore, and, by so doing, cuts the primary circuit. As each plug is reached a spark is delivered, and thus the passage of the projectile along the bore is recorded at regular intervals. Some idea may be conveyed of the minute intervals of time which can be measured by this means, from the fact that the distances between the parts of a X-inch gun at which the time-records have been obtained are in some instances only 2.4 inches, while the total time the projectile takes to reach the muzzle of the gun—a distance of 100 inches—when fired with a full charge, is about the one-hundreth part of a second. By this means the time may be recorded which the projectile occupies, from the commencement of motion, in reaching different parts of the bore, and from these time-records may be deduced the velocity with which the projectile is passing through the different parts of the bore, and the pressures in the gun which correspond to these velocities. See *Chronoscope*.

NOISY.—A term applied to projectiles in flight. The passage of a rifled projectile through the air causes a shrill, tearing sound. An experienced ear at experimental practice can detect from this sound whether the projectile is properly centered; if not,it is said to be *noisy* in flight.

NOIZET SYSTEM OF FORTIFICATION.—The School of Application for engineer and artillery officers, first established at Mézières and subsequently at Metz, has given to France, from about the period of the French Revolution down to the present day, many able officers who have gained universal and deserved celebrity for these two corps. In these schools the precepts of Vauban and Cormontaigne have been jealously regarded as the highest authority,and their manuscripts and works have formed the basis of the instruction given in them. Some slight modifications were proposed in the front of Cormontaigne by two engineers, *Chatillon* and *Durigneau*, and taught by them in the course of permanent fortification given in the school. These changes chiefly consisted in enlarging the demi-lune and making it more salient ; and in placing casemates for cannon in the flanks of its redoubt, with reverse views on the breaches that might be made in the bastion faces. The teaching of the school of Metz has received its principal impress in later years from General Noizet. For nearly fifty years, General Noizet was engaged in the study and practice of his profession, serving for many years as professor of the art of fortification in the school at Metz. He had the good fortune to apply practically on a large scale the principles taught by him in the school. He was for ten years a member of what we would call the Board of Engineers for France, and has visited every fortification in France. He is regarded as *first* among the successors of Vauban and Cormontaigne. The front planned by him has been taken as an elementary exercise for instruction in the art of fortification for the cadets of the U. S. Military Academy at West Point, N. Y. In it, there is no sensible departure from the views and method of Cormontaigne, excepting to introduce such modifications as would remedy some of the acknowledged defects of his method. This front combines the principles of the science of fortification to as great an extent as any one system or method that can be given to the student. Another object has been kept in view in using this front. That is, to present in its combinations, a *problem*, in the solution of which the pupil would have to apply to a special case, both the elementary principles of fortifications, and the geometrical methods used by the military engineer in the practice of his profession. Noizet, in the plan of his enceinte, has adopted dimensions and constructions which gives results for the most part, the same as those of Vauban and Cormontaigne, making the defensive properties of these different methods about equal. The extent of the exterior side, the length of the curtain, the diminished angle, and the direction assumed for the flanks, produce a combination giving an efficient flanking, both as to direction and amount of fire, for the entire scarp, and a powerful cross-fire upon the covered-way and its glacis in advance of the bastion salient. The lines of defense, by this combination, are within the effective range of the most improved small-arms, and the flanks are capable of receiving a battery superior to the counter batteries that can be brought against them from the glacis crest of the opposite covered-way. The dimensions and form of the profile are such as experience has shown will give durability and stability to the masonry from the pressure of the embankments,and the ordinary causes of destructibility to which it is liable when exposed to the weather. The rampart and parapet have sufficient strength to resist the action of the heaviest siege artillery in ordinary use, whilst they offer to the assailed every convenience for their prompt action, and the use of their arms. The width and slopes of the ramps are regulated for the passage of artillery. Where the height to be overcome is slight, as that between the terre-plein and barbette, the slope of the ramp may be as great as $\frac{1}{6}$, and its width be 3.30 yards. Where the height is greater, the declivity of the ramp should be proportionally less steep, and its width be 4.30 yards at least. The position of the terre-plein with respect to the interior crests is that usually considered necessary to give shelter to the troops and *matériel* on it. By inclining that of the bastion, the guns and troops on the faces and flanks are better covered from the enfilading and ricochet fire than they would be if the terre-plain was horizontal; as a ball passing over the salient will of necessity reach an inclined terre-plein at a point much farther from the salient than one which is horizontal. The following is the summary of the principles, and essential details involved in this system. 1st. The enceinte of every permanent work should present an uninterrupted line of scarp wall, which, when the ditch is dry, should be at least 30 feet high above the bottom of the ditch. 2d. All the approaches to the work, beyond the ditch within the effective range of its fire, as well as the ditch itself should be completely swept by this fire. 3d. All scarp walls should be sheltered from the fire of the enemy's artillery, to the latest moment, by earthen masks. 4th. All parapets should be proof against the heaviest projectiles, to which they may be exposed. 5th. The terre-plein of the rampart should be masked by the parapet from the enemy's view ; it should be wide enough for the infantry and artillery service ; should have convenient communications for these between all its parts : and between it and the parade. 6th. All outworks, except the covered-ways, should be regarded as accessories rather than indispensable additions to the main work. When properly placed, they strengthen weak points and delay the enemy's progress, by forcing him to gain possession of them before he can advance beyond the points they occupy. Their scarps, and the gorges liable to be turned by the enemy, should be of masonry, not less than 12 feet in height. The more retired of these works should command the more advanced, and where this rule is violated, the retired work should be defiled from any establishments that the enemy might be able to make on the advanced one by which it is commanded. They should be commanded by the enceinte, and as far as practicable flanked by the fire of its small-arms. 7th. The covered-ways are regarded as indispensable. Without them the communications between the main work and the exterior would not be secure. Their embankments form,in a great majority of cases,the only masks for the scarps of the works in their rear, and by affording advanced cover for the garrison, give the means of annoying the enemy by sharpshooters, and retarding his approach by sorties in small parties. They should be thoroughly swept by the fire of small-arms of all the works in their rear, and have their terre-pleins defiled from all commanding points liable to fall into the hands of the enemy. 8th. The glacis should be thoroughly swept by the fire of artillery and small-arms of the main work and outworks where a fire can be brought to bear upon it. For this purpose, the surfaces should be so arranged that their intersections shall not form hollows or ridges, which might be of advantage to the enemy in advancing upon the work. 9th. The tenaille is an essential addition to all fronts of attack. Without it, the postern in the curtain would be not only insecure but absolutely unserviceable as soon as the enemy could in any manner gain a position where his fire could be brought to bear on its outlet. It also enables the defense to form retrenchments resting either on the flanks or curtain of the enceinte, that cannot be turned by the enemy, and also offers a sheltered place-of-arms, in the ditch, between it and the curtain, which can be used for assembling troops against the enemy in the ditches. Its relief is so determined that it shall not mask the fire of the flanks on the bastion-faces, whilst at the same time it affords cover to the scarp of the curtain and flanks. 10th. The demi-lune, when properly arranged, forms an important addition to the defense. It covers the curtain and portions of the bastion-faces near the shoulder angle from the fire of the enemy's artillery, and secures the main outlet from the enceinte from surprise. The arrangement of the demi-lunes places the bastions in strong re-enterings, thus forcing the enemy to take them before he can attempt the assault of the enceinte; and when the faces of the bastions prolonged fall within the demi-lunes, they mask them from enfilading views. These advantages are the more decided as the demi-lune is the larger and more advanced. Its scarp is taken 22.50 feet high to afford the necessary security against an open assault, and to obtain a very efficient cut across its face. 11th. The demi-lune redoubt adds to the strength of the demi-lune. Its arrangement with flanks adds directly to the strength of the enceinte, as the reverse fire from the flanks on the breach in the bastion-face will force the enemy to carry the redoubt before he can risk an assault on the breach. 12th. The redoubt of the re-entering place-of-arms, adds greatly to the *strength* and *security* of the covered way. From its retired position, it can be occupied after the dimi-lune has fallen, provided there is an efficient cut in the demi-lune face, and the redoubt has been defiled from the establishments of the enemy on the parapet of the demi-lune. It also, in connection with the demi-lune, covers that portion of the curtain which is exposed through the ditch between the tenaille and enceinte flank. Its crest should mask as little as practicable the fire of the bastion-face on the glacis in advance of it. 13th. The cut in the demi-lune face is an important addition, as it secures the redoubt of the re-entering place of arms from being turned. Its position should be so chosen that the face of the redoubt may be flanked through it by the fire from the demi-lune redoubt. A parapet is thrown up behind the cut to defend it after the enemy has gained possession of the demi-lune salient. It should command the salient and its terre-plein should be defiled from the same point. 14th. The ditches should furnish the earth required for the embankments. Their dimensions, therefore, will depend upon the amount necessary for this purpose. When water can be used, it is more advantageous to increase the width at the expense of the depth. The ditches of the different works should afford no communications through which an enemy might penetrate from one into that of another, and thus assault the works by the rear. 15th. The communications, in accordance with our general principles already stated, should be of convenient dimensions, and of easy access; be swept by the fire of the works in their rear; be covered from the fire from all points that the enemy can occupy whilst they are needed; be secure from surprise, and from being approached in the rear by the enemy; and not compromise the safety of any work through which they may lead.

A fortification constructed in keeping with these principles, possesses the advantage of having its ditches thoroughly swept from the main work itself; of bringing a cross and flank fire to bear upon the approaches on the salients of the enceinte; and furnishing a strong direct and cross fire upon the site in advance of the curtains and the faces of the bastions. The principal objections urged against this particular system are: 1. That its chief characteristic, a perfect flanking disposition for the entire line of the scarp, is attainable only under certain relations between the requisite relief for a permanent work and the lengths of the exterior side and curtain, which therefore restricts it in its application to fortifications of a permanent character. 2. That, in order to secure a sufficient length of flank for an effective flanking disposition, the angle between the face of the bastion and the exterior side, termed the *diminished angle* of the polygon, has to be made so great as to decrease considerably the space inclosed within the polygon, whilst the development of the line of the enceinte is greatly increased by it. 3. That the direction necessarily given to the faces from this cause throws their prolongations in positions very favorable to the erection of all the enfilading batteries against them. 4. That the flanks, upon which the whole system is based, lie in positions in which, like the faces, they can be not only easily enfiladed, but are further exposed to a reverse fire, from shot which may pass over the parapet of the faces as well as the opposite flank. 5. And that these objections are much the stronger as the salient angles of the polygon are smaller or as the number of the sides is decreased. See *Cormontaigne System of Fortification*, *Fortification*, and *System of Fortification*.

NOLAN RANGE-FINDER.—The principal parts of this instrument are: 1. Two instruments for measuring angles. 2. One tape-line. 3. One reckoning cylinder. Each of the two instruments consists of two telescopes, which lie crosswise one above the other under an angle of about 90°; the smaller of the two has a long arm, with a vernier at one end; to the other a sector is fastened, which is divided up into degrees. By means of a screw, an angle of about 20° can be described by the upper or smaller telescope. The reckoning cylinder consists of a solid body and two rotating rings. The lower ring and the lower edge of the body are divided into 100 equal parts. On the upper ring are the logarithms of the figures, and on the upper edge of the body are the logarithms of the signs, from 6″ up to 2° 15′.

To find the range, the instruments on their tripods are arranged at the end of the assumed base-line, which is perpendicular to the range; or the instruments may be attached to the right and left guns of a battery. The long telescopes are turned toward the object whose distance is to be found; the smaller ones upon each other, and the cross-threads of each made to cover the cross-lines on the leather disc through which each small telescope points. The coincidence obtained by directing the longer telescope on the object, the two angles at the base are determined; the base-line being measured, one side and two angles of the triangle are obtained. With this data recourse is then had to the reckoning cylinder. The arrow marked "band" is set on the figure that corresponds with the distance between the instruments or base-line—say 34 yards; then set the arrow on the lower ring on the figure corresponding with the angle found through the instrument—say 18°; then find the figure for the number of degrees of the other angle—say 42°, on the lower ring. Just above that is the figures 60 on the other division of the lower ring; coinciding with this on the lower edge of the upper ring is the distance, 1,320 yards. The bases used are conveniently taken from 30 to 40 yards for a range of 3,000 yards and over. See *Pratt Range-finder*.

NOLLE PROSEQUI.—An entry upon the records of a Court-Martial by the plaintiff or the prosecutor, declaring that the proceedings against the defendant shall be discontinued. A *Nolle Prosequi* is not equivalent to an acquittal, but acts merely as a stay of proceedings, and the defendant is liable at any time to be re-indicted. It may be entered as to one of several defendants, and is often done so to allow his testimony to be introduced against the others. It is generally in the discretion of the prosecuting officer to enter a *nolle prosequi*, but in some cases leave must be obtained from the Court.

NOMBRIL POINT.—A term in Heraldry. See *Escutcheon*.

NOMENCLATURE.—Technical designation. The term, as applied to military stores, signifies a systematic classification of words pertaining to each article used in the service. For nomenclature of ordnance, etc., see appropriate headings in this work.

NON COMBATANT.—Any person connected with an army, or within the lines of an army, who does not make it his business to fight, as any one of the Medical Officers and their assistants, Chaplains, and others; also, any of the citizens of a place occupied by an army. In the English Army, the duties of all non-combatants are restricted to the Civil Department.

NON-COMMISSIONED OFFICERS.—Subordinate officers of the General Staff, Regiments and Companies who are appointed, not by commission, but by the Secretary of War or Commanding Officers of Regiments: They are usually selected on account of good conduct or superior abilities. In the British Army, the Non-commissioned Officers constitute a numerous and very important class in the regimental system between the Commissioned Officers and the men. As the former are not permitted to mix with the private soldiers, lest familiarity should diminish the sway of absolute discipline, it is necessary to have an intermediate class to overlook the men in their barracks and at all times when off the parade. None are so suited for this duty as the best conducted of the men themselves, who are promoted by selection to Non-commissioned rank, and hold many privileges and powers unattainable by the privates. The Non-commissioned Officers comprise the Sergeants-Major, and all the Sergeants, the Trumpeters, Drummers, and Buglers, and, in the Life Guards, and Royal Horse Guards only the Corporals. They can be reduced to the ranks by sentence of a Court Martial, or by their Colonel Commandant; but not by a Lieutenant Colonel nor by any Junior Officer. Non-commissioned Officers are entitled to quarters for their wives, or lodging money in lieu of quarters. Accustomed themselves to obey, the Non-commissioned Officers are admirable assistants in preserving discipline; veterans, to whom military life is a second nature, they are looked up to by their comrades as examples, to lead in battle or to teach in drill. The Non-commissioned Officers have a mess to themselves. In a battalion of infantry at home, there were, in 1874, 58 Non-commissioned Officers to 520 rank and file; in India, 66 to 820; but the rank and file may be greatly augmented without affecting the number of Non-commissioned Officers. In the whole British army (European) for the year 1874-75, there were 20, 949 Non-commissioned Officers. This rank is a necessity in all armies; in France, the Non-commissioned Officers are termed *Sous-Officers*; in Germany, *Vinter-Offizieren*.

NON-EFFECTIVE.—The term applied to the portion of the personnel of the army or navy not on active service or in immediate readiness for active service. It thus comprises all officers on retired or half-pay, pensioners, and superannuated officers. In a force liable to frequent augmentations and reductions,the non-effective charge must be considerable, and a large retirement is necessary, in order to rapid promotion. The great French war, also, with the reductions following it, bequeathed to the British an annual non-effective charge of several millions, which is not yet wholly expunged. In 1878-79, the non-effective charges were £2,344,912 for the the army, and £1,887,571 for the navy, being upwards of 16 per cent on the gross cost of the two services.

NOOSE.—A running knot, which binds the closer the more it is drawn. See *Cordage*, *Knots*, and *Lasso*.

NON-POLAR PROJECTILES.—A designation applied to projectiles which do not keep the same end or aspect foremost throughout their courses.

NORDENFELT MACHINE GUN.—In addition to the older mechanism devised by Mr. Nordenfelt for his well-known four-barrel 1-inch gun, he has lately introduced modifications more suitable for two or three barrels, and as several of these new guns have been recently tried with great success at Portsmouth and elsewhere, we give a complete description of all the Nordenfelt volley guns now made. In order to explain the differences in the mechanism used for the several guns, we will commence our description

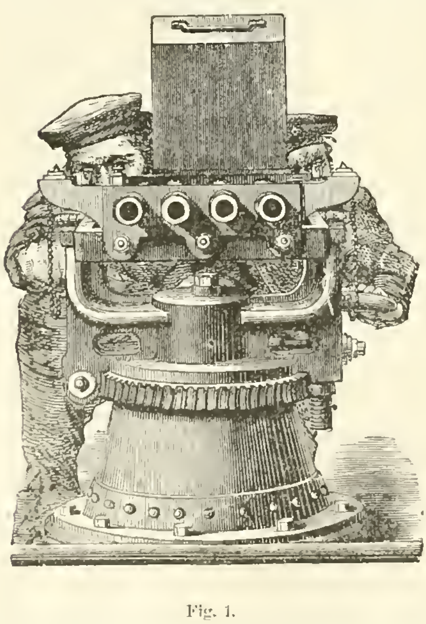


Fig. 1.

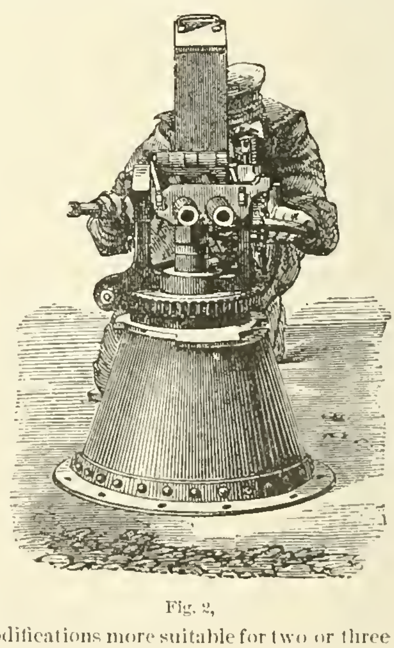

Fig. 2.

with two of the 1-inch guns as representatives of the two systems.

The four-barrel 1-inch gun, Admiralty pattern.—When the use of the torpedo boat became general, it followed as a necessary consequence that a means of defence must be provided against these swift and destructive little vessels, and the British Admiralty searched for a weapon having sufficient penetrating power to damage the boiler of a torpedo boat at a distance of from 300 to 500 yards. Other essential conditions required were that the gun could be fired so rapidly that it would almost certainly score a sufficient number of hits on an approaching torpedo boat to insure its being disabled during its run at full speed from the distance named, before it could reach the vessel attacked, or which could be fired so rapidly as to make it impossible for the boat to discharge a Whitehead torpedo at such a range that the missile would have any reasonable chance of hitting its mark. After various competitions the Admiralty decided in favor of the Nordenfelt gun.

The four-barrel gun, shown in Fig. 1, consists of a rectangular framework of wrought iron, the sides of which are connected by three plates or transoms. The four barrels are placed side by side in the frame, their muzzle ends passing through the front cross-piece, while the breech ends are screwed into the middle transom. In the rear of the middle cross-piece is the action block, which is capable of movement backwards and forwards. In front of this action block are four breech plugs, corresponding to the barrels. These are of steel pierced with a channel, in which a firing pin or striker moves freely, and they are furnished with an extractor on the right side. Behind each plunger is a hammer, with a projecting tenon, and behind the hammer is a strong spiral spring.

The trunnions fit into a cross-head pivoting on a cone, which is firmly fixed to the side or other part of the ship, where the gun is to be fired. The training is given by a hand-wheel, which works a worm gearing into a horizontal toothed rack attached to the top of the cone. The elevation is produced by a wheel working a differential screw. One turn of the training wheel gives 6 degrees of training, and one of the elevating wheel 12 degrees of elevation or depression. The action of the mechanism is as follows. Supposing the discharge to have been just completed, that the lock closes the breech end of the barrels, and is still secured in its place by the two bolts; 1. The handle begins to move to the rear; the friction roller traverses the concentric part of the action plate, and the action block remains steady. The spring and the heel of the lever, acting on the trigger comb, drive it from right to left. 2. As the movement continues, the action lever acts on the locking-bolt plate, and withdraws the bolts leaving the action block free. 3. At the moment these bolts are withdrawn the friction roller engages in the straight part of the action plate, and the action block begins to move back, drawing with it the breech plugs, which extract the cartridge cases 4. When the breech plugs are clear the friction roller on the action block bears against the forked arm and so pushes the carrier to the left. At the same time the cocking cam begins to press against the tooth of the trigger comb, carrying the latter to the right. The empty cartridge cases fall to the ground and are readily replaced by filled ones. The tenons of the hammers pass behind the teeth of the trigger comb, which is driven to the left by the spring, or by the cocking cam, as the action block moves forward. The handle moves forward with the following effects: 1. The friction roller on the action lever acts on the director, and moves the action block to the front. The action block, pressing against the fork, drives the carrier to the right, thus placing the cartridges in line with the barrels. 2. The action block advances to the front and the spiral springs are compressed by the hammers, which are kept back by the trigger comb. The plungers push the cartridges into the barrels. 3. When the cartridges are quite home, the action block stops, and the stud on the action lever causes the closing cam to drive the bolts into the holes in the gun frame, so that the breech closing is complete. 4. The action lever now begins to carry the trigger comb to the right. Each hammer is released in turn from the tooth which retains it, and the striker pertaining to it is driven forward in consequence. The action of the drill stop is this: The hand lever is brought up by it before it has completed the back stroke, so that the hammers cannot pass behind the trigger comb. Thus, the gun is not full cocked, because the springs are not compressed when the action block moves forward. The gun is sighted up to 1,800 yards, and the sight is so fitted that it can be moved up and down by means of a rack and pinion. The following are some of the principal advantages claimed for guns made on the Nordenfelt system: They are strong and simple, and the whole mechanism, as well as the springs and firing pins, can be taken out without the use of any tools; they fire either single shots or volleys of four shots each as desired. The cartridges are fed to each barrel from its own compartment, and independent of the others, so that if one or more barrels become damaged the fire can be continued from the remaining barrels. The gun is free from any possible liability to jam, more especially after some of the improvements recently adopted by the Admiralty. In order to test these improvements, 2,000 rounds were fired very rapidly without any hitch or jam whatever and most of the vessels at the bombardment of Alexandria were armed with these guns, firing many thousands of rounds without any failure or difficulty. Besides their principal object as defense against torpedo boats, these guns are especially useful for firing against the guns and riflemen in the enemy's tops, even if protected by shields—against conning towers and gun-ports—and in Egypt they have been recently used for firing through the port-holes of forts, and mounted on railway trucks, they have served for long range firing against troops. The capacity of the system for very rapid firing of steel projectiles of larger caliber than rifle bullets, makes it a very valuable weapon, even for purposes where, perhaps, strictly speaking, small shells might be more suitable, because with the modern swift vessels a slow-firing machine gun has really very little chance against a quick-volley gun for purposes where the latter has sufficient penetrating power.

The double-barrel 1-inch gun—This double-barrel 1-inch gun, shown in Fig. 2, has been made for the purpose of being mounted on torpedo boats, where the four-barrel 1-inch gun has been considered too heavy. The gun weighs only 1½ cwt., and its naval carriage and stand weigh together 165 pounds. Counting 345 pounds for 500 rounds of ammunition, 80 pounds for hoppers, and 132 pounds for the gunner, the weapon, with mounting ammunition and gunner complete, weighs 8 cwt., which is well within the limits that can conveniently be carried on a torpedo boat. When not in action, *i. e,* when the gunner and ammunition are below, the weight of gun and mounting is only one-third of the weight of the Nordenfelt four-barrel gun. It fires the same 1-inch steel-shot cartridges as the four-barrel gun, and with exactly the same initial velocity of 1,500 feet. Its penetrating power is consequently the same as that of the four-barrel 1-inch gun already described. The accuracy of fire is also the same when firing very slowly, and is somewhat higher when firing more rapidly, because its volley of two shots causes less vibration to the weapon from accumulated recoil than the volley of four shots. The rapidity of fire in proportion to the number of barrels is somewhat greater than that of the four-barrel gun, because the stroke of the lever is shorter. The four-barrel gun fires ten volleys in eight to ten seconds, this two-barrel gun fires ten volleys in six to seven seconds. This gun thus fires twenty shots in six to seven seconds, and it fires sixty shots in the half minute. As will be seen, the rectangular frame is made in one piece, with the center cross-bar dovetailed into it, and the front cross-piece bolted on to its fore end. The barrels are screwed into the center cross-piece and pass through the front cross-piece. The action cam is cut into the cam plate and is driven by the friction roller on the action lever, which again is moved by the firing handle, keyed on to the axis pin. The breech plugs are made in one piece with the cam plate, and contain the firing pins. On the upper face of the cam plate are two studs which pull back the hammers. The action block is moved right and left by the rear end of the action lever. In the action block there are four grooves, two of which receive the breech plugs when drawn back, the other two contain the hammers and spiral springs, which are held within them by the back plate, which carries the pressure of the action block on to the rear of the frame itself. The cartridge receiver is moved right and left in front of the action block by two lugs or cams on the cam plate. The trigger comb is inserted into the action block, and is held by a spring; the sloping surfaces of the hammer studs move it to the one side to catch the hammers, and the trigger comb is pushed against the side of the frame in order to release the hammers when the shots are to be fired, showing the parts separately. The operation of the mechanism of the Nordenfelt machine-gun may be described briefly as follows, supposing a discharge to have just taken place: 1. The firing handle travels to the rear, while the friction roller moves along the concentric part of the action cam, the plungers remaining steady in order to give sufficient support to the cartridge case after the discharge. The rear end of the action lever during this movement brings the action block over to the left and allows the spring to push the of trigger comb into position. 2. The continued rearward movement causes the cam plate to draw back the breech plugs into their grooves in the action block, after which the lugs upon it move the cartridge receiver over to the left to take a fresh layer of cartridges. 3. Just before the rearward movement is completed the hammers are caught by the studs on the trigger comb. The forward movement of the firing handle has the following effect: 1. It forces the lugs on the cam plate against the cartridge receiver and pushes it to the right so that the cartridges are in a line with the chambers in the barrels. 2. The cam plate is driven forward, and the breech plugs enter the grooves in the cartridge receiver, pushing the cartridges into the chambers. 3. When the breech plugs have closed the breech, the rear end of the action lever pushes the action block over to the right until the hammers come in a line with the firing pins, when the action block fully supports the rear of the breech plugs, the back plate of the action block resting firmly against the rear of the frame. 4. The movement of the action block to the right pushes the trigger comb against the inner side of the frame until the hammers are released and the shots fired. The principal advantages claimed for this system, in addition to those mentioned above for the four-barrel gun, and which also apply to this weapon, are the great simplicity of the mechanism, in which the number of parts is 16 in all, or only 8 parts per barrel. The movements of the parts of the mechanism are all inside the frame, so that the action block does not move beyond the rear part of the frame. When the firing handle is held forward in the position in which the gun would travel, the entire mechanism is inclosed, so that not even the slots for the extraction of fired cartridge cases are open. This makes this system especially suitable for guns which are exposed to dust and storms of sand.

In the following article are described all the Nordenfelt volley-firing guns which are at present manufactured: No. 1. *Two-barrel* $1\frac{1}{2}$ *inch gun*—This type weighs $4\frac{1}{2}$ cwt., and fires steel shot and shell weighing 22 ounces, with an initial velocity of 1,600 feet, giving a penetration of $1\frac{1}{2}$ inches into an iron plate at 300 yards; the shells have 580 grains bursting charge. This gun is made to compete with revolving cannon of the same caliber which fire 16 ounce shells with 337 grains bursting charge and 1,390 feet initial velocity, giving a penetration of $1\frac{1}{4}$ inches at 300 yards range. The rapidity of fire is about 40 shots per half minute. Both guns are about the same weight; the Nordenfelt is, however, the more rapid of the two, as it fires a volley of two shots for every single shot fired by the revolving gun. No. 2. *Two-barrel* $1\frac{1}{4}$ *inch gun*. This weighs $3\frac{3}{4}$ cwt., and is made in the same way as No. 1, and for the same purposes. Its shell weighs $14\frac{1}{2}$ ounces, with 460 grains bursting charge, but its greater initial velocity of 1,500 feet gives to this gun the same penetrating power as the $1\frac{1}{2}$ inch revolving gun, with its rapidity of fire and slightly less weight of gun. No. 3. *Two-barrel* 1-*inch* (*heavy*) *gun*.—Is made to No. 2 pattern, with exceptionally long barrels. The weight is 4 cwt. and it fires solid steel shot of $9\frac{3}{4}$ ounces (shells are not allowed for this weight of projectile). This steel shot gave at Portsmouth an initial velocity of 2,000 feet per second and penetrated a 2-inch solid iron plate at 300 yards range. This gun has been made for defense against torpedo boats if in future any country should carry out the idea to arm such vulnerable parts as boiler and engines with 1-inch steel plates. No. 4. *Four-barrel* 1-*inch* (*medium*) *gun*—The type of this gun is illustrated by Fig. 1. It fires 8.9-ounces solid steel bullets, with 1,650 feet initial velocity, and gives greater penetration than the four-barrel 1-inch English Admiralty gun; it

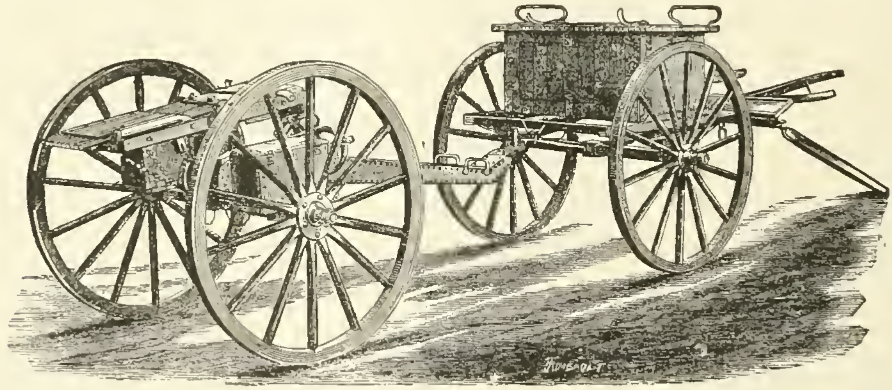

Fig. 3.

weights about ½ cwt. more, and is meant to be used for the same purposes and in the same manner as the ordinary four-barrel 1-inch gun No. 6, by any Navy that may desire to have greater penetrating power at the cost of more expensive ammunition and without reducing the rapidity of fire. No. 5. *Five-barrel 1-inch gun.*—This gun is similar to No. 6 and fires the same ammunition; it consequently has the same penetrating power but fires 20 per cent. more rapidly and weighs ½ cwt. more than the four-barrel gun. No. 6. *Four-barrel 1-inch gun.*—This gun has been already fully described as representing the Nordenfelt volley guns with more than three barrels. No. 7. *Two-barrel 1-inch gun.*—This gun has also been noticed (Fig. 2), as representative of the pattern of volley guns with less than four barrels, and is proposed for arming torpedo boats, as being the lightest volley gun made with sufficient penetrating power for this purpose, the only other gun of less weight of any other system with sufficient penetrating power, being the Nordenfelt single-barrel 1¼ inch shell-gun. No. 8. *Twelve-barrel rifle-caliber gun;* and No. 9. *Ten-barrel rifle caliber gun* fully illustrated in Fig. 3. These machine-guns weigh about 2½ cwt. and 2 cwt., respectively, and fire 1,200 and 1,000 rounds per minute. They are constructed after the same pattern as the four-barrel English gun, and are especially designed for naval as well as for land service, in competition with the five-barrel Gardner gun. At the Shoeburyness trials in February, 1881, the ten-barrel Nordenfelt did not act quite so well as it should have done in consequence of it having been adjusted to incorrect ammunition, but after the extracting and feeding gear had been put in order, the gun worked to perfection at all the Portsmouth trials in July, 1882. On that occasion it fired 3,000 rounds in three minutes three seconds without any hitch or jam whatever, and it worked so easily that the same man fired the whole of the 3,000 rounds without any relief; immediately after the firing ceased, the officers ascertained that the gun was in perfect order and worked quite as easily as at the commencement.

For land service they have been recommended more especially for two purposes. First, for acting on the flanks of artillery for the protection of artillery against infantry fire. The enemy's infantry could never advance so close up to a battery of artillery as to force it to retire if the battery had on each flank a ten-barrel gun firing rifle cartridges, and cavalry would never charge, or could never reach a battery protected thus by two guns capable of a very rapid fire continuously poured out of it, while the gunner who aims the gun would all the time follow the movements of the advancing cavalry. The ten-barrel guns are mounted on an ordinary light field carriage with its limber which holds 4,000 rounds (Fig. 3). Four horses easily manage the gun and limber, three men ride on the limber, and the Captain of the gun is separately mounted. The second purpose for which this type is adapted is especially for position defense. Wherever machine-guns can be used in such positions that there is little or no difficulty to provide ammunition, and where it is not required to lift the gun about too often, the ten-barrel Nordenfelt is to be recommended. Even with its great rapidity of fire it does not require any greater number of gunners to serve it than the five-barrel guns.

It has been stated that a machine-gun wastes ammunition, but this is not the case, because it must score a much greater percentage of hits than has been recorded in recent wars from rifle fire. This is quite natural, because the gun has no nerves and is not fired from the unsteady shoulder of a man panting with fatigue or excitement—and a soldier would commence to fire his rifle at long range (where he wastes his shots) for fear that he might not be able to stop in time an enemy who outnumbers him. If he has a gun that fires 1,000 rounds a minute, he would keep cool and aim carefully, well knowing that when he does commence fire at short range no enemy can face it. The No. 10. *Seven-barrel rifle-caliber gun;* and the No. 11. *Five-barrel rifle-caliber gun* are each made to the pattern of the four-barrel gun, with such alterations in the inner mechanism as are necessary, in consequence of the gun being narrower. They weigh 1½ cwt. and 1 cwt. respectively, and fire with a rapidity of 750 and 600 rounds per minute. The five-barrel gun has fired 3,000 rounds in 5 minutes 5 seconds without any hitch or jam; the same man firing the whole of the 3,000 rounds without relief. It has also fired at 30 degrees elevation, and at 30 degrees depression, the feeding and extraction giving perfect satisfaction. For the very rapid movements of mounted infantry, and to save time in dismounting the gun for firing, and mounting it again when it has to be moved, a very light carriage has been made at the suggestion of Lord Charles Beresford, on four wheels, to be drawn by two horses driven by a man sitting on his box on the two front wheels. The gun is mounted at the rear of the carriage, and is fired from it without taking out the horses; 3,000 rounds of ammunition are carried on the same carriage, as well as the gunner who fires the gun, and a second man who looks after and supplies the ammunition. The remainder of the service for the gun are mounted on spare horses, harnessed so as to replace quickly any of the driven horses that become disabled. The carriage itself is so light that it carries a shield to protect the gun and the gunners, and also to protect the horses against direct fire from the enemy's rifles during the time the gun is fired. This shield enables the gun to advance within shorter distance of the enemy's rifle fire than could otherwise be done, and allows the gun to be kept at shorter and more effective ranges when retiring before infantry. The essential idea of this mode of using the gun is of course to make all possible use of its exceedingly rapid movements, to rush forward to a comparatively close range against infantry or artillery, taking the risk of being disabled while galloping forwards (much in the same way as the men in a torpedo boat take the risk when approaching a vessel). In infantry service the gun is mounted on its own limber (Fig. 4), from which it is fired; the limber, as represented in the drawing, is on two wheels, the pole acting as a trail when the gun is to be fired. In this case, as well as in the previous one, the gun can be trained nearly all round by means of a traversing screw without shifting the position of the carriage. When mounted for infantry on the two-wheel limber carriage it can be served with six men with drag-ropes. If desirable, there can be four men dragging, the other two acting as reliefs when changing the men at the ropes, or as spare men if any of the others are disabled. With the Captain of the gun there would thus be only seven men required. The five-barrel gun can also be used for mountain service with advantage, the gun and the trail being quite light enough to be carried each on a mule, a third mule taking the wheels and axle, and a fourth the ammunition, hoppers, and implements, with other mules for spare ammunition—the only difference from the three-barrel gun being that this would require an additional mule for the gun and carriage and more ammunition. On the other hand its fire would be more effective, and only the same number of men are required to serve it. It could also be placed in an ammunition wagon for the use of infantry, though only four five-barrel guns could be carried, if closely packed, by the wagon within the same weight as six five-barrel guns. No. 12. *Three-barrel rifle-caliber gun;* and No. 13. *Two-barrel rifle-caliber gun.* These are made to the pattern of the two-barrel volley gun. They weigh respectively 55 pounds and 40 pounds, and fire at the rate of 400 and 300 rounds per minute. For naval service they are not used at present, because the five-barrel Nordenfelt is quite light enough for all naval purposes, but for land service they are very useful, in consequence of their lightness and simplicity. The three-barrel gun does not weigh more than the Gardner one-barrel, and the Nordenfelt three-barrel gun consists of thirty-five pieces compared to thirty-three pieces in the Gardner one-barrel. All these light Nordenfelt guns are, like those of larger calibers, made almost entirely of best wrought steel instead of the gun-metal so freely used in some other types of machine-guns. In order not to be exposed to rust, these light Nordenfelt steel guns are carefully and completely covered over in a galvanic bath with a coating of copper which protects the guns as well as all the various parts of the mechanism except the actual wearing surfaces. These types are designed especially for the following purposes: 1. *For cavalry.*—The gun is so light and so convenient in shape that it can be carried on a led horse at the same speed as the cavalry advances without disabling the horse. One led horse would then be required for the gun and implements, one led horse for the stand from which it is to be fired when the gun is dismounted, and one led horse for the cartridge hoppers or feed cases filled with ammunition. Other horses or baggage wagons would carry the extra supply of ammunition. 2. *For mountain service.*—A gun mule which can carry 2 cwt., including sad-

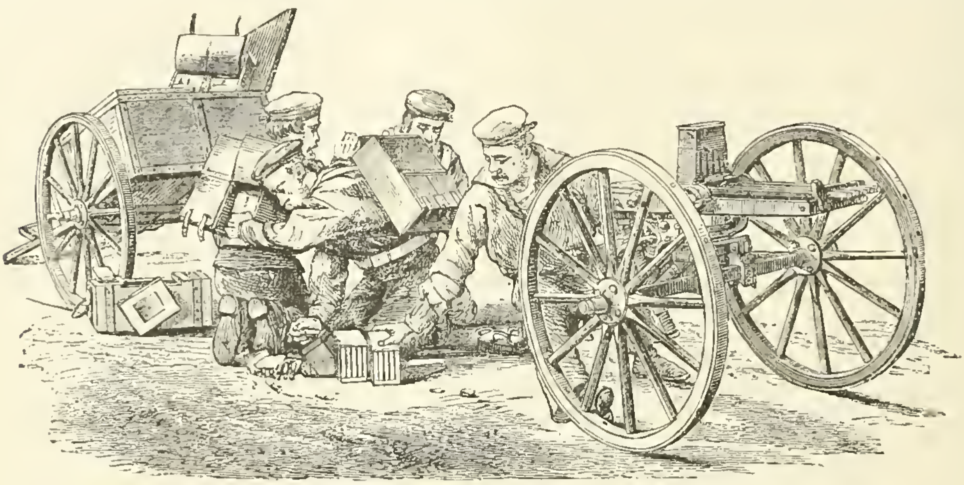

Fig. 4.

dle, would carry the gun and stand. A second mule would carry the wheels, axle, and cartridge hoppers filled, and other mules would carry the extra supply of ammunition wanted for the gun. 3. *For infantry.*—Six of these guns, with their stands, wheels and hoppers can be stowed away in one baggage wagon or extra ammunition wagon, and follow the ammunition train which is nearest to the front. Whenever a comparatively small force of infantry is hard pressed, or when it has to protect a threatened point, a larger cantonment, or temporary intrenchment, the six guns can be lifted off the wagon and be ready to commence fire in a few minutes. Two men can drag each gun on its wheels for considerable distances, and one man can carry the gun with two men carrying the stand, if such difficult ground is met with that such a light gun cannot conveniently be dragged over on its wheels. No. 14. *Single-barrel rifle-caliber gun.*—This gun is made with a different mechanism from the two patterns above named. It weighs 13 pounds, and it fires at the rate of 180 rounds per minute; it has often fired successive spurts of 30 shots each in eight to ten seconds. This gun has been made in order to show that a single-barrel machine-gun need not be more than 4 pounds heavier than an ordinary rifle; at the same time no single-barrel rifle-caliber would really be used in war—except, perhaps, as a wall piece—when it is proved that even a three-barrel gun can be made light enough to be carried by a man on his shoulder. A General would probably not submit to the expense and inconvenience of a machine-gun equipment and service of men and mules for gun and ammunition, when the efficiency of the gun is entirely dependent on one single rifle barrel. See *Machine-gun.*

NORMAL PROFILE.—Profile which would be constructed for a work located upon a level site, and when there is time to build it. It is evident that great variations must occur, influenced largely by the kind of earth and the surrounding circumstances at the time of the construction. Slopes which are practicable in one kind of earth will not retain their shapes in other kinds. Parapets placed on sites commanding all ground in common range need not be so high as those on lower ground commanded by neighboring heights. The principles laid down and the reasons expressed for the normal profile apply equally well to all its variations. A consideration of the following principles will lead to the construction of a strong profile which is essential to a vigorous defense. Men of the greatest ordinary stature, in bringing their muskets to an aim, do not fire at a higher level than about five feet; therefore any mass of this height in front of them will just intercept their fire; but this mass would not shelter a man standing behind it; to effect this, in the case of the tallest men usually found in the ranks, the interior crest should be at least six feet six inches above the terre-plein. The command must then be regulated by these two facts, and this principle may be laid down. The command of a field work over the ground occupied by the assailant, should be at least five feet; and six feet six inches over that occupied by the assailed. In following this rule for the command, we deprive the assailant of a plunging fire upon the parade; but as a breast-height of five feet is too high for men of ordinary stature to fire over it and give their pieces any sensible depression, as is very often requisite, it would be necessary to throw up a sufficient banquette for this purpose behind the parapet, which would add to the time and labor of constructing the work. On this account it is best to give the parapet only the height to admit effective firing over it, which is about four and a quarter feet. But this minimum command would give the assailed only a slight advantage, as the men, when on the banquette, would be still much exposed; and in an assault the height of the parapet would present an inconsiderable obstacle. These defects of low works have led Engineers to adopt *eight feet as the least height of parapet* which will admit of any respectable defense. The *greatest height* has been fixed at *twelve feet*, owing to the difficulty of throwing up a work with the ordinary means at hand, which are usually only the pick and shovel.

The thickness of the parapet, which is always estimated by the horizontal distance between the interior and exterior crests, is regulated by the material used for the parapet; the kind of attack; and its probable duration. The rule adopted for this is to add to the depth of penetration of the projectile, given by experiment, one-half for this thickness. In following this rule there will always be a thickness of earth between the extreme penetration of a projectile, at any point below the exterior crest and the interior of the work, greater than one-third the thickness of the parapet. The superior slope is arranged to defend the crest of the counterscarp; to effect which the fire should not strike below the crest, nor pass more than three feet over it; otherwise, either the counterscarp would be damaged, or the assailed by stooping when near the crest, would find a shelter. The inclination of the superior slope, however, should not be greater than one-fourth, nor less than one-sixth. If greater than one-fourth, it would make the portion of the parapet, about the interior crest, too weak; and if less than one-sixth the ground directly in front of the work would not be so well defended; moreover, as artillery cannot be fired at a greater depression than one-sixth, without injuring the carriage, this inclination of the superior slope serves as a check in rapid firing.

The exterior slope *is the same that the earth naturally assumes*. Any means used to make it steeper would be injurious; because they would be soon destroyed by the enemy's fire, and the earth giving way, the necessary thickness of the parapet would be diminished.

The interior slope *receives a base equal to one-third its height*. This is a result of experience, which has shown that it is the most convenient for the soldier in leaning forward to deliver his fire over a parapet.

The tread of the banquette *is placed four feet three inches below the interior crest;* this will admit men of the lowest ordinary stature, to fire conveniently over the parapet. Its width is *two feet, for a defense with one rank; and four feet for two or three ranks;* because the third rank does not fire, and is therefore placed on the banquette slope, *the base of which is twice the altitude*, to render the ascent convenient. When the tread of the banquette is very high, and particularly in enclosed works, where interior space is wanted, steps may be substituted for a slope.

The berm is a defect in field works, because it yields the enemy a foothold to breathe a moment, before attempting to ascend the exterior slope. It is useful in the construction of the work for the workmen to stand on; and it throws the weight of the parapet back on the scarp, which might be crushed out by this pressure. In firm soils, the berm may be only from *eighteen inches to two feet wide;* in other cases, as in marshy soils, it may require *a width of six feet*. In all cases, it should be *six feet below the exterior crest*—to prevent the enemy, should he form on it, from firing on the troops on the banquette.

The ditch should be regulated to furnish the earth for the parapet. To determine its dimensions, the following points require attention: its depth should not be less than six feet, nor its width less than twelve feet, to present a respectable obstacle to the enemy. It cannot, with convenience, be made deeper than twelve feet; and its greatest width is regulated by the inclination of the superior slope, which, produced, should not pass below the crest of the counterscarp. The slopes of the scarp and counterscarp will depend on the nature of the soil, and the action on it of frost and rain. The scarp is less steep than the counterscarp, because it has to sustain the weight of the parapet. It is usual to give the slope of the scarp a base equal to two-thirds of the base of the natural slope of a mound of fresh earth whose altitude is equal to the depth of the ditch; the base of the counterscarp slope is made equal to one-half the same base. In excavating the ditch it will be found that more earth will be furnished at the salients than is required there for the parapet; and that the re-enterings will not always furnish enough. On this account, the width of the ditch should not be uniform, but narrower at the salients than the re-enterings. The salients of the parapet on horizontal sites, are sometimes made higher than the re-enterings, a gradual slope being given to the interior crest from the salients to the re-enterings, with a view to cover better the terre-plein, towards these last points, from the plunge of an enfilading fire on the faces. The effect of this, however, is but trifling, as the descending plunge of the projectile is the greater, as the salient is higher over which it passes. On such sites, therefore, the profile of the parapet is usually uniform throughout. See *Field Fortification* and *Profiling*.

NORTON LIQUID FIRE.—In the character of its effects, this rivals all that has been recorded of the old *Greek fire*. The composition here used consists of a chemical combination of sulphur, carbon, and phosphorus. The composition is enclosed in a shell, and is instantly ignited upon the shell striking any object.

NORWEGIAN ARMY.—By the terms of the laws of 1866 and 1876, the army of Norway is composed of Troops of the Line, the Military Train, the Militia or Landevaern, the Civic Guards, and the Landstorm, or final war levy. In 1878 the Troops of the Line numbered 12,000 men and 750 officers. All young men above twenty-one years of age are liable to serve, with the exception of the inhabitants of the three northern amts of the kingdom. The only fortified spots are Fredericksteen at Frederickshald, Frederickstad, Akershuus, Bergenshuus, Munkholm, and Vardohuus.

NOSE-BAG.—A bag of stout canvas with a leather bottom, and having straps at its upper, open end. by

which it may be fastened to a horse's head while he is eating the contained provender. It is generally used for feeding the grain out of the stables. The drawing represents a nose-bag properly provided with means for ventilation. Horses suffer much when their noses are confined in a close nose-bag, where the jaws cannot be opened without compressing the nostrils and preventing the ingress of sufficient air.

NOSE-BAND.—The lower band of a military bridle, passing over in front and attached to the cheek-straps.

NOTABLES.—The name formerly given in France to persons of distinction and political importance. As the States General were inconvenient to the despotism of the Monarchy, the Kings of the House of Valois adopted the expedient of calling in their stead *Assemblies of the Notables*, the time of calling them and the composition of them being entirely dependent on the pleasure of the Crown, by which also their whole proceedings were guided, so that they generally consented at once to whatever was proposed to them. They showed a particular readiness in granting subsidies, to which they themselves, as belonging to the privileged classes, were not to contribute. An Assembly of Notables, convened in Paris by Richelieu in 1626, and presided over by Gaston, brother of Louis VIII., consisted of only 35 members. For more than a century and a half even this poor acknowledgment of any other mind or will in the nation than that of the Sovereign ceased to be made; but when the state of the finances brought the monarchy into difficulties and perils, Louis XVI., at the instigation of the Minister Calonne, had recourse again to an Assembly of Notables, which met Feb. 22, 1787, and was dissolved May 25. It consisted of 137 members, among whom were 7 Princes of the Blood, 9 Dukes and Peers, 8 Marshals, 11 Archbishops, 22 Nobles, 8 Councilors of State, 4 Masters of Requests, 37 Judges, 12 Deputies of the Pays d'Etats, the Civil Lieutenant, and 25 persons belonging to the Magistracy of different cities of the kingdom. Calonne's representations of the state of the finances induced the Notables to adopt many reforms in the matter of taxation; but no sooner was the assembly dissolved, than many of them joined the Parliaments in opposition to resolutions adverse to their private interests, so that the King was compelled to determine upon assembling the States General. Necker, who had meanwhile been placed at the head of affairs, assembled the Notables again, Nov. 6, 1788, to consult them concerning the form in which the States General should be convened. The Notables declared against every innovation, and so compelled the court to half measures which helped to prepare the way for the Revolution. The Parliament of the new principality of Bulgaria is spoken of as the Assembly of the Notables.

NOTE.—A brief writing intended to assist the memory. Members of Courts-Martial sometimes take notes. They are frequently necessary to enable a member to bring the whole body of evidence into a connected view, where the case is complex.

NOT GUILTY.—The form of verdict in a criminal prosecution, and also in some civil actions, when the Court find in favor of the defendant or accused party. The verdict is conclusive, and the accused cannot, in criminal cases, be tried a second time.

NOT PROVEN.—A form of verdict used in criminal prosecutions when the Court thinks there is some foundation for the charge, but the evidence is not strong enough against the prisoner to warrant a verdict of guilty. In such a case, a verdict of "Not Proven" is substantially a verdict of acquittal. The prisoner cannot be tried afterward, even though new and conclusive evidence come to light after the verdict.

NOYADES.—The execution of political offenders in great numbers at once by drowning them, one of the atrocities of the French Revolution, practiced at Nantes by Carrier, the deputy of the Convention. This mode of execution was also called, in cruel sport, *Vertical Deportation.*

NOYAN.—1. The whole of the vacant space or bore of a cannon, under which are comprehended the diameter of the mouth, the vacant cylinder, the breech, and the vent. 2. With respect to bombs, grenades, and hollow balls, that which is called *Noyan* consists of a globular piece of earth, upon which the cover is cast. The metal is poured in between the cover and the Noyan, after which the Noyan, or core, is broken and the earth taken out.

NUGGAR.—A term in the East Indies for a fort.

NUMEROS.—Round pieces of brass or other metal, which were numbered and used in the old French service in the detail of guards.

NUNCIO.—The name given to the superior grade of the Ambassadors sent by the Pope to Foreign Courts, who are all called by the general name of Legate. A Nuncio is an Ambassador to the Court of an Emperor or King. The Ambassador to a Republic, or to the Court of a Minor Sovereign, is called Internuncio.

NUNCUPATIVE WILLS.—A nuncupative will, so termed from naming an executor by word of mouth, is a verbal testamentary declaration or disposition. By the common law, it was as valid in respect to personal estate as a written testament. A will could not only be made by word of mouth, but the most solemn instrument in writing might be revoked orally. In a rude and uncultivated age, to have required a written will would have been a great hardship, but with the growth and progress of letters, the reason for permitting a verbal testament diminished in force, until an effort to establish such a will by means of gross fraud and perjury gave rise to the provisions of the Statute of Frauds. Nuncupative wills, not being regulated by statute as to their mode of celebration or execution, the single question for the judgment of the Court is, whether the nuncupation was made by a person entitled to that privilege. The restrictions of the Statute of Frauds were not applied to wills made by "any soldier being in actual military service, or any mariner or seaman being at sea." By the revised statutes of New York it was provided that nuncupative wills should not be valid, "unless made by a soldier while in actual military service, or by a mariner while at sea." The terms of the exception in the statute are briefly stated as follows:—"Any soldier being in actual military service, or any mariner or seaman being at sea." The phraseology is slightly different in these statutes; but the rule is substantially the same in all—that the nuncupation is only valid when made by a soldier in actual military service, or a mariner at sea, at the time of the testamentary act. It is not enough to be a soldier or a sailor, but there must be actual service. The military testament was first conceded by Julius Cæsar to all soldiers, but it was subsequently limited by Justinian to those engaged in an expedition—*solis qui in expeditionibus occupati sunt.* The exception was borrowed with the rule from the civil law, and the courts have invariably adhered to the principle that there cannot be actual warfare and the soldier not be engaged *in expeditione.* So also the nuncupation of a mariner to be valid must be made at sea. It is sometimes difficult to determine when the mariner is to be considered at sea. For example, Lord Hugh Seymour, the Admiral of the station at Jamaica, made a codicil by nuncupation while staying at the house on shore appropriated to the admiral of the station. The codicil was rejected on the ground that he only visited his ship occasionally, while his family establishment and place of abode were on land at the official residence. But when a mariner belonging to a vessel lying in the harbor of Buenos Ayres, met with an accident when on shore by leave, made a nuncupative will, and died there, probate was granted for the reason that he was only casually absent from his ship. The will of a shipmaster made off Otaheite has also been allowed. The principle upon which the privilege of nuncupation is conceded applies to all persons of whatsoever classes engaged in the marine service, whatever may be their special duty or their occupation on the vessel. As in the army, the term "soldier" embraces every grade, from the private to the highest officer, and includes the gunner, the surgeon, or the general; so in the marine, the term "mariner" applies to every person in the naval or mercantile service, from the common seaman to the captain or admiral. It is not limited or restricted to any special occupation on shipboard, but a purser, or any other person whose particular vocation does not relate to the sailing of the vessel, possesses the same right as the sailor. A cook is certainly as much a necessary part of the effective service of a vessel as the purser or the sailor; and there would seem to be no reason why he should be excluded from the advantage of a rule designed for the benefit of men engaged in the marine, without reference to the particular branch of duty performed in the vessel. As well because the wills of soldiers and mariners were excepted from the operations of the provisions of the Statute of Frauds, as for the reason and ground of the exception, and the peculiar character of the military testament, it was never held requisite that their nuncupations should be made during the last sickness. Nor has any particular mode been prescribed in respect to the manner of making the testament. The very essence of the privilege, however, consists in the absence of all ceremonies as legal requisites—or, as Merlin states the proposition, "their form was properly to have no form." It is true the Roman law prescribes two witnesses; but this, however, did not relate to the essence of the act, but only to the proof. In respect to evidence, we do not follow the civil or canon law; no particular number of witnesses is required to verify an act judicially, and all the court demands is to be satisfied by sufficient evidence as to the substance of the last testamentary request or declaration of the deceased. This ascertained, the law holds it sacred, and carries it into effect with as much favor and regard as would be paid to the most formal instrument executed with every legal solemnity. And so, according to numerous decisions, made in Great Britain, quoted by Prendergast, "whenever a military officer on full pay makes an informal will its validity can only be supported by showing the testator to have been on actual military service at the time the will was made. And the result of the decisions appears to be, that an officer serving with his regiment, or in command of troops in garrison or quarters, either in the United Kingdom or the Colonies, is not deemed on *actual* military service. To satisfy the meaning of the Act of Parliament in that respect, he must be on an expedition, or on some duty associated with positive danger."

NURSE.—A person whose whole business is to attend the sick in hospital. In the United States service, nurses are detailed in post hospitals from the companies who are serving at the post. Ordinarily one nurse is allowed to every ten persons sick in hospital. In Continental Armies the "Sisters of Charity" usually carry their mission of mercy into the military hospitals. Protestant England having no such organization to fall back upon, the soldiers have been dependent on the regular male hospital attendants for their care during sickness, or when suffering from wounds. The Crimean campaign, however, disclosed so melancholy a picture of the want of women's co-operation, that a band of self sacrificing ladies, headed by Miss Nightingale, proceeded to Turkey, and were soon acknowledged as messengers of health and life by the unfortunate wounded. The example thus set has not been without effect. In the Franco-German war of 1870-71 lady-nurses in large numbers and of various nations ministered in all the military hospitals, and the like took place again during the Russo-Turkish war of 1877-78.

NUTHALL RIFLE.—In the ordinary mode of grooving rifles, sharp angles are left between the groove and "land" (those parts of the smooth-bore left in their original state after the process of grooving has been completed). These create great friction with the projectile, both in loading and discharging. Major Nuthall removes these objections by rounding off the "lands" into the grooves, that is, making them a series of convex and concave curves, the bore assuming a beautiful appearance to the eye, for the smoothness and evenness with which the lands and grooves blend into each other.

O

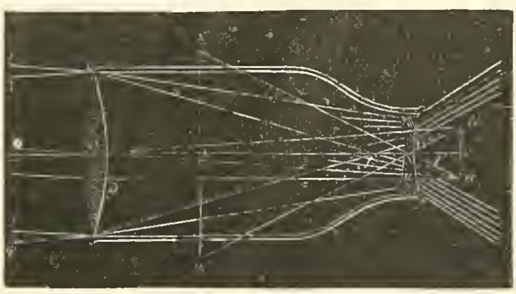
OAKUM.—A tangled mass of tarred hempen fibers, made from old rope by untwisting the strands and rubbing the fibers free from each other. Its principal use is in caulking the seams between planks, the space round rivets, bolts, etc., for the purpose of preventing water from penetrating. It is much used in artillery for packing shot and shell, wiping the vents of guns after firing, cleaning elevating screws and implements, and in making washing sponges.

OATHS.—The taking of the oath of fidelity to Government and obedience to Superior Officers, was, among ancient armies, a very solemn affair. A whole corps took the oath together, sometimes an entire army. In modern times, when so many other checks are used for maintaining discipline, the oath has become little more than a form. In the United Kingdom a recruit enlisting into the army or militia, or a volunteer enrolling himself, swears to be faithful to the Sovereign, and obedient to all or any of his Superior Officers; also to divulge any facts coming to his knowledge which might affect the safety of his Sovereign, or the stability of that Sovereign's Government. The Members of a Court-Martial take oath to try the cases brought before them justly, according to the evidence, to keep secret the finding until confirmed by the proper authority, and to keep secret always the opinions given by the members individually. The only other military oath is the common oath of a witness before a Court-Martial to tell the truth the whole truth, and nothing but the truth. See *Articles of War*.

OBEDIENCE.—Submission to the lawful orders of a Superior. Two questions arise under this article: Who is to judge of the *legality* of the command, and who may constitute a *Superior Officer?* It is evident that if all officers and soldiers are to judge when an order is *lawful* and when not, the captious and the mutinous would never be at a loss for a plea to justify their insubordination. It is, therefore, an established principle, that, unless an order is so manifestly against law that the question does not admit of dispute, the order must first be obeyed by the Inferior, and he must subsequently seek such redress against his Superior as the laws allow. If the Inferior disputes the legality before obedience, error of judgment is never admitted in mitigation of the offense. The redress now afforded by the laws to Inferiors is not, however, sufficient; for doubtful questions of construction of Statutes, instead of being referred to the Federal Courts of Law for their true exposition, have received variable expositions from the Executive, and left the army in an unfortunate state of uncertainty as to the true meaning of certain laws, and this uncertainty has been most unfavorable to discipline. Again, while the punishment of death is meted to officers and soldiers for disobedience of *lawful* commands, the law does not *protect*, officers and soldiers for obeying *unlawful* commands. Instances have occurred in our country, where officers and soldiers have been subjected to vexatious prosecutions, simply for obeying orders, according to their oath of office. Would it not be just if the law, instead of requiring officers and soldiers thus nicely to steer between Scylla and Charybdis, should hold the Superior who gives an illegal order, alone responsible for its execution? By *Superior* Officer in the Articles of War, is meant an officer who has the right to command his inferiors in the military hierarchy. The word superior, therefore, embraces, within their appropriate circle of of command, Commanding Generals, Superior Regimental and Company Officers, Superior Officers of Corps or Departments, and the Commanding Officer on guards, marches, or in quarters of whatever corps of the line of the army, marine corps or militia authorized to command the whole, whenever different corps come together. This construction of the words "officers appointed over me, according to to the Rules and Articles of War," is manifest by an attentive examination of those articles. See for example, ART. 24, which gives authority to "all officers of what condition soever to part and quell all quarrels, frays, and disorders, *though the persons concerned should belong to another regiment, troop, or company*." Here it is seen that the ordinary subordination, by grades, is found only in the same "*regiment, troop, or company*." The power to part and quell quarrels, is, however, made an exceptional case, in favor not only of officers of *different* regiments, but the power is even extended to those of an "inferior rank." In a company, regiment, or corps, subordination by grades is established by the terms of the commission held in such regiment or corps. So, also, where officers hold commissions in the army at large, their right to command when on duty is co-extensive with their commissions. Within regiments and corps the muster-roll, then, at once determines the question of superiorty of officers on duty.

OBERER.—One of the three parts of which the enciente is formed, in the German system of fortification.

OBJECT-GLASS.—The glass in a telescope or microscope, which is placed at the end of the tube nearest the object, and first receives the rays of light reflected from it. The office of the *object-glass* will be clearly understood by an examination of the common opera-glass, shown in the drawing. This is a double tele-



scope, constructed optically on the same principle as the telescope invented by Galileo, and is used for looking at objects that require to be clearly seen rather than greatly magnified—such as scenery and performances in theaters and public halls. Each tube contains a convex achromatic object lens and a double concave eye lens, which are placed at nearly the difference of their focal length apart. Thus, if the object-glass is five inches focus, and the eye-piece one inch negative focus, the length of the bodies will be about four inches, and the power will be nearly five times—that is, the objects looked at through the opera-glass will be seen as distinctly as they would be with the naked eye if brought four times nearer the observer. Opera-glasses, are short and light, and can be easily managed with one hand; they have small magnifying power, say from two to four times. The two object-glasses or large lenses are the most important ones, and upon their perfection the quality of the opera-glass depends.

With the opera-glass a low magnifying power and large and clear field of view are the great objects to be desired, on account of the comparative nearness of the objects looked at; but when the objects are one or more miles distant, power becomes a more important quality than field of view. To obtain a greater magnifying power with glasses constructed upon the principle of the opera-glass, the distance between the object-glasses and eye-pieces must be increased, and the greater that distance the higher the power. In order to keep up fair proportion of light with the increase of power, the object-glasses must increase in diameter. Such glasses, as they are only intended for outdoor use, are called Field or Marine-glasses, have shades to extend beyond the object-glasses to keep off the sun or rain, and are made throughout very substantially, in order to bear rough handling of field or sea service. They are put up in strong leather cases, with strap to sling over the shoulder. The power of field-glasses varies from five to eight times, and their clearness and efficiency depend upon the accuracy of finish of the object-glasses, and their durability to the strength and good workmanship of the body. See *Spy-glass*.

OBJECTIVE POINT.—The point to be reached or gained by an army in executing a movement, has been termed the *objective point*. There are two classes of objectives, viz: *natural* and *accidental*. The term *geographical* is frequently used to designate the first of these. A *natural objective* may be an important position, strong naturally, or made so by fortifications, the possession of which gives control over a tract of country, and furnishes good point of support or good lines of defense for other military operations. Or, it may be a great business center, or a capital of the country, the possession of which has the effect of discouraging the enemy and making him willing to sue for peace. *Accidental objectives* are dependent upon the military operations which have for their object the destruction or disintegration of the enemy's forces. These objectives are sometimes called "*objective points of manœuver*." The position of the enemy determines their location. Thus, if the enemy's forces are greatly scattered, or his front much extended, the central point of his position would be a good objective point, since the possession of it would divide the enemy's forces, and allow his detachments to be attacked separately. Or, if the enemy has his forces well supported, a good objective would be on that flank, the possession of which would allow his communications with his base to be threatened. It is well to remark that the term "point" used in this connection is not to be considered merely in its geometrical sense, but is used to apply to the *object* which the army desires to attain, whether it be a position, a place, a line, or even a section of country. See *Base of Operations* and *Line of Operations*.

OBLAT.—A disabled soldier formerly maintained by abbeys.

OBLIQUE.—This term, in tactics, indicates a direction which is neither parallel nor perpendicular to the front, but more or less diagonal. It is a command of warning in the tactics for the movement. It is used when referring to diagonal alignments, attacks, orders of battle, squares against cavalry, changes of front, fires, etc. The *oblique step* is a step or movement in marching, in which the soldier, while advancing, gradually takes ground to the right or left at an angle of about 25°. It is not now practiced.

As soon as recruits are well established in the principles of the direct march, they should be exercised in marching obliquely. The squad marching in line, the Instructor commands: 1. *Right* (or *left*) *oblique*, 2. MARCH. At the command *march*, each man makes a half face to the right, and then marches straight in the new direction. As the men no longer touch elbows, they glance along the shoulders of the nearest files, toward the side to which they are obliquing, and regulate their steps so that their shoulders are always behind those of the next man on that side, and that his head conceals the heads of the other men in the rank. The men preserve the same length of pace and the same degree of obliquity, the line of the rank remaining parallel to its original position. To resume the original direction, the instructor commands: 1. *Forward*, 2. MARCH. At the command *march*, each man makes a half face to the left in marching, and then moves straight to the front. If the squad be at a halt, the men half face to the right at the command *right oblique*, and step off at the command *march*. If halted while obliquing, they will, after halting, face to the front without further command. In the oblique march in line, the guard is always on the side toward which the oblique is made, without any indication to that effect being given; and, when the direct march is resumed, the guide is, equally without indication, on the side where it was previous to the oblique. *This rule is general.* The squad in column of files obliques by the same commands and means as when in line, the leading file being the guide.

OBLIQUE EMBRASURE.—A direct embrasure is one in which the directrix is perpendicular to the interior crest at the point of intersection with the crest; an *oblique embrasure* is one in which the directrix makes an angle with the interior crest. When possible, direct embrasures are the ones which are made. If oblique embrasures are to be made, their method of construction is practically the same as that given for direct embrasures. Oblique embrasures do not admit of the muzzle of the gun being inserted so far as the direct ones, and they weaken the parapets more. Oblique embrasures are not used, as a rule, if the directrix makes with the normal to the crest an angle exceeding ten degrees. In case the angle is greater, the embrasure is provided for, in field works, by modifying the interior crest. The manner of laying out an oblique embrasure is similar to the direct; the mouth is of a rectangular form, but is made wider in proportion to the obliquity, in order that the part of the embrasure which corresponds to the muzzle of the gun may be nearly of the same width in both the direct and oblique embrasures. The exterior width of the sole is made equal to one-half the length of the directrix, measured on the sole. The cheeks are laid out as in the last case. The muzzle of a gun should enter at least six inches into the embrasure, to prevent the blast from injuring the cheeks; this limits the obliquity of the directrix to about sixty for long guns. The height of the cheeks must not be more than four feet for the same reason; it will, therefore, in most cases, be necessary to raise the ground on which the wheels rest, giving to the top surface the same dimensions as for a barbette, and forming the side slopes and ramps in like manner. See *Embrasure*.

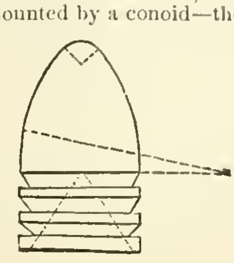
OBLIQUE FIRE. When two batteries bring their fire obliquely upon one point of the enemy's line, they make, what is called, a cross or concentrated fire, which is very destructive upon columns, though not so effective as enfilade fire. If a pointed projectile strike an iron plate at a less angle than that formed by a tangent to the curve of the head, it will probably glance off, as the tendency of the shoulder will be to slide along the plate, and the point will find a difficulty in "biting." If the angle be greater than about 50 degrees, the resistance will approximately be increased in the proportion of the extra thickness to be traversed. In this case the sharp point of the projectile "bites" the plate on striking, and the shot has a tendency to bring its axis perpendicular to the face of the target; perforation then depends upon the energy with which the projectile may be animated. Thus the side of the *Monarch* (7-inch plates) could be perforated "directly" by a projectile having a zone-energy of 90 foot-tons, but it would require 120 foot-tons to send the same projectile through at an angle of 60 degrees. The defense, therefore, should not rely too much on the chance of shot striking "obliquely"; for the projectiles fired from large modern rifled ordnance would probably perforate all thinly armored ironclads at all fighting angles and ranges.

OBLIQUE FLANK.—In fortification, that part of the curtain from whence the face of the opposite bastion may be discovered; and is the distance between the lines *rasant* and *fichant*, which are rejected by some engineers, as being liable to be ruined at the beginning of a siege, especially when made of sandy earth. This oblique or second flank defends very obliquely the opposite face, and is to be used only in a place attacked by an army without artillery.

OBLIQUE ORDER OF BATTLE. Military writers describe this order of battle as one in which the primitive parallel order has been departed from, with the design of giving the one force, by maneuvering, a superiority over the other, or, in other words, if an army attacks its enemy in flank, say the right, its own right must be refused, and hence, when it arrives on the enemy's line, the army will be in oblique order. In order to make use of the oblique order with success, the enemy must be deceived as to the intention to attempt it, otherwise it may be in his power to frustrate its execution by reinforcing the menaced flank; extreme caution, therefore, in the preparation for such a maneuver, and the utmost rapidity in its execution, are indispensably requisite. The aim of using this order of battle is to turn or outflank the enemy. See *Order of Battle*.

OBLIQUE STEP.—A step or movement in marching, in which the soldier, while advancing, gradually takes ground to the right or left at an angle of about 25°. It is not now practiced.

OBLONG BULLET.—This form of bullet at present used in the United States' service, is composed of a cylinder surmounted by a conoid—the conoid being



formed of the arcs of three circles. The cylinder has three grooves cut in it, in a direction perpendicular to its axis, to hold the grease necessary for lubricating the bore of the piece in loading, and possibly to guide the bullet in its flight, after the manner of the feathers of an arrow. A conical cavity is formed in the bottom, in which the gas of the charge expands, and forces the sides of the bullet into the grooves or rifles of the gun. From these grooves it receives a rotary motion around its long axis, which prevents it from turning over in its flight. See *Bullet*, *Projectiles* and *Round Bullet*.

OBSERVATORY.—For the purpose of observing the flight and effect of the projectiles, a look-out termed an observatory, is arranged on one of the flanks of the battery; in most cases the end of an epaulement will afford a safe point, where a secure shelter of sand-bags can be made so as to enable an officer with a field-glass to note the range and effect of the fire, so as to regulate it and give the greatest efficiency.

OBSERVER SERGEANTS.—In the United States, Sergeants in the Signal Service, stationed in large towns and important commercial centers to give timely warning of the approach of storms, rise of rivers, and all other important weather news for the guidance of merchants and others.

OBSIDIONAL CROWN.—A crown so called among the ancients, which was bestowed upon a Governor or General, who by his skill and exertions, either held out or caused the seige to be raised of any town belonging to the Republic. It was made from the grass which grew on the spot, and was therefore called *graminens*.

OBSTACLES.—No obstacle is insurmountable. Obstacles may hinder, and even stop for a while, an enemy's approach, but they can be overcome. Their passive resistance must be aided by the active resistance of the defense. These obstacles, in order that they should be *accessory* means of defense, should detain the enemy in a position where he will be under the fire of the defenders at close range. Hence, the following conditions should be observed in arranging the obstacles in front of a field work. 1. The obstacles should be placed within close musketry range of the defense. 2. They should be arranged so as not to afford shelter to the enemy. 3. They should, as a rule, be protected from the fire of the enemy's artillery. 4. They should be arranged so as not to interfere with an active defense of the work. Their uses as obstacles will depend upon the degree of resistance which they offer in harmony with the foregoing conditions. Abatis placed in the ditch will, in one case, be in the best position: in another, it should be placed some distance in front of the work. A fraise placed in the scarp, when the ditch is swept by a fire from the work or from ditch defenses, will be better than if along the counterscarp. Torpedoes, military pits, entanglements, etc., may all be combined. In some cases the ground in front of the work will be the better position; in others, the crest of the counterscarp and the ditches offer the best conditions for their use. As a general rule, it is advisable to place the obstacles not nearer than fifty yards to the interior crest, if the profile is a weak one. When the profile is strong, it is not a matter of so much importance, so long as the assaulting columns are exposed to the fire of the defense. It is well to remark with respect to inundations, that they should not be used until the last moment. The unhealthiness due to the presence of stagnant water is apt to produce more casualties than are to be feared from the enemy's attacks. If the dams can not be protected or hidden from the enemy's artillery fire, they should be built, as far as possible, so that the enemy can bring his fire to bear only upon the upper side. The amount of the dam exposed to his fire will then only be the portion between the top and the surface of the water. See *Accessory Means of Defense*.

OBSTRUCTIONS.—Water may be made a very important accessary means of defense in many localities, as in a flat, marshy country where the level of the natural surface lies but at a slight elevation above the water-level; or as, in the case of an undulating surface, where small streams running through valleys, can be dammed back, so as to produce an inundation of some extent.

In the former case, the defensive works can be easily girdled by a zone of marshy ground, which will give an assailant great trouble to construct his trenches and other siege-works upon, whilst the work itself can be secured from attempts at surprise, by keeping its ditches filled with water to the depth of six feet at least. In such a locality—moreover, if in a climate where the winters are mild—revetted scarps and counterscarps, the chief use of which is to prevent an attempt at an open assault, may be replaced by earthen ones, a strong stockade being formed along a wide berm, answering as a corridor, to give greater security on the more exposed fronts of the work.

In the latter case, portions of the ground, in the immediate vicinity of the works, may be covered by a sheet of water, of sufficient depth to prevent their being used by the assailant in his approaches; and within the inundation thus artificially produced detached works may be erected, which, by taking flank and reverse views over other lines of approach of the assailant, may force him to make his approach upon other points which will have been strongly fortified to meet this condition of things.

To form these artificial inundations the locality must lend itself to the construction of dams, in such a position that they cannot be reached by the assailant's missiles, and will be secure from any other means he may take to destroy them. This supposes, then, that the stream should either run through the works, so that the dam could be erected within them or so near to them that, in combination with some advanced work, the dam may be made secure.

In a locality having these features, the inundation would, as a general rule, have to be formed on the upstream side of the work, since, if made below it, the dam would have to be placed further from the work, and the inundation itself might spread up too far within. Besides these objections to this position, an assailant would evidently have greater facilities for tapping the inundation and running the water off than when it occupies the upstream position. The position and extent of the dams, and the other necessary constructions connected with them, as sluices, waste weirs, etc., will depend entirely upon the local features of the site, and will form a particular study in each case for the engineer.

Besides these uses of water as a passive obstruction, arrangements may be made, when the locality is favorable to it, for producing a powerful current to sweep away the assailant's works in the ditches by letting loose a large body of water, which has been dammed back for the purpose, with a rush into the ditches. This, in like manner, will require the same constructions as in the preceding case, and flash gates which can be suddenly turned about a horizontal or a vertical axis, so as to give an outlet to the water in considerable volume and with great velocity. These gates have to be placed in some secure point of the ditches, inaccessible to the assailant and covered from his missiles, and, if effectively used, may prove a source of great annoyance to him by frequently frustrating his attempts to make a passage of the ditch.

Solid hard rock, or even thin layers of soft rock alternating with layers of soil, as was the case at Sebastopol, are great obstructions to an assailant's siege works, as the rock has, in many cases to be blasted out to gain partial cover, and a large amount of earth, with trench materials, has to be brought forward at great risk of life to form the parapets. In constructing a work, nothing should be omitted which, if placed on the line of the assailant's approaches, will delay his operations and force him to greater efforts and exposure. To this end, where fragments of rock can be readily had in sufficient quantities, it should be used in forming the embankment of the glacis, and also be thrown in upon other points, over which important lines of trenches must necessarily run.

Besides these accessory means of delaying the progress of the besieger's works, a site of solid rock offers the farther advantage of giving natural scarps and counterscarps, where the ditches are excavated out of the rocks, of far greater resistance to the assailant's means of destruction than any masonry, however solidly and carefully constructed, can offer; besides forcing the assailant to construct galleries through the rock to attain the level of the bottom of the ditch where his passage of it is to be constructed. With a similar purpose, the stumps of large trees may be left in like positions, and trees may be planted when the work is constructed with the object of cutting them down and leaving their stumps when the work is threatened with a siege.

Mines, when properly arranged and well planned, are so important a defensive means that they should constitute a part of the permanent dispositions of defense of every work where the character of the soil will admit of it, at least on those points which are otherwise weakest, and therefore most liable to be assailed. The general arrangement of a combination of galleries and mine chambers, as well as the details for their construction, are given in the articles, MINES, and COUNTERMINES; therefore, nothing further is called for here than to state that the principal galleries of the combination should be constructed with the work, and of durable materials, leaving the other parts to be done when the exigency calling for them may happen. See *Accessory Means of Defense*.

OBTURATEUR.—A kind of stopper, which is usually made of wrought iron, and used with the Baden, and similar fuses. The *obturateur* is screwed into the table, and assists in preventing the soft metal of the fuse from being driven into the shell by the force of the charge.

OBTURATION.—The escape of gas at the junction of the breech-block and the end of the bore must be prevented; the system of *obturation* employed by the English in their modern B. L., (interrupted screw) ordnance was a carefully made steel cup attached to the breech-block; when the gun was fired the expanding gases pressed the sides of the steel cup against the bore and over the junction with the block, thus closing all small orifices. Immediately afterwards the elasticity of the steel caused the cup to regain its former shape, and the breech could be opened again. The French have obtained good results from the lateral expansion of a wad of asbestos and tallow acted on by a hemispherical steel block at the end of the bore. With B. L. small arms the *obturation*, is effected by the use of a metallic cartridge-case.

OBUS—OBUSIER.—A species of small mortar, resembling a mortar in everything but the carriage, which was made in the form of that belonging to a gun, only shorter. It has been frequently used at sieges; and was well calculated to sweep the covered-way and to fire ricochet shots. They were usually loaded with cartouches. A howitzer, called *Obusier*, was known under the name of *Husenieze*, in 1434.

OC.—An arrow used by Turkish archers and bowmen.

OCCUPATION ARMY.—An army that remains in possession of a newly conquered country, retaining it as a kind of hostage, until peace is signed and the war indemnity paid. Armies of Occupation are generally fed at the expense of the defeated nation.

OCTAGON.—A plane closed figure of 8 sides. When the sides are equal, and also the angles, the figure is called a "regular octagon"; in this case, each angle is 135°, or equal to three half right angles. If the alternate corners of a regular octagon be joined, a square is constructed; and as the angle contained between the sides of the square and of the octagon is one-fourth of a right angle, the octagon may easily be constructed from the square as a basis. The octagon in fortification is well calculated in its ground for the construction of large towns, or for such as have the advantage of neighboring rivers, especially if the engineer can so place the bastions, that the entrances and outlets of the rivers may be in some of the curtains. By means of this disposition, no person could come in or go out of the garrison without the Commandant's permission, as the sentinels must have a full view from the flanks of the neighboring bastions.

ODA.—A name given to the different corps or companies into which the Janissaires were divided. The word *Oda* means a room, and the companies were so called from messing separately.

ODA-BACHI.—A term applied to a Captain superintending the gunners at Constantinople.

ODIUS.—A herald in the camp of the Greeks before Troy.

ODOMETER.—An instrument attached to a carriage or other vehicle, for the purpose of registering the distance it has traveled. Such machines have been in use from an early period, and one is described by Vitruvius in that part of his work *De Architectura*, which is devoted to machines. The instrument, as commonly employed, consists of a train of wheel-work, which communicates motion from the axle of the carriage wheel to an index which moves round the circumference of a dial fixed in one side of the carriage over the axle. The wheel-work is arranged so as to produce a great diminution of the velocity impressed by the axle of the vehicle, and the dial is so graduated that the index can show the number of miles, furlongs, yards, etc., traversed. The instrument is also constructed to work independently, being in this case provided with wheels and an axle of its own; when this is done the wheel is made of such a size that its circumference is an aliquot part of a mile, an arrangement which greatly simplifies the calculation of the distance traversed. The complete Odometer can then be drawn along by a man on foot, or attached behind a carriage.

The Odometer, shown in Fig. 1, consists essentially of a square brass weight or pendulum, hung within a rectangular frame which revolves with the wheel, while the pendulum remains vertical. Upon the front face of the pendulum are two brass wheels,

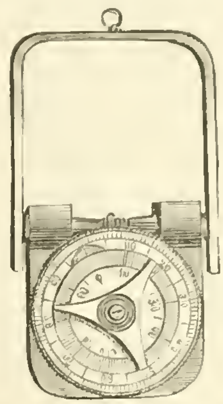


Fig. 1.

two inches in diameter, the inner surfaces of which are in contact, the edges of both uniting to make a groove corresponding to a worm cut in the middle of a shaft fastened to the sides of the frame. The front wheel has one hundred teeth, the rear one ninety-nine, and both pitch into and are moved by the revolving worm of the frame. There are also the same number of divisions as of teeth on each wheel, and they are figured, the front wheel from 0 to 100, the rear one from 0 to 9000. The front wheel has three spokes, an index being also cut down on its perimeter to read the divisions of the rear wheel. the front wheel itself being read by a slender steel wire fastened to the brass weight and curving over the worm, so as to be immediately over the divisions of the wheel. Now when the frame is made to revolve by the revolution of the wagon wheel, the worm will turn both wheels, and each will be moved forward one tooth by every turn, and when one hundred turns are made, the front wheel will have moved completely around, and the index of its zero division will have been carried over one division of the inner wheel. And thus by noting the positions of the indices of both wheels, the number of revolutions of the wagon wheel can be easily obtained up to 9900, when both wheels will be at zero again. The wagon wheel being of a given size, the number of feet traveled can be at once ascertained by noting the readings of the wheels, at the beginning and end of the journey, subtracting one from the other, and multiplying the perimeter of the wagon wheel by the number of turns made.

An excellent form of Odometer devised by Messrs Gurley, United States, is represented in Fig. 2. The pendulum is fastened to a shaft turning in the center of a strong circular metal box on this shaft, and turning with it is a pinion giving motion to a train of wheels, each of which has also a shaft to the end of which an index is fastened. There are dials for each index as shown, and the number of turns of the wagon wheel can thus be counted up to 100,000. A strong bezel ring with thick glass covers the dials and allows them to be easily read. The Odometer is securely fastened to the spokes of the wheel by three carriage-bolts, there being also a thick leather washer on each side confined between the bottom of the projecting arms, and a metal washer of same shape on the other side of the spokes. In using this Odo-

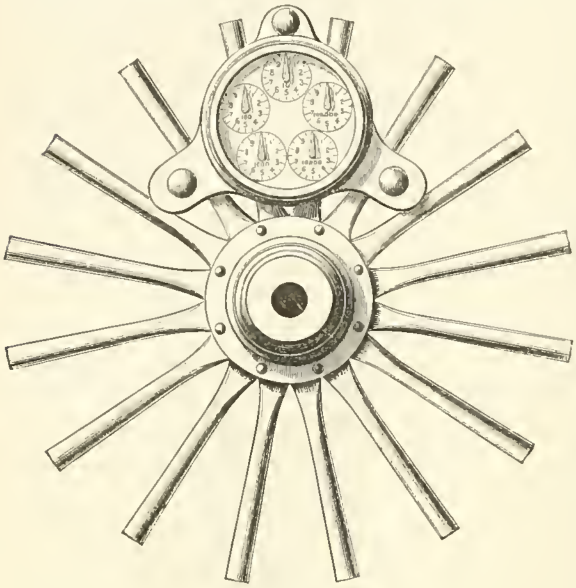

Fig. 2.

meter the reading of the dials must be taken at both ends of the journey, the one subtracted from the other, and the remainder showing the number of turns of the wagon wheel, multiplied into its perimeter. See *Pedometer*.

ŒIL DE BŒUF.—A French term literally signifying ox's eye, applied in architecture to those small round or oval openings in the frieze or roof of large buildings, which serve to give light to spaces otherwise dark. The most famous is that in the anteroom (where the courtiers waited) of the Royal Chamber at Versailles, which gave name to the apartment. Hence the expression, *Les Fastes de l' Œil-de-Bœuf*—i. e., the history of the courtiers of the Grand Monarque, and by extension, of courtiers in general.

OFF.—Most distant; a term commonly used in speaking of horses harnessed to a carriage, in contradistinction to *near*. It means the animal which is harnessed on the right hand facing the front of a team. The term is variously compounded, as in the expressions, *to march off, to sound off, to tell off*, etc.

OFFENSE.—A crime committed by an officer or soldier for which he deserves punishment. All acts that are contrary to good order and discipline, omissions of duty, etc., may be called military offenses, and subject the offender to be tried by Court-Martial. The principal offenses are specified in the Articles of War.

OFFENSIVE BATTLE.—In a purely Offensive Battle, an army seeks the enemy and attacks him wherever he is to be found. To know what we are going to encounter is half the battle in almost all affairs of life; for we are, thus far, secure from the surprise of finding something in our way that we had not counted upon. In no transaction is this beforehand knowledge more important than in preparing for a battle. There is hardly any labor, any personal risk to which a General should not subject himself to gain precise and accurate information on this head. Here he must see for himself, at the risk of finding his orders misconstrued, and his plans defeated by the carelessness or stupidity of his subordinates.

A personal reconnoissance therefore of the enemy's position is indispensable, and if this is made on the eve of the attack the General should take another last look in the morning, before moving, to see that the enemy has not anticipated him, and taken steps that call for changes on his part. Of course, whatever is advantageous to the defensive will particularly engage his attention; but, as his great object is, not only to drive back the enemy, but to bring on him a great disaster, the chief point to which he will bend his thoughts, will be to see by what mode and by what point of attack he can secure the greatest strategical results.

Considerations therefore both of tactical and strategical character must receive the careful examination of the Commanding General, in deciding upon his plan of attack. The first, as carrying with it the most important advantage, is the strategical result; the two principal of which are, first, either to direct the main effort upon that wing of the enemy which, if overthrown, will naturally bring us on the line of retreat of his forces, or, second, upon some point between his two wings which, if pierced, may force his disconnected forces on divergent lines of retreat, and thus expose them to the disaster of being beaten in detail, or to the capture or destruction of one of the fractions. In the battle of Austerlitz, for example, in which the Allies at first acted offensively, their plan was made subservient wholly to the strategical result. The right of the French position was nearest to their line of retreat on Vienna; by forcing this point, the Allies would have been brought between the French and Vienna, thus throwing them further from their base. If repulsed in this attempt, which was possible, the Allies still covered their own line of retreat, so long as their center and right held firm. The strategical object of Napoleon, on the contrary, was to pierce the Allied center, and thus secure the advantages of a successful operation of this kind. Next in importance come what may be termed the *grand tactical* considerations; that is, the means of doing most damage to the enemy on the field of battle itself. For example, if the enemy's position is such that he has an impassable obstacle on one of his wings, as a river, lake, or a narrow defile, tactical considerations alone would suggest to direct our main attack on the opposite wing, since it is evident that by defeating this, the center and the remaining wing may be very easily thrown upon the obstruction which it either cannot pass, or must pass with difficulty, and thus be captured or greatly cut up. In like manner, tactical considerations would engage us to attack a height on the enemy's position which, if gained, would give our forces a decided advantage; or, if his line of battle presents a very salient point, upon which our efforts can be concentrated to attack this point; or if his line at any point presents a wide break, into which we can force our way, to do so; any one of these points, if gained, would give decided tactical advantage.

Though not necessarily leading to the same decisive results as the two preceding, a third consideration, in choosing the point of attack, is the facility which the natural features of the ground, over which we must move upon it, afford for the combined operation of the troops of the different arms that are to make the attack. Too much weight, however, is not to be given to this, in selecting the point of attack; as ground, however difficult, may almost always be got over by troops of all arms, and very often it more than compensates for the labor of doing so, by the cover and other advantages it may afford in advancing.

In the battle of Austerlitz the tactical advantages were greatly against the Allied point of attack, as they, in the first place, had to advance against the villages occupied by the French and through narrow, hollow roads, in which their columns became confused and disordered; and they had, moreover, on the flank and rear several ponds, with only narrow causeways between them, on which, if thrown, there was no outlet of escape except over these narrow defiles, all of which were exposed to the artillery of the French. The result, as we know, was a frightful disaster. Prudence counsels, in all such cases, to forego the tempting object of a grand result if to gain it we expose ourselves, if unsuccessful, to a great disaster. The General who looks forward alone, not providing for his own rear or flanks, or who, intent only upon some striking success, rushes recklessly in the pursuit of it, within the jaws of destruction, has learned but half his trade, and that the most easily acquired and the most dangerous in its application in such hands. It is in nicely weighing these considerations and selecting the best, that the great General shows his powers. Recognizing settled principles as his guides, he does not apply them blindly.

Although but one point, known as the *key-point*, is usually selected for the main effort of the assailant, still the whole line of the assailed is more or less menaced, to prevent the key-point from receiving reinforcements. A different course, one by which we endeavor, so to speak, to envelop the assailed, can only be attempted with a prospect of success, when we are greatly superior in force. Had the Allies at Austerlitz, instead of pressing with such vigor the French left whilst they weakened their center in moving on the French right, thus leaving the plateau of Pratzen a comparatively easy prey to the French, simply menaced the left and held the plateau with a strong force, not succeeded in their main attack, they would at least have avoided the subsequent disaster. Connected with enveloping attacks is that of sending a strong detachment, by a circuitous route, to fall on the enemy's rear, whilst an attack is made on him in front. Such maneuvers are wrong in principle, and military history presents stiking instances of their failure in practice. The topographical features of the immediate theater of operations can alone determine whether to risk turning operations. When this is in a very broken or obstructed country so that such a movement may be concealed for the time necessary to perform it, the risk will be less, but the chances are still against it.

An attack on the center is the obvious operation when the enemy's line is too extended for the number of his forces. It may also be the best course when the enemy's line of retreat is through a defile in the rear of his center, as, in case of success, each wing is cut off from the line of retreat, and the troops of the center, if forced upon the defile, cannot escape from a serious disaster. Where both flanks of the enemy's position are secure, and it becomes a case of necessity to attack some point of the front must be selected for the main effort, which, if gained, will give a decided advantage. For example, if there is a commanding eminence on his front, every effort should be made to carry it, as, from there, the field of battle being overlooked the enemy would be obliged to fall back. In this case the order of battle would necessarily become *convex;* the divisions of the center, to make the assault, being in advance whilst their flanks and rear would be secured by the divisions of the wings advancing in echelon, those nearest the center being most advanced. Eliminating all exceptional local features, the general case which presents itself is that, where the entire line of the enemy is equally exposed, and where success therefore depends upon the ability of the assailant to keep the whole line so threatened that its reserve alone can be moved with safety from one point to another, whilst a powerful effort with concentrated forces is made on some one point, usually one of the wings. In this case the assailing wing will be strongly reinforced, particularly with artillery; the center also strengthened, whilst the opposite wing will be refused, the divisions receding from towards the center, in echelon, so as to parry any attempt at turning them, or at making a flank attack on this part. The only general rules that can be well laid down for the distribution of the different arms on the field of battle have already been given. Details on this point must be necessarily left to the subordinates, who, if well acquainted with the true functions and resources of their respective arms, will seldom fail to post them so as to do as much injury to the enemy and be exposed to as little danger to themselves as the natural features of the field of battle will admit of. The plan of the battle having been decided on, the maneuvers to carry it out should be as simple as possible, so as to guard against the failures that almost invariably attend any attempt at complex movements, within striking distance of the enemy. All distributions for what are termed passages of lines should be avoided, even in the case of thoroughly drilled troops. The distribution of infantry in echelons, wherever it can be adopted, is one of the best, as each division has its support at hand on its flank, whilst the interval left between the flank of the one in advance and that of the one next it in rear, should offer sufficient space for cavalry or artillery to move forward to the front if wanted. See *Battles, Defensive Battle*, and *Mixed Battle*.

OFFENSIVE PATROLS.—That class of patrols made exterior to the line of out-posts, with a view of gaining intelligence of the enemy's whereabouts. They are composed of larger bodies of men than defensive patrols, the number being proportioned both to the distance to be gone over, and the extent of front to be examined. In a position, presenting but few cross-roads, and sparsely settled, a patrol of ten or twenty horsemen may be found ample, to search, with all desirable thoroughness, from twenty to forty miles in advance of the position, along the principal avenues to it ; whereas, with a more extended front, presenting many lateral avenues, double this number might be required for the same duty. From the information obtained, through the ordinary channels of maps, and by questioning the inhabitants at hand, the commanding-officer can usually settle, with sufficient accuracy, the strength of a patrol.

OFFENSIVE WAR.—Military acts of aggression constitute what is called an *Offensive War.* Those who assail an opposite or adverse army, or invade the dominions of another power, are said to wage an *Offensive War.* See *War.*

OFFENSIVE WEAPONS.—All arms of the present day, such as cannon, small-arms, swords, and other weapons which would be used on an army taking the field for offensive operations. See *Ordnance* and *Small-arms.*

OFFICER.—*Military Officers* are combatant and non-combatant, the latter term including Paymasters, Medical Officers, Commissariat, and other Civil Officers. Commissioned Officers in the English army are those holding commissions from the Crown, or a Lord-Lieutenant, and comprise all holding the rank of ensign, or corresponding or superior rank. Divided by duties, they are Staff Officers (see Staff), or Regimental Officers (see Regiment) : divided by rank, General Officers, Field Officers, and Troop or Company Officers. The last are Captains, Lieutenants, and Sub-Lieutenants, and, except in the cavalry, are unmounted. The only Warrant Officers in the army are Master Gunners and Schoolmasters. Non-commissioned Officers are described under that heading.

OFFICER IN CHARGE.—An officer, at the United States Military Academy, charged with the enforcement of all regulations governing the Corps of Cadets. Each of the Assistant Instructors of Tactics are in turn detailed as *Officer in Charge ;* his tour of duty to commence at guard-mounting, at which time he reports for orders to the *Commandant of Cadets*. Between thirty minutes after *reveille roll-call* and *taps* he stations himself in, or near his office, and at no time during his tour absents himself from it, except on duty or at meals, without the sanction of the *Commandant of Cadets*. He is in the Cadets' mess-hall at their meals, is present at every parade and roll-call during his tour, and sees that all duty during the day which does not require the presence of the *Commandant of Cadets* is performed in a soldier-like manner, and according to regulations and orders. He sees that all signals are sounded at the proper time, and takes effectual measures to suppress all irregularities and disturbances that may occur in the quarters or their vicinity, and corrects all violations of orders or regulations coming to his knowledge. He visits the sentinels at his discretion during his tour, to see that they are well acquainted with their duties. On being relieved, he embraces in his report all suggestions that may be of service to the Commandant for the preservation and promotion of health, police and discipline, and reports all offenses against discipline, coming to his knowledge, which have occurred during his tour of duty.

OFFICER IN WAITING.—In the British service, the Officer next for duty. He is mentioned in orders, and ought to be ready for the service specified at a minutes warning. He must not on this account quit the camp, garrison, or cantonment.

OFFICER OF THE DAY.—An officer whose immediate duty is to attend to the interior economy of the corps or garrison to which he belongs, or of those with which he may be doing duty. The Officer of the Day has charge of the guard, prisoners, and police of the garrison; and inspects the soldiers barracks, messes, etc. Both the old and the new Officer of the Day are present at guard-mounting. While the old guard is being relieved, they inspect the guard-house, or tents, and verify the number of prisoners. They then proceed to report to the Commanding Officer, when the Officer relieved presents the report of the Officer of the Guard, upon which he previously makes such remarks as circumstances reqnire. At the same time, the new Officer of the Day receives his instructions. The Officer of the Day is responsible for the enforcement of the police regulations, and the cleanliness of the post or camp. Fatigue parties are furnished him when the number of prisoners is insufficient for police purposes. The Officer of the Day visits the guards during the day at such times as he may deem necessary, and makes his rounds at night at least once after 12 o'clock. The Officer of the Day sees that the Officer of the Guard is furnished with the parole and countersign before *retreat*. In war time, the Officer of the Day satisfies himself frequently during the night of the vigilance of the police guard and advanced posts. He prescribes patrols and rounds to be made by the Officer and Non-commissioned Officers of the Guard. The Officer of the Guard orders them when he thinks necessary. He visits the sentinels frequently.—

OFFICER OF THE GUARD.—An officer detailed daily for service with the guard. It is his duty, under the Officer of the Day, to see that the Non-Commissioned Officers and men of his guard are well instructed in all their duties; he inspects the reliefs, visits the sentinels, and is responsible for the prisoners and the property used by them and the guard. He is also responsible for good order, alertness, and discipline. Officers remain constantly at their guards, except while visiting their sentinels, or necessarily engaged elsewhere on their proper duty. The Officer of the Guard inspects his guard at reveille and retreat, and sees that the countersign is duly communicated to the sentinels at the proper time before twilight. See *Guard Report*.

OFFICIAL COURTESIES.—The interchange of official compliments and visits between foreign military or naval officers, and the authorities of a military post, are international in character. In all cases it is the duty of the Commandant of a military post, without regard to his rank, to send a suitable officer to offer civilities and assistance to a vessel-of-war (foreign or otherwise) recently arrived. After such offer it is the duty of the Commanding Officer of the vessel to send a suitable officer to acknowledge such civilities, and request that a time be specified for his reception by the Commanding Officer of the post. The Commanding Officer of a military post, after the usual offer of civilities, is always to receive the first visit without regard to rank. The return visit by the Commanding Officer of the military post is made the following day, or as soon thereafter as practicable.

When a Military Commander officially visits a vessel-of-war he gives notice of his visit to the vessel previously thereto, or sends a suitable officer (or an orderly) to the gangway to announce his presence, if such notice has not been given. He is then received at the gangway by the Commander of the vessel, and is accompanied there on leaving by the same officer. The officer who is sent with the customary offer of civilities is met at the gangway of a vessel-of-war by the Officer-of-the-Deck; through the latter he is presented to the Commander of the vessel, with whom it is his duty to communicate. A vessel-of-war is approached and boarded, by commissioned officers, by the star-board side and gangway, when there are gangways on each side. In entering a boat, the *junior* goes first and other officers according to rank; in leaving a boat, the *senior* goes first. The latter is to acknowledge the salutes which are given at the gangway of naval vessels. Naval vessels fire personal salutes to officers entitled to them when the boat containing the officer to be saluted has cleared the ship. It is an acknowledgment for his boat to "lie on her oars" from the first until the last gun of the salute, and for the officer saluted to uncover, then at the conclusion to "give way." The exchange of official visits between the Commanding Officers of a post and vessel, opens the door to both official and social courtesies among the other officers

To a boat with the flag of an Admiral, Vice-Admiral, or Rear-Admiral, or the broad pennant of a Commodore, boats with narrow pennants "lie on their oars" or "let fly their sheets," and boats without pennants "toss their oars." In both cases officers in them salute. In the case of two boats meeting or passing each other, each with the same insignia of a Commanding Officer, the junior is the first to salute. Officers of inferior grade to a Commanding Officer passing him in a boat, "lie on their oars" or "let fly their sheets," and salute. All other officers passing each other in boats are to exchange salutes, the junior saluting first. Cockswains steering boats are, whenever commissioned officers are saluted, to stand up and raise their caps, and whenever warrant officers are saluted they raise their caps only. The officer or Cockswain of a loaded boat, or of boats engaged in towing, salute a boat with the flag of an Admiral, Vice-Admiral, or Rear-Admiral, or the broad pennant of a Commodore, by standing and raising their caps. When boats are rowing in the same direction, an inferior is not to pass a superior in grade unless he is on urgent duty, or authorized by the superior. When boats are pursuing opposite directions, the rule of the road to prevent fouling is, that both shall "put their helms to port"—*i. e.*, to pass to the right, circumstances permitting. When boats are approaching the same landing or vessel, an inferior is always to give way to a superior in rank. Boats about leaving a ship's side or landing are to give way in ample time to others approaching. It is not proper to land over another boat without permission, and only when it cannot be avoided is permission to be asked. Boats display their ensigns when they shove off, and keep them flying until their return.

To distinguish officers in boats, Commanding Officers of fleets, squadrons, or divisions carry the distinguishing marks of their rank on the bow of their barges. Flags and pennants distinguishing rank are also worn at the bows of boats. An Admiral's flag is a blue flag bearing four white stars; that of a Vice-Admiral bears three stars; a Rear-Admiral, two stars; a Commodore's pennant, one star, and is a swallow-tailed flag. The narrow pennant is worn by Commanding Officers of lesser rank. In addition, Captains in the Navy wear a gilt ball on the end of their boat staffs, and Commanders a gilt star. To the ships, boats, and officers of the United States Navy, as well as foreign officers, the foregoing is due; and courtesy between the land and naval services is indispensable to good order and discipline, as well as necessary to the national dignity and honor. Military officers of assimilative rank are entitled to and should carry the above boat insignia. Navy regulations require officers and men never to omit, on any occasion, to extend the same compliments to officers of the Army as are paid by them to officers of the Navy.

When a civil functionary entitled to a salute arrives at a military post, the Commanding Officer meets or calls upon him as soon as practicable. The Commanding Officer will tender him a review, providing the garrison of the place is not less than four batteries of artillery, or their equivalent of other troops. When an officer entitled to a salute visits a post within his own command, the troops are paraded and he receives the honor of a review, unless he directs otherwise. When a salute is to be given an officer junior to another present at a post, the senior will be notified to that effect by the Commanding Officer. Military or naval officers of whatever rank, arriving at a military post or station, are expected to call upon the Commanding Officer. Under no circumstances is the flag of a military post *dipped* by way of salute or compliment.

OFFICIAL ENVELOPES.—In the United States, it is lawful to transmit through the mail, free of postage, any letters, packages, or other matters relating exclusively to the business of the Government of the United States: *Provided*, That every such letter or package to entitle it to pass free bears over the words "Official business" an indorsement showing also the name of the Department, and, if from a bureau or office, the names of the Department and bureau or office, as the case may be, whence transmitted. And if any person makes use of any such official envelope to avoid the payment of postage on his private letter, package or other matter in the mail, the person so offending is deemed guilty of a misdemeanor, and subject to a fine of three hundred dollars, to be prosecuted in any court of competent jurisdiction. For the purpose of carrying this act into effect, it is the duty of each of the Executive Departments of the United States to provide for itself and its subordinate offices the necessary envelopes; and in addition to the indorsement designating the Department in which they are to be used, the penalty for the unlawful use of these envelopes is stated thereon. These Envelopes, with the penalty clause printed thereon, are confined to the War Department and its bureaus and offices in Washington City. For small packages of public property, weighing not more than four pounds, the mails may be used, as authorized by law, provided the cost of freight is not less than the postage at legal rates. Such packages may be prepaid with official postage stamps at the rates required by law for the matter inclosed; and by authority of the Post Office Department packages containing public property *may be sealed*, provided a written certificate is affixed, signed by the officer mailing the same, that they contain no matter subject to a higher rate of postage than has been prepaid thereon. Under the provisions of the Universal Postal Union Convention, concluded at Paris on the 1st of June, 1878, the prepayment of postage on every kind of correspondence exchanged in the mails between countries of the Postal Union can only be effected by means of postage stamps valid in the country of origin for the correspondence *of private individuals*. The only correspondence exempted from this requirement is official correspondence relative to the postal service and exchanged directly between Postal Administrations. Correspondence addressed to Postal Union countries and colonies can only be prepaid by means of the ordinary United States postage stamps which are furnished to the public. See *Franking Letters*.

OFF RECKONINGS.—An allowance formerly given to the Commanding Officers of regiments and Captains of companies, out of the annual clothing money set aside for their men The allowance was subsequently paid only to the Colonels of regiments, and was a fluctuating sum, depending on the amount of the surplus left after the clothing was made up. About twenty-five years ago, an average of thirty years was struck, and a fixed sum from that period allowed yearly to Colonels, termed *Colonel's Allowance*, amounting to about £600 a year in line regiments, in addition to the regular pay. The term *off-reckonings* is therefore now obsolete.

OGEE.—A molding consisting of two curves, one concave and the other convex. It is called (in classic architecture) *cymatium* or *cyma reversa*. The ogee is also much used in Gothic architecture. An arch having each side formed with two contrasted curves is called an ogee arch. The ogee, sometimes written *ogive*, frequently constituted the ornamental molding on guns, mortars, and howitzers.

OGIVAL.—The form usually given the head of oblong projectiles. It was found by Borda that this shape experienced less resistance from the air than any other. See *Oblong Bullet*, and *Projectiles*.

OHM'S LAW.—This law is singularly in accordance with experimental results. It assumes that the electro-motive force for a particular galvanic pair is constant, and that the strength of the curent it produces is the quotient which results from dividing it by the resistance of the circuit. This resistance arises from two sources, the first being the resistance within the cell offered by the exciting liquid, and the second the interpolar resistance. If e represent the electromotive force; l, the resistance within the cell; w, the interpolar resistance; and S. the strength of the current, or the quantity of electricity actually transmitted, the statement of the law for one couple stands thus: $S=\frac{e}{l+w}$. The application of the law in a few particular cases will best illustrate its meaning. If we increase the number of cells to n, we increase the electromotive force n times, and at the same time we increase the liquid resistance n times, for the current has n times as much of it to travel, then $S=\frac{ne}{nl+w}$. If w be small compared with nl—that is, if the external connection be made by a short, thick wire—it may be neglected, and so $S=\frac{ne}{nl}=\frac{e}{l}$. This shows that one cell gives in these circumstances as powerful a current as a large battery. But if nl be small with respect to w—as in the interpolar circuit of an electric telegraph battery—nl may be neglected, and $S=\frac{ne}{w}$. Here we learn that the strength of the current increases directly as the number of cells. We may learn from the same that the introduction of the coil of long, thin wire of a galvanometer into such a circuit, introducing but a comparatively small increase of resistance, causes a very slight diminution of the current strength. If, again, we increase the size of the plates of a galvanic pair n times, the section of the liquid is proportionately increased, so that whilst the electromotive force remains the same, the cell resistance diminishes n times; therefore $S = \frac{e}{l + \frac{w}{n}}$, or $S = \frac{ne}{l + nw}$. If the exterior resistance is small, nl may be neglected, and $S = \frac{ne}{l}$, and the strength is thus shown to increase n times. These are only a very few of the conclusions arrived at by this law. With the aid of a tangent galvanometer, which gives the value of S expressed in absolute magnetic units, or centimeters of voltameter gas, we ascertain e and l for any pair. By making two observations with two wires of known resistance separately included in the circuit, we have two simple equations with two unknown quantities, from which e and l can be easily found. In doing so, we must adopt a *unit of resistance*. The unit proposed and determined by the British Association, the B. A. unit, or the ohm, is the only one now used in this country. The resistance of the liquid of the pair would be expressed in units of this, and the electromotive force in absolute units or centimeters of gas, with a circuit offering a unit of resistance. See *Galvanism*.

OIL-BATH.—A bath employed in tempering steel. The tube of steel is drawn out of the furnace and sunk into a large iron tank about twenty feet deep, containing several hundred gallons of oil. The heated steel in passing into oil will sometimes cause the surface-oil to take fire, which is extinguished by closing the top of the tank. A covering of coal is also formed round the steel by the burned oil, which greatly retards transmission of heat. The tank has a water-space surrounding it, and as the steel parts with its heat, raising the temperature of the oil, the temperature of the water is also raised. The water, as it is heated, is drawn off by an escape-pipe, and a supply of cold water is continually running in, thus the heat is gradually taken from the mass. Exceeding toughness is the result of the operation; the tensile strength of the steel is made higher, and it is harder and more elastic. See *Tempering*.

OILLETS.—Small openings often circular, used in mediæval buildings for discharging arrows, etc., through. Also written *Oeillets*.

OIL TEMPERING.—In English gun construction, all tubes being procured by contract with the different steel producers in great Britain, are delivered at Woolwich as solid ingots, and, of course, untempered. The facilities at that place are ample for all needs for tempering in oil. The general details of this process as practiced at Woolwich have been published in the English text-books, and need not be in consequence described in this work. The effects of Oil-tempering are to increase the hardness, tensile strength, and elastic limit of the metal, but somewhat at the expense of its ductility. It is a process, however, which is applied to all steel products for heavy ordnance in England, and also in France, and has been so long practised, with confidence in it remaining so long unshaken, and, in fact, increasing, that it must be recognized as probably an important process to be employed in constructions where steel tubes of about equal diameters throughout their entire length are designed for use in built-up guns. For ingots, however, wherein unequal diameters find place, the process becomes one of doubtful benefit in its application, as it evidently disturbs the molecular conditions of the metal; sections of different diameters being unequally acted upon by the tempering process, injurious strains are introduced similar to those produced by unequal cooling in masses of cast iron where the areas of adjacent cross-sections are sensibly and abruptly different.

The increased hardness and diminution of the percentage of elongation in the metal introduced by the application of the process are subjects for consideration, and should leave the question of tempering one for consideration and further experiment. The increased tenacity and hardness secured by the process was a matter of great moment to the English constructors when the Palliser stud system of projectiles was standard in the British service, as the enormous strains brought to bear on the bearing edges of a few deep rifle grooves required these qualities to be present in the highest degree attainable; but now, when the Palliser stud system for securing rotation is a thing of the past, it remains to be considered if the merits of the oil-tempering process should not be further inquired into, both theoretically and experimentally, if praticable, and the result may be that a modification of the process, securing an increase in toughness and tenacity to a more limited extent, may be attained without sacrificing too much the extensibility of the metal, which, by permitting a *yielding* at the critical period in gun practice with high pressures, instantaneously produced, adds largely to the ability of the construction to withstand the effects of those powerful, dangerous, and suddenly applied strains.

The steels used have not changed in quanties since 1872, and about the same physical properties obtain now as then, as exhibited by their tests. A soft steel of 31 tons per square inch at the breaking point, and when tempered in oil raising to 47 tons, is now, from the latest information in print, about the standard required at the Woolwich arsenal. The untempered steel reaches its elastic limit, at, say 13 tons per square inch, and the tempered at 31 tons per square inch. It is thus apparent that the oil-tempering not only increases the tensile strength of the metal, but also increases in much greater ratio its elasticity. It is stated on good authority that no standard of heat required for tempering has been established—different specimens requiring different heats—and hence tests for the required temperatures are made for each tube from specimens taken from their ends. The more hammered steels require less heating than the less denser or softer ones, and hence the degree of heat required varies in every case depending on the grade of the steel under treatment as to its physical properties as determined by tests. See *Tempering*.

OIL TESTER.—A machine used for ascertaining the relative value of lubricants, giving the co-efficient of friction, and pressure per square-inch of journal; also the temperature at the same time. The drawing on the opposite page shows such a contrivance with the following:

DIMENSIONS

Extreme height	21 inches.
Extreme length	46 "
Extreme width	28 "
Weight	350 pounds.

ADAPTATION.

Provided with three sizes of journals, viz, 2 inches, $2\frac{3}{4}$ inches, and 3 inches, also a cone-pulley to run at 3 different speeds.

