
FLOOD ROCK EXPLOSION, OCTOBER 10, 1885.

LOCATION OF CAMERA 1,200 FEET WEST OF THE EXPLOSION. EXPLOSIVE USED 240,399 POUNDS OF RACKAROCK THE PRIMERS USED CONTAINED 42,331 POUNDS OF DYNAMITE No. 1, AND 240 POUNDS OF FULMINATE AREA OF EXPLOSION 9½ ACRES

FARROW'S

MILITARY ENCYCLOPEDIA

A DICTIONARY OF MILITARY KNOWLEDGE

ILLUSTRATED

WITH MAPS AND ABOUT THREE THOUSAND WOOD ENGRAVINGS

BY

EDWARD S. FARROW, U. S. ARMY,

LATE ASSISTANT INSTRUCTOR OF TACTICS AT THE UNITED STATES MILITARY ACADEMY,
WEST POINT, NEW YORK

"What is obvious is not always known, and what is known is not always present."—JOHNSON.

COMPLETE IN THREE VOLUMES. VOLUME III.

NEW YORK:
PUBLISHED BY THE AUTHOR,
240 BROADWAY.
1885.

DEDICATED

TO THE

NATIONAL GUARDS OF AMERICA

In Appreciation of their Enterprise and Valor

AND AS A TRIBUTE OF HOMAGE

TO

GALLANT SOLDIERS.

PREFATORY NOTICE.

The design of this work is that of a Library of Military Knowledge for the People—not a mere collection of elaborate treatises in alphabetical order, but a work to be readily consulted as a Dictionary on every military subject on which people generally require some distinct information—no article being longer than is absolutely necessary. The several topics are not handled with a view to the technical instruction of those who have to make a special study of particular branches of military knowledge or art. The information given may be characterized in many instances as *non-professional*, embracing those points of the several subjects which every intelligent man or woman may have occasion to speak or think about. At the same time every effort is made that the statements, so far as they go, shall be precise and scientifically accurate.

Although about 30,000 subjects have been compiled from the various publications and records of the War Department, Foreign War Offices, and Military Works of reference, more than 5000 original articles have been prepared by specialists in America and abroad. While the Tactics, Ordnance, Gun Machinery, Implements, and Equipments of all ages and of all military powers have been fully described and illustrated under appropriate headings, a complete system of cross-references enables the military student to quickly locate several hundred articles pertaining to the general subject under investigation. Thus, under the article Magazine Gun will be found the following references: *Boch*, *Buffington*, *Bullard*, *Burgess*, *Burton*, *Chaffee-Reece*, *Clemmons*, *Colt*, *Dean*, *Elliott*, *Franklin*, *Hunt*, *Lee*, *Lewis-Rice*, *Miller*, *Remington*, *Russell*, *Spencer-Lee*, *Springfield-Jones*, *Tiesing*, *Trabue*, *Whitney*, and *Winchester Magazine Guns*. Under each of these articles are references to articles describing and illustrating all other arms of the respective classes. The Compiler has made special effort to set forth in detail the numerous decisions, rendered by the War Department and Tactical Department at West Point, on the tactical points raised and submitted from time to time by the Officers of the Army and National Guard. The descriptions and illustrations of more than 500 varieties of Gun Machinery, Steam Hammers, Cranes, etc., constitute a novel feature of the work to be appreciated by those wishing to investigate the subjects of construction, testing, etc.

The original plan has been strictly adhered to throughout; and if, as the work proceeded, there has been any change in the method or quality of the execution, it may at least be affirmed that the change has not been for the worse. After some experience, it became easier to find the person specially qualified to write a particular kind of article, and thus the circle of contributors became widened, and the distribution of the work more specialized. It was also seen to be desirable, in regard to certain classes of subjects, to admit a rather ampler selection of heads. This has been effected without increasing the scale of the work, not so much by less full treatment of the subjects, as by increased care in condensing the statements and omitting everything superfluous. A great quantity of matter pertaining to Foreign Armies has been introduced in this work, so as to enable the military student to compare the organization, arms, etc., of all armies with those of his own service. The Encyclopedia contains also descriptions of ancient armor, and of arms, lately in use, which have become obsolete, as it may be of some interest to follow the changes which have taken place in the mode and means of fighting from the earliest period down to the present time. The insertion of veterinary terms and of remedies for the common complaints of horses will be found useful under conditions where a Veterinary Surgeon is not available, as is often the case in detached parties of Cavalry. A description of all tools and machines found commonly in workshops may prove acceptable to Departmental Officers on their first joining Government Manufacturing Establishments.

Of the Sciences, the least adapted to encyclopedic treatment is Mathematics. All terms of common occurrence in Gunnery, Reconnoissance, etc., however, have been introduced, and a brief exposition of the subjects given, as far as could be done in an elementary way. Natural Philosophy has received ample attention, and all the leading doctrines and facts of general interest will be found under their appropriate heads, treated in a popular way, and divested as far as possible of the technicalities of mathematics. Chemistry, some knowledge of which is becoming daily more indispensable in all departments of military life, receives a comparatively large space. Prominence has been given to those points of the subject that have either a direct practical military bearing or a special scientific interest. During the progress of the work, several changes in the nomenclature and notation of the Science have come into general use; these have been duly noted under the appropriate headings. The new and far-reaching doctrines of the Correlation of Forces and the Conservation of Energy have produced vast changes in the nomenclature and classification of the various sections of Military Physics; while the more complete investigations into the phenomena and laws of light, heat, motion, and electricity have created virtually new sections, which must find a place in any adequate survey of scientific progress. Mechanical invention has, indeed, so kept pace with the progress of Military Science and the Art of War, that in almost every department of Physics improved machines and processes have to be described, as well as new discoveries and altered points of view. The manufacture of gunpowder and high explosives is a signal instance of the extent to which in our day scientific discovery is indebted to appropriate machinery and instruments of observation and analysis. These extensive changes in Physics involve corresponding changes in the method of their exposition. The scientific department of the work is consequently treated in all its branches in the most effulgent manner, and over 1000 very fine engravings are used for the purpose of illustration.

True to its projected plan as a LIBRARY OF MILITARY KNOWLEDGE FOR THE PEOPLE, this Encyclopedia will be found to be especially rich in notices of miscellaneous military matters. Some of the subjects introduced might perhaps be considered beneath the dignity of a book aspiring to a more severely scientific character; but all of them are, if not instructive, at least curious or entertaining, and likely to occur in the course of reading or conversation. During the progress of the work, the Compiler has received numerous assurances from parents as to how highly it was prized, even though only partly issued, by their sons at Military Schools, as a repertory of the kind of things they are constantly in search of and often puzzling their elders about. This use of the Encyclopedia has been steadily kept in view; and it is gratifying to learn that it is found efficiently to serve the purpose intended.

In conclusion, the Compiler asks the indulgence of Military Critics wherever errors or discrepancies have crept into this work, and begs to acknowledge the valuable help obtained from the works of many authors, both military and scientific, through the courtesy of Messrs. John Wiley & Sons and Mr. D. Van Nostrand, publishers, and the assistance he has received from various friends. To General Stephen V. Benét, Chief of Ordnance, United States Army, he is especially indebted for courteous assistance in the preparation of the work. To economize in space and to avoid crowding up the text, the name of the author from whom information has been derived has not been inserted after each quotation; but a list of all works which have been consulted, and from which extractions have been made, will be found at the commencement of each volume.

It is intended, with the view of meeting the changes which are constantly taking place in the *matériel* of armies, new processes, military inventions, etc., to issue a Supplement at suitable intervals, containing all alterations and additions.

Vive le Roi. (Fr.) Long live the King.
Voilà. (Fr.) See there; behold.
Vox, et præterea nihil. (L.) A voice, and nothing more.
Vox populi, vox Dei. (L.) The voice of the people is the voice of God.

INDEX OF MATTERS NOT HAVING SPECIAL ARTICLES.

At the close of Volume III. will be found an Index of Subjects not having Special Articles. It has not been thought necessary to repeat in this Index the titles of the many thousand articles composing the body of the work. A person consulting the Encyclopedia is supposed, in the first instance, to look for the subject he is in quest of in its proper alphabetical place. If it is not to be found there, or by a *cross-reference*, by turning to the Index he is likely to get a reference to it under another name, or as coming in for notice in connection with some other subject. It frequently happens that subjects, having articles of their own, are further noticed under other heads; and where it seemed of importance, a reference is given in the Index to this additional information. The title of the article referred to is printed in *italics;* and when the article is of considerable length, the page is given in which the information is to be found.

CONTINUED REVISION.

The process of revising Farrow's Military Encyclopedia is constantly carried on, thus keeping up the information to the latest possible date. These revisions and additions will be supplied every few years in the shape of Supplements. A few blank pages are inserted at the close of each volume for the purpose of noting the reference to the various articles in the Supplements, which would naturally find alphabetical arrangement in the respective volumes.

SABANDER.—The familiar of Shah-bander, an Eastern title for Captain or Governor of a post.

SABANTINES.—Steel coverings for the feet. The term is frequently applied to slippers and clogs also.

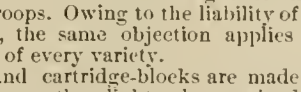
SABARCANE.—The Malays, and also the savages of Borneo, discharge their arrows and light darts through a long tube, called the *sabarcane*, by applying the tube to their lips and blowing through it. In this manner, they strike objects at great distances, with great force, and with astonishing precision of aim.

SABBATONS.—A round-toed armed covering for the feet, worn during a part of the Sixteenth Century.

SABLE.—One of the tinctures in Heraldry, implying black. In heraldic engravings it is represented by perpendicular and horizontal lines crossing each other.

SABOT.—*Sabots* are circular blocks of wood, fastened with tin straps to hollow projectiles for smooth-bore guns. Their object is to prevent the projectile from turning in the bore and bringing the fuse in contact with the charge of the piece. The diameter of the sabot corresponds to that of the projectile; it has a shallow dish-shaped cavity for the projectile to rest in, and is always attached to the side opposite the fuse-hole. When the piece is fired, the fragments of the sabot fly a short distance from the muzzle; consequently it is dangerous to use this kind of ammunition when firing over the heads of our own troops. Owing to the liability of premature explosions, the same objection applies to hollow projectiles of every variety.

Sabots and cartridge-blocks are made of poplar, bass-wood, or other light, close-grained wood; it must be well seasoned and should be clear of knots and splits. The assistant saws the scantling to the proper length for a sabot, roughs it out, and marks its center. The turner puts it in a lathe and turns, first, the exterior and grooves, and then the cavity for the projectile. The holes for the handles are bored with a bit, and countersunk on the inside to receive the knot on the end of the cord. Distance between them, for shells is 1.5 inch; for canisters, 2.3 inches. Length of cord for handles, for shells



12 inches; for canisters, 20 inches; diameter of cord, .15 inch. The cartridge blocks and sabots for shot and spherical case-shot for guns have one groove, (*a*). Sabots for gun-canisters and mountain-howitzer shells, spherical case-shot, and canister have two grooves, (*b*). All the grooves are .3 inch wide and .15 inch deep. They are .8 inch apart, from center to center, for guns, and .5 for the howitzer. The corners and bottom of the grooves are slightly rounded. The dimensions of finished sabots and blocks are verified with appropriate gauges. One man can make 350 sabots for 12-pounder gun, or 300 sabots for howitzer, or 600 cartridge-blocks, small charge, or 700 cartridge-blocks, large charge.

In siege and garrison service, sabots are required for the 8-inch canisters, for siege-howitzer, and all shells and spherical case-shot for smooth-bore guns. For canisters and the smaller guns, the sabots are turned in a lathe; for the larger calibers they are sawed from thick pine or poplar planks, and the cavity cut in a lathe; or the cavity is first cut by a tool of the proper curvature, and the sabot afterward sawed out with a circular saw. One man can make 350 sabots for a 10-inch columbiad in 10 hours; or 400 sabots for an 8-inch columbiad.

In positions where the pieces of sabots might prove dangerous to our own troops, as in firing over their heads when making an attack, sabots made of thick shavings of soft wood or pasteboard are used. For this purpose select black-walnut, pine, or fir, not too dry, and as free as possible from knots. Pieces of the proper length and width are dressed out, and by means of a coarse plane, shavings are cut .06 inch in thickness. Each shaving is rolled in a circle on a cylinder of iron, in which a longitudinal groove is cut. One end is thinned down, moistened and inserted in the groove, and the shaving is rolled on the cylinder, the smooth side turned outward; one man turns the cylinder by a crank, making three revolutions, the other holds the shaving so as to roll it evenly on itself, pulling it tight.

The different turns are then tacked together, the tacks being riveted on the inside against the iron cylinder; the end is thinned down with a rasp, and the sabot taken from the cylinder is immersed in a warm bath of thin glue. Pasteboard may be used instead of shavings of wood. The sabot is attached to the shell by means of four pieces of tape 1 inch wide. Each piece is folded around the sabot, and the ends sewed together; the seam is turned on the inside of the sabot, and is made fast to it by tacks, the four pieces of tape being attached to the sabot at the extremities of two diameters perpendicular to each other. The sabot is laid down on the table and the shell placed in it, the fuse-hole down; the ends of the tape are then drawn together and tied on top of the shell with a piece of strong twine. See *Field and*

Mountain Ammunition, Siege and Garrison Ammunition, and *Stand of Ammunition.*

SABRE.—A heavy sword, with which cavalry and dragoons are armed. The back is thick, that a blow may carry the more force, and also to render the weapon useful in the rough thrust of the cavalry charge. A saber is occasionally curved at the point, in the form of a cimeter. See *Hand-arms.*

SABRE EXERCISE.—When performing this exercise, the squad should be armed only with the saber, and placed in single rank. The object of the moulinets is to give suppleness to the wrist, which increases the dexterity and confidence of the men. Each lesson is begun and ended with the moulinets, executed with a quickness proportioned to the progress of the men, remembering that force is less necessary than skill. In teaching the saber exercise on foot, special reference must be had to its application when mounted. To this end, recruits are not to lean to one side, which would derange their seats on horseback; nor direct the blade so as to strike the hand, closed, six inches from the body, and as high as the elbow, fingers toward the body, little finger nearer than the thumb (position of the bridle-hand); at the same time place the right hand in tierce in front of and a little higher than the right hip, thumb extended on the back of the gripe, little finger by the side of the others, the point of the saber inclined to the left, and two feet higher than the hand, which grasps the saber without constraint. To return to the *carry*, the Instructor commands; 1. *Carry*. 2. SABER. At the command *saber*, the recruits resume the position of the soldier, and come to the *carry*. The saber exercise is taught in the following order, and by the following commands, all the movements being executed from *guard*. 1. *Left*, 2. MOULINET. Extend the arm obliquely to the left and front to its full length, the hand in tierce and as high as the eyes, the point of the saber to the front, and a little higher than the hilt. (Two.) Lower the blade, edge to the front, and make rapidly a circle around the hand, to the left of and near the horse's neck, the blade pass-

Fig. 5.

Fig. 6.

head or haunches of the horse, or the knees of the rider. All cuts, when not executed by motions, are terminated by a half moulinet, so as to bring the saber to the position of *guard.* The thrust requires less force, and its result is more prompt, sure and decisive than the cut. The saber is held in the full grasp, and in all motions in the saber exercise, except *right point* and *rear point*, the thumb is extended along the back of the gripe, and pressed against the guard. During the first lessons the Instructor takes care to rest the men from time to time, and to always give his explanations when the squad is at a *carry*, only keeping the arm extended long enough to correct faults.

The files being opened to at least three yards' interval, and the sabers at a *carry*, the Instructor commands: *Guard.* Carry the right foot about two feet to the right, heels on the same line: place the left ing close to the left elbow; return to the first position. (THREE.) Resume the guard, Fig. 1. 1. *Right*, 2. MOULINET. Extend the arm to the front to its full length, the hand in quarte, and as high as the eyes, the point to the front, and a little higher than the hilt. (Two.) Lower the blade, edge to the front, make rapidly a circle around the hand, to the right of and near the horse's neck, the blade passing close to the right elbow; return to the first position. (THREE.) Resume the guard, Fig. 2. To combine the execution of the preceding moulinets. 1. *Left and right* (or, *right and left*), 2. MOULINET. Execute the left moulinet; turn the wrist without pausing, and then execute the right moulinet. 1. *Rear*, 2. MOULINET. Raise the arm to the right and rear to its full extent, the point of the saber upward, the edge to the right, the body slightly turned to the right. (Two.) Begin by moving the point of the saber toward the left, and describe a circle in rear. (Three.) Resume the guard, Fig. 3. In executing the moulinets, the right arm is kept as steady as possible in position, the saber being controlled by motions of the wrist and hand. When the men execute the moulinets well, the Instructor requires them to execute several in succession without pausing, until the command *guard*. 1. *Tierce*, 2. Point. Raise the hand in tierce as high as the eye, throw back the right shoulder, carrying the elbow to the rear, the point of the saber to the front, the edge upward. (Two.) Thrust to the front, extending the arm to its full length, edge up. (Three.) Resume the guard, Fig. 4. 1. *Quarte*, 2. Point. Lower the hand in quarte near the right hip, the point a little higher than the wrist. (Two.) Thrust to the front, extending the arm to its full length. Three.) Resume the guard, Fig. 5. 1. *Left*, 2. Point. Turn the head and shoulders to the left, draw back the hand in tierce toward the right and near the right shoulder, the hand at the height of the neck, the edge of the blade upward, the point to the left and as high as the hand. (Two.) Thrust to the left, extending the arm to its full length. (Three.) Resume the guard, Fig. 6. 1. *Right*, 2. Point. Turn the head to the right, carry the hand in quarte near the left breast, the edge of the blade upward, the point to the right and as high as the hand. (Two.) Thrust to the right, extending the arm to its full length. (Three.) Resume the guard, Fig. 7. 1. *Rear*, 2. Point. Turn the head and shoulders to the right and rear, bring the hand in quarte near the left breast, the point to the rear and as high as the hand, the edge upward. (Two.) Thrust to the rear, extending the arm to its full length. (Three.) Resume the guard, Fig. 8. 1. *Against infantry*, 2. *Left*, 3. Point. Same as left point, except the point is downward. (Two.) Thrust down in tierce. (Three.) Return to the position of guard, Fig. 9. *Against infantry*, 2. *Right*, 3. Point. Same as quarte point turning the head and shoulders to the right, inclining the point downward. (Two.) Thrust in quarte. (Three.) Resume the guard, Fig. 10. 1. *Against infantry*, 2. *Front*, 3. Point. Bend well down to the right, extend the right arm well downward, the hand in rear

Fig. 7.

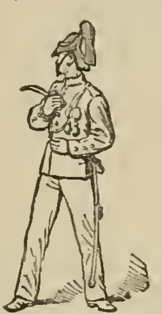

Fig. 8.

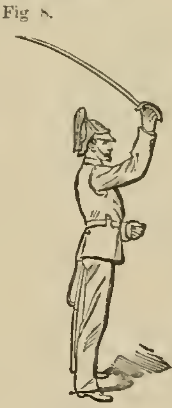

Fig. 12.

Fig. 13.

of the thigh, the back of the saber upward. (Two.) Thrust forward. (Three.) Resume the guard, Fig. 11. 1. *Front*, 2. Cut. Raise the saber, the arm half extended, the hand in front of the right shoulder, and and a little higher than the head, the edge upward, the point to the rear, and higher than the hand. (Two.) Cut, extending the arm to its full length. (Three.) Resume the guard, Fig. 12. The first position of *front cut* is the position of *raise saber*. Being at *raise saber*, to *carry saber*, the Instructor commands: 1. *Carry*, 2. Saber. 1. *Left*, 2. Cut. Turn the head and shoulders to the left, raise the saber, the arm extended to the right, the hand in quarte and as high as the head, the point higher than the hand. (Two.) Cut diagonally to the left. (Three.) Resume the guard, Fig. 13. 1. *Right*, 2. Cut. Turn the head to the right, carry the hand opposite the left breast, the point of the saber upward, the edge to the left. (Two.) Extend the arm quickly to its full length, and give a back-handed cut horizontally. (Three.) Resume the guard, Fig. 14. The *left* and *right cuts* are used against infantry, inclining the body forward, and cutting at the required angle. 1. *Rear*, 2. Cut. Throw the right shoulder well back, and execute the first motion of *right cut*. (Two.) Extend the arm quickly to its full length, and give a back-handed cut horizontally to the rear. (Three.) Resume the guard, Fig. 15. 1. *Left in quarte and tierce*, 2. Cut. Execute the first motion of *left cut*. (Two.) Execute the second motion of *left cut*. (Three.) Turn the hand in tierce, and cut horizontally. (Four.) Resume the guard. 1. *Right in tierce and quarte*, 2. Cut. Execute the first motion of *right cut*. (Two.) Execute the second motion of *right cut*. (Three.) Turn the hand in quarte, and cut horizontally. (Four.) Resume the guard. 1. *Rear in tierce and quarte*, 2. Cut. Execute second motion of *rear cut*. (Three.) Turn the hand in quarte, and cut horizontally. (Four.) Resume the guard. *Tierce*, 2. Parry. Carry the hand quickly a little to the right, point of the saber as high as the eyes, and opposite the right shoulder, edge to the right. (Two.) Resume the guard. 1. *Quarte*, 2. Parry. Turn the hand in quarte, and carry it opposite the left breast, edge of the blade to the left, point to the front, as high as the eyes, and a little to the left of the left shoulder. (Two.) Resume the guard. 1. *Left*, 2. PARRY. Raise the hand above and six inches in front of the eyes, the elbow somewhat bent, edge of the blade to the left, point downward, and parry the blow aimed at the left side. (Two.) Resume the guard. 1. *Left head*, 2. PARRY. Raise the saber quickly above the head, the right arm vertical, edge upward, point to the left and twelve inches below the guard. (Two.) Resume the guard. 1. *Right head*, 2. PARRY. Raise the saber quickly above the head, edge up, point to the left and higher than the hand, the right forearm nearly vertical. (Two.) Resume the guard. 1. *Against infantry*, 2. *Left*, 3. PARRY. Turn the head and shoulders to the left, raise the saber, the arm extended upward to the front and left, the hand in tierce, back of the blade to the front, point upward. (Two.) Describe a circle quickly on the left, from front to rear, parallel to the horse's neck, the arm extended; turn aside the bayonet with the back of the blade, bringing the hand, still in tierce, above the left shoulder. (THREE.) Resume the guard. Fig. 16. 1. *Against infantry*, 2. *Right*, 3. PARRY. Turn the head to the right, throwing back the right shoulder, raise the saber, the arm extending upward to the right and rear, the hand in tierce, edge of the blade to the left, point upward. (Two.) Describe a

Fig. 14.

Fig. 15.

Fig. 16.

Fig. 17.

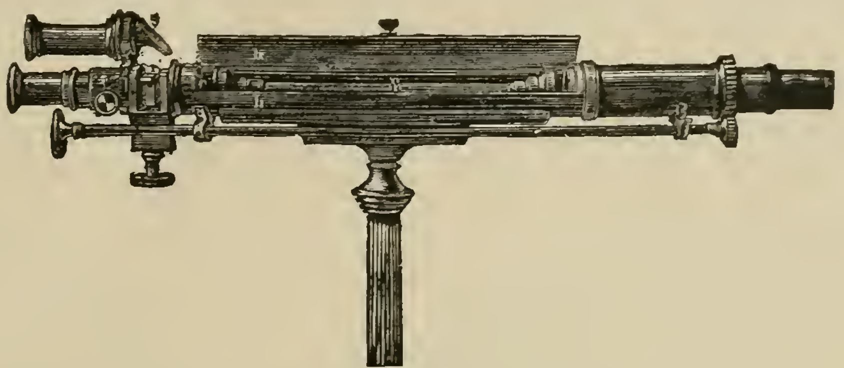
circle quickly on the right from the rear to front, the arm extended; turn aside the bayonet with the back of the blade, bringing the hand as high as the head, point upward. (THREE.) Resume the guard. Fig. 17. When the recruits begin to execute correctly the above cuts, thrusts, and parries, the Instructor requires them to make application of them by combined motions, such as: 1. *In tierce point and front*, 2. CUT. 1. *In quarte point and front*, 2. CUT. 1. *Left point and right* (or *left*), 2. CUT. 1. *Right point and left* (or *right*), 2. CUT. 1. *Rear point and rear*, 2. CUT. 1. *Against infantry, right point and right*, 2. CUT. 1. *Against infantry, left point and left*, 2. CUT.

Thrusts are preferable to cuts, as wounds made by cuts are generally trifling compared with those made by thrusts. Great attention must be paid to the position and balance of the body, as, by too great an exertion in giving a cut or thrust, a man may be thrown or so unsettled in his seat as to lose the advantage of his skill; he must depend upon his parries, and not trust to avoiding the attack of the enemy by turning or drawing back his body. In giving a forward thrust or cut, with the horse in rapid motion, very little force is required, as the impetus of the horse makes it effective. Choose the point of attack, and avoid if possible attacks made upon the left rear; in the latter case a change of position can alone place a man upon an equality with his opponent. This relative change may be effected by making a sudden halt, allowing an adversary to pass, or by turning quickly to the left about, bringing him on the right. If a man cannot do this, he is forced to keep on the defensive, being unable to make effective blows, and must crowd up to his opponent, whose cuts would otherwise tell.

In meeting an enemy on the left front, a man should turn sharply to the left on his own ground, bringing his right arm in position to act upon the enemy's left. In meeting him on the right front, press quickly on, and by a sharp turn to the right gain his left rear. If pursued, keep an adversary on the right rear; when attacked by more than one, try to keep them either to the right or to the left, but, should they succeed in placing themselves on each side, press close to the one on the left, and endeavor to keep the one on the right at a distance. The lance is parried like the saber. A man must close upon his enemy at once, and try to gain his right rear, where he is least able to attack or to defend himself; the same is true if he be armed with the bow and arrow. In pursuit, always approach at the right rear. When opposed to infantry, endeavor to meet an opponent on the right. See *Cuts*, *Fencing*, *Guard*, *Moulinets*, *Parry* and *Points*.

SABRETACHE.—A useless square accouterment which dangles against the legs of officers in some cavalry regiments. It purports to be a pocket for the conveyance of dispatches, etc., but probably is never used. The sabertache is hung by smaller ornamental belts from the sword-belt, and is itself covered with gold brocade, the emblems of the regiment and other devices.

SACCHARIMETER.—An apparatus based upon the rotary power of liquids, for analyzing saccharine substances. The instrument, as shown in the drawing, is made by Messrs. Richards & Co., New York, and is used by the United States Government in the Subsistence Department, and in the Custom House Laboratories. The principle of this instrument is not the amplitude of the rotation of the plane of polarization, but that of *compensation;* that is to say, a second active substance is used, acting in the opposite direction from that analyzed, and whose thickness can be altered until the contrary action of the two substances completely neutralize each other. Instead of measuring the deviation of the plane of polarization, the thickness is measured which the plate of quartz must have in order to obtain perfect compensation. The apparatus consists of three parts —a tube containing the liquid to be analysed, a polarizer, and an analyser. In making the analysis of raw sugar, before issuing to troops, a normal weight of 16.471 grains of sugar is taken, dissolved in water, and the solution made up to 100 cubic centimeters, with which a tube 20 centimeters in length is filled, and the number indicated by the vernier read off, when the *primitive tint* has been obtained. This number being 42, for example, it is concluded that the amount of crystallisable sugar in the solution is 42 per cent. of that which the solution of sugar-candy contained, and, therefore, 16.471 grains $\times \frac{42}{100}$, or



Saccharimeter.

6.918 grains. This result is only valid when the sugar is not mixed with uncrystallisable sugar, or some other left-handed substance.

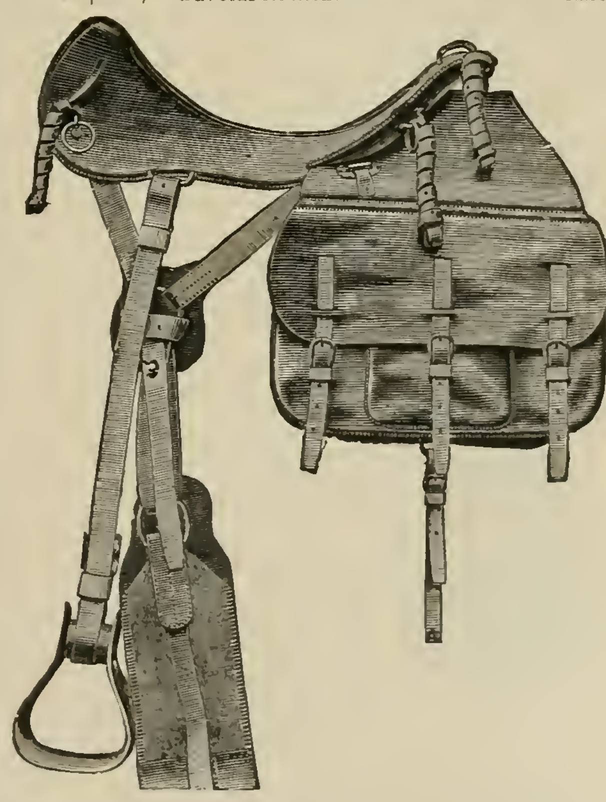
SACHEM.—A chief of a tribe of the American Indians; a Sagamore.

SACK.—An expression used when a town has been taken by storm and given up to pillage.

SACKRAMENTUM MILITARE.—The oath formerly taken by the Roman soldiers when they were enrolled. This oath was pronounced at the head of the Legion, in an audible voice, by a soldier who was chosen by the Tribune for that purpose. He thereby pledged himself before the gods to expose his life for the good and safety of the Republic, to obey his Superior Officers, and never to absent himself without leave. The aggregate of the Legion assented to the oath without going through the formal declaration of it.

SACRED BATTALION.—A band of infantry composed of 300 young Thebans, united in strict friendship and affection, who were engaged, under a particular oath, never to fly, but to defend each other to the last drop of their blood. At the famous battle of Leuctra, in which the Spartans were signally defeated by Epaminondas, the Sacred Battalion was commanded by Pelopidas, and mainly contributed to the success of the day.

SADDLE.—1. The seat which is put upon a horse for the accommodation of the rider. In the earlier ages the Romans used neither saddles nor stirrups. They can be traced back as far as the year 304, where we find accounts of their being made of leather. Every country has its own saddles in great variety. Those employed in the military service are made plain and strong, consisting of the following principal parts: The *saddle-tree*, including *pommel*, *seat*, and *cantle*; the *stirrups*; *stirrup-leathers*; the *girth*; the *girth-straps*; *surcingle*; the *coat-straps*; and frequently the *saddle-bags*. It is as difficult to describe and clearly define the very peculiar and superior lines of a saddle as those of a clipper yacht. An expert may in either case approve of them, but the real proof of excellence is the *trial*. The word saddle comes direct from the Spanish *silla* (*chair*). This term is still in use in that language, "The chair of the horse." While every one is ready to pronounce a chair in common use comfortable or otherwise, few would know how to proportion even a common household chair to give the maximum of comfort. But they would know several points of discomfort to avoid.



Starting from this point, we are first taught by experience to avoid all *padding*. The so-called English, or padded saddle, is unfit for common use. The padding hardens, shifts, and demands constant care and repairs; it absorbs sweat, remains damp, becomes mouldy, moth-eaten and rotten; forms hard lumps and *inevitably* makes sore backs. If the *seat* be padded, while it feels comfortable to a novice, it will *inevitably* produce chafing, tenderness of the skin, and not unfrequently piles. The seat should be as hard and smooth as possible. The slightest motion of the body *ventilates* the seat and keeps it cool, and avoids friction. The first effect of the hard seat is to sore the muscles, which is soonest relieved by frequent riding. A chafe can only be cured by abstaining from riding.

The saddle should be as light as is consistent with strength, and the pressure of the whole and each part of the rider should be distributed over the middle of the horse's back, which is constructed in such a manner as to admit of a certain amount of elastic action. The shape of the seat should be such as to allow the rider to sit well down into it, and balance himself in every position of the animal. The most graceful rider is the bareback rider. That saddle which enables one to approach nearest the bareback seat is by far the best.

In the mounted branch of the English service, the pattern saddle is termed *universal*. In a battery of artillery there are three descriptions of saddles, viz.: the *universal*, the *drivers*, and the *luggage*. The weight of the universal saddle is 28 pounds 2¼ ounces complete. Besides these, there are *pack saddles* suitable for the transport of military stores and mountain artillery, which in mountainous countries can only be carried by beasts of burden. The weight of this pack saddle is 27 pounds, and is known in the service as *saddle pack, general service*.

2. A command, directing that the saddle be placed on the horse's back, executed as follows: The saddle being at hand, the stirrups, girth, and surcingle crossed over the seat, and blanket folded and laid upon them, the Instructor commands: SADDLE.

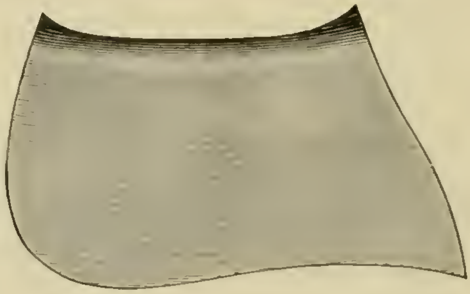
Place the blanket on the horse as previously explained; sieze the pommel with the left hand, and the cantle with the right, and place the saddle on the horse's back, well forward on the withers, bringing it from the direction of the croup in order not to frighten him: let down the girth and right stirrup, pass by the head of the horse to the off side, see that the stirrup and girth are properly adjusted, and the blanket smooth, return by the front to the near side. Take the girth-straps with the right hand, reach under the horse for the girth with the left, pass the end of the strap through the ring from below, and through the upper ring from the inside; sieze the end of the strap with the left hand, turn the right side to the horse, place the right hand on the strap near the upper ring, and press well down. Retain the end of the strap with the left hand, and pass the right between the strap and side of the horse, to smooth the hair and wrinkles of the skin; resieze the strap with the right hand, and pass the end through the buckle with the left, and buckle tight; pass the surcingle over the saddle, buckling it less tightly than the girth, and let down the left stirrup.

3. In pontooning, a *saddle* forms part of the superstructure of the bridge. It consists of a frame of timber placed centrally over the axis of the pontoon, and secured to it by lashings. See *McClellan Saddle, Mexican Saddle, Pack Saddle*, and *Whitman Saddle*.

SADDLE-BAGS.—Bags, usually of leather, united by straps, for transportation on horseback, one bag being placed on each side. A pair of saddle-bags should always accompany the saddle. The drawing represents a very suitable style, manufactured especially for scouting purposes, and furnished with a small assortment of instruments and necessities for the march. In the United States service, saddle-bags are issued to the cavalry as a portion of the horse equipments.

SADDLE-BLANKET.—A blanket which is used under the saddle. This blanket, after being shaken, is folded into six thicknesses, as follows: Hold it well up by two corners, the longway up and down, and double it lengthwise, the double corner in the right, the folded corner in the left hand; let go with the right hand, and seize the folded edge, the back of the hand to the body, just below the left hand; slip the left hand down the folded edge, and seize it near the other end; raise the left hand, extend the arms horizontally, the middle of the folded edge under the chin; then fold again in three equal parts, by first closing the left arm over the breast, and then the right, which is brought under the left and grasps the corner thus folded; reverse the blanket, bringing it in front of the body, and even the folds; hold the blanket between the chin and neck, slip the hands half-way down, and there grasp the blanket: let the upper part fall forward: the hands then hold the folded blanket, thus doubled, by each new upper corner, the right hand at the portion which will go towards the croup; the left hand at the part which will go over the withers; then flirt the outer part of the blanket over the right forearm. This is the position in which the blanket is held just before placing it on the horse. To put on the blanket, approach the horse on the near (left) side, with the blanket folded and held as above prescribed; place it on his back, sliding it once or twice from front to rear to smooth the hair, and carefully remove any locks of the mane; pass the buckle end of the surcingle over the middle of the blanket, and buckle it on the near side, a little below the edge of the blanket. The blanket should lie well up on the withers, and extend down equally on the sides.

SADDLE CLOTH.—In the military service, a cloth of regulation pattern placed under the saddle. It is used in particular as an absorbent of perspiration, thus adding to the horse's comfort, on the same principle as woolen underwear does to man's in summer. It also preserves the saddle. It is, therefore, necessary that it should be made of the best material. In



the United States Army, the saddle-cloth is prescribed as follows:

For General Staff Officers, and Officers of the Staff Corps: Dark blue cloth, of sufficient length to cover the saddle and holsters, and one foot ten inches in depth, with an edging of gold lace one inch wide.

For all other Officers.—Dark blue felt, according to pattern; is worn under the saddle and trimmed around the edges with cloth one and one-half inches wide, color as follows: Infantry, sky-blue. Artillery, scarlet. Cavalry, yellow.

The drawing shows the government pattern, the cloth being twenty-five inches on the back line. See *Housing*.

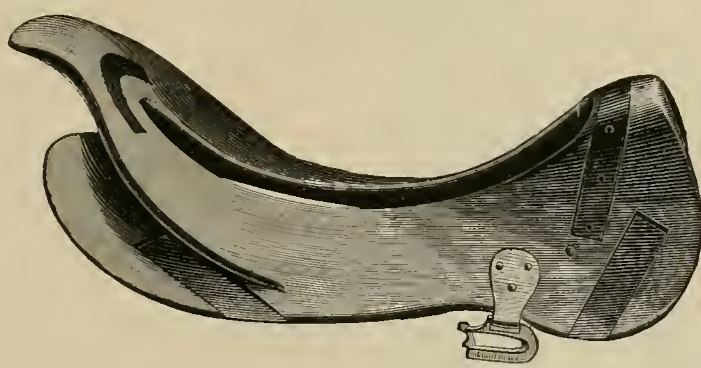
SADDLER.—One whose occupation is to make and repair saddles. Each company of cavalry in the United States Service is allowed one saddler. Saddlers are also employed in the Cavalry Service of European countries.

SADDLER CORPORAL.—In the British Service, a Non-commissioned Officer who has charge of the saddlers in the Household Cavalry.

SADDLER SERGEANT.—A Sergeant in the Cavalry who has charge of the saddlers. In the United States Army, Saddler Sergeants are Non-commissioned Staff Officers, one in each cavalry regiment.

SADDLE-TREE.—The frame of a saddle. Upon the good qualities of the *saddle-tree* will depend the prominent merits of the saddle. Shape, weight, smoothness, and regular bearing surface are the prominent considerations in connection with the saddle-tree. A noticeable objection to most saddle-trees at present constructed, is the raw-hide covering. The Indian and Mexican, having no skilled mechanics in wood or iron, and to whom raw-hides were worthless, made use of them, not only to cover up their rudely made saddle-frames, but to hold them together. In imitating, American work has frequently degraded into seaming together refuse hide, to cover up the rudest and most imperfect work. Raw-hide adds weight and expense, without producing any good effect. In wetting and shrinking, it will either warp the tree or crack, and one crack either on the upper or lower side will ruin the tree.

The Whitman saddle-tree, an invention of an officer of long cavalry experience, is a near approach to perfection, and can be depended on for practical results as well as to meet theoretical views. It is at present used by the United States cavalry, and is highly commended by foreign army officers, and urged by them for adoption in their respective countries. Its great advantage over all other wooden saddle-trees is the carefully adjusted bearing surface and seat. By use of machinery the two sides of this tree are made absolutely equal, a fact never before accomplished. It will be readily understood how soon the placing of any substance, say a penny, under one side of the saddle, would produce sore back. And yet any saddle-tree made by the old, careless process is likely, almost sure, to have greater irregularities at some points in its bearing surface.



SAEGMULLER SOLAR ATTACHMENT.—An apparatus consisting essentially of a small telescope and level; the telescope being mounted in standards, in which it can be elevated or depressed. The standard revolves around an axis, called the polar axis, which is fastened to the telescope axis of the transit instrument. The telescope, called the "solar telescope," can thus be moved in altitude and azimuth. It is provided with shade-glasses to subdue the glare of the sun, as well as a prism to observe with greater ease when the declination is very far north. Two pointers attached to the telescope to approximately set the instrument are so adjusted that when the shadow of the one is thrown on the other the sun will appear in the field of view. The drawing (page 8) shows the solar attachment fixed to an engineer's transit. Its adjustments are simple, and two in number:—

First. Attach the "polar axis" to the main telescope axis in the center at right angles to the line of collimation. The base of this axis is then provided with the three adjusting-screws for this purpose; by means of the level on the solar telescope this condition can be readily and accurately tested.

Second. Point the transit telescope—which instrument we assume to be in adjustment—exactly horizontal and bisect any distant object. The transit level will then be in the middle of the scale. Point the "solar telescope" also horizontally by observing the same object and adjust it, level to read Zero, for which purpose the adjusting-screws are provided.

In using the attachment, first take the declination of the sun as given in the Nautical Almanac for the given day, and correct it for refraction and hourly change. The correction for refraction is equal to the refraction of the sun in altitude, multiplied by the cosine of the angle $Z\ S\ P$. The meridianal refraction may be used as an approximation when the sun is not very near the horizon. Incline the *transit telescope* until this amount is indicated by its vertical arc. If the declination of the sun is north, depress it; if south, elevate it. Without disturbing the position of the transit telescope, bring the solar telescope to a horizontal position by means of its level. The two telescopes will then form an angle which equals the amount of the declination, and the inclination of the solar telescope to its vertical axis will be equal to the polar distance of the sun.

Without disturbing the *relative* positions of the two telescopes, incline them and set the vernier to the co-latitude of the place. By moving the transit and the solar attachment around their respective *vertical* axes, the image of the sun will be brought into the field of the solar telescope, and after accurately bisecting it the *transit telescope must be in the meridian, and the compass-needle indicates its deviation at that place.* The vertical axis of the solar attachment will then point to the pole, the apparatus being in fact a small equatorial. Time and azimuth are calculated from an observed altitude of the sun by solving the spherical triangle formed by the sun, the pole, and the zenith of the place. The three sides, $S\ P$, $P\ Z$, $Z\ S$, complements of the declination, latitude, and altitude, are given; we hence deduce, $S\ P\ Z$, the hour angle, from apparent noon, and, $P\ Z\ S$, the azimuth of the sun. The solar attachment solves the same spherical triangle by construction, for the second process brings the vertical axis of the solar telescope to the required distance, $Z\ P$, from the zenith, while the first brings it to the required distance, $S\ P$, from the sun. If the two telescopes, both being in position—one in the meridian, and the other pointing to the sun—are now turned on their *horizontal* axes, the vertical remaining undisturbed, until each is level, the angle between their directions (found by sighting on a distant object) is, $S\ P\ Z$, the time from apparent noon. This gives an easy observation for the correction of timepiece, &c., which is reliable to within a few seconds. See *Engineer's Transit* and *Solar Attachment.*

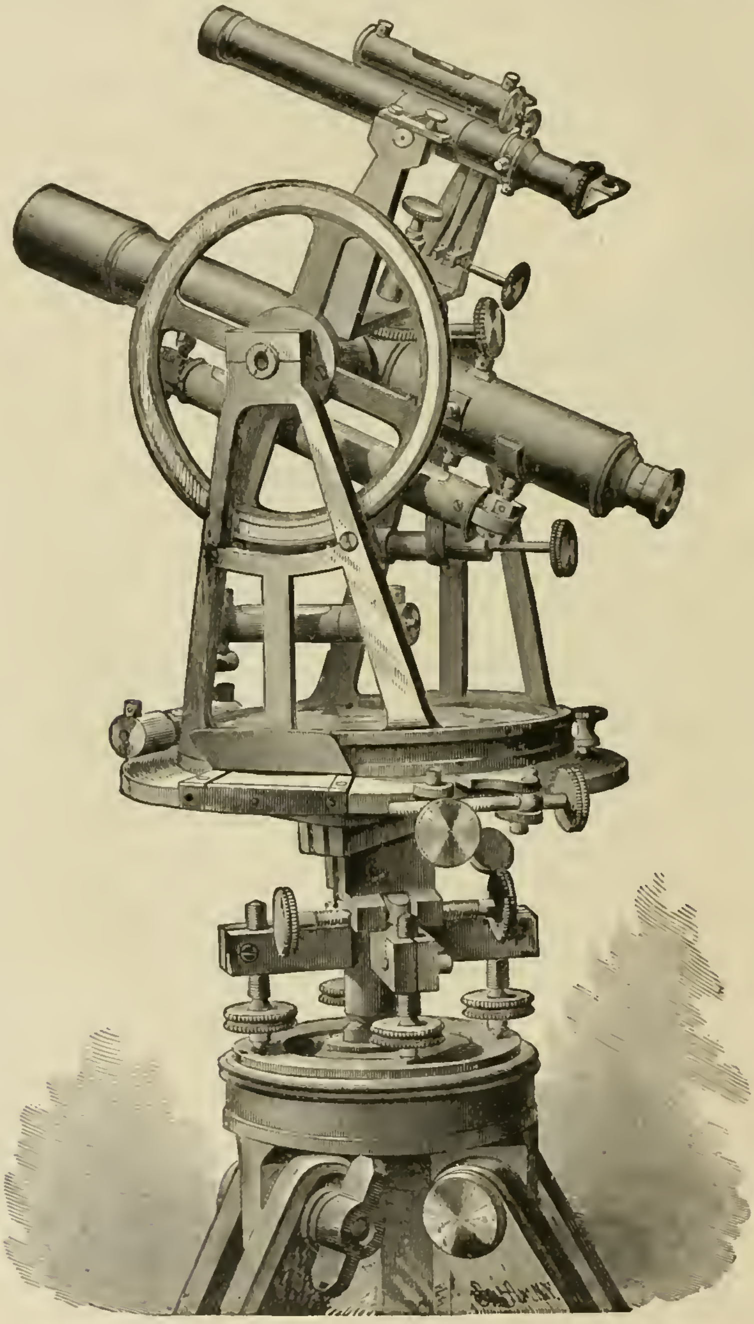
SAFE-CONDUCT.—A passport granted, on honor, to a foe enabling him to pass where it would otherwise be impossible for him to travel with impunity. All intercourse between the territories occupied by belligerent armies, whether by traffic, by letter, by travel, or in any other way ceases. This is the general rule, to be observed without special proclamation. Exceptions to this rule, whether by safe-conduct, or permission to trade on a small or large scale, or by exchanging mails, or by travel from one territory into the other, can take place only according to agreement approved by the Government, or by the highest military authority. Contraventions of this rule are highly punishable. Ambassadors, and all other diplomatic agents of neutral powers, accredited to the enemy, may receive safe-conducts through the territories occupied by the belligerants, unless there are military reasons to the contrary, and unless they may reach the place of their destination conveniently by another route. It implies no international affront if the safe-conduct is declined. Such passes are usually given by the supreme authority of the State, and not by subordinate officers.

SAFEGUARD.—A protection granted to persons or property in foreign parts by the Commanding General, or by other Commanders within the limits of their command. Safeguards are usually given to protect hospitals, public establishments, establishments of religion, charity, or instruction, museums, depositories of the arts, mills, post-offices, and other institutions of public benefit; also to the individuals whom it may be to the interest of the Army to respect. paper delivered to the party whose person, family, house and property it is designed to protect.

The following is a form of the safeguard:

By authority of —— ——.

A safeguard is hereby granted to [A. B —— ; *stating precisely the place, nature, and description of the person, property, or building.*] All officers and soldiers belonging to the Army of the United States are therefore commanded to respect this safeguard,



Saegmuller Solar Attachment.

A safeguard may consist of one or more men of fidelity and firmness, generally non-effective Non-commissioned Officers, furnished with a paper setting out clearly the protection and exemptions it is intended to secure, signed by the Commander giving it, and his Staff Officer; or it may consist of such a

and to afford, if necessary, protection to [*the person, family, or property of —— ——, as the case may be.*]

Given at Headquarters, the —— day of ——

A. B ——

C. D —— *Major General, Commanding-in-Chief.*

Adjutant General.

Whosoever, belonging to the Armies of the United States in foreign parts, or at any place within the United States or their Territories during rebellion against the supreme authority of the United States, forces a safeguard, shall suffer death. [Fifty-seventh Article of War.] See *Articles of War*, and *Field-service*.

SAFETY-FUSE.—This species of fuse invented by Messrs. Bickford for use in the Cornish mines, and now generally employed in the chief mining districts, consists of a hollow cord of spun yarn or hemp, tarred on the outside to render it waterproof, and filled with tightly-rammed gunpowder. This fuse ignites steadily at the rate of about 2 feet per minute, so that the time of the explosion can be easily regulated. The use of this contrivance has contributed to prevent those accidents arising from premature explosions, formerly of very common occurrence in mines. The fuse-tube is sometimes made of gutta-percha. See *Fuse*.

SAFETY-LAMP. — It has been long known that when marsh-gas or light carbureted hydrogen, which is frequently disengaged in large quantities from mines, is mixed with seven or eight times its volume of atmospheric air, it becomes highly explosive, taking fire at the approach of a light, and burning with a pale blue flame. Moreover, this gas in exploding renders ten times its bulk of atmospheric air unfit for respiration, and the *choke-damp* thus produced is often as fatal to miners as the primary explosion. With the view of discovering some means of preventing these exceedingly dangerous results, Davy instituted those important observations on flame which led him to the invention of the safety-lamp. He found that when two vessels filled with a gaseous explosive mixture are connected by a narrow tube, and the contents of one fired, the flame is not communicated to the other, provided the diameter of the tube, its length, and the conducting power for heat of its material, bear certain proportions to each other; the flame being extinguished by cooling, and its transmission rendered impossible. In this experiment, high conducting power and diminished diameter compensate for diminution in length; and to such an extent may this shortening of length be carried, that metallic gauze, which may be looked upon as a series of very short square tubes arranged side by side, completely arrests the passage of flame in explosive mixtures. The following are Davy's directions regarding the structure of his lamp: "The apertures in the gauze should not be greater than $\frac{1}{22}$ of an inch square. As the fire-damp is not influenced by ignited wire, the thickness of the wire is not of importance; but wire from $\frac{1}{40}$th to $\frac{1}{60}$th of an inch in diameter is the most convenient. Iron-wire and brass-wire gauze of the required degree of fineness, are made for sieves by all wire-workers, but iron-wire gauze is to be preferred; when of the proper degree of thickness, it can neither melt nor burn, and the coat of black rust which soon forms upon it superficially defends the interior from the action of the air. The cage or cylinder should be made of double joinings, the gauze being folded over so as to leave no apertures. When it is cylindrical it should not be more than two inches in diameter; for in larger cylinders the combustion of the fire-damp renders the top inconveniently hot, and a double top is always a proper precaution, fixed at the distance of half or three-quarters of an inch above the first top. The gauze cylinder should be fastened to the lamp by a screw of four or five turns, and fitted to the screw by a tight ring. All joinings should be made with hard solder; and the security depends upon the circumstance that no aperture exists in the apparatus larger than in the wire gauze." The cylinder is protected by three external, strong, upright wires, which meet at the top; and to their point of junction a ring is attached, by which the lamp is suspended. The oil is supplied to the interior by a pipe projecting from the cylinder, and the wick is trimmed by a wire bent at the upper end, and passed through the bottom of the lamp, so that the gause need not be removed for this process. When a lighted lamp of this kind is introduced into an explosive mixture of air and fire-damp, the flame is seen to gradually enlarge as the proportion of light carbureted hydrogen increases, until at length it fills the entire gauze cylinder. Whenever this pale enlarged flame is seen, the miners should depart to a place of safety, for although no explosion can occur while the gauze is sound, yet at that high temperature the metal becomes rapidly oxidized, and might easily break; and a single aperture of sufficient size would then occasion a destructive explosion. In a strong current of air, the heated gas may be blown through the apertures of the gauze before its temperature is sufficiently reduced to prevent an explosion; but such a contingency may be guarded against by placing a screen between the draught and the lamp. It was in the year 1815 that Sir Humphry Davy presented his first communication to the Royal Society respecting his discovery of the safety-lamp; and at the meeting held on Jan. 11, 1816, the lamp, as shown in Fig. 1, was exhibited. Sir Humphry Davy's claim as an original discoverer was immediately challenged by various persons, among whom may be especially noticed the late Dr. Reid Clanny, of Newcastle, and the great engineer, George Stephenson. Clanny's safety-lamp, shown in Fig. 2, was based on the principle of forcing in air through water by bellows; but the machine was ponderous and complicated, and required a boy to work it; moreover, he had been anticipated by Hum-

Fig. 1.