Capacity . . . . . 2,200 pounds.

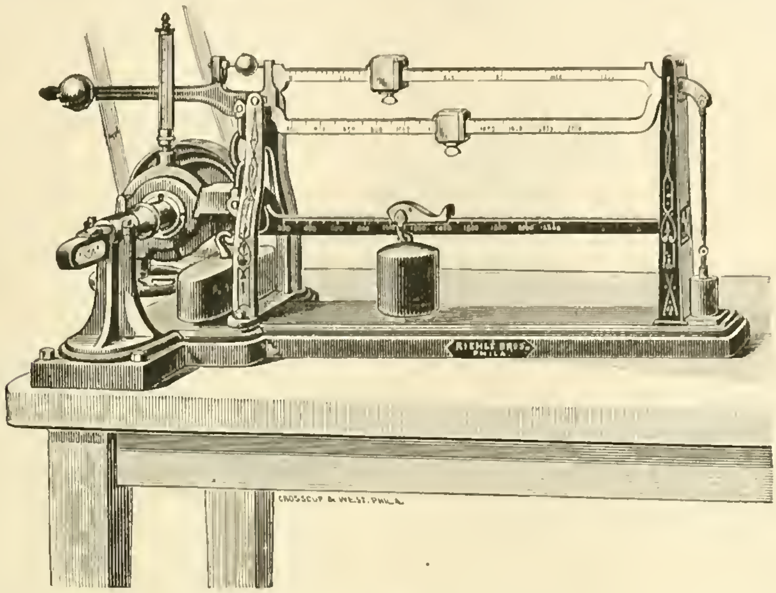
In using the machine, a small and determinate quantity of the oil to be tested is placed on the journal, the pressure is adjusted to that at which the oil is desired to run under test; and the machine is started at a speed which will give the desired relative velocity of rubbing surfaces. Observations are made at short intervals, and recorded, until the test is closed by rapid heating, as shown by the thermometer, and excessive increase of friction is indicated. Competing oils are similarly tried, and the records afford a perfect means of comparison. The relative power of resisting high temperatures without decomposition is another important point which may be tested. See *Testing-machine*.

OLEOMETER.—An instrument for ascertaining the densities of fixed oils. It consists of a very delicate thermometer-tube the bulb being large in proportion to the stem. It is divided into fifty degrees, and floats at zero in pure oil of poppy-seed, at 38° to 38½° in pure oil of almonds, and at 50° in pure olive oil. Also written *Elaiometer*.

OLIFANT.—A horn which a Paladin or Knight sounded in token of defiance, or as a challenge. Commonly written *Oliphant*.

OLINDE.—A term applied to an early form of sword-blade.

OLYMPIC GAMES.—The most splendid National Festival of the Ancient Greeks, celebrated every fifth year in honor of Zeus, the father of the gods, on the Plain of Olympia. Their origin goes back into Prehistoric Ages. According to the myth elaborated or preserved by the Elean Priests, they were instituted by the Idæan Herakles in the time of Kronos, father of Zeus; according to others, by the later Herakles, son of Zeus and Alkmene; while Strabo, rejecting the older and more incredible legends, attributes their origin to the Herakleidæ after their Conquest of the Peloponnesus. But the first glimpse of anything approaching to historic fact in connection with the games is their so-called revival by Iphitos, King of Elis, with the assistance of the Spartan lawgiver, Lycurgus, about 884 B. C.; or, according to others, about 828 B. C., an event commemorated by an inscription on a disc kept in the *Heræum* at Olympia, which Pausanias saw. That festive games were celebrated here—in other words, that Olympia was a sacred spot long before the time of Iphitos, can indeed hardly be doubted: the universal tradition that the Elean King had only "revived" the games proves this; but nothing whatever can be historically ascertained concerning their origin, character, or frequency, in this remoter time. Iphitos may, therefore, be regarded as their founder, yet the reckoning of time by Olympiads—the real dawn of the historical period in Greek history—did not begin till more than a century later. At first, it is conjectured, only Peloponnesians resorted to the Olympic Games, but gradually the other Greek States were attracted to them, and the Festival became *Panhellenic*. Originally, and for a long time, none were allowed to contend except those of pure Hellenic blood; but after the Conquest of Greece by the Romans, the latter sought and obtained this honor, and both Tiberius and Nero figure in the list of Roman victors. Women—with one exception, the Priestess of Demeter Chamyne—were forbidden to be present, on pain of being thrown headlong from the Typæan rock. The games were held from the 11th to the 15th of the Attic month *Hekatombæon* (our July–August), during which, first throughout Elis, and then throughout the rest of Greece, heralds proclaimed the cessation of all intestine hostilities; while the territory of Elis itself was declared inviolable. The combatants were required to undergo a preparatory training for 10 months in the gymnasium at Elis, and during the last of these months the gymnasium was almost as numerously attended as were the games themselves. Much uncertainty prevails as to the manner in which the contests were distributed over the different days. Krause suggests the following order: On the first day the great initiatory sacrifices were offered, after which the competitors were properly classed and arranged by the Judges, and the contests of the trumpeters took place; the second day was set apart for the boys who competed with each other in foot-races, wrestling, boxing, the *pentathlon*, the *pankration*, horse-races; the third and principal day was devoted to the contests of men in foot-races of different kinds (as, for example, the simple race, once over the course; the *diaulos*, in which the competitors had to run the distance twice; and the *dolichos*, in which they had to run it seven or twelve times); wrestling, boxing, the *pankration*, (in which all the power and skill of the combatants were exhibited), and the race of *hoplites*, or men in heavy armor; on the fourth day came off the *pentathlon*, (contest of five games—viz: leaping, running, throwing the discus, throwing the spear, and wrestling), the chariot and horse races, and perhaps the contests of the heralds; the fifth day was set apart for processions, sacrifices, and banquets to the victors (called *Olympionikoi*), who were crowned with a garland of wild olive twigs cut from a sacred tree which grew in the Altis, and presented to the assembled people, each with a palm branch in his hand, while the heralds proclaimed his name, and that of his father and country. On his return home; he was received with extraordinary distinction; songs were sung in his praise, statues were erected to him, both in the Altis and in his native city; a place of honor was given him at all public spectacles: he was in general exempted from public taxes, and at Athens was boarded at the expense of the State in the Prytaneion. The regulation of the games belonged to the Eleans, from whom were chosen the *Hellanodikai*, or Judges, whose number varied. At

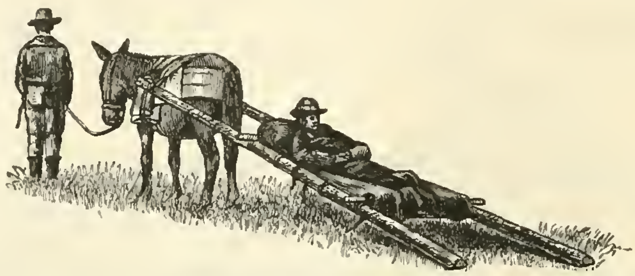


Oil Tester.

first there were only two, but as the games became more and more national, and consequently more numerous, they were gradually increased to ten, sometimes even to twelve. They were instructed in their duties for ten months beforehand at Elis, and held their office only for one year. The officers who executed their commands were called *Alytiæ*, and were under the presidency of an Alytarch.

ONAGER.—A warlike machine, which was used by the ancients to throw stones of different sizes. It is mentioned by Vegetius. See *Balista*.

ONE-HORSE LITTER.—A litter intended to be dragged by one horse or mule. It is variously extemporized from such material as may be at hand. The drawing, from a photograph of one of these



contrivances, used in the Powder River Indian Campaign, in 1876, shows the manner of its construction and use. When two animals can be spared, or when the country to be passed over is exceedingly rough, the *two-horse* litter will usually give better satisfaction. See *Litter*, *Stretcher* and *Travée*.

ONEIN.—An offensive weapon of mediæval times, consisting of a staff with a hooked iron head.

OPEN.—A term frequently used in military movements and dispositions, in contradistinction to *close;* as *open column*, *open distance*, *open order*, etc. It also constitutes part of a word of command; as, *rear open order*. By *open distance in column* is meant that the intervals are always equal in depth to the extent in front of the different component parts of the column.

OPEN DEFENSES.—To this class belong the arrangement of the parapet which has already been described; simple *loop-holed walls* for musketry used as inclosures of gorges, etc.; *exterior corridors* which are covered either by a wall or an earthen parapet; and *barbettes and embrasures* for artillery. Walls of this class, when used as the inclosures of the gorges of lunettes or other isolated works, placed in advance of the enciente, but within the reach of its artillery fire, should be high enough to secure the work from an open assault, and sufficiently thick to resist the occasional shot which may reach them over the parapet by which they are covered. For these purposes the height should be from 12 to 15 feet, and the thickness from 4 to 5 feet. The loop-holes are not placed nearer to each other than from 3 to 4 feet, estimated between their axes. They should be at least 6 feet above the exterior foot of the wall, and 4½ feet above the ground or banquette within. The loop-holes are usually placed at regular intervals along the line of the wall; or only opposite that portion of the exterior ground upon which a fire is to be brought to bear.

The form and dimensions of the loop-hole will depend upon the thickness of the wall and the field of view, both vertically and horizontally, which is to be covered by its fire. The plan is either trapezoidal, widening from the front of the wall inwards, or else it widens from the center each way to the front and back; or, as is the more usual form in our works, the interior portion from the center widens inwards, whilst the exterior part is rectangular in plan, and of the same width as the width on the interior or the back of the wall. The first form is best adapted to walls not more than 2½ feet thick, the others to heavier walls; the object being to lessen, as far as practicable, the weakness which loop-holes necessarily cause to the wall; this defect increasing as the exterior or interior opening is greater.

For thin walls, where the plan of the loop-hole is trapezoidal, the width of the exterior opening may be from 2 to 4 inches, and that of the interior from 15 to 18 inches. These dimensions, however, may vary according to the field of fire to be brought within the range of the loop-hole, the more or less cover to be given to the troops, and the strength of the masonry of which the wall is formed. The vertical dimensions of the loop-hole, both on the interior and the exterior, will depend upon the field of fire to be embraced in this last direction, and they will be regulated accordingly; the top and sole of the loop-hole receiving a suitable slope or direction for this purpose.

The foregoing details can only be determined upon from the special object to which the loop-holed defenses are to be applied. Care only is to be taken that in attempting to give cover to the troops their field of view be not too restricted by too narrow an opening for the use of the firearms. Where the throat or narrowest part of the loop-hole is within the wall, the exterior opening leaves a wider mark for the missiles of the assailed, and when the sides of the loop-hole gradually widen outwards, a shot striking one of them may glance inward and do injury. To prevent this accident, the sides and sometimes the sole are made in offsets. A more convenient form for construction, and one better adapted to arresting the enemy's balls, is to make the exterior portion rectangular in plan for half the width of the wall, as already described.

In open exterior corridors the troops covered in front either by an earthen parapet, which is usually only musket-proof, the scarp wall being run up to the superior slope; or else the scarp wall serves as the cover, in which case it is pierced either throughout its length or at suitable points with loop-holes. The floor of the corridor serves as a banquette tread for the loop-holes, and is therefore placed with reference to the direction of the fire from the loop-holes. The height at which the scarp wall rises above the floor of the corridor will depend upon the level of the floor and that of the bottom of the ditch; this height, however, should not be less than 6½ feet to afford a sufficient cover to the troops. See *Barbette Battery*, *Covered Defenses*, *Embrasure Battery*, and *Machicoulis*.

OPEN FLANK.—In fortification, that part of the flank which is covered by the orillon.

OPENING OF THE TRENCHES.—This operation, in the progress of a siege, supposes that all the measures preparatory to it have been taken; the *depots* of trench materials established and well provided; careful reconnaissances of the site and the defenses made; an accurate map made from such instrumental surveys as were practicable, and other information gained; the positions of the defenses marked out upon the map giving the directions of the faces and capitals of the principal works; the distances and heights of their salient points from that of the first parallel, etc.; and the approximate positions of the first parallel and of the approaches to it from the depôts in its rear, and of those leading from it upon the defenses. With the *data* furnished from these sources the engineers can proceed to stake out upon the ground the directions of the portions of the trenches upon which ground is to be first broken, either on the same night, or a night or two before, as opportunity may serve. This duty is readily performed with the aid of rough sketches, dark lanterns, small pocket compasses, and pickets painted white, with all of which the officers are provided, and with the aid of several intelligent non-commissioned officers or soldiers of the engineer troops.

Everything being in readiness, the workmen are assembled in detachments, at the proper moment towards night-fall, at the depots of the trenches, where they receive their trenching tools, and whatever else is necessary to carry on the work with. They are then led, in single file, to the positions they are to occupy in breaking ground, by an officer or engineer soldier; sometimes each man grasping with the right or left hand a tracing rope or tape, on which his position is marked in the usual way, or else the tracing-tape is first stretched and the men placed in their position near it. When once in position, the working parties are commanded to lie down and keep perfectly quiet until ordered to rise and commence work; to give time to the engineer officers to rectify any mistakes of direction in the lines. So soon as this is done, the order is given to rise and break ground. This will be done by each man digging a hole as speedily as posssible, and throwing the earth towards the defenses, so as to give cover for himself, and from which he can gradually, and with security, work forward in the direction of the trench he is to excavate. This operation is supervised by the engineers on duty, who see that any mistakes made by the men digging are corrected at the proper moment. In the prosecution of the works during this period, the simple trench, flying sap, or full sap will be used, as opportunity may offer, and as the fire of the defenses is more or less certain and destructive. As the flying sap will afford the most speedy cover against case shot, it will be employed generally so soon as the trenches have been advanced within destructive range of this; using, however, the simple trench at night, or at any other opportune moment. The full sap must be used when within the certain range of small-arms, and when the cannon fire of the defenses is very deadly; resorting, however, to the flying sap whenever the risk is but slight. See *Siege*.

OPEN ORDER.—In tactics, an interval of about three yards between each rank. See *Rear Open Order*.

OPERATIONS.—Under the term Military Operations are included: field operations; offensive and defensive operations; underground operations; siege operations, etc. All consist in the resolute application of preconcerted measures in secrecy, dispatch, regular movements, occasional encampments, and desultory combats or pitched battles.

OPHICLEIDE.—A musical wind-instrument of brass or copper, invented to supersede the serpent in military bands. It consists of a conical tube, terminating in a bell like that of the horn, with a mouthpiece similar to that of the serpent, and ten ventages or holes, all stopped by keys like those of the basson, but of larger size. Ophicleides are of two kinds, the bass and the alto. The bass ophicleide offers great resources for maintaining the low part of masses of harmony. Music for it is written in the bass clef, and the compass of the instrument is from B, the third space below the bass staff to C, the fifth added space above it, including all the intervening chromatic intervals. The alto ophicleide is an instrument of very inferior quality, and less used. Its compass is also three octaves and one note. The music for it is written in the treble cleff, and an octave higher than it is played. Double bass or monster ophicleides have sometimes been used in large orchestras, but the amount of breath which is required to play them has prevented their coming into general use.

OPINION.—1. Decision, determination, and judgement formed upon matters that have been laid before a Court-Martial or Court of Inquiry. 2. The technical name for the advice given by an Advocate. The Attorney or Solicitor writes a statement of facts, called "a case" in England, and "a memorial" in Scotland, which ends by asking certain queries, and the answer written by the Counsel is his opinion. A Counsel is not liable for any damages caused by his giving a wrong opinion, though the result of gross ignorance, this being one of the privileges of Counsel.

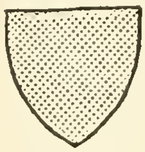
OPLITAI.—A Grecian army, at the period when the military art was in the greatest perfection among them, was composed of infantry and cavalry. The former was made up of three different orders of soldiers; termed, 1. The *Oplitai*, or heavily armed, who wore a very complete defensive armor, and bore the *sarissa*, or Macedonian pike, a formidable weapon either for the attack or defense, about 24 feet in length. 2. The *Psiloi*, or light infantry, who were without defensive armor, and carried the javelin, bow, and sling. 3. The *Peltastæ*, who were intermediate between the other two, carrying a lighter defensive armor, as well as a shorter pike than the oplitai.

The oplitai, when formed for exercise or parade, were drawn up in open order; leaving an equal interval between the men of each rank and between the ranks. When ready to charge, each man occupied a square of 3 feet, and the six leading ranks brought their pikes to a level; thus presenting an array in which the pikes of the sixth rank extended 3 feet in advance of the front one. In attacks on intrenchments, or fortified cities, the men of each rank closed shoulder to shoulder, a sufficient interval being left between the ranks to move with celerity; the leading rank kept their shields overlapped to cover their front; the others held them above their heads for shelter against the weapons of the enemy.

OPTICAL ILLUSION.—Of all the senses none is more deceptive than the sense of sight; it often deceives us as to the distance, size, shape, and color of objects; it frequently makes them appear as if in situations where their existence is impossible; and often makes us think them movable when they are not so, and *vice versa*. An object appears to us as large, near or distant, according as the rays from its opposite borders meeting at the eye form a large or a small angle: when the angle is large, the object is either large or near; when small the object must be small or distant. Practice alone enables us to decide whether an object of large apparent size is so on account of its real size, or of its proximity; and our decision is arrived at by a comparison of the object *in position* with other common objects, such as trees, houses, etc., which may chance to be near it, and of which we have by experience come to form a correct idea. The same is, of course, true of apparently small objects. But when all means for comparison are removed, as when we see a distant object floating on an extensive sheet of water, or erect in an apparently boundless sandy plain, where no other object meets the eye, then our judgment is completely at fault. Imperfection in the acquired perceptions of sight, as it is called, produces many other illusions: it leads us to consider spherical solids at a distance as flat discs, and deceives us regarding the size of objects, by their color; the sun appears larger than he would if illumined by a fainter light, and a man in a white habit seems larger than he would if he wore a dark dress. Illusions are also produced by external causes. The property which the eye possesses of retaining an impression for a very brief, though sensible period of time (about one-quarter of a second), after the object which produced the impression has been removed, produces a third class of illusions. Common examples of this are the illuminated circle formed by the rapid revolution of an ignited carbon point, piece of red-hot iron, or other luminous body, and the fiery curve produced by a red-hot shot projected from a cannon.

OPTIMATES AND POPULARES.—In the politics of republican Rome, the conservative or aristocratic, and the democratic or progressive parties respectively. The *Populares* comprised the great body of the people, including not only the proletariat but many men of wealth, but without personal influence. The *Optimates* were the aristocracy, the great official houses, and their followers. The two parties perpetuated the old contests between the patricians and plebians. The *Populares* triumphed under the leadership of C. Gracchus, and were crushed by Sulla.

OR.—In Heraldry, the metal gold represented in heraldic engravings by an unlimited number of dots.



Or.

ORB.—In tactics, the disposing of a number of soldiers in circular form. The orb is a good formation for a body of infantry in an open country when resisting cavalry, or a superior force of infantry, inasmuch as it is regular and equally strong, and gives an enemy no reason to expect better success by attacking one place than another. Cæsar drew up his whole army in this form when he fought against Labienus. The whole army of the Gauls was formed into an orb, under the command of Sabinus and Cotto, when fighting against the Romans. The orb was generally formed six deep.

ORDER.—This word is applied to an aggregate of conventual communities comprehended under one rule, or the societies, half military half religious, out of which the institution of Knighthood sprang. Religious Orders are generally classified as Monastic, Military, and Mendicant.

The earliest comprehension of Monastic Societies under one rule was effected by St. Bazil, Archbishop of Cæsarea, who united the hermits and cenobites, in his diocese, and prescribed for them a uniform constitution, recommending at the same time a vow of celibacy. The Basilian rule subsists to the present day in the Eastern Church. Next in order of time was the Benedictine Order, founded by St. Benedict of Nursia, who considered a mild discipline preferable to excessive austerity. The offshoots from the Benedictine Order include some of the most important Orders in ecclesiastical history, among others the Carthusians, Cistercians, and Præmonstrants. The order of Augustinians professed to draw their rule from the writings of St. Augustine; they were the first Order who were not entirely composed of laymen, but of ordained priests, or persons destined to the clerical profession.

The Military orders, of which the members united the military with the religious profession, arose from the necessity under which the monks lay of defending the possessions which they had accumulated, and the supposed duty of recovering Palestine from the Saracens, and retaining possession of it. The most famous Orders of this kind were the Hospitallers or Knights of St. John of Jerusalem, the Knights Templars, and the Teutonic Order. Many other Military Orders existed, and not a few continue to exist, particularly in Spain and Portugal. The phraseology of the old Military Orders is preserved in the Orders of Knighthood of modern times, into which individuals are admitted in reward for merit of different kinds, military and civil.

The three Mendicant Orders of Franciscans, Dominicans, and Carmelites were instituted in the 13th century. Their principal purpose was to put down the opposition to the Church, which had begun to show itself, and also to reform the Church by example and precept. At a later period the Order of Jesuits was founded, with the object of increasing the power of the Church, and putting down heresy.—Notices of the more important Orders, Monastic, Military, and Mendicant, will be found under separate articles. See *Orders*.

ORDER ARMS.—A position in the Manual of Arms, executed as follows: The Instructor commands 1, *Order*, 2. ARMS. Grasp the piece with the left hand, the forearm horizontal, let go with the right hand; lower the piece quickly with the left; regrasping it with the right above the lower band, the little finger in rear of the barrel, the hand near the thigh, the butt about three inches from the ground, the left hand steadying the piece near the right, the fingers extended and joined. (Two.) Lower the piece gently to the ground with the right hand, drop the left hand by the side, and take the position to be described. The position of Order Arms has the arm hanging naturally, elbow close to the body, the back of the hand to the right, the fingers extended and joined; the barrel between the thumb and forefinger extended along the stock; the butt against the toe of the right foot, the barrel to the rear and vertical. See *Manual of Arms*, *Fig.* 4.

ORDER BOOK.—A book kept at all military headquarters, in which orders are written for the information of officers and men. Every order in this book should be *signed* by the Officer whose signature was attached to the originals sent from the office, and each order should be separated from the one following by a red line. The mode of numbering, distribution, and general form of orders are prescribed by the regulations; but the distribution in each particular case should be noted in red ink in the margin to show that the regulations have been complied with; and where orders, are sent to one officer, under cover to his Commander (which course ought always to be pursued), or furnished at a date subsequent to that of their issue—these facts should likewise be added: where the order has been *printed*, it will be sufficient to write the word "*printed*" in red ink in the margin, to indicate that the widest circulation has been given to it. There are *two* indexes attached to the book—one of *names*, the other of *subjects*—every order will be indexed in the *latter* immediately after being copied. For *names*, a *detached* index will first be used until the record book is full, when they will be arranged under each letter as in City Directories, and thus classified, transferred to the *permanent* alphabetical index attached to the record book. Every proper name will be indexed and a red line drawn in the body of the order under it, to facilitate a reference to it.

ORDER OF BATTLE.—The combination which is made to attack one or more points of an army in position, is called the *order of battle*. The four principal orders of battle are the *parallel*, *oblique*, *concave*, and *convex*. The lines of battle of the opposing forces being sensibly *parallel* to each other is an example of the *parallel* order of battle. This order of battle naturally results when a simultaneous attack is made along the whole front of an enemy's position. The results will usually be very decisive for the army which gains the advantage, but the price paid for success will also be very dear. When the line of battle of the assailant makes an angle with that of the assailed, the order of battle is said to be *oblique*. This order of battle results when the attack is made with one wing, the other wing at the same time being held back, or *refused*. When the attack is made by both wings, the center being *refused*, the order of battle is *concave*; and, when made by the center, with the *wings refused*, *convex*. The *order* of battle then results from the dispositions made to atttack the enemy's position; so it naturally follows, that when the enemy is found, the first point to be decided is, *how to make the attack with the greatest damage to the enemy and with the least to the attacking force*. Owing to the great loss which usually follows attacks along the whole line, even when successful, they should seldom be made, except when the chances of success and the probable results of victory are very great.

ORDERLIES.—Non-commissioned officers and soldiers appointed to wait upon General and other Commanding Officers, to communicate their orders, and to carry mes ges. The *Orderly Officer*, or Officer of the Day, is the officer of a corps or regiment, whose turn it is to superintend its interior economy, as cleanliness the goodness of the food, etc. *Orderly Non-commissioned Officers* are the Sergeants in each company who are "orderly,' or on duty for the week. On the drum beating for orders, they proceed to the Orderly Room take down the general or regimental orders affecting their respective companies, show them to the Company Officers, and warn the necessary men for any duties specified in those orders An *Orderly Book* is provided by the Captain of each troop or company in a regiment for the insertion of general or regimental orders from time to time issued.

ORDERLY DRUMMER.—The drummer that beats the orders, and gives notice of the hour for messing, etc.

ORDERLY ROOM.—The court of the Commanding Officer, where charges brought against the men of his regiment are investigated, and sentence passed. It is also the office of the Commanding Officer, usually in the barracks, from which all orders emanate.

ORDERLY SERGEANTS.—The First Sergeant of a company is commonly so called. On hearing the drum beat for orders, Orderly Sergeants repair to the Adjutant's Office, and, having taken down the orders in writing, they are immediately to show them to the officers of their company, and to warn the men for duty.

ORDER OF MARCH.—The formation assumed by troops on the march, and which depends on the nature of the country they are moving in, the object to be attained, and the characteristic of the enemy, as well as the number of troops composing the force. If at any distance from the enemy, the comfort of the men, as well as the means of giving them the necessary supplies, must be studied. When in the proximity of the opposing force, tactical considerations must alone weigh in disposing of the order of march. In all cases an army is preceded by an advance guard, covered by the main force, the rear of which is followed by a rear guard.

ORDER OF MERIT.—A military distinction given to officers or soldiers for some signal service, the badge of which is generally expressive of the service. Such was the Medal or Order of Merit, presented by the Austrian Emperor to the Officers of the 15th British Light Dragoons for their bravery in the affair of Villers en Couché in 1794.

ORDERS.—The intructions, injunctions, or commands issued by superior officers. The orders of Commanders of Armies, Divisions, Brigades, and Regiments are denominated orders of such Army, Division etc., and are either General or Special. Orders are numbered, General and Special in separate series, each beginning with the year. Those issued by Commanders of Posts, Battalions, Companies or Detachments are simply denominated "Orders," and numbered in one series, beginning with the year. In the British service, orders are General, Divisional, Brigade, or Regimental. General Orders are issued by the Commander-in-Chief of an army, and affect the whole of his force. The others emanate from Generals of Division or Brigade, or from officers commanding Regiments, and severally affect their respective commands. In the United States, a General Order or an important Special Order, is read and approved by the officer whose Order it is before it is issued by the Staff Officer. An Order states at its head whether it is Special or General; its number, date, and place of issue; and at its foot, the name of the Commander by whose authority it is issued. An Order may be put in the form of a letter addressed to the individual concerned, through the proper channel. Such Orders should be in strict military—not semi-official—forms. Every Commander who gives an Order involving an expenditure of public money sends a copy, without delay, to the Bureau of the War Department to which the expenditure appertains, and if such Commander be serving in a Military Department, he sends a copy of the order to the Headquarters of the Department. If a Military Commander gives to a disbursing officer any order in conflict with orders received by him from the officer in charge of his Department at any superior headquarters, such Commander forthwith transmits the order to such headquarters, with explanation of the necessity which justifies it. Commanding officers of Military Divisions, Departments, and Districts forward, direct, copies of all the orders affecting the officers of the General Staff under their command to the Departments at Washington to which the duties of the officer pertain. It is important that advices of leaves of absence, changes of locality, duties, etc., of subordinate officers of the General Staff be early communicated to the heads of their respective Departments. Orders and instructions are transmitted through intermediate Commanders, in the order of rank, except when they are of such a character as to leave the intermediate Commanders no discretionary power to modify or suspend them. In such exceptional cases, the Orders or instructions will be sent direct to the officer under whose authority they are to be executed, copies being furnished to the intermediate Commanders. Orders for any body of troops are addressed to its Commander, are opened and executed by the Commander present, and are published and distributed by him when necessary. Copies of all orders of the Commanders of Armies, Departments, Divisions, and detached Brigades, and of the Superintendents of the Recruiting Service, are forwarded at their dates, or as soon thereafter as practicable, in separate series on full sheets of letter-paper, or as printed, to the Adjutant General's Office. A file of the printed orders is kept with the headquarters of each Regiment, with each Company, and at each Military Post, and is regularly turned over by the Commander, when relieved, to his successor. The orderly hours being fixed at each headquarters, the Staff Officers and chiefs of the special services either attend in person or send their assistants to obtain the orders of the day; and the 1st Sergeants of companies repair for that purpose to the Adjutant's office. During marches and active operations, and when the regular orderly hours cannot be observed, all orders are either sent direct to the troops, or the respective Commanders of Regiments or Corps are informed when to send to headquarters for them. Under the same circumstances, orders are read to the troops during a halt, without waiting for the regular parades. See *General Orders*, and *Special Orders*.

ORDINAIRE.—The common French term for the soldiers' mess.

ORDINARIES.—In Heraldry, certain charges composed of straight lines, and in very common use, to which writers on Heraldry had assigned abstruse symbolical meanings, but whose real chief peculiarity seems to be that they originally represented the wooden or metal fastenings of the shields in use in actual warfare. The Ordinaries are usually accounted nine—the chief, pale, fess, bar, bend, bend sinister, chevron, saltire, and cross. Heralds vary a little in their enumeration, some taking in the pile in place of the bar. Each is noticed under a separate article. See *Heraldry*.

ORDINARY OF ARMS.—In Heraldry, an index or dictionary of armorial coats, arranged, not according to names, like an armory, but according to the leading charges in the respective shields, so as to enable any one conversant with heraldic language, on seeing a shield of arms, to tell to whom it belonged. A very imperfect Ordinary for England is appended to Edmonson's *Heraldry*: a far more complete and elaborate work of the same kind, Papworth's *Ordinary of British Armorials*, partly edited by Alfred Morant, was published in 1874.

ORDNANCE.—The term ordnance includes cannon of all kinds fired from carriages, slides, beds, tripods, etc. Cannon are classified according to their nature, as guns, howitzers, mortars, and machine-guns, and according to their uses as field, mountain, siege, and sea-coast. Guns are further classified as to their construction, as smooth-bore and rifle; as muzzle-loading and breech-loading; and as cast and built up cannon. All ordnance for land service in the United States is made by private Contractors, under the direction of officers of the Ordnance Department. Rifled howitzers and mortars, and guns with chambers for large charges, are now under consideration. Rifled breech-loading field-guns are also under trial. For the present, until superior armament can be provided, guns of obsolete patterns and kinds are retained in service. Standard guns, howitzers, and mortars take their denomination from the caliber in inches.

Heavy modern ordnance dates properly from the casting of the great Rodman smooth-bores in the United States. To the impetus thus given may be ascribed the origin of the powerful guns of the present day. In Rodman's study of gunpowder and the improvements introduced by him, lay the germ of all subsequent progress in ordnance. His most important invention, *perforated cake powder*, was transplanted bodily to the Continent of Europe, where, under the name of *prismatic powder*, it has been used ever since. So perfect is the theory of this powder, that invention and science toiling over the subject for twenty years has produced nothing better. Since the first half of the decade—1860-70—the United States has fallen behind the nations of Europe in the power of her armament. Having been committed by her two great inventors, Rodman and Dahlgren, to cast-iron smooth-bores, which were fabricated in great numbers, her attitude has been that of Micawber—"waiting for something to turn up." England occupies the other extreme,—of all the powers she has ventured the greatest sums upon the theories of her gun-makers. Her private manufacturers have received such encouragement at home or abroad that they are now able to supply the whole world. Their only great rival on the Continent is Krupp, who finds his market principally in Germany, Russia and Turkey.

The early adoption of the rifle principle by all European powers placed them at once on a plane of advancement. The vexed questions of breech and muzzle-loading and of gun construction have been decided by each nation in the manner most satisfactory to itself. Opinions differ widely, and it is probable that many changes may be made in these matters. Still they all possess powerful guns which have certain features in common, essential to heavy ordnance in the present stage of its development. Large-grained powder, the first of these requisites, is universally used. Great length of bore, to utilize the whole force of the powder, is another characteristic. Great power is secured by immense charges of powder and weight of shot. A caliber of at least 12 inches, giving an oblong shot of about 700 pounds, seems to be regarded as a *sine qua non* for all armaments. England has taken the lead in all these improvements, and though it would appear from recent events that her choice of gun systems is unfortunate, there is no question that all great advances since Rodman's day have been based upon her expensive experiments. The work of the celebrated "Committee on Explosives," 1875, of which Col. Younghusband and Capt. Noble (now a member of Sir Wm. Armstrong's firm), were members, did more to this end than any other investigation since General Rodman's experiments in gunpowder. Acting upon the obvious idea that the peril to the life of the gun is relieved by air-space, the Committee recommended the enlargement of the bore at the seat of the charge, or the use of a chamber larger than the bore. This simple expedient led at once to an increase in the power of guns while the pressure endangering them was kept at a point lower than before. Every good thing can be pushed too far. The immense charges made possible by the English chamber have been continually added to by the Italians in their 100-ton Armstrong monsters and the vital air-space greatly reduced till a charge of about 552 pounds of powder has recently (1880) burst one of these magnificent guns.

The following table gives an interesting comparison between the largest guns at present existent:

Type of Gun.	Calibre.	Length of gun.	Weight.			Initial velocity.	Total energy at the muzzle per kilogramme of the weight of gun.
			Gun.	Shot.	Charge.

* Except for machine-guns and the Hotchkiss mountain breech loading gun, shot and shell for rifled guns are fitted with an expanding sabot, to communicate to the projectile the rotation due to the rifling. No special sabot, however, has as yet been adopted as standard. The Butler, Parrott, Arrick, and Dana all give good results.

The Russian 6″ mortar was employed to test the penetration of mortar shells on an iron-plated deck, 16′×32′, placed at 1,026 yards distance. The angle of fire was 60°. The projectiles fell point foremost, and the results—as regards penetration—were good. Nothing is stated respecting the accuracy of the fire. The Austrian 6″.5 mortar was considered unreliable as to accuracy at the time it was tested. The Belgian 6″ has not been fabricated as yet; the above figures being the details proposed. The English 6″.3 howitzer, as given above, is the latest model, of which a large number have recently been ordered for the siege-train.

The French howitzer and the Austrian mortar of 8 pouces permit of the attainment of the greatest ranges, but their weights are very considerable; the Austrian mortar, particularly, appears to have an excessive weight relatively to the effects attainable with it. It is possible by the system of banding to reduce this weight say, at least 1,760 pounds, to give the piece a greater length of bore, which would permit the use of larger charges and of a more progressive powder, by means of which ranges of 5,460 yards should be obtained. The French howitzer has above all a notable inferiority in point of accuracy of range. In the Russian 8-inch mortar, with 17 pounds prismatic powder, the pressure was 17,800 pounds, while in their 8 inch gun (light) with same charge, the pressure was only 15,560 pounds per square inch. The Prussian mortar (so far as we are able to judge from the limited information at our disposal) has a sensible superiority over the Austrian mortar in point of accuracy of range; but in accuracy of direction on the centers the Austrian mortar is very much superior to the Prussian. This latter fact would tend to prove that the Prussians, notwithstanding the improvements made in their shell, have not yet succeeded in giving to it as great a stability in flight as is possessed by the Austrian shell. In respect to this, however, it should be observed that the inclination of the rifling in the Prussian mortar is 7°, while in the Austrian mortar the inclination is only 3°. It is generally admitted in France that the inclination of the rifling for large pieces should but little exceed 4°. As the French 22 c. m. howitzer, on the whole, compares unfavorably with those of other countries, a new model has been prepared, of which the following are principal features: Caliber. 21 c. m.; material, cast-iron, steel-hooped, or bronze; weight, 7,700 pounds; length of rifling, 5 calibers; number of grooves 24; twist, one turn in 30 calibers; system of breech mechanism, cylindro-prismatic wedge; projectile, copper banded; weight, 176 pounds; weight of bursting charge, 11 pounds; gas-check, copper or brass ring; carriage, of plate-iron; kind of powder, medium-sized grain, giving about 5,500 pounds pressure. Weight of carriage, 5,500 pounds. The French are now experimenting with a new rifled howitzer, the details of construction of which are not definitely known; the material is said to be steel.

ORDNANCE AND ORDNANCE STORES.—The general denomination "Ordnance and Ordance Stores" comprehends all cannon and artillery carriages and equipments; all apparatus and machines for the service and maneuver of artillery; all small-arms, accouterments and horse equipments; all ammunition and all tools, machinery, and materials for the Ordnance service; and all horse equipments and harness for the artillery; and, in general, all property of whatever nature supplied to the military establishment by the Ordnance Department.

It is a duty of the Chief of Ordnance to furnish estimates, and, under the direction of the Secretary of War, to make contracts and purchases, for procuring the necessary supplies of Ordnance and Ordnance Stores; to direct the inspection and proving of the same, and to direct the construction of all cannon and carriages, ammunition-wagons, traveling forges, artificers' wagons, and of every implement and apparatus for ordnance, and the preparation of all kinds of ammunition and Ordnance Stores constructed or prepared for the service.

ORDNANCE BOARD. In the United States Army, a Board composed of such officers of the Ordnance Department as the Secretary of War may designate, and which is advisory to the Chief of Ordnance and is charged with the investigation of such subjects and the performance of such duties, and at such times and places as the Chief of Ordnance may direct. No changes are made in the established models or patterns of Ordnance and Ordnance Stores for the service of the United States except on the recommendation of the Ordnance Board, approved by the Secretary of War. See *Board of Ordnance*.

ORDNANCE DEPARTMENT.—In the United States Service, the Ordnance Department of the Army consists of one Chief of Ordnance, with the rank of Brigadier-General, three Colonels, four Lieutenant-colonels, ten Majors, twenty Captains, sixteen First Lieutenants, ten Second Lieutenants, and thirteen Ordnance Store-keepers. The Ordnance Store-keeper at Springfield Armory has the rank of Major of Cavalry. All other Ordnance Store-keepers have the rank of Captain of Cavalry. No Officer of the Army is commissioned as an Ordnance Officer until he shall have been examined and approved by a Board of not less than three Ordnance Officers, senior to him in rank. If an Officer of the Army fail on such examination he is suspended from appointment for one year, when he may be re-examined before a like Board. In case of failure on such re-examination he can not be commissioned as an Ordnance Officer. Any number, not exceeding six, of the Ordnance Store-keepers may be authorized to act as Paymasters at armories and arsenals. The Ordnance Department was first established in the United States in 1812. It was not provided for in the reduction of the army in 1815, but continued in the service. In 1821, the Department was merged into the Artillery, attaching to each regiment of Artillery one supernumerary Captain, and giving to each Company four subaltern officers. The Ordnance Corps was re-established April 5, 1832.

In the British service, the Ordnance Department was abolished by an Order in Council of May 25, 1855, after an existence of at least 400 years. Its constitution, its important functions, and the causes which led to its dissolution, will be found under Board of Ordnance. The early history of the Department is lost in the Middle Ages; but it appears to have risen gradually under the Lancastrian kings. A Master of the Ordnance is mentioned in the time of Richard III.; but we read of John Louth being Clerk of the Ordnance as early as 1418. Henry VII. constituted the Board, adding a Lieutenant, a Surveyor, and a Store-keeper, to whom a Clerk of the Cheque, was subsequently joined. With the exception of the last, whose office was abolished in the beginning of the present century, this organization was maintained until the abolition of the whole. In 1604 James I. dignified the Master and Lieutenant with the respective titles of Master-General and Lieutenant-General. The history of the Ordnance Office is of importance in British history, as in all wars it has been responsible not only for the management of the *matériel* of the armies, but also for the direction of the *personnel* of the artillery and engineers. By an Order in Council of June 23, 1870, the Department of Ordnance in a very modified form was revived under the Surveyor-General of the Ordnance, as a section of the War Office, responsible for all supplies and *matériel* of War. See *Board of Ordnance*.

ORDNANCE OFFICE.—Before the invention of guns, this office was supplied by officers under the following names: the Bowyer, the Cross-Bowyer, the Galeater, or Purveyor of Helmets, the Armorer, and the Keeper of the Tents. Henry VIII. placed it under the management of a Master-General, a Lieutenant, Surveyor, etc. The Master-General was chosen from among the first Generals in the service of the Sovereign. The appointment was formerly for life; but since the restoration, was held *durante bene placito*, and not unfrequently by a Cabinet Minister. The letters patent for this office were revoked May 25, 1855, and its duties vested in the Minister of War. The last Master-General was Lord Fitzroy Somerset, afterwards Lord Raglan.

ORDNANCE PROJECTILE.—A projectile having a cast-iron body, with a sabot composed of an alloy of lead and tin, which is cast on the base of the projectile, and held in position by undercuts and dovetails; the action of the charge being to force the sabot on the cast-iron body and to make it take the grooves.

ORDNANCE SELECT COMMITTEE.—A Committee composed of scientific officers, to advise the Secretary of State for War on all inventions in war *matériel*. It had its officers at Woolwich, in the midst of the manufactories of the Royal Arsenal, and near the head-quarters of the Royal Artillery, by whom most of the designs had to be practically tested. The President of the Committee was usually a General Officer of Artillery; and a Captain in the Royal Navy served as Vice-President. Since 1870 these functions have been fulfilled by officers of the Department of the Director of Artillery and Stores, who has his head-quarters at the War office.

ORDNANCE SERGEANTS. — Non-commissioned Staff Officers appointed, by the Secretary of War, from Sergeants who have faithfully served eight years in the Line, four of which shall have been in the grade of Non-commissioned Officers. Sergeants receiving these appointments are dropped from the rolls of the regiment or company in which they have been serving. Captains report to their Colonels such Sergeants as, by their conduct and service, merit appointments as Ordnance Sergeants, setting forth the description and length of service of the Sergeant; the portion of his service he was a Non-commissioned Officer; his general character as to fidelity and sobriety; his qualifications as a clerk, and his fitness for the duties of the position for which he is recommended.

The duties of Ordnance Sergeants relate to the care of the ordnance, arms, ammunition, and other military stores at the post, under the direction of the Commanding Officer. Should the post be evacuated, he remains at the station, under the direction of the Chief of Ordnance, in charge of Ordnance and Ordnance Stores, and of such other public property as is not in charge of some Officer or agent of other Departments; and for this property he accounts to the Chief of the Department to which it belongs. If in charge of stores at a post where there is no Commissioned Officer, he is responsible for the safe keeping of the property, and is governed by the Regulations of the Ordnance Department in issuing and accounting for the same. If the means at his disposal be insufficient for the preservation of such property, he reports the circumstances to the Chief of Ordnance.

ORDNANCE STORE-KEEPER.—An Officer of the Ordnance Department who holds the rank of Captain of Cavalry, excepting the Ordnance Store-keeper at Springfield Armory who, by law, has the rank of Major of Cavalry. There are, at present, five Ordnance Store-keepers in the service; but the grade has been abolished by a recent Act of Congress, and henceforth the duties appertaining to the office will be performed by other officers of the Ordnance Department.

In the British service, the Ordnance Store-keeper is a civil officer in the Artillery who has charge of all the stores, for which he is accountable to the Ordnance Office. See *Ordnance Department.*

ORDNANCE SURVEY.—By this term is understood the various operations undertaken by the Ordnance Department of the British government for preparing maps and plans of the whole kingdom and its parts. The idea of a general map of the country to be executed by the government was first proposed after the Rebellion in 1745, when the want of any reliable map of the northern parts of Scotland was much felt by the officers in command of the Royal troops. A drawing, on a scale of one inch and three-fourths to the mile, was completed in 1755; but in consequence of the war which broke out in that year, was never published. In 1763 it was proposed to extend the survey to the whole kingdom; but the first steps to effect this were taken only in 1784, when Major-General Roy commenced measuring a base-line on Hounslow Heath, near London, This principal triangulation was designed partly for astronomical purposes, and partly as a basis for a map on a small scale. The base-line was remeasured with great care in 1791; and detailed plans were commenced by officers of the Royal Engineers, partly for practicing them in military drawing, and partly for the purpose of forming plans of some portions of Kent for the use of the Ordnance. The principal object was, however, the instruction of a Corps of Military Surveyors and Draughtsmen, the plans themselves being regarded as of secondary importance. In 1794 the survey for the one-inch map was begun, and some sheets were published in 1796. As the series of principal triangles were extended westward towards the Land's End, it was thought right to measure another base, for fortification, on Salisbury plain in 1704; and two other base-lines were subsequently measured—one in 1801 at Misterton Carr, and the other in 1806 on Ruddlan Marsh. Though first intended chiefly as a military map, the publication of the survey soon created a desire on the part of the public for better maps, and surveyors were then hired to hasten its progress. This, however, was very slow, the map being at one time entirely suspended during the war in the beginning of this century, and even the parts which were executed, having been done by contract, were found very inaccurate. In this condition the survey of England continued during the first quarter of the present century, sometimes delayed by the government from motives of economy, at other times urged on by the county gentlemen, who wished the map either as a hunting-map or for local improvements.

In Scotland, the principal triangulation was begun in 1809, but was discontinued in the following year, to enable the persons who had been employed there to carry forward the subordinate triangulation required for constructing the detail maps in England. In 1813 it was resumed, and continued steadily up to 1819; a new base line having been measured on Belhelvie Links, near Aberdeen, in 1817, and the great sector used at various stations, both on the mainland and in the islands. It 1820 it was again suspended, was resumed in 1821 anp 1822, and anew broken off in 1823, the large theodolite being wanted in order to proceed with the principal triangulation in South Britain. In 1824 the survey of Ireland was begun, and nothing more was done in Scotland till 1838, except that some detail surveying for a one-inch map was continued for a few years in the southern Counties. The chief strength of the surveying corps was now transferred to Ireland. A map of that country was required for the purpose of making a valuation which should form the basis of certain fiscal arrangements and other improvements which the social evils and anomalies of Ireland urgently demanded. For this map a scale of 6 inches to the mile was adoped, as best suited for the purposes in view. On this scale the whole map was completed, and published in 1845, though the first portions were in an imperfect form, and needed revision which was proceeded with in 1873.

This great national undertaking has been conducted at different times on different scales and plans, and the system now pursued was only adopted after much discussion both in Parliament and out of doors. The map was originally begun as a military map, and the scale of one inch to the mile chosen, without considering whether some other scale would not offer greater advantages. Many now think that a scale a little larger, and an aliquot part of nature such as 1-50,000, or about $1\frac{1}{4}$ inch to the mile, would have been preferable for the small map; in which case a scale of 1-10,000 of nature, or about $6\frac{1}{3}$ inches, might have been chosen for the intermediate, instead of the six-inch scale selected at first for mere local purposes in Ireland. Be this as it may, the arguments in favor of the one-inch map are that it is the most convenient both as a general and traveling map. For general views of the structure of the country, the distribution and relations of its mountains, plains, valleys, and rivers, the one-inch is admitted to be superior to the six-inch, and thus better adapted in the first instance for laying roads, railways, or other extensive public works, or for the publication of a general geological survey. Such a map, on the other hand, is on too small a scale to admit of correct measurement of small distances; it is in some respects a generalized picture, and not a correct plan. The six-inch maps were at first selected in Ireland as the smallest size on which correct measurements of distances and areas could be made. On them every house and field, and almost every tree and bush might be laid down. Hence they are superior for working out details, as in minute surveys of railways and roads, or the complex geological structure of rich mineral districts. On such sheets, too, a proprietor or farmer may find every field laid down, and the relative heights indicated by contour lines, and may therefore use them for drainage and other improvements. It has also been proposed to use these six-inch maps as a record of sales or encumbrances of land, thus lessening the cost and simplifying the transfer of property. On the other hand, their size unfits them for most of the purposes for which the one-inch map is useful, and the contour lines give a far less vivid and correct impression of the physical features of a country than the hill sketching of the one-inch map. Most of the purposes of the six-inch plans are attained in a still more perfect manner from the 25-inch plans or cadastral survey. The last name is taken from the French *cadastre* (a register of lands), and is defined as a plan from which the area of land may be computed, and from which its revenue may be valued. The purposes to which these large plans may be applied are, as estate plans, for managing, draining, and othewise improving land, for faciliating its transfer by registering sales or encumbrances; and as public maps according to which local or general taxes may be raised, roads, railways, canals, and other public works, laid out and executed.

Nearly all the States of Europe have produced trigonometrical surveys, many of them of great excellence as scientific works. All of these have been published, or are in course of publication, on convenient scales; generally smaller than one inch to a statute mile.

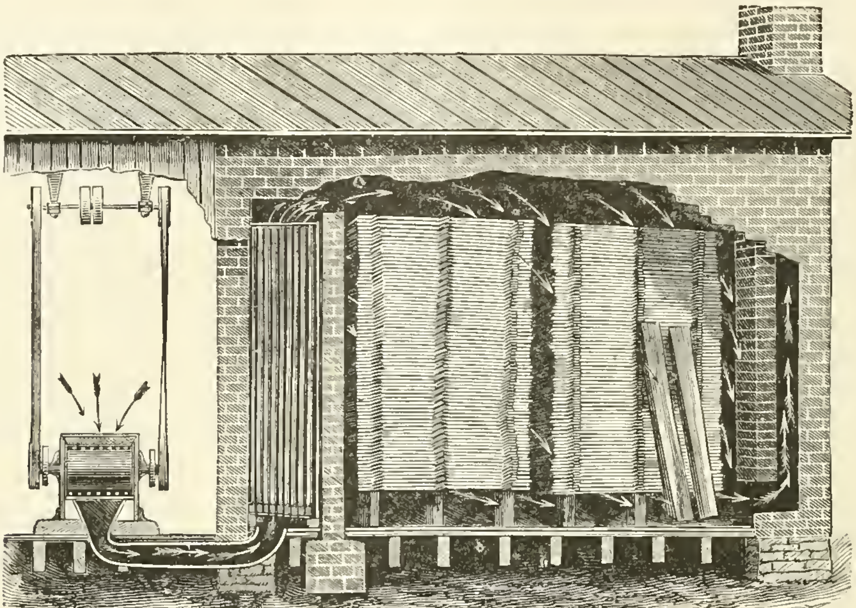
The greatest extra European work of this kind is the Trigonometrical Survey of India, which was begun over seventy years ago, and has been conducted with great ability. The work is drawing to a close, but will still occupy several years. The maps are published on a scale of $\frac{1}{250000}$ or $\frac{1}{4}$ of an inch to the mile. In America, the Coast Survey of the United States, a map of great accuracy and minute detail, has been going on for many years. The general charts are published on a scale of $\frac{1}{80000}$ or $\frac{4}{5}$ of an inch to a mile; the harbors and ports $\frac{1}{20000}$ or $3\frac{1}{5}$ of an inch to a mile. No systematic survey has yet been undertaken for the interior of the country.

ORDNANCE TIMBER.—Timber and wrought iron are the principal materials used in the construction of artillery carriages and machines. Timber for the arsenal is usually purchased in pieces of the size required to make each part. A list of the pieces for a certain kind of carriage, including the contents of each piece, in board-measure, is called a *bill of timber*. None but the best wrought iron should be employed in ordnance constructions. Large and peculiar-shaped pieces, as *axle-trees*, *trunnion-plates*, etc., as well as those requiring great strength, are made from *hammered shapes*, furnished by the iron manufacturer, according to prescribed patterns; other parts are made of rolled iron. The following varieties of timber are briefly noticed as being most frequently required in the various ordnance constructions: *White oak*—The bark of white oak is white, the leaf long, narrow, and deeply indented; the wood is of a straw-color, with a somewhat reddish tinge, tough, and pliable. It is the principal timber used for ordnance purposes, being employed for all kinds of artillery-carriages. *Beech*—The white and red beeches are used for fuzes, mallets, plane-stocks, and other tools. *Ash*—White ash is straight-grained, tough, and elastic, and is therefore suitable for light carriage-shafts; in artillery, it is chiefly used for sponge and rammer staves, sometimes for handspikes, and for sabots and tool-handles. *Elm*—Elm is used for felloes and for small naves. *Hickory*—Hickory is very tough and flexible; the most suitable wood for handspikes, tool-handles, and wooden axle-trees. *Black walnut.*—Black walnut is hard and fine-grained; it is sometimes used for naves, and the sides and ends of ammunition-chests; it is exclusively used for stocks of small arms. *Poplar*—White poplar, or tulip -wood, is a soft, light, fine-grained wood, which grows to a great size; it is used for sabots, cartridge-blocks, etc., and for the lining of ammunition-chests. *Pine.* White pine is used for arm-chests and packing-boxes generally, and for building purposes. *Cypress*—Cypress is a soft, light, straight-grained wood which grows to a very large size. On account of the difficulty of procuring oak wood of a suitable kind in the Southern States, cypress has been used for sea-coast and garrison carriages. It resists better than oak the alternate action of the heat and moisture to which sea-coast carriages are particularly exposed in casemates; but being of inferior strength, a larger scantling of cypress than oak is required for the same purpose; and on account of its softness, it does not resist sufficiently the friction and shocks to which such carriages are liable. *Basswood.*—Basswood is very light, not easily split, and is an excellent material for sabots and cartridge-blocks. *Dogwood.*—Dogwood is hard and fine-grained, suitable for mallets, drifts, etc.

The principal circumstances which affect the quality of growing trees are *soil*, *climate*, and *aspect*. In a moist soil, timber grows to a larger size, but is less firm and decays sooner, than in a dry, sandy soil; the best is that which grows in a dark soil, mixed with stones and gravel; this remark does not apply to the poplar, willow, cypress, and other light woods which grow best in wet situations. In the United States the climate in the Northern and Middle States is most favorable to the growth of timber used for ordnance purposes, except the cypress. Trees growing in the center of a forest, or on a plain, are generally straighter and freer from limbs than those growing on the edge of a forest, in open ground, or on the sides of hills, but the former are, at the same time, less hard. The aspect most sheltered from prevalent winds is generally most favorable to the growth of timber. The vicinity of salt water is favorable to the strength and hardness of white oak. The selection of timber trees should be made before the fall of the leaf. A healthy tree is indicated by the top branches being vigorous and well covered with leaves; the bark is clear and smooth, and of uniform color. If the top has a regular, rounded form; if the bark is dull, scabby, and covered with white and red spots, caused by running water or sap, the tree is unsound. The decay of the topmost branches, and the separation of the bark from the wood, are infallible signs of the decline of the tree.

The most suitable season for felling timber is that in which vegetation is at rest, which is the case in midwinter and midsummer. Recent experiments incline to give preference to the latter season, say the month of July; but the usual practice is to fell trees for timber between the first of December and the middle of March. The tree should be allowed to attain full maturity before being felled; this period, in oak timber, is generally at the age of seventy-five to one hundred years, or upward, according to circumstances. The age of the hard wood is determined by the number of rings which may be counted in a section of a tree. The tree should be cut as near the ground as possible, the lower part being the best timber; the quality of the wood is, in some degree indicated by the color, which should be nearly uniform in the heart-wood, a little deeper toward the center, and without any sudden transitions. Felled timber should, as a rule, be immediately stripped of its bark, and raised from the ground, The white wood next to the bark, which very soon rots, should never be used, except that of hickory. There are sometimes found rings of light-colored wood surrounded by good hard wood; this may be called the *second sap*; it should cause the rejection of the tree in which it occurs. *Brashwood* is a defect generally consequent on the decline of the tree from age; the pores of the wood are open, the wood is reddish-colored, it breaks short, without splinters, and the chips crumble to pieces. This wood is entirely unfit for artillery carriages. Wood which died before felling should, generally, be rejected; so should *knotty trees*, and those which are covered with tubercles and excrescences. Wood in which the grain ascends in a spiral form is unfit for use in large scantlings; but if the defect is not very decided, the wood may be used for naves and for some light pieces. Splits, checks and cracks extending toward the center, if deep and strongly marked, make wood unfit for use, unless it is intended to be split. *Wind-shakes* are cracks separating the concentric layers of wood from each other: if the shake extends through the entire circle, it is a serious defect. The *center-heart* is also to be rejected, except in timber of very large size, which cannot, generally, be procured free from it. As soon as practicable, after the tree is felled, the sapwood should be taken off, and the timber reduced, either by sawing or splitting, nearly to the dimensions required for use. Pieces of thickness, or of peculiar form, such as those for the bodies of gun-carriages and for chassis, are got out with a saw; smaller pieces, as spokes, are split with wedges. Naves should be cut to the right length, and bored out, to facilitate seasoning and to prevent cracking. Timber of large dimensions is improved by *immersion in water* for some weeks, according to size, after which it is less subject to warp and crack in seasoning. To season or dry timber, it should be piled under shelter, in such manner as to allow a free circulation, but not a strong current of air, around each piece. The piles should be taken down and put up again at intervals, varying with the length of time the timber has been cut. The seasoning of timber requires from two to eight years, according to size. Oak timber loses a little more than *one-fifth of its weight* in seasoning, and about one-third of its weight in becoming perfectly dry.

From the fact that certain blowers are used with equal facility either for forcing or exhausting air, or producing a continuous current, which can be reversed at will by simply changing the motion of the blower without any other alteration whatever, they are peculiarly adapted to drying lumber. It is owing to the fact that air has the capacity to take up moisture and hold it in solution, that the process called drying is possible. The water thus taken up is, in this



condition, invisible. At a low temperature, this capacity is very small; at 32° Fahrenheit, a cubic foot of air will only hold in solution two grains of water. This capacity is rapidly increased as the temperature is elevated, in the ratio of about three grains per foot for every ten degrees of heat; so that at 200° Fahrenheit, a cubic foot of air would take up about fifty grains of water. For rapid drying, therefore, it is necessary to have an elevated temperature. But at any temperature, the air can be saturated with moisture, that is so loaded that it can hold no more, even though it be very hot. Hence it is necessary for rapid drying, not only to have heated air, but also to have a constant change, so that as fast as the air becomes saturated with moisture, it may pass off, carrying its load with it, and a fresh supply presented that may, in its turn, carry off its quantum. In simple language, this is the process of drying. The drawing shows Root's Blower as arranged for seasoning timber or lumber. A notice of the drawing will explain the operation. The dry air is taken in at the inlet of the Blower and forced through the heating apparatus, which may be a hot-air furnace, or coils of pipe heated by steam, as shown in the cut, or any other device for heating air. After passing through the heater the rarified air rises to the ceiling of the dry-house, but being positively forced into the room, it displaces an equal quantity of the air already there, which is forced out at the bottom of the flue, as shown by the arrows. By this means a constant and regular change of air in the dry-house is secured, the air passing out being loaded with moisture. By this arrangement a nearly uniform temperature is secured between the air at the ceiling and the floor, seasoning all the lumber alike. Lumber seasoned in this way is not nearly so liable to crack and check as when seasoned with unequal heat.

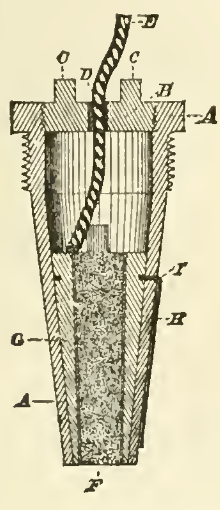
Timber for gun-carriages is now, almost entirely, worked into shape by machinery; the operations are *sawing, planing, turning, mortising and tenoning, dove-tailing*, etc., and are described in detail, under the various machines, in this work. In joining together the different pieces of a carriage, regard should be had to the character of the fiber of the wood, and the effect of drying in changing the form of the piece. If a piece be supported at both ends, as in the cases of carriage-stocks, chassis-rails, etc., the greatest convexity of the fiber should be placed uppermost; if in the middle, as in cases of hounds of limbers, side-rails of caissons, etc., it should be placed downward. When the pieces are to be united in pairs, as cheeks, side-rails, etc., use such pieces as have nearly the same curvature of fiber. In drying a piece of timber, the sapwood shrinks more than the heart, and the effect will be to warp in the direction of the sap; therefore to prevent the joint, formed by the two pieces which constitute a carriage-stock, from opening, the heart-wood should be placed on the outside. To prevent the cheeks from warping inward, place the heart-wood on the inside. In hounds and side-rails, the heart side should be placed on the outside, as this will have a tendency to tighten the joints. When pieces are to be joined, the surfaces of contact and the dowels should be covered with a good coat of white-lead. Bolts and bolt-holes should be well covered with tallow moistened with neat's-foot oil. The surface of holes for elevating screws and pintles should be always well painted. If woodwork is to be painted immediately, it should have a good priming coat of lead before the irons are put on; if not, it should receive a good coat of linseed oil. For service, the woodwork of carriages and machines is painted, in addition to the priming of lead-color, with two coats of olive paint; the iron-work, with one coat of lead, and one coat black paint. Great care should be observed to protect iron fortress-carriages against the corroding influence of the sea-coast atmosphere; the best means remains to be determined by experience; at present they are covered with one coat of hot linseed oil and three coats of a reddish brown paint.

Models, etc.—The models, etc., of all ordnance "*matériel*," are determined by the Ordnance Board, subject to the revision of the Chief of Ordnance, and the final approval of the Secretary of War. When a model has been duly approved, copies, or drawings of it, are sent to the different arsenals of construction, and from these, patterns and gauges are made for the guidance of the workmen. Patterns are generally made of well-seasoned mahogany, and bound with strips of brass; gauges are made of sheet iron or steel. To secure uniformity of work at the different arsenals, it is made a part of the duty of the inspector of arsenals to see that the patterns correspond with the originals; and it is always the duty of the officers stationed at an arsenal, to see that the work, as it progresses, corresponds with the patterns, and that none but suitable materials are used.

OREILLERE.—The ear-piece of an ancient helmet, shaped like an oyster shell, employed to protect the ear and cheek.

OREILLON.—The ear of a sword, languet, or small slip of metal on the hilt, which, when the sword is sheathed, extends along the scabbard.

O'REILLY COMBINATION-FUSE.—This fuse consists of a metal stock, A, open at the rear, but closed



at the front end by a screw-cap, B, from which projects two studs, C C, for screwing and unscrewing the caps. There are also two holes, D D, in the screw-cap through which is passed and secured a strand of quickmatch, E.

The fuse, F, is tightly pressed into a conical shaped, snug-fitting plunger, G, held in place by a wire, H, which passes through a hole, I, in the side of the stock and enters a cannelure on the plunger.

The operation of the fuse is as follows: At the instant of discharge the quick-match is ignited by the flame from the charge of powder; this ignites the fuse, which continues to burn as an ordinary time-fuse; when the flight of the projectile is arrested, the plunger, by its inertia, is driven forward, sheering off the pin which holds it, and, being followed by loose powder in the shell, ignition and explosion follow. See *Fuse.*

ORGAN GUN.—A gun consisting of a number of tubes or barrels placed in arrow like the pipes of an organ. See *Orgue à Serpentin.*

ORGANIZATION.—For the purpose of supply, discipline, rapidity and precision of movement, an army is divided into corps; corps into divisions; divisions into brigades; brigades into regiments; regiments into battalions, and battalions into companies. For the purpose of employing to advantage the different weapons and of providing for that mutual support and aid so essential to success, an army is organized into different arms of service, viz.: Infantry, Cavalry, Artillery and Engineers. These four arms of the service are called *Troops of the Line.* A battalion is the tactical unit of infantry, but the company should undoubtedly be considered the fighting unit, for it is the only organization that will in future wars fulfill all the requirements of a unit, viz: All the men be known to, overlooked by, and within reach of the voice of the officer commanding it. The squadron of two troops is the unit of cavalry. The battery of six guns is the unit of artillery. An army corps usually consists of about thirty thousand men, divided into two or more divisions, depending upon the strength of the corps. Each division is generally composed of the four arms of the service—infantry, cavalry, artillery, and engineers—the artillery being assigned to the corps by battery, and the engineers by company. The corps is, as a rule, provided with a *reserve* of artillery, which, with the artillery assigned to the different divisions, is under the orders of one commander. The organization of an army into corps was introduced by Napoleon about the year 1804, while preparing his army for the contemplated invasion of England. The idea is to make each corps a complete army in itself, in order that it may be detached at any time from the main army when the necessity arises, and be ready to act as an independent force. The division is composed of two or more brigades, and rarely of more than four. Brigades are composed of two or more regiments, and regiments of two or more battalions, each consisting of two or more companies, generally four. The battalion organization is for administrative purposes, and for instruction in the movements prescribed in tactics. As all the duties devolving upon the General in command of an army cannot well be performed by one man, he is assisted in his duties by the officers who compose his Staff. The duties of Staff-officers are: to transmit the General's orders; to procure information, both of the enemy, and of the condition of his own forces; to prepare reports, obtain guides, spies, etc.; to inspect the troops to see that they are properly supplied and in good condition of drill and discipline; to preserve the correspondence and records; in fact, to perform all those duties required of the General in command, which will enable him to have his army at all times prepared in every respect to meet the enemy. The principle of Staff organization is also extended to the divisions, brigades, and regiments, composing the army; the duties being less important and arduous as the body of troops is smaller.

The necessity for a body of officers specially trained in staff duties has been greatly increased in consequence of the fact that wars are now waged by much larger armies than formerly. Therefore every army should be provided with a body of officers who in time of peace should be thoroughly instructed in all duties pertaining to the staff, so when war is declared they will be fully competent to enter upon the active and efficient discharge of their duties. Nearly all European armies have such an organization, which is commonly known as the *General Staff.*

Jomini lays down the following general conditions, as essential to the perfect organization of an army:—1. A good system of recruiting. 2. An efficient formation. 3. A well organized system of national reserves. 4. That officers should be well instructed in drill and maneuvers, and in all the duties of a camp and in the field, and that there should be a good system of interior economy. 5. A discipline strict, but not humiliating; a spirit of subordination as far as possible on a conviction pervading all ranks of its importance, rather than on the mere orders of the service. 6. A well regulated system of rewards and a spirit of emulation. 7. A special corps, engineers and artillery, well instructed. 8. An armament well understood, and, if possible, superior to that of the enemy, comprising arms defensive as well as offensive. 9. A staff capable of applying all these elements to the greatest advantages and with an organization adapted to the theoretical and practical instruction of its members. 10. Well organized commissariat and medical departments. 11. The command of armies and the supreme direction of operations by a sound practical system. 18. The maintenance of a high military spirit.

ORGUE A SERPENTIN.—A machine composed of a great number of guns of small bore loaded either from the muzzle or at the breech. Each separate chamber was encased, as far as the muzzle in wood or metal, and they were fired in succession or all at once. The term *orgue* was applied to several patterns of ordnance, composed of a number of musket barrels, all so joined on the same carriage, and the touch-holes corresponding with each other, that they could be discharged simultaneously. This weapon may be said to have been the origin of the *Mitrailleur.*

ORGUES.—Thick and long wooden beams, pointed and shod with iron, hung vertically by separate ropes in the gateway of and over the entrance to a fortified place. They answer the purpose of a portcullis or door, and are dropped into position by cutting the ropes from which they hang. Their descent is inevitable, in which they possess an advantage over the portcullis, which may be held up by the enemy or blown in by petards, whereas petards have little effect on orgues, for if one beam be destroyed another can be dropped to fill up the gap.

ORIENTAL POWDER.—A variety of gunpowder made at the Oriental Powder Mills at South Windham, Me., on the Presumpscot River, where every facility is at hand for making powder to the best advantage. The following brands are well known and are regarded as excellent:

Falcon Ducking—Especially adapted for breech-loading guns and target practice Its sizes are No. 1 (fine), No. 2, No. 3, and No. 4 (coarse). Packed in kegs of 6¼ lbs., and in canisters of 1 lb. each.

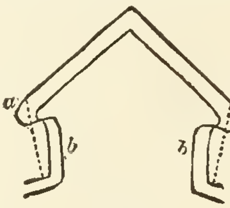
Western Sporting—A clean and moist burning powder, and used for ordinary purposes in the field. Its sizes are FG (coarse), FFG and FFFG (fine). Packed in wood or metal kegs of 25 lbs., 12½ lbs., and 6¼ lbs., and in canisters of 1 lb. each.

Wild Fowl Shooting — Of a coarser grain than "Western Sporting," and especially prepared for use in very damp places, and for muzzle or breech-loading guns. Its sizes are No. 1 (fine), No. 2, No. 3, No. 4. (coarse). Packed in wood or metal kegs of 25 lbs., 12½ lbs., and 6¼ lbs., and in canisters of 5 lbs. and 1 lb. each.

Blasting — A superior grade, and especially adapted for military and mineral mining, also for railroad work. Its sizes are C (coarse), T, TFG, F, FF, FFF (fine). Packed in wood or metal kegs of 25 lbs.

ORIFLAMME.—A banner which originally belonged to the Abbey of St. Denis,and which was borne by the Counts of Vexin, patrons of that church, but which, after the county of Vexin fell into the hands of the French crown, became the principal banner of the Kingdom. It was charged with a saltire wavy or, with rays issuing from the center crossways. In later times the oriflamme became the insignia of the French infantry. The name seems also to have been given to other flags; according to Sir N. H. Nicolas, the oriflamme borne at Agincourt was an oblong red flag split into five parts. Also written *Auriflamme.*

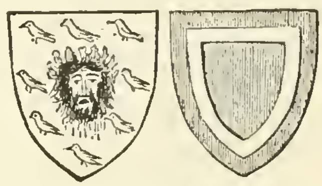
ORILLON.—In fortification, and especially in the earlier systems, the orillon is a semicircular projection at the shoulder of a bastion, intended to cover from the observation of the enemy the guns and defenders on the flank, which, with such a construction, is somewhat retired or thrown back. The flank thus protected is held by many distinguished engineers to be most valuable in the defense of the ditch, when clearing it from an attacking party, or from hostile miners. The retired flank is sometimes



Orillon:
a, a, orillons; *b, b,* retired flanks (the dotted lines show the original bastion).

straight, at others curved. The orillon is as old as the bastion, and is found in the works of Pagan and Speckle.

ORLE.—In Heraldry, one of the charges known under the name of sub-ordinaries, said to be the diminutive of a Bordure, but differing from it in being detached from the sides of the shield. It may be the sole charge in a shield. Or, an orle gules was the



Orle.

coat borne by John Baliol. An orle of heraldric charges of any kind denotes a certain number (generally eight) of these charges placed in orle, as in the coat of the old Scottish family of Gladstanes of that Ilk; argent, a savage's head couped, distilling drops of blood proper, thereon a bonnet composed of bay and holly leaves all proper, within an orle of eight martlets sable.

ORMOLU.—A variety of brass, consisting of zinc 25 parts, and copper 75 parts, which has a nearer resemblance in color to gold than ordinary brass. It is extensively used for castings of ornaments. When the casting is made, its color is brought out by a pickle of dilute sulphuric acid, after which the acid is removed by water, and a liquor varnish is put on to keep it from tarnishing.

ORNAMENTS.—Those parts of the dress of a soldier which are more for appearance or distinction than for absolute use; as belt-plates, shoulder straps, trimmings, etc.

ORPIMENT.—A sulphuret of arsenic. There are many varieties of orpiment, one in fine golden colored scales, another in dense yellow stony lumps, a third in earthy-looking masses, called *King's Yellow*, a familiar paint; but the orpiment required in the laboratory for blue lights, signal-lights, and parachute light-balls, is the *red proto-sulphuret* or *realgar.*

OUTER.—A term applied to a portion of the target. On the regulation targets it is all the space outside of the larger circle, or the space outside the vertical lines. See *Inner*

OUTFIT ALLOWANCE.—In the British army, a sum of £150 for the cavalry and, £100 for the infantry, granted to Non-commissioned Officers promoted to Commissions, to enable them to meet the heavy charges for uniform and equipments. The larger sum is given in the cavalry because the newly Commissioned Officer has to purchase his charger.

OUTFLANK.—To turn the flank or flanks of an enemy. See *Flank Movement.*

OUTGUARDS.—Small bodies of troops stationed at a greater or less distance beyond the limits of a camp or main army, for the purpose of preventing an enemy approaching without notice, and also to offer opposition to his progress, while the main force prepares for resistance. Outguards march off to their position silently, and pay no compliments of any kind to officers or others. As soon as the officer commanding an outguard arrives on his ground, he proceeds to carefully examine the environs, noting all heights within rifle-range, roads and paths by which an enemy may approach, etc. He also takes such impromptu means of strengthening his position as occur to him—felling a tree here, cutting brushwood there, blocking a path in another place, and resorting to any expedient which may serve to delay the foe at point-blank range—an object of importance, as a stoppage at such a point is known to act as a great discouragement to advancing troops. See *Outposts.*

OUTLET.—Outlets, in fortification, are the passages made through a parapet, or an enclosure of a gorge, for the services of the work. They should in all cases be made in the least exposed part of the work. Their width need not be more than six and a half feet, when used only for the service of the work; but when they serve as a common passage for wagons, etc., in the case of the intrenchment crossing a road, they should be at least ten feet wide. When cut through a parapet, the sides receive a slope of three perpendicular to one base, and are revetted with sods, etc. A gate, termed a *barrier*, serves as an enclosure to the outlet. The framework of the barrier is made like an ordinary gate, consisting of two uprights, or *stiles*, a cross-piece, or *rail*, at top and bottom, and a *swinging bar*, or a *diagonal brace*. Upright palisades, about seven feet long and four inches thick, are spiked to the frame about four inches apart; they are finished at top with spikes. A barrier thus constructed will not offer a shelter to the enemy should he attempt to cut it away. The barrier is hung on hinges like an ordinary gate. See *Gorge.*

OUTLINE.—In fortification, the succession of lines that show the figure of the works, and indicate the direction in which the defensive masses are laid out, in order to obtain a proper defense.

OUTLYERS.—A term formerly applied, in the British service, to men who were permitted to work, on condition that the whole of their pay was left in the hands of their Captain for the time they were so employed. This sum the officer appropriated to his own use, to enable him to increase his pay and keep a handsome table when he mounted guard. It was also a common practice to place on the muster-rolls the names of officers' children, and instances have occurred of girls receiving men's pay as outlyers.

OUT-LYING PICKETS.—Detachments of cavalry and infantry, accompanied sometimes with light guns, and posted on the front and flanks of an army in the field, in order to guard against surprise, and to keep reconnoitering parties at a distance. See *Out-posts.*

OUT OF GEAR.—For most heavy guns, the motion of the top carriage to and from battery is regulated by a pair of truck-wheels, one on each side, which work on an eccentric axle placed underneath and a little in front of the axis of the trunnions. The wheels are thrown *out of gear* by means of handspikes inserted into sockets upon the ends of the eccentric axle. See *Into Gear.*

OUT-PENSIONER.—A pensioner attached to a hospital, as Greenwich or Chelsea, England, who has liberty to live where he pleases.

OUT-POSTS.—The detachments of troops and the method of arranging them, by means of which an Army when in bivouac, in camp, or in cantonment, is protected from surprise by an enemy. The duties of the out-posts, and of the grand-guards which form their supports, are strictly those of observation. If attacked, they offer no resistance farther than to enable them to feel the enemy perfectly, and never lose sight of him. The task of holding the enemy in check by a vigorous resistance, so as to procure sufficient time for the main-body to make its dispositions for battle, is consigned to the pickets. The position of the out-posts, with respect to the main-body, will be regulated by the more or less broken character of the country. As a general rule the mean distance may be taken at about two miles. The line occupied by these posts should take in all the approaches to the front and flanks of the main position. When a position is to be held for a considerable time, the out-posts may be thrown farther in advance; to procure greater repose and security for the main-body. The ground on which the line of out-posts is established should be carefully examined; with a view both to observation and defense. As far as practicable, those points should be selected for posts which present some natural advantages for the defense; will screen the troops from the enemy's view; and enable them to watch all his movements. Whenever the features of the ground do not offer natural obstacles to cover the posts, artificial means of a slight character should be resorted to. The flanks of the line should rest upon strong natural obstacles; when such cannot be found, without giving the line too great an extent, these points must be secured by strong pickets of cavalry or infantry, thrown back to form crotchets; from which patroles must be constantly kept up on the flanks in the presumed direction of the enemy.

The strength of each out-post, and the distance from one to the other, will be regulated by the features of the ground, and the number of sentinels, or vedettes that each post must throw out. The posts should, as far as practicable, be within sight of the grand-guards to which they belong; and the sentinels of their respective posts. When the ground does not permit this arrangement, sentinels should be placed at intermediate points, to communicate promptly whatever may happen at the line of posts, or of sentinels to the rear. Posts of infantry should not, as a general rule, be placed farther apart than 600 paces; nor their sentinels more than 300 paces in advance of the posts. Those of cavalry may be some 1,500 paces apart; and their vedettes from 600 to 800 paces in advance. The strength of each post should be calculated at the rate of four men for each sentinel, or vedette. An officer in command of any of the out-posts must be capable of untiring vigilance and activity; to perform the various duties that devolve upon him. He should be provided with a good map of the country, a telescope and writing materials. He will thoroughly reconnoiter the ground upon which he is to dispose his command; and also as far in advance as circumstances admit questioning closely any inhabitant he may find. After taking up his position, he should go forward with the half of his command; and post each sentinel himself. If however, he relieves another in the command, and deems it advisable to make any changes in the dispositions of his predecessors, he should promptly report the facts to the Commanding Officer in his rear. When the officer finds that the enemy is not in his immediate neighborhood, he should endeavor to feel his way cautiously towards him by patrols; and when in immediate presence, he should omit no means to watch the enemy's movements; and from the occurrences of the moment, such as noises, the motion of the clouds of dust, camp fires, conflagrations, etc., endeavor to divine what is passing in his camp, and his probable intentions. Accurate written reports should be promptly sent to the officer in command, in the rear, on all these points. The reports should be *legibly* written, and should clearly but *concisely*, state what has fallen under the officer's eye; what he has learned from others; and the character of the sources from which his information is drawn. See *Advanced Posts.*

OUTRANCE.—To the utmost; to the last extremity. Thus the French say, *Se battre à outrance*, to fight to the last extremity.

OUT-SENTRY.—A sentry posted to guard the entrance or approach to a place. See *Outguards*.

OUTSIDE.—In fencing, that part which is to the right of the line of defense. The *Outside Guard* is used with the broadsword and saber, to defend the outside of the position.

OUTWARD FACE.—A word of command for troops to face to the right and left from their center.

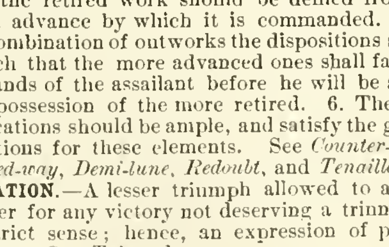
OUTWARD FLANK.—The extreme file on the right or left of a division, subdivision, or section, according to the given front, when the battalion is at close or open column, and which is the farthest wheeling point from line into column, or from column into line. It is likewise called the *reverse* flank.

OUTWORKS.—A work consisting of an enceinte alone is more or less exposed to surprise, as it must have outlets of some description to keep up a communication with the exterior, and a bridge, or other means for crossing the ditch. This is not the only defect of a fortification of this simple character; for having no covers beyond the ditch for its garrison, their action must be restricted to what may be termed a passive resistance alone; in any attempt to operate on the exterior, they are exposed to fire as soon as they emerge from the ditch, and in a retreat towards the work, if closely pursued by the assailant, they will not only run the risk of being cut off, but a retreat under such circumstances may lead to the capture of the work itself, by the assailant being enabled to enter it with the retreating force. To provide against dangers of so grave a character, engineers have devised other defenses beyond the ditch, and which they have placed in immediate defensive relations with the enceinte, being under its fire, and in positions where, if assaulted, they can be readily succored by the garrison. To this class of exterior defenses the term *outworks* has been applied.

The outworks should satisfy the following conditions to render them very effective and secure: 1. They should have revetted scarps of a sufficient height to secure them from any ordinary open assault. 2. As far as practicable their scarps should be flanked by the enceinte and be masked from the positions of the assailant's batteries. 3. Their parapets and covered shelters should be shot-proof. 4. Those which are most retired should command those in advance; and whenever this cannot be done the retired work should be defiled from the one in advance by which it is commanded. 5. In any combination of outworks the dispositions should be such that the more advanced ones shall fall into the hands of the assailant before he will be able to gain possession of the more retired. 6. The communications should be ample, and satisfy the general conditions for these elements. See *Counter-guard*, *Covered-way*, *Demi-lune*, *Redoubt*, and *Tenaille*.

OVATION.—A lesser triumph allowed to a Commander for any victory not deserving a triumph, in the strict sense; hence, an expression of popular homage. See *Triumph*.

OVEN.—A very necessary apparatus in military economy to preserve the health of troops, by enabling them, at a comparatively small expenditure of



OVEN OF GABIONS, DIMENSIONS IN METRES.

fuel, to cook many rations together. In the British army little attention was paid to such subjects, until, in 1858, the inquiries of Mr. Sidney Herbert (afterwards Lord Herbert) brought to light the excessive mortality among soldiers, which was partly—and, as the event has shown, justly—attributed to the bad cookery of their food. Captain Grant has bestowed much attention to army cookery, and has invented ovens for barrack use and for the field. While great improvements on the system—or want of system—which preceded them, these ovens are still admitted to be far from perfect in their arrangements. For boiling meat, etc., in the field, he employs detached cylinders, which, when empty, he proposes to join and floor over for use as pontoons; when in use they are united crosswise, one in the middle serving for a chimney. One or more empty barrels can be attached for steaming potatoes, and the roasting of coffee is performed, though not altogether successfully, in another cylinder made to revolve over the

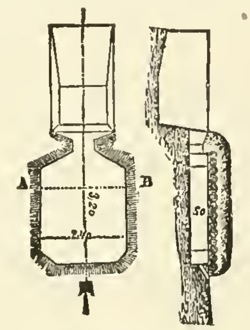


Fig. 2.

chimney. Up to the present time other systema have been partially resorted to; but none has as yet been definitively adopted to the exclusion of others. Cylindrical ovens are preferable for field service, and the want of brick for the arch and fireplace may be supplied by two gabions of semi-circular or semi-elliptical form 1m. 44 in diameter; the basket work is not so close as the ordinary gabion, and is 1m. 32 in height. The two gabions, resting one over the other upon the flat side, make a cradle 2m. 64 long, 1m. 44 broad, and 0m. 72 high. (Fig. 1). The interior and exterior is then plastered with clay, which must penetrate the interstices of the basket work. The front and back part is shut in the same manner, or with sods. The cradle is then covered with earth to retain the heat, and in order that the superincumbent weight may not cause it to give way. Withes are attached to the top of the basket work, and passed vertically through the embankment, and then fastened to the longitudinal beam of a wooden horse straddled against the exterior curve. Eight of these furnaces may be made in 24 hours. The wooden oven (Fig. 2) is made by digging an excavation of 3m. 20 in length by 2m. 40 in breadth, and 0m. 50 in depth, making the fireplace slightly descending towards the mouth. This trench is covered with pieces of wood of 0m. 15 to 0m. 25 square, placed close together; the wood is covered with earth carefully packed, the chimneyplace is sodded. The fireplace is dried by heating for 7 or 8 hours, and subsequent heatings require two hours. Such ovens resist very well five or six bakings.

OVERCHARGED MINE.—A mine whose crater is wider at the top than it is deep. See *Crater*.

OVERCOAT.—A part of the uniform, worn in cold weather and when specially ordered. In the United States army it is prescribed as follows:—

For General Officers.—Of dark blue cloth, closing by means of four frog buttons of black silk and loops of black silk cord; cord down the breast, and at the throat by a long loop "*à l'échelle*," without tassel or plate, on the left side, and a black silk frog button on the right; cord for the loops fifteen hundredths of an inch in diameter; back, a single piece, slit up from the bottom from fifteen to seventeen inches, according to the height of the wearer, and closing at will by buttons, and button-holes cut in a concealed flap; collar of the same color and material as the coat, rounded at the edges, and to stand or fall; when standing to be about five inches high; sleeves loose, of a single piece and round at the bottom, without cuff or slit; lining wooden, and, with the facings, to correspond in color with the trimmings of the uniform; around the front and lower borders, the edges of the pockets, the edges of the sleeves, collar, and slit in the back, a flat braid of black silk one-half an inch wide; and around each frog button on the breast a knot two and one-quarter inches in diameter, of black silk cord, seven hundredths of an inch in diameter. cape of the same color and material as the coat, removable at the pleasure of the wearer, and reaching to the cuff of the coat sleeve when the arm is extended; coat to extend down the leg from six to eight inches below the knee, according to height. To indicate rank, there is on both sleeves, near the lower edge, a knot of flat black silk braid, not exceeding one-eighth of an inch in width, and composed of five braids, double knot.

For all other Officers—Dark blue, close-fitting double-breasted surtout-coat, having a cape, made to detach from the coat and fall to the tips of the fingers when the arm and hand are extended; the skirt of the coat for mounted officers to reach half way between the knee and the sole of the foot; for dismounted officers, three inches below the knee.

The coat has seven buttons on each breast, of the same pattern as those on the uniform coat. The insignia of rank is on the sleeve. as follows, viz: Colonel, five braids, single knot. Lieutenant-colonel, four braids, single knot. Major, three braids, single knot. Captain, two braids, single knot. 1st Lieutenant, one braid, single knot. 2d Lieutenant and Additional 2d Lieutenant, without braid. Military Storekeepers, same as officers of the General Staff of like rank. Chaplains, without braid.

On the frontier and campaign, officers may wear the soldier's great-coat, with the insignia of rank on the sleeve. See *Great-coat*.

OVERHAUL.—A term used in artillery appliances in "overhauling" a tackle, that is, in separating the blocks. This should invariably be done from the standing, and not from the movable block.

OVERLAP.—In marching by echelon for the purpose of forming upon any given point, and particularly in wheeling from column into line, troops may lose their relative distances by not taking ground enough; when this occurs, the rear division, company, or section, unavoidably crowds upon its preceding one, and is then said to *overlap*.

OVERSEER.—An officer in the Ordnance Department, who superintends the artificers in the construction of works, etc. He is called *Superintendent*.

OVERSLAUGH.—To hinder or stop by an unexpected impediment; as to overslaugh a military officer, that is to hinder or stop his promotion or employment by the appointment of another to his rank or duties.

OWN.—A term which has been attached to some British regiments since the Revolution in 1688. Thus the 4th Foot, which landed with William III., was called the 4th Kings Own.

OX.—A ruminant quadruped of the family *bovidæ*, much used as a draught animal in military trains. The ox is more frequently employed as a beast of draught in some parts of the continent of Europe than in Britain. From the earliest historic times the horse has been more generally thus employed, and has now almost entirely superseded the ox. The gait of the ox is slow and plodding, but its strength enables it to perform a great amount of work, and it is not easily exhausted. It needs, however, intervals of rest inconvenient for the marches; and it is not capable of exertion at all equal to that of the horse on any occasion of emergency. See *Bullock*.

OXFORD BLUES.—The third heavy cavalry regiment of the Household Brigade. It was raised in 1661, and took part in Marlborough's campaigns; it also served under Wellington in the Peninsula and at Waterloo. This regiment, like the two regiments of Life Guards, wears a steel cuirass, but over a blue coatee, whereas the coatee of the two latter regiments is red. See *Horse-Guards*.

OXIDES. Metallic oxides are the most important of all the compounds of the metals, and in many cases occur naturally as abundant and valuable ores. They are divided by chemists into three classes viz., (1) basic oxides or bases, (2) saline or indifferent oxides, and (3) acid oxides or metallic acids. The different oxides of the same metal usually afford illustrations of two, and not unfrequently of all three of these classes. Thus (to take the case of manganese) the protoxide (MnO) is a powerful base, the red oxide (Mn_3O_4) is a saline or indifferent oxide, showing little tendency to combine either with acids or alkalies, while permanganic acid (Mn_2O_7) presents all the properties of an acid. As a general rule, the greater the number of atoms of oxygen which an oxide contains, the less is it disposed to unite with the acids; on the contrary, it frequently possesses acid properties, and then unites with bases to form salts. Protoxides generally are strong salifiable bases; they require one equivalent of a monobasic acid to form neutral salts. Sesquioxides are weaker bases; their salts are usually unstable; they require three atoms or equivalents of a monobasic acid to form a salt which is neutral in composition, though it may not be neutral to test-paper; and in general, all oxides require as many equivalents of acid as they contain atoms of oxygen in their composition. Some of the metallic acids, like the stannic and titanic, contain two atoms of oxygen to one atom of metal, but most of them contain three atoms of oxygen—such, for example, as the manganic, ferric, chromic, tungstic, molybdic, and vanadic acids; whilst in a few cases, such as the arsenic, antimonic, and permanganic, the proportion of oxygen is still higher. Of the basic oxides, which form by far the most important class, it may be observed that they are devoid of all metallic appearance, and present the characters of earthy matters, and that six only of them are soluble in water to any considerable extent, viz, the three alkalies and baryta, strontia, and lime. All the oxides are solid at ordinary temperatures, and as a general rule, the addition of oxygen to a metal renders it much less fusible and soluble; the protoxide of iron, the sesquioxide of chromium, and molybdic acid being the only oxides that melt more readily than the metal.

OXYHYDROGEN BLOW PIPE.—An instrument for the purpose of burning oxygen and hydrogen gases in their equivalent proportions, so as to get the greatest heat from the combination. Two volumes of hydrogen and one of oxygen form an exceedingly powerful explosive mixture, in consequence of their instantaneous union upon the application of sufficient heat, as the electric spark or a taper, the result being the formation of water. It was, therefore, early known to be dangerous to experiment with the mixed gases. In some instances, when the gases were contained in separate reservoirs and connected by tubes at their extremities, they have become mingled in one of the reservoirs in consequence of a backward flow of the mixture, and serious accidents have resulted. This led to the early use of concentric tubes for the delivery of the gases, the hydrogen tip usually surrounding the one discharging the oxygen. By properly regulating the pressure in the gas-holders the two gases may be mingled without danger, near the end of the tubes, at the entrance of the burner. Hemming's safety jet is used for burning the gases mixed in the same reservoir; but it is not thought safe to have this of metal, but of a membrane. The ordinary burner, which mingles the two gases for some inches before their exit, is all that is sufficient to produce thorough admixture previous to ignition, and will furnish as "solid" a flame as may be desired. The chief uses of the oxyhydrogen blow-pipe are to readily fuse metals, and to render lime incandescent in the Drummond light. See *Drummond Light.*

P

PACE.—In its modern acceptation, the distance, when the legs are extended in walking, between the heel of one foot and that of the other. Among disciplined men the pace becomes of constant length, and as such is of the utmost value in determining military movements, the relative distances of corps and men being fixed by the number of paces marched, and so on. The pace in the British army is $2\frac{1}{2}$ feet for ordinary marching, and 3 feet for "double quick" or running time. With the Romans the pace had a different signification, and it is important to bear the distinction in mind, when reading of distances in Latin works; the single extension of the legs was not with them a pace *(passus)*, but a step *(gradus)*; their pace (*passus*) being the interval between the mark of a heel and the next mark of the *same* heel, or a double step. This pace was equivalent to 4.84 English feet. The pace was the Roman unit in itinerary measure; the mile being 1,000 paces, or 5,000 Roman feet, equal to .917 of an English mile. Whether measurements were effected by actually counting the paces, or by the time occupied, is not clear; but either method would, with disciplined troops, give a safe result. In the Middle Ages, writers confuse accounts of distances by allusion to a geometrical pace, a measure which varied with different authors.

PACING DRILL.—In the United States Army, before teaching the soldier to estimate distances simply by sight, he is first instructed to measure them by walking over them and carefully counting the number of equal paces thus taken. The Instructor causes a distance of one hundred yards to be measured off on smooth, level ground, and marked by a stake and small flag at each end. The squad is marched to the ground under arms, and formed in single rank, in a line passing through the first stake and at right angles to the measured line. The Instructor directs each man to march straight forward until he comes opposite to the flag planted at the 100-yard stake, and to carefully preserve his natural step without either increasing or diminishing its length, at the same time counting the number of steps taken. This is repeated three times. From the mean of the three trials the Instructor will give to each man a number of steps that he will take in measuring 10 yards and 100 yards, so that if he march with equal paces he can step 100 yards with some degree of accuracy. When the men have learned to measure distances on smooth and level ground, they are next practiced on that which is more or less broken. The Instructor reminds them that in ascending, a shorter step is always taken, and the reverse in descending. Where it is possible, he selects different practice grounds, which will give the men the opportunity of determining the number of steps taken in a given distance in going up or down hill, and also that which is more or less broken by ruts and furrows. The number of steps taken under these circumstances are recorded by each man, giving the inclination of the ground and other irregularities as nearly as possible. The men are then exercised in measuring unknown distances, embracing as great a variety of surface as convenient, and continued until they are able to reduce the error made to within five per cent. of the distance measured. The difficulty of correctly estimating any given distance without the aid of proper instruments for the purpose increases rapidly as the distance becomes greater. The exercises for the instruction of the men are for this reason divided into three parts, and the men are assigned to one of three classes according to their proficiency in the drill. The third section of the course has reference only to distances varying from 100 to 300 yards; the second section to those from 300 to 600 yards, and the first from 600 to 900 yards. Beginners form the third class; those who become expert in estimating the distances of the third section are advanced to the second; and when the drill has been mastered as regards the distances of the second section, the pupil is passed into the first class, and practices estimating all distances up to 900 yards.

PACK-ANIMALS.—Pack-animals may be advantageously employed in sections of country not permitting the use of wheeled carriages. Horses, ponies, mules, oxen, elephants, camels, goats and dogs are more or less used as pack-animals in different countries, and the variety of packing gear is very great. The nature of the country to be traversed and of the load to be transported, will in a great measure determine the form and adjustment of the gear. The *mule* is a favorite pack-animal in many countries, but the ox is far superior, and would be in greater demand, were it only fashionable to use him as a pack and saddle animal. Oxen hold out much better than mules over *long* marches, are much cheaper, are less liable to be stampeded by the enemy, are easily caught when needed, and in case of emergency may be used for beef. In some respects the mule is a superior pack-animal to the horse. His peculiar build gives him, in proportion to his weight, a greater power to transport a load on his back; besides this, the mule eats less than the horse, and is more sure-footed.

The load, gait, journey, forage, intervals of rest, etc., of a pack-animal should be so proportioned that he will be no more fatigued one day than another. It has been determined by experience that a pack-animal, traveling at a walk, over a good road, can carry from 220 to 300 lbs., 30 miles in 10 hours; or if he moves at a trot, 175 lbs. over the same distance; and the daily work of a pack-animal is equal to that of five men, under the same circumstances. If the road be hilly the advantage will be in favor of the men. The above data supposes that the animal is regularly fed on the service-ration. If he be fed on grass alone, an allowance must be made for its quality and abundance. Over difficult and long-continued journeys, with pastures seldom good, the net weight of the packs should not exceed the half of those readily transported over a level country, furnishing a sufficiency of grain and camps at regular intervals. The question *how must the animal be loaded and urged to obtain the maximum work or useful effect*, is an important one. If he transports a light weight, he may make a long day's journey; if he transports an excessive weight, he may soon come to a standstill, and in either case the "useful effect" is little or nothing. Let D=the distance an animal could travel daily if unloaded. W=the weight under which he could not travel at all. W′=some weight less than W, under which he could travel D′ miles per day. Then, there obtains $W'D^2 = W(D-D)'^2$. Now the work or 'useful effect" will be a maximum when W′D′ is a maximum, or when $W'^1 = \frac{4}{9}W$, and $D' = \frac{1}{3}D$, or in other words, the animal will accomplish the most work when he transports $\frac{4}{9}$ths of the load under which he would stagger, and he will travel just $\frac{1}{3}$ the distance he could if he carried no load at all. For example: Suppose an animal is able to travel 20 miles per day, bearing a load of 200 lbs., and 45 miles per day, when he carries nothing; then, from the equation $W'D^2 = W(D-D')^2$, we find $W = \frac{200 \times 2025}{625} = 648$ lbs., the load under which he would be brought to a standstill, and from $W' = \frac{4}{9}W$ and $D' = \frac{1}{3}D$, we find the best load to be 288 lbs., carried 15 miles per day.

An army requires to be accompanied by several thousand pack-animals, sometimes horses, but preferably mules; and in Asia, commonly camels, or even elephants. Pack-saddles are variously fitted, according to the objects to be carried; some for provisions or ammunition; others for carrying wounded men, tents, and, in mountain warfare, even small cannon. In battle, the immediate reserves of small-arm ammunition are borne in the rear of divisions by pack animals; the heavy reserves being in wagons between the army and its base of operations. See *Buffalo*, *Camel*, *Elephant*, *Llama*, *Mule*, *Packing*, and *Pack-saddle*.

PACKFONG.—A Chinese alloy or white metal, consisting of arsenic and copper. It is formed by putting two parts of arsenic in a crucible with five parts of copper turnings, or finely divided copper; the arsenic and copper require to be placed in alternate layers, and the whole is covered with a layer of common salt, and pressed down. When melted, the alloy contains nearly the whole of the arsenic, and is yellowish-white in color when in the rough state, but takes a fine white polish resembling silver. It is not very ductile, and cannot be fused without decomposition, as the arsenic is easily dissipated. It is seldom imported now, the nickel alloys of Europe having quite superseded its use; in China, however, it is extensively employed in the laboratory. Also written *Petong*.

PACKING.—The art of making up and adjusting the load of a pack-animal. The mode of packing varies with the pack-saddle and gear. With the aparejo, used in the United States Army, the packing process is very simple. It requires two men to properly pack the animal. Designating the packers as No. 1 and No. 2, their duties are as follows:

No. 1 is habitually on the near or left side, and No. 2 on the off or right side of the animal. To teach the art, the Instructor commands:

1. *Prepare*. 2. To Pack.

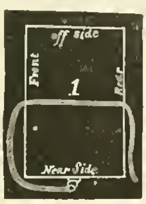
At this command, No. 2 places the hackamore upon the animal, leads him on the off side of and near the rigging, places the blind and assumes his position on the off side. No. 1, assisted by No. 2, on the off side, then places and carefully adjusts the saddle blanket and corona. (Two). No. 1 seizes the aparejo, the left hand near the center of its front, the right hand near the off and rear corner, and places it well to the rear on the back of the animal, when No. 2 immediately adjusts the crupper, and assists No. 1 in moving the aparejo as far forward as possible. (Three). No. 1 passes the aparejo cinch to the off side, till the slider end reaches directly under the animal, and assisted by No. 2, passes the latigo strap downwards over the slider and inwards through the ring, and again over the slider. While No. 1 is drawing the latigo strap moderately tight, No. 2 reaches over the animal, in front of the aparejo, seizes its front corners and draws them upward and forward, placing the aparejo squarely over the animal. This being done and the aparejo *set*, No. 1 places his left knee against the aparejo, and seizes the latigo strap as far down as possible, the left hand in advance. (Four). The latigo strap is drawn until the cinch is sufficiently tight, when No. 1 doubles it, and passes it through the loop on the cinch, drawing it tight. No. 2 removes the blind, and ties the animal at or near his cargo. If No. 1 is not sufficiently strong, No. 2 passes around to the near side, faces No. 1 and assists him in drawing the latigo strap.

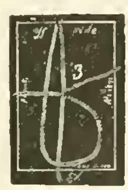
1. *Sling*. 2. The Pack.

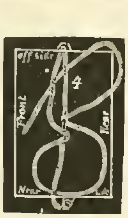
At this command, No. 2 unties the animal, places the blind, and takes his position near the cargo. No. 1 seizes the sling rope, doubles it and throws the loop well over on the off side. (Two). No. 2 quietly raises his side of the pack high up on the aparejo, and holding it there with his left hand passes, with his right hand, the loop of the sling-rope over the cargo to No. 1, who passes the ends of the sling-rope through the loop, drawing them tight. (Three). No. 1 quickly places his side of the pack on the aparejo against that of No. 2, holds it there with his left hand, and passes one end of the sling-rope to No. 2, who passes it under a branch of the sling rope already on his side, and back to No. 1. No 1, resting his left arm against the pack, quickly brings the ends of the sling-rope together and ties them in a square knot, after drawing tight. (Four). Nos. 1 and 2 seize the pack at the lower and inner edges, settle it to the full extent of the sling-rope, and carefully balance it, No. 2 removing the blind, and gently leading the mule a few steps forward, while No. 1 observes the pack from the rear. No. 1 then places the pack cover, and is assisted by No. 2 in adjusting it. When the mantas are not in use, they are folded and carried on the aparejos under the cinches.

1. *Lash*. 2. The Pack.

At this command, No. 1 takes the lash-rope, and holding it coiled in his right, seizes it with his left hand near the cinch, and throws it to its full extent to the right; whereupon he passes the cinch hook from him, under the mule, and holding it steady, he places the rope lengthwise on the center of the pack (Fig. 1.)







(Two.) No. 1 now moves forward to the animal's shoulder, draws the lash rope forwards two-thirds of its length, seizes it 5 or 6 feet from the cinch, and passes it doubled to No. 2 (Fig. 2), who takes the double in his right hand, and the hook of the cinch in his left. No. 2 then moves his hands, until he feels the rope tight, when he passes the rear branch of the rope from above into the hook and the slack back to No. 1, who draws it tight with his left hand. He then passes his right hand under his left, seizes the rope in front of the pack and passes it to the rear (Fig. 3). (Three.) No. 1 passes the rope in his left hand under the standing branch from rear to front, pulls it well up on the pack (Fig. 4) and forces the bight thus formed below the aparejo. In the meanwhile, No. 2 grasps the end of the rope, passes it under the front standing branch on his side (from front to rear or from rear to front), pushes it to the top of the pack, and throws the end in front of the pack on the side of No. 1; No. 2 then seizes the front standing branch with both hands, well down, and places his left knee against the aparejo. No. 1 seizes the front branch on his side, placing his left shoulder against the pack. No. 2 pulls while No. 1 takes in the slack. When all is sufficiently tight, No. 1 says "good," and seeing the pack well balanced passes to the rear and tightly pulls the branch under the aparejo. (Fig. 5). (Four.) No. 2 goes to the rear, pulls the branch on his right and passes it forward under the points of the aparejo. No. 1 moves forward, on his own side, takes the end of the rope, tightens it, passes it down under the points of the aparejo, back to the center of the pack and there fastens it by drawing it under the standing branches (Fig. 6). If the lash rope is very long, No. 1 passes the end to No. 2, who makes it fast as stated. All set, No. 2 removes the blind, ties up the hackamore strap and drives off the animal.

1. *Unsling*. 2. THE PACK.

At this command, No. 2 loosens the end of the lash rope, goes to the animal's shoulder and pulls out the branch on his side. (Two.) No. 1 slackens the rear and front branches on his side in succession, passes the front branch under the standing branch from front to rear, withdraws it and passes the slack to No. 2, who unhooks it, whereupon Nos. 1 and 2 throw the lash rope to the rear. (Three.) No. 1 unties the sling rope quickly. (Four.) Nos. 1 and 2 take down the portions of the pack on their sides.

The aparejo is taken off in the inverse order in which it is put on. This being done, No. 1 arranges the cargoes while No. 2 collects and assorts the rigging, placing the aparejos in line, resting on the lower ends of the pads. As the train moves out, each animal should be carefully noticed. Raising the hips and twiching the mouth or nose indicates *galling*, and should lead to immediate examination. The hackamores should fit very closely. Nothing is so liable to irritate an animal and give him "fits of fury" as sore ears. If possible, the cargo should be made into two packages of equal weight and bulk, of about 100 or 125 pounds, and the highest loads should be the bulkiest and most valuable stores. All rattling pans, camp kettles, buckets, etc., should be closely packed in sacks and securely lashed on top between the side packs. If carelessly packed and allowed to rattle, the animals will frequently become alarmed and as frequently succeed in dropping their packs.

PACKING-BOX.—A box used for keeping fixed shot or shell in store, or in transit from place to place, or on the march with siege trains. The name is given to any box or case containing military stores.

PACKING OF POWDER.—Government powder is packed in barrels of 100 pounds each. Powder barrels are made of well seasoned white oak, and hooped with hickory or cedar hoops, which should be deprived of their bark; the cedar is not so liable as hickory or white oak to be attacked by worms, and it should therefore be used in preference; or the hoops may be prepared by immersion in a solution of corrosive sublimate. The hoops should cover two-thirds of the barrel. The grain powders may be packed in canvas bags before being barreled. Instead of a bung on the side, a screw-hole 1.5 inches in diameter is made in the head of the barrel, for mortar and musket powder; it is closed by a wood-screw with an octagonal head, which must not project beyond the ends of the staves; under the head of the screw is a washer of thin leather, steeped in a solution of beeswax in spirits of turpentine. This screw-plug renders it unnecessary to take out the head of the barrel, and the hoops may therefore be secured with copper nails; for transportation, a piece of cloth should be glued over the head of the plug. Some barrels have been made with six copper hoops, and others with four copper and eight or ten cedar hoops; the copper hoops are one inch wide and one-eighth of an inch thick, fastened with two rivets and nailed each with three copper nails 0.625 inch long. Average weight of a hoop $2\frac{1}{4}$ pounds. Powder boxes lined with galvanized iron and copper with large screw lids are now on trial, holding 100 pounds. It has been found that lining powder barrels with India-rubber cloth has an injurious effect on the powder in consequence of the affinity of the caoutchouc for sulphur. The heads of powder barrels are painted *black* in order to show the *marks* more plainly in dark magazines. The following are the dimensions of powder barrels:—

Whole length	20.5 inches.
Length, interior, in the clear	18 inches.
Interior diameter of head	14 inches.
Interior diameter of bilge	16 inches.
Thickness of the staves and heads	0.5 inch.
Weight of the barrel	25 pounds.

The barrels have generally 12 hoops, 14 to 16 staves, and two or three pieces in each head. The dimensions are such that with 100 pounds of powder there shall be a vacant space on the barrel to allow for shaking to prevent caking. The barrel will hold 120 pounds settled by shaking. See *Gunpowder*.

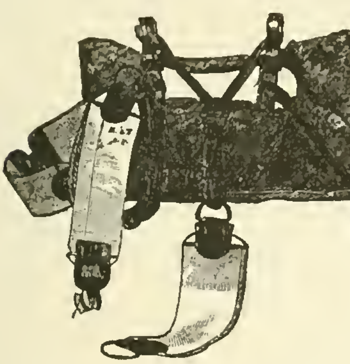
PACKING SMALL ARMS.—When small-arms are to be sent on a long sea voyage the arm-chests are provided with tin linings, securely soldered, so as to exclude all dampness. The clamps for the bayonets are screwed down precisely as in the unlined chest. The tenons of the packings (muzzle, butt, top, and middle) are cut off, as the tin does not extend in the grooves ordinarily filled by them. In a chest intended to be lined the grooves are omitted. A leather strip is placed under each bottom muzzle-clamp to prevent the butt-plate rubbing on the lining. Two strips of wood $\frac{1}{8}$ inch wide and 1 inch thick are placed lengthwise with the box, one on each side, their ends resting in notches cut in the ends of the top clamps. The edges of the lining are about one inch above the level of the chest. They are bent inward, and hammered down on the strips of wood before mentioned. The edges are then carefully soldered to the cover. To open the box a soldering-iron and thin knife are required to open the soldered joint.

In the field, or under other circumstances, when the proper arm-chests are not on hand, it may sometimes be necessary to pack arms with straw. The interior dimensions of a box for twenty muskets may be the same as for the regular packing-box. The straw should be long, perfectly dry, and free from dust; *rye straw* is the best; *hay* should not be used; about twenty-five pounds of straw are required to a box. *To prepare the musket for packing*—Oil it; let down the hammer, pass the bayonet up to the socket into the guard-bow, on the right side, in front of the trigger. Make a rope of about forty straws, slightly twisted, and forty inches long; wrap it about the musket, commencing on top of the hammer going round the bayonet below, again over the hammer and round the piece in front of the guard, then over the socket of the bayonet near the neck, and wrapping the rest around the handle of the stock.

Lay a bed of straw 2 inches thick in the bottom of the box; in the middle and at 6 inches from the ends, place three cushions of straw 6 inches thick and 12 inches wide. Put in a tier of 10 muskets, crossing each other, the butts resting alternately against the ends of the box, the guards uppermost and the hammers bearing on the cushions. Put small trusses of straw under the upper and middle bands by raising the muskets at one end and then pressing them down between the others. Pack between the butts wads of straw 8 inches long, made of a handful of straws folded in three; cover the guards and guard-bows with the ends of the straw that form these wads, which will be still about 12 inches long. Put in another tier of 10 muskets in the same manner, making the cushions 4 inches thick. Pack the implements in straw in the vacant spaces. Fill the box with straw, so that the cover shall require strong pressure to keep it down. Put two hoops round the box, at 18 inches from the ends. Other arms, swords, etc., are packed in a similar manner. Arms should not be wrapped in paper, unless it be oiled, as it attracts moisture more readily than straw does. See *Small-arms*.

PACK SADDLE.—Pack-saddles are variously fitted, according to the nature of the loads to be carried: some for provisions or ammunition; others for carrying wounded men, tents, and, in mountain warfare, even small cannon. *The cross-tree saddle and gear*, represented in the drawing, is used to a great extent by the Indians and traders in Northwestern America. This description of saddle is very well adapted for smooth roads and evenly formed packs. but for scouting trains or the professional packer, where objects of every imaginable shape and various weights are to be transported, nothing has yet been invented so suitable as the *aparejo*, composed entirely of hide.

In very early times the saddle to which the bundles were fastened consisted of two pieces of wood,

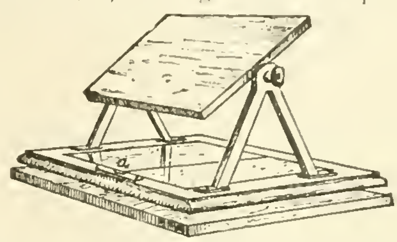


curved so as to fit the horse's back, and joined together at the ends by two other straight pieces. This frame was well padded underneath, to prevent injury to the horse's back, and was firmly fastened by a girth. To each side of the saddle a strong hook was attached, for the purpose of carrying packages, panniers, etc. Panniers were sometimes simply slung across the horse's back with a pad under the band. The panniers were wicker baskets, and of various shapes, according to the nature of their usual contents, being sometimes long and narrow, but most generally having a length of three feet or upwards, a depth of about two-thirds of the length, and a width of from one to two feet. The pack-horse with panniers was at one time in general use for carrying merchandise, and for those agricultural operations for which the horse and cart are now employed; and in the mountainous regions of Spain and Austria, and in other parts of the world, it still forms the sole medium for transport; though the mule has, especially in Europe and America, been substituted for the horse. See *Aparejo* and *Packing*.

PACK TRAIN.—A troop of pack-animals. When fitting out a train, as few different kinds of animals should be taken as possible, as they will run in different herds and require much more attention.

PADDLING. The removal, by means of a copper spud, of such lumps of gunpowder as adhere to the faces of the rollers during the incorporating process in the manufacture of gunpowder. The operation requires great care, and should only be resorted to under exceptional circumstances. Generally water poured on the face of a roller will, to some extent, loosen the powder.