Fig. 2.

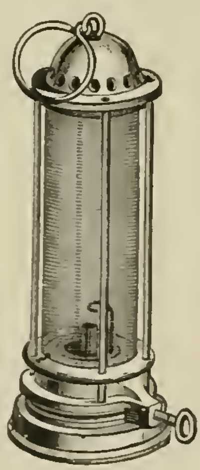


Fig. 3.

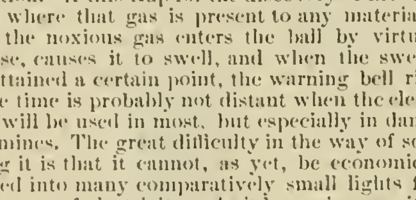
boldt in 1796. Stephenson's lamp is shown in Fig 3. In the French and Belgian collieries, Mueseler's lamp is in almost universal use. It consists of a glass cylinder immediately around the flame, and of the wire gauze above. An internal metal chimney opening a short distance above the flame creates a strong upward draught, which causes the feed air to pass briskly down from the wire gauze, and so keeps the glass cool and insures thorough combustion. Mueseler's lamp is also used in a few English collieries; but modifications of Davy's, Stephenson's, and in a less degree of Clanny's later lamp are still in general use in England, the best kinds of each having their wire-gauze covers secured by patent lever locks. In the catalogue of the collection of scientific apparatus shown at South Kensington in 1876, there is given an interesting table, with remarks, of the different forms of safety-lamps which either are or have been in use. It was compiled by the North of England Institute of Mining Engineers. Closely connected in its objects with the safety-lamp is a most ingenious invention pattented by Mr. Ansell of Her Majesty's mint. Its object is to determine, by a simple application of the law of osmotic force, the presence of any light carbureted hydrogen in mines. Mr. Ansell gives two or three forms to his apparatus, of which the following is the most simple: A thin India-rubber ball is filled with atmospheric air, and is placed on a stand under a lever which slightly presses its upper surface. This lever is connected with a spring, which it liberates when, from any cause, the lever is raised; and the liberation of the spring sets a bell in vibration. If this trap for the discovery of fire-damp is set where that gas is present to any material extent, the noxious gas enters the ball by virtue of osmose, causes it to swell, and when the swelling has attained a certain point, the warning bell rings.

The time is probably not distant when the electric light will be used in most, but especially in dangerous, mines. The great difficulty in the way of so applying it is that it cannot, as yet, be economically divided into many comparatively small lights from one source of electricity. As it burns *in vacuo* it can be rendered perfectly safe in an explosive mixture of fire-damp and air. Some twenty years since Mr. Holmes, the well-known electrician, invented a miner's electric lamp in which the light—equal to that of an ordinary candle—was produced by a small portable galvanic battery. Its cost was estimated at between £3 and £4. More recently MM. Dumas and Benoit have constructed a lamp the light of which is produced by a current of electricity from a Rhumkorff coil passing through a Geissler's vacuum tube. The tube, however, really contains a highly rarefied gas such as carbonic acid, and the light has only the character of a rich phosphorescent glow. Neither of these, nor any other form of an electric light, has as yet come into practical use in mining operations.

SAFETY LOCK. A lock so constructed as to guard against all accidental discharges of the piece. There



have been, from time to time, numberless patents for safety apparatus, but all have fallen far short of absolute safety, inasmuch as such safeties had to be removed by the thumb before firing, or in reality, only safeties at the will of the user. In the Scott locks of recent manufacture, a block-safety always interposes itself automatically between the hammer and striker before the hammer is half way to full-cock. By this new invention, the gun is always safe from the light pull of a lock jarring off in closing the breech action or the sear sticking through rust, or letting the gun fall. Should the lock go off in any possible way other than by the pull of the trigger, the hammer will be intercepted and blocked by a bar, as is shown in the drawing, and no discharge can take place. It is readily seen how the hammer with projecting lump, B, having been jarred off at full-cock, is caught by the safety-block, A, before it reaches the striker, E.

SAFETY REDOUBT.—In enclosed works a place of retreat, into which the troops may retire in safety after a vigorous defense of the main work, will remove the fears of the garrison for the consequences of a successful attack of the enemy, and will inspire them with confidence to hold out to the last moment. This interior work, which may very properly be termed the *keep*, can only be applied to works of large interior capacity. It may be formed of earth, or consist simply of a space enclosed by a defensive stockade, or palisading. In either case it should be about four feet higher than the main work, to prevent the enemy from obtaining a plunging fire in it from the parapet of the main work. The best arrangement for the keep is the construction termed the *block-house*. This work is made of heavy timber, either squared on two sides or four; the pieces which form the sides of the block-house are either laid horizontally, and halved together at the ends, like an ordinary log-house, or else they are placed vertically, side by side, and connected at top by a cap-sill. The sides are arranged with loop-hole defences, and the top is formed by laying heavy logs, side by side, of the same thickness as those used for the sides, and covering them with earth to the depth of three feet.

With regard to the details of the construction, the timber for the sides should be twelve inches thick, to resist an attack of musketry, and to resist field-pieces two feet, in which case the sides are formed of two thicknesses of twelve-inch timber. If the timber is placed upright, each piece should be let into a mortise in the cap-sill; and every fourth piece of the top, at least, should be notched on the cap-sill, to prevent the sides from spreading out.

The plan must conform to its object generally; it may be square or rectangular. If flank defenses are required, its plan may be that of a cross. The interior height should not be less than nine feet, to allow an ample room for loading the musket; this height will require that the timber of the sides shall be twelve feet long, in order to be firmly set in the earth. Sometimes a ground-sill is placed under the uprights, but this is seldom necessary. The width may be only twelve feet in some cases, but it is better to allow twenty feet; this will admit of a camp bed of boards on each side, six and a half feet wide, and a free space of seven feet. If cannon are to be used for the defense, the width must be at least twenty-four feet; this will allow eighteen feet for the service of the gun, which is generally ample, and six feet for a defense of musketry on the opposite side. A greater width than twenty-four feet cannot well be allowed, because the bearing would be too great between the sides for twelve-inch timber; and even for a width of sixteen feet it would be well to support the top pieces by placing a *girder* under them resting on *shores*. See *Keep* and *Redoubt*.

SAFETY STOP.—A device to prevent the accidental discharge of a gun. Usually a flat spring catches against the rear of the hammer and locks it against the nipple: when the spring is pressed against the stock, the hammer is free to be cocked.

SAGAIE. A dart or javelin used by the inhabitants of Madagascar. Also written *Zagie*.

SAGAMORE.—The head of a tribe among the American Indians, generally used as synonymous with *Sachem*. Some writers distinguish between them, making the *Sachem* a chief of the first rank, and a *Sagamore* one of the second.

SAGITTARII.—In the Roman Army, under the Emperors, young men armed with bows and arrows, who, together with the *Funditores*, were generally sent out to skirmish before the main body. They constituted no part of the *Velites*, but seem to have succeeded them at the time when the Socii was admitted into the Roman legions; for, at that period, the *Velites* were discontinued.

SAGUM.—An ancient military garment or cloak, made of wool, without sleeves, fastened by a girdle around the waist, and a buckle. It was worn by the Romans, Greeks, and Gauls. The Generals alone wore the *Paludamentum*, and all the Roman soldiers, even the Centurions and Tribunes, used the *Sagum*.

SAIKYR.—In the Middle Ages, a species of cannon smaller than the demi-culverin, much employed in sieges. Like the falcon, it derived its name from a species of hawk. See *Saker*.

SAINT MICHAEL.—The Order of Saint Michael was instituted in 1469 by Louis XII. in honor of the great services done to France by that Archangel at the siege of Orleans, where he is supposed to have appeared at the head of the French troops, disputing the passage of a bridge, and to have repulsed the attack of the English, whose affairs ever after declined in that Kingdom. The Order is a rich collar, with the image of that Saint pendent thereto, with the inscription, *Immensi tremor oceani*.

SAINT PETERSBURG CONVENTION.—A convention signed in December, 1868, in that city by all the European powers except Bavaria, and the United States of America, for interdicting the use of all explosive bullets in time of war.

SAINT REMY SYSTEM OF FORTIFICATION.—The enciente in this system is composed of isolated forts well covered by ravelins, counterguards and lunettes. Each fort contains a barrack for the garrison. The great defect is, that the loss of one fort deprives the collateral ones of flanking defence on half their perimeters.

SAJI MUTTEE.—An Indian term for carbonate of soda. It is found in many parts of India on the surface of the soil as a carbonate or sulphate of soda, in the proportion of 50 per cent. of the former to 10 or 15 of the latter. By washing, heating, and evaporation, the sulphate is converted into a sulphuret of sodium, which, by further heating and exposure to the atmosphere, is changed into carbonate of soda. In its crude state it is commonly used in India in clearing off the old coat of paint from gun-carriages previous to applying the new one, and for removing grease, etc.

SAKER.—An ancient 4-or 5-pounder of 13 feet, weighing from 2500 to 2800 pounds. According to Tartaglia, the *Sacre*, in 1546 was a 12-pounder of 9 feet, and weighing 2150 pounds. It was similar to the *Aspec*, but longer.

SALADE.—In ancient armor, a kind of bascinet, but projecting much behind the head, and having a movable visor. It was introduced in the reign of Henry VI. It is also written *sallet*.

SALADIN.—1. The original term for the coat of arms; so called because the Christians who conquered Palestine assumed it in imitation of the Turks, whose Chief was at that time Saladin. 2. The name given by the western writers to SALAH-ED-DIN YUSSUF IBN AYUB, the Sultan of Egypt and Syria, and the founder of the Ayubite Dynasty in those countries. As the great Moslem hero of the third crusade, and the beau ideal of Moslem chivalry, he is one of the most interesting characters presented to us by the history of that period. He belonged to the Kurdish tribe of Ravad, and was born at Tekreit (a town of the Tigris, of which his father Ayub was *Kutwal* or Governor under the Seljuks) in 1137. Following the example of his father and uncle, he entered the service of Noureddin, Prince of Syria, and accompanied his uncle in his various expeditions to Egypt in command of Noureddin's army. Saladin was at this time much addicted to wine and gambling, and it was not till at the head of a small detachment of the Syrian army he was beleaguered in Alexandria by the combined Christians of Palestine and Egyptians that he gave indications of possessing the qualities requisite for a Great Captain. On the death of his uncle Shirkoh, Saladin became Grand-Vizier of the Fatimite Caliph, and received the title of *El-melek-el-nasr*, "The Victorious Prince"; but the Christians of Syria and Palestine, alarmed at the elevation of a Syrian Emir to supreme power in Egypt, made a combined and vigorous attack on the new Vizier. Saladin foiled them at Damietta, and transferred the contest to Palestine, taking several fortresses, and defeating his assaillants near Gaza; but about the same time his newborn power was exposed to a still more formidable danger from his master, Noureddin, whose jealousy of the talents and ambition of his able young Lieutenant required all the skill and wariness at Saladin's command to allay. On Noureddin's death in 1174, Saladin began a struggle with his successor, which ended in his establishing himself as the Sultan of Egypt and Syria, a title which was confirmed to him by the Caliph of Bagdad.

SALEETAH.—An Indian term for a bag containing a soldier's bedding, &c. on the march. Saleetahs are also used in packing the compotent parts of tents. They are made of gunny cloth.

SALE OF STORES.—The President is authorized to cause to be sold unserviceable ordnance or stores of any kind, but the inspection or survey of unserviceable stores should be made by an Inspector General, or such other officer or officers as the Secretary of War may appoint for that purpose; and the sale should be made under such rules and regulations as may be prescribed by the Secretary of War. In all cases where lands have been, or shall hereafter be, conveyed to or for the United States, for forts, arsenals, dock-yards, light-houses, or any like purpose, or in payment of debts due to the United States, which are not used, or necessary for the purposes for which they were purchased, or other authorized purpose, it is lawful for the President of the United States to cause the same to be sold, for the best price to be obtained, and to convey the same to the purchaser by grant or otherwise.

SALIENT.—In Heraldry, that attitude of a lion or other beast, differing but slightly from *rampant*. He is supposed to be in the act of springing on his prey, and both paws are elevated. Two animals *counter-salient* are represented as leaping in opposite directions.

In a fortification, that which points outward from the interior of any work. For example, the central angle of a bastion, pointing toward the enemy, is a salient angle.

SALIENT ORDER OF BATTLE.—An order of battle, the front of the army being formed on a salient or outward angle. This formation is seldom resorted to, as it presents many disadvantages. Certain attacks of necessity assume the salient form, not to await the enemy, but for immediate attack, provision being made by reinforcing the head of the attack, for insuring and following up its successes, and by feints carried on elsewhere to weaken the resistance. On the defensive, the salient order can be resorted to, without entailing a defeat, if the wings can be strongly protected by obstacles, and the open of the triangle placed in such a manner as to deprive the cross-fire of the enemy's artillery of its full effect. Masses of cavalry may operate, however, with great effect from the apex of a salient order.

SALIENT PLACES OF ARMS.—In fortification, that part of the covered-way which is opposite a salient of a bastion or demi-lune.

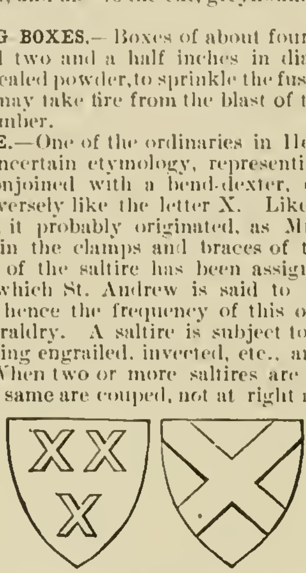
SALLY.—A sudden offensive movement by the garrison of a fortified place, directed against the troops or works of the besiegers.

SALLY-PORT.—A gate or passage by which the garrison of a fortress may make a sally or sudden attack on the besiegers. The name is applied to the postern leading from under the rampart into the ditch; but its more modern application is to a cutting through the glacis, by which a sally may be made from the covered-way. When not employed, sally-ports are closed by massive gates of timber and iron.

SALTANT.—In Heraldry, in a leading position, or springing forward; applied especially to the squirrel, weasel, rat, and also to the cat, greyhound, monkey, etc.

SALTING BOXES.—Boxes of about four inches altitude and two and a half inches in diameter, for holding mealed powder, to sprinkle the fuses of shells that they may take fire from the blast of the powder in the chamber.

SALTIRE.—One of the ordinaries in Heraldry, its name of uncertain etymology, representing a bend-sinister conjoined with a bend-dexter, or a cross placed traversely like the letter X. Like the other ordinaries, it probably originated, as Mr. Planché suggests, in the clamps and braces of the shield. The form of the saltire has been assigned to the cross on which St. Andrew is said to have been crucified; hence the frequency of this ordinary in Scotch Heraldry. A saltire is subject to the variations of being engrailed, invected, etc., and may be *couped*. When two or more saltires are borne in a shield, the same are couped, not at right angles, but

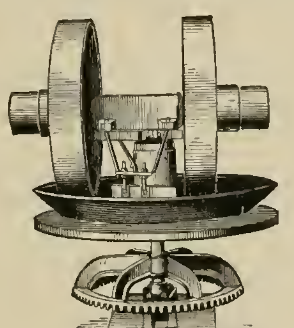


Saltire.

horizontally; and as they are always so treated, it is considered superfluous to blazon them as couped. Charges disposed in the form of a saltire are described as placed *saltireways*, or *in saltire*. The former term is more properly applied to two long charges, as swords or keys, placed across one another (in which case the rule is, that the sword in bend-sinister should be uppermost, unless otherwise blazoned); and the latter to five charges placed two, one, and two. See *Heraldry*.

SALTPETER.—The saltpeter, or niter, which is employed in the manufacture of gunpowder, and is the principal ingredient therein, is a natural production found in various parts of the world, but chiefly in the East Indies, Ceylon, and in Asia Minor. In the condition, however, in which it is imported it always contains a large quantity of earthy matter and other impurities, such as chloride of sodium, magnesia, and other salts, that have to be eliminated before the saltpeter is fit to be used in making gunpowder. Efflorescent salts are sometimes present, but the quantity being small, they are comparatively innoxious and do not weaken the powder, but only slightly impede the rapidity of deflagration. The refining of the saltpeter, therefore, is for the purpose of removing the before-named impurities and all earthy matters which may be present, and is affected by boiling and skimming the grough or impure saltpeter in large open boilers, and afterwards drawing off the liquor and straining it through canvas bags. The *modus operandi* is as follows: About 40 cwts. of salpeter in its crude state are put into an open copper boiler capable of containing 500 gallons; about 270 gallons of water are added to this, or about .66 of water to 1 of saltpeter, and these are allowed to stand all night; in the morning a fire is lighted under the boiler, and in about two hours afterwards they will be found to have reached a temperature of 300° Fahr., and will be boiling freely. During ebullition, and by constant stirring, the light matter—containing many impurities—rises to the surface, and is skimmed off; as soon as the scum ceases to rise, cold water is freely dashed on the surface of the boiling liquid to precipitate the chlorides that would otherwise be retained on the surface by the ebullition. After boiling until the solution of the nitrous salts is effected, the fire is allowed to go out; when all the ebullition has ceased, the foul salts and chlorides—being the heaviest—are precipitated, and, as the boiler is provided with a false bottom perforated with holes, the foul salts and other impurities pass through the perforations and remain at the real bottom of the boiler. In about an hour after the fire has been extinguished, the temperature of the solution will have fallen to about 220° Fahr., or sufficiently to allow of a syphon being introduced, the end of which is kept 1″ from the false bottom of the boiler, so as not to disturb the foul salts. The liquor is now drawn off by means of this syphon into a filter or trough, the bottom of which is fitted with four or five gun-metal taps, communicating with suspended Dowlas canvas filtering bags, of the shape of an inverted cone. If crystals form on these filtering bags, and prevent the liquor from passing freely through, hot water is poured over them to keep the canvas open, a constant supply of hot water for the purpose being obtained from a vessel provided with a flexible pipe, having a finely-pierced rose head, the whole being fixed in close proximity to the filtering trough, ready for use whenever required. When all the liquor has passed through the filtering bags, it is run into a shallow trough or cooler, which is about 12′ long by 6′ wide by 1′ deep, and is lined with sheet copper and placed by the side of a washing vat. The liquor in the cooler is now agitated by a wooden rake until the temperature is reduced to about 180° Fahr., at which temperature the mother-water separates from the saltpeter held in solution; when it falls below 180°, a large number of very minute crystals are formed, and these are collected and thrown on to a wire-cloth drainer, fixed at an angle immediately above the cooler, so that the strainings or liquor may run back again into the cooler; and the saltpeter, when sufficiently drained, is raked into the washing vat, which also is furnished with a false bottom, covered with fine copper wire-cloth. When the whole charge is in the washing vat, it receives three washings; in the first and second, pure water is freely sprinkled over the saltpeter from a rose-ended pipe, and after being allowed to stand for about fifteen minutes, the liquor—being very rich in mother-water and saltpeter—is run off into crystallizing pans by means of a tap at the bottom of washing vat. In the third washing, the vat is filled with cold water, and the liquor, after standing for about half an hour, is drawn off in the same manner; but as it now only contains a small quantity of saltpeter, it is not run into the crystallizing pans, but is collected in an underground tank for future use. The saltpeter obtained by the above process is almost perfectly pure, and has the appearance of snow. It is now placed in stone bins, perforated with small holes in the ends and sides, where it is allowed to drain. When placed in these bins the saltpeter contains from seven to twelve per cent. of water, but during the time it remains in them about six or seven per cent. is drained off. It is now fit for making gunpowder if used immediately; but if a supply be required for storage or transport, it is better to evaporate the remaining water, and this is done by drying it in a hot chamber in the following manner. The saltpeter is spread out about 2″ thick on shallow trays made of sheet copper, and placed on racks in the hot chamber, which is heated up to about 260° Fahr. by means of a flue underneath the floor. The saltpeter, while in the hot chamber, is stirred once or twice, and it is found that from four to six hours is sufficient to evaporate the remaining moisture. It is now taken out of the hot chamber and emptied into shallow trays, where it is allowed to cool; it is then put into barrels and sent into store.

By the above process about three-fourths of the saltpeter is crystallized, the remaining portion being held in solution by the mother-water that remains in the large cooler. When this has cooled down to within 7° or 8° of the temperature of the atmosphere, large crystals are formed, and adhere to the sides and bottom of the cooler; these are collected and put with the grough into the next charge of the boiler; all the mother-liquor is also collected in the underground tank, whence it is pumped into another boiler, where it is evaporated to a fourth of its original quantity; it is then drawn off by means of a syphon, passed through filtering bags, and collected in a receiver, whence it is run off into copper pans holding about thirty-six gallons each, and there allowed to crystallize. Though the crystals obtained in this manner are pure, still they contain cavities wherein the mother-water is enclosed, and it is found that the simplest and best plan is to use them in the next charge as grough. Over the foul salts and impurities left in the bottom of the evaporating pan hot water is poured, and the whole well stirred in order to extract any saltpeter that may remain; after being allowed to settle for a short time, this solution is also drawn off and passed through the filtering bags, previous to its being run into the crystallizing pans before mentioned. Should the filtering bags become clogged or full of impurities, they are removed and placed in larger bags hung in a cleaning apparatus, where they, together with the bags in which the saltpeter is imported, are well washed by having hot water run through them, and this water—containing a small percentage of niter—is also collected in the mother-liquor tank. The bag cleanser is also used



for washing the skimmings and foreign salts, etc., taken from the copper boiler; the residue from this is generally sold for manure, together with the refuse from the evaporating pans. The water from the various washings and drainings is all conveyed by gutters under the floor to the underground tank, whence it is pumped into the copper boiler as required, and used instead of pure water in the next charge; and as it contains a small percentage of saltpeter, a less quantity of grough is required to give the requisite proportions. To test the saltpeter, dissolve a small quantity in a test tube or phial with distilled water, add a few drops each of nitric acid and nitrate of silver. If the solution remains clear, the saltpeter is pure; but if a milkiness appears, it indicates the presence of a chloride, and this is generally the chloride of sodium. The saltpeter—if used immediately after being purified—is so fine as to require no further reduction of its particles before mixing; but if it has been dried for storage it must, like the sulphur, be reduced to a very fine powder. They are each ground separately in a small machine somewhat similar in character to a mortar mill. The machine consists of one pair of edge rollers or runners, travelling round a strong circular cast-iron bed, and revolving at the same time on their own axis. The speed of these rollers is eight revolutions per minute round the bed, and they are each 4' in diameter, and weigh 30 cwt. Each one travels on a different path, one being near to the inside curb or "cheese," as it is technically called, whilst the other one is further away from the center, and nearer to the outer curb. A shaft or spindle common to both rollers passes through their centers, and between them is a crosshead fixed on a vertical shaft that is driven by means of level gearing, the pinion being secured on the main horizontal driving shaft underneath the machine, whilst the vertical shaft or spindle, upon which the large bevel wheel is fixed, passes through the crosshead, this latter being provided with suitable brass bushes in order to allow the rollers to rise or fall according to the thickness of the material under them. The material to be ground—whether saltpeter or sulphur—is spread evenly over the bed of the machine to a thickness of about 1".05 or 2"; the rollers are then set in motion, and a very short time suffices to complete the operation of grinding. The material, when sufficiently ground, is shovelled from the bed into tubs and these are emptied into a hopper placed above a sifting reel, which is similar in all respects to the charcoal reel. As this reel revolves, certain projections provided on the shaft strike against similar projections on the bottom of the trough that conveys the material from the hopper to the reel, and as this trough is slung under the hopper it is thus made to vibrate, and so causes the material to be shaken gradually from the hopper into the reel. The ingredients are now weighed out very accurately, in the proportions of 15 of saltpeter to 3 of charcoal and 2 of sulphur, and as about 50 lb. of this mixture constitutes a charge for the incorporating mill, the quantities are—saltpeter, 37½ lb.; charcoal 7½ lb., and sulphur, 5 lb. These are placed separately in small bags, and taken to the mixing machine. See *Gunpowder*.

SALUTE.—A salute with cannon is a certain number of guns fired in succession with blank cartridges, in honor of some person, to celebrate an event, or to show respect to the flag of a country. The rapidity with which the pieces are discharged depends upon their caliber. Field-guns should have intervals of five seconds between discharges; siege-guns, eight; and guns of heavier caliber, ten. The minimum number of pieces with which salutes can be fired is two for field, four for siege, and six for all sea-coast guns. Mortars, as a rule, are not used for saluting purposes.

Personages entitled to salutes, if *passing* a military post, as also foreign ships-of-war, are saluted with guns of heavy caliber, the most suitable being the 10-inch smooth-bore. When troops are drawn up for the reception of a dignitary, and it is practicable to have a battery of field-guns on the ground, a salute from it should form part of the ceremony; otherwise guns in position are used. The national salute, and minute-guns upon funeral occasions, are, when praticable, fired from heavy pieces.

The pieces used for a salute should, if possible, be of the same or equivalent caliber; and when the number on the front of a work admits of it, the entire number required, and two or three over, should be loaded and made ready previous to commencing the salute; the detachments are then dispensed with, and a single cannoneer at each piece discharges it at the proper time. When the number of pieces is insufficient for the entire salute, as many as possible should be used, so as to avoid frequent reloadings. The pieces are numbered from right to left—*one, two, three*, and so on—and each detachment or the cannoneer, as the case may be, is made to clearly understand the number of the piece. To insure regularity of intervals, the officer in charge of the firing should habituate himself to uniformity in giving the commands to fire.

At the proper moment the officer in charge commands: *Number one*, FIRE, and observing the proper interval, *Number two*, FIRE, and so on to the left piece, when he returns to the first and repeats the same commands until the entire number required for the salute is discharged. In giving the command *fire*, he looks towards the piece to be fired, and gives it in such a pronounced manner, accompanied by a signal with his sword, as to be unmistakable. Immediately after each piece is discharged it is reloaded and made *ready*. The cartridges are withdrawn from the pieces that remain loaded at the conclusion of the salute. See *International Salute*, *National Salute*, *Official Courtesies*, *Personal Salutes*, and *Salvo*.

SALUTES.—Movements of the hand previous to addressing and subsequent to being addressed by a superior. To execute the authorized salute without arms, the Instructor commands: 1. *Right* (or *left*) *hand*, 2. SALUTE. Raise the right hand smartly, pointing in the same direction as the right foot, the palm of the hand down, the thumb close to the forefinger, the arm extended, and horizontal. (Two.) Bring the hand around till the point of the thumb and side of the forefinger touch the lower edge of the cap or visor, at the same time turn the head a little to the left, look towards the person to be saluted, and retain this position till the salute is acknowledged. (THREE.) Bring back the hand and arm to the position of the first motion, at the same time cast the eyes to the front. (FOUR.) Drop the arm quickly by the side.

Officers salute (without swords) as follows: (*First motion.*) Raise the right hand till the tips of the fingers touch the visor opposite the right eye, the thumb closed, the fingers and hand extended in prolongation of the forearm, the elbow down. (*Second motion.*) Lower the hand briskly and to the right till the point of the fingers are at the height of the shoulder and in front of it, the elbow advancing slightly; the hand and fingers still extended in prolongation of the forearm. (*Third motion.*) Drop the hand by the side. In rendering honors with troops, officers execute the first motion of the salute at the command *present*, the second motion at the command *arms*. The sword is returned to the *carry* at the command, 1. *Carry*, 2. ARMS.

The Sergeants salute (with arms) is executed as follows: Being at a carry, raise the left hand and arm horizontally to the front, palm of the hand down, the fingers extended. (Two.) Bend the left elbow, carrying the hand around till the forefinger strikes the piece in the hollow of the right shoulder, retaining it there till the salute is acknowledged. (THREE.) Return to the position of the first motion. (FOUR.) Drop the left hand by the side.

SALUTING COLOR.—An ordinary camp color, distinguished by a transverse red cross; or when the facings are red, by a transverse blue cross.

SALVO.—Concentrated fire from a greater or less number of pieces of artillery. Against a body of men, a salvo is generally useless, as the moral effect is greater in proportion to the area over which devastation is spread; but with fortifications, the case is otherwise. For the purpose of breaching, the simultaneous concussion of a number of cannon-balls on masonry, or even earth-work, produces a very destructive result. At Almeida, after the French had fired a few salvos of 65 guns, the castle sunk in a shapeless mass. The effect of a salvo of modern artillery, with its enormous steel shot, against iron-plated ramparts, has never yet been tried in actual war. The concentrated fire of a ship's broadside forms a powerful salvo.

Salvos, corresponding to volleys of musketry, are frequently fired by way of salutes over the graves of officers at the time of burial.

The order designating a funeral escort prescribes whether the fire shall be three volleys of musketry or three salvos of artillery. See *Salute*.

SAMBUQUE.—An ancient musical instrument of the wind kind, resembling a flute. It was also the name of an ancient engine of war used by Marcellus in besieging Syracuse. Plutarch relates that two ships were required to carry it. A minute description of this engine may be seen in Polybius.

SAND BAG REVETMENT.—Sand-bags are sometimes used for revetments when other materials cannot be procured; though their object, in most cases, is to repair damages done by the enemy's fire. They are made of canvas, or a good quality of gunny-cloth, sewed with cotton twine with lock-stitch; the bag, when empty, is 2 feet 8 inches long and 1 foot 4 inches wide. When filled and laid they occupy a space of 6 by 10 by 24 inches, and contain 0.85 of a cubic foot of sand, weighing very nearly 85 pounds. Thirty-two make a cubic yard.

The bags are laid as headers and stretchers, either in the English or Flemish bonds. They should not be more than three-fourths full when laid; if full they do not lay well, and are more liable to burst on becoming wet, or under great pressure. When time is of importance, the bags need not be tied, but the throat is given a twist and turned under the end of the bag as it is laid. To prevent decay, they should be payed with coal-tar before being filled or before being laid; this, furthermore, renders them the less liable to take fire when dry. One hundred and forty-four sand-bags, laid as above, makes ten superficial yards of revetment. Sand-bag reveting requires less anchoring to make it stand than any other. If the reveting is kept wet, the sand will not so readily escape through rents, nor will the bags take fire from the blast of the pieces; this, however, hastens their decay. From six to ten months, depending upon usage, is the duration of reveting made of sand-bags. When used near the muzzle of the piece in the revetment of embrasures, they soon wear away, from the blast of the piece, unless well protected. See *Revetment*.

SAND BAGS.—Canvas bags, in military constructions which are filled with sand or earth, and form a ready means for extemporizing a parapet or traverse against the enemy's fire; they are likewise used for protecting the head of a trench, or tamping the charge in a mine.

The sand-bag, for the revetment of batteries, when empty and laid flat, is 2 feet 8 inches long, and 1 foot 4 inches wide; those used in the construction of the trenches are 2 feet long and 12 inches wide. See *Mines*, *Revetment*, and *Sand-bag Revetment*.

SAND BLAST.—A method of engraving, cutting, and boring glass, stone, metal, or any other hard substances, by the percussive force of a rapid stream of sharp sand driven against them by artificial means. The process was invented by General Benj. C. B. Tilghman, of Philadelphia, who took out a patent for it in October, 1870. In the world of nature the abrading power of sand, when driven by air or water against hard substances, has long been recognized, and General Tilghman's invention was merely an application of this principle to the mechanical arts. The means of propulsion may be supplied either by an air or a steam blast, the former being produced by a boiler at high pressure, and the latter by a fan revolving with a great velocity. In either case the abrading material, which is usually a common hard sand, although small granules of iron or crushed quartz are occasionally used, is directed by a tube upon the object to be cut or engraved, the latter being so adjusted by means of slides that each part in succession can be brought under the action of the cutting particles. The engraving of the surface of glass with ornamental figures, etc., may by this process be very easily accomplished, simply by laying upon it patterns of the desired objects cut out of some resistant medium in the manner of stencils. The sand, of course, does not touch the protected parts, but indents those which are uncovered, until the result sought for is attained. Another method very commonly used is to cut the proposed pattern in sheet copper or brass, which is then placed over the glass, a brush of melted beeswax being drawn over the whole. The stencil is then raised, and the pattern left in exposed glass may then be operated upon by the blast. The ornamentation of glass in colors may also be performed by the sand-blast, for as the ordinary colored glass of commerce is mere window glass, with a thin layer of color on one side only, the use of the stenciled pattern as before will entirely remove the color from the exposed parts and leave it where protected. By the use of a photographed coating of gelatine upon glass (the well-known gelatine process in photography) very beautiful reproductions of line engravings may be made upon the glass at a small cost. The sand-blast has also been used successfully in the cutting of ornaments and inscriptions upon stone. Iron stencils are sometimes used for the purpose, but the most satisfactory material is found to be sheet rubber of about 1-16th of an inch in thickness. This is cemented upon the stone, and a movable jet pipe is caused to traverse the surface of the latter until the exposed portions have been sufficiently abraded. The wear upon the rubber itself is wonderfully slight, and the same stencil may be used over and over again. Another use to which the sand-blast has been successfully put is in turning blocks of stone and metal into circular and other forms in the lathe. Balcony pilasters, etc., have in this way been finished in a few hours which would have needed as many days to be cut out by hand. Upon wood the action of the sand-blast is not so satisfactory, being slow and tedious, and the only way in which it can be utilized on this material is in cutting out the large block type used in printing posters. The foregoing are only a few of the ways in which the sand-blast has manifested its usefulness, but as the invention is still in its infancy it is impossible to say what applications in the arsenal and workshop may not be found for it in the future. From its first appearance the sand-blast has attracted much attention both at home and abroad, many foreign patents have been taken out, and the use of the process is gradually spreading.

SAND-CRACK.—A splitting or fracture of the horny fibers of the horse's hoof, extending usually from above downward; when reaching to the quick it causes lameness, and in all cases it constitutes unsoundness. Horses with thin, weak, brittle feet, spoilt by much rasping, and rattled on the hard roads, furnish the majority of cases. The horn must be thinned for an eighth of an inch on either side of the crack, across the upper and lower ends of the crack, to prevent its extension, the firing-iron should be drawn, making a line nearly through the horny crust. The opening may further be held together by winding round the foot several yards of waxed string, or fine iron wire. Except in very bad cases, slow work on soft land may be permitted, but road work is very injurious. The growth of healthy horn is promoted by applying round the coronet, at intervals of 10 days, some mild blistering liniment.

SANDHURST ROYAL MILITARY COLLEGE.—In 1802 it was determined to institute a College for the training of military officers, in which professional education should be grafted on the groundwork of general instruction. The College was opened at Great Marlow; but, in 1812, it was transferred to a handsome stone building at Sandhurst. Up to 1862 this was devoted to the education of boys from the age of 13 upward. In that year, however, the system was changed; the course limited to one year immediately before entering the army, and the subjects of instruction confined to the higher mathematics, modern languages, and military science. Entrance was on the nomination of the Commander-in-Chief; and the payment by the Cadet's parent or guardian varies from £100 to *nil*, according to the circumstances and rank of the parent. Those for whom no payment is made must be orphans, and are styled "Queen's Cadets." Under the purchase system, all first commissions in the Cavalry and Infantry of the Line, which were granted without purchase, and not to men from the ranks, were given to Cadets from the Royal Military College, who competed for these prizes, and obtained them in order of merit. The abolition of purchase in 1871 brought about a radical change. The students are no longer boys intending to become officers, but Sub-lieutenants, who, having passed by competition for the army, spend a year at Sandhurst in acquiring the theoretical part of the war science. To be confirmed in the army as Lieutenant, the officer must pass creditably out of Sandhurst, and then serve a year on probation with a regiment. It cannot be doubted that this change of system must tend, as years go on, to secure for the army a great body of scientific officers. The Staff College is a separate Institution, about 2 miles distant. The estimated charge for the Royal Military College for 1878-79 was £36,281, of which about £5,000 is covered by the payments for the students.

SAND-SHOT.—Small cast-iron balls, such as grape, canister, or case, cast in sand. Larger balls are cast in iron moulds. This nature of shot varies in weight from 4 pounds to 1½ ounces.

SANFORD TARGET.—A canvas target possessing all the essentials of the Wimbledon target, but having a simpler mechanism, based on the principle of a window with upper and lower sashes, made to balance themselves, so that when one is pulled down the other is proportionately and simultaneously elevated. The frame work of this target is made of wood, and by increasing or diminishing the length of these frames, any class target can be erected at will, provided the length of the pit is sufficient. The pit should be at least eight feet long by six feet wide at the top, and seven feet deep for a second or third-class target. The framework of the target has two legs, which are secured to the sash by passing through staples fastened thereon. With this target a ricochet is signalled by waving the red flag three times in front of the target; otherwise, the marking and signalling are the same as when using the Wimbleton target.

SANGIAC.—A situation or appointment of dignity in Turkey. The Sangiacs are Governors of towns or Cantons, and take rank immediately after the *Beglerbegs*. The name is also applied to the banner which he is authorized to display, and has been mistaken for Saint Jacques.

SANITARY.—Having reference to measures for securing health. Within the last twenty years increased means have been adopted to reduce the state of mortality amongst the soldiery. During the Crimean war, the casualties were large at first, but from sanitary measures being taken, the number of deaths per 1,000 men was greatly reduced. In England, up to 1853, the mortality per 1,000 amongst the soldiery was 17.5, whereas that of the male population amounted to 19.2. The great mortality was in those days amongst the Foot Guards, and appears to have arisen in a great measure from want of proper sanitary arrangements. But a great improvement of late years has taken place in the health of the soldier; his barracks are better ventilated, his comforts and amusements are greater, and indeed all the measures adopted to keep him in health are more numerous than they formerly were. In 1874 the strength of the army in Great Britain was about 90,000; the average rate of mortality during that year was 8¾ per 1,000; this was a higher death rate than in 1873, which is accounted for in the higher death rate among the general population in 1874. The report from which the above information is gained observes that "no doubt the rate of admission and death in 1874 was also somewhat raised by the circumstance that many invalids from abroad, instead of being sent to Netley, joined their depots, and the records of their admission and deaths were not always kept distinct from those of the other soldiers."

SANITARY REPORT.—A report made yearly, or oftener, by Army Surgeons. The Report usually embraces the following subjects:

GARRISON—PERSONEL.

1. Present strength—mean strength, composition

and changes during the year, transient troops and the destination.

2. Civil employes and servants.

3. Women, children, and servants.

QUARTERS.

4. Barracks—Geographical and physical site, material, capacity, character, special features, etc.

5. Dormitories—superficial area and cubic air-space per man, ventilation.

6. Dormitories—warming and lighting, natural and artificial.

7. Dormitories—bedding, bunks, material, single, double, or superimposed.

8. Dormitories—fixtures for clothing, arms, seating, police.

9. Barrack offices, clothing and provision rooms, cellars, coal sheds.

10. Kitchens and company bakeries.

11. Mess-rooms, mess-furniture, quantity, condition, and material. Separate for N. C. O.'s.

12. Bath-rooms, lavatories, and facilities for ablution.

13. Married soldiers' quarters—relative site, number of sets, material, usual number of occupants to each room.

14. Officers' Quarters—Number of sets—material and character. Bathing and water facilities, condition and sufficiency.

15. Guard-house—Site, suitability, character, material, internal construction and arrangement, ventilation, warming, lighting, police, facilities afforded for cleanliness of inmates, minimum, maximum, and average occupancy by prisoners.

FOOD.

16. Rations—quality, quantity, variety, suitability for seasons and geographical situations, deficiencies, portions from which company savings are made.

17. Fresh Meat—kind, quality, mode of procuring, issuing, inspecting, preserving, and how often issued to troops.

18. Facilities for marketing for officers.

19. Extra supplies kept by Sub. Dept. for sale to officers—quality, sufficiency, and variety. Deficiencies, if any.

20. Extra vegetables, pickles, and other articles of food, game and fish—amount and how obtained.

21. Cooking—how often, by whom and when inspected, and hours for serving meals.

22. Gardens—post or company, how cultivated, disposition of produce.

23. Cows kept by companies—number of each.

24. Post-bakery—character, capacity, condition, and management.

25. Water-supply—Whence and how obtained, distributed, kept for use, quality and quantity. If well-water is used, give means for protection against sewage and drainage.

26. Ice—how obtained and preserved, quantity qualtity, allowance, and months of issue.

27. Store-houses—capacity and suitability for preserving rations.

28. Fuel—kind, quality, quantity, and suitability to climate and season.

CLOTHING.

29. Quality, condition, appropriateness for season and locality, especially in regard to blankets, boots, shoes, socks, and hats.

EMPLOYMENT.

30. Character and amount of martial and fatigue duties.

POLICE.

31. Personal habits, temperance, cleanliness, and bearing of men.

32. Sinks, latrines, privies, urinals, and water-closets—relative situation to barracks and quarters, condition, facilities for flushing, emptying, or how contents disposed of.

33. Drainage and Sewage—extent and character, natural and artificial, general and special, effects or defects.

34. Stables—relative site of cavalry, quartermasters, and others for the accommodation of officers private horses. Capacity, condition, and material. Police and disposal of manure.

35. Cow-pens, mule-corrals—relative position and police.

36. Are pigs or chickens kept for the benefit of the soldiers' mess?

37. Regulations governing the keeping of dogs at post and precautions against danger of hydrophobia.

38. Police—general, of post, how, when, and by whom done. Police—special, nature, whitewashing of fences, facilities, frequency. Police of yards and out-buildings attached to officers' quarters.

39. Recreation—facilities for boating, hunting, fishing, swimming, skating, games of strength and dexterity, ten-pins, billiards, base ball, cricket, theatricals, music, etc.

40. Post School—Site, capacity, and suitability, number of teachers and pupils, attendance by enlisted men, heating, ventilation, water-closets for pupils, etc. Divine service—facilities for attendance on.

41. Post or Company Libraries—number and the character of volumes, facilities afforded men for reading.

42. Recruits—physique and character.

43. Nature and frequency of punishment, effects on health and morals of soldiers.

HOSPITAL AND SANITARY.

44. Hospital buildings—site, relative position, condition, and suitability.

45. Hospital grounds—extent, cultivation, drainage, shade.

46. Heating, shading, lighting, ventilation, and protection from lightning.

47. Hospital wards—capacity, superficial area and air-space per bed, average occupation of each ward, isolation ward for the treatment of contagious diseases.

48. Hospital wards—fixtures and furniture.

49. Hospital kitchen and laundry—position, furniture, fixtures, and condition.

50. Hospital mess-room—fixtures and furniture.

51. Hospital offices, dispensary, store-rooms—fixtures, furniture, suitability, cellars, coal-sheds, out-buildings, condition, and use.

52. Hospital post-mortem room—the situation, fixtures, furniture, and condition.

53. Hospital lavatories—bath-extent, convenience, water-supply, drainage, etc.

54. Hospital water-closets, sinks, urinals—site and drainage.

55. Hospital drainage and sewage—separate or connected with other systems.

56. Hospital police and hospital grounds and vicinage.

57. Hospital diet—how cooked, inspected, served, and difference from diet-table.

58. Hospital garden—size, how cultivated, amount and variety of produce.

59. Cows, chickens, milk, butter, eggs, kept and raised for hospital.

60. Ice—how supplied to hospital, amount, and months issued.

61. How and when are purchases made from hospital fund, and its monthly average.

62. Hospital stewards—name, length of service, general and special character.

63. Attendants—names, length of service, character and discipline.

64. Officers, facilities for treatment of, in hospital.

65. Hours of sick-call, winter and summer

66. Percentage of sick to command, ditto of mortality to sick.

67. Aggregate number of days' service lost to Government by sickness of soldiers during year.

68. Cleanliness of patients on admission, discipline.

69. Nursing—how and by whom performed, night service.

70. Occupation and amusements of convalescents, reading matter, games, etc.

71. Prevalent diseases at post and vicinity.

72. Nature and amount of diseases amongst women, children, civil employés, camp followers at post, number and cause of deaths, and number of births at post during year.

73. Diseases, if any, of local origin.

74. Diseases supposed to be checked by hygienic measures.

75. Hospital supplies—whence obtained, quality, and condition in which received and kept.

76. Instruments—hospital and personal, condition.

77. Amount, nature, and condition of hospital bedding.

78. Amount, nature, and condition of the hospital clothing.

79. Amount and condition of hospital appliances.

80. Hospital Library—number of volumes, condition, and conveniences for preservation.

81. Hospital records, blanks, condition, supply, completeness; files of orders, condition.

82. Average monthlytemperature—extremes,wind, moisture.

83. Means of subduing fire at post, and special at hospital.

84. Means for transportation of sick and wounded —ambulances, stretchers.

85. Hospital tents—extra number, how kept, condition, and use.

86. Interments—how conducted, post cemetery—area, care, and condition.

87. Inhabitants of surrounding country, the Indian tribes, etc.

88. Sanitary measures recommended at the post—copies marked and appended herewith.

89. Extra sanitary measures enforced in hospital.

90. Miscellaneous facts and general recommendations.

SANJAK.—A Turkish word signifying "a standard," employed to denote a subdivision of an *Eyalet*, because the ruler of such a subdivision, called *Sanjak Beg*, is entitled to carry in war a standard of one horse-tail. The Sanjak is frequently called *Liva*, and its ruler a *Mirmiram*.

SANJAK-SHERIF.—The sacred banner of the Mohammedans. See *Flag of the Prophet*.

SANSCULOTTES.—The name given in scorn, at the beginning of the French Revolution, by the Court Party to the democratic "Proletaires" of Paris. The latter accepted this superfine reproach with sardonic pride, and the term soon became the distinctive appellation of a "Good Patriot," more especially as such a one often made a point of showing his contempt for the rich by neglecting his apparel, and cultivating rough and cynical manners. As the Noblesse prided itself on an illustrious pedigree, so the genuine child of the Revolution boasted that he was come of a long line of—noteless Sansculottes; that his "Ancient but ignoble blood had crept through scoundrels ever since the flood"

Toward the close of the Convention the name, connected as it had been with all the sanguinary excesses of the period, naturally fell into bad odor, and soon after totally disappeared: nor do the French appear to wish that its memory should be preserved, for they have not given it a place in their encyclopedias.

SAP.—In military engineering, the narrow ditch or trench, by which approach is made from the foremost parallel toward the glacis or covert-way of a besieged place. The sap is usually made by four sappers, the leading man of whom rolls a large gabion before him, and excavates as he progresses, filling smaller gabions with the earth dug out, and erecting them on one or both sides to form a parapet. The other sappers widen and deepen the sap, throwing more earth on to the parapet. A sap is considered to advance in average ground about eight feet per hour. From the nearness of the enemy's works, running a sap is an extremely dangerous operation. When possible,therefore, it is carried on at night: in any case, the sappers are relieved at least every hour. When a sap is enlarged to the dimensions of a trench, it bears that name. See *Double Sap*, *Half-double Sap*, *Flying Sap* and *Full Sap*.

SAP-FAGOTS.—Short fascines of straight brushwood at least one inch in diameter, used in regular approaches. Sap-fagots are two feet and nine inches long, and five inches in diameter. The center stake should be from one and one-half to two inches in diameter, and project nine inches beyond one end of the sap-fagot; this projecting portion is sharpened, to enable the sap-fagot to be planted firmly in the ground in an upright position.

SAPPER.—1. The name given to a private soldier in the Corps of Royal Engineers. The name of the Corps was formerly Royal Sappers and Miners. The pay of the sapper is £20 10s. 7½d. a year, with extra pay when at work: the number of such men for 1877-8 was 2,952. Only men of good character, already adepts in a mechanical trade, are eligible for this service, which is very popular, as an intelligent sapper frequently passes into some situation in civil life for which his practical military training specially fits him. Many sappers are excellent surveyors, photographers, and draughtsmen. 2. There is attached to the Corps of Engineers. United States Army, a company of sappers, miners, and pontoniers, called engineer soldiers. The company is composed of Sergeants or master workmen, Corporals or overseers, musicians, privates of the first-class or artificers, and privates of the second class or laborers. The said engineer company is subject to the Rules and Articles of War, is recruited in the same manner and with the same limitation, and is entitled to the same provisions, allowances, and benefits as are allowed to other troops constituting the present military peace establishment. The company is officered by officers of the Corps of Engineers, it performs all the duties of sappers, miners, and pontoniers, and aids in giving practical instructions in those branches at the Military Academy; and is under the orders of the Chief Engineer, liable to serve by detachments in overseeing and aiding laborers upon fortifications or any other works under the Engineer Department, and in supervising the finished fortifications, as fort-keepers, and preventing injury and applying repairs. In marches near an enemy, every column should have with its advance a guard detachment of sappers, furnished with tools to open the way or repair the road. It would be well if these sappers, as suggested by General Dembinski, were mounted, in order rapidly to regain the advance guard, after having finished their work.

SAPPING.—A mode of making trenches by continually advancing the head of the trench when the execution of common trench-work or the flying sap would expose the workmen to a close fire of musketry, before they could obtain cover.

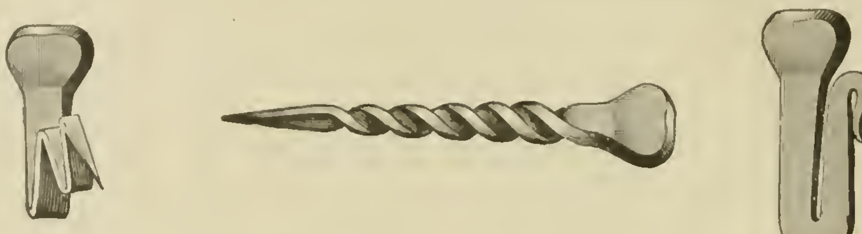
SAP-ROLLER.—A large gabion, 7½ feet in length, and 4½ feet exterior diameter. It requires for its construction 15 stakes, each from 1¼ inches to 2 inches in diameter. After it is completed, it is stuffed compactly with fascines 7½ feet long. The sap-roller is sometimes made of two concentric gabions, the diameter of the smaller being 2½ feet, and the space between the two compactly stuffed with fascines. The use of the sap-roller is to protect the squad of sappers, in their approach, from the fire of the place.

SAP-SHIELD.—A steel plate mounted on wheels for the purpose of giving cover to the sapper in a single sap, should the earth thrown up by him not be of sufficient thickness to give him shelter. The shield used in the English service is that invented by Sergeant Major Knight, R.E.

SARACEN'S HEAD.—A not unfrequent bearing in

Heraldry. It is represented as the head of an old man with a savage countenance.

SARANAC HORSE NAIL.—A nail of American manufacture which has attained a remarkable degree of success. The nail is much used by the United States Government, with satisfactory reports on it from officers in the field. The principles and effects of hand-made nails are fully retained in its process of manufacture, and insure for it a pre-eminence for toughness, strength, freedom from flaws, and beauty and superiority of finish. Being hammered at nearly welding heat, it is firmer and tougher, maintaining the stiffness and ductility without deteriorating, but rather improving the quality of the iron, producing absolute freedom from any tendency to sliver in driving, a cause of lameness and injury to so many horses. The drawings show how these nails may be twisted and bent when cold. The machinery or "mills" by which these nails are made are of very peculiar construction, and to the unmechanical mind seem complicated, but their operations are easily understood. The nail is forged (or hammered) hot, the machine making about 700 revolutions per minute, each eleven forming one nail. Thus it will be seen that about 65 nails are forged per minute. From the forging machines the nails are placed in tumblers for polishing, into which a strong current of air is forced, blowing all dust, etc., therefrom, and the product leaving in a remarkably bright form. The nails are then put through finishing-machines, by which the points are rolled out and trimmed cold. There are five of these machines in operation, known as Woodford's patent. The process of manufacture embraces the principles and effects of the old method of forging by hand, avoiding all straining of the iron, while the finish is very superior.



SARBACANE.—A blow-pipe, or long tube of wood or metal, through which poisoned arrows were shot by blowing with the mouth.

SARCELED.—A term in Heraldry, signifying a cut through the middle.

SARDAR.—In the East Indies, a chief or leader.

SARDINIAN HUTS.—Wooden huts made by many English officers in the Crimea and by the Sardinians for their men. They were 14 feet 3 inches long and 7 feet 1 inch wide in the clear; they could contain 6 infantry soldiers, and were found very comfortable.

SARISSA.—A Macedonian pike, a formidable weapon either for attack or defense, about 24 feet in length. The sarissa was borne by the *oplitai* of the Romans, and the other heavily armed troops. Also written *Sarisse.*

SARRAZINE.—An old name for a rough portcullis.

SARRE.—When artillery was first invented, a name given to a long gun, of smaller dimensions than the *Bombarde.*

SASH.—In the British Service the sash is a military distinction, worn on duty or parade by Officers and Non-commissioned Officers. For the former it is crimson silk; for the latter, crimson cotton. By officers it is worn over the left shoulder, and by Non-commissioned Officers it is worn over the right shoulder. There are no sashes in cavalry regiments. The sashes for the Austrian army are of crimson and gold; the Prussian army, black silk and silver; the Hanoverians wear yellow silk; the Portuguese, crimson silk with blue tassels, and the French have their sashes made of three colors, white, pink and a light blue, to correspond with the national flag. Sashes are generally worn around the waist, and were originally invented for the convenience and ease of wounded officers, as they might by such means be carried off the field with the assistance of two men.

SATELLITES.—Certain armed men, of whom mention is often made in the history of Phillip Augustus, King of France. The Satellites of Phillip Augustus were men selected from the militia of the country, who fought on foot and on horseback. The servants or batmen who attended the Military Knights when they went into action were likewise called Satellites, and fought in their defense mounted or on foot.

SATRAP.—In the ancient Persian Monarchy the Governor of a Province, whose power—so long as he enjoyed the favor of the King—was almost absolute. He levied taxes at his pleasure, and could ape the tyranny of his Great Master without let or hindrance. When the Monarchy of Cyrus began to decline, some of the Satraps threw off their slight allegiance, and founded independent Kingdoms or Sultanates of their own, the most famous of which in very ancient times was the Mithridatic Kingdom of Pontus.

SATURN.—In Heraldry, the black color in blazoning arms; sable.

SAUCISSON.—A fascine of more than the ordinary length; but the principal application of the term is to the apparatus for firing a military mine. This consists of a long bag or pipe of linen, cloth, or leather, from about 1 inch to 1½ inches in diameter, and charged with gunpowder. One end is laid in the mine to be exploded; the other is conducted through the galleries to a place where the engineers can fire it in safety. The electric spark is now preferred to the saucisson. See *Blasting* and *Mines.*

SAUL.—A tree well known in India, especially in the North-west Provinces. It is used in the construction of parts of gun-carriages. The wood is strong, tough, coarse-grained, and fibrous, not easily worked, and when dressed has a hard horny surface, and the fibers appear to be interlaced with each other. A cubic foot of the unseasoned wood weighs from 68 to 72 lbs. This tree grows also in Assam and Burmah.

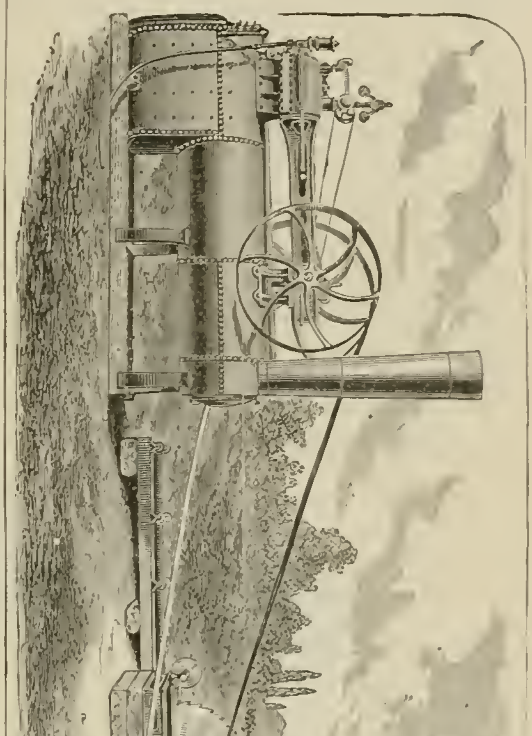
SAVAGES.—In Heraldry, *Savages* or *Wild Men* are of frequent occurrence as supporters. They are represented naked, and also, particularly in the later Heraldry, are usually wreathed about the head and the middle with laurel, and often furnished with a club in the exterior hand. Savages are especially prevalent in the Heraldry of Scotland. In more than one of the Douglass seals of the first half of the 15th century, the shield is borne in one hand by a single Savage, who acts as sole supporter.

SAVING-BANKS.—In 1842 an Act was passed for establishing military saving-banks in connection with the Regimental Pay Departments of the English Army. Another Act was passed in 1859, affording greater facilities to the frugal soldier. The proceedings of these banks in the first four years present the following figures:

	Deposits in Year.	Withdrawals in Year.
1859	£70,736	£64,497
1860	163,491	116,393
1861	167,136	149,090
1862	152,203	164,775

The figures have fluctuated through causes not stated in the Parliamentary Returns, being about the same in 1871 as in 1861, after being much lower in some of the intervening years, and much higher in 1866. The number of accounts open in the latest years was about 14,500, including those of many army charitable funds. By means of such banks the soldier can profitably deposit his money under Government security to the extent annually of £30, the whole deposit being confined to £200, inclusive of interest. Interest at the rate of £3 15s. per cent. per annum is paid; no interest is allowed on other parts of a pound than 6s. 8d. and 13s. 4d., nor on sums that have not remained on deposit one month. In the United States Army the soldier deposits with the Paymaster.

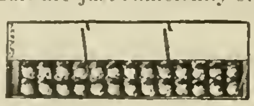
SAW MILL.—As troops are frequently called upon to construct their own quarters, and to assist in the erection of the buildings at newly established posts, it becomes necessary to investigate the construction and full operation of the saw mill, the proper management of which is essential in order to supply suitable timbers to the carpenters. Portable saw mills are variously designed with a view to lightness and fewness of parts. The Watertown Circular Saw Mill is much used in the United States, and will serve to illustrate the points which should be observed by all those entrusted with the management of a mill. The drawing represents the mill set up with an ordinary traction or agricultural engine. It will be noticed that the center frame, which is made of wood or of iron, is very solid and substantial. It can be very readily taken apart, when convenience in shipping is an object. The saw arbor is very heavy, with forged collars and a nut to hold the saw. The saw and pin holes are of standard size, so that a saw can be supplied by any saw manufacturer, with the certainty of its fitting. The arbor runs in long bearings, lined with anti-friction metal, and readily adjustible in any direction. At the same time the saw can be given any lead desired. The driving pulley can be placed within the frame, or on the outside as preferred. The feed is extremely simple. A belt passes loosely over a cone pully on the saw arbor, and a corresponding pulley on a parallel shaft, which has on its outer end a small friction roller. A pinion in the feed shaft engages the rack, and a lever is so arranged that a motion in one direction tightens the belt and feeds the log up to the saw, while a motion in the opposite direction presses the friction roll against the rim of a large flange pulley, connected by belting to the saw arbor, and gives a rapid return to the carriage. The carriage is made of Norway pine, six inches square, well seasoned, and securely and heavily stayed with wrought-iron. It is made in sections of twelve feet, and is shod with heavy V-shaped iron. It runs on chilled rollers, with babbitted boxes. The ratchet wheel upon the connecting shaft is so divided that each cog will set the log $\frac{1}{4}$ inch. The ratchet wheel is actuated by a set lever and four pawls of unequal lengths, which divide each cog in the ratchet in four parts, so the log may be moved, if required, $\frac{1}{16}$ inch by one movement of the set lever. Bolted to the head-block is a half circle, (called a "set circle,") in which are holes drilled at equal distances apart throughout its entire length. To these holes is fitted a pin to which is attached a cast-iron block having four sides, each side of which is at a different distance from the center of the pin. The sides of this block are marked as follows: $\frac{1}{16}$, $\frac{1}{8}$, $\frac{3}{16}$, $\frac{1}{4}$. Now, if the pin is put into the *first* hole in the set circle, with the side of the block marked $\frac{1}{16}$ towards the set lever, by bringing the lever against the block the log will move $\frac{1}{16}$ of an inch; if the pin is turned around, so the lever strikes the side marked $\frac{1}{8}$, the log will move $\frac{1}{8}$ inch, and so of all the sides. Putting the pin in the second hole, the log will move $\frac{1}{2}$ inch; third hole $\frac{3}{4}$ inch, and so of all the holes in the circle. Of course



the thickness of the stuff to be sawed can be varied $\frac{1}{16}$ of an inch in each hole of the circle if required. There is also a scale on each side of the head-block that can be used if desired. Knees slide directly upon the head-blocks, and are connected by gears with the set rod, which extends nearly the whole length of the carriage. The following points may be noted in connection with the mill: 1st. The friction feed and gig-works will slip instead of breaking in case of accident. 2d. A single lever controls all the movements of the carriage. 3d. The feed lever can be operated *outside* of the carriage—enabling *one man* to do both setting and feeding, thus doing all the work that *two men* perform in mills of other make. 4th. The set is exceedingly accurate and reliable. The last board is as perfect as the rest. 5th. Both ends of the log are set equally and at once, by a single lever. Or the head-block may be disconnected, and either end be set independently of the other, if preferred. 6th. The mill is reversible, and can be set up either right or left hand, adapting it to any mill site, without the expense, annoyance, and liability to error in setting.

SAWYER PROJECTILES.—The Sawyer projectile has upon its sides six rectangular flanges or ribs to fit into corresponding grooves of the bore. To soften the contact with the surface of the bore, the entire surface of the projectile is covered with a coating of led and brass foil. The soft metal at the corner of the base is made thicker than at the sides to admit of being expanded into the grooves, and thereby closing the windage. In the latest pattern of Sawyer projectiles the flanges are omitted, and the projectiles are made to take the grooves by the expansion of the soft metal at the base, which is peculiarly shaped for this purpose.

The Sawyer canister-shot consists of a casing of malleable iron, in one piece, in the form of a hollow cylinder, having one end closed by a head cast therewith, through which head is forced one or more small holes, through which a portion of the gas occasioned by the explosion of the charge of powder enters, driving forward the small iron balls and disengaging the metal cover placed in the forward end of the casting to hold the contents in position till fired. The casting has cut through its walls one or more series of oblique slits, the end of each slit slightly overlapping the end of the next slit in the same series, thus nearly severing the casting into two or more sections; said sections being held only by the narrow bars of metal between the contiguous ends of two slits; which bars are just sufficiently strong to with-



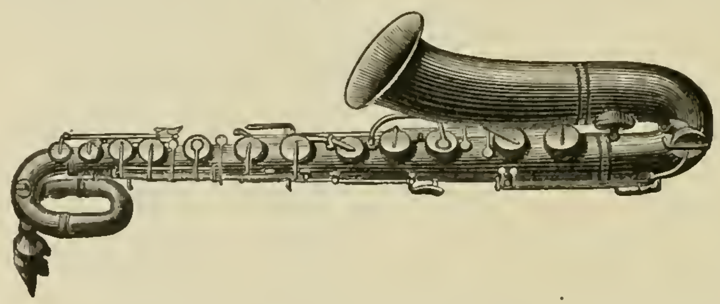
stand the ordinary shock of handling and transportation, but not strong enough to resist the shock of the explosion of the charge of powder in the gun; so that when the shot is discharged from a gun the cover is stripped from the mouth of the casing, and the casing is broken into two or more sections, from which the small shot are more readily and completely discharged than they would be if the casing remained intact, and each of said sections of the shell serve as a solid shot, doing greater execution than could be done were the shell to remain in one piece. See *Canister-shot, Expanding Projectiles*, and *Projectiles*.

SAXE.—A sort of Roman *gladius*, with a grooved blade, and very sharp on one side. Frequently called *Scramasaxe*.

SAXE SYSTEM OF FORTIFICATION.—In this system wood is substituted for masonry. The body of the place consists of an earthen cavalier, inside of which wooden barracks are constructed. This is surrounded by an enciente of small bastions. A third enciente is formed by large ravelins, the rampart of which is pierced with long embrasures for the defense of the main ditch. A fourth enciente of narrow counter-guards is constructed with wood and earth, and it has also embrasures through which guns mounted on rafts can be fired. A lunette, with retired flanks, defends the ditch, and a covered-way surmounts the whole. At about 3,000 paces from the center of the fortress, a continuous line of redans (36 in number) and curtains forms an advanced enciente. The redans contain solid towers of masonry, 25 feet high, several of which the besieger must take before he can open the trench. The immense quantity of wood required, and the rapid decay, are rather against this system.

SAXON.—A German powder-horn, about 12½ inches in length, invented at the close of the 16th century.

SAXOPHONE.—A brass musical instrument with a single reed and a clarionet mouth-piece. The body of the instrument is a parabolic cone of brass provided with a set of keys. Although these instruments are not a new invention, they have been comparatively unknown in this country until the past few years.



An instrument capable of such beautiful effects should not be left unnoticed by the military bands. They are by no means difficult to play, being considered by most musicians easier to master than a clarionet. Two of them, the B♭ Soprano and E♭ Alto, or where it is possible a full quartette, add immeasurably to the production of that class of music so very difficult to interpret satisfactorily with brass bands—overtures, and operatic selections. They have only to become better known to be considered a necessity in all leading bands.

SAYETTES.—A name given to arrows in the twelfth century, according to the Chronicles of Saint Denis.

SCABBARD.—The objects of the scabbard are to carry the sword and protect the blade from injury. Scabbards are generally secured to a belt, which passes over one of the shoulders, or around the waist of the wearer. For foot-troops, scabbards are made of leather, mounted with metal to protect them from wear. For scabbards for mounted troops, leather has not sufficient stiffness and strength, and steel is used in the place of it. The principal objections to metal scabbards are that they are heavy, dull the edge of the blade, and make considerable noise in striking against the equipments of the horse and rider. In certain parts of Asia these objections are overcome by making the scabbards of wood, covered with leather or rawhide. See *Hand-arms*.

SCALADE.—A furious attack upon a wall or rampart, contrary to form, and with no regularity, frequently carried on with ladders, to insult the wall by open force.

SCALE.—A line or rule of a definite length divided into a given number of equal parts, and used for the purpose of measuring other linear magnitudes. In map or plan drawing, the scale expresses the relation which the dimensions of the map bear to the natural features of the ground; this relation is frequently expressed by a representative fraction. For example, the representative fraction of a map on a scale of 1 inch to a mile is $\frac{1}{63360}$, that is, one inch on the map is equal to 63,360 inches (one mile) on the ground; in other words, the map represents all features on the ground 63,360 times smaller than their natural size. The following is the rule given for finding the fraction of a given scale. Reduce the number of yards in a mile into inches; divide the number found by the number of inches on which the scale is made, and the dividend will be the number of inches represented by one mile.

All countries have adopted special scales for their various classes of maps and plans; the following are those in use in the English Ordnance Survey:

Natural Scale.	Inches to 1 Mile.	Remarks.
$\frac{1}{500}$	126.720	Plans of towns.
$\frac{1}{528}$	120	Ditto.
$\frac{1}{1000}$	63.36	Ditto.
$\frac{1}{1056}$	60	Ditto.
$\frac{1}{1760}$	36	Special maps.
$\frac{1}{2376}$	26.6	Ditto.
$\frac{1}{2500}$	25.344	Parish Plans. Cadastral survey.
$\frac{1}{2640}$	24	Special maps.
$\frac{1}{5280}$	12	Ditto.
$\frac{1}{10560}$	6	County maps. Reconnoissances.
$\frac{1}{12672}$	5	Indexes.
$\frac{1}{15840}$	4	Special maps.
$\frac{1}{21120}$	3	Indexes. Reconnoissances of roads.
$\frac{1}{31680}$	2	Special maps.
$\frac{1}{63360}$	1	General map of the United Kingdom.
$\frac{1}{253440}$	0.25	Special maps (4 miles to an inch).
$\frac{1}{316800}$	0.2	Ditto (5 miles to an inch).
$\frac{1}{633600}$	0.1	Index map (10 miles to an inch).
$\frac{1}{1900800}$	0.03	Special maps, etc., (30 miles to an inch).

The best scales for field surveys are 2, 4, and 8 inches to a mile; for an index plan, 2 and 3 inches to a mile. Continental nations indicate the scale upon which a map is drawn, by the fraction that any linear distance measured thereon is of the actual distance on the ground. The principal scales used for military maps in Europe are as follows:

Austria ... ... $\frac{1}{14400}$ = 4·4 inches to the mile.
$\frac{1}{28800}$ = 2·2 " "
$\frac{1}{86400}$ = 0.733 inch "
Belgium ... ... $\frac{1}{20000}$ = 3.168 inches "
$\frac{1}{40000}$ = 1.584 inch "
$\frac{1}{80000}$ = 0.792 " "
Denmark ... ... $\frac{1}{20000}$ and $\frac{1}{500000}$
$\frac{1}{160000}$ = 0.396 " "
France ... ... $\frac{1}{80000}$ and $\frac{1}{400000}$
$\frac{1}{320000}$ = 0.198 " "
Germany ... ... $\frac{1}{25000}$ = 2.534 inches "
$\frac{1}{50000}$ = 1·268 inch "
$\frac{1}{100000}$ = 0.634 " "
$\frac{1}{80000}$ and $\frac{1}{200000}$ "
Holland ... ... $\frac{1}{25000}$ and $\frac{1}{50000}$. "
Italy ... . $\frac{1}{86000}$ and $\frac{1}{50000}$ and $\frac{1}{250000}$.
Russia ... . $\frac{1}{84000}$ = 0.754 inch to the mile.
$\frac{1}{126000}$ = 0.508 " "
Spain ... ... $\frac{1}{60000}$ = 1.056 " "
$\frac{1}{100000}$.
Sweden and Norway $\frac{1}{20000}$ and $\frac{1}{100000}$ and $\frac{1}{1000000}$.
Switzerland ... ... $\frac{1}{25000}$ and $\frac{1}{50000}$.

By dividing 63,360 (number of inches in a mile) by the denominator of the fraction of the scale, the number of inches it is to the English mile will be found. Thus—

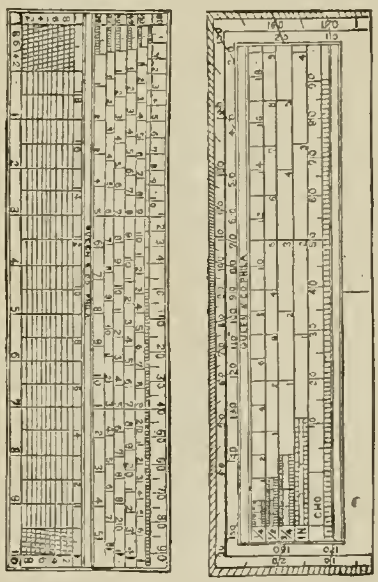
$$\frac{63360}{86400} = 0·733,$$

or the scale of $\frac{1}{86400}$ is equal to
0·733 inch to the mile.

A *scale of shade*, the invention of Colonel Scott, R. E., has been introduced into the service, and is used as a guide in determining the thickness and distance apart of each hachure for different angles and slopes. This scale is engraved for convenience on the back of a protractor, and is graduated for 35°, 25°, 15°, 10°, 7°, 5°, 3°, and 2°.

The term *scale* is also applied to a mathematical instrument consisting of an assemblage of lines engraved on a rule of wood or ivory, by means of which certain proportional dimensions or proportions are obtained by means of compasses. The principal are the *plain scale*, the *diagonal scale*, and *Gunter's scale*.

The *diagonal scale* is a mathematical instrument which is used when minute parts of a measurement are required, such as the tenth or hundredth part of



an inch. The formation of this scale is thus described in Heather, on "Mathematical Instruments":—"Draw eleven parallel equidistant lines; divide the upper of these lines into equal parts of the intended length of the primary divisions, and through each of these divisions draw perpendicular lines, cutting all the eleven parallels, and number them 1, 2, 3, etc., commencing from the second. Subdivide the first of these primary divisions into ten equal parts, both upon the highest and lowest line of the eleven parallel lines, and let these subdivisions be reckoned in the opposite direction to the primary divisions, as in the simply divided scales. Draw the diagonal lines from the tenth subdivision below to the ninth above, and so on, until a line from the first below joins the zero point above. Then, since these diagonal lines are all parallel and equidistant, the distance between any two of them in succession, measured upon any of the eleven parallel lines which they intersect, is the same as this distance measured upon the highest or lowest of these lines, that is, as one of the subdivisions; but the distance between the perpendicular, which passes through the zero point, and the diagonal through the same point, being nothing on the highest line, and equal to one of the subdivisions on the lowest, is equal to one-tenth of a subdivision on the second line, two-tenths on the third, and so on; so that this, and consequently each of the other diagonal lines, as it reaches each successive parallel, separates further from the perpendicular through the zero point by one-tenth of a subdivision, or one-hundredth of a primary division."

Gunter's scale is a flat brass rule, usually 2 feet in length, and about 1½ inch broad, having on one side equal parts, rhombs, chords, etc., as on the other plane scale, and on the other, the logarithms of these numbers; hence the lines on this side are called the logarithmic lines.

The term *scale* is also given to a graduated steel or wooden bar attached to guns, and known as the *tangent-scale.*

The *tangent-scale* attached to S. B. ordnance is a rod of metal or wood, made to slide perpendicularly in a groove at the breech, having engraved upon it the actual lengths of the tangents to the different angles of elevation. The object of the tangent-scale is to give elevation to a piece of ordnance beyond what the line of metal affords.

In rifled guns the tangent-scales, of which there are two attached to each gun, do not rise in a vertical plane, as in smooth-bore ordnance, but are set at an angle to the left from the vertical, to compensate for the lateral deviation caused by the right-handed rifling. They each consist of a rectangular steel bar, on which is engraved all information for the successful discharge and laying of the gun, such as the range, length of fuse, nature of charge, etc. On the top of the scale a tangent-sight is attached, which has a cross-head with a sliding-leaf and a clamping screw, by means of which the deflection caused by the wind blowing across the range, or one wheel being higher than another, can be met. This is known as the *deflection-scale.* This scale is graduated to 30′ on each side of the cross-head, each 30′ being divided into three spaces of 10′ each. By the aid of this scale, as shown above, compensation can be made to the right or left for the deflection of the shot by wind or inequality of the ground on which the carriage may be standing. This scale must not be mistaken for the scale for *permanent deflection* caused by the rifling of the gun. This deflection is met by the position of the tangent-scale or sight.

SCALE-ARMOR.—That armor of the Middle Ages, which consisted of small plates of steel riveted together in a manner resembling the scales of a fish. From the small size of the plates, it possessed considerable pliability, and was therefore a favorite protection for the neck, in the form of a curtain hanging from the helmet. Scale-armor is now obsolete, except, perhaps, among some Eastern Potentates.

SCALET.—An ancient name given to a lifting-jack. It was chiefly used in extricating wheels from deep ruts and soft ground.

SCALING.—Scaling a piece of artillery is flashing off a very small quantity of powder to clean out the bore; about one-twelfth of the shot's weight. The practice of scaling is now discontinued.

SCALING-LADDERS. When a place is badly guarded, all parts are accessible with ladders, but it is sometimes best to choose the highest walls for the escalade, as the enemy will probably, from a feeling of security, be less vigilant at such parts of the body of the place. Thus, at the siege of Badajoz in 1812, the English escaladed the highest walls in the city, and penetrated into the interior, while the attack directed upon breaches in the lower walls, although vigorously made, was repulsed. When it is considered how slow a process it is to bring up ladders to the counterscarp, in order to descend by them into the ditch, then to cross the ditch, and to rear the ladders against the escarp, and to mount them, it is evident that success will, in a great measure, depend upon the number of men that can mount at the same moment; in other words, upon the number of ladders. A ladder beyond a certain length becomes unwieldy, and the rearing of it difficult. The distance from the foot of the ladders to the wall should be at least equal to one-fourth of their height. If the distance be greater, the ladders are easily broken under the weight of the men mounting them; if much less, they will be so erect that the soldiers, as they ascend, must be continually in danger of falling headlong down. The scaling-ladders introduced by Sir Charles Pasley are in pieces of 12′ 8″ and 7′ 6″ in length, fitting into each other with strong double iron sockets, and tied by stout ropes. These can be arranged for any length, and quickly adjusted. Ladders made of long spars are awkward to carry; especially if there be any narrow sharp turnings in approaching the point of escalade; nor can long sound spars be always procured. It is desirable that ladders should be made of a light, tough wood; teak wood is too heavy. If a guy-rope be attached to each side of the ladder, they greatly assist in adjusting it and fixing it against the wall; the men told off for the guy-ropes should stand close to the wall, within the slope of the ladder; and these guy-ropes should be fixed at 5 or 6 feet below the top of the ladder, to prevent their being cut by the enemy on the wall. The total lengths of the ladders should exceed the height to be escaladed by 3 or 4 feet, in order that the men may step easily off the ladders on to the parapet or wall. Many failures have occurred from ladders being too short. It is desirable to have a pair of stout lifting bars, 3 or 4 feet long, with hooks, for each ladder. When an escalade is to take place, be sure to practice the men intended for the service thoroughly in carrying, in fixing, in ascending, and descending the ladders; descending, for going down a counterscarp; ascending, for getting up an escarp. Always use as many ladders as possible. If there be a counterscarp to descend, leave half the ladders there, while the other half are used against the escarp, that no time may be lost. Ascend the ladders together, on as large a front as possible. When an escalade is opposed by an enemy, take care that a good firing-party covers the escalade, with especial directions to fire upon any work that may flank the ladders. Avoid night attacks, except under peculiar circumstances: the example of gallant men is lost at night, whilst timidity is infectious. Make all arrangements under cover of darkness, but assault at day-break.

SCALLOP —This term, more commonly written *escalop,* signifies, in Heraldry, a species of shell. It has been considered the badge of a pilgrim, and a symbol of the Apostle St. James the Greater, who is usually represented in the garb of a pilgrim.

SCALPING.—A custom among the Indian warriors of North America, resorted to as a token of victory over an enemy. It is accomplished by grasping the hair above the top of the head, raising it with the skin to which it is attached, and quickly cutting the latter loose. Scalping *alone* is not fatal.

SCARF.—In Heraldry, a small ecclesiastical banner suspended from the top of a crozier.

SCARP.—The side of the ditch adjacent to the parapet. When the ditch of a fortress is dry, the scarp is usually faced with mason-work, to render it difficult of ascent; and behind this facing (*revêtement*) there are often passages or casemates for a defense. In temporary fortifications, the *revêtement* is sometimes of wood; while in field-works, palisades at the foot, or fraises on the *berme* or edge of the ditch, are held sufficient. The scarp is always made at as large an angle as the nature of the soil will allow; the design being to offer the greatest possible obstacle to an assailant. See *Counterscarp.*

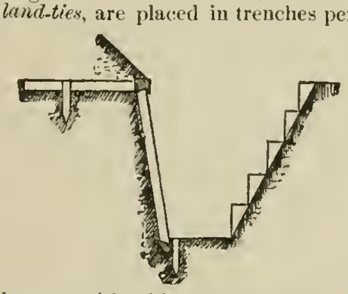
SCARPE.—In Heraldry, a diminutive of the bend sinister, being half the breadth of that ordinary.

SCARP GALLERY.—Galleries used to sweep the ditch with their fires are either scarp or counterscarp galleries, according to the position which they occupy. The usual method of building such a gallery is to excavate the earth behind the scarp or counter carp, as the case may be, until there is room to place the frame, if there is one to be used, or until there is room to accommodate the men who are to occupy the gallery. This excavation is then closed in front by a stockade built along the line of the scarp or counterscarp; it is closed overhead by a bomb-proof roof, the top of which is the parapet, in the case of a scarp gallery, and the glacis or natural surface of the ground, if a counterscarp gallery.

The arrangements of loop-holes, dimensions, etc., are all similar in kind and character to those for caponières. The entrance to a scarp gallery is by a covered passage; the same might be used for a counterscarp gallery; generally, the entrance to the latter is by openings into the ditch, at the ends of the gallery, which openings can be closed by bullet-proof doors. Counterscarp galleries are used at the salients of a work; scarp galleries at the re-entrants. These galleries should not be placed in positions where they would be exposed to artillery-fire. If there was any danger of exposure to this fire, and it was necessary to use one of these defenses, it is plain that the counterscarp gallery is to be preferred.

A scarp gallery, either for musketry or for one or two pieces of cannon, may be constructed to procure a flank fire in ditches with dead angles. These galleries may be made in all respects like a double caponière; the bottom of the gallery being sunk low enough to allow the greater portion of the ditch to be swept. As the top of the gallery must support that portion of the parapet of the work above, it must be firmly shored by strong timber. The rear of the gallery must be open, and there should also be an escape for smoke at the berme of the parapet above the gallery. A construction of a like character may be used to form a blind for one or two guns which it may be particularly desirable to place under cover from an enemy's artillery. The sides of the blind may be farther secured by placing against them either gabions or sand bags. See *Counterscarp Gallery* and *Gallery*.

SCARP REVETMENT.—This revetment is serviceable where the foot of the scarp is subject to wash, as in a wet ditch. It is formed of a frame-work of heavy timber, and is used chiefly for important field forts. A piece, termed a *cap*, is imbedded in a trench made along the line of the berme; and other pieces, termed *land-ties*, are placed in trenches perpendicu-



lar to the cap, with which they are connected by a dovetail joint; they are about 8 or 10 feet apart. Cross-pieces are halved into the land-ties near their extremities, and two square piles, about 5 feet long, are driven in the angles between the land-ties and the cross-pieces; inclined pieces, serving as supports to the cap, are mortised into its under-side at intervals of 8 or 10 feet. These supports usually receive a slope of ten perpendicular to one base; they rest on a *ground-sill* at the bottom of the ditch, to which they are mortised, this still being held firm by square piles.

Behind this frame-work, thick plank, or a heavy scantling is placed side by side, having the same slope as the supports; or else a rabate may be made in the cap and ground-sills, and the scantling be let in between these two pieces, serving as a support to the cap. This is the more difficult construction, but it is the better, since, should the heavy supports be cut away, the cap will still be retained in its place. Scarp revetments are sometimes formed by laying heavy timber in a horizontal position; but this method is bad, as it enables the enemy to gain a foothold by thrusting their bayonets between the joints. The length of the land-ties should be at least equal to two-thirds the depth of the ditch. The counterscarp is seldom reveted. A frame-work similar to that for the scarp might be used, and thick boards, laid horizontally, be substituted for the inclined scantling.

When a scarp revetment is made, the excavation of the ditch must be conducted in a different manner from that already explained. In this case, after the cap-sill and land-ties are laid, the excavation is continued to the bottom of the ditch, by removing only earth enough to allow the frame-work to be put up. A scaffolding of plank is then raised in the ditch on which the earth, that remains to be excavated, is thrown, and from there on the berme. See *Revetment.*

SCARP WALL.—To give strength and durability, the faces of the ditch are revetted with walls of masonry which sustain the pressure of the earth, protect them from the effects of the weather, and by their height and steepness present an additional obstacle to an open assault. The wall of masonry towards the rampart rises to the level of the foot of the exterior slope of the parapet, sustaining the pressure of rampart and parapet, and is called *scarp wall* or *scarp revetment;* the face of it towards the ditch, the *scarp.* The top of the scarp wall is finished by a course of broad, flat stones called the *coping*, which project beyond its face, and, serving as a *larmier* or a *drip*, protects it from the effects of the rain-water that runs from the parapet upon the coping.

Scarp walls are of three kinds: first, the ordinary retaining walls, strengthened by counterforts supporting directly the earth of the rampart; second, the same with relieving arches; and third, detached, wholly or in part, from the rampart. A scarp wall 30 feet high is usually admitted as a sufficient protection in all dry ditches against an escalade. That scarps over 30 feet high have been scaled is too true; but the success was owing to a want of ordinary precautions on the part of the assailed, and to the garrison not being of suitable strength to guard all points efficiently.

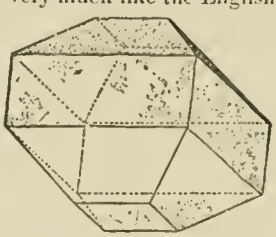
That heavy assaults upon comparatively weak field-works have been repulsed with great slaughter, we have also plentiful records of in our own and European contests. But in these cases the numerical strength of the contending parties under fire was nearly equal, and the defense of the most vigorous character, so that any shelter, however slight, would have inclined the balance on the side of the assailed. These are extreme cases, upon which it would be very unsound to base any rules for practice. As the object of all fortifications is to supply the place of numerical weakness on the part of the defense, the safer practice would seem to be to do this by placing such an obstacle in the way of an open assault that but a few men, promptly availing themselves of it, might frustrate long enough the attempt of the assailant to give time to gather sufficient force at the point assailed to render the attack abortive. When they act as retaining walls, to hold up the excavated side of the ditch towards the rampart, the rampart itself, and the parapet, they should receive a thickness and form of profile adapted to this end.

In the scarp walls of Vauban and Cormontaigne, and in many of the more modern fortifications of Europe, the scarp walls are built solid, with counterforts on their back, of the forms and the dimensions adopted by Vauban. This engineer gave his scarps a batir of $\frac{5}{1}$. Cormontaigne, finding that the faces of these walls were soon injured by the weather, adopted a batir of $\frac{6}{1}$. This for the same reason was increased by some to $\frac{12}{1}$, by others to $\frac{20}{1}$; and, in our climate, where the action of the weather on masonry is very injurious, our engineers have varied their batir from $\frac{24}{1}$ to $\frac{48}{1}$. Although no ordinary scarp walls can resist breaching, and have to be covered by earthen masks to screen them from the distant fire of the assailed, they should be so constructed as to render breaching a difficult operation;

limiting the breach made to the part of the wall actually destroyed by the assailant's projectiles. To give greater efficacy to the resistance offered to breaching, and to prevent such breach from taking a very gentle slope when formed, it has been proposed by some to back the wall and counterforts by a variety of pisé work, or with beton with but little lime in it, and of several feet in thickness. Others have proposed, for the same purpose, to connect the end of the counterforts by vertical arches, and to fill the cells thus formed either with pisé, or with this poor beton. See *Counterscarp Wall*.

SCEPTER.—Originally a staff or walking-stick, and hence in course of time, also a weapon of assault and of defense. At a very early period the privilege of carrying it came to be connected with the idea of authority and station. Both in the Old Testament and in Homer, the most solemn oaths are sworn by the scepter, and Homer speaks of the scepter as an attribute of Kings, Princes, and Leaders of Tribes. According to Homer, the scepter descended from father to son, and might be committed to any one to denote the transfer of authority. Among the Persians, whole classes of persons vested with authority, including Eunuchs, were distinguished as the "Scepter-bearing Classes." The scepter was in very early times a truncheon pierced with gold or silver studs. Ovid speaks of it as enriched with gems, and made of precious metal or ivory. The scepter of the Kings of Rome, which was afterwards borne by the Consuls, was of ivory and surmounted by an eagle. While no other ensign of sovereignty is of the same antiquity as the scepter, it has kept its place as a symbol of royal authority through the Middle Ages down to the present time. There has been considerable variety in its form; the scepter of the Kings of France of the first race was a gold rod as tall as the King himself.

SCHAGHTICOKE POWDER. A polyhedral powder, constructed very much like the English. The drawing shows the shape of the grain.



It is granulated from properly compressed ordinary press-cake in the following way: The cake is placed on a movable table or form, which is made to pass between two pairs of rollers. A set or comb of stationary cutters meets the cake on its passage and marks a series of grooves on its surface. By turning the cake half-way round, it is marked out into squares on a second passage. This process applied to the reverse face gives it a similar character, and determines the planes of fracture along which the cake will brake up to form the grains.

As tests in an 8-inch rifle in 1876, the following results were obtained: the density of the powder being 1.784 and the granulation 74:

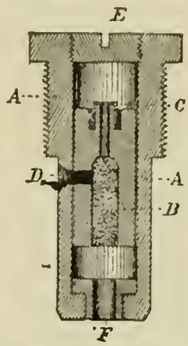
Nature of gun.	Kind of powder.	Weight of charge.	Weight of projectile.	Velocity.	Pressure.
8-inch rifle	Polyhedral. Laflin & Rand.	*Lbs.* 35	*Lbs.* 180	*Feet.* 1,360	*Lbs.* 37,500

See *Gunpowder*.

SCHAIFE.—In the Middle Ages, a term applied to a quiver or bundle of arrows.

SCHEITER SYSTEM OF FORTIFICATION.—This system borrows from Castriotto the detached bastions, gives to them a fausse-braye, as well as to the enciente, and surrounds the place by a double covered-way. All the counterguards consist of two walls 18 feet thick, 50 feet apart, with a roof of timber and earth; the interior space is divided by a floor into two stories, affording ample room for two tiers of guns.

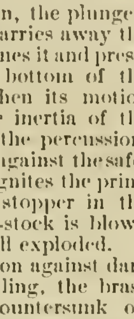
SCHENKLE PERCUSSION FUSE. This fuse consists of a metal fuse-stock, *A*, inclosing a movable core-piece or steel plunger, *B*, bearing a musket-cap, *C*. The plunger, primed and capped, is held in place by a screw or pin, *D*, which passes through a hole in the side of the stock and plunger. A safety-cap, *E*, is screwed into the top of the fuse-stock, and its bottom is closed by a cork or leather stopper, *F*.



When the projectile is set in motion, the plunger, by its inertia, carries away the pin which confines it and presses against the bottom of the fuse-stock. When its motion is arrested, the inertia of the plunger causes the percussion-cap to impinge against the safety-cap, which ignites the priming, when the stopper in the bottom of fuse-stock is blown out and the shell exploded.

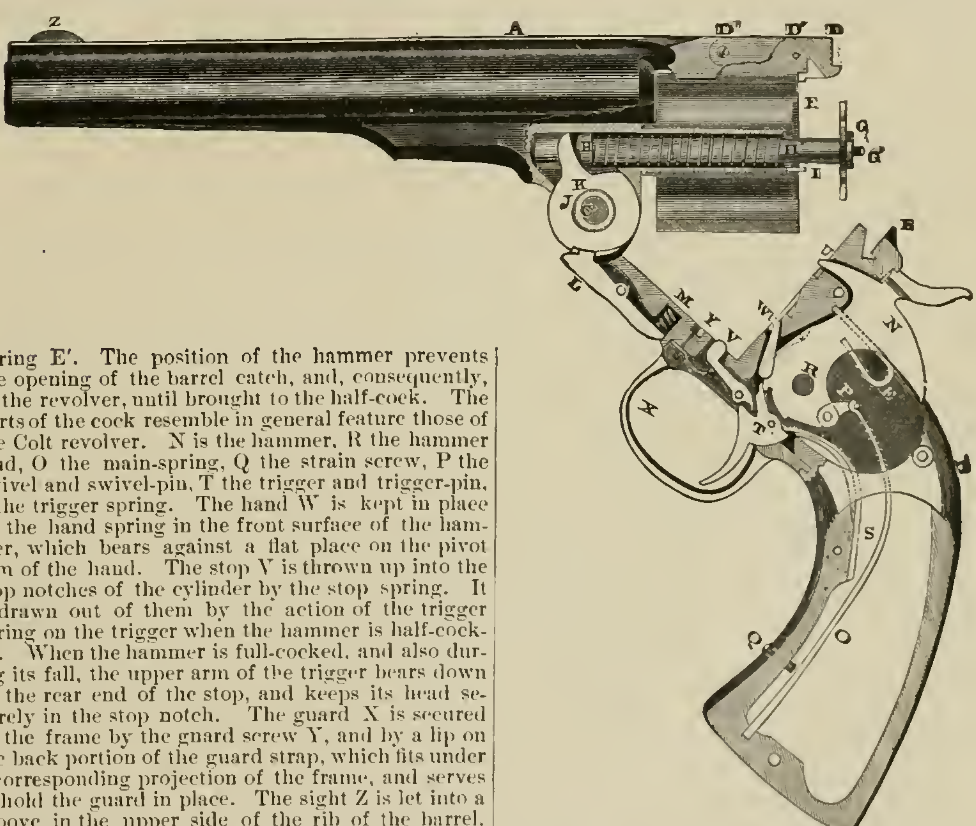
As a precaution against danger while handling, the brass safety-cap is countersunk on one end and flat on the other. It is kept with the countersunk end down except when loading; while this end is down, should the plunger become loose, the percussion-cap is prevented from coming in contact with the hard surface of the safety-cap, but on being turned end for end a plane surface is opposed to the percussion-cap, upon which it might strike. There is a slit cut in the top of the fuse-stock and cap, which is designed for the entrance of the fuse-wrench. See *Fuse*.

SCHENKLE PROJECTILE.—This projectile, which is shown in the drawing, is composed of a cast-iron body (*a*), the posterior portion of which is a cone. The expanding portion is a *papier maché* sabot or ring (*b*), which is expanded into the rifling of the bore by being forced on the cone by the action of the charge. On issuing from the bore the wad is blown to pieces, leaving the projectile unencumbered in its flight. A great difficulty has been found in practice in always getting a proper quality of material for the sabot, and in consequence, these projectiles have not been found to be reliable. See *Expanding Projectiles* and *Sabot*.



SCHIAVONE.—A sword having a basket hilt, used by the Doge's Guards in the sixteenth and seventeenth centuries. They were not known in Scotland until the eighteenth century.

SCHOFIELD SMITH AND WESSON REVOLVER.—The principal changes in this revolver, now used in the United States Army, from the original Smith and Wesson revolver, are in the extractor, the cylinder catch, and the barrel catch. By referring to the sectional drawing, the operation of the parts may be readily understood. A is the barrel joined to the frame B by the joint screw C. Under and behind the barrel projects the base pin upon which the cylinder F revolves. This is kept in its place on its pivot by the inner hook of the cylinder-catch D″, and is held down by the cylinder-catch cam D′, the upper part of the middle portion of which is cut away and allows the catch to rise when the cam is turned to a certain position. The base pin is hollow, and contains the extractor stem H, made in two parts, which screw together. Between the head of the stem and the bottom of the hole of the cylinder is confined the extractor spring H′, which is compressed when the extractor moves out. The extractor G is recessed into the face of the cylinder. The ratchet by which the cylinder is revolved, is cut in the face of the extractor, and the extractor stud G′ forms a rear bearing for the cylinder on the frame when the revolver is closed. The steady-pin I keeps the extractor exactly in place when it is down. The lifter J moves upon the friction collar K under the influence of the pawl L; the pawl is pressed against the lifter by the pawl spring M; the lifter is moved by the pawl in one direction only, and is therefore free to follow the motion of the extractor spring. In closing the revolver, the outer hook of the cylinder catch presses back the barrel catch E, and engages it under the influence of the barrel catch



spring E′. The position of the hammer prevents the opening of the barrel catch, and, consequently, of the revolver, until brought to the half-cock. The parts of the cock resemble in general feature those of the Colt revolver. N is the hammer, R the hammer stud, O the main-spring, Q the strain screw, P the swivel and swivel-pin, T the trigger and trigger-pin, S the trigger spring. The hand W is kept in place by the hand spring in the front surface of the hammer, which bears against a flat place on the pivot arm of the hand. The stop V is thrown up into the stop notches of the cylinder by the stop spring. It is drawn out of them by the action of the trigger spring on the trigger when the hammer is half-cocked. When the hammer is full-cocked, and also during its fall, the upper arm of the trigger bears down on the rear end of the stop, and keeps its head securely in the stop notch. The guard X is secured to the frame by the guard screw Y, and by a lip on the back portion of the guard strap, which fits under a corresponding projection of the frame, and serves to hold the guard in place. The sight Z is let into a groove in the upper side of the rib of the barrel. The recoil plate U receives the bearing of the cartridge head at the time of the fire. The following table gives the principal dimensions, weights, etc., of the revolver:

DIMENSIONS.

Total length	12″.5
Length of barrel	7″.5
Diameter of bore	0″.45
Grooves, number of	6
Grooves, twist of, uniform	1 turn in 16″—left-handed
Grooves, depth, uniform	0″.005

WEIGHTS.

Total weight	2.31 lbs.
Weight of powder charge (service)	28 grs.
Weight of bullet	230 grs.

The powder charge and weight of ball have been lightened to adapt the cartridge to the Schofield Smith and Wesson revolver. See *Smith and Wesson Revolver*.

SCHONSTEDT FUSE.—This fuse is very similar in its action to the Prussian, but has the advantage of acting both as an ordinary fuse and as an explosive one, and in having neither fulminating powder nor sulphuric acid in its construction. The case is made of a mixture of lead and tin, and the bottom part of it is made thick enough to allow the cutting of a side channel, which enters the central one near its end. The breaker is similar to the one in the Prussian fuse. A tube of glass open at both ends, and wrapped so as to fit, as in the Prussian fuse, takes the place of the closed tube. The side-channel is filled with ordinary fuse-composition, and the space around the thimble with a composition which burns out in two seconds. The glass tube is filled with fine powder, and a strand of quick-match, the lower end of which last is inserted in the mouth of the side-channel, where it enters the central one. When the shell is fired the quick composition takes fire, and being consumed in two seconds, sets fire to that in the side-channel, at the same time that it leaves the breaker unsupported. This upsets by the shock of striking, and the flame in the side-channel communicating with the powder and the quick-match in the broken glass tube, explodes the shell. In case the explosive apparatus does not act, the shell acts like one with a time fuse, and explodes when the side-channel composition burns out. See *Fuse*.

SCHOOL-MASTER.—In the English Army, the School-master is a Non-commissioned Officer of the first class, ranking next to a Sergeant Major. His pay varies with the length of service, rising gradually from 4s. a day on appointment, to 8s. a day after long service. He has an advantage over other Non-commissioned Officers in quarters and certain allowances. To become an Army School-master, it is necessary either to be a Certificated School-master, or to have served the apprenticeship as a Pupil-teacher, and to pass through a course of training for one year at the Normal School in the Royal Military

Asylum, Chelsea. After the completion of the training, the candidate is required to enlist as a common soldier for ten years' general service, whereupon he is immediately promoted to the rank of School-master. A few of the most deserving School-masters are promoted to Sub-inspectors of Schools, when they rank as Lieutenants, having 10s. a day for pay. The duties of the School-master are to teach the soldiers and their children the rudiments of general knowledge, to examine the girls' school, and to deliver lectures to the soldiers. There were in 1874, 180 Army School-masters, besides 13 Sub-inspectors.

SCHOOL MISTRESS. A person attached to each English Regiment or Corps for the purpose of instructing the daughters of soldiers and their sons under eight years old in the rudiments of English and in plain needlework. She must be a Certificated School-mistress, or a Pupil-teacher who has served her apprenticeship. After admission to the service, she is specially trained for six months at one of the four training institutions. This training is at the expense of the Government. The salary of a School-mistress varies from £30 a year in the third class to £50 a year in the first class. Proper provision is made for the quarters and supplies of the School-mistress, whose somewhat anomalous position among rough men calls for the most circumspect behavior. The annual charge (1873-74) for Army School-mistresses amounted, for 161, to the sum of £5,362.

SCHOOL OF GUNNERY.—A School established at Shoeburyness for the purpose of giving practical instruction to Officers and men of the artillery, and for carrying out the experiments connected with their branch of the service. This School consists of a Commandant and a Brigade Major, with 6 Instructors in Gunnery and 2 Superintendents of Experiments. Officers, Non-commissioned Officers, as well as squads of men selected from brigades of artillery, are sent thither from Woolwich for instruction in gunnery and the use of military machines, etc. The course of instruction at this establishment is divided into a *long* and *short* course. The *long course* is an annual course of instruction for Officers and Non-commissioned Officers of the Royal Artillery, partly carried out at Woolwich, and partly at Shoeburyness. One Officer is selected from every brigade at home and abroad, and 2 or 3 Non-commissioned Officers from a home brigade; they assemble at Woolwich on February 1, and go first through the manufacturing departments of the Woolwich Arsenal for 2 months. They then go to Shoeburyness, and remain there 9 months, during which time they complete a course of gunnery, signaling, bridging, etc. At the end of this period, they have to be examined, and certificates are given according to their qualifications. Officers obtaining a first-class certificate are eligible for the appointment of Instructors, and Non-commissioned Officers for that of Assistant Instructors. The *short course* is a similar course, but only lasts 2, 3, or 4 months, and is formed as circumstances allow, but at no specified time. It is usually composed of 2 or 3 Non-commissioned Officers from each or several home brigades. This course is usually confined to gun exercises and the uses of the various kinds of ammunition.

SCHOOL OF MILITARY ENGINEERING.—A school formed at Chatham for the special training of Officers of the Royal Engineers, after they have passed through the Academy at Woolwich, and also for the men and recruits of the Corps. This School consists of a Commandant, a Brigade Major, 2 Discipline Officers, and 11 Officer Instructors in construction, surveying, field-fortification, telegraphy, etc. Officers of the cavalry and infantry are permitted to attend the classes of instruction given at Chatham in flag-signaling, surveying, etc. A branch of this School has been established on board her Majesty's ship *Hood*, in the Medway, for the training of Engineers in submarine or torpedo duties. The men forming the torpedo companies are selected, on the completion of their course of instruction in field-works, from the depot companies of the School of Military Engineering, where, later on, extensive and practical knowledge of electricity in its application to the ignition of mines is imparted to them.

SCHOOL OF MUSIC.—The School at Kneller Hall, near Hounslow, for the training of the Band-masters and Musicians. Men showing musical talent and abilities, and desirous of being trained as Band-masters and Musicians, may offer themselves as candidates to this School on the recommendation of Band Committees, and are admitted into it under certain conditions.

SCHOOLS OF INSTRUCTION.—Establishments for the education of the officers of the Regular English Army and of the Auxiliary Forces in the advanced branches of their profession. To give officers an opportunity of going through the course carried on at these Schools, they are detached in turn from their regiments. Schools have been established in all the large garrison towns of the United Kingdom, and specially for the Auxiliary Forces, at Glasgow, London, Manchester, and Dublin, where they are placed under Garrison Instructors. In India, similar means of instruction are given to officers, and for this purpose Garrison Instructors are appointed to each of the principal cantonments or districts.

The Royal Hibernian Military School, which is situated at Dublin, Ireland, is for the maintenance, education, and training of boys for purposes of enlistment and service in the Army. The children to be admitted into the Institution must be free from mental or bodily defect or infirmity. They must be the children of a Non-commissioned Officer or Soldier in her Majesty's regular forces, or of a Non-commissioned Officer or Soldier deceased or discharged from the service. Children to be admitted must not be under 7 nor above 12 years of age. In the selection of boys for admittance, a preference in general is given:—Firstly, to orphans; Secondly, to all those whose fathers have been killed or have died in the foreign or home service: Thirdly, to those who have lost their mothers, and whose fathers are absent on duty abroad; Fourthly, to those whose fathers are ordered abroad on foreign service, or whose parents have other children to maintain.