PADDOCK INTERPOLATER. When, owing to the interposition of an intermediate obstacle, the object to be fired at cannot be seen from the mortar, a point must be interpolated on the required line in such position that it can be seen from the mortar. This is most readily effected by this most simple and convenient instrument, consisting of two small mirrors attached to a metallic frame. One of these, termed the upper mirror, revolves on a horizontal axis; the other is called the lower mirror, and to it is attached a small spirit level, *a*. Hair-lines are marked on these mirrors, representing the trace of a plane nor-



mal to the axis of the level at its center, and also to the axis of the upper mirror. To use the instrument, the observer places himself approximately on the line from the mortar to the object to be fired at. Keeping the bubble in the center of the level, he turns the instrument so that the mortar will be reflected from the upper mirror onto the hair-line of the lower mirror. He then revolves the upper mirror, and, catching the reflection of the object, observes on which side of the hair-line of the lower mirror it falls. He moves in that direction until both images—that of the mortar and of the object—fall upon the lower hair-line, the two hair-lines being coincident. A pin or plummet is placed in prolongation of this line to mark the required point. To make the last part of the observation with accuracy, the instrument should be rested on some convenient object.

When the foregoing instrument is not to be had, a point may be interpolated by two persons, each using a light, slender stake. They place themselves as near as practicable on the required line, one facing towards the mortar, where he can see it, and the other towards the object, where he can see it, and both within view of each other. Holding their stakes vertical, they sight and move them alternately, until finally they have them in such position that they range both upon the mortar and the object. The stakes or, better, plummets are then adjusted at these points, and sighting by them back to the mortar, a plummet is suspended in the usual manner behind the platform. The plummets thus established mark the desired plane of sight. This operation is more conveniently performed by using a strip of board, ten or twelve feet long, in which is set at each end a priming-wire. The board is placed at the intermediate point in a position approximately in the plane of sight, and where the mortar can be seen by sighting past both wires back upon it, and the object can be seen by sighting forward in the same manner. Two persons, one at each end, by alternately sighting and moving the board, readily establish the wires in the required line. A plummet is then suspended, at some convenient point in front of the mortar, in line with the two wires on the board. The plummet in rear of the mortar is suspended on the same line. The two plummets thus established determine the plane of sight.—See *Plummet.*

PADS.—In the artillery and cavalry service, pads are used to protect saddle and draught horses from galls. The pad recommended is in the form of a folded blanket, or pad made of sheep or kid's skin, stuffed with hair, 6 inches by 4 inches. When placed above and below the gall considerable relief will be afforded. If a piece of harness is seen to be commencing to rub a horse, besides altering the fitting, friction may be prevented by rubbing in any lubricant (tallow will do on an emergency). To cure a gall or sore while the horse continues his work, pads must be judiciously applied. Sheep skin is the favorite specific of many collar-makers; it sometimes effects more than would be expected; it enables the harness and skin side of the sheep skin to move, while the ends of the hair remain without motion on the tender part of the horse. The rubbing of a trace is sometimes difficult to prevent; we have seen the pressure completely removed by attaching a short, flat piece of wood along a hip or bearing strap, with the ends extending 2 inches past the trace, small pads being fixed on it above and below the trace. It looks ugly, but it works well. Elastic pads constructed of a certain number of tubes of vulcanized caoutchouc united together, and invented, some years ago, by General Angelini, of the Italian army, are stated to have been very successful in the Italian cavalry in preventing galls.

PAGAN SYSTEM OF FORTIFICATION.—This system paved the way for Vauban. It included three kinds of Fortification, the great, the mean, and the small, with fronts of 390 yards, 350 yards, and 312 yards respectively; and was the first to employ the perpendicular (which equaled 58 yards) to draw the line of defense. The faces of the bastion were equal to $\frac{3}{10}$ of the front. The flanks were perpendicular to the lines of defense, the ditch 30 yards wide at the salient, and its counterscarp directed on the shoulder-angle of the bastion. Inside the bastions were constructed interior retrenchments, with magistrals parallel to, and 32 yards from the enceinte. The flank was triple; the first retired and level with the ground, the third level with the inner bastion, and the second of intermediate command. The ravelin had a 90 yards' face, and occasionally received a reduit, while a counterguard sometimes covered the bastions. In another method, called "re-inforced," the enceinte was preceded by a continuous envelope. The weak point of this system was the possibility of breaching the curtain from the re-entering place of arms, thereby turning the interior bastion. The triple flanks were also defective, the defenders being too much exposed to the splinters of the upper scarps

PAGEANT.—In ancient military history, a triumphal car, chariot, or arch, variously, adorned with colors, flags, etc., carried about in public shows, processions, etc. Also a gorgeous show or spectacle.

PAGEANT SHIELDS.—Richly embossed shields of the 16th century. Although they were pieces of defensive armor, they were rather intended to be worn on gala days, when the Nobles rivalled one another in the magnificence and artistic richness of their equipments.

PAH The name of the stockaded intrenchments of the New Zealanders.

PAILLER.— An ancient body of French Militia. The soldiers belonging to it were probably so called either from the circumstance of their wearing straw in their helmets, in order to know one another in action, or because they were accustomed to set fire to the habitations of their enemies with bundles of straw, which they always carried with them for that purpose.

PAINTS.—Prepared or unprepared compositions by which wood, iron and other materials are coated with a preservative surface of oil, mixed with an earthy matter to give it color and consistency The art of painting in its primitive state consisted merely in applying such natural, mineral, and vegetable colors as were spontaneously yielded, without any vehicle to render them permanent, consequently they had to be renewed as often as they were rubbed or washed off from the surfaces to which they were applied. The paints now in use are nearly all mixed with a liquid vehicle, and are applied in the liquid state. The mixing materials are varied according to the requirements of the work. Thus for some kinds of decorative work, and for water-color drawings, gum, glue, size, or other adhesive materials dissolved in water, are employed; whilst for the painting of buildings, etc., oils of various kinds are used for mixing and thinning the colors. Thus, for painted work exposed to the weather, it is found that linseed oil boiled with the sulphates of lead (litharge) or zinc, or with acetate of lead (sugar of lead), is the best. The preparation of boiled oil is one requiring particular care, as it is desirable to have it bright and clear. Hence the proportions of the metallic salts are much varied by different manufacturers, and by some various other ingredients are added. The time of boiling and the method of filtering are also much varied. For indoor work, plain linseed oil and oil (spirit) of turpentine are used; if a *glossy surface* is wished, the linseed oil must be in excess; if a *dull*, or *flattened surface*, then the quantity of turpentine, or *turps*, as it is often technically called, must be increased; and it is usual to add a small quantity of ground litharge and sugar of lead, which are prepared for this purpose, and sold under the name of *driers*. For artists' colors, very fine linseed or nut oil is used, unboiled, and in small quantity, and turpentine is employed to dilute them. Paints for very rough purposes, such as ordnance work, stone walls, etc., are often mixed with whale oil boiled with white vitriol (acetate of zinc), litharge, and vinegar, and they are diluted with common linseed oil and turpentine.

Most of the paints used for ordinary purposes are composed first of the coloring matter, then of a quantity of white-lead, with which and the oil they are worked into a paste of the shade required, and afterward thinned down with oil and turpentine when used. The white-lead which thus forms the basis of most paints, and by itself a color, is a carbonate and oxide of the metal, produced by exposing pieces of lead to the action of the steam of acetic acid in beds of fermenting tan. It is the principal white paint used, but is liable to discoloration from the gases contained in impure atmospheres. Other white pigments are prepared from the oxide of zinc, and the carbonate and sulphate of barytes. *Olives*, for carriages, are produced by mixtures of yellow ochre, boiled oil, litharge, lamp black, spirits of turpentine, and Japan varnish. *Reds* are either purely mineral, or they are *lakes*, i. e., organic colors precipitated on alumina bases. Of the latter there are madder-lakes, prepared from madder-roots, and carmine-lakes, prepared from cochineal; of the former, vermilion (bisulphuret of mercury), Indian red (a native oxide of iron), Venetian red (an oxide of iron), red lead (red oxide of lead or *minium*). *Blues* consist of the artificial ultramarine, and for artists' purposes of the real ultramarine, also the silicate of cobalt, and for water-colors, indigo and Prussian blue. *Greens* are either produced by mixtures of *yellows* and *blues*, or they are made directly from the phosphates, carbonates, acetates, and arsenites of copper, also from the sesquioxide of chromium and from *terre verte*, a native mineral, consisting of iron, silica, potassa, and magnesia. *Browns* are numerous, and various in their composition. Decomposed peat, burned madder, burned Prussian blue, burned terre verte, asphalt, manganese brown, catechu, umber (which is an oxide of iron with maganese), and mummy, or the asphalt mixed with other matters taken from Egyptian mummies, are amongst the best known and most used. *Blacks* are made of lampblack and bone-black, peroxide of manganese, and blue-black, which is made of the charcoal of burned vine twigs. In all cases the coloring materials of paints require to be very finely ground, and as very many are poisonous, great care is required in their preparation, and several forms of mill have been invented for the purpose. The principle upon which all are made is to secure the operator from the poisonous dust and exhalations, and to reduce the coloring material, if ground dry, to an impalpable powder, or, if mixed with the oil, to a perfectly smooth paste.

The following table shows the quantity of paints required for carriages:

Kind of carriage.	Lead color.	Olive.	Black.	Metallic.
	Pounds.	*Pounds.*	*Pounds.*	*Pounds.*

A priming of lead color and two coats of olive color are applied to new wood-work, and one coat of lead color and one of black, to the iron-work of field-carriages. Two coats of metallic paint are required for the iron carriages. Add 60 per cent. for 10″ and 40 per cent. for 15″ carriages with pneumatic buffers, and 30 and 20 per cent. for these carriages with hydraulic buffers. One coat will last a year. *Oriental red* is the best for iron-work, most durable, and retains its full, rich, red color better than other metallic paints. For use mix 100 pounds of oriental red paint (in a dry state) with 5 gallons of raw linseed-oil to prepare it for grinding; for use, add 10 gallons boiled linseed-oil, 1 gallon spirits of turpentine, ½ gallon Japan dryer; mix thoroughly. This mixture will make about 230 pounds. Brown metallic paint requires about the same quantity of oils, etc. The oriental red has a good body, spreads, and adheres well to iron. Vermilion red and red ochre are good substitutes when the oriental is not available; their color may be moderated by yellow ochre. Spanish brown is also a good substitute for oriental red. Mix as follows: 100 pounds of Spanish brown, with 25 pounds of red lead; grind each in raw linseed-oil before mixing. Mix as for oriental red; the red lead makes this paint dry harder and firmer, and stands exposure well. It requires about 2 gallons more oil than the oriental red.

Before painting, all blisters, rust, or accumulation of old paint should be removed with a scraper. The top of the chassis rails should neither be painted nor oiled, but kept clean by dry scraping. All iron handspikes, elevating-bars, and similar implements, are painted black, using for this purpose common black paint. Heads of bolts and edges of rails may likewise be painted black. The damp location of most artillery posts is particularly favorable to the rapid decay of material. Rust gradually eats away iron parts of carriages and machines. These defects are frequently hidden by repeated coats of paint or lacquer, making them extremely liable to lead to accident or disaster. Such parts should be carefully examined by means of punches and hammers, and no such material be suffered to remain where it is dangerous. See *Lackers*.

PAIRING. When the web of a gabion is made with two rods at a time, the process is called *pairing*.

PAIXHANS GUN. This gun, intended for ships of war or coast fortresses, and adapted to throwing shells and hollow shot, was adopted in France about 1824, and afterwards in England. It was used by the Russian fleet which destroyed the Turkish forts and ships in the harbor of Sinope. Paixhans recommended cylindro-conical projectiles as going more directly and striking more powerfully than round balls, and exposed to less resistance from the air. He believed in small ships carrying heavier guns for firing shell and hollow shot. The original Paixhans gun was $9\frac{1}{3}$ feet long, with a bore of $8\frac{2}{3}$ inches, and a weight of about 7,400 pounds. The charge was between $10\frac{1}{2}$ and 18 pounds of powder. It would bear hollow shot of 60 pounds, or solid shot of 86 to 88 pounds. The shell was mostly employed for incendiary purposes, and was either charged with gun powder alone, or, as in the French service, with gun powder and carcass composition. See *Ordnance*.

PALADIN.—A term originally derived from the Counts Palatine or of the Palace, who were the highest dignitaries in the Byzantine Court, and thence used generally for a Lord or Chieftain, and by the Italian romantic poets for a Knight-Errant.

PALAESTRA.—In Grecian antiquity, a public building where the youth exercised themselves in the military art, wrestling, running, etc.

PALANKA.—A species of permanent intrenched camp attached to Turkish frontier fortresses, in which the ramparts are revetted with large beams, rising 7 or 8 feet above the earthwork, so as to form a strong palisade above.

PALANQUIN—PALKI.—A vehicle commonly used in Hindustan by travelers, and for the transport of sick and wounded. It is usually a wooden box, about 8 ft. long 4 ft. wide, and 4 ft. high, with wooden shutters which can be opened or shut at pleasure, and constructed like Venetian blinds for the purpose of admitting fresh air, while at the same time they exclude the scorching rays of the sun, and the heavy showers of rain so common in that country. The furniture of the interior consists of a cocoa mattress well stuffed and covered with morocco leather, on which the traveler reclines; two small bolsters are placed under his head, and one under his thighs, to render his position as comfortable as possible. At the upper end is a shelf and drawer, and at the sides are nettings of larger dimensions than the ordinary pockets in carriages, for containing those articles which may be necessary during the journey. At each end of the palanquin, on the outside, two iron rings are fixed, and the *hammals*, or palanquin-bearers, of whom there are four, two at each end, support the palanquin by a pole passing through these rings. Traveling in this mode is continued both by day and night. The palanquin is also used at the present day in Brazil, with the prominent exception of Rio Janeiro.

Similar modes of traveling have been at various times in use in western Europe, but only for short distances. The Roman "litter," the French "chaise à porteurs," and the "sedan-chair" were the forms of vehicle most in use, and the two latter were in general use till they were superseded by hackney coaches. The Roman "litter" was one of the criteria of its owner's wealth, the rich man generally exhibiting the prosperous condition of his affairs by the mulitude of the bearers and other attendants accompanying him. See *Stretcher* and *Two-horse Litter*.

PALE. 1. In Heraldry, one of the figures known as ordinaries, consisting of a perpendicular band in

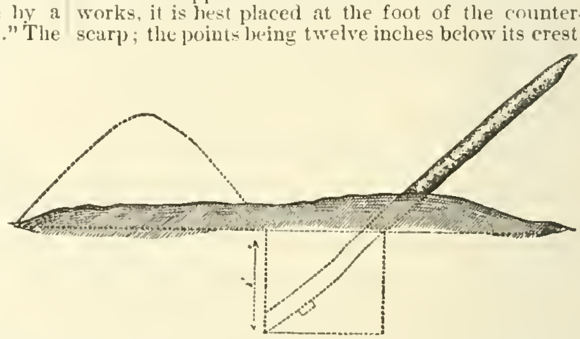
the middle of the shield, of which it is said to occupy one-third (No. 1). Several charges of any kind are said to be "in pale" when they stand over each other perpendicularly, as do the three lions of England. A shield divided through the middle by a perpendicular line is said to be "parted per pale." The Pallet is the diminutive of the pale, and is most generally not borne singly. Three pallets gules (No. 2), were the arms of Raymond, Count of Provence. When the field is divided into an even number of parts by perpendicular lines, it is called "paly of" so many pieces as the (No. 3), Paly of six argent and gules, the arms of the family of Ruthven. When divided by lines perpendicular and bendways crossing, it is called pal bendy (No. 4). An Endorse is a further diminutive of the pallet, and a pale placed between two endorses is said to be endorsed (No. 5). 2. In Irish history, pale means that portion of the Kingdom over which the English rule and English law was acknowledged. There is so much vagueness in the meaning of the term that a few words of explanation appear necessary. The vagueness arises from the great fluctuations which the English authority underwent in Ireland at various periods, and from the consequent fluctuation of the actual territorial limits of the pale. The designation dates from the reign of John, who distributed the portion of Ireland then nominally subject to England into twelve counties palatine, Dublin, Meath, Kildare, Louth, Carlow, Kilkenny, Wexford, Waterford, Cork, Kerry, Tipperary and Limerick. To this entire district, in a general way, was afterwards given the designation of the Pale. But, as it may be said that the term is commonly applied by the writers of each age to the actual English territory of the period, and as this varied very much, care must be taken to allude to the age of which the name Pale is used. Thus, very soon after the important date of the statute of Kilkenny, at the close of the reign of Edward III., the English law extended only to the four counties of Dublin, Carlow, Meath, and Louth. In the reign of Henry VI. the limits were still further restricted. In a general way, however, the Pale may be considered as comprising the Counties of Dublin, Meath, Carlow, Kilkenny, and Louth. This, although not quite exact, will be sufficient for most purposes.

PALEAGAS.—Chiefs of mountainous and woody districts in the peninsula if India, who pay only a temporary homage. Also written *Polygars*.

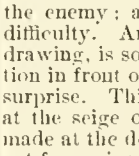
PALETTES.—The part of the armor protecting the arm-pits. *Palettes* date back to the middle of the fifteenth century, and disappear at the end of the sixteenth.

PALINTONE.—An ancient machine of war, described by Heron, Philon and Vitruvius. It was a variety of the catapult.

PALISADES.—A palisade is a stake about ten feet long, and of triangular form, each side of the triangle being eight inches. The trunks of straight trees should be selected for palisades. The diameter of the trunk should be from sixteen to twenty inches. The trunk is sawed into lengths of ten and a half feet, and is split up into rails, each length furnishing from five to seven rails. The palisade is pointed at top; the other extremity may be charred if the wood is seasoned, otherwise the charring will be of no service. A *palisading* is a row of palisades set in the ground, either vertically, or slightly inclined towards the enemy. To plant the palisades, a trench is dug three feet deep; they are then placed about three inches asunder, with an edge towards the enemy. Each palisade is nailed to a strip of thick plank, termed a *riband*, placed horizontally about one foot below the ground; another riband is placed eighteen inches below the top. The earth is firmly packed in the trench. A palisading is sometimes used as a primary means of defence, particularly for low works. A banquette is thrown up for this purpose against it; the tread of the banquette being six feet below the top of the palisading, and four feet three inches below the upper riband. As an obstacle in flanked works, it is best placed at the foot of the counterscarp; the points being twelve inches below its crest,



or else covered by a small glacis. In this position the palisading fulfills all the conditions of an efficient obstacle; it is under the fire of the work; covered from the enemy's fire; will not afford a shelter to the enemy; and cannot be cut down without great difficulty. An inclined palisading, as shown in the drawing, is sometimes placed in an advanced position in front of an ordinary trench to secure it from surprise. This was done to secure a line of trench at the seige of Fort *Wagner*. The palisading was made at the depôt in panels of four or five palisades, cut from pine saplings varying from four to eight inches in diameter, those above five inches being split in two, and placed with the bark side upwards. The spaces between the palisades were left only small enough to prevent a man forcing his body through them. See *Accessory Means of Defence*, and *Stockade*.



Pall.

PALL.—In Heraldry, the upper part of a saltire conjoined to the lower part of a pale. It appears much in the arms of ecclesiastical sees.

PALLISER BOLT.—A screw bolt for securing armor-plates. The end upon which the screw-thread is cut is larger than the shank. See *Bolts*.

PALLISER GUN.—Major Palliser, of the British Service, describes his manner of making a gun to consist in introducing into a cast-iron gun a barrel or hollow cylinder of coiled wrought-iron, of such thickness in proportion to its caliber, that the residual strain borne by the tube shall have a relation

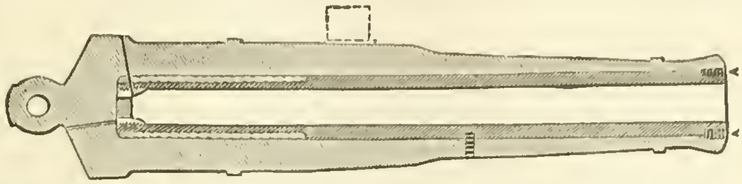
to the strain it transmits to the surrounding cast-iron, which shall be most suitably proportioned to their respective elasticities. The precise proportions will depend on various circumstances, viz: the excessive expansion of wrought-iron due to heat, also the greater range between the limits of elasticity and rupture of this metal, and that the cast-iron will have to do nearly all the longitudinal work. By varying the thickness of the tube, the transmitted strains can be regulated with the greatest nicety.

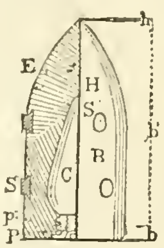
The method of construction is very simple. The gun having been bored, a coiled wrought-iron tube is inserted, as shown in the drawing. The tube consists of two thin wrought-iron barrels, the outer one being much shorter than the inner one, and shrunk to it at the breech-end. Two are used for the purpose of obtaining the benefit of the tension, and also to break the continuity of any internal fracture. The



tube is made to slightly taper, and the bore of the gun is tapered correspondingly; the tube is placed in the bore, and as soon as it comes in contact throughout its length, a screw-locking ring, A, which takes against a shoulder on the tube, is screwed into the muzzle, and sets the tube home; and since in practice it has been found that the elasticity of the wrought-iron inner tube is not proportioned to its greater elongation, the deficiency is supplied by putting the tube under slight compression, which is effected by permanently stretching the wrought-iron in the gun by heavy proof-charges. The tube is further secured in the gun by means of a screw which passes through the cast-iron shell a short distance before the trunnions at right angles to the bore, and screws into the tube.

In the larger guns Captain Palliser proposes to use two or more concentric tubes. In the very largest guns he proposes three tubes, the inner one to be of the softest and most ductile wrought-iron; the next may be of a stronger and harsher nature; the third of steel for some distance in front of the chamber. The system is being applied in the United States, and with most promising results, in the conversion of 10″ Rodman guns into 8″ rifles. In these guns the rifling consists of fifteen grooves and lands of equal width, with a uniform twist of one turn in forty feet. The shape of the groove is flat. The center of gravity is, by this alteration, thrown in front of the axis of the trunnions. This renders a special elevating apparatus necessary. The rifle thus obtained, though giving to a projectile a less muzzle velocity than does the 10″ smooth-bore, has, on account of the increased weight of shot, greater penetrating power at all ranges, being doubled at some and trebled at others. Its accuracy is three times greater and the capacity of its shell twice that of the original gun. See *Built-up Guns*, *Converted Guns*, and *Ordnance*.

PALLISER PROJECTILES.—The French and Woolwich systems differ only in the form and position of the studs, and the material of which they are made; in each system, the number of buttons varies with the size of the gun, there being, however, always one set for each groove in the piece. The body of these projectiles is made of cast-iron; the form is cylindro-ogival. The studs, of an alloy of copper and tin, are secured to the projectile by being pressed into undercut holes; their shape differs with the kind of rifling employed. Two studs to each groove are used for all guns smaller than 12 inches in caliber, and, except for cored shot, are at equal distances from the center of gravity, and the same distance apart on all projectiles for the same gun. The bearing of the projectile is on the studs alone. The solid shot are constructed on the plan of Major Palliser, formerly of the Royal Artillery, and are designed especially for the penetration of armor. They consist, as shown in the drawing, of the *body* B, from *(b)* to *(b′)*; of the *head* H, from *(b′)* to *(h)*; the *cavity* C; the *studs* S; the *screw-plug* P, with its *bushing (p)*; and two *extractor-holes*, one shown at E. The essential feature of this projectile is that the body is cast in a sand mold and the head in one of metal. By this means, the head is chilled white nearly to the center, and acquires the properties of intense hardness, crushing strength, brittleness, and high density. Hardness here relates to the rigidity of actual particles, and crushing strength to the rigid connection or building up of particles so as to resist their being forced in upon each other. The deficiency of the head in tenacity is met by the form given to it. The body of the projectile, being cast in sand, has greater tenacity than the head; a sounder casting is ensured; and the metal is rendered much less subject to the action of the molecular forces which may either split it in store, or crack it so as to cause rupture in the bore of the gun; the presence of the cavity



also reduces this liability, and adds to the strength of the projectile, as it is very difficult to obtain a solid casting from such a metal, and any defect in this respect would be a source of weakness. The shape of the cavity is especially adapted to the work required. The iron is cast about the bushing in the base, which is of wrought-iron, as the metal employed, even when cast in sand, is too hard to admit of tool work. The Palliser Shell also is designed for the penetration of armor, and differs from the shot in construction only, having a larger cavity in order that a bursting-charge may be used. No fuse is employed, the charge being ignited by the heat produced in the metal on impact. To prevent the explosion from taking place before penetration is accomplished, the interior of the shell is covered with a lacker, and the charge is placed in a woolen bag. The Boxer shrapnel, named from its inventor, embodies all the features essential to such a projectile. The charge being at the base, the tendency is, on explosion, to increase the forward velocity of the bullets instead of their lateral spread. See *Studded Projectiles*.

PALM.—That measure of length, originally taken from the width of the hand, measured across the joints of the four fingers. In Greece it was known as *palaiste*, and was reckoned at 3 in., or $\frac{1}{8}$ of a cubit, which was their standard unit. The Romans adopted two measures of this name—the one was the Greek *palaiste*, and was called *palmus minor*; the other, which was not introduced till later times, was called *palmus major*, or *palma*, and was taken from the *length* of the hand, being therefore usually estimated at three times the length of the other. At the present day, this measure varies in a most arbitrary manner, being different in each country, and occasionally varying in the same. The English palm, when used at all, which is seldom, is considered to be the fourth part of an English foot or 3 inches.

The following is a list of the most common measures to which the name palm is given :

	Value in Eng. inches.
Greek *palaiste* . . . . . . =	3.03375
Roman *palmus*, or lesser palm . =	2.9124
" *palma*, or greater palm . =	8.7372
English palm (¼ of a foot) . . =	3.0000
Hamburg palm (⅓ of a foot) . . =	3.7633
Amsterdam "round" palm . . =	4.1200
" "diameter" palm . . =	11.9687
Belgian palm / Lombard palm } properly the *decimeter* =	3.9371
Spanish Palm, or *palmo major* . . =	8.3450
" " or *palmo minor* . =	2.7817
Portuguese palm, or *palmo de Craveira* =	8.6616

In Germany and in the low countries the palm is generally confined to wood-measurement, while in Portugal it used to be the standard of linear measure.

PALMER EQUIPMENT.—The Equipment, invented by Lieutenant George H. Palmer, of the U. S. Army, consists of carrying-braces, coat-straps, knapsack, and haversack—the whole weighing 3½ pounds. The haversack, which is a little smaller than the knapsack, is carried on the right side, the knapsack on the left side The carrying-braces consist of a back-pad and double shoulder-straps—two straps for each shoulder. The shoulder-straps are attached to the back-pad by rivets, so as to be movable on their fastenings. The back-pad gives additional bearing-surface for the weight carried. Its shape enables the shoulder-straps to be attached in such a manner as to separate them on the back and shoulders. The back-pad, in connection with the shoulder-straps, prevents the weight carried from pulling directly downward on the shoulders, instead of which it tends to pull toward the center of the back by means of a pad supporting a portion of the weight. Two straps are attached to the front ends of each shoulder-strap, for supporting the front corners of the bags, the waist-belt, and cartridge-boxes. To the back-pads are fastened rings which hold the blanket-straps. Two straps are attached to the pad for supporting the rear corners of the bags. On these straps is a double loop, which may be moved down or up, for the purpose of drawing the bags together at the back, or to permit them to hang at the sides. A strap looped at each end is on the blanket-straps and passes underneath the straps supporting the bags, for the purpose of holding the blanket more firmly in place when marching at double time. At the bottom of the bags are straps with buckles for drawing the bags together at the back and to retain them more firmly in place.

PALUDAMENTUM.—A military mantle, worn by the ancient Romans, differing little, if at all, from the Chlamys. It was worn by the officers and principal men in the time of war, who were therefore called *Paludati*, and this distinguished them from the common soldiers, who, because they wore the *Sagum*, were called the *Sagati*. The Paludamentum, which was generally white or red, came down to the knees or lower, was open in front, hung loosely over the shoulders, and was fastened across the chest by a clasp. Also written *Paludimentum*.

PALY.—A term used in Heraldry, to signify division into four or more equal parts by perpendicular lines, and of two different tinctures disposed alternately. See *Pale*.

PAN.—1. That part of the lock of a musket, pistol, etc., which holds the priming powder, the necessity of which is superseded by the use of percussion-caps. 2. The distance which is comprised between the angle of the epaule and the flanked angle in a fortification. 3. In military history, one who was Lieutenant General to *Bacchus* and his Indian expedition. He is recorded to have been the first author of a general shout, which the Grecians practiced in the beginning of their onsets in battle.

PANACHE.—A plume worn upon the crest of an ancient helmet. The term is now commonly applied to any military plume or feather.

PANCARTE.—An ancient exercise or tournament, which was performed in the Roman Amphitheater, when strong, athletic men were opposed to all sorts of enraged animals.

PAN COUPE.—The short length of parapet by which the salient angle of a work is sometimes cut off.

PANDOURS.—A people of Servian origin who lived scattered among the mountains of Hungary, near the village of Pandour in the county of Sohl. The name used to be applied to that portion of the light-armed infantry in the Austrian service which is raised in the Slavonian districts on the Turkish frontier. The Pandours originally fought under the orders of their own proper chief, who was known as Harun-Basha, and rendered essential service to the Austrians during the Spanish war of succession, and afterward in the Seven Years War. They originally fought after the fashion of the "free lances," and were a terror to the enemy whom they annoyed incessantly. Their appearance was exceedingly picturesque, being somewhat oriental in character, and their arms consisted of a musket, pistols, a Hungarian saber, and two Turkish poniards. Their habits of brigandage and cruelty rendered them, however, as much a terror to the people they defended as to the enemy. Since 1750 they have been gradually put under a stricter discipline and are now incorporated with the Austrian frontier regiments.

PANIC.—A term employed where fear, whether arising from an adequate or inadequate cause, obtains the mastery over every other consideration and motive, and urges to dastard extravagance, or hurries into danger or even unto death. An inexplicable sound causes a rush from a church, a vague report in the market-place causes a run on a bank, and precipitate the very events that are dreaded. This emotion either differs from natural apprehension, or presents so intense and uncontrollable a form of the feeling, that it is propagable from one person to another, and involves alike the educated and ignorant —those who act from judgment as well as those who act from impulse. There are, besides this feature, several grounds for believing that such manifestations of involuntary terror are of morbid origin, and should be regarded as moral epidemics. They have generally arisen during, or have followed, seasons of scarcity and of physical want and disease, the ravages of war or periods of great religious fervor and superstition. The dancing mania, the retreat of the French Army from Moscow, and recent and familiar commercial panics afford illustrations of certain of these relations. The most notable instance of universal panic, and that which demonstrates most aptly the connection here indicated, is the dread of the approaching end of the world which pervaded all minds, and almost broke up human society, in the 10th century. The Empire of Charlemagne had fallen to pieces ; public misfortune and civil discord merged into misery and famine so extreme that cannibalism prevailed even in Paris ; superstitions and vague predictions became formalized into a prophecy of the end of all things and universal doom in the year 1000. This expectation suspended even vengeance and war. The "Truce of God" was proclaimed. Enormous riches were placed upon the altars. Worship and praise never ceased. The fields were left uncultivated ; serfs were set free ; four Kings and thousands of Nobles retired to the cloister ; and all men, according to their tendencies, prepared to die. It is worthy of note that during all pestilences there have arisen epidemic terrors, not so much of the devastations of disease, as of plots and poisonings directed by the rich against the poor. Even where these epidemic terrors are legitimately traceable to local and physical causes, as in the case of the singular affection timoria, which occurs in the marshy and unhealthy districts in Sardinia, the tremor and trepidation, and other phenomena, are ascribed to the magical influence of enemies.

PANNELS.—In artillery, the carriages upon which mortars and their beds are conveyed on a march.

PANNIERS.—1. Shields of basket work formerly used by archers, who set them up in front during battle. 2. Wicker baskets of various shapes, usually slung in pairs over the back of a pack-animal to carry a load. Also leather bags used in the same way; and especially the cases used for carrying medicines. See *Pack-saddle.*

PANONCEAU.—An ancient name for an ensign or banner.

PANOPLY.—Complete armor or defense; a full suit of defensive armor.

PANTAGRAPH — PANTOGRAPH.—An instrument for copying maps and other drawings. Its invention is ascribed to Christopher Scheiner, a Jesuit, in 1603. It has since undergone various modifications and improvements. It usually consists (Fig. 1) of four metallic rules, jointed two and two, and perforated with holes, a tracer, a pencil or picker; and a screw or point which is forced into the drawing-board or table to hold the instrument in position. For use, the rules are secured to each other by inserting thumb-screws through the holes corresponding with the scale to which the drawing is to be reduced or enlarged. The micropantagraph, used for copying *microscopic dispatches*, may be described as a system of connected pantagraphic levers, the least of which carries a piece of glass on which the original is reduced in a proportion determined by the relation between the lengths of the longer and shorter arms of the series. The glass rests and moves upon a diamond-point while the point remains stationary. The diamond may be raised or lowered by appropriate mechanism, to regulate the width and depth of the cut, or entirely remove it from the glass. With an instrument of this kind the Lord's Prayer has been written within the space of $\frac{1}{356000}$ of a square inch. In the same ratio the whole of the Old and New Testament would be contained within $\frac{1}{27}$ of

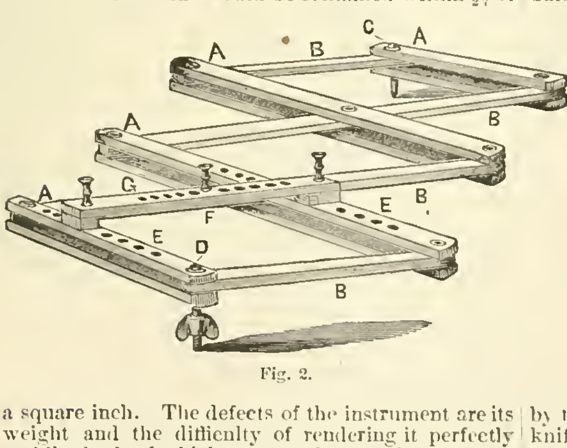


Fig. 2.

a square inch. The defects of the instrument are its weight and the difficulty of rendering it perfectly mobile, both of which prevent that steady motion of the tracer which is necessary for making an accurate copy. To remedy these defects, the pantagraph has been constructed in a variety of forms, all of which, however, like the one described, depend upon the principle that the two triangles which have, for their angular points, the fulcrum the pencil-point and a joint, and the fulcrum, the tracer-point, and a joint, must always preserve their similarity.

Fig. 2 shows the instrument arranged for use as an accessory to the indicator, to reduce the motion between the cross-head, or any other part of the engine, and the indicator.—See *Lazy Tongs.*

PANTHER.—A term in Heraldry. The *panther* is borne gardant and incensed, *i.e.*, with fire issuing from his mouth and ears.

PANZERBRECKER.—An ancient small, three-sided poniard. It figured conspicuously at the battle of Bouvines, in 1214.

PAPEGAI. A popinjay; a bird made of wood or pasteboard, stuck upon a lance, and used as a mark when practicing with the bow, cross-bow, musket, etc.

PAPER AMMUNITION FOR SMALL ARMS. There are two kinds of paper cartridges used in the United States Service, the ball-cartridge, made with a single elongated ball, and the blank cartridge.

Lead balls are made by compression, by means of machines for that purpose. Balls thus made are more uniform in size and weight, smoother, more solid, and give more accurate results than cast balls.

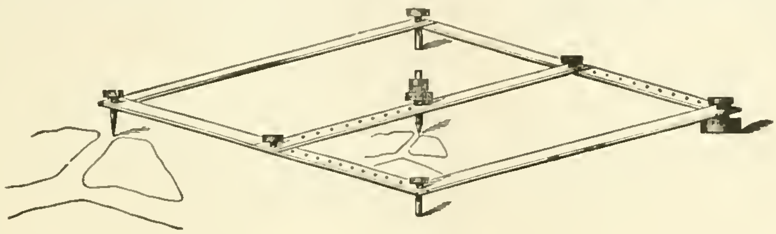

Fig. 1.

The lead is first cast into round cylindrical bars, .58 inch in diameter for the calber .58, and 21 inches long, and then rolled to .46 inch in diameter; length, 25 inenes. These bars are fed to the machine, which cuts off a part sufficient for one ball and transfers it to a die, in which the ball is formed, with cavity and rings, the surplus metal being forced out in a thin belt around the ball in the direction of its axis. The balls are trimmed by hand, with a knife, and are then passed through a cylinder-gauge of the proper size. One man can make with the machine 30,000 balls in ten hours, the bars of lead being prepared for him. One man can cast 1,500 bars in ten hours, and can trim and roll 2,000 bars in ten hours. A boy can trim and gauge 5,000 in 10 hours. Bullet-molds are provided to cast balls where the pressed balls cannot be had. The mold is so constructed as to trim the balls by a single operation before they are taken from the mold. To grease the balls, place them on their bases on a tin frame capable of holding 50 balls, and immerse it in a melted mixture of one part of tallow and eight of beeswax, kept warm, until the cylindrical part of the ball is covered. Remove the frame and let it stand till the grease hardens. Three frames are required for each boy.

The paper is first cut into strips of a width equal to the length of a trapezoid, using the pattern as a guide. The paper and ruler are kept from moving by means of a lever, one end of which is fixed and the other is moved by the foot by means of a cord and treadle. The knife is held in both hands. From six to eight reams may be cut at a time in this way. A cutting-machine like that used by book-binders facilitates the operation when many hands are employed. When only a knife and ruler are used, about 12 sheets are cut at a time.

The following implements are required by each workman when making the cartridges:

Two *boxes* to hold cylinders, 20 inches long, 8 inches wide, and 4 inches high, in the clear, made of ½-inch boards, without a cover; they are placed on their sides, their backs inclined against the partition in the middle of the cartridge-table, the front resting on cleats nailed to the table; 1 *former*, cylindrical, of hard wood, of the same diameter as the ball, 6 to 7 inches long, one end pointed almost as much as the ball, and marked with a shallow groove 4 inches from the end; 1 *sabot* or *frame*, tacked to the table, to hold balls, placed at the left hand of the boy; 1 *spool of thread*, turning on a vertical spindle fixed in the table near the balls; 1 *choking-string*, made of four or five cartridge-threads twisted together, about 9 inches long, with a wooden toggle at the end, fastened to the edge of the table at the right hand of the boy; 1 *knife blade*, 1½ inch long, hooked, driven into the front of the table below and near the choke-string.

To form the cylinder, lay the trapezoids on the table with the sides perpendicular to the bases, toward the workman, the broad end to the left. Take the former in the right hand and lay it on a trapezoid, the groove in the former against the right edge of the paper, bringing the pointed end ⅓ inch from the broad end of the paper; envelop the former with the paper; then, with the fingers of the left hand laid flat upon the paper, turn the former and roll all the paper upon it; hold it firmly with the left hand and, with the choking-string in the right, take one turn around the cylinder at about ⅜ inch from the end; hold the former firmly in the left hand and draw gently upon the choking-string, pressing at the same time with the left forefinger upon the projecting end of the cylinder, thus folding it neatly inder on it, on a second trapezoid; put a ball over the end of the former; roll the paper on the former and the ball; hold the cylinder in the left hand and choke and tie it as thus described for the inner cylinder; withdraw the former, pressing the cylinder with the left hand, and place it in the box.

The following implements are required to fill the cylinder:

One *charger*, made of a cylinder of wood or brass pierced with two holes through its length, holding the exact charge of powder; a funnel attached to one end of the cylinder, and a discharge pipe to the other. The holes in the cylinder are made to communicate and shut off, alternately, from the funnel holding the powder, and the discharge-pipe at the lower end, by a reciprocating motion given to the cylinder by the hands. Fill the funnel with powder, insert the discharge-pipe in a cartridge, holding the charger in both hands, and turn the cylinder; the charge of powder is deposited in the cartridge; insert the pipe in the next, and turn the cylinder in the opposite direction, and continue in the same way for all the rest. Cartridges may be filled with a copper charger made to hold the exact charge, pouring the powder by means of a small funnel, which is inserted in the cartridge.

To pinch the cartridge, take it in the right hand, strike it lightly on the table to settle the powder; flatten the empty part of the cylinder and bend it flush with the top of the powder at right angles to the cartridge, the oblique side of the trapezoid on top, the cartridge standing vertical on the table; fold the flattened part in the direction of its length, with two folds from the exterior, meeting in the middle; bend this folded end back on itself and strike it on the table to set the folds.

The following utensils are required to bundle the cartridges:—1 *box* without ends or top, width equal to five times the diameter of the ball, height equal to twice that diameter, and length that of the cartridge.

CARTRIDGES FOR SMALL-ARMS.

Kind of cartridge	Expanding-ball.		Blank.	Elongated ball.			
Kind of arm	Musket and rifle (1855).	Cadet musket (1857).	Musket and rifle (1855).	Pistol, carbine.	Revolver, Army.	Revolver, Navy.	Sharp's carbine.

Packing-box for 1,000 balls — Weight ... pounds	73	59.5	....	59.5	....	....	....

down upon the end of the former. Having choked the cylinder close, carry it to the right side, and with the thread in the right hand, take two half-hitches firmly around the part that has been choked; cut the thread on the knife-blade and press the choke in a cavity in the table; place the former with a cyl- It is tacked to the table, the sides parallel to and near the edge of the table.

Put a wrapper in the box, the long side perpendicular to the edge of the table, the middle of the paper in the middle of the box; parallel to the sides of the box, two tiers of cartridges of 5 each, the balls alternating; bring the short ends of the paper together and fold them twice close down on the cartridges; insert a package of caps in the end of the bundle next to the ends of the lower tier; fold the wrapper on the ends and tie the bundle, first in the direction of the length, then its breadth, with the twine fastened in a single-bow knot.

When making blank cartridges, cut the paper into trapezoids, as for the ball-cartridges; roll the trapezoid on the former one turn, fold down this much of the paper on the head of the former with the left hand; roll the rest of the paper; fold down the rest of the paper; touch the fold with a little paste on the finger; press the end of the informer on a ball imbedded in the table for the purpose; remove the cylinder from the former; place it in a box to dry. Fill the cylinders, as described, for ball-cartridges.

Balls are packed in boxes with tow or saw-dust, to prevent their bruising. The boxes are made of 1-inch boards, and contain 1,000 balls. They are marked on both ends with the number and kind of balls, and on the inside of the cover with the place and date of fabrication. The cover is fastened with six 2-inch screws, and the boxes must be hooped with iron for transportation. They are not painted.

The cap for small-arms is made of copper. It is very slightly conical, with a rim or flange at the open end; it has four slits, extending about half the height of the cap. The cap is charged with *fulminate of mercury*, mixed with half its weight of niter, the object of the *niter* being to render the fulminate less explosive and to give body to the flame. To protect the percussion-powder from moisture, and also to secure it from falling out, it is covered over, in each cap, with a drop of pure shellac varnish. *The copper for making the caps* is obtained in sheets 48 inches long and 14 inches wide, weighing 3 pounds; a variation of 4 ounces, more or less, is allowed. The copper should be pure, free from seams, holes, or blisters, well annealed, and as evenly rolled as possible, with straight and smooth edges. The copper is cleaned by immersion in a pickle made of one part (by measure) of sulphuric acid and forty parts water; it is scoured with fine sand and a hand-brush, and washed in running water; after which it is well dried in clean saw-dust and rubbed over with a cloth slightly oiled; it is then ready for the machine. See *Ammunition*.

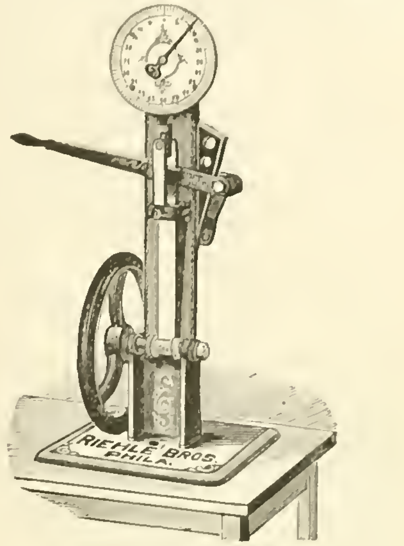
PAPERSHELL.—A species of fireworks, in the shape of an ordinary shell made of paper, filled with decorative pieces, and fired from a mortar. It contains a small bursting charge of powder, and has a fuse regulated to ignite it when the shell reaches the summit of its trajectory.

PAPER-TESTER.—A machine for ascertaining the strength of various papers. The drawing shows such a contrivance with the following:

DIMENSIONS.		ADAPTATION.
Extreme height.......	2 ft.	Tensile specimens 12 in. long
Extreme length........	1 ft.	by 1 in wide or less.
Extreme width.........	1 ft.	Capacity.............. 100 lbs.
Weight	45 lbs.	

A weight balance indicates the strain. There are no loose weights. A weighing beam can be substituted for a spring balance if desired. When the specimen is secured, the wheel at the end of the machine being turned, causes the mandrel to turn and apply the strain to specimens. The indicator, on the face of the dial, remains stationary at the breaking point. A test can be made with speed and accuracy. The machine is quite valuable in testing the qualities, etc., of papers for the laboratory. See *Testing Machine*.

PAPER TIME FUSE.—A fuse consisting of a cylindrical column of burning composition packed in a paper case, gradually increasing in thickness from its lower to its upper or outer extremity: to insure ignition, it is primed with rifle-powder at the larger end. It is inserted at the time of loading the piece into a brass or wooden plug previously driven into the fuse-hole of the shell. The composition has the same ingredients as gunpowder, the proportions being varied to suit the required rate of combustion; pure *meal powder* gives the quickest composition; by adding certain proportions of sulphur and niter, the composition burns more slowly. The rate of burning also depends upon the density of the composition



Paper tester.

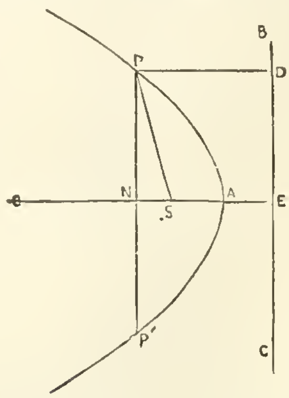
and the purity and thorough mixture of the ingredients. These fuses vary in length, burning from 4 to 40 seconds; they are graduated in seconds on the outside of the case, and can be cut to a length corresponding to any time of flight. See *Fuse*.

PAPIER-MACHE.—From the extension of the applications of papier-maché in the laboratory, modifications have taken place in its composition, and it is now of three kinds—1st, the true kind, made of paper pulp; 2d, sheets of paper pasted together after the manner of pasteboard, but submitted to far greater pressure; and 3d, sheets of thick millboard cast from the pulp are also heavily pressed. The term papier-maché is in trade held to apply rather to the articles made of the pulp than to the pulp itself; and a vast manufacture has sprung up during the present century, particularly in Birmingham, in which a great variety of articles of use and ornament are made of this material. They are coated with successive layers of asphalt varnish, which is acted upon by heat in ovens until its volatile parts are dissipated, and it becomes hard, and capable of receiving a high polish. The fine surface which can be given to the asphalt varnish also permits of burnished gilding and other decorative applications with excellent effect.

PAPILIO.—A square Roman tent for eight men.

PAPYROGRAPHY.—A term applied to a modified process of photolithography for enlarging copies of maps, which is considered to possess certain advantages for use in the field. The process is carried out by means of an ink invented by Captain Abney, which is not greasy, and drawings made with which upon ordinary paper might be transferred to stone or zinc, for the reproduction of topographical maps and military sketches. This invention has been introduced into the British Army.

PARABOLA.—One of the conic sections, produced by a plane not passing through the vertex, which cuts the cone in a direction parallel to that of a plane touching the convex surface of the cone. A little consideration will show that a section so produced cannot be a closed curve, but its two branches, though continually widening out from each other, do not diverge so rapidly as in the hyperbola. The nearer the cutting plane is to that touching the cone, the less the two branches diverge; and when the two planes coincide, the branches also coincide, forming a straight line, which is therefore the limit of the parabola. It may otherwise be considered as a curve, every point of which is equally distant from a fixed straight line and given point; the fixed straight line is called the *directrix*, and the given



point the *focus*. Thus PAP′, is a parabola, any point P in which is equally distant from the focus S and the directrix CB, or $PS = PD$. If, from S, a perpendicular, SE, be drawn to the directrix, and produced backward, this line, AO, is the *axis* or *principal diameter* of the parabola, and the curve is symmetrical on both sides of it. As A is a point in the parabola, $AS = AE$, or the *vertex* of a parabola bisects the perpendicular from the focus to the directrix. All lines in a parabola which are parallel to the axis cut the curve in only one point and are called *diameters*. All lines, such as PP′, which cut the curve in two points, are ordinates, and the diameter to which they are ordinates, is that one which bisects them; the portion of this diameter which is intercepted between the ordinate and the curve, is the corresponding abscissa. From the property of the parabola that $PS = PD$, the equation to the curve may be at once deduced for $PS = PD = EN$, therefore PS^2 (which $= PN^2 + NS^2$) $= EN^2$; hence $PN^2 = EN^2 - NS^2 = (ES + SN)^2 - NS^2 = ES^2 + 2\ ES.SN =$ (since $ES = 2AS$) $4AS^2 + 4AS.SN = 4AS (AS + SN) = 4AS.AN$; and calling PN, the semi-ordinate, y; AN, the abscissa, x; and AS, a; the equation to the parabola becomes $y^2 = 4ax$, where a (the distance of the vertex from the focus) remains the same for all points in the same curve. It is evident from the equation, as well as from the geometrical derivation of the parabola, that it must have two, and only two branches, and that the further it is extended the nearer its branches approach to the condition of straight lines parallel to the axis, though they never actually become so. The parabola has no asymptotes, like the hyperbola, but it possesses many properties which are common to it with that curve and the ellipse. In fact, the parabola is nothing more than an ellipse, whose major axis is infinitely long. If parallel rays of light or heat fall upon the concave surface of a paraboloidal mirror, they are reflected to the focus, and conversely, if a light be placed in the focus of a paraboloidal reflector, its rays will be reflected in parallel directions, and would appear equally bright at all distances did light move without deviation, and unabsorbed. Also, if a body be projected in a direction not vertical, but inclined to the direction of gravity, it would, if undisturbed by the resisting force of the atmosphere, describe accurately a parabola whose axis is vertical, and whose vertex is the highest point reached by the body. The term parabola is used in analysis in a general sense, to denote that class of curves in which some power of the ordinate is proportional to a lower power of the abscissa. Thus the curve we have just described, and which is distinguished as the *common* or Apollonian parabola, has the square of its ordinate proportional to its abscissa; the *cubical* parabola, has the cube of its ordinate proportional to its abscissa; and the *semicubical* parabola has the cube of its ordinate proportional to the square of its abscissa.—See *Projectiles* and *Trajectory*.

PARACHUTE.—A machine invented for the purpose of retarding the velocity of descent of any body through the air, and employed by aëronauts as a means of descending from balloons. It is a gigantic umbrella, strongly made, and having the outer extremities of the rods on which the canvas is stretched, firmly connected by ropes or stays to the lower part of the handle. The handle of the parachute is a hollow iron tube, through which passes a rope connecting the balloon above with the car (in which are the aëronauts and their apparatus) beneath, but so fastened, that when the balloon is cut loose, the car and parachute still remain connected. When the balloon ascends, the parachute collapses like an umbrella; but when the balloon rope is severed, and the car begins to descend, the parachute is extended by the action of the air, and prevents the car from acquiring a dangerous velocity of descent; the final velocity in those cases where the machine is of a size proportioned to the weight it has to support, being no more than would be acquired by a person leaping from a height of between two and three feet. But the slightest derangement of the parachute's equilibrium, such as might be caused by a breath of wind, or the smallest deviation from perfect symmetry in the parachute itself, immediately produces an oscillatory motion of the car, having the apex of the parachute as a center, and the oscillations becoming gradually greater and more rapid, the occupants of the car are in most cases either pitched out or are along with it dashed on the ground with frightful force. This defect in the parachute has been attempted to be remedied in various ways, but hitherto without success. The first successful experiment with the parachute was made by Blanchard at Strasburg in 1787, and the experiment has been often repeated by Garnerin and others; very frequently, however, with fatal results. The parachute was employed by Captain Boxer, R.N., as an essential part of his patent light-ball, for discovering the movements of an enemy at night, and was so arranged as to open up when the lighted ball had attained its greatest elevation, so as to keep it for a considerable period almost suspended in the air.

PARACHUTE LIGHT.—A suspended light invented by General Boxer, R.A., and which is used for the same purposes as *ground light-balls*, viz.: to light up the enemy's works and working parties. It is preferred to light-balls, as they can be extinguished or their lights hid with a few shovels full of earth, whereas the parachute has the advantage of being out of reach, so it cannot be interfered with.

The *parachute light* consists of two outer and two inner tinned iron hemispheres; the two outer are lightly riveted together, the two upper hemispheres are connected by a chain; the inner upper hemisphere has a depression at the top, to admit the bursting charge and fuse. A quick-match leader conducts the flash from the bursting charge to the fuse composition in the lower inner hemisphere. The inner upper hemisphere contains the parachute tightly folded up. To insure its opening, a cord is passed between its folds, and through a hole in the top of the parachute, and is fastened to the upper inner hemisphere, so that, when the hemisphere is blown away, the cord is pulled and the parachute expanded. The lower inner hemisphere contains the composition. A hole is bored, and driven with fuse composition, and matched as usual: this hemisphere is connected with the parachute by cords and chains;

The bursting charge is issued in the parachute, the fuse is bored to the required length and well hammered in; the parachute placed in the mortar, and fired.

The action is further described as follows: The fuse ignites the bursting charge, the outer hemispheres are blown away, and the inner upper hemisphere, which is chained to the outer one, is blown away with it; the parachute is opened by the cord and expands, the composition in the lower hemisphere being ignited by the quick-match leader, which ignites the fuse composition, the composition burning about three minutes when fired from the 10-inch mortar.

PARACHUTE LIGHT-BALL.—A thin shell, the upper half of which is blown off by the charge at a certain height. The lower half, filled with composition, which is kindled by the explosion, is kept floating in the air by means of a small parachute, which is set free when the upper half of the shell flies off.

PARADE. This word signified in its original sense a prepared ground, and was applied to the court-yard of a castle, or to any inclosed and level plain. From the practice of reviewing troops at such a spot, the Review itself has acquired the name of Parade. In its modern military acceptation, a *Parade* is the turning out of the garrison or of a regiment in full equipment, for inspection or evolutions before some superior officer. It is the boast of British troops that their line and discipline are as perfect under an enemy's fire as on the parade-ground. Parades are General, Regimental, or Private (Troop, Battery, or Company), according to the strength of the force assembled. See *Dress Parade*, and *Undress Parade*.

PARADE OFFICER.—An officer who attends to the minutiæ of regimental duty, but who is not remarkable for military science.

PARADE ORDER.—When a regiment of horse or foot, a troop or company, is drawn up with the ranks open and the officers in front, it is said to be in *Parade Order*.

PARADE REST.—A position of rest for soldiers, in which, however, they are required to be silent and motionless; used specially at parade. Also, the command for the position. When without arms, to give the men rest, imposing both steadiness of position and silence, the Instructor commands: 1. *Parade*, 2. REST.

Carry the right foot three inches directly to the rear, the left knee slightly bent; clasp the hands in front of the center of the body, the left hand uppermost, the left thumb clasped by the thumb and fore-finger of the right hand.

When under arms, and at an order arms, the Instructor commands:

1. *Parade*, 2. REST.

At last the command *rest*, carry the muzzle in front of the center of the body, the barrel to the left; grasp the piece with the left hand just above, and with the right hand at the upper band; carry the right foot three inches straight to the rear, the left knee slightly bent.

To resume order arms the Instructor commands: 1. *Squad*, 2. ATTENTION.

1. *Carry*, 2. ARMS. Raise the piece vertically with the right hand, grasping it at the same time with the left above the right, resume the carry with the right hand, (Two.) Drop the left hand by the side. See *Manual of Arms, Fig. 5.*

PARADOS.—Another name for a traverse. It is an intercepting mound, erected in various parts of a fortification for the purpose of protecting the defenders from a rear or ricochet-fire.

PARALLEL.—In siege operations, parallels are trenches cut in the ground before a fortress, roughly parallel to its defenses, for the purpose of giving cover to the besiegers from the guns of the place. The parallels are usually three, with zigzag trenches leading from one to another. The old rule used to be to dig the first at 600 yards distance, but the improvements in artillery have rendered a greater distance necessary; and at Sebastopol, the Allies made their first trench 2,000 yards from the walls. The third trench is very near to the besieged works, and from it saps and zigzag approaches are directed to the covered-way. The trenches of the parallels receive a width at bottom of 10 feet; their depth in front is 3 feet, and in rear, 3 feet 6 inches. Two steps, each 18 inches high and 18 wide, lead from the bottom of the trench, on the front side, to the natural ground. The reverse of the trench receives a slope of 45°; or else, is also cut into steps. The steps in front are alone revetted with fascines. Vauban, in his maxims, prescribes that there shall be at least three parallels, or places-of-arms to be occupied by the troops of the besieging force immediately on duty, with a view to meet any sorties of the garrison on the besieger's works; and further, that these parallels should embrace so wide a front as to control all the defenses which bear in any manner upon the ground over which the besiegers will have to run their trenches.

In Vauban's time, and to within quite a recent day, it was considered that when the site was completely exposed to the fire of the besieged, the first parallel might be laid out at about 600 yards from the most advanced points of the defenses to be embraced within it, and concentric with a line joining these points, and extended so far each way as to guard all the batteries thrown up along its front to silence the fire of the defenses, from assaults in front and on either flank of the parallel. The position of the 1st parallel, Vauban makes dependent on the site, as affording more or less of shelter from the fire of the defenses; and, at the celebrated siege of Sebastopol, the French established their 1st parallels at two separate points, the one at nearly 1000 yards, the other at nearly 1800 yards from the defenses; and the English, in their attack, also placed their 1st parallel at nearly 1800 yards from the defenses in their front. This departure from usage was owing to the great caliber of the guns and the large quantity of fire of the Russian defenses. Instead of three parallels, the French found it quite necessary to throw up as many as seven, the nearest of which to the Russian defenses was about 30 yards, when the final open assault was made from it upon the key point of the Russian position.

The greater range and accuracy of fire of rifled guns will necessarily lead to establishing the first batteries against the defenses at much greater distances than formerly, when smooth bores were alone used; and assuming the 30-pounder, as the probable largest ordinary caliber of siege guns for the attack, the first batteries will probably, in futute sieges, occupy positions at from 2,000 to 3,000 yards from the defenses. These distances will secure for these batteries, what is essential for all those of the attack, a good range for destroying the artillery of the defenses, and security, if properly guarded, either by placing them within strong inclosed works, with sufficient troops to defend the works, or by troops occupying trenches so disposed as to meet a front or flank attack on the battery. Anything like a continuous line of parallel would seldom be requisite at this distance, as the garrison would hardly venture sorties so far from their defenses. Besides which, considering the great extent of front that the batteries would have to embrace at this distance, to control all the fire of the defenses, it would require too great a length of continuous entrenchment.

Tactical considerations require that, in the establishment of the successive parallels, the one most advanced should be laid out nearer to the one in its rear, by which the workmen completing the former are protected, than to the defenses; so that it can receive timely succor against an assault upon it by the besieged. Considering the first line of batteries and trenches as a 1st parallel, the position of the 2d parallel may be safely placed at 1,000 yards in advance of it; that is, nearer to it by 100 yards or more than to the defenses. As it is usual to place the 3d parallel so near to the defenses as to bring the covered ways, or other most advanced defenses, which may be assaulted openly, within range of stone mortars, placed in batteries either within or in front of this parallel; its position, for this object, should be some 60 yards from the salient points of the most advanced portions of the defenses, or as to bring their interior within the range of the stones and other missiles thrown from the mortars.

In giving the 3d parallel this position, there will be a wide zone of ground between it and the 2d parallel, over which the approaches connecting these two parallels must be run, which would be very much exposed to the sorties of the besieged, as well as the 3d parallel, were its protection left to troops stationed as a guard in the 2d parallel. To provide protection for these approaches and for the 3d parallel, whilst in process of construction, ends of trenches, termed *demi-parallels*, are run out, on the right and left of the lines of the approaches, far enough to contain sufficient bodies of troops to protect all the men working on the trenches in advance of them from sorties. The positions of the demi-parallels will be regulated by the same tactical considerations as those which regulate the positions of the parallels. The length to which they should be extended on the flanks of the approach, will be regulated by the number of troops that it may be deemed necessary to post within them, and also from the considerations that they shall not obstruct or be endangered by the fire of any batteries to their rear. See *Approaches* and *Siege*.

PARALLEL FORCES.—Those forces which act upon a body in directions parallel to each other. Every body, being an assemblage of separate particles, each of which is acted upon by gravity, may thus be considered as impressed upon by a system of parallel forces. The following demonstration will exhibit

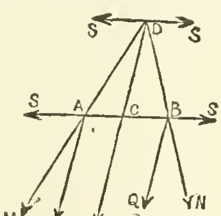


Fig. 1

the mode in which the amount and the position of the resultant forces are found: Let P and Q be two parallel forces acting at the points A and B respectively, either in the same (Fig. 1) or in opposite (Fig. 2) directions: join AB, and in this line, at the points A and B, apply the equal and opposite forces S and S, which counterbalance each other, and therefore do not affect the system. Find M and N, the resultants of P and S, and Q and S respectively, and produce their directions till they meet in D, at which point let the resultants be resolved parallel to their original directions; then there are two equal forces, S and S, acting parallel to AB, but in opposite directions, and thus, as they counterbalance each other, they may be removed. Then there remain two forces, P and Q, acting at D, in the line DC, parallel to their original directions, and their sum (Fig. 1) or difference (Fig. 2) represented by R, is accordingly the resultant of the original forces at A and B. To find the position of C, the point in AB, or AB produced, through which the resultant passes, it is necessary to make use of the well-known property denominated the *triangle of forces*, according to which the three forces S, M, and P are proportional to the lengths of AC, AD, DC, the sides of the triangle ADC; then S : P :: AC : CD, similarly Q : S :: DC : CB, therefore Q : P :: AC : BC, and Q P or R : P :: AC BC or AB : BC, from which proportions we derive the principle of the lever, $P \times AC = Q \times BC$, and also that $R \times BC = P \times AB$, whence $BC = \frac{P}{R} \times AB$, and the point C is found. The failing case of this proposition is when P and Q acting in opposite parallel directions at different points are equal, in which case the resultant $R = Q - P = Q - Q = 0$. In all other cases there is a progressive motion, such as would be caused by the action of a single force R ($= Q \pm P$) acting at the point C in the direction of CR; but in the failing case, since $R = 0$, there is

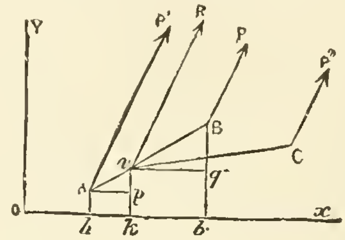

Fig. 2.

no progressive motion but a rotatory movement round the center of AB. It is of no consequence whether A and B be the true points of application of the forces P and Q, provided their directions when produced pass through these points, and the point of application of the resultant need not be in the line joining the points of application of the component forces, but its direction must, when produced, pass through C. If there be more than two parallel forces, the resultant of the whole is found by compounding the resultant of the first two with the third in the way given above, thus obtaining a new resultant, which is similarly combined with the fourth force; and so on till the final resultant is found. The center of gravity is only a special name for the point of application of the final resultant of a number of parallel forces. See *Couple*

PARALLELOGRAM OF FORCES.—The fundamental problem in statics is to find the magnitude and direction of the resultant of two forces; in other words, to compound them into a single force, which shall be in every respect their equivalent. Intensity and direction being the only elements necessary to entirely describe a force, forces in statics are represented by lines, which are obviously capable of being made to represent them both in magnitude and direction. When two forces act along the same straight line on a particle, it is sufficiently obvious that if they act in the same direction, the resultant will be their algebraical sum; if in opposite directions, their algebraical difference. This being premised, the relation between two forces acting at the same point, but not in the same line, and their resultant, is set forth in the following theorem, which is known as the Parallelogram of Forces. If two forces, P,

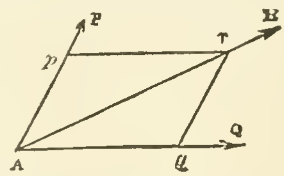

Fig. 1.

Q, acting on a particle A, be represented in direction and magnitude by the lines A*p*, A*q*, then the resultant will be represented in direction and magnitude by the diagonal A*r* of the parallelogram described upon A*p*, A*q*. The proof of this depends upon the simple principles, that a force may be supposed to act at any point of its direction, that point being conceived to be rigidly attached to the particle on which the force acts; and what may be accepted as an axiom of universal experience, that when any number of forces are impressed on a particle or body, each exerts itself, as if the others were not acting, to produce its full effect. The doctrine of the parallelogram of forces has given rise to much controversy, not as to its truth, but as to its derivation, some appearing to contend that it is directly deducible from the axiom above stated, without the necessity of further reasoning. Knowing how to compound two forces acting at a point, we are able to compound or determine the resultant of any number. If the forces, though in the same plane, do not act at the same point of a body, those of them whose directions meet may be compounded by the preceding rule; if they are parallel, their resultant is a force parallel to them and equal to their algebraical sum, counting those acting in one direction as positive, and in the opposite direction as negative. The singular case is that of equal parallel forces acting in opposite directions. These constitute a couple, and cannot be represented by any single force.

The resolution of forces is the converse problem. To resolve a given force R, whose direction and magnitude is Ar, into two forces acting in any directions that may be chosen, as AP, AQ, we have only to draw

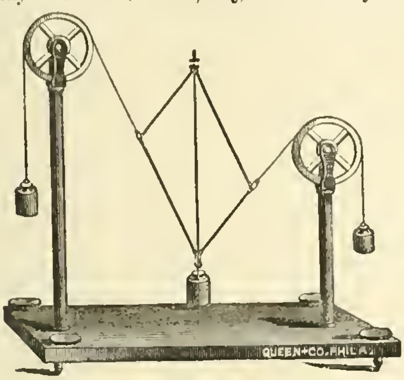

Fig. 2.

parallels through r, which determine the lines Ap, Aq, representing the magnitude of the forces required. It is evident that there is an indefinite number of pairs of forces into which Ar might be resolved, according to the direction in which the new forces are to act. It is usual, however, to resolve a force into forces that are at right angles to each other.

The composition of motions is analogous in every way to that of forces; motions are the results of forces, and the analogy might be expected. If a body be actuated simultaneously by two velocities having different directions, it will evidently move in a direction intermediate to the two, and with a velocity which will in some way depend on each of them, and which is called their resultant. The proposition which sets forth how to find the resultant, is called the Parallelogram of Velocities. It is: If two velocities, with which a particle is simultaneously impressed, be represented in direction and magnitude by two straight lines drawn from the particle, the resultant velocity of the particle will be represented in direction and magnitude by the diagonal of the parallelogram described on those two straight lines. The proof is very simple. There is no reason why the full effect of both velocities should not be produced, as if the body moved first with one of them, and then with the other, in their respective directions. If in one second the body moving with the one velocity would reach p, and if we suppose it then to move on pr for another second, parallel with the other velocity, it would at the end of the second second be at r. Hence, under their joint influence, it will be at r at the end of one second. The resolution of motions is altogether analogous to that of forces. All the principles of the Parallelogram of Forces may be readily illustrated by the apparatus shown in Figure 2. See *Falling Bodies*.

PARALLEL ORDER OF BATTLE.—In tactics, the natural order of battle is when troops coming upon ordinary ground are ranged in line of battle by the prescribed tactical means, and when they are formed in column right in front.

The parallel order operates on the contrary against the whole front of the enemy. Turenne and Condé fought habitually in parallel order, although they sometimes made a skillful use of oblique attacks. *Guibert* well says that a contiguous and regular parallel order can be of no use in war.

The *oblique* order is contradistinguished from the parallel, and in general means every tactical combination the aim of which is to produce an effect upon two points of an enemy's line by bringing a superior force to bear down on those two points. Such combinations constitute the oblique order, whatever maneuvers may be used to accomplish the object.

PARALLEL RETREAT.—Great advantages sometimes arise in conducting a retreat parallel to our frontier, when the topography lends itself to this operation; as, the enemy, in following up, really gains but little ground in advance. If a retreat of this kind, termed a *parallel retreat*, is made in the enemy's country, the army subsists at the enemy's expense; the evils of war fall on him; and he is almost as badly off as if he had not the upper hand. If this retreat takes place within our own frontier we draw after us the victorious army; we force him to move onwards without gaining a foot of ground towards the interior; we abandon to him only our borders, whilst we force him to offer his flank to any force we may have in the interior. But, with all these obvious advantages, we must look out how we attempt anything of the kind in a territory which is open, and would give the enemy an easy means of cutting us off from our base. Such a retreat, therefore, requires to be covered by a river, a mountain chain, or some other obstacle that an enemy cannot cross with safety, to interrupt our communications to the interior. If the parallel retreat is covered by a river, all bridges by which the enemy might intercept our communications, or attack in flank, should be timely destroyed, the fords obstructed and guarded. Like precautions are to be taken, when covered by a mountain chain, in occupying the main defiles, and obstructing other less important passes. Our troops should be so disposed as to fall in mass upon any corps of the enemy that attempts to force its way through; and we should not show too much anxiety respecting any weak body of troops that may have risked a raid upon our rear, as the peril is for it and not for our troops. It will be readily seen that a parallel retreat can only be resorted to with effect along a frontier of some considerable extent. Although a frontier of this character is more difficult to guard than one more limited, it presents, on the other hand, the advantages above pointed out, and lends itself well to the *defensive—offensive* on our side, which of itself, in the hands of an able General, is the surest means of success in a defensive war.

PARALLEL RULER.—A draughtsman's instrument consisting of two wooden or metallic blades, so joined together by jointed cross-pieces as to open to different intervals and yet retain their parallelism, Fig. 1. A still simpler form is a rolling cylinder. Fig. 2, represents a rolling parallel ruler, consisting of a flat ruler, and a roller rotating in bearing-posts fastened to the ruler. This instrument is very useful for constructing the plans and elevations of fortifications and numerous other military subjects. The illustrations are on page 482. See *Drawing*.

PARAMETER.—This term, used in conic sections, denotes, in the case of parabola, a third proportional to the abscissa of any diameter and its corresponding ordinate; in the ellipse and hyperbola, a third proportional to a diameter and its conjugate. The parameter of any diameter is, in the case of the parabola, the same as the double ordinate of that diameter which passes through the focus, and is four times as long as the distance between the diameter's vertex

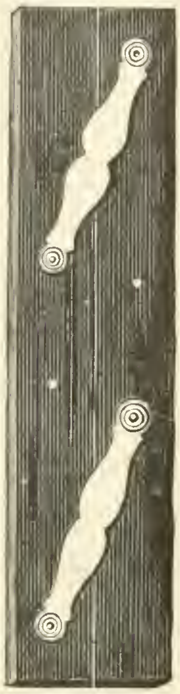

Fig. 1.

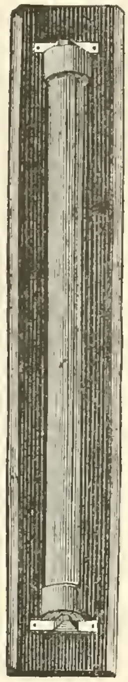

Fig. 2.

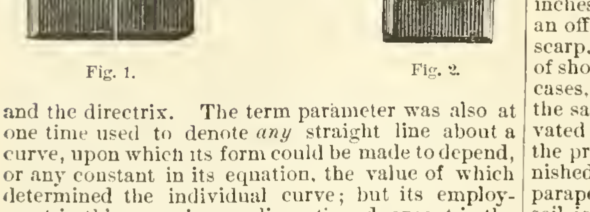
and the directrix. The term parameter was also at one time used to denote *any* straight line about a curve, upon which its form could be made to depend, or any constant in its equation, the value of which determined the individual curve; but its employment in this sense is now discontinued, except in the theory of homogeneous differential equations, where the constants, for the purpose of aiding the solution, are supposed to vary, and the method is consequently denominated the "variation of the parameters."

PARAPET.—1. A wall raised higher than the gutter of a roof for protection; in domestic buildings, churches, etc., to prevent accident by falling from the roof. Parapets are of very ancient date. The Israelites were commanded to build "a battlement" round their flat roofs. In classic architecture balustrades were used as parapets. In Gothic architecture parapets of all kinds are used. In early work they are generally plain, but in later buildings they are pierced and ornamented with tracery, which is frequently of elaborate design, especially in French flamboyant work. Shields and little arcades are also



used as ornaments to parapets; and the battlements of castles are imitated in the parapets of religious and domestic buildings. 2. In field fortifications the main features are the covering masses of earth of which they are constructed, and which are intended to shelter the assailed from the view and fire of the assailant. When the covering mass is so constructed as to afford the assailed a view and fire over the assailant's line of approach, it is termed a *parapet.* The rifle trench is the simplest form of work. In this, the parapet is formed by throwing the earth from a trench within to the front. The earth thus thrown up, together with the depth of the trench, affords the desired shelter. The troops stand or squat in the trench and deliver their fire over the bank of earth in front. The method of intrenching affords the speediest means of obtaining cover, and is the one resorted to when troops are under fire, or when they intrench their camp or position for a temporary stay. Rails, logs, in fact, almost anything at hand may be used as a rough interior revetment for sustaining the earth. For artillery, the trench is made somewhat wider than is necessary for infantry. In the more elaborate class of field fortifications, such as the inclosed works of various descriptions, the earth to form the parapet is taken from the exterior, thus forming in front of the parapet a ditch which makes a formidable obstacle in the way of an assailant attempting to enter the work by escalade.

Having fixed upon the profile, the pick commences the construction of the parapet by breaking ground so far from the counterscarp crest that, by digging vertically three feet, he will arrive at the position of the counterscarp. The excavation is carried on at the same depth of three feet, advancing toward the scarp, where the same caution is observed as at the counterscarp. The earth is thrown forward, and evenly spread and rammed, in layers of about twelve inches, from the banquette slope to the exterior slope. For the facility of entering the ditch, whilst working, the offsets at the scarp and counterscarp may be formed into steps with a rise of eighteen inches each; and if the ditch is deeper than six feet, an offset, about four feet broad, should be left at the scarp, about mid-depth of the ditch, to place a relay of shovels to throw the earth on the berm. In some cases, a scaffold of plank is raised in the ditch for the same purpose. When the ditch has been excavated to the bottom, the offsets are cut away, and the proper slope given to the sides. The earth furnished by the offsets, if not required to complete the parapet, may be formed into a small glacis. If the soil is stony, the vegetable mold on the surface should be scraped off, and reserved to form the top of the parapet, which should be made of earth of this kind, to the depth of at least eighteen inches, to prevent injury to the troops from the effect of a shot striking the top, and scattering the pebbles in their faces. In making the parapet, care should be taken to form a drain, at some suitable point, to carry off the water from the interior into the ditch. The water from the drain should not be suffered to run down the scarp, as it would soon destroy it. A gutter formed of boards, should be made to prevent this. See *Field Fortifications* and *Normal Profile.*

PARASANG.—A Persian military measure, sometimes assumed as a league, but equal to about four English miles.

PARAZONIUM.—A name given by the early Greeks, to a short sword or dagger worn in the belt at the right side.

PARBUCKLES.—Four-inch ropes, 12 feet long, with a hook at one end and a loop at the other. To parbuckle a gun, is to roll it in either direction from the spot in which it rests. To do this, place the gun on skids, and if it is to be moved up or down a slope, two $4\frac{1}{2}$-inch ropes are made fast to some place on the upper part of the slope, the ends are carried under the chase and breech of the gun respectively round it, and up the slope. If the running ends of these ropes are hauled upon, the gun ascends; if cased off, it descends. If the ground is horizontal, handspikes only are necessary to move the gun.

PARBUCKLING.—A mode of drawing up or lowering down an inclined plane any cylindrical object, as a barrel or a heavy gun, without the aid of a crane or tackle. It consists in passing a stout rope round a post or some suitable object at the top of the incline, and then doubling the ends under and over the object to be moved. This converts the cask or gun into a pulley in its own behalf, and limits the pressure at each end of the rope to one-fourth the weight of the object moved, as felt on the incline. By hauling in the ends equally, the gun ascends, or *vice versâ*. See *Mechanical Maneuvers*.

PARCEL.—A term, meaning in the artillery service, as applied to a rope, to put around it canvas well daubed with tar and bound with spun yarn to protect it from chafing.

PARCHMENT.—There are several kinds of parchment, prepared from the skins of different animals, according to their intended uses. The ordinary writing parchment is made from those of the sheep and of the she-goat; the finer kind, known as *vellum*, is made from those of very young calves, kids, and lambs; the thick, common kinds, for drums, tambourines, battledores, etc., from those of old he-goats and she-goats, and in northern Europe from wolves; and a peculiar kind is made from asses' skins, the surface of which is enameled. It is used for tablets, as black-lead writing can be readily removed from it by moisture. The method of making parchment is at first the same as in dressing skins for leather. The skins are limed in the lime-pit until the hair is easily removed. They are then stretched tightly and equally, and the flesh side is dressed as in currying, until a perfectly smooth surface is obtained. It is next *ground* by rubbing over it a flat piece of pumice-stone, previously dressing the flesh side only with powdered chalk, and slaked lime sprinkled over it. It is next allowed to dry, still tightly stretched on the frame. The drying process is an important one and must be rather slowly carried on, for which purpose it must be done in the shade. Sometimes these operations have to be repeated several times, in order to insure an excellent quality, and much depends upon the skill with which the pumice-stone is used, and also upon the fineness of the pumice itself. When quite dried, the lime and chalk are removed by rubbing with a soft lambskin with the wool on.

PARCOURIR.—A term expressive of those movements which are made by General Officers, Officers Commanding Brigades, etc., for the purpose of encouraging their soldiers in the heat of an engagement.

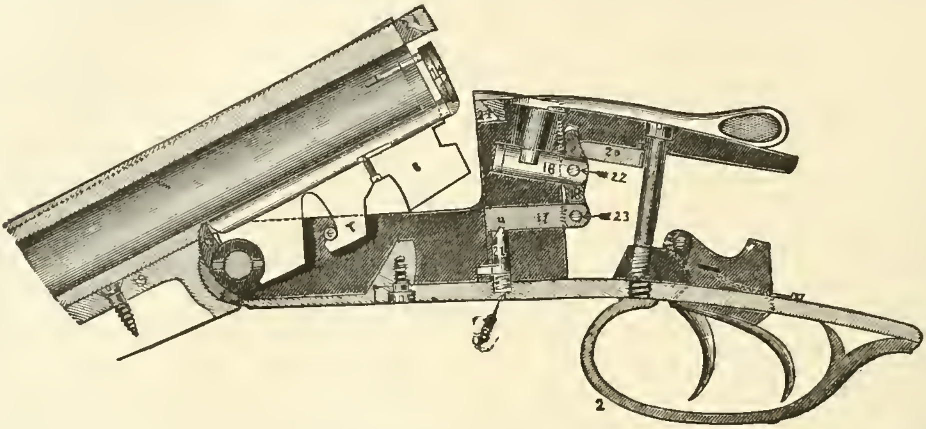
PARDON.—An act of grace emanating from that power in the State intrusted with the execution of the laws, and exempting the individual on whom it is bestowed from the punishment to which he has been legally sentenced after conviction of crime, or to which he is by law liable for an offence on which he has not been tried and convicted. Every officer authorized to appoint a General Court-Martial, has the power to pardon or mitigate the sentence of death; or of cashiering an officer, which, in cases where he has no authority to carry them into execution, he may suspend, until the pleasure of the President of the United States can be known, which suspension, together with copies of the proceedings of the Court-Martial, the said officer immediately transmits to the President for his determination. And the Colonel or Commanding Officer of the regiment or garrison where any Regimental or Garrison Court-Martial is held, may pardon or mitigate any punishment to be inflicted.

PARK.—An enclosure, or any place, where guns, wagons, animals, etc., can be placed in safety. A *Park of Artillery* is the whole train of great guns with equipment, ammunition, horses, and gunners for an army in the field. It is placed in a situation whence rapid access can be had to the line of the army in any part; and at the same time where the divisions of the force can easily mass for its protection. The horses of the park are picketed in lines in its rear. The term is also applied to the ground on which all guns stand or are parked. During a siege the park must be sheltered and screened as much as possible from the view and fire of the enemy; but, in a position to communicate freely with the besieger's trenches. If possible, its locality should also be chosen close to some good line of communication, either a road or river. Great care should be given to the position of the laboratories; they should be as far away from the enemy as the park will permit. The officer in charge of the park should be assisted by well trained men of the Ordnance Department and a sufficient number of artificers. An *Engineer Park* comprehends all the materials, tools, etc., attached to that branch of the service. A *Siege Park* comprises the guns collected together at the commencement of the investment of a fortress, taken from the artillery park, and manned by artillery, aided by the men of the Ordnance Department. The carriages of a battery are parked in two ranks, all the pieces limbered and in the front rank, the caissons covering their pieces; the interval is such as is most convenient; the distance from the rear part of the pieces to the end of the poles of the caissons is about eight yards. The carriages of each section are arranged from right to left in the order of their permanent numbers, the 1st section on the right. In *horse batteries*, the distance is seventeen yards, but may be decreased to eight yards if the nature of the ground requires it.

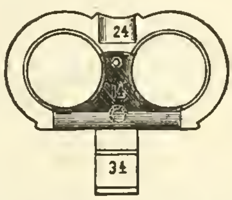
To form the park, the Captain directs the column of sections toward either flank, or in rear, of the position to be occupied by the park, and establishes the Guidon near the point where the lead-driver of the leading carriage is to halt. He then directs the column forty-seven yards in rear of, and parallel to, the line to be occupied by the lead-drivers of the front-rank carriages, and commands:

1. *Right* (or *left*) *into park*, 2. *At* (so many) *yards' interval*, 3. MARCH, 4. FRONT. The Chief of the leading section commands: *Right wheel*, at the first command, and repeats the third. At the command *march*, given when the leading section is three and one-quarter yards from the point opposite the position which it is to occupy, the leading section wheels to the right moves forward and is halted by its Chief when the leading driver arrives in line with the Guidon. Each of the other sections continues the march until three and one-quarter yards from the point opposite its place in park, then wheels to the right at the command of its Chief, and moves forward; on arriving at three yards from the line, the Chief commands: 1. *Section*, 2 HALT, 3. *Left*, 4. DRESS. The Chiefs of platoon superintend the movements of their sections, but do not repeat the commands. The Captain and Chief of caissons go to the left and superintend the alignment as previously explained. The Captain commands *right into park*, or *left into park*, according as the column is left, or right, in front. See *Train*.

PARKER GUN.—This gun is a distinctively American production, and has all the advantages of the American system of manufacturing. The different parts are made by special machinery, and by workmen who make a speciality of one thing only, and are subjected to rigid inspection so that no defective or imperfect part can find its way into the finished gun. The number of parts is reduced to a minimum, and the construction is so simple that anyone with no tool but a screw-driver can take the gun apart for cleaning or repairs. No breech-loader has less to get out of order, and none will stand better the ordeal to which a breech-loader is subjected. The drawing shows the top action. Pressing the thumb against the lever, throws it to the right, and acting through the piece, 16, forces the piece, 18, to the rear. This piece being pivoted at the top withdraws the bolt, 17, from the mortise which is cut in the lug, 6, and releases the barrels. When the gun is closed the sides of the extension rib, 24, being upon the arc of a circle, with the hinge joint, 13, as a center, have a bearing along their entire surface, and the extension rib fits securely into its seat, 24, in the frame. When the barrels are brought to place for firing, the bottom of the lug, 6, strikes the trip, 21, withdrawing it from the bolt, 17, which then enters the mortise in the lug, 6, and securely locks the gun. The taper-

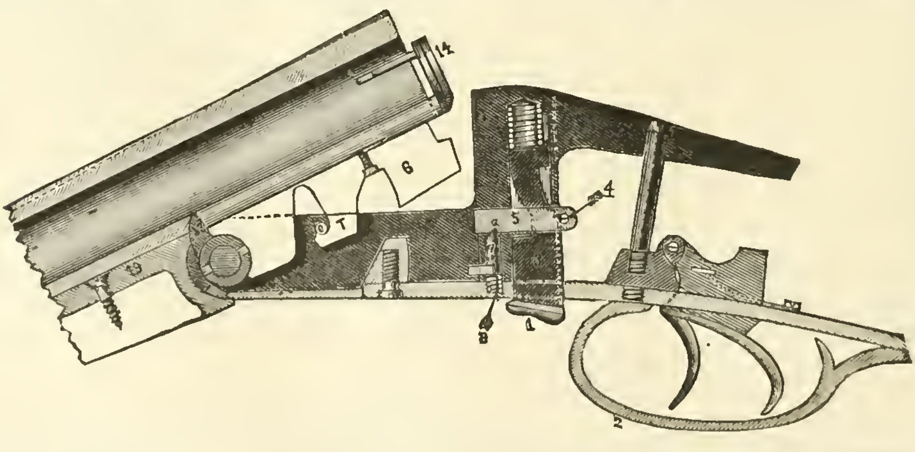


bolt, 17, locks the barrels positively firm, and the use of a taper-bolt for fastening the gun gives it a decided advantage, as it does not allow a little dirt (which is very liable to get under barrels when open) to prevent the gun from locking. Many times when shooting, marksmen are balked in this way, but this gun closes with the same ease and locks as securely even if there is a little dirt in the way. When the gun is opened, the check-hook, T, comes in contact



with the pin, E, which avoids any strain on the joint, 13, and thus prevents the gun becoming shaky by constant use.

This gun has an automatic extractor which draws the shells or cartridges from the barrels during the



operation of opening the gun. The extractor, 14, is inserted in a hole drilled in the lug, 34, with its rear end enlarged and extending into and around a portion of the chambers of the barrels, as shown in the drawing (which represents an end view of the breech of the barrels). When the gun is closed, the extractor, 14, extends from the rear end of the barrels to the projection on the joint, 13, and as the barrels swing on this joint, 13, which remains stationary, this projection forces the extractor, 14, from the rear end of the barrels, so that when they arrive at the position as shown above, the cartridges are withdrawn from them quite far enough to be entirely removed by hand. In connection with the lock, which is *rebounding*, attention should be called to the direct blow of the firing-pin exactly in the center of the cap and at right angles with the head of the shell. By this arrangement the chance of a miss-fire is very much lessened, and the efficiency of the arm is increased. The locking-bolt is held back while the gun is open, doing away with the wear on the hinge joint which all breech-loaders are subjected to when the barrels are forced down against a strong spring in the rear of the bolt.

The following drawing explains the *lifter action* peculiar to this gun: Pressing up on the finger-piece, 1, in front of the guard, 2, raises the lifter, 3, and its beveled side—coming in contact with the screw, 4—acts as a wedge to draw the bolt, 5, from the mortise which is cut in the lug 6, and releases the barrels ready for the insertion of the cartridges. It will be observed that when the bolt, 5, is back to the position as shown, the small hole which is drilled in the under side of said bolt comes directly over the trip, 7, which, by the assistance of the small spiral spring, 8, is made to enter this hole in the bolt, 5, and thereby holds it in position. The finger-piece, 1, is solid and a part of lifter, 3. The action of *the lifter*, 3, *is positive*, not only to withdraw the bolt *from*, but to force it forward *into* the mortise in the lug, 6. For the purpose of cleaning, it can be very easily removed by taking off the locks and removing the small screw, 4, from the end of bolt, 5, then press down on trip, 7, which will allow the lifter to be withdrawn without removing either stock, guard, or trigger-plate. The improved roll, 13, gives great strength to the joint. This gun has been issued by the United States Government for arming Paymasters' escorts, etc., when light shooting and rough usage were anticipated.

PARKHURST MACHINE GUN.—In machine-guns the heating of the barrels has limited the number of charges that could be rapidly fired before they become too hot for use, so that after a period of rapid firing the gun would become dangerous if not allowed to cool. The Parkhurst gun has a device for keeping the barrels cool by surrounding them with water under atmospheric pressure, thus preventing the temperature from rising above the boiling point of water. A temperature not exceeding 212° Fahrenheit does not impair the action of the gun. The barrels are inclosed in a metallic water-tight casing having a vent for the escape of steam. The casing is filled from time to time during the firing, as may be required. The mechanism for rapidly loading and firing is also improved.

PARKINSONIA.— A shrub found commonly in Bengal. It has been stated to yield a very fair charcoal for gunpowder purposes; but from trials made of it, of late years, at the Government Powder Works at Ishapore, it was not found to be equal to that made from *urhur* or *dhall stalk*. Nevertheless it might be used if the latter crop failed.

PARK PALING.—A very inferior gun-material, from which vast numbers of very inferior guns were made during the existence of the slave-trade.

PARK PICKETS.—Small wooden posts which support the rope line round the artillery park. They are carried either on carts or camels in India when on the march. Dimensions—length 53 inches, and diameter 3 inches.

PARLEY.—In military language, an oral conference with the enemy. It takes place under a flag of truce, and usually at some spot—for the time neutral—between the lines of the two armies. *To beat a parley*, is to give a signal for such conference by beat of drum or sound of trumpet.

PARMA.—A kind of round buckler used by the Velites in the Roman Army. It was 3 feet in diameter, made of wood, and covered with leather. Its form was round, and its substance strong; but Servius on the Aeneid, and even Virgil, say that it was a light piece of armor in comparison with the clypcus, though larger than the pelta.

PAROI.—A stout wooden frame having long, sharp-pointed stakes driven into it horizontally. It is placed upon the parapet to oppose scaling parties.

PAROLE.—1. A watch-word differing from the countersign in that it is only communicated to Officers of Guards, while the countersign is given to all the members. The *parole* is usually the name of a person, generally a distinguished officer, while the countersign is the name of a place, as of a battle-field. 2. A declaration made on honor by an officer, in a case in which there is no more than his sense of honor to restrain him from breaking his word. Thus a prisoner of war may be released from actual prison on his *parole* that he will not go beyond certain designated limits; or he may even be allowed to return to his own country on his *parole* not to fight again, during the existing war, against his captors. To break *parole* is accounted infamous in all civilized nations, and an officer who has so far forgotten his position as a gentleman, ceases to have any claim to the treatment of an honorable man, nor can he expect quarter should he again fall into the hands of the enemy he has deceived. The following rules in regard to *paroles* are established by the common law and usages of war: An officer who gives a *parole* for himself or his command on the battle-field is deemed a deserter, and will be punished accordingly. For the officer, the pledging of his *parole* is an individual act, and no wholesale paroling by an officer, for a number of inferiors in rank, is permitted or valid. No prisoner of war can be forced by the hostile Government to pledge his *parole*; and any threat or ill treatment to force the giving of the *parole* is contrary to the law of war, and not binding.

No prisoner of war can enter into engagements inconsistent with his character and duties as a citizen and a subject of his State. He can only bind himself not to bear arms against his captor for a limited period, or until he is exchanged, and this only with the stipulated or implied consent of his own Government. If the engagement which he makes is not approved by his Government, he is bound to return and surrender himself as a prisoner of war. His own Government cannot at the same time disown his engagement and refuse his return as a prisoner.

No one can pledge his *parole* that he will never bear arms against the Government of his captors, nor that he will not bear arms against any other enemy of his Government, not at the time the ally of his captors. Such agreements have reference only to the existing enemy and his existing allies, and to the existing war, and not to future belligerents.

While the pledging of the military *parole* is a voluntary act of the individual, the capturing power is not obliged to grant it, nor is the Government of the individual paroled bound to approve or ratify it.

Paroles not authorized by the common law of war are not valid till approved by the Government of the individual so pledging his parole.

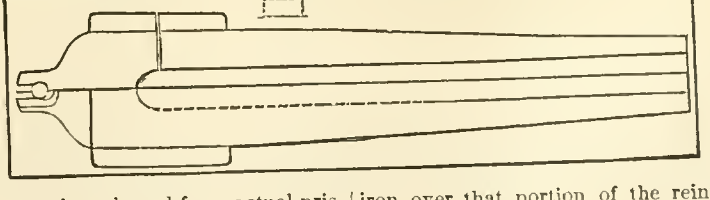
The pledging of any unauthorized military *parole* is a military offense, punishable under the common law of war.

PAROLE EVIDENCE.—In law, it is such evidence as is given by witnesses by word of mouth at a trial or hearing of a cause. Parole agreement, in English law, means any agreement made either by word of mouth or by writing not under seal. If the agreement is made by writing under seal, it is called a deed, or indenture, or covenant, according to the nature of its contents.

PARRAIN.—In military orders, the person who introduces or presents a newly-elected Knight. The term is also used to signify the comrade who is selected by a soldier who is condemned to be shot to bind the handkerchief over his eyes.

PARROT-BEAKED.—A term applied to a battle-axe and the like when very short in the handle and resembling a parrot's beak.

PARROTT GUN.—The Parrott rifle-gun is a cast-iron piece of about the usual dimensions, strengthened by shrinking a coiled band or barrel of wrought-iron over that portion of the reinforce which surrounds the charge. The bodies of the larger Parrott



guns are cast hollow, and cooled from the interior on the Rodman plan. The barrel is formed by bending a rectangular bar of wrought-iron spirally around a mandrel and then welding the mass together by hammering it in a strong cast-iron cylinder, or tube. In bending the bar, the outer side being more elongated than the inner one, is diminished in thickness, giving the cross section of the bar a wedge shape, which possesses the advantage of allowing the cinder to escape through the opening, thereby securing a more perfect weld. The barrel is shrunk on by the aid of heat, and for this purpose the reinforce of the gun is carefully turned to a cylindrical shape, and about one-sixteenth of an inch to the foot larger than the interior diameter of the barrel in a cold state. To prevent the cast-iron from expanding when the barrel is slipped on to its place a stream of cold water is allowed to run through the bore. At the same time and while the bands hang loosely upon it, the body of the gun is rotated around its axis to render the cooling uniform over the whole surface of the barrel. A large number of these guns were used in the late war, both on sea and land; and the amount of work done by them, especially in breaching masonry, is probably not exceeded by the rifle-guns of any other system. While a few of them have failed in the service, others have shown very great endurance. The cause of this failure has been attributed to the bursting of shells in the bore, the presence of sand in the bore, etc., but late investigations show that the Parrott projectiles were frequently broken at the bottom by the force of the powder in such manner as to wedge the body against the bore. It is quite probable that this cause had much to do with the bursting of the guns. The inventor thinks he has corrected this evil.

The following table gives the more important dimensions, etc., of Parrott guns; ranging from the 10-pounder to the 10-inch.

Gun.	Length of Bore.	Diam. of Bore.	Diam. of Barrel	Weight.	Number of Grooves.	Depth of Grooves.	Twist Increasing.	Charge.	Weight of Projectile.
	Inches.	Inches.	Inches.	Lbs.		Inches.	1 turn in ft. at Muzzle.	Lbs.	Lbs.
10-pounder............	70	3.	11.3	890	3	0.1	10	1	10
20-pounder............	79	3.67	14.5	1,750	5	0.1	10	2	19
30-pounder............	120	4.20	18.3	4,200	7	0.1	12	3	28
100-pounder............	130	6.4	25.9	9,700	9	0.1	18	10	86
8-inch..................	136	8.	32.	16,300	11	0.1	23	16	150
10-inch..................	144	10.	40.	23,500	15	0.1	30	25	250

The proof of these guns consists in firing each piece *ten* rounds with service charges. The table given below shows the ranges of the 100-pounder Parrott gun; charge, 10 pounds of cannon powder; projectile, Parrott shell, filled, 100 pounds; initial velocity being 1,080 feet. See *Cast-iron Guns* and *Ordnance*.

PARROTT LIFE-SAVING MONSTER.— A mortar made of cast-iron and lined with a steel tube. The piece is cylindrical about the seat of the charge, gradually tapering to the face of the muzzle. The breech is hemispherical. The trunnions are placed near the breech; their projection upon a plane through the vent and axis of the bore, being in front of and tangent to a plane perpendicular to that axis and containing the front end of the chamber. The chamber has the form of the frustum of a cone. The projectile is of cast-iron, cylindrical, with the ends rounded. An eye-bolt is screwed into the base for the attachment of the line. The eye of this bolt is close to the base of the shot. The cylindrical portion is turned in a lathe so as to be almost a perfect fit for the bore.

This apparatus is provided with a safety attachment, consisting of a piece of rubber, rectangular in cross-section, about 1′ long, 0″.75 wide, and 0″.5 thick, and of three or four galvanized-iron wires about 6′ long, laid parallel to each other, loosely twisted and coiled into a helix of from 18 to 19 turns. The rubber strap is sometimes placed inside the coil, and at others outside of it. This combined strap and spring is interposed between the shot and line in firing. The object of the combination is to absorb the shock of the discharge and thus prevent the breakage of the line, by letting the first jerk come upon the rubber, which will generally break, and then upon the coiled wire spring. The wires will be straightened out before the full strain falls upon the line. See *Life-saving Rockets*.

PARROTT PROJECTILES.—These projectiles are composed of a cast-iron body and a brass ring cast

into a rabbet formed around the base. The flame presses against the bottom of the ring and underneath it, so as to expand it into the grooves of the gun. To prevent the ring from turning in the rabbet the latter is recessed at several points of its circumference.

Parrott's incendiary shell has two compartments formed by a partition at right angles to its length. The lower and larger space is filled with a burning composition; the upper one is filled with a bursting charge of powder, which is fired by a time or concussion fuse. The burning composition is introduced through a hole in the bottom of the shell, which is stopped up with a screw-plug.

A more recent form of the Parrott Projectile for large calibers shown in the drawing. The sabot is cast on to the projectile, and is provided with a lip and cannelure. It is prevented from turning on the projectile and from stripping by means of recesses and undercuts upon the base of the projectile, into which the metal when liquid enters. See *Expanding Projectiles* and *Projectiles*.

PARRY.—A defensive movement in bayonet and saber exercises, executed as follows: *With the bayonet*—The Instructor commands: 1. *Tierce*, 2. PARRY. Move the point of the bayonet five or six inches to the right. 1. *Quarte*, 2. PARRY. Move the piece quickly to the left, the small of the stock passing under the left elbow, the piece covering the left shoulder; the barrel to the left, bayonet in front of, and higher than the shoulder, the left forearm on the right of the piece, the elbow touching the right wrist, the fingers on the stock. 1. *Seconde*, 2. PARRY. Move the point of the bayonet quickly to the left, describing a semi-circle from left to right, the point of the bayonet at the height of and in front of the right knee, barrel to the left; the left elbow in front of the body, the flat of the butt under the right forearm, the elbow two or three inches higher than the right shoulder. 1. *Butt*, 2. PARRY. Move the piece quickly to the left, covering the left knee and shoulder; the barrel to the right, the butt three inches above, and to the left of the left knee; the left hand and arm as in quarte parry. 1. *Prime*, 2. PARRY. Lower the point of the bayonet and describe a semicircle to the left, carry the piece to the left, covering the left shoulder; the barrel downward, the left fore-

Fig. 10.

arm behind the piece, the bayonet at the height of and to the left of the left knee; the butt higher than the head, the right forearm above the eyes and six inches in front of the forehead. The double parries are combinations of the simple parries, and are executed by the following commands: 1. Tierce, 2, Quarte. 1. Prime, 2. Seconde. 1. Quarte, 2. Tierce. 1. Seconde, 2. Prime. 1. Tierce, 2. Seconde. 1. Tierce, 2. Butt. 1. Seconde, 2. Tierce. 1. Butt, 2. Tierce. The *tierce* and *quarte parries* are used against blows aimed above the arms; *seconde* and *butt parries*, below the arms; *prime parry*, for blows either above or below the arms. In all parries, care must be taken not to uncover the body, by moving the piece farther than necessary to parry the blow. These positions are shown in Figures 1, 2, 3, 4, and 5. *With the Saber*—The Instructor commands: 1. *Tierce*, 2. PARRY. Carry the hand quickly a little to the right, point of the saber as high as the eyes, and opposite the right shoulder, edge to the right. (Two.) Resume the guard. 1. *Quarte*, 2. PARRY. Turn the hand in quarte, and carry it opposite the left breast, edge of the blade to the left, point to the

Fig. 11.

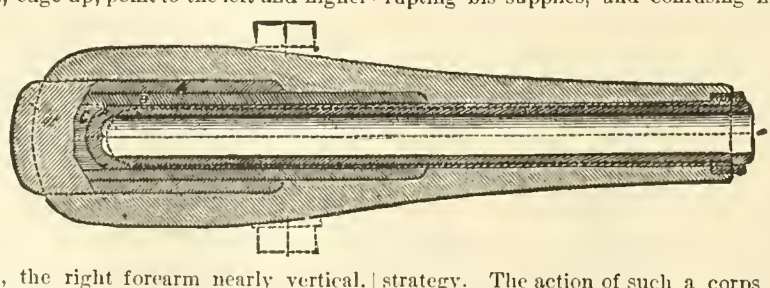
Fig. 12.

front, as high as the eyes, and a little to the left of the left shoulder. (Two.) Resume the guard. 1. *Left*, 2. PARRY. Raise the hand above and six inches in front of the eyes, the elbow somewhat bent, edge of the blade to the left, point downward, and parry the blow aimed at the left side. (Two.) Resume the guard. 1. *Left, head*, 2. PARRY. Raise the saber quickly above the head, the right arm vertical, edge upward, point to the left and about twelve inches below the guard. (Two.) Resume the guard. 1. *Right head*, 2. PARRY. Raise the saber quickly above the head, edge up, point to the left and higher than the head, the right forearm nearly vertical. (Two.) Resume the guard. 1. *Against infantry*, 2. *Left* 3. PARRY. Turn the head and shoulders to the left, raise the saber, the arm extended upward to the front and left, the hand in tierce, back of the blade to the front, point upward. (Two.) Describe a circle quickly on the left, from front to rear, parallel to the horse's neck, the arm extended; turn aside the bayonet with the back of the blade, bringing the hand, still in tierce, above the left shoulder. (THREE.) Resume the guard. 1. *Against infantry*, 2. *Right*, 3. PARRY. Turn the head to the right, throwing back the right shoulder, raise the saber, the arm extending upward to the right and rear, the hand in tierce, edge of the blade to the left, point upward. (Two.) Describe a circle quickly on the right, from rear to front, the arm extended; turn aside the bayonet with the back of the blade, bringing the hand as high as the head, the point upward. (THREE.) Resume the guard. See *Bayonet Exercise*, *Cavalry Parries*, *Fencing* and *Saber Exercise*.

PARSONS GUN.—The principle upon which Mr. Parsons makes his gun would seem to be similar to that of Captain Palliser's, *i. e*, by varying elasticity. As applied to strengthening a 68-pounder cast-iron gun, his method consists of boring into the breech of the gun, coincident with its axis, reaming out the bore into a slightly conical shape as far as the front of the trunnions, and then inserting into this space a reinforced wrought-iron tube, which is secured in its place by a breech-plug. The exterior of this compound tube is turned to fit the conical space easily, its length being cut so that it will be compressed longitudinally by screwing up the breech-plug, thus communicating to the outer cast-iron portion the entire longitudinal strain of the powder. This method is based on the fact that wrought-iron may be stretched three times as much as cast-iron, and will offer from three and a half to six times the resistance within the limit of its elasticity. Mr. Parsons has also proposed that the tube should be made of steel, having a solid breech, A, as shown in the drawing, the ingot not being bored through its entire length. He proposes to reinforce the tube with jackets of steel shrunk on, B, and to insert the whole tube and jacket, from the rear of the iron casting, the cast-iron gun being so bored out as to require force to insert the tube in its place. The tube being inserted, a steel plug, C, is to be screwed on from the rear, which presses against the rear of the tube, and the breech is then closed by a cast-iron lug representing the cascabel of the piece. See *Converted Guns*, *Ordnance*, and *Palliser Gun*.

PARTIALITY.—An unequal state of judgment or leaning in favor of one of two parties. Every member of a Court-Martial is sworn to do justice, without partiality, favor or affection. A previous opinion expressed by a member, before the Court is sworn, is deemed a good and sufficient cause of challenge by either the prisoner or prosecutor, and the individual cannot sit on the trial and judgment of the case.

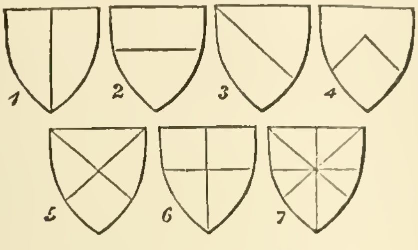
PARTISAN.—1. A name for a halberd or pike, or for a Marshal's baton. The name is also given to the leader of a detached body of light troops, who make war by harassing the enemy, rather than coming to direct fighting, by cutting off stragglers, interrupting his supplies, and confusing him by rapid strategy. The action of such a corps is known as *Partisan Warfare*.



2. Partisans are soldiers armed and wearing the uniform of their army, but belonging to a corps which acts detached from the main body for the purpose of making inroads into the territory occupied by the enemy. If captured, they are entitled to all the privileges of the prisoner of war.

Partisan warfare is advantageously pursued only in mountainous or thickly-wooded districts. In an open country, the cavalry very readily destroys them. See *Guerrillas*.

PARTITION LINES.—In Heraldry, lines dividing the shield in directions corresponding to the ordinaries. According to the direction of the partition lines, a shield is said to be party or parted per fess, per pale, per bend, per cheveron, per saltire; a shield divided by lines in the direction of a cross, is said to



Partition Lines in Heraldry.

be quartered; and a shield parted at once per cross and per saltire, is said to Gironné of eight. The partition lines are not always plain; they may be engrailed, invected, embattled, wavy, nebuly, indented, dancetté or raguly—forms which will be found explained under separate articles. See *Heraldry*.

PARTIZAN.—A species of *halberd*. The iron is long, broad, and double-edged; there is no axe, but barbs in the style of the ranseur. The *partizan* was known in France from the time of Louis XI. (1461) until the end of the 17th century, but its invention was not earlier than 1400. Also written *Partisan*.

PARTRIDGES.—In artillery, very large bombards formerly in use at sieges and in defensive works. They are mentioned in Froissart.

PARTY.—1. In Heraldry, parted or divided;—used in reference to any division of a field or charge. 2. Any small number of soldiers detached from an army or regiment on any particular duty either in peace or war time. A party is often sent out to forage, reconnoiter, and gain intelligence. The term is also applied to other duties which small bodies of men are engaged on such as *recruiting parties, working parties, storming parties, etc.*

PAS D'ANE.—The ring-shaped sword-guard below the cross-piece, on each side of the blade. It is not generally met with until the second half of the 16th century.

PAS DE SOURS.—Steps leading from the bottom to the top of a ditch in permanent fortification.

PASHA.—A title used in the Ottoman Empire, and applied to Governors of Provinces, or Military and Naval Commanders of high rank. The name is said to be derived from two Persian words—*pa*, foot or support, and *shah*, ruler—and signifies "The support of the Ruler." The title was limited in the early period of the Ottoman Empire to the Princes of the Blood, but was subsequently extended to the Grand-Vizier, the Members of the Divan, the Seraskier, Capitan-Pasha, the Begler-Begs, and other civil and military authorities. The distinctive badge of a Pasha is a horse's tail, waving from the end of a staff, crowned with a gilt ball; in war this badge is always carried before him when he goes abroad, and is at other times planted in front of his tent. The three grades of Pashas are distinguished by the number of the horse-tails on their standards; those of the highest rank are Pashas of three tails, and include, in general, the highest functionaries, civil and military. All Pashas of this class have the title of Vizier; and the Grand-Vizier is, *par excellence*, a Pasha of three tails. The Pashas of two tails are the Governors of Provinces, who generally are called by the simple title of "Pasha." The lowest rank of Pasha is the Pasha of one tail; the Sanjaks, or lowest class of Provincial Governors, are of this rank. The Pasha of a Province has authority over the military force, the revenue, and the administration of justice. His authority was formerly absolute, but recently a check was imposed on him by the appointment of local Councils. The Pasha is in his own person the military leader and administrator of justice for the Province under his charge, and holds office during the pleasure of the Sultan—a most precarious tenure, as the Sultan can at any moment, in the exercise of his despotic power, exile, imprison, or put him to death; and this has frequently been done in cases where the Pasha's power has excited the apprehension, or his wealth the avarice of his Royal Master. Also written *Bashaw* and *Pacha*.

PASS.—1. A straight, difficult, and narrow passage, which, well defended, shuts up the entrance to a country. 2. Permission granted by a Commanding Officer to a soldier to be absent from his quarters, recorded and signed by the Commanding Officer, so that the soldier may be able to show to others, if necessary, the authority for his being absent from his regiment. 3. A road or path leading from one side of a mountain to another. In latitudes where much snow falls, the "passes" are only open for egress or ingress during the summer months. In warfare, mountain passes play a very important part, if the operations, whether defensive or offensive, are carried on in a mountainous country.

PASSADE.—In fencing, a push or thrust; a sudden movement to the front. Often written *Passaod*.

PASSAGE—A movement in the School of the Soldier Mounted, for gaining distance to the right or left, executed as follows: To passage to the right, gather the horse and incline him to the right, by carrying the bridle-hand slightly to the right, and closing the right leg; then carry the bridle-hand well to the right, close the left leg behind the girth without leaning to the left, so that the haunches may move last, and hold the right leg near to support the horse and moderate his movement. The horse having obeyed, keep up the passage by a gentle application of the same means. To halt, replace the bridle-hand and left leg by degrees, and straighten the horse by carrying the bridle-hand slightly to the left and closing the left leg. In passaging, the movement of the horse's shoulders always precedes that of his haunches. To facilitate this, the horse is held inclined to the side toward which the passage is to be made. If the horse oblique too much, the rider carries the hand a little to the left, and increases the effect of the left leg. If the horse step too quickly to the side toward which he passages, diminish the effect of the reins and left leg, carrying the bridle-hand to the left, and holding the right leg close. If the horse back, bear his shoulders well toward the side toward which he should passage, diminish the effect of the reins, and increase that of the legs; a horse usually backs on account of the constraint he feels when his haunches have begun to move before his shoulders.

PASSAGE OF DITCHES.—In siege operations the passage of a dry ditch consists in the descent (which is by a blindage, if the ditch is not too deep, or a blindage and gallery for deep ditches) and a full sap, which leads from the outlet of the *descent* to the bottom of the breach. The passage of a wet ditch is more difficult, and specially perilous if the besieged can produce sudden freshets by flood-gates or other contrivances. The method usually followed is to build a dike or bridge of fascines and hurdles across the ditch. The abutment for this bridge is formed by excavating a grand gallery behind the counterscarp and throwing the earth taken from it into the ditch through the outlet of the DESCENT. The dike is carried forward from this abutment by sappers, who work on a raft carrying a musket-proof mask on the side of the enemy. A gabionade parapet on the exposed side of the dike serves to protect the men in bringing forward the fascines, hurdles, etc., to extend the dike.