SCHOOLS OF MUSKETRY.—When the introduction of the Minié rifle in the French service, and the subsequent arming of the British troops with the still more delicate Enfield rifle in 1851, brought the accuracy of a soldier's fire to be an important consideration in estimating his value (which with the old musket was not the case, as it was proverbial that the bullet never hit the point aimed at, however carefully), the English Government at once saw the necessity of providing instruction in the manipulation of the rifle. Accordingly, Instructors of Musketry were attached to the troops, one to each regiment; and a School was established at Hythe in 1854, under the late General Hay, where lessons on the theory of the arm, and practice in its actual employment, were the sole occupation of the day. Officers and promising men were sent there in great number, and soon became instructors to their comrades, so that the shooting of the whole army soon rose in a surprising degree. Whereas, before the establishment of this School, the English stood low in the scale of shooting, the competitions held during recent years at Wimbledon have demonstrated that no nation can hardly excel them as marksmen. The formation of the Volunteer Corps, in 1859, led to a greatly increased demand for musketry instruction, which the Government met by forming a second School of Musketry at Fleetwood (now abandoned), where the troops and volunteers of Scotland, Ireland, and the northern English counties found the necessary teaching. The Hythe School is superintended by a Commandant and Inspector General of Musketry Instruction, with subordinate Instructors. The

Inspector General is responsible also for the instruction throughout the regiments all over the world, and to him the musketry returns from each regiment are sent annually. See *Musketry Instruction.*

SCHULTZ CHRONOSCOPE.—This instrument, invented by Captain Schultz, of the French Artillery, is designed for the measuring of very short intervals of time. By means of it, periods varying from thirty seconds to the one-five thousandth part of a second

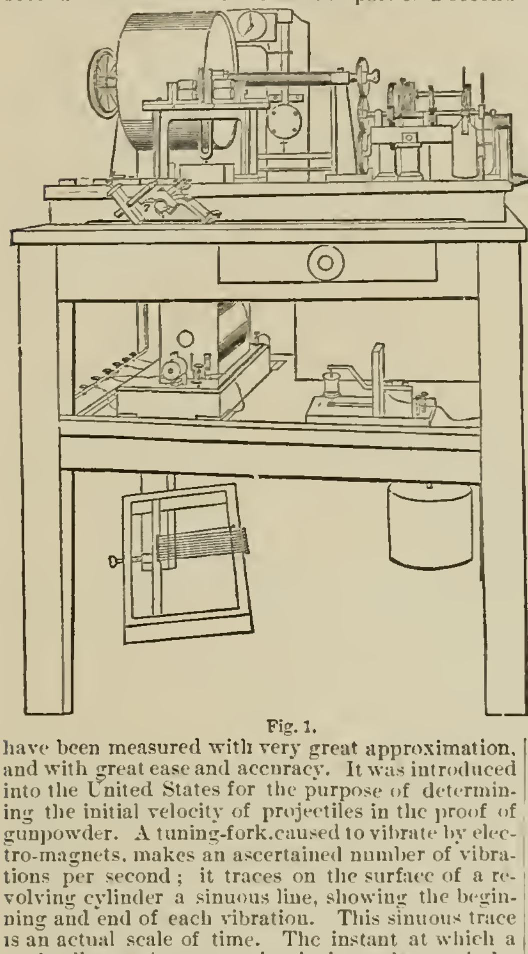


Fig. 1.

have been measured with very great approximation, and with great ease and accuracy. It was introduced into the United States for the purpose of determining the initial velocity of projectiles in the proof of gunpowder. A tuning-fork, caused to vibrate by electro-magnets, makes an ascertained number of vibrations per second; it traces on the surface of a revolving cylinder a sinuous line, showing the beginning and end of each vibration. This sinuous trace is an actual scale of time. The instant at which a projectile reaches any point in its trajectory is by the application of electricity marked upon the cylinder beside the scale of time. The number of vibrations comprehended between any two consecutive marks, is an exact measurement of the time elapsing between the instants at which the projectile occupied the corresponding positions in its trajectory. The measurement of time depends on the equality of duration of the vibrations made by the fork; the number of these vibrations in the unit of time is fixed by the construction of the fork.

The principal parts of the machine, Fig. 1, are the *cylinder*, *vibrating fork*, *electro-magnets*, the *wheel-work*, and the *electric interrupter*, *Ruhmkorff coil*, *pendulum*, and *micrometer*, and while experimenting, the *galvanic batteries* and *targets*. The cylinder has a double motion of rotation and translation, given by means of a weight acting on a system of clock-work. These motions can also be given separately by hand. The silvered face of the cylinder is covered with a thin coating of lamp-black, which is removed by the trace and spark, exposing the surface in strong contrast to the blackened parts. The vibrating fork stands immediately in front of the cylinder; on each side of it is an electro-magnet to originate, sustain, and equalize the amplitude of the vibrations. The left branch of the fork is armed with a flexible quill-point, which, by an eccentric roller, can be made to touch the cylinder at pleasure, and thus make the traces upon it. The interrupter is the mechanism by which the current for the fork's electro-magnets is made and broken. The "Russell Interrupter" is now used in the United States with the machine. In the Schultz chronoscope at West Point the detached mercury interrupter has been replaced by a light metallic spring, which is pressed against the tuning-fork on the inner side of the prong, making the fork its own interrupter when the electrical current is passed through it. The sparks indicating the time of rupture of the targets are produced by means of the Ruhmkorff coil. To use the coil, the primary wire is connected with a battery and the targets, the secondary wire with the instrument. One end of the latter wire is brought through a glass tube close to the cylinder, just over the fork; the other end is connected with the bed-plate and hence with the cylinder. By this arrangement, when the primary current is broken by rupturing the target wire, a secondary current is induced, and a spark is projected from the end in the glass tube to the face of the cylinder. The pendulum is used to determine the exact number of vibrations or "*tarage*" of the fork in a second of time, a matter of the greatest importance. It is connected with an ordinary clock-work, and should be regulated to beat half seconds with accuracy. To determine the number of the fork's vibrations, the Ruhmkorff coil is put in connection no longer with the targets, but with the pendulum, which is so arranged that, at every double beat, the current is broken and a spark made on the cylinder, marking each second of time. As the cylinder can run for thirty seconds, the number of vibrations sought can be obtained with close approximation by dividing the entire number of vibrations registered on the cylinder by the number of seconds. The micrometer serves to divide a vibration on the cylinder into very small parts for close reading. A double vibration of ordinary length may then be divided by it into 2,000 parts, and as each of the former is about the one-two hundred and fiftieth of a second, the reading of the micrometer may approximate to the one-five hundredth portion of a second of time. The vibrations made by the fork are recorded on the cylinder in the form of a sinuous line, Fig. 2, making the scale of time. The middle line, *a*, traced by the fork when at rest, is of great importance, as it divides the sinuous line, and gives the exact points of the origin and end of each vibration. Even when not in the middle, no error can occur when double vibrations are counted. To determine the value of the interval between two sparks, the number of double vibrations is then counted. Where both sparks fall immediately opposite to the intersections of the two lines, the value will be summed up in entire double vibrations, as in Fig. 2, *x* and *y* then being the sparks. Where one or both of the sparks do not fall opposite an intersection, the value of the interval is easily found. Two galvanic batteries are used, one connected with the interrupter, the other with the Ruhmkorff coil. In working the instruments it is essential that the current pass through only one target at a time, there being but one coil and battery,

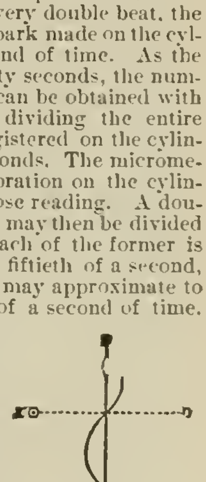

Fig. 2.

no matter how many targets may be used. After the first target is ruptured the current must be transferred to the succeeding one before the projectile reaches it, and so on throughout the series. There are different arrangements by which this may be effected.

The cylinder is coated by revolving it over the flame of an oil lamp. The operator, standing in front of the instrument, releases the translating screw, pushes the cylinder to the right, clamps it to the wheel-work, and throws the translating screw into gear again. He then sets the point of the quill, at the extremity of the fork, very lightly against the face of the cylinder, and releases the brake to the wheel-work. While rotating the cylinder is moved toward the left by the translating screw, and receives the trace of the middle line in the form of a helix. This done, the quill is raised, and the cylinder pushed to the right, as before. The quill is again set with its point exactly on the middle line, the translating screw thrown into gear, the circuit of the battery and the interrupter closed, and the spring on the interrupter moved by the adjusting screw till the proper vibration of the fork is obtained. At this point the caution "Ready" is given, the circuit of the battery and the Ruhmkorff coil promptly closed, and the cylinder started rotating, when the command "Fire" is given. As soon as the report is heard, the machine is stopped by the brake, both currents opened and interrupted, the quill point removed, and the cylinder detached from the wheel-work; the operator then counts the result. The vibrations of the fork are known to be isochronal for the same fork, when their amplitude is constant and are in no way affected by the motions of other parts of the machine. The "*tarage*" of the fork should be verified occasionally, and should always be taken when from any cause it may be supposed to have varied. To insure the greatest accuracy, it should be taken before each series of experiments. The limit to the precision of the machine depends upon the greater or less instantaneousness in the production of the spark; but the construction of the targets acts as a remedy, requiring, as they do, but one coil and one battery, whatever may be their number. See *Chronoscope*, *Galvanic Battery*, and *Russell Interrupter*.

SCHULTZE POWDER.—Captain Schultze, of the Prussian army, in the course of his investigations some twenty years ago into the properties of gun-cotton, with the view of determining its fitness for military purposes—a duty to which he was assigned by the War Department—was led to propose a substitute for gun-cotton, and prepared a new explosive, which he claimed, after numerous and extensive trials, possessed great advantages in many ways over both gunpowder and gun-cotton. The process of manufacture is as follows: Wood is sawed with fine saws into thin veneers across the grain; these are cut into small cubes by means of a machine for the purpose. In this state it much resembles sawdust. The best woods are those generally used for gunpowder—the alder and buckthorn. They are preserved in water till used, that they may retain their toughness. The grains are first passed through several processes by which the acids and all soluble substances are removed, when they are ready for the acids. Nitric acid of 1.48 to 1.50 is mixed with sulphuric acid, specific gravity 1.84, in the proportion of 40 parts by weight of the former to 109 of the latter, and set aside to cool. Six parts of the prepared wood are gradually added to 100 parts of the acids, stirring the whole constantly for two to three hours. A portion of the nitric acid combines with the wood, the sulphuric acid unites with the water, and the nitric acid is thus retained in its original strength. The grains are next placed in a centrifugal drying-machine, which removes the surplus acid, and is then washed for a considerable time in cool running water. It is boiled in a weak solution of carbonate of soda, and again washed in running water and dried. The grains are now heated with saltpeter, or baryta nitrate, as is preferred for most varieties. They are now dried at a temperature of 90° to 112° Fahr. for 12 to 18 hours, when they are ready for use.

It is manufactured in England and used in considerable quantities for sporting purposes, but has not been found to fill the requirements for military uses. It gives less recoil, smoke, and dirt than gunpowder. See *Gunpowder*.

SCHULTZ WIRE GUN.—The successful test in France of a 6-inch wire gun on the Schultz plan has given such an impetus to the development of this mode of construction that not only the French naval authorities have decided to push experiments in this direction on a large scale, but also English manufacturers have made, and are making, rapid strides in the development of systems involving the use of steel in this form.

Referring to the 34-centimeter gun, it may be here stated that wire 0.118 inch in diameter, to the extent of 43 layers, is wound round the body, giving a wire thickness of about 4.42 inches, the exterior being covered by a cast-iron jacket to protect the wire. The breaking strain of the wire is reported at 200 kilometers per millimeter, and it is put on under a tension of about one-third its ultimate strength. Longitudinal strength is given by 12 steel rods of about 7¼ inches in diameter, passing from the trunnion-ring to the breech-block receptacle, and secured at each end by suitable nuts. One statement gives the charge at 440 pounds, with a 900-pound projectile; another as 330 pounds powder and a 990-pound projectile.

The 24-centimeter guns—cast-iron bodies—are all unlined except one, which has a short steel tube. Thirty-five layers of wire about 0."8 thick from breech to center of trunnion-ring, and 16 layers from thence to about half the length of the chase, complete the wire wrapping. A jacket of copper over all, of 8 millimeters thickness, is superimposed over the wire. The breech-blocks are steel, and are secured as in the case of the 34-centimeter gun.

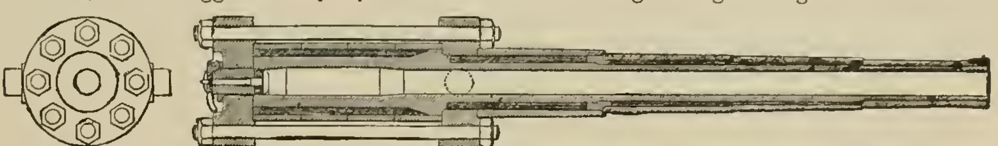
The following table gives some of the principal dimensions of these guns, and other data:

Kind.	Weight.	Caliber.	Chamber.		Length of bore.	Breech-piece.		Charge.	Projectile	Velocity (estimated.)
			Length.	Diameter.		Length.	Diameter.			
	Tons.	Inch's	Inch's	Inch's	Inch's	Inch's	Inch's	Pounds.	Pounds.	Feet.
34............c. m...	50	13.4	60.23	14.56	354	189	59	440	935	....
24............c. m...	18	9.44	56.30	11.4	269.25	....	....	176	352	2,362
10............c. m...	1.3	3.93	19.15	4.9	81.4	....	....	16.72	33	....

It will be seen by computation that Captain Schultz has an extraordinary excess of longitudinal strength, amounting—taking steel rods at 100,000 pounds per square inch—in tensile strength to over 50,000,000 pounds. The pressures on the bottom of the chamber or face of the fermeture would only be about 6,000,000 pounds, taking the gas pressures at 40,000 pounds per square inch. This ratio of resistance to pressures to be withstood, even if somewhat abnormal, seems excessive, and although it is necessary to keep, in providing for the strains, within the elastic limits of the metal used, yet even then we have a larger reserve than seems at all necessary. It results in an unnecessarily cumbersome and also weighty structure. The diameter of the breech-block is stated to be 59 inches; and it is estimated approximatively that the walls do not exceed nine-tenths of a caliber in thickness, if they attain that limit.

Referring to a 9-inch construction on the Shultz plan, represented in the drawing below, the following brief remarks may be made regarding its general features:

Assuming 40,000 pounds pressure as normal strain, and placing the tensile strength—attainable in good quality steel rods—at 100,000 pounds per square inch, it results, approximatively, that we have a ratio of strength to resist the stress on the face of the fermeture as at least six to one. The strains would have to be largely abnormal to reach the elastic limit of the rods, or, say, 80,000 pounds gas pressure per square inch, allowing 40,000 pounds per square inch as the statical pressure at which permanent set will take place. That solidity which insures the maximum of rigidity appertaining to undivided constructions is, however, wanting in this construction, and hence we have to contend with a tendency to a spring in the bolts, which is aggravated by repeated straining, and a vibrating action which will possibly sooner or later result in a tendency at each discharge to cause a transient play between the divisions of the gun, causing a slight momentary separation between the fermeture and the gas-check.



The advantage of separation of strains would be almost altogether lost if we attempted to screw the fermeture partly in the breech-block and partly into the body of the gun. This presumed possible disadvantage, however, can be fully met, it is believed, by the introduction of the De Bange gas-check—a check now adopted in the French land service, even up to the highest calibers (24 centimeters), both for pure steel and cast-iron and steel constructions. This is a check of extreme simplicity, cheap, light, readily applied, sufficiently durable, is replacable; is standard in the French army; is being developed at Woolwich, starting from 28-pounder guns, in which it has proved a success; and it requires no gas seat or enlargement of the chamber of bore to receive it. Its advantages in the construction under consideration are, that it *finds its seat* in firing not necessarily at one point, but that it has a tolerance in this regard, and hence can perform its functions under a play which cannot be successfully allowed for in the seating of the Broadwell ring, now universally used in obturation. This latter, however, can undoubtedly be used, but it is apparent that if desirable to experiment with the De Bange plan it can be readily and inexpensively tested in any construction, which is evidently designed for the Broadwell ring and the French fermeture, advantage being taken to test the former system prior to the application of the metallic gas-check obturation. It is proper, however, to state here that some objections have been raised regarding the De Bange check by the French naval authorities; the principal imperfections alleged being deterioration of the checks by repeated firings, and by time and climatic influences; and also a liability of the stem of the "mushroom head," between which latter and the face of the screw fermeture the check works. The difficulties of securing a central fire may be increased, but it is not seen but that by increasing the diameter of the *queue* of the roundellen, or "mushroom head", that objection and also that of liability to breaking of the *queue* can be satisfactorily met. The general principle that a great advantage cannot long remain subordinate to increased difficulties in securing other desideratums will soon vindicate itself by invention affording a solution of the difficulties surrounding the problem. These imperfections, if they prominently exist, are of such a nature as to be easily overcome; and we are sustained in this belief by the fact of the universal application of this mode of obturation in the French land service, and the successful experiments with it in Great Britain.

The model presented has thirty calibers of length; eight steel rods 5 inches in diameter, to support the breech-block; the steel tube—fluid compressed—and the wire to be wound and fastened after any well known good plan for securing the ends: and the gun finished after any of the common modes of jacketing or hooping. Its weight should not exceed 18 tons. One of the advantages of this rod system, it will be seen, is that the rods can be replaced when their elasticity is gone, *and as long as the body of the gun is intact, the gun is repairable.* The number of rods in this mode of construction should not, it would seem, be less than four; but the minimum number which can be used to the best advantage will give us greater stiffness in the system, and the number for this reason should be made but few, due regard being had to the demands in dimensioning and fastening the other parts of the construction. In the Schultz system it will be seen that cast iron, as well as steel bodies, are contemplated; and in such a system only can cast-iron without tubing be tolerated even for secondary purposes.

If the division of strains with wiring or fretting can make it available, yet inferiority in strength and reliability, besides other objections, *must result*, and we have but at best a make-shift construction. The cast-iron, besides, is more subject to deterioration by the action of the powder, and such guns present less endurance (about, say, one to three) than the others of the *same system* having steel barrels. Nothing but economy and facility of construction warrant any efforts to further contemplate experiments looking to its use. The current opinion in French army circles, is that the Schultz construction is the best elaborated, and that which has the greatest power for endurance at the present writing. It is regarded as perfectly rational in theory, and experiments, as far as made, give weight to its claims.

Before closing this discussion on the Schultz Wire Gun, with its peculiar feature of separate and independent provisions for both the tangential strain and the longitudinal breech strain, it is to be remarked that the advantages of the introduction of the latter principle in gun construction cannot be overlooked, and that every consideration warrants, if not demands, deep inquiry into the feasibility of its practical introduction in a system otherwise well digested to meet the other important requirements of maturely planned models. Increased strength must follow, and we would have, in the satisfactory introduction of this feature, an additional guarantee of the safe admission of much greater strains than can be borne by ordinary constructions in which no provision is found for the separation of the two forces which now act together at the breech to rupture the best constructed guns. See *Ordnance*, *Tubage*, and *Wire Guns*.

SCHUWALOW GUN.—A gun named after the inventor, a Russian General. It differed from a common gun in having an oval bore; the greater diameter lay in a horizontal direction; it had also a long cylindrical chamber.

SCIMITER.—A description of sword used among Eastern nations. It is considerably curved, and has its edge on the convex side. Being usually of high temper, and its shape favorable to incision, it forms an admirable cutting instrument, but is powerless as a thrusting weapon. The Scimiter is not, however, any match for the bayonet. Also written *Cimeter* and *Scimitar*.

SCLOPETTE – SCLOPOS.—A name given to the early hand-culverins, such as were in use at the end of the 14th Century. See *Escopette*.

SCONCE.—In fortification the term applied to any small redoubt or fort, detached from the main works for some local object, as the defense of a pass or ford, etc. The word is not now often used.

SCOPETIN.—A term formerly applied to a rifleman who was armed with the escopette.

SCORE.—In the United States Service, each soldier is provided with a target score-book, and is assisted and encouraged to keep a correct record of every shot fired, marking on the diagram the point struck by each shot. In stating the score made at any time, the percentage of the maximum possible is given, and this is taken of not less than five consecutive shots. The target-record is kept at each post by the Instructor of Musketry, and every shot fired is entered in it, with the name of the party who fired it, and also the range and score. In making the monthly report of the progress of his company in the practice of musketry, the Captain transmits along with it the target-record of the best firing made during the month, if any firing has been done. If the score-book is carefully kept a fund of valuable information, as regards the allowance to be made for a given wind, temperature, or quantity of moisture in the air, will be treasured up and form a useful guide for the future practice. The value of the record will depend greatly upon the care and minuteness with which the entries are made.

The following table arranged by N. P. Phister, U. S. Army, may be advantageously used to find the percentage of three scores when their aggregate is known:

Rule 1. Look in vertical column of index figures for the first figure of the aggregate, the percentage will be found in the same horizontal line and under the index figure corresponding to the second figure of the aggregate. Rule 2. To find percentage of six scores. Divide aggregate by two and take percentage from table. If the aggregate is an odd number,

2	26.67	28.	29.33	30.67	32.	33.33	34.67	36.	37.33	38.67
	0	1	2	3	4	5	6	7	8	9
3	40.	41.33	42.67	44.	45.33	46.67	48.	49.33	50.67	52.
4	53.33	54.67	56.	57.33	58.67	60.	61.33	62.67	64.	65.33
5	66.67	68.	69.33	70.67	72.	73.33	74.67	76.	77.33	78.67
6	80.	81.33	82.67	84.	85.33	86.67	88.	89.33	90.67	92.
7	93.33	94.67	96.	97.33	98.67	100				

divide the next lower number by two—take percentage from table and add $66\frac{2}{3}$. The figures for scores between 20 and 30 are put above indices for convenience.

The following table, prepared by Lieutenant Henry A. Reed, U. S. Army, is used for finding the number of points allowance for drift and wind to be made on the rear sight of the service rifle with the new service ammunition, (70 grains powder, 500 grains bullet).

WIND FROM—	RANGE—YARDS.									
	100	200	300	400	500	600	700	800	900	1000
XII. or VI. o'clock	0	0	0	0	0	0	0	0	0	0
XII½, V½, VI½, or XI½ o'clock	$\frac{1}{12}$	$\frac{1}{4}$	$\frac{1}{2}$	1	$1\frac{3}{8}$	$1\frac{7}{8}$	$2\frac{1}{2}$	$3\frac{1}{4}$	$4\frac{1}{4}$	$5\frac{1}{2}$
I., V., VII., or XI. o'clock	$\frac{1}{8}$	$\frac{1}{2}$	1	2	$2\frac{3}{4}$	$3\frac{3}{4}$	5	$6\frac{1}{2}$	$8\frac{1}{2}$	11
I½, IV½, VII½, or X½ o'clock	$\frac{1}{6}$	$\frac{3}{4}$	$1\frac{1}{2}$	$2\frac{3}{4}$	$4\frac{1}{8}$	$5\frac{5}{8}$	$7\frac{1}{2}$	$9\frac{3}{4}$	$12\frac{3}{4}$	$16\frac{1}{2}$
II., IV., VIII., or X. o'clock	$\frac{1}{4}$	1	2	$3\frac{1}{3}$	5	$6\frac{1}{2}$	9	$11\frac{1}{4}$	15	19
II½ to III½ or VIII½ to IX½ o'clock.	$\frac{1}{3}$	$1\frac{1}{8}$	$2\frac{1}{4}$	$3\frac{3}{4}$	$5\frac{1}{2}$	$7\frac{1}{2}$	10	13	17	22
Drift:—Inches	1	3	5	8	17	16	22	28	36	43
Value of a point—inches	6	11	17	22	28	33	38	42	48	53

Multiply the velocity of the wind in miles per hour, by the number at the intersection of horizontal and vertical columns giving wind direction and range respectively; then apply the drift as follows:—Add if wind is from left; substract if from right. Divide the result by the value of a point and the quotient is the required number of points deviation.

EXAMPLE:—The rifleman is to fire at 600 yards; wind blowing from 4 o'clock, velocity 10 miles; $10 \times 6\frac{1}{2} = 65$; $65 - 16 = 49$; $49 \div 33 =$ about $1\frac{1}{2}$. The sight should be moved a point and a half right.

Move the slide *against* the wind except when with a wind from the right, the product of wind velocity by number in table is less than the drift.

SCORING.—When large charges are used, the rush of gas over the projectile produces what is termed *scoring* or *erosion* of the bore.

SCORPION.—1. A very ancient Egyptian weapon, roughly made from bronze or iron, and very much resembling an Indian whip-goad. 2. An ancient gun whose dolphins represented the scorpion.

SCORPION CATAPULT.—An ancient form of the catapult. It is described by Heron, Philon, and Vitruvius. One of these machines was recently made for the collection of arms of Napoleon III.

SCOTLAND.—The Royal Arms of Scotland, are—Or, a lion rampant gules, armed and langued azure, within a double tressure flory counterflory of fleur-de-lis of the second. Supporters—Two unicorns argent armed, maned, and unguled, or gorged with open crowns, with chains affixed thereto, and reflexed over the back of the last. Crest—A lion sejant affronté gules crowned, or holding in the dexter paw a sword, and in the sinister a scepter, both erect proper. The lion is first seen on the seal of Alexander II., and the tressure on that of Alexander III. The unicorn supporters do not appear on any of the royal seals of Scotland till the time of Queen Mary, on whose first great seal (1550) they are represented as chained and gorged with crowns. They were, however, sculptured on Melrose Abbey as early as 1805. In 1603, in consequence of the union of the crowns of England and Scotland, the Scottish Arms came to be quartered with those of England and Ireland, while one of the English lions

Royal Arms of Scotland, previous to the Union.

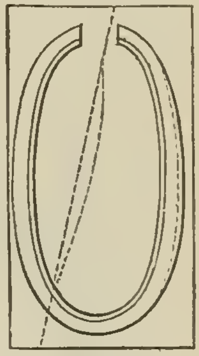
was adopted as a supporter. Precedence was, however, given within Scotland to the Scottish ensigns, which occupied the first and fourth quarters, and the unicorn also obtained the place of honor, being dexter supporter. From about the time of Charles I. to 1707, it became the practice to represent the unicorn as not merely gorged with an open crown, but crowned with an imperial crown. The treaty of union of 1707 declared that the ensigns of the United Kingdom should be in future such as Her Majesty should appoint "on all flags, banners, standards and ensigns, both on sea and land;" the same mode of marshaling being adopted in England and Scotland. But Art. 24 has been supposed to leave room for a different mode of marshaling on the seals in use in matters relating exclusively to Scotland, and on the great and other seals of Scotland. Since, as well as before the union, precedence has been given to Scotland. The question of the proper marshaling of the royal arms within Scotland was raised in 1853 by a petition to the Queen by the magistrates of Brechin; a reference was made by the home office in the first instance to Garter King-at-arms, and Garter's report was transmitted to the office of the Lord Lyon, where it was returned with observations by the Lyon Depute, who considered Scotland entitled to a precedence on the judicial seals of the country; and his views have since continued to be acted on.

SCOTS GRAYS.—The second regiment of dragoons in the British service. They are considered a superior body of cavalry, and bear as their motto, "Second to None."

SCOTT MAGAZINE-GUN.—A breech-loading small-arm having a fixed chamber closed by a movable barrel, which rotates about an axis parallel to the axis of the barrel. The gun is opened by cocking the hammer, releasing the barrel-catch, and allowing the barrel to revolve on an axis parallel to and beneath it, until the chamber comes opposite to the magazine. It swings aside the magazine-lid as it passes over the mouth of the magazine, and is automatically loaded by the action of the magazine-spring. By reversing the action of the barrel, the barrel-catch springs into place and holds it shut. The gun has a sliding extractor moving in a spiral cam recess on the axis during the revolution of the barrel. There is no ejection—the shell readily drops out as the gun is opened.

The magazine lies in the butt-stock, is charged from in front, and is closed by a sliding lid, which is kept in place by the action of a suitable spring.

SCOTT PROJECTILE. The shell devised by Commander Scott, of the British Navy, for firing molten iron, is shown in the drawing. It has three ribs cast upon it, which fit grooves so constructed as to center it in the bore of the gun when fired. The interior of this shell is lined with loam to prevent the heat of the charge from entering through to the bursting charge. It is supposed to be broken and its contents diffused on striking the object. See *Studded Projectiles*.



SCOTT SYSTEM OF RIFLING.—In this method the bore is rifled with narrow, shallow grooves, deeper on the driving than the loading-side. The projectile is one iron casting, having ribs almost triangular in section, extending the full length of the cylindrical body, and set to the angle of the rifling. In cross-section the ribs give a deep bearing-surface on the driving side. By shallowing the loading-side of the groove, the ribs rest on inclined planes, so that the projectile, when forced into its seat, has a natural tendency to slip round so as to cling to the driving-side before the gun is fired, to start easily, and to mount into the centring position the moment it begins to move out. Less windage is given to the ribs on the projectile than to its body, so that it rests upon its projections, and its body does not touch the bore at all. The ribs almost fill up the grooves, and check the escape of the gas, with its consequent erosion of the bore, and unequal action on the projectile. While by striking the curve of the cross-section of the groove and of the rib with two different radii, the latter is driven up into the center of the bore at once, causing the axes of the projectile and of the bore to coincide. In this system there are three grooves for the nine-ton guns and under; five grooves for twelve and eighteen-ton guns and upwards. The grooves are of the same size for all guns. Width, 0.8 inch; depth, 0.125 inch. This system has not as yet been generally adopted by any nation. See *System of Rifling*.

SCOUR.—A term very frequently used to express the act of discharging ordnance or musketry, rapidly and heavily, for the purpose of dislodging an enemy. Hence, to scour the rampart, or the covered-way. The term likewise signifies to clear, to drive away; as to scour the seas; also to run about in a loose desultory manner; as, to scour the country. *To scour a line*, is to flank it, so as to see directly along it, that a musket ball entering at one end may fly to the other, leaving no place of security.

SCOUT.—A person sent out in the front or on the flank of an army to observe the force and movements of the enemy. He should be a keen observer, and withal fleet of foot, or well mounted.

Scouts or single soldiers, if disguised in the dress of the country, or in the uniform of the army hostile to their own, employed in obtaining information, if found within or lurking about the lines of the captor, are treated as spies, and suffer death.

SCOUT-MASTER GENERAL.—A person formerly so called, under whose direction all the scouts and army messengers were placed.

SCRAMASAXE.—A dagger or cutlass about twenty inches in length, used by the early Frank soldiers. This weapon has been frequently found in the tombs of warriors laid side by side with the long *Spatha*. It was hollowed, so as to have two channels on each face, one of them being on each side of the central ridge of the blade; and these channels were filled with poison. The etymology of the word is as follows:—*Saxe* means knife, and *Scrama* may be derived from the word *Scamata*, a line traced on the sand between two Greek combatants; or from *Scaran* to shear, from which the German *Schere*, scissors, is derived.

SCRAPER.—An implement in use to scrape the residue of powder from the bores of mortars and howitzers, and to remove it from the piece. It consists of a handle of iron, having a scraper at one end, and a spoon for collecting dirt at the other, both being made of steel.

SCRAP-METAL.—A term applied to fragments of any kind of metal which are only of use for remelting. Copper and brass scrap consist of the turnings from the lathe, and all the useless and worn pieces, whether old or new. They are readily remelted. Scrap-tin consists of the clippings and fragments of tinned iron and worn-out tinned vessels; these are frequently dipped into hydrochloric acid, to dissolve off the tin-coating from the iron; and the muriate of tin so formed is of commercial value for dyeing purposes. Scrap-iron consists of any waste pieces of iron, although the term is usually held to mean malleable iron only; and for many purposes it is particularly valuable, as it is found that a greater strength can be obtained by welding small fragments of iron together, than is found in large masses, the fiber being much more twisted and interwoven, from the mingling of pieces in every imaginable direction.

SCRATCH-BRUSH.—A cylindrical bundle of fine steel or brass wire tightly bound in the center, with the ends projecting at both extremities so as to form a stiff brush for cleaning and scratching metals preparatory to gilding or silvering, or, as in the case of small-arms, preparatory to the browning them. As well as the shape above described, there is another, in which the steel wire is fastened in long lengths on leather or cloth, and in this form is known as *scratch card*.

SCREW DRIVER.—An appendage for turning screws in or out of their places. It has an end like a blunt chisel, which enters the nick or slit in the screw-head. The screw-driver for taking apart and re-assembling fire-arms is composed of two blades of steel, one of which turns on a pivot, passing through the other, or it may have an additional pivoted arm. The larger arm has a perforation at one end fitting the square of the "cone" or nipple, for the purpose of unscrewing the nipple from its seat. Fig. 1. represents the screw-driver, model 1870, used in the United States Army. A is the *large blade*, B the *small blade*, C the *rivet*. In taking apart the lock, the *notch* (D) should be clamped over the main-spring and used as a spring vise. Fig. 2. represents the combination screw-driver, which it is proposed to issue in the United States as soon as the present supply of appendages is exhausted. A is the *small screw-driver*.

Fig. 1.

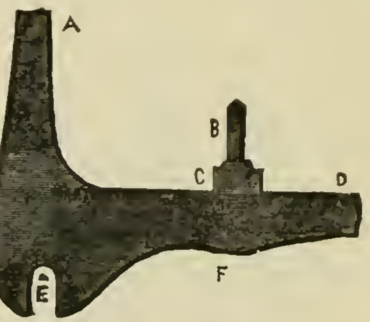


Fig. 2.

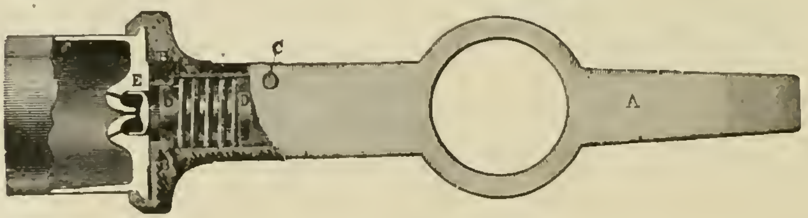

Fig. 3.

B is the *punch* to be used in removing the band springs. C is the *shoulder*, which is used to drive out the tumbler, in order to remove the hammer. To do this, after removing the tumbler screw, insert the punch (B) into the tumbler cavity, bring the shoulder (C) to bear evenly on the tumbler, and drive it out by hammering at the *point* (F). In so doing, the sides of the shoulder must be parallel with the sides of the square, to avoid striking on the hammer. D is the *large screw-driver*. E is the substitute for the *spring vise*, to be used in dismounting and assembling the lock. Bring the hammer to the full-cock notch; put the notch (E) over both branches of the main-spring; uncock the hammer, unhook the swivel, and remove the main-spring. Care must be taken to keep the spring in the notch in order to re-assemble the lock without a spring vise. The guard, butt-plate, and side screw-heads have concave slits for which the screw-driver is adapted. This lessens the danger of the stock being marred by accident in letting the screw-driver slip out of the slit. By keeping the screw threads well oiled, there will be no difficulty in taking out or replacing the screws.

A handy combination tool much used in military service is represented in Fig. 3. It consists of a screw-driver, A, combined with a capper, D, and hand-shell extractor, B, which is applied to the head of a shell, E. The capper is operated by pressure brought to bear when, A, is turned about the pivot, C.

SCREWED-IN SIGHT.—A variety of trunnion sight. The sight is made of steel and has a steel leaf, dove-tailed into its top. It is screwed into a hole above the trunnion. The leaf is hog-backed in shape, and its rear face is roughened to prevent the reflection of the light interfering with the *laying* of the gun.

SCREW-MACHINES.—Screws were little known or used before 1836, being rudely made by hand with imperfect tools. The head was forged or swedged up by a blacksmith; the thread and nick were formed by the use of hand dies and hack screws. In 1836, American ingenuity was directed to the subject, and the old hand tools were associated in machines having the capacity of imparting to each tool its proper motion. The swedge hammer became the heading machine, receiving the end of a coil of wire and regularly cutting the required length for a blank, which then received such a blow as to "set up" one end of the wire to form the head—the operation continuing automatically until the whole coil was made into blanks. These blanks were then handled individually and presented to organized machines, first for shaving the head, then for nicking, and lastly for cutting the thread. The above constitutes the second era in this manufacture; and such machinery, partly automatic, was all that was in use before 1846. Then a third era ensued, and an entire revolution was effected by constituting the machines entirely automatic. The blanks are by this system supplied in mass by the operator, the machine separating and handling each blank respectively as the nature of the operation demands, and producing with wonderful rapidity, regularity, and perfection. Chief among the inventors and constructors of this machinery was General Thomas W. Harvey, widely known for inventive genius in many directions. After him, perfecting and developing, were Sloan, Whipple, Rogers, and others; while the leading mind that organized this intricate business into probably the most successful manufacturing interest in this country was the late William G. Angell, of Providence, R. I., President of the American Screw Company. General Harvey was the first inventor of the partly automatic and of the entirely automatic machines. It is noticeable that though he produced gimlet-pointed

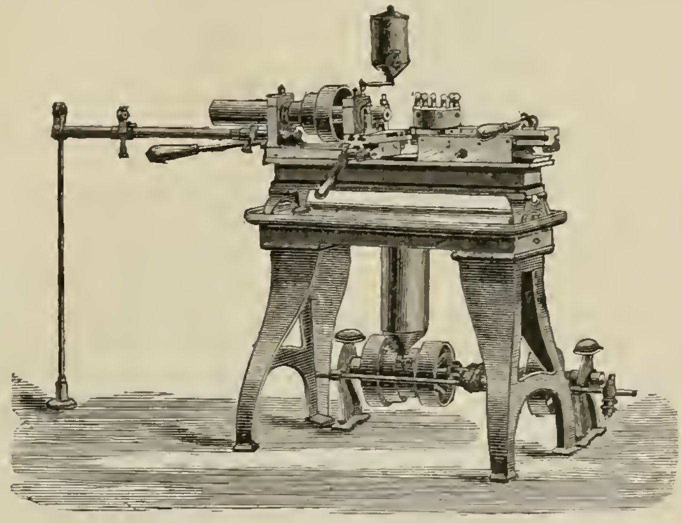

Fig. 1.

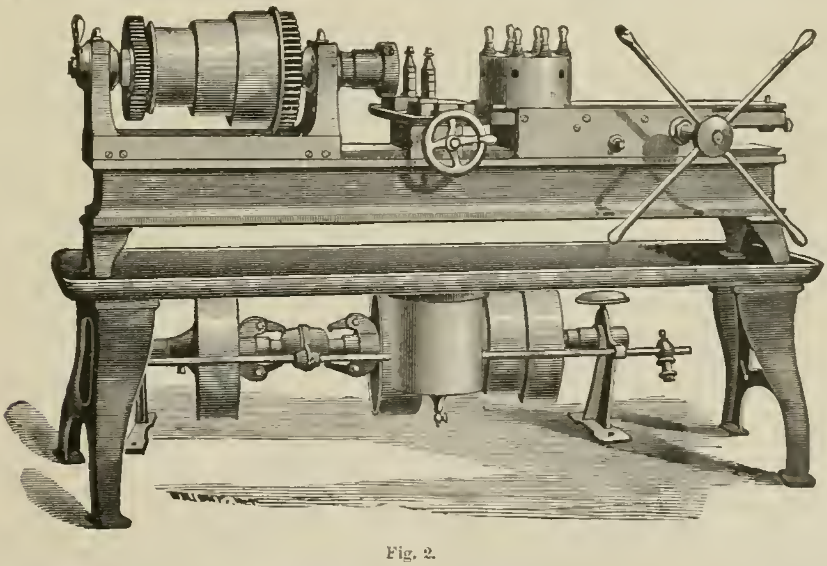

Fig. 2.

screws in 1836, it was not till 1846 that any considerable market was found for them. His son, Hayward A. Harvey, of Orange, N. J., likewise a skillful inventor in many departments, has made important improvements in the automatic machines, and this American invention is now in use throughout the world wherever screws are made. It is estimated that the consumption of screws throughout the world is not far from 100,000 gross per day—about 100 tons; and about 500 tons of iron are required for the daily production of machine and wood screws.

A light screw-machine, provided with the Parkhurst wire-feed attachment, made by the Pratt and Whitney Company, United States, and used to a great extent in arsenals, is shown in Fig. 1. On this machine every operation (except slotting the head), in the production of screws from wire or rod, is performed successively, without removal of the work from the chuck, stopping of the machine, or change of tools. The turret of the machine is self-rotating and self-fastening. One leg of the machine is arranged to swivel to accommodate itself to unevenness in the floor, with set-screws for adjustment. The wire-feeding device is simple in construction and efficient in operation. It is not liable to derangement, and is operated by the movement of a hand-lever. It feeds the wire forward to a length regulated by an adjustable gauge-stop held in the turret, and the same movement that brings the wire foreward closes the jaws of the chuck, holding the wire firmly. The reverse movement opens the jaws to receive another length. These movements are performed instantaneously without stopping the machine, so that the use of the device results in a great saving of time. It may be used on all sizes of machines, and is adapted to rods up to 1¼ inches diameter. Collets, for holding rods in the chuck, are provided in various sizes. The cone of this machine, usually carries a belt 1½ inches wide, and the countershaft has a speed of 310 revolutions.

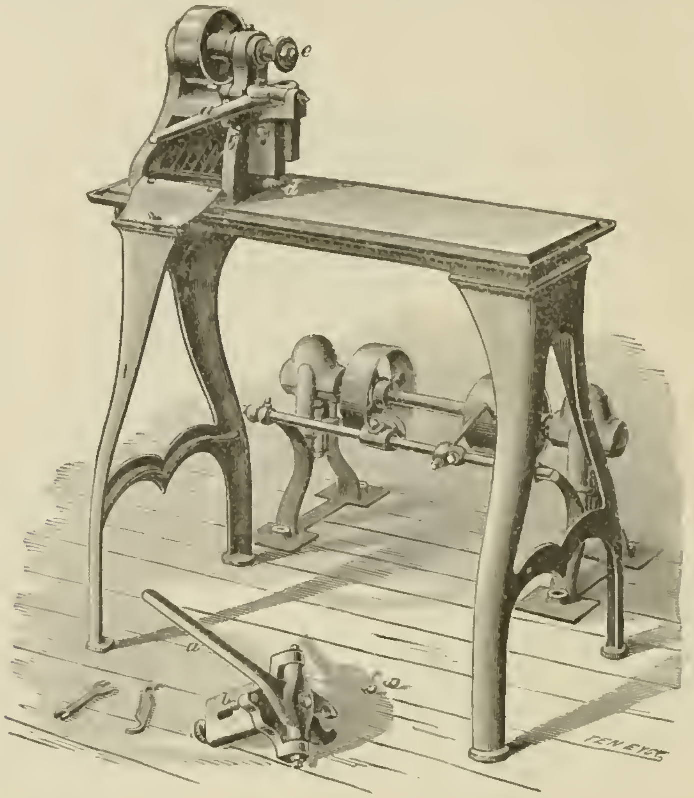

Fig. 3.

A very heavy screw-machine, having back-gears, adapted to the production of screws and studs from the rod of 1½ inches and smaller diameter, is represented in Fig. 2. It has an automatic feeding apparatus, with self-operating stop-motion, attached to the turret-slide. This is operative the entire length of the machine, and may be adjusted to feet as desired. The cone carries a 4-inch belt. The relative capacities of the machines of these and intermediate sizes is shown in the above table:

Size.	Diameter of hole through spindle.	Largest diameter wire-feed apparatus will take.	Diameter of hole in revolving head.	Length that can be milled.	Weight, with countershaft.
0	$\frac{5}{8}$ inch.	$\frac{1}{4}$ inch.	$\frac{7}{16}$ inch.	2 inch.	350 lbs.
1	$\frac{3}{4}$ inch.	$\frac{3}{8}$ inch.	$\frac{9}{16}$ inch.	2½ inch.	400 lbs.
2	$\frac{15}{16}$ inch.	$\frac{9}{16}$ inch.	$\frac{11}{16}$ inch.	3½ inch.	780 lbs.
3	$1\frac{5}{16}$ inch.	$\frac{15}{16}$ inch.	1 inch.	5½ inch.	1,225 lbs.
4	$1\frac{9}{16}$ inch.	1¼ inch.	1½ inch.	8½ inch.	2,200 lbs.

In the plain screw-slotting machine, the screw, held in a chuck mounted on a slide, is raised, by means of a hand-lever, pinion, and rack, to the cutter revolving in the spindle for simply sinking a nick in the head. This vertical slide has a movement of 4 inches, which may be limited by a screw and check-nuts. A rod, arranged to pass up through the chuck as it descends with the slide to starting point, pushes the screw out of the chuck, so as to be caught by the table. For slotting across screw-heads, and for light milling cuts, a cross-slide with traverse of 3 inches, operated by hand-lever, is added to the vertical slide. Fig. 3. shows the slotting-machine usually employed in the arsenal. It will be observed that it is very simple and is well adapted for slotting studs and screws expeditiously. Duplicate bushings, suitable for the different sizes of screws, can be fitted to the clamping jaws. The machine contains a closet, in which is a rack for holding the various sizes of cutters, and also furnishing a place for the bushings, wrenches, etc. Countershaft should run 160 turns per minute. Tight and loose pulleys 6 inches diameter, $2\frac{1}{2}$ inches face. Weight of entire machine, with countershaft, 370 lbs.

Quite an expensive machine is often used by gun-makers and others for slotting the heads of screws.

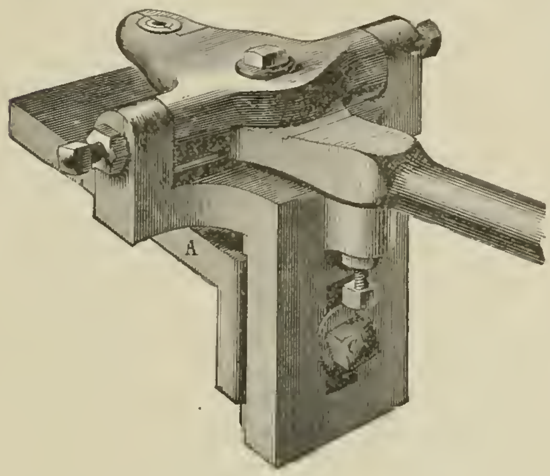

Fig. 4.

The device shown in Fig. 4, which can be attached to any ordinary hand-lathe, is believed to be more efficient for the purpose than any machine heretofore made. An active boy can slot from ten to fifteen thousand screws per day. A single bolt fastens the platform, A, of this apparatus to the bed of a hand-lathe, the long lever projecting in front at a right angle with the bed. An arbor carrying a circular cutter is held in the centers of the lathe. The long lever is moved horizontally to open the jaws for inserting and removing the screws, and downward to bring the screws to be slotted against the saw. A stop screw governs the downward motion, and thus regulates the depth of slot in the screw head. The working part of the apparatus can be raised or lowered on the platform front by means of a bolt provided for the purpose.

SCREW-THREAD GAGE.—A gage for giving the proper bevel to the edges of screw-cutting tools. For the general purpose of bolts and nuts there are three different forms of thread now in use. These are the ordinary sharp V, the Whitworth, and the U. S. Standard forms.

The sharp V-thread has its surfaces inclined to each other at an angle of 60°. A section of this thread is therefore an equilateral triangle, each side of which is equal to the pitch of the screw, and the depth of the thread, measured perpendicularly to the axis of the bolt, will be expressed by the formula—

$$d=p \cos 30^\circ=.866\,p$$

in which p represents the pitch, d the depth of the thread, and 30° half the angle included between the thread surfaces. The effective diameter of the bolt is expressed by the formula—

$$d=\mathrm{D}-2\times .866\,p=\mathrm{D}-1.732\,p$$

in which D and d represent the *nominal* and *effective* diameters respectively.

The Whitworth thread has its plane sides inclined to each other at an angle of 55°, with the angle formed by these surfaces, at both the periphery and root of the thread, so rounded that the depth of the finished thread is two-thirds the depth of a V-thread, having its surface inclined at an angle of 55°. In this form of thread the depth is readily determined by the formula—

$$o=\tfrac{2}{3}\times\frac{p}{2\tan 27^\circ\,30'}=.65\,p$$

and the diameter of the effective section of the bolt by—

$$d=\mathrm{D}-2\times .65\,p=\mathrm{D}-1.3\,p.$$

The U. S. Standard thread is simply the ordinary V-thread with surface inclined at an angle of 60°, and with the angles cut off at the top and filled in at the bottom to the extent of one-eighth of the depth of the V-thread each, so that the depth of the thread is three-fourths that of the ordinary V-form, and is expressed by the formula—

$$o=\tfrac{3}{4}\,p\cos 30^\circ=65\,p.$$

The effective diameter will then be—

$$d=\mathrm{D}-2\times .65\,p=\mathrm{D}-1.3\,p.$$

Collecting the results for the effective diameters of bolts having threads of the different forms, we have—

"V"	form,	$d=\mathrm{D}-1.732\,p$
Whitworth	"	$d=\mathrm{D}-1.3\,p$
U. S. Standard	"	$d=\mathrm{D}-1.3\,p$

With equal pitches it appears, therefore, that the maximum effective diameter of bolt is insured when threads of Whitworth or U. S. Standard forms are used, while the usual V-form insures the minimum effective diameter.

SCROLL-IRONS.—Iron brackets attached underneath the frame sides of the body, or the futchells of the fore-carriage in all carts and wagons where springs are used, to which these latter are connected by means of single bolts in front and double bolts and shackles in rear.

SCURVY.—A disease which is characterized by depraved conditions of the blood. In consequence of this morbid state of the blood, there is a debility of the system at large, with a tendency to congestion, hemorrhage, etc., in various parts of the body, and especially in the gums. It is a disease that has probably existed from the earliest times, but the first distinct account of it is contained in the history of the Crusade of Louis IX., in the 13th century, against the Saracens of Egypt, during which the French army suffered greatly from it. In the 16th century it prevailed endemically in various parts of the north of Europe, and it seems only to have abated about a century ago. It was in badly fed armies, in besieged cities, and on board ship, that its ravages were most appalling, and it is believed that more soldiers perished from scurvy alone than from all other causes combined, whether by sickness, tempest, or battle. Whole companies were prostrated by this scourge.

Scurvy so closely resembles purpura in its general symptoms that it will besufficient for us to refer to that disease, and here merely to indicate the leading points of difference between the two diseases, which, notwithstanding their similarity, are essentially different. Scurvy is caused by a privation, for a considerable time, of fresh succulent vegetables, while purpura often makes its appearance when there has been no deficiency of this food, or special abstinence from it. Scurvy is most commou in winter or the early spring, while summer and autumn are the seasons for purpura. In scurvy the gums are invariably swelled and spongy, and bleed readily; in purpura this is not necessarily the case. In scurvy there is extreme debility and depression of spirits, venesection and mercury do positive harm, while a cure is rapidly effected by the adminstration of lemon-juice or of fresh fruits and vegetables; whereas in purpura there is very little or no mental or bodily depression ; venesection and mercury often give relief, while no marked and certain relief follows the administration of the lemon-juice and fruits that are all powerful in scurvy.

Although the virtues of lemon-juice in scurvy were known as far back as 1636, when John Woodhall, Master in Surgery, published *The Surgeon's Mate, or Military and Domestic Medicine*, this invaluable medicine was not made an essential element of diet till1795. The effect of this official act maybe estimated from the following numbers: In 1780 the number of cases of scurvy received into Hasler Hospital (a purely naval hospital) was 1457, while in 1806 there was only one case, and in 1807 only one case Many Naval Surgeons of the present day have never seen a case of the disease. The potato posseses almost equally great antiscorbutic properties, and, fortunately potatoes when cooked are as active as when taken raw. The late Dr. Baly, to whom we are indebted for this discovery, states " that in several prisons the occurrence of scurvy has wholly ceased on the addition of a few pounds of potatoes being made for the weekly dietary." The salutary action of potatoes is probably owing to their containing a considerable amount of tartaric acid, partly in combination with potash and lime, and partly free. In addition to the dietetic treatment, which should include easily digested animal food, potatoes, such ripe fruits as can be procured, and an abundance of lemonade, little further need be prescribed. If necessary all constipation must be relieved by mild laxatives, such as rhubarb and castor-oil ; the appetite may be stimulated by bitter tonics, and opiates given to procure rest in case of pain or obstinate wakefulness. When the gums are very troublesome, the solutions of tannin, chloride of lime, or of nitrate of silver, may be applied to them. For an excellent account of this disease, the reader is referred to the article "Scurvy" by Dr. Budd, in *The Library of Practical Medicine.*

SCUTUM. A Roman buckler made of wood, the parts being joined together with little plates of iron, and the whole covered with a bull's hide. In the middle was an *umbo*, or boss of iron, which jutted out, and was useful to glance off stones, darts, etc. The *scuta*, in general, were four feet long, and different in size from the *clypei*, which were less and quite round.

SCYTHE KNIFE.—A modified form of the *war-scythe*. It is single-edged, and has the point curving from the edge to the back. The point is double-edged, and at the base of the blade there is a hook or spur. See *Glaive*.

SCZAROCH.—A shell adopted by the Russians. It is either a percussion or time shell and a shot, the latter of which ricochets beyond the point of explosion of the bursting charge. The shell portion is a simple iron cylinder, to one end of which is secured, by a thin sheet of lead, a spherical shot. On leaving the gun, the combined projectile acts like an ordinary elongated shell; but as soon as the explosion of the charge takes place, the cylinder flies in pieces, while the shot, impelled by the additional velocity and by reason of its form, ricochets for hundreds of feet ahead. In firing at batteries,the double effect of this projectile comes into excellent use, as the shell might be exploded among the guns, while the ball would strike far in the rear among the reserve troops; or while the shell might burst in the front rank of an advancing line, the ball would continue plowing its way through several succeeding ranks.

SEA COAST AND GARRISON CARRIAGES.—Prior to the introduction of heavy charges and elongated projectiles for use in heavy guns, the chassis was of sufficient length that the recoil of the top-carriage should be absorbed by its friction on the chassis-rails before the entire length of the latter had been traversed ; but of late years, when the improvement in powder has been such as to render it a practicable thing to fire heavy charges with projectiles weighing two or three times the weight of a round shot of the same caliber, the increase in the recoil has become so great as to render it imperatively necessary to resort to other means by which it may be controlled within the limits of the chassis-rails. Different methods of more or less merit have been from time to time proposed. That of multiplied friction of numerous plates, or the compressor, as it was called, seemed for a time to find most favor throughout Europe until Captain Fraser, of the English Navy, proposed the hydraulic buffer,and showed its successful practical operation, when soon after it was adopted by Krupp in the construction of his heavy carriages for Russia and Germany, since which time it has been generally adopted by every nation for heavy carriages to be usedin the land service, France, perhaps, excepted. Its simplicity and economy of construction, its efficiency, and its automatic operations are the features which commend it to general favor.

A hollow cylinder fastened to the chassis, abutting the middle of the rear transom, a piston-rod secured to the top-carriage and working in this cylinder, with four holes in the piston-head for the passage of the fluid which partly fills the cylinder, compose the essential parts of the hydraulic buffer as it has been universally adopted. In some carriages made by Krupp for the German Navy the cylinder,instead of being placed on the rear part of the chassis,against the rear transom, has been placed in front so that the piston-rod will be gradually pulled out of the cylinder instead of being thrust in, as is usually the case. It was supposed that for naval carriages there might be some advantages in this arrangement which did not apply to land carriages, whereas the greater expense that necessarily attends its construction,and the greater difficulty of preventing leakage around the piston, has operated to prevent the adoption of this arrangement for other carriages. The cost of the hydraulic buffer, as well as the weight added to the carriage, is less than those of the pneumatic buffer by about one-third.

United States.—In this service the carriages are designated as *barbette*, *casemate*, and *flank-defense*, carriages, according to the portion of a work in which they are mounted. Formerly nearly all sea-cost carriages were made of wood; but in consequence of great difficulty of preserving this material from decay, especially when exposed to the dampness of casemates, it has been determined to replace it by wrought-iron ; and strong, cheap, and manageable carriages have been devised and tested for this service. The principal feature in the construction of the new carriages, is a peculiar combination of boiler-plate and roller-beams, which gives, with requisite lightness, great strength and stiffness to the important parts. All sea-coast carriages are composed of the *gun-carriage* and the *chassis*. The purpose of the gun-carriage being to support the piece,it should be so constructed that the piece can be elevated or depressed in aiming,and run into and out of battery, in firing. The term "in batery," as applied to sea-coast guns, refers to the position which the piece occupies when it is ready to be fired ; in casemate pieces the muzzle must be in the throat of the embrasure, and in barbette pieces, directly over the superior slope of the parapet.

The gun-carriage is composed of two *cheeks*, held together by two plates of boiler iron called the *front* and *rear transoms*. Each cheek is formed of two pieces of boiler iron cut to a triangular shape, separated at the edges by interposing the vertical portion or web of a T-shaped bar. The horizontal branches project over each side to form a double rim, which gives stiffness to the cheeks. Flat bars of iron are also placed between the plates at suitable intervals to stiffen the cheeks in the direction in which the weight and recoil of the piece bear upon them. All these parts are held together by screw bolts.

The motion of the carriage to and from battery is regulated by a pair of *maneuvring wheels* which work on an eccentric axletree, placed underneath and a little in front of the center of the trunnions. The 13 and 15-in. carriages have two pairs of these wheels. When it becomes necessary to check the recoil of the gun-carriage, the wheels are thrown out of gear by means of a handspike, and the forward part of the carriage moves on sliding friction. When it is necessary to move to battery, the wheels are thrown into gear and the carriage moves on rolling friction.

All sea-coast cannon having no preponderance are elevated and depressed by a lever, (or other suitable contrivance,) the point of which works in a ratchet cut in the breech of the piece. The fulcrum is made of cast-iron and rests on the rear transom of the gun-carriage. It has several notches for adjusting the position of the elevating lever. This apparatus is exceedingly simple, and affords the means of changing the elevation with ease and rapidity. The piece is pointed, 1st, by two fixed sights, one attached to the breech and the other to a lug between the trunnions; 2d, by a brass graduated arc attached to the breech, parallel to the ratchet, and a pointer attached to the fulcrum. By the fixed sights the piece is brought in line with the object, and the arc and pointer mark the elevation necessary to strike it.

The chassis is the movable railway along which the gun-carriage moves to and from battery. It is composed of two wrought-iron rails inclined 3° to the horizon and united by transoms; there are certain diagonal braces to give stiffness to the chassis.

center of the front transom, as with an equal space it affords a greater horizontal field of fire, or affords a better opportunity to use heavy traverses of earth to protect the pieces from an enfilading fire.

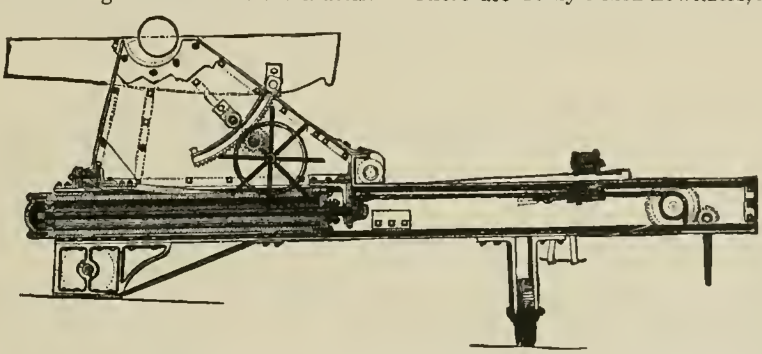
The carriages are at present maneuvred by handspikes applied to holes in the circumference of the traverse and maneuvring wheels. This mode is defective, inasmuch as power is wasted by continually overcoming the inertia of the gun and carriage when the handspikes are readjusted. It is proposed to supersede this by the continuous motion produced by cranks, and the experiments that have been made indicate that the heaviest pieces may be moved with much greater ease than heretofore.

Much attention is now being paid towards obtaining a more effective cover for barbette guns and the men that work them. It is understood that several plans to this end are under consideration by the Engineer Department, and among them are fixed and revolving turrets, the latter similar to those used on the monitors, except that they are to be moved by man rather than steam power.

The sea-coast carriages of the present system are:

The 15-inch Rodman gun, . . .	Barbette.
" 10-inch " " . . .	"
" 8-inch " " . . .	"
" 13-inch " " . . .	Casemate.
" 10-inch " "	"
" 8-inch " "	"
" 24-pdr. flank defense howitzer,	

There are many 8-inch howitzers, and 42 and 32-



For the 10-inch and smaller carriages, the chassis-rails are single beams of rolled iron, 15 inches deep; for all calibers above, the rails are made of long rectangular pieces of boiler plate and T-iron, in a similar manner to that of the cheeks of the gun-carriage. That the carriage may be moved horizontally in the operation of aiming the piece, the chassis is supported on traverse-wheels, which roll on circular plates of iron, fastened to a bed of solid masonry, called the *traverse-circles.*

The motion of the gun-carriage is checked front and rear, by pieces of iron bolted to the top of the rails, called *hurters* and *counter-hurters*; and it is prevented from slipping off sideways by *friction rollers* and *guides*, which are bolted to the cheeks and transoms.

The pintle is the central piece around which the chassis is traversed. It is formed of a stout cylinder of wrought-iron inserted in a block of stone, if the battery be a fixed one, or it is secured to cross pieces of timber bolted to a platform firmly imbedded in the ground, if it be of temporary nature. In casemate batteries the pintle is placed immediately under the throat of the embrasure, and the chassis is connected with it by a stout strap of iron, called the *tongue.* The muzzle of the piece when in battery, is situated in the throat of the embrasure—a position which, taken in connection with that of the pintle, gives the greatest horizontal field of fire. The center pintle carriage, or the one in which the pintle is in the center of the chassis, is preferable for barbette batteries to the one in which the pintle is in the

pdr. guns of the old system mounted in sea-coast batteries, but they are being replaced by those of larger caliber as fast as they can be provided by the private founders.

Germany.—The heavy carriages for both the land and sea-services are made, not in government shops under the direction of its own officers, but are furnished by private parties who have granted to them in their contracts a wide latitude both as to the kind of material to be used as well as other matters of detail; they are not obliged to follow a given model or produce constructions which shall be nearly alike. The result is that the carriages constructed by different contractors are widely different from each other, though they may be intended for the same purpose and even for the same gun. An expression of opinion was heard in opposition to this system of procuring supplies, as it tended, or was so believed, to make the carriages in some cases heavier than were needed to perform the work required of them.

Some of the carriages built by Krupp for the Navy have the cylinder for the hydraulic buffer placed on the front part of the chassis, so that the strain brought on the piston-rod shall be one of tension instead of compression. This disposition of the cylinder was suggested under the belief that in a ship's carriage, which is subjected to violent motions from the waves of the sea, the regular action of the carriage would be less interfered with when so constructed than when arranged in the ordinary way.

In carriages for the land-service these reasons do not obtain, and as this arrangement of the cylinder involves a greater cost of the carriage, and it is more difficult to prevent the loss of the fluid by leaking around the piston-rod where it passes through the head of the cylinder, this mode of construction has not been adopted.

The parties who have heretofore furnished nearly all of the heavy carriages are Krupp, of Essen, and Gruson, of Buckau, near Magdeburg. For a full description of these carriages see *Gruson Sea-coast Carriage* and *Krupp Sea-coast Carriages*.

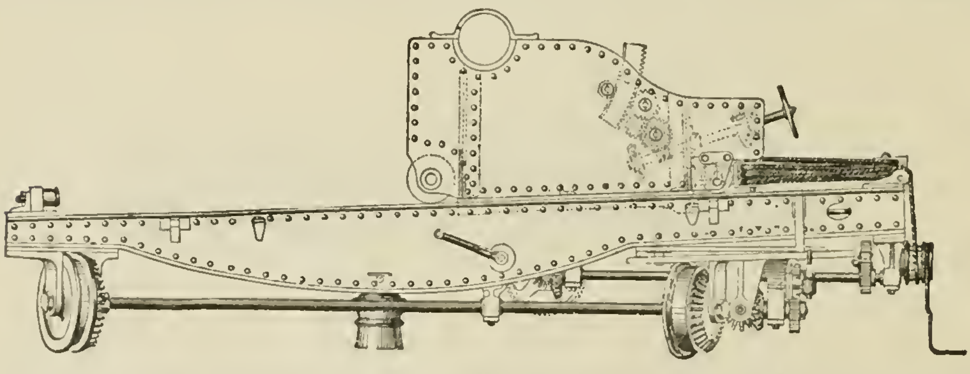
England.—The English carriages are made principally at the Royal Carriage Department, at Woolwich, but some are built from time to time by contract, by outside parties. Several different kinds of carriages are constructed to meet the varied wants of service in forts erected at so widely remote periods of time, but the differences are rather in details than in principle, and a general description covering the whole, with a brief notice of some of the principal variations, will suffice to give a very clear idea of their main characteristics.

The top-carriage is composed of two cheeks connected together by a vertical and a bottom transom, the attachment of the latter being strengthened by two knee-stays. Each cheek is made of a wrought-iron frame from 3½ to 4 inches thick, forged to the required shape, and planed on both sides. The plates, from .375 inch to .75 inch thick, and corresponding in general form to the frame, project beyond, both in front and rear, thus forming recesses for the truck-wheels, and are riveted to the frame, an inside brace being inserted between the plates where the vertical transom comes against them. The top and bottom surfaces of the cheeks are planed, the top being horizontal and the ends vertical when the carriage is on its chassis.

A metal trunnion-bed is made fast in each trunnion-hole by countersunk screws, and cap-squares are held in place by two feather-keys, which are attached to the cheeks by small chains. The bottom transom is a plate from .875 to 1 inch thick, is secured to the bottom of the cheeks by screws with countersunk heads, and is planed where it comes in contact with the cheeks and rails, that it may have even bearing-surfaces and guides of angle-iron are riveted to the lower side, to keep the carriage straight on the chassis. The vertical transom is a plate of .625 inch thickness, riveted along the lower edge and sides to an angle-iron frame, which is bolted to the cheeks and bottom transom. The upper edge is cut out in a curve, to allow the gun to turn on its trunnions freely without striking it. The knee-stays are riveted to the bottom transom, near its rear edge, and are bolted to the cheeks, one to each cheek.

The truck-wheels are between the plates of the cheek. The front wheels have axles from 2 to 2½ inches in diameter, and rest in gun-metal bearings secured to the cheek by two screws, which act as feathers in slots in the head of the axle, and prevent it from turning round in its bearing. The axle is put in from the outer side, and keyed in place. The axles of the rear wheels are eccentric, and are secured in the cheeks by what are called drop-plates. By taking out the rear bolt of the drop-plate, and turning it upward around the front bolt as a pivot, the axle is freed. The axles are joined by a "connecting-bar," in which are two holes to take the end of an iron hand-spike, so that the bar may be turned and both truck-wheels may be thrown in or out of gear at the same time. The inner end of each axle is made hexagonal, to receive a handspike socket in case the connecting-bar should be damaged. To prevent the rear-wheels from coming into play when the carriage recoils, a stop is riveted on the inside of each cheek.

The elevating apparatus consists of two wrought-iron circular racks pivoted to the gun and passing between the two plates of each cheek. The teeth are cut on the rear and convex edge, and work in the teeth of a pinion fixed to a spindle fastened in the cheek. On the concave edge a groove is cut, in which a friction-roller runs and keeps it engaged in the teeth of the pinion, and also prevents it moving sideways. The axles of the pinion and friction-roller pass through gun-metal bearings in the cheek; that of the latter is secured by a nut, and the former has upon it a capstan-head and clamp-screw for holding the gun in any desired position. The capstan-head has holes in the periphery for the end of an iron lever by which it is turned. By turning this head the gun is elevated or depressed, for the head has feathers which enter slots in the spindle,



so that any motion to the head is communicated to the spindle, and by the spindle to the pinion and rack. The clamp-screw binds the pinion and prevents it from moving.

The thread of the spindle in the right cheek is left-handed, so that the gun is held clamped by turning the clamping lever to the rear. For the 10-inch and larger carriages, and for the 9-inch of future construction, the gearing of the elevating apparatus is somewhat different. The pinion which engages the teeth of the rack is driven by a worm and wheel, with one or two intermediate pinions. The worm and wheel are placed on the inside of the cheek and held in place by two journal-boxes and caps bolted to the side of the cheek. To the rear journal-box a hinged clutch is screwed by a steel pin, and kept in place by a swivel-key. To throw the worm out of gear with the worm-wheel, open the clutch, turn the worm-shaft and draw it to the rear until the collar on it is in rear of the clutch; replace the clutch, and the shaft is held with the worm out of gear. On carriages of the most recent manufacture the worm-shaft is inclined upward to the rear. The hand-wheel for turning this shaft is in all carriages just in rear of the end of the cheek.

A front and rear eye-bolt for tackle is bolted to each cheek and a buffer-block of elm is bolted to the front transom. A loop for the priming-wire is attached to the right cheek.

The recoil of the gun is controlled in all carriages for the land-service by the hydraulic buffer. It consists of a wrought-iron lap-welded cylinder, with cast-iron cover-cap and flange, and wrought-iron piston-head and rod, a packing-gland and emptying-cock of brass. The cylinder is 77.375 inches long in the clear, and 8.07 inches in diameter, and holds 12 gallons 5 pints. The cap closes up the rear end, being screwed on. The flange is screwed on the front end, and the cover is bolted to the flange. Both the flange and cover are flat on top, to allow the top-carriage to pass over them without striking.

The chasses vary in height according to the use for which they are intended, whether in casemates or open batteries. The former have an imaginary pivot in front, the chassis being prevented from recoiling and guided in its motion by the traverse-wheels, which have in their periphery a deep groove for the traverse-circle to fit into. The chassis for open batteries are divided into three classes: the first has the pintle in front, and, like the casemate, it is imaginary; the second, the pintle is in the center, and the third has the pintle in rear of the center. The height of the chassis at the front end is 32.5 inches. When increased height is to be given, it is done by putting in a knee-stay bolster.

For the 7 and 9-inch guns the chassis-rails are rolled each in one beam 10 inches deep and 5½ in width of flange, bent round in front, and planed on the upper and lower surfaces and sides of the flanges. The front transom is a plate 1 inch thick, riveted along the sides and top to a frame of angle-iron. It is let slightly into the rails. A top plate is riveted to the front end of the chassis, and has an oblong hole in its length to give access to the nuts below it. The rear transom is a 7-inch beam, the flanges being 4 inches. It is fastened to the rails by a knee-plate bolted to it and the web of the rail. The traverse-forks are of wrought-iron, with a flange or knee to strengthen it to resist the thrust of the recoil.

The front forks are secured to a truck-plate 1 inch thick, bolted to the chassis-rail. The rear forks are riveted to a connecting-plate, which is fastened to the truck-plate, and these are bolted to the rails, wrought-iron bolsters being used to give the slope of 4°. A front bottom plate, .875 inch thick, joins the rails near their middle, and a rear bottom plate is bolted to the underside of the rear ends of the rails and the rear transom.

A diagonal brace of 1-inch plate, with a center piece and four arms like the letter X, is bolted to the underside of the chassis, and its center to the front bottom plate. The bent ends of the rails where they come together in front are joined by a connecting-plate which is bolted to the web of the two rails.

The traverse-wheels are of wrought-iron, having brass bushings. They are cylindrical, with a deep groove turned in the face to fit over the traverse-circle. The rear traverse-wheels have only one flange and on the front side. The journals of the traverse-wheels are steel, and are secured by a nut on the inner side. India-rubber hurters and counterhurters are provided. Eye-bolts for the tackle are bolted on each rail, one in front and one in rear; and a fifth is placed in the middle of the rear edge of the bottom plate, for use in transporting the chassis. Axle-tree bands to receive an axle for transporting the chassis are riveted to the front bottom plate.

The 9-inch chassis is provided with gear for traversing and running the gun from battery, the same arrangement serving for either purpose by disconnecting by a shipper the parts not required. The gear is worked by the crank-handles on either side of the rear end of the chassis.

A brass bevel-wheel is screwed fast to each of the rear traverse-wheels. An inclined shaft, with a capstan and spur-wheel on the rear and a bevel-wheel on the front end, extends from the rear end of the chassis down to two horizontal shafts running across the chassis just in rear of the traverse-wheels. These two shafts have a bevel-wheel on each end; one engages with this inclined shaft, and the other with the brass wheel attached to the traverse-wheels. Motion is given to the inclined shaft by means of two crank-handles on a shaft running across the rear end of the chassis with a bevel-piston on it, and is communicated by the horizontal shafts to the traverse-wheels.

The inclined shaft can be thrown out of gear with the shafts communicating with the traverse-wheels. If then the fall be made fast to the top-carriage, and passed around the capstan, the top-carriage may be run back from battery by turning the crank-handles.

In center-pintle carriages, in which the front and rear traverse-wheels are of the same size, the chassis is traversed by communicating motion to one front and one rear wheel. This is done by means of a long shaft running under the left side of the chassis, and having pinions on it to engage in the wheels made fast to the traverse-wheels. Motion is given to this long shaft by means of a short inclined shaft, as already described.

In chasses having the pintle nearer the rear end, the front wheels, being much the larger, are chosen as those to which motion is to be communicated. This is done by a long shaft running under the chassis. It is driven, as already mentioned, except in this case the cross-shaft is placed under the chassis-rails, instead of in rear of the rear transom.

The rails of the 10-inch chassis are built beams, fish bellied in shape, in order to get the required strength with the least amount of material. Two plates ¾-inch thick, cut to the required shape, are riveted to two T-pieces 6¾ inches wide. The webs come together at their front ends, but have an inner brace between them at the rear ends. The upper T is straight; the under one is bent to correspond to the plates. The depth at the front is 6½ inches, 11½ at the rear, and 18 inches in the middle. The 10-inch chassis, increased in height, is the same, except wrought-iron knee-bolsters are put in to give the required height. The rails of the 11-inch chassis have a depth of 18 inches in the middle, and a width of 6¾ inches.

The 35-ton gun-carriage differs from the preceding in some of the details. The cheek-plates are about .75 inch thick. The cheeks are joined together by a bottom transom of boiler-plate extending the entire length of the carriage, and two vertical transoms, each strengthened by angle-iron riveted to it around the sides and bottom. The elevating apparatus is worked by a wheel outside of the cheeks.

The truck-wheels of the top-carriage are thrown in gear by means of a hydraulic jack, which acts on a crank on the eccentric axle.

The front transom of the chassis is made fish-bellied, with the view of getting as much room as possible in rear of it for the piston, and the hurters, five in number, made of India rubber, are made fast to it. The counter-hurters are placed on the inside of the rail. The piston is placed as far to the front as possible. The cylinder for the hydraulic buffer is a wrought-iron lap-welded ⅜-inch tube, about .31 inch thick when bored out. The holes in the piston-head are .6 inch in diameter. The recoil usually varies less than 2 inches in length, and only 4 inches when the extreme charges are used.

France.—The top-carriage is made in the usual way, with two plates of boiler-iron more than a half inch in thickness, riveted together with a thick iron frame between them. The trunnion beds in the top of the cheeks are provided with cap-squares like those for the field-carriage.

The cheeks are connected to each other by transoms, the front one being of good cast-iron, and very heavy. The others are of rolled iron plates, the bottom one being very wide and curved downward between the cheeks. It is stiffened by iron bars riveted to it, the front end being re-enforced by a 6-inch trough-beam curved to fit it.

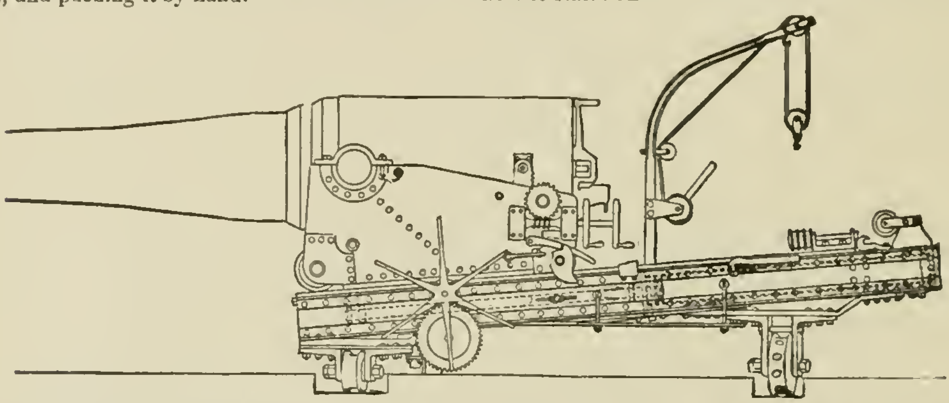
The elevating apparatus consists of a bar-link chain passing underneath the breech of the piece, which has a preponderance, and made to wind on an axle made fast to each one of the cheeks, and is turned by means of a rim-wheel on their outer face. By turning the wheels in one direction the chain is unwound from the axles, thereby made longer between the cheeks, the breech is lowered, and the angle of elevation of the gun increased. By turning the wheels in the opposite direction, the chain is drawn up, the breech raised, and the elevation of the gun is diminished. The top-carriage is provided with four truck-wheels for running the gun into battery. They are placed in the front and rear of the cheeks, between the plates. The rear ones are on eccentric axles, by which they can be thrown in gear at pleasure, and when thrown in, the rear end of the carriage is raised more than an inch from the rail, and the whole weight is brought on the four truck-wheels.

The handspike sockets on the eccentric axles are made of wrought iron as a matter of economy instead of bronze. Two iron rings are made fast to the front face of the cheeks for the purpose of attaching the hooks of pulley-blocks, by which to haul the gun into battery if for any reason it fails to run in when the truck-wheels are thrown in gear; ordinarily this will be sufficient, giving the gun a start, and pushing it by hand.

ing the handle in the opposite direction the pressure is relieved. A lug or stop is bolted to the side of the chassis-rail, and when the gun recoils, the handle, striking this lug, turns the screw, increases the compression on the friction-bars, and adds to the friction with which the carriage commenced to move back.

The chassis is composed of two solid rolled-iron beams, connected by front, rear, middle, and bottom transoms. In the smaller carriages for the 32 and 42 pounder guns the two rails are in one piece, bent in the arc of a circle in front. In the carriage for the 10.75-inch gun, the top of the rail is about 7 inches wide. It is about a foot deep, and the web is about an inch thick. The inclination of the chassis for sea-coast carriages is 4°. The pintle-transom is composed of three wide plates, laid one upon the other and firmly riveted together. The front transom is of cast-iron, very heavy; the middle of it rises some distance above the top of the chassis, and is rounded for a belaying-post, the breeching passing around it to check the recoil in case the brake should be disabled or get out of order. A spring-buffer is made fast to the rear side, against which the top-carriage strikes when running into battery too quickly.

The bottom transom covers the rear part of the chassis and forms a convenient flooring for the gunners to stand on.



The top-carriage for casemate guns is sometimes made of wood, it being protected from the weather in the casemates; and for the barbette carriages cast iron is sometimes used.

To check the recoil a compressor or friction brake is applied. It is composed of several long flat iron bars placed on their edges between the rails of the chassis, and parallel to them, one-half of the number on the right and the other half on the left of the middle line between the rails. These bars are fastened at each end on a bolt, so that they can move freely within narrow limits to or from each other, but cannot move in the direction of their length. Between these flat bars there are interposed short plates, suspended by notches on the front and rear edges from transoms of the top-carriage, just behind the front truck-wheels. These short plates are pressed forcibly together by means of a screw, which runs from one cheek-plate to the other through bronze boxes secured in them. On the screw are two nuts, which bear against the short plates and are prevented from turning with the screw, so they must move in the direction of the length of the screw toward one or the other end, depending upon the direction it is turned. The screw is prevented from moving lengthwise by means of a key at each end. The left end of the screw, where it projects through the cheek-plate, is cut into numerous teeth, like a cog-wheel, to receive a strong lever-handle, which can be thus put on in a great many different positions. By moving this handle to the front when the lever is below the screw the nuts are brought to bear on the short plates, and press them against the long friction-bars. By turning the handle in the opposite direction the pressure

Between the rails and parallel to them are sixteen friction-bars about ⅝ inch thick, placed on edge, and between the middle line of the chassis and the rail, eight in each group. They are fastened at each end to the chassis by two bolts, as already described.

On the inside of the rails, near the rear end, the counter-hurters are placed. They are made of India rubber, with a wooden face for the top-carriage to strike against.

The traverse-wheels, instead of being under the chassis as is usual, are very low and placed on the outside of the rails, the curved traverse-forks being bolted to the outside of the rails. This gives greater stability to the carriage, which for a ship's carriage is a matter of importance.

Concentric with the rear traverse-circle, and a little below its level, there is a second circle made of bronze, with recesses cut in it to engage the teeth of a large wheel, by means of which the lateral traverse of the carriage is given. In the rear of the chassis the crank is placed which operates this wheel through a system of wheels and pinions, so that two men can traverse the gun with ease.

The carriage is a very heavy and expensive one, weighing from 18 to 20 tons, and costing $10,000.

Sweden.—The cheeks of the top-carriage, instead of being formed of two plates of boiler-iron riveted together with an iron frame between them, as usual, are made each of a single plate of iron 1½ inches thick, cut to the required shape. The journals for the truck-wheels are formed by boring holes in the cheek-plates at the proper places, and re-enforcing them by circular iron plates 1 inch thick, fastened to the cheek-plate by four bolts each. The transom, which is usually vertical, has in this carriage an inclination of 45° with the vertical, sloping down from the trunnion-beds to the rear.

The elevating apparatus, placed on each side of the carriage, consists of a worm on the outside of the cheeks, operating a wheel and pinion, the latter playing in a rack attached to the breech of the gun. The rails are built beams, the web being a plain flat plate 1 inch in thickness, to which is riveted on either side at top and bottom a piece of angle-iron, forming a double T-rail, which is further strengthened by riveting to the angle-irons a flat bar on top and bottom.

The recoil is checked by a hydraulic buffer, constructed after the English pattern. The gun being a breech-loader, the carriage is so constructed that the gun shall be returned by the force of the recoil into the position in battery, in the same way as has been described in speaking of the German carriages. The traverse-wheels are like those used generally in Europe.

The carriage is traversed by means of a crank at the rear end of the chassis, the crank operating an endless screw and wheel, which turns the traverse-wheels. See *German Naval Carriage, Gruson Sea-coast Carriage, Hydraulic Gun-carriage, Krupp Sea-coast Carriages, Moncrieff Depression Carriages, Muzzle-pivoting Carriages*, and *Turret Carriage.*

SEA-COAST ARTILLERY.—Sea-coast defenses are intended to protect the entrances of rivers and harbors, to defend military establishments and points of commercial importance, to oppose the landing of an enemy on any part of the coast, and to prevent the approach of his vessels, either for aggressive purposes or for taking the soundings, observations, etc. The efficiency of the guns depends on their caliber, combined with facility of maneuvre, or rapidity of fire. As sea-coast cannon generally occupy permanent positions, the weight of the piece and projectile is not a serious objection to an increase of caliber, provided the proper mechanical facilities are supplied for moving them with celerity. Projectiles of 10-inch caliber are handled by two men. Those of 15-inch caliber require the aid of machinery to lift them quickly to the muzzle of the piece. It is proposed to mount special cannon of very large caliber at certain points commanding the entrance to the most important harbors. The intention in such cases is that the projectile shall contain powder enough to constitute a *mine*, and destroy an enemy's vessel at a single shot. As the fire of such pieces is necessarily slow, and the speed of steam vessels very great, it is evident that success depends on the certainty with which a single shot strikes the object. A system of obstructions, like rafts or torpedoes, should therefore be combined with them. A 20-inch gun has been made and mounted in accordance with this idea, for the defense of the New York Harbor. It weighs 117,000 lbs., carries a solid shot weighing 1,080 lbs., with a charge of 100 lbs. of powder. The most effective projectiles that can be brought to bear against wooden ships are shells and hot shot. The destructive superiority of the former was well attested in the Crimean war, and particularly in the naval engagement of Sinope, when the entire Turkish fleet was destroyed by Russian shells in about one hour's time. In the sea-fight between the Kearsarge and Alabama, the victory of the former was won by the great destructive power of its 11-inch shells. Modern mechanical skill has succeeded in covering vessels of war with plates of wrought-iron which are proof against shells and solid projectiles of less caliber than 8 inches. Rifle projectiles of a less caliber have the power to penetrate such plates, but they do not make the irregular holes and produce the shattering effects of larger round shot; holes that cannot be plugged, and injuries that cannot be repaired in action. Sea-coast cannon comprise *guns, columbiads, howitzers* and *mortars*. The solid shot pieces of the United States sea-coast service are the 32-pdr. and 42-pdr. guns, and the 8-inch, 10-inch, 13-inch, and 15-inch columbiads and Rodman guns.

It has been found that, 1st, no fort now built can keep out a large fleet without channel obstructions; 2d, a partial obstruction of the channel is not sufficient; 3d, no fleet can pass a battery if kept under fire of heavy guns by proper obstructions. It has, therefore, become necessary that sea-coast defenses shall consist of: 1st. Forts and land batteries; 2d. Floating batteries; 3d. Passive obstructions; 4th. Submarine mines. These may be used singly, but the most effective defense is made by combining them according to circumstances. The introduction of steam vessels of war, and their protection by armor plates, have necessitated great change in the construction and armament of sea-coast forts. The best temporary fortifications are made of earth, with large masses, as parapets, traverses, etc., for covering the guns. A better covering in the form of iron turrets has been proposed, as reveting the masonry of casemates with armor has not been found to give good results. Vessels of war, or floating batteries propelled by steam, are necessary for the complete defense of some harbors. If the channel be unobstructed, steam vessels can run past shore batteries, however well the latter may be armed and served. On the other hand, should there exist passive obstructions, the vessels have not the endurance and power to effect much damage to land defenses. The most effective channel obstructions are submarine mines. The object, then, of the obstructions used in connection with batteries is, 1st, to detain attacking vessels under the fire of the guns; and, 2d, to not only delay the advance of vessels, but to assist in injuring them. The obstructions must, therefore, be within range of the shore or floating batteries. The passive obstructions may rest on the bottom of the channel, as dams, sunken vessels, or masses of stone; or they may be floating, as rafts, booms, chains, or ropes. The active obstructions are the mines, in the form of torpedoes; these may be stationary or movable; the use and application of the latter belong properly to the Navy, and of the former to the Army, which employs them as auxiliary to the shore batteries. The mines adopted by the U. S. Engineers are constructed to be self-acting, exploding by contact, or to be exploded by electricity, the firing being in the hands of an operator on shore. The mines are laid in lines of many groups; the guns of the batteries can be trained upon any group, and be fired by electricity by the operator controlling the mines. The two explosions can thus be made simultaneous, and a vessel attacked both above and below water at the same time.

The armament of sea-coast batteries depends on their importance and on the depth and width of the channel to be defended. Deep channels, permitting the entrance of large vessels, and wide channels, requiring long ranges, should be defended by pieces of the largest caliber. When smooth-bored and rifled pieces are combined in the same work, the power of the piece will indicate the point at which it should be placed to render it most effective; those faces which bear directly on the channel may be armed with smooth-bored guns, and those which enfilade the channel, with rifled pieces. Each work must be provided also with light cannon and machine-guns for its own protection, and to oppose the landing of troops. The depth and width at different points of the body of water to be defended being known, and also the draft, armor and armament of the war-ships of the different foreign powers, the construction and armament of the necessary works of defense can be determined. No armored vessel can attack a work successfully if the latter be properly situated and armed with the same number of guns, each of which shall be capable of racking or penetrating her armor. As vessels, however, can keep in motion, and can pass by and out of range of shore batteries in a given time, the chance of their being disabled will be in direct proportion to the number of guns employed against them: this number should, therefore, be as great as circumstances will permit. The distance of the vessel, the direction in which moving, rate of speed, her size, and the time of flight of the projectile, are all elements to be considered. For the purpose of bombardment, sea-coast smooth-bored mortars are effective at about two and one-half miles, and rifled guns at five miles. The size of the object to be struck renders such fire of more value from ship-board, though land batteries would interfere very seriously with a fleet anchored at such distances. Long range gives comparative immunity to forts, but not to ships; the latter can, by selecting their position, sometimes bring a larger number of guns to bear upon a given point than can a battery. On the other hand, the guns in a battery are fired from stationary platforms, and the ranges would generally be known; the battery does not present so good an object as a vessel, unless it be on a level with the water; and if an earth-work, it is little affected by the projectiles. For rifled guns, the maximum effective range for accuracy has been placed at 4,000 yards. This, however, cannot be relied upon for penetration, even though at this distance the power of the projectile may not be too much diminished, since the actual piercing depends upon the angle which the axis of the projectile makes with the plane of the armor; 1,600 to 2,000 yards must for this purpose be at present considered the maximum effective range.

A projectile capable of piercing an armored vessel makes a hole larger than its own diameter, and the back of the plate is usually bulged, cracked, and carried away; the wood backing is torn, splintered, and racked for several feet around, making immediate repair impossible. The machinery of the vessel is always below the water-line, but if it can be reached by a shot, the result may be most disastrous. In firing, then, at a vessel's broadside, aim to strike at the water-line about opposite the machinery; if the projectile strike the water, it will either penetrate to the hull below the water-line, or rebound and strike above it. With a turreted ship, the most vulnerable part is the lowest circumference of the turret; shot striking at that line will jam the turret and impede or prevent the use of the guns within it. The ports of vessels are also points which can be fired at to great advantage. *Shot* or special *shells* will always be employed against the armor of war ships. Which shall be used will depend upon the construction of the vessel and the thickness of its armor. *Common shells* should be used when firing at a port, or at the crew when exposed, and also against wooden ships. *Grape* and *canister* can be employed only against landing parties, or against the ports when a vessel approaches sufficiently near to the battery. They can also be used against the rigging and wooden masts of ships. *Direct fire* is the only one that can be used to advantage against the sides of armored vessels. Against wooden ships it should be always used when the surface of the water is rough.

Against all unarmored vessels, ricochet fire is the most effective, and to secure the flattened ricochet, batteries should be placed as low as possible. The inaccuracy of the oblong projectile and the loss of velocity of a spherical one, with this fire, renders its employment useless against armored vessels. At all distances not exceeding 2,000 yards, the ricochet of projectiles from the 15-inch gun is extremely formidable.

This fire can be employed to advantage by iron-clads against low batteries, particularly when the size of the port will not permit sufficient elevation being given for the range required. A work elevated 50 feet above the water deprives the enemy of ricochet.

Shells of almost any size falling under a high angle will pass through the deck of any wooden vessel; against iron-clads, however, shells of large caliber only would be of value. Such a projectile would penetrate at least one deck of an armored ship; its effect on the vessel's bottom would then depend upon the number of decks of iron through which it would have to pass. A shell should not burst till after it has entered the vessel, when its action would probably be most destructive.

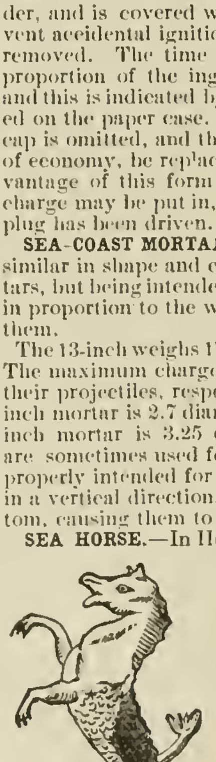
It is by no means easy to direct vertical fire upon ships with a sufficient accuracy to produce the desired effect, even when a large number of them forms a target of considerable size. This fire is effective when it is desirable to prevent an enemy from occupying certain anchorage, as no fleet nor vessel can remain under well directed fire from heavy mortars. A battery of one hundred such pieces will keep at bay all the iron-clads that can maneuver or anchor within their range. See *Columbiads*, *Ordnance*, *Rodman Gun*, and *Submarine Mines*.

SEA COAST FUSE.—This fuse is principally distinguished from the mortar-fuse by its having a metal cap, constructed to prevent the burning composition from being extinguished when the projectile strikes against water. It is composed of a *brass plug*, which is firmly driven into the fuse-hole of the projectile; a *paper-fuse* inserted into the plug, with the fingers, immediately before loading the piece; and a *water-cap*, screwed into the plug after the paper-fuse has been inserted. The water-cap is perforated with a crooked channel, which is filled with mealed powder; the mealed powder communicates fire to the paper-fuse, and the angles of the channel break the force of the water. The top of the cap has a recess which is filled with a priming of mealed powder, and is covered with a disk of sheet lead to prevent accidental ignition; before loading, this disk is removed. The time of burning is regulated by the proportion of the ingredients of the composition; and this is indicated by the number of seconds marked on the paper case. In firing over land, the water-cap is omitted, and the brass plug may, for the sake of economy, be replaced by a wooden one. One advantage of this form of fuse is, that the bursting-charge may be put in, or be taken out, after the fuse-plug has been driven. See *Fuse* and *Mortar-fuse*

SEA-COAST MORTAR.—The sea-coast mortars are similar in shape and construction to the siege mortars, but being intended for greater range, are heavier in proportion to the weight of the projectiles used in them.

The 13-inch weighs 17,120 lbs.; the 10-inch, 7,300 lbs. The maximum charge is one-tenth of the weight of their projectiles, respectively. The bore of the 13-inch mortar is 2.7 diameters in length: that of the 10-inch mortar is 3.25 diameters. Sea-coast mortars are sometimes used for siege purposes, but they are properly intended for striking the decks of vessels in a vertical direction, hence penetrating to the bottom, causing them to sink. See *Mortar*.

SEA HORSE.—In Heraldry, a fabulous animal, consisting of the upper part of a horse with webbed feet, united to the tail of a fish. A scalloped fin is carried down the back. The arms of the town of Cambridge are supported by two sea-horses, proper finned and maned or.

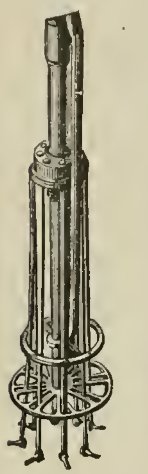


Sea-horse.

SEA LION.—In Heraldry, a monster consisting of the upper part of the lion combined with the tail of a fish.

SEAR.—The pivoted piece in a gun-lock, which enters the notches of the tumbler to hold the hammer at full or half-cock, and is released by pulling the trigger in the act of firing. The *half-cock* notch is made so deep that the sear cannot be withdrawn by the trigger. The *sear-spring* causes the sear to catch in the notch of the tumbler.

SEARCHER.—An instrument used in the inspection of cannon. It consists of a long staff of wood, fitted with a head of eight steel points, as shown in the drawing. The points are arranged at equal intervals around the head, and attached with a tendency to spring out and increase their diameter; this tendency is restrained by a hoop of iron embracing them, and capable of being worked in and out on the head of a rod extending along the staff.



The searcher is used for detecting the presence of small cracks or flaws. To use the instrument the hoop is pushed out on the head, thus contracting the points; it is then introduced in the gun to the bottom of the bore, and the hoop being pulled back allows the points to spring out and take against the surface of the bore. The searcher is then also slowly withdrawn, turning it at the same time; if one of the points catches, its distance from the muzzle is measured on the staff, and its position on the bore noted, and marked on the exterior of the gun. The size and figure of the cavity is then determined by taking an impression of it in wax. See *Inspection of Ordnance.*

SEASONED TROOPS.—Troops that have been accustomed to climate, and are not so liable to become the victims of any endemical disorder as raw men unavoidably are.

SEAT OF THE CHARGE.—The *form* of that part of the bore of a fire-arm which contains the powder, will have an effect on the force of the charge, and the strength of the piece to resist it. The points to be considered as most likely to affect the force of the powder, are, the form of the surface, and its extent compared to the enclosed volume. In the first place, to obtain the full force of a charge, its form should be such that its inflammation will be nearly completed before the gas begins to escape through the windage, and the projectile is sensibly moved from its place; in other words, the length of the space occupied by the charge should be nearly equal to its diameter; in the second place, as the tension depends much upon the heat evolved by the combustion, the absorbing surface should be a minimum compared to the volume.

The charges with which solid projectiles are generally fired being greater than ⅓ of their weight, the cartridge occupies a space, the length of which is greater than the diameter; and in cannon, therefore, which fire solid projectiles; the form of the seat of the charge is simply the bore prolonged; this arrangement, when compared with the chamber, makes the absorbing surface of the metal a minimum, and reduces the length of the charge so that its inflammation will be as complete as possible, before the gas escapes and the projectile is moved.

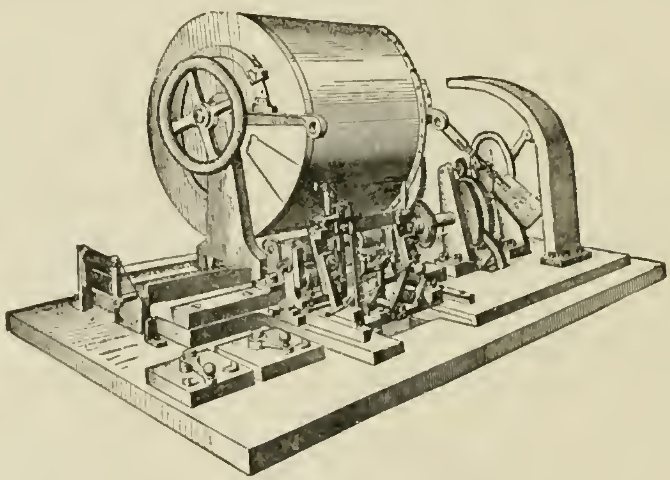
To give additional strength to the breech, and to prevent the angle formed by the plane of the bottom and sides of the bore from becoming a receptacle for dirt, and burning fragments of the cartridge-bag, it is rounded with the arc of a circle whose radius is one-fourth the diameter of the bore at this point. Instead of its being a plane bottom, it is sometimes made hemispherical, tangent to the surface of the bore. In all cannon of the most recent model, the bottom of the bore is a semi-ellipsoid. This is thought to fulfil the condition of strength more fully than the hemisphere. When a light piece is used to throw a projectile of large diameter and great weight, the effect of the recoil can only be diminished by employing a small charge of powder. If such a charge were made into a cartridge of a form to fit the bore, its length would be less than its diameter, and being ignited at the top, a considerable portion of the gas generated in the first instants of inflammation, would pass through the windage, and a part of the force of the charge would be lost. To obviate this defect, to give the cartridge a more manageable form in loading, and to make the surface a minimum, as regards the volume, the diameter of this portion of the bore is reduced so as to form a *chamber.*

SEAT OF WAR.—The country in which a war is being carried on.

SEBERT AND MARCEL-DEPREZ CHRONOGRAPH.—This new chronograph retains the principle modifications introduced into the Schultz chronograph, as shown in the drawing. For example, the new mode of supporting the vibrating fork, the arrangement by which it is made to mark only at the moment desired, and, finally, the employment of Marcel-Deprez electro-magnetic registers. The principal modifications which distinguish it from the latter apparatus are the following: The cylinder designed to receive the registration is much longer, so as to admit of placing in a single row the 20 Marcel-Deprez registers, designed to signal the entire movement of the 10 pistons of the apparatus called manometric balances. The great length rendering more difficult the displacement of the cylinder with reference to its axis it is left stationary, and the fork and the connector-registers, designed for measuring phenomena whose duration exceeds that of a revolution of the cylinder, are mounted on a moveable slide. This slide is moved by an endless chain, operated by a wheel-work with which it can be connected at will by a special gearing, which also can be worked automatically at the moment of firing.

In order to extend the duration of the rotation of the cylinder as long as may be necessary, it is provided with a motor-wheel work similar to those which are employed in the Hughes' telegraph-printers, and which permit the motor-weights to be wound up during the motion without interrupting the movement. The arrangement giving the means of utilizing the apparatus for experiments of long duration, as, for instance, the observation of the law of the movement of a projectile over the whole extent of its trajectory, during the lapse of several seconds, the cylinder is furnished with a regulator, so arranged as to cause the velocity of rotation at the circumference to vary within very extended limits from 0.50 to 15 meters (1.64 to 49.213 feet) per second, and the means of regulating this velocity is assured, even during the working, by employing a regulator with movable fans arranged so that it can be adjusted under all circumstances. A velocity indicator was added to the apparatus, which shows at each instant the approximate velocity acquired by the revolving cylinder, which gives the means, by operating on the regulator, of bringing the velocity to the proper rate, according to the nature of the experiment in view, and of not causing the firing until the moment when it is certain that the apparatus is brought under the conditions required. The arrangements applied last of all to the Schultz chronograph for the readings is retained; that is to say, the employment of a stationery microscope mounted on the slide and of a graduated scale on the cylinder; but, in order to increase the precision of the measures, this scale was traced on a disk furnished with a toothed gearing with a micrometric endless screw, the head of which is furnished with a graduated roller movable before a vernier. Finally, in order to facilitate the employment of electric currents both for the working of the registers and for setting in motion the fork and the divers automatic attachments applied to the apparatus, there is annexed to the chronograph a special switch board by which all the necessary combinations of currents are easily effected, and the number of the battery elements, according to circumstances, grouped on each register. The switch board is provided with an apparatus for communicating fire, by which the relative retardation of this communication of fire is regulated at will at the moment of setting in motion the slide which contains the registers, and at the moment when the pen of the fork rests on the cylinder: it is furnished also with a special apparatus, designed to produce a simultaneous rupture of the currents which animate the 20 registers placed before the cylinder, in the case of experiments with the manometric balance with 10 pistons.

The drawing represents a front perspective view of the arrangement given to the Schultz modified chronograph when ready for work with a single-connector register. In this case the handle is pushed down which engages the screw attached to the cylinder, which is displaced longitudinally by a movement proportional to its movement of rotation. The pen of the register then traces on its surface a continuous helicoidal curve by the side of sinusoidal tracing of the fork, which is also developed helically. The examination of this drawing makes easily recognizable the principal modifications which have been made to the original arrangement of the Schultz chronograph. The organs for setting in motion, and those for regulating the velocity have not received any modifications: but the fork, and its system of support, have been lowered by making, for this purpose, a lodgment in the table, so as to leave more available space for the registers which permits, in case of need, of placing before the cylinder two rows, one above the other, each composed of 10 registers, simply disconnectors. When connector-registers are employed, these registers, are placed on a small special support, near the fork. When simply disconnector-registers are employed for registering a phenomenon whose duration is less than that of a revolution of the cylinder, in which case the cylinder is allowed to turn in its place, it is necessary to prevent the tracings of the diapason from overlaying each other by being made during more than one consecutive turn; this result is obtained by mounting the fork on a movable jointed base so that the pen of the cylnder can be brought nearer or farther at will, without interrupting the vibrations of the fork. The movement of the base, besides, is directed by means of a handle, acting on a joint in the form of a knee, so that with a simple movement from right to left, or *vice versa*, of this handle there is a corresponding double movement from rear to front, then from front to rear of the fork.