PASSAGE OF RIVERS.—The passage is effected by surprise or by main force, and detachments are thrown by one means or the other upon the enemy's bank of the river before proceeding to the construction of bridges. The passage by force ought always to be favored by diversions upon other points. Infantry cross bridges without keeping step. Cavalry dismount in crossing, leading their horses. Wagons heavily loaded, pass at a gallop. See *Bridges* and *Ford*.

PASSAGES.—Openings cut in the parapet of the covered-way, close to the traverses in order to continue the communication through all parts of the covered-way. See *Traverses*.

PASSAGE WARRANT.—One among the numerous royal warrants issued for the guidance of the army. It relates, as its name implies, to the rules and regulations to be observed in applying for passages on board troop and other government ships. The accommodation granted to officers, and the quantity of baggage allowed, as well as messing costs, will be found in the copy of this warrant.

PASSANDEAU.—An ancient 8 pounder gun, which was 15 feet long, and weighed about 3,500 pounds.

PASSANT.—A heraldic term used to express the attitude of an animal in a walking position, with his

1 2 3

head straight before him, Fig. 1. Fig. 2. represents the attitude, *Passant gardant;* Fig. 3. *Passant regardant.*

PASS-BOX.—A wooden or metallic box with a lid and handles, used for carrying cartridges from the service magazine to the piece. The boxes are of various sizes to suit the caliber of the piece, one cartridge being carried at a time. The top is fastened on with two butt hinges and kept closed by strong hook and staple. A wooden handle is fastened with screws diagonally on one end, by which the box is carried.

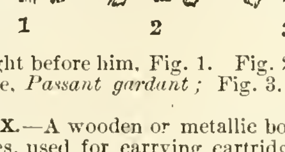
PASSEGARDES.—In ancient armor, ridges on the shoulder-pieces to turn the blow of a lance.

PASSE-MUR.—An ancient 16-pounder gun, which was 18 feet long, and weighed about 4200 pounds.

PASSES-BALLES.—Boards or machines made of iron or brass, used in disparting cannon, and fitted to every species of caliber.

PASSEVOLANT.—A light piece of ordnance, used in France in the 15th century.

PASSION CROSS.—A cross of the form on which our Saviour suffered, with a long stem and a short traverse near the top. It is of occasional occurrence



Passion Cross.

as a heraldic charge, though less frequent than many other varieties of cross. A passion cross, when elevated on three steps or degrees (which have been said by heralds to represent the virtues of Faith, Hope, and Charity), is called a Cross Calvary.

PASS OF ARMS.—In ancient chivalry, a bridge, road, etc., which the Knights undertook to defend, and which was not to be passed without fighting the person who kept it. He who was disposed to dispute the pass touched one of the armories of the other Knight who held the pass, that were hung on pales, columns, etc., erected for the purpose; and this was a challenge which the other was obliged to accept. The vanquished gave the conqueror such prize as was agreed upon.

PASSOMETER.—A watch-shaped instrument carried about the person to register the steps taken in walking. It consists of a dial and two hands, which are moved by a ratchet worked by a weight which the motion of walking causes to vibrate.

PASS PAROLE.—An order passed from front to rear of an army by word of mouth.

PASSPORT.—A warrant of protection and permission to travel, granted by the proper authority, to persons moving from place to place. Every Independent State has the right to exclude whom it pleases from its territory, and may require that all strangers entering it be furnished with properly authenticated documents, showing who they are, and for what purpose they are visiting the country. Passports are sometimes issued by the Ministers and Consuls of the country which the traveler intends to visit, which cannot, however, be done without the consent or connivance of the State of which the holder of the instrument is a subject; they properly proceed from the authorities of the State to which the traveler belongs, and ought to bear the *visa* or countersignature of the Minister or Consul of the country which he is about to visit. In some European States no one is allowed to go abroad without a passport from his Government authorizing him to leave the country—a provision used as a means of detaining persons charged with crime; and passports are even required by the natives to enable them to go from place to place in their own country. The regulations of different States have varied much regarding the use of passports; and of late years there has been a great relaxation of the stringency of the regulations connected with them. Since the facilities of traveling have so greatly increased, it seems to have become the prevalent opinion that the passport system tends to obstruct the free intercourse that is desirable between citizens of different countries; while it is ineffectual to prevent the entrance of dangerous or suspicious characters, who can obtain passports on false pretences, or make their way in without them. Within the United Kingdom no passports are required; but for a British subject traveling in some parts of the Continent they are still requsite. At one time the greater part of British subjects traveling abroad used to be furnished with passports from the Ministers or Consuls of the countries which they purposed to visit; the Lord Provost of Edinburgh was also in the way of issuing passports to Scotchmen. Of late years the passport most used by British subjects is that of the British Secretary of State for Foreign Affairs, which is now granted to any British subject for a fee of two shillings, and is good for life. If the applicant be not personally known to the Secretary of State, he must either be recommended to him by some person who is known to him, or produce an application in his favor by some banking firm established in London or elsewhere in the United Kingdom, or a certificate of identity signed by a Mayor, Magistrate, Justice of the Peace, Minister of Religion, Physician, Surgeon, Solicitor, or Notary, resident in the United Kingdom. In certain cases the production of a certificate of birth may be required. If the applicant be a naturalized British subject, his certificate of naturalization must be forwarded to the Foreign Office. If it be dated subsequently to Aug. 24, 1850, and previously to Aug. 1, 1858, his passport will be good for one year only; if subsequently to Aug. 1, 1858, for six months only. The passport of a British subject naturalized by Act of Parliament is good for life. Where the passport system is in full force, it is required that the passport be countersigned by the Minister or Consul of the country which the holder means to visit, the visa being only of force for a year. The French Government allows British subjects to enter and leave France, and travel in it without passports;

but they are said to be sometimes asked for when France is entered from the South and East. In Belgium, Holland, Germany, Switzerland, Austria, Italy, Denmark, Norway, and Sweden, passports are no longer required. For Greece and Portugal they are necessary, and the visa is insisted on in Russia, Turkey, and Egypt. In time of war, passports or safe-conducts are granted by the Supreme Authority on the spot—*i.e.*, the Officer in Command—to insure safety to the holders when passing from spot to spot, or while occupied in the performance of some act specified in and permitted by the passport. Passports may be granted for goods as well as individuals; and in time of war, the passport of a ship is the formal voucher of its neutral character. It purports to be a requisition on the part of the Government of a State to allow the vessel to pass freely with her company, passengers, goods, and merchandise, without hindrance, seizure, or molestation, as being owned by citizens or subjects of such State.

PASTE.—A tenacious mixture of flour and alum in the proportion of 2 lbs. of flour to 1 oz. of pounded alum mixed with 1 gallon of boiling water. The mode of preparing it is as follows: Heat it gently, stir it, and let it boil ¾ of an hour; when it becomes ropy, pour it into bowls, and pass it through a sieve before it is quite cold. It should be used cold, and only 2 or 3 days' supply made at a time, but it may be preserved longer by adding alum in the proportion of one-tenth the weight of flour. Paste is used in the laboratory in case-making, for portfires, rockets, light-balls, etc.

PATAREMO.—A sort of small swivel artillery, having a movable chamber.

PATCH.—1. A greased piece of cloth wrapped around a rifle bullet. 2. A block on the muzzle of a gun to do away with the effect of dispart; making the line of bore and line of sight parallel.

PATE.—1. In fortification, a sort of platform or terre-plein, irregularly built, yet generally constructed in an oval form. It is surrounded by a parapet, without anything to flank it, and having no other defense than what is front or fore right. *Patés* are usually erected in marshy grounds to cover the gate of a fortified town or place. 2. An iron or earthen pot filled with powder and grenades for throwing against besiegers; some were used at Lille, in 1708.

PATEREROS.—Small pieces of ordnance, now obsolete, worked on swivels; most commonly used on board ships, where they were mounted on the gunwale, and discharged showers of old nails, etc., into hostile boats. The French called them Pierriers from loading them with stones.

Patonce

PATONCE.—In Heraldry, a cross with its terminations expanding like early vegetation or an opening blossom.

PATOO.—A very formidable weapon with sharp edges, used by the Polynesian Islanders and New Zealanders as a sort of battle-axe to cleave the skulls of their enemies.

Patriarchal Cross.

PATRIARCHAL CROSS.—A cross like the patriarchal crosier, having its upright part crossed by two horizontal bars, the upper being shorter than the lower. A cross patriarchal fimbriated *or* was a badge of the Knights Templars.

PATRICK.—The Order of Saint Patrick is the national order of knighthood for Ireland, established by George III. Feb. 5, 1783, and enlarged in 1833. It consisted of the Sovereign, the Grand-master (who was the Lord-Lieutenant of Ireland for the time being), and 15 Knights. By the statutes of 1833 the number of Knights was increased to 22. The *Collar* of the order (of gold) is composed of roses alternating with harps, tied together with a knot of gold, the roses being enameled alternately white within red, and red within white, and in the center is an imperial crown surmounting a harp of gold, from which the badge is suspended. The *Badge* or the *Jewel* is of gold, and oval; surrounding it is a wreath of shamrock proper

Order of St Patrick.

on a gold field; within this is a band of sky-blue enamel charged with the motto of the order, QUIS SEPARABIT MDCCLXXXIII, in gold letters; and within this band a saltire gules (the cross of St. Patrick), surmounted by a shamrock or trefoil slipped vert, having on each of its leaves an imperial crown or. The field of the cross is either argent, or pierced and left open. A sky-blue RIBBON, worn over the right shoulder, sustains the badge when the collar is not worn. The STAR, worn on the left side, differs from the badge only in being circular in place of oval, and in substituting for the exterior wreath of shamrocks eight rays of silver, four of which are larger than the other four. The MANTLE is of rich sky-blue tabinet, lined with white silk, and fastened by a cordon of blue silk and gold with tassels. On the right shoulder is the HOOD, of the same material as the mantle. The order is indicated by the initials K. P.

PATROLS.—Patrols are of two classes, from the different objects had in view. The first are those made with a view of insuring greater security from the enemy's attempts to pass, or force the line of outposts, and may therefore be termed *defensive patrols*. They consist usually of three or four men, who go the rounds, along the chain of sentinels and between the posts; seldom venturing farther than a few hundred paces beyond the sentinels chain; the object being to search points which might present a cover to the enemy's scouts, and to keep the sentinels on the alert. The second class are those made exterior to the line of out-posts, with a view of gaining intelligence of the enemy's whereabouts; and may therefore be termed *offensive patrols*. They are composed of larger bodies of men than the first class, the number being proportioned both to the distance to be gone over, and the extent of front to be examined. In a position, presenting but few cross-roads, and sparsely settled, a patrol of ten or twenty horsemen, may be found ample, to search with all desirable thoroughness, from twenty to forty miles in advance of the position, along the principal avenues to it; whereas, with a more extended front, presenting many lateral avenues, double this number might be required for the same duty. From the information obtained, through the ordinary channels of maps, and by questioning the near inhabitants, the Commanding-Officer can usually settle, with sufficient accuracy, the strength of a patrol.

From the duties to be performed by patrols, cavalry are usually employed alone; in cases of very broken country, infantry may be necessary, but they should always be accompanied by some horse, if for no other purpose than to transmit intelligence promptly to the rear. The main duties of a patrol are to find the enemy if in the neighborhood; gain a good idea of his position and strength; to make out his movements, and to bring in an accurate account of his distance from the out-posts of their own force; and the character of the ground between the position occupied by the respective forces. From the nature of these duties; it is evident that both officers and men, for a patrol, should be selected with a special reference to their activity, intelligence, and the aptitude they may possess, from previous habits of life, for a service requiring a union of courage, prudence, and discriminating observation—usually to be met with only in individuals who have been thrown very much upon their own resources. When the character of the country admits of it, the employment of such individuals, singly, or in very small bodies, as scouts, is one of the most available means of gaining intelligence of an enemy, without betraying the secret of our own whereabout.

In conducting a patrol, the Commanding Officer should provide himself with a good map, telescope, and guides; and gain all the information he can before starting, by questioning persons in the neighborhood. Nothing should escape his eye along his line of search; and he should particularly note points which might be favorable to his defense, if driven back by the enemy; or by which his retreat might be endangered. The order of march of the patrol will be regulated by the circumstances of its strength, kind of troops employed, the character of the country passed over, the hour of the day, and the particular object in view. The intelligence and judgment of the officer in command will have sufficient exercise on these points; as he will be continually called upon to vary his dispositions. The general and obvious rule of keeping a look-out on all sides, will prompt the general disposition of an advanced-guard, rear-guard, and flankers, according to the circumstances of the case, however small his command. The sole object being to carry back intelligence of the enemy, no precautions should be omitted to cover and secure his line of march, without making, however, too great a subdivision of his force.

Too much circumspection cannot be shown in approaching points favorable to ambuscades; as woods, ravines, defiles, inclosures, farm-houses, villages, etc. The main-body should always be halted, in a good position beyond musket-shot, or where cover can be obtained, whilst a few men proceed cautiously forward, following at some distance in the rear of, but never losing sight of each other, to examine the suspected spot. If the officer deem it necessary, at any point, to detach from his command smaller patrols, to examine points at some distance on his flanks, he should halt the rest, at the point where they separate, until the detachments come in and report; or, if he decides to move forward, he should leave three or four men at the spot, to convey intelligence promptly to the rear; if anything is discovered, as well as to himself. It may frequently be found that some eminence on the flanks may present a good view of the surrounding country, in which case, if it be decided to use it, two or three men ought to be detached for the purpose, with orders to keep in sight of each other, but far enough apart to guard against a surprise of the whole. When the officer finds himself in the presence of the enemy, he should halt his command at a convenient spot, where they will be screened from the enemy's view; and, having made his dispositions against a surprise, he will proceed with a few picked men, to the most favorable point from which he can obtain a good look-out, to reconnoiter the position occupied, and the other points of interest. If he deem it advisable to keep his position, or change it for some other point more favorable, he will first transmit a report to the rear of what he has observed.

When the patrol moves by night, the ordinary precautions must be redoubled. Signals must be agreed upon to avoid danger, should any of the party become separated from the main body. Careful attention must be given to everything passing around; as the barking of dogs, noises, fires, etc. On approaching any inhabited spot, the command should be brought to a halt, whilst a few picked men move noiselessly forward, and if practicable, by stealing up to the windows, learn the character of the inmates. It cannot be too strongly impressed upon the mind of the officer in command of a patrol, that he must be all ears and eyes; that he will be called upon in turn, to exercise great boldness, caution, presence of mind, and good judgment, in accomplishing a mission where the enemy must be seen but not encountered; and such roads and halting points be selected, both in moving forward and returning, as shall be most favorable to his movements, and least liable to expose him to a surprise, or a disadvantageous collision with the enemy. See *Reconnoissance.*

PATTE D'OIE.—A term used in mining to describe three small branches which are run out at the extremity of a gallery. They are so called from their close resemblance to the foot of a goose.

Pattée.

PATTEE.—A cross in Heraldry, also called Cross Formée, a cross with its arms expanding towards the ends, and flat at their outer edges.

PATTERN.—The wooden model used in casting is technically called the Pattern. Models for casting should be made of one or several pieces, according to the form of the mold required. When the form is such that the whole model can be withdrawn from the sand at once, without injuring the mold, a single piece will suffice; but generally the model is composed of several pieces, so fitted that they can be put together in succession as the molding progresses, and finally taken apart and removed by piecemeal when the molding is complete. See *Molding.*

PATTISON PROJECTILE.—This shot has projections cast upon it to fit the rounded grooves of the gun. The windage is stopped by a simple leather band, which is driven upon the conical base of the shot by the powder-gas.

PAUL.—The name given to a Sepoy's tent. It is of a different pattern to the European soldier's tents being much smaller and lighter.

PAULDRONS.—In ancient armor, reinforcing metal plates covering the shoulders.

PAULIN.—A kind of *tarpaulin.* It is made of thick, unpainted canvas, and forms part of the equipment for each carriage of a field-battery of artillery. They are of four sizes, viz;—Magazine, large; Magazine, small; Camel paulins; Cart paulins. *Large paulins* are used on the floors of laboratory tents. *Small magazine paulins* are used in covering powder barrels and live shells in the batteries. *Camel paulins*, being of small size, are frequently very convenient, and are used for the same purposes as small magazine paulins. *Cart paulins* are used with tilts for artificers' carts. With the exception of the camel and cart paulins, which are made of coarse country canvas, all others are made of vitry.

PAVADE.—A term formerly applied to a short dagger in Scotland.

PAVAVA.—A conveyance drawn by a buffalo, and employed in the Philippine Islands. The drawing shows the manner of its construction and use. The shafts, framework, and body, are of bamboo; the collar and nose-band of the buffalo of chair cane, and the roof of the pandanus leaves. This arrangement furnishes a hint for making travées more comfortable. Unhappily, the bamboo, admirably suited

to the construction of litters and stretchers, is not available in this and many other countries.

PAVESIER.—An ancient militia who carried the (*pavois*) shield. Also written *Pavecheur*.

PAVILION.—1. In Heraldry, a covering in the form of a tent, investing the armories of Kings. 2. A tent raised on posts; a flag, colors, ensign, or banner.

PAVISE.—A large shield covering the whole body, having an inward curve, managed by a Pavisier, who with it screened an archer. Also written *Pavais*, *Pavas*, *Pavese* and *Pavesse*.

PAVISIERS.—Warriors armed with the pavise. In ancient encounters, bodies of *Pavisiers* were formed on each side; and, doubtless, these strong defenses were opposed, as much as possible, to the hostile archers. Also written *Pavisors*.

PAVOIS.—A small cuirass first worn by infantry soldiers about 700 B. C. It consisted of plates of metal sewed on to woven stuffs or skins. See *Pavise*.

PAVOIS D'ASSAUT.—A German shield of the fifteenth century, 44 inches by 72 inches, composed of wood covered over with leather. It was also constructed in various shapes and sizes.

PAVOISIENNE.—A small hand shield of the middle of the fourteenth century. It was one foot and one quarter of an inch in diameter.

PAVON.—An ancient military flag shaped like a right-angled triangle.

PAY.—The stipend or salary allowed for each individual serving in the army. The following is a table of the monthly pay allowed in the United States Army:—

Pay of Officers in Active Service.

GRADE.	PAY OF GRADE.		MONTHLY PAY.			
	Yearly.	Monthly.	After 5 years' service.	After 10 years' service.	After 15 years' service.	After 20 years' service.
			10 *per ct.*	20 *per ct.*	30 *per ct.*	40 *per ct.*
General	$13,500 00	$1,125 00				
Lieutenant-General	11,000 00	916 67				
Major-General	7,500 00	625 00				
Brigadier-General	5,500 00	458 33				
Colonel	3,500 00	291 67	$320 83	$350 00	$375 00	$375 00
Lieutenant-Colonel	3,000 00	250 00	275 00	300 00	325 00	333 33
Major	2,500 00	208 33	229 17	250 00	270 83	291 67

The General of the Army has been retired, without any reduction in his current pay and allowances. The maximum pay of a Colonel is by law $4,500 per annum; hence full 40 per cent. cannot accrue. The maximum pay of a Lieutenant-Colonel is by law $4,000 per annum; hence full 40 per cent. cannot accrue. An Aid-de-Camp to a Major-General is allowed $200 per year in addition to the pay of his rank, not to be included in computing the service increase. An Aid-de-Camp to a Brigadier-General is allowed $150 per year in addition to the pay of his rank, not to be included in computing the service increase. An Acting Commissary of Subsistence is allowed $100 per year in addition to the pay of his rank, not to be included in computing the service increase. Assistant Surgeons are entitled to pay of Captain after five years' service. Retired officers receive 75 per cent. of pay (salary and increase) of their rank. A retired Chaplain receives three-fourths of the pay (salary and also increase) of his rank (Captain not mounted). The officer having charge of the public buildings and grounds (Washington) has, while so serving, the rank, pay, and emoluments of a Colonel. The Aides-de-Camp and Military Secretary to the Lieutenant-General, selected by him from the Army, have, while so serving, the rank and pay of Lieutenant-Colonel. The principal assistant in the Ordnance Bureau of the War Department receives a compensation, including pay and emoluments, not exceeding that of a Major of Ordnance. Only one Veterinary Surgeon, at $75 per month, is allowed each of the cavalry regiments, from the First to the Sixth Regiment, inclusive; two, one at $100 and one at $75 per month are allowed each of the Seventh, Eighth, Ninth, and Tenth Regiments; the senior in date of appointment entitled to the higher grade. The Teacher of Music, who shall be leader of band at Military Academy, receives $90 per month. The clothing account is settled June 30 and December 31 of each year. Balances found due United States are charged soldier on muster-rolls of those dates. Balances due soldier are carried forward on company books credited to his current clothing account; any balance remaining due him at discharge is credited on final statements. Enlisted men of Signal Corps have the pay of Engineer soldiers of a similar grade.

PAY ACCOUNTS.—The Paymaster's vouchers for payments of salary made to officers and in final settlements with discharged soldiers. The form of the account used by officers is shown on page 496.

PAY BILLS—In the British Service, accounts regularly tendered by Captains of troops or companies of the money required by them for the effectives of such troops or company.

PAY DEPARTMENT.—That department of a government which takes charge of all matters relating to the pay of the army. In the United States Army, the Pay Department consists, at present, of one Paymaster-General, with the rank of Brigadier-General; two Assistant Paymaster-Generals, with the rank of Colonel of Cavalry; two Deputy Paymaster-Generals, with the rank of Lieutenant-Colonel of Cavalry; and forty-eight Paymasters, with the rank of Major of Cavalry. An Act of Congress, making appropriations for the support of the Army for the year ending June 30, 1884, *provides* that vacancies that may hereafter occur in the Pay Corps of the Army in the grades of Lieutenant-Colonel and Major, by reason of death, resignation, dismissal, or retirement, shall not be filled by original appointment until the Pay Corps shall, by such vacancies, be reduced to forty Paymasters, and the number of the Pay Corps shall then be established at forty and no more.

PAYMASTER.—An officer appointed in the army for the purpose of keeping its pay accounts, and the disbursing of moneys in payment of troops. In the United States Service, it is the duty of Paymasters to pay all the regular and other troops; and to insure punctuality and responsibility, correct reports must be made to the Paymaster-General once in every two months, showing the disposition of the funds previously transmitted, with accurate estimates for the next payment of such regiments, garrisons, or departments, as may be assigned to each. When volunteers or militia are called into service, the President may assign to any officer of the army the duty of Paymaster. Paymasters are required to give bonds.

In the British Service, Military Paymasters are either "Control" or "Regimental." Of the latter, who constitute by far the more numerous class, there is one to every brigade of artillery, regiment of cavalry, and battalion of infantry. The Paymaster holds no other commission, but the appointment is nearly always conferred upon some person who has previously held a combatant rank in the army. The functions of Paymaster comprise issuing and accounting for the pay of officers and men, and having charge generally of all the finances of the corps. In discipline, the Paymaster is responsible to the Officer Commanding the Regiment; but in all money matters he looks for orders to the War Office alone. He commences with a pay of 12s. 6d. a day, with the relative rank of Captain; and after 20 years' service attains the pay of £1, 2s. 6d. a day and relative rank as Major. Regimental Paymasters were first appointed during the French war. Control Paymasters have financial charge in the military districts or sub-districts. They form a separate Department under the Surveyor General of the Ordnance, comprising Paymasters, Deputy Paymasters, and Assistant Paymasters.

PAYMASTER-GENERAL.—The Paymaster-General, in conformity with the laws and regulations, is charged with all necessary instructions to his subordinates in reference to the supply and distribution of funds for the payment of the Army, and all other things pertaining to the financial duties of his Department, and the accountability of its officers. In these and all other matters having relation specially to the internal administration of the Pay Department, the correspondence between the Paymaster-General and his subordinates, and between the Division and Department Chief Paymaster and their subordinates, is direct. In England the Paymaster-General is an officer of the British Ministry, but not of the Cabinet, charged with superintending the issue of all moneys voted by Parliament. He is virtually the Paymaster of the public service, having no control over the sums issued, paying merely on the order of the Department concerned and receives £2,000 a year as Chancellor of the Duchy of Lancaster. He is always either a Peer or a member of the House of Commons, and changes with the Ministry. Of late years the office has been held in conjunction with that of Vice-President of the Board of Trade. The Paymaster-General is assisted by a Deputy and a staff of clerks, the annual cost of the whole department amounting to about £25,000. The first notice of this office is in the early part of the reign of Charles II., when the Paymaster-General was nothing more than the sole Paymaster of the Army. The present extensive duties of the office have been added by degrees during the 19th century.

PAYMASTER-SERGEANT.—A Non-commissioned Officer, in the British Army, whose duty it is to act as clerk to the Paymaster. He ranks with other staff sergeants, and receives from 1s. 11d., to 2s. 11d. a day, according to his corps, with an increase of 6d. after 3 years' uninterrupted service as Paymaster-Sergeant.

PAYNIZING.—A process for preserving and hardening wood, invented by a Mr. Payne. It consists in placing well-seasoned timber in an air-tight chamber, and then, when, by means of a powerful air-pump, the wood is deprived of its air, a solution of *sulphuret of calcium*, or a sulphuret of barium is admitted, and readily fills up the empty vessels all through the wood. The air-pump is again used, and the superfluous moisture is drawn out, and a solution

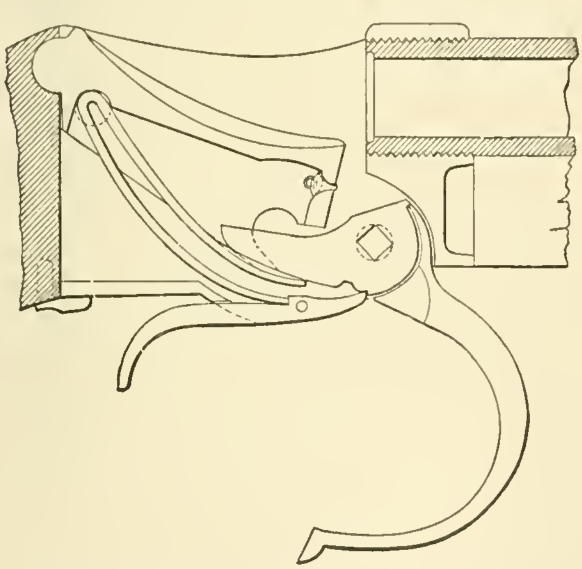
of sulphate of iron is injected; this acts chemically upon the sulphuret of barium or of calcium, and forms all through the wood either the insoluble sulphate of barium (heavy spar) or of lime (gypsum). The addition of these mineral materials renders the wood very heavy, but it becomes also very durable, and almost incombustible.

PAY-ROLL.—A roll or list of persons entitled to payment, with the sums which are to be paid on them. In the United States Army, at each regular muster of the troops, one ordinary muster-roll and three Muster and Pay-rolls are made. The muster-roll is transmitted by the mustering officer to the Adjutant General's Office, at Washington, within three days after the muster. Two copies of the pay-roll are for the Paymaster, the other is kept with the company records. Muster, and Muster and Pay-rolls are made on the printed forms furnished from the Adjutant General's Office; and in making the rolls special attention must be given to the printed directions thereon. The calculations on the Pay-rolls are made by the Paymaster. They are transcribed by the Captain on the copy retained with the company records, in order that an exact account of each soldier's pay may be kept. If it should become necessary to use manuscript forms, they should embrace all the data required to insure justice to the soldier, and guide the Paymaster in making payment. Companies are designated on the Muster, and Muster and Pay-rolls by the names of their Captains, whether present or absent. Soldiers in hospital, patients, and nurses, except stewards, are mustered on the rolls of their company, if it be present at the post.

PEABODY-MARTINI RIFLE.—This rifle is a combination of the Peabody and Martini systems, the former covering the mechanism for closing the breech and extracting the cartridge shell, after the rifle has been fired, and the latter covering the device for igniting the cartridge. This rifle was adopted by the



English and Turkish Governments, after long and exhaustive trials in competition with all the prominent breech-loading rifles of the world. It endured the test of actual experience in war during the contest between Russia and Turkey, and obtained the highest reputation for solidity, accuracy, long range, and other desirable qualities of a military weapon. The official reports from the armies in the field, and the letters of army correspondents, unite in praise of the Turkish rifles. The parts composing the breech mechanism combine the greatest possible strength with simplicity of construction, and the system, in its present perfection, is the result of long and careful study to produce a rifle meeting all the requirements of military service. Its form is compact and graceful, and the symmetry of its lines is nowhere infringed upon by unseemly projections, which besides being offensive to the eye, are often prejudicial to the comfort of the soldier on the march or in the performance of its necessary manipulations. No movement of the barrel, or any other parts, except those immediately connected with the block, is required in the performance of any of its operations. These are performed in the simplest possible manner, and without in the least infringing upon the strength and durability of the rifle, which is equal, in these respects, to the best muzzle-loader. In the operation of loading, the whole movement of the block is made within the breech-frame or receiver the end of the block-lever falling but a short distance from the stock. The block itself is a strong, substantial piece, and when in position for firing, is so firmly secured as to ensure its perfect safety, as has been repeatedly shown in the severe tests to which it has been subjected.

The drawing shows the Peabody-Martini breech system. The position of the block, when it is drawn down for loading, is such as to form an inclined plane, sloping toward the breech of the barrel, and the groove in its upper surface corresponding with the bore of the barrel, facilitates the entrance of the cartridge so that it slides easily into the chamber, without the necessity even of looking to see that it is properly inserted. The adoption of the coil main-spring in place of the common gun-lock main-spring, is considered a great improvement, and this opinion is confirmed by the experience of the English and Turkish troops who have been supplied with the Peabody-Martini rifles. It has been found that, in several instances, where the coil main-springs were broken, the defects were not noticed, and the springs compressed in the blocks worked as usual. Had such mishaps occurred to the old gun-lock mainsprings, the arm would have been rendered useless. The accuracy and range of this rifle are very remarkable. The system of rifling used is that known in England as the Henry. There are seven grooves, of peculiar shape, with a sharp twist (one turn in twenty inches). After a long series of experiments, with different kinds of rifling, the English Arms Commission finally decided upon this system as giving the most satisfactory results, both with regard to accuracy and range.

The manipulations for loading and firing are of the simplest kind: Throw down the block-lever with considerable force, pressing with the thumb of the right hand: insert the cartridge; and return the lever to its place, which raises the block to its proper position when the rifle is ready for firing.

After firing, throw down the block-lever with force, and the empty cartridge shell is thrown out clear from the rifle, leaving the chamber ready for the insertion of another cartridge. This extraction of the cartridge shell is effected by the action of an elbow lever, which throws it out with unerring certainty, the instant the block-lever is lowered. This elbow lever derives its power simply from the action of the block itself, and cannot become deranged, as its action is not dependent upon any spring and is of such strength as to prevent the possibility of breakage or derangement by any service to which it can be subjected. If it is desired to preserve the cartridge shell for reloading, throw down the block-lever with a gentle movement, and it is drawn out into the groove of the block, from whence it can readily be taken by the person firing.

For rapidity of firing, this rifle is believed to be equal, if not superior to any other single loader, and in continuous firing, to any repeater. It cannot be fired until the block is in its proper position, so that it is impossible for accidents from premature explosion to occur. The objection to the excessive recoil of this rifle, which has been raised in some quarters, has been obviated in the arms manufactured by the Providence Tool Company, by the adoption of a different form of ammunition. After the decision of the English Arms Commission in favor of the Peabody-Martini rifle, and its subsequent adoption as the standard national arm, the Imperial Ottoman Government contracted with the Providence Tool Company to manufacture 600,000. The productive capacity of this Company's factories is 1000 rifles per day. In conclusion it may be said, that wherever the rifle has been introduced, its superior qualities of safety, strength, simplicity, easy manipulation, accuracy, and range, have been fully conceded. See *Martini-Henry Rifle*.

PEACE ESTABLISHMENT.—The reduced number of effective men of an army during peace time; regiments are raised to their full complement in war time, or, as it is termed, to a *war establishment*. In Great Britain the raising of the army from a peace to a war establishment is effected by calling out the reserve, the militia, enrolled pensioners, and volunteers; in continental armies, where the compulsory service is in force, by calling out the men on furlough and the reserves.

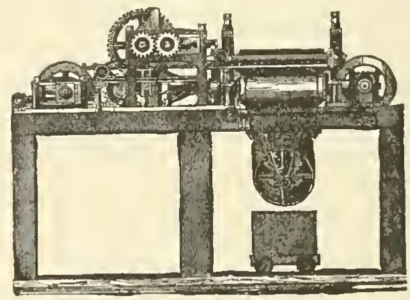
Pean.

PEAN.—One of the furs borne in Heraldry, differing from Ermine only in the tinctures: the ground being sable, and the spots of gold. See *Heraldry*.

PEA-ORE.—A form of compact brown iron ore (hydrated peroxide of iron), consisting of round, smooth grains, from the size of mustard-seed to that of small pease. Sometimes the grains are still smaller and flattish. This iron ore is very abundant in some places in France, and is smelted.

PEA-RIFLE.—A rifle of small bore carrying a ball of the size of a pea.

PEBBLE POWDER.—Since the pellet powder was first brought into use, another description of large grain powder, called "pebble powder," has been introduced for service with guns of large caliber. This pebble powder is formed of large grains ranging from $\frac{1}{16}$ of an inch to as much as 2″ cubes; and to manufacture this class of powder expeditiously and cheaply, has brought forth another description of machine for forming the pebbles by cutting up previously compressed cake into cubes of the required dimensions. This is done in the following manner, by a very simple self-acting machine: The cake as brought from the press-house is, to begin with, of the thickness of the required cubes, and this cake the machine has to cut up—first, into long strips of the same width as the thickness of the cake; and, secondly, to cut these long strips transversely into cubes. This is accomplished in the machine by means of two pairs of rollers in the following manner: The cake is fed into a hopper placed immediately above the first pair of rollers, and, as these are provided with knives upon their surfaces, they cut the cake up into long strips. These strips fall upon an endless traveling band, which conveys and carries them forward to the second pair of rollers, where they are cut transversely into cubes. They then drop into a spout, and are delivered into a revolving sifter covered with copper wire, which conveys the perfect cubes into a number of wooden boxes contained in a small gun-metal truck; but the dust and small pieces fall through the sifter into other boxes, and are taken back to the press-house and worked up again. The framing of this machine (like most of the other machines used in the manufacture of gunpowder), is composed entirely of gun-metal, and has the requisite seatings cast upon it for the reception of the several brackets and pedestals which are also of gun-metal, as well as the cutting rollers, each pair being about 7″ in diameter, with a number of equidistant teeth or knives formed upon their surfaces, cut out of the solid metal. These rollers are securely fixed upon wrought-iron shafts, which receive their motion from a main driving shaft by means of spur gearing. The underside of the bearings of these rollers are planed and faced so as to slide in their respective brackets. One of each pair of bearings is fitted with a spring box controlled by a set-screw, by means of which the amount of resistance to the opening of the rollers is adjusted. Blocks of hard wood are also fitted between each pair of bearings to act as stops, and thus determine the minimum distance between the surface of the rollers, and an adjustable gun-metal scraper is fitted to each roller for removing the surplus powder from its surface. A skeleton carrying band, made of two leather belts fitted with ash cross-bars of a triangular section and at about 3″ apart, is provided. These



wooden cross-bars are rivetted with copper rivets to the leather belts and to gun-metal strips upon their underside, these strips being of such a form as to serve the purpose of teeth for driving the band. This endless band works upon two gun-metal drums; the one is driven by gearing from the main shaft, and the other is fitted in adjustable bearings, which can be tightened by means of a screw so as to take up any slack in the band. These drums are made with flanges at each end, and have recesses formed on their barrels to receive the gun-metal projections or strips upon the carrying band. A sliding table made of hard wood and provided with four gun-metal grooved wheels, which travel upon V rails, also made of gun-metal, is fitted to work underneath the carrying band, and travels at the same uniform rate of speed. The top surface of this table is covered with leather, and made perfectly smooth; a reciprocating motion is given to it by means of an endless chain made of sheet copper, upon one link of which a stud is fitted and works in a gun-metal block that slides in a bracket fixed upon the underside of the table. A weighted gun-metal frame is also provided, and so adjusted that the underside of it rests upon the upper surface of the bars of the carrying band; the ends of this frame are fitted with gun-metal stay-rods, which project and work in slotted brackets connected to the machine; the frame is by this means free to rise if the pressure from any cause exceeds that of the weight by which it is held down. The underside of this frame is planed and made perfectly smooth, so as to allow the carrying band to work freely between the underside and the upperside of the sliding table.

The feeding web—which is made of strong Dowlas canvas—is driven by a gun-metal drum 7″ in diameter, the following roller being 1¼″ in diameter; the top surface of this web is supported by a board to prevent its sagging, and, in addition, the bearings wherein the shaft of the driving drum revolves are provided with slides made adjustable by means of screw gearing. A revolving sifter is fitted underneath the second pair of rollers, and works in bearings bolted to the underside of the framing of the machine; this sifter is composed of a number of gun-metal drums keyed upon a shaft, and its periphery is covered with copper wire, the whole being enclosed in a wooden casing. Underneath the sifter three sliding boxes are placed to receive the dust and small pieces which pass through the copper wire covering of the screen. At the end of the sifter a gun-metal traveling truck or carriage is provided, with four wheels adapted to run on V gun-metal rails fixed upon the floor; this carriage is capable of holding five wooden boxes, each about 18" square, into which the finished pebbles fall from the end of the sifter as it slowly revolves. A wooden hopper of sufficient width to cover the entire length of the rollers is provided for feeding the press-cake into the first pair, and a sheet copper casing is fitted to the second pair, with a spout at the bottom for conveying the pebbles into the sifter. All exposed parts, such as the ends of wrought-iron shafts, etc., are covered with recessed gun-metal washers securely fixed to them, and any others which may be made of iron or steel are covered with leather. All bearings are fitted with suitable lubricators, and channels or pipes for conveniently and efficiently lubricating the rubbing surfaces; and, as it is of the utmost importance that no oil or grease be permitted to come in contact with the powder, the bearings of the cutting rollers are fitted with sheet copper casings made in halves and hinged, so that the upper part can be lifted and the bearings cleaned. The copper casings at the geared end of the rollers are sufficiently large to contain the wheels and act as drip-pans. The pebbles from this machine, as well as the pellets from the hydraulic apparatus are generally taken to the glazing barrels, the treatment they there receive glazes them and also rounds off the sharp corners, thereby rendering them much better adapted for transport, storage etc. See *Gunpowder*.

PECTORAL.—Among the Romans, the poorer soldiers, who were rated under 1,000 drachmas, instead of the *lorica*, or brigantine (a leathern coat of mail) they wore a *pectoral*, or breast-plate of brass, about twelve fingers square. Some modern troops, such as the Cuirassiers, etc., wear pectorals for the direct purposes of defense and bodily protection; but, in general, small ornamental plates with clasps have been substituted.

PECULATION.—A term used in a military sense for embezzling public moneys, stores, arms, or ammunition. See *Articles of War*, 60.

PEDDOWK.—A tree which grows in the forests of Burmah and the Andaman Islands. It resembles mahogany in its color. It was formerly much used by the Burmese for gun carriages, and was introduced, some years back, into the gun carriage manufactory at Madras. A cubic foot of unseasoned wood weighs from 65 to 70 lbs.

PEDESTALS.—Props made of wood, and used for the support of stool beds of carriages when the elevating screws are removed.

PEDIEUX.—Coverings for the feet, used in the fourteenth century, and made of thin plates of steel or iron.

PEDOMETER.—An instrument for measuring walking distances. A common form consists of a string with a piece of lead at the end, and knotted at distances of 44 feet apart. It is to be used in connection with a seconds watch. Forty-four feet bears the same relation to an English statute mile (=5280 feet) that $\frac{1}{2}$ minute does to an hour; that is, the knots are $\frac{1}{120}$ of a mile apart. Drop the lead and allow the string to pass through the hand, the number of knots slipping through the hand indicate the rate of walking in the number of miles per hour. Small Pedometers, to be worn on the person, consist of a train of wheels in a small case, and a dial which registers the number of impulses derived from a cord attached to the foot. In this form it becomes a register of the number of *paces*. In Payne's English pedometer there is a repeating watch, which shows seconds minutes and hours; and also the day of the month. See *Odometer*.

PEDRO.—An early gun of large caliber, employed for throwing stone balls.

PEEL.—1. A small tower or fort. The term *Peel-house* is applied to any small fortified place. 2. To strip; to plunder; to pillage.

PEEL-TOWERS.—The name given to the towers erected on the Scottish borders for defense. They are square, with turrets at the angles, and the door is sometimes at a height from the ground. The lower story is usually vaulted, and formed a stable for horses, cattle, etc. For an account of these old towers, now mostly in ruin, see *History of Peebles-shire*, by W. Chambers, 1864.

PEE-MAH.—A tree which grows in India and Burmah, and is made use of in the Madras gun carriage factory for certain portions of gun carriages. It is a light and tough wood. There are two descriptions of it, red and white colored; the former is the tougher of the two. A cubic foot of unseasoned wood weighs from 50 to 52 lbs.

PEEP-SIGHT.—The basis of the sights used at Creedmoor in the most approved long-range rifles is the old-fashioned "peep and globe." To insure accurate shooting, the rear sight is made with a vernier

scale operated by a screw, by which an alteration of one-hundreth of an inch, and even of half that amount, can be made in the elevation, the result being exact, and recorded in figures—the only way in which a correct record of elevations can be kept. On the Remington rifle the divisions on the vernier are termed degrees and minutes, and on the Sharps decimals of an inch. On the former each minute is $\frac{1}{92}$ of an inch, and corresponds upon a 34-inch barrel with $1\frac{1}{18}$ of an inch, at each 100 yards. On the Sharps rifle each subdivision is $\frac{1}{100}$ of an inch, corresponding theoretically to $1\frac{1}{2}$ inch to every one hundred yards. As no man can hold or sight a rifle at 1 000 yards within ten inches, the elevation on both rifles is practically the same, or about two inches to each 100 yards for each subdivision on the vernier that is, twenty inches at 1,000 yards. The elevations on the Metford and Rigby rifles is about the same. The subdivisions upon the wind-gauge of both the

Remington and Sharps rifles are about $\frac{1}{40}$ of an inch, and are equivalent in practice to two inches at each 100 yards, or 20 inches at 1,000 yards, on the 34-inch barrel.

As the errors incident to aiming at long range will, in most cases, increase the effect of any alteration in the sights, care should be taken to keep well within the elevations which would be mathematically correct. It must also be recollected that the velocity of a bullet decreases with the distance, and as it loses its velocity it becomes more likely to be affected by currents of air. Consequently the effect of any change upon the sights is greater proportionately at long than at short range. The effect of wind, etc., increases in a still greater proportion, that which would require an alteration of 2 points in the elevation at 800 yards, requiring 2½ at 900, and 3 at 1,000. The best riflemen prefer to have the peep-hole of the rear sight of considerable size, as affording more light, and consequently allowing a better sight to be taken. In the Metford rear sight, discs having different sized apertures may be used; and it has been stated by some of the Irish team of 1874 that they have, in foggy or dark weather, done good shooting by removing the disc entirely, so as to leave an aperture of nearly a quarter of an inch. Every rifleman should, therefore, have an extra disc, with a large aperture, to use in dusky weather. The vernier sight is usually placed upon the small of the stock. General Dakin and others who shoot on their backs, have it placed upon the heel of the butt. When the latter is the case, it makes the distance between the two sights nearly a third greater than when placed upon the small of the stock, and consequently a proportionately greater allowance both for elevation and wind will be required.

PEETERS BULLET.—A form of bullet first used with the rifled musket by the Belgian infantry. It has a considerable cavity of a peculiar form. The metal of the projectile is left about the axis and projects downward, filling about one half of the forward half of the cavity. In consequence of the cavity, this bullet is somewhat lighter than the bullet for the rifle à tige.

PEISHWA.—The title of the personage third in rank and authority at the Court of the Mahratta Maharajahs of Satara, there being only the *Priti-nidhi* (Delegate of Rajah), between him and his Sovereign. However, during the weak reigns of Sevajee's descendants, the Minister increased in importance, till, about the commencement of the 18th century, Balajee Biswanath, the then Peishwa, and a man of distinguished administrative ability and diplomatic talents, made himself virtually the Ruler of the Mahrattas.

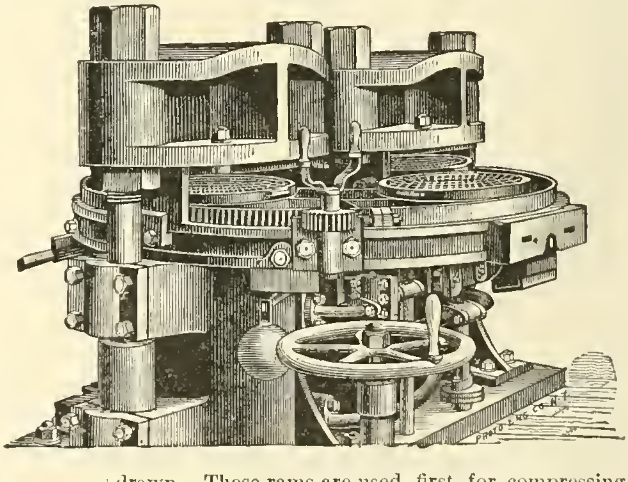
PELICAN.—In Heraldry, the pelican is drawn with wings indorsed, and wounding her breast with her beak. When represented in her nest feeding her young with her blood, she is called a pelican *in her piety.*

Pelican, in Heraldry.

PELLET.—1. An old word for shot or bullet. 2. In English Heraldry, a roundle sable. *Ogrees* has the same signification.

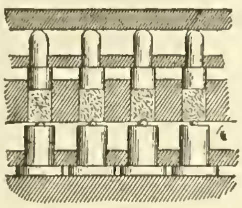
PELLET POWDER.—In consequence of the very great increase in the size of modern rifled cannon, and the large charges of gunpowder which have now to be used (from 300 lbs. to 500 lbs. being frequently employed), it soon became evident that some modification would have to be made in the description of gunpowder used. It was found that the ordinary large-grain powder hitherto adopted for small charges was not suitable for guns of large caliber, owing to the very rapid generation of the gases, and the inordinate strain to which the gun was thereby subjected. Extensive experiments were therefore carried out, with a view to determine the kind of powder that would give to the projectile a high initial velocity, and at the same time reduce the strain upon the gun to a minimum. This resulted in the adoption of a very large-grain powder called "pellet powder," which upon trial was found to give very remarkable results, as high an initial velocity as 1,600 per second being obtained, with a low pressure in the interior of the gun of not more than from 21 to 23 tons per square inch. These pellets are formed by compressing the powder meal into metal molds; various shapes and sizes were tried, some were flat discs, others prisms, but the shape which found most favor at first was the cylindrical pellet, 3-4" in diameter by ½" in length, and weighing 95 grains. Originally, these were made by hand, but it was soon apparent, that, if required in large quantities, machinery would have to be devised for their production; consequently a large machine of somewhat novel description, and capable of making 400 pellets at one time, was designed by Dr. John Anderson, and manufactured at Birmingham. This machine is worked entirely by means of hydraulic power derived from an accumulator, which affords a pressure equal to 1,000 lbs. per square inch.

This machine—which has given most excellent results—consists of two hydraulic cylinders, with a division in the center of each—thus, in reality, making four cylinders; in the two upper ones a plain cylindrical ram is fitted, which merely rises and falls as the water is admitted underneath the ram or is withdrawn.



These rams are used, first, for compressing the pellets, and second, for ejecting them, when finished, out of the mold plates. The two lower divisions are fitted with piston rams, securely attached to crossheads, which are united together, and also connected to two other crossheads above the cylinders by means of strong wrought-iron side rods, provided with collars working between lugs cast upon the hydraulic presses, and so adjusted as to allow only a certain limited travel either up or down. The upper crossheads can be adjusted to their exact positions by means of screwed threads and lock nuts on the upper end of the side rods. The use of the lower piston rams is to close the upper openings in the mold plates by bringing the top punches—which are connected to the upper crossheads by a gun-metal plate, down upon the mold plate, and thus confine the meal powder in the molds. The upper rams are now slowly raised, and these, acting upon the lower punches, compress the powder in the mold plate. After the proper density has been secured, the action of the lower rams is reversed, by which means both the lower and upper crossheads receive an upward motion, thereby raising the upper punches clear out of the way, so as to admit of the compressed pellets being ejected out of the mold plate, and this is done by giving a further upward motion to the two plain cylindrical rams. This will be better understood by referring to the enlarged view, where the mold plate—which is double—may be supposed to contain a charge of meal powder in the mold ready for compressing into a pellet. The lower part of the mold is closed by the lower steel punch that fits the mold very accurately, while the point of the punch rests upon the top surface of the plain cylindrical ram in the upper part of the hydraulic cylinder. The upper punch is also of steel, but much larger in diameter than the lower one.

To compress the powder in the mold, and form a pellet, requires four distinct movements of the machine. First, the upper punch is brought down until it rests upon the mold plate and closes the mold; this is effected by a downward motion of the two lower piston rams, to which the upper and lower



crossheads are connected together with the upper punches. Secondly, the lower punches are raised by the two upper plain rams, and the powder is compressed in the mold between the two punches. Thirdly, when the pellet is sufficiently compressed, the upper punches are raised from off the mold plate, this being done by reversing the action of the two lower piston rams until the upper crosshead and punches are at a sufficient height to admit of the compressed pellet being ejected out of the mold plate. This fourth and last operation of ejecting the pellet is effected by allowing the upper plain rams to rise still further, and thus force the finished pellet out of the mold by means of the lower steel punches. All these operations are simply and readily performed by means of a very ingenious arrangement of valves, the attendant having nothing to do beyond placing a handle in the several positions indicated on a dial. These valves are so constructed that the water power is admitted to the two presses simultaneously, whilst, by a self-acting arrangement, the pressure is shut off by the press itself when it has traveled the required distance. A relief valve is also provided, to allow any excessive pressure to escape should it accumulate from any cause, and this prevents damage happening either to the pipes or other parts of the apparatus.

It will thus be seen that a machine of this description is capable of easily making pellets of almost any shape, such as cylindrical, hexagonal, prismatic, or —what is possibly the best of all—spherical, by merely altering the form of the mold and punches. In the machine referred to, there are (on a revolving table, the framework of which is made of gun-metal) four mold plates fitted; each contains 200 holes, but as there are only two hydraulic presses to the machine, it follows that only two sets, or 400 molds, are under compression at one time, so that when we number these mold plates consecutively, then Nos. 1 and 3 will be under pressure whilst No. 2 and 4 are being filled. When the powder in Nos. 1 and 3 mold plate is sufficiently compressed, and the pellets formed therein have been removed, the entire table is turned one-fourth of the way round by means of a handle and toothed pinion working into corresponding teeth provided round the periphery of the gun-metal table, the revolving of which is much assisted by eight small anti-friction rollers fixed to the cast-iron frame of the machine; these rollers support the gun-metal table as it revolves upon its own center. Nos. 2 and 4 mold plates, which have been wholly filled with meal powder, are now brought under the crossheads of the machine and are in position for the powder contained therein to be compressed into pellets, whilst Nos. 1 and 3 in turn take their places to be refilled; the operation, therefore, of pressing and refilling are continuous, and the machine is capable of producing a large quantity of pebble powder per day, and with very little waste. See *Gunpowder*.

PELTA.—A small, light shield, sometimes attributed to the Amazons, but used by numerous nations of antiquity, such as the inhabitants of Thrace, Spain, and Mauritania, before its general introduction among the Greeks. It consisted mainly of a frame of wood or wicker-work covered with skin or leather, without the metallic rim, and of a great variety of shapes. It was sometimes round, as in the special case of the *Cetra*, sometimes elliptical, but most commonly crescent-shaped or lunated. Soldiers bearing the *pelta* were called *Peltastæ*.

PELTASTÆ.—Grecian soldiers who were intermediate between the *Oplitai* and the *Psiloi*. The peltast corresponded to our *élite* corps of infantry, selected for enterprises requiring both celerity and a certain firmness. The formation of the peltastæ and psiloi was analogous to that of the oplitai, the number of files being 8, instead of 16 as in the last. See *Oplitai*.

PEMMICAN.—This was originally a North American Indian preparation only, but it was introduced into the British Navy victualing-yards, in order to supply the arctic expeditions with an easily preserved food, containing the largest amount of nutriment in the smallest space. As made by the Indians, it consists of the lean portions of venison dried by the sun or wind, and then pounded into a paste, and tightly pressed into cakes; sometimes a few fruits of *amelanchier ovata* are added, to improve the flavor. It will keep for a very long time uninjured. That made for the arctic voyagers was chiefly of beef. In making pemmican, it is necessary to remove the fat completely.

PENAL SERVITUDE.—A punishment awarded by the Articles of War for certain crimes committed by soldiers.

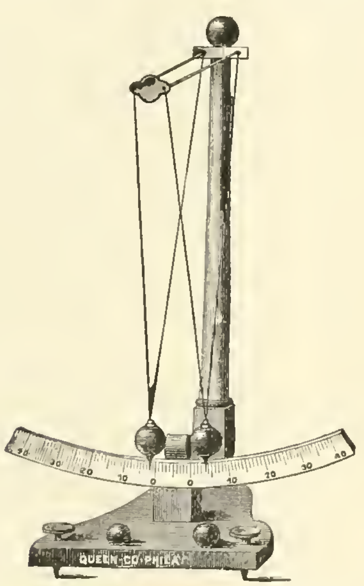
PENALTY.—A sum of money declared by some statute or contract to be payable by one who commits an offense or breach of contract. It is considered as a kind of punishment, and constituting indirectly a motive to the party to avoid the commission of the act which induces such a consequence. Many contracts executed between parties and government contain a clause that one or other of them who fails to perform his part of the contract will incur a penalty, *i.e.*, will be liable to pay a fixed sum of money to the other party. In such cases, a distinction is drawn between a liquidated and unliquidated penalty; and whether it is of the one kind or the other, depends on the language used in the contract. If it is a liquidated penalty, then, when the breach of contract is committed, the party in default must pay that precise sum, neither more nor less; but if it is unliquidated, then he is not to pay the whole sum, but merely such part of it as corresponds to the amount of injury or damage done, and of which proportion a jury is the sole judge in an action of damages.

PENCEL.—A small flag or streamer which was formerly carried at the top of a lance. Also called *Pennoncel*.

PENDANT—PENNANT.—1. In Heraldry, a part hanging from the label, resembling the drops in the Doric frieze. 2. A narrow flag of great length, tapering to a point, and usually carried at the head of the principal mast in a royal ship, to show that she is in commission. In the British Navy the Pendants are borne of three colors—red, white, or blue—according to the color to which the Admiral commanding the fleet pertains. On shore, Pendants are frequently employed at rifle ranges to indicate the strength and direction of the wind.

PENDULUM.—In its widest scientific sense, a pendulum is a body of any form or material which, under the action of some force, vibrates about a position of stable equilibrium. In its more usual application, however, this term is restricted, in conformity with its etymology, to bodies suspended from a point, or oscillating about an axis, under the action of gravity. The *simple* pendulum consists (in theory) of a heavy point or particle, suspended by a flexible string without weight, and therefore constrained to move as if it were always on the inner surface of a smooth spherical bowl. If such a pendulum be drawn aside into a slightly inclined position, and allowed to fall back, it evidently will oscillate from side to side of its position of equilibrium, the motion being confined to a vertical plane. If, instead of being allowed to fall back, it be projected horizontally in a direction perpendicular to that in which gravity tends to move it, the bob will revolve about its lowest position; and there is a particular velocity with which, if it be projected, it describes a circle about that point, and is then called a *conical* pendulum.

If the bob of the simple pendulum be slightly displaced in any manner, it describes an ellipse about its lowest position as center. This ellipse may, of



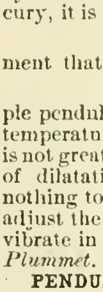
course, become a straight line or a circle. The bob does not accurately describe the same curve in successive revolutions; in fact, the elliptic orbit just mentioned rotates in its own plane about its center, in the same direction as the bob moves, with an angular velocity nearly proportioned to the area of the ellipse. This is an interesting case of *progression of the apse*, which can be watched by any one who will attach a small bullet to a fine thread; or, still better, attach to the lower end of a long string, fixed to the ceiling, a funnel full of fine sand or ink which is allowed to escape from a small orifice. By this process, a more or less permanent trace of the motion of the pendulum is recorded, by which the elliptic form of the path and the phenomena of progression are well shown. The very simple arrangement of apparatus, shown in the drawing, will be found convenient for the demonstration of the principles of pendulums, as also the laws of impact, both in elastic and non-elastic bodies.

It is readily seen that there should be no progression if the pendulum could be made to vibrate simply in a straight line, as then the area of its elliptic orbit vanishes. It is, however, found to be almost impossible in practice to render the path absolutely straight: so that there always is from this cause a slight rate of change in the position of the line of oscillation. But as the direction of this change depends on the direction of rotation in the ellipse, it is as likely to effect the motion in one way as in the opposite, and is thus easily separable from the very curious result obtained by Foucault, that on account of the earth's rotation, the plane of vibration of the pendulum *appears to turn* in the same direction as the sun, that is, in the opposite direction to the earth's rotation about its axis. To illustrate this now well-known case, consider for a moment a simple pendulum vibrating at the *pole* of the earth. Here, if the pendulum vibrates in a straight line, the direction of that line remains absolutely fixed in space, while the earth turns round below it once in 24 hours. To a spectator on the earth, it appears, of course, as if the plane of motion of the pendulum were turning once round in 24 hours, but in the opposite direction. To find the amount of the corresponding phenomenon in any other latitude, all that is required is to know the rate of the earth's rotation about the vertical in that latitude. This is easy, for velocities of rotation are resolved and compounded by the same process as forces, hence the rate at which the earth rotates about the vertical in latitude λ is less than that of rotation about the polar axis in the ratio of sin. λ to 1. Hence the time of the apparent rotation of the plane of the pendulum's motion is $\frac{24 \text{ hours}}{\sin \lambda}$. At the pole, this is simply 24 hours; at the equator, it is infinitely great, or there is no effect of this kind; in the latitude of Edinburgh (56° 57′ 23.2″), it is 28 hr. 37 m. 48 seconds.

We have not yet alluded to the obvious fact, that a *simple* pendulum, such as we have described above, exists in theory only, since we cannot procure either a single heavy particle, or a perfectly light and flexible string. But it is easily shown, although the process cannot be given here, that a rigid body of any form whatever vibrates about an axis under the action of gravity, according to the same law as the hypothetical simple pendulum. The length of the equivalent simple pendulum depends upon what is called the radius of gyration of the pendulous body. Its property is simply this, that if the whole mass of the body were collected at a point whose distance from the axis is the radius of gyration, the moment of Inertia of this heavy point (about the axis) would be the same as that of the complex body. The square of the radius of gyration of a body about any axis, is greater than the square of the radius of gyration about a parallel axis through the center of gravity, by the square of the distance between those lines. Now, the length of the simple pendulum equivalent to a body oscillating about any axis is directly as the square of the radius of gyration, and inversely as the distance of the center of gravity from the axis. Hence, if k be the radius of gyration of a body about an axis through the center of gravity, $\sqrt{k^2+h^2}$ is that about a parallel axis whose distance from the first is h; and the length, l, of the equivalent simple pendulum is $l=\frac{k^2+h^2}{h}$. This expression becomes infinitely great if h be very large, and also if h be very small (that is a body vibrates very slowly about an axis either far from, or near to, its center of gravity). It must therefore have a minimum value. By solving the equation above as a quadratic in h, we find that l cannot be less than $2k$, which is, therefore, the length of the simple pendulum corresponding to the quickest vibrations which the body can execute about any axis parallel to the given one.

As the length of a rod or bar of any material depends on its temperature, a clock with an ordinary pendulum goes faster in cold, and slower in hot, weather. Various contrivances have been devised for the purpose of diminishing, if not destroying, these effects. The most perfect in theory, though perhaps not the most available in pratice, is that of Sir D. Brewster, founded upon the experimental discovery of Mitscherlich, that some crystals *expand* by heat in one direction, while *contracting* in the perpendicular one; and therefore that a rod may be cut out of the crystal in such a direction as not to alter in length by any change of temperature. In the method of correction usually employed, and called *compensation*, advantage is taken of the fact that different substances have different coefficients of linear dilatation; so that if the bob of the pendulum be so suspended as to be raised by the expansion of one substance, and depressed by the expansion of another, the lengths of the effective portions of these substances may be so adjusted that the raising and depression, taking place simultaneously, may leave the position of the bob unaffected. There are two common methods of effecting this, differing a little in construction, but ultimately depending on the same principle. Of these, the *mercurial* pendulum is the more easily described. The rod and framework are of steel. Inside the framework is placed a cylindrical glass jar, nearly full of mercury, which can be raised or depressed by turning a nut. By increase of temperature, the steel portion is lengthened by an amount proportional to its length, its coefficient of linear dilatation, and the change of temperature, conjointly—and thus the jar of mercury is removed from the axis of suspension. But neglecting the expansion of the glass, which is very small, the mercury rises in the jar by an amount proportional to its bulk, its coefficient of cubical dilatation, and the change of temperature, conjointly. Now, by increasing or diminishing the quantity of mercury, it is obvious that we may so adjust the instrument that the length $\left(\frac{k^2}{h}\right)$ of the equivalent simple pendulum shall be unaltered by the change of temperature, whatever be its amount, so long as it is not great enough to sensibly change the coefficients of dilatation of the two metals. The screw has nothing to do with the *compensation*, its use is to adjust the length of the pendulum so that it shall vibrate in one second. See *Bob*, *Gun-pendulum*, and *Plummet*.

PENDULUM-HAUSSE.—A contrivance used to point field-pieces, and at the same time to obviate the error which arises when the wheels of the carriage stand on uneven ground. It consists of a *scale* and *slider*. The scale is made of sheet-brass; at the lower end is a brass bulb filled with lead. The slider is of thin brass, and is retained in any desired position on the scale by means of a brass set screw with a milled head. The scale is passed through a slit in a piece of steel, with which it is connected by a brass screw, forming a pivot on which the scale can vibrate laterally; this slit is made long enough to allow the scale to take a vertical position in any ordinary inequality of the ground on which the wheels of the carriage are required to stand; the ends of this piece of steel form two journals by means of which the scale is supported on the seat attached to the piece, and is at liberty to vibrate in the direction of the axis of the piece. The *seat* for suspending the pendulum-hausse upon the piece is screwed to the base of the breech in such a manner that the centers of the two journal notches shall be at a distance from the axis equal to the greatest exterior radius of the base of the breech. The height of the front-sight being equal to the dispart of the piece, a line from the top of the muzzle-sight to the zero, which is the pivot of the scale, is parallel to the axis of the piece; hence the vertical plane of sight passing through the center line of the scale and the top of the muzzle-sight, will be parallel to the axis in any position of the piece; the scale will therefore always indicate correctly the angle which the line of sight makes with the axis. The hausse, the seat, and the muzzle-sight, vary, in their construction and arrangement, with the piece for which they are intended. The graduations on the scale are the tangents of each quarter-degree to a radius equal to the distance between the muzzle-sight and the center of the journal-notches, which are in all cases one inch in rear of the highest point of the base of the breech.



PENETRATION OF PROJECTILES.—The most common substances encountered by projectiles are arranged in the following series, in the order of their resistance to penetration: *air*, *water*, *sand*, *wood*, *lead*, *copper*, *wrought-iron*, *soft steel*, *cast-iron*, *chilled-iron*, *hardened steel*, etc. All other substances may be arranged between these, or in continuation of the series. *Air* opposes the motion of a projectile by its inertia, elastic force, and the pressure due to its weight. The projectile compresses the air in its front and disperses it laterally, while the rear of the projectile is relieved by its motion of the normal pressure of the air. A small amount of resistance is also met with in the shape of friction. In the case of *water* these resistances are increased by the greater density and weight of this substance, and there is also a slight additional resistance due to the cohesion among the particles. *Sand*, being a solid, or at least made up of solid elements, presents the additional resistance of "crushing-strength." It cannot be penetrated at a high velocity without crushing some of the grains, and the higher the velocity the greater the amount of work expended in this manner. This resistance to crushing implies a continuation of the elastic force beyond the elastic limits, and involves indirectly tensile strength, since a solid in being crushed must enlarge laterally and finally yield to a strain of tension. In penetrating *wood*, *lead*, or any of the other materials, "tensile strength" forms the chief element of the resistance, while inertia and friction become of minor importance.

The office of elasticity in all these cases is to transmit the effect of the projectile from those particles first acted upon to those more remote, and thus calling into play their inertia or tensile strength, as the case may be; and were it not for this property, the statical resistance of a plate of any material to perforation would be entirely independent of the thickness of the plate; a thick plate would offer no greater resistance than a thin one, since each layer or unit of thickness would be perforated without receiving any assistance from its neighbors. The *work* of penetration would then vary directly with the distance penetrated, or the thickness of the plate; elasticity, however, has its maximum point of usefulness in resisting penetration, and beyond this it becomes a great disadvantage. While increasing the number of fibers or elementary portions of the material broken at once, thereby increasing the statical resistance, it diminishes the time during which this resistance opposes the motion of the projectile in like ratio; and the amount of motion destroyed or generated increases with the time as well as with the force or resistance. For this reason hardened steel and chilled iron are less efficient in stopping projectiles than soft iron, although they offer a much greater statical resistance to penetration. There are many reasons for believing that a general formula for the penetration of projectiles in all materials may be deduced, when experiments have been sufficiently extended, in which the constants will simply require changing to suit any particular case under consideration.

That the penetration of an elongated projectile is influenced by the form of its head has been shown by experiment, many different forms of head having been tried. The flat head has been strongly advocated, because it is asserted to be a better form for punching than any of the pointed heads, and because it is also asserted that it will bite into an iron plate at such an oblique angle as would cause a pointed head to merely glance. But the truth of these assertions has not been generally admitted. The flat-headed projectile is objectionable both as regards accuracy and velocity, and it has also a tendency to upset or bulge at the head on impact, and this result is very marked. The pointed projectile is superior in accuracy and range, and does not upset on impact to any thing like the same extent. It is asserted that it cuts through an iron plate to a better advantage, or rather tears through, bending back the plate.

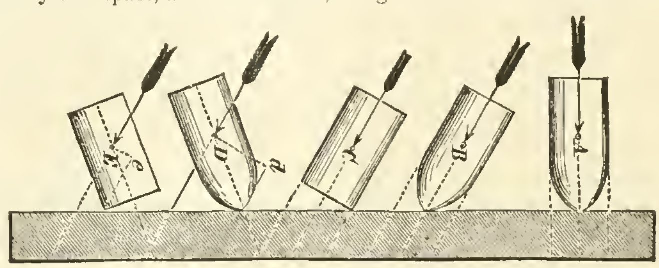
Another point in connection with the penetration of elongated projectiles is the effect of different forms of head upon the rotation of the projectile when the impact is oblique. If the axis of the projectile is tangent to the trajectory on impact, and at the same time normal to the target, there will be no tendency to rotate about any axis parallel with the plane of the target. In the drawing, if we suppose a projectile to arrive at A, under these conditions it will undoubtedly penetrate the plate directly. But let one arrive at D or E, and there will be a tendency to rotate, and this tendency will depend upon the form of the projectile as well as upon the angle between the trajectory and its axis.

It is often asserted, however, that the advantage in the latter case will be in favor of the flat-headed projectile, since the moment of the rotating-force will be the variable resistance of the plate multiplied by the lever arm *Dd*, for the pointed projectile, and the same multiplied by a much shorter lever arm, *Ee*, in case of the flat-headed projectile, and this may be negative; or in other words, there may be a tendency to rotate towards the normal, which would be a decided advantage. This would take place when the line of the trajectory passed within the base of the shot. In the third case, represented at B and C, a projectile is moving with its axis tangent to the trajectory, but oblique to the target; here there is also a tendency for the flat-headed projectile to rotate toward the normal, but it is questionable whether such rotation would be advantageous. The pointed projectile would have a less tendency to such rotation.

On the other hand, the respective motions of a flat and pointed headed projectile on oblique impact are explained as follows: It is asserted that the flat-headed projectile, on striking, cuts out a portion of the face of the plate, which it carries along in front, thus increasing the thickness to be penetrated; and, remaining nearly parallel to its original direction, it has to pass through the plate obliquely. While, if the projectile has a pointed head, the point enters at first more deeply into the plate than the flat head, and the center of gravity moving forward, the projectile turns around more readily than with the latter, so that its axis becomes perpendicular, or nearly so, to the face of the plate, having then only the least thickness to penetrate.

It is difficult to obtain for comparison the results of practice with the flat and pointed headed projectiles of the same material fired at targets inclined to the line of the range; the former having been so little used, as its form is so objectionable, both as regards accuracy and velocity. On the whole, it may be said that in the case when the projectile ought to be capable of piercing the plate or target, there is little difference between the effect of a flat head and a hemispherical head; but when the target is beyond the power of the projectile, the hemispherical head makes the deepest indent.

The impact of a projectile, in addition to indenting or penetrating a target, produces more or less bending, tearing, and other damage at a distance from the point of impact; which effects may be classed under the term "Concussion." The effect of concussion is transmitted from the point of impact in all directions, in the same manner as sound-waves, and increases with the elasticity of the material. Whatever tends to diminish the elasticity of the structure, as dividing it into many pieces, or using soft ductile material to receive the projectile, will diminish the effect of concussion. This effect is expended in two ways—*First*, in giving motion to the structure or in developing inertia; and, *Second*, in overcoming the tenacity of the material, either in bending or tearing those portions first acted upon from those more remote. Both of these components increase with the whole amount of work expended by the projectile, other conditions being equal. See *Impact of Projectiles* and *Projectiles*.



PENETRATIVE EFFECT.—Generally speaking, the penetrative effect depends on the shape and material of the projectile, on its energy and diameter, and the direction with which it strikes the target. It is quite impossible to accurately determine the coefficients of resistance for the different materials of projectiles and plates; but practically the amount of penetration, whether for iron or steel plates, or masonry, or earth, may be determined by experiment. Various empirical laws suffice to give approximate results; but they do not stand the test of any general application. In consequence of the varying qualities of resistance both in projectiles and targets, the variation in shape of the projectile on impact, the possibility of the projectile breaking up, and the amount of heat developed on impact, strictly analytical investigations cannot be made. If V is the velocity required for a projectile to pierce an armor-plate with right-angled impact, its energy per inch of circumference (See *Energy*) is $\frac{WV^2}{2g.\pi d}$. But if the projectile strikes obliquely at an angle A, then, if it turns in on its point and perforates *normally*, it is readily seen that the velocity for perforation must be $\frac{V}{\text{Sin } A}$, and consequently the energy per inch of circumference for oblique perforation will be $\frac{WV^2}{2g\pi d.\sin^2 A}$;

that is the number of foot-tons per inch of circumference to perforate an armor-plate obliquely is found by dividing the number of foot-tons required for perforation by right-angled impact by the square of the sine of the angle of impact. If the projectile goes straight through the plate without turning in, the energy per inch of circumference for oblique perforation will be $\frac{W V^2}{2g \pi d. \text{ Sin } A}$

In this case we would have best results for flat-headed projectiles and comparatively thin armor-plates.

The results of experiment show that the amount of penetration is directly proportional to the product of the weight of the projectile. multiplied by its velocity raised to powers that vary but little from unity for the different resisting bodies. The penetration into masses, such as earthen parapets and thick plates, is inversely proportional to the area of cross-section of the projectile. From these deductions we obtain the expression $W = \frac{p v}{d^2}$ in which W, called the penetrative effect, is taken as a measure of the projectile's power, p = weight of the projectile in pounds, v = velocity of impact in feet. d = diameter of shot in inches. Letting S = penetration of the shot in inches, we have (1) $S = \frac{1}{A} \cdot \frac{p v}{d^2} = \frac{W}{A}$, A being a coefficient, depending upon the shape of the projectile and the nature of the resisting substance, to be determined by experiment. For the best quality of wrought-iron plates, subjected to the action of ogival projectiles of steel or chilled cast-iron, the above formula may be used. For plates not exceeding $2\frac{1}{2}$ inches in thickness A = 575, whence (2) $S = \frac{W}{575}$. For plates of a greater thickness than $2\frac{1}{2}$ inches (3) $S = \frac{W}{360} - 1.5$ inches. For plates not exceeding 20 inches in thickness, this formula gives results closely approximating those determined by experiment. The depth to which a projectile will bury itself in a resisting body, which is too thick to be perforated, is less than the thickness of the obstacle that it will just pass through. For example, the shells of the 2.76 inch Italian field-gun, at 1,000 yards range, pass through a brick wall 1.97 feet thick, but only penetrate 1.66 feet into a similar wall 3.94 feet thick. In speaking of the penetration into masses of earth, wood, or masonry, the depth of penetration is meant, and S in formula (1) gives the number of inches the projectile will bury itself in a resisting body too thick to be perforated. The thickness of plate that the projectile can just pass through is generally taken as a measure of the power of guns against iron plates, and S in formulas (2) and (3) has this signification. The penetration of a projectile depends not only on its velocity, but also upon the direction in which it strikes the object, the component of the velocity normal to the surface struck determining the penetration. In this case the cosine of the angle of incidence should be introduced.

To find the penetrating power of a projectile, at any point of its flight, into armor-plates, the empirical formula of Major Noble, of the Royal Artillery. is used ·

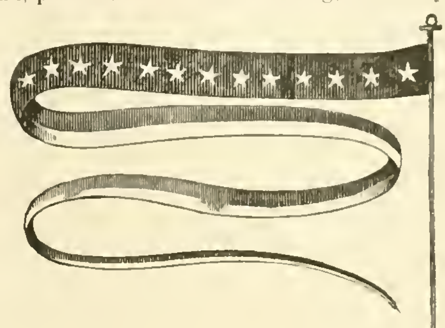
$$b = v \left(\frac{W}{4 r R g k} \right)^{\frac{1}{2}}$$

in which, b = penetration in feet; v = velocity on impact, in feet per second; W = weight of shot, in pounds; r = ratio of diameter to circumference of circle, 3.14159; R = radius of shot, in feet; g = force of gravity, 32.16 pounds; k = a co-efficient determined by experiment, depending on the nature of the wrought-iron in the plate, and the nature and form of the head of the shot. For a spherical projectile against an unbacked plate, (k) is 5,357,200. For an ogival headed projectile against a backed plate (k), is assumed to be 4,821,480. The plate is considered to be vertical, and the trajectory to be in a plane perpendicular to the plate. Should the shot strike the plate obliquely, the value of (b) determined as above, must be multiplied by the sine of the angle of incidence. For a given projectile and a plate of known thickness, the work required to produce penetration will be found from the equation placed under the form, $\frac{W v^2}{2g} = 2 r R k b^2$; and the velocity needed at impact, from the same equation solved with reference to (v).

PENNATED DAGGER.—An Italian *main gauche* with three blades expanding by means of a spring when a button was pressed in the handle, and forming a guard of great length and breadth, in which the adversary's sword might be caught and snapped.

PENNETIÈRE.—A pocket or small bag in which slingers carried stones and leaden balls. Also written *Panetiere*.

PENNON.—1. Formerly a copper wing of a long, light arrow (*Vireton*) substituted for a feather. 2. A small, pointed, or swallow-tailed flag, carried by the



mediæval knight on his lance, bearing his personal device or badge, and sometimes richly fringed with gold. The device was so placed as to appear in its proper position when the weapon was laid for the charge. *Pennoncelle* is a long streamer-like flag, the diminutive of the pennon. See *Flags*.

PENSIONS. — In the United States pensions are most generously granted by Act of Congress in the many cases of persons who have seen active service in the Army or Navy, and who have been honorably discharged. They are also awarded to widows, orphans, or other persons dependent on those instanced above. The existing pension-list of the United States includes those which have been granted for account of services rendered in the War of 1812; the Mexican War, and the War of the Rebellion. For the laws governing the distribution of pensions, and their amounts, etc., see *Revised Statutes of the United States*.

In England, pensions are awarded for good service, for mere faithful ordinary service, for wounds, and to representatives of deceased officers. *Good-service Pensions* are rewards to selected Officers in the British Navy for distinguished service. In 1873 they were as follows: 12 Admirals had £300 each, 25 Captains £150, 1 General of Marines £300, 5 do. £200, 2 Colonels £150, and 5 Medical Officers £100: total £9,150. In 1875-76 the total was £7,500. The corresponding pension in the Army is called a Reward for Distinguished Service.

The *Pensions for Long Service* are awarded in the army to Non-commissioned Officers and Soldiers who have served 21 years in the infantry, or 24 years in the cavalry, or earlier if disabled from further service, according to the wounds, loss of health, and conduct of the pensioner. The amount is fixed by the Commissioners of Chelsea Hospital, and varies from 1½d. to 3s. 6d. a day, the lower rates being mainly confined to Negro Pensioners from the West India regiments. Pensioners are either In-Pensioners of Chelsea, or Kilmainham Hospitals, in which case they forego their proper pensions, and receive board, lodging, and a small sum for tobacco-money, or Out-Pensioners residing where they please, and drawing their pensions from the Staff Officers of Pensioners, of whom there is one in every considerable town. These men can follow other pursuits, often do so with very great success, as their military habits of regularity stand them in good stead in civil life.

Pensions for *Wounds* are common to both services, and are limited to officers. They are awarded respectively by the Secretary of War and Lords of the Admiralty, for serious bodily injury, as the loss of a limb or eye, and vary according to the rank of the recipient and other circumstances. In cases of serious injury, temporary pensions are sometimes granted, or gratuities. The charge for Pensions for Wounds for 1875-76 was—army, 172 recipients, £16,-453; navy, 85 recipients, £9,036; total; £25,479. In the case of Common Soldiers and Sailors, wounds may serve to hasten or augment the pension for service, but they have no distinctive Pension for Wounds.

Widows of Commissioned and Warrant Officers in the army and navy receive pensions so long as they remain unmarried, provided they have been married severally twelve months when their husbands die, and that the latter were under 60 years of age (50 for Warrant officers) when they married the Claimants. Such pension is not granted if the widow be left in wealthy circumstances, and lies dormant during a second marriage, though it may be revived should she again become a widow. The amount of pension varies according to rank, and there are three distinct classes for each rank: 1st, When the husband was killed in the battle, or died within six months of wounds received therein; 2d, When he died from some cause distinctly falling within the sphere of his duty, but not from wounds in action; 3d, When he died in the course of nature.

In an elaborate opinion given by Mr. Attorney-General Cushing, published by the War Department in General Orders, No. 11 of 1855, he draws the conclusion that "the phrase 'line of duty' is an apt one, to donote that an act of duty performed must have relation of causation, mediate or immediate, to the wound, the casualty, the injury, or the disease producing disability or death." Every person (says Mr. Cushing) who enters the military service of the country—officer, soldier, sailor, or marine—takes upon himself certain moral and legal engagements of duty which constitute his official or professional obligations. While in the performance of those things which the law requires of him as military duty, he is in the line of his duty. But at the same time, though a soldier or sailor, he is not the less a man and a citizen, with private rights to exercise and duties to perform; and while attending to these things he is not in the line of his public duty. In addition to this, a soldier or sailor, like any other man, has the physical faculty of doing many things which are in violation of duties either general or special; and in doing these things he is not acting in the line of his duty. Around all those acts of the soldier or sailor which are official in their nature the pension laws draw a legislative line, and then they say to the soldier or sailor: If, while performing acts which are within that line, you thereby incur disability or death, you or your widow or children, as the case may be, shall receive pension or allowance; but not if the disability or death arise from acts performed outside of that line; that is, absolutely disconnected from, and wholly independent of, the performance of duty. Was the cause of disability or death a cause within the line of duty or outside of it? Was that cause appertaining to, dependent upon or otherwise necessarily and essentially connected with, duty within the line; or was it unappertinent, independent, and not of necessary and essential connection? That is the true test-criterion of the class of pension cases under consideration.

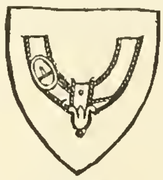
PENSTOCK.—A machine composed of timber, which, by means of a movable board, enables the defenders of a fortress to allow such a rush of water from the batardeaux as to inundate and destroy the works which the enemy may have constructed in the ditch.

PENTAGON.—In fortification, a figure bounded by five sides, which form so many angles, capable of being fortified with an equal number of bastions.

PENTATHLON.—The five exercises performed in the Grecian games, namely, leaping, running, quoiting, darting, and wrestling.

PENTHOUSE.—1. A shed hanging forward in a sloping direction from the main wall of a place. 2. A small house, made of boards united by hooks and staples, for protecting a gun and its carriages mounted *en barbette* from the weather.

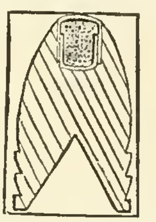
PEON.—In India, a term formerly given to a foot-soldier, but in these days it does not bear this signification. Native servants or messengers attached to the Government offices in India are designated Peons, and wear a belt with a brass plate bearing the name of the office to distinguish them from private servants.



Perclose.

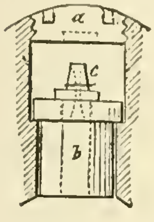
PERCLOSE.—PERCLOSE or DEMI-GARTER, in Heraldry, is the lower half of a garter with the buckle.

PERCUSSION BULLETS.—Percussion bullets may be made by placing a small quantity of percussion powder, enclosed in a copper envelope, in the point of an ordinary rifle-musket bullet, or by casting the bullet around a small iron tube, which is afterward filled with powder and surmounted with a common percussion-cap. The impact of the bullet against a substance no harder than wood is found to readily ignite the percussion charge or cap, and produce an effective explosion. These projectiles can be used to blow up caissons and boxes containing ammunition at very long distances. See *Bullet* and *Projectiles*.



PERCUSSION CAPS.—Small copper cylinders, closed at one end, for conveniently holding the detonating powder which is exploded by the act of percussion in percussion-arms. Caps were not used with the earliest percussion-arms, which the Rev. Mr. Forsyth, of Belhelvie, Aberdeenshire, patented in 1807; but they became tolerably general between 1820 and 1830, and were adopted for the army by 1840. With the adoption of breech-loading arms, the use of *separate* caps has been discontinued. The cap now forms a part of the cartridge, and at one operation is placed with it in the opened breech of the gun. The manufacture is extremely simple: A sheet of thin copper is stamped into pieces of appropriate shape, which are bent into the form of caps by stamping-apparatus closing round a mandril, the whole being done in one machine by two operations. The caps are then placed in a tray, mouths upward; and the inside of each is touched with a strongly adhesive varnish. Over this is dusted the detonating powder, all the particles which fail to adhere being blown, dusted, or shaken out. A stamper once more is forced into the cap, to fix and compress the powder, and the operation is completed. For muskets, the caps are charged with equal parts of fulminating mercury and chlorate of potash; for cannon, with a mixture composed of two parts of chlorate of potash, two parts of native sulphuret of antimony, and one of powdered glass; the last ingredient taking no part in the chemical action, and being added merely to increase the friction. See *Center-fire Metallic-case Cartridge*, and *Lock*.

PERCUSSION FUSE.—A percussion-fuse explodes by the striking of some particular point of a projectile against an object, as in the case of rifle-cannon projectiles. One of the best and simplest forms of this kind of fuse is the ordinary percussion-cap placed on a cone affixed to the point of the projectile. The piece to which the cone is attached may be fixed or movable; in either case, the apparatus should be covered with a safety-cap to prevent the percussion-cap from taking fire by the discharge of the piece. The drawing represents a fuse of the percussion kind, in which *b* is a movable cone-piece, bearing a musket-cap (*c*); and *a* is the safety-cap which covers the fuse-hole. When the projectile is set in motion, the cone-piece, or "plunger," by its inertia, presses against the shoulders of the fuse-hole; when its motion is arrested, the inertia of the cone-piece causes the percussion-cap to impinge against the safety-cap, which produces explosion. The explosion of the projectile may be made to take place at any desired time, after the explosion of the cap, by interposing grain, or mealed powder, between the cap and bursting charge. Experience has shown that the plunger should be enclosed in a tight metal case to prevent it from being fouled by the action of the powder; and to prevent premature explosions, the cone-piece should be confined by a screw or other device, to prevent it from moving until the projectile strikes its object.



The essential requirements of a good percussion-fuse are: that it should not be ignited by the shock of discharge or on striking water; that it shall be ignited on the impact of a shell against the object, and that it may not be liable to explode by handling or during transport. The percussion-fuse has many points in its favor: it assures the bursting of the projectile; it can be used for all ranges, be they never so great; it admits—a very important desideratum in war—of estimating distances, and of correcting the error of the estimation; it augments the result of firing by adding great moral to physical effect, due to the explosion of the projectile in the midst of the enemy. Its only inconvenience is its inability to cause the bursting of the projectile before it has touched the object, thus rendering the effects of fire dependent upon the nature and conformation of the target at the point of impact. See *Fuse*.

PERCUSSION-LOCK.—A lock of a gun in which gunpowder is exploded by fire obtained from the percussion of fulminating powder. Before the invention of friction-tubes, percussion caps or wafers were used in connection with a lock, which was screwed to the body of field pieces, and to the lock-pieces in heavier ordnance. The percussion powder was placed in a thin layer between two circular pieces of cartridge-paper, united by glue, pressed firmly together, dried and varnished with any water-proof varnish forming the *wafer*. The *caps* were made by forming the wafer at the bottom of a paper cap which fitted on the end of the lock hammer.

PERCUSSION-POWDER.—Powder composed of such materials as to ignite by slight percussion; fulminating powder. See *Gunpowder*.

PERCUSSION-PRIMERS.—The percussion-primer has a wafer or flat-head attached to a quill-barrel. The process usually observed in selecting the material and manufacturing the primers is as follows: Each quill must be clarified and furnish a barrel at least two and a half inches long. The barrel is to be round, free from flaws, pith, and brittleness occasioned by clarifying, or any other defect which may render it unfit for the purpose required. It must not exceed in diameter nineteen-hundredths of an inch at any part, nor be less than seventeen-hundredths of an inch, within one and one-half inches of the end that is cut from the quill. The small end must not be broken or bruised. Cut the barrels of the quills close from the feather, and insert them into the socket of a wooden block made two inches deep and two-tenths of an inch in diameter. A punch, having ten cutters radiating from the stem, is entered into each quill-barrel, and driven down with a smart tap, so as to slit the upper end of the barrel into ten prongs, and as far as the upper surface of the block permits. Turn back the prongs, so that they will lie on the surface of the block; a circular punch is applied to each, and made by a blow to cut off the prongs to its own diameter (0.52 inch). Very stout paper, previously prepared by two coats of shellac-varnish (gumlac dissolved in alcohol), is punched with holes 0.17 inch in diameter, and so arranged as to correspond with the sockets of the wooden block. The quill-barrels are freed from pith, the punched paper laid on the block, the holes corresponding and the varnished side up, the quill-barrels put through the paper into the sockets of the block, filled with grained powder, seven grains Troy, and pressed firmly down with their prongs flat on the varnished side of the sheet of stout paper. Brush the shellac-varnish over the spaces of paper between the heads of the quill-barrels, and spread a sheet of good writing-paper, slightly moistened with water, over the entire surface of the stout sheet and the prongs of the quills. Put the block and the sheets thus stuck together, with the quill prongs between them, into a press, apply a force of about thirty tons, and keep them long enough to set the prongs and make the sheets of paper adhere firmly. Each quill is separated from the card by means of a circular punch, which cuts out a disc 0.62 inch in diameter, and of course includes the prongs enclosed between them. A stellated disc to cover the head of the primer is punched out of linen-made paper of the finest and closest fabric. This disc has twelve points—diameter from exterior points, 1.25 inches, from interior 0.7 inch. Metal plates are at hand with superficial recesses about 0.65 inches in diameter. On each of these a stellated cover is placed, and four grains of fulminate deposited on it. This is composed of five parts of fulminating mercury and one of mealed powder, both dry. Place the head of the primer on the charge of fulminate, holding it by the quill-barrel and pressing it down firmly; brush good wheat-paste on the points of the cover and on the under surface of the head, turn the points over, and unite them neatly and closely on the paper head. The primer is now made and only requires to be protected from moisture. For this purpose, shellac is dissolved in alcohol, so as to be thin enough to be laid on with a brush. This is of a brownish yellow; a portion is prepared with lamp-black. Coat over the the quill-barrel with shellac, then the under side of the wafer with the black shellac-varnish. Then shellac the upper surface of the wafer. Tip the end of the quill-barrel with black varnish, and apply a second coat of uncolored shellac thickly about the primer. See *Friction-primers*.

PERCUSSION-WAFER.—The earliest percussion-primers in use were made in the form of wafers. The wafer was placed in the vent of the piece, the metal of the gun being cut away in such a manner as to form a recess at the exterior orifice of the vent, in which the wafer was deposited, and exposed to the direct action of the hammer.

PERDU.—A word adopted from the French, signifying to lie flat and closely in wait. It likewise means employed on desperate purposes; accustomed to desperate enterprises.

PERER.—An old form of gun, used mostly on ships, for throwing stone-shot.

PERFORATED DISC GUNPOWDER.—Compressed gunpowder, perforated with a certain number of holes. From the excessive pressure given to the discs, the powder burns slowly; it has been, and is still used for discharging rifled ordnance by some foreign artilleries. In the British artillery it is not used. See *Gunpowder*.

PERJURY.—The crime committed by one who, when giving evidence on oath as a witness in a Court of Justice, or before some constituted authority of the same kind, gives evidence which he knows to be false. But in order to make the giving of the false evidence liable to criminal punishment, it must have been not only false to the knowledge of the witness, but the matter must have been material to the issue raised. If the falsehood occurred as to some trifling or immaterial fact, no crime is committed. Moreover, it is necessary, in proving the crime, that at least two persons should be able to testify to the falsehood of the matter, so that there might be a majority of oaths on the matter—there being then two oaths to one. But this rule is satisfied though both witnesses do not testify to one point. The perjury must also have taken place before some Court or Tribunal which had power to administer the oath. Though in some Courts affirmations are allowed instead of oaths, yet the punishment of false affirmation is made precisely the same as for false swearing. The punishment for perjury was, before the Conquest, sometimes death or cutting out the tongue; but, latterly, it was confined to fine and imprisonment, and at present the latter is the only punishment, with the addition of hard labor. The crime of subornation of perjury—*i. e.*, the persuading or procuring a person to give false evidence, is also punishable as a distinct offense.

PERKERNUCKA.—An Indian term for Petty Officers.

PERMANENT ANGLE.—It is always important that the gunner should be able to aim directly at the object, so as to reduce the *personal equation* to a minimum. But in consequence of the deviation due to the rifling, there is always a deflection from the line of sight. To avoid this, the rear sight is set at a *permanent angle* of deflection, so that, no matter how much it is raised, the line of sight will always pass through the object. The formula for determining the angle for each range is

$$\tan A = \frac{\text{deflection}}{\text{range}} \times \text{cosec. elevation.}$$

Let $b\,c$ represent a perpendicular rear sight, and f the front sight of the gun; then $b\,f\,t$ represents the

line of sight, the gun being laid on the target, t, at the angle of elevation, $b\,f\,c = e$. Suppose s to be the point where the shot falls, then $t\,s$ measured at right angles to the line of sight, represents the deflection of the shot. Join $s\,f$, produce it to a, draw $b\,a$ at right angles to $b\,t$, and join $a\,c$; now a is the point at which the head of the rear sight should be placed in order to compensate for the deflection $t\,s$; and $a\,c\,b = A$ is the angle of deflection required. Let the range $f\,t$ equal r, and the deflection $t\,s$ equal d. Now, in the similar triangles,

$$\frac{ab}{bf} = \frac{st}{tf} = \frac{d}{r};$$

but, $ab = bc \tan A$, and $bf = bc \operatorname{cosec} e$,

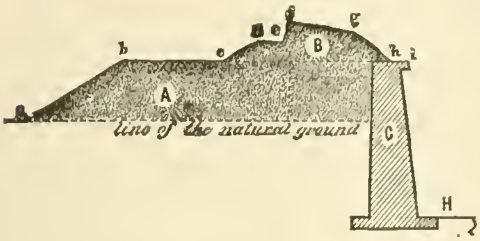
$$\therefore\ \frac{d}{r} = \frac{bc \tan A}{bc.\operatorname{cosec} e};\quad \tan A = \frac{d}{r}\operatorname{cosec.} e.$$

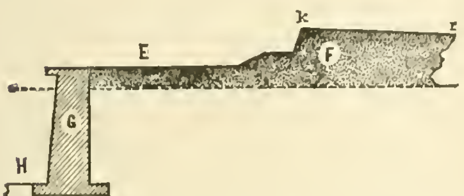
It is found practically that for ordinary service angles of elevation, the values of the ranges and lateral deviations vary in such a way that when the angle e is changed, the product of the three variables in the expression $\frac{d}{r}$ cosec e is always very nearly constant. A is always small and never exceeds about 38. It varies for different ordnance, and is practically found by firing a series of rounds at different ordinary elevation to find the corresponding mean ranges and drifts; the value of tan A, from the above formula, for each elevation is then calculated, and the mean of all the values of A thus found is called the *permanent angle of drift*. By this means one adjustment of the scale is sufficient instead of two, and the deflection leaf is only used for occasional fine adjustment and for accidental circumstances, such as cross wind or difference of level of wheels. With howitzers, however, the varying charges prevent the use of this plan, and no *permanent angle of drift* can be found for them, which will do under all circumstances; their tangent scales are therefore exactly perpendicular to the axes of the piece and of the trunnions, and they are provided with long deflection bars.

PERMANENT FORTIFICATION.—Permanant fortifications are designed to secure the possession of those points that are of importance to the safety of the country, and also those that will or may have an important influence on the operations of a defensive or an offensive war, in which the country may be engaged. To secure them, they must be made so strong that to gain possession of them, an enemy would have to resort to the tedious, laborious, and costly operations of a siege or blockade. Whatever diversity of opinion may be found amongst engineers and writers on permanent fortification, as to the best mode of arranging the elements of these defenses to attain this end, most of them agree on certain general conditions as necessary.

These conditions, thus generally admitted, may be enunciated as follows: 1st. They should be of sufficient strength to resist with success all the ordinary means resorted to by an assailant in an open assault. 2d. Have secure and easy means of communication for the movement of the troops, both within the defenses and to the exterior. 3d. Be so planned that every point exterior to the defenses within cannon range shall be thoroughly swept by their fire. 4th. Be provided with suitable shelters to protect the troops, the armament, and the magazines of provisions and munitions of war, required for their defense, against the destructive measures of the assailant of every description. 5th. And, finally, be provided with all such accessory defensive means as the natural features of the position itself may afford, to enable the garrison to dispute with energy the occupancy by the assailant of every point both within and exterior to the defenses. The defensive branch of the military engineer's art consists in a knowledge of the means which are employed to fulfil the above conditions, and of their suitable adaptation to the natural features of the positions he may be called upon to fortify.

The most simple mode of fortifying a position in a permanent manner consists in inclosing it with a rampart surrounded by a parapet, with a ditch the scarp of which, when dry, is revetted with masonry, and so covered by an earthen mask that it cannot be breached except by batteries placed on the border of the counterscarp. The general form of the parapet and ditch to fulfil the *first* of the general conditions given above will be better understood by an examination of the profile which is a section made by a vertical plane perpendicular to the general direction of the principal bounding line, in plan. The rampart serves to give the troops and armament, which are placed on top of it and behind the parapet, a commanding view over the ground to be guarded by the fire of the defenses; whilst at the same time, it increases the obstacle to an open assault, by the additional height it gives to the scarp. The top sur-





A, Rampart; B, Parapet; C, Scarp wall; H, Ditch G, Counterscarp; E, Covered-way; F, Embankment of covered-way. a b, rampart slope; b c, terre-plein; c d, banquette slope; d e, banquette tread; e f, interior slope; f, interior crest; f g, superior slope; g h, exterior slope; h i, berm; k r, glacis.

face of the rampart, b,c. in rear of the parapet, termed the *terre-plein*, affords the troops and armament a convenient position for circulation from point to point, where they are sheltered from the direct views of the assailants' fire. The rampart is usually terminated on the interior, a,b, by allowing the earth to assume its natural slope, or one somewhat less steep, and which is termed the *rampart-slope*. In cases where this slope would take up too much of the ground within the defenses it is replaced by a wall, termed the *parade-wall*, which rises from the level of the interior ground, termed the *parade*, to the interior line of the *terre-plein*. Inclined planes of earth, termed *ramps*, lead from the parade to the terre-plein, being placed against the rampart-slope, or the parade-wall. The ramps are, in some cases, terminated, inwardly, with the same slope as that of the rampart; in others, this slope is replaced by a wall, which rises to the top surface of the ramp, or a little above it. The essential properties of the parapet are to afford cover to the troops and armament from the missiles of the enemy, and every facility for sweeping his positions by the fire of its artillery and small-arms. Its form and dimensions are therefore so adjusted as to fulfil these requirements. The *exterior slope*, gh, is the part of the parapet towards the enemy; it is usually made with the same slope that the earth when first thrown up naturally takes. The top of the parapet, fg, called the *superior slope*, is the line along which the assailed fire on the enemy. Its inclination is generally taken at $\frac{1}{6}$ that is, six base to one perpendicular. A greater slope than this would make the portion of the parapet about the interior crest, weaker, and less would not so well defend the ground directly in front. A greater slope would be attended by the inconvenience of firing, under a greater depression than $\frac{1}{6}$, which would necessitate using very deep embrasures for the guns or raising the platform so high to the rear that the men serving the guns would be exposed to fire. The *interior slope*, ef, sometimes called the *breast height*, is the part against which the assailed naturally lean in the act of firing. It has usually a slope of $\frac{3}{1}$, three perpendicular to one base. This is a result of experience, being the most convenient one for a soldier leaning forward to fire over the parapet. The *banquette* is a small terrace on which the soldier stands when firing; the top is called the *tread*, and the inclined plane by which it is ascended, the *slope*. The *tread* is placed four and one-half feet below the interior crest and is two feet wide. This width is increased when more than one rank are to use it or where other causes require it. The *slope* of the banquette may have an inclination of $\frac{1}{2}$, or $\frac{1}{1}$, or may be replaced by steps. The *terre-plein* is placed generally from eight to twelve feet below the interior crest with a fall to the rear of one foot to drain off the surface-water.

The *thickness* of the parapet, which is estimated by the horizontal distance between the interior and exterior crests, seldom exceeded twenty feet. This was the dimension usually given in European constructions of important works. Experience showed that it was sufficiently great to afford protection against the fire of the heaviest guns then used. At present, the profile most generally adopted for this part of the parapet and rampart is one in which the portion of the top of the rampart, for a distance of 15 feet back from the interior crest, is held on a level of $6\frac{3}{4}$ feet below the interior crest and serves as a general barbette for heavy guns; whilst the remaining portion of the top surface is placed at a level of eight feet below the interior crest, and made wide enough to serve as a roadway in rear of the general barbette; the two levels being connected by a slope of $\frac{1}{1}$ or $\frac{1}{2}$; and the roadway receiving a slight pitch to the rear for drainage. In the later profile, the interior slope is $\frac{1}{1}$, and has a banquette tread of only 2 feet, with only a banquette slope of only $\frac{1}{1}$. Where guns are mounted either in barbette or embrasure, the interior slope is increased to $\frac{3}{1}$, and the banquette and its slope removed; the earth taken off by these modifications serving to form the merlons between the shallow embrasures cut into the parapets. When the foot of the exterior slope rests on the top of the scarp wall, a berm of two feet in breadth is left between it and the edge of the coping. This breadth of berm is objectionable, as giving a good landing-place for a scaling party in an open assault; and it is proposed, when the work is in danger of an attack, to reduce the berm to 18 inches or one foot, by increasing the thickness of the parapet 6 inches or one foot.

Circumjacent to the rampart a wide and deep ditch is made, which from its position and proximity to the parapet, serves the double purpose of increasing the obstacle which the enemy must surmount before reaching the assailed, and of furnishing the earth to form the rampart, parapet and glacis. Its width and depth will depend mainly upon the amount of embankment required, and therefore will result from the calculation for equalizing the excavation and embankment which these demand. It has been the practice to make the main ditch when dry, from 20 to 30 yards wide, and from 30 to 45 yards when wet. These dimensions may be reduced to within 10 or 12 yards where the embankments are not great and circumstances are unfavorable to an attempt at escalade. The bottom of the ditch, when dry, usually receives a slight slope from the foot of the scarp and counterscarp to its center, where a small drain, termed a *cunette*, is dug to receive the surface water and keep the ditch dry. In some cases, from motives of economy, the difference of level between the cunette and the foot of the counterscarp wall is increased, thus giving a less height of wall.

To give strength and durability, the faces of the ditch are revetted with walls of masonry which sustain the pressure of the earth, protect them from the effects of the weather, and by their height and steepness present an additional obstacle to an open assault. The wall of masonry toward the rampart rises to the level of the foot of the exterior slope of the parapet, sustaining the pressure of the rampart and the parapet, and is called the *scarp wall* or *scarp revetment;* the face of it towards the ditch, the *scarp.*

The line in which the face of the scarp wall if prolonged would intersect the upper surface of the coping is termed the *magistral.* This is a very important line in drawing the plans of permanent works, serving as the directing line to fix, both upon the drawing and upon the ground, in setting out the work, the dimensions and relative positions of all the bounding lines. The top portion of the coping, from the foot of the exterior slope outwards, is termed the *Berm.* The opposite face of the ditch is usually revetted in the same manner. It is called the *counterscarp wall*, and its face towards the ditch, the *counterscarp.*

The *command* of the parapet over the exterior ground and any outworks of the defenses, its *relief*, or height above the bottom of the ditch, and its *height* above the top of the scarp wall, are all points which call for a careful consideration on the part of the engineer in any combination of these that he may be called upon to make. The fire over the parapet should thoroughly sweep all the ground within range, at least up to the glacis crest; and the more so as the closer the assailant's trenches approach the work, the greater will be the plunge obtained upon them, and the more difficult it will be for the assailant to cover himself by his trenches. The parapet should command all outworks within range of its fire, otherwise, when seized by the assailant, these outworks would have a plunging fire upon the main work. The relief of the parapet of the flanking parts of the work should be such that every point along the foot of the scarp wall shall be swept by its fire. This supposes also a certain correlation between the relief and the length of the lines flanked, so that this condition shall be satisfied; a relation that can always be easily found, either by calculation, or by geometrical construction.

The width and depth of the ditch also call for a careful consideration on the part of the engineer. A deep and narrow ditch offers the advantage of presenting more difficulty to the assailant in reaching the bottom of it, either in an open assault, or by a gallery in the attack by regular approaches, thus prolonging the defense. It masks better the sally-ports from the enemy's fire by allowing them to be placed so low that the projectiles coming over the counterscarp cannot reach them. In like manner by drawing in the crest of the glacis nearer to the scarp the latter will be better masked by it from the plunge of the distant fire of the assailant's batteries; and cannot be breached so low down from his batteries placed along the glacis crest. On the other hand, when the ditch is narrow and deep it may be partly filled by breaching the scarp, and then blowing in the counterscarp so as by the united *débris* to form an easy roadway for an assaulting column to enter the work. A wide ditch, on the other hand, requires more labor to construct the trench across it by which the assailant can reach the foot of the breach under cover. This is a consideration of some importance in wet ditches, where the assailant is obliged to construct a dike upon which the parapet of his cover is placed.

These considerations suggest that nothing like absolute rules can be laid down so as to give a routine character to the practice of this branch of the military art. The rules here given with respect to the form and dimensions of the general profile of the enceinte are founded upon reasons growing out of the nature of the question, and as such have served as guides to engineers in the practice of their profession. As they have stood the test of long experience, it is safe to follow them, whilst at the same time the engineer should not hesitate to vary from them when satisfied, after careful examination, that the case before him requires it. Fortification, it must be remembered, is like all other arts. It has its canons, which are founded upon the nature of the question and its rules of practice based upon these and upon experience. As the latter presents to the Engineer new facts, his practice must be made to conform to them; but the general principles of his art must ever remain the same, and be his invariable guide. See *Counterscarp Wall, Fortification, Frontier Defense, Interior Retrenchments, Irregular Sites*, and *Scarp Wall.*

PERMANENT RANK.—A rank in the military service which does not cease with any particular service, or locality of circumstances; in opposition to local or temporary rank.

PERMUTATIONS AND COMBINATIONS.—A combination, in mathematics, is a selection of a number of objects from a given set of objects, without any regard to the order in which they are placed. The objects are called elements, and the combinations are divided into classes, according to the number of elements in each. Let the given elements be the four letters *a, b, c, d;* the binary combinations or selections of two are *ab, ac, ad, bc, bd, cd*—six in all; the combinations of three are *abc, abd, acd, bcd*—four in all; while there is only one combination of four, namely, *abcd.*

Permutation, again, has reference to the order of arrangement; thus, the two elements *a* and *b* may stand *ab* or *ba*, so that every combination of two gives two permutations; the three elements *a, b*, and *c* may stand *abc, acb, bac, bca, cab, cba*, one combination of three thus affording six permutations. The combinations of any order with all their permutations are called the *variations.* Formulas are given in works of algebra for calculating the number of permutations or combinations in any given case. Suppose seven projectiles marked 1, 2, 3, to 7, and that two are to be drawn; if it is asked how many possible pairs of projectiles there are this is a question of the number of combinations of seven elements, *two* together, which is found to be 21. If we want to know how many times the same seven persons could serve at a piece of artillery, with a different arrangement each time, this is to ask how many permutations seven objects admit of, and the formula gives $7\times6\times5\times4\times3\times2=5{,}040$. The theory of probabilities is founded on the laws of combination. Thus, in the case of drawing two tickets out of seven, since there are 21 possible pairs, the chance or probability of drawing any particular pair is 1 in 21, or $\frac{1}{21}$. In working out questions in "combinations," advantage is often taken of the fact that whatever number of elements be *taken* from a group to form a combination, the number *left* gives the same number of combinations; thus the number of combinations of 10 elements *three* together, is the same as that of 10 elements *seven* together, etc.

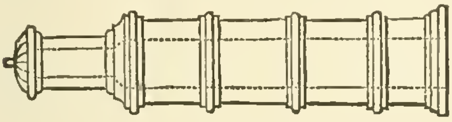
PERPENDICULAR.—A straight line standing on another straight line is said to be perpendicular to that other when the angles it makes on both sides are equal. A line is said to be perpendicular to a plane when it is at right angles to any line in that plane meeting it. Planes are said to be perpendicular to each other when any line in the one plane perpendicular to their common line of intersection is also perpendicular to all lines meeting it in the other plane. The word "perpendicular," in common usage refers to a direction at right angles to the surface of still water, and is synonymous with vertical.

PERPENDICULAR DIRECTION.—In the march of a line, the direction at right angles to the line which each man should take in a direct movement to the front. Without the strictest attention is paid to this essential principle in all movements, the greatest irregularity, and ultimately the greatest confusion, must ensue. Perpendicular and parallel movements constitute, indeed, the whole system of good marching. When several columns, divisions, or companies advance, the lines and directions of marching must be strictly perpendicular and parallel to each other, otherwise the distance will be lost, and the ultimate object of forming a correct line must be defeated.

PERPENDICULAR FORTIFICATION.—This system of fortification owes its origin to the Marquis de

Montalembert, a distinguished French General, who published his work upon the subject in 1776. Vauban had, it was admitted, rendered the art of attack superior to that of defense. Montalembert strove to reverse this relation, and in his endeavors, rejected entirely the bastion system of the older engineers. Instead of the occasional bastions, with intervening curtains, with which they surrounded their *enceinte*, he broke the whole polygon into salient and re-entering angles, the latter being generally right angles. Before the connected redans thus formed were counter-guards of low elevation and ravelins, to which the approaches were through casemated *caponnières*. In the salient angle of each redan, he built a brick tower, 40 feet in diameter, twelve-sided, and four stories high. The second and third tiers were built for heavy guns, and the upper loopholed for musketry. In the center of the tower was a circular *réduit*, intended as a last refuge for the garrison. Montalembert maintained that from these towers every possible approach could be commanded, which to a great extent is true; but it must be also remembered that the greater space a gun commands, by so much the more is it raised above the plain, and rendered visible. These towers would have little chance against the rifled ordnance of the present day. Montalembert's system was violently attacked by the French engineers, but Carnot subsequently adopted it, with some modifications, and it enters largely into the modern German defensive works. The system has never, however, found favor with British engineers.

PERRIERE.—The early bombards being very unsatisfactory, to economize the action of the powder, and give a more accurate direction to the projectile,



the interior space, or bore, was made nearly cylindrical, from 4 to 8 calibers long; it was terminated at the bottom by a very narrow and deep chamber, the object of which was to increase the effect of the powder, by retarding the escape of the gas before it acted on the projectile. These cannon were further improved by making the bores perfectly cylindrical; and were called *perrieres*, from the fact that they fired stone balls. They were principally employed to breach stone walls, and for this purpose were fired horizontally. See *Bombard*.

PERSIAN WHEEL.—A contrivance for raising water from a well or stream, and used in the country from which it takes its name. It is also extensively used in Egypt, where it is known as the *saguieh*, in nothern India, in the Punjab, in Sinde, and also in Spain as the *noria*. It consists of a wheel, about 4 feet in diameter, revolving on a wooden axle, which is flush with the mouth of the well, and is set in motion by means of a driving wheel turned by a pair of bullocks. The wheel has on its rim pins of wood inserted into it, at short distances apart, to which buckets or jars are suspended by means of an endless band or double rope; the buckets descend on one side into the well and ascend on the other filled with water, and discharge themselves into a reservoir at the mouth of the well. The Persian wheel, used for raising water from a stream instead of a well, has the buckets somewhat differently arranged for lifting the water, but the principle is the same.

PERSONAL SALUTES.—Civil and diplomatic authorities receive salutes as follows: The President of the United States receives a salute, to be given both on his arrival at and final departure from a military post or station provided with artillery, of 21 guns. The Vice President of the United States, 19 guns. Members of the Cabinet, the Chief Justice, the Speaker of the House of Representatives, the Governors within their respective States or Territories, 17 guns. A Committee of Congress officially visiting a military post or station, 17 guns. The Sovereign or Chief Magistrate of a foreign State, to be given both on arrival at and final departure from a military post or station provided with artillery, 21 guns. Members of the Royal Family, *i. e.*, the Heir-apparent and Consort of the reigning Sovereign of a foreign State, 21 guns. The Viceroy, Governor-General, or Governors of Provinces belonging to foreign States, 17 guns. Ambassadors Extraordinary and Plenipotentiary 17 guns. Envoys Extraordinary and Ministers Plenipotentiary, 15 guns. Ministers Resident accredited to the United States, 13 guns. Chargés d' Affaires, or subordinate diplomatic agents left in charge of missions in the United States, 11 guns. Consuls-General accredited to the United States, 9 guns.

Military and naval officers receive salutes as follows: The General-in-Chief, Field Marshal, or Admiral, 17 guns. Lieutenant General or Vice Admiral, 15 guns. Major General or Rear Admiral, 13 guns. Brigadier General or Commodore, 11 guns. Officers of volunteers and militia, only when in the service of the United States, the salute specified for their rank. Officers of foreign services visiting any military post or station provided with artillery, are saluted in accordance with their rank.

In addition to the foregoing, occasions of a public nature frequently arise when salutes are both desirable and proper. Orders will govern in such cases. Personal salutes are, however, strictly confined to the foregoing, and are fired but once, unless otherwise specified. The President of the United States, the Sovereign or Chief Magistrate of a foreign country traveling in a public capacity, is saluted when *passing* in the vicinity of a military post. A vessel-of-war on which the President of the United States is traveling displays the nationel ensign at the main. In the case of foreign sovereigns, vessels diplay the royal standard of the sovereign in like manner.

Personal salutes, in compliment to foreign diplomatic authorities,are to be fired only for those whose nations pay the same compliments to United States diplomatic ministers in their territories. Personal salutes at the same place and in compliment to the same person, whether civil, diplomatic, military, or naval, are never to be fired oftener than once in twelve months, unless such person shall have been, in the meantime, advanced in rank. Officers on the retired list, whether military or naval, are not to be saluted. This, however, does not apply to funeral ceremonies. An officer, whether civil, or military,or naval, holding two or more positions, either of which entitles him to a salute, receives only the salute due to the highest grade. In no event is the same person to be saluted in more than one capacity. When several persons, each of whom is entitled to a salute, arrive together at a post, the one highest in rank or position is alone saluted. If they arrive successively, each is saluted in turn. An officer assigned to duty according to brevet rank receives the salute due to the full rank of the grade to which he has been assigned. As a rule, a personal salute is to be fired when the personage entitled to it enters the post. When the troops at a military post are to be reviewed by a personage entitled to a salute, it is most appropriate to fire the salute from field guns at the place of review; and at the time, just previous to the review, when the personage arrives on the ground. See *Salutes*.

PERSONAL SERVICE.—The term "*Personal Services*," employed in section 3,705, Revised Statutes, means services which are contracted for because of some special confidence reposed in the person who is to render them, based upon his supposed peculiar fitness as an expert, and irrespective generally of his pecuniary or any other resources; such, for instance, as the services of a Civil Engineer or Surveyor, a Lawyer or Surgeon, Telegraph Operator, etc.

No person belonging to, or employed in, the military service of the United States shall, in behalf of the United States, purchase from any other such person, or make any contract with such person to furnish supplies or services; nor make any purchase or contract in which such person shall be admitted to any share or part, or to any benefit to arise therefrom.

No person belonging to, or employed in, the military service of the United States shall be pecuniarily interested, directly or indirectly, in the purchase or sale, on behalf of the United States, of any article appertaining to such service; nor shall take, receive, or apply to his own use any gain or emolument, under the guise of presents or otherwise, for negotiating or transacting any public business, other than what is or may be allowed by law.

PRESONNEL.—In speaking of an army, this term represents the officers and soldiers, as opposed to the *Matériel*, in which are comprised the guns, provisions, wagons, and stores of every description. The *Personnel of a Battery* comprises all the officers and men necessary for the maneuvering, management, and care of a battery.

PERSPECTIVE.—The art of representing natural objects upon a plane surface in such a manner that the representation shall affect the eye in the same way as the objects themselves. The distance and position of objects affect both their distinctness and apparent form, giving rise to a subdivision of perspective into *linear perspective* which, as its name denotes, considers exclusively the effect produced by the position and distance of the observer upon the apparent *form* and *grouping* of objects; while *aerial perspective* confines itself to their *distinctness*, as modified by distance and light. The necessity of attending to the principles of perspective in all pictorial drawing is apparent when we consider, for instance, that a circle, when seen obliquely, appears to be not a circle, but an ellipse, with its shortest diameter in line with the spectator and its longest at right angles to this. A square, when looked at from a position opposite the center of one of its sides, appears as a trapezoid, the sides which are perpendicular to the direction of the vision appearing to be parallel, while the other two appear to converge to a point in front of the spectator, etc. For the same reason, two rows of parallel pillars of equal height, seen from a point between and equidistant from each row, appear not only to converge at the further end, but to become gradually smaller and smaller. An excellent idea of a perspective plan can be easily obtained by interposing a vertical transparent plane (as observance of which painters may be enabled to produce an effect true to nature. After the "scope" (*i. e.*, the number of objects to be introduced, and the distance at which they are to be viewed) of the picture has been determined, and before the design is commenced, it is necessary to draw upon the perspective plan three lines: 1. The *base line*, or *ground line*, which limits the sketch towards the operator, and is the base line of the picture. 2. The *horizontal line*, which represents the ordinary position of the sensible horizon. The height of the horizontal line is about one-third of the height of the picture, when the sketcher is placed at or a little above the level of the horizon; but it may rise in a degree corresponding to his increase of elevation till it reaches near to the top of the perspective plan. The general rule is to have a high horizontal line when the view is taken, or supposed to be taken, from an eminence; but when the station is on a level, either actual or assumed, as is the case when a statue or a mountainous landscape is figured, the horizontal line must be low. The horizontal line in nearly all cases is supposed to be level with the spectator's eye. 3. The *vertical line*, which is drawn from the supposed position of the sketcher, perpendicular to the *ground* and *horizontal* lines, meeting the latter in a point which is called the *point of sight*, or center of the picture. The vertical line has no representative in nature, and is merely a mechanical adjunct to the construction of the picture, all vertical lines in nature being parallel to it in the picture. The point of sight, being the point directly opposite to the observer, is properly placed in the center of the picture, for it is most natural that the view should lie symmetrically on each side of the principal visual line; but this is not by any means a universal rule, for we very frequently find it on the right or left side, but always, of course, on the horizontal line. All lines which in nature are perpendicular to the ground line, or to a vertical plane which is raised upon it as a base, meet in the point of sight, which is thus their *vanishing point* (see the line of the tops and bottoms of the pillars in Fig. 1). The *points of distance* are two points in the horizontal line on each side of the point of sight, and in a "direct" sketch are at a distance from it equal to the horizontal distance of the sketcher's eye from the ground line. The equality of distance of these points from the point of sight is not, however, necessary, as it occurs only in those cases where the lines, of which the points of distance are the *vanishing points*, are inclined (in nature) at an angle of 45° to the base line; but, in all cases, the two points of distance are about twice as far apart as the

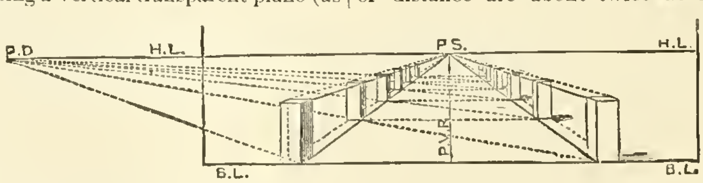


Fig. 1.—Illustrating the more important points and lines; PVR is the principal and visual ray.

of glass—a window, for instance) between the observer and the objects of his vision, and supposing that the objects he sees are not seen *through* the glass, but painted *on* it. A sketch made on a glass plane in this position, by following with a pencil all the lines and shades of the objects seen through it, the eye being all the time kept quite steady, would form a picture in perfect perspective. In practice, however, it is found, unfortunately, that the glass is not a suitable material for sketching on, and that the vertical position is not the most convenient; it is therefore preferable to make a careful study of the effects produced by change of position and distance on the appearance of objects in nature, and from the results of this to compile a body of rules, by the eye is from the picture. One important use of the points of distance is to define the distance of objects in a row (Fig. 1) from each other. For this purpose two points of distance are not necessary, as when the position of one pillar is found, that of the opposite is at once obtained by drawing a line parallel to the base or ground line. We have seen that the point of sight is the vanishing point of all level lines which meet the ground line or a vertical plane on it at right angles, and that the points of distance (in a *direct* picture) are the vanishing points of all lines which cut the ground line at an angle of 45°; but there are many other groups of parallel lines in a picture which have different situations, and therefore different vanishing points. Such lines with their vanishing points (called for distinction's sake, *accidental points*) are represented in Fig. 2. If the accidental point is above the horizontal line, it is called the *accidental point aerial*—if below, the *accidental point terrestrial;* and a little consideration makes it evident that these points may or may not be situated within the plane of the picture. Such are the points and lines necessary for the construction of a plan in true perspective; and from the above explanation, we may deduce the two general principles: 1. That all parallel straight lines in nature are no longer parallel when projected on the perspective plane, but meet in a point which is called the vanishing point, and is some one of the three above described, unless these lines happen to be also parallel to the ground line or the vertical line, in which

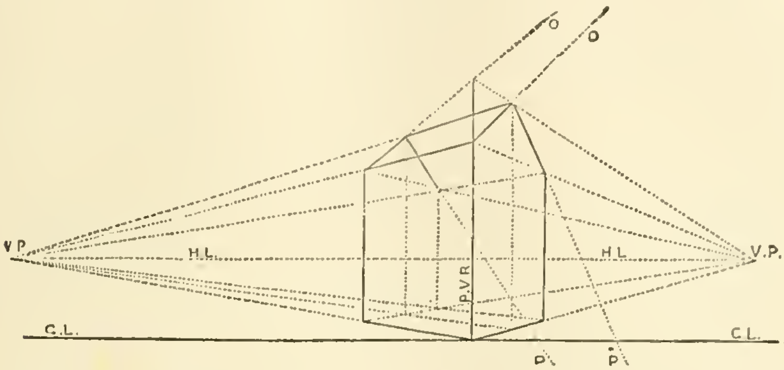

Fig. 2.—The lines O O converge to the accidental point aerial, and P P to the accidental point terrestrial.

case they remain parallel when transferred to the picture; and 2. That since the bodies drawn below the horizontal line are seen as if from above, those above as if from below, and those to the right and left of the point of sight as if observed from the left and right, it follows, that straight lines which in the picture are above the horizontal line lower themselves, and those below raise themselves to it; those to the left, following the same law, direct themselves to the right, and *vice versâ*. *Aerial perspective*, consists in a modulation of the brightness and colors of objects in accordance with the state of the atmosphere, the depth of the body in the perspective plane (*i.e.*, distance in nature from the ground line), and other accidents of place and time. As the distance of objects increases, their illuminated parts are made less brilliant, and their shaded parts more feeble. The bluish tint imparted by a large mass of the atmosphere to the bodies seen through it, is frequently imitated by the mixing of a slight tint of blue with the colors to be applied; a yellow object thus assumes a greenish tint; a red one a violet tint, etc. The air, when charged with vapor, is represented by a diminution of the brightness of colors, and by the grayish tint imparted to them. But in this part of the subject rules are of little avail, for experience alone can guide the painter in faithfully copying the myriad aspects presented by nature. A thorough knowledge of perspective is a *sine qua non* to the painter or designer, and though many are inclined to think it a superfluity, and that the sketcher has only to make use of his eyes, and copy justly, the very fact that such is their opinion shows that they have never made the attempt; for it is impossible for the painter, and much more so for the designer, to execute a copy of nature with sufficient accuracy by the sole aid of the eye and hand, a fact that is unfortunately much too frequently proved by many of the sketches exhibited in fine-art collections. Perspective was known to the ancients, but seems to have become extinct during the disturbances that convulsed Italy, and was revived by Albert Drürer, Pietro del Borgo, and Bramantino of Milan (1440), whose body of rules was extended and completed by Peruzzi and Ubaldi about 1600.

PETARD.—An instrument for blowing open gates, demolishing palisades, etc. It consists of a half-cone of thick iron filled with powder and ball; this is firmly fastened to a plank, and the latter is provided with hooks, to allow of its being attached securely to a gate, etc. The Petardiers attached the petard, lighted the slow-match by which it was to be fired, and fled. When the explosion took effect a supporting column charged through the breach, while the defenders were yet in consternation. The petard has been almost universally superseded by the use of powder-bags. Large petards contained as much as 13 lbs. of powder. Various curious devices were employed, in ancient times for preventing the close propinquity between the petard and the gate; one of the most curious of which was a kind of enormous rat gin, set in such a manner as to close at once on the petard and the soldiers applying it.

PETARDS.—In pyrotechny, small paper cases filled with powder. One end is entirely closed, and the other has only a small hole left for a piece of quick-match, to communicate fire to the powder. Petards are placed at the bottom of lances; they are also used to imitate the fire of musketry. See *Fireworks*.

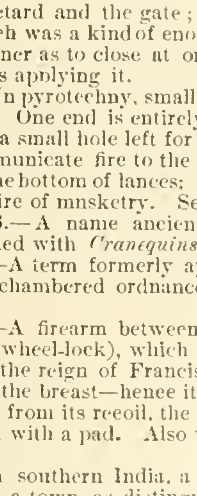
PETAUDIERS.—A name anciently given to the foot-troops armed with *Cranequins*.

PETERERO.—A term formerly applied to a very short piece of chambered ordnance. Also written *Pedrero*.

PETRONEL.—A firearm between a carbine and a pistol (with a wheel-lock), which was used by the French during the reign of Francis I.; it was fired resting against the breast—hence its name. To prevent any injury from its recoil, the soldier who used it was provided with a pad. Also written *Petrinal* and *Poitrinal*.

PETTAH.—In southern India, a term applied to the *Enceinte* of a town, as distinguished from the fortress by which it is protected.

PETTMAN-FUSE.—This fuse consists of the fol-



lowing parts: A, body; B, top-plug; C, plain ball; D, steady plug; E, detonating ball; F, cone plug; G, lead cup; and H, suspending wire. The steady and top plugs are cupped in the center to receive the small plain ball of brass wire which holds them apart; and to prevent the ball adhering from corrosion, the cups are slightly larger in diameter than the ball. Round the top of the steady plug runs a groove filled with detonating composition, and two fire-holes pass from the composition down through the plug.

The composition in the annular groove is covered with thin sheet brass. The detonating ball, which is coated with composition, is covered with two hollow hemispheres of sheet-copper, and over these with silk. The cone plug (not at present coned) has three fire-holes and is supported by a copper wire which passes through the tube; but the hollow of the latter is enlarged below the wire to prevent its being choked. The lead cup (pure lead) does not rest on the bottom of the fuse, but is supported at the top on a shoulder on the cone plug.

The detonating composition in the steady plug and on the detonating ball consists of—

	Parts.
Chlorate of potash	12
Sulphide of antimony	12
Sulphur	1
Mealed powder	1

On the discharge of the gun the suspending wire is broken and the lead cup crushed in consequence of the inertia of cone and steady plugs and of balls, which do not move instantaneously with the fuse and lead cup; sufficient space is therefore left for the disengagement of the balls, and on impact the fuse ignited by the concussion of the detonating ball on the inside of the body, or by the plain ball on the composition in the groove of the steady plug, which continuing to move, after the sudden check to the motion of the fuse, presses the plain ball between itself and the top plug. See *Fuse*.

PEWTER.—A common and very useful alloy of the metals, tin and lead. Two other kinds of pewter have a more compound character. Common, or *ley-pewter*, consists of 4 parts of tin and 1 part of lead; *plate-pewter* is made of 100 parts of tin, 8 parts of antimony, 2 parts each of bismuth and copper; another kind, called *trifle*, is composed of 83 parts of tin and 17 parts of antimony. Although these are the standard formulas, each kind is often much varied to suit the purposes of the manufacturer; the chief alteration being the addition of a large proportion of lead to the last, and a large increase of the same metal in the other two.

PFEIL.—The German name of the arrow for the long bow.

PHALANX.—The ancient Greek formation for heavy infantry, which won for itself a reputation of invincibility, may be described as a line of parallel columns, rendered by its depth and solidity capable of penetrating any line of troops. The oldest phalanx was the Lacedæmonian or Spartan, in which the soldiers stood eight deep; the Athenian phalanx had been the same, until, at the battle of Marathon (480 B.C.) Miltiades reduced the depth to four men in order to increase his front. When Epaminondas organized the Theban army against Sparta, he felt that the Spartan line of battle would be impregnable to troops organized in their own manner. He therefore increased the depth and lessened the front of his phalanx, which enabled him to burst through the Spartan line, inflicting the sanguinary defeat of Leuctra (371 B.C.). Philip of Macedon had learned the Art of War under Epaminondas, and when he resolved to make his state a military power, he formed the celebrated Macedonian phalanx (359 B.C.), which enabled him to conquer Greece, and with which his son Alexander subdued the Eastern World. The Macedonian phalanx, as the latest form that organization assumed, and as the shape in which the phalanx encountered the military skill of the West, is deserving of description. The line was 16 deep; a grand-phalanx comprising 16,384 *Hoplites*, or heavy-armed soldiers, subdivided as follows: the grand-phalanx composed of four phalanxes or divisions, each under a General Officer, called a *Phalangarch;* his command was divided into two brigades or *Merarchies* (sometimes called *Telarchies*), each of these comprising two regiments, or *Chiliarchies*, of four battalions or *Syntagmata* each. A *Syntagma* answered accurately to a modern battalion, except that it was smaller. It was a perfect square, with 16 men each way, was commanded by a *Syntagmatarch* or *Xenagos;* and had an Adjutant, with one or two other Staff Officers who stood behind. Eight files united were under a *Taxiarch*, four under a *Tetrarch*, corresponding probably to a modern Captain, two files were under a *Dilochite* or Subaltern. A single file of 16 men was called a *Lochos* and the best man was placed at its head; a picked man, the *Ouragos*, also marching in the rear. The arms of all these phalanx-men were pikes or spears, 24 feet long, of which 6 ft. were behind and 18 ft. held in front of the combatant. As each man occupied with his shield 3 feet, the phalanx, when it advanced, had six tiers of spear-points in front, a wall of steel which no troops could withstand, especially as the bearers of the spears were pressed on by the ten ranks in their rear. By rapid movements the phalanx could change front, form in close column of syntagmata, and execute other critical maneuvers. The heavy-armed phalanx was ordinarily flanked by *Peltastes* or light infantry, similarly formed, but only eight deep, while the cavalry were but four deep. The phalanx, as representative of the heavy formation, came in contact with the lighter legion of Rome during the wars of Pyrrhus in Italy. At the great battle of Heraclea (279 B.C.), the phalanx won the day; but the victory was attributable to other causes as much as to any superiority of formation.

PHEON.—In Heraldry, the barbed head of a dart. It is represented as engrailed on the inner side, and its position is with the point downward, unless otherwise blazoned.

PHOENIX RIFLE.—A breech-loading rifle formerly manufactured by the Whitney Arms Company. This, like the Whitney and Kennedy rifles, which are improvements on it, is very simple of construction, and perfectly strong, safe and durable, while the ease of manipulation in opening and closing the breech, and extracting the shell or cartridge cannot be surpassed. These arms have less parts than any other breech-loading rifles in use, and the parts are of such form as to render them as strong and safe as rifles can be made. They have short top action, and are symmetrical in form. See *Kennedy Rifle* and *Whitney Rifle*.

PHOSPHOR-BRONZE.—Of the many useful inventions and discoveries recently made in the arts, that of phosphor-bronze has proved to be one of the most important. The invention is the result of a long series of careful experiments, which have established, as a scientific fact, the great superiority of phosphorized alloys of copper and tin over other alloys and metals. The chemical action of phosphorus on the metals composing the alloys is claimed to be two-fold; on the one hand it reduces any oxides dissolved therein, and on the other it forms with the purified metals a most homogeneous and regular combination, the hardness, strength and toughness of which are completely under control. No other metal combines, in so high a degree as phosphor-bronze, the conditions of toughness, rigidity, hardness, and great elastic resistance. From the drop-tests following its comparative relation in this respect to some of the best grades of wrought-iron is made very apparent; moreover, if jointly with these qualities the fact of the total absence of easily corroded metals, such as zinc, be taken into consideration, the advantages offered by the use of phosphor-bronze can scarcely be over-estimated.

In the following drop-tests, the weight of the drop was one hundred and forty-eight pounds; height of stroke, twelve inches, except where otherwise stated;

distance between supports, four inches; striking-face of drop, a blunted wedge-shape; test-bars, six inches long, two inches wide, and one-half inch thick. The fractions of inches stated in the table represent the permanent set of the test-bar after the blow.

The letters inserted in the table indicate the state of the surface of the test-bar, on the side opposite to that upon which the blow has been given:—*a*, sound; *b*, slight cracks at edge; *c*, cracks at edge increase in size; *d*, slight cracks in the middle of the test-bar; *e*, cracks in the middle increase in number; *f*, cracks in the middle increase in size; *g*, remains unaltered; —, straight; ⌢, test-bar reversed. It is apparent from these drop-tests that the rigidity of phosphor-bronze is greatly superior to that of best wrought-iron, for it takes thirteen blows to bend the bar XIV. B to the depth of one inch, whilst the best quality of forged charcoal iron takes eight blows, and the best charcoal scrap iron but six blows for the same bend. The strength of the phosphor-bronze bar No. 6×17 is superior to that of best charcoal scrap iron, it having stood five more blows of twelve inches than the latter before being again completely straightened. The relative strength of phosphor-bronze as to that of other qualities of iron tested needs no comment.

Renewed in consequence of their freedom from any adhering slag is a great point in their favor. Phosphor-bronze chisels, hammers, swages, scissors, key wedges, etc., are made of various sizes and possess fine temper, great hardness and are without any liability to give forth sparks. The application of phosphor-bronze will also be appreciated by all who have experienced the difficulty of removing brass or iron wood screws after they have been exposed to the weather for a short time. Brass screws are more likely to twist off than withdraw, and those made of iron become so rusted that their removal is next to impossible. For all fortification work, carriage finishing, and exterior fastenings, especially at the sea-side Garrisons, phosphor-bronze screws are recommended as the best article yet produced. See *Bronze*.

PHOSPHORUS.—One of the most unwelcome ingredients in iron ores, from the ease with which it passes into the metal during the smelting process, producing the most injurious effects, if present in more than a very small proportion. Practically speaking, all the phosphorus in the ore and in the fuel passes into the pig-iron made. Like silicon, it makes pig-iron weak; although it is thought that when the amount is not more than one-half to three-

The important applications of phosphor-bronze have received constant and careful attention, and the use of the special alloy has become so widely extended into almost every branch of industry that it has become known as the "best" metal for bearings; it has been adopted by many of the leading railroads for bearings of their locomotives and cars, and large quantities are in use in rolling mills, foundries, steam engines, steam ships, and industrial works of all kinds throughout the country. Phosphor-bronze tuyeres have been in use for several years in the iron furnaces of the United States with great success. They have proved much more durable than those made of iron, and after long service are found to be free from incrustation by scoria of the furnace. The facility with which they can be re-

fourths per cent., the strength of the pig-iron is not materially affected by it.

Phosphorus occasionally forms between one-fiftieth and one-sixtieth part of the weight of cast iron, but about one-hundredth part is a more common proportion of phosphorus. It exists in combination with a portion of the metal as *phosphide* of iron, and is derived either from phosphate of iron contained in the iron, or from phosphate of lime, which is frequently present in the limestone employed as a flux, and in minute quantity in the coal. These phosphates contain phosphorus in a state of combination with oxygen, which is abstracted by the carbon of the fuel in the blast-furnace, and the phosphorus, thus set free enters into combination with the iron. So completely is the phosphorus taken up by the metal, that only traces of that element in the form of phosphates are usually found in the slag from the blast-furnace.

The effects of phosphorus are to harden cast-iron, decrease its strength, and to increase its fusibility. Iron made from ores containing much phosphorus is always *cold-short*, or incapable of being wrought cold under the hammer without breaking. See *Cast-iron*.

PHOTO-GLYPHOGRAPHY.—A process, invented by Mr. Fox Talbot, for etching a photograph into a steel plate. It consists in coating the plate with a mixture of bichromate of potash and gelatine, and exposing under a negative. The effect of this treatment is to render the gelatine insoluble, just in proportion to the intensity of the light's action, after which a solution of perchloride of iron, of a certain definite strength, is poured over the film, which solution penetrates those parts unacted on by light, reaching the steel plate, and biting itself in, but is repelled by that portion of the gelatine rendered insoluble; the plate being thus protected from the action of the solvent. Because a dilute solution of perchloride of iron soaks into a film of gelatine more readily than a strong solution, it is very important that the etching fluid should possess that amount of dilution which has been found by practice to yield the best results.

The utility of such a process for copying old and rare original manuscripts or maps and plans of all kinds for the use of engineers and others will at once be apparent, and it has already been largely adopted in the Ordnance Survey Office, Southampton, for the reproduction of maps and old manuscript records; at the India Museum, London, for the reproduction of the patterns of Indian fabrics; and at Woolwich Arsenal, for the reproduction of drawings of ordnance, equipment, etc. It is also largely used by the War Departments of the various European States and in America, but in no country in the world has Photo-glyphography been so extensively and so usefully applied to the reproduction of maps as in India, where skilled lithographic draughtsmen and engravers are very scarce. It has been most successfully worked in the Surveyor General's office, Calcutta, in the office of the Superintendent of the Great Trigonometrical Survey, Dehra Dhoon, and in the Photozincographic Office of the Bombay Government at Poonah. By its aid the maps of the various surveys are issued to the public within a few months after the completion of the survey, instead of being kept back for years, as they would be, had they to be lithographed or engraved. Besides being used in so many Government Offices, this process is extensively worked by many private individuals in Europe and America.

PHOTOGRAPHY. The art of producing pictures by the action of light upon certain chemical preparations. The adaptation of this art to military purposes, in copying, enlarging, and in reducing maps, etc., also in reconnoissances, has been greatly extended during the last few years. One of its most useful applications to surveying consists in taking small circular pictures or panoramas round each station of the triangulation into which the survey is divided. These panoramas are printed by the ordinary photographic method, and are cut out and fastened on a sheet of drawing paper in the relative position to each other which they occupied on the ground to be surveyed; and straight lines or radii being produced from the center of each, through the objects shown in them, give by their intersections the relative position of each object on the paper, so that the "filling in," as it is technically termed, is completed as rapidly as these intersections can be found. Such a system dispenses with the very slow process of observing each object separately, and the liability to any possible error in recording the observation in the field-book, which is now quite done away with. The great interest taken in field photography of late years, at posts and on the march, is due in a great measure to the improvements made in the apparatus, which began with the introduction of the dry plates. These are sensitive gelatino-bromide dry plates, and can be carried about with little trouble. Formerly, when the wet plates were in use, it was necessary for an amateur to carry around with him a chemical laboratory and an extemporized dark-room. Solutions had to be ready beforehand. With dry plates it is not necessary to bother with chemicals while in the field. All that is necessary is to keep the plates, after the exposure, from the light. They can be packed away in cases to be developed in the dark room at home. If the party wishes to make his picture at the time, a dark closet can be arranged under canvas. Only two solutions are necessary, and they can be carried in small bottles. Many explorers develop their plates when they get back at night from a day's photographing tramp. Others save their plates and take them to a professional in the city to be developed.

Fig. 1, shows a camera designed especially for field-service by the Rochester Optical Company. It is a very accurate, simple and practical instrument and may be operated by any soldier, of ordinary intelligence. The camera-box, in three sizes, is made of the best seasoned cherry, well finished in the natural wood. The focusing screen is *hinged* to the camera-back, which is more convenient than where loose, and liable to loss and breakage. The back with screen slides upon the bed, being fastened by a set screw when the focus has been obtained. The tripod is attached to the bed by a screw which, while it allows of the swinging of the box horizontally, or its

removal, remains in its socket at all times, thus obviating loss. The lens is of remarkably fine quality, giving sharp definition and great depth. The diaphragms are *removable*—a point of the greatest importance, to compensate for the varying strength of different lights. The plate-holder is made on an improved plan, doing away with ledges and thus exposing the full plate to the action of the light, making a picture the full size of the glass. By the old method a quarter of an inch all around was lost. The Tripod Legs are jointed, capable of folding to half length, but when in position are rigid and firm. These cameras are provided with rising and falling fronts, swinging backs, hinged and folding beds (almost indispensable adjuncts on some views), and are adjustable for stereoscopic work, having double lenses, on interchangeable fronts and partitions.

Figures 2 and 3, show a swivel-bed camera. The front is mitered in four pieces, giving it a very elegant appearance. The bed swivels under the box, as shown in the drawing *L*, Fig. 3, is a focusing screw, and *M*, a lock nut for fastening the box in position when the focus is obtained. The tripod head, *E*, is adjustable, so that the camera may be leveled without the necessity of moving the tripod legs. The rising and falling front, *G*, is reversible for packing more compactly. The diaphragms are removable. The focus screen is hinged and falls down at the camera back, thus offering the least resistance to wind. This camera is but two inches thick when closed, thus making it most compact for transportation. The lens is of great depth, and fine quality, giving a sharp and clear cut picture.

One of the latest of instantaneous cameras consists of a small wooden box which can be carried easily under the arm. Inside the box is the lens through which the picture is taken. This is covered by a shutter, which by the mere pressing of a little knob on the outside uncovers the lens for an instant. On the upper side is another lens, and underneath a ground-glass plate. This is simply to enable the photographer to see the image he wishes to take. When it falls on the right spot in the plate he presses the little knob for less than a twentieth of a second, the dry plate is exposed and the picture is taken. Troops in motion, exploding shells, etc., have thus been photographed. With a little practice, instantaneous photographing reaches so fine a point that a longer exposure than one-twentieth of a second is not required.

It is not within the province of this article to go into an abstruse demonstration of optical, chemical or mechanical facts, but simply to direct attention to an art of no little value to Topographical Engineers, and all others in the active service of the military profession. The dark room, preparation of chemicals, manipulation of camera, development, printing, and toning may form special studies for those desiring to become experts. The art of photography is now taught as a part of the regular course at the Artillery School, Fortress Monroe, and in most of the Military Schools of other Countries.

PHOTO-LITHOGRAPHY.—The application of photography to engraving on stone. A lithographic stone is coated with a mixture of water, gum-arabic, sugar, and bichromate of potash, dried in the dark, exposed in the camera, or under a negative. The effect of the luminous action is to render the gum almost insoluble. A solution of soap is then applied, which serves the double purpose, by its decomposition, of yielding a greasy printing surface, and by its solvent action to remove those portions unacted on by light; its action being inversely proportionate to the extent to which the gum was fixed by the light. In this condition the stone is freely washed with water, and when dry, receives a coating of printer's ink from the roller, which, by uniting with the soap, gives additional body to the picture. This process was patented by Mr. W. E Newton; but, in common with others of a kindred character, the resulting pictures were invariably deficient in middle tint, possessing a degree of hardness very unpleasant to the eye, which prevented its coming into general use.

PHOTO-MICROGRAPHY.—The enlargement of microscopic objects, by means of the microscope, and the projection of the enlarged image on a sensitive collodion film. The manipulatory details are the same as in the collodion process, only that, on account of the delicate nature of the markings to be rendered, it is necessary to employ a collodion yielding what is termed a structureless film. The principle upon which the enlargement is effected is that of the conjugate foci. This branch of microscopic and photographic science has proved a useful aid in the study of the sciences of botany, physiology, and entomology, by delineating, with unerring accuracy, woody fiber, ducts, starch granules, muscular fiber, blood discs, nerve papillæ, etc. Among the numerous experimenters attracted by this interesting study, Dr. Maddox is perhaps the only one who has attained to any renown; and by him, minute animalculæ, all but invisible by unassisted vision, have been magnified to a superficial area of 3 square inches, in which the most delicate details have been faithfully preserved. By reversing the arrangement necessary for these enlargements of microscopic objects, it will be seen that minute photographs of engravings, or other objects, may be produced which would require a microscope for their inspection. In this way communication was maintained, during the investment of Paris, when copies of letters and newspapers were inserted in quills, and fastened to carrier pigeons; and this is really by no means so difficult to accomplish as it may seem at first sight, since photographs no larger than a pin's head have been produced, including in that small space portraits of no less than 500 eminent men.

PHOUS-DAN.—An East Indian term for a commander of a large body of forces.

PHYLÆ.—A Greek word, meaning tribes, applied specially to the divisions of Attica, originally four, but made ten by Cleisthenes after the Pisistratidæ were driven from Athens. The number was still later raised to twelve. Each *Phyle* had a leader or Phylarch, who possessed certain authority, both of a civil and military nature, and each tribe sent fifty representatives to the Athenian Senate. In time the civil duties, such as presiding over the assemblies, were taken from the Phylarch and given to an officer called the Epimeletes.

PHYLARQUE. —A Grecian cavalry officer who commanded the cavalry of his tribe.

PIBROCH.—Music played on the bagpipe, which has a wonderful power in exciting the martial instincts and hilarity of the Highlanders. Its rythm is so irregular, and its notes in the quicker parts so much jumbled together, that a stranger has difficulty in following the modulations or reconciling his ear to them. The earliest mention of the military music of the bagpipe is in 1594, at the Battle of Balrinnes; indeed, prior to that period, the bagpipe can hardly be looked on as a national instrument of Scotland. There are appropriate pibrochs belonging to various clans and districts, but some of these may not be older than the beginning of the last century. One of the oldest known pibrochs is called the "Battle of Harlaw," but it may be doubted whether it was contemporary with that event (1411). In the ballad account of that battle there is mention of trumpets and horns, but none of the bagpipe; and the pibroch style of music has so obvious a relation to the bagpipe that it is difficult to suppose that it preceded the use of that instrument. According to Sir Walter Scott, the connoisseurs in pipe-music affect to discover in a well composed pibroch the imitative sounds of march, conflict, flight, pursuit, and all the current of a heady fight. Many remarkable instances have been recorded of the effect of the pibroch on the Highlanders. At the Battle of Quebec, in April, 1760, whilst the British troops were retreating in confusion, the pipers were ordered to strike up a favorite pibroch, and the result was that the Highlanders, who were broken, rallied the moment they heard the music, and formed with great alacrity in the rear.

PICADOR.—A horseman armed with a lance, who commences the exercises of a bull-fight by attacking the animal without attempting to kill him.

PICAROON.—A pillager or plunderer; one who violates the laws.

PICCOLO.—A flute of small dimensions, having the same compass as the ordinary flute, while the notes all sound an octave higher than their notation. In joyous as well as violent passages this instrument is sometimes very effective in a band.

PICKER.—A small, pointed brass wire, which was formerly supplied to every infantry soldier for the purpose of cleaning the vent of his musket.

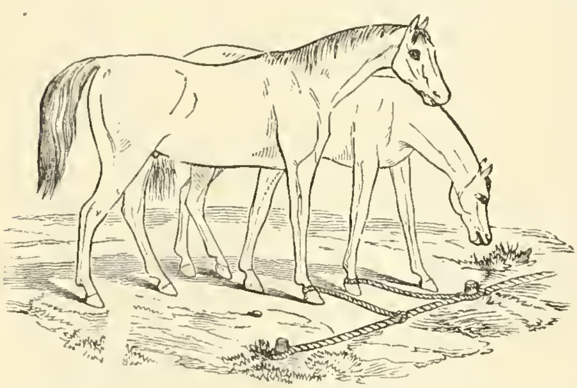
PICKERING.—A little flying skirmish, which the marauders make when detached for pillage, or before a main battle. Also writen *Pickerooning*, and *Picqueering*.

PICKET.— A technical term for an elongated conoidal projectile. See *Pickets.*

PICKET-GUARD.—A guard of horse and foot, always in readiness in case of alarm. See *Pickets.*

PICKET-LINE.—1. A position held and guarded by small bodies of men placed at intervals. 2. A rope to which horses are secured when groomed. The rope, which usually passes through holes near the tops of posts planted in the ground, is frequently replaced by a timber framed on the posts.

In the Crimea, the cavalry usually encamped in line with two rows of *picket-lines* and a line of shelter tents in front of and behind the picket-lines; the arms and equipments between the shelters and the



picket-lines. The picket-lines were stretched on the ground, and the horses secured to them by hobbles on the right fore-feet; the hobble being about three feet long and buckling around the pastern-joint. The drawing shows this arrangment, which is spoken of by the French officers as being the best manner of securing the horses.

PICKET-PIN.—An iron pin with a ring at the top. It is driven in the ground, and the lariat is attached to it to secure a horse while grazing.

PICKETS.—1. Stout wooden stakes driven into the ground and used for securing purposes, and in the construction of holdfasts. The ordinary stakes for siege-gun platforms answer for most cases. When very heavy strains are to be borne, posts from five to eight feet long are required, and are set into the ground by digging holes, or with a pile-driver. When the latter is used, the post should be shod with an iron point, and have a ring upon the head to prevent splitting.

2. An early military punishment where the culprit was held by the raised arm in such a position that his whole weight fell on one foot, which was supported on a picket with a blunt point. The time the man thus stood was proportioned to the offense. The punishment became, after a few moments, extremely painful; it has long been discontinued on sanitary grounds.

3. Detachments of troops whose principal duty is to guard an army from surprise, and oppose such small parties as the enemy may push forward for the purpose of reconnoitering. The main-detachments or pickets, which form the supports to the grand-guards and out-posts, occupy the principal avenues to the position of the main-body. As their duty is to hold the enemy in check, the points which they take up should be susceptible of a good defense; such, for example, as villages, defiles, etc.; whenever these advantages are not found at hand, resort should be had to any temporary obstacles, as abatis, etc., which can be readily procured, to place the troops under shelter. The points thus occupied should, as a general rule, be about midway between the line of out-posts and the position of the main-body. Small posts should be thrown forward by the pickets, between their position and the line of grand-guards; both for the greater security of the detachments, and as supports to the grand-guards. In like manner, when the line of pickets is of considerable extent, intermediate posts must be established,to keep open a communication between them, No pains should be spared to obstruct the approaches of the enemy to the points occupied by the pickets; particularly those which lead to the flanks; leaving open such only as will oblige the enemy to attack under the most unfavorable circumstances; and if, between the advanced-posts and the main-body, a defile, or other unfavorable pass should occur, which the enemy, by turning the line of the advanced-posts, might seize upon, and thus cut off their retreat, it should be occupied by a strong detachment; both to prevent such a manenver, and to favor the retreat on the main-body.

The entire strength of the advanced-posts, as well as the relative strength of the pickets, grand-guards, and out-posts, will depend upon the character of the ground covered by them; as being more or less open, and presenting more or less facilities for circumscribing the approaches of the enemy to the main-position. It rarely occurs that sufficient troops can be detached to cover all the accessible ground, and perform the duties in a thorough manner The strength of each picket, and the kind of troops of which it is composed, will depend on the degree of resistance to be offered to the enemy's attack; and the character of the position occupied. In most cases where a vigorous defense is called for, they will consist of troops of all the arms; and an aggregate of several hundred men. The grand-guards, out-posts, and patrols, should not as a general rule exceed one-third the strength of the pickets to which they belong. They will be composed of cavalry, or infantry, according to the more or less broken features of the ground. It rarely occurs that artillery is placed at the out-posts. Whenever it happens that a piece, or two, may be deemed necessary, to sweep some passage, or defile, in advance of the line of out-posts, the guns must be protected by a strong post, to insure their safety in a retreat. If, from the character of the ground, the out-posts are mainly of infantry, some cavalry should always be attached to them, to patrol in advance of the position, and to convey intelligence to the rear of what may be passing in the neighborhood of the out-posts. When the advanced-posts cover an advanced-guard, the Commanding Officer of the whole should take a position, with his artillery and the main-body of his command, at some central point, in the rear of the pickets; in order to be ready to support them if hard pressed by the enemy. The choice of this position is an object of the greatest importance; as the safety of the advanced-posts as well as that of the main-body, may depend upon the degree of judgment shown in his selection. So soon as the advanced-posts have taken up their stations, instructions should be given to the officers of the different posts, with respect to the points upon which they are to fall back, in case of their being forced in; the lines of communication they must of necessity retire by; and the position they must take up, when joining the supports to which they respectively belong. An officer in command of any of the out-posts must be capable of untiring vigilance and activity; to perform the various duties which devolve upon him. He should be provided with a good map of the country, a telescope, and writing materials. He will thoroughly reconnoiter the ground upon which he is to dispose his command; and also as far in advance as circumstances will admit; questioning closely any inhabitant he may find. After taking up his position, he should go forward with the half of his command, and post each sentinel himself. If, however, he relieves another in the command, and deems it advisable to make any changes in the dispositions of his predecessors, he should promptly report the facts to the commanding-officer in his rear. When the officer finds that the enemy is not in his immediate neighborhood, he should endeavor to feel his way cautiously towards him by patrols; and when in immediate presence, he should omit no means to watch the enemy's movements; and from the occurrences of the moment, such as noises, the motion of clouds of dust, camp fires, conflagrations, etc., endeavor to divine what is passing in his camp, and his probable intentions. Accurate written reports should be promptly sent to the officer in command, in the rear, on all these points. The reports should be *legibly* written, and should clearly, but *concisely*, state what has fallen under the officer's eye; what he has learned from others; and the character of the sources from which his information is drawn. The post under the officer's command, whether horse or foot, should not all be allowed to sleep or eat at once. The horses, when wanted, should be taken singly or by pairs, and always mounted. At night one-half of the command should be under arms, prepared for an attack; the others seated, their arms and the bridles of their horses in hand. The men should never be permitted to occupy a house; and if the weather is such that a fire out of doors is indispensable, it should be as much concealed as practicable; one-half being only allowed to sit near it; the other posted, at a convenient spot at hand, to fall on the enemy should he attempt a stroke. When the position taken up is to be held for some time, it will be well to change the locality of the posts occasionally; this should be done, particularly at night, in a hilly district, changing the post from the brow of the hill, where the men can best keep a look-out by day, to the low ground at night, as more favorable to detect any movement above. The out-posts are usually relieved at day-break, as being the most favorable moment for the enemy to attempt a surprise; the new-guard, will serve to reinforce the old. For the same reason, the old-guard should not be suffered to retire before the patrols come in and report all safe. See *Advanced-posts*, *Field-service*, *Grand Guards*, and *Outposts*.

PICRATES.—The picrates are salts of picric acid. Picric or trinitrophenic acid is a nitro-substitution product, formed by the action of nitric acid on carbolic acid (phenol, C_6H_6O). Three substitution products may be derived from this action, but only one, picric acid, possesses any marked explosive properties. Picric acid has the composition indicated by its symbol—$C_6H_3(NO_2)_3O$, or $C_6H_3N_3O_7$. Picric acid is found in commerce, being used to dye silk and wool yellow. If the acid is heated, it takes fire and burns sharply and rapidly without explosion. The picrates are all exploded with more or less violence by heat or blows. When used as explosive agents they are mixed with potassium nitrate (saltpeter) or potassium chlorate. A large number of picrates are known, but the potassium and ammonium salts are the only ones that have been much used in explosive preparations.

Potassium Picrate, $C_6H_2KN_3O_7$, is the most violently explosive of the picrates. Potassium picrate and potassium chlorate form a mixture nearly as powerful as nitro-glycerine, but it is so sensitive to friction or percussion as to render it practically useless. With potassium nitrate instead of chlorate a less violent mixture is obtained, but one still too liable to accidental explosion.

Ammonium Picrate, $C_6H_2(NH_4)N_3O_7$, has been proposed by Abel as an ingredient of a powder for bursting charges of shells. The properties of ammonium picrate are very different from those of the potassium salt. If flame is applied to the former, it burns quietly, with a strong, smoky flame. If heated it melts, sublimes, and burns without explosion. It is almost entirely unaffected by blows or friction. This salt mixed with saltpeter forms Abel's picric powder (Brugère's powder). Experiments with this powder in England indicate that it possesses some advantages when used in shells. A number of shells charged with it were fired from guns of different caliber without accidents. It is more powerful than gunpowder and less violent than nitro-glycerine and gun-cotton. It is insensitive to ordinary means of ignition. If flame is applied to it, the particles touched burn, but the combustion does not readily extend to the others. Blows or friction do not explode it. It must be confined in order to develop its explosive force. It does not absorb moisture from the air, so that it may be stored and handled like gunpowder, and is at least equally safe and permanent. It is prepared for use by the usual gunpowder processes of incorporation—pressing, granulation, etc.; so that it has the same form and may be handled in the same way. It may therefore be a good substitute for powder when a more violent explosive is wanted and neither gun-cotton nor nitro-glycerine are available. The mixture contains 46 parts of saltpeter and 54 parts of the picrate.

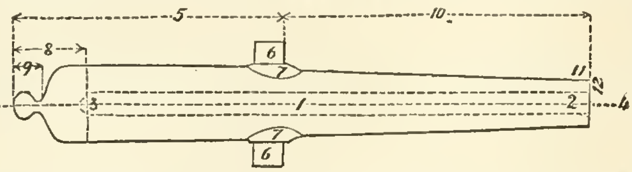
The picrate is prepared from picric acid and ammonia. The picric acid is dissolved in water, and ammonia added to neutralization. Another charge of picric acid is then dissolved in the same liquid, and ammonia again added. This is repeated several times, and the liquid allowed to stand for some time, when the ammonium picrate crystallizes out in large quantities. The mother liquor is drawn off, the crystalline deposit drained and dried. The mother liquor may be used for the preparation of successive lots of the ammonia salt until it becomes charged with impurities, when it may be otherwise treated or thrown away. In this way a considerable amount of the salt can be expeditiously prepared with little labor and without much loss. The working of the mixture is, of course, to be done at a powder-mill. See *Explosive Agents*.

PICRIC POWDER.—Picrate of potash. This powder, of a bright yellow color, has been recommended as stronger than gunpowder, and less susceptible to ignite by means of friction or a blow.

PICTS' WALL.—One of the barriers erected by the Romans across the northern part of England to restrain the incursions of the Picts.

PIECE.—1. In Heraldry, an ordinary or charge; as the fesse, the bend, the pale, the cross, the saltire, the chevron, called honorable pieces. 2. The terms *cannon* and *ordnance* are applied to all heavy fire-arms which are fired from carriages, in contradistinction to *small-arms*, which are fired from the hand. The term *piece* is applied to cannon; it also used to designate a cannon in union with its carriage with or without the limber.

The light artillery of the United States now comprises the following pieces, viz.: *three-inch rifle* and *three-and-one-half-inch rifled-guns; half-inch* and *one-inch mitrailleurs;* and the *twelve-pounder smooth-bore* gun. A .45-inch mitrailleur has just been adopted (1874); it is intended to ultimately replace the half-inch mitrailleur. The *three-inch rifle* was adopted in 1861. It is made of wrought-iron, by wrapping boiler-plate round an iron bar, so as to form a cylindrical mass, which is brought to welding heat and passed through rollers, so as to unite it solidly; the trunnions are afterward welded on, and the piece is bored and turned to its proper size and shape. The method originated at the Phœnixville Iron Works, Pa. The model for the *three-and-one-half-inch rifle* was adopted in 1870. It is to be made of wrought-iron or bronze, and in its general appearance will



closely resemble the three-inch rifle. The *mitrailleurs* are Gatling's, and were adopted in 1868; they are made of steel, some of the smaller parts being of brass. The *twelve-pounder*, or *Napoleon gun*, adopted in 1857, is still (1874) retained in the United States service, though abandoned by all other civilized nations. It is cast in gun-metal or bronze, which consists of ninety parts of copper and ten of tin, allowing a variation of one part more or less.

Description and nomenclature of light guns: The *bore* (1) is the hollow cylinder which receives the charge. The *mouth* (2) is that part of the bore nearest the front of the piece. The *bottom of the bore* (3) is its extreme rear; in the three inch rifle, it is a semi-elliptical surface. The bores of rifled-guns have *grooves;* the intervals between the grooves are called *lands*; the grooves and lands are of equal width. The *vent* is a cylindrical hole, perpendicular to the *axis of the piece* (4), near the bottom of the bore, through which fire is communicated to the charge. The surface of the piece in the immediate vicinity of the exterior orifice of the vent is called the *vent-field.* The *body* (5) is that part of the piece in rear of a plane perpendicular to the axis of the piece and tangent to the front part of the *trunnions* (6,6), or projecting cylinders at the sides of the piece, which are intended to support it on its carriage; their axes are in a line perpendicular to the axis of the piece, and in the same plane with it. The *rimbases* (7,7) are the short masses of metal which unite the two trunnions with the gun; their ends, or the *shoulders of the trunnions*, are planes parallel to each other and perpendicular to the axis of the trunnions. The *breech* (8) is that part of the piece in rear of a plane passing through the vent and perpendicular to the axis of the piece. The *base of the breech* is the plane, or curved, surface at the rear of the piece. The *seat for the pendulum-hausse* is screwed into the base of the breech. The breech includes the *cascabel* (9) which consists of a *knob* terminating the rear of the piece, and of a *neck*, or narrow part, which unites the knob to the base of the breech. When the body of the gun is strengthened by a band, or jacket, this addition is termed a *reinforce.* The *chase* (10) is that part of the gun in front of the trunnions. The *muzzle* (11) is the general term for the front of the gun; if the chase be enlarged at the muzzle, the enlargement is called the *swell of the muzzle*, and the part of the chase where the swell begins is called the *neck.* The *front*, or *muzzle, sight* is screwed into the muzzle, or into the swell of the muzzle at its highest point. The *face* (12) is the perpendicular plane terminating the front of the gun. *Preponderance* is the excess of the weight of the piece in rear of the trunnions over that in front; it is measured by the lifting power in pounds, which must be applied at the base of the breech to balance the piece when suspended freely on the axis of the trunnions. It is decided to dispense with preponderance in all guns hereafter cast. The bore is kept as dry as possible by depressing the piece and using a vent-cover and tompion. Great care must be taken not to bend or injure the front-sights, as it affects the accuracy of pointing. After firing, the bore of the gun must be washed out, and the piece depressed. Steel guns are bronzed or lackered on the exterior. Mitrailleurs are kept cleaned and oiled to prevent them from getting rusty; after marching over dusty roads and, if possible, before going into action, the barrels and carrier-block are wiped and the parts oiled, the crank being reversed to avoid unnecessary snapping. The foregoing are the principal dimensions and weights of pieces.

In bronze, the weight of the three and one-half inch rifle is 1,299 lbs. There are seven grooves in the three-inch and three-and-one-half-inch rifles, and six grooves in the barrels of the mitrailleurs. In the twelve-pounder, the *windage*, or difference between diameters of bore and projectile, is 0.1 inch. See *Cannon*, *Gatling Gun*, and *Mitrailleur.*

PIERCED.—In Heraldry, a term used to indicate that a charge is perforated so as to show the field beneath it. The aperture is presumed to be circular, unless some other form, as square-pierced or lozenge pierced, be specified in the blazon.

PIERCER.—An instrument employed in the fabrication of ordnance. The boring of a cannon is commenced by placing the boring-rod, armed with the first cutter, called the *piercer*, in the prolongation of the axis of the piece, and pressing it against the metal. The piercer is used till it penetrates to the bottom of the chamber, after which a second cutter, or reamer, is attached to the boring-rod, and with this the boring is made complete to the round part of the chamber.

PIERRIER.—A term originally applied to an engine for casting stones, and later to a small kind of cannon. The term is now generally applied to a mortar used for discharging stones, etc.

PIERS.—In fortification, the buttresses on which the roadway of a bridge rests. In the case of wooden bridges, piers are made of barrels, etc.

PIES.—Counts Palatine, who were created in 1560 by Pope Pius IV, and who had precedence at Rome over Knights of the Teutonic Order and Order of Malta.

PIEZOMETER.—An instrument invented by Oersted for measuring the compressibility of liquids. It has been proposed to ascertain the pressure of the gases evolved by the combustion of gunpowder, by including in the cavity within which the pressure should be restrained a piezometer, which, by registering the compression of a liquid contained within it, should afford an indication of the pressure to which it had been exposed. This instrument, as employed in these experiments, is shown in the drawing. Fig. 1, is a section through its axis; Fig. 2, an exterior side view. The same letters are used in re-

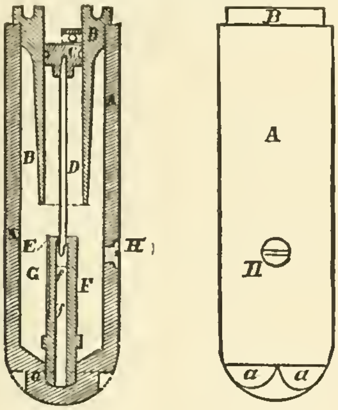

Fig. 1. Fig. 2.

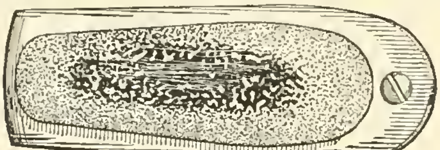
ferring to like parts in each of the figures. A, is the body of the instrument. The general form of its lower (or outer end) is hemispherical, but it is flattened on four sides (as at *a* and *a*) for fitting a socket attached to the middle of a small oil-pan used in filling it. B, is the barrel to which the piston is fitted. It screws freely into the body, and makes with it a close joint. C, is the piston, packed with a leather ring occupying a groove; *c*, is the eye of the piston, by means of which it is withdrawn or turned when required. A special implement (not represented) is fitted to the eye for this manipulation. D, is a stem screwed into the piston. The lower end is squared, to fit a socket like that of a watch-key. As it is desirable to use a new stem for each experiment, special appliances were prepared for making duplicates readily and with accuracy. They are coated with a thin film of black varnish to render the marks they are to receive more distinct. E, is the point from which the stem receives the mark recording compression. F, is a tubular support for the point, and also a guide for the stem of the piston. To it is attached the spring, G, pressing the point against the stem; *f f*, are holes in the support to permit the oil within it to escape freely when the stem is suddenly thrust in, under the action of surrounding pressure. H, is a screw permitting the escape of oil when the instrument is being "set" for use, but also capable of closing tightly the opening in which it is situated. Tests were made of the tightness of the piston and of the joints.

In preparing the piezometer for an experiment, two items are to be specially observed; it must contain no air, and the "setting," or adjustment of the quantity of oil contained, must be done at the precise temperature the instrument is to have at the moment of firing. The procedure is simply as follows: All the parts are first oiled, over their whole surfaces. The adjusting-screw is inserted into the body of the instrument, which is then set upright in a socket attached to the middle of a small pan intended to catch any overflow, and is nearly or quite filled with oil, which should be made to flow down the side of the cavity rather than in a stream. The support of the marking-point, quite clean but covered with oil, is now screwed into its place, with the aid of a special implement, not described. When this is withdrawn, it will be necessary to replace the oil caused to overflow by its insertion. The barrel is now slowly put in its place and screwed firmly down. The hole in the piston for receiving the stem is filled with oil, the stem screwed in, and the piston inserted in the barrel. The adjusting-screw is loosened a little, permitting the piston to be pressed just below the top of the barrel, and again tightened. The next step is to bring the instrument and its contents to the setting temperature. For this purpose a water bath (a common wooden pail) is provided; also a narrow tin cup, deeper than the bath and weighted at the bottom so as to stand upright within it; and a pair of wooden pinchers for handling the piezometer, which instrument could be inserted in them in such a way as to be nearly enveloped and yet to leave the adjusting screw and piston readily accessible. The piezometer, seized in the pinchers, is placed at the bottom of the cup in company with the tools to be used in setting it, and is covered with a loose wad of cotton. The cup is set in the middle of the bath and surrounded with water kept as nearly as possible at the desired temperature, for a sufficient time to impart, as nearly as appreciable, the same to the instrument. It is then withdrawn, the screw loosened, the piston depressed a little to a regulated depth with a special tool, the screw tightened, and the piston rotated a few degrees, which completes the setting. The object of this last movement is to inscribe a transverse line on the stem, affording a starting point in measuring the length of the stroke.

Small changes of temperature after the instrument is set are of no consequence, as the oil will of course return to the same volume, and the piston stand at the same place, on returning to the same temperature. Before placing the piezometer in the hollow plug, a thin leather envelope, kept saturated with oil, is drawn upon it, (with the intention of affording protection against the shock of firing), and when inserted, the remaining space within the plug is filled with oil, which is retained by stopping the opening through the retaining ring (which forms the communication with the bore of the gun) with a loosely-fitted disk of cork or leather. One particular to be noted is the position of the eye of the piston with reference to the line in which the gun will recoil on firing. The metal surrounding the eye occupies a position at one side of the piston's axis of rotation in the barrel, thereby throwing the center of gyration out of that line; and if that center be so situated as to fall outside of a plane coincident with the line of recoil, it is evident that the piston will have a tendency to rotation when the gun is fired.

PIFFARD HEEL-PLATE.—This device consists of a soft rubber pad or cushion about half an inch in thickness. It is applied to the butt of the gun (after removal of the iron heel-plate), and is retained in position by a skeleton plate. The latter is attached to the stock by using one of the original screws, and in addition a small screw inserted near the toe of the heel-plate, as shown in the drawing. The stock of the gun is not altered in any manner, and the original butt-plate can be re-applied at will. Experience has shown that, when using this contrivance, the effect of recoil has been greatly modified, and a charge of as much as 110 grains of powder, with 420



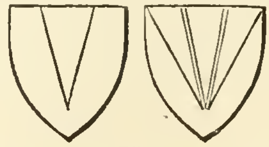
of lead, can be shot without discomfort. The benefits accruing from the lessened recoil are: Recruits and beginners will not become "gun-shy," and contract the habit of flinching; increased accuracy from absence of flinching; target practice can be more continuously and efficiently carried on than is practicable without the elastic-plate, owing to the bruising and other injuries attendant on the use of the service cartridge; and, the powder charge for service ammunition could be materially increased, thereby flattening the trajectory, and in other respects rendering the weapon more effective.

It is evident that the use of this description of heel-plate insures greater safety and increased accuracy. The dropping of a loaded gun (cocked or half-cocked), butt downwards, on a stone or hard ground may result in breaking the point of the sear or one of the notches of the tumbler, causing a premature discharge. This heel-plate would diminish the force of the concussion and lessen the liability to accident. In repeating rifles, in which the cartridges are arranged in the magazine with the bullet of one pressing on the primer of the one in front of it, the dropping of the gun might cause an explosion in the magazine. The liability to this accident would be diminished by the use of the plate. Practical marksmen have found that when using this heel-plate the butt of the rifle is retained in proper position against the arm with less exertion, the rubber not slipping from the arm as readily as the iron butt-plate. On drill, *Order Arms* is accompanied with less noise, and less jar to the mechanism of the weapon. By a recent resolution of the Directors of the National Rifle Association, the use of this heel-plate is permitted in all military and other competitions held under their auspices.

PIKE.—Previously to the use of the bayonet, infantry of the line of battle—that is, the heavy-armed troops—were from the earliest times armed with pikes or spears. The Macedonians carried pikes 24 feet long; those of modern warfare averaged 12 or 14 feet. They were of stout wood, and tipped with a flat iron spearhead, which sometimes had cutting edges. As a defense against cavalry, the pike, from its length and rigidity, was of great value; but though it long survived the introduction of gunpowder, that event was really fatal to it. For success with the pike, especially in offensive war, a depth of several men was essential, and this depth rendered the fire of artillery peculiarly fatal. The pike is now superseded by the bayonet on the end of the musket.

PIKEMEN.—Men who were armed with the pike. From the reign of Henry VIII. to that of William III. the greater part of the English Army was formed of Pikemen.

PILE.—1. In Heraldry, an ordinary, or, according to some Heralds, a subordinary, in the form of a wedge, issuing generally from the middle chief, and extending towards the middle base of the shield. It is said that a pile should occupy one-third of the breadth of the chief, or, if charged, double that breadth. When a pile is borne issuing, not from the



Pile.

middle chief, but from some other part of the bounding-line of the shield, this must be specified in the blazon. Three piles are sometimes borne conjoined in point. A pile *transposed* is one whose point is upward.

2. A round or squared log of wood used in engineering operations, such as dams, bridges, roads, etc. They are sharpened at the point, and, if necessary, protected with iron points, to enable them to cut through the strata they encounter as they are driven into the ground. When used for coffer-dams, or such temporary purposes, they are placed close together, and driven firmly into the earth; the water is then pumped out, and the piles form a dam, to enable workmen to lay foundations of piers, etc. When the force of the water round the dam is great, two rows of piles are driven in all round, and the space between the rows filled with clay, and puddled. Piles are also used for permanent works, when they are driven through loose soil till they reach a firm bottom, and thus form a foundation on which buildings, roads, etc., may be placed. Cast-iron is frequently used for piles, which are cast hollow. Wharf-walls are sometimes built of piles; they are then cast with grooves on the sides, into which cast-iron plates (forming the walls) are fitted. A kind of pile has been invented by Mr. Mitchell, which is of great use in very loose and shifting substances. It is called the screw-pile, and consists of a long shaft (of wrought iron), with a broad cast-iron disc, of a screw form, at the lower end. These piles are especially useful for light-houses, beacons, etc., which have to be placed on sands. They are fixed by means of capstans, which give them a rotatory motion. In 1843 Dr. L. H. Potts obtained a patent for a new kind of pile, which consists of hollow tubes of iron, from which the sand, etc., within them is removed by means of an air-pump, and the pipes are then sunk. In recent railway bridges, cylinders have been much used to form both piles and piers. They are of cast-iron, and made in pieces (of about 6 feet in height), which are applied one on top of another. The sand or gravel is removed from the inside of the first laid, which thus sinks down; another cylinder is placed above it, and the same process continued till it also has sunk sufficiently; and so on, cylinder over cylinder, till a solid foundation is reached. The requisite number of cylinders is then piled up to form the pier above ground.

PILE ARMS.—To place three muskets, with bayonets fixed or unfixed, in such a relative position that they shall mutually support each other. This is done when men stand from their arms either on parade, on the march, or in camp. See *Stack Arms*.

PILE BRIDGE.—A form of bridge much used in military operations, having the piers built with piles. These may be either temporary wooden structures, in which wooden piles, driven into the ground, serve also as piers, or they may be permanent bridges, with iron cylinders forming the piles below the surface, and piers above.

PILE-DRIVER.—A machine having a rising and falling weight to drive a pile into the bed. Nearly forty years ago an eminent Scotch Engineer, James Nasmyth, the inventor of the steam-hammer, constructed the first steam pile driver which, although a great improvement on the ordinary drop-hammer in many respects, never came into general use for several reasons. Principal among which were the liability of the machines through complication of parts to get out of order, and the fact that the end of each separate pile required to be accurately fitted and banded before it could be driven. Subsequent

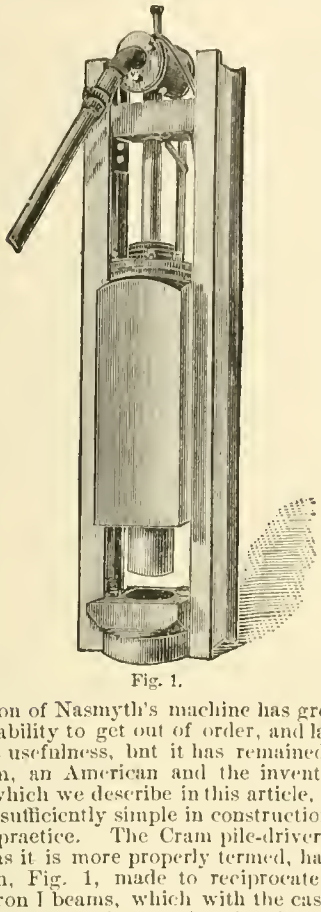


Fig. 1.

modification of Nasmyth's machine has greatly lessened its liability to get out of order, and largely increased its usefulness, but it has remained for Mr. R. J. Cram, an American and the inventor of the machine which we describe in this article, to devise an engine sufficiently simple in construction and effective in practice. The Cram pile-driver, or pile-hammer, as it is more properly termed, has a cylindrical ram, Fig. 1, made to reciprocate between wrought-iron I beams, which with the casting connecting the upper ends, carrying the piston rod and valve and the *bonnet casting*, holding the head of the pile, and connecting the bottom ends, make the frame which guides the machine while being hoisted between the leaders, or when following a pile which is being driven. These pile-hammers may be readily applied to any machine of the ordinary patterns without any alteration excepting such as may be necessary to accommodate the width of the hammer, and afford an opportunity for connecting the flexible pipe which conveys steam from the boiler to operate the hammer. The hammer being hoisted to a rest at a convenient height, the pile to be driven is placed in position and the hammer lowered until the bonnet casting, which forms the bottom of the frame, receives the head in the conical aperture through which the pintle-like projection on the bottom face of the hammer strikes, when a blow is delivered. The weight of the hammer being on the pile, the clutch on the winding drum or other device controlling its descent, is cast adrift and the valve thrown open to admit the passage of steam through the flexible pipe and the hollow piston rod sufficient to operate the hammer at any desired speed.

On the admission of steam the hammer immediately rises in its frame or cage, to the full extent of the stroke at which it may be set, ordinarily about four inches, and on reaching the end of its stroke the steam is exhausted and the cylinder falling delivers its blow, and thereafter continues to rain blows upon the pile with a speed at the will of the operator until the pile be down, or the supply of the steam cut off, when the machine is hoisted to the rest at the top of the leaders ready for a repetition of the performance just described. In this connection it may be stated that light or heavy blows may be struck at the will of the operator, as a reverse motion of the valve lever, which, in the hands of the operator, admits steam to the hammer, causes the steam to be exhausted at any desired point in the stroke, and a blow corresponding to the height from which the ram falls delivered; making it possible, if desired by the operator, to test the pile by one or more light blows before the machine is permitted to work automatically at full stroke, or if it is desired to drive the pile in position under the hammer to any desired point. It is possible, when the pile is found to be nearly home, to stop the automatic working of the hammer and deliver the remaining blows required to bring the pile to its proper position by hand. This feature in the working of this hammer is particularly advantageous, because since the heads of the piles driven with this hammer are neither bruised nor shattered, the ability to drive to any desired level with accuracy and expedition precludes, in many cases, the necessity of cutting off the piles to gain a common level. In the use of this machine, whether on land or mounted on a float, it is found that with the point of the pile in position, and the head held by the bonnet casting, no other guides of any sort are required to insure accuracy of position when driven. The bonnet casting referred to in this machine is so constructed that no preparation of the heads of the piles is necessary

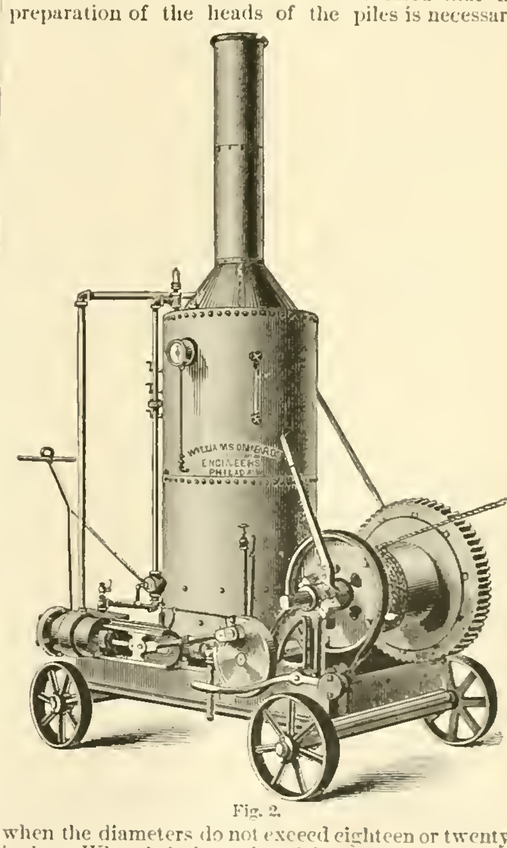

Fig. 2.

when the diameters do not exceed eighteen or twenty inches. When it is desired to drive piles of a greater diameter the heads are roughly chamfered with a chopping axe. It is an exceedingly difficult matter to compare the work done by this simple machine with that of the ordinary drop-hammer, because this steam-hammer will so readily do work that the ordinary drop-hammer will not do at all, for instance, after a pile has been driven with an ordinary drop hammer until it has become necessary to remove the ring and cut a section off the pile to form a new and solid head, by experiment it has been found that the steam-hammer experiences no difficulty in forcing the pile until the point reaches hard pan or rock, and it will, perhaps, be sufficient to state that in the machine here illustrated, the ram weighing 5,500 lbs., when working under a pressure of 75 lbs. of steam delivers upwards of 100 blows per minute, more than sufficient to force a pile through hard sand or clay to the depth usually desired.

The fact that the ram, when the blow is delivered, is free, unattached to piston rod, valve gear, or any other part, will recommend the machine to practical men, as will also the fact that the valve is a perfectly balanced, positive action valve, with a travel of but $\frac{5}{8}$ of an inch in a steam jacketed chest, and that the attachments of the hose at either end are flexible, thus avoiding any cramping, or twisting which otherwise would occur. The tappit or trip operating the valve is adjustable, permitting the operator to control the length of stroke when the machine is working automatically, thereby making the force of the blows suit the work in hand. Spiral percussion springs are fitted in pockets in the "bonnet casting" to receive any chance blow, and in practice are found to effectually prevent any loosening of the fastenings connecting the bonnet casting with the I beams. Fig 2 shows a portable spur-geared pile-driver engine, having a cone friction single drum. The engine is designed for either portable or stationary purposes, and is constructed either with or without wheels. The drum is loose on the shaft, having a conical friction clutch which is thrown into or out of contact with the large gear wheel by means of a hand lever operating a spiral sleeve on the drum shaft. The drum, in lowering, revolves back free of the gear, and is controlled by a strap brake lined with wood, operated by a foot lever. A relief valve is also fitted to the engine, which allows it to back down with the load. This style of engine is the favorite in the United States for land pile driving machines. It is also well adapted for other kinds of work where speed in lowering is required. The engine may be made either vertical or horizontal, single or double cylinder, either connected or independent of each other, and with single or double drums. The foregoing table shows the power required for a specified duty. See *Gunpowder-hammer*.

Style of Engine.	Power.	Cylinder. Bore.	Cylinder. Stroke	Boiler. Dia.	Boiler. H'ight	Tubes. No.	Tubes. Dia.	Tubes. L'ngth	Dia. of Drum.	Duty of Engine lbs.
Horizontal or Vertical. Single Engines. One Drum.	6	6	8	32	63	41	2	39	10	1800

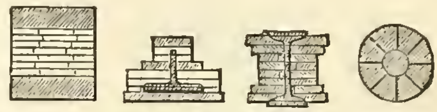
	20	7	10	40	90	85	2	60	12	6000
Horizontal or Vertical. Double Engines connected to same crank shaft. Two Drums.	12	6	8	36	78	55	2	54	12	1800
	20	7	10	40	90	85	2	60	12	3000
Double Vertical Independent Engines.	6	6	8	36	78	55	2	54	10	1800
	10	7	10	40	90	85	2	60	12	3000

Dia. of Drum can be varied to suit the work.

PILETUS.—A kind of armor formerly used, having a knob upon the shaft, near the head, to prevent it from penetrating the object aimed at too deeply.

PILING.—In iron-working, the process of building up piles of iron bars, to be charged into the balling-furnace. The amount of work put into bar-iron varies with the quality. For the common kinds, puddled bars, or No 1 iron, cut into lengths, are piled, and when brought to a welding-heat are rolled off, either with or without first being worked into a bloom under the hammer. More usually, however, the iron of second-rolling, No. 2, is employed at the top and bot-



tom plates of the piles when making finished No 3. or best iron. Beyond this, if further piled and welded, the iron is distinguished as *best-best* and *treble-best* according to the number of heatings and weldings to which it has been subjected. The drawing shows samples of piling for plate, T, girder and bar-iron; the deeper shaded inner outlines representing finished sections. The harder and more granular kinds of iron are worked almost exclusively under the hammer, the rolling-mill being only used in giving the proper figure to the bar at the finishing stage.

The great improvement in the strength of malleable iron by the processes of piling and rolling has been more satisfactorily established by experience than explained by theory. One obvious effect of the violent compression between the rollers is the squeezing out of slag, which is liable to become entangled in the iron during hammering and rolling of the balls taken from the puddling-furnace. The occurrence of small masses of slag in malleable iron is not an uncommon cause of weakness, each particle of slag giving rise to a flaw in the metal. In the process of reheating the bars this slag is melted, and may then be squeezed out by the action of the rollers.

A marked diminution in the proportions of carbon and silicon present in the iron is also effected during the process, as shown by the following results of chemical analysis:

In 100 parts	Carbon.	Silicon.
Puddled bar...............	0.296	0.120
Best bar....................	0.111	0.088

This may be explained by the action of the oxide of iron formed upon the surface of the bar during exposure to air at a welding-heat. The rolling of several bars into one single bar would render the structure of the metal uniform, so that the bar would be equally strong throughout.

During the operation of fagoting, or piling and rolling, the iron acquires a remarkable fibrous structure, so that if a bar of the best iron be notched with a chisel, and broken across by a steady pressure, the fracture will present a stringy appearance, resembling that of a green stick; whilst a puddled bar thus treated would exhibit a crystalline, shining fracture, not unlike that of cast-iron. That this *nerve*, or reed, as the fibrous structure is sometimes called, should materially increase the resistance of a bar to any transverse strain, can readily be believed, for such a bar resembles a bundle of wires firmly bound together, whilst a crystalline bar must be regarded as composed of a number of particles of iron stuck together in a confused manner. See *Iron*.

PILING OF BALLS.—Balls are piled according to kind and caliber, under cover if practicable, in a place where there is a free circulation of air, to facilitate which the piles should be made narrow, if the locality permits; the width of the bottom tier may be from 12 to 14 balls, according to the caliber. Prepare the ground for the base of the pile by raising it above the surrounding ground so as to throw off the water; level it, ram it well, and cover it with a layer of screened sand. Make the bottom of the pile with a tier of unserviceable balls, buried about two-thirds of their diameter in the sand; this base may be made permanent; clean the base well and form the pile, putting the fuse-holes of shells downwards, in the intervals, and not resting on the shells below. Each pile is marked with the number of serviceable balls it contains. The base may be made of bricks, concrete, stone, or with borders and braces of iron. Good and imperfect balls should not be used in the same base; and, to avoid confusion, the unserviceable should be left unpainted, or painted of a different color from the serviceable.

To find the number of balls in a pile: Multiply the sum of the three parallel edges by one-third of the number of balls in a triangular face. In a square pile one of the parallel edges contains but one ball; in a triangular pile two of the edges have but one ball in each. The number of balls in a triangular face is $\frac{n\,(n+1)}{2}$; n being the number in the bottom row. The sum of the three parallel edges in a triangular pile is $n + 2$; in a square pile, $2n + 1$; in an oblong pile, $3N + 2n - 2$, N being the length of the top row, and n the width of the bottom tier; or $3m - n + 1$, m being the length, and n the width of the bottom tier. If a pile consists of two piles joined at a right angle, calculate the contents of one as a common oblong line, and of the other as a pile of which the three parallel edges are equal.

To find the length of a pile which shall hold a given number of balls, the width of the base being fixed: A = the number of balls to be piled. n = the number in the width of the base of the pile. m = the number of balls in the length of the base of the pile; then

$$m = \frac{6A + n\,(n+1)\,(n+1)}{3n\,(n+1)}$$

In the table of the number of balls in a pile, on page 526, the second line shows the number in a triangular pile, the base of which is the corresponding number in the first line. The other numbers show the contents of square and oblong piles; the length and width of the base being in the upper line and in the left-hand column, respectively.

For rifle projectiles: Divide the number of projectiles to be piled by the number in the triangular face decided upon, and multiply this number by the caliber in feet of the particular projectile to be piled. The dimensions provisionally adopted for service rifle projectiles are as follows, viz: Total length, $2\frac{1}{2}$ calibers. Radius of head, $1\frac{1}{2}$ diameter of projectile. Windage, 0″.05. The cavity for cored shot and for shells is of a somewhat similar form to the exterior of the projectile, except that the bottom is rounded, and its size is so proportioned as to secure the proper weight to the projectile.

The following formulas are useful in connection with this subject:

For an ogival head of 1 diameter radius: Volume of head $= D^3 \times 0''.395592$.

For an ogival head of $1\frac{1}{4}$ diameter radius: Volume of head $= D^3 \times 0''.44765$.

For an ogival head of $1\frac{1}{2}$ diameter radius: Volume of head $= D^3 \times 0''.49425$

(D = diameter of shot.)

Center of gravity of ogival head; Distance from

$$\text{base} = \frac{\frac{1}{2}(r^2 + a^2)\,g^2 - \frac{1}{4}\,g^4 + a\,(\frac{2}{3}\,a^3 - r^2,}{(r^2 + a^2)\,g - \frac{1}{3}g^3 + 2a\,s}.$$

in which g = length of head, r = radius of head, a = radius of head — radius of projectile.

Weight of cored shot; Small calibers $\frac{(\text{Diam.})^3}{3}$ · large calibers $(\text{radius})^3 \times 2.8$.

PILING OF BARRELS.—The following formulæ refer to the usual manner of piling barrels in magazines.

Case 1.—Pyramid pile.

$$S = 1+2+3. \ldots + n\cdot$$

where S = number of barrels,

n = number in bottom row.

$$\therefore S = \frac{n\,(n+1)}{2} \;.\;.\;.\;.\;.\;.\;.\;.\;.\;.\;.\;.\;.\;.\; (1)$$

In an incomplete pyramid pile,

$$S = \frac{n\,(n+1)}{2} - \frac{(m-1)\,m}{2}$$

$$= \frac{n^2 - m^2 + n + m}{2}$$

$$= \frac{(n+m)\,(n-m\times 1)}{2};\;.\;.\;.\;.\;.\;.\;.\;.\;.\; (2)$$

where m = number in top row.

Case 2.—Where *one* end of the pile rests against an upright, and *the top row does not touch* the upright.

$$S = n^2 - m^2;$$

where n = number in bottom row, and m number in top row.

Suppose the pile continued till $m = 1$. Then,

$S = 2\,(1+2+3. \ldots +n) - n - 1$

$= n\,(n+1) - (n+1)$

$= (n+1)\,(n-1) = n^2 - 1; \ldots \ldots \; (3)$

and in an incomplete pile,

$S = (n^2 - 1) - (m^2 - 1) = n^2 - m^2 \;.\;.\;.\;.\; (4)$

Case 3.—If the top row touch the upright.

$S = n^2 - m^2 + m \;.\;.\;.\;.\;.\;.\;.\;.\;.\;.\;.\;.\;.\;.\;.\;.\; (5)$

Case 4.—Where the barrels are piled *between two uprights* so that if bottom row $= n$, second $= n-1$, third $= n$, and so on.

If top row $= n - 1$, *i.e.* if top row do not touch the uprights,

$$S = mn - \frac{m}{2} = \frac{m}{2}\,(2n - 1);\;.\;.\;.\;.\;.\;.\;.\;.\;.\;.\; (6)$$

where m = number of courses.

When top row $= n$, *i.e.* when top row touches uprights,

$S = mn - \frac{1}{2}\,(m - 1)$

$$= \frac{m\,(2n - 1) + 1}{2}\;.\;.\;.\;.\;.\;.\;.\;.\;.\;.\;.\;.\;.\;.\;.\; (7)$$

These results, being only calculated for piles of one barrel in depth, must of course be multiplied by the number of barrels in the *depth* of the piles.

PILLAGE.—The act of plundering; that which is taken from another by open force, particularly and chiefly from enemies in war.

PILLAR CRANE.—A crane of this class is entirely supported from below, and the masonry which forms the foundation must have sufficient stability

Table of the number of balls in a pile.

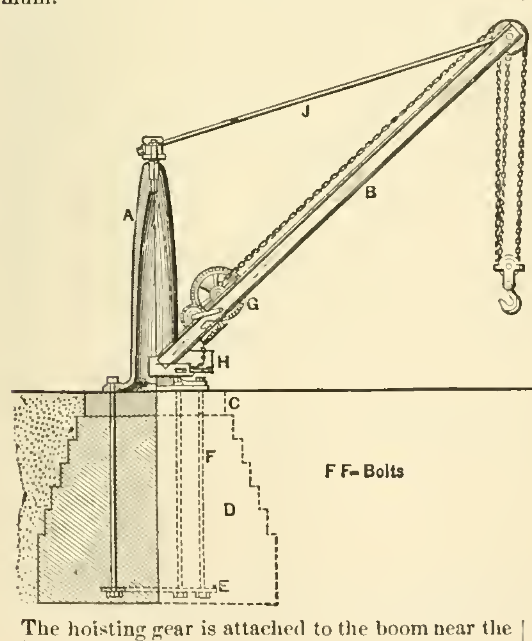
to resist the overturning tendency caused by the load hanging from the outer end of the boom. Where the surrounding ground is sufficiently firm the proportions of this foundation are about as represented in the drawing. On filled ground, piling or a timber platform beneath the masonry, or both, may be necessary. These questions can only be properly determined by a consideration of the fact in each case. Referring to the drawing, A is the column of the crane, and B the boom carrying the upper block and revolving around the fixed mast or column, A; D is the masonry foundation; E,a heavy iron plate or ring embedded in the masonry near its bottom; FF foun ation-bolts passing through this ring and also through the base of the pillar, A, thus securely fastening the latter to the foundation. The foundation, D, may consist of ordinary rubble masonry, covered with a cap stone, C, the upper surface of which should be dressed smooth to receive the base of the pillar, A. After the completion of the foundation the ground surrounding it should be refilled and thoroughly packed by ramming or puddling, so as to assist the foundation in resisting the strains caused by the crane.

The pillar or column of the crane is of cast-iron, and of simple but symmetrical design, its form being proportioned to the strains it has to resist. It has a broad base, thus giving it a good footing on the foundation and spreading the holding down bolts well apart. Fixed in the head of the column is a steel pin or pivot upon which rests the cross head or yoke. The latter is bushed with bronze and has proper provision for lubrication, so that the cross-head shall always turn freely on the pin. The boom or strut consists of two wrought-iron channel beams, well braced together and united at the upper end by a head casting carrying the upper chain sheaves over which the chain passes to the running-block. The foot of the boom is supported vertically by two suspension rods, hung from the ends of the cross-head, and its upper end or head is held by two guy rods, also extending back to the cross-head. The horizontal thrust at the foot of the boom is transmitted to two turned rollers, placed within the foot casting of the boom and traveling upon a turned path around the base of the column. The weight, both of the boom and load, is entirely carried by a steel pin at the top of the column, and the friction of rotation is thus reduced to a minimum.



The hoisting gear is attached to the boom near the column and rotates with the former. It consists of a train of spur gearing provided with an automatic safety ratchet and with the Weston disc-brake for lowering, substantially as in the jib-crane, so that the load is always self-sustained and cannot run down, nor the handles recoil on the operator. Lowering is effected by turning the cranks backward, the load descending easily and smoothly so long as this motion is continued, but coming to rest if the backward motion be discontinued or the handles let go. Two changes of speed are provided. Swinging or rotation of the crane is effected by pushing or pulling the suspended load, and the construction is such that the maximum load can be easily swung by one man.

This type of crane is designed for yard use where there is no roof or ceiling to support the top of crane, and where guy rods are objectionable. It is particularly adapted to railroad and wharf use, for loading and unloading heavy ordnance from cars or boats, and is a useful addition to the yard appliances of any large foundries. They are constructed for operation by hand, by power, or by direct steam, according to the requirements of the case. See *Cranes*.

PILLENLICHTE. Short cylindrical tubes of laboratory paper, filled with a composition resembling that used in port-fires. A countersink is formed in one end, at the bottom of which is placed a small disk of fulminate covered with a water-proof cap. The entire exterior is varnished. These are used to light the fuses of the life-saving and anchor rockets of the Germans. They are put up in packages of twenty each. The following are the dimensions and weight:

	Inches.	Centimeters.
Total length	1.55	3.93
Exterior diameter	0.625	1.58
Depth of countersink in end	0.1	0.25
Time of burning	Seconds. 45	....
Weight	Grains. 230	....

See *German Life-saving Rocket*.

PILLES.—A name given to arrows in the twelfth century, according to the chronicles of Saint Denis.

PILON.—A half-pike, 7 feet long exclusive of the iron, which was 18 inches. It consisted of a fir tube covered with parchment and varnished. Marshal Saxe proposed to draw up an army four deep, the two front ranks armed with muskets, and the two rear with both pilons and muskets.

PILUM.—A formidable spear used by the Romans. It bore no resemblance to any other weapon of the same class, either lance, pike, or javelin. Each soldier of the legions carried two pila. The weight of the pilum caused it to be regarded rather as a spear than as a dart.

PIN.—A short piece of wood or metal, generally with a head and hole at the other end to receive a key. There are many sorts used in army material. See *Bolt*, and *Linch-pin*.

PINCH.—To *pinch* a gun or other object is to move it by small heaves with a pinch-bar or handspike, without allowing it to turn on its axis. A piece is pinched one end at a time, the other end being chocked. The bar or handspike is placed as a lever, with the beveled side down, and the power applied at the other end by bearing down.

PINCH-BAR.—A stout handspike, of iron, with a round-beveled butt, turned up into a blunt edge for the purpose of catching under a gun or other similar object. It is used as a lever, by pressing down, thus *jumping* the gun forward a very short distance at a time. The butt end is of steel. The length of the bar is from five to seven feet. Those used with the 15-inch gun are of the largest size, and weigh 53 pounds; the shorter size weigh 26 pounds. See *Mechanical Maneuvers*.

PINCHBECK.—An alloy of zinc and copper, in which the proportions slightly differ from those which constitute brass; 3 parts zinc to 16 of copper constitute this material, instead of 1 part of the former to 2 of the latter as in common brass. Pinchbeck, when new, has a color resembling red gold.

PINDAREES.—In the East Indies, plunderers and marauders who accompany a Mahratta army. The name is properly that of persons who travel with grain and merchandise; but war affording so many opportunities and creating so many necessities, the merchants, as it is all over the world, become plunderers and the worst of enemies.

PING.—The whistle of a shot, especially the rifle-bullet in its flight.

PINTLE.—The vertical bolt around which the chassis is traversed. In the center-pintle carriage it is in the center of the chassis, but in the front-pintle carriage it is in the center of the front transom. It is a stout cylinder of wrought-iron inserted in a block of stone, if the battery be a fixed one; or it is secured to cross pieces of timber bolted to a platform firmly embedded in the ground, if it be of a temporary nature. In casemate batteries the pintle is placed immediately under the throat of the embrasure, and the chassis is connected with it by a stout strap of iron, called the *tongue*. Casemate carriages differ from barbette carriages in being much lower, but their mode of construction is essentially the same.

PINTLE-HOLE.—An oval-shaped aperture made in the trail transom of a field-carriage, wider above than below, to leave room for the pintle to play in.

PINTLE-HOOK.—In ordnance, a hook attached to the rear of the limber axle-tree bed of a light field carriage to enable the gun or ammunition carriage to be limbered up to it. In this position the gun forms a counterpoise to the weight that would otherwise rest on the shafts. In heavy howitzers and siege carriages formed with bracket sides, the pintle-hook is either a stiff or movable iron perch, attached to the top of the limber axle-tree, to which the gun carriage is limbered up by a hole passing through the rear transom.

PINTLE-PLATE—A flat iron, nailed to both sides of the bolster, and through which the pintle passes.

PINTLE WASHER.—An iron ring, through which the pintle passes, placed close to the bolster for the trail to move upon.

PIONEER.—A military laborer employed to form roads, dig trenches, and make bridges as an army advances, and to preserve cleanliness in the camp when it halts. Formerly, the pioneers were ordinary laborers of the country in which the army was, impressed for military purposes; but now such persons are only brought in as auxiliaries, a few men being attached to every Corps as a permanent body of pioneers. In the British Army one man is selected, for his intelligence, from every company. These pioneers march at the head of the regiment, and the senior among them commands as Corporal. Instead of a musket each man carries a saw-backed sword, which is at once tool and weapon. Each bears also an axe and two gun-spikes, other necessary tools being distributed among them. There is something rather conflicting between the functions of the pioneers and those of the engineer force.

PIONEER SERGEANT.—In the British service, the Non-commissioned Officer who commands the pioneers.

PIPE BOX.—The cylindrical box in the nave of a wheel in which the axle-tree arm works, and in which is a recess for holding grease. A hard alloy, technically known as "metal," composed of copper, tin, and zinc, is now used as the material for pipe-boxes in preference to cast-iron, on account of the less development of friction between it and the iron arm.

PIPE-CLAY.—A fine clay, free from iron and other impurities, having a grayish-white color, a greasy feel, and an earthy fracture. It adheres strongly to the tongue, and is very plastic, tenacious, and infusible. The localities where it is chiefly obtained are Devonshire, and the Trough of Poole in Dorsetshire. It is also found in various places in France, Belgium, and Germany. This substance is much used by soldiers for the purpose of keeping their buff belts, etc., clean.

PIPER GIN.—In this gin, the windlass is attached by placing it in windlass seats of peculiar construction, and is secured in position by *keepers* attached to the legs. The keepers are placed under the axles of the windlass. Two stay chains connect the pry-pole and legs at the upper brace-bands, and prevent them from spreading. They also serve to connect the parts for transportation. Two braces (upper and lower) connect and secure the legs when the gin is put together, and serve to distinguish the right from the left leg—the long brace being permanently attached to the right and the short brace to the left leg. The clevis and clevis bolt are attached to the head of the pry-pole with keyes which secure the clevis bolt when the gin is assembled; double and single blocks, with fall, are used. This gin was designed by the late Captain J. W. Piper, Fifth artillery.

Length of legs	13 feet 8 inches.
Length of pry-pole	13 feet 8 inches.
Weight of gin	365 pounds.
Weight of windlass	88 pounds.
Weight of block and fall	100 pounds.
Weight of bail and dowels	41 pounds.

The parts are estimated to be sufficiently strong to bear a weight of of 5,000 pounds. The advantages of this gin are, its superior lightness and portability, and its great facility of being assembled, taken apart packed up, and transported. See *Gin*, and *Mechanical Maneuvers*.

PIQUICHINS.—Irregular and ill-armed soldiers, of which mention is made in the history of the reign of Philip Augustus. They were attached to the infantry.

PIRACY.—Robbery on the high seas, and is an offense against the Law of Nations. It is a crime not against any particular State, but against all mankind, and may be punished in the competent tribunal of any country where the offender may be found, or into which he may be carried, although committed on board a foreign vessel on the high seas. It is of the essence of piracy that the pirate has no commission from a Foreign State, or from one belligerent State at war with another. Pirates being the common enemies of all mankind, and all Nations having an equal interest in their apprehension and punishment, they may be lawfully captured on the high seas by the armed vessels of any particular State, and brought within its territorial jurisdiction for trial in its tribunals. The African slave-trade was not considered piracy by the Law of Nations; but the municipal laws of the United Kingdom and of the United States by statute declared it to be so; and since the treaty of 1841 with Great Britain, it is also declared to be so by Austria, Prussia, and Russia.

PIRAMETER.—An instrument for measuring the power required to draw a gun carriage, etc., upon a road or track. See *Dynamometer*.

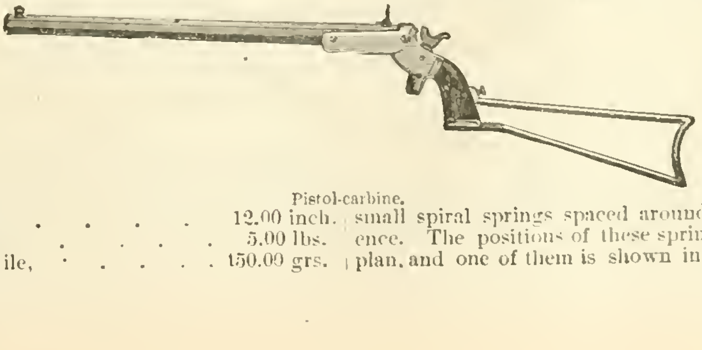
PIRATES.—Men, or squads of men, who commit hostilities, whether by fighting or inroads for destruction or plunder, or by raids of any kind, without commission, without being part and portion of the organized hostile army, and without sharing continuously in the war, but who do so with intermitting returns to their homes and avocations, or with the occasional assumption of the semblance of peaceful pursuits, divesting themselves of the character or appearance of soldiers—such men, or squads of men, are not public enemies, and, therefore, if captured, are not entitled to the privileges of prisoners of war, but shall be treated summarily as highway robbers or pirates.

PIRSCHER SYSTEM OF FORTIFICATION. In this system, the enceinte is circular, and the ditch is occupied by two lines of works mutually flanking each other. The covered way and glacis are replaced by advanced works.

PISA REVETMENT.—A wall of clay built against a slope in the following manner: Common earth, mixed with clay and moistened with water, is kneaded until the particles will adhere when pressed or squeezed together. Sometimes chopped straw is mixed in the mass. A row of pickets, with the proper inclination given to them, is driven along the foot of the interior slope, the tops extending a short distance above the height marked for the interior crest. A shallow trench about twelve inches wide is dug in the parapet, behind the line of pickets, and a board laid horizontally on edge on the side next to and supported by the pickets. The tempered clay is then placed in the trench and rammed. Successive layers are placed in until the clay reaches the top of the board, the earth of the parapet being carried up simultaneously with the revetment. A second board is then placed upon the first, and the clay rammed in, rising simultaneously with the parapet as in the first course; and this process is continued until the top layer is on the same level with the interior crest. When the clay has dried, the boards and pickets are removed.—See *Revetment*.

PISTOL.—The smallest description of fire-arm, and is intended to be used with one hand only. Pistols vary in size from the delicate saloon-pistol, often not six inches long, to the horse-pistol, which may measure eighteen inches and sometimes even two feet. They are carried in holsters at the saddle-bow, in the belt, or in the pocket. Every cavalry soldier should have pistols, for a fire-arm is often of great service for personal defense, and almost indispensable for giving an alarm or signal. Sailors, when boarding an enemy's ship, carry each two in their waist-belts. As early as the reign of Henry VIII. the English cavalry carried clumsy pistols called "Dags." The latest improvement on the pistol is the revolver. The *pistol* probably derives its name from the word *pistallo*, which means "pommel," and not from the word *Pistoja*, for it appears not to have been first made at Pistoja, but at Perugia.

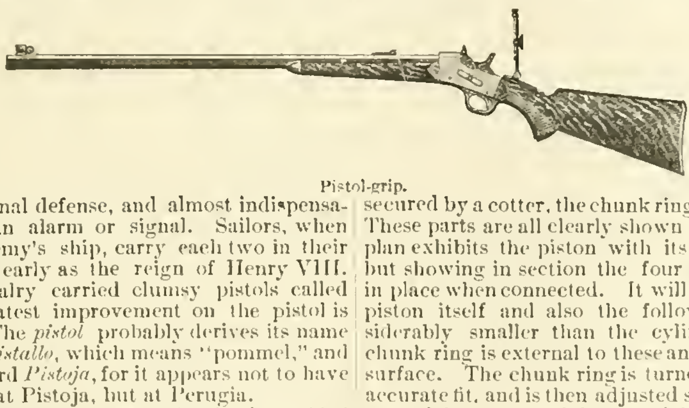
PISTOL CARBINE.—A horseman's pistol provided with a removable butt-piece, which may be secured to its stock by a spring-catch, or detached, so that the weapon may be fired either from the hand or the shoulder. The pistol-carbine used in the United States, and particularly suited to the service of light artillery, has the following particulars:



Pistol-carbine.

Length of barrel,	12.00 inch.
Weight complete,	5.00 lbs.
Weight of projectile,	150.00 grs.
Weight of powder,	40.00 grs.
Initial velocity,	603.00 feet.

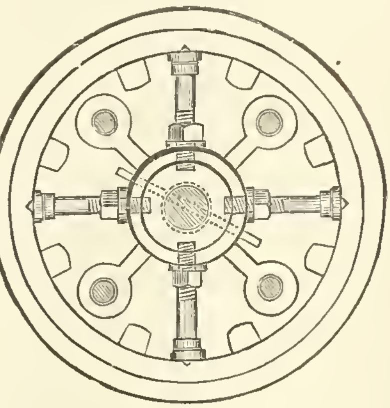
PISTOL GRIP.—A shape given to the small of the stock in shot-guns and rifles, to give a better hold for the hand. The pistol-grip has of late become quite popular and nearly all the recent models of sporting arms embody it. See *Pistol-carbine*.



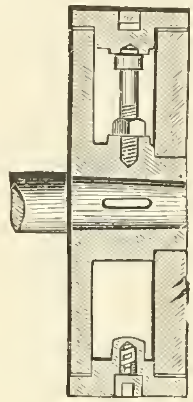
Pistol-grip.

PISTON. A device so fitted as to occupy the sectional area of a tube, and be capable of reciprocation by pressure on either of its sides. It may be of any shape corresponding accurately to the bore of the tube; but the cylindrical form is almost exclusively employed for both, as in the common pump and steam-engine. One of its sides is fitted to a rod, to which it either imparts reciprocatory motion, as in the steam-engine, or by which it is itself reciprocated, as in the pump. In the former case it is termed solid, though generally not really so; but in the latter, an aperture controlled by a valve permits the passage of the fluid from one side to the other during its downward movement. The piston usually requires "packing" to cause it to fit closely within its cylinder, and at the same time allow its free backward and forward motion. For this purpose its ends are usually formed by two connected discs, or have a deep annular groove between them for receiving the packing material, which may be hempen cord wound around it, or other somewhat expansible substance, which will not wear too rapidly nor cause excessive friction. In modern practice, metallic rings, cut through at one side, so that their expansion may compensate for any wear, are largely employed in the steam-engine.

The cut on page 530 shows the plan and section of the Cummer piston. It is made large enough to give ample wearing surface, and with sufficient weight and careful distribution of metal, to secure strength, no extra weight being given for any other purpose. The piston consists of three parts, the piston proper, to which is fitted the tapered end of the piston rod secured by a cotter, the chunk ring, and the follower. These parts are all clearly shown in the section. The plan exhibits the piston with its follower removed but showing in section the four bolts which hold it in place when connected. It will be noticed that the piston itself and also the follower are made considerably smaller than the cylinder, and that the chunk ring is external to these and forms the bearing surface. The chunk ring is turned up so as to be an accurate fit, and is then adjusted so as to be perfectly central by means of four stud bolts, which appear in the plan and section; their outer ends have a conical point which bears against the chunk ring, while the other ends are tapped into the boss of the piston and are provided with jam nuts. The center of the chunk ring is grooved to receive the cast-iron piston ring which is pressed well outwards by several small spiral springs spaced around the circumference. The positions of these springs appear in the plan, and one of them is shown in the section. An additional packing is provided by turning two small grooves in the chunk ring on either side of the central piston ring. The advantage of using a chunk ring is, that we can make a very exact fit, and by using the central adjustment, secure perfect alignment, and we obtain a greater wearing surface for the same thickness of piston because the chunk ring is the same width as the piston itself and bears over its whole surface, whereas in the ordinary form a



Plan.



Section.

part of the piston, and the follower also, are turned down below size and do not bear at all. By this arrangement, also, whenever after long wear it becomes necessary to rebore the cylinder, we have only to turn up a new chunk ring instead of fitting up a whole new piston. See *Steam-engine.*

PISTOS.—Broad, short, double-edged swords of the fifteenth century, which do not differ materially from the *anelaces.*

PIT.—The pit, in gun-casting, is usually a circular well, nineteen feet deep, and twelve feet in diameter; the walls are of brick, and the bottom, an iron tank of one-half inch sheet-iron, extending upwards eight feet. The mouth of the pit is provided with iron covers, made to fit closely to prevent escaping of heat from the fire built around the flask. During the casting, the gas which is generated and passed out through the holes in the flask is ignited by dropping small quantities of molten metal into the pit, and as soon after "cast" as possible, a fire is built in the pit, about the bottom of the flask—wood and bituminous coal being used in sufficient quantities to burn four or five days; the mouth of the pit being covered, after the mass is thoroughly ignited. See *Molding.*

PITAUX.—This term, sometimes written *Petaux,* was formerly used to distinguish those peasants who were pressed into the service, in contradistinction to soldiers who were regularly enlisted.

PIT-BURNED CHARCOAL.—This description of charcoal is used in the manufacture of what is known as "pit gunpowder," and is found to be more suitable for filling fuses, port-fires, etc., than that made from retort-burned charcoal; it is also used for pyrotechnic compositions and other purposes of a similar kind. Charring the wood in a pile covered up with straw and sods is found to produce a charcoal which will give to the gunpowder the peculiar qualities required for the before-mentioned purposes; the process employed is as follows: The wood is built up in a cone about 10′ in diameter at the base and from 5′ to 7′ in height, a vertical hole being left in the center of the pile or cone reaching from the bottom to the top, so as to act as a chimney. The wood is then entirely covered over with a layer of straw from 4″ to 5″ in thickness, then a covering of charcoal refuse or sweepings from the store, if such can be obtained, and over all a covering of sods with the grass side inwards. The pile is now fired by a few pieces of lighted charcoal being dropped to the bottom of the vertical hole or chimney (which is afterwards closed at the top), and the process of charring commences, beginning at the center and spreading all round until the whole pile is charred. A shifting screen is generally employed so as to regulate the draught on the windward side, and small holes are made through the sods with a half-inch iron rod, these allow the vapor to escape and draw the fire to any side of the pile that may be desired. From seventy to eighty hours are required to char the whole mass, and as the charcoal produced by this process contains more of the woody fiber than the cylinder retort-burned charcoal, it consequently burns more slowly, is heavier, has a reddish tinge, is not so brittle, and has a more metallic sound when dropped. See *Charcoal.*

PITCH.—A thick substance obtained by boiling down tar to the requisite consistency, either by itself or combined with a portion of rosin; it becomes solid on cooling, but is soon softened by the heat of the hand, in which state it is very adhesive. When of good quality, it is clear and hard. It is used in making carcasses, light-balls, kit, and smoke-balls.

The term is also used in wheel-work, signifying the distance between the centers of two contiguous teeth. *Pitch-line* is the circle concentric with the circumference which passes through all the centres of the teeth.

What is known as the *pitch of a screw* is the interval between the points of starting and of arrival of a complete revolution of a screw, and consequently of the thread of a screw, which is traversed by the screw, or its thread, when it has completed an entire revolution. The pitch is therefore independent of the diameter of the screw.

In rifling, the *pitch* is described as term resistance of the direct progressive motion of the projectile through the bore. This resistance varies according to the incline as well as the pattern of rifling; for as the more defined the pattern the more the resistance, so the sharper the pitch the greater the rotation of projectile around the axis of progression, and consequently the more difficult its initial and the slower its direct forward motion There are two natures of pitch, an increasing and decreasing pitch. See *Twist.*

PITCHED BATTLE.—A battle in which the hostile forces have firm or fixed positions, in distinction from a skirmish. See *Battle.*

PITCHED FASCINE.—Pitched fascines are fagots of dry twigs, covered over with an incendiary composition, and used to set fire to buildings or to light up a work. The following materials and utensils are required to make pitched fascines: *Dry branches,* about .5 inch diameter, or other light, combustible wood; *iron wire,* about .05 inch diameter; *four pickets,* about 40 inches long and $1\frac{1}{4}$ inch diameter; *cylindrical sticks,* 20 inches long, $1\frac{1}{4}$ inch diameter; 2 *trace-ropes;* 1 *rope* for a capstan; 2 *levers;* 1 *small* *cord*; 1 *flat punch*; 1 *saw*, or *bill-hook*; 1 *block*. To make the fascines, form two crotches, 1 foot apart, with the 40-inch pickets; cut the branches 20 inches long, and tie them in the middle of their length, and about 2 inches from their ends, with annealed wire, and place in the axis a cylindrical stick, intended to preserve a vacant space; draw the branches tightly together, that they may hold the composition better, and cut off the ends square.

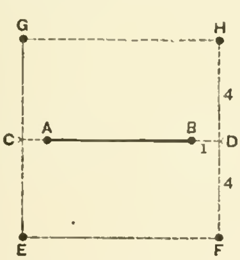
The fascines receive two coats of composition, when pitched. For the first coat, melt 20 parts of pitch and one of tallow in the pots, filling them not more than half full. Having first well oiled the cylindrical stick, plunge the fascine into the liquid with the fork, first one end and then the other, each time pouring on the upper end two ladlefuls of the composition. Let the composition harden, holding the fascine over the pot, turning it slowly and then immerse it in the tub of water. The assistant, with his hands covered with oil, fashions the fascine, rolling it on the bottom of the tub, and places it on the planks.

The second coat is put on 24 hours after the first; it is composed of equal parts of pitch and rosin melted and mixed together in the pot. The cylindrical stick is taken out, and the fascine immersed in the composition, as with the first coat; it is permitted to drip, and is then laid in saw-dust and powdered all over with it. A fascine requires about 1.1 pound of each composition. Fascines should be primed only a short time before being used. For this purpose, dip each end, for a distance of half an inch, into a kettle holding melted rock-fire.

When used for incendiary purposes, fascines are placed in piles, and pieces of quick-match and portfire scattered over them, to make the whole mass take fire at once. See *Fireworks*.

PITCHING FIRE.—Fire is pitching when the shot is projected against an object, covered in front by a work or obstacle, the ordnance being fired at full charge.

PITCHING TENTS.—There is an art in pitching a tent, and the men of a regiment should be instructed from time to time how to pitch their tents and to strike them ready for a march; but they will soon come to know how to do so, even if they have had no previous experience, when once they enter on camp life. The following is the proper method of pitching the ordinary wall tent: After selecting a suitable spot, place the ridge pole, *A B*, upon the ground, approximately beneath its place when in position. Drive pins at *A* and *B*. From *A* and *B*



continue *A B* to *C* and *D*, by stepping one pace from each end. From *C* and *D* make four paces at right angles with *C D* on each side, and determine the points *E*, *F*, *G*, *H*. At these points drive the corner tent pegs. By following these directions the tent may be promptly pitched and will make a beautiful appearance, every portion of canvas being in proper position and free from wrinkles. An important point to be observed in pitching a tent is not to dig inside but outside of it, viz., to use such means, in case of rain, that water shall not flood the tent. This, however, cannot always be prevented, but a drain dug all round the tent to the lowest ground may save a flooding. Then, again, to secure a tent from being blown down, the corner ropes should be bushed.

PITS.—Military pits, whether round or square, should be so arranged as to cause an advancing enemy as much delay and annoyance as possible. They are usually made about six feet in diameter at top, and about one foot at the bottom, and are placed so that the centers shall be about ten feet apart. They shall be placed in rows, at least three in number, the pits being in quincunx order. The earth obtained by the excavation, should be heaped up on the ground between the pits. Shallow pits should not be deeper than about two feet, so that the enemy could not obtain shelter by getting in them. They should cover the ground in zig-zag arrangement, the upper bases being made square or rectangular in form, and in contact with each other. The side of the upper base should be made about equal to the depth of the pit. The earth obtained from the holes is thrown in front of the arrangement, making a glacis. See *Trous-de-loup*.

PIVOT.—The soldier or guide upon whom a line of troops wheels,or partly wheels. The pivot is either *fixed* or *movable*.

In a wheel on a movable pivot the radius is:

For a column of files	2 yards.
For a column of twos, fours, or double column of fours	3 "
For a platoon	6 "
For a company	12 "

PIVOT BOLT.—The axis of horizontal oscillation. A traversing platform passing through the pivot transom and the front sleeper of the platform.

PIVOT FLANK.—When a regiment is drawn up in column right in front that is, when the company which stood on the right, when in line, is in front the left-hand man will be the pivot flank of each company. When the column is left in front, the right-hand man will be the pivot flank of each company.

PIVOT GUN.—A cannon which turns on a pivot in any direction.

PLACAGE.—In fortification, a kind of revetment, which is made of thick, plastic earth laid along the talus of such parapets as have no mason-work, and which is covered with turf.

PLACATES.—In ancient armor, small plates placed in front of the shoulders.

PLACE DU MOMENT.—When the operations of an army render it necessary that a position should be fortified and occupied for the whole campaign, the works assume more importance, and many consist of forts having five or six bastioned fronts. Such a fort is called a *place du moment*.

PLACES-OF-ARMS.—The covered-way, from the direction given to the counter-scarps of the enceinte and outworks, forms a line of communication with salient and re-entering parts. The salient portions are termed *salient places-of-arms*; and the re-entering parts the *re-entering places-of-arms*.

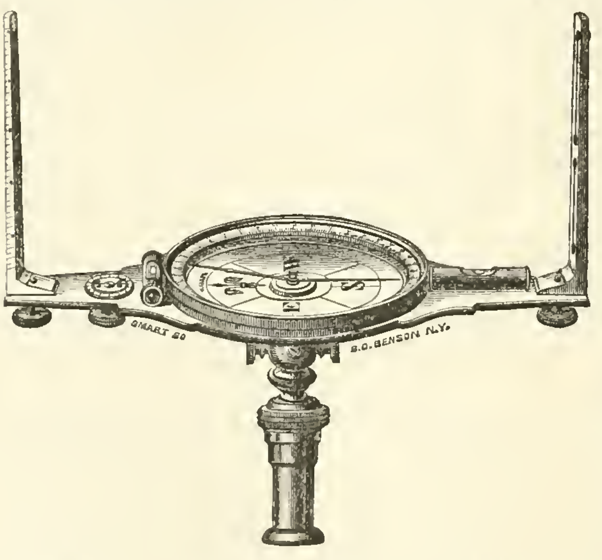
The salient places-of-arms result from the general plan of the covered way; but the re-entering places-of-arms are formed by changing the directions of the two branches where they form the re-enterings, so as to make a salient within the re-enterings; thus enlarging the covered-way at these points, and producing a flanking arrangement, by which the glacis can be swept, and a cross-fire be brought to bear on the ground in advance of the salients. See *Outworks*.

PLAID.—A woolen shawl of a tartan pattern, worn over the shoulder by the Scotch Highlanders, and still worn by Highland regiments.

PLAIN.—In geography, an extensive tract of country which, on the whole, preserves a nearly uniform elevation. When referred to the level of the sea, plains may be distinguished into low plains or low-lands, and elevated plains called plateaux or *table-lands*. Plains differ much in appearance, according to the nature of their soil and the climate, from the frightful sandy wastes of Africa, to the luxuriant fertility of the South American silvas. They are occasionally crossed by hills of moderate altitude, which, however, are generally detached, and exhibit no connection with any neighboring mountain system. These hills often, as in the North American Plains degenerate into mere undulations, quite uniform in structure. The term "Plains" is, in a limited sense, confined to the Plains of Western Europe; those of other parts of the world receiving special designations, and differing from each other in many important points thus we have the *Steppes* of Eastern Europe and Asia: the *Deserts* of Arabia and Africa; the *Savannahs* and *Prairies* of North America; and the *Llanos, Pampas* and *Silvas* of South America. The chief Plains of Europe are, the country stretching from the foot of the Carpathians in Galicia to the Ural Mountains, including Poland and Russia, the drainage area of the Danube in Hungary, and the portion of Europe which is bounded by the Elbe, the Hartz mountains, France, and the sea. Plains of comparatively small extent, but presenting the necessary characteristics in perfection, are found in almost all countries.

PLAIN CLOTHES.—A citizen's every-day dress, as applied to an officer not in uniform; this dress is also known by the familiar name of *mufti.* It is left to the discretion of General Officers Commanding, to permit the use of plain clothes for the purpose of recreation; otherwise all Officers must appear in uniform in camp or quarters, or when attending public balls within the district in which they are quartered.