The position of the pen is also regulated so that in this movement it rests lightly on the cylinder when it reaches its extreme position in front, so that it is sufficient to give to the handle a complete movement, in one direction or the other, in order that the pen may trace on the cylinder in motion some undulations, which suffice to show the velocity of the latter at this precise moment. The number of these vibrations, also, may be increased or diminished according to greater, or less, rapidity with which the movement is executed. It is evident that with this arrangement the exact velocity of the cylinder can be ascertained at the precise moment of the production of a phenomenon by moving the handle of the fork at the same moment that this phenomenon is produced, that is to say, in the case of the experiments in which we are at present engaged, at the same moment that the inflammation of the powder is produced. In order that the observer may avoid giving this movement to the fork too soon or too late, this latter case occurring, for instance, when he gives the order to fire and there is delay in executing the command, an arrangement is added to the apparatus which causes the displacement of the fork, automatically, at the very moment of the firing. This addition is seen in the drawing; it consists, on the one hand, in the employment of a caoutchouc spring, capable of a variable tension, and which draws the handle of the fork constantly towards the left; and, on the other hand, of a special electro-magnet, placed at the other extremity of the stroke, and whose attraction retains, in ordinary circumstances, the lever of the handle, which is furnished for this purpose with a small armature of soft iron. The electro-magnet is traversed by a special circuit which is interrupted at the moment of firing, either by the traction on the firing lanyard, if the fire is communicated in the usual manner, or by the working of the conjunctor for communicating fire, if electricity is employed for the inflammation of the priming. The handle of the fork is then loosed at the very moment when the inflammation takes place, and the tension of the caoutchouc spring that draws it may be regulated in such a manner as to take into account the functional retardation of the apparatus for communicating fire. So that the tracing of the vibrations may be protracted till the precise moment when the signals to be registered are produced. See *Chronograph*, *Drop-chronograph*, and *Marcel-Deprez Register*.

SECONDARY BASES.—As an army advances, other bases, termed secondary are commonly assumed, to enable the army to have its supplies at hand. These bases, which should present the same qualities as do the original base, are usually established by detached bodies of troops, or by the re-enforcements sent forward, so that the army will not be delayed in its onward movement. The importance of establishing secondary bases increases in proportion as the army removes from its primitive base. Napoleon's long line of operations in the Russian campaign, 1812, required such bases to provide for the safety of his army. A study of this campaign cannot fail to be instructive as illustrating the immense difficulties to be overcome in conducting a campaign at a great distance from the primitive source of supplies and re-enforcements. The Tennessee river, being navigable, formed a secondary base for General Sherman in his Atlanta campaign. Chattanooga—the principal point on this river, being also on the line of railroad from Louisville to Atlanta, the main source of supply for his large army of 100,000 men—was the principal depot of supplies and the most important point of this line or base.

A power which is master of the sea, is enabled to assume a base at pleasure and still have a strong point of support. This fact was illustrated during our late war, when General McClellan, in 1862, assumed his base at the White House on York river. After his line of communication was cut by General Lee, McClellan changed his base to the James river without any risk of failing to find a strong support. Later,also General Grant changed his base from the Potomac to the James river. General Scott, from the same cause, was able to select Vera Cruz as his base during the Mexican war. England from her superiority on the sea, would have great advantages in this respect.

The length of the base of operations should be in proportion to the distance that an army may be required to operate from it. If the base is too contracted, the different roads leading to the objective point will be very much resrticted, which would greatly facilitate any movement of the enemy to separate the army from its base.

SECOND COVERED WAY.—In fortification,that beyond the second ditch. This ditch is made on the outside of the glacis, when the ground is low and there is plenty of water.

SECONDING.—A temporary retirement to which Officers of Royal Artillery and Royal Engineers are subjected when they accept civil employment under the Crown. After six months of such employment the officer is *seconded*, by which he loses military pay, but retains his rank, seniority, and promotion in his Corps. After being seconded for ten years he must elect to return to military duty, or to retire altogether.

SECRECY.—In military economy this quality is peculiarly requisite. It signifies fidelity to any secret; taciturnity inviolate; close silence. Officers in particular, should be well aware of the importance of it, as the divulging of what has been confidentially intrusted to them, especially upon expeditions, might render the whole project abortive. The slightest deviation from it is very justly considered a breach of honor, as scandalous conduct unbecoming an officer and a gentleman. In all official matters the person so offending is liable to the severest punishment and penalty.

SECRETARY.—The Chiefs of the Executive Departments of the United States Government, forming the Cabinet, are termed Secretaries, except in the case of the Post-office Department and the Department of Justice. They are the Secretary of State, whose charge is the foreign relations of the Government; the Secretary of the Treasury, who has charge of the national finances, including the customs revenue; the Secretary of War,who has in charge the U. S. Army and controls its disposition—under the direction of the President, who is Commander-in-Chief of the Army and Navy—and who has charge of all forts and all military movements; the Secretary of the Navy, who bears a similar relation to the naval force; and the Secretary of the Interior, in whose charge are the Indian tribes, Government lands, pensions, the Patent Office, and Bureau of Education. These officials are appointed by the President and confirmed by the Senate. They report annually, and as much oftener as required, to the President, who lays their reports before Congress. The salary of each of the Heads of Departments is $8,000 per annum. Each is subject to removal by the President, whenever in the judgment of the latter the interest of the Government shall so demand. During the administration of President Johnson the power of removal was taken from him by what was known as the Tenure of Office Act, which was applied in the case of Secretary of War Stanton, whom the President had removed from office. The difficulty resulted in the impeachment of the President and his acquittal; when Secretary Stanton resigned. See *Minister*.

SECRETARY AT WAR.—Formerly a high officer of the British Ministry, who had the control of all the financial arrangements of the Army,and who was the responsible medium for parliamentary supervision in military affairs. In the time of the Tudors, the war business of the country appears to have been transacted by the Department of the Secretary of State. The formation of a War Office proper took place about 1620. The office rose in importance as the Army increased; but was limited to financial authority, neither the Commander-in-Chief nor Master General of the Ordnance being subject to it. At length, during the Russian war the evils of this divided authority led to the creation of a Secretary of State for War, to control all the military departments. The Secretaryship-at-War was merged in this superior office in 1855, and although for some years preserved technically a separate appointment held by the Secretary of State, was abolished by Act of Parliament in 1863.

SECRETARY OF LEGATION—The title of the Second Diplomatic Official accompanying full missions to Foreign Courts, and who fulfills the duty of the Minister in his absence. Such Officials are sent by the United States to the Courts of Great Britain, Russia, France, Spain, Germany, Austria-Hungary, Italy, Japan, China, Mexico, Brazil, and Turkey; at the last-named Court, supplying all the functions of Consul General. The Foreign Countries having Secretaries of Legation at Washington are: Argentine Republic, Austria-Hungary, Belgium, Brazil, Chili, Colombia, France, Great Britain, Hayti,Mexico, Peru, Russia, Spain, Sweden and Norway,Turkey, China, Japan.

SECRETARY OF STATE.—An ancient and important office in the government of England. The oldest record of its existence is in the reign of Henry III., when John Maunsell is described as "Secretarius Noster." Prior to the restoration, the holder of this office was generally styled the "King's Chief" or "Principal Secretary;" he had the custody of the King's signet, and discharged his duties with the assistance of four clerks. Two Secretaries are said to have been first appointed toward the close of the reign of Henry VIII. The office, always one of influence, gradually grew in importance. On the union of 1707, Anne added a third Secretary of State for Scotland, which office, however, was done away with. In the reign of George III. there were at first but two Secretaries; for a time there was a third for America, but his office was abolished by statute in 1782. While the Secretaries were two in number, both equally directed home affairs; to one of them were committed the foreign affairs of the Northern to the other of the Southern Department. Irish affairs belonged to the province of the elder Secretary.

There are now five principal Secretaries of State who are respectively appointed for the Home Affairs, the Foreign Affairs, War, the Colonies, and India. They are all appointed by the Sovereign by the mere delivery of the seals of office, without patent, and are always members of the Privy Council and of the Cabinet. Though each has his own Department, he is considered capable of discharging the duties of the others; a member of the House of Commons, if removed from one Secretaryship to another, does not thereby vacate his seat.

The Secretary of State for the Home Department has the charge of the maintenance of the internal peace of the United Kingdom, the security of the laws, and the administration of justice, so far as the royal prerogative is involved in it. He directs the disposal and employment of the regular troops at home, and provides for the suppression of riots. The militia, yeomanry, and volunteers are entirely under his control. He has the ultimate supervision of all that relates to prisons and criminals; and numerous statutory powers have been given him regarding police, sanitary-matters, the regulation of labor, etc.

The Secretary of State for Foreign Affairs is the responsible adviser of the Crown in all communications between the Government and Foreign Powers. He negotiates treaties, either directly with the Foreign Ministers resident in the country, or through the British Ministers abroad. It is his duty to inquire into the complaints of British Subjects residing in foreign countries, to give them protection and to demand redress for their grievances. The Foreign Secretary recommends to the Sovereign all Ambassadors, Ministers, and Consuls, to represent the country abroad. He grants passports to British subjects and naturalized foreigners.

The Secretary for the Colonial Department has the supervision of the laws and customs of the Colonies, watches over their interests, directs their government, apportions the troops necessary for their defense or police, appoints the Governors of the Colonies, and sanctions or disallows the measures of the Colonial Governments: rarely, however, prescribing measures for their adoption.

Each of these four Secretaries of State is assisted by two Under Secretaries of State nominated by himself; one usually permanent, while the other is dependent on the administration in power.

The Secretary of State for India, whose office dates from the abolition in 1858, of the double government of India by the Court of East India Directors and Board of Control, has the same control over the government of India which was formerly exercised by these bodies, and countersigns all warrants and orders under the sign-manual relating to India. He is assisted by an Under Secretary who is also a Member of the Legislature, and loses office with the Cabinet, and by a permanent Under Secretary and Assistant Secretary, as also by a Council of fifteen members, over whom he presides. Every order sent to India must be signed by the Secretary, and all dispatches from governments and presidencies in India must be addressed to the Secretary.

There is also Chief Secretary for Ireland, resident in Dublin, except during the sitting of Parliament, and under the authority of the Lord Lieutenant. His office resembles that of a Secretary of State, but he is generally called Secretary to the Lord Lieutenant. He is assisted by an Under Secretary.

The Secretary of State for War (see SECRETARY AT WAR) has the superintendence of all matters connected with the Army, assisted by the Commander-in-Chief, and is responsible for the amount of the military establishment. He prepares for the royal signature and countersigns commissions in the Army, and recommends to the Sovereign for the Order of Knighthood of the Bath.

SECRETARY OF WAR.—The principal officer of the Executive Department of War. Mr. Attorney General Wirt, in an opinion, dated January 25, 1821, says, the Secretary of War "does not compose a part of the Army, and has no duties to perform in the field." The duties assigned by law for the Secretary of War are the following: 1. The Act creating the new Department (*Act* Aug. 7, 1789) gives to the Secretary, besides the custody of records, books, and papers of the old Department, the record of military commissions, the care of warlike stores and other duties clearly ministerial. 2. Section 5, *Act* March 3, 1813, continued in force by the 9th section of the *Act* of April 24, 1816, delegates jointly to the President and Secretary of War the power to make regulations better defining and describing the respective powers and duties of Staff Officers. 3. Articles of War intrust the Secretary of War with muster-rolls and returns, and give him authority over the forms of such papers, and to require stated returns. 4. Articles of War authorize him to grant discharges to Non-commissioned Officers and soldiers, and make him the medium in passing proceedings of certain Courts-Martial, and the organ of the President's orders thereon. 5. Another Article of War charges the Secretary with receiving accounts of the effects of deceased officers and soldiers. 6. *Act* May 18, 1826, Section 1, respecting clothing, etc., charges certain duties upon the Quartermaster General "under the direction of the Secretary of War." 7. Several *Acts* authorize the Secretary to purchase sites for Arsenals. 8. The Ordnance Department and its *matériel* are made subject to the Secretary by the *Act* February 8, 1815. 9. Under the *Act* March 2, 1803, Section 1, the Secretary of War is authorized to give direction to the State Adjutants General, in order "to produce uniformity" in returns, and to lay abstracts of the same, etc. 10. The Secretary shall lay before Congress on the 1st of February in each year a statement of the appropriations of the preceding year showing the amount appropriated, and the balance remaining unexpended on the 31st of December preceding. He shall estimate the probable demands which may remain on each appropriation, and the balance shall be deducted from the estimates of his Department for the service of the current year; (*Act* May 1, 1820.) 11. He shall render annually accounts exhibiting the sums expended out of such estimates, together with such information connected therewith as may be deemed proper; (*Act* May 1, 1820.) 12. The Secretary of War shall cause to be collected and transmitted to him at the seat of Government all flags, standards, and colors, as may be taken by the Army of the United States from their enemies; (*Act* April 18, 1814.) 13. The Secretary may employ for the office of the War Department one chief clerk, and such other clerks as may be authorized by law; (*Acts* April 20, 1818, and May 26, 1824.) 14. The Secretary of War may furnish to persons who design to emigrate to Oregon, California, or New Mexico, such arms and ammunition as may be needed to arm them for the expedition at the actual cost of such arms and ammunition; (*Resolution* March, 2, 1849.) 15. All purchases and contracts for supplies or services for the military service of the United States, shall be made by or under the Secretary of War; (*Act* July 16, 1798.) 16. He shall annually lay before Congress a statement of all contracts, with full details; (*Act* April 21, 1808.)

Not one of the numerous Acts of Congress relative to the War Department gives him authority to command troops. His lawful duties are all purely administrative, and "as he does not compose a part of the Army," the President, in the exercise of his office of Commander-in-Chief, can of course only use the military hierarchy created by Congress. The English, from whom our system is borrowed, opposed to centralization of authority as adverse to freedom, have judiciously recognized the fact, in practice as well as in theory, that the War Department is not of such a nature that it can be directed as other Departments of the Cabinet, or even be made to work by the simple play of constitutional changes in the Ministry. They have consequently separated the *action* of the public force from the *direction* of all financial matters. But as the safety of the State depends upon the stability of its military institutions, the steadfastness of the means at work, and the skilful direction of all details, the Minister of War, who is changed by every triumph of opposite opinion, is not a military officer, and not charged with military authority. The permanent military institutions of the country do not depend upon him. The Army does not look to him for nominations to office, discipline, or military control. He is simply the great provider, the superintendent of accounts, the financier, the interpreter of the plans of the Cabinet for exterior and politico-military operations. He is aided by Under Secretaries, who do not go out of office with the Cabinet, and who are charged with the administration and payments for the *matériel*. The Commander-in-Chief, on the contrary, is the conservator of discipline, the center of nominations, the life-spring which animates and directs the Army, the source of orders, the regulator of tactics. He occupies himself with improvements of all kinds, and with the destination of *matériel*. It is to him that the Minister of State for War has recourse when he communicates to Parliament or the Cabinet the condition of the Army, details of organization, and other military information. Military finance and support of armies are thus left with the Secretary of War, while command, discipline, and improvements are regulated by the Commander-in-Chief. The Minister of War thus follows the fortunes of a Cabinet without the military institutions of the country being in any manner affected by any party changes. Practice in the United States has widely diverged from this theory.

SECRET PATROLS.—Secret patrols consist of a few men, and are generally sent out on the flanks, sometimes in the rear of the enemy's army. They have frequently to go far, and be long gone, to make the necessary observations; and of all the duties of Light Cavalry, therefore, this is the most difficult to perform. Many of the rules laid down for other patrols, are likewise applicable here. A patrol of this kind marches without advance or rear-guard. Only one man must be detached to look over the country from the hill-tops. The high roads must be avoided as much as possible, and the patrol march by by-roads, deep valleys, etc., etc. A guide on horseback will be of great service to such a patrol; but he is to be paid for it, and well treated. The patrol, to feed, must go off the road into a thicket or wood, and a look-out be set from a tree. If anything hostile approach, the patrol must escape unperceived and seek out another place of concealment, until it may continue its march without danger. A fire can rarely be lighted—never without being very careful to hide it: but it is better to do without one. An inhabitant who meets with the patrol at night, must remain with it until the march is resumed. Should a secret patrol, in spite of all these precautions, be discovered by the enemy, it must fly. But, as soon as the enemy gives up the pursuit, it must make a renewed attempt to get, by roundabout ways, to where it is to execute its commission. A well-informed and clever officer is required for this kind of duty; one who speaks the language of the country, and has a knowledge of the customs, habits, hopes, and fears of the inhabitants. The leader of a patrol should always be able to answer the following questions about the roads he has passed over:

As to whether they are rocky, sandy, or boggy?

How many streams were passed; their distance from one another: their breadth, depth, and strength of current?

The character of their banks; whether steep, miry, etc.?

Whether fordable at every season for Cavalry, Infantry, or Artillery, etc.?

How many bridges span them; whether of wood or stone, massive or slight?

How many villages there are on the road; their names; and the distances from one to the other?

Whether the road runs much through woods, or at some distance from them; the woods, of what size and kind, etc.? See *Patrols* and *Side Patrols*.

SECRET SERVICE.—Under the U. S. Government, a Department or Bureau, not created by law, nor recognized by specific appropriation for its cost. Its duties are not defined, and vary with the occasion which may create them. During the War of the Rebellion the service was extended: its Chief was a soldier with the rank of a Brigadier General of Volunteers, and its power and authority—under the Government—were practically unlimited. This service is, since the close of the War, represented by the Bureau of Special Agents of the Revenue Department of the U. S. Treasury. These Officials are charged with the investigation of suspected frauds in the collection of the revenue, either through fraudulent invoices, undervaluation, or false appraisement. They are authorized to inspect invoices and other records in the various Custom-houses; and to investigate the books of mercantile houses, and require them to be brought into Court for examination, on suspicion of any fraudulent importation of goods.

SECTION. 1. A certain proportion of a battalion or company, when it is told off for military movements and evolutions. 2. If a plane pass through work in any direction, the cut made by it is a section; if the cut be vertical and perpendicular to the face of the work, it is a ground-plan: thus, when the foundation of a house appears just above the ground, it shows the ground-plan of the building.

SECTION CUTTER.—A cutting instrument for making thin sections for microscopic examination. The

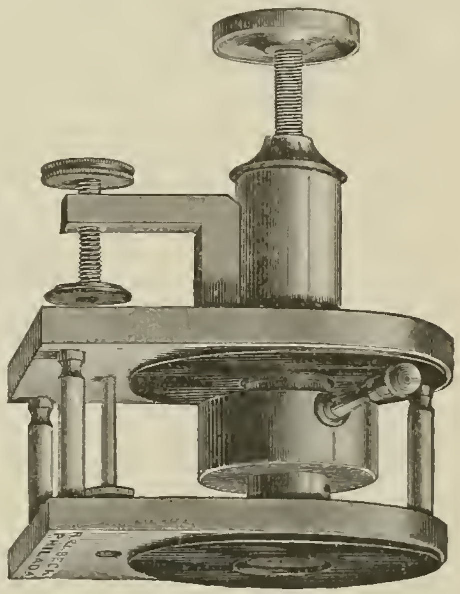


Fig. 1.

drawings show two forms of the instrument. Fig. 1, represents Walmsley's adaptation of Dr. Bevan Lewis's ether-spray microtome.

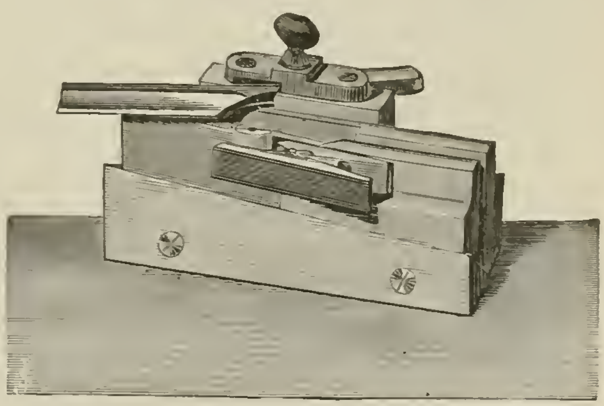

Fig. 2.

This form is largely in use by our leading Histologists, and by the Medical Department of the Army. To the excellent section instrument, of the Army Medical Museum pattern, a second table, with glass top, is added, through which a brass-topped tube, with condensing chamber beneath, is advanced by the same micrometer screw. Some thickened gum-water being put upon the top of this tube, a piece of tissue, say a portion of spinal column from a freshly-killed animal, may be placed in it, and the nozzle of the freezing atomizer having been introduced into the tube beneath, the tissue will be solidly frozen in from one to three minutes. Ether may be used, but rhigolene is much better; a considerable portion of it will be condensed in the chamber, and can be drawn off by the tube, shown in the illustration, for further use. The knife should be kept cold by being placed on a block of ice before using. The instrument is made in two sizes, with tubes of 1 inch and 1½ inches diameter. Fig. 2 shows the instrument after the pattern of M. Rivet, in brass, and furnished with a micrometer screw and knife.

SECTION LINER.—An instrument for indicating sections of objects in fortification and architectural drawings, for drawing screw-threads, laying out the spaces for brick work, letterings on drawings, and in all cases where narrow spaced parallel lines are needed. With it a person of moderate ability or practice can produce an effect of great uniformity and neatness in sectional drawings, almost, or quite equal to the engine-dividing of engravings. The instrument consists of a ruler, covered on the underside with an India-rubber cloth, a triangle with a clamping-screw, passing through near one of its edges and a plate, with the necessary arrangement for producing a movement over equal spaces. The several parts are placed together as represented in the engraving, Fig. 1., there being a little spring beneath the front edge of the top plate, which presses against one edge of the ruler, while the triangle is clamped against the other edge. The ruler may be placed upon the paper in any desired position, the India-rubber cloth underneath keeping it there with great security; and it thus acts as a guide for the triangle which can be moved along over equal steps by alternately pressing down the ivory button and letting it spring back. This movement is produced by the action of a little pawl upon the ruler, which is always to be kept pretty sharp, so that it will take a quick and certain hold. The length of the steps taken, or the distance between the lines drawn, is regulated by the screw above the spring, the distance moved over each time being greater as the spring is allowed to have more play. By changing the clamping-screw on the triangle, any edge can be placed against the ruler. Fig. 2. represents a sample of work done with Bergner's Section Liner.

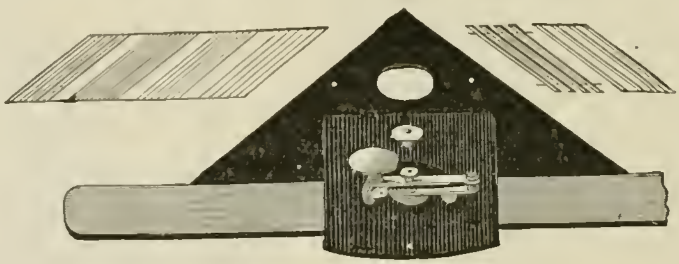

Fig. 1.

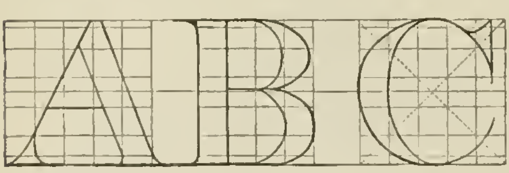

Fig. 2.

SECTOGRAPH.—A scale for use with a contoured map or plan, which enables the Surveyor to make a section of the ground with the least possible expenditure of time and labor. The contours on the map furnish the data, and enable the Surveyor to produce the required sections. It is, as stated by the designer, Lieutenant Tressider, R.E., a means of giving to a map the advantages of a model without its defects.

SECTOR OF EXPLOSION.—At the moment that a gun is fired, there is a sort of spherical sector of fire formed in front of the piece, whose extremity presses against the bottom of the bore, while the external portion of it terminates in the air, which this sector compresses and drives in every direction; the air thus forming a support, the sector reacts with its full force upon the bottom of the bore and causes the recoil of the piece.

SECTOR WITHOUT FIRE.—The star and bastioned forts were devised to remedy the defects of *sectors without fire*, and of the *dead spaces*, found in redoubts. A sector without fire is the name given to that space exterior to a work which is not defended by the direct fire of the adjacent faces. The space is included between lines drawn through a salient, perpendicular to the faces.

SECURE ARMS.—A position in the Manual of Arms, executed as follows: The Instructor commands. 1. *Secure*, 2. ARMS. Advance the piece slightly with the right hand, the barrel turning to the right; grasp the piece with the left hand, the forearm horizontal, and turn the barrel to the front, at the same time change the grasp of the right hand to the lower band, the barrel vertical. (Two.) Drop the muzzle to the front, the guard under the right arm, the hand supported against the hip, the thumb on the rammer; drop the left hand by the side.

1. *Carry*, 2. ARMS. Grasp the piece with the left hand, back down, midway between the upper and lower bands; resume the carry with the right hand, the barrel turning to the right. (Two.) Drop the left hand by the side. See *Manual of Arms*, Fig. 11.

SECURE PIECE.—A command, in artillery, directing that the piece be moved in battery, the muzzle depressed, the tompion inserted in the muzzle, and the vent-cover placed on the vent.

SECUTEUR.—A gladiator who was armed with a helmet, shield, and sword, or leaden club, and who fought with the *Retiaire*.

SEDAN CHAIR.—A portable covered vehicle for carrying a single person, borne on two poles by two men. The name is derived from the town of Sedan, in France, where this species of conveyance is said to have been invented. It is said that the Duke of Buckingham was in the practice of using one in the reign of James I., a proceeding which gave general offense, it being made matter of public remark that this royal favorite used his fellow countrymen to do the work of beasts. The general introduction of sedan chairs into England dates from 1634, about the same period that hackney coaches came into use. Sedan chairs were largely used during the greater part of last century, being found very well adapted for transporting persons, in full dress, to public and private entertainments. Not only were there numerous public conveyances of this kind in London and all considerable towns, but the owner of every large mansion had his private sedan handsomely fitted up. In Edinburgh, a century ago, sedan chairs were far more numerous than hackney coaches, and were almost all in the hands of Highlanders. Sedans are now seldom seen except for the transport of the sick, in the field.

SEDENTARY TROOPS.—The bodies of troops that remain at home to garrison towns, fortresses, etc., after the active Army and the Reserve have left the country. By the new English mobilization scheme a large force, including a few regular regiments and the garrison artillery, forms the garrison or sedentary Army of the country. It is divided into 13 separate commands, and will in time of war have to watch and defend the coasts.

SEDITION.—A general name given to such offenses against the State as fall short of treason. In the law of England it is not a strictly technical word. Writing, publishing, or uttering words tending to excite subjects to insurrection, though not urging them to rebellion or a total subversion of the Government, come under this denomination. There are various English statutes directed against particular acts of sedition, such as seditious libels, and seditious meetings and assemblies, which are punishable as misdemeanors. Act 36, George III., directed against all seditious practices and attempts pending to high treason, is extended to Ireland by 11 Vict., and additional provisions are added to it. By this latter Act the compassing or devising, either to depose the Queen; to levy war against the Queen, for the purpose of changing her Majesty's measures, or constraining or overawing Parliament; or to move any foreigner to invade the Queen's dominions, is made felony, punishable by transportation for life, or for a period not less than seven years, and that notwithstanding the facts should amount to treason.

In Scotland sedition is distinguished from leasing-making in so far as the object of the latter is to disparage the private character of the Sovereign, while the former crime is directed against the order and tranquility of the State. The punishment of sedition formerly arbitrary, is now restricted to fine and imprisonment.

SEGBANS.—Horsemen among the Turks who have care of the baggage belonging to cavalry regiments.

SEGMENT-SHELL.—An elongated projectile invented by Sir William Amstrong. The first iron body is coated with lead, and contains a number of segments of iron in successive rings, leaving a hollow cylinder in the center for the bursting-charge. The charge bursts on impact or by a time-fuse, and scatters the segments in all directions. It may be used as case-shot by arranging the fuse to explode the shell on leaving the muzzle. The object originally of introducing the segment-shell was that it might, by its construction, take the place of common shell, which, it was found, did not break up into sufficiently small pieces. Then it was hoped that it would act as Shrapnel, but again it was observed that, from the bad shape of the segments, it did not fly forward with sufficient velocity, and it scattered too much. Again, fired with a time-fuse, it was not reliable as to bursting at the exact moment required; so it was not considered efficient as Shrapnel, and contained too small a charge of powder to make it useful as a common shell against buildings, field-works, etc.

SEJANT.—Sejant, or Assis, in Heraldry, is the term of blazon applied to a beast in his usual sitting posture. A lion borne in full face, with his forepaws extended sideways, is blazoned sejant affronté, as in the crest of Scotland.

SELECTION.—The act of choosing and taking from among a number. In the British Army, selection according to merit is the system observed in promoting officers from a lower to a higher grade. In the United States all officers select their quarters according to rank.

SELF-CONSUMING CARTRIDGE.—The original cartridge of the needle-gun and of the chassepôt; it is made of a linen or silk envelope and the explosive composition is situated in the center of the powder. Experience has shown that no cartridge can be trusted to consume entirely in the barrel, under all circumstances, as the metal conveys the heat away so rapidly that often the thin paper in contact with it is untouched from the combustion of the powder. This cartridge therefore leaves in the chamber a mass of débris, paper, caoutchouc, copper, and dirt. In order to counteract this, the chamber has to be made a little larger than is necessary; hence, frequent missfires. The grease with which the cartridge is covered gets decomposed, and remains useless, if it does not penetrate through the paper and attack the powder, so that after twenty rounds the dirt in the rifle is solidified, accuracy is lost, and firing is stopped from the impossibility of loading. The cartridge is besides very liable to get damp, on account of the paste it contains, and it is quickly damaged in magazines. The chassepôt (as modified by Major Gras) and the German needle-gun (Mauser) now fire a metallic cartridge.

SELF-DEFENSE.—In law, defense of ones' person or property from an injury. A person upon whom violence is inflicted may defend himself by so much counter-violence as is necessary for his protection and no more. If assaulted by blows, he may defend himself by blows. A man may defend himself, even to the extent of his committing homicide, to prevent any violent crime, whose perpetration would constitute a felony. He may retnrn force with force in defense of his person or property against an attempt at forcible felony; and he need not retreat, but may even follow his assailant. When there is no threatened or intended felony, a man may defend himself in a mutual fight caused by any sudden quarrel, or where without a mutual fight the assailant attempts or commits an assault and battery; and the assailed person, where an attempt to strike him is made and the assailant is near enough to be able to strike him, need not wait to be struck first.

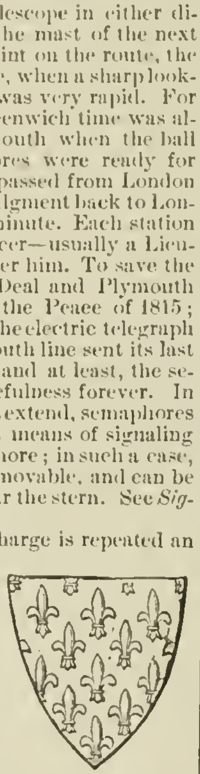
SELF-DENYING ORDINANCE.— A measure carried through Parliament in 1645 by the influence of Cromwell and the Independents, with the view of removing Essex and the Presbyterians from the command of the Army. It was on motion of a fanatic of the name of Zouch Tate, who on the ground that "there is but one way of ending so many evils, which is, that every one of us freely renounce himself," proposed, that "No member of either House shall, during this war, enjoy or execute any office or command civil or military, and that an ordinance be brought in accordingly." The ordinance, which was clearly intended to take all the executive power out of the hands of the more moderate politicians, and form an army independant of Parliament, was the subject of violent and protracted debate, but eventually passed in both Houses, and became law. The consequence was that Essex, Warwick, Manchester, and others gave in their resignations, and the conduct of the war was intrusted to Fairfax; Cromwell, to whom, as a member of the Lower House, the self-denying ordinance extended, as much as to Essex and the rest, had the duration of his commission prolonged by the Commons on account of his invaluable services as a leader of cavalry, and by his brilliant achievements soon surpassed his Commander in reputation.

SELICTAR.—A Turkish saber formerly much used.

SELLING OUT.—The permission formerly given to an Officer in the English Army, on retiring from the service, to sell his commission for the stipulated sum laid down by the Regulations. Since the non-purchase system has been established, this sanction is only granted to those Officers who entered the service previous to 1871, in which year the purchase of commissions was abolished. Officers who were in the service prior to that year receive the value of their commissions from the Army Purchase Commissioners.

SEMAPHORE.—The name applied to the system of telegraphy in use before the application of the electric current. Semaphores were first established by the French in 1794, as a plan for conveying intelligence from the capital to the armies on the frontier. In the following year, Lord George Murray introduced them in England; and by their means the Board of Admiralty were placed within a few minutes of Deal, Portsmouth, or Plymouth. These semaphores consisted of towers built at intervals of from 5 to 10 miles on commanding sites. On the top of each tower was the telegraph apparatus, which at first comprised 6 shutters arranged in 2 frames, by the opening and shutting of which, in various combinations, 63 distinct signals could be formed. In 1816 Sir Home Popham substituted a mast with 2 arms, similar to many of the present railway signals. The arms were worked from within the tower by winches in the look-out room, where a powerful telescope in either direction constantly commanded the mast of the next station. If a fog set in at any point on the route, the message was delayed; otherwise, when a sharp look-out was kept, the transmission was very rapid. For instance, the hour of one by Greenwich time was always communicated to Portsmouth when the ball fell at Greenwich; the semaphores were ready for the message, and it commonly passed from London to Portsmouth and the acknowledgment back to London within three-quarters of a minute. Each station was in the charge of a Naval Officer—usually a Lieutenant with one or two men under him. To save the cost of this Establishment, the Deal and Plymouth lines fell into disuse soon after the Peace of 1815; and the superior advantages of the electric telegraph being incontestable, the Portsmouth line sent its last message Dec. 31, 1847, and, on land at least, the semaphore closed its career of usefulness forever. In calm weather, when flags will not extend, semaphores are employed on board ship as a means of signaling from vessel to vessel, or to the shore; in such a case, the post containing the arms is movable, and can be readily shipped or unshipped near the stern. See *Signals*.

SEME.—In Heraldry, when a charge is repeated an indefinite number of times so as to produce the appearance of a pattern, then the term *semé* (sometimes *aspersed* or *powdered*) is applied to it. When a field is semé, it is treated as if it were cut out of a larger extent of surface, some of the charges being divided by the outline of the shield. The term *crusilly* denotes semé of cross crosslets, and *billetty* semé of billets.



Seme.

SEMISPATA.—A Frankish dagger or scramasaxe, having a single edge and several grooves on the back of the blade. Its length, including the haft, is about 24 inches.

SEMI STEEL.—If, in the operation of puddling, or in decarbonizing cast-iron, the process be stopped at a particular time, determined by indications given by the metal to an experienced eye, an iron is then obtained of greater hardness and strength than ordinary iron to which the name of semi-steel, or puddled steel, has been applied. The principal difficulty in its manufacture is that of obtaining uniformity in the product, homogeneity, and solidity throughout the entire mass. It is much improved by reheating and hammering under a heavy hammer, but it has not been found a very reliable material for even cannon of small caliber. See *Puddled Steel* and *Steel*.

SENATE.—The Upper House of Congress; composed of twice as many members as there are States in the Union, the two members from each State being elected by the respective State Legislatures, to hold office for six years. The Senators are held to represent the local sovereignty of their respective States. All Bills in Congress must pass both Houses to become laws; though the same may originate in either House. Of special functions, the Senate possesses that of ratifying treaties with foreign powers; of confirming the nominations to office made by the President, and of sitting as a High Court of Impeachment in case of the trial of public officials. The different States have each an Upper House corresponding in its duties and powers with the United States Senate.

SENESCHAL.—In the origin of the office, probably an attendant of the servile class who had the superintendence of the household of the Frankish Kings. In the course of time, however, the Seneschalship rose to be a position of dignity, held no longer by persons of servile race, but by Military Commanders, who were also invested with judicial authority. The Lieutenants of the great Feudatories often took the title of Seneschal. A similar office in England and Scotland was designated Steward, but is rendered into Latin as *Senescallus*.

SENIORITY.—Priority given to a regiment or an officer; it has reference to the date of the raising of the former or the date of commission of the latter.

SENTENCE.—The judgment of a Court-Martial in allotting the punishment of a convicted soldier. The punishment to be awarded is arrived at by the votes of every Member of the Court. Before deciding as to the quantity, the Court should settle as to the nature of punishment. In all cases the opinion of the majority should be absolute, but when the votes are equal, the more lenient sentence should be given. No sentence of death can be passed unless two-thirds of the Members of the Court concur therein.

SENTINEL—SENTRY.—A private soldier, marine, or sailor posted at a point of trust, with the duty of watching the approach of an enemy or any person suspected of hostile intentions. Sentries mount guard over depots of arms, the tents of Commanding Officers, etc. During the night each sentry is intrusted with the "word," or the countersign; and no person, however exalted in position, may attempt to approach or pass him without giving that as a signal. In such case the sentry is bound to arrest the intruder, and, if necessary, to shoot him. It has happened before now that the Commander-in-Chief of an army has been a prisoner in the hands of one of his own sentries. When an army is in the field the sentries are its eyes, for they guard the approaches in every direction some distance in front of the main body of troops. In the event of attack they give the alarm and retire slowly on their supports. There is usually an agreement, tacit or expressed, between Commanders that their outlying sentries shall not fire upon one another as such, would only be productive of useless bloodshed. Under martial law death is the penalty to any sentry for sleeping on guard.

SENTRY-BOX.—A place of shelter for a sentry in bad weather or against the effects of the sun. It is made either of masonry or wood.

SEPADAR.—An East Indian term for an officer of the rank of Brigadier General.

SEPAHI.—An East Indian term given a feudatory chief, or military tenant.

SEPOY.—A term corrupted from the Indian word *sepahi*, a soldier. This word sepahi, in its more familiar form of *spahee*, is known in most Eastern armies; and is itself derived from *sip*, a bow and arrow, the ordinary armament of an Indian soldier in ancient times. The word sepoy now denotes a native Hindu soldier in the British Army in India. The present sepoy force numbers about 140,000 men. See *East India Army*.

SEPTEMBRISERS—SEPTEMBRISTS.—A name given to the frantic executioners in what are known as the "September Massacres" in Paris. The causes of this ferocious outburst were twofold—mad fear of domestic traitors and of foreign despots. The news came pouring into Paris, ever more and more maddening, of Prussian and Austrian hordes marching victorious over the frontiers; insolent Royalists obtruding themselves in the van of the invading armies and breathing threatenings and slaughter; while the numerous *Aristocrates* (*i.e.*, favorers of the King and

Court) were believed to be making preparations to receive them in Paris. At the very same moment broke out the Royalist Insurrection in *La Vendée*, rendering France still further delirious, whereupon Danton, "Minister of Justice," got a decree passed, August 28, 1792, ordering domiciliary visits for the arrest of all suspected persons, and for the seizure of arms of which patriotic France stood very much in need. Upward of 2,000 stands of arms were got in this way, and 400 head of new prisoners. On the morning of Sep. 2 the news of the capture of Verdun by the Prussians arrived. The mingled rage and panic of the people cannot be described. All the bells in Paris were set a-clanging; men and women hurried in myriads to the *Champ de Mars* to get themselves enrolled as volunteers. Danton entered the Legislature—"The black brows clouded, the colossus figure tramping heavy, grim energy looking from all features of the rugged man"—and made that famous speech, ending: "*Pour les vaincre, pour les atterrer que faut-il? De l'audace, encore de l'audace et toujours de l'audace.*" The effect was electrical. He obtained from the assembly a decree condemning to death all "Who refused to march to the frontiers or to take up arms." But patriotism against foreigners was not enough. Were not the traitors at home deserving of death? Marat thought so: multitudes of ardent frantic men and women shared his conviction; but it is not proved that either Marat or Danton formally ordered the massacres, or, indeed, that anybody ordered them. They were rather only the spontaneous outburst of patriotic insanity, beholding aristocratic treachery and plots everywhere. Priests, Swiss soldiers, aged and infirm paupers, and women, both reputable and disreputable, and criminals, were mercilessly cut down or shot. From Sunday afternoon till Thursday evening the wild butchery went on at the Bicêtre, the Abbaye, the Convent of the Carmelites, the Conciergerie du Palais, the Grand Châtelet, St. Firmin, La Force, and the Salpêtrière. One gathers a glimpse of the savage sincerity of the Septembrisers when one reads that the gold rings, watches, money, etc., found on the persons of the massacred were all religiously brought to the town-hall; not a single thing was stolen or furtively appropriated.

SERAKHUR.—In the East Indies, a Non-commissioned Officer who is employed in the artillery. The title answers to that of *Sergeant*. In the naval service, the *Serang* is a similar person, and answers to the title of *Boatswain*.

SERASKIER—SERIASKER.—The name given by the Turks to every General having the command of a separate army, and, particularly, to the Commander-in-Chief or the Minister of War. The Seraskier, in the latter sense, possesses most extensive authority, being subordinate only to the Sultan and Grand Vizier; he is selected by the Monarch from among the Pashas of two or three tails.

SERDANS.—Colonels in the Turkish Service.

SERENADE.—Originally the music performed in a calm night. Serenading has been chiefly practiced in Spain and Italy. It is very common among the students of the German Universities to assemble at night under the window of a favorite Professor, and give him a musical tribute. A piece of music characterized by the soft repose which is supposed to be in harmony with the stillness of the night, is called a serenade, or sometimes a *nottorno*. It is a common practice in the Army to serenade Officers visiting or returning to Military Posts and Head-quarters.

SERGE.—A quilted cloth, made of woollen, and manufactured in many Counties of England, especially in Devonshire. Serge was used very recently in the manufacture of gun-cartridges, but it has been superseded by silk cloth. White serge is used for lining the panels of saddles.

SERGEANT ARMORER.—A skilled mechanic attached to regiments of infantry and cavalry, for the purpose of repairing and keeping the arms in order.

SERGEANT-AT-ARMS.—Formerly a sort of body-guard attendant upon the person of the Sovereign or of the Lord High Steward when sitting in judgment on a traitor. They numbered about thirty. The functions of this body have long ceased.

The Houses of Lords and Commons have each a Sergeant-at-Arms, both of whom execute the commands of the House to which they belong, as regards the apprehension or custody of all persons committed by order of Parliament. The office is generally held by a military man, who is very seldom under the rank of a Field Officer.

SERGEANT D'ARMES.—Philip Augustus, fearing to be assassinated on the instigation of the Sheik of the Mountain, during his stay in Palestine, organized for the protection of his own person, a corps of *Sergeants d'Armes*, consisting of gentlemen, whom he armed with bronze war-clubs and bows and arrows. It was their duty to accompany him everywhere.

SERGEANT INSTRUCTORS.—In the British Army, Sergeants who assist in the instruction of fencing, gunnery, and musketry.

Sergeant Instructor in Fencing.—A Sergeant attached to each cavalry regiment, to instruct the officers and men in the art of fencing.

Sergeant Instructor in Gunnery.—A Sergeant appointed to assist the Gunnery Instructor, attached to each brigade of artillery.

Sergeant Instructor of Musketry.—A Sergeant attached to each line regiment, and two to the Engineers, whose duty it is to assist the Instructor of Musketry in teaching the use of small-arms.

SERGEANT MAJOR.—The senior Non-commissioned Officer in a regiment. His duties are of a very important nature, as will be realized when it is considered that he is the Adjutant's right-hand man. In him should be embodied all that is manly, soldier-like, and zealous. His duties are so manifold that for the proper performance of them he should be the smartest and most intelligent man in the regiment, and his example and conduct such as shall cause him to be esteemed and respected by every soldier in it. Besides the Sergeant Major of a regiment, there are *Troop Sergeants Major* in the cavalry, and *Battery Sergeants Major* in the artillery.

SERGEANT MASTER TAILOR.—A Non-commissioned Officer who oversees the tailoring of a regiment. He is taken from the soldier tailors instructed at the Royal Army Clothing Depot at Pimlico; it is not, however, necessary that he should be educated at the above depot, as a civilian tailor on enlistment, after undergoing the prescribed examination in his trade at the Royal Army Clothing Depot, can be appointed.

SERGEANTRY.—A tenure by which all lands were held in the feudal times in England. After the Conquest the forfeited lands were parcelled out by William to his adherents upon condition of the performance of services of a military character. The military tenants of the Crown were, however, of two descriptions: some held merely *Per Servitium Militare*, by Knight-service; others held *Per Sergentiam*, by Grand Sergeantry, a higher tenure, which involved attendance on the King not merely in war, but in his Court at the three festivals of the year, and at other times when summoned. Although the word Baron, in its more extended sense, was applied to both classes of Crown Tenants, yet it was only those holding by Grand Sergeantry whose tenure was said to be *Per Baroniam*. In its earliest stage the distinction between the greater nobility and lesser nobility or gentry in England was, that the former held by Grand Sergeantry, and the latter by Knight-service only. In theory, lands held by Sergeantry became gradually extinct before the abolition of military holdings. Considerable misapprehension on the part of Dugdale and later writers has arisen from a double use of the word *Serviens*, or Sergeant, which is sometimes applied to a tenant either by Grand Sergeantry or Knight-service who had not taken on himself the obligations attendant on knighthood.

The term *Petty Sergeantry* was applied to a species of socage tenure in which the services stipulated for bore some relation to war, but were not required to be executed personally by the tenant, or to be performed to the person of the King, as the payment of rent in spurs or arrows.

SERGEANTS.—Non-commissioned Officers of the Army and Marines in the grade next above Corporal. They are selected from the steadiest among the Corporals, and their duties are to overlook the soldiers in barracks, and assist the Officers in all ways in the field. They also command small bodies of men as guards, escorts, etc. Every company has four Sergeants, of whom the senior is the First Sergeant. A superior class are the Staff Sergeants, as the Quartermaster Sergeant, Armorer Sergeant, Hospital Sergeant; and above them all is the Sergeant Major. The daily pay of a Sergeant varies from 1s. 1d. in the Infantry, to 2s. 11d. in the Horse Artillery. In ancient times the rank of Sergeant was considerably more exalted. In the 12th century the Sergeants were gentlemen of less than knightly rank, serving on horseback. Later, the Sergeants-at-Arms were the Royal Body Guard of gentlemen armed *cap-à-pie*. Also written *Serjeant*.

SERPENTEAU.—A round iron circle, with small spikes, and squibs attached to them. It is frequently used in the attack and defense of a breach. It likewise means a fusee, which is filled with gunpowder and bent in such a manner, that when it takes fire, it obtains a circular and rapid motion, and throws out sparks of light in various directions.

SERPENTIN.—A sort of small *lin-stock* employed to hold the match when applied to the cannon.

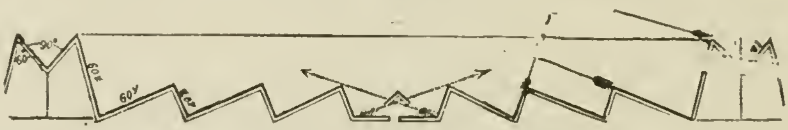
SERPENTINE.—A very ancient wall-piece, with a match-lock, carrying an 8-ounce leaden ball, with a charge of 4 ounces of powder. Its length was 6 or 7 feet, and weighed from one to two hundred-weight.

SERPENTIX.—The cock of the very ancient match-lock, also the lock itself. The term is also applied to an ancient 24-pounder gun, of 13 feet, weighing 4360 pounds, whose dolphins represented the figures of serpents.

SERPENTS.—Small rocket-cases charged with composition, consisting of two parts of charcoal and sixteen parts of mealed powder. The case is made by rolling a rectangle of paper No. 4 with the hand-rolling board, and choking it at one end. The cases are driven $\frac{2}{3}$ their length, giving each ladleful of the composition three blows with the mallet. The case is choked over the composition, and the remainder of it is nearly filled with mealed powder, upon which a small paper wad is placed. A clay head is then driven on it, and the end of the case turned down to secure it. The other end is primed with priming paste, or a small strand of quick-match. See *Compositions* and *Fireworks*.

SERRA FUSE.—This fuse originally consisted of a cast-iron case with a flat head, which was screwed into the eye of the shell to receive the fuse proper, which was made of bronze and was screwed into the case when required, having for that purpose a square head. The end of the iron fuse-plug projected slightly into the shell, and was hollowed out and notched, in order to receive a priming to render the explosion of the charge more certain. The fuse was filled with meal powder, compactly and regularly driven. It was designed for use with Shrapnel shot, and each caliber had three lengths, corresponding to the three most important distances, and differing in the time of burning, $\frac{1}{5}$ of a second in the 12-pounder, and one second in the 24-pounder, so that for the former piece, the fuses would burn 2″, $2\frac{1}{5}$″, and $3\frac{3}{5}$″, and for the latter piece, $2\frac{2}{5}$″, $3\frac{2}{5}$″, and $4\frac{3}{5}$″. The hole in the fuse-plug was kept closed with a tow wad, until just before inserting the fuse. It was found to be an improvement, when the plug or case was made of bronze, instead of cast-iron. This fuse has undergone many improvements. The plug has been made smaller, with no screw on its exterior, which was instead made slightly conical, and was driven into the fuse-hole, like an ordinary wooden fuse. Instead of iron; it was made of a mixture of tin, lead, and zinc, one part of each. In this manner, it could be applied to any shell without the trouble and expense of cutting a screw in the eye, and consequently could be used with the shells already manufactured, without any change. See *Fuse*.

SERRATED LINE.—A line principally used in place of a straight curtain between two advanced works, which are too far apart to protect each other and the space between them. When the ground between the advanced works is level, or nearly so, the branches of the crémaillère form salient and re-entering angles, which are on the same right lines. The long branches alternate from the middle point, where either a salient or re-entering angle is formed; the latter is preferable, as it is stronger, and may be arranged with flanks and a curtain, which will be better situated for defense than the two faces forming a salient angle. See *Lines*.



Plan of a Cremaillere Line between two salient Priest-caps.

SERRE DEMI-FILE.—That rank in a French battalion which determines the half of its depth, and which marches before the demi-file. Thus a battalion standing six deep, has its *serre demi-file* in the third rank, which determines its depth.

SERRE FILE.—The last rank of a battalion, by which its depth is ascertained, and which always forms its rear. When ranks are doubled, the battalion resumes its natural formation by means of the *serre-files*. *Serre-file* literally signifies a "bringer up."

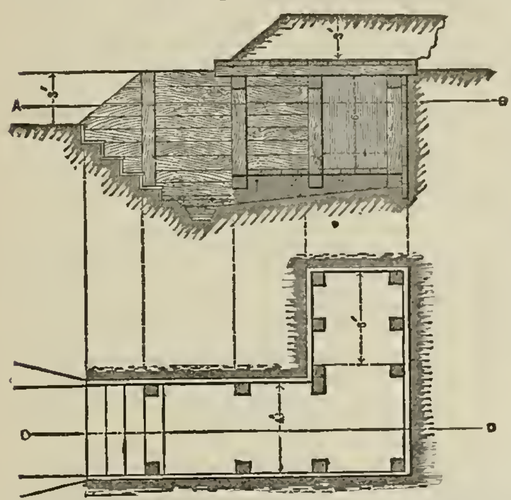
SERVANS D'ARMES.—Persons who belonged to the third class of the Order of Malta. They were not Noblemen, although they wore both the sword and cross. Also called Chevaliers Servans.

SERVANTS.—In the British Service soldiers are taken from the ranks for the purpose of waiting upon Officers. This privilege of having a soldier servant is not granted on Indian service, or where a Colonial allowance is granted in lieu of servants. Each *Infantry* Regimental Officer is allowed to have *one* soldier to attend on him: Field Officers and Adjutants keeping horses for regimental purposes, as well as all *Cavalry* Officers when present at Head-quarters or employed on duty, *two* each. In the United States Service, Officers are not permitted to employ soldiers as servants.

SERVICE.—In a military sense, the art of serving the State in war. All studies, acts, and efforts of the profession of arms have this end in view. To belong to the Army and to belong to the land service, are the same thing. In a more restricted sense, service is the performance of military duty. In its general sense, service embraces all details of the military art. But in its restricted sense, actual service is the exercise of military functions.

SERVICE MAGAZINE.—The size of a service magazine will depend upon the number of rounds it is desirable to have ready for immediate use; usually, twenty rounds for sea-coast guns, and from fifty to one hundred for those of smaller caliber, will be sufficient. The capacity of the magazine to hold this amount or any other that may be fixed upon will be determined by the rules given in the article Storage Magazine. When the magazine is to hold barrels, it should be 6½ feet high and 7½ feet wide; this will accommodate four tiers of three rows, leaving a passage-way of 30 inches. The length will depend upon the number of barrels, and this will be governed by the number and caliber of pieces to be provided for; generally, 15 feet will be ample. The magazine is usually constructed of coffer-work or gabions.