PLAIN COMPASS.—The plain compass, as shown in the drawing, has a 6-inch needle, and is furnished with levels, sight-vanes, socket, etc. The compass-box is in the same piece with the main plate, and the



instrument is used mainly in the surveys of new lines, or in the preparation of maps, where the variation of the needle is not required. To adjust the compass, first bring the bubbles into the center, by the pressure of the hand on different parts of the plate, and then turn the compass half-way around; should the bubbles run to the end of the tubes, it would indicate that those ends were the highest; lower them by tightening the screws immediately under, and loosening those under the lowest ends until, by estimation, the error is half removed; level the plate again, and repeat the first operation until the bubbles will remain in the center, during an entire revolution of the compass. The sights may next be tested by observing through the slits a fine hair or thread, made exactly vertical by a plumb. Should the hair appear on one side of the slit, the sight must be adjusted by filing off its under surface on that side which seems the highest. The needle is adjusted in the following manner: Having the eye nearly in the same plane with the graduated rim of the compass-circle, with a small splinter of wood or a slender iron wire, bring one end of the needle in line with any prominent division of the circle, as the zero, or ninety degree-mark, and notice if the other end corresponds with the degree on the opposite side; if it does, the needle is said to "cut" opposite degrees; if not, bend the center-pin by applying a small brass wrench, furnished with the compasses, about one-eighth of an inch below the point of the pin, until the ends of the needle are brought into line with the opposite degrees. Then, holding the needle in the same position, turn the compass half-way around, and note whether it now cuts opposite degrees; if not, correct half the error by bending the needle, and the remainder by bending the center-pin. The operation should be repeated until perfect reversion is secured in the first position. This being obtained, it may be tried on another quarter of the circle; if any error is there manifested, the correction must be made in the center-pin only, the needle being already straightened by the previous operation. When again made to cut, it should be tried on the other quarters of the circle, and corrections made in the same manner until the error is entirely removed, and the needle will reverse in every point of the divided surface.

In using the compass, the Surveyor should keep the south end towards his person, and read the bearings from the north end of the needle. He will observe that the E and W letters on the face of the compass are reversed from their natural position, in order that the direction of the line of sight may be correctly read. The compass-circle being graduated to half-degrees, a little practice will enable the surveyor to read the bearings to quarters or even finer—estimating with his eye the space bisected by the point of the needle, and as this is as low as the traverse table is usually calculated, it is the general practice. Sometimes, however, a small vernier is placed upon the south end of the needle, and reads the circle to five minutes of a degree—the circle being in that case graduated to whole degrees. This contrivance, however, is quite objectionable on account of the additional weight imposed on the center-pin, and the difficulty of reading a vernier which is in constant vibration; it is therefore but little used.

To take angles of elevation.—Having first leveled the compass, bring the south end towards you, and place the eye at the little button, or eye-piece, on the right side of the south sight, and with the hand fix a card on the front surface of the north sight, so that its top edge will be at right angles to the divided edge, and coincide with the zero mark; then sighting over the top of the card, note upon a flagstaff the height cut by the line of sight; then move the staff up the elevation, and carry the card along the sight until the line of sight again cuts the same height on the staff, read off the degrees and half-degrees passed over by the card.

For angles of depression, proceed in the same manner, using the eye-piece and divisions on the opposite sides of the sights, and reading from the top of the sights. When the instrument is to be used in making new surveys, the vernier should be set at zero and securely clamped by screwing up the nut beneath the plate. In surveying old lines, the change of the variation of the needle should be ascertained by setting the compass on some one well-defined line of the tract, and making the bearing to agree with that of the old survey, by moving the circle as already described. Then the circle can be clamped, and the old lines retraced from the bearings given by the original Surveyor. When the variation of the needle is known,it can be easily set off by the vernier, and the compass used to run a true meridian by the needle.

A little caution is necessary in handling the compass, that the glass covering be not excited by the friction of cloth, silk, or the hand, so as to attract the needle to its under surface. When, however, the glass becomes electric, the fluid may be removed by breathing upon it, or touching different parts of its surface with the moistened finger. An ignorance of this apparently trifling matter has caused many errors and perplexities in the practice of the inexperienced Surveyor.

The railroad compass is an instrument of the highest grade, in which by the addition of a divided limb and verniers the Surveyor is enabled to take angles, and run lines unaffected by the imperfections of the magnetic needle.

The vernier compass has a neat compass-circle, to which is attached a "vernier," movable about a common center a short distance in either direction, thus enabling the Surveyor to set the zeros of the circle at any required angle with the line of sights; the number of degrees contained in this angle or the "variation of the needle" being read off by the vernier. See *Solar Compass*.

PLAN.—The representation on paper,on a reduced scale, by means of conventional signs and process, of any portion of the earth's surface. In fortification, a plan shows the tracing, also the horizontal lengths and breadths of the works, the thickness of the ramparts and parapet, the width of the ditches, etc. It exhibits the extent, division, and distribution of the works, but the depth of the ditches and the height of the works are not represented in the plan. See *Plan of Campaign*, and *Plan of Defense*.

PLANE.—1. A surface without curvature, and the test of it is, that any two points whatever being taken in the surface, the straight line which joins them lies wholly in the surface. When two planes cross or intersect one another, their common section is a straight line; and the inclination of the planes to each other is measured by taking any point in their common section, and drawing from it two straight lines, one in each plane, perpendicular to the common section: the angle contained by these lines is the angle of inclination of the planes. When the angle is a right angle, the planes are perpendicular to each other.

2. A tool used for rendering the surface of wood smooth and level. It consists of an oblong block of wood or metal (the latter has only recently come into use), with an opening through the center; this opening is square on the upper side, and is always large enough to admit the cutting instrument; it diminishes down to a mere slit on the under side, just wide enough to allow the cutting edge of the plane-iron and the shaving of wood which it cuts off to pass through. The essential part of the tool is the plane-iron, a piece of steel with a chisel-shaped edge, and a slot in its center for a large- headed screw to work and to attach to it a strengthening plate. They are held in place by the hard-wood wedge. By driving in the wedge, the irons are held very firmly in their place, and they are so adjusted that only the fine sharp chisel-edge of the cutting-tool projects through the slit in the bottom of the body of the plane, so that when the tool is pushed forward by the force of the hand, the cutting edge pares off all irregularities, until the wood is as smooth as the under surface of the plane. There are many modifications in this tool, which can have its cutting edge and under surface made to almost any contour, so that mouldings of all kinds may be made. The two commonest are the jack-plane for rough work, and the smoothing-plane for finishing off plane surfaces. See *Planing-machine*.

PLANE OF COMPARISON.—A plan of a fortress, and of the surrounding country, on which are expressed the distances of the principal points from a horizontal plane, imagined to pass through the highest or lowest points of ground, in the survey. This imaginary plane is called a plane of comparison.

PLANE OF DEFILEMENT. A plane, which containing the interior crest of a work, passes at least eight feet above those points to be sheltered, and at least five feet above the ground which can be occupied by an enemy within cannon range. The amount of space in rear of a parapet which is required to be defiladed, depends upon circumstances. In some cases, the entire space enclosed, and in others only a part, is to be protected from this fire from a commanding height. Thus, it is usual to require that the whole interior space of an enclosed work should be defiladed; that the interior as far as the gorge should be defiladed for a half-enclosed work; and that so much of the interior,or so much of the terreplein behind the parapet as may be necessary for the free movements of the defense, should be defiladed in open works or lines.

It is not convenient in practice to place the eye at a distance of eight feet from the ground, nor is it an easy thing to judge, from a distance, what should be the position of a point which shall be five feet above the ground. The method used is to place the eye at a convenient distance from the ground, observe the highest point of the top of the hill, and determine the position of a visual plane tangent to the hill. Knowing the position of this visual plane, a second plane is passed parallel to it and five feet above it. The tangent visual plane is known as the rampant plane, and the plane parallel to it is the plane of defilement. The position of the rampant plane and the plane of defilement may be fixed as follows: To illustrate the method, a redan is supposed to be the field work which is to be built, upon a position commanded by a neighboring height, and that the salient and extremities of the faces are marked by upright poles planted in the ground. The trace marked, the next step is to profile the work, and this requires the height of the interior crest to be determined. Two stakes, at a convenient distance apart, are erected upon the gorge line; if not too far apart, the poles already erected to mark the extremities of the faces may be used. A line, three feet from the gronnd, is marked by a strip of wood having a straight edge,or by a cord tightly stretched, and fastened to these uprights. An observer is placed in rear of this line; he sights along it and tangent to the hill, and determines where the visual plane containing this line cuts the pole placed at the salient. This point is carefully marked, and with the line joining the two uprights on the gorge line, fixes the position of a plane tangent to the hill and three feet above the ground at the gorge. If on the three posts, points be marked, five feet above the points of intersection of the posts by the rampant plane, these will be points of a plane which will pass eight feet above the gronnd at the gorge and five above the ground at the top of the hill. If the faces of the redan are held in this plane, the whole interior of the redan will be defiladed from this hill, and the last plane determined will be the plane of defilade, or defilement. The extremities of the faces at the gorge have parapets of the ordinary height, viz., eight feet; the parapets from these points, increase in height nntil the salient is reached, where the height is the greatest. The height of the interior crest can then be determined, at the points where the profiles are to be placed. The site being level, there is no reason why any one part of the interior crest should be higher than another. It is nevertheless the practice, even in this case, to give additional height to the parapet at a salient, not for the purposes of defilading the interior, but to lessen the effect of any enfilading fire which an enemy might obtain upon the faces, and to allow for the descent of the trajectory of a projectile which might graze the interior crest at the salient.

A slight deviation from the method just described is made when the work to be defiladed is a lunette, instead of a redan. Two uprights, about twelve feet apart, are planted upon, and near the center of, the gorge line. A third upright is placed in front of the gorge and ten or twelve feet from it upon the line joining the center of the gorge line with the salient. The points are then marked where the rampant plane, three feet above the ground, cuts these three uprights and the uprights planted at the salient, and at the shoulders. A distance of five feet is marked above the points just determined, and this will fix the position of the plane of defilade for the lunette. See *Defilement*, *Direct Defilement*, and *Reverse Defilement*.

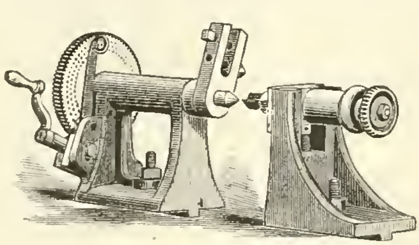
PLANE OF FIRE.—In Gunnery, a vertical plane through the line of fire. See *Pointing*.

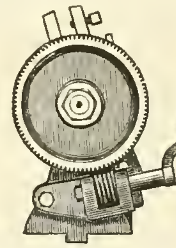
PLANE OF SIGHT.—In Gunnery, a vertical plane through the line of sight. See *Pointing*.

PLANE OF SITE.—The general level of the ground, or ground line, upon which the works are constructed, is called the plane of site, whether that plane be horizontal or oblique to the horizon.

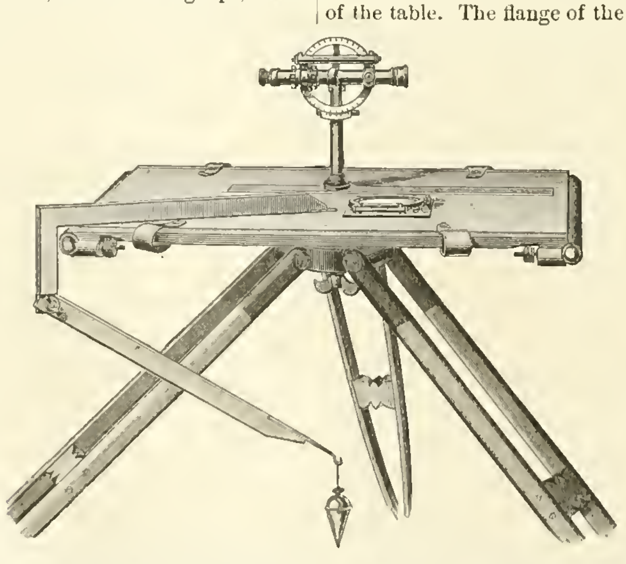
PLANE OF SYMMETRY.—In artillery, an imaginary plane everywhere bisecting the space between the two cheeks of a gun carriage.

PLANER-CENTERS.—Devices for supporting small work on the bed of a planing-machine. One of the two is provided with a worm and worm-wheel, by which the work may be rotated, so as to present each face in succession to the cutter; the other has





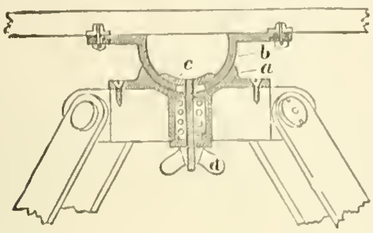
an inclined plane by which the slope of the work is regulated so as to give a taper, if required. The drawing shows an improvement in the device for dropping the worm out of gear, as in many cases it is not needed, thereby saving time. The dials are so drilled that they are calculated to plane any shape that is generally required, and for fluting taps, reamers, etc.



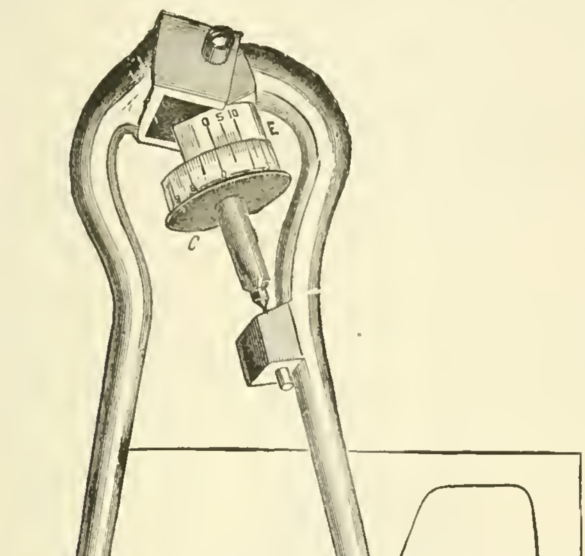
PLANE TABLE.—Plane tables may be used to determine distances and to note the fall of projectiles in target-practice or firing for ranges; also in topography and map drawing. As shown in the drawing, the plane table consists mainly of a drawing-board set upon a very firm tripod, and having upon its upper surface a movable straight edge or *alidade*, arranged either with sight-vanes or telescope, by which it may be directed to any given point, the line being then drawn on the paper along the edge of the alidade. A rectangular plate of brass to which is attached a small compass and two spirit-levels, is also shown, and serves both to level the table and when applied by the edges parallel to the zero points of the compass circle, to determine the magnetic bearing of the lines drawn on the paper, or the direction of the table itself. The table is made of wood arranged in sections so as to prevent warping, and has an adjustable wooden roller at each end by which the paper is brought down snugly to the board, or upon which a long sheet can be rolled and unrolled at will. In place of the rollers, sometimes, and often in combination with them, a number of brass clamps as shown are used in holding the paper firmly. The plumbing arm shown in the figure has its end brought to a point, that it may be set at any given point on the paper, the plummet hanging from the under arm determining the corresponding point on the ground; the lower arm moves upon a hinge, an index on the side showing when the ends of the two arms are plumb with each other as applied to the table.

The construction of the socket and tripod-head is shown in the drawing on page 535, in which *a* represents the hemispherical concave metal cup fastened by six screws to the wood top of the tripod, *b* the upper or convex part fitting nicely into the cup and clamped to it at will by the clamping piece *c* and nut *d*; a strong spiral-ring in the hollow cylinder between *c* and *d*, serves to hold the two spherical surfaces of the socket together, and allow of the easy movement of the one within the other in the leveling of the table. The flange of the socket *b* supports the table and is connected with its under surface by three segments of brass, two of which are shown at *e e*; these are brought down firmly upon the shoulder of the flange by capstan-head screws as shown, or released at will, thus allowing the plane table to be moved horizontally when desired. A set of three leveling-screws is sometimes added for more accurately leveling the table, but ordinarily the pressure of the hand upon it with the socket alone will be all that is required. When desired, a tangent movement in azimuth may also be added.

When estimating distance, if the target is on the water, a point along the shore, the distance of which



from the battery has been ascertained, is selected so that a line drawn from it towards the place where the first grazes are expected to occur will be at right angles to the line of fire, or nearly so: here one of the plane tables is placed. The other is situated as nearly in line with the target and battery as convenient; sufficiently removed, however, not to be in-



convenienced by the smoke. The two stations should be so situated that lines drawn from them to the target will be nearly at right angles to each other. Their distances from each other and from the battery are known. The table is adjusted with the small metal plate over the stake that marks the station, and leveled. The observer places his alidade on the pivot-pin, sights carefully on a given point at the battery, and marks on the paper affixed to the table the direction assigned by the beveled edge of the ruler. The direction of the other station is noted in the same way, as is also the target and any stakes which may be placed in the line of fire. When the cannon is ready to fire, a preparatory signal is hoisted at the battery; seeing this, the observer points the alidade in the expected direction of the first graze. The signal is lowered and the gun fired. The instant the jet takes place, the sights of the alidade are aligned upon it, and the direction indicated by the beveled edge of the ruler marked upon the paper. The line connecting the two stations is a base from which is determined the position of the point struck and of the battery. The projection of this base on any scale will enable one to ascertain in terms of that scale the distances desired. After the firing, the tables are returned, the observations made on one table transferred to the other, and the intersections of the lines locate the positions of the points struck. See *Alidade*.

PLANIMETER.—An instrument for ascertaining the contents of all irregular plane figures. More than thirty years ago, Oppikoffer, of Berne, invented an instrument of this description, which seemed to fulfill all the requirements of the case; but its cost and the practical difficulties attending its use prevented its general adoption. More recently, Amsler-Laffon, of Schoffhausen, devised a simpler and much less costly instrument of the kind, which was exhibited at the Paris Exposition of 1867. The principle of each is nearly the same, the area being measured by a roller of given surface, the number of revolutions of which are indicated by a disc. The drawing shows the Amsler polar planimeter, which, in addition to the ordinary requirements of the instrument, is well adapted for measuring the area of *indicator diagrams*. To use the instrument, press the point A slightly into the paper, not clear through, in such position that the tracer B will follow the desired line without bringing the roller C against any projection. The roller must move on a continuous flat surface. It is also well to fasten the diagram to a drawing-board, or some other flat surface, by means of pins or springs, to prevent it from slipping. Mark a starting point at any point on the outline of diagram D, set the tracer on that point, and place zero on the roller so it exactly coincides with zero on the vernier E. Now trace the line, moving in the direction traveled by the hands of a watch, stop at the starting point and take the reading. 1st. Find the highest figure on the roller that has passed the zero on the vernier, moving to the left, which we will assume to be 4; now the construction of the instrument is such, that each figure on the roller represents an equal number of square inches. 2d. Find the number of *completed* divisions between four on the roller and zero on the vernier, which we will assume to be 5. 3d. Find the number of the mark on the vernier which coincides with some mark on the roller, which in this case may be 6. We now have the exact reading, $4\frac{56}{100}$ inches area. In measuring diagrams of more than 10 inches area, add 10 to the result.

To those who are familiar with the instrument, it is not necessary to place the zeros together; but take the reading as it is, and subtract it from the result. Should the second reading be less than the first, add 10 to the second reading before making the subtraction. If the area to be measured is very large, divide it by lines into areas of less than 20 square inches, and take separate measurements. If the drawing is to a scale, multiply the result by the square of the ratio number of the scale. In using the Planimeter for indicator diagrams, and for which it is *specially* adapted, we find the area of the diagram, according to the foregoing directions, which we will assume to be 2.48; we now measure the length of the diagram parallel with the atmospheric line, which we will say is this case is 4 inches. Now divide the area by the length; the quotient is the mean, or average height of the diagram, in inches, which is .62 inches: this we multiply by the scale of the indicator, which we will assume to be 40; the product gives us 24.8 lbs. mean pressure on each square inch of the piston.

PLANING-MACHINE.—Planing-machines have recently been much in use, by which both wood and metal are planed. In the case of those intended for wood, the cutting instruments are moved forward over the wood by machinery in the same manner as in the hand-plane. The precision and rapidity with which these machines work have given great facilities for building, as one machine will do as much work as sixty men. The planing-machines used for metal are different in principle. A well-tempered, chisel-edged steel cutter is held in a fixed position, pressing downwards upon the metal plate, which is moved forward by powerful machinery. The action of this movement is that a groove is plowed into the metal of the size of the steel cutter; when the metal has traveled its full length, and has made the groove complete, the downward pressure of the tool is removed, and by the action of the double screw which has carried it forward, it is returned, and readjusted for another groove to be formed by the side of the first; and this is repeated until the whole surface of the plate is reduced to the required level. However tedious this process may appear, it offers such facilities for metal working as were previously unknown.

In its usual form, the metallic object is dogged to a traversing-table and is moved against a relatively fixed cutter. In practice, the cutter is adjusted in a stock, and is usually fed automatically between strokes. The machine is variously constructed, and in sizes to suit the work in hand. The drawings illustrate the Pond machines of the latest patterns, and including novel features. Fig. 1 shows a 26-inch machine which is intended for light work. Its bed has great depth and its length in proportion to the length of table is greatly in excess of usual practice. The uprights have sufficient metal and breadth of base to resist heavy cuts without jar when the tool is at the greatest height. The table is very thick, with three bolt-slots truly planed and pin-holes drilled and reamed, and receives back and forward motion from an open and cross belt through a powerful train of cut gears and rack. These gears are mounted on shafts having very large diameters and more than twice the usual length of the journal. These journals are carefully scraped together and straight surfaces scraped to surface plates. The automatic belt-shifter transfers but one belt at same time, thus obviating squealing of belts and jar of machine, it is entirely disconnected from feeding apparatus and is arranged to throw out to clear the reversing dogs on the table which can then be run backward to examine the work. The feeding device gives automatic

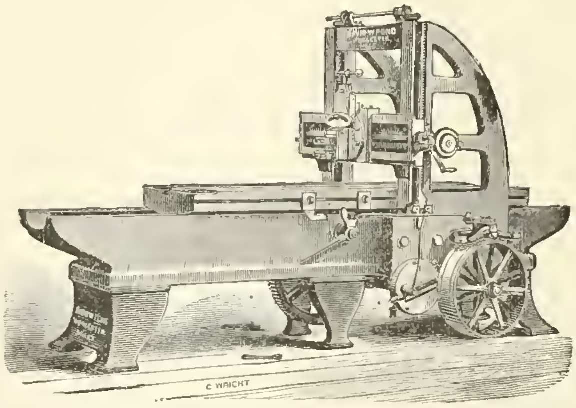


Fig. 1.

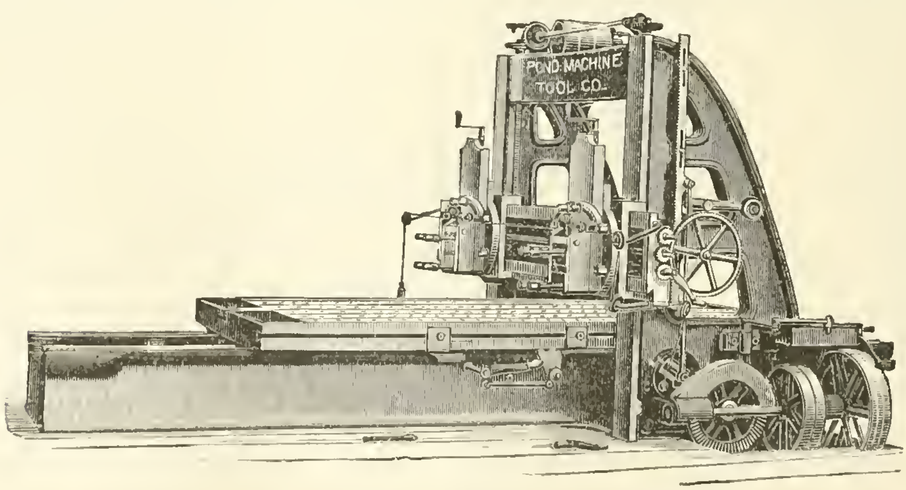

Fig. 2.

feed in all directions and is adjustable from 0 to ⅝ of an inch wide and takes no power except at the moment of feeding. The down and angular feeds can be operated by hand, if more convenient, from both ends of the cross-head as well as the top of the saddle. The countershaft has two pulleys, each 12 inches diameter, by 3 inches face for the 3-inch belt and should make 310 revolutions every minute. Weight 5,500 pounds.

Fig. 2 shows an 84-inch planer, designed for the heavier work. It possesses all the features above enumerated, the countershaft having two pulleys each 24 inches, by 5 inches face for 5-inch belt, and making 200 revolutions a minute. The weight of this machine is 56,000 pounds. See *Rotary Planer*, and *Shaping-machine*.

PLANK REVETMENT.—Plank is an excellent material for revetments where durability and very great strength are not required. The ease of working and convenience of handling are its great advantages. When it can be easily obtained and can be spared for the purpose, it will always be used in works of hurried construction.

Revetments may be made with it by driving posts or pieces of scantling into the earth, three or four feet apart, giving to them the same inclination as the interior slope. Boards, in a horizontal position, to retain the earth, are then nailed to these scantlings or posts. Or, the scantlings may be capped, and the boards having been cut into suitable lengths, placed in an upright position, similar to the posts in the timber revetments. The moisture of the earth soon produces rot in the boards, and renders the revetment a very perishable one. See *Revetment*.

PLAN OF CAMPAIGN.—Before undertaking any military operation, great or small, we should first settle down upon some decided end to be gained; determine upon beforehand, as far as practicable, the steps to be taken to attain our object. In one word, we should clearly see what we propose to accomplish, in order that we may not go blindly to work and leave anything to chance. The mental process by which all that is here supposed is elaborated is termed *The lay'ng out the Plan of Campa'gn.* In the first place, it stands to reason that this plan should be so limited as to comprise only the leading strategical dispositions, thus presenting only the outline features, within which the meshwork of the minor operations is to be confined; thus leaving ample latitude for all movements of detail and their execution. Nothing could be more absurd than to pretend to dictate to the Commanding General what he shall do from day to day; yet this has been done, and with but few exceptions, with disastrous results. Once within the sphere of the enemy's operations, a Commanding General is no longer at liberty to do what he wishes, but what he best can. Marches, maneuvers, combats depend on circumstances for the most part imperative; decisions arrived at are often sudden, and brought about by the attitude, resources, strength, and the *morale* of the enemy. The Commanding General should have *carte blanche* for carrying out the details of the campaign, the plan of which may have been decided upon by a council, but even this is far better left in the hands of him who has the whole responsibility of its execution on his shoulders, and has the greatest interest in its success. It is with the aid of the general maps of a country, made to a small scale, as embracing a wider territory, that the general plan of campaign is marked out. All that is wanted for this object is that the map should contain the exact positions of the places upon it; the water courses, the mountain crests, the principal lines of communication, and the political and geographical boundaries. The less detail on such maps the better they are for this purpose, as the mind is not distracted by them from the main features. For all points of detail topographical maps, on a large scale, are necessary. To these we have recourse when it is a question to choose an encampment; to decide upon a military position; to dispose an order of battle, etc. The plan of campaign lays down the points where the troops are to be assembled, the base and line of operations, and the strategical points to be attained. The choice of the positions where the troops are to be assembled is not only dictated by the facility of subsisting them, although this is a point of great importance; but by their suitableness to deceive the enemy as to the point on which we intend to make an advance, so that we may take the initiative and follow up our blow with the most crushing effect. The advance, where practicable, should be made over commodious roads rather than upon narrow and obstructed byways. The nature of towns or defiles to be traversed may force us to leave them on one side to take byways, although bad; for we overcome with less difficulty material obstacles on our line of march than we can towns and defiles well defended. When an army can, in its onward movement, rest one wing upon a natural obstacle to an enemy, it will be well for it to keep as near that obstacle as practicable; because it will be better covered by the army, the front of which during the march occupies always several miles in extent; at least so long as a battle is not imminent. When the two wings of the army are not supported in this way, the line of operations should cut the middle of the front of the army, in order that it may be equally well covered on each side. There is one general rule both on the march and for battle, which is, never to expose your line of operations; every disposition, on the contrary, should be taken to cover it and defend it in the best possible manner. The plan of campaign for the defensive is usually termed the *Defensive Plan.* It chiefly consists in deciding upon the character of the warfare to be adopted; one which will depend upon national traits, the resources, topography, and climate of the country. The French, for example, make a defensive warfare by assailing their enemies; the Germans, on the contrary, carry on patiently a methodical defensive behind their own frontiers; the Spaniards have been seen to carry on an exterminating war of detail; whilst the Russians, under like circumstances, have laid waste whole provinces, and destroyed by fire their capital city, to deprive their invaders of every material resource. A brave people, but not habituated to privations, will not drag out a war by patient endurance, but will endeavor to bring it speedily to a close by a few brilliant actions; its preferences will be for sledge-hammer blows, preferring the hazard of a great decisive battle, in which it may fall with glory, to a series of petty combats which only serve to exhaust the resources of the country without bringing about any decisive results. Carrying the war into the heart of the assailant's country, or that of his allies, is the surest plan of making him share its burdens and foiling his plans. The courage and conduct of troops are improved in this way, and the chances in their favor increased. But to be successful, the party adopting it must not be too inferior in strength, and the nature of the frontiers should favor it; as there would be too great a risk under less favorable circumstances, and in these even it would not be prudent to advance too far beyond our own frontier. The army will chiefly depend for the supply of its wants upon the zone of territory adjacent to the frontier, and this should be desperately disputed, by uniting all its forces against the enemy's invading corps. If this succeeds, from the defensive the army can assume the offensive. If unsuccessful, nothing remains to be done but to concentrate all the troops possible and fall back upon positions selected beforehand, either of very great natural or artificial strength, as rivers, mountain-passes, fortresses, etc. In this manner the enemy is drawn forward into a region the devastations of which are upon his shoulders. The skilful Montecuculi, in his memoirs, argues strongly for the adoption of such a plan of defensive measures; remarking that upon the territory of our enemy we arouse the discontented, whilst the fountains of men, money, and whatever else war calls for, are only disordered and fail in this portion in which the war rages.

PLAN OF DEFENSE.—The determination of the points on which resistance is to be made, those upon which we are to fall back in case of disaster, and the roads leading to these, in retreat; the dispositions of our forces at the outset so as to anticipate the enemy on every point; an indication of the points in rear of our frontier for concentration, so soon as the enemy has unmasked his projects; the mode of supporting our advanced corps and those of observation by central reserves; finally, the designation of the points to be fortified by art, bridges to be destroyed, roads to be repaired, etc., etc.: such are some of the objects upon which attention must be directed in any defensive plan. The suitable military dispositions in all such plans will be controlled by the local topography; it is, therefore, impracticable to lay down invariable rules on this point; the most that can be said is, that too great a dissemination of our force is always dangerous; therefore that, so far from attempting to defend every pass some must be abandoned to their fate, in order to effectually guard those which are most important and the more directly threatened by the enemy. If, instead of moving upon the latter, the enemy makes a show of gaining the former, he must be met by analogous movements, and our task should be to be in readiness to meet him by whatever route he may arrive; and also with the most troops he can concentrate. It is from this cause that the configuration of frontiers, and the direction and nature of the roads by which they are approached, have so great an influence upon the defensive measures against invasion. If these last are such as to permit our moving on right lines, from a center, upon the enemy maneuvering on the periphery, every advantage of mobility is on our side, and we ought to reach any point before the enemy. But, in any case, it is next to impossible to close every pass. To do so would require a continuous line of troops, which, from its extent alone, would be weak at all points, and which an enterprising enemy would easily pierce at any one. Instead of attempting any such impracticable plan it would be better to place a considerable force at some one favorable point in rear of our frontier, and, from there, take the chances of anticipating the enemy on any point he may threaten by moving on him promptly. In advance of this central force, and upon its front and flanks, small bodies can be thrown forward to occupy the principal passes momentarily and give warning of the enemy's movements. These detachments, by retiring slowly and holding the enemy in check, will give the main body time to make its dispositions, either to advance or to receive the enemy at any point further back. With these precautions the main body will be secured from surprise, and all the troops can be kept near enough to concentrate for battle. Such are the general defensive dispositions recommended by the highest military authority. It is readily seen that great discretion is necessarily left to the Commanding General, and that his measures should lend themselves to the local features of his line of defense. All that is requisite that these should be good is that they should be based upon the simple idea of concentration. This is always preferable to a feeble continuous line, with separated bodies that cannot afford mutual support; which are too far removed from the supervision of the Commanding General, who cannot be everywhere, and which, owing to the distances between them, cannot be rallied and concentrated in time when the line is pierced at any point. With the foregoing dispositions there should be combined some suitable system of signals, or other means of transmitting intelligence promptly from the interior line of detachments to the main body. No pains should be spared to have this system as perfect as practicable, and not liable to mistakes. A position chosen on the direct road that the enemy must follow is not always the best to check with advantage his onward march; flank positions can also often be found of superior advantage for this purpose from which the enemy's line of operations can be threatened if he persists in neglecting this position. This is particularly the case when the force thrown on the flank is of such strength that the enemy dare not to leave it in his rear, and therefore must attack and drive it back so that he may not expose himself to be separated from his base. In this simple manner the enemy is forced to give battle on a ground, of our own choice, and where we will have had time to make every defensive disposition. The searching out and establishing, on sound principles, flank positions for concentration of troops, forms an essential feature in laying down any plan of defense. Having decided upon the most advanced positions to be occupied, attention should next be directed to those of a secondary character, which will naturally be controlled by the water courses and mountain chains in rear of the first line. These will demand in their selection very careful study. The best of this class are those which have their wings or extremities resting upon natural obstacles that an enemy cannot turn—as the sea, lakes, unfordable rivers, which, in some respects, overlook the lines of approach on them; are accessible from the front only by a few practicable roads which can be easily guarded; the general outline of the position being convex towards the enemy, and in rear having good roads leading to all points of it, along which troops can be rapidly moved to any point in danger. Fortified places on a frontier will, of course, play an important part in any defensive plan; even open towns, by properly covering them with field works, may give the means of effective resistance to any usual mode of attack. When these places lie upon a river, which is itself a line of defense, particularly when they occupy both banks of it, they afford great facilities for the operation of an army which can maneuver on either shore with safety, so long as the place itself is not invested. Fortifications so placed completely prevent the enemy from using the river as a means of transportation, whilst they assist us in so using them; and, in most cases, they would therefore force an enemy to take all the known measures for gaining possession of them before he would dare to pass beyond them. In whatever way a river may lie, which has fortified points on it, the disadvantages to an invading force are necessarily great. If parallel to our line of frontier an enemy cannot cross the river, leaving these occupied in his rear, without running the risk of a great disaster. When perpendicular, he cannot with safety divide his forces to operate on both banks at once, as we have, by means of the fortified points, the ready facility of concentrating on either side at our pleasure. Without such strong points on it, a river, on the contrary, might be a positive advantage to the enemy, by allowing him to secure one of his own wings from attack by resting it upon the river, whilst he would also thus facilitate his own means of transportation. As to military positions, properly so called, that is localities favorable to accepting battle, great care should be taken in designating them on the plan of defense, and in preparing them beforehand for every eventuality, by field works, lines of retreat, the removal of all obstructions between the points of the position, etc. In every plan of defense, particular care should be taken in pointing out what roads should be carefully preserved, and which, in any emergency, may be broken up, or otherwise obstructed. These measures of destruction are almost always put off so late as to become impracticable at the moment of need.

PLANT.—In a military sense, to place or to fix; as *to plant a standard.* It likewise signifies to arrange different pieces of ordnance for the purpose of doing execution against an enemy or his works; hence, *to plant a battery*. Some authors apply this word to the act of directing a cannon properly.

PLANTATIONS.—Trees which are sometimes planted on the glacis of fortresses. When judiciously placed, they form a valuable aid to the defense. First, in the wood being used for timber, as they would be cut down when the place was about to be attacked. Secondly, in the roots of the trees which run under the glacis forming a considerable obstacle to the besieger's saps. Care should be taken to leave a space of about 20 feet clear in front of the crest. This part will be of no use to the besieger, as the sap of his lodgment will probably be excavated outside of it; and the defenders may have occasion during the siege to cut ramps in it ascending from the covered way to facilitate sorties, or to construct lodgments thereon for riflemen. For the same reason it would be advisable to avoid planting any parts of the glacis where it is likely the defenders will have to excavate counter-approaches.

PLASH.—A term commonly used to signify the interweaving of branches, as for gabions, dikes, weirs, hurdles, etc.

PLASTRON.—1. A stuffed pad or cushion, formerly worn at the shoulder to sustain the recoil of heavy muskets and other fire-arms, and still used

by fencers upon the right side. 2. A breast-plate or half cuirass. In the old French service, the Gens d'Armes, the heavy cavalry, the light horse, etc., were obliged to wear them on all occasions, at reviews, etc. Sometimes written *Plaston*.

PLATE.—1. In Heraldry, a roundle argent. It is represented flat, and in the Heraldry of Scotland is known as a *bezant argent*. 2. Metallic armor composed of broad pieces, and thus distinguished from mail.

PLATE-ARMOR.—The employment of thick slabs of iron to protect the sides of ships of war and the fronts of fortifications, is quite a recent invention; or rather, the modern system is the practical realization of plans suggested long ago by Mersenne and others. In 1842, Mr. Balmano, of New York, proposed that war-ships should be clad with several thicknesses of iron plate, riveted one upon another, the plates being individually ¾th inch thick. Soon afterwards, Mr. Stevens, an American ship-builder, made further suggestions on the subject, and other practical men kept the matter before the attention of the authorities in various countries. In 1854, the French sent several floating-batteries to the Black Sea, clad with iron plates; and the English Admiralty hastily imitated this example, producing eight very slow and unmanageable batteries in 1855-56. Then came in a flood of suggestions for arming regular ships of war in a similar way. The Admiralty, dismayed at the thought of dismantling the existing fleet, which had cost so much, delayed the subject as long as they could, but without abandoning it. In 1860, the French sent to sea *La Gloire*, a timber-built ship of war, altered from a 90-gun three decker to a 40-gun corvette, clad with 4½-inch iron plates having a burden of 3,000 tons. This proceeding at once set the English Government on the alert they saw that further delay would be imprudent, and they set about the creation of an armor-clad navy. Many problems had to be solved—whether to case old wooden ships with armor; to build and case new wooden ships; or to build new vessels, of which the hull as well as the armor should be of iron. Then arose further problems—how near the bulwarks should the armor-plates come, how near the bottom of the vessel, how near the stem and stern; also, what thickness of iron, and whether the same thickness in every part.

From 1861 to 1876, the British Admiralty were engaged on a series of costly constructions and reconstructions, intended to afford eventually solutions to the above problems. Several of the ships built have cost from £300,000 to £450,000 each; several half-finished timber three-deckers have been cut down and converted into iron-clads; and variations of detail almost innumerable have been introduced. The following is a list of English vessels which in 1876 formed the Iron-clad Navy. Those which are wholly clad—*i. e.* covered with armor plates in all parts of the hull needing protection—are the *Minotaur*, *Agincourt*, *Northumberland*, *Royal Oak*, *Prince Consort*, *Caledonia*, *Ocean*, *Lord Clyde*, *Lord Warden*, *Audacious*, *Invincible*, *Prince Albert*, *Scorpion*, *Wyvern*, *Monarch*, *Iron Duke*, *Sultan*, *Glatton*, *Cyclops*, *Hecate*, *Hydra*, *Gorgon*, *Dreadnought*, *Devastation*, *Thunderer*, *Swiftsure*, *Triumph*, *Rupert*, *Hotspur*, *Hercules*, *Inflexible*, *Alexander*, and *Shannon*. Those which are only partially clad—*i. e.* covered with armor-plates only in the more exposed portions—comprise the *Black Prince*, *Warrior*, *Defense*, *Resistance*, *Achilles*, *Hector*, *Valiant*, *Royal Alfred*, *Bellerophon*, *Zealous*, *Pallas*, *Favorite*, *Research Enterprise*, *Viper*, *Vixen*, *Water-witch*, *Penelope*. Regarded as to the material of which the hulls are mostly built, and on which the armor-plates are laid, the following are timber-built: *Royal Oak*, *Prince Consort*, *Caledonia*, *Ocean*, *Royal Alfred*, *Zealous*, *Lord Clyde*, *Lord Warden*, *Pallas*, *Favorite*, *Research*, and *Enterprise*. The *Vixen* is wood and iron; the *Swiftsure* and *Triumph* are iron sheathed with wood; all the rest are iron. The dimensions and weight of these ships, laden with armor-plates from 3 to 24 inches thick, are enormous. The load displacement of five of them exceeds 10,000 tons each; six, 9,000 to 10,000; four, 7,000 to 9,000; twelve, 6,000 to 7,000; seven, 4,000 to 6,000. Some of the steam engines for these ponderous ships, nominally of 1200 horse-power, work up to (indicated) 8000 horse-power. Whatever the thickness of the armor, the plates are nicely tongued and grooved to fit closely together edgewise. The bolts which fasten them to the ship are generally 2 to 2½ inches thick, expanded at one end to form a head, and having a screw-thread at the other to receive a nut.

It is not yet known whether the thickest armor will resist any shot that can be hurled against it; whether, in other words, the thickest practical armor will overcome, or be overcome by, the heaviest practicable shot. Experiments at enormous cost have been conducted for some years to determine this important question: a natural result has been that cannon are made larger and larger, and armor-plates thicker and thicker, in the struggle between artillery and ship-building. The experiments (so far as England is concerned) have been conducted principally at Shoeburyness. The usual mode is, to construct a target resembling the armed side of one of the iron-clads, and then to try to pierce it with shot fired from guns at various distances. A *Warrior* target, for instance, consists of a 4½-in. armor-plate, backed by 18 in. of teak, and an inner skin of ¾-in. iron; while a *Lord Warden* target has 4½ in. plate, 30 in. teak, and 1½ in. skin. A few examples will serve to illustrate the method of proceeding. In August, 1866, a *Warrior* target was built up at Shoeburyness—*i. e.*, a target similar in strength and construction to the side of that ship. Alderson's steel shell, Armstrong's conicle shell, and Palliser's chilled-iron shell were fired at it from a 7-in. gun at 200 yards: the Palliser shot excelled the others, going clean through the target, armor and all, and bursting behind. On another occasion, a Palliser 115-lb. shot went through the target even at an angle of 30° from the perpendicular. The *Lord Warden* target has been pierced by 9½ and 10-in. shot at a distance of 1,000 yards; while the thinner *Warrior* target was pierced at 2000 yards. The *Bellerophon* and *Hercules* targets were more ponderous. At the end of 1878, the British navy consisted of 64 ships, afloat or building, of which 46 were efficient. They were divided into five classes, the first two of which contain only the formidable turret-ships. The armor of the first class comprising 4 ships, ranged from 12 to 24 in. in thickness: the *Inflexible* has armor from 16 to 24 in. The second class, of 9 ships, has armor from 8 to 14 in. thick. The third, of 16 ships, from 5 to 12 in. The fourth, of 4 ships, from 6 to 10 in. In the fifth class, 13 ships, the armor is from 4½ to 5½ in. The last class comprises the two old iron-clads, the *Warrior*, *Black Prince*, and others.

Armor-clad forts are also attracting attention. Iron has been used largely in the defenses of Plymouth and Portsmouth. In 1864, a line of iron-clad fort was built up at Shoeburyness, to test several modes of construction. In the same year, the Russian Government employed the Millwall Company to build a wrought-iron shield, as an experiment for the defenses of Cronstadt. The front was made of 12 in. thick of iron in horizontal bars; this was backed by 14 in. of thickness in upright bars; and the whole strengthened with enormous struts, brackets, ribs, and dovetails of iron. The shield was to form the facing or armor for a battery of three of Krupp's 600-pounder steel guns, and measured 43 ft. by 10. The shield, with its foundation-plate, weighed 140 tons. In one experiment at Shoeburyness, a plate 13 in. thick was placed in front of a mass of granite 14 ft. thick, and fired at with 200-pounders; four shots cracked the granite, although the plate was not pierced. The

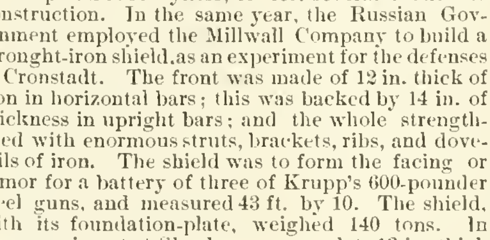

Fig. 1.—Front View of "Warrior" target, after practice with 600-pounder Armstrong Gun.

Americans made an experiment in Chesapeake Bay, in September, 1866, on a temporary fortification, made of enormous granite blocks faced with 10-in. armor; shots of 430 and 620 lbs. were fired from the Rodman guns, at a range of about 350 yards, and eleven such shots destroyed the whole fabric. The *Thunderer* was fitted up as a target-ship at Portsmouth, partly to test very thick plates at very short distances. The plates were fastened to an enormous bulkhead near one end of the ship, and the guns placed near the other end. On one special occasion, a Palliser 115-lb. chilled shot, with an extra charge of powder fired at 25 ft. off, went clean through a 7-in. plate and 45 in. of teak bulkhead. On another occasion soon afterwards, a *Hercules* target, with a 9-in. plate, was fired at with an 8-in. spherical shot at 30 ft.; the shot made a dent 2½ in. deep, but did not further disturb the plate. The 24-in. armor of the *Inflexible* is divided into two 12-in. plates, with 9 in. of teak between—the theory of this arrangement being that the outer plate, even if pierced, will shatter the shot, which will then be stopped by the inner armor. Dr. Collis Brown has suggested a system of sloping armored sides which would give a ship armor of 36 in. at any given point in a displacement not exceeding that of existing iron-clads. In the trial of the 100-ton Armstrong gun at Spezzia, a steel armor-plate was fired at, and the shot, though it penetrated the plate, was stopped in the backing.

Regarded as articles of manufacture, armor-plates were first produced mainly by hammering, several thicknesses of iron being welded one upon another,

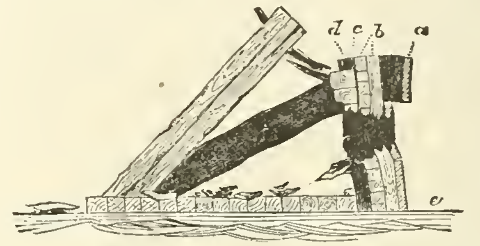

Fig. 2.—Section of "Warrior" Target, showing the hole made by the 600-pound Shell, and displacement of the upper plate. a, armor plating, 4½ in. thick (displaced); b, teak backing, 18 in. thick; c, boiler plate skip, ⅝ in. thick; d, wrought-iron beams; e, platform.

at a white heat, by blows of a ponderous steam-hammer; but it is now more customary to produce them by rolling than by hammering—pressure being considered to produce more satisfactory results than percussion. Whatever the thickness of the slab is to be, operations are commenced with plates about an inch thick; these are heated, rolled, cut, piled up, heated and rolled over and over again, until the required thickness is produced. The rollers are placed further and further apart, as the slab becomes thicker and thicker. Some of them are truly enormous masses of metal, solid cylinders 8 ft. long by 32 in. diameter. At the Atlas works of Messrs. Brown & Co., Sheffield (the chief manufactory for armor-plates), there has been produced a rolled slab 17 ft. long, 7 ft. wide, and 14 in. thick, weighing 30 tons. At Grüser, in Germany, some excellent armor-plates of chilled (cast) iron have been manufactured. For armor-plates, the metal is very scrupulously selected, and every part of the processes conducted with great caution.

PLATFORM-BOARD.—A side-board on an ammunition carriage for forage.

PLATFORM-WAGON.—A carriage on four wheels; having no sides, and used for the transport of guns, mortars, traversing platforms, and for every description of heavy stores.

PLATFORMS.—To insure accuracy of fire with heavy guns and mortars, it is absolutely necessary to have solid and substantial platforms. For casemate and barbette batteries in fortifications, fixed platforms are constructed with the works. The barbette platform consists essentially of the pintle block, which is of granite firmly imbedded in concrete; in the block is inserted the pintle, of iron, and around this is the friction plate for the pintle transom of the chassis to rest upon. Traverse circles, of iron, form level and smooth tracks, upon which the traverse-wheels run. The pintle of a casemate carriage is inserted in a hole in the sole of the embrasure, and is lifted out when the chassis is to be removed. The chassis is attached to it by a tongue, and is provided with a front set of traverse-wheels. Platforms for siege pieces accompany troops in the field, and it is desirable to have them as light as is compatible with sufficient strength to endure the shock of firing. Those used in the United States Service combine, in a high degree, the essential qualities of strength and portability. All the pieces composing them are of the same dimensions, and, as the weight of each piece is only fifty pounds, a soldier can carry one from the depot to the batteries, or any moderate distance, in addition to his arms and equipments. Another platform for mortars is described, which is very simple, strong, and well suited to positions where trees or timber can be easily procured. This is designated the *rail platform*. When a siege gun or howitzer is to be fired constantly in one direction, it is best to give the platform an inclination to the rear. This prevents excessive recoil, and also serves to carry off water from rain. The degree of inclination is not absolute. When the piece is to be traversed over a wide field of fire, the platform should be perfectly level; the recoil is then checked by placing a bag of earth or a pile of sods at a proper distance (about five feet) behind each wheel. The following is the method of laying the platform when it has an inclination. To lay it horizontally, simply omit what is said with reference to the slope: The direction in which the piece is to fire is established by stretching a cord over the center of the place where the platform is to be laid. This line is the directrix

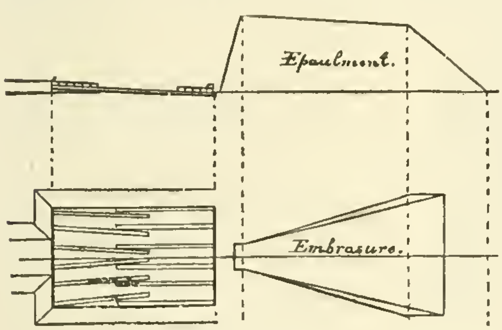

Fig. 1.

of the platform. Prepare a bed for the platform by excavating the earth so that it will have the proper inclination to the rear and be perfectly level across. The earth, if not already firm, should be well rammed. Lay the outside sleepers parallel to the directrix, their outside edges being fifty-four inches distant from it. The four other sleepers are laid parallel to these, the edge of each fifteen and a half inches from the edge of the next. The upper surface of the front ends of these sleepers is fifty inches below the sole of the embrasure, and they are laid with an elevation to the rear of one and a half inches to the yard, or four and a half inches in their whole length. This elevation is determined by placing a block four and a half inches high on the front end of the sleeper, and laying a straight-edge, with a level on it, from this block to the rear end; the earth is then arranged so as to bring the level true in this position. The next set of sleepers are laid against and inside of the first, overlapping them three feet, having the rear ends inclined outwards, so that the outer edges of the exterior ones shall each be fifty-four inches from the directrix, and the space between the rear edges of the others the same as in the first set, viz., fifteen and a half inches from the edge of one to the edge of the next; all having an elevation to the rear of one and a half inches to the yard, and perfectly level across. The earth is then rammed firmly around the sleepers and made even with their upper surface. The first deck-plank, with a hole through each end for the eye-bolts, is laid in place, perpendicular to the directrix, its holes corresponding with those in the sleepers. The hurter is placed on it, and the bolts driven through the corresponding holes in these pieces. The hurter should be so placed as to prevent the wheels from striking against the epaulement when the piece is in battery. If the interior slope has a base of two-sevenths of its height, the inner edge of the hurter should be two and a half inches from the foot of the slope. The other planks are laid, each being forced against the preceding, with the dowels fitting into their respective holes; the last plank has holes for the eye-bolts. By drawing out or driving in the outside sleepers, the holes through their rear ends are made to correspond with those in the last deck-plank. The bolts are then driven. Drive stakes in rear of each sleeper, leaving their tops level with the upper surface of the platform. Raise, ram, and level the earth in rear of the platform, so as to have a plain, hard surface to support the trail when the recoil is great. The earth should be raised nearly as high as the platform along the sides, and well rammed, giving it a slight inclination outward to allow water to run off. The platform is fifteen feet long and nine feet wide. Instead of twelve sleepers, each nine feet long, it is preferable to use six, each fifteen feet long. See Fig. 1.

The field platform is for siege guns and howitzers when serving with an army in the field, and the method of constructing it indicates the way in which platforms may be extemporized from such material as may be at hand. To lay this platform, level off the ground and mark the directrix; dig trenches for the sleepers; place the latter in the trenches so that the holes for the eye-bolts will correspond in place to those in the wheel-planks; place the wheel-planks in position, and drive in the eye-bolts. The front eye-bolts pass through and secure the hurter; apply the level and make the structure perfectly level; secure the front sleeper with stakes; it is well to secure also the rear ends of the wheel-planks with stakes; lay on the trail-plank and secure it with an eye-bolt to the third sleeper; ram the dirt well in around the sleepers. Fig. 2. To check recoil, place

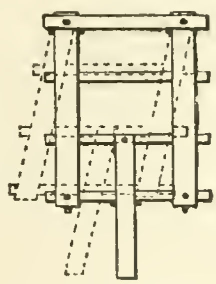

Fig. 2.

sacks of earth or piles of sods over the eye-bolts of the third sleeper, or a stick of timber, similar to a sleeper, laid across will effect the same object. This platform admits a change of direction of about ten degrees on each side of the directrix, thus covering as much of a field of fire as is ordinarily required. To make this change of direction, slightly loosen or remove the earth about the three rear sleepers, and heave the rear ends of the wheel-planks over with handspikes. The platform then has the position indicated by the dotted lines in the figure.

The siege mortar platform is composed of six sleepers and twenty-one deck-planks. It is laid level, and the front and rear deck-planks are connected by eye-bolts to each sleeper. A bed for the platform is first prepared by leveling off the ground, and, if not already solid, the earth should be well rammed. This bed should be sunk only so deep as to allow the upper surface of the platform to be slightly above the surrounding ground, for drainage. The sleepers are laid parallel to the directrix or plane of fire, three on each side of it, at equal distances apart, so that the holes in their ends shall correspond to the holes in the front and rear deck-planks. The front deck-plank is laid first, and the eye-bolts driven to secure it; the remaining planks are driven up against it, and the last secured, like the first, with eye-bolts. At the rear end of each sleeper a securing stake is driven. Fig. 3. The earth. on all sides, should be raised nearly as high as the platform, and well rammed. giving it a slight inclination outwards to allow the water to run off. It

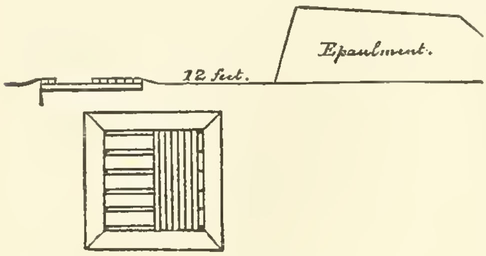

Fig. 3.

is of the first importance that the upper surface of the platform should be level and true.

The rail platform for siege mortars consists of three sleepers and two rails for the shoes of the mortar to rest on. It is very strong, and easily constructed and laid. The rails and sleepers are notched and fitted together as represented in Fig. 4. The distance between the center lines of the rails is equal to that be-

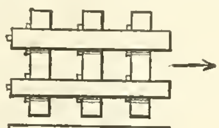

Fig. 4.

tween the center lines of the cheeks of the mortar carriage. The pieces are put together at the battery, and the earth is excavated eight inches in depth, and of suitable length and width to receive the platform. The bottom of this excavation is made perfectly level. The directrix being accurately marked by stakes, the platform is placed in position, its center line coinciding with a cord stretched between the stakes marking the directrix. The earth is filled in as high as the upper surface of the sleepers and firmly rammed; stakes are driven in the rear angles formed by the sleepers and the rails, and one at the rear end of each rail.

The platform for sea-coast mortars is 15 feet by 15 feet by 2 feet 2 inches. To lay it, a pit is dug 2 feet deep and about 18 feet square on the bottom. The earth on the bottom is well rammed and leveled. The two inch-planking is laid level on the rammed earth, perpendicular to the directrix. The cylindrical bolts are put in the sleepers, and the sleepers, with bolt-heads down, are laid compactly on, and perpendicular to the planking and parallel to the directrix. As the deck-timbers are laid the bolts pass through the holes in them. These timbers are laid compactly upon the sleepers, perpendicular to the directrix. The nuts are put on the bolts and screwed down. Both the nut and bolt-heads are countersunk. The iron plates are laid parallel to the directrix, and secured firmly with screws to the deck-timbers, covering nine feet in the center of the platform and leaving three feet on each side uncovered. The earth is then filled in, and rammed compactly around the platform, with a slight inclination outwards, so as to shed water. The platform for the center-pintle classis is 17 feet square; the bottom of the pit must therefore be 20 feet square.

The 10-inch sea-coast mortar platform is 12 feet by 12 feet by a 1 foot 8 inches. To lay it, a pit is dug 1 foot 6 inches deep by 15 feet square; the remainder of the operation is similar to that for the 13-inch mortar. See *Mortar Carriages*, and *Siege Carriages*.

PLATINUM FUSE.—A fuse of great value introduced by the Laflin and Rand Powder Company, and used with their *magneto* machines. These fuses have become noted for their surety, regularity, and perfect safety. They cannot be fired by a spark or by the effects of free electricity, but need a current of sufficient strength and persistence that in its passage through the circuit it shall heat to redness a small bridge of fine platinum wire in the body of the fuse. The drawing shows, in section, one of these fuses nearly of actual size. The following are its parts: A, the shell, of copper, having a corrugation, thrown out from the inside, which holds the sulphur cement more firmly in place. B, chamber containing the charge of explosive, composed mainly of fulminate of mercury—very powerful. C, the fuse wires, of copper, entering the shell, having a covering which is a partial insulator sufficient for all ordinary purposes. D, the bare ends of the copper fuse wires, projecting above the sulphur cement and into the charge. E, the small platinum wire, or bridge, soldered to and connecting the two ends of the fuse wires: this is heated to redness or combustion by the passage of the electric current. F, the sulphur cement holding the fuse wires firmly in place. These fuses are of cotton-covered wires; the nicety of insulation by gutta percha not being needed for general work, but only where blasting is to be done in deep water, and not then unless several fuses are to be fired simultaneously through a great length of submerged wire.

In March, 1880, these fuses were submitted to a rigid and careful testing at Willet's Point, N. Y., and were found to be remarkably uniform both in resistance and in the current required to explode them. The blasting machine with which they are intended to be used is a small magneto-electric instrument, weighing only about sixteen pounds, and occupying considerably less than one-half of a cubic foot of space. The capacity of this machine is for about twelve or fifteen holes, though under entirely favorable circumstances many more can be fired. As to durability, the construction is such that one should last as long as a clock. No uncertainty exists. In the deep mining of the Territories, especially in Colorado, many of them have been used in very wet shafts, and have been found invaluable. The patent self-discharging arrangement, a remarkable invention, has made them far superior, for practical use, to any instrument ever made. See *Blasting*.

PLATOON.—A subdivision of a company. This term (probably from the French *ploton*) was formerly used to designate a body of troops who fired together. A battalion was commonly divided into 16 platoons, and each company into 2 platoons, the platoon thus corresponding to the present subdivision. The word is obsolete in this its original sense; but it survives in the expression "platoon exercise," which is the course of motions in connection with handling, loading, and firing the musket or rifle.

PLEA.—A technical term in law. In England it had a very restricted meaning, being confined to the pleading of a defendant to an action at common law. Now in all actions in the High Court it is called the "Statement of Defense." In Scotland it is not used in the same sense, but denotes the short legal ground on which a party, whether pursuer or defender, bases his case or pleading. Hence the pleas in law are only short propositions of law. Pleas are subdivided according to their subject-matter, into pleas dilatory and peremptory, pleas of abatement, pleas to the jurisdiction. Pleas in bar are the same as peremptory pleas; but in criminal cases in England, special pleas in bar are pleas stating some ground for not proceeding with the indictment, such as a plea of formal acquittal or autrefois acquit; or of conviction, or autrefois convict; or a plea of pardon. In Scotland a "Plea of Panel" means a plea of guilty or not guilty. "Pleas of the Crown" was an expression anciently used to denote the divisions of criminal offenses generally, as in the well-known work called *Pleas of the Crown*, by Sir Matthew Hale, and other writers. The phrase was so used because the Sovereign was supposed in law to be the person injured by every wrong done to the community, and therefore was the prosecutor for every such offense.

PLOMBEE.—An ancient war-club, whose head was loaded with lead.

PLONGEE.—In artillery and fortification, a slope toward the front. Thus, in speaking of the course of a shell through the air, its plongée is from the point of greatest altitude to the point at which it strikes the earth. So, in fortification, the plongée is the top of the parapet sloping gently toward the front. This slope is ordinarily 1 in 6; but a deviation is permissible of from 1 in 9 to 1 in 4; the sharper the slope, however, the more liable is the crest of the parapet to be destroyed by an enemy's fire. Moreover, as flat a plongée as possible is desirable, that sandbags may, when required, be laid upon it to form cover for riflemen.

PLOUGH.—A wooden wedge ,or a shoe, shod with leather. It is attached to a gunpowder incorporating mill, for confining the charge under the path of the runner. There are two attached to each pair of runners.

PLOYMENTS.—A general term for all tactical movements by which column is formed from line upon a designated subdivision. The following points are general:

If *right* is to be in front, heads of companies incline to the *right*.

If *left* is to be in front, heads of companies incline to the *left*.

Always wheel by fours *away from* the file-closers.

In all ployments (except to or on the right or left) the designated company, unless it is to be the *rear* company of the close column, moves forward 19 yards, if from line, and 15 yards, if from column.

In ploying on a flank, or leading company, dress on side which company enters the column.

In ploying on an *interior* company, if { *right* companies ploy in front, dress to *left*. / *left* companies ploy in front, dress to *right*. }

In ployments *to* or *on* the right or left, the companies clear the columns by 30 yards before forming line.

PLUMACHER PERCUSSION-FUSE.—This fuse consists of a tube, the interior of which has three peculiar-shaped communicating chambers of different sizes, a screw cap, a screw-bottom, a winged needle-discharging plunger in the upper chamber, and a charged plunger in the lower chamber, the two plungers being kept apart by the third smaller or intervening chamber, as will be shown by reference to the drawing. Fig. 1 is a vertical section of the charged fuse in repose, top end up. Fig. 2 is a vertical section of the charged fuse at the point of striking, after having been discharged from the gun, top end down. Fig. 3 is a vertical section of the empty fuse-case. In external appearance the fuse-tube, A, is an ordinary cylinder, having a screw-thread, *t*, cut to a proper depth at one end on the periphery of the projectile. It is made of the size usual for percussion-fuses, so that it may be used in any pattern of elongated shell. The cavity of this cylinder is tapped at both top and bottom at *v v'*, and is provided with a screw-cap, D, and a screw-bottom, E, and the interior is divided, by abutting shoulders, *o o*, into three different-sized chambers, *f*, *g*, and *h*, in which the sliding plungers operate. The screw-cap, D, has a groove, *r*, that it may be handled by a screw-driver, and an indent, *s*, on the lower side, to admit the point of a needle, should it be deemed necessary to reverse the discharge-plunger when shipping the projectile. The screw-bottom, E, has keyholes, *u u*, by which it is screwed, etc., and an escape-hole, *e'*, through its axis, to permit the passage of fire into the magazine of the shell. The discharging-plunger, B, is a cone-crowned piece of metal, smaller in diameter than either of the chambers, with a tapped hole, *c*, in the apex, into which a pointed steel needle is screwed, holding in place by a shoulder on the needle a many-pointed steel spring, *k*. The steel spring, *k*, is just sufficiently stiff to hold the plunger in place and to prevent it from being forced into the center or chamber, *g*, by any power less than the impact produced by the discharge of the projectile from the gun. The plunger is contained, needle-point down, in the chamber, *f*, but by the impact produced by the discharge of the gun it is thrown forward and secured by the flaring springs in the chamber, *g*. The sliding plunger, C, incased in the chamber, *h*, larger and heavier than the plunger, B, is of cylindrical shape—a body of metal with a cone-shaped crown, having through its axis a hole, *e*, in which is secured by a drop of varnish or other suitable material, the fulminating powder or pill. Through this hole also passes the fire into the magazine of

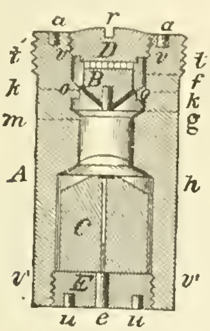

Fig. 1.

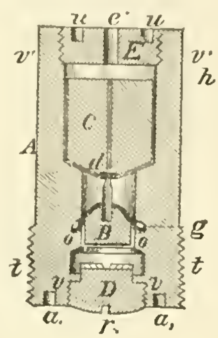

Fig. 2.

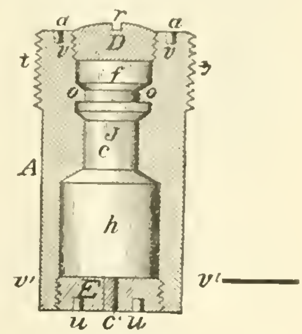

Fig. 3.

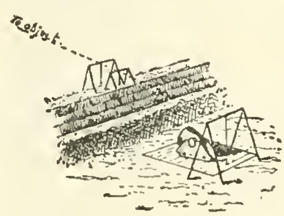
the shell Extra security in transportation may be obtained by unscrewing the cap, D, and taking out and reversing the needle-plunger, B, securing the point of the needle in the indent in the lower side of the cap. When fired, the impact produced upon the projectile by discharging the gun from which it was thrown forces the plunger, B, from its normal position into the center chamber, *g*, where it is held, at the bottom, by the narrow entrance to the lower chamber, and from the top by the ends of the many-pointed spring coming in contact with projecting shoulder, *o o*, dividing chamber, *f*, from *g*, the point of the needle protruding into the larger chamber, *h*. Then, by the check on the projectile when striking, the plunger, C, is thrown violently forward on to the plunger, B, the point of the needle entering and discharging the pill or fulminating-powder, thereby exploding the shell. See *Fuse*.

PLUMES.—Large and handsome feathers knots of buffalo-hair, etc., worn as ornaments on helmets, chapeaux, military hats, etc. In the United States, the General-in-chief wears three black ostrich feathers. All other general officers, officers of the General Staff and Staff Corps, except the Signal Corps, wear two black ostrich feathers. See *Helmet*.

PLUMMET.—A lead or iron weight suspended by a string, used by artificers to sound the depth of water, or to regulate the perpendicular direction of any building. Pendulums, called also plummets, which vibrate the required times of march in a minute, are of great utility. The different lengths of these plummets are as follows: For common time, 90 steps in a minute, 17.37 inches; quick time, 110 steps in a minute, 11.6 inches; double time, 165 steps in a minute, 5.17 inches.

The plane of sight is established by plummets; one suspended in front and another in the rear of the mortar. A convenient method of suspending the plummets is by means of trestles, made light and easy to handle. The one in rear of the mortar should be about six feet high, to permit the gunner to sight without stooping. The one in front being on the parapet, need not be more than eighteen inches high. They should have their upper edges scored with fine saw-cuts, close together, to secure the plummets when adjusted in position. The plummet-cord should be of fine thread or silk, and if affected by wind when suspended, the bob should swing in a bucket of water. A third trestle and plummet is required temporarily for placing the first two in position. To establish the plummets in position, the Instructor commands: 1, PLACE THE PLUMMETS.—The gunner, assisted by No. 2, places a trestle upon the parapet near the interior crest, and suspends from it a plummet in such position that it will be approximately in the line passing through the center of the platform and the object to be fired at. No. 3 brings up another trestle, which the gunner causes him to place a few feet in advance of the first, and in line with it and the object; sighting by the plummet first established, he causes the second plummet to be accurately adjusted on the line to the object; then, going to the front plummet and sighting back, he causes, No. 4 to place in position the trestle in rear of the mortar, and suspend from it the plummet, being careful to have it in exact line with the two on the parapet. The front trestle is then removed by No. 3. The trestle in rear of the mortar should be about three yards from the platform. Should the fire from the enemy endanger the plummet on the parapet, a priming-wire may be stuck there in its place to mark the line. When, owing to the interposition of an intermediate obstacle, the object to be fired at cannot be seen from the mortar, a point must be interpolated on the required line in such position that it can be seen from the mortar. This is most readily effected by using the Paddock interpolater. See *Bob*, *Mortar*, and *Paddock Interpolater*.



PLUNDER.—That which is taken from an enemy by pillage or open force. In the United States the Articles of War declare that every officer or soldier, who shall quit his post or colors to plunder and pillage, shall suffer death, or such other punishment as may be ordered by a General Court-Martial.

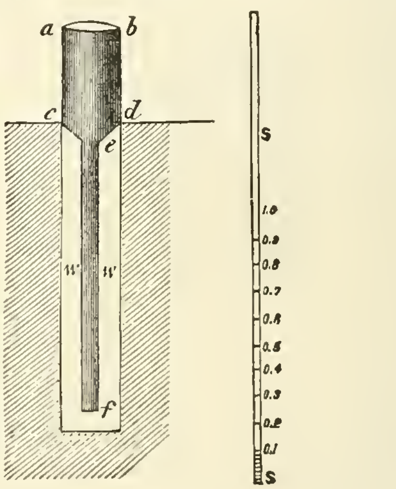
PLUNGER.—A form of striker used in some breech-loading fire-arms. See *Firing-pin*.

PLUNGING FIRE.—When a battery is raised considerably above the object, so that the shot impinges at a great angle, and is buried without grazing, the fire is termed "Plunging Fire."*

PLUNGING RICOCHET.—The description of *ricochet* fire, when the *angle of fall* is comprised between 6° and 10°. In this fire, the ball is given a small velocity, and the curve described is short and high.

PLUTEUS.—A kind of wicker helmet covered with raw ox-hide, worn by the ancient Greeks when engaged in sapping walls. Others were made of hurdles, covered in the same way, running upon three wheels, and affording cover to 7 or 8 miners.

PLUVIOMETER.—An instrument to measure the quantity of rain that falls. It usually consists of a metal funnel from 5 to 7 inches in diameter, the rain being collected in a glass bottle. This bottle should be placed in a small stand near the surface of the ground, to protect the bottle from the action of the sun. The amount of rain fallen in a given time is measured in a graduated glass-jar, one-tenth the area of the funnel, and so divided that every inch in depth of the tube shall indicate $\frac{1}{10}$ inch falling in the funnel. The amount of rain which has fallen can be measured by such an instrument to $\frac{1}{5000}$ part of an inch, or even less.



Another kind of rain-gauge may also be adopted. It consists of a cylinder of copper or other metal, from 5 to 7 inches in diameter, and 30 inches long. A float, just so much smaller as to allow it to rise freely, is placed within the cylinder, and to the center of the float an upright staff is attached, marked in inches and tenths of an inch, which, rising through a hole in the bottom of the funnel, indicates the depth of rain received into the guage. The drawing shows this instrument as employed in the United States Signal Service. See *Rain-guage*.

PNEUMATIC BUFFER.—A device for checking recoil through the agency of atmospheric air. At present, only the 15-inch gun is thus provided. Between the front ends of the chassis-rails are attached two cast-iron cylinders each 110 inches long, with an interior diameter of 14.25 inches. The ends of the cylinders are closed with tight-fitting heads secured with screw bolts. A piston works in each cylinder. The rods of the pistons pass out through the rear cylinder heads and are attached, by nuts, to a heavy transom on the rear end of the top-carriage. The cylinders have the same inclination as the chassis-rails, and are secured to the latter by three cylinder transoms. When the piece recoils the piston-rod is withdrawn, and the air contained in the cylinder compressed between the piston and the rear head of the cylinder. A small hole in the front head admits air to supply the vacuum in front of the piston. The air in rear of the piston thus forms an elastic cushion, offering but slight resistance to the first movement of recoil, but gradually increasing in resisting force as the carriage moves back, until finally the force of recoil is overcome and the top-carriage is brought to a state of rest. The shock of recoil is to a great extent absorbed without sudden strain to the carriage. The top-carriage must be *out of gear* whenever the piece is discharged; it then moves on the chassis with sliding friction. This, together with the inclination of the chassis-rails, assists in checking the recoil. When the carriage is in good running order, it generally runs forward a short distance by the reaction of the compressed air after recoil. To run the piece *in battery*, the top-carriage is thrown *into gear;* it then moves forward, the air is compressed in front of the pistons, and, escaping gradually through the small holes in the heads of the cylinders, allows the carriage to move forward with a gentle motion. The weight of the air-cylinders with attachments is about 5000 pounds. See *Hydraulic Buffer*.

PNEUMATIC DISPATCH.—This name is given to a mode of sending parcels, mail-bags, or telegram pa-

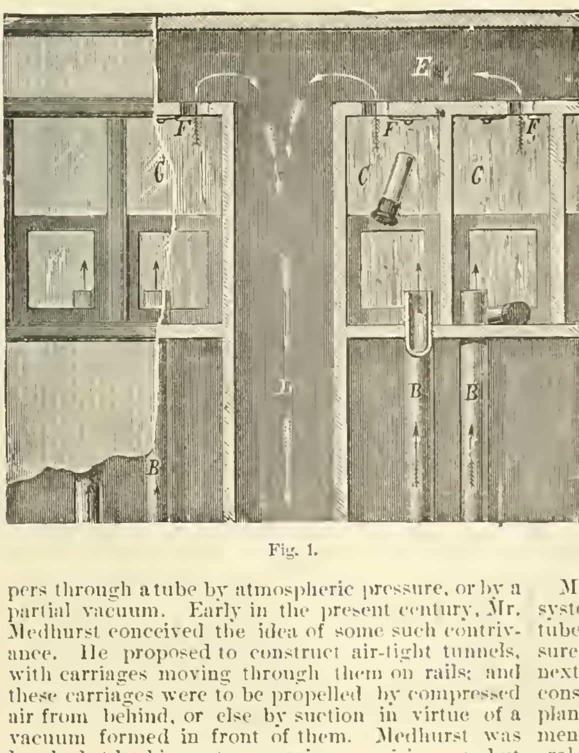


Fig. 1.

pers through a tube by atmospheric pressure, or by a partial vacuum. Early in the present century, Mr. Medhurst conceived the idea of some such contrivance. He proposed to construct air-tight tunnels, with carriages moving through them on rails; and these carriages were to be propelled by compressed air from behind, or else by suction in virtue of a vacuum formed in front of them. Medhurst was laughed at by his contemporaries as a visionary; but his speculations were called to mind in later years, and led to the establishment of ATMOSPHERIC RAILWAYS. In 1861 was announced a *Pneumatic Dispatch* project, based on a reconsideration of the causes of failure in the earlier schemes. The conveyance of passengers and of bulky goods was not here contemplated; parcels and mail-bags were the articles held chiefly in view. To test the theory, a quarter of a mile of iron tube was experimentally laid down near Battersea, with a very fair average of gradients and curves purposely given to it. The tube was about 30 inches in diameter; and it was found easy to propel a train through the tube consisting of two iron-carriages of 7 cwt. each, at a rate of 30 miles an hour. After many financial discouragements, a *Pneumatic Dispatch Company* obtained capital in 1862, and began operations in 1863. The experimental tube was removed to London, and laid down beneath the roadway of Seymour Street, Euston Square—a distance of one-third of a mile. Mail-bags being successfully transmitted in this way, the Company commenced in 1861 the construction of a tube on a larger scale, and this has since been completed. The tube has been laid down from Euston Square to St. Martin's-le-Grand, by way of Tottenham Court Road, Holborn, and Newgate Street—over a distance of 2¾ miles. The tube is of large size, nearly 4½ feet in diameter, laid down at as small a depth beneath the carriage-way of the several streets as the water and gas pipes will permit. It is chiefly of cast-iron; but some portions on a sharp curve are of brick. There is a large engine-house on the south side of Holborn, near Lincoln's Inn Fields, to supply all the power for working the whole tube in both directions. Rarefied air in one-half of the tube draws a train of iron carriages, laden with parcels and mail-bags, from Euston Station to Holborn; and compressed air drives them through the other length of tube from Holborn to the General Post-Office—there being a suction in the one case and pressure in the other. A reverse action brings trains in the other direction. The necessary amount of rarefaction in the one case, and of compression in the other was determined by experiment; but both are produced by means of a revolving fan of peculiar construction and large dimensions worked by a powerful steam-engine at the Holborn Station. If this mode of transmission were to come into general use, there would be great saving of time in the delivery of letters and parcels, and a material lessening of the number of parcels and mail-vans and carts in the overcrowded streets of cities. It is to be regretted that a work so successful in a scientific and engineering point of view should still remain undeveloped in a commercial sense. The Postmaster General, the Railway Companies, and the great Carriers, have made no practical working engagements with the Pneumatic Dispatch Company; and this costly tube, with the engine-house in Holborn, has now remained silent and unused for several years. This of course has checked any extension of the system into other districts. We cannot resist the conviction that a better result will present itself sooner or later. The problem of *passenger* conveyance with a pneumatic tube was shown to be practicable by Mr. Rammell, in an experiment tried at the Crystal Palace in 1864; but nothing further has been done in the matter.

More success has attended the introduction of a system for transmitting small rolls of paper through tubes of a few inches diameter, by pneumatic pressure. Mr. Siemens introduced it at Berlin; it was next tried with success at Paris; Mr. Latimer Clark constructed similar apparatus in London; and the plan is now in regular use in the telegraph department of the new buildings connected with the General Post Office in St. Martin's-le-Grand, while it is also used in some of the chief provincial cities and towns. In 1875 the number of tubes in London was 24, with an aggregate length of nearly 18 miles; there were 4 tubes in Liverpool; 3 in Dublin; 5 in Manchester; 3 in Birmingham; and 1 in Glasgow. Small tubes, two or three inches in diameter, are arranged for the reception of telegraph forms or papers, made up into a roll, and put into a felt cylinder. The purpose is to economize time and expense in conducting the Government Postal Telegraph business by *blowing* along the telegraph forms at a rate of 30 miles an hour, instead of sending them by street conveyance. Two parallel tubes have been laid down beneath the pavements of the streets from the General Post Office to various parts of London, and also in some of the large provincial cities and towns; additions being made to the length of tube according as the system becomes practically developed. One tube in each pair may be called the down line, the other the up; the two are placed in connection at each end, and one steam-engine works them both. The felt cylinder very nearly fills up the tube,

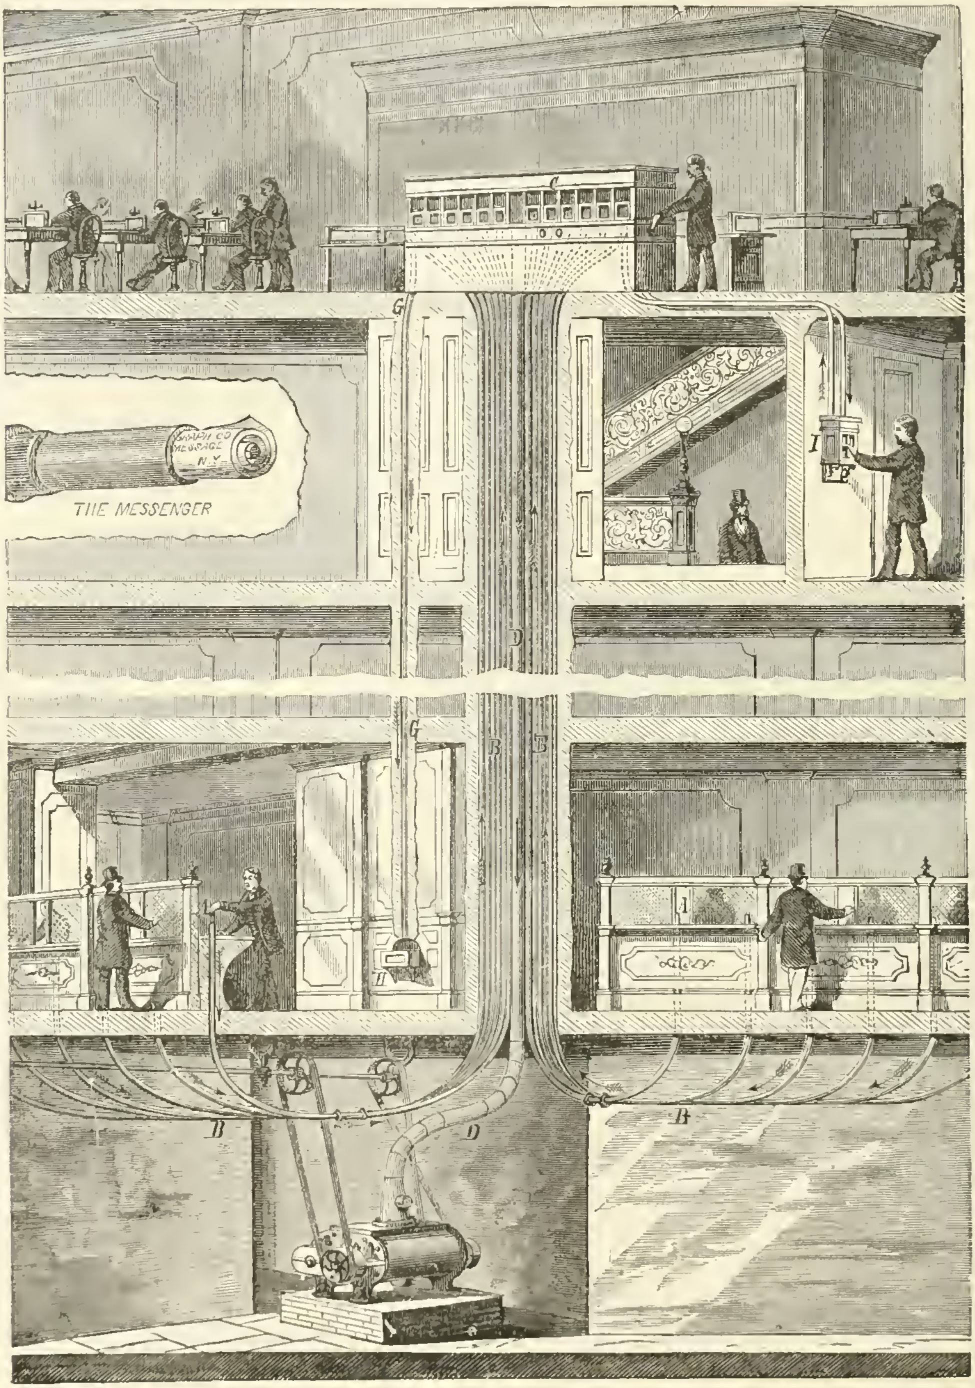

Fig. 2.

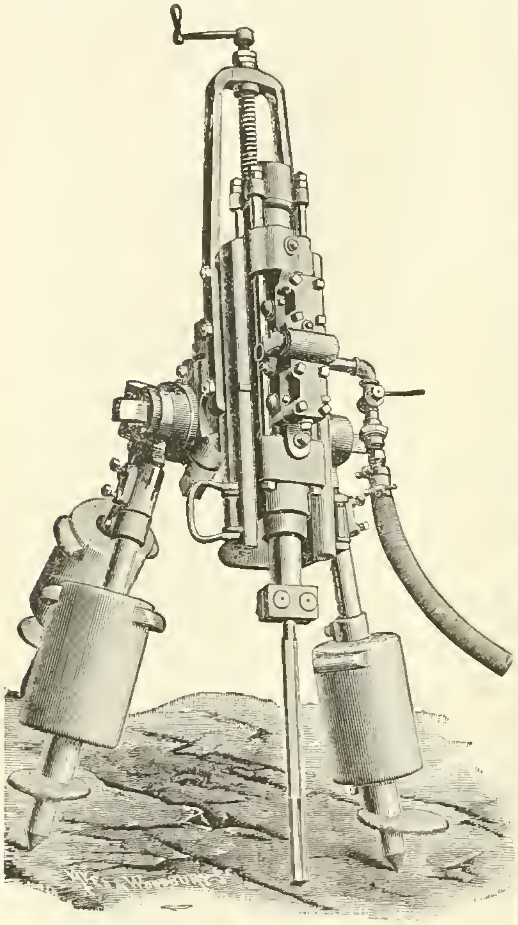
but still moves easily along it; this movement is brought about either by the formation of a partial vacuum in front of the cylinder, or by compressing the air behind it; and the steam power is so applied as to produce either or both of these two results, according as convenience may suggest. An ingenious plan is adopted for accommodating one or more intermediate offices, just as local stations are accommodated between the two termini of a railway. The cylinder or *carrier* travels from end to end of the tube, unless a block or check action is purposely put in force at an intermediate station; and the mode of effecting this is one of the most beautiful of Mr. Siemen's inventions relating to the subject. Two pieces of pipe, the *receiver* and the *transmitter*, are made exactly alike, and are so pivoted together that either may be adjusted into a cavity cut in the tube, and made temporarily to form part of it. The carrier, we will suppose, is intended to stop at the intermediate stations, to admit of the removal of some telegram papers and the introduction of others. A click is heard, the carrier strikes against an obstruction in the receiver; the cavity is opened; the exchange of papers is made; the carrier is re-introduced, but into the transmitter instead of the receiver; the cavity is closed again, and the carrier resumes its journey. All this is the work of a few seconds merely. If the intermediate station has nothing to send and nothing to receive, the transmitter alone is used, and the carrier travels on without stopping. The up-tube and the down-tube have each its apparatus of receiver and transmitter. The felt cylinder and its contents being very light, a slight rarefaction of the air in front of it, or condensation of the air behind it, is sufficient to produce a speed equal to twenty or thirty miles an hour. Practically, there is a *current* of air maintained, circulating through the two tubes and their terminal connections; wherever a carrier is placed in this current it is blown along, and there may be two or more carriers traveling at the same time.

We have recently examined, with considerable interest, the pneumatic system of transmitting telegraphic messages between the operating and receiving rooms in the newly constructed building of the Western Union Telegraph Company, in New York. In such an immense edifice, comprising eleven stories, it would obviously involve great delay to maintain the necessary communication by means of messenger boys, and consequently the apparatus which we describe and illustrate herewith has been introduced, with remarkably successful results. In the large engraving, Fig. 2, sections of several of the stories are represented, showing the numerous tubes through which the necessary current of air which propels the packages, are maintained. Those of our readers who have had occasion to send a telegram at the Central Office above named, may remember that, after they had delivered the writing to the clerk, that functionary rolled the paper in a little parcel and inserted it in a wood and leather case, of the manner and form shown in the upper portion of the illustration, Fig. 2. He then dropped the case into an open tube, leading up through his desk, at A, and perhaps announced that the packet had reached the operating room, in the seventh story, almost before the curious watcher of his proceedings had had time to draw a second breath. The packet appeared to be sucked into the tube, and so in fact it is, and in about two seconds it is drawn up almost to the top of the great building. After leaving the clerk's hand it passes down through the wide curve in its conduit, at B, and thence ascends the straight portion of the same, until it jumps forth from the end of the tube i none of the compartments of the receptacle, C, in the operating room. A section of a good portion of this receptacle is also well represented in Fig. 1, in one compartment of which a packet is seen emerging from its tube. The compartments, C, are entirely cut off from the main portion of the case, being constructed within the same, so that above them and extending over all is a large empty chamber, E. With the latter, however, each compartment communicates by an orifice, F, which is provided with a cover opened or closed at pleasure, thus, as will be seen further on, throwing any tube into or out of action, or moderating the air current therein as is desired. In the center of the receptacle and opening into the upper chamber, E, is a large tube, D, which extends down beside the pipes, B, and connects with a blower in the cellar. It is a positive blast rotary blower, invented and constructed by the well known firm of P. H. & F. M. Roots, of Connersville, Ind. The machine has long been in use in iron founderies, machine and blacksmith shops, and other establishments, and, besides, has met with extensive employment for ventilating purposes in buildings, ships, mines, and other localities. It will be understood that, in the present instance, the blower forces the air out beneath, so that the current is drawn down the tube, D, through the chamber, E, in the receptacle above, thence through the orifices, F, and compartments, C, and finally up through the pipes, B. Thus used as an exhauster, and at the slow speed of 120 revolutions per minute, it draws down five cubic feet of air per revolution, or 36,000 cubic feet per hour, thus propelling the packets, and at the same time (by removing the last mentioned aggregate quantity of air from the atmospheres of the rooms with which the pipe orifices communicate) serving as an excellent and efficient ventilating apparatus.

After a packet arrives in the upper story, the person stationed at the receptacle lifts a little window in the compartment which it enters, takes out the case, extracts the paper therefrom, and passes the message at once to the proper operator, who immediately telegraphs its contents to their destination. The case is then returned to the first story by dropping it into the open tubes, G, through which it falls by its own gravity, landing in the box, H, whence it is again taken out to be filled and started back on its journey. The general adoption of this system by all Military Headquarters, allowing that it will operate through tubes of half a mile length as effectively as it does at the Western Union Office, would expedite the collection and distribution of official matter, and greatly promote the public service and convenience.

PNEUMATIC DRILL.—A drilling-machine operated by compresseed air admittted alternately above and below a piston connected with gear-wheels which rotate the drill. The air-reservoir and force-pump may be placed at any required distance from the cylinder, and connected therewith by a flexible pipe. The introduction of the first Burleigh drill into the Hoosac Tunnel ten years ago marked a new era, not only in that great engineering enterprise, but in the history of rock work throughout the world. Up to that date many had been the attempts to produce a machine that would supersede the severe manual labor of the sledge and hand drill, but all proved failures. Eventually Mr. Burleigh took up the matter and solved the problem by producing the machine which bears his name,and which is a monument to his genius. The main elements of the drill, shown in the drawing, are the cage, the cylinder, and the piston. The cage is merely a trough, with ways on either side, in which the cylinder,by means of a feed-screw and an automatic feed-lever, is moved forward as the drill cuts away the rock. The piston moves back and forth in the cylinder, propelled and operated either by steam or compressed air, like the piston of an ordinary steam-engine. The drill point is attached to the end of the piston,which is a solid bar of steel. The piston is rotated as it moves back and forth by ingenious and simple mechanism. The forward motion of the cylinder in the trough is regulated by an automatic feed as the rock is cut away, the advance being more or less rapid, as by the variation in the nature of the rock the cutting is fast or slow. It will thus be seen that the drill-point and solid steel piston alone receive the shock of the blow; and it also should be stated, that the piston-rod, arranged with a double annular cam and spiral grooves, in its movements performs three important functions. First. The movement of the valve admitting the steam or compressed air to the cylinder. Second. By the operation of the annular cam acting upon the feeding device, the cylinder is moved forward (as the rock is penetrated) in the cage or slide. Third. By the spiral grooves and a spline in the ratchet, the piston bar is automatically rotated, a partial revolution taking place at each upward movement of the piston, the ratchet remaining perfectly stationary while the rotating movement occurs, and moving only as the piston again descends. When the cylinder has been fed forward the entire length of the feed-screw, it may be run back, and a longer drill-point inserted in the end of the piston.



By an ingenious peculiarity in the form of the cutting-edge of the drill-point, perfectly round holes are ensured; thus giving a greater area to the hole, and a larger percentage of the powder near its bottom. The regular rotation of the drill insures the delivery of each blow at the point of greatest efficiency; each wing of the drill-point striking the rock at a point just far enough in advance of the cut of the preceding blow to chip away the rock lying between. The yielding of the chip saves the edge of the drill-point; and thus the advance of the drill-point in the rock, without sharpening, is *ten times greater* than is possible in hand-drilling, where the hole is formed by the crushing and pulverising of the rock. The drilling-machine is attached to a clamp by means of a circular plate, with a beveled edge cast upon the bottom of the cage near its center. This plate fits a corresponding cavity in one side of the clamp, and is held there firmly in any required position by the tightening of screws. The clamp is clasped about a bar of iron to which it may be quite tightly held by screws.

By the motions—upon one plane, of the plate in its cavity, and upon another, at a right angle to the first, of the clamp upon the bar, and the sliding endwise of the clamp upon the bar—it will be seen at once that any position and direction of the drill is attainable. It only remains to securely attach the bar, of any reasonable length, to a convenient carriage or suitable frame, and the machinery is ready for operation. These machines are applicable to all kinds of rock work, whether in mining, quarrying, cutting, tunneling, or in sub-marine drilling. They combine simplicity, strength, lightness and compactness, are easily handled, and require but few repairs. With them, holes may be drilled from three-fourths of an inch to five inches diameter, and to a depth not exceeding thirty to thirty-five feet, at the rate of from two to ten inches per minute, according to the nature of the rock. They are driven by either steam or compressed air as a motor, and, under a pressure of fifty pounds to the inch, work at two hundred to three hundred blows per minute, according to the size of the machine.

PNEUMATIC GUN-CARRIAGE.—Facility of maneuver is of the greatest importance, after strength and stability, in a gun-carriage, and the training and running of heavy carriages, and the elevating and depressing of the gun, are now generally accomplished by means of toothed-gear. Modern guns should be trained very quickly and smoothly, and facility in that respect is of inestimable advantage in combat, hence a simple carriage that will return a B. L. gun, automatically to battery after each discharge is greatly to be desired.

Simplicity of construction also is a very important quality in a gun-carriage for sea-service, where the liability to rust, deterioration and damage from shot is very great, and the facilities for repair limited. Unfortunately, the modern carriages are entirely too elaborate in construction, and the aim in the design should be always to make the working parts as accessible as possible, and as simple as is consistent with the object in view.

The endurance of a carriage is greatly enhanced by a real judicious application of the recoil check. Though it is desirable, on general principles, to allow the carriage free recoil, it is not usually possible to do so in practice, and, in fact, since the introduction of B. L. cannon, it has been an object to limit the recoil as much as possible, with a view to return the gun quickly to battery. Any device that will give an increasing check is much the easier on the carriage.

A comparison of the foregoing will demonstrate the advantages of the pneumatic carriage in rapidity of maneuver, simplicity of construction, certainty of action in any climate, protection of the vital parts, and endurance. The use of water as a recoil check makes a summer gun-carriage; other fluids are liable to cake or clog the cylinders at an important moment. Any misadjustment or accident to the valves of any hydraulic check would cause an instant splitting of the cylinders, thereby disabling the gun—an impossible occurrence when using an elastic gas.

As a familiar example of the application of pneumatic force, the Westinghouse air-brake may be here cited. The introduction of this appliance was baffled for six years by the adverse opinion of eminent Engineers as to its practical utility. It never freezes clogs or splits the pipes, and one man controls with ease a great train of cars. In this connection it may be remarked that the use of hand-gearing in modern gun-carriages is comparable to the old style "brakes" on a railway train. The operating of the gun-carriages, either in the forts or on ships, by means of com-

pressed air supplied to the working parts from the pipe led to the breast of the carriage, and controlled by simple levers, for rapid training, for rapidly raising or lowering the gun to aim, for checking the recoil without shock, and for running in and out when desired, is absolutely practical, certain in its action, and the least liable to accident.

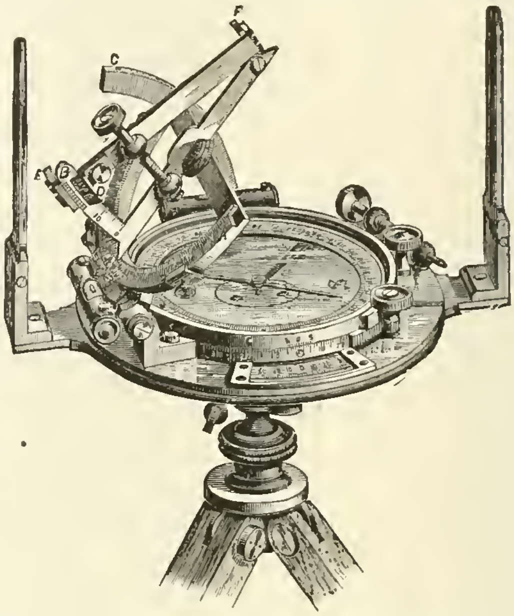
A section of the Westinghouse air-pump is shown in the drawing. The parts are numbered as follows: Steam-cylinder Head (with reversing-cylinder, piston, and valve bushes),2; Steam-cylinder (with the main valve and bushes,) 3; Center-piece, 4; Air-cylinder (with lower discharging-valve), 5; Steam-piston and Rod, 7; Air-piston, 8; Main Piston Packing-ring, 9; the Reversing-valve, the Reversing-valve Plate, the Plate Bolt and Stem, 13, 10, 11, 12, Main Steam-valve, 14; Packing-rings for the Upper and Lower Piston-valves, 15, 16; the Upper and Lower Main Steam-valve Bushes, 17, 18; Reversing-cylinder and Cap, 19, 22; Reversing-piston and Packing-ring, 20, 21; Reversing-valve Bush and Cap, 23, 24; Piston-rod Nut, 25; Discharge-valve Stop-bolt, 26; Piston-packing Nut and Gland, 27, 28; Right and Left Chamber Caps, 29, 30; Upper Discharge-valve and Seat, 32, 31; Receiving-valve, 34; Half-inch Union, 35; Three-quarter-inch Union, 36; One-inch Union, 37; Top and Bottom Steam-cylinder Gaskets, 40, 41; Top Air-cylinder Gasket, 42. The steam from the boiler enters the top cylinder between two pistons forming the main valve, 14. The upper piston being of greater diameter than the lower, the tendency of the pressure is to raise the valve, unless it is held down by the pressure of a third piston, 20, of still greater diameter, working in a cylinder directly above the main valve.

The pressure on this third piston is regulated by the small slide-valve, 13, working in the central chamber on the top head. This valve receives its motions from a rod, 12, extending into the hollow piston, which, as shown in the drawing, has a knob at its lower end and a shoulder just below the top head. This valve chamber in the top head, by a suitable steam-port, is constantly in communication with the steam space between the two pistons of the main valve. The steam acting on the third piston, 20, and holding the main valve down, enters below the main piston; as the main piston approaches the upper head, the reversing-valve rod, 12, and its valve, 13, are raised until the slide-valve exhausts the steam from the space above the third or reversing piston, when the main valve is raised by the steam pressure on the greater area of its upper piston, which movement of the main valve admits the steam to the upper end of the main cylinder.

When the main valve is moved up to admit steam to the upper end of the cylinder, it opens an exhaust-port at the lower end, just below the lower steam-port, which latter is closed by the lower piston of the main valve; and when the main piston is on its upward stroke, the upper exhaust-port is similarly opened. The air-valves of the pump are similar to those used in all pumps. The lift of a discharge valve should not exceed one sixteenth of an inch. See *Powlett Gun-carriage*.

POCKET LEDGER.—A small account-book with which a soldier in the British service is provided, and in which is inserted the monthly settlement of his accounts, having reference to his pay, the state of his savings-bank account, date of enlistment, etc. Commanding Officers are to see that these books are kept with the utmost regularity, the officer commanding the company of the soldier being responsible that the book is kept correctly, his signature being a voucher for the same. This book is familiarly termed by the soldier his "Tommy Atkins."

POCKET SOLAR COMPASS.—This instrument has a needle 3 inches long, and a limb of 4½ inches diameter, divided to half degrees and reading by its one double vernier horizontal angles to single minutes. The arrangement of the plates is similar to that of the large solar compass, the under plate carrying the sights revolving around the upper or compass-plate to which are attached the solar apparatus, levels, etc.; there is also a clamp with tangent-screw between the two plates, and another to the whole instrument about its spindle. The distance between the sights is nearly 7 inches, the sights themselves are 4½ inches high, and have a slot and hair in half their heights; they are hinged so as to fold down in packing. The compass-circle is arranged with pinion and movable part so as to set off the variation of the needle to five minutes; the needle has a lifting-lever, as usual, by which it is raised against the glass. The solar ap-



paratus is attached to the flange of the upper plate, and consists of the usual *hour*, *latitude*, and *declination arcs*, marked respectively, A, C, and B, in the drawing, with an arm, F F, to the last named, carrying the solar lenses and lines as in the larger instruments. The latitude and declination arcs are each divided to half degrees, and read by verniers, the latitude arc to five minutes, and the declination arc to single minutes of a degree; the hour arc is divided on its inner edge into hours and twelfths, or spaces of five minutes each, the index of the declination arc above easily enabling one to read the time to single minutes.

The hour arc is made movable on its supporting segment to either side, its outer edge being also divided on the middle portion to spaces of five minutes of time, and read by a vernier upon the segments to single minutes; in this way the *equation of time* for any given day is set off at once, and the time given by the index of the hour arc thus made to agree with mean time or that given by the ordinary clock.

The solar lenses and lines are placed as in the larger instruments, the declination arc being also reversible, as the sun changes from north to south of the equator.

When packed in the case the declination arc with its arm is detached from the hour arc; and this itself, together with the latitude arc, folds very closely to the compass box.

The pocket solar is set up for use either upon the ball spindle, with staff mountings, or upon a light tripod like the other pocket compasses, and very often with small leveling-head with clamp and tangent screws.

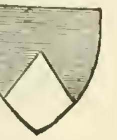
Sometimes a side telescope with counterpoise is substituted for the sight-vanes.

When about to use the instrument, it is set upon its tripod or staff, and carefully leveled; the declination of the sun for the given day and hour is obtained from the Ephemeris supplied with this and other solar instruments, and set off upon its arc, and the hour arc is raised until its vernier marks the latitude of the place upon the latitude arc. The equation of time for the day is also set off as before described, the zero of the hour circle being moved to the right when the equation is to be added, and to the left when it is to be subtracted from apparent time. The index of the declination arc being then set to the proper division on the hour arc, and the declination arm directed to the sun, the limb being also set at zero, and the sun's image brought between the hour lines of the silver plate by turning the whole instrument upon its spindle, the sights will indicate the *true meridian* precisely as with the larger solar compass. The compass-circle being now turned by the pinion until the needle points to zero, the needle also will be set to the true meridian, and the variation of the needle can be read off upon the outside divisions of the compass-box.

The adjustments and the use of this solar arc substantially the same as those of the solar compass, and its indications so accurate that after repeated trials it will give the true meridian within an error of less than three minutes of a degree, which taken in connection with the deflection of the magnetic needle will indicate with certainty the presence and direction of veins of magnetic iron ore.

Indeed, we have the assurance of competent Surveyors that while it is much more portable it is also very nearly or quite as accurate in all its indications as the large solar compass. Its weight, excluding box and tripod, is $4\frac{3}{4}$ lbs. See *Solar Compass*.

POINT.—In Heraldry, a triangular figure issuing from the dexter and sinister base of the shield. It is common in French and German Heraldry, and occurs in the shield of Hanover, which was a part of the royal arms of Great Britain from the accession of George I. till that of the present Sovereign. A shield charged with a point is in heraldic drawing hardly distinguishable from one parted per cheveron. See *Points*.



Point.

POINT-BLANK.—With all small-arms, the second point in which the natural line of sight (when horizontal) cuts the trajectory. With artillery, it is the point where the projectile first strikes the horizontal plane on which the gun stands, the axis of the piece being horizontal.

Usually, the object aimed at has a certain height; hence, it will not only be struck when at *point-blank*, but also when at points in rear or in front of the point-blank where the vertical distances of the trajectory from such points shall be equal to or less than the height of the object. This distance between these two points, known as the dangerous space, is greater as the trajectory is flattened or as the height of the object is greater.

In the drawing, A F, is the line of fire; A′ F P, is the natural line of sight; and A″ F P′, is an artificial

line of sight. It will be seen that the object P P′, beyond the *point-blank*, is struck at the bottom, P′. If it were at *point-blank*, it would be struck at P. Were the object increased in height, above P, it would also be struck when placed between *point-blank* and the piece. The sum of the distances in front and rear of the point-blank, at which the object could be struck at its bottom and top, is the dangerous space. This permits us to make slight errors in estimating distances; we can either over or under estimate them so long as the errors do not exceed the limits of the dangerous space. See *Artificial Point-blank*.

POINT BLANK RANGE.—The distance from the muzzle of the piece to that point in the projectile's trajectory where it cuts the prolongation of the natural line of sight, a second time, the natural line of sight being horizontal. The British define *point-blank range* as, the distance from the muzzle to the first graze when the axis of the piece is parallel to the horizontal plane upon which the carriage stands; but this is really nothing more than the range due to the *angle of elevation* equal to the angle subtended by the height of the gun from the point struck. See *Point-blank*.

POINT BLANK SHOT.—The shot of a gun pointed directly toward the object to be hit.

POINT D'APPUI. A fixed point of support in rear of the operations of an army, or on its flanks, such as a fortress or some convenient locality to resort to in case of necessity. A *Point d'Appui* is of great importance in military tactics. Few battles have been fought without making use of villages, hills, and even trees as *Points d'Appui*. In changes of front, one flank, or part of the force, should be held securely appuyed. Artillery massed in batteries have also served as *Points d'Appui*, as instanced at the battles of Borodino, Ramilies, Hohenkirch, etc.

POINTED STAKES.—A form of impediment used on the berm, at the bottom of the ditch and beyond the counterscarp. They are placed about one foot in the ground, and stand about one foot above it.

POINTING.—To point or aim a fire-arm, is to give it such direction and elevation that the projectile shall strike the object. To do this properly, it is necessary to understand the relations which exist between the line of sight, the line of fire, the trajectory, etc. The *line of sight* is the right line containing the guiding points of the sights. The sights are two pieces, *A* and *B*, on the upper surface of the gun, the situation of which with regard to the axis of the bore is known. The *front* sight is situated near the muzzle, or on the right rimbase, and is generally fixed; the *rear* sight is placed near the breech, and is movable in a vertical, and sometimes in a horizontal direction. The *natural line of sight* is the line of sight nearest the axis of the piece; the others are called artificial lines of sight. The *line of fire* is the axis of the bore prolonged in the direction of the muzzle, or *C D*. The *angle of fire* is the angle included between the line of fire and horizon; on account of the balloting of the projectile, the angle of fire is not always equal to the angle of departure, or projection. This is evident. The *angle of sight* is the angle included between the line of sight and line of fire; angles of sight are divided into natural and artificial angles of sight, corresponding to the natural and artificial lines of sight which enclose them. The *plane of fire* is the vertical plane containing the line of fire. The *plane of sight* is the vertical plane containing the line of sight. The *point-blank* is the point at which the line of sight intersects the trajectory, or *P*. Strictly speaking, the line of sight intersects the trajectory at two points, *C* and *P*; but, in practice, the latter point *P* is only considered. The distance, *B P*, is called the point-blank distance. The *natural point-blank* corresponds to the natural line of sight; all other point-blanks are called *artificial point-blanks*. In speaking of the point-blank of a piece, the natural line of sight is supposed to be horizontal. In the British service, the point-blank distance is the distance at which the projectile strikes the level ground on which the carriage stands, the axis of the piece being horizontal. It is evident that this definition of point-blank distance conveys a better idea of the power of the piece than the former, which makes it depend on the form of the piece, as well as on the charge. As the angle of sight *A C C′*

is increased, the point-blank distance is increased; as it is diminished, the intersections of the line of sight and trajectory approach each other until they unite, when the line of sight and trajectory are tangent to each other; beyond this, the point-blank is imaginary. As the angle of fire increases, the force of gravity acts more in opposition to the force of projection, and the point-blank distance is diminished, until at 90° it becomes zero. Under an angle of depression, the force of projection acts more nearly in the direction of gravity, and the point-blank distance is increased, becoming infinite when the angle of depression is equal to 90° minus the

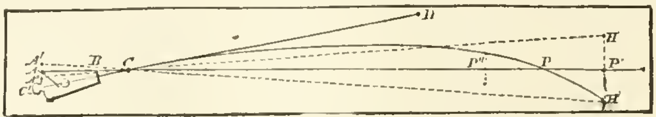


Fig. 1.

angle of sight. In ordinary firing, it is not considered that the trajectory changes its position with reference to the line of sight and line of fire, for any angles of elevation and depression, less than 15°. In aiming at an object, therefore, the *angle of elevation* of which is less than 15°, aim exactly as though it were in the same horizontal plane with the piece. For the same piece, the point-blank distance increases with the charge of powder; for the same initial velocity, a large projectile has a greater point-blank distance than a small one; a solid shot than a hollow one; an oblong projectile than a round one; or, in other words, it varies with the value of *c*, before referred to. *Range* is the distance at which a projectile first strikes the ground on which the carriage is situated; *extreme range* is the distance to the point at which the projectile is brought to rest.

In pointing guns and howitzers under ordinary angles of elevation, the piece is first directed toward the object, and then elevated to suit the distance. The accuracy of the aim depends—1st. On the fact that the object is situated in the plane of sight; 2d. That the projectile moves in the plane of fire, and that the planes of sight and fire coincide, or are parallel and near to each other; and 3d. On the accuracy of the elevation. The first of these conditions depends on the eye of the gunner, and the accuracy and delicacy of the sights; the errors under this head are of but little practical importance. When the trunnions of the piece are horizontal, and the sights are properly placed on the surface of the piece, the planes of sight and fire will coincide; but when the axis of the trunnions is inclined, and the natural line

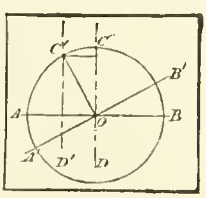

Fig. 2.

of sight is oblique to the axis of the bore, the planes are neither parallel nor coincident, and the aim will be incorrect. If the natural line of sight be made parallel to the line of fire, by making the height of the front sight equal to the dispart of the piece, the planes of sight and fire will be parallel, and at a distance from each other equal to the radius of the breech multiplied by the sine of the angle which the axletree makes with the horizon. To show this, let the circle $A\ C\ B\ D$, in Fig. 2, represent the section of the breech taken at right angles to the axis, and C the projection of the natural line of sight upon this plane; let $A'\ B'$ be the inclined position of the axletree, or trunnions, C'' marks the revolved position of the natural line of sight, and $C''\ D'$ the trace of the plane of sight, which is parallel to $C\ D$, the trace of the plane of fire. As the lines of sight and fire are parallel in their revolved position, the planes of sight and fire must also be parallel. The angle $COC'' = BOB'$, therefore $CC'' = OC'$ sin. BOB'. It is easily seen that with this arrangement of the front sight, the error of pointing can never exceed the radius of the breech. By an inspection of the figure, it will also be seen, that in the revolved position of the line of sight, the elevation is diminished by a small quantity, which is equal to the versed sine of the arc CC''.

If the natural line of sight be not parallel to the axis of the piece, the planes of sight and fire intersect at a short distance from the muzzle; hence, it follows, that as the object is situated in the plane of sight, the projectile will deviate from the object to the side on which the lower wheel is situated, and at a distance from it, which is proportional to the distance of the object from the piece; to correct for this source of error, the line of sight should be pointed to the side of the higher wheel, and at a distance from the object, which is proportional to the distance of the object from the piece. Siege and sea-coast cannon are generally fired from fixed platforms, which renders the axis of the trunnions horizontal; they are, therefore, not furnished with pendulum sights. In case the axis of the trunnions is not horizontal, and the piece has not a pendulum hausse, the highest points of metal at the breech and muzzle may be determined by the gunner's level and marked with chalk; the center line of the tangent scale, or breech-sight, is placed on the mark at the breech, the slider is placed at the proper elevation, and the aim is taken along the notch of the slider and the mark on the muzzle. This method, however, does not give a perfectly accurate aim. In the absence of a breech-sight, the piece can be pointed with the natural line of sight so as to strike objects not situated at point-blank distance if the object be within point-blank range, as at P'', Fig. 1, the natural line of sight should be depressed below the object as much as the trajectory is above it; if it be beyond point-blank, as at P', the natural line of sight should be directed to a point H, which is as much above the object, as the point H', of the trajectory, is below it. Owing to the shape and size of the reinforce of sea-coast cannon, the natural line of sight is formed by affixing a front sight to the muzzle, or to a projection cast on the piece between the trunnions. Although the latter arrangement does not give quite so long a distance between the sights as is desirable, it permits the use of a shorter breech-sight, and the front sight does not interfere with the roof of the embrasure, when the piece is fired under high elevation.

In pointing small-arms and mortars, the piece is first given the elevation, and then the direction necessary to attain the object. Mortars are generally fired from behind epaulements, which screen the object from the eye of the gunner. The elevation is first given by a gunner's quadrant; and the direction is given by moving the mortar-bed with a handspike, so as to bring the line of sight into the plane of sight, which, by construction, passes through the object and the center of the platform. The plane of sight may be determined in several ways; the method prescribed is to plant two stakes, one on the crest of the epaulement, and the other a little in advance of the first, so that the two shall be in a line with the object, and the gunner standing in the middle of the rear-edge of the platform; a cord is attached to the second stake, and carefully held so as to touch the first stake; a third stake is driven in a line with the cord, in rear of the platform, and a plummet is attached to this cord so as to fall a little in rear of the mortar. It is evident that the cord and plummet determine the required plane of sight into which the line of sight of the mortar must be brought. The usual angle of fire of mortars is 45°, which corresponds nearly with the maximum range. The advantages of the angle of greatest range are: 1st. Economy of powder; 2d. Diminished recoil, and strain on the piece, bed, and platform; 3d. More uniform ranges. When the distance is not great and the object is to penetrate the roofs of magazines, buildings, etc., the force of fall may be increased by firing under an angle of 60°. The ranges obtained under an angle of 60° are about *one tenth* less than those obtained with an angle of 45°. If the object be to produce effect by the bursting of the projectile, the penetration should be diminished by firing under an angle of 30°. When the object is not on a level with the piece, the angle of greatest range is considered in practice to be $45° + \frac{1}{2}A$, or $45 - \frac{1}{2}A$, A being the angle of elevation or depression of the object. Thus, to attain a magazine, for instance, situated on a hill, for which $A = 15°$, the angle of greatest range is $52\frac{1}{2}°$ instead of 45°. The angle of fire being fixed at 45° for objects on the same level with the piece, the range is varied by varying the charge of powder. The practical rule is founded on the knowledge of the amount of powder necessary to diminish or increase the range 10 yards. For the French 8 and 10 inch siege mortars, this amount is about 60 grains for the former, and 125 grains for the latter. A practical rule for finding the time of flight by which the length of the fuse is regulated, is to take the square root of the range in feet, and divide it by four; the quotient is the approximate time in seconds. Stone-mortars are pointed in the same manner as common mortars: the angle of fire for stones is from 60° to 75°, in order that they may have great force in falling; the angle for grenades is about 33°, in order that their bursting effect may not be destroyed by their penetration into the earth. Cannon are pointed at night by means of certain marks, or measurements, on the carriage and platform, which are accurately determined during the day. See *Cannon* and *Firing*.

POINTING-BOARD.—In gunnery, a piece of board 1 foot long, 2 or 3 inches wide, and 1 inch thick, having a notch cut in the middle of one side to fit on the stake, and graduated into equal divisions from its middle. When not in use the pointing cord may be wound on it. This board is used for pointing mortars.

POINTING-CORD.—A cord used in pointing mortars By means of *pointing-stakes*, one of the fixed points is established upon the crest of the parapet or at the foot of the interior slope, and another in rear of the piece. Then by a cord called the *pointing-cord*, stretched between these two points, with the plummet suspended from it, a vertical plane is determined with which the line of metal is made to coincide.

POINTING-RINGS.—Two rings, one smaller than the other, attached to the upper surface of the trail of the stock of a field gun-carriage, for the reception of a handspike, which enables the cannoneers to raise the trail and carry it to the right or left. The trail-handles serve the same purpose, but are used principally for raising the stock.

POINTING-RODS.—Pickets or rods of iron $\frac{3}{4}$ inch round, and about 2 feet long, two of which are placed upon the epaulement of a battery in front of each mortar, by means of which, with the aid of a plummet, the mortar can be directed with tolerable accuracy upon the object to be struck. The pickets are first lined upon the object; the plummet, which is in the hands of the laying officer, who stands behind the mortar, is made to coincide with them, and the mortar is then traversed until the line of the plummet covers the center line on the mortar, which is denoted by a notch on the muzzle, and another behind the vent; a chalked line is generally drawn on the exterior surface of the mortar between these notches. In masonry works, they must be placed on a fir plank, and about 6 inches from each end. The plank should be fitted with a grummet or handle at each end. In earthworks, two ramrods will answer for pointing-rods.

POINT OF ATTACK.—In siege operations, after obtaining all the information that can be had from reconnaissances, surveys, and other sources, the next object is to decide upon the portion of the defenses which it will be necessary to gain possession of to force the garrison to a surrender; this portion, which usually embraces one or more fronts of the position, with the outworks and any advanced works that may be connected with them, and which must be reduced before the points of the main work can be assailed, is termed the *Point of Attack*. It is in the choice of this point—a decision which mainly rests with the Commanding Officer—that the judgment and skill of this Officer are shown. In making this selection, not only must the relative strength of the various points of the defenses which are accessible be carefully weighed, but the nature of the site as to soil, natural surface, etc., upon which the trenches and other works of the attack must be laid out, and the facilities afforded of an easy communication between the parks, *depôts*, etc , and the point selected.

In considering the strength of the defenses, those parts are regarded as unassailable by the ordinary measures of an attack, which border upon precipices, marshes, a water-course that cannot be forded; or are protected by works on inaccessible points, the fire from which sweeps in flank and reverse the ground over which the trenches must be run. Those parts, again, are considered as offering peculiar difficulties which present a series of works in good defensive relations which can only be carried in succession; or works which are mined; or those which have their ditches arranged for a play of water; which have dry ditches of unusual depth; or, those parts where the works to be carried are displayed on a right line, embracing nearly the same extent of front that the besiegers can take up with their trenches; or, finally, portions which present a concave front to the attack. The points which are looked upon as most advantageous to the attack are those in which the general combination of the works forms a salient point with respect to the rest of the defenses; as a point so situated can receive but little support from the collateral portions, and can be enveloped by a line of trench of much greater extent than itself, along which positions can be obtained for enfilading and other batteries, the fire of which will be convergent upon that of the defenses. See *Key-point*.

POINT OF FALL.—The point at which the projectile strikes the ground, when permitted to do so. When the gun and *point of fall* are on the same level, the *angle of fire* is always less than the *angle of fall*.

POINT OF FORMATION.—The point taken, upon which troops are formed in military order.

POINT OF HONOR.—A nice discrimination in matters affecting one's honor. A delicacy of feeling, which is most generally acquired by education, and strengthened by intercourse with men of strict integrity and good conduct. It is likewise very frequently the offspring of peculiar habits, received notions, and established etiquettes.

POINT OF IMPACT.—That point or spot which a projectile first strikes on meeting an opposing body. The method of finding the *point of mean impact* is as follows: The horizontal distance of each shot upon the target from a fixed vertical base (generally one side of the target) is first found, and a mean horizontal distance obtained, by dividing the sum of the distance by the number of shot; the same process is followed to obtain a mean vertical distance from a fixed horizontal base (generally the bottom of the target). The intersection of the two lines drawn parallel to the bases respectively and at distances equal to the horizontal and vertical mean distances already found, gives what is termed the *points of mean impact*. The distance of each shot from the *point of mean impact* is measured; these distances are added together, and the sum, divided by the number of shot on the target, gives the *figure of merit*. Half a diagonal is allowed for every shot that does not strike the target.

POINT OF WAR.—A loud and impressive beat of the drum, the perfect execution of which requires great skill and activity. The *Point of War* is beat when a battalion charges.

POINTS.—Movements in Sabre Exercise executed as follows:

Tierce Point.—Being at guard, raise the hand in tierce as high as the eye: throw back the right shoulder, carrying the elbow to the rear, the point of the saber to the front, the edge upward. (Two.) Thrust to the front, extending the arm to its full length, edge up. (Three.) Resume the guard.

Quarte Point.—Being at guard, lower the hand in quarte near the right hip, the point a little higher than the wrist. (Two.) Thrust to the front, extending the arm to its full length. (Three.) Resume the guard

Left Point.—Being at guard, turn the head and shoulders to the left, draw back the hand in tierce toward the right shoulder, the hand at the height of the neck, the edge of the blade upward, the point to the left and as high as the hand. (Two.) Thrust to the left, extending the arm to its full length. (Three.) Resume the guard.

Right Point.—Being at guard, turn the head to the right, carry the hand in quarte near the left breast, the edge of the blade upward, the point to the right and as high as the hand. (Two.) Thrust to the right, extending the arm to its full length. (Three.) Resume the guard.

Rear Point.—Being at guard, turn the head and shoulders to the right and rear, bring the hand in quarte near the left breast, the point to the rear and as high as the hand, the edge upward. (Two.) Thrust to the rear, extending the arm to its full length. (Three.) Resume the guard.

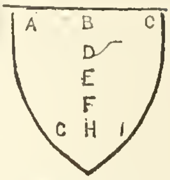
Against Infantry, Right Point.—Being at guard, this movement is executed the same as quarte point, turning the head and shoulders to the right, inclining the point downward. (Two.) Thrust in quarte. (Three.) Resume the guard.

Against Infantry, Left Point.—Being at guard, this movement is executed the same as Left Point, except the point is downward. (Two.) Thrust down in tierce. (Three.) Resume the guard.

Against Infantry, Front Point.—Being at guard, bend well down to the right, extend the right arm well downward, the hand in rear of the thigh, the back of the saber upward. (Three). Resume the guard. See *Saber Exercise.*

POINTS OF PASSING.—The ground on which one or more bodies of armed men march by a Reviewing General.

POINTS OF THE ESCUTCHEON.—In Heraldry, in order to facilitate the description of a coat-of-arms, it is the practice to suppose the shield to be divided into nine points, which are known by the following names: A, the dexter chief point; B, the middle chief; C, the sinister chief; D, the collar or honor point; E, the fess point; F, the nombril, or naval point; G, the dexter base point; H, the middle base point; and I, the sinister base point. The dexter and sinister sides of the shield are so called, not in relation to the eye of the spectator, but from the right and left sides of the supposed bearer of the shield.



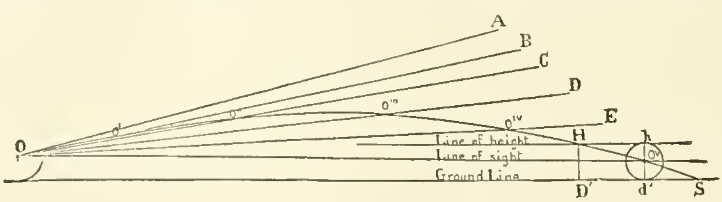
Points of the Escutcheon.

POITRAIL.—That portion of the horse armor which covers the breast, fitted either with hinges or like a flounce. Also written *Poitrel.*

POITRINAL.—In ancient armor, the horse's breast-plate, formed of metal plates riveted together as a covering for the breast and shoulders. The term *Pectoral* has a like signification, and is commonly used.

POLANS.—A term applied to knee-pieces in ancient armor.

POLAR DISTORTION.—In the practice of gunnery, trajectories are generally constructed by the system of *polar distortion*. By this method the angles of elevation are multiplied by an assumed co-efficient of distortion. The data necessary are the angles of elevation and the corresponding ranges. Assume a range scale, a co-efficient of distortion, and a point as the origin of the curve. Through the origin draw a straight line representing the axis of fire, and from this line, with the origin as a center, plot successively (commencing with the least) the angles of elevation multiplied by the co-efficient of distortion. Upon the lines of sight so established mark points at distances from the origin equal to the corresponding ranges reduced to scale. A curve drawn through the origin and the points located will represent the trajectory. Let O, be the origin; OA, the axis of fire; AOB, AOC, AOD, etc., the angles of elevation, multiplied by the co-efficient of distortion, to which correspond respectively the ranges from 100 to 500 yards; then will O^{i}, O^{ii}, O^{iii}, O^{iv}, O^{v}, be points of the curve. The portion of the curve lying above each line of sight will represent the trajectory for that range. The *dangerous space*, or the limits in distance within which the object aimed at is liable to be hit, is dependent, with the same arm, on the extent of that object above and below the point of aim. To determine this, describe

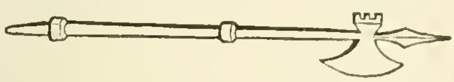


two circles one about the origin as a center, the other about the point aimed at; the former with a radius equal to the assumed muzzle height multiplied by the co-efficient of distortion, and the latter with a radius equal to the height of the point aimed at above the ground multiplied by this same co-efficient. A straight line tangent to these circles at their lowest point will be the *ground line*; and a line tangent to the second circle and parallel to the ground line, will be the *line of height*. The dangerous space will be the projection, on the ground line, of the portion of the trajectory comprised between these two lines. With the U. S. Rifle the dangerous space is calculated for the muzzle fifty-six inches from the ground, aimed at a point thirty-four inches from the ground; for 500 yards, this extends 40 yards before the object (a foot soldier) and 30 yards behind it. The distance on the figure is D'S, D'd' being equal to H*h*. To ascertain the vertical height above the ground line of a particular point of the trajectory at any distance from the origin; with this distance as a radius describe an arc cutting the trajectory. The length of the perpendicular to the ground line from this intersection is the required height. The number 10 may be employed as a convenient co-efficient of distortion. By this method of plotting, the relative curvature of consecutive portions of the trajectory is represented with sufficient accuracy to determine the "dangerous space."

POLAR PROJECTILES.—A designation applied to projectiles which pursue their flight through the air, always keeping one end or aspect foremost.

POLE.—In artillery, that portion of a carriage to which the wheel horses are attached. At the extremity of the pole are placed two pole-chains, by which it is held up, and a pole-yoke with two movable branches, to prevent, as much as possible, the pole from oscillating and striking the horses.

POLE-AXE.—A weapon much used by the early northern nations, Celtic and Scandinavian, requiring great strength in its use. Some were held with one hand; some with two, the former kind could be wielded equally by horse and foot, but the latter was for foot-soldiers only. The pole-axe had a longer handle, and a broader, stronger, and sharper blade than the common axe. During the Middle



Ages, and somewhat earlier, it was much used in sorties, and to prevent the escalading of a besieged fortress. The pole-axe differed but little from the battle-axe. The *black bill* and *brown bill* where a sort of halbert, having the cutting part hooked like a woodman's bill, with a spike projecting from the back, and another from the head. The *glaive* was a kind of pole-axe, or bill, used by the Welsh.

POLE HAMMER.—An early weapon of war, consisting of a spiked hammer placed at the end of a very long shaft or pole. See *War-hammer*, and *Luzerner*.

POLE MARCH.—Originally, in Grecian antiquity, the Commander-in-Chief; but, afterwards, a civil Magistrate, who had under his care all strangers and sojourners in the city.

POLE-PAD.—A pad placed on the end of the pole in field-gun carriages, to prevent injury to the horses.

POLE PROP.—A bar for supporting the end of the pole or tongue, especially used with the various carriages of the artillery service.

POLE STRAP.—A heavy strap by which the pole of the carriage is attached to the collar of the horse. Also called *Pole-piece*.

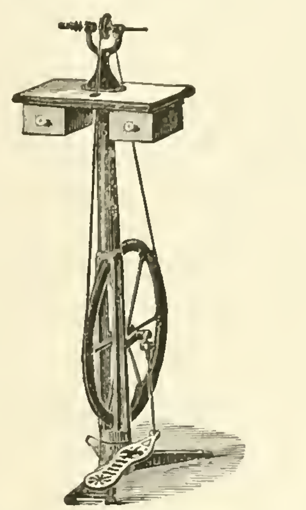
POLIABOLE.—A ballista, which was capable of throwing both arrows and stones. Also written *Palintonne*.

POLICE.—1. The term *Military Police* has two significations—1st, the organized body employed within an army to preserve civil order, as distinct from military discipline; and, 2d, a civil police with a military organization. The police of an army commonly consists of steady, intelligent soldiers, who act under the orders of the Provost-Marshal, and arrest all persons out of bounds, civilians not authorized to pass the lines, disorderly soldiers, etc.; they also attend to sanitary arrangements. As in all military matters, the police of an army possess summary powers, and a sentence of the Provost-Marshal is carried out immediately after it is pronounced. Of civil police with military organization may be instanced, as specimens, the Gendarmerie of France, the Sbirri of Italy, and, in an eminent degree, the Irish Constabulary.

2. The cleaning of a camp or garrison, or the state of a camp in regard to cleanliness. The working party engaged in policing is called the *Police Party*, and the Sergeant in charge of the same, the *Police Sergeant*.

POLICE GUARD.—An interior guard, having the care of the arms, property and prisoners; also charged with enforcing the regulations of the camp in regard to order and cleanliness. In each regiment, in the field, a police guard is detailed every day, consisting of two Sergeants, three Corporals, two drummers, and men enough to furnish the required sentinels and patrols. The men are taken from all the companies from each in proportion to its strength. The guard is commanded by a Lieutenant, under the supervision of a Captain, as Regimental Officer of the Day. It furnishes ten sentinels at the camp—one over the arms of the guard; one at the Colonel's tent; three on the color front, one of them over the colors; three, fifty paces in rear of the field-officers' tents; and one on each flank, between it and the next regiment. If it is a flank regiment, one more sentinel is posted on the outer flank. See *Field-service*.

POLISHING.—Polishing, in the armory, is effected by first removing any tarnish or oxidation by means of some material which will chemically act upon it; for this purpose sulphuric, hydrochloric, oxalic, and acetic acids are used, and in various states of dilution. Usually, it is necessary to remove the acid with clean water, and dry rapidly, to prevent re-oxidation; and then either friction with various polishing materials, or rubbing with a smooth, hard surface or burnisher, brings out the luster of the metal. The *foot*-polishing lathe, shown in the drawing, is used for all small articles and parts. It has a spindle, one end of which is threaded and tapers



to a point for holding a brush, buff, or other polishing wheels. The other end of the spindle forms an arbor for holding emery and other grinding wheels, also for small drills. *Polishing Pastes* vary according to the materials upon which they are to be employed. For brass, the best kind is a mixture of 2 parts of soft soap with 4 parts of rotten-stone in very fine powder. Another sort is 8 parts of fine rotten-stone powder, 2 parts of oxalic acid powdered, 3 parts olive oil, and enough of turpentine to make them into a paste. For iron, a mixture of emery powder and lard is used; and for pewter a mixture of finely-powdered bath-brick and soft soap. For wood, a paste called furniture paste is made by adding spirit of turpentine to beeswax, sufficient to form it into a soft paste, which is rubbed on thinly with a brush and woolen rag, and afterwards polished with a dry woolen cloth and soft brush. See *Emery*.

POLITICS.—That branch of ethics which has for its subject the proper mode of governing a State, so as to secure its prosperity, peace, and safety, and to attain as perfectly as possible, the ends of civil society. Among the subjects which political science embraces are the principles on which Government is founded, the hands in which the supreme power may be most advantageously placed, the duties and obligations of the governing and governed portions of society, the development and increase of the resources of the State, the protection of the right and liberties of the citizens, the preservation of their morals, and the defense of the independence of the State against foreign control or conquest. While the philosophy of governing constitutes the *science* of politics, the *art* of politics consists in the application of that science to the individual circumstances of particular States. The ancient Greek writers treated politics with reference to an ideal perfect State, which each propounded according to his own speculative views, pointing out the variation of every existing government from his standard. The politics of a country, in common parlance implies the course of its Government, more especially in its relations with foreign powers.

POLKOWNICK.—A Colonel of a Polish regiment.

POLO.—This may be described as hockey on horseback. It is a game of Asiatic origin, and was introduced into England in 1872 by Cavalry Officers who had learned it in India. Two goals, as for football, are set up about 350 yards apart, and the object is to drive a ball about the size of a cricket-ball through the goal by striking it with long sticks having bent or crooked ends. The players are mounted on ponies, and much depends on the skill with which these are managed. Four or five a side are the usual numbers, and those scoring the greater number of goals win the game. Polo has become very popular among English Cavalry Officers, and a few clubs have also been formed.

POLRON.—That part of the armor which covers the neck and shoulders.

POLTROON.—A coward; a dastard; one who has no courage. The origin of this word is stated by some to come from the Latin *pollex truncus*, in consequence of the frequent instances of men cutting off their thumbs to disqualify themselves for military service. Others, however, derive it from High Dutch, *polster*, a bed, from poltroons taking to their beds whenever any peril presents itself; or again, from the Italian *poltrone*, a colt, because of that animal's readiness to run away.

POLYGAR HELMET.—A casque of Central India, with fixed nose-piece, cheek pieces, and very long neck-guard, or mail hood.

POLYGON.—1. A school of practice for artillery in Japan. 2. The name applied to the many-angled forms in which the outer walls of all fortified places are built. Polygons of 5, 6, 7, 8, etc., sides are denominated pentagons, hexagons, heptagons, octagons, etc., and when the number of sides exceed twelve, the figure is merely mentioned as a polygon of so many sides. The quindecagon, or figure of 15 sides, is the only common exception to this rule. Polygons have many general properties; such as that the sum of the angles of a polygon, when increased by four right angles, or 360°, is equal to twice as many right angles as there are sides in the polygon, and that (supposing the number of sides of the polygon to be expressed by n) the number of its diagonals is $\frac{n(n-3)}{2}$; also, if a polygon of an even number of sides be circumscribed about a circle, the sums of its even and odd sides are equal; and if a polygon of an even number of sides be inscribed in a circle, the sums of its even and odd angles are equal. A polygon which has all its sides and angles equal is called a *regular* polygon. All polygons of this class are capable of being inscribed in or circumscribed about, a circle; but though the problem is merely to divide the circumference of a circle into a number of equal parts, corresponding to the number of sides in the polygon, geometry was till lately only able to perform it in those cases where the number of sides of the polygon belongs to one or other of the series 2, 4, 8, 16, etc.; 3, 6, 12, 24, etc.; or 5, 10, 20, 40, etc. Gauss, however, in the beginning of the present century, showed how it could be done in the case of all polygons, the number of whose sides was of the form $2^n + 1$ (provided it be a prime number), or a multiple of this prime number by any power of 2. This discovery supplies us with innumerable series representative of the numbers of the sides of polygons which can be described around or inscribed in a circle, such as 17, 34, 68, etc.; 257, 514, 1028, etc.

POLYGONAL SYSTEM OF FORTIFICATION.—The polygonal system has been proposed by several engineers of distinction, but its most ardent advocate has been the celebrated Montalembert. Consisting of either a simple polygonal enceinte without re-enterings, the sides of which are flanked by casemated caponnières, placed at the middle point of the fronts; or of fronts either slightly tenailled or of a bastion form, with short casemated flanks to flank the faces of the central caponniéres, this system affords more interior space, and from the mode adopted of flanking the enceinte, will admit of much larger fronts than either the bastioned or the tenailled systems. The salient angles moreover will be more open in this than in the other two systems. From these peculiarities of this system the positions suitable for the erection of batteries to enfilade the faces of the enceinte are less advantageous, from their being thrown in nearer to the adjacent fronts than in either of the other systems; whilst a greater development of trenches will also be requisite to envelop the fronts of attack. The polygonal tracé has certain prominent advantages and defects which may be seen by a slight comparison with the bastioned system. As the exterior sides are longer and the re-enterings of the enceinte less deep than in the bastioned systems, it follows: 1. That the interior space enclosed by the enceinte is greater in the polygonal tracé. 2. That the faces of the enceinte are less exposed to ricochet from the greater obtuseness of the salient angles. 3. That the fire of the faces has thus a better bearing on the distant defence. 4, That requiring fewer fronts on a given extent of line to be fortified, there will be fewer flanks and more artillery therefore disposable for the faces and curtains. 5. That, in the usual mode of attack; the besiegers will be forced into a greater development of trenches for the same number of fronts.

The defects of the system are: 1. That the enceinte, having no other flanking defense than the main caponnière, will be exposed to an escalade so soon as the fire of this defense is silenced. 2. That the progress of the besiegers during the last and most important period of the siege is but little delayed, owing to the want of the concentrated cross-fires which are afforded in both the bastioned and tenailled systems, in advance of the salients of the enceinte, and upon the ground generally in advance of the fronts, due to the slighter re-entering formed by the independent works in front of the enceinte salient. It is further objected that in the German method, *First*. The system makes use of numerous works of masonry that can be easily ruined by distant batteries of heavy caliber, especially when pierced with embrasures and loop-holes like the casemated caponnières and defensive barracks of the German method. *Second*. That the distribution of troops and *matériel* of war throughout the independent works deprive the defense of the union and concerted action that can only exist under a single commander. *Third*. That the expense of construction is much greater, in consequence of the numerous works of masonry requiring nice workmanship. And, *Fourth*. That it is imprudent to abandon existing systems that have stood the test of experience for those not possessing this advantage. See *German System of Fortification*, *Montalembert System of Fortification*, and *System of Fortification*.

POLYSPASTE.—The crane of Archimedes, an engine which was used to raise and shatter to pieces whole vessels, and identified with those enormous hooks that were used to pull off the heads of the battering-rams.

POLYTECHNIC SCHOOL.—An Institution, first established in Paris (1794) by the National Convention, under the name of *Ecole des Travaux Publics* (School of Public works). No students were admitted but those who intended to enter the public service; and though the general object of the Institution was the supplying of well-educated youths to all branches, it was more particularly devoted to the thorough instruction of recruits for the Corps of Civil and Military Engineers. The Institution received the name of "Ecole Polytechnique" in 1795. The pupils were at first 319 in number, and each received, during his stay of two years in the Institution, an annual stipend of 1,200 francs (£48 nearly); the teachers were in most cases the most eminent savants of France. In 1799 some modifications were introduced into the working of the School; the number of pupils was at the sime time limited to 200, and they were put into uniform. The advantages of an Institution of this sort, when ably conducted, soon made themselves evident, and the Polytechnique, in consequence, rose into high estimation, not only in France, but throughout Europe, so much so, that it became common for foreign nations, when entering into a treaty with France, to stipulate for the admission of a certain number of their subjects into the Institution, after passing the prescribed entrance examination. In 1804, the Emperor Napoleon introduced various modifications into its working, and gave it a military organization; it was also removed from the Palais Bourbon (where it had existed from its first establishment) to the Old College de Navarre. The Institution became more and more, as the end of the Napoleonic Empire drew near, a training-school for young artillerists and engineers; and such was the enthusiasm of the pupils in the Emperor's cause, that, after the disasters of 1814, they demanded to be enrolled *en masse* in the ranks of the French Army. However, Napoleon was (to use his own words) not inclined "to kill the hen for the golden eggs;" but he allowed them to form three out of the twelve companies of which the Artillery Corps of the National Guard was composed. These three companies rendered important service in manning the walls of Paris, and behaved heroically in the battle of March 30, 1814. After the First Restoration, the Polytechnique, being considered to be evil-disposed to the Government, suffered considerable reductions; but was restored to its former importance for the brief period of the "hundred days." After the Second Restoration (July, 1815), the Staff of Professors was remodeled; Lacroix and some others were dismissed, and replaced by Poisson, Arago, Cauchy, etc. Notwithstanding these changes, the Government still had its doubts as to the loyalty of the establishment, and took advantage of an outbreak, April 3, 1816, to break it up. It was reconstituted in September of the same year, under a revised code of regulations, and in 1822 the old severity of military discipline was restored. During the war of 1870-71, the Government of National Defense ordered the pupils to meet at Bordeaux, and classes were opened there under distinguished pupils of the School brought from all parts of France. However the attempt had to be abandoned, and the pupils having sought permission to take part in the war, were divided among the different sections of the army, in which their services were highly appreciated. The Constitution of the School, which has so frequently suffered change, was, in the end of 1873 regulated by *Décret* of Nov. 30, 1863, and Ministerial Rules issued on Mar. 5, 1857. 1. No pupil can be admitted unless he has been successful in the public competitive examination which is held each year. 2. The conditions of admission to the competitive examination are, that the candidate shall be a Frenchman; that he shall be more than 16, and less than 20 years of age, on the 1st of January of that year; and that he shall be either a Bachelor of Letters or a Bachelor of Sciences of the University of France. If he holds both degrees he is allowed 50 marks in the examination for admission. 3. Regular soldiers are admitted up to the age of 25 years, provided they have been on real and effective service for two years. 4. The charge for board is 1,000 francs (£40) per annum, and the cost of outfit (to be also paid by the pupil) about 600 francs. 5. The duration of the course of instruction is two years; the pupils, after finishing their course, must pass a final examination; the successful candidates, if found to be physically qualified, are arranged in order of merit, and choose in order what branch of the public service they wish to enter. 6. The branches of the public service which are recruited from the Polytechnique are, the Corps of Land and Naval Artillery, Military and Naval Engineers, the Imperial Marine, the Corps of Hydrographic Engineers, that of Engineers of Roads, Bridges, and Mines, the Corps of Staff Officers, the Superintendence of Telegraphs and Gunpowder and Tobacco Manufactories; and generally every Department which, requiring special scientific knowledge, may be added by *Décrets* to these. The following branches of study are embraced in the curriculum: Mathematics, Physics, Chemistry and Chemical Manipulation, History and Literature, German, Written Exercises, Drawing, Geodesy, Mechanics, Architecture, Art Militaire. Lessons in Fencing, Music, and Dancing are given out as optional, and must be separately paid for. The number of pupils varies with the requirements of the public service. In 1794 there were 396 pupils; in 1820 only 66. During the First Empire, the numbers increased from 110 in 1808, to 227 in 1813; under Louis Philippe the average number was 130. During the Second Empire, it had risen to 140 and 150. After the war with Germany in 1870-71 the number rose to 260. The numerous and admirably equipped Technical Schools of Germany, often called *Polytechnica*, have received no military restriction, and are available for all interested in the industrial arts; they are in many cases scientific centers comparable to the Universities.

Pommettée Cross.

POMADA.—An exercise of vaulting the wooden horse, by laying one hand over the pommel of the saddle. See *Gymnastics*.

POMEL CROSS.—In Heraldry, a cross whose extremities terminate in single knots or pomels, like the *Bourdon* or Pilgrim's Staff. Also written *Pommettée Cross*.

POMERIUM.—In ancient architecture, that space of ground which lay between the walls of a fortified town and the inhabitants' houses. The term is still used among modern architects, particularly by the Italians, to describe the breadth of the terreplein of the rampart, its inward talus, and the vacant space which is usually left between this talus and the houses of the town.

POMME.—In Heraldry, a bearing or device representing, or in the form of, an apple.

POMMEL.—The knob on the hilt of a sword. Also the protuberant part of a saddle-bow. The term *Pommeled*, or *Pommelled*, signifies furnished or mounted with one or more pommels, as a sword, dagger, or the like.

POMMELION.—The cascabel, or hindmost knob of a cannon. See *Cascabel*.

POMPON.—A tuft of wool, or other material, sometimes worn by soldiers on the top of the hat in front, instead of a feather.

PONCHARRA RIFLE.—In 1833, Colonel Poncharra suggested placing a "sabot" of hard wood underneath the ball with a greased patch, which, resting on the offsets of the mouth of the chamber, was prevented from entering it. This rifle was objected to as a war weapon on account of the complicated nature of its ammunition, and the difficulty of procuring it in the field; besides which, the sabots frequently broke in loading, from the ramming necessary to expand the bullet into the grooves.

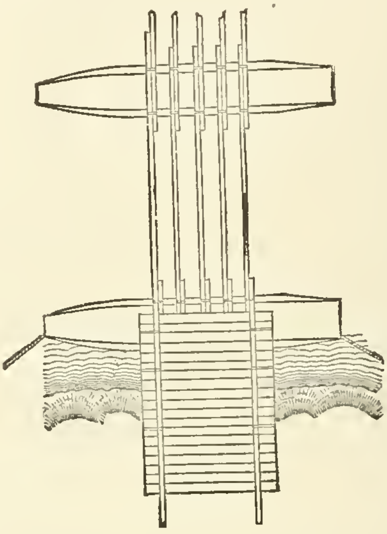
PONCHO.—A Spanish-American garment, consisting of a piece of woolen cloth, 5–7 ft. long, 3–4 feet broad, having in the middle a slit through which the wearer passes his head, so that the poncho rests upon the shoulders and hangs down before and behind. In the fashions of recent times, the poncho has been introduced in Europe. In the United States Army, mounted troops are issued a waterproof poncho, consisting of painted cotton or rubber cloth.

PONIARD.—A pointed instrument for stabbing, usually borne in the hand, at the girdle, or in the pocket. See *Dagger*.

PONTONES.—Ancient square-built ferry-boats for passing rivers, as described by both Cæsar and Aulus Gellius.

PONTOON.—The name given to buoyant vessels used in military operations for supporting a temporary bridge. Pontoon bridges have been constructed, with greater or less skill, from the earliest times. Darius passed the Hellespont and Danube by pontoon bridges, and the former was traversed by Xerxes' immense army on similar temporary bridges, very admirably formed. A pontoon train is a necessity for every army maneuvering in a country where there are rivers, and many campaigns have proved failures for want of this cumbrous but indispensable apparatus. In most armies the pontoons are under the charge of the engineers; but in the Anstrian army there is a distinct and highly-trained corps, called *pontonieren*. Marlborough used clumsy wooden pontoons. Napoleon and Wellington had them lighter of tin and copper. They were flat-bottomed, rectangular boats, open at the top. Anchored at stem and stern, beams were laid over from one to another, and transoms with planks crossing these beams completed the roadway of the bridge. These open pontoons were exposed to the disadvantage that they were very liable to be filled with water, and thus ceased to support the bridge. They were, moreover, very heavy, one pontoon, with appurtenances, constituting a wagon-load. As 36 were deemed necessary for the train, a pontoon equipment was a serious item in the *impedimenta* of an army. The open pontoons are now, however, obsolete, modern science having substituted closed cylindrical vessels of copper (or occasionally of India-rubber), which are far lighter, can in an emergency be rolled along, and can only be submerged if perforated. Against the last contingency, they are divided within into water-tight compartments, so that one perforation may not seriously detract from the total buoyancy of a pontoon. In the British service two pontoons are used: the larger, with hemispherical ends, being 22 ft. 3 in. in length, and 2 ft. 8 in. in diameter; the smaller, cigar-shaped, with conical ends, 15 ft. in length, 1 ft. 8 in. diameter. Two of the largest used to form a raft weigh 8 cwt. 7 lbs.; the superstructure 18½ cwt. At 24 ft. apart from center to center, this raft will carry infantry four deep, marching at ease; cavalry, two deep, and light field guns; at 16 ft. interval, heavy guns. A raft of three pontoons, at close distances, will support siege-ordnance. The pontoons can be used in very wide rivers as rafts, in their proper sense, or they can be connected, when the width permits, to form a bridge. In the latter case, each is towed into line, anchored above as it drops to its place, and a second time when its exact spot is reached. It is computed that each pontoon requires 1½ minutes to take its position, and that when the pontoons are placed, the roadway can be laid, if properly arranged previously, in 1½ minutes for each interval between two pontoons. A river of 600 feet may thus be bridged in less than 1¼ hours. The process of throwing a bridge over in face of an enemy is fraught with the utmost danger to the engineers employed. Pontoon bridges have to be passed with great care, and every measure should be adopted, such as breaking step, etc., which can reduce the peculiarly dangerous vibration. The following is the method generally employed for building bridges with the bridge equipage of the United States Army, and known as the construction by *successive pontoons*.

The place for building the bridge having been selected, the pontoons are brought to the banks of the stream, near the spot, and the boats are launched into the water. Each boat is provided with an anchor. Some of the boats cast their anchors up-stream, while others cast them down-stream. The

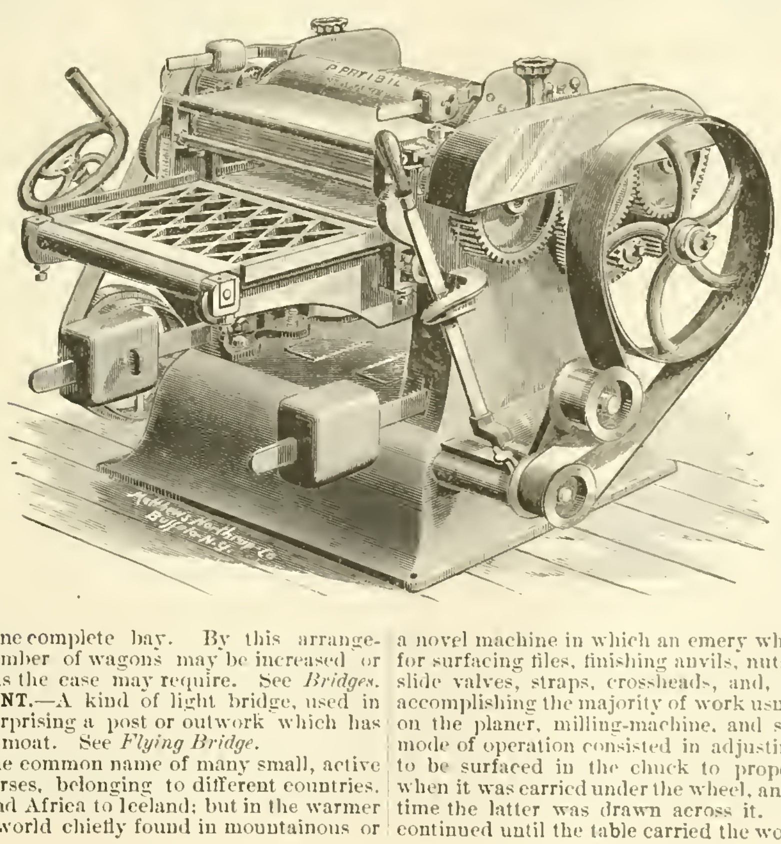


number of anchors to be cast will depend upon the rapidity and strength of the current. Under ordinary circumstances, an anchor cast up-stream from every alternate boat, and half the number down-stream, will be sufficient. The boats casting up-stream anchors are launched above the bridge; the others below. If none exists, an easy approach for the wagons and artillery should be constructed, leading down the bank to the bridge. A strong sill is then imbedded in a trench, perpendicular to the axis of the bridge, and is held firmly in place by four stout pickets, driven about eight inches from each end. This sill is horizontal, and should be as nearly as possible on a level with the flooring of the bridge. A pontoon is then brought up opposite to this sill, and close to it. Five balks are brought forward, and the ends placed upon, and lashed to the outer gunwale of the boat, in the proper places The men holding the balks push the pontoon off, until the ends of the balks on shore rest upon the abutment sill. The pontoon is then secured in position by shore-lines running out from the bow and stern, and fastened to mooring-pickets. The chess are brought forward and laid upon the balks, to within one foot of the boat. A second pontoon is brought alongside of the first; five balks are again used, and this second boat pushed out. The balks are firmly lashed together and to the gunwales of the first pontoon. The intervals between the pontoons are known as bays. The chess are laid as soon as the balks are lashed; and when a bay is completely covered, the side rails are laid and lashed to the balks beneath. This operation is continued until the entire length of bridge is obtained. It is recommended to strengthen the first bay by using two additional balks—one between the first and second, and in contact with the latter; the other, between the fourth and fifth, in contact with the fourth. When the water is not deep enough to float the first pontoon, a trestle, or other fixed point of support, may be used instead of the pontoon. The great objection to this pontoon is its weight, which makes its transportation over bad roads difficult. For bad roads and rapid movements a lighter pontoon than this wooden boat has to be used. The one employed under these circumstances is the canvas pontoon, which consists of a wooden frame covered with canvas. The wooden frame comes apart, so as to be easily loaded on wagons for transportation. It has two side frames, trapezoidal in shape, the upper piece being twenty-one feet long; the lower, eighteen feet and four inches long. The depth of this frame is two feet and four inches. The frames are connected by pieces called transoms, framed into the side frames, and these latter are fastened together by ropes passing through rings in the ends of the frames. The inner width of the boat frame, or distance between the side frames, when the parts are arranged, is four feet and eight inches. In some cases, the side frames are hinged in the middle, so that when taken apart, they may be folded up. The canvas cover is made of cotton duck. The balks are twenty two feet long, with a cross-section of four and and one-half inches, and are provided with claws as before described. The chess is the same as that described, but only eleven feet long, instead of thirteen. The reserve equipage is divided into trains, each train being composed of four pontoon divisions, and one supply division. Each pontoon division contains all the material necessary to construct a bridge of eleven bays, or a bridge two hundred and twenty-five feet long. The advance guard equipage is also divided into trains each train having four pontoon divisions. A division contains eight pontoon wagons two wagons for chess and two for trestles. The pontoon wagons of this equipage are so loaded that each wagon will have all the material necessary to construct one complete bay. By this arrangement the number of wagons may be increased or diminished, as the case may require. See *Bridges*.

PONTVALENT.—A kind of light bridge, used in sieges, for surprising a post or outwork which has but a narrow moat. See *Flying Bridge*.

PONY.—The common name of many small, active breeds of horses, belonging to different countries, from India and Africa to Iceland; but in the warmer parts of the world chiefly found in mountainous or sterile regions. They are in general the property of man, and not truly wild, although, in very many cases, they live almost in a wild state, and receive no care or attention except when they are wanted for use. They are in general very hardy, and their strength is great in proportion to their size. They are often vicious, or at least playfully tricky to a much greater degree than is usual with large horses. Ponies are very often covered with rough hair, and have large, shaggy manes and forelocks. The *Shetland pony* is a very good example of these small races of horse. The *Iceland pony* is scarcely different from it, and is hardy enough to endure the winter of Iceland without shelter. The *Galloway*, *Welsh*, *Dartmoor*, *Exmoor*, and *New Forest* breeds are British races of pony larger than the Shetland. The progress of inclosure and cultivation in their native regions has so changed the circumstances in which they long subsisted, and in which, perhaps, they originated, that scarcely any of them are now to be seen of pure and unmixed race. Sardinia and Corsica have small races of ponies which have subsisted unchanged from ancient times. In the Morea there is a race of ponies, driven in herds to Attica for sale, exceedingly wild and vicious, but capable of being rendered very serviceable. But it is unnecessary to mention the many races both of Europe and Asia. They differ considerably in size, some, like the Shetland pony, suggesting a comparison with a large dog, some much larger. They also differ much in color: a dun or tan color, with a black stripe along the back, is prevalent in many of them. Ponies are seldom employed in agricultural labors; but they are of inestimable value for campaign purposes in many wild and mountainous regions, from their hardiness and surefootedness, and are often used as saddle-horses, the largest kinds being even employed as horses for light cavalry.

PONY PLANER.—Until quite recently the more important arsenals and armories were equipped with a novel machine in which an emery wheel was used for surfacing files, finishing anvils, nuts, gibs, keys, slide valves, straps, crossheads, and, in short, for accomplishing the majority of work usually surfaced on the planer, milling-machine, and shaper. The mode of operation consisted in adjusting the object to be surfaced in the chuck to proper elevation, when it was carried under the wheel, and at the same time the latter was drawn across it. This motion continued until the table carried the work out of the

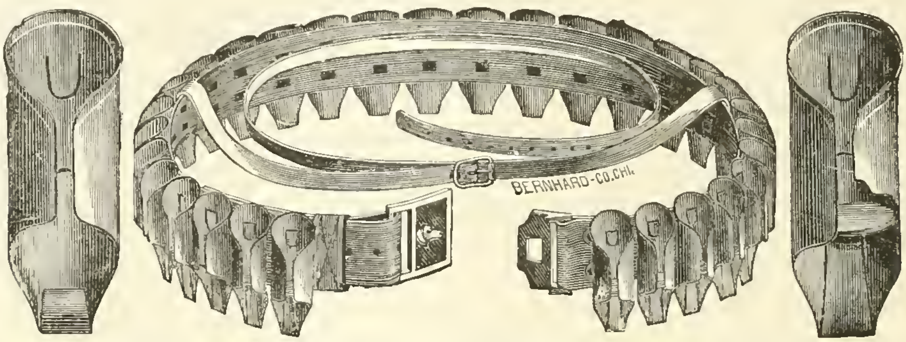


action of the grinder. Then, by means of suitable mechanism, the operator slightly elevated the object and caused it to run back again under the wheel. Of this machine, the invention of the Tanite Company is a modification. The main difference is that the planer bed is made to slide to and fro on its ways by the action of a crank, the work being thus moved to and fro in the line of the emery wheel's revolution, while the wheel also has a cross motion imparted to it by another crank. This motion of the table corrects the inaccuracy resulting from gradual decrease in the wheel's diameter, there being a perceptible wear in the wheel, so that it grinds a long, flat piece taper instead of plane, when the work slowly passes under it; while, by this crank throw, the whole length of work is brought into contact with the wheel at each throw. A chuck rests on four springs, and rises and falls vertically in planed ways. When the adjustable stops have been adjusted, and the wheel no longer cuts, the work must be plane. The springs force the (chuck) work against the wheel, and yet act as safety appliances against over-friction and pressure. The whole table and bed has a vertical adjustment by a screw. Three belts are needed: one to the wheel mandrels, one to the suction fan, and one to the driver. The gears, being interchangeable, allow the proportion of speeds between the wheel shafts and the table to be altered in various ways. The machinery stands 32 inches high, and is 2 feet 8 inches each way. It will grind work 9 inches long by 5 inches wide. It is adapted to all small, flat work, especially to dies of hardened steel and chilled iron, to parts of gun and pistol locks, machine work, small levels, machine keys, locks, etc. It is claimed that thousands of small parts can, by this means, be finished to a gauge with greater exactness than can be done in any other way. The remaining portions of the device are similar to those in the device first alluded to above.

The name Pony Planer is also given to a most useful wood-planing machine. One of the best machines of this class, and one adapted for a great variety of work, is shown in the drawing. It has very powerful, geared, double feed-rolls, four inches in diameter. Those in front are weighted, those behind are provided with self-adjusting scrapers. The machine can take a $\frac{3}{4}$ inch cut, and is adjustable to different thicknesses of stuff by a single bandwheel, $\frac{1}{16}$ of an inch to a turn. Either plane is smooth enough for any work, but three admit of faster feed, and the feed cones are made accordingly. Two pressure bars are close to the cutterhead, the front one hinged and weighted. The machine is suitable for heavy as well as for light and very short stuff. The shaving guard and feed-roll covers are hinged, to give access to the knives, which can be whetted when in place. The principal bearing boxes are self-oiling. The heavy boxed shaped base is proof against twisting even when standing on a weak floor, which will often yield from the weight of lumber, thereby straining the bearings of the machines, and causing them to work hard and wear out quickly. The driving belt can come from above, below or from the back. When standing in front of the machine the cutter-head pulley is at the left hand. See *Emery-grinder*.

POOLER-JONES CARTRIDGE-BELT.—A belt having cartridge holders attached to it, suitable for either paper or brass shells. These holders can be easily attached to any hunting vest, coat front, or belt. An ordinary vest will hold from 36 to 50, each hoder weighing about $\frac{1}{4}$ of an ounce. A belt with 30 holders attached (weighing one pound) is shown in the drawing. The belts can be perfectly adjusted by wearer to fit either a slim or large man, with waist measuring from 30 inches to 41 inches. It can be worn over or under a coat, and it is impossible to lose the cartridges. The belt is intended to be worn or put on with the buckle behind. The cartridges are nearly all to the front and can be easily reached. The holder, B, with the side cut away to show the wad supporter, is for carrying brass or paper shells without being crimped. The form shown at, A, is for carrying paper shells crimped, or with ends turned down.

A



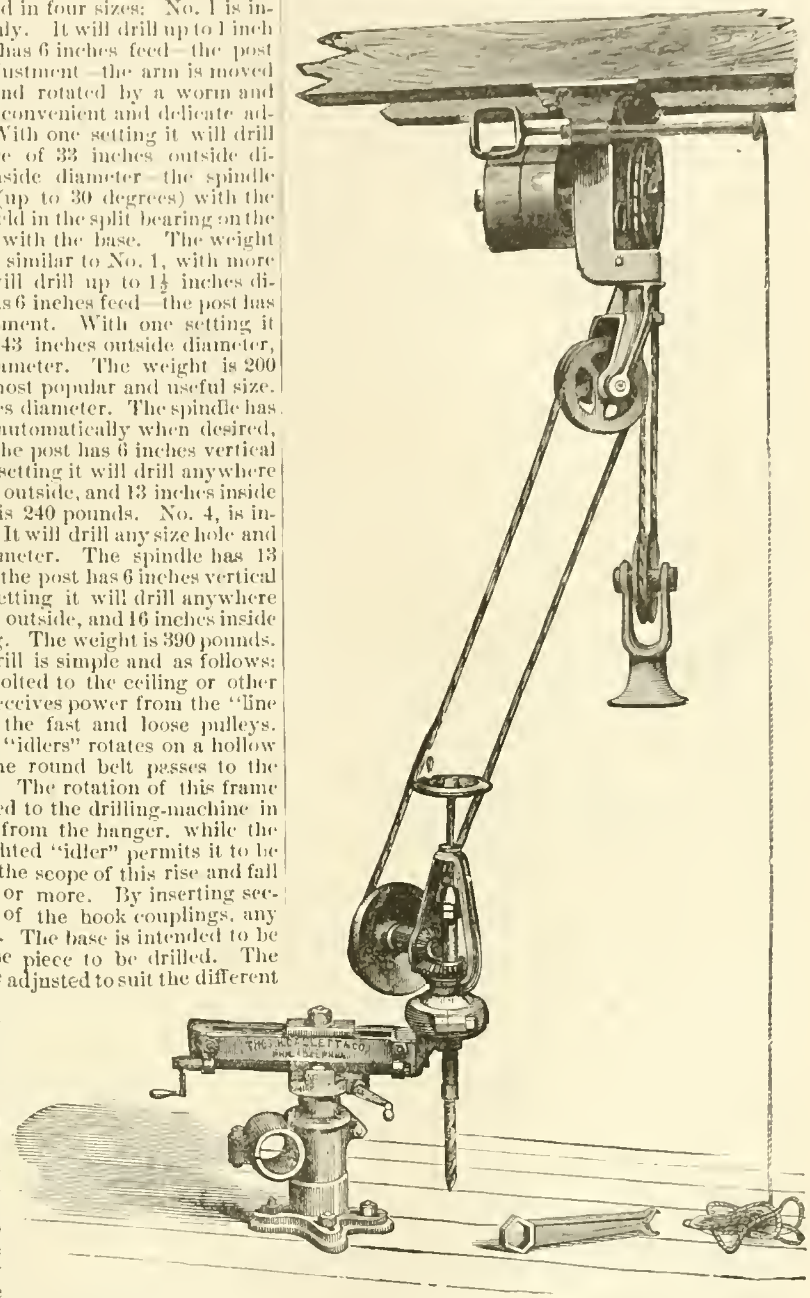
B

POOR KNIGHTS OF WINDSOR.—An institution of Military Knights at Windsor, England, which owes its origin to Edward III., and is a provision for a limited number of old officers. These officers consist of a Governor and 12 Knights on the upper foundation, and 5 on the lower, together 18, and are composed of officers selected from every grade, from a Colonel to a Subaltern, chiefly veterans, or on half-pay. They are allowed three rooms each in Windsor Palace, and 2 shillings per diem for their sustenance, besides other small allowances.

POPPET-HEAD.—That part of a lathe which holds the back-center, and can be fixed on any part of the bed. Boring-machines have a poppet-head.

POROSITY.—By this term we express the experimental fact that no kind of matter completely fills the space it occupies; in other words, that all bodies are full of minute cavities or interstices, such as are illustrated on a large scale by a sponge. On the atomic theory, it is obvious that this must be the case if the atoms of matter are spherical, or, indeed, if they have any form save one or two special ones, such as cubes or rhombic dodecahedrons. It is commonly asserted that all bodies must be porous, because they are compressible; but this is a great mistake, since we have no reason to believe that matter is not *per se* compressible, independently of the existence of interstices. The Florentine Academicians, in their attempts to compress water, proved the porosity of silver by flattening sphere of that metal, filled with water, nd soldered. The water escaped through the pores of the silver, and stood in fine drops on its surface. The porosity of liquids is easily shown by mixing alcohol and water. The bulk of the mixture is considerably less than the sum of the bulks of the components, showing that these must in part have entered each other's pores. This property of matter is of great importance in the Arsenal and Laboratory.

PORTABLE DRILL.—A form of drill much employed in arsenals. It drills at any angle, in any position, at any distance, and in any direction from the power. It is especially adapted to drilling all pieces which are inconvenient to move, or which cannot be readily adjusted under stationary drilling machines. The drawing shows the drill as employed at the Watertown Arsenal. It is used in four sizes: No. 1 is intended for light work only. It will drill up to 1 inch diameter. The spindle has 6 inches feed—the post has 5 inches vertical adjustment—the arm is moved in and out by a screw, and rotated by a worm and tangent-wheel, giving a convenient and delicate adjustment to the drill. With one setting it will drill anywhere over a surface of 33 inches outside diameter, and 11 inches inside diameter—the spindle can be set to any angle (up to 30 degrees) with the base—the post can be held in the split bearing on the side for drilling parallel with the base. The weight is 125 pounds. No. 2, is similar to No. 1, with more power and range. It will drill up to 1½ inches diameter. The spindle has 6 inches feed—the post has 6 inches vertical adjustment. With one setting it will drill over a surface 43 inches outside diameter, and 13 inches inside diameter. The weight is 200 pounds. No. 3, is the most popular and useful size. It will drill up to 2 inches diameter. The spindle has 8 inches feed, working automatically when desired, with 3 speeds of feed—the post has 6 inches vertical adjustment. With one setting it will drill anywhere over a surface 43 inches outside, and 13 inches inside diameter. The weight is 240 pounds. No. 4, is intended for heavy work. It will drill any size hole and bore up to 8 inches diameter. The spindle has 13 inches automatic feed—the post has 6 inches vertical adjustment—with one setting it will drill anywhere over a surface 56 inches outside, and 16 inches inside diameter. Back gearing. The weight is 390 pounds. The operation of the drill is simple and as follows: The counter-hanger is bolted to the ceiling or other convenient place, and receives power from the "line shaft" by a flat belt on the fast and loose pulleys. The frame carrying the "idlers" rotates on a hollow stud, through which the round belt passes to the grooved driving pulley. The rotation of this frame permits the belt to be led to the drilling-machine in any direction, radially, from the hanger, while the rise and fall of the weighted "idler" permits it to be led to any point within the scope of this rise and fall—say ten to fifteen feet or more. By inserting sections of belt, by means of the hook couplings, any distance can be reached. The base is intended to be bolted or clamped to the piece to be drilled. The height of the post can be adjusted to suit the different lengths of drills and chucks used in the spindle. The radial slotted arm is fastened to the post by the stud and nut; the position of the drill being adjusted by the screw which travels the arm, and the worm and tangent-wheel that rotates it on the post. When it is required to drill parallel with the base, the post is held by the clamp bearing on the side of the base. There is a shoulder turned on the bottom of the ball on the gear frame (of sizes 1, 2, and 3), and a half collar fitted to it and bolted on the arm; this keeps the spindle square with the base. When this half collar is removed, the spindle can be set to an angle in any direction. When not being used on the floor, it serves the purpose of a bench drill press. See *Drilling-machine.*



PORTABLE FIRE-ARMS.—The portable-fire arms employed as military weapons of war are rifles, carbines, and pistols; these generally vary in construction with the Nation by which they are used. The term "breech-loading" applies to those arms in which the charge is inserted through an opening in the breech, and in the loading of which no ramrod is required. All military breech-loaders, now in use, employ the metallic case cartridge; they may be divided into *simple breech-loaders* and *repeaters.* The essential parts of all such arms are the *barrel*, the *chamber*, the *breech-mechanism*, the *lock*, the *stock*, the *sights*, and the *mountings*, and in repeaters the *magazine*. If the chamber be made in the piece which closes the breech, commonly called the *breech-block*, the arm is said to have a *movable* chamber; if it be formed by counterboring the barrel, it is said to have a *fixed* chamber. The latter has great advantages, and is generally used. With the fixed chamber the interior of the barrel is divided into two distinct parts, viz., the *bore* proper, or space through which the projectile moves under the influence of the powder, and the *chamber* in which the charge is deposited. The principal parts peculiar to simple breech-loaders are; 1st. The *movable breech-block*, by which the chamber is opened and closed. 2d The *breech-frame*, upon which the breech-block is mounted and united to the barrel. 3d. The *chamber*, with its recess, to receive the rim of the cartridge. 4th. The *firing-pin*, which transmits the blow of the hammer to the cartridge. 5th. The *extractor*, by which the empty case is removed after firing.

The foregoing named parts may be said to be essential to all breech-loading arms in which the metallic cartridge is used; the different ways in which they are combined mark the systems. These combinations have reference chiefly to the modes of operating and locking the breech-block. The different systems may be classified into: 1st, those with a *fixed* chamber; 2d, those with a *movable* chamber. The latter have now become obsolete. The first class have: 1st, a *movable barrel*; 2d, a *movable breech-block*. With each the motion may be *sliding*, in which case it moves in grooves; *rotating*, when it swings on a hinge; or *sliding* and *rotating* combined. The greater number of systems belong to the class of a "movable breech-block rotating about an axis." In arms of this class the axis of motion may be parallel to the axis of the barrel, and above, below, or to one side of it; or perpendicular to that axis, being vertical or horizontal, and lying in or out of the plane of the axis. The position of the hinge has an important influence on the facility of operating the block, inserting the cartridge, and extracting the empty shell; the most suitable position is deemed to be in front of the center of the block. In this case the motion of opening and closing the block is natural and easy; the cartridge is pushed into its place by the block, and a very simple retractor serves to withdraw the empty shell after firing. The most serious defect found in breech-loading arms was the escape of the flame through the joint, which not only incommoded the soldier, but, by fouling the machinery, seriously interfered with its operations. At present this is entirely overcome by the elastic metallic case of the cartridge. The advantages of breech-loading over muzzle-loading arms are: 1st. Greater certainty and rapidity of fire. 2d. Greater security from accidents and loading. 3d. The impossibility of getting more than one cartridge into the piece at the same time. 4th. Greater facility of loading under all circumstances, and particularly when the soldier is mounted, lying on the ground, or firing from behind any cover. The greater security with which the charge is kept in place when the piece is carried on horse-back with the muzzle down.

There are certain functions performed by, and certain important conditions to be fulfilled in, the construction of the different portions of a small-arm. The barrel is by far the most important part of a fire-arm, its office being to concentrate the force of a charge of powder on a projectile, and give it proper initial velocity and direction; for these purposes, and for the safety of the firer, it should be made of the best material and with the greatest care. In determining the *exterior form*, it is not only necessary to give such thickness to the different parts as will best resist the explosion effect of the charge, but such as will prevent it from being bent when used as a pike, or when subject to the rough usage of the service. *Weight*, to a certain extent is necessary to limit recoil, to give steadiness to the barrel in aiming, and to prevent it from "springing" in firing. The latter defect generally arises from bad workmanship, whereby there is a greater thickness of metal, and consequently less expansion, on one side of the bore than on the other. In some sporting rifles the barrel weighs from 12 to 15 lbs., but in the military service, where it is carried by the soldier, it seldom weighs more than 4½ lbs. The *length* of the barrel is determined by the nature of the service to which it is applied, rather than by the effect which it exerts on the force of the charge. It was shown by experiment that the velocity of a projectile in a smooth-bored musket increased with the length of the bore up to 108 calibers at least, but such length of barrel would be too heavy for a fire-arm and too unwieldy as a pike; in a rifled barrel the increase extended to about 250 calibers.

Three points are to be considered in determining the *caliber* of small arms: 1st. It should be as small as possible to enable the soldier to carry the greatest number of cartridges. 2d. To diminish the amount of ammunition required to supply the wants of an army, and to prevent the confusion liable to arise from a variety of calibers, there should not be more than two for all arms of the same service, viz., one for the rifle and the carbine, and one for the pistol. 3d. This point relates to the force and accuracy of the projectile, and to the flatness of its trajectory. The introduction of elongated projectiles afforded the means of increasing the accuracy and range of fire-arms, without increasing the weight of the projectile, simply by reducing the caliber, which diminished the surface opposed to the air. Too great reduction of caliber, however, gives a very long and weak projectile, and besides the effect of a projectile on an animate object depends not only on its penetration, but also on the shock communicated by it to the nervous system, or upon the surface of contact. These considerations have led to a general reduction of caliber of military rifles.

The *grooves* being for the purpose of communicating a rotary motion to the projectile around an axis coincident with its flight, their construction will depend upon the form, dimension and material of the projectile, charge of powder, and angle of fire. The points to be considered in determining the form of grooves for military arms are range, accuracy of fire, endurance, and facility of cleaning the bore. Experiment, in this country, has shown that for breech-loaders these points are best attained by making the grooves broad and shallow, and with a rapid twist. The *chamber* being a receptacle for the charge, its shape is made to conform to that of the cartridge. Its diameter is made a little larger, and that of the bore a little smaller than that of the projectile, this facilitates the insertion of the charge, and causes the projectile to be compressed and held firmly by the lands in its passage through the bore. The bottom of the grooves and the surface of the chamber are generally continuous.

The *breech-mechanism* comprises the principal parts that are peculiar to arms loading at the breech. The functions of these parts are the opening, closing, and locking of the breech, firing the charge, and removing the empty cartridge shell. These are the objects for the accomplishment of which the different systems are variously contrived, and with which alone they are concerned. The most important conditions to be fulfilled in the arrangement of this mechanism are: 1st. The number of parts should be as few as possible, and all should be of the simplest construction. 2d. The strength and union of the parts should be such as not only to resist repeated discharges, but the bursting of a cartridge case, which sometimes occurs from defective material or workmanship. 3d. The locking of the breech-block should not only be secure, but all the parts by which it is effected should work freely without sticking. 4th. The parts should be so arranged that the hammer cannot strike the firing-pin until the breech-block is properly locked. 5th. The hammer should not necessarily rest on the firing-pin when the piece is carried loaded 6th. The breech should be unlocked without the hammer being brought necessarily to full cock. 7th. The working parts should, as far as possible, be covered from dust and water. 8th. The extractor should be so arranged as to require no cuts or openings in that part of the chamber which surrounds the body of the cartridge case. The *lock* is the machine by which the charge in the cartridge is ignited. Those of the present day belong to the percussion class, in which fire is produced by a blow upon the fulminating powder contained in the cartridge-case. Locks are divided into *side* and *center* locks, depending upon the position occupied in the stock; each of these may be either *front-action*, wherein the mainspring is in front of the tumbler, or *back-action*, where this spring is in rear of the tumbler. The mortise, which forms a bed for the lock of the latter construction, seriously affects the strength of the stock at the handle, and for this reason the front-action lock is generally preferred for all military arms, except revolvers. The conditions to be fulfilled in the construction of a military lock, are simplicity, strength, certainty of action, and freedom from such accidental motion of the parts as might produce explosion of the charge in the barrel.

The stock is the wooden part of the fire-arm, to which all the parts are assembled; for military arms it is preferable that it should be in one piece. The material should be light, strong, and well seasoned. The butt, the part intended to rest against the shoulder and to support the recoil of the piece, should be of such length and shape as will enable it to transmit the recoil with the least inconvenience to the soldier. The longer it is, to a certain extent, the more firmly will it be pressed against the shoulder, and the effect of the recoil will be a *push* rather than a *blow*. The stock is crooked at the handle for convenience in aiming, and for the purpose of diminishing the direct action of the recoil. Changing the direction of the recoil in this manner causes the piece to rotate around the shoulder; but if the stock be made too crooked, the butt will be liable to fly up and strike the soldier's face. The *sights* are guides by which the piece is given the elevation and direction necessary to hit the object. There are two; called *front* and *rear sights*. The *front sight* is fixed to the barrel near the muzzle. The *fineness* of its point is regulated by the length of the barrel, or distance from the eye, and the size and distance of the object generally aimed at; it is made coarser in military than in sporting arms, to prevent injury. The *rear sight* is attached to the barrel a short distance from the breech; it has a movable part, capable of being adjusted for different elevations of the barrel. A sight for a military arm should satisfy the following conditions, viz.: 1st, it should be easily adjusted for all distances within effective range; 2d, the form of the notch should permit the eye to catch the object quickly; 3d, it should not be easily deranged by the accidents of service. *Globe* and *telescopic* sights are used for very accurate sporting arms, but they are too delicate in their structure and too slow in their operations for general purposes.

The *mountings* may be divided into three classes, viz.: 1st, those which serve to connect the principal parts, generally bands and screws; 2d, those which protect from wear or strengthen the stock at certain points, as the butt-plate, guard-plate, tip; 3d, the minor parts which secure the different parts (including the mountings proper) in their place, consisting of springs, screws, rivets, pins, washers and nuts.

A *butt-plate* is to protect the end of the stock from injury by contact with the ground; it is generally curved to fit the shoulder in firing. A *guard-plate* is to strengthen the handle of the stock; it may serve as a fulcrum for the trigger. A *tip* is a shield placed on the end of the stock towards the muzzle. If the piece be intended to be carried upon the soldier's back, it is provided with *swivels* for that purpose, generally two, one of which may be fastened to a band and the other to the guard-plate, or to a point of the stock in rear of that plate. The *trigger* is a lever used to set the lock in motion. Triggers are divided, according to their construction and the force required to draw them, into *common* and *set* or *hair* triggers; the latter are employed only in sporting arms. The force required to set off the trigger, if very great, may disturb the accuracy of the aim; if it be slight, the piece will be liable to accidental discharges. The trigger has a guard which protects the finger-piece from injury, and from accidental blows that might produce explosions. The *ramrod* is a long, slender piece, carried with an arm; with breech-loaders it is only employed to wipe out the barrel to remove from it any obstruction, as a defective cartridge-shell. See *Small-arms*, and *Springfield Rifle*.

PORTABLE FORGE.—A light and compact blacksmith's forge, with bellows or blowers, etc., all so arranged as to be readily moved from place to place. Fig. 1, shows a most complete portable forge, designed for army usage. Its height is 22 inches; size of firepan, 22×27 inches, weight, 200 pounds; and diameter of the fan 9 inches. The firepan is made of wrought-iron, and is 10 inches deep, containing all the other parts of the forge when packed for transportation. The blower and gearing are compactly framed together, and fit into a slot on the

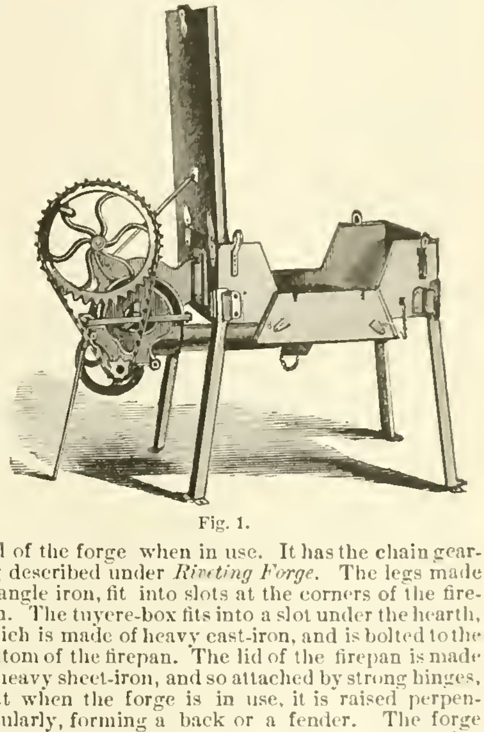


Fig. 1.

end of the forge when in use. It has the chain gearing described under *Riveting Forge*. The legs made of angle iron, fit into slots at the corners of the firepan. The tuyere-box fits into a slot under the hearth, which is made of heavy cast-iron, and is bolted to the bottom of the firepan. The lid of the firepan is made of heavy sheet-iron, and so attached by strong hinges, that when the forge is in use, it is raised perpendicularly, forming a back or a fender. The forge can be set up for use, or packed for transportation in one minute. To pack the forge for transportation,

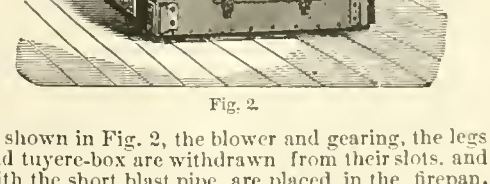

Fig. 2.

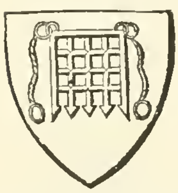
as shown in Fig. 2, the blower and gearing, the legs and tuyere-box are withdrawn from their slots, and with the short blast pipe, are placed in the firepan. The falling doors at the sides of the firepan are closed and fastened. The lid is shut down, and fastened by a hasp. The entire forge thus packed occupies a space only 22×27 inches square and 10 inches deep. This forge will produce a quick welding heat on iron three inches diameter, and on larger iron if required, as there is an abundance of spare blast.

PORTABLE MAGAZINE.—A wooden box or metal-lined case, covered with canvas, and of such size as to be easily carried in a battery from place to place when there is only one expense magazine for several batteries; but this would scarcely ever be the case in the future, as expense magazines in the present fortifications are provided in the proportion of 1 to every 4 or 5 guns, or in the case of very heavy guns, 1 to every 2 or 3.

PORT ARMS.—This old command in musketry drill, is derived from *portare*, to carry, and applies to a motion in which the fire-arm is brought to a slanting position in front of the body, lock to the front, the barrel crossing opposite the front of the left shoulder. See *Arms Port.*

PORTATE.—In Heraldry, borne not erect, but athwart an escutcheon; as, a portate cross.

PORTCULLIS.—A barrier, termed a *portcullis*, which can be lowered or raised vertically by machinery, is sometimes added to secure a passage-way from surprise. The ancient portcullis was a framework of heavy beams, placed vertically, leaving a few inches only between each pair of beams. These vertical beams were either solidly confined between horizontal beams, or clamping-pieces, in pairs; or else they were so arranged that they could slide upwards between the clamping-pieces. Each of the vertical beams was shod at the bottom with a strong pointed iron shoe. The horizontal pieces were framed securely with two heavy vertical beams that formed the sides of the frame, and were fitted into vertical grooves made in the side walls of the passage-way in which the frame could slide when raised or lowered. By arranging the vertical beams to slide upwards between the clamping-pieces, it enabled the passage-way to be closed where an obstruction might be designedly placed before the portcullis to prevent this being done; as the beams which meet the obstruction would be pushed upwards, whilst the others would fall to their ordinary level and close the passage-way on each side of the obstruction.



In the works recently constructed with us the portcullis, and even the doors preceding them, have been constructed of a strong open lattice-work of wrought-iron bars bolted strongly to the wrought-iron uprights and cross-pieces, forming the framework of the lattice. This is a great improvement for these purposes, both as to durability and defense.

Passage-ways of this description should be secured by all the means at an engineer's disposal. A large guard-room, with loop-holes bearing on the passage, should be erected on one side, near the gateway; and if the enceinte is a simple one, without outworks beyond its ditch, a small lunette, or loopholed tambour of masonry, or timber, should be constructed beyond the counterscarp, forming a tête-de-pont, for the security of the bridge from surprise.

2. In Heraldry, the portcullis is represented with rings at its uppermost angles, from which chains depend on either side. It was a badge of the Beaufort family, and borne in virtue of their Beaufort descent by the Tudor Sovereigns. Portcullis is the title of a pursuivant in the English College of Arms, whose office was instituted by Henry VII.

PORTER BAR.—In iron working, when a mass is too large to be handled conveniently with the tongs, a large iron rod, called the porter-bar, is welded to it to serve as a porter or guide-rod. Sometimes a part of the porter-bar is made to form the core of the forging, and the slabs of iron which form the forging are welded and built up on the bar. When the mass of iron is too large to be handled by the forge-man, it is supported by a crane, which serves to swing it from the fire to the hammer. See *Welding.*

PORT-FIRE.—A sort of slow match for firing guns. It consists of a paper tube from 16 to 20 inches in length, filled with a composition thus proportioned: Saltpeter 666 parts, sulphur 222 parts, mealed gunpowder 112 parts. The composition is rammed with force into the paper barrel, and then when ignited it burns for a considerable period. As a substitute may be employed soft brown paper dipped in a solution of two ounces of niter to a gallon of water, dried, and rolled up to the size of a common port-fire. Another port-fire consists of a rod cut square, of lime, birch, or poplar, boiled for six hours in a solution formed by dissolving 1 lb. of nitrate of lead in one quart of water. The rod is subsequently boiled in spirits of turpentine. When thoroughly dried, one yard will burn three hours.

Port-fires are packed in boxes containing 100 or 200. The contents of the box should be marked in white letters on each end, and the place and date of fabrication on the inside of the cover. The following are the particulars of the packing-boxes for port-fires.

	Length.	Width.	Depth.	Weight.
For 100 port-fires,	18	9.1	5.1	38
For 200 port-fires,	18	9.1	10.1	70

See *Fireworks.*

PORT-FIRE CLIPPER.—The name formerly given to the cutting implement which was fixed on the off side of the beam trail of a gun carriage, for cutting off the lighted end of the port-fire. Port-fires being no longer in use, except on emergency, and having been superseded by friction tubes, the sockets and cutters have been removed from all artillery carriages.

PORT-FIRE CUTTER—An implement for cutting port-fires to place in shells or for other purposes. It is simply a strong pair of steel scissors, with an indentation one inch wide and four inches deep made in one of the blades for the purpose of holding the port-fire.

PORTGLAVE.—An ancient name for a sword-bearer.

POSITION OF THE SOLDIER.—When dismounted, the proper position of the soldier is as follows: Heels on the same line, and as near each other as the conformation of the man permits. The feet turned out equally, and forming with each other an angle of about sixty degrees. The knees straight, without stiffness. The body erect on the hips, inclining a little forward. The shoulders square, and falling equally. The arms hanging naturally. The elbows near the body. The palms of the hand turned slightly to the front, the little fingers behind the seams of the trousers. The head erect and square to the front. The chin slightly drawn in, without constraint. The eyes straight to the front, and striking the ground at about the distance of fifteen yards.

These points will be better understood by a reference to the following remarks: *Heels on the same line.* If one be in rear of the other, the shoulder on that side will be thrown back, and the position constrained. *Heels more or less closed.* Men who are knock-kneed, or who have legs with large calves, cannot, without constraint, make their heels touch while standing. *Feet turned out equally, and not forming too large an angle.* If one foot be turned out more than the other, the shoulders will be deranged, and if both feet be too much turned out, it will be impossible to incline the upper part of the body forward without making the whole position unsteady. *Knees straight, without stiffness.* If stiffened, constraint and fatigue will be unavoidable. *Body erect on the hips.* This gives equilibrium to the position. The Instructor will observe that many recruits have the bad habit of dropping a shoulder or advancing a hip, These defects he will labor to correct. *The upper part of body incling forward.* Recruits are commonly disposed to the reverse, to project the belly and throw back the shoulders, which causes great inconvenience in marching. The habit of inclining forward the upper part of the body is so important to contract, that the instructor must enforce it from the beginning, particularly with recruits who have naturally the opposite tendency. *Shoulders square.* If the shoulders be advanced beyond the line of the breast, and the back arched (the defect called round-shouldered), the man cannot align himself nor use his arms with address. Unless the coat fits easily about the shoulders and armpits, it will be difficult to correct this defect. The shoulders must not be thrown too far back, as this will make the belly project, and curve the small of the back. *Arms hanging naturally; elbows near the body; palms of the hands turned slightly to the front; little fingers behind the seams of the trousers.* These positions prevent the men from occupying unnecessary space in the ranks, and keep in the shoulders. *Head erect and square to the front; chin slightly drawn in without constraint.* If there be stiffness in these positions, it will be communicated to the upper part of the body, embarrass its movements, and give pain and fatigue. *Eyes straight to the front.* This is the surest way of maintaining the shoulders in a line—an essential object to be insisted upon and attained.

When mounted (horse unsaddled) the proper position of the soldier is as follows: The buttocks bearing equally upon the horse's back, and as far forward as possible. The thighs turned upon their flat side without effort, embracing the horse equally, and stretched only by their own weight and that of the legs. The knees bent without stiffness. The legs and feet free, and falling naturally, the feet, parallel to the horse. The body erect and unconstrained. The shoulders equally thrown back. The arms free, the elbows falling naturally. The head erect, square to the front, and without constraint. One rein in each hand, the rein coming into the closed hand on the side of the little finger, and passing out over the first finger, on which the thumb is pressed, the bight (end) of the reins falling to the front and between the right rein and the horse's neck; the hands as high as the elbows, and six inches apart; the fingers turned toward each other.

These points will be better understood by a reference to the following remarks: *Buttocks bearing equally upon the horse's back.* If they do not support equally the weight of the body, its steadiness will be impaired. *As far forward as possible.* That the thighs may readily clasp the horse. *Thighs turned upon their flat side, without effort, embracing the horse equally.* The more the thighs adhere to the horse, the greater is the stability of the rider; if they do not clasp the horse equally, the seat will be deranged. *Stretched only by their own weight, and that of the legs.* If they do not fall naturally, they can only be extended by an effort, which will cause constraint. *Knees bent without stiffness.* To give facility in carrying the legs more or less to the rear, without deranging the position of the thighs. *Legs and feet free, and falling naturally; feet parallel to the horse.* Stiffness in the legs will impair their action; if the feet be parallel to the horse, the thighs will be in proper position. *Body erect and unconstrained.* This gives ease, and enables it to conform with suppleness to the motions of the horse. *Shoulders equally thrown back.* If thrown forward, the back will be curved, and the breast contracted; if not thrown back equally, the position of the body will be distorted. *Arms free, and elbows falling naturally.* That they may contribute to the steadiness of the seat, and not stiffen the shoulders or forearms. *Head erect, square to the ront, and without constraint.* If not erect, the body will incline to one side; if there be stiffness, it will be communicated to the upper part of the body, and prevent the head from moving with freedom.

POSITIONS.—The skill of the Engineer is chiefly shown in adapting the resources of his art to the great variety of topographical features met with in the positions that an army is necessarily obliged to occupy when acting on the defensive. No less skill is called for on the part of the General in the selection of his defensive points, as no engineering skill can remedy, in other than a defective manner, a position which is strongly commanded by points which the assailed can occupy within good cannon range, or the flanks of which can be readily turned. To fortify similar positions demands a degree of effort in the inverse ratio of their strength, and for the most part is but labor in vain. Two principal questions present themselves in a strictly defensive war; the one *strategical*, the other *tactical*. The first is based upon the general features of the territory to be defended as affecting the operations of the assailing force, and the system of warfare the best adapted to the assailed; the second on the particular topographical features of the positions where resistance is to be made. The first attention will naturally be given to the system of defense for the frontier, whether one or more strong points shall be alone occupied from which the assailed can be observed; or whether a continued line of natural and artificial obstacles shall be presented to obstruct the movements of the invading force. Although opinion is against the latter method, the question is one that cannot be decided in an absolute manner. The numbers and quality of the army on the defensive; political as well as numerous military considerations; the character of the frontier in great detail; the facilities for the rapid concentration of the troops; and the security of the line of retreat have an important bearing upon it and at all times demand the most careful consideration. That a very extended line is necessarily a weak one is generally admitted; still a system of continued lines, in a country difficult to penetrate, may be used with advantage, and if weak when assailed by a strong force, may serve as an obstruction to a weak one, and be particularly serviceable againts raids. Such a line may be made to play the same part as the lines thrown up in siege operations to prevent the garrison besieged from obtaining succor or supplies by detachments trying to penetrate them. The tactical considerations are the same in the application of field fortifications a position as for the distribution of troops for its defense. Their principal value depends upon the character of the site itself. If it has the qualities of a good defensive field of battle, and lends itself to such a disposition of intrenchments as the troops themselves would naturally assume, then the essential tactical considerations can be secured. In all such cases both the plan and the command of the system employed must be subordinate to the site; to attempt more than this would require the time and means far beyond the command of an army in the field.

Positions derive their great importance from the influence of fire-arms in the decision of battles; for whatever enables one party to deliver its fire with effect against the other, whilst it, at the same time, remains sheltered in any degree from that of its adversary, places the advantage, all other things being equal, greatly on its side: and it is this advantage which should be principally kept in view in selecting a position. *Woods, commanding heights, precipices,* and *villages,* constitute the strong points of a position. They serve as points of support against which the wings of the army rest; or else, by covering parts of the front, they may serve as the key points in the defense. A wood, if properly intrenched, covers the infantry from the attacks of cavalry; conceals its maneuvers, and enables it to deliver its fire without being exposed to that of the enemy. Heights, by giving a commanding view of the surrounding ground, increase both the range and the effects of fire-arms; whilst they, at the same time, serve to screen the troops behind them until they are required to be brought into action. Precipieces offer similar advantages to heights, and are moreover unassailable. Villages serve as secure shelters for detachments, which, by their fire, cover the maneuvers of the troops in their rear; and, if properly intrenched, will cause the enemy great loss in his effort to force his way into them. *Rivers, marshes, hollows* and *ravines*, are the most unfavorable features of a position, because they may prevent a free circulation from one point to another, and thus impede the maneuvers; and they are exposed to the full fire of the enemy. They may, however, be of service when they are so placed as to support the wings, or, when the position being too extended for the number of troops, they render parts of the front unassailable. The best positions are those which, being in due proportion to the force by which they are occupied, command all the surrounding ground within cannon range, the ground descending in a gentle slope to the front, presenting woods, villages, etc., to support the wings and cover parts of the front, and admitting of a free circulation from one point to another, with secure communications in their rear in case of retreat. If with these advantages, they present marshes, or other obstacles, which will embarrass the enemy's movements, and force him to advance in column, exposed to the fire and free maneuvers of the assailed, they will unite everything desirable in a favorable field of battle.

POSITIVE FEED.—The earlier model Gatling guns had cartridges fed to them by means of feed cases, or by a drum, but recently a new method for supplying the cartridges to the gun has been devised, which is *positive and certain in its action*. In the old methods of supplying ammunition to the gun, it was possible for the cartridges to jam in feeding down from the feed cases into the carrier or receiver, but in this newly-improved feed, the mechanism never loses control of the cartridges from the time they leave the feed magazine, until they enter the chambers, are loaded, fired, and the empty cases extracted. With this new feed, it is impossible for the gun to fail in its operation, even when it is worked by men unacquainted with its use. This new improvement not only greatly increases the rapidity and certainty of fire, but enables the gun to be fired at the rate of over 1,200 shots per minute, and at all degrees of elevation or depression, which is something no other machine gun can do. By firing the gun at proper elevations, ascertained by means of a quadrant, the bullets discharged from it can be made to fall upon men behind breastworks, or entrenchments, at all distances, from 200 to 3500 yards from the gun. This "high angle," or "mortar" fire, adds greatly to the effectiveness of the gun, and will, no doubt, prove of inestimable value in future warfare. Experiments have proved that musket-size balls, fired from a Gatling gun at high angles, strike the ground with sufficient force to penetrate from two to three inches of timber. About 1,200 shots per minute can be fired from the gun, raining down a hailstorm of bullets on the heads of men behind entrenchments, thus making such positions, in a short space of time, untenable. Open breastworks, or uncovered entrenchments, would furnish little or no protection to troops against the fire of this formidable weapon.

POSSE COMITATUS.—A Sheriff or Marshal, for the purpose of keeping the peace and pursuing felons, may command all the people of his county, above 15 years old, to attend him, which is called the *Posse Comitatus*, or Power of the County.

It is not lawful to employ any part of the Army of the United States, as a Posse Comitatus, or otherwise, for the purpose of executing the laws, except in such cases and under such circumstances as such employment of said force may be expressly authorized by the Constitution or by some special Act of Congress; and no money appropriated is used to pay the expenses of any kind incurred in the employment of any troops in violation of this law; and any person willfully violating the same is deemed guilty of a misdemeanor, and on conviction thereof is punished by fine not exceeding ten thousand dollars or imprisonment not exceeding two years, or by both such fine and imprisonment. The provisions of the Constitution and of Acts of Congress understood as intended to be excepted from the operation of this law, authorizing the employment of the military forces for the purpose of executing the laws, are as follows:

1. The United States guarantees to every State in this Union a republican form of government, and protects each of them against invasion; and on application of the Legislature, or of the Executive (when the Legislature cannot be convened), against domestic violence.

2. It is lawful for the President of the United States, or such persons as he may empower for that purpose, to employ such part of the land or naval forces of the United States, or of the militia, as may be necessary to aid in the execution of judicial process issued under any of the provisions of the "Civil Rights" bill, or as shall be necessary to prevent the violation, and enforce the due execution of the same.

3. No military or naval officer, or other person engaged in the civil, military, or naval service of the United States, can order, bring, keep, or have under his authority or control, any troops or armed men at the place where any general or special election is held in any State, unless it may be necessary to repel the armed enemies of the United States, or to keep the peace at the polls.

4. The military forces of the United States may be employed at any time in such manner and under such regulations as the President may direct—First. In the apprehension of every person who may be in the Indian country in violation of the law; and in conveying him immediately from the Indian country, by the nearest convenient and safe route, to the civil authority of the Territory or judicial district in which such person shall be found, to be proceeded against in due course of law; Second. In the examination and seizure of stores, packages, and boats, authorized by law; Third. In preventing the introduction of persons and property into the Indian country contrary to law; which persons and property shall be proceeded against according to law; Fourth. And also in destroying and breaking up any distillery for manufacturing ardent spirits set up or continued within the Indian country. No person apprehended by military force under the preceding laws can be detained longer than five days after arrest and before removal. All officers and soldiers who may have any such person in custody shall treat him with all the humanity which the circumstances will permit. The superintendents, agents, and subagents, endeavor to procure the arrest and trial of all Indians accused of committing any crime, offense, or misdemeaner, and of all other persons who may have committed crimes or offenses within any State or Territory, and have fled into the Indian country, either by demanding the same of the chiefs of the proper tribe, or by such other means as the President may authorize. The President may direct the military force of the United States to be employed in the apprehension of such Indians, and also in preventing or terminating hostilities between any of the Indian tribes.

5. The President is authorized to employ so much of the land and naval forces of the United States as may be necessary effectually to prevent the felling, cutting down, or other destruction of the timber of the United States in Florida, and to prevent the transportation or carrying away any such timber as may be already felled or cut down; and to take such other and further measures as may be deemed advisable for the preservation of the timber of the United States in Florida.

6. The quarantines and other restraints established by the health laws of any State, respecting any vessels

arriving in, or bound to, any port or district thereof, are duly observed by the officers of the customs revenue of the United States, by the masters and crews of the several revenue-cutters, and by the military officers commanding in any fort or station upon the sea-coast; and all such officers of the United States faithfully aid in the execution of such quarantines and health-laws, according to their respective powers and within their respective precincts, and as they shall be directed from time to time, by the Secretary of the Treasury.

7. Whenever any person is delivered by any foreign government to an agent of the United States, for the purpose of being brought within the United States and tried for any crime for which he is duly accused, the President has power to take all necessary measures for the transportation and safe-keeping of such accused person, and for his security against lawless violence, until the final conclusion of his trial for the crimes or offenses specified in the warrant of extradition, and until his final discharge from custody or imprisonment for or on account of such crimes or offenses, and for a reasonable time thereafter, and may employ such portion of the land or naval forces of the United States, or of the militia thereof, as may be necessary for the safe-keeping and protection of the accused.

8. Every person who, within the territory or jurisdiction of the United States, begins, or sets on foot, or provides or prepares the means for, any military expedition or enterprise, to be carried on from thence against the territory or dominions of any foreign prince or state, or of any colony, district, or people, with whom the United States are at peace, is deemed guilty of a high misdemeanor, and is fined not exceeding three thousand dollars, and imprisoned not more than three years.

9. In every case in which a vessel is fitted out and armed, or attempted to be fitted out and armed, or in which the force of any vessel of war, cruiser, or other armed vessel is increased or augmented, or in which any military expedition or enterprise is begun or set on foot, contrary to the provisions and prohibitions of the Neutrality Acts, and in every case of the capture of a vessel within the jurisdiction or protection of the United States as before defined; and in every case in which any process issuing out of any court of the United States is disobeyed or resisted by any person having the custody of any vessel of war, cruiser, or other armed vessel of any foreign prince or state, or of any colony, district, or people, or of any subjects or citizens of any foreign prince or state, or of any colony, district, or people, it is lawful for the President, or such other person as he shall have empowered for that purpose, to employ such part of the land or naval forces of the United States, or of the militia thereof, for the purpose of taking possession of and detaining any such vessel, with her prizes, if any; and also for the purpose of preventing the carrying on of any such expedition or enterprise from the territories or jurisdiction of the United States against the territories or dominions of any foreign prince or state, or of any colony, district, or people with whom the United States are at peace.

10. It shall be lawful for the President, or such person as he shall empower for that purpose, to employ such part of the land or naval forces of the United States, or of the militia thereof, as shall be necessary to compel any foreign vessel to depart the United States in all cases in which, by the laws of nations or the treaties of the United States, she ought not to remain within the United States.

11. In case of an insurrection in any State, against the government thereof, it is lawful for the President, on application of the Legislature of such State, or of the Executive, when the Legislature cannot be convened, to call forth such number of the militia of any other State or States, which may be applied for, as he deems sufficient to suppress such insurrection; or, on like application, to employ, for the same purposes, such part of the land or naval forces of the United States as he deems necessary.

12. Whenever, by reason of unlawful obstructions, combinations, or assemblages of persons, or rebellion against the authority of the Government of the United States, it becomes impracticable, in the judgment of the President, to enforce, by the ordinary course of judicial proceedings, the laws of the United States within any State or Territory, it is lawful for the President to call forth the militia of any or all the States, and to employ such parts of the land and naval forces of the United States as he may deem necessary to enforce the faithful execution of the laws of the United States, or to suppress such rebellion, in whatever State or Territory thereof the laws of the United States may be forcibly opposed, or the execution thereof forcibly obstructed.

13. Whenever insurrection, domestic violence, unlawful combinations, or conspiracies in any State so obstructs or hinders the execution of the law there of, and of the United States, as to deprive any portion or class of the people of such State of any of the rights, privileges, or immunities, or protection, named in the Constitution and secured by the laws for the protection of such rights, privileges, or immunities, and the constituted authorities of such State are unable to protect, or, from any cause fail or refuse protection of the people in such rights, such facts, are deemed a denial by such State of the equal protection of the laws to which they are entitled under the Constitution of the United States; and in all such cases, or whenever any such insurrection, violence, unlawful combination, or conspiracy, opposes or obstructs the laws of the United States, or the due execution thereof, or impedes or obstructs the due course of justice under the same, it is lawful for the President, and it is his duty, to take such measures, by the employment of the militia or the land and naval forces of the United States, or of either, or by other means, as he may deem necessary, for the suppression of such insurrection, domestic violence, or combinations.

14. It is unlawful to take any vessel or cargo detained under section 9 from the custody of the proper officers of the customs, unless by process of some court of the United States; and in case of any attempt otherwise to take such vessel or cargo by any force, or combination, or assemblage of persons, too great to be overcome by the officers of the customs, the President, or such person as he shall have empowered for that purpose, may employ such part of the Army or Navy or militia of the United States, or such force of citizen volunteers as may be necessary, to prevent the removal of such vessel or cargo, and to protect the officers of the customs in retaining the custody thereof.

15. The President is authorized, at his discretion, to employ the land and naval forces of the United States to protect the rights of the discoverer [of a guano island] or of his widow, heir, executor, administrator, or assigns.

Officers of the Army can not permit the use of the troops under their command to aid the civil authorities as a *Posse Comitatus* or in execution of the laws except as authorized in the foregoing enactments. If time will admit, the application for the use of troops for these purposes must be forwarded, with a statement of all the material facts, for the consideration and action of the President; but, in cases of sudden and unexpected invasion, insurrection, or riot, endangering the public property of the United States, or in cases of attempted or threatened robbery or interruption of the United States mails, or other equal emergency, officers of the Army may, if they think a necessity exists, take such action before the receipt of instructions from the seat of Government as the circumstances and the law under which they are acting may justify; and will then promptly report their action and the reasons therefor to the Adjutant-General for the information of the President. See *Civil Authority*, and *Execution of Laws*.

POST.—1. A soldier's beat while on sentry, or a position assigned to or taken up by a soldier or body of men; it generally consists of an entrenched village or position, or any building placed in a state of defense. The necessity of strengthening a post is admitted to be of paramount importance, and every endeavor should be made by an officer in command to place himself in such a defensive position as shall prevent his being taken unawares, or, if attacked, enable him to make a good fight. Often neither time, material, intrenching tools, nor men, will permit of solid works, such as a redoubt or other elaborate field-works, being thrown up, but it is possible, when villages or detached houses are occupied by troops, to throw up temporary cover which shall greatly strengthen the position. The following are principles to be borne in mind in forming a post, or in strengthening a position: 1—To obtain cover for the men and animals from the enemy's fire. 2—To enable the troops to fire, in the most advantageous manner, on the ground over which the enemy must advance. 3—To hinder the approach of the enemy by obstacles, which, even if surmountable, shall be sufficient to break his order and detain him for some time under fire. 4—To enable the troops to pass freely from one part of the works to another, in order to concentrate on any point attacked. 5—To impede the flank movements of the enemy as much as possible, and thus prevent his different parties from supporting each other effectually.

2.—*Post*, in a military sense, frequently means to station; as, to *post* a sentinel or relief. *To be posted* signifies to be formed ready for action. Thus, when troops are brought up in column, and ordered to deploy, it frequently happens that some part of the line is refused, in order to flank an enemy, or to cover a weak position; the part that is aligned is said to be *posted*. The phrase also means, in a familiar sense, to be publicly announced as an infamous or degraded character.

3.—In the British service, the term *Post* is given to the bugling which precedes the tattoo. This is the *First Post*, the *Last Post* that which follows it. See *Advanced Post*, *Garrison*, *Military Post*, *Outpost*, and *Station*.

POST BAKER.—The person who bakes bread for a garrison. In the United States service the Post Baker is an enlisted man, who receives additional pay for his labor.

POST CEMETERIES.—The Commanding Officers of all posts, situated on all public lands of the United States, see that a suitable portion of such land is set apart and properly maintained for the burial of deceased officers, and soldiers, and their families, and of Government employés. The burial ground is suitably and securely inclosed with the best material available—a stone or adobe brick wall, or a neat wooden picket fence—and maintained by the labor of the garrison. At each grave is placed a head-board, plainly marked with a number, and with the name, company, regiment, and date of death of the occupant, the number on the head-board to correspond with the number on the record of burials. The head-boards are about four feet long, ten inches wide, and one and three-eighths inch thick; and stand two feet out of the ground; of well-seasoned wood, and painted with three coats of white paint; inscription in black letters one inch long. The walks are about four feet wide, neatly rounded up, properly drained, and graveled when the material is at hand. Where practicable, a good grass sod covers all the rest of the ground, including the graves; and native trees and shrubs are preserved or planted for ornament and shade. A record of interments is kept at each post by the Acting Assistant Quartermaster in the form on page 569; and when he is relieved, is turned over by him to his successors; and if the post be broken up, is transmitted to the Quartermaster General.

A list of the names of those buried (including a transcript of the items embraced in columns 1, 2, 7, 8, 9, 10, 11, 22, and 25) is forwarded to the Quartermaster General at the end of each year.

A public Cemetery is established near Salt Lake City, Utah, under the provisions of an Act approved May 16, 1874. This Cemetery is under control of a Board of which the Commanding Officer, Camp Douglas, Utah, is *ex-officio* a member. See *Battle-grounds Cemeteries*, *National Cemeteries*, and *Superintendent of National Cemeteries*.

POSTERN.—Posterns are arched, bomb-proof passage-ways constructed under the terre-pleins and ramparts, forming subterranean communications between the parade and the enceinte ditch, or between the ditches and the interior of the outworks. The width and height of the interior of posterns depend upon the use to which the communication is to be applied. For artillery the width is usually taken at 10 feet, and the height under the crown or key of the arch at least 8 feet. Posterns for infantry may be only from 4 to 6 feet wide, and from 6 feet 6 inches to 8 feet high under the crown of the arch. The thickness of the piers of the arches is generally taken at about half the width of the postern. The arches are from 18 inches to two feet thick, and are covered with a thickness of earth sufficient to protect them from any injury from shells bursting over them. A strong wooden door is placed at each outlet of the postern to secure it against surprise. The doorway in posterns for the service of artillery should be of just sufficient height for the convenient passage of a gun.

The most important postern is the one leading from the parade to the main ditch. This generally receives a width of 12 feet and the same height under the crown. For greater security from surprise, its outlet is at least 6 feet above the bottom of the ditch, this difference of level being overcome by means of a temporary wooden ramp which receives an inclination of at least $\frac{1}{6}$. Besides two strong doors at the two ends of the postern, there is a partition of masonry about midway between the two ends, which is pierced with a doorway of the same size as the doorways of the ends, and closed by a strong door which, as well as the partition wall, is loop-holed for musketry.

In cases where the postern forms the main entrance to the work, an arched chamber is placed on one side of it, at the outlet, which serves as a guard-room for a few men, to secure the outlet from surprise. The wall between this chamber and the postern is loop-holed, so that a fire can be brought to bear on the doorway of the postern; and as a further precaution against surprise a machicoulis defense is sometimes arranged at the top of the scarp wall just above the doorway of the postern. See *Communications*.

POST FLAG.—In the United States Army, the Post Flag is the National Flag, It is twenty feet fly and ten feet hoist, is furnished to all posts garrisoned by troops, and is hoisted only in pleasant weather. See *Flags*.

POST FUND.—In the United States Army, a fund constituted by the troops baking their own bread and thereby saving $33\frac{1}{3}$ per cent., the difference between bread and flour. The Post Trader also pays an assessment of 10 cents, or less, a month for every officer and soldier in the garrison, which is carried to the credit of the *Post Fund*. The following (exclusive of sums transferred to the regimental fund) are the objects to which the Post Fund may be appropriated, and Councils will give them precedence in the order named: 1. Expenses of bake-house. 2. Garden seeds and utensils (for all troops serving at the post). 3. Post schools. 4. Post library and reading-room. 5. Gymnasium. When the necessary material and labor are in the Post Quartermaster's Department, and can be spared from more im-

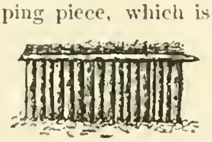
portant work, the necessary apparatus for the gymnasium, and for such games and exercises as the Council may consider desirable for the health and amusement of the soldiers at the post may be constructed by the Quartermaster's Department. 6. Chapel. 7. For fruit and shade trees. 8. For fruit-bearing vines and bushes. 9. For printing press. The Quartermaster General, under direction of the Secretary of War, procures and forwards to the post librarian such periodicals and newspapers as his appropriation for incidental expenses can afford to pay for, or school books in lieu of periodicals, when the Post Fund is not sufficient to supply them and the post does not desire periodicals. The periodicals, newspapers and school books are intended for the use of the enlisted men, and must not be taken from the library or school-room. If used at all by officers it must be at a time when other duties prevent their use by enlisted men. The necessary school books for soldiers and for soldiers' children are purchased from the Post Fund, except in cases provided for in the foregoing paragraph. See *Company Fund* and *Regimental Fund*.

POST GARDENS.—Commanding Officers of posts, at or near which suitable public lands are available, set aside for Company or Post Gardens such extent of those lands as may be necessary for the production of vegetables for the command, and cause the same to be duly cultivated by the garrison, and such varieties and quantities of vegetables to be raised as may be necessary for the subsistence or health of the troops. On approved requisitions, the Subsistence Department procures for sale to companies or posts, seed potatoes, garden seeds, and agricultural implements necessary for establishing, cultivating, and perpetuating company or post gardens. Payment to the Subsistence Department for these articles, at cost price, is made from the company or post fund. The Commissary General of Subsistence gives to the officers of his Department the necessary instructions for the purchase and distribution of seeds and agricultural implements. If in changes of station a company or garrison is succeeded by another, the latter succeeds to the garden of the former, reimbursing the fund of the former for its actual expenditures for seeds, agricultural implements, etc. Commanders of Divisions and Department give such detailed instructions as may be necessary for carrying these regulations into effect, and for the proper distribution of products of gardens among those entitled to them. Surplus products may be sold, and the proceeds credited to the post fund, or divided among the company funds of the garrison, whichever may have borne the expense of the cultivation.

POST OF HONOR.—The guard in the advance. The right of the two lines is also the post of honor, and is generally given to the eldest corps; the left is the next post, and is given to the next eldest, and so on. The laws of military discipline forbid an inconvenient accordance with this practice, as the circumstances of the case may require a very different arrangement, which it would be wanton to oppose.

POST REVETMENT.—A revetment constructed of posts from 4 to 6 inches in diameter, cut into lengths of 5.5 feet, and set with proper slope, in close contact, in a trench two feet in depth, at the foot of the breast-height. The tops of the posts, if not already so, are sawed off level, to receive a horizontal capping piece, which is spiked on. Anchor ties are dove-tailed into the cap and secured to an anchor log imbedded in the parapet. On top of the cap are laid several courses of sods, raising the interior crest to the proper height. With a good quality of timber this revetment is durable. It is easily constructed, and next to sods, is the best. See *Revetment*.



POST SCHOOLS.—Schools are established at all the posts, garrisons, and the permanent camps at which troops are stationed, in which the enlisted men may be instructed in the common English branches of education and especially in the history of the United States; and the Secretary of War details such officers and enlisted men as may be necessary to carry out this provision. It is the duty of the Post or Garrison Commander to set apart a suitable room or building for school and religious purposes. The teachers and schools are under the control of the Post Commander, or such officer as the Post Commander may designate. School teachers are detailed from the enlisted men of the Army. The number of teachers detailed cannot exceed one for each company serving at the post. At any post at which there are no soldiers suitable for detail as school-teachers, application is made to the Adjutant General of the Army by the Post Commander for the necessary number of teachers. A soldier while serving as school teacher receives extra-duty pay as overseer (35 cents per day) from the Quartermaster's Department, not deducting for Saturdays and Sundays. Soldiers while detailed as school teachers will attend such parades, inspections, and drills as, in the judgment of the Post Commander, are necessary to keep them well instructed in their company duties. While it is left optional with soldiers whether to attend school or not, yet they are advised to avail themselves of the means afforded to improve themselves, and Commanding Officers not only give them all possible opportunities, but advise and encourage them to use them. The children of soldiers are required to attend the post school for children, unless specially excused by the officer in charge of schools. The children of citizens living near a post are allowed to attend the post school for children. For the instruction given them they are required, if able, to pay a small rate into the post fund. Officers and citizens furnish the school books necessary for their own children. The Post Council of Administration decide whether it is advisable or practicable to have separate schools for adults and children. An officer is detailed by the Secretary of War to visit and inspect regularly the various post schools. It is made his duty to examine into the system of instruction; to advise Commanders of Posts of defects which he may discover, and to suggest methods of improvement; to endeavor to bring about uniformity in the methods of management and instruction, and to make known throughout the Army the best methods and systems in existence at any Military Post. He reports the results of his inspection fully to the War Department from time to time. His inspections do not dispense with or interfere with those of the Inspector Generals of the Army, but are specially and directly addressed to the schools alone.

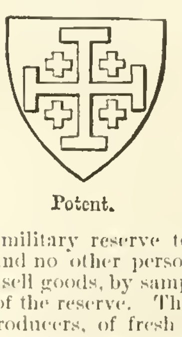
POST TRADER.—In the United States, every military post may have one Trader, who is appointed by the Secretary of War, on the recommendation of the Council of Administration, approved by the Commanding Officer. Post Traders are furnished with a letter of appointment from the Secretary of War indicating the posts to which they are appointed. They are subject, in all respects, to the rules and regulations for the government of the Army. They actually carry on the business themselves, and habitually reside at the station to which they are appointed. They can not farm out, sublet, transfer, sell or assign the business to others. They are permitted to erect buildings for the purpose of carrying on their business upon such part of the military reservation or post where they are assigned as the Commanding Officer may direct. Such buildings are in convenient reach of the garrison. [*Circ. A. G. O., Aug.* 28, 1879.] When a Trader is removed from his post, he has a right to remove and dispose of the materials of the buildings erected by him as his own property. He cannot lease or sell his buildings to another Post Trader without permission of the military authorities; but such permission would have the same force as a license to a new Post Trader to erect such a building at that spot. Post Traders have the exclusive right of trade upon the military reserve to which they are appointed; and no other person is allowed to trade, peddle, or sell goods, by sample or otherwise, within the limits of the reserve. This does not prohibit the sale, by producers, of fresh fruit or vegetables by permission of the Post Commander. Post Traders in the Indian country have no right to maintain a traffic in goods with the Indians, unless they be properly licensed for such trade. For the exclusive privilege allowed them, Post Traders are assessed and held to pay for the benefit of the post fund, at a rate to be determined by the Post Council of Administration, not exceeding ten cents per month, for every officer and enlisted man serving at the post—the monthly average to be determined equitably by the Council. The Council of Administration once in six months, and not oftener, examines the Post Trader's goods and invoices or bills of sale, and, subject to the approval of the Post Commander, establishes the rates and prices (which should be fair and reasonable) at which the goods shall be sold. A copy of the list thus established is kept posted in the Trader's store. Should the Post Trader feel himself aggrieved by the action of the Council of Administration, he may appeal therefrom, through the Post Commander, to the War Department. In determining the rate of profit to be allowed, the Council considers not only the prime cost, freight, and other charges, but also the fact that the Trader has no lien on the soldier's pay, and is without security in this respect. Post Commanders report to the War Department any misconduct, breach of military regulations, or failure on the part of Post Traders to comply with the requirements of regulations.

When any cause of complaint against a Trader arises, the Post Commander places the same before the Council of Administration, and the Council examines the evidence for and against the Trader, and makes a report of the facts, through the Post Commander, to the Adjutant General of the Army, for the action of the Secretary of War, in whom alone is the power vested to remove a Post Trader. When a new Trader is selected, and his appointment is issued, the appointment of the former Trader will be revoked; but, in order that injustice may not be done the former Trader in the total loss of his investment in buildings and goods, the new appointee will be required to purchase a portion or all of the same at a fair valuation—the articles to be so purchased and the appraisement of their value to be determined by the Council of Administration. The former Trader is not debarred from withdrawing his goods if he so elect, nor from entering upon the reservation to attend to the settlement of his business until the same has been closed; such privilege, however, does not entitle him to continue to trade at the post. See *Canteen* and *Sutler*.

POT.—The paper cylinder forming the head of a signal-rocket and containing the decorations. To diminish the resistance of the air the pot is surmounted by a paper cone.

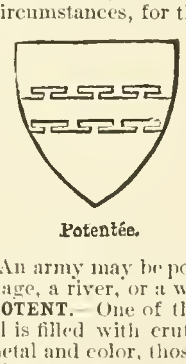
POT-DE-FER.—A heavy helm worn in siege operations. It is related that Louis XIV., like the other soldiers, went into the trenches in full armor, and wearing the *pot-de-fer*. See *Pot Helmet*.

POTENCE.—Troops are ranged *en potence* by breaking a straight line, and throwing a certain proportion of it either forward or backward, from the right or left, according to the circumstances, for the purpose of securing that line. An army may be posted *en potence* by means of a village, a river, or a wood.



Potent.

Potent Counter-Potent.



Potentée.

POTENT COUNTER POTENT.—One of the heraldic furs, in which the field is filled with crutch-shaped figures alternately of metal and color, those of opposite tinctures being placed base against base, and point against point. The metal and color are understood to be argent and azure, unless they be specially blazoned otherwise. Potent counter-potent is sometimes blazoned vairy-cuppy.

POTENT CROSS.—In Heraldry, a cross crutch-shaped at each extremity.—It is also called a Jerusalem cross, from its occurrence in the insignia of the Christian kingdom of Jerusalem, which are, argent a cross potent between four crosslets or. This coat is remarkable as being a departure from the usual heraldic rule which prohibits the placing of metal upon metal.

ed tunic and *chausses*, was frequently worn by the Knights of this period beneath the surcoat, which was, as a general thing, considerably lengthened, and very richly emblazoned with the arms of the wearer.

POWDER.—A common term for gunpowder. Under this name is found a variety of powders in use at the present day for small-arms and guns.

Countries	Gunpowder. Saltpeter.	Charcoal.	Sulphur.	Small-arm Powder. Saltpeter.	Charcoal.	Sulphur.
America	75	12·50	12·50	75·50	13·20	11·30
Austria	70	17	16	75·50	13·20	11·30
England	76	15	10	76·50	14·50	9
	76	14·50	9·50	76	13·50	9
France	75	14·50	9·50	75	12·50	12·50
Germany	75	13·50	11·50	75	12·50	12·50
Italy	76	12	12	75·50	13·20	11·30
Russia	71	17·50	11·50	80	11·30	8·70
Spain	76·50	12·70	10·80	75·50	13·20	11·30

POTENTEE.—A heraldic line of division which takes the form of the outline of a succession of crutch-shaped figures.

POT-GUN.—A mortar for firing salutes. The name is derived from its shape being formed like a pot. It is now obsolete.

POT-HELMET.—A sort of skull-cap of thick iron, and very heavy. It was used, particularly in sieges in the 16th and 17th centuries. The word *pot-helmet* is also very commonly used for iron hats much lighter in weight, that were much worn by Cromwell's foot-soldiers.

POT-METAL.—An alloy of lead and copper, obtained by throwing lumps of copper into red-hot melted lead. It is of a gray color, brittle and granular.

POUCH.—A stout leather box, black or brown, lined with tin, covered with a strong flap, and ornamented with the device of the regiment. It serves to carry the cartridges required by a soldier for immediate use. When cartridges are supplied for a whole day's service, two pouches are worn, one on the front point of the hip, and a larger one on a belt suspended over the left shoulder. The leather cases containing primers, lanyard, etc., in field and heavy artillery, and those containing a gunner's level, vent-punch, gimlet, etc., in heavy artillery, are also called pouches.

POULEYNS.—In ancient armor, a variety of knee-guards, which were very elaborately and variously enriched.

POUNDER.—The name by which different natures of ordnance and shot and shell are distinguished. By being so denominated, the weight of the projectile which the gun throws is implied. Projectiles fired from heavy howitzers and mortars are distinguished by the diameter of the pieces, such as those propelled from the 10-inch and 8-inch howitzer and mortar; and it would be advisable to denominate all projectiles by the diameter of the piece, and also by the weight of the projectile itself. This is done in the case of shot and shell used with the heavy M.L. R. guns of 7-inch caliber and upwards, but below this caliber they are known only by the weight of the shot. The weight of heavy rifled ordnance is always expressed in tons, if of 5 tons or upwards; otherwise in cwts.

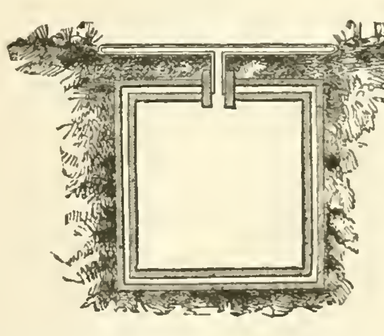
POURPOINT.—A military habit worn in the thirteenth century, but which was subsequently modified, and from the peculiar work with which it was then ornamented, obtained the name of *Pourpoint* or *Counterpoint*. A complete suit, consisting of a sleev-

The following table gives the proportions of the composition most generally used in the manufacture of gunpowder in the countries mentioned. See *Gunpowder*.