Magazines of this kind are sometimes built in the adjacent traverses if there be any; generally under the parapet, near the guns; and often under the barbettes. It may be entirely above the ground, or be partly or wholly under the ground, as shown in the drawing, where the magazine or passage-way are lined with wooden frames. The frames are made of timbers or scantlings of the proper dimensions,



each frame consisting of two uprights, called stanchions, a ground-sill, and a cap. The frames are then placed upright, about three feet apart, and in the position which they are to occupy. Their tops and sides are then planked over; this planking is called the sheeting. The bottom of the excavation is sloped from the sides to the middle, and from the rear to the front, to allow all water leaking through the magazine to collect in a shallow trench made along the middle line, and to run off into a drain prepared to receive it, or into a dry well dug near the entrance. The ground-sills are then floored with boards. Great care must be taken to make the top water-tight, before the earth is placed upon it. This done, it is covered with several feet of earth depending upon the degree of exposure to which it is subjected. The plane, and horizontal section of themagazine and entrance, made by the plane, A B; and the elevation, and section by the vertical plane, C D, are shown in the drawing. The entrance to the magazine should be closed by a stout door, and the approach to it should be protected by a splinter-proof. If field-artillery is employed to defend the work, the limber boxes are taken off and placed within the magazines. See *Powder Magazine* and *Storage Magazine*.

SESSION.—The actual sitting of a Court, Council, etc., or the actual assembly of the members of such a body for the transaction of business. Hence, also the time, period, or the term during which a Court, Council, and the like, meet daily for business; or the space of time between the first meeting and prorogation or adjournment.

SETENDY.—A term commonly applied to the Militia in the East Indies.

SET OF THE ARM.—An expression for the *lead* and *hollow of the arm* of an axletree, when taken together.

SETTER.—In gunnery, a wooden instrument, the mouth of which is slightly hollowed out; it is used with the aid of a mallet to set the fuse into common and diaphragm shells. Mallets and setters are issued with garrison S.B. guns, and form part of a set of fuse implements.

SETTING UP DRILL.—Exercises devised for the *setting up* of recruits and soldiers of non-military appearance. The exercises constituting the Setting Up Drill in the United States are four in number and are executed as follows: The Instructor commands:

1. *First*, 2. Exercise.—Bring the hands to the front till the little fingers meet nails downward, arms horizontal. (Two.) Raise the hands in a circular direction over the head, the ends of the fingers touching, and pointing downward so as to touch the top of the forage-cap, thumbs pointing to the rear, the shoulders kept down, elbows pressed back. (Three.) Extend the arms upward to the full length, the palms of the hands touching; then force them obliquely back, and gradually let them fall to the position of the soldier.

1. *Second*, 2. Exercise.—Raise the arms from the sides, extended to their full length, until the hands meet above the head, palms of the hands to the front, fingers pointing upward, thumbs locked, right thumb in front, the shoulders pressed back. (Two.) Bend over till the hands, if possible,can touch the ground, keeping the arms and knees straight. (Three.) Resume the position of the soldier.

1. *Third*, 2. Exercise – Extend the arms horizontally to the front, the palms of the hands touching. (Two.) Throw the arms extended, well to the rear, inclining slightly downward; at the same time raise the body upon the toes. (Three.) Resume the position of the soldier. The first and second motions of this exercise should be continued by the commands, *one, two—one, two*, till the recruits, if possible, are able to touch the hands behind the back.

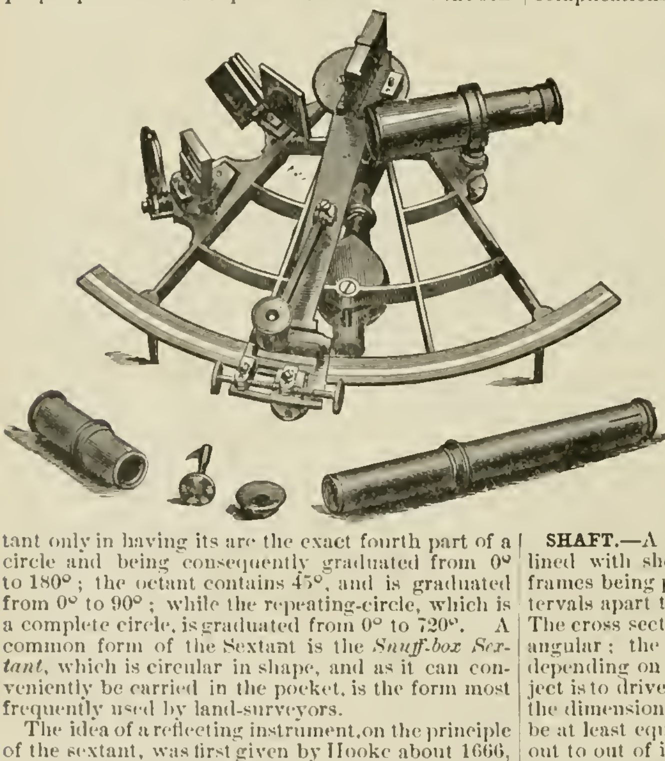
1. *Fourth*, 2. Exercise.—Raise the arms laterally until horizontal, palms of the hands upward. (Two.) Swing the arms circularly, upward and backward, from front to rear. (Three.) Resume the position of the soldier. As soon as the recruits understand the various exercises, they are continued without dwelling upon the numbers, the Instructor prefacing the exercise by the command *continue the motion*, and giving the command *three*, for the conclusion. See *Gymnastics*.

SEVERUS WALL.—A rampart of stone built by the Roman Emperor Severus in Britain, 208 A. D., between the Tyne and the Solway. On the first subjugation of Britain by the Romans, a line of forts had been constructed by Agricola extending from the Forth at Edinburgh to the Clyde at Dunbarton. The Emperor Hadrian, on visiting Britain, 120 A. D., threw up for the protection of the Roman Province a wall of turf extending across the narrowest part of the island, between Tyne and Solway. Twenty years later Antoninus Pius, whose Lieutenant Lollius Urbicus, had gained fresh advantages over the northern tribes, endeavored to check the inroads of the Caledonians by erecting another rampart of earth between the Forth and Clyde, connecting Agricola's line forts. But after a vain struggle of 60 years, the Romans found it necessary to abandon the whole district between the walls, and Septimius Severus built a strong rampart of stone immediately to the north of the wall of Hadrian. Toward the close of the 4th century, Theodosius, for a brief period, reasserted the Roman dominion over the district between the walls of Antonine and Severus, which, in honor of the Emperor Valens, obtained the name of Valentia. But this newly-established Province was soon lost, and it was not long before the Romans finally abandoned Britain. Many remains of the Roman walls are yet to be traced.

SEVIR.—A term applied to a Captain of Cavalry among the Romans.

SEXTANT.—An instrument used for measuring the angular distance of objects by means of reflection. The principle of its construction depends upon the theorem, that *if a ray of light suffer double reflection the angle between the original ray and its direction after the second reflection is double that of the angle made by the reflecting surfaces.* It is a brass sector of a circle in outline; the sector being the sixth part of a complete circle, for which reason the instrument is called a sextant. The drawing shows the essentials of its construction. The instrument is capable of very general application, but its chief use is on board ship to observe the altitude of the sun, the lunar distances, etc., in order to determine the latitude and longtitude. For this purpose it is necessary to have stained glasses interposed between the mirrors, to reduce the sun's brightness. These glasses (generally three in number) are hinged on the side, so that they may be interposed or not at pleasure.

The sextant is liable to three chief errors of adjustment; 1° if the index-glass be not perpendicular to the plane of the instrument; 2° if the horizon-glass be not perpendicular to the plane of the instrument; and 3° if, when the mirrors are parallel, the index does not point accurately to 0°; this last is called the *index-error*, and is either allowed for, or is remedied by the means of a screw. The first two errors are also frequently remedied by the means of screws working against a spring, but in the best instruments the maker himself fixes the glasses in their proper position. The quadrant differs from the sex-



tant only in having its arc the exact fourth part of a circle and being consequently graduated from 0° to 180°; the octant contains 45°, and is graduated from 0° to 90°; while the repeating-circle, which is a complete circle, is graduated from 0° to 720°. A common form of the Sextant is the *Snuff-box Sextant*, which is circular in shape, and as it can conveniently be carried in the pocket, is the form most frequently used by land-surveyors.

The idea of a reflecting instrument, on the principle of the sextant, was first given by Hooke about 1666, but the first instrument deserving the name was invented by John Hadley early in the spring of 1730 and a second, and much improved form of it, was made by him a short time afterwards Hally, at a meeting of the Royal Society, claimed for Newton the priority of invention; and in Oct., 1730, a Philadelphian, named Godfrey, also asserted his claim as the original inventor, but that learned body decided that Newton's claim was unsupported by even probable evidence, and that Hadley's and Godfrey's inventions were both original, but that the second form (which is almost the same as the common sextant now employed) of Hadley's instrument was far superior to his first form and also to Godfrey's. See *Engineer's Transit.*

SEYMENY BASSY.—An appellation given to the Lieutenant General of Janissaries in the Turkish Service.

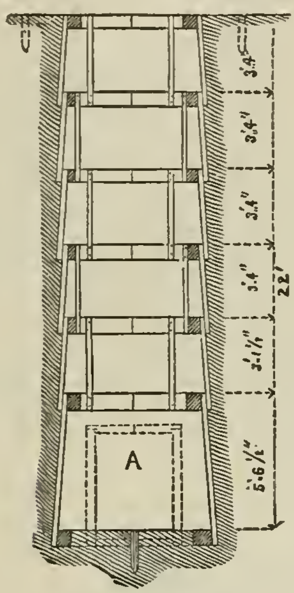
SEYMOUR HORSE-SHOE.—This shoe, a recent invention, possesses several advantages over most shoes, and is specially adapted for campaign and rough service. The nails required to hold the shoe in position are very small, and three on a side are amply sufficient. The heads of the nails being also well driven into the countersink are fully protected from disturbing forces, by being at the bottom of the corrugations. The shoe is ready to nail on when it leaves the factory, and requires no work whatever except in the special cases of suiting the exact shape of certain hoofs. It possesses the very great advantage of permitting the *frog to get to the ground*, in order that it may assert itself, keep in a good condition, and fulfill its natural and proper functions of keeping the heels well spread, defending the wall from concussion, and thereby lessening the liability to diseases and complications of the feet, legs, and shoulders. Very many of the troubles incident to the limbs of horses are due to *high-heel calks*; keeping the frog from the ground and thereby depriving it of the exercise it should have to keep it healthy and in good order. Another feature of advantage in this shoe is, that it is admirably adapted for use on "interfering" horses. No part ever projects beyond the hoof. See *Horse-shoeing.*

SHABRACK.—A Hungarian term, generally used among Cavalry Officers, to signify the cloth furniture of a troop-horse. Also written *Shabraque.*

SHACKLE.—In artillery material, the iron ring attached to a triangle gin, from which the block and tackle are suspended. It is fastened to the upper part of the prypole and cheeks by means of a bolt called the "shackle bolt." The term is also given to the ring at the end of the shaft of an anchor.

SHAFT.—A vertical pit made in the earth and well lined with sheeting to keep the soil from caving in, frames being placed horizontally and at suitable intervals apart to sustain the pressure on the sheeting. The cross sections of shafts are either square or rectangular; the dimensions of the sides of the section depending on the object of the shaft. When the object is to drive a gallery from the bottom of the shaft, the dimensions of the shaft-frames, in the clear, must be at least equal to that of the gallery, measured from out to out of its sheeting. A shaft sunk for establishing a mine-chamber simply, should usually be of the least dimensions; which, to allow the miner to work with facility, are at least 3 ft. by 2 ft. in the clear. Two kinds of frames are usually requisite in sinking shafts, a *top frame*, formed of four pieces, halved to fit each other, which, when put together, have the same dimensions in the clear as the shaft; each piece projecting beyond the sides, or having an *over length* of 1½ to 2 ft. and a *side frame* which also consists of four pieces of smaller scantling than the top frame, halved at the ends to fit; its dimensions from out to out being the same as of the top frame in the clear. In very loose soil it may be necessary to use a temporary frame, termed an *auxiliary frame.* This is somewhat larger in the clear than the ordinary shaft-frame, and is used only for a temporary purpose in setting the ordinary frame. The opposite pieces of each frame are marked with a saw-cut, termed a *score*, at their middle, on the upper side. The scores serve to fix the position which the frame should occupy when laid. The scantling for top frames is usually 6 in. square; that of side and auxiliary frames $4\frac{1}{2}$ in. for a shaft over $4\frac{1}{2}$ ft. in the clear. For smaller shafts the scantling may be of smaller dimensions.

To construct a shaft in a loose soil, there will be

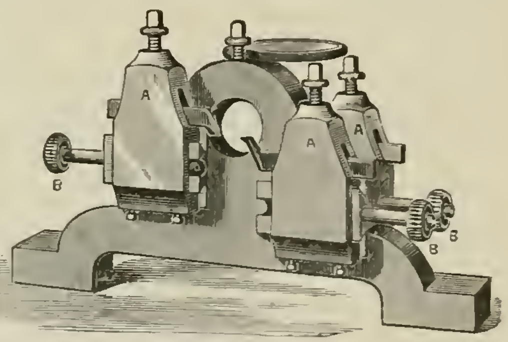


Vertical Section of Shaft showing the Frames and Gallery A at bottom of Shaft.

required a top frame; five side frames for the intervals above estimated; two for the remaining lower portion of the shaft; one auxiliary frame; four battens for each interval, each of the length of the interval added to the thickness of the shaft-frame; from twelve to twenty square pickets about 18 inches long; with the machinery and mining tools requisite for the operation. The work is laid out by first driving a picket to mark the axis of the shaft, and two others which, with the first, should be in the vertical plane containing the axis of the gallery. A level bed is then made for the top frame; the pieces of which are accurately laid and confined by pickets, one at the end of each piece; care being taken to drive the two pickets of each piece at the same time, so that their true position may be kept. Other pickets may be driven temporarily on the outside of the frame, at the angular points. After the frame is laid the accuracy of its position is tested by seeing whether the distances from the center of the central picket to the interior angular points, or, in other words the *semi-diagonals* of the figure, are equal; if they are the position is correct. The excavation is next commenced, and, if the crumbling of the soil does not interfere, may be carried as far as the position of the first frame below the top frame; the sheeting boards, inserted between the sides of the excavation and the exterior of the top frame, being gradually advanced with the excavation. Having reached its place, the first side frame is hung by four battens, two being nailed to each piece of the opposite sides of the top frame, and also to the two corresponding pieces of the side frame, the halvings of which are turned upwards; after these pieces are adjusted by their scores, and securely fixed by the battens, the other pieces are laid on them, with the halvings down, and secured by nails. This frame being fixed, the ends of the sheeting of the next interval may be inserted between it and the sheeting of the first interval, and the excavation continued. The soil now becoming troublesome by its crumbling, measures must be taken to retain it firmly until the second frame is laid. For this purpose the auxiliary frame is introduced, and hung midway in the interval, as the ordinary frames. The sheeting which, thus far, has been gradually advanced with the excavation, is also inclined outwards at bottom, to gain room for the auxiliary frame, by wedges inserted between the boards of the two intervals. After the auxiliary frame is fixed, the excavation and sheeting are carried on to the end of the interval, the next frame is hung, and the sheeting for the new interval introduced. The auxiliary frame is now removed and placed in the next position it is to occupy, as soon as reached by the excavation. The work proceeds in this order until the shaft is completed; then a picket is driven in the bottom to make the central point. A sketch made to a suitable scale, should be in hand for immediate reference in conducting such works. This is more particularly necessary for gallery work, the sketches for which should be very accurately drawn, referenced, and numbered; as they serve not only for reference to guide the miner, but to determine the positions and dimensions of some of the important portions. See *Auxiliary Frame*, *Gallery*, *Shaft Intervals*, and *Shafts à la Boule*.

SHAFTED.—In Heraldry, borne on a shaft. This term is applied to a spear-head.

SHAFTING ATTACHMENT.—A useful device employed in the armory. When used in connection with the usual form of lathe, it makes a convenient arrangement for turning a large amount of shafting,



and does not lessen the value of the lathe for general or other special work, as it can be easily removed.

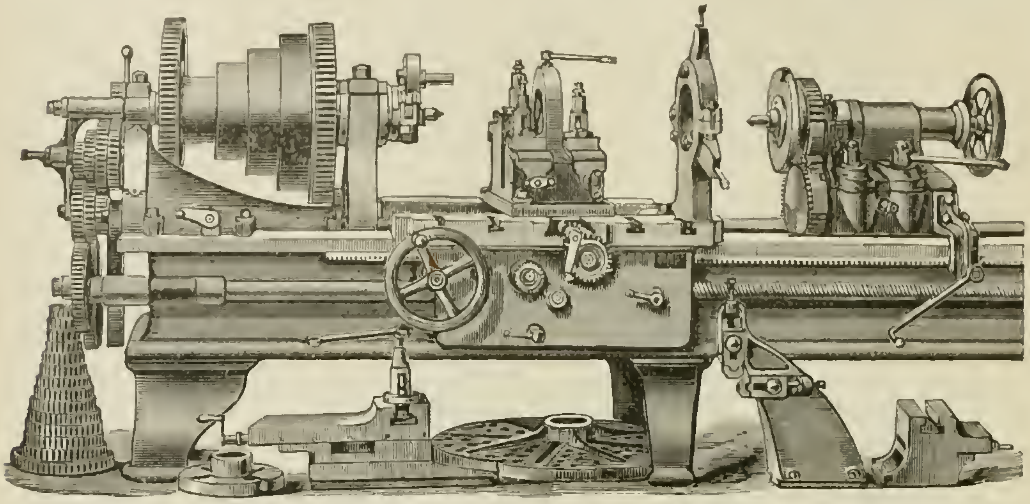
It consists of a *heavy arch piece* bolted on to the rest or carriage, carrying *three turning-tools*, two on the front and one on the back of the shaft, and having a hole bored out in the upper part of the arch to receive bushes for steadying the shaft while turning, or to hold fluted rings for finishing the shaft.

The first tool on the front takes off the first chip, and the tool on the back turns the shaft to its proper size.

After it passes through the bush the water-polishing tool finishes the shaft, leaving it *perfectly round and smooth*. The drawing represents the attachment as made by the Pond Machine Co., and used in the United States armories and factories. Each tool-holder, A, is adjustable by a screw, B, operating the tool block. See *Lathe*.

SHAFTING-LATHE.—A lathe much used in all armories for turning rods for shafting. The shaft is usually held between two tail-centers and is dressed off longitudinally by a series of annular cutters secured to a slide rest. The shaft may be rotated, in which case the cutters in the annular holder will be modified to suit the direction of cut.

The drawing shows a shafting-lathe, swinging 28 inches over shears; 21 inches over rest-carriage; the cone has four changes for $3\frac{1}{4}$-inch belt; double geared; steel spindles; metal boxes; dead spindle clamped by adjustable conical binder; hand movement of the carriage by a balance-wheel attached in wrought-iron rack on bed; reverse feed motion to apron attached to rest-carriage; independent-geared friction feed; compound tool-rest; cross feed; self-oiling slides to carriage; slide block for turning pulleys; turning and screw-cutting feeds cannot be engaged at the same time; large and small face plates;



screw and screw-gearing, with standard and traverse rests; counter-shaft, hangers, pulleys, 20 × 8 inches, to run 75 turns per minute, with 10½ feet bed, to turn a 6 feet shaft; the weight is about 5500 pounds. See *Lathe*.

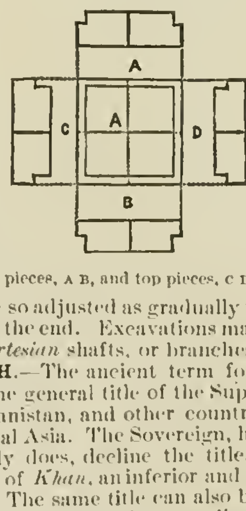
SHAFT INTERVALS.—The term *interval*, both in shafts and galleries, expresses the distance between two adjacent frames added to the thickness of the scantling of one frame, and measured in the direction of the axis of the shaft, etc. With scantling and sheeting of the usual dimensions, the interval should not be greater than 3½ ft. Having given the depth of a shaft, and the height of a gallery to lead from the bottom of the shaft, we may estimate the shaft interval as follows: take the height of the gallery frame, estimating from the top of its ground sill to the top of the cap sill; the thickness of the top sheeting; and the thickness of the shaft frame; two inches for free space between the gallery frame and the shaft frame next above it, to introduce the top sheeting, and add them into one sum; subtract this sum from the total depth of the shaft, and divide the remainder into any convenient number of equal or unequal intervals, each not greater than 3½ feet, for the shaft interval required. See *Shaft*.

SHAFT-IRONS. Rectangular bands or brackets of iron, fastened to the lower surface of the splinter-bar, by means of which the shafts are attached to it.

SHAFTS.—The thills of a carriage, attached to the splinter-bar. The chief point of strain on the shafts, both vertically and horizontally, is by the splinter-bar; here, therefore, their sectional dimensions should be the greatest, tapering off vertically and horizontally both towards foot and point. The shaft sockets or crutches are liable to severe straining pressures in directions *opposite* to the *traction*, as well as to transverse pressures. Their form and mode of union with the axletree-bed or futchells must be specially designed to withstand these strains.

SHAFTS A LA BOULE.—These shafts are lined with frames made of plank, as shown in the drawing. This kind of shaft can only be used with advantage in favorable soil, on account of the difficulty of introducing the frames sufficiently near each other: they are commonly placed one foot apart, as shown in drawing. Large gabions, 6 ft. long, and from 3 ft. 6 in. to 4 ft. in diameter, are sometimes used for lining of shafts, near the surface, smaller gabions being introduced as the work is proceeded with

For the purposes of quickly establishing small camoutlets and fougasses, a boring-apparatus has been resorted to, the diameter of the boring-tool being 4 in. This machine is worked like ordinary tools of this kind. The chamber is charged by inserting powder in cylindrical cartridges of somewhat less diameter than the shaft, which are well pressed forward. If a large charge is requisite the end of the shaft can be enlarged by a tool with a joint, which will admit



Plan A, under pieces, A B, and top pieces, C D, of shaft case.

the tool to be so adjusted as gradually to increase the excavation at the end. Excavations made in this way are termed *artesian* shafts, or branches. See *Shaft*.

SHAG BUSH.—The ancient term for a hand-gun.

SHAH.—The general title of the Supreme Ruler in Persia, Afghanistan, and other countries of Southern and Central Asia. The Sovereign, however, may, and frequently does, decline the title, assuming in its place that of *Khan*, an inferior and more common appellation. The same title can also be assumed by any of the Shah's son, and upon all the Princes of the Blood the cognomen *Shah-zadeh* is bestowed.

SHAMBRIE.—A long thong of leather, made fast to the end of a cane or stick, for the purpose of animating a horse, or of punishing him if he refuses to obey the rider.

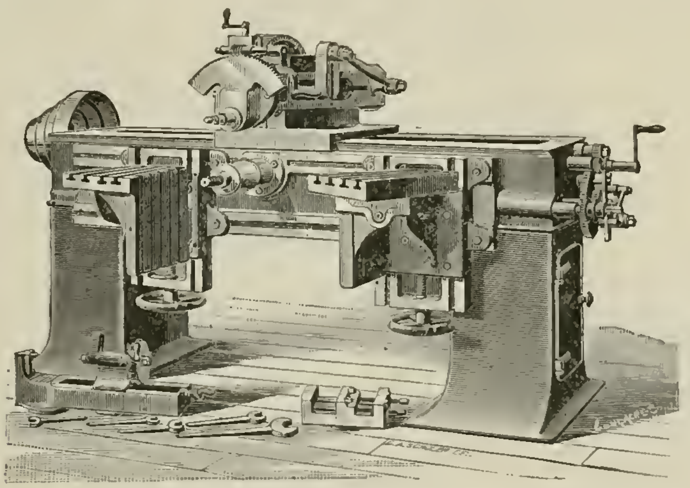
SHAM DAMN.—A very inferior quality of iron used in the manufacture of cheap guns.

SHAMROCK.—A national emblem of Ireland, a leaf with three leaflets, or a plant having such leaves, sometimes supposed to be the wood sorrel, but more generally believed to be some species of clover, or perhaps some common plant of some of the nearly allied genera, as the bird's-foot trefoil, or the black medick. It is not improbable that the name has a sort of general reference to plants with trifoliolate leaves, and that a more exact determination of the species may be as difficult as the attainment of botanical accuracy in regard to the emblematic thistle of Scotland.

The small-leaved clover *(trifolium repens)* has had superstitious respect attached to it from early times. According to the elder Pliny no serpent will touch it. It is said to have been first assumed as the Badge of Ireland from the circumstance that St. Patrick made use of it to illustrate the Doctrine of the Trinity. See *Trefoil.*

SHANK.—A large ladle to contain molten metals; it is worked by a straight bar at one end, and a cross-bar with handles, called the *crutch,* at the other end, by which it is tipped to pour out the metal. Shanks are made of various sizes, from those handled by two men to those containing several tons, and slung from a crane. Nasmyth, of Manchester, England, has added to the pivot of the large crane-ladle a tangent-screw and worm-wheel, by which it may be gradually tilted by a man standing directly in front and at any convenient distance.

SHAPING MACHINE.—A metal planing-machine in which the object is dogged to a table with vertical and horizontal adjustment, or to a mandrel, and the tool above it has a reciprocating motion. The machine, in various sizes, is adopted for a variety of work in the arsenal. In the 14-inch machine, shown in the drawing, the cutter-bar has an adjustable stroke of 14 inches, or any less distance, is 30 inches long, and has a bearing upon the saddle of 28½ by 8 inches.



By means of an eccentric, in combination with a slide, the tool has a nearly uniform cutting stroke, and, as a resultant, a quick return and consequent saving of time in doing work. The saddle-slide that holds the cutter-bar is fed longitudinally by a screw extending from end to end of the machine. The tool-head on the cutter-bar has an automatic angular feed, the degree of the angle determined by a graduated disc. It has also a circular feed, designed for planing the inner arcs of circles. The machine has also an independent, automatic, circular feed, which will feed the entire circle, a device that greatly increases the capabilities of the tool. A spindle with two cones accompanies this circular feed. The base of the vise is grduated, and has a cross movement of 3 inches, by means of a crank-wrench. The vise can be readily removed, so that both platens may be used to support long pieces. The platens are gibbed to the vertical ways so that no dirt can fall between them and the ways when the bolts are loosened. The slides and surfaces are carefully fitted by scraping. The speed of the countershaft, having 14 by 4-inch tight and loose pulleys, is 220 revolutions per minute. The traverse of the saddle-slide on the bed is 50 inches. Weight of the machine, 5,100 pounds. See *Column Shaper* and *Planing-machine.*

SHARP-SHOOTERS.—An old term applied in the army to riflemen. It is now appropriated to naval use, to the men stationed in the top to annoy those on the deck of an enemy's vessel.

SHARPS RIFLE.—This gun belongs to that system in which a fixed chamber is closed by a bolt, by direct action, and in which the lock is concealed. The receiver has a slot in its upper surface for the purpose of loading the chamber or filling the magazine. It is bored through at rear for the reception of the breech-bolt, which is composed of two principal parts, viz: The body and the locking-tube. The bolt is locked by lugs on the locking-tube, turning in corresponding cuts in the receiver. The bolt carries on its upper surface the extractor, which is of the ordinary spring-hook pattern, and in its axis the firing-pin, which extends the whole length of the bolt. The spiral form of the face of the locking-tube, and of the shoulder of the bolt, is such as to cam the bolt up against the head of the cartridge when the bolt is locked.

On the rear face of the locking-tube are two spiral surfaces, which bear against corresponding surfaces of the firing-pin. When the handle is turned down to lock the bolt, the firing-pin spring is compressed between the shoulders on the pin, and nut on the extreme rear of the bolt. On withdrawing the nose of the sear, the firing-pin, under the influence of its spring, moves forward and explodes the cartridge. The shell is ejected by the ejector-pin, which strikes against the lever of the carrier, when the bolt is withdrawn, and is driven forward against the lower side of the head of the shell, while the extractor is pulling on the upper. The firing-pin spring and rear of bolt are protected by a thin shell. The bolt is prevented from being drawn completely out of the receiver by the lever of the carrier and by a key striking on the upper surface of the extractor.

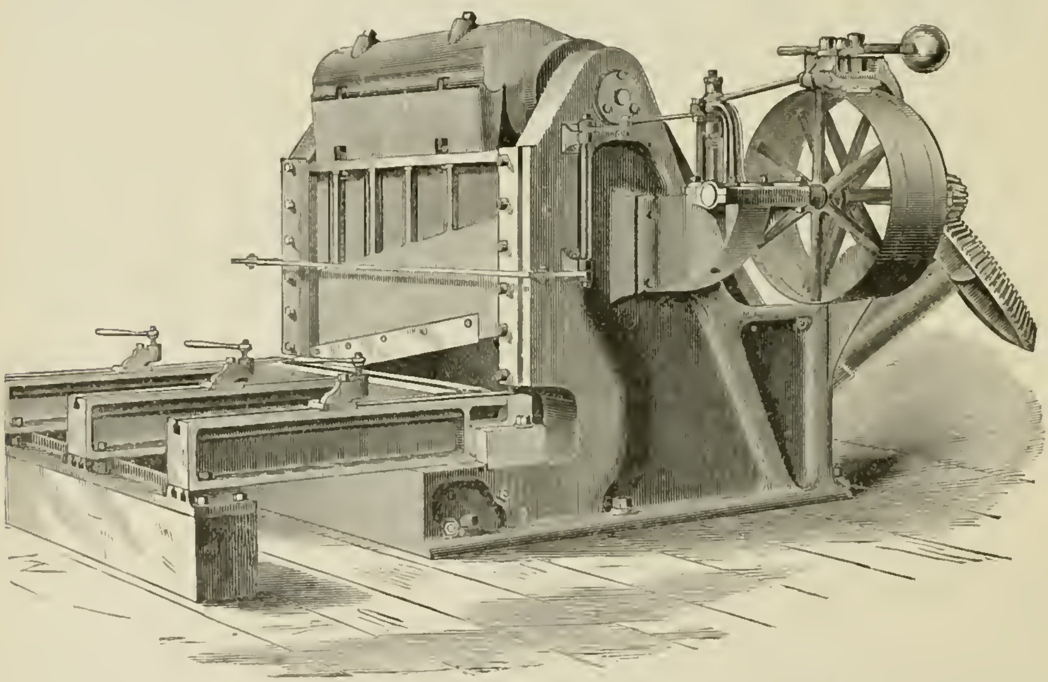
The magazine is in the tip-stock. When the breech-bolt is withdrawn the projection in which the ejector-pin is situated, strikes the lever of the carrier, tipping the latter up in a position oblique to the axis of the bore, bringing the point of the cartridge nearly opposite the center of the chamber. The carrier is held in this position by a pin and spring. When the bolt is closed the cartridge is driven in the chamber, while a projection on the bolt strikes the lever, causing the front of the carrier to descend opposite the mouth of the magazine to receive another cartridge. The carrier is of such thickness at its front as not to uncover the magazine-tube completely when the former rises. Cartridges are thus prevented from escaping from the magazine except when the carrier is in position to receive them. No magazine cut-off is applied to this gun; consequently it can only be used as a single-loader when the magazine is empty.

As a magazine-gun, 3 motions are necessary to operate it, viz.:opened, closed, fired. As a single-loader, 4 motions are necessary, viz.: opened, loaded, closed, fired.

This gun carries 9 cartridges in the magazine, 1 in the carrier, and 1 in the chamber. See *Magazine-gun.*

SHEARING MACHINE.—A machine variously designed, and indispensable in the construction of ordnance, iron carriages, and also armor. The drawing shows the most improved machine of this class, and is made by Wm. Sellers & Co. In designing it, the wants of modern war constructions have been kept in view. The plate clamped to its place can be sheared with exceeding exactness, either in trimming the edge of long plates or cutting off plates five feet wide and under, to lengths. The driving device is new and very efficient. The blade being at all times under the control of the operator, can be made to cut to any fixed point in its length and then stopped or raised. It is provided with an automatic adjustment to its belt-shifting motion, gauging the length of its stroke. It makes the down stroke, immediately reascends, and stops up, to wait for the readjustment of the plate. A hand rod in front of the machine is convenient to shift the belts and start the cut.

The machine is so constructed as to have its strains all within itself, and is not in any great measure de-



pendent upon stone foundations for its rigidity, other than the proper maintaining of the structure in the level position. The vertical slide is arranged to receive curved blades, and the bed-plate, to which the lower blade is attached, is capable of ready removal, to receive a curved bed-plate with a shear-blade bent to match the curve of the upper blade.

The machine as represented is used for trimming edges of long plates, or cutting off to length plates 5 feet wide. It will shear wrought-iron plates of one inch thick. The upper blade is guided vertically in the frame of the machine, and driven down by a pitman as wide as the blade is long; this pitman receiving its motion from a long rocking-shaft above it. The driving-arm or lever of the machine is a rack segment engaging with the teeth of a spiral pinion which is driven by a bevel-wheel and pinion and open and crossed belt, after the manner of planing-machines. The cutting-blade is adjustable in length of stroke, returning at double the speed of its down stroke. Countershaft has 24-inch pulleys, 7-inch face, 272 revolutions per minute.

Another variety of the machine is a very efficient tool for cutting bar-iron. There is a rest provided on which the bar, resting at the required point of cut, can be pushed under the blades when open without stopping the machine, while, as in all shearing and punching-machines, a very convenient stop-motion is provided.

The following are the capacities of the machines, in ordinary use:

Shearing-machine, 26 inches over-reach, will shear plates $\frac{15}{16}$ inch thick.

Shearing-machine, 23$\frac{3}{4}$ inches over-reach, will shear plates 1$\frac{1}{2}$ inches thick.

Bar shearing-machine is capable of cutting iron 6 inches by 1$\frac{1}{2}$ inches.

Plate shearing-machine, having 12 inches stroke, making cut 60 inches long, capable of shearing 1 inch iron plate, over-reach for edges of long plate 7 inches, will cut across plates 5 feet wide at any point of their length.

Lever-shear for angles, will cut 6 inches by 6 inches by 1$\frac{1}{2}$ inches angles square without spoiling the crop end.

Very frequently punching and shearing-machines are combined. The shear is intended for cutting plate-iron of usual thickness, while the punching side has its dies so arranged in a holder as to permit the punching of flanges which are as small as 12 inches in diameter; the punching being done from the outside or marked side; and flanges turned out on end of flues can be punched vertically. The holes in the dies are made larger than the punches by the following formula, expressing the diameter and thickness in sixteenths of an inch. The diameter of the die hole =diameter of punch, plus $\frac{2}{10}$ the thicknes of the plate $(D = d + 0.2t)$. Thus, for iron plate $\frac{6}{16}$ of an inch thick, the diameter of the punch being $\frac{13}{16}$ of an inch, the diameter of the die hole will be 14.2 sixteenths of an inch, say $\frac{7}{8}$ inch. The method of making the die hole larger produces a taper hole in the plate, but allows the punching to be done with less consumption of power and, it is said, with less strain on the plate. To run these machines efficiently, the fast and loose pulley on the machine should make at least 120 revolutions per minute; this will punch 12 holes to the minute; if a faster speed is admissible on the work, the speed of pulleys can be increased. By means of an independent stop motion, one stroke can be made at a time on either side of the machine without stopping the machine itself, or interrupting the work being done on the other side. In this respect it is as convenient as two entirely distinct machines. See *Angle Shearing-machine*, *Lever Shearing-machine* and *Power-shears*.

SHEARS.—The elemental form of a pair of shears consists in two spars fastened together near the top,

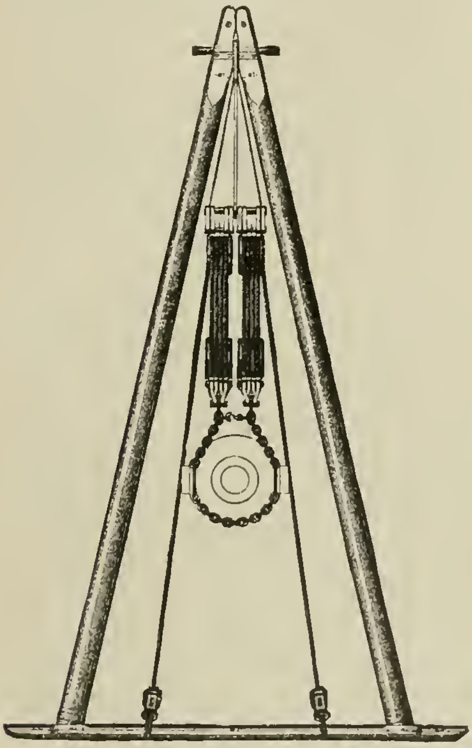


Fig. 1.

with a pully at the point of junction, and held by a rope, fastened to any convenient object, in such a position that the weight lifted hangs nearly between the spars. This forms an easily improvised crane. An apparatus of this kind, of great height and strength, is useful for masting vessels. In the principal dock-yards there are tall permanent shears, mounted either on the side of the masting-dock or on a floating shear-hulk.

Shears are much used for lifting guns and heavy weights over the face of a wall or cliff, or in other situations where the gun could not be used for want of a footing for the pry-hole. The proper dimensions of the spars are given in the table in the next column;

The upper and lower ends are respectively called the *head* and *heel*, and the part where the lashing is applied is termed the *cross*. The stores necessary to equip a pair of shears are: Two *single blocks*, two *double blocks*, one *double block*, one *treble block*, one *snatch block; main-tackle fall*, 100 fathoms 3 to 5-inch Manila rope; *guys*, 50 fathoms 3 to 6-inch Manila rope; *head lashing*, 10 fathoms 3 to 4-inch Manila rope; *heel lashing* (two each), 10 fathoms 3 to 4 inch Manila rope; also *contingencies* (two each), 50 fathoms 3 to 4-inch Manila rope; *main tackle*, one fathom 6-inch Manila rope; *snatch block*, 6 feet 4-inch Manila rope; *holdfasts* (six) each made of 1 fathom 4-inch Manila rope; *contingencies* (six), each made of a half fathom

Weight.	Diameter.	Length.
Tons.	Inches.	Feet.
2	Head 6 to 9 heel.	20 to 30
5	" 10 to 14 "	30 to 40
12 and upwards.	" 14 to 20 "	30 to 45

of 4-inch Manila rope; *spun-yarn* for mousing, stops, etc., one ball of 100 fathoms; two *cleats* for heels, to prevent the lashing from slipping up, made by cutting lengthwise, diagonally, a piece of 6 by 6-inch scantling 2 feet long; twelve *stakes* for holdfasts for guys, 6 feet by 6 feet by 8 inches; four *stakes* for heel-posts, and two *shoes* for heels, 6-inch plank, 15 feet by 15 feet.

To rig the shears, lay the heads of the spars on a trestle about three feet high, the right leg above the left, so that they cross at about twice their thickness from the ends, with the heels in their proper positions. Take a good piece of 3½ or 4-inch rope well stretched, middle it, and make fast to the shear-leg, below the cross; with one end pass the requisite number of figure-of-eight turns around both spars, having each turn well taut, and hitch the end to the upper part of the shear-leg; with the other end pass riding-turns around both legs, filling up the intervals between the first turns; come up with the hitch of the first end, and pass frapping-turns around all parts of the lashing between the shears; finish with a square knot, and stop the ends back with a good spun-yarn stop; if necessary tighten up with wedges. Lay the middle of the back guy in the cross; bring the left-hand end up around the right leg and over the head of the left leg; then carry the right-hand end around under both legs; let it cross over the left-hand end, and seize them together with spun-yarn. Make a bowline knot in the end of the fore-guy and slip it over the head of both legs. Lay the middle of the main-tackle strap under the cross above the fore guy; bring the ends up over the cross; hook the upper block to them under the cross before the fore-guy, *and mouse it*, taking care that the splice comes in the middle of the strap and that the fall leads to the rear.

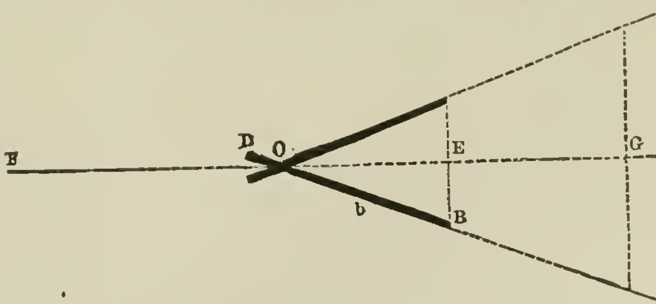

Fig. 2.

Then drive the heel-posts on each side of the heels about a foot toward the head, and one foot outside; lay the shoes under the heels; make a timber-hitch around the inner posts with the heel-lashings; pass three times over the legs below the cleats, and hitch the lashings to the outer posts. Drive four holdfasts for each back-guy as follows; Two on each side the line of the legs prolonged, three feet apart, and two six feet in rear of these. Lay the ends of the guy straps over the front stakes; connect each pair of front and rear stakes with a strap twisted up taut to insure the strain being distributed properly. Drive two holdfasts for the fore-guy, one in the rear of the others in the prolongation of the axis of the shears. Hook the upper blocks of the guy-tackles to a bowline in the end of the guys, and the single block to the guy-strap, and *mouse them all*. Ordinarily the fore-guy can be worked without a tackle, belaying it over the holdfasts, first taking a round turn over the one next the shears.

If not too heavy, the shears may be made by lifting the head and hauling on the guy-tackles, slacking the heel lashings as required, and tending the fore-guy carefully to prevent the shears falling over towards the rear. When raised, hook the snatch-block to a strap placed below the cleat on either leg. If the shears are too heavy to raise in this way, bring both guys together at the heels; form a crutch by lashing together two poles (or use the legs of the garrison gin); place the guys in this crutch; pass the end of a small rope over *both* guys, in *front* of the crutch, down *under* the lashing, and take a rolling-hitch with it around *one* of the guys, in *rear* of the crutch; haul the rope well taut, and secure it to the lower end of the crutch leg. Raise the crutch with an inclination of one-sixth to the front, and heave up the shears by the guy-tackles. When the crutch ceases to act, slack it to the ground by means of the small rope.

The inclination or the *rake* of the shears should not exceed 20 degrees, or four-elevenths of their height, and each leg should have about one-half this inclination. In this position the strain on the guys will never exceed one half the weight. Allowance of seven or eight degrees, or one foot in eight, should be made for the stretch of the guys. The diagram (Fig. 2.) will serve as a guide in placing shears, holdfasts, etc.

Make A B = $\frac{1}{6}$ C E;
C D = 2 *a b*;
E F, E G = at least 2 A C.

When the locality will not admit of rigging the shears in position as described, they may be raised from the foot of the wall or cliff by means of a gin or lighter shears in the following manner:—Pass the shear lashing and attach the front-guy; lash a stout spar across the legs about two feet above the center of gravity, giving the heels the proper spread; fasten a small rope to each heel to serve as guys; hook the gin tackle to a strap firmly attached to the middle of the cross-spar, and heave away, *tending the guys carefully*. As the head of the shears comes above the crest of the wall, put on the back-guys and main-tackle strap, and hook on the tackle; *mouse all hooks;* raise the shears, place the heels on the shoes, pass the heel lashings, set up the guys, and lower the gin to the ground by means of its tackle, leaving the spar in position.

When the garrison or casemate gin is used as shears, the pry-pole is replaced by a parting block of the same diameter. The guys are attached as follows: Middle the rope for the back-guys; push the bight through the clevis from below and slip it around both legs; haul the ends back tight and lay them over the head of the gin to the rear, each part lying between the nearest leg and the parting block, taking care to place canvas under the ropes to prevent chafing. The fore-guy is hitched around the clevis bolt. A single back-guy may be used, formed of a tackle of the same size as the gin tackle, hooked into a strap applied as described for the guy-ropes. In this case particular care must be taken to bring the axis of the shears in the vertical plane containing the holdfast and the center of gravity of the weight to be lifted. The shears are lowered by slacking the guys and heel-ropes, or by using small shears. When no capstan is available, a windlass may be improvised as follows:

Nail a strong cleat on the lower side of each leg, three feet from the heel, butt-end down; lay a round spar a little more than one-third the length of the shears across the legs, one foot above the butt of the cleats, and pass a strong lashing, frapping it loosely between the spar and legs, taking care to have the lashings of equal length, *grease the spar under the lashing*; pass a strap around each end of the spar, put one end through the other, take a round turn around the spar, and put a hand-spike through the free end, to be used as a lever to turn the windlass. The straps should be nailed to the spar to prevent slipping. Additional levers may be applied in the same manner if required. The windlass is chocked by allowing the ends of two hand-spikes (or more) to touch the ground. No person should be permitted to stand or pass under the shears while a weight is being raised. The shears proposed by the Ordnance Department to be furnished for hoisting a 15-inch gun are represented in Fig. 1. See *Cranes*, *Gin*, and *Mechanical Maneuvers*.

SHEAR STEEL.—Blistered or natural steel refined by piling thin bars into faggots, and then rolling or hammering them into the bars after they have been brought to a welding heat in a reverberatory furnace. The quality is improved by a repetition of this process, and the steel is accordingly known by the names *half shear*, *single shear*, and *double shear;* or 1 *mark*, 2 *marks*, and 3 *marks*. See *Blistered Steel*, *Natural Steel*, and *Steel*.

SHEATHE.—To put into a sheathe, a case, or scabbard; to inclose or cover with a sheath or case. *To sheathe the sword*, means to put an end to war or enmity, or to make peace.

SHEETING.—A term applied to the coarse hempen cloth used for making tarpaulins.

SHEIK.—A title of reverence, applied chiefly to a learned man, or a reputed Saint, but also used sometimes as an ordinary title of respect, like the European Mr., Herr, etc., before the name. It is, however, only given to a Moslem. The Sheik Al-Islam is the Chief Mufti of Mohammedanism at Constantinople; a title supposed to have been first assumed by Mohammed II. at his Conquest of Constantinople in 1453, when this place became the Seat of his Empire. The Sheik of Mecca, by virtue of his supposed descent from the Prophet, levies a kind of tribute on all the pilgrims to the Kaaba. The term is also applied to heads of Mohammedan Monasteries, and to the higher order of religious preachers. Sheik Al-Gebal (ancient of the mountain) is the name of the Prince of the Assassins, or those Ishmaelites of Irak, who undertook to assassinate all those whom their chief would pronounce to be his enemies.

SHELL.—A term applied to the semicircular hilts, such as the Spanish rapiers have, which protected one side of the hand.

SHELL-BULLET.—A bullet made of lead, hollow, and oblong, with the pointed end formed like the nipple of a gun, snd pierced to communicate with the interior space, which is filled with powder. A common percussion-cap is placed on the end, and the bullet is then sent home with a concave rammer-head. Fired from a rifle, the bullet goes point foremost, and at the impact explodes the cap and the powder in the bullet, igniting any powder it may come in contact with, or setting fire to any inflammable material. Caissons or ammunition-wagons of any kind may in this way be destroyed.

SHELL-FOUGASSES.—Shells may be buried singly, or in small heaps, and be made to burst either under the ground, or on its surface. If they are to burst under the earth, they must be sufficiently charged to produce a crater, through which the pieces are projected. If they are to burst on the surface, the requisite quantity of powder to produce a crater and throw out the shells must be lodged under them, while these latter need only have a sufficient charge to burst them. In all cases a box is used, divided into two parts by a partition. The shells are placed in the upper part; their fuses project through the partition, and extend from $\frac{1}{2}$ to 1 inch below it. In the lower part, the hose only is placed when the shells are intended to produce their own crater; but powder sufficient to produce the crater is introduced when they are intended to burst on the surface of the ground. The effects produced by common and shell-fougasses are very limited, and only destructive near to their craters, consequently they should not be exploded until the enemy is above them. The following table gives the charges and craters of loaded shells for fougasses:

Description of Shell.	Full Charge of the Shell.		Depth at which the full Charge Produces a Crater	
	lbs.	oz.		
Caliber, 5½	1	0	2′	0″
" 8	2	9	2	10
" 10	5	0	3	6
" 13	11	0	4	7

See *Fougasses.*

SHELL-GAUGE.—An instrument for verifying the thickness of hollow projectiles. It is provided with a set of removable curved arms, each corresponding to a particular variety of shell, which screw into a socket on the leg of the calipers, are inserted within the fuse-hole of the shell. The thickness of the wall is measured between the points of the arm and leg. An arc is so graduated as to show the proper thickness for each caliber, and any deviation beyond certain limits causes the rejection of the shell. It is customary, in the inspection of a shell, when determining thickness of the metal, to take three points at least, on the great circle at right angles to the fuse-hole; also one at the fuse-hole, and one at the bottom. The instrument shown in Fig. 1, is employed to determine the thickness of the shell at all points except at and opposite the fuse-hole. Fig. 2. shows the gauge for the thickness opposite the fuse-hole. See *Calipers, Inspection of Projectiles,* and *Shells.*

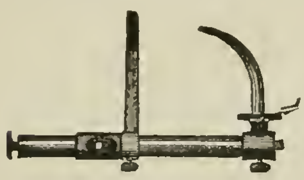

Fig. 1.

Fig. 2.

SHELL-HOOKS.—For mortar and other heavy shells which cannot easily be handled, *shell-hooks* are used. These consist of two bent iron arms connected by a pivot; one end of each is bent inwards to enter the ear of the shell, whilst the other ends are joined to a handspike ring, by two small rings.

A handspike being run through the large ring, and the lower ends of the arms adjusted to the ears of the shell, these ends approach each other, taking hold of the shell as soon as the handspike is raised.

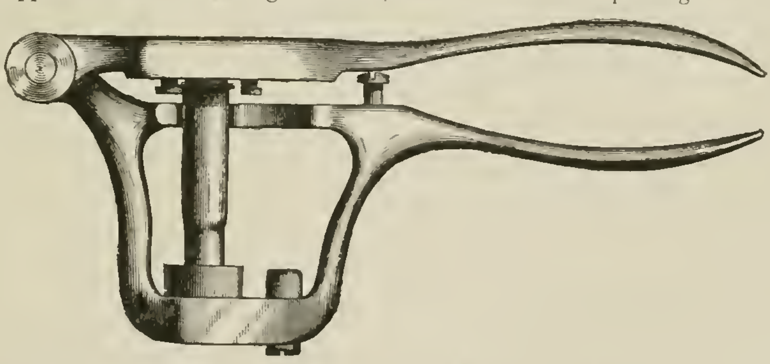
SHELL-IMPLEMENTS.—For transportation, shells are carried uncharged. For charging them, two men and the following implements, in addition, are required, viz.: One set of *powder-measures*, one *funnel*, one *fuse-mallet*, one *fuse-setter*, one *rasp*, two *grummet-wads*, two *wipers*, one *budge-barrel*, together with a supply of fuse-plugs and tow. The fuse-plugs are of wood, and the tow is to stop the fuse-holes until the shells are to be taken to the piece. The shells should be well cleansed on the outside from rust and dirt. This is done at the filling-room of the service magazine. The shells for the howitzer should be strapped to sabots, in which case the loading would be greatly facilitated.

SHELL-JACKET.—A common term for an undress military jacket.

SHELL PLUG-SCREW.—An iron or a hard wooden screw with a handle, used to extract the corks or wooden plugs with which the fuse-holes are stopped. The handle is usually in the shape of a ring about 2 inches in diameter.

SHELL-REDUCER.—An implement for reducing the mouths of cartridge-shells, in order that the bullets may fit very snugly, when loading. The drawing shows a very effective *shell-reducer*, which also performs the office of a shell-expander. After cleaning the shells thoroughly, hold the instrument in the right hand, open far enough to allow the shell to be entered sideways into its seat, catching the flange under the hook of the top piece and entering the open end of the shell into the die; then press the handles together.