POWDER-BARREL.—Barrels in which gunpowder is stored. There are three sizes, called *whole*, *half*, and *quarter*, holding respectively 100 lbs., 50 lbs., 25 lbs., of ordinary powder. The whole barrel is capable also of containing 125 lbs. of pebble powder. There is also a barrel in the service termed a *bouge* barrel, which is the size of a quarter barrel, and intended to be used, not for storage, but for holding loose powder for mortars or cartridges in a standing battery. This barrel is distinguished from the ordinary powder barrel, in having a leather bag attached to it, which takes the place of one head of the barrel, and is closed by a leather thong. The word *bouge* or *budge* is a corruption of the French word *bouget*, a leather bag.

Powder barrels are composed of heads and staves bound round with copper and ash hoops, and are made by hand or by machinery. The wood used in English barrels is usually American oak, whereas the Indian powder barrels are made of teak, if anything a stronger and closer-grained wood than the oak alluded to, so that it is not found necessary to bind them round with ash hoops, as in the English barrels.

POWDER BOXES.—Contrivances analogous to fougasses, used by the Russians at Sebastopol. Each consisted of a double deal box, of a capacity suffi-



cient to contain 35 pounds of powder, water-tight, and effectually secure it from the penetration of damp, into the top of each box was inserted a vertical tin tube, connected with a horizontal tin tube at the surface of the ground. Within the latter was a glass tube, filled with sulphuric acid, and coated with a composition of chlorate of potassa, sugar, sulphur, and gum-water, which immediately takes fire on coming in contact with the acid. The space between the interior of the tin tube, and the exterior of the glass tube, as well as the vertical tin tube, is filled with gunpowder. A little earth spread lightly over the whole completes the arrangement. A person walking over the ground, and treading on the tin tube, crushes it and the glass tube contained in it, causing the escape of the sulphuric acid, and the explosion of the gunpowder. See *Fougasses*.

POWDER CART.—A two-wheeled carriage covered with an angular roof of boards. To prevent the powder from getting damp, a tarred canvas is put over the roof; and on each side are lockers to hold shot, in proportion to the quantity of powder.

POWDER DEPOTS.—Large depots for the storage of powder, and the materials for its manufacture. In selecting sites for these depots, the following considerations should be observed: 1st. That the depot should be in a region of country which does not admit of being populated, so that destruction of life and property in case of accident would be a minimum. 2d. The tract should be sufficient in extent to contain suitable positions for magazines for storage of 10,000 tons of powder, material for its manufacture, etc.,and the necessary buildings for a government powder-mill. 3d. It should be near enough to rail and water transportation to afford facilities of transportation to the seaboard, interior, and the lakes, having a short line of government railroad connecting the site with rivers and trunk-lines. When the present arsenals in the United States were established, their locations were but sparsely settled. The rapid increase of population in the adjacent towns and cities has, however, in the majority of cases, rendered these magazines dangerous to the communities in which they are located and hence the Government either has abandoned, or eventually will have to essentially abandon, the storage of powder at all of our arsenals. The damp sea-air renders our fortifications unfitted for this purpose, and the Government has now large quantities of powder rapidly deteriorating at these places for want of proper storage-facilities. See *Lightning Conductors*, *Magazine*, and *Preservation, Storage, and Transportation of Powder*.

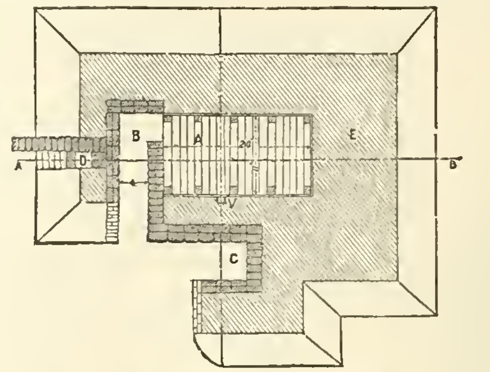
POWDER DUST.—All gunpowder, in the process of reeling, gives off a certain amount of dust. It is a great object to remove the dust from the powder, as it quickly absorbs moisture from the atmosphere, and, consequently, impairs its preserving qualities. This dust is not lost to the factory, but is worked over again, receiving first the process of incorporation for a short time, and then going through the rest of the mills until it becomes perfect gunpowder. The operation of dusting is effected by cylindrical reels covered with canvas, which revolve at a given rate. See *Dusting Reels*.

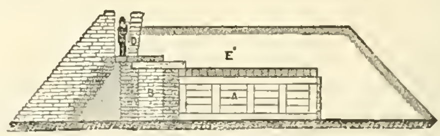
POWDERED.—In Heraldry, *Powdered*, or *Semée*, signify strewn with an indefinite number of small charges.

POWDER-FLASK.—A pouch or metallic case for holding gunpowder, and having a charging nozzle at the end. A horn is often fitted to hold powder and used as a flask.

POWDER-HOSE.—A tube of strong linen, about an inch in diameter, filled with powder, and used in firing military mines.

POWDER MAGAZINE.—The main objects to be obtained in constructing a powder magazine are, to place it in a position convenient to the pieces to be served, and one least exposed to the fire of the enemy; to make it shot-proof; and to secure the contents from moisture. It is usually placed 30 feet in rear of the parapet of the battery. The ceiling of the magazine should not be more than a few inches above the natural level. The interior height need not be more than 5 feet. The width may be 6 feet, and the length 12 feet in the clear. The sides of the magazine may be formed of frames and sheeting boards; or, of a row of gabions crowned with two courses of fascines. The magazine is covered at top by splinter-proof of timbers, 6 by 9 inches, laid in





juxtaposition and covered with at least 3 feet of earth, both on top and on the sides towards the parapet. A passage leads into the magazine on the side from the parapet, which is reached by one or two inclined trenches.

The drawing shows the plan and section of a powder magazine employed at the siege of Fort Wagner A, the Magazine; B, the covered entrance; C, the telegraph office; D, the lookout on top; E, an embankment of sand covering the magazine. The plan is taken just below the ceiling. In the section, A′, is the interior of the magazine; B′, the entrance; D′, the lookout; E′, the covering of sand. The rules given for the construction and location of bomb-proof shelters for men, apply equally to shelters of this class. The only difference in construction is in the size of the shelters, it being much smaller, as a rule, than that required for the use of troops. Large magazines are not constructed in ordinary field works. They take up too much room, and even the best of them are but poor places in which to store ammunition for any length of time. The usual method adopted is to construct as many service magazines as may be necessary, near the guns to be served by them, making them large enough to contain the amount required for a definite service of the gun or guns to which they belong.

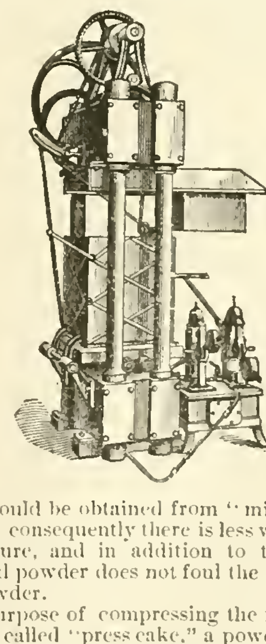
In Permanent Fortification, powder magazines are built with strong, full center bomb-proof brick arches, supported on heavy stone piers which form the outward walls, and to which interior buttresses are sometimes added. The capping of the arches is covered with from 4 to 10 feet of solidly packed earth. The interior of the magazine, the floors, and the doors and windows, are built with a view to security from fire; and to preserve the powder from dampness, by a good system of drainage around the foundations, and of ventilation by means of air-holes made through the piers, and panels of copper pierced with small holes placed in the doors. No iron or steel fastening or sheeting is allowed in any part of the structure; and in arranging the air-holes through the piers they receive a broken direction, and have a copper mesh-work placed across them, to prevent any combustible material or rats, or mice, penetrating to the interior of the magazine. In large works the magazines are isolated, as far as practicable, from the enceinte, so as not to endanger it should an accidental explosion take place. The magazine is inclosed by a strong, high wall for security, and is provided with lightning rods. In small works some one or more of the casemates in the position least exposed to the assailant's fire are built for the purposes of a magazine.

The following memoranda respecting the ventilation of powder magazines is herewith appended: 1. The dampness complained of in buildings will frequently be found to arise from condensation of the watery vapor of the air which enters the building. Buildings with thick walls and vaulted roofs, and especially those covered with earth, are particularly liable to dampness from this cause. 2. Air always contains some proportion of watery vapor. When the proportion is small, the air is said to be dry, and when large, the air is said to be damp; when the proportion is the greatest that can be diffused through air at a given temperature, the air is said to be saturated at that temperature. 3. The proportion of watery vapor which saturated air contains varies with the temperature, being greater for high than for low temperatures. Air containing a particular proportion of moisture is rendered less capable of depositing moisture by its temperature being raised, and the reverse when it is lowered. 4. Air may be brought to a state of saturation by reducing its temperature. If the air contain but little moisture, the reduction of temperature must be considerable; but if it contain much, a slight reduction will bring it to a state of saturation. 5. If air be cooled below the degree of temperature at which it will be in a state of saturation, a portion of the watery vapor contained therein will be deposited on any cold substance with which it may come in contact. The degree of temperature at which air will thus begin to deposit moisture is called its *dew-point*. 6. When warm air enters a comparatively cold building, the temperature of the air is reduced by coming in contact with the interior walls and other cold surfaces; and if its temperature be thus reduced below the *dew-point*, condensation will take place. In the latter case it is obvious that the admission of fresh air will not tend to dry a building, but to render it damp. 7. If a magazine 40 feet by 24 feet by 12 feet, the temperature of whose internal walls, etc., is 45°, were to be filled with saturated air having a temperature of 50°, and the magazine were then closed, nearly a pint of moisture would be deposited during the cooling of the fresh air to the temperature of the walls. The pint of moisture would result from the quantity of air sufficient merely to fill the magazine; but if the ventilators were opened, the air might be renewed many times in the course of a day, and very much more than a pint of moisture be deposited. 8. Air entering a building whose temperature is higher than its own becomes capable of absorbing moisture from damp surfaces. 9. The efficiency of the ventilation of a magazine will depend upon the degree of dryness which the fresh air admitted into it possesses, and the rapidity of the current of dry air passing through the building. 10. The dryness of air is indicated by the number of degrees by which its temperature exceeds its dew-point. 11. The ventilators of magazines should, in all cases, be constructed so as to exclude or admit the external air at discretion, *and the instructions for their use should be framed with a view to the exclusion of the external air when the temperature of its dew-point is above that of the interior of the building, and the admission of the air when its dew-point is below the temperature of the interior of the building.* 12. The interior of a bombproof magazine with thick walls and a vaulted roof is commonly colder than the outside air in summer and warmer in winter. Winter is therefore the more favorable season for ventilation; but in the climate of England the exceptions to this rule are numerous, owing to the prevalence during winter of warm, damp winds from the south and west, and during summer of cold, dry winds from the north and east. 13. Whenever, notwithstanding a careful attention to ventilation, magazines are found to be damp, their condition may be improved by the use of quick-lime, which has the property of absorbing from the air about one third of its own weight of water. 14. The proper time for using lime is when the condition of the magazine would not be improved by ventilation, and when, consequently, the ventilators are closed. Lime would be of very little service while a rapid current of air was passing through the building. 15. Lime will be used during the seasons of the year least favorable for ventilation in all magazines that show signs of dampness. 16. The lime should be fresh from the kiln, broken into lumps not larger than about the size of a pigeon's egg, and exposed to the air of the interior of the magazine in shallow vessels. It should be kept in air-tight casks until spread out for use.

POWDER MILL.— Works in which the materials for gunpowder are prepared and compounded, and the powder grained and faced. See *Gunpowder*.

POWDER MINE.—A cave or hollow in which powder is placed to be fired at any particular time. These were first used in 1503, at Naples, when it was besieged by the Spanish General Gonzalvo, of Cordova.

POWDER PRESS.—The last operation of breaking down the mill cake, and the one now about to be described, of pressing the meal into a solid cake, is merely for the purpose of fitting it to be made into a hard grain of equal density. In the pressing process, the powder that has passed through the breaking-down machine is brought from the small magazines to the press-house, where it is compressed into hard cake. Many advantages are gained by this operation, first, the cake when made into grain of the required size absorbs less moisture from the atmosphere than if it had been soft and not pressed, and the lasting qualities of the powder are much increased, especially if glazed; again, by having been compressed the powder is less liable to be reduced to dust in transport, for if properly made it may safely be kept for a number of years, even on board ship at sea, without any appreciable deterioration. Further, by a closer connection of the ingredients a larger volume of gas is produced, bulk for bulk, than from a soft light powder; it also produces more



grain than could be obtained from "mill cake" not pressed, and consequently there is less waste by dust in manufacture, and in addition to this, a hard, clean-grained powder does not foul the gun so much as a soft powder.

For the purpose of compressing the meal powder into what is called "press cake," a powerful hydraulic press is employed. The apparatus for holding the meal consists of a very strong gun-metal box incased on the outer and inner sides with oak; it is

2′ square and 2′ 6″ deep, the bottom and one side are permanently fixed to each other, but the other three sides are hinged to the bottom, so as to allow of their being opened; when shut these sides are firmly held together by strong, coarse-threaded metal screws. The box, when about to be filled, is first laid on its side in front of the press, and the uppermost side is then opened and laid back. Two guide racks, of gun-metal, with wooden ribs on them, forming a number of grooves one-tenth of an inch in width and five-eighths of an inch apart, are hung on the inside of the box to those sides that have not been opened; into these grooves a series of gun-metal plates one-tenth of an inch thick are slid, the racks keeping them upright and equidistant. The spaces between the plates are now filled in with the meal powder, and this being done, the racks are withdrawn, leaving the plates supported in their position by the powder between them. The third side—which has remained open until now—is then lowered down and screwed fast up to the two sides already in position. The box is provided with two projecting gun-metal claws that fit into a mandrel attached to the front of the press; upon this mandrel the box is now turned by means of overhead tackle, the mandrel being so adjusted that when the box is raised partly into a vertical position it is pushed over and lowered down exactly on the center of the press table. Attached to the press cross-head are two overhead rails, carrying a large block of hard wood, which is hung and travels upon these rails by means of four wheels; when the box is turned over on its side for the purpose of filling, this block is drawn back to the extremity of the rails, and when the box is filled and replaced on the table and in the proper position for pressing, the block is drawn forward again until it arrives exactly over the center of the box, where it is retained in position by means of a catch.

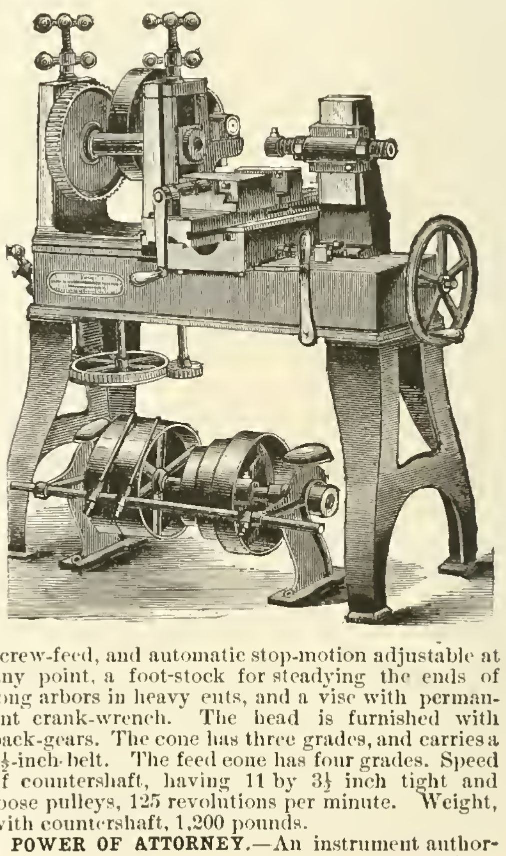
The press is now put in motion by means of pumps, which are driven either by steam, water, or hand power, and are placed in a separate building, on the opposite side of a high traverse that divides the one building from the other. In the pump-house the attendants remain in safety while the pressing operation is being performed. The pumps are of the description generally used for such purposes, and are fitted with large and small plungers. At first, when the material to be pressed is soft, the large plungers are used and the box is raised rapidly, but when the press has traversed about three-fourths of its distance the use of the large plungers is discontinued, and the smaller ones worked until such time as the powder is subjected to a pressure of 70 tons per square foot of surface. When the pumps are first put in motion, one of the attendants remains in the press-house for a short time to see that the block enters the box fairly, and that it is in the center; a clearance of about a quarter of an inch is allowed all round between it and the box. If all is in order, the attendant then retires to the pump-house, and when the requisite pressure has been obtained, the press is allowed to stand for a few minutes with the full pressure on it; this allows the air to escape and the powder to consolidate. Should the pressure go down from this cause, the pumps are again set in motion until the full pressure is attained; and, after allowing a few minutes to elapse, the escape valve is opened and the ram with the box descends. The overhead block is now run back out of the way, the box turned over on its side, and all the fixing screws removed from the three sides, the uppermost one is lifted up and turned over, and the other two are opened out. The powder, with the gun-metal plates between it, will now be found to be standing like a solid mass on the side of the box underneath, and which for the time forms the bottom.

The plates and powder cakes are now separated by copper chisels, and the cake—being from three-eighth of an inch to one-half inch in thickness, and looking like slabs of slate—is broken into pieces about the size of a man's hand by means of wooden mallets. It is now collected, put into tubs, and removed to the next magazine, where it is allowed to remain for two or three days; this renders it so hard that it is not easy to break it. Some difficulty is at times experienced in obtaining precisely the same density in the pressed powder, and it is an ascertained reality that any great difference in this particular causes the powder to vary considerably in quality and strength; in fact, until the greatest precision and certainty are obtained, firstly, in purifying the ingredients, so as to ensure their containing the same percentage of gases and carbon; and, secondly, by an equally precise amount of incorporating and pressing, absolute uniformity in the quality and strength of the powder manufactured cannot be secured. See *Gunpowder*.

POWDER PROOF.—All *gunpowder* for proving ordnance should be of the best quality, of the kind used in the gun to be proved, and giving not less than the standard initial velocity; it should be tested immediately before being used unless it shall have been tested within one year previously, and there be no reason to suspect that it has become deteriorated.

POWER.—In military affairs, as well as in all others power is knowledge—of human passions, of arms, of distance, of the skill and numbers of an enemy. To be in the *power* of an enemy, is to have taken up, injudiciously, such a position as to expose to defeat whenever the enemy may think proper to attack.

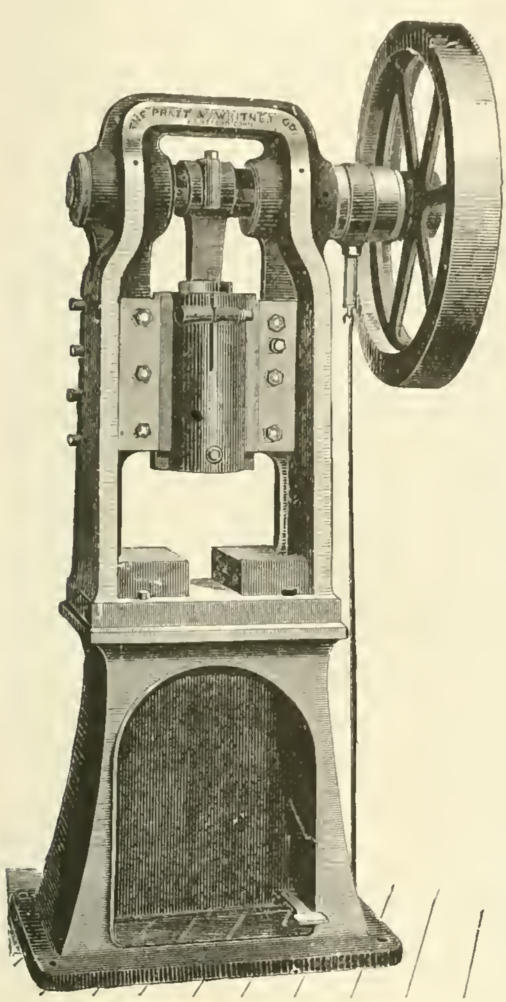
POWER MILLING-MACHINE.—A machine much used in the manufacture of small-arms. The drawing represents the Pratt & Whitney No. 2 Power Milling-Machine (Lincoln Pattern), which is in extensive use in armories and manufactories in America and Europe, and is highly approved at the National Armory, Springfield, Mass. It has automatic



screw-feed, and automatic stop-motion adjustable at any point, a foot-stock for steadying the ends of long arbors in heavy cuts, and a vise with permanent crank-wrench. The head is furnished with back-gears. The cone has three grades, and carries a 1½-inch belt. The feed cone has four grades. Speed of countershaft, having 11 by 3½ inch tight and loose pulleys, 125 revolutions per minute. Weight, with countershaft, 1,200 pounds.

POWER OF ATTORNEY.—An instrument authorizing a person to act as the agent or attorney of the person granting it. A general power authorizes the agent to act generally for the principal. A special power limits the agency to particular things. A power of attorney may be by parole, or under seal. The attorney cannot execute a sealed instrument that will bind his principal unless his own power is given under seal. Grants of this nature are very strictly construed. Authority given to one person cannot be delegated by him to another, unless expressly set forth in the original grant: The death of the principal at once cancels a power of attorney. All conditions in the power must be strictly observed to render the attorney's action legal.

POWER PRESS.—A form of press extensively employed in the manufacture of fire-arms. That repre-



sented in the drawing is provided with Stannard's hydraulic adjustment. A foot-lever actuates a stop-motion that instantly stops the plunger, always at the highest point of the stroke. The crank-shaft, of steel, is made with a throw of 2½ inches, or less, as it may be ordered for trimming or for punching purposes. The shaft-bearings are 3 inches diameter and 8 inches long. The driving-wheel, 32 inches diameter and weighing 380 pounds, receives a 4-inch belt. The plunger is a hollow cylinder, open at the top, and bored to receive a piston, which is also hollow. The plunger travels in gibbed slides, and has a portion of one of its flanges toothed, to engage with a pnion operated by a crank-wrench. The hollow piston contains oil, or glycerine (preferably the latter, as being unaffected by changes of temperature). This piston is attached to the crank by a connecting-bar. By means of a thumb-value in the bottom of the piston, operated by a rod extending up through the top and terminated by a knob, the liquid may be allowed to pass from the piston to the plunger, and *vice versá*, as the plunger is lowered or raised by the pinion and toothed flange. The adjustment of the punch can thus be made very minute and exact, and the relative positions of the plunger and piston may be firmly secured by a binding-screw on the former, which is split a portion of its length for this purpose. The bed of the press may receive a die-plate, 12 by 14 inches. Weight of the machine, 2,750 pounds. Speed of driving-wheel, 175 revolutions per minute. The hydraulic adjustment being quite costly, is seldom ordered. In lieu of it, one is made by substituting for the hollow piston, a solid one, having its circumference threaded to match an annular nut placed in the central part of the plunger, and projecting therefrom sufficiently to be readily turned to raise or lower the plunger. The press is also furnished without plunger adjustment.

POWER SHEARS. A shearing-machine manufactured by the Pratt & Whitney Company, for use in armories. The machine, as represented on page 576, is novel in style and action, noiseless in its operation, and all its parts liable to be clogged by dust or injured by scale are contained inside of the pedestal, but are still fully accessible through the medium of doors. On a shaft passing through the machine from end to end is a worm engaging with a large worm-wheel. This shaft is driven by a faced balance-wheel (used as a pulley for belt) from which connection with the shaft is made by means of Pratt's Patent Friction-clutch. The transverse shaft carries the worm-wheel, which has an eccentric, forming a part of the wheel, a connecting-rod from which engages with the lower end or prolongation of a vertically vibrating horizontal cutter-head, furnished with steel jaws on either side the central bearing, which engage as shears with corresponding fixed jaws. One pair of these jaws is made with recesses of the form of segments of circles to receive round bars, and the other is straight. In front of the jaws are adjustable sliding rests, to resist the upward tendency of the piece to be cut, and at the back is an adjustable gauge for determining its length. The machine is started or stopped instantaneously, without the slightest shock, and there is no loss of power by starting it from a perfect stand-still. Speed of pulley on machine is 280 to 300 every minute. The steel cutting-blades may be removed from the jaws for sharpening or replacement with very little trouble. The combination of the screw, worm-wheel, eccentric, and lever results in a machine of immense power. One size machine is made. It will cut round iron to 1⅝ inches diameter; or flat iron ¾ inch thick to 3 inches wide. Weight, with countershaft, 4,600 pounds. Speed of countershaft, having 16 by 6 inch tight and loose pulleys, about 240 revolutions per minute. See *Angle Shearing-machine, Lever Shearing-machine*, and *Shearing-machine*.

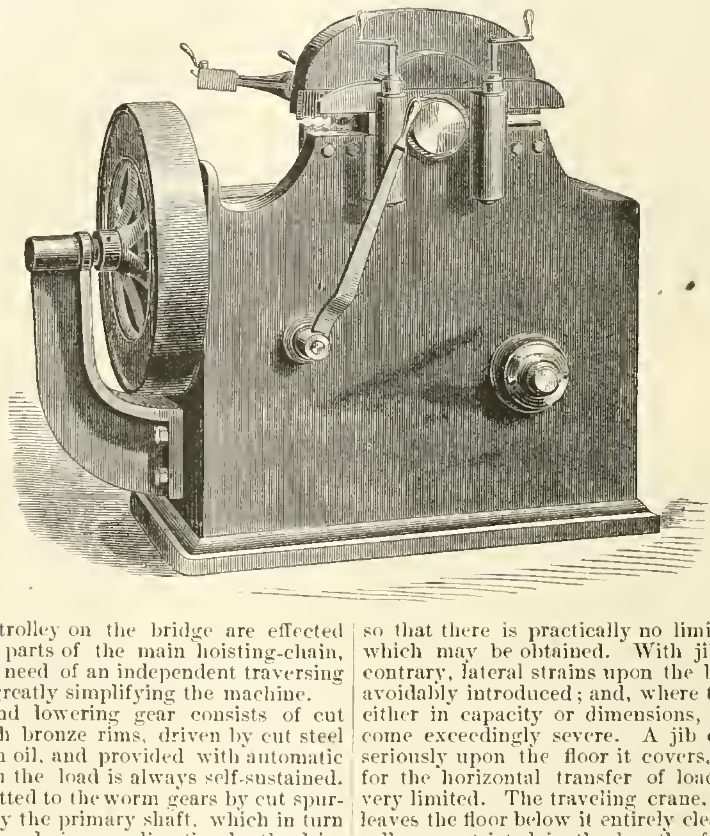
POWER TRAVELING CRANE.—This crane consists of a bridge composed of two wrought-iron girders carried at each end by a two-wheeled truck with double-flanged truck wheels having chilled treads. At one end of the bridge is a crab containing the operating mechanism, and suspended beneath this is the operating platform. Power is communicated to the crane by an endless rope, moving continually in one direction, and driven by a suitable wheel on a stationary shaft at one end of the longitudinal tracks, this shaft being driven by the power transmitted in any convenient manner from a stationary engine, either directly or through the line shafting. The mechanism of the crab is such that the operator, standing upon the suspended platform, is enabled by means of three levers, to apply power so as to cause the bridge to travel longitudinally on the tracks in either direction, or the trolley to travel in either direction, across the bridge, or to raise or lower the load. The bridge and trolley may be moved independently or simultaneously, at will.

The illustration on page 577 shows Weston's Travelling crane, driven by power transmitted from a stationary source, and controlled by an operator standing on a platform suspended from the crane at one end of the bridge. The bridge is arranged to travel longitudinally upon overhead tracks, and the trolley to travel transversely across the bridge, so that the efficiency of the crane covers the entire rectangle included between the tracks, which latter may if desired, be 400 or 500 feet, or more, in length. Cranes of this construction are built of any desired capacity from 5 to 50 tons, and of any span.

The motions of the bridge are effected by fixed wire cables, so arranged as to constitute a perfect squaring device, which insures the absolute parallelism of the end trucks of the bridge with their tracks under all conditions, so that the bridge always moves smoothly and with the least possible friction. The motions of the trolley on the bridge are effected through the two parts of the main hoisting-chain, thus avoiding the need of an independent traversing mechanism and greatly simplifying the machine.

The hoisting and lowering gear consists of cut worm-wheels with bronze rims, driven by cut steel worms running in oil, and provided with automatic devices by which the load is always self-sustained. Motion is transmitted to the worm gears by cut spur-gearing, driven by the primary shaft, which in turn is driven continuously in one direction by the driving rope. Automatic stops are provided for arresting the transverse motion of the trolley at either end of the bridge, and also of the bridge at either end of the longitudinal tracks, so that over-travel, either of the bridge or of the trolley, cannot by any accident occur.

Provision is always made for two speeds of hoisting and lowering, and when desired back gearing is added to the crab, thus affording four speeds of hoisting and lowering and two speeds of travel, both of bridge and trolley. When desired, hand gearing can be also added to enable the crane to be moved by hand in the event of the power being temporarily disabled. This adds somewhat to the expense of the crane and is usually not desirable, as the motions by hand are necessarily very slow and the occasions for its use very rare. The operating platform should, if possible, be arranged as shown in the engraving, beneath the bridge, as in this position the operator has best command of the floor below. Where the head room does not allow of this, or where other obstructions interfere, the platform can be arranged at each side of the bridge, and projecting but slightly below the crab. But, for the reason above given, this arrangement is not so good as that shown in the engraving. A foot way across the bridge gives access to the parts attached to the latter, and also to the trolley. The main chain sheaves have anti-friction bushings, and the action is such as to distribute the wear equally throughout the entire length of the chain. The power traveling crane constitutes the most perfect and complete apparatus for handling heavy loads, and is to be preferred to all other types of cranes, wherever the construction of the building, and the other surrounding conditions admit of its use. It avoids all strains other than vertical upon the building in which it is contained, and for its support requires merely a trestle or wall of sufficient stability to resist the direct pressure of the crane and its load,



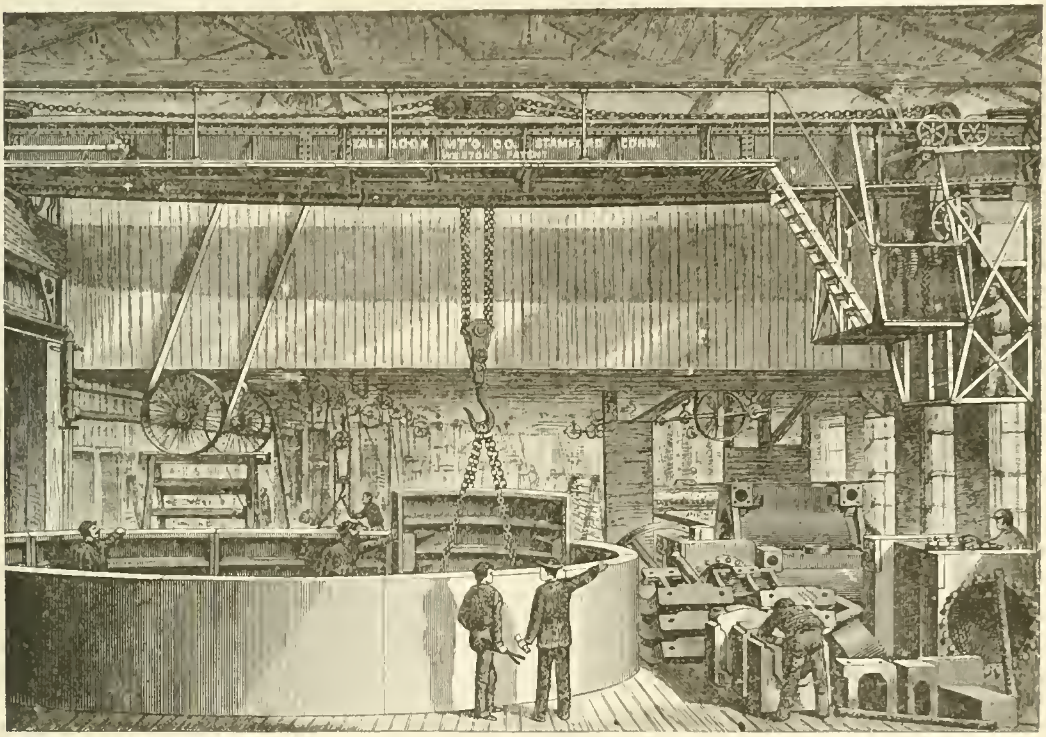
so that there is practically no limit to the capacity which may be obtained. With jib cranes, on the contrary, lateral strains upon the building are unavoidably introduced; and, where the crane is large, either in capacity or dimensions, these strains become exceedingly severe. A jib crane encroaches seriously upon the floor it covers, and its capacity for the horizontal transfer of loads is necessarily very limited. The traveling crane, on the contrary leaves the floor below it entirely clear, and is practically unrestricted in the length of its travel. The designing of the Weston power traveling cranes has been a subject of the most careful study and thorough experiment, extended over a number of years. It is believed that these are the most highly organized and mechanically perfect cranes which have ever been built. Cranes of this construction are adapted for use in foundries, armories, forges, machine shops, rolling mills, stone yards, and other places where heavy loads are to be handled, and where it is desired to accomplish this in the most efficient and economical manner. Where actively employed cranes of this type will do the work of from 20 to 50 men using the ordinary devices of tackles, jacks and screws, so that it is demonstrable in many cases that the economy effected by a crane within one or two years will entirely cover the cost of procuring it. See *Cranes*, and *Hand Traveling Crane*.

POWLDRON.—In Heraldry, that part of armor which covers the shoulders.

POWLETT GUN CARRIAGE.—A pneumatic carriage consisting of an improved slide fitted with suitable cross-transoms and angle-knees for the support of running and recoil cylinders, which are placed underneath the gun and between the slide rails in such a manner as to be entirely protected thereby from the chances of disarrangement by a shot or shell in action. A rack-piece runs along the inside of one of the slide rails with a rolling, eccentric clutch, with a lever attached to its collar, so that when the gun is fired and the recoil is "brought up", the lever falls and automatically secures the gun in that position until it is desired to run in battery, or to be brought back to the rear buffers for loading. The running cylinders are firmly fixed to the cross-transoms of the slide, and are fitted with pistons, the rods of which are secured to the forward transom of the brackets of the sliding carriage carrying the gun. This attachment of the collar of the piston-rod to the carriage has a slot motion, so arranged that when the gun is fired there is sufficient play not to strain the piston-rod in the gland stuffing box at the forward end of the cylinder head.

This running cylinder is fitted with supply and exhaust pipes, with reversing valves or cocks, whereby compressed air furnished from below at a pressure may be supplied to either end of the cylinder, at will, by moving the lever attached to the stem of such reversing valves forward or backward, for running out or running in. When the gun is run out and fired, a pressure of any number of pounds of compressed air as may be desired remains at the rear end of the cylinder for picking up the recoil, and, if it is desired, the clutch-lever may be elevated and secured and the gun made to run immediately in battery again, automatically, after each fire. In training this carriage, which is done without tackle, winch, or chain wheel, there is placed at the rear of the carriage slide and between the same a pair of oscillating cylinders laid horizontally with a plane of the slides and attached directly with a worm geared into a worm wheel having a pinion geared into a cogged racer wheel, so arranged and meshed that any motion to the right or to the left will traverse or train the gun to right or left, as desired. The oscillating cylinders are placed at such an angle that there is no center of axis or motion, and, likewise, there are no slide valves for reversion of motion, as this is accomplished by two pairs of supply pipes leading to the ports or base of the cylinders on both sides of the trunnion support; therefore, by moving the lever to the right or left, the training engine would follow that motion and train the gun to the right or left, as desired.

The elevating and depressing gear of this carriage is operated by an upright cylinder, with sufficient drift to give instantaneously the extreme degree of elevation or depression required by the action of compressed air. On either side of the breech of the gun are racked standards, with movable slot, having a compressor screw encompassing a racked die or slot-plug, by which, with one-half turn of the screw lever, the breech of the gun is firmly secured at any degree of elevation or depression desired. By this method of working heavy guns, two men and a gunner are all the crew that is required to work and load the heaviest ordnance, and all the power is furnished from below, from an air compressor engine and receiver of suitable size. The drawing represents a 25-ton B.L.R. gun mounted on the Powlett carriage. Connected with this carriage is an ingenious stand-by recoil check device, which, should any accident happen to the compressed-air machinery or pipes during action, can be thrown by a lever and clutch instantly into service. This recoil check is mechanical, and has no cogged gearing, and keeps itself in order by running perfectly free during all maneuvering, until thrown into gear in an emergency. See *Brake*.



POWWOW.—A priest or conjuror among the North American Indians; also, conjurations performed for the cure of diseases and other purposes, attended with great noise and confusion, and often with dancing. When an accepting Chief wishes to organize his war party, he mounts his horse, both in full war paint, raises a pole to which is attached a bunch of feathers and a small red blanket, and rides about the village singing the war song. Those wishing to go, mount their ponies and follow the chief. This is continued several days, until there is a sufficiency of volunteers for the work.

During the absence of the war party, the people at home become very anxious, and all the conversation is centered on the absent party and its probable time of return. When it is announced that the warriors are returning victorious, there is a great excitement throughout the village. The womnn chant songs of victory, while the old men narrate the deeds of their forefathers and themselves to excite the emulation of the young. The "Medicine Men" gallop through the camp beating their drums and shouting encouragement, while the warriors painted black, with their horses in the full war paint, perform the scalp dance.

If the expedition turns out to be a failure, and some of the party are killed, the relatives of the killed cut off their own hair and the tails and manes of the favorite horses of the deceased, and cry without cessation for days, weeks, and even months.

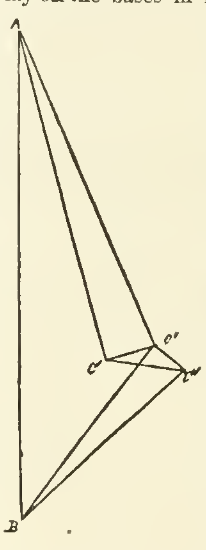
POYNADO.—An early name for a poniard.

PRAELIARES.—Among the Romans, fighting days on which they thought it lawful to engage in acts of hostility; for during the time of some particular feasts, they reckoned it a piece of impiety to raise, march, or exercise men for war, or to encounter the enemy, unless first attacked.

PRAIRIE.—The name given, by the early French Explorers of the northern portion of the Mississippi Valley, North America, to the vast fertile plains which extend from western Ohio and southern Michigan, across the States of Indiana, Illinois, Missouri, Arkansas, Iowa, Kansas, Nebraska, and Dakota Territory, including the southern portions of Wisconsin and Minnesota. These great plains or savannas are sometimes flat, but oftener rolling like the long swells of the ocean, and rise in gradual elevation from 800 to 1,500 feet above the level of the sea. They are drained by numerous rivers, branches of the Ohio, Mississippi, and Missouri, or emptying into Lake Michigan, whose channels seem to have been worn to the depth of 50 to 300 feet, with vertical walls or bluffs of limestone, sandstone, displaying in some places banks of clay, sand, and loam, 200 feet in thickness. Beneath the prairies, northwest of the Ohio, are extensive coal-fields, with deposits of iron, lead, etc. The soil is finely comminuted, rich, and extremely fertile, varying in thickness from 1 or 2 feet to the bottom-lands on the borders of the rivers, which are of great depth and inexhaustible fertility. These plains are destitute of trees, except in isolated groves, a few rocky ridges, and the borders of streams. They are covered with fine grasses, and brilliant flowers of various species of the helianthoid *compositæ*. Water is found from 15 to 30 feet below the surface. These great prairies, covering an area of about 400,000 square miles, formerly fed vast herds of buffalo, deer, wild turkeys, prairie-hens or grouse, prairie-dogs, squirrels, etc. In the autumn, the dried grasses, fired by the Indians, converted them into seas of flame. The lack of timber is attributed by some to the fineness of the soil. Remains of ancient mounds, fortifications, and cities show that they were, at some distant period, inhabited by a more civilized race than the Indians found by European discoverers. These great rolling plains, or natural pastures, with only the labor of plowing, produce large crops of wheat or maize, and, penetrated by navigable rivers, and crossed by cheaply built railways, they form one of the most easily cultivated and prolific regions of the world, and are capable of sustaining immense populations.

PRAIRIE CARRIAGE.—The necessity for a small carriage for the mountain howitzer, when used on our western prairies, has led to the adoption of a special carriage for that service, with a limber attached as in a field carriage. This renders the carriage less liable to overturn, and preferable in every respect to the two-wheeled one. The limber is furnished with two ammunition boxes, placed over the axle-tree, and parallel to it, and just wide enough for one row of shells and their cartridges. See *Gun-carriages*.

PRATT RANGE-FINDER.—Any device, by means of which the distance between two objects may be measured with such accuracy as will warrant its application in determining what elevation should be given to a fire-arm discharged at one of the points, in order that its projectile shall strike the other, or within effective proximity, may be called a range-finder. For military purposes, a range-finder should be as small inexpensive, durable, and simple as is possibly consistent with necessary accuracy. It should also not be limited in its application to one base, and the base should not be long in comparison with the range. It is thought that the method of use suggested by Lieut. Sedgwick Pratt, Third Artillery, U. S. A., may materially increase the value of fixed-angle telemeters. An outline of this method is here given as applied in general to telemeters with fixed angles. It enables the observer to obtain the distance between two points even when he can occupy neither of them. The observer being at C, to obtain the distance between the points A and B, he lays off the bases C C′ and C C″, as if to determine the distances C A and C B, respectively. Without measuring these bases he measures the distance C′C″, and this is multiplied by the number corresponding to the instrument, 20, for instance, giving the distance A B. This is because the angle C′ C C″ is equal to the angle A C B, and the sides C C′ and C C″ are proportioned to the sides A C and B C in the triangles C C′ C″ and A B C. Care must be taken to lay off the bases in the same direction from C, that



is, both to the right or both to the left of the observer at C as he stands facing the points A and B for the two bases respectively. Where the instrument is adapted to laying off a right angle also, the observer can place himself on the line between two points, A and B, and obtain the distance between them in a very simple manner. Being at C, he lays off in the same direction the bases C C′ and C C″, one corresponding to the distance C A and the other to C B, adds the bases, and multiplies their sum by the usual number. Lieutenant Pratt's instrument consists of four mirrors. Two are set at an angle of 45° and two at a lesser angle. The number of mirrors is the same as in the modified Azémar instrument, which gives three angles. The bases are $\frac{1}{10}$ and $\frac{1}{20}$ of the distance to be determined, and with the longer base the instrument is used like Weldon's. The method shown in the figure is applicable to the Weldon range-finder, as well as to those giving a right angle. When the right-angle instruments are used, care must be taken to lay off this angle at the right or at the left extremity of the base in both observations. When A C C′ and B C C″ are both right angles the line C′ C″ will be perpendicular to the line A B, and this affords an easy method of laying off a perpendicular to an inaccessible line, two points of which are visible to the observer. This method can be used also with variable-angle telemeters. See *Nolan Range-finder*, *Russell Prism Range-finder*, *Telemeter*, *Watkins Range-finder*, and, *Weldon Range-finder*.

PRECEDENCE.—Priority in rank or precedenc in military life is regulated by the date of an officer's commission, or the standing in the Corps to which he may belong. The following is the order of precedence of the several Regiments and Corps of her Majesty's service, viz:— (1) The Regiments of Life Guards, and the Royal Regiment of Horse Guards. (2) The Royal Horse Artillery; but on parade, with their guns, this Corps will take the right and march at the head of the Household Cavalry. (3) The Regiments of Cavalry of the Line, according to their number and order of precedence. (4) The Royal Regiment of Artillery. (5) The Corps of Royal Engineers. (6) The Regiments of Foot Guards. (7) The Regiments of Infantry of the Line according to their number and order of precedence. (8) The Departmental Corps. The Royal Marines, when acting with the Troops of the Line, take rank next to the 49th Regiment. The Rifle Brigade rank next to the 93d Regiment. The Militia Regiments have precedence after those of the Line, according to their respective numbers as fixed by lot. When Regiments of British and Irish Militia of the same arm are serving together, the Militia of that part of the United Kingdom in which the Regiments may at the time be quartered has precedence over other Militia, but Regiments of Artillery Militia always have precedence over the Infantry Militia. On parade for purposes of maneuvering, Corps are to be distributed and drawn up in the mode which the General or other Officer commanding may judge most convenient, and best adapted to the purposes of the service. Rifle Battalions should be formed upon a flank.

PRECEPTORY.—The name given to certain houses of the Knights Templar, the Superiors of which were called Knights Preceptor. All the preceptories of a province were subject to a Provincial Superior, called Grand Preceptor; and there were three of these who held rank above all the rest, the Grand Preceptors of Jerusalem, of Tripolis, and of Antioch. Other houses of the order were called "Commanderies."

PRECISION.—Exactness; accuracy; scrupulous observance of certain given rules. In military phraseology, this term is often employed when remarking on the drill or marching of a regiment. The term is also applied to rifled arms under the name of *Arms of Precision*.

PREDAL WAR.—A war carried on by plunder and rapine. Commonly written *Predatory War*.

PREFECT.—A common name applicable to various Roman functionaries. The most important was the *Præfectus Urbi*, or warden of the city, whose office existed at an early period of Roman history, but was revived under Augustus, with new and greatly altered and extended authority, including the whole powers necessary for the maintenance of peace and order in the city, and an extensive jurisdiction civil and criminal. The *Præfectus Prætorio* was the Commander of the troops that guarded the Emperor's person.

PREFECT PRETORIAN.—In Roman antiquity, the Commander of the *Praetorian Guards*.

PREFET.—The name of an important magistrate in modern France, so called from his exercising functions somewhat similar to those of the *præfectus urbi* at Rome. In old times, the officers whose duty it was to superintend the details of administration in the Provinces were called *Maitres de Requetes*. Under Henry II., their office was rendered permanent; and at a later period, their powers were much extended, and they were known by the designation of *Intendants*. The Intendants were abolished at the Revolution; and a law of 1800 first appointed Préfets for the departments, with powers greatly similar to those of the Intendants. The office, as it now exists, includes the superintendence of police establishment, the enforcement of the laws, and the entire control of the administration of the departments. The Préfet is the head of the executive, exercises most of the government patronage, including the appointment of a *sous préfet* for each *Arrondissement*, and in time of tumult may call out the military, or provisionally declare a state of siege. The chief check on these extensive powers is to be found in the *Conseil de la Préfecture*, which acts in some measure as a court of appeal from the decisions of the Préfet.

PREPONDERANCE.—The excess of weight of the part of the piece in rear of the trunnions over that in front. It is expressed by the lifting force, in pounds, which must be applied at the cascabel to balance the piece upon the trunnions. It is useful only for pieces mounted on traveling carriages, to keep them steady in transportation. For all other pieces of recent model the axis of the trunnions intersects the axis of the piece at the center of gravity, thus enabling the piece to be elevated and depressed with greater ease. The discharge does not sensibly change the position of the piece before the projectile leaves the bore.

PRESBYOPIA.—This condition is an accompaniment of the later years of life; it is a physiological or natural, not an abnormal change, and effects all eyes. It depends almost solely upon the failure of the accommodation, due to a gradual hardening of the lens and decrease of the power of the ciliary muscle as age advances. Although this decrease in the power of adjustment for near objects is not noticed until, perhaps, the 40th or 45th year, yet, from the age of nine or ten, the accommodation is gradually growing weaker, that is, fine print can no longer be seen as close to the eye as formerly.

This defect is not of itself a cause for the rejection of a recruit, but those in whom it exists are usually over age. All eyes undergo the changes producing presbyopia; we frequently, however, hear of persons, ripe in years, who have never felt the necessity of glasses for reading or other fine work, and whose "strong" eyes are their especial pride. Such persons have been near-sighted, probably, all their lives their defect neutralizing the normal changes taking place; a weak concave glass before such eyes will usually improve distant vision.

The popular opinion that the use of glasses should be postponed as long is possible, is erroneous. As soon as unpleasant feelings denote the approach of presbyopia, glasses should be resorted to at once, as the longer the eyes are deprived of the aid which they need, and consequently are subjected to strain, the more rapidly will the changes in the eye become developed.

The treatment of presbyopia is found in convex glasses, of such strength that fine print may be seen readily at 7 to 8 inches. Here such a glass is employed not to correct the refraction, as the case of the convex lenses in hypermetropia, but to aid the power of the eye in accommodating. Presbyopia, in a perfectly healthy eye, does not affect the sharpness of distant vision, although in extreme old age, distant vision also is somewhat diminished, owing to other changes which affect the eye.

The glasses should be used at first only while reading by lamp or gaslight. When the unpleasant sensations show themselves also in the day-time, then the glasses previously worn at night should be used for reading by daylight, and their place supplied by a pair of slightly stronger glasses for night-work. In old persons, when distant vision is improved by weak convex glasses, those of the proper strength may be worn constantly. See *Recruits*.

PRESENT.—A term used in the British service, meaning to bring the musket to a horizontal position, the butt resting against the right shoulder for the purpose of discharging its contents at a given object.

PRESENT ARMS.—A command in tactics directing that the musket be brought to a certain prescribed position, for the purpose of paying a military compliment. The movement is executed as follows: The Instructor commands: 1. *Present*, 2. ARMS. Carry the piece with the right hand, in front of the center of the body, at the same time grasp it with the left hand at the lower band, the forearm horizontal and resting against the body. (Two.) Grasp the small of the stock with the right hand, below and against the guard. 1. *Carry*, 2. ARMS. Resume the carry with the right hand. (Two.) Drop the left hand by the side. See *Manual of Arms, Fig.* 2.

PRESERVATION OF AMMUNITION AND FIREWORKS.—Storehouses and magazines should be kept in the neatest possible order, the stores arranged as much as possible, by classes, kinds, and calibers, and labeled. They should be ventilated from time to time, in the middle of the day, in fine weather, particularly those which contain ammunition and fireworks, which are injured by moisture. *Leaden balls* are generally kept in cellars, on account of their weight; the boxes should be kept as dry as possible, and so piled as to admit the circulation of air about them. *Cartridges for small-arms* are kept in magazines, the barrels or boxes being piled 3 or 4 tiers high at most. *Fixed ammunition for cannon*, if not in boxes, should be placed in piles formed of two parallel rows of cartridges, with the sabots together, in 4 tiers for 12-pounder; chock the lower tier with strips of wood fastened with small nails; put a layer of tow 2 inches thick between the shot; let the piles rest on planks, if there be no floor, and cover them with paulins; have the place swept, and the cartridge-bags brushed off. Leave a passage of 18 inches between the double rows, and keep them 2 feet from the walls. Fixed ammunition should not be put into powder-magazines if it can be avoided; it should be kept in a dry place, above the ground-floor if practicable. The store-rooms should always be aired in fine weather; the piles should be taken down and made up again every six months at most, the bags examined, repaired, and the damaged cartridges broken up. A ticket on each pile should show the number and kind of cartridges, the additions to the pile, and the issues. Canisters are piled up like fixed ammunition, in 4 or 5 tiers. Empty cannisters in 10 or 12 tiers, the bottoms and covers separately. *Cartridge-bags* are filled and kept like fixed ammunition, or packed in boxes or barrels. When empty, they are stored in bundles of 50, sealed up in paper cases, carefully closed with strips of thin paper pasted over the seams. Paper cartridge-bags are kept in bundles,packed in boxes or on shelves,in a dry place, with pounded camphor and black pepper or tobacco; the flannel bottom dipped in a solution of the sulphate of copper. *Loaded shells* should never be put into magazines, except from absolute necessity; powder is not well preserved in them. They should be piled on the ground-floor of a secure building, on planks, if the floor be not boarded, in 6 tiers at most; the fuses of the lower tier, in the vacant spaces between the shells; those of the other tiers, turned downwards, like the fuse-holes of empty shells. The pile should be covered with a paulin. Use the same precautions against moisture and accidents as in a powder-magazine. The different kinds of *canister shot* are kept together, in bins or boxes. *Slow-match* is kept in a dry place, such as a garret, in boxes or barrels, or are piled on the floor. *Quick-match*, if not in boxes, may be hung up in bundles on ropes or pins and covered with paper. *Friction-primers* should be kept in tin boxes. *Port-fires*, in bundels of ten, are placed in boxes or in barrels on end in safe and dry situations. *Fuses* are packed in boxes, the same kind, as much as possible, in the same box, in very dry and well-ventilated stores. *Cylinders of rock-fire* are kept in boxes or barrels like fuses. *Fire-balls* are kept in cool but dry and airy places, suspended by the handle, the bottom resting on a board or floor that they may not become deformed. Each ball should be labeled, stating its caliber, weight, and year of fabrication. *Signal-rockets* are packed in boxes, the sticks tied together. Each box should contain rockets of but one caliber, and should be marked with the size and the kind of decoration. If the sticks be attached they are tied in bundles of 5 according to the kind of decoration. *War-rockets* are preserved in dry places with the same precautions as loaded shells. *Tarred links* are strung on a rope and hung up. For transportation they are packed in barrels with straw between the tiers. *Fascines* and *torches* are packed like tarred links. The parts of ornamental fireworks, owing to their liability to deteriorate in store, are generally made as required. They may be packed in the same manner as port-fires. See *Ammunition*.

PRESERVATION OF PROJECTILES.—Projectiles for rifle guns should be neither lacquered nor painted, for the reason that either of these substances would adhere to and foul the grooves of the piece. When practicable, they should be kept under cover, in a dry place, and if unboxed, should be oiled once a year with sperm oil. They are piled, according to kind and caliber, on their sides, in tiers of convenient height. The fuse holes should be stopped with tow or cotton-waste. Great care should be taken when handling them to avoid injuring the sabot. No shells of any description should be kept habitually charged. This is done, as occasion requires, when firing. Empty shell, whether in store or in transportation, are most carefully protected from dampness. They have the fuse-bouching coated with composition, and the fuse-hole is stopped by a plug of very soft wood which is well coated with a mixture of oil and tallow, and screwed in. The ends of the plugs are not sawed off even with the shell, but left square, and project sufficiently to allow them to be unscrewed by means of a wrench; and when these plugs are removed for the purpose of fitting the shells for service, they are not thrown away, but preserved for future use.

When projectiles have been allowed to become very rusty, they may be thoroughly cleaned in the following manner: Provide stout rectangular wooden tubs, fitted with faucets and troughs, for conducting the waste water, acids, etc., to the gutters. The loose rust having been removed with a file-card, place the projectiles in the tubs, and cover them with a mixture of three parts muriatic acid and four parts water. After pickling for an hour, or an hour and a half, remove the acid directly into another tub, if convenient, as the same mixture may be used many times. Then thoroughly rinse the projectiles in running water; if any rust remains it will be in a spongy,half-dissolved condition,easily removed with a file-card. After rinsing, the projectiles are wiped with a dry cloth and piled, when they will be ready for lacquering.

Whenever projectiles are to receive lacquer, care is taken that the quantity applied does not increase the diameter more than is indispensably necessary, and in no case above established high gauge. Old lacquer and rust are removed by scraping, as far as can be conveniently done, before a new coating is applied. Neither hammering nor beating is resorted to for this purpose. After numerous experiments upon different lacquers employed for the preservation of projectiles from rust, the French have abandoned all of them. The projectiles are simply piled, under sheds when practicable, or in the open air, and, when put on board of ship, cleaned of rust and rubbed over with whale-oil; the same means are adopted every three months of the cruise.

In emptying shell they are handled carefully and placed on a bench with a hole in it to receive and support the inverted shell. A wooden vessel placed below receives the powder. The powder which has been removed from shells is only used for filling shell, as it always contains a small quantity of grit, which renders it unfit for general service. All powder taken from shell is sifted, and all dust and particles of dirt removed, as far as possible, before putting it into barrels. Should the powder have become caked, so as not to be easily removed by washing out the shell, a handful of small iron shot put in the shell facilitates this operation. See *Piling of Balls* and *Projectiles*.

PRESERVATION, STORAGE, AND TRANSPORTATION OF POWDER.—In the powder-magazines the barrels are generally placed on the sides, three tiers high, or four tiers, if necessary. Small skids should be placed on the floor and between the several tiers of barrels, in order to steady them, and chocks should be placed at intervals on the skids to prevent the rolling of the barrels. The powder should be separated according to its kind, the place and date of fabrication and the proof-range. Fixed ammunition, especially for cannon, should not be put in the same magazine with powder in barrels, if it can be avoided. In a room 13 or 14 feet wide, the barrels may be arranged in a double row in the center, two alleys 2½ feet wide, and two single rows 6 to 12 inches from the walls; in this way the marks of each barrel may be seen and any barrel can be easily reached. In a room 12 feet wide, an equal number of barrels may be placed in two double rows, with a central alley of 3 feet, and two side alleys, next the walls, of about 10 inches each. There should be an unencumbered space of 6 or 8 feet at the door or doors of the magazine.

Should it be necessary to pile the barrels more than four tiers high, the upper tiers should be supported by a frame resting on the floor; or the barrels may be placed on their heads, with boards between the tiers. Besides being recorded in the magazine book, each parcel of powder should be inscribed on a ticket attached to the pile, showing the entries and the issues.

For the preservation of the powder, and of the floors and lining of the magazine, it is of the greatest importance to preserve unobstructed the circulation of air under the flooring as well as above. The magazine should be opened and aired in clear, dry weather, *when the temperature of the air outside is lower than that inside the magazine*. It should not be opened in damp weather if it can be avoided. The ventilators must be kept free; no shrubbery or trees should be allowed to grow so near as to protect the building from the sun. The magazine yard should be paved and well drained. The moisture of a magazine may be absorbed by chloride of lime suspended in an open box under the arch, and renewed from time to time; quicklime is dangerous, and should not be used. The sentinel or guard at a magazine, when it is open, should have no fire-arms, and every one who enters the magazine should take off his shoes, or put socks over them; no sword or cane, or anything which might occasion sparks, should be carried in. The windows should have inside shutters of copper wire-cloth. Fire should never be kindled near the magazine for the repair of the roof or lightning rods. Barrels of powder should not be rolled for transportation; they should be carried in hand-barrows, or slings made of rope or leather. In moving powder in the magazine, a cloth or carpet should be spread; all instruments used there should be of wood or copper, and the barrels should never be repaired in the magazine. When it is necessary to roll the powder for its better preservation and to prevent its caking, this should be done, with a small quantity at a time, on boards in the magazine yard.

In the spring an inspection of the barrels should be made, and the hoops swept with a brush wherever they can be got at, to remove the insects which deposit their eggs at this season. In wagons, barrels of powder must be packed in straw, secured in such a manner as not to rub against each other, and the load covered with thick canvas. In transportation by railroad, each barrel should be carefully boxed and packed, so as to avoid all friction. The barrels should have a thick paulin under them. The cars should have springs similar to those of passenger cars. When powder has been damaged by being stored in damp places, it loses its strength, and requires to be worked over. If the quantity of moisture absorbed does not exceed 7 per cent., it is sufficient to dry it to restore it to service. This is done by exposing it to the sun, or in a drying room. When powder has absorbed more than 7 per cent., of water it is sent to the powder-mills to be worked over, or sold as condemned powder. When it has been damaged by salt water, or become mixed with foreign matters which cannot be separated by sifting, the saltpeter is dissolved out from the other materials and collected by evaporation.

Proportions of ingredients.

	Saltpeter.	Charcoal.	Sulphur.
By the atomic theory	74.64	11.51	11.85
In the United States:			
For the military service (the latter proportion is generally used)	76.	14.	10.
	75.	15.	10.
For sporting	78.	12.	10.
	77.	13.	10.
In England same as United States:

For the military service	76.5	12.7	10.8
In Austria:			
For the military service	74.	16.	10.

See *Gunpowder* and *Powder Depots.*

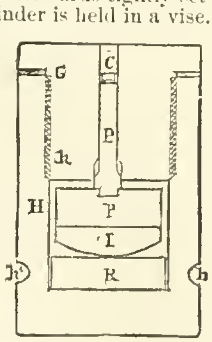
PRESIDENT.—The President of the United States is Commander-in-Chief of the army, navy, and militia called into service. His functions as such are assigned by Congress, but embrace of course whatever authority may be assigned to any Military Commander, on the principle that the authority of the greater includes that of the less. For the command, government, and regulation of the army, however, Congress has created a military hierarchy or range of subordination in the army with rights and duties regulated by Congress, and the Commander-in-Chief cannot make use of any other agents in exercising his command; and all orders issued by him must be according to the rules and articles made by Congress for the government of the army. In his capacity of Chief Magistrate of the Union, Congress has also invested the President with many administrative functions relating to military affairs; and for the performance of the latter duties the Secretary of the Department of War has been made his Minister, upon matters connected with *matériel*, accounts, returns, the support of troops, and the raising of troops.

PRESIDENT OF COURT.—The President of a Court-Martial is the senior member. He preserves order in Court; administers the oath taken by the Judge-Advocate, and the proceedings of the Court are authenticated by his signature and that of the Judge-Advocate. See *Courts-Martial.*

PRESIDIO.—A place of strong defense; a garrison guard-house.

PRESS CAKE.—Gunpowder after it has been subjected to hydraulic pressure. The different natures of powder used in the service receive a pressure of so many tons on the square foot, with reference to the density required. Pebble powder receives a pressure which gives it a density in excess of the usual powders. The amount of pressure varies with the season of the year, less pressure being required in summer than in winter. See *Gunpowder.*

PRESSURE-GAUGE.—An apparatus invented by General Rodman for measuring the pressure exerted by the gases of exploded powder. The drawing shows the construction of the instrument. It consists of the *housing*, H, closed by the *plug*, h; of the *piston*, P, with its *head*, p, to which is attached the *indenting-tool*, I; and the *recorder*, R, of copper. The *gas-check*, C, a thin copper cup, and the *gasket*, G, a copper ring, exclude the gas from the cavity of the housing. When the gauge is placed in the cartridge-bag, it is securely tied to it at the groove. h′ h′. In using this instrument, all its parts, except the exterior of the outer cylinder, are carefully cleaned before each fire, and the threads of the screw-plug and the indenting-piston carefully oiled; the copper specimen is then placed in the bottom of the cylinder, the indenting-piston inserted into the screw-plug, and with the outer cylinder horizontal the plug is screwed home, being afterwards tightly set in with a wrench while the cylinder is held in a vise. The cylinder is



then carefully set down upon its closed end, and the indenting-piston gently pushed down till the point of the indenting tool rests upon the copper specimen; a small gas check is then inserted, mouth outward, till it rests upon the end of the indenting-piston. It gives additional security against the passage of gas to place a small wad of cotton or tow over the gas-check, pressing it in firmly without driving, as a very light blow, several times repeated, might give a greater indentation than that due to the pressure to which it was to be subjected, and thus give erroneous results. The instrument is inserted into the gun with the screw-plug toward the muzzle, and is generally found in the bore of the gun after its discharge, when the screw-plug is withdrawn and the specimen removed, having an indentation in its surface, due to the pressure that has been exerted upon the outer end of the indenting-piston. The indications of pressure are found to be, generally, something less, for equal charges, by this instrument than by the external housing; this may be, and probably is, due to the retardation of the rate of inflammation of the charge by the presence of the instrument, and to the heat absorbed by it. Another reason for this is probably owing to the fact that in the external gauge the gas has a considerable space to travel through between the powder-chamber and the indicating parts, so that before reaching the piston the gases have attained a high *vis-viva*, especially with quick-burning powders. For these reasons this instrument should be as small as may be compatible with its practical use. See *Crusher-gauge, External Pressure-gauge,* and *Internal Pressure-gauge.*

PRESSURE-SCREW.—A screw variously applied in ordnance constructions to exert pressure and hold parts in proper positions. An example of the importance of the *pressure-screw* may be seen in the Breithaupt fuse, when gauging the fuse for firing.

PRESUMPTION.—An inference drawn by the law in certain circumstances or conditions of facts, and is used generally as a mere starting point in an argument or litigation. Presumptions are often divided into *presumptio juris* and *presumptio juris et de jure.* The former serves as a mere starting-point, and may be rebutted by proof to the contrary. Thus, a person who has possession of goods, is presumed to be the owner till the contrary is proved. A man is presumed to be innocent until the contrary is proved. A *presumptio juris et de jure* is said to be a presumption which cannot be rebutted; but there are few instances of this. Presumptions abound in all departments of the law, and are adopted from the necessity of coming to some conclusion or other in most cases where the evidence is general or inconclusive.

PRETENSE.—In Heraldry, an *Escutcheon of Pretense* or Escutcheon Surtout, is a small shield placed in the center of the field of another shield. The husband of an heiress may bear the arms of his wife in an Escutcheon of Pretense; instead of impaling them. Feudal arms are also sometimes placed on an Escutcheon of Pretense, particularly in the insignia of Elective Sovereigns, who have been in use of bearing their own proper arms in surtout over those of the dominions to which they are entitled. The Crown of Charlemagne is placed in surtout in the Arms of Hanover; and from 1801 to the accession of Queen Victoria, the Hanoverian insignia occupied an Escutcheon of Pretense in the center of the Royal Arms of the United Kingdom.

PRETOR.—Among the ancient Romans, the title given to the Consuls as leaders of the armies of the State; but it was specially employed to designate a Magistrate whose powers were scarcely inferior to those of a Consul. The Pretorship, in this specific sense of the term, was first instituted in 366 B. C., as a compensation to the Patricians for being obliged to share with the Plebeians the honors of Consulship. It was virtually a third Consulship; the Pretor was entitled *Collega Consulibus;* he was elected by the same auspices and at the same Comitia. For nearly 30 years, Patricians alone were eligible for the office; but, in 337 B.C., the Plebeians made good their right to it also. The Pretor's functions were chiefly judicial. Though he sometimes commanded armies, and, in the absence of the Consuls, exercised considerable authority within the city, yet his principal business was the administration of justice both in matters civil and criminal; and "to the edicts of successive Pretors," says Mr. G. Long, "the Roman law owes, in a great degree, its development and improvement."

Originally, there was only one Pretor; but, as the City and State increased, and their relations with other nations became more complicated, others where added. In 246 B. C. a second Pretor was appointed, to settle disputes that might arise between Romans and Foreigners temporarily resident at Rome, for trading or other purposes, hence called *Prætor Peregrinus* (Foreign Pretor), to distinguish him from the original *Prætor Urbanus* (City Pretor). In 227 B. C., two new Pretors were appointed, to administrate affairs in Sicily and Sardinia; and in 197 B. C., two more for the Spanish Provinces, or 6 in all. Sulla increased the number to 8, and Julius Cæsar to 16. Augustus reduced the number to 12; but at a later period we read of 18, if not more. The city Pretor-ships were reckoned the highest; and after a person had filled these offices, he sometimes received the administration of a province with the title of *Propritor* or *Proconsul*.

PRETORIAN BANDS.— The name given more particularly during the period of the Roman Empire, to a body of soldiers, organized for the purpose of protecting the person and maintaining the power of the Emperors. We indeed read of a *Prætoria Cohors*, or select guard of the most valiant soldiers attached to the person of Scipio Africanus, who, according to Festus, received six-fold pay, and the exigencies of the civil wars naturally increased their number; but it was to Augustus that the institution of them as a separate force is owing. He formed 9 or 10 cohorts, each consisting of 1,000 men (horse and foot); but kept only three of them in Rome, the rest being dispersed in cities not far off. Tiberius, however, assembled the 9 cohorts at the capital in a permanent camp, and Vitellius increased their number to 16. The Pretorians served at first for 12, and afterward for 16 years; they received double pay; the privates were held in equal rank to the Centurions in the regular army, and on their retirement each received 20,000 sesterces. They soon acquired a dangerous power, which they exercised in a most unscrupulous manner, deposing and elevating Emperors at their pleasure. Aspirants for the Imperial Dignity found it advisable, and even necessary, to bribe them largely; while those who acquired that dignity without their assistance were accustomed on their accession to purchase their favor by liberal donations. The Pretorians, however, had no political or ambitious views; they were simply an insolent and rapacious soldiery, fond of substantial gratifications, and careless how they got them. After the death of Pertinax (193 A. D.), they actually sold "the purple" for a sum of money to Didius Julianus; but in the same year their peculiar organization was entirely broken up by Severus, who formed new cohorts altogether out of the best legions serving on the frontiers, which he increased to four times the number of the old. After several other changes, they were entirely abolished by Constantine (312 A. D.), who dispersed them among his regular legions.

PRETORIUM.—The Hall or Court where the Pretor lived and administered justice. It also denoted the tent of the Roman General, in which councils of war were held. The place where the Pretorian Guards were quartered or lodged was likewise called pretorium.

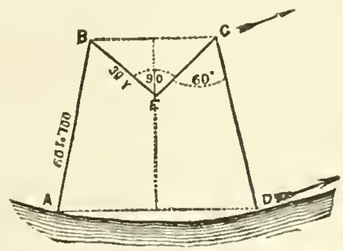
PREVENTOR ROPE.—A contrivance for checking the forward motion of a carriage. It is attached to the rear block of the carriage, and being twisted round the *bollard* of the platform, is held by one of the cannoneers.

PRICE RETORT FURNACE.—The Price furnace is in part a gas furnace, and it embraces some of the features of the regenerative system, as the temperature of the air, as well as that of the gaseous and fixed constituents of coal, is raised by the waste heat before it enters the chimney. It consists of a combustion chamber or fire-box, furnished with grate-bars in the ordinary way; a heating chamber or hearth, separated from the combustion chamber by the usual bridge; and a neck leading into a flue, which opens to the retort chamber. In the center of the retort chamber is a circular firebrick pillar, on which is placed a cast-iron cylindrical air-vessel protected all round by firebrick. On this air-vessel is built the retort, the lower part of which is made of brick while the upper part is cast-iron. At the top of the retort and above the closed end of the chamber is placed a hopper, in the throat of which are fitted two doors worked by a lever from the ground. This feeding apparatus may be of any other suitable construction. In the firebrick portion of the retort are two passages, the one leading to the combustion chamber, and the other to the outside of the furnace for the insertion of stoking tools to force the fuel forward into the combustion chamber. The entrance to the outer passage is closed by a tight door. Near the bottom of the retort chamber, and in a line with the center of the air-vessel, are pipes inserted in the walls of the chamber and passing all around it. On the inner side of these pipes and opening into the retort chamber are a number of holes leading into the space around the pipes. This space affords room for expansion and for a free circulation of heat. The pipes are connected with the blast from a fan or from any suitable blower. The air passes into the air-vessel and is delivered through an outlet in the ash-pit, directly under the grate. It will be seen from this description that the retort furnace embraces some of the best features of the regenerative system, while it entirely dispenses with its complications of producers, regenerators, and reversing valves. See *Furnace*.

PRICKER.—1. An early name for a light horseman. 2. A priming-wire.

PRIDE.—A term in Heraldry. A peacock, or other bird, when the tail is spread out in a circular form, and the wings dropped, is said to be "in his pride."

PRIEST-CAP—When the faces of a redan cannot be so placed as to sweep well the flank approaches without making the salient angle too acute; or when

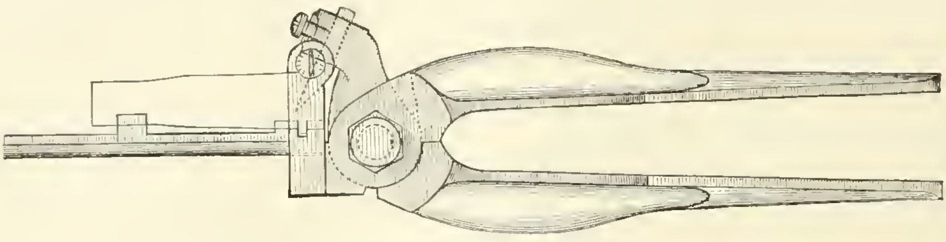


the flank approaches extend towards the rear; then the plan may, in the first case, be what is termed a *priest-cap*, or *swallow-tail*, in which the two main faces sweep the flank approaches, and, instead of a *pan-coupé*, a broken line forming a reentering angle, placed in the salient, affords a cross-fire on the ground in front. In the second case a flank is added to each face of the redan, and receives such a direction as to sweep that portion of the flank approach which cannot be reached from the faces except by a very oblique fire. The priest-cap is so named from its shape. See *Field Works* and *Swallow-tail*.

PRIME.—1. In fencing, one of the chief guards. 2. To charge with the powder, percussion-cap, or other device for communicating fire to the charge, as a fire-arm.

PRIMER.—A wafer, cap, tube, or other device for communicating fire to the charge of powder in a cannon. The cap or tube usually contains a friction or percussion-powder. The *friction-primer* is generally used in the land service. For service on ship-board, a quill filled with rifle-powder, having on the top a capsule of fulminate of mercury, is generally employed. The capsule is exploded by a blow from the lock-hammer. The *tape-primer*, used sometimes in blasting, is formed of long, flexible strips of paper or fabric containing fulminate or other quick-burning substance. The *electric primer* is used to fire simultaneous discharges, both in ordnance and blasting. In firing wet gun-cotton, the small charge of dry gun-cotton used in conjunction with the *detonating exploder* is called a primer. In small-arms, the term is specially applied, at the present time, to the percussion-caps used in reloading metallic cartridge-cases. See *Cannon-primers*.

PRIMER EXTRACTOR.—A reloading tool, whose function is to extract the *primer* from the cartridge-shell, when it is required to reload the shell. It is variously designed. The drawing shows a very handy and efficient form of extractor, suitable for reloading central fire cartridge-shells of any caliber. To operate it, it is only necessary to insert the shell, close the handles just enough to cause the chisel to penetrate the primer, and elevate the tongue sufficiently to throw it out.



PRIMIGENIA.—A kind of *pike* very much resembling the pilum.

PRIMING-TUBE.—A tube to contain an inflammable composition, which occupies the vent of a gun whose charge is fired when the composition is ignited. There are several kinds of priming-tubes, fired by *port-fire*, *lock*, or *friction*. The tube is made of *quill*, *paper*, or *metal*, and is charged with mealed powder damped with methylated spirit, or by a detonating composition, such as chlorate of potash and antimony. The tube is slightly smaller than the gun vent, in the relative proportions of $\frac{2}{10}$ and $\frac{2}{9}$ of an inch, and a hollow is made down the middle of the composition, so that the fire may involve the whole length instantaneously. The simplest form is that in which the tube is merely a holder for the priming, which is touched off by a port-fire. This is the *quill*, Dutch, or *common metal tube*. Another variety has a cross-head or snipe to contain a detonating composition which is exploded by a hammer. This is the *cross-head*, or *detonating tube*. A third variety is operated by friction, a roughened bar occupying the hollow in the composition, and exploding by friction the detonating composition in the head of the tube. The rough bar is jerked out by a lanyard. See *Friction-primer*.

PRIMING-WIRE.—An implement used to prick the cartridge before priming when the quill or metal tubes are used. It is made of wire a little less in diameter than the vent, sloping to a point at one end, and at the other vent into a circle, which serves to hold it by, as well as prevent it from slipping through the loop on the primer pouch, where it is carried when not in use.

PRIMIPILUS.—The Centurion belonging to the first cohort of a legion. Among the Romans, the *Primipilarii* were such as had formerly borne the office of Primipilus. Among other privileges which they enjoyed, they became heirs to what little property was left by the soldiers who died in the campaign.

PRINCE.—An epithet which was originally applied to the *Princeps Senatus* of the Roman State and afterward became a title of dignity. It was adopted by Augustus and his successors; hence the word was afterward applied to persons enjoying kingly power, more especially the Rulers of small States, either Sovereign, as in the case of the ancient Princes of Wales, or Dependent, like the Rulers of certain States in Germany. The title is now very generally applied to the sons of Kings and Emperors, and persons of the Blood-Royal. In various parts of Continental Europe, the title Prince is borne by families of eminent rank, but not possessed of sovereignty; and in England a Duke is, in strict heraldic language, entitled to be styled "High Puissant and Most Noble Prince," and a Marquis or Earl as "Most Noble and Puissant Prince." Practically, however, in Britain, the term Prince is restricted to members of the Royal Family. The eldest son of the reigning Sovereign is by a special patent created Prince of Wales, and this is the only case in which the title Prince is connected with a territorial distinction. In Germany, the ambiguity of applying the same title to the members of Royal Houses and Princely Families, not Sovereign, is avoided, the former being styled "Prinz," the latter "Fürst." The German Fürst takes rank below the Duke (Herzog). Most of the Counts who had a seat in the old German Diet were elevated to the dignity of Prince on the acquiescence in the dismemberment of the German Empire. In a more general acceptation, the term Prince is often used for a Sovereign or Ruler of a State.

PRINCE ALFRED GUN.—This gun was forged hollow, on a plan intended principally to overcome the defect of unequal shrinkage and initial strain and rupture. Broad plates, bent to the proper curve, were laid and welded upon a barrel made of rolled staves. Its dimensions are: length (without cascabel), 1,151 inches; length of bore, 137 inches; diameter over the chamber, $31\frac{3}{4}$ inches; diameter at muzzle, $14\frac{1}{2}$ inches; diameter of bore, 10 inches; weight, 24,094 pounds. The gun is rifled with three grooves $\frac{1}{4}$ inch deep, but cut the wrong way, so that the projectile would be rotated by the inclined instead of the radial surface of the grooves. It will therefore have to be bored out to $10\frac{1}{2}$ inches, and will then carry a 156 pound spherical shot. The test proposed by the makers is one round with one shot and 100 pounds of powder.

PRINCEPS SENATUS.—An officer of the Roman Senate, who, under the Monarchy, was a royal appointee for life, *Custos Urbis*, and had precedence among the *Decemviri*. Under the Republic, he was the appointee of the Curies, B. C. 487, the *Paties Minorum Gentium*, previously ineligible, were made eligible, and afterward the senior Ex-Censor held the office *Ex-Officio*. Later, any Senator was eligible, but the office was simply honorary, and did not carry with it the Presidency of the Senate. Finally the title belonged to the Emperor.

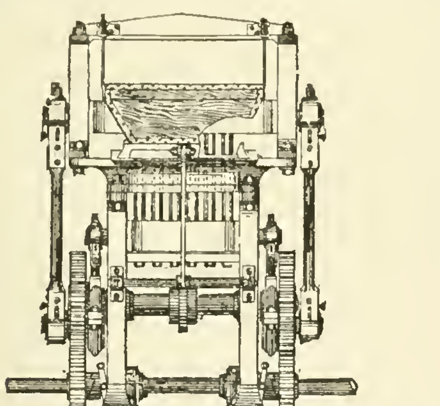
PRINCIPES.—In the Roman armies, Principes were the infantry, who formed the second line in the order of battle. They were armed like the *hastati*, with this difference, that the former had half-pikes instead of whole ones. See *Hastati*.

PRISE-BOLTS.—The projecting bolts at the rear of a mortar-bed or garrison gun-carriage, under which the handspikes are inserted for training and maneuvering the piece. They are formed by the prolongation of the assembling bolts. Also written *Prize-bolts*.

PRISMATIC POWDER.—The adoption of this form of powder by some nations, and production of machinery for its manufacture, necessitated the use of presses of peculiar construction to insure sufficient and uniform density; the press to be so devised as to produce uniform size and shape of grains, and allow their ready withdrawal from the molds; the surfaces such as to allow close packing in a given space. These considerations led to the adoption of a regular geometrical figure: the hexagon offers good shape for piling, the angles being all sufficiently obtuse to prevent breaking or spawling at the edges. Each layer and the whole cartridge is easily made up. Perforations were found necessary to insure better and more uniform control of combustion in the grain. The number of perforations first adopted were seven—one central, the other six at equal distances from the central one although one perforation in the center has been found sufficient.

The ingredients for the manufacture of the powder base are the same as used in the manufacture of ordinary powder. The pulverized materials for 220 pounds are placed in wooden drum lined with sole-leather, with 330 pounds of bronze balls, and subjected to 1,440 revolutions at the rate of 8 or 10 per minute. The powder is then brought to the moistning table of wood surrounded by an upright edge, over which is suspended a graduated glass measure having a pipe of copper and rose at the bottom. On the table a charge of 55 pounds of powder is spread and moistened with $2\frac{3}{4}$ quarts of distilled water. It is then passed from a hopper to an endless canvas belt 20 inches wide, between a lower paper and upper bronze roller, weighing 2,425 pounds, making a revolution in twelve minutes. The bronze roller can be weighed to exert a pressure of 60,000 pounds. The powder is then broken into coarse lumps by wooden mallets, and granulated to two sizes of grains; the first, cannon powder—used for manufacture of the prisms— is passed through a sieve of 0.26 inch diameter of holes.

Ordinary grain powder, made as above, is of a specific gravity of 1.5, and too elastic for the use in the press. By reworking it loses a part of its elasticity, and is then fit for formation of the prisms by the following process: The powder-base, as above, is moistened with 10 per cent. of water, passed through the



spindle press with the prescribed pressure and granulated grain and dust being collected in a receptacle. This mixture of grain and dust is dried in the air or by artificial heat till $1\frac{1}{2}$ per cent. of the moisture remains. It is placed in a mixing-drum—220 pounds of powder and 330 pounds of bronze balls—and subjected to 1,440 revolutions, moistened and pressed as before, giving it a specific gravity of 1.675 to 1.75. It is granulated and separated, the cannon size again dried by air till 6 per cent. in dry weather of moisture remains, and placed in barrels covered with damp cloths for use.

The press for this purpose is constructed to give a pressure of 65,000 pounds per square inch. It consists of a heavy casting on a stone foundation; a main and secondary shaft, one fixed and two movable cross-heads. The main shaft carries a heavy wheel at each end, over which belts conduct the power from the center shafting to the press. It has a clutch operated by a lever for starting and stopping the machine; two pinions on the main operate geared wheels on the secondary shaft, on which two eccentrics and cranks operate respectively, by connecting rods, the lower and upper movable cross-heads. These have each six hexagonal stamps perforated with seven holes which enter corresponding hexagonal molds on the lower cross-head. Six groups of seven needles are fixed in such position that they extend up through the perforations of the lower stamps throughout into the molds and enter the perforations of the upper stamps as the latter descend to press the powder in the molds; these form the perforations in the prisms. The eccentrics and cranks operating the cross-heads are timed so that when the upper stamps have reached their lowest point of descent, the lower ones are moving upward giving the extreme pressure, after which the upper stamps ascend and the lower ones simultaneously push the perforated prisms up from the molds. The lower stamps constitute the bottom of the molds. The molds are filled from a hopper having a table with forward-and-back motion, containing six suitable measures which receive the powder from the hopper; the charging table moves forward and drops the charge in the molds; its edge carries the prisms brought up from the mold to an inclined shelf, whence they are removed. The capacity of the powder measures can be regulated as desired. Two rooms are required for each press; one for the press, the other for the prisms.

Before starting the press, the mold-needles and stamps, and all rubbing surfaces ought to be oiled with a light, pure oil or graphite. All surplus lubricant must be wiped off. The powder to be pressed ought to have at least $5\frac{3}{4}$ per cent. of moisture. The moist prisms weigh about 620 grains each, and must not vary more than 5 grains. The first two sets of prisms should be rejected because of excess of oil. The weight of prisms must be verified. Three men can work a press; a carrier for every press is also required. The height and weight of the prisms must be verified from time to time, and the powder in the hopper stirred from time to time. Loose powder must be brushed away from the stamps and top of the molds; lubricate as often as once an hour. If a needle breaks, stop the press and replace it at once. On dry days, the powder loses moisture: this will be indicated by increased height of prisms or vibrations of the press, in which case moisten with $\frac{1}{4}$ per cent. of moisture, which is done in a drum by a fine rose sprinkler. The prisms pressed by the press contain about 5 per cent. of moisture, and must be dried to about $\frac{3}{4}$ per cent. by exposure to air or on shelves in a suitably arranged drying-room; they are then exposed to a temperature of 120° Fahr. for 48 hours, and are ready for packing.

The prisms are packed in wooden boxes in layers (12 rows of 11, and 11 rows of 9, 6 deep) weighing about 110 pounds to the box. The prisms are regular hexagons 0".992 high and 1".6 width across the angles. The packing-boxes are of inch stuff, and may be tin-lined. Two sheets of felt—the smaller at one end, the other on top—keep the prisms from rubbing against each other in transportation. The boxes have rope handles, and are marked with the weight, kind, place, and date of fabrication of the powder. See *Gunpowder*.

PRISMATIC TRANSIT.—This form of transit, suggested by Steinheil, and designed by Mr. G. N. Saegmuller, was manufactured for the United States Coast Survey. It is intended to be set up in the prime vertical, the telescope pointing east and west. By the use of a prismatic objective, any star passing the meridian will be reflected and seen in the field when the instrument is set up correctly; by turning it in its bearings it will sweep the meridian. The pivot-rings are of phosphor-bronze, and, to avoid flexure as much as possible, these rings are again connected by a tube, so that the telescope body is really double. By one of the three setting-screws the instrument is moved in azimuth. It is provided with a reversing apparatus, which also carries the illuminating lamp. The fine level over the telescope is held by a projection from the reversing apparatus, which secures the great advantage that the level need not be taken off on reversing the instrument; it remains on whether observing in the zenith or horizon. The setting-circle is attached behind the micrometric eye-piece with level alidade, divided on silver, and reading to minutes. It also carries the latitude level, which is chambered and reads to single seconds. This instrument, being very simple and portable, is especially adapted for work in a rough or mountainous country. See *Engineer's Transit*.

PRISON.—In a military sense, a building constructed for the retention of prisoners of war, or for the safe-keeping and punishment of offenders against military law. Sometimes during war, forts and other strong structures are utilized for these purposes. A permanent military prison was established at Fort Leavenworth, Kansas, in 1873. The Department Commander stationed at Fort Leavenworth, is *ex-officio* Commandant of this prison. The other officers of the prison, detailed by the Secretary of War, from the officers of the Army, are a Governor, an Adjutant, a Disbursing officer, Commissary, Surgeon, and Chaplain. Division and Department Commanders may designate this prison as the place of confinement for all prisoners sentenced to be confined for one year or upwards, except such as are convicted of offenses which lawfully subject them to punishment in a State penitentiary. Discharge papers, descriptive lists, orders promulgating or modifying sentences, and statements of conduct since under sentence, are forwarded to the Commandant of the prison with each prisoner sent there for confinement. Before sending convicts to the military prison, a careful medical examination is made of those whose physical or mental condition appears to be such as might be seriously affected by the confinement, or be in danger of ending in permanent disability which might cause them to be discharged before the expiration of their sentence. Special report is made of cases found to be of this description, with a view to avoid unnecessary expense of transportation.

The following were noted prisons during the Civil War, 1861–65, for the retention of Federal prisoners of war. Andersonville, Belle Isle, Castle Thunder, Libby and Salisbury. The prison at Andersonville, was notorious for unhealthfulness and its discipline for barbarity; and in 1865, after the close of the war, Henry Wirz, a Swiss, the chief instrument of ill-treatment, was indicted for "injuring the health and destroying the lives of prisoners by subjecting them to torture and great suffering, by confinement in unhealthy and unwholesome quarters, by exposing them to the inclemency of the winter and the dews and burning sun of the summer, by compelling the use of impure water, and by furnishing insufficient and unwholesome food; for establishing the dead line and ordering the guards to shoot down any prisoner attempting to cross it; for keeping and using bloodhounds to hunt down prisoners attempting to escape; and for torturing prisoners and confining them in stocks." He was found guilty and hanged. Under orders of the Government, the place where the bodies had been rudely buried in long trenches was arranged as a cemetery, and adorned with gravel walks and trees; 12,461 dead soldiers of the Union Army were identified, and their places of burial marked with tablets; 451 were "unknown." Prisons were also established for the retention of Confederate prisoners at Camp Douglas, Utah; Chicago, Illinois; Camp Chase, Ohio; Elmira, New York; Point Lookout, Maryland; and Rock Island, Illinois.

PRISONERS OF WAR.—A prisoner of war is a public enemy armed or attached to the hostile army for active aid, who has fallen into the hands of the captor, either fighting or wounded, on the field or in the hospital, by individual surrender or by capitulation. All soldiers, of whatever species of arms; all men who belong to the rising *en masse* of the hostile country; all those who are attached to the army for its efficiency and promote directly the object of the war; all disabled men or officers on the field or elsewhere, if captured; all enemies who have thrown away their arms and ask for quarter, are prisoners of war, and as such exposed to the inconveniences as well as entitled to the privileges of a prisoner of war. Moreover, citizens who accompany an army, for whatever purpose, such as sutlers, editors, or reporters of journals, or contractors, if captured, may be made prisoners of war, and be detained as such. The monarch and members of the hostile reigning family, male or female, the chief, and chief officers of the hostile government, its diplomatic agents, and all persons who are of particular and singular use and benefit to the hostile army or its government, are, if captured on belligerent ground, and if unprovided with a safe-conduct granted by the captor's government, prisoners of war. If the people of that portion of an invaded country which is not yet occupied by the enemy, or of the whole country, at the approach of a hostile army, rise, under a duly authorized levy, *en masse* to resist the invader, they are now treated as public enemies, and if captured, are prisoners of war. No belligerent has the right to declare that he will treat every captured man in arms of a levy *en masse* as a brigand or bandit. If, however, the people of a country, or any portion of the same, already occupied by an army, rise against it, they are violators of the laws of war, and are not entitled to their protection. The enemy's chaplains, officers of the medical staff, apothecaries, hospital nurses and servants, if they fall into the hands of the American Army, are not prisoners of war, unless the commander has reasons to retain them. In this latter case, or if at their own desire, they are allowed to remain with their captured companions, they are treated as prisoners of war, and may be exchanged if the commander sees fit.

By the laws or recognized principles of war, the entire people of a vanquished town, state, or nation become the absolute property of the victors; but civilization has greatly modified this stern rule, and except when a country is devastated for military reasons, it is rare for non-combatant citizens to be subjected to penalties of conquest, beyond the levying of contributions in money or provisions. The combatants who have laid down their arms become prisoners of war. Their lives and liberty are at the disposal of their conquerors, and even in modern times, their lives are sometimes taken, as, for instance, when Napoleon put the Turkish prisoners to death at Jaffa in 1799; otherwise, prisoners of war are kept in confinement until peace ensues, or they are exchanged for prisoners of their conqueror's nation, held in captivity by their own countrymen. It is unusual to subject prisoners of war to penal discipline; but the loss of liberty and hard fare (for, of course, they are allowed no more than a bare subsistence) render a captivity sufficiently irksome. In ancient times, the treatment of prisoners of war was far more severe. In the Greek wars, it was no uncommon thing to put the whole adult male population of a conquered state to the sword, while the women and children were enslaved. Although the putting to death of prisoners became less frequent, they and their families were commonly reduced to slavery to as recent a period as the 13th century. About that time the more humane custom of exchanging prisoners came into practice. Notwithstanding frequent exchanges, large numbers of prisoners accumulate during war. In 1811 about 47,600 French were prisoners in England.

Money and other valuables on the person of a prisoner, such as watches or jewelry, as well as extra clothing, are regarded by the American Army as the private property of the prisoner, and the appropriation of such valuables or money is considered dishonorable and is prohibited. Nevertheless, if *large* sums are found upon the persons of prisoners, or in their possession, they shall be taken from them, and the surplus, after providing for their own support, appropriated for the use of the army, under the direction of the commander, unless otherwise ordered by the government. Nor can prisoners claim, as private property, large sums found and captured in their train, although they had been placed in the private luggage of the prisoners. All officers, when captured, surrender their side-arms to the captor. They may be restored to the prisoner in marked cases, by the Commander, to signalize admiration of his distinguished bravery, or approbation of his humane treatment of prisoners before his capture. The captured officer to whom they may be restored cannot wear them during captivity. A prisoner of war, being a public enemy, is the prisoner of the government, and not of the captor. No ransom can be paid by a prisoner of war to his individual captor, or to any officer in command. The government alone releases captives according to rules prescribed by itself. Prisoners of war are subject to confinement or imprisonment such as may be deemed necessary on account of safety, but they are to be subjected to no other intentional suffering or indignity. The confinement and mode of treating a prisoner may be varied during his captivity according to the demands of safety. Prisoners of war shall be fed upon plain and wholesome food, whenever practicable, and treated with humanity. They may be required to work for the benefit of the captor's government, according to their rank and condition.

A prisoner of war who escapes may be shot, or otherwise killed in his flight; but neither death nor any other punishment shall be inflicted upon him simply for his attempt to escape, which the law of war does not consider a crime. Stricter means of security shall be used after an unsuccessful attempt at escape. If, however, a conspiracy is discovered, the purpose of which is a united or general escape, the conspirators may be rigorously punished, even with death; and capital punishment may also be inflicted upon prisoners of war discovered to have plotted rebelion against the authorities of the captors, whether in union with fellow-prisoners or other persons. If prisoners of war, having given no pledge nor made any promise on their honor, forcibly or otherwise escape, and are captured again in battle, after having rejoined their own army, they shall not be punished for their escape, but shall be treated as simple prisoners of war, although they will be subjected to stricter confinement. See *Cartel*, and *Parole*.

PRITCHET BULLET. — The English retained a wedge made of wood, which was placed in the base of the Pritchet bullet used with the Enfield rifle, and which prevented the gas from penetrating any fissures that might exist, while at the same time it was driven before the gas into the cavity, expanding the ball.

PRIVATE.—The title applied in the British Army to a common soldier of the Cavalry and Infantry, the corresponding rank in the Artillery being gunner or driver, and in the Engineers the sapper. The pay of a private is one shilling a day in the infantry, and 1s. 2d in the cavalry—exclusive of a free ration or corresponding allowance. A private in the cavalry is sometimes called a trooper. In the United States Army all soldiers below the grade of non-commissioned officers are called privates.

PRIVATEER.—A ship owned by a private individual, which, under government permission, expressed by letter of marque, makes war upon the shipping of a hostile power. To make war upon an enemy without this commission, or upon the shipping of a nation not specified in it, is piracy. Privateering was abolished by mutual agreement among European Nations by the Treaty of Paris in 1856. It is doubtful, however, how far that abolition would stand in a general war, for privateering is the natural resource of a nation whose regular navy is too weak to make head against the maritime power of the enemy, especially when the latter offers the temptation of a wealthy commerce. An effort was made at an early period by the government of the United States to have provisions in treaties with foreign countries which would abolish privateering in case of war; and the laws of the United States are more prohibiting in this respect than those of most other nations. At the time of the mutual agreement among European nations to abolish the custom mentioned above, the government declared its willingness to unite with them, provided a certain clause of the treaty was amended so that the private property of the subject or citizen of a belligerent on the high seas should be exempted from seizure by public armed vessels of the other belligerent, except it be contraband of war. But this was declined, and consequently no arrangement with the United States was included in the treaty.

PRIVY COAT.—A light coat or defense of mail, concealed under the ordinary dress.

PRIZE.—Property captured from an enemy, or an enemy's property captured from a neutral in time of war. Prize-money is distributed in the United States in accordance with the provisions of the Act of June 30, 1864. This statute directs that where the prize is equal or superior in force to the capturer the Captors shall have the whole; where it is inferior in force, the Captors shall have half, and the United States the other half. In the case of Letters of Marque and Privateers, the Captors shall have the whole, unless otherwise stipulated in the commissions issued to such vessels. Strictly speaking, *booty* is the military term, the word *prize* being more frequently used in the Navy. See *Blockade*, *Contraband of War*, *Neutrality*, and *Privateer*.

PRIZE AGENTS.—Officers belonging to an army in the field, who are chosen after a campaign to collect all property belonging to the enemy which has fallen into the hands of the victors. In England all military booty is apportioned as the Sovereign from time to time may direct. Deserters, and those who do not claim their share within six years, receive none. The officers appoint two Prize Agents, by letters of attorney: the Field Officers naming one, and the Subordinate Officers another. The Officer commanding the successful expedition sends to the military authorities a list of the persons entitled to booty. The Agents collect the property, convert it into money at the best advantage, and hand over the proceeds to the authorities, receiving a small percentage for their trouble. A scale of distribution is then made out, and the money is paid after a certain interval. When an army and a fleet join in a capture, the Admiralty calculates the army share, and sends the amount to the military authorities. Prize and booty originally belonged to the Sovereign, and are only distributed to the Captors as an act of grace; for, if the Sovereign pleases, the property can be given back again to the enemy.

PRIZE MONEY.—The value of the property captured from the enemy after its realization by sale. To carry out the rules having reference to prize property, Prize Agents are appointed, selected by the army, to collect all property which has been captured in each of the towns and fortresses through which the conquering army has passed. No oppression is permitted in the matter; all that is demanded is that what, by the rules of war, falls to the possession of the captors be given up. Such property is sold, and finally divided among the army.

PROBABILITY FACTORS.—A table of factors, which multiplied by the width of a zone containing 50 per cent. of the hits, will give the widths of zones containing any other percentage of hits. Thus, if the width of a 50 per cent. zone is 1.00, we would find from such a table that the widths of 20, 40, 60, 80, and 99 per cent. zones are .38, .78, 1.25, 1.90, and 3.82 respectively. From such a table, we would also see that a zone twice as wide as that of 50 per cent. will not contain all the hits, but only a little over 82 per cent.

PROBABLE RECTANGLE.—The relative accuracy of different guns at different ranges is estimated by the dimensions of a rectangle, called the *probable rectangle*. If we determine the lateral and longitudinal *probable zones*, and suppose them to be superposed, we shall have a rectangle which must contain 50 per cent, of 50 per cent, or 25 per cent of the total number of hits. Then by reference to a table of *probability factors*, we can find the proportionate widths of any other zones (containing a different percentage of hits) to one of 50 per cent. as unity. To illustrate take the following example:

Suppose a raft, 25 yards square, is fired at by the 40-pr. R. M. L. at an elevation of 5°, how many rounds may be expected to hit, when the range is accurately obtained? Here, the mean error in range is 17.9 yards and the mean lateral deviation is 9.02 yards. Consequently, the 50 per cent. longitudinal zone $=17.9\times1.69=30.25$ yards in width, and the 50 per cent. lateral zone $=9.02\times1.69=15.23$ yards in width. Hence, the zones are respectively $\frac{25}{30.25}=.83$, and $\frac{25}{15.23}=1.64$ of the width of the 50 per cent. zone. From a table of *probability factors*, we find, that a zone .83 the width of the 50 per cent. one would receive about 42.5 per cent., and one of 1.64 would have 73 per cent. of the total number of rounds fired. Consequently the rectangle formed by the intersection of the zones would receive 42.5 per cent. of 73 per cent., or 31 per cent. of the total fired.

PROBABLE ZONES.—It can be shown by the theory of probabilities, that if each of the three mean errors (range-vertical and lateral) is multiplied by the factor 1.69, we will have the breadth of three zones (of infinite length), each of which will contain 50 per cent. of the hits. If the mean errors in two directions are given, we can find two 50 per cent. zones, and hence a rectangle, in the plane of the zones, which must contain 50 per cent. of 50 per cent., or 25 per cent. of the total number of hits.

PROCEEDINGS.—The proceedings of Courts-Martial of the previous day are usually read over each day by the Judge Advocate. Much time is lost by adopting this measure, and there is no rule directing the Court to read them. All *orders* which have been issued, modifying the detail of a Court, after its original organization, should be included in the proceedings of every case. The *entire proceedings* of the Court in each case should be fully set forth. All orders, motions, or rulings of the Court itself—all motions, propositions, objections, arguments, statements, etc., of the Judge Advocate and the prisoner —the entire testimony of each witness, given in his own language—and, indeed, every feature of the proceedings material to a complete history of the case and to a correct understanding of every point of the same by the reviewing authority—should be recorded at length. The record of proceedings, and the final defense of the accused, should be written upon legal-cap paper of uniform size. The proceedings in each completed case should be immediately signed by the President and Judge Advocate. *Recommendations to Clemency* should not be placed in connection with the sentence, but should be appended to the record. The *original proceedings* of a Court are not the rough minutes kept by the Judge Advocate or Recorder; but those finally authenticated by the signatures of the President and Judge Advocate (or recorder). All documentary evidence submitted to the Court must be attached to the proceedings, lettered in the order of submission, as Exhibits "A," "B," etc.

PROCLAMATION.—A public notice given by the Sovereign to his subjects. The power of issuing proclamations is part of the prerogative of royalty as the fountain of justice. They sometimes consist of an authoritative announcement of some matter of state, or act of the executive government affecting the duties and obligations of subjects. The demise of the Crown, and accession of a new Sovereign, a declaration of war, and the issue of new coin, are all occasions on which a royal proclamation is issued. A proclamation may also be issued to declare the intention of the Crown to exercise some prerogative or enforce some law which has for a long time been dormant or suspended. In time of war, the Crown by a proclamation may lay an embargo on shipping, and order the ports to be shut. But the most usual class of proclamations are admonitory notices for the prevention of offenses, consisting of formal declarations of existing laws and penalties and of the intention to enforce them; such as the proclamation against vice and immorality, appointed to be read at the opening of all courts of quarter sessions in England. Proclamations are only binding when they do not contradict existing laws, or tend to establish new ones, but only enforce the execution of those which are already in being, in such manner as the Sovereign judges necessary.

PROCONSUL.—A Roman Magistrate not holding the Consulship, who was invested with powers nearly approaching those of a Consul, not however, extending over the city and its vicinity. The Proconsul was, at first, one who had held the office of Consul, whose *Imperium* was prolonged to enable him to bring an unfinished campaign to a close. The duration of the office was a year. During the latter period of the Republic, when the Consuls were expected to spend a year of their consulate at Rome, they were generally appointed at its close to undertake, as Proconsuls, either the conduct of a war in some Province, or its peaceful administration. Occasionally, the office of Proconsul, with the government of a Province, was conferred on a person who had never held the Consulship. Under Constantine, parts of certain Dioceses came to be governed by Proconsuls.

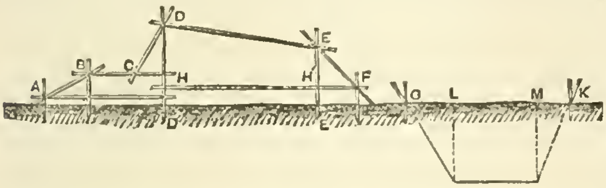
PRODD.—A light cross-bow, used chiefly in field sports, in the sixteenth century. It usually projected bullets.

PROFESSORS OF THE UNITED STATES MILITARY ACADEMY.—The Professors of the Academy, being Staff Officers of the Army, are assimilated in rank to the grades of which they are entitled by law to the pay and allowances. They are respected and obeyed according to their rank and office in the Academy. The uniform of Professors is that of officers of the General Staff of the Army of their assimilated rank, with the letters M. A. on the shoulder-knot. Or they may at their option wear a citizen's blue cloth coat, with buttons of the General Staff of the Army; black dress hat; pantaloons and vest plain, white or dark blue; cravat or stock, black. The uniform of the Chaplain is that prescribed for Chaplains in the Army. See *United States Military Academy*.

PROFILE-BOARDS.—Boards employed in the inspection of cannon for measuring distances in front and rear of base line. Their lower edges are adapted to the shape of the gun, and the upper ones are parallel to the axis of the bore. The distances from the base line of the several parts, and of points at which diameters are to be measured are laid off accurately on the upper edge, and then marked in lines perpendicular to it on the sides and lower edges of the profile. An iron strap is attached to the upper edge to prevent warping, and the whole is well coated with shellac-varnish to keep it from absorbing moisture.

The following instruments are used in connection with the profile-boards: A *rule*, for verifying the marks, of such a length that not more than one fleeting may be necessary, and to be graduated decimally according to the standard. A small *square* of steel, to be used in referring the marks on the board to those on the rule. A *steel straight edge*, long enough to extend across the muzzle-face and several inches on the board, used to ascertain the extreme length from base to muzzle. It is also used for the same purpose at the extreme end of the cascabel. A steel *scratcher*, to mark the gun at points, not otherwise indicated, where diameters are to be measured. See *Inspection of Ordnance*.

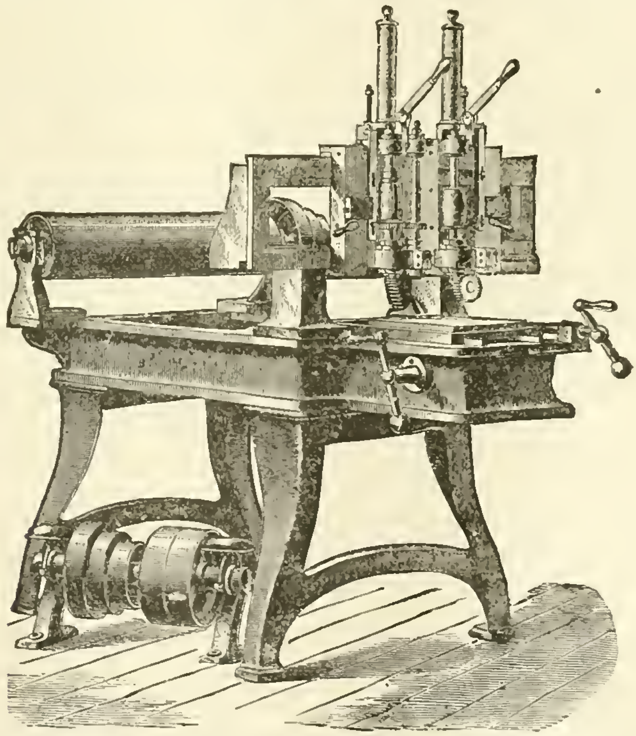
PROFILING.—An operation in the construction of field works which consists in erecting at proper points along the sub-crests, wooden *profiles* which give the form of the parapets at those points, and which guide the workmen in the construction of the works. Profiles are placed at the extremities of a parapet; at points along the sub-crest from twenty to thirty yards apart; at the salients and re-entrants; and at any points where a change of direction or dimensions are to be made. The profiles or poles having been planted at the angles of the work, and the height of the interior crest marked on them, a line is traced on the ground with a pick, showing the direction of the interior crests. When the ground is sensibly level, lines perpendicular to the direction of the interior crest are traced upon it, at suitable distances, from twenty to thirty yards apart, to mark the positions



of the profiles, and the horizontal distances for the thickness of the parapet; the bases of the slopes, etc., are set off on these lines. But when the ground along the direction of the profile is undulating, or slopes in either direction, cords are stretched above the surface, in a horizontal line, between two stout pickets, in the direction of the profiles, and so as to include all of its lines. This cord serves to measure the horizontal distances on, and to find the points of the profile, above and below it, by means of an ordinary plummet. A stout square picket is driven firmly into the ground, where the cord crosses above the pick-line, and a slip of pine, on which the height of the interior crest is marked, is nailed to the picket. The thickness of the parapet is measured on the cord, and a picket driven into the ground to mark the point. The base of the interior slope, and the tread of the banquette, are set off in a similar manner; and a slip of deal is nailed to each of the pickets. The height of the interior crest, and the tread of the banquette, are easily ascertained, from the position of the cord and the interior crest; these points having been marked on their respective slips, the outline of the parapet is shown by connecting them by other slips, which are nailed to the uprights; the banquette slope and exterior slope will be determined by a similar process.

From the profiles thus formed perpendicular to the interior crests, the oblique profiles at the angles can readily be set up, by a process which will suggest itself without explanation. Having completed the profiling, the foot of the banquette, and that of the exterior slope, are marked out with the pick, and also the crests of the scarp and counterscarp. All the arrangements preparatory to commencing the excavation are now complete. See *Field-fortification, Normal Profile, Parapet*, and *Tracing*.

PROFILING MACHINE.—A machine much used in armories, and by which an object of a given contour or outline may be duplicated; or one by which any given profile may be given to a piece by adequate manipulation of the parts, in the absence of the pattern which forms an automatic guide for the tool. In the former case, the machine is used for duplicating templets, gauges, and patterns (now much used in making various machines) in great numbers to an



exact size and proportion, to be afterwards assembled. Fire-arms, sewing-machines, watches, and many other articles are thus made.

The drawing shows a two-spindle profiling machine, as manufactured by the Pratt & Whitney Company, who make a specialty of gun machinery. It is built with or without Parkhurst's device for cutting formers without reversing the fixtures. With this improvement, to produce the forming pattern, the model piece is secured in the place and position afterward occupied by the work to be machined, and the piece to be cut for the forming pattern is placed in the position it will permanently retain. The guide-pin is put in the spindle which usually carries the cutter, and follows the outline of the model piece, while the cutter, in the spindle, which afterward holds the guide-pin, cuts the forming pattern in the exact position it will retain in use. After disconnecting the gearing upon the spindles, reversing the relative positions of the guide-pin and cutter, and smoothing the edge of the forming pattern (if this be necessary), the machine is ready for work. The gearing for moving the table and cross-slide is adjustable by means of double gears, set to prevent back-lash by two independent adjusting screws, and also by a double rack adjusted in the same manner. This arrangement is indispensable to secure perfect accuracy in cutting irregular forms, especially in turning corners. The No. 1 two-spindle machine has an area of table of 10½ by 8 inches, distance between top of table and under side of cross-head 3 inches, and distance between center of guide-pin and cutter also 3 inches. Weight, 1,350 pounds. Speed of countershaft, with 9 by 2¼ inch tight and loose pulleys, 125 revolutions per minute. The No. 2 two-spindle machine has an area of table of 15 by 12 inches, distance between top of table and under side of cross-head 4½ inches, and between centers of guide-pin and cutter 4½ inches. Weight, 2,600 pounds. Speed of countershaft, with 14 by 3 inch tight and loose pulleys, 140 revolutions per minute. The cutter will profile or surface work to the extreme limit of the table area. The height between table and cross-head may be increased, if so required. The machine may be constructed with one to three spindles, running in one adjustable head sliding on the cross-head. See *Edging-machine.*

PROGRESSIVE POWDER.—The excellent results obtained in Italy with what was termed "Progressive Powder," suggested the advisability of making trials of similar powders in some of the United States larger calibers, all of which have resulted satisfactorily. Progressive powder is fabricated as follows: After passing through the first stage of manufacture, and being brought to the condition of mealed powder, it is pressed into cakes which have a density of 1.79; the cake is broken up into irregular grains of from 0.3 in. to 0.6-in. in thickness, as is required, which are not to be glazed. These grains are mixed with 40 per cent. of mealed powder, taken from the same working as that from which the grains themselves are made, and the whole mass pressed into a cake having a less density than the original small grains, say 1.75. The cake is then granulated as may be prescribed. Each grain of the resulting powder is thus a conglomerate grain, consisting of one or more small grains of very dense powder imbedded in a mass of less density, the mean density being 1.75. The theory of the combustion of this powder is that the powder of less density being more quickly consumed, the whole charge breaks up into a much greater number of smaller grains, thereby exposing a greatly increased surface to the action of the flame. In using this powder that size of the regular-shaped grains is employed most suitable to the caliber of the gun, and is mixed with a certain proportion, to be determined by experiment, of the powder of irregular or mammoth grain. See *Fossano Powder,* and *Gunpowder.*