This will reduce the shell at the mouth. By opening the handles the shell will be withdrawn from the die; and as it then may be a little too small it can be brought to the exact size of the bullet by the repetition of the same process, using the plug instead of the die. With new shells it will generally be quite sufficient to use the expanding tool only. It is best to always oil the shells slightly on the outside and inside of the mouth, before reducing or expanding them.



SHELLS.—Vessels of metal, containing gunpowder or other explosive compound, so arranged that it shall explode at a certain point, and spread destruction around by the forcible dispersion of its fragments. The invention of this murderous missile cannot be accurately traced. Shells were employed in 1480 A. D. by the Sultan of Gujerat, and by the Turks at the siege of Rhodes, in 1522. The Spaniards and Dutch both used them during the War of Dutch Independence; and they appear to have been generally adopted by about 1634. As shells required mortars for their projection, they were not used in naval warfare until the French constructed special bomb-ves-

sels in 1681; but since that period, shell-guns, being cannon of large bore, have been introduced, and shells are now employed by all ships of war.

Until within a few years, every shell was a hollow sphere of cast-iron, varying in thickness from half an in. to 2 in., and in diameter from 5½ in. to 13 inches. The sphere had a fuse-hole (like a bung-hole) an inch across, through which the charge was inserted, consisting of pieces of metal and powder to burst the shell. The hole was plugged by a fuse, which was a tube of slow-burning powder, timed to communicate fire to the charge after the lapse of a certain number of seconds. This fuse might either be kindled by hand the moment before the mortar was fired, or its ignition might be effected by the act of firing itself. The Shrapnel shell, introduced by Colonel Shrapnel of the Royal Artillery, in the year 1808, contained a number of bullets, and being fired at bodies of men, it was timed to explode about 100 yards before reaching them, when the shell burst, and the bullets with the fragments continued their course, diverging continually as they went, until they reached object in a death-cloud. The *concussion shell*, or *percussion shell*, is one in which the charge is fired by the detonation of a cap on striking an object. If sufficiently delicate to explode on touching a soft object, and at the same time not to be exploded by the resistance of the air to its rapid flight, this form of shell is the most certain in execution.

Since the introduction of rifled ordnance, the shell has become the commonest form of projectile. It has ceased to be spherical, and is usually in the shape of an elongated bolt. Several rival shells at present divide public favor, and compete for adoption into war-service. Without noticing the numerous varieties which are in course of trial, the following are well known competitors: The *Armstrong* shell is a pointed bolt of iron (usually percussion), containing an inner "segment shell," made up of 49 segments of cast-iron. Seven of these segments form a circle, or ring, and 7 circles give the necessary length. A coating of lead affords a soft medium for fitting into the grooves of the gun. The shell thus made somewhat resembles a bottle without a neck. The necessary bursting charge having been inserted, the rear end is plugged with lead, the fuse is screwed into the front, and the shell is ready for action. This projectile has a great and accurate range, and its segments cannot fail, on explosion, to do a great damage. The principal drawback has been found in the lead-casing, which is often thrown off in parts soon after the shell leaves the gun, and which thus falls among the foremost ranks of the army using it, sometimes inflicting severe wounds. The *Whitworth* shell is an elongated hexagonal bolt of iron or steel, cast in one piece, and with a bursting charge at the rear end. It explodes on percussion; but the space allowed for the burster is deemed insufficient to produce the full effect which the length and correctness of the weapon's range give cause to expect. The *Lancaster* shell is oval, to fit the bore of the *Lancaster* gun. *Martin's* shell is charged with molten iron, which sets on fire all combustible matter on which it can be thrown. The *Diaphragm* shell, invented by Colonel Boxer, R. A., has an iron division or diaphragm to separate the powder in the shell from any balls or slugs, in order that the friction of the latter may not prematurely cause the powder to explode. A six-pounder diaphragm shell contains 30 carbine-balls, an eight-inch shell, 322 musket-balls. The *Palliser* shell, which is now employed in the British Service, is chiefly remarkable for the hardness imparted to its fire-point by a process of "chilling" during casting. This gives it a great power of penetration into iron plates, etc.

The table in preceding column gives the particulars of the shell, used in the United States Service. See *Carcass, Case-shot, Grenade, Hollow Projectiles, Hotchkiss Shells,* and *Projectiles.*

SHELTER-PITS.—Pits made for the protection of skirmishers. The men make these for themselves.

In most instances it is only necessary to improve a natural cover. These pits may be constructed in ordinary soil in from 3 to 5 minutes. The depth need not be uniform, but should be about ten inches where the man's body will be, and about six inches in other parts. See *Rifle-pit.*

SHELTERS.—1. In a military sense, all those structures which protect the troops in the field. There are many means resorted to for this purpose. When without cover of any description, a shelter may be frequently made by selecting several small trees or bushes, cutting away the lower branches and draw-

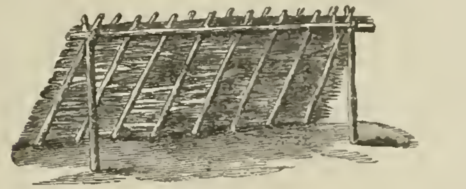

Fig. 1.

ing together and interlacing the upper ones. Others, if needed, may be added—loose grass and twigs being thrown over all. A still more substantial shelter may be made, if the material is at hand, by sinking two forked uprights, as in Fig. 1, placing a horizontal pole across them, inclining a number of shorter poles and closely interlacing small twigs, grasses or reeds. A very simple shelter may be formed by placing the several poles in a semi-circle, and binding the small ends together with a rope or thong and covering this frame with canvas, blankets, hides or brush. It is preferable to the foregoing, having its sides covered.

In very many localities, bark is a most suitable and convenient article for use in the construction of shelters. The Australians strip the bark very rapidly in the following manner: Two rings are cut around the tree; the one as high as can be reached, the other low down. A vertical slit is then made, and the whole piece forced off with axes, &c. In spring the bark comes off readiest from the sunny side of the tree. A large sheet of bark is exceedingly heavy. It is flattened, as it lies upon the ground, by weighting it with large stones, and allowing it to dry, partially at least, in that position. Straw walls of the following kind are very effective as shelters, and they have the advantage of requiring a minimum of string (or substitute for string) in their manufacture. The straw, or herbage of almost any description, is simply nipped between two pair of long sticks, which are respectively tied together at the two ends, and at a sufficient number of intermediate places. The whole is neatly squared and trimmed. A few of these would help in finishing the roof or walls of a house. They can be made movable, so as to suit the wind, shade, and aspect. Even the hut door can be made on this

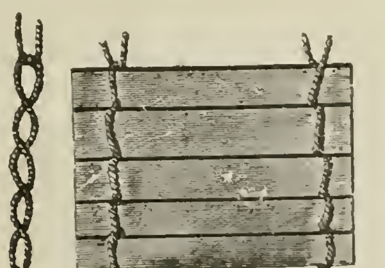

Fig. 2.

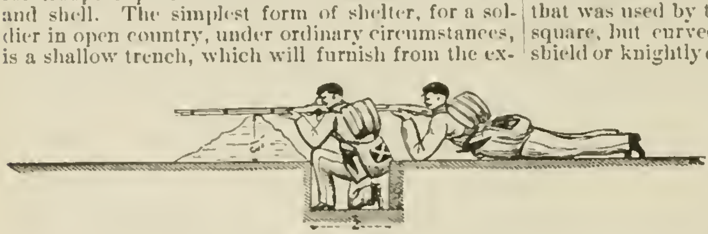
principle. In building log-huts, four poles are planted in the ground to correspond to the four corners: against these, logs are piled one above another; they are so deeply notched where they cross one another, that the adjacent sides are firmly dovetailed together. When the walls are entirely completed, the doors and windows are all chopped out, and the spaces between the logs well caulked with moss, &c., or the log-cabin will be little better than a log-cage. The Malay hitch, shown in Fig. 2, affords a simple way of attaching together wisps of straw, rods, laths, reeds, planks, poles, or any thing of the kind, into a secure and flexible mat; the sails used in the far East are made in this way, and the movable decks are made of bamboos joined together with a similar but rather more complicated stitch. Soldiers might be trained to a great deal of hutting practice in a very inexpensive way if they were drilled at putting together huts whose roofs and walls are made of planks lashed together by this simple hitch, and whose supports were short scaffolding-poles planted in deep holes dug without spades or any thing but the hand and a small stick. The poles, and planks, and cords might be used over and over again for an indefinite time. Further, bedsteads could be made in a similar way by short cross-planks lashed together, and resting on a framework of horizontal poles lashed to uprights planted in the ground. The soldier's bedding would not be injured when being used on these bedsteads, in the way it would be if it laid on the bare ground. Many kinds of designs and experiments in hutting could be practised without expense in this simple way. Few travellers have habitually made snow houses, except Sir J. Franklin's party, and that of Dr. Rae. Great praises are bestowed on the comfort of snow houses by travellers, but skill and practice are required in building them. The mode of erection of these dome-shaped buildings is as follows: It is to be understood that the hard, compact, underlying snow is necessary for the bottom of the hut; and that the looser textured, upper layer of snow is used to build the house. First, select and mark out the circular plot on which the hut is to be raised. Then, cut out with knives deep slices of snow, six inches wide, three feet long, and of a depth equal to that of the layer of loose snow, say one or two feet. These slices are curved, so as to form a circular ring when placed on their edges, and of a size to make the first row of snow-bricks for the house. Other slices are cut for the succeeding rows; and, when the roof has to be made, the snow-bricks are cut with the necessary double curvature. A conical plug fills up the center. Loose snow is then heaped over the house, to fill up crevices. Lastly, a doorway is cut out with knives; also a window, which is glazed with a sheet of the purest ice at hand. For the inside accommodation, there is a pillar or two, to support the lamps. Underground huts are used in all quarters of the globe. The experience of the British troops encamped before Sebastopol tells strongly in their favor, as the habitations during an inclement season. The timely adoption of them was the salvation of the British Army. They are, essentially, nothing else than holes in the ground, roofed over. The shape and size of the hole correspond to that of the roof it may be possible to procure for it; its depth is no greater than requisite. If the roof have a pitch of 2 feet in the middle, the depth of the hole need not exceed 4½ feet. In the Crimea, the holes were rectangular, and roofed like huts. Where there is a steep hill-side, an underground hut is very easily contrived; because branches laid over its top have sufficient pitch to throw off the rain, without having recourse to any uprights, etc.

2. A good defense of a field-work is greatly aided by shelters, arranged for the men and the stores, so that the men can rest in them, and the stores can be kept safe from the enemy's fire. The shelters generally used are known as bomb-proofs and splinter-proofs, which differ from each other only in capacity and strength. Bomb-proofs must be strong enough to resist the effects both of the impact and of the explosion of the projectiles which strike them. They should be roomy, and when used by the men, should be well ventilated. Splinter-proofs are so placed that they are not exposed to the impact of projectiles.

They are liable to be struck by fragments of shells or splinters knocked off by the impact of a projectile, and are therefore made only strong enough to resist the effects of the flying fragments and splinters produced by shells bursting, or by projectiles striking near them. Bomb-proofs may be built during the construction of the parapets, or after the parapets are finished. The latter is the more usual method. The position in a field-work occupied by a bomb-proof depends upon the size of the work, the kind of trace, degree of exposure of the interior of the work, the convenience of the position, etc. Hence, bomb-proofs are sometimes placed under the parapet; sometimes in the gorge of a half-closed work; sometimes in the middle of the parade, etc.; the position being determined by the circumstances of each case.

Ingress and egress of the men who use the bomb-proof may be facilitated by cutting some steps into the side of the trench. The part of the bomb-proof resting against the side of the trench should be revetted by a covering of plank, fascines, or other suitable material, to keep the shelter dry, and to make it more comfortable. Guard beds should be constructed, when the bomb-proof is wide enough, so that the men can lie down at full length; if not wide enough, benches can be made which will allow the men to assume easy positions. Shelters which are not exposed to the impact of the projectiles of the enemy, need not be so strong as the bomb-proof. It will be sufficient if they are proof against the splinters and fragments of shells produced by the enemy's fire. Shelters of this kind are usually constructed in inclined positions, and they are made by placing strong timbers, or bars of railroad iron, in an inclined position against the surface to be protected, and in juxtaposition, and then covering them with earth sufficient to make the interior safe against the fragments which may strike the shelter. No absolute rule, or set of rules, can be made which will apply to all cases in practice. Each particular work must be considered by itself and in connection with its surroundings. Interior arrangements, extremely necessary in one particular work, might be useless in another; the position occupied by these arrangements in one work might be the very worst places for them in a work of another kind, or in a work situated in a different locality. See *Bomb-proof Shelters*, *Hut*, *Splinter-proof Shelters*, and *Tent*.

SHELTER TRENCHES.—Trenches constructed usually in the presence of the enemy, to provide cover for troops exposed in the field to the action of shot and shell. The simplest form of shelter, for a soldier in open country, under ordinary circumstances, is a shallow trench, which will furnish from the excavation, sufficient earth, when heaped upon the side towards the enemy, to screen the soldier in the trench from the enemy's view. A log laid in front of the trench and the earth thrown over and against it, adds materially to the protection afforded by the shelter. Having arrived on the line (not necessarily straight, but being determined by features of the ground, so as to secure all natural cover), the men either stack or ground arms, and begin to throw the earth to the front (using both hands if necessary) so as to form a parapet from 16 to 20 inches high. All available turf, logs, or rocks should be used as a revetment to the interior slope of the parapet.



One rank kneeling in trench, and file-closers lying down in rear.

When the trench has been made 2 feet wide and 15 inches deep it will afford excellent cover for one rank kneeling in it, and file-closers lying down in rear. If the trench be made 4½ feet wide, it will afford cover for two ranks kneeling inside of it; if it be 7 feet wide, it will allow the men to lie down in it.

The main object of these trenches is to afford cover from the fire of the enemy until the proper moment for advancing against him. They should, therefore, offer no impediment to a forward movement, and troops should be able to march straight over them when necessary. When the trenches form a long line, at every 100 yards or so, to enable the artillery, cavalry, etc., to pass, slight ramps should be formed or intervals left in the trenches, which may at these places be made to overlap.

In about one hour's time, a soldier can make his trench (5 feet wide), to 18 inches throughout and raise the parapet to a corresponding height. This will allow him to take a kneeling position when firing. In from two to three hour's time, the trench can be enlarged to a width of 8 feet, and the earth excavated thrown upon the mound, raising it to a height of 3 feet with a thickness of about 4 feet. A trench of these dimensions allows the soldier to occupy a standing position when firing, and it approximates to the form of trench to be constructed finally, when the position is to be held. See *Hasty Intrenchments*.

SHERLOCK EQUIPMENT.—This consists of a knapsack, two haversacks, two canteens, with waist-belt and straps over the shoulder to support the knapsack, etc.

The knapsack is made of rubber cloth, with a light, square frame of wood to preserve its shape, 11 by 11 inches and 4 inches deep. On the sides are two little pouches containing square canteens.

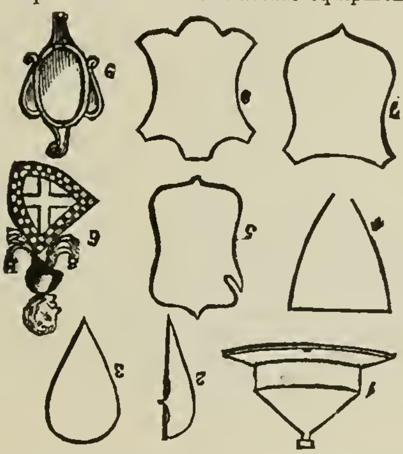
Haversacks are two little sacks suspended on each side of the body under the arms, and attached to a brace-yoke by hooks.

The waist-belt behind is a broad piece of leather, fitting across small of back and supporting bottom of the knapsack. The blanket is rolled and suspended to the bottom of the knapsack.

Straps to waist-belt terminate in brass hooks, adjustable to any size by means of leather keepers.

SHIELD.—A piece of defensive armour, borne upon the left arm, to ward of the strokes of the sword and of missiles. It has been constantly used from ancient times through the Middle Ages, till the invention of firearms rendered it useless. The large shield worn by the Greeks and Romans was circular, and often ornamented with devices. Another form of shield that was used by the Roman heavy-armed infantry, square, but curved to encircle the body. The early shield or knightly escutcheon of the Middle Ages was circular in outline, and convex, with a boss in the center; the body generally of wood, and the rim of metal (No. 1). In the 11th century, a form came into use which has been compared to a boy's kite (No. 2), and is said, with some probability, to have been brought by the Normans from Sicily. It was on all of the shields of this shape that armorial designs were first represented. These shields were in reality curved like the Roman *scutum;* but after Heraldry began to be systematised, we generally find them represented on seals, monuments, etc., as flattened, in order to let the whole armoral design be seen. In the 13th century this long and tapering form began to give place to the pear-shape (No. 3), and a triangular or heater-shape (No. 4). During the 14th century, these new forms became more generally prevalent, and the heater-shape, which was perhaps most frequently represented on armorial seals, began to approach more to an inverted equilateral arch. The same variety of forms, with some modifications, continued during the 15th century, a tendency appearing in all representations of the heater-shaped shield to give it more breadth below. A notch was often taken out in the dexter chief for the reception of the lance, in which case the shield was said to be *à bouche* (No. 5). Subsequent to the middle of the 14th century, when the shield came to be depicted as surmounted by the helmet and crest, the shield is often represented *couché* that is, pendent from the corner (No. 6), an arrangement said to have originated in the practice of competitors hanging up their shields prior to a tournament, where, according to De la Colombière if they were to fight on horseback, they suspended from the sinister chief, and if on foot, by the dexter chief. A square shield denoted a knight-banneret. Shields of arms were often represented as suspended from the *guige*, or shield-belt, which was worn by the knights to sustain the shield, and secure it to their persons.

After the introduction of firearms made shields no longer a part of the warrior's actual equipment, the



Shields.

form of the shields on which armorial bearings were depicted, on seals, monuments, brasses, etc., varied greatly in form, and generally speaking became gradually more tasteless, fanciful, and unmeaning (Nos. 7, 8, 9). A tendency has, however, been shown in recent Heraldry to recur to the artistic forms prevalent in the 14th and 15th centuries.

In early times, shields of the form which generally prevailed at the period. were exhibited on the seals and monuments of ladies; but about the 15th century, the practice began, which afterwards became usual of unmarried ladies and widows (the Sovereign excepted) bearing their arms on a lozenge instead of a shield.

The heraldic insignia of towns, corporations, etc., as well as individuals, are placed on shields. The bearing of Merchants' Marks in a shield was prohibited by the heralds of the 16th century under severe penalties, and yet not a few instances are to be found on monumental brasses of these devices being placed on shields.

SHIFTING-PLANK.—This is usually a piece of $2\frac{1}{4}$ inch plank, 1 foot wide, 5 feet 7 inches long, and beveled at both ends on opposite sides. It is used principally for shifting pieces from one carriage to another.

SHINGLING-MILL.—A rolling-mill or forge, where puddled-iron is hammered to remove the dross, compact the grain, and turn out malleable-iron.

SHOEBURYNESS.—A locality in the County of Essex in England, where Ordnance Experiments are carried out. As far back as 1842, ground was set apart at Shoeburyness as ranges for use and practice of artillery. Since then it has become a School of Gunnery for the regiment of artillery, where two courses of instruction are carried out, viz., the *long* and *short course*. Detachments of the volunteer artillery are sent yearly to Shoeburyness for a training lasting a fortnight.

SHOOTING.—Shooting, with an intent to wound, is felony in the law of England, and punishable with penal servitude for life. The offense consists in the shooting at another, or drawing a trigger, or in any other manner attempting to discharge loaded arms. It is not, however, an offense unless there was a possibility of injuring some person; the intent must not only exist, but the relative situation of the parties must be such that serious injury might have ensued. The extent of the actual wound is immaterial.

SHOOTING-IRON.—A term sometimes applied to a firearm.

SHOP.—An Egyptian iron weapon about six inches in length. Sometimes known as *Khop.*

SHORT-ROLLER.—This roller is formed like the *long-roller*, but is only one foot long. It is used in positions where the long-roller can not act, as between the cheeks of a carriage, in placing the gun in its trunnion-beds, or removing it from them.

SHORT SERVICE.—A period of six years and not less than three, which soldiers must serve in the English Army under the colors. By a recent order from the Horse Guards, recruits enlisting for short service into all regiments but cavalry may do so up to the age of thirty.

SHOT.—This term is applied to all solid projectiles fired from any sort of firearms; those for cannon and carronades being of iron, those for small-arms of lead. The latter are known as bullets and small-shot. The shot used for guns at present vary from the 3-pounder, for boat and mountain artillery, to the 13-in. shot, which weigh about 300 pounds as a shell, or 700 lbs. as an elongated bolt. Generally, shot are cast. There are simple practical rules for calculating the weight of *spherical* shot from the diameter, and *vice versa*, which are often useful in reading of artillery actions. Given the diameter in inches, to find the weight in pounds:—Cube the diameter, and multiply the result by 14; reject the two right hand figures: those remaining will give the weight in pounds. Given the weight in pounds, to find the diameter in inches:—Multiply the cube-root of the weight by 1.923, and the result is the diameter of the shot in inches.

Small-shot are of various sizes, from swan-shot, nearly as large as peas, to dust-shot, and made by dropping molten lead through a colander in rapid motion from a considerable height into water. The lead falls in small globular drops. The holes in the colander vary in size according to the denomination of the shot, No. 0 requires holes $\frac{1}{50}$ in. in diameter, No. 9, $\frac{1}{360}$ inch. The colanders are iron hemispheres, 10 inches in diameter, and coated within with the *cream* or scum which is taken off the molten metal. A small portion of arsenic is melted with the lead, and the fusion in the colanders is maintained by those vessels being surrounded by burning charcoal. The discovery of the advantage attending a long fall was made in England toward the end of the last century. Previously the shot had dropped from the colanders at once into the water. The lead was then so soft that the shot were flattened by the water. The fall through the air enables the lead to cool and harden before taking its plunge. The smaller sizes require less fall than the larger—100 feet suffices for sizes Nos. 4 to 9—the larger sorts demand 150 feet. The highest shot tower is at Villach, in Carinthia, where there is a fall of 249 feet. After cooling, shot are sifted in successive sieves to separate the sizes. Misshapen shot are found by their inability to roll; and finally, the whole are polished by rotary motion in small octagonal boxes, into which a little plumbago has been thrown. See *Bar-shot, Bullet, Projectiles,* and *Solid Shot.*

SHOT BOTTOM.—The block of wood attached to spherical shot and shell to steady them in their passage through the bore of the gun, and to keep the fuse in the axis of the bore when being loaded. The bottom was fastened at one time by tin straps; at another with an adhesive composition. Both methods have been superseded in England by General Boxer's mode, viz.: by attaching the bottom or sabot to the projectile by means of a copper rivet driven through the center of the wood into a small undercut cavity in the shot; the shape of the hole and the malleability of the metal causing the sabot to cleave most closely to the shot or shell.

SHOT-GARLANDS.—Stands on which shot and shell are piled; they are used to retain shot placed on defences, and are made either of iron or wood. Hitherto, garlands have been made of cast-iron and of a square pattern, but they are ordered to be used up and replaced by wrought iron of a rectangular form. They preserve the shot from deterioration, and it is usual to place a tier of unserviceable shot under the serviceable pile.

SHOT GAUGES.—Instruments used for ascertaining the measurement of spherical projectiles. They are simply iron rings with metal handles, and of varying dimensions, for determining the diameter of the shot or shell. Only one high gauge for each caliber is issued. The projectiles should pass in all directions through the high gauge, but must not pass through the low gauge. Ring gauges will also be used for rifled projectiles as well. Low and high gauges are issued to fire-masters and inspectors of warlike stores and store stations. See *Iron Cylinder-gauge.*

SHOT-GUN.—A smooth-bore firearm used for short range shooting. Shot-guns are frequently made double-barreled, and of late years the breech-loading principle has been extensively introduced. Some breech-loaders are provided with interchangeable rifle and shot barrels. The drawing represents the American Arms Company's semi-hammerless single-gun, which combines all the advantages of the hammerless without the *danger* of the self-cocking principle. The extractor is made to allow the shell to be pushed altogether *home* in loading, avoiding any strain on the gun in closing. To cock the gun, press down the little lever on the side. The lockplate is easily removed to get at and oil the lock. Its construction is such that no water or dirt can penetrate to the lock. See *Baker Gun* and *Parker Gun.*

SHOT-LINES.—These lines are intended to be used in connection with a gun or mortar and a projectile, to effect the communication between the shore and stranded vessel, or, in certain cases, between vessels at sea. They should be made of the very best materials. The English method of faking has been adopted in the United States, in laying up these lines for firing. Rockets may be used instead of a gun and projectile for carrying the line.

It is found necessary during firing to have some method of taking up the lines rapidly, and, at the same time, one that would keep them from becoming entangled. A light reel is designed for this purpose which answers all the requirements. This simple contrivance consists of a frame, reel, and crank of wood, and of two wire pins. The frame is dovetailed together, and has four small D-rings attached to it by bits of leather. These rings engage with the snap-hooks of the carrying-braces. The reel is composed of an arbor, carrying cross-pieces at each end. The arbor is retained in the frame by the wire pins.

A strip of leather passes over the extremities of the cross-pieces at each end to keep the radial arms from catching in the line when winding it up. See *Life-saving Rockets.*

SHOT METAL.—An alloy of lead 56 parts, and arsenic 1-part. Used for making small shot.

SHOT POUCH.—A receptacle for small shot, carried on the person. It is usually made of fine leather, the mouth-piece being provided with a measure, having an adjustable cut-off to determine the quantity of the charge. The pouch is sometimes adapted for carrying charged cartridges. It has two receptacles, united behind by a strap and buckle, and communicating with a common mouth-piece, which has a gate permitting the escape of one cartridge at a time.

SHOT-TABLE.—The device for insuring the equal shrinkage of shot in all directions while cooling. It has an annularly grooved surface with a conoidal central projection, and turns on an upright spindle. The hollow spherical mold is placed thereon after the cast is made, and rotated until the casting is cool enough to be removed.

SHOT-TOWER.—A lofty tower for making shot by dropping from its summit melted lead, which cools in the descent, and is received into a cistern of water or other liquid.

SHOULDER.—That portion of the axle-tree body immediately contiguous to the arm. Also, the upper part of the blade of a sword.

SHOULDER ANGLE.—In fortification, that angle formed by the meeting of face and flank of a bastion.

SHOULDER-BELT.—A very wide belt worn over the shoulder for various purposes. The belt is usually crossed from the right shoulder, and supports the cartridge-box, or other articles of equipment. In some armies the sword is suspended from the shoulder-belt. See *Belt* and *Sword-belt.*

SHOULDER-KNOTS.—The ornamental knots of gold cord on cloth of the same color as the facings of the arm to which the officer, wearing them, belongs. The insignia of rank and number of regiment or corps are embroidered on the cloth ground. The prescribed patterns for the United States Army, are as follows:

For Officers of the Adjutant General's and Inspector General's Departments, and for Aides-de-Camp to General Officers.—Of gold cord, Russian pattern, on dark blue cloth ground; insignia of rank and letters of corps or designation of regiment embroidered on the cloth ground, according to pattern; an aiguillette of gold cord is to be worn with the right shoulder-knot, according to pattern.

The aiguillette, instead of being permanently attached to the shoulder-knot, may be made separate, so as to be attached to the coat underneath the knot by means of a strap or a tongue passing through the lower fastening of the knot.

For Officers of other Staff Corps.—Same as above described, without the aiguillette.

For Officers of the Signal Corps.—Same as above described, without the aiguillette. The distinctive insignia will be according to the pattern deposited in the office of the Chief Signal Officer.

Whenever the full-dress coat is worn by officers on duty, the prescribed epaulettes or shoulder-knots are attached. Letters are embroidered on the shoulder-knots in old English.

For the Engineer Corps.—A silver turreted castle of metal one and four-tenth inches in width by nine-tenths of an inch in height.

For the Ordnance Department .—A shell and flame in silver embroidery one and four-tenths inches in width by nine-tenths of an inch in height.

For Officers of Cavalry, Artillery, and Infantry.—

For a Major.—Two gold embroidered leaves, one at each end of the pad.

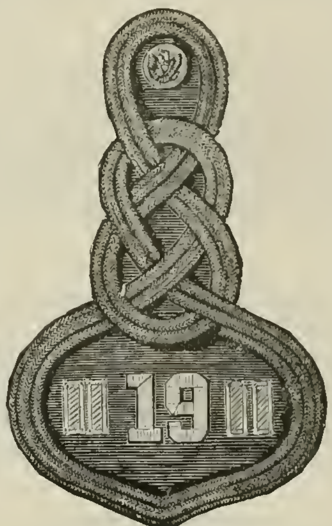
For a Captain.—Two silver embroidered bars at each end of the pad.

For a First Lieutenant.—One silver embroidered bar at each end of the pad.

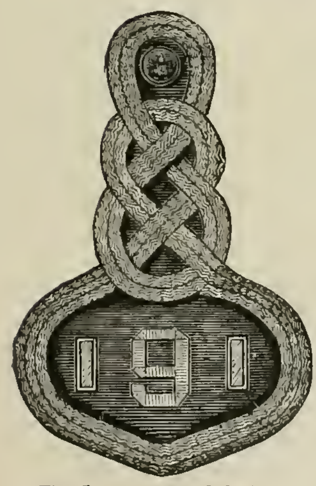
For a Second Lieutenant, or an Additional Second Lieutenant.—Plain. The above insignia are the *same* as prescribed for the shoulder-straps. See *Epaulettes.*

SHOULDER-STRAPS.—Narrow straps, 1$\frac{3}{8}$ inches wide by 4 inches long, bordered with an embroidery of gold $\frac{1}{4}$-inch wide. They are worn on the shoulders of Commissioned Officers, and are indicative of rank. They are prescribed as follows in the United States Army :

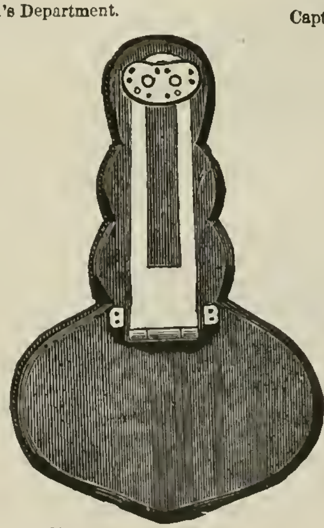
Colonel Inspector General's Department.



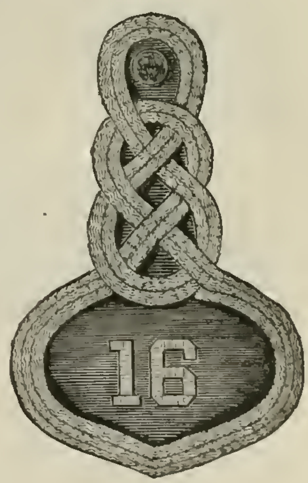
Captain 19th Infantry.



First Lieutenant 9th Infantry.



Shoulder-knot Fastening.



Second Lieutenant 16th Infantry.

Of the same pattern as for the Staff Corps, but on cloth of the same color as the facings of their arm, with insignia of rank and number of regiment embroidered on the cloth ground, according to pattern.

For Regimental Adjutants.—Of same pattern as for other officers of their arm, but having aiguillettes attached.

The insignia of rank on the shoulder-knots is as follows :

For a Colonel.—A silver embroidered eagle at the center of the pad.

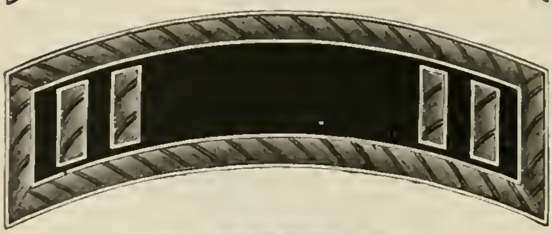
For a Lieutenant Colonel.—Two silver embroidered leaves one at each end of the pad.

For the General of the Army.—Dark blue cloth, one and three-eighths inches wide by four inches long, bordered with an embroidery of gold one-fourth of an inch wide; two silver-embroidered stars of five rays each, and gold-embroidered "Arms of the United States" between them.

For Lieutenant General.—The same as for the General, except that there will be three silver-embroidered stars of five rays, one star on the center of the strap, and one on each side, equidistant between the center and outer edge of the strap, the center star to be the largest.

For a Major General.—The same as for the Lieutenant General, except that there will be two stars instead of three; the center of each star to be one inch from the outer edge of the gold embroidery on the ends of the strap; both stars of the same size.

For a Brigadier General.—The same as for a Major General, except that there will be one star instead



of two; the center of the star to be equidistant from the outer edge of the embroidery on the ends of the strap.

For a Colonel.—The same size as for a Major General, and bordered in like manner with an embroidery of gold; a silver-embroidered spread eagle is on the center of the strap, two inches between the tips of the wings, having in the right talon an olive branch, and in the left a bundle of arrows; an escutcheon on the breast, as represented in the "Arms of the United States." Cloth of the strap as follows: For the General Staff and Staff Corps, dark blue: Artillery, scarlet; Infantry, sky-blue; Cavalry, yellow.

For a Lieutenant Colonel.—The same as for Colonel, according to corps, omitting the eagle, and introducing a silver embroidered leaf at each end, each leaf extending seven-eighths of an inch from the end border of the strap.

For a Major.—The same as for a Colonel, according to corps, omitting the eagle, and introducing a gold-embroidered leaf at each end, each leaf extending seven-eighths of an inch from the end border of the strap.

For a Captain.—The same as for a Colonel, according to corps, omitting the eagle, and introducing at each end two silver-embroidered bars of the same width as the border, placed parallel to the ends of the strap, at a distance between them and from the border equal to the width of the border.

For a First Lieutenant.—The same as for a Colonel, according to corps, omitting the eagle, and introducing at each end one silver-embroidered bar of the same width as the border, placed parallel to the ends of the strap, at a distance from the border equal to its width.

For a Second Lieutenant, or an Additional Second Lieutenant.—The same as for a Colonel, according to corps, omitting the eagle.

For Chaplains.—A shoulder-strap of black velvet, with a shepherd's crook of frosted silver on the center of the strap, may be worn.

Officers serving in the field may dispense with prominent marks likely to attract the fire of sharp-shooters; but all officers must wear the prescribed shoulder-strap, to indicate their rank. It is worn whenever the epaulette or shoulder-knot is dispensed with.

SHOWER.—A term often applied to gold-rain, small stars of slowly burning composition, etc., constituting the decoration of a rocket or shell, and which produce the effect of a shower of fire in falling.

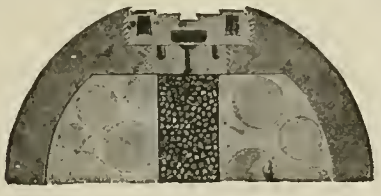
SHRAPNEL.—Thin-sided shells, in which also are placed, besides the bursting-charge of powder, a number of small balls embedded in sulphur. They are cast in the same manner as ordinary shell, excepting that their sides are made thinner to allow for a greater number of balls. The charge of powder is quite small, being only sufficient to rupture the case and liberate the balls.

The thickness of the metal should be such that it will resist the explosion of the charge within the bore of the gun, but open readily with a small bursting-charge. The bursting-charge should be merely sufficient to open the shell without affecting the flight of the bullets. A spherical shell of this class has a less thickness of metal than a common shell, viz., about one-tenth of its diameter, and its weight when empty is about half that of a solid shot of similar diameter.

To fill a shrapnel a funnel is screwed into the fuse-hole, and the case filled with the requisite number of balls. A round, hollow steel mandrel, made slightly tapering towards the lower end, which is rounded off, and having a score cut on either side throughout its length, to admit of a free passage for the melted sulphur to the interior of the shrapnel, is driven and worked through the fuse-hole to the bottom of the case. The projectile is thoroughly warmed, generally in warm water, to prevent the cold metal from solidifying the sulphur before it has filled all the interstices.

It is then filled with melted sulphur, and as soon as the sulphur is set, the mandrel is withdrawn: this is accomplished by first heating it from the interior by the insertion of a hot rod, when it is readily removed. The funnel is also removed, and the magazine formed by the mandrel is cleaned, and the fuse-hole carefully tapped out. In this magazine is deposited the charge of powder, where it is protected against all injury from the movement of the balls. By this arrangement the quantity of powder required to open the shrapnel is very small, and the bullets are prevented from striking by their inertia against the sides of case and cracking when the piece is fired.

Lead being much more dense than iron, the shrapnel is, when loaded, nearly as heavy as a solid shot of the same caliber for the lighter guns. A shell of this class, is in fact, simply a canister-shot adapted to long range. The rupture may be made to take place



at any point of its flight; and in this respect it is superior to canister and grape, which begin to separate the moment they leave the piece. See *Boxer Shrapnel Shell*, *Case-shot*, *Projectiles*, and *Rifle-shrapnel*.

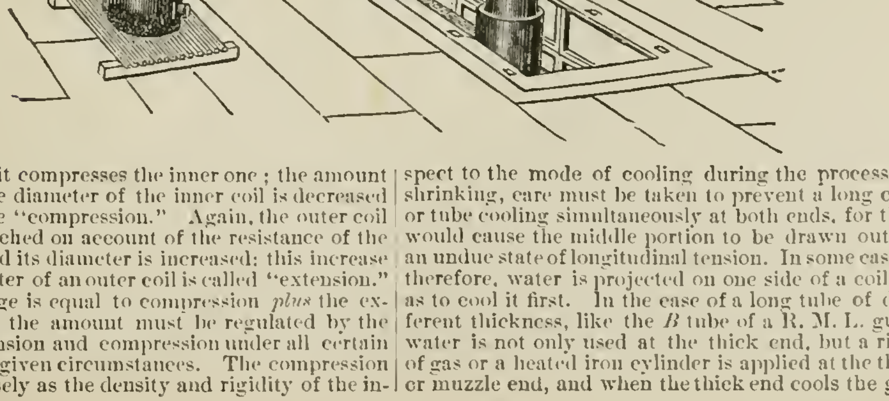
SHRAPNEL FUSE.—The French, in the affair of Traktir, made good use of shrapnel with a fuse of the following description: It was made of hard wood having three channels parallel to its axis. These were filled to different heights with composition, corresponding thus to three different bursting distances. Each of these channels was provided with a tin tube in which the composition was placed. The longest channel was always left open. The other two were closed with a covering of leather, over which was placed, for the shorter column, a disk of rose-colored paper, for the other, one of blue. On these paper coverings were marked the distances at which the columns would cause explosion. These distances were also placed on the face of the fuse near the top of the channels. The fuse was capped with a rondelle of fringed paper, over which was placed a plain rondelle of parchment with a piece of tape attached, by means of which the fuse was uncapped. The composition in the three channels burned in $1\frac{1}{2}''$, $2\frac{1}{2}''$ and $3\frac{1}{2}''$. It was proposed to modify this fuse by adding a fourth column, intended to burst the shell at only 250 yards' distance, but at this short distance, canister shot will do quite as well, if not better, than shrapnel.

SHRINKING.—In the construction of built-up guns, the inside diameter of the outer tube when cold must be rather smaller than the outside diameter of the inner tube: this difference in the diameter is called the "shrinkage." While the outer coil is cooling and contracting it compresses the inner one; the amount by which the diameter of the inner coil is decreased is termed the "compression." Again, the outer coil itself is stretched on account of the resistance of the inner one, and its diameter is increased; this increase in the diameter of an outer coil is called "extension." The shrinkage is equal to compression *plus* the extension, and the amount must be regulated by the known extension and compression under all certain stresses and given circumstances. The compression varies inversely as the density and rigidity of the interior mass; the first layer of coils will therefore undergo more compression than the second, and the second more than the third, and so on. Shrinking is employed not only as an easy and efficient mode of binding the successive coils of a built-up gun firmly together, but also for regulating as far as possible the tension of the several layers, so that each and all may contribute fairly to the strength of the gun.

The operation of shrinking is very simple; the outer coil is expanded by heat until it is sufficiently large to fit easily over the inner coil or tube (if a large mass, such as the jacket of a Fraser gun, by means of a wood fire, for which the tube itself forms a flue; if a small mass, such as a coil, in a reverberatory furnace at a low temperature or by means of gas). It is then raised up by a traveling crane overhead and dropped over the part on to which it is to be shrunk, which is placed vertically in a pit ready to receive it, as in the drawing.

The heat required in shrinking is not very great. Wrought-iron on being heated from 62° F. (the ordinary temperature) to 212°, expands linearly about $\frac{1}{1000}$th part of its length; that is to say, if a ring of iron 1,000 inches in circumference were put into a vat of boiling water it would increase to 1,001 inches; and according to Dulong and Petit, the co-efficient of expansion, which is constant up to 212°, increases more and more from that point upward, so that if the iron ring were raised 150° higher still (*i. e.*, to 362°) its circumference would be more than 1,002 inches. No coil is ever shrunk on with so great a shrinkage as the $\frac{2}{1000}$th part of its circumference or diameter, for it would be strained beyond its elastic limit. Allowing, therefore, a good working margin, it is only necessary to raise a coil to about 500° F., though in point of fact coils are often raised to a higher degree of temperature than this in some parts, on account of the mode of heating employed. Were a coil plunged in molten lead or boiling oil (600° F.) it would be uniformly and sufficiently expanded for all the practical purposes of shrinking, but as shrinkings do not take place in large numbers or at regular times, the improvised fire or ordinary furnace is the more economical mode, and answers the purpose very well.

Heating a coil beyond the required amount is of no consequence provided it is not raised to such a degree of temperature that scales would form; and in all cases the interior must be swept clean of ashes, etc., when it is withdrawn from the fire. With respect to the mode of cooling during the process of shrinking, care must be taken to prevent a long coil or tube cooling simultaneously at both ends, for this would cause the middle portion to be drawn out to an undue state of longitudinal tension. In some cases, therefore, water is projected on one side of a coil so as to cool it first. In the case of a long tube of different thickness, like the *B* tube of a R. M. L. gun, water is not only used at the thick end, but a ring of gas or a heated iron cylinder is applied at the thinner muzzle end, and when the thick end cools the gas



or cylinder is withdrawn from the muzzle and the ring of water raised upward slowly to cool the remainder of the tube gradually.

SHUNT RIFLING.—This is one of Sir William Armstrongs systems of rifling, and combines both the *centering* and the *compressing* systems. As the inventor deemed it important to prevent the shot from moving laterally, by direct pressure on its sides, instead of by allowing it to center itself, as in the *centrical* system; and, as the expansion system did not meet his views, his ingenious resort was to arrange the rifling so that the shot runs home easily, and is then *shunted*, or switched off, or turned a little in the gun, so that, when it comes out, a shallower position of the groove will nip it, and prevent its lateral movement. The driving-side of groove near the muzzle is made shallow. The projectiles have soft copper studs, which fit easily with a windage of .025 inch into the deep portion of the groove; when the gun is loaded, the studs travel down this deep part until they reach about the middle of the bore, where they meet with an incline, by which they are *shunted* into a narrow part of the groove, of the same depth, down which they travel to the chamber. On discharge the studs bear against the other side of the groove, until they come to the incline, up which they travel, the studs being thereby compressed. With this compression they pass through the remaining part of the bore. There are three grooves with a uniform pitch of one turn in 40 calibers, the edges being angular. This system embraces the theories of centering the projectile and its retardation, the latter of which is now conceded to be a disadvantage. The Russians have a "Shunt system" borrowed from Armstrong's, but differing in details. American guns, on similar principles, have been made experimentally. There is only a minute difference between the diameters of the bore and projectile.

SHUTERNAUL. In the East Indies, a sort of arquebuse, which is fixed upon the back of a camel.

SIBLEY TENT.—A tent of peculiar construction, in the center of which a fire can be made, and all its occupants sleep with their feet to the fire. It is conical, light, easily pitched, erected on a tripod holding but a single pole, and will comfortably accommodate twelve soldiers with their accouterments. Where means of transportation admit of tents being used, this tent is very handy and satisfactory. The tent is still much used in the United States Service. See *Tent*.

SICK AND HURT.—A Board so called, to which the agents, commissaries, etc., belonging to the several military hospitals in Great Britain, were responsible.

SICK CALL.—A military call which is sounded on the drum, bugle, or trumpet, whereby the sick men are warned to attend the hospital.

SICK FLAG.—The yellow quarantine flag hoisted to prevent communication; whence the term of Yellow Flag and Yellow Admirals. There are two others, one with a black-ball, the other with a square in the center, denoting plague or actual diseases.

SICK LEAVE.—A leave of absence granted to officers and military subordinates in consequence of any sickness or disability. In the United States Service, leaves of absence on account of sickness are not granted to go beyond the limits of the Military Department within which they are stationed, unless the certificate of the Medical Officer shall explicitly state that a greater change is necessary to save life, or prevent *permanent* disability. Nor are sick-leaves to go beyond the Department limits given in any case, except of an immediate urgency, without the previous sanction of the War Department.

Commanders of Geographical Departments and Divisions are authorized to grant leaves of absence, on account of sickness, subject to the limits fixed by the General Regulations of the Army for ordinary leaves. The application must be accompanied by Surgeon's certificate of disability. Leaves not are granted unless they originate at the post of duty of the applicant. No application for *extension* of sick-leave will be granted from the Head-quarters of the Army, or the War Department, unless such extension shall have been approved by the Department or Division Commander. On the expiration of a leave of absence on account of any sickness, if the party be able to travel (without endangering his ultimate cure), he will forthwith proceed to his post, although his disability may not have been removed. Exceptions to this general rule must be made in each case by the War Department.

When an officer is prevented by sickness from joining his station, he transmits the prescribed medical certificates, monthly, to the Commanding Officer of his post, and regiment or corps, and to the Adjutant General—all through Department Head-quarters; and when he cannot procure the certificate of a Medical Officer of the Army, he substitutes his own certificate, on honor, as to his condition, the certificate to embrace a full statement of his case. The certificates, when approved by the Department Commander and forwarded to the Adjutant General of the Army, will be sufficient authority for his absence until he is able to travel to his post. If the Officer's certificate is not satisfactory, he will be informed; if satisfactory, the Adjutant General will furnish him, for the advice of the Pay Department and to secure his pay, an official letter of acceptance. Whenever an officer has been absent on account of sickness for one year, he may be examined by a Medical Board and the case specially reported to the President.

When an officer is absent under an accepted certificate of disability, he will be entitled to the same pay as if an order had been issued granting him leave of absence on account of disability.

The following is the form of medical certificate, given by the Medical Officer:

————, of the———Regiment of——, having applied for a certificate on which to ground an application for leave of absence, I do hereby certify that I have carefully examined this officer and find that—[*Here the nature of the disease, wound, or disability is to be fully stated, and the period during which the officer has suffered under its effects*], and that, in consequence thereof, he is, in my opinion, unfit for duty, and not able to travel without endangering his ultimate cure. I further declare my belief that he will not be able to resume his duties in a less period than—[*Here state candidly and explicitly the opinion as to the period which will probably elapse before the officer will be able to resume his duties. When there is no reason to expect a recovery, or when the prospect of recovery is distant or uncertain, or when a change of climate is recommended, it must be so stated.*] Dated at ——, this——day of—— ———— ————

[Signature of the Medical Officer.]

SICKLEGHAR.—An Indian term. A native of India employed in arsenals for cleaning metal work.

SICK REPORT BOOK.—A book in which the names of any of the men who are sick in a company, troop, etc., are entered, also the names of their diseases, and probable cause of same. This book is signed by one of the Company Officers to which the men belong and the attending Surgeon. On the next page is the form of the monthly report of sick and wounded to be made out in duplicate; one copy to be sent to the Medical Director, and the other to the Surgeon General direct. Separate reports are to be made in every case for white and colored troops.

SIDE BARS.—1. The longitudinal side-pieces of a traveling-forge or a battery-wagon. 2. Two plates which unite the *pommel* and *cantle* of a saddle. In some saddles they are of steel, and give elasticity to the seat, which is suspended from the *pommel* and *cantle*.

SIDE BONES.—Enlargements situated above the horse's heels, resulting from the conversion into bone of the elastic lateral cartilages. They occur mostly in heavy draught horses with upright pasterns, causing much stiffness, but, unless when of rapid growth, little lameness. They are treated at first by cold ap-

plied continually, until heat and tenderness are removed, when blistering or firing must be resorted to.

SIDE-LINES.—Fetters for horses, or other animals, when turned out to graze. They are similar in their construction to *hobbles*; but instead of being placed on both front or on both hind-legs they are attached to a fore and hind-leg on the same side. An animal bearing *side-lines* can gallop, though with labor, to a short distance, should he scent a wild beast approaching him; but, hobbles will not permit him to move at all rapidly. In anticipation of such dangers, *side-lines* would be preferable. They should be issued to troops of at least three sizes (the length of chain being about 18, 24, and 30 inches) to suit the different sized animals and the emergencies requiring their use. The pattern, used by the United States cavalry, is composed of leglets of leather fastened by a steel-wire snap, connected by a chain, $\frac{3}{16}$-inch iron link. As with hobbles, it would be better to have the side-lines constructed of steel, with a locked connecting-chain. See *Hobble*.

SIDE PATROLS.—Side patrols are placed as shown in Fig. 1. The two men in A must not only from time to time communicate with the advanced guard —that is to say, one of them incline to the left until he can see it—but the other, when there is a height near, even at a thousand yards' distance, must ride to the top of it and look over. When attacked, side patrols behave as advanced and rear-guards; they meet the enemy, and do not suffer him to come too near the column. When the side patrol meets with a wood in the direction of its march, the disposition is altered, as shown in Fig. 2. The officer detaches, the Sergeant's troop to the right, the Corporal and four men to the left, and himself remains with his men in the center. The Sergeant sends two men to the skirts of the wood; these must look at the tracks, and one of them occasionally rides to the top of a height, if any be near; the remainder divide themselves to the left of these two men, at such a distance that they can keep one another in sight. The Corporal divides his men in the same manner, between the right flank of the column and the officer's troop. If the officer perceive that these two lines are not extensive enough to cover the ground toward his troop, he detaches a sufficient number of men to the right and left, to form a perfect line, which line must be careful never to pass the head of the column. The Non-commissioned Officers endeavor to keep all their men in the same line with the officer's division. All this should be done quietly, without hurry or fuss, and will be so done, wherever the men have been previously instructed in their duty. To see men unnecessarily galloping and fatiguing their horses on such occasions, from mere want of instruction, and without doing any more good than if at a walk, really excites one's pity.

Patrols of discovery consist generally of a considerable force, so as to be enabled to defend themselves against small parties or patrols of the enemy, and are sent for the purpose of ascertaining whether a certain place is in the enemy's possession, whether he is on the move against us, or whether a certain district is occupied by him. Such a patrol usually has three men for an advanced and two for its rear-guard, and, if necessary, sends one man to its right, and another to the left, along its heights. As not only the safety of the patrol frequently, but the very object for which it is sent, depends upon its not being seen by the enemy, it is of the utmost importance to impress well upon the men in the front. that they are not to be satisfied with merely looking out before them, but to examine closely the tracks along the cross-roads, ascend the hills with caution, etc If this be well done, the patrol will sometimes have a chance of making prisoners. A patrol which sees the enemy advancing towards it with not too strong a force, must conceal itself, and at the proper moment attack him vigorously; whereby he will be thrown into confusion, fly, and perhaps lose some prisoners. When the enemy is too strong, the patrol avoids him, and, if circumstances permit, continues its march, and endeavors to carry out the object for which it was sent. A patrol must never enter a village or wood, which has not been examined: but this is to be so managed as not to delay the patrol.

For, it must be borne in mind, that the officer who sent it out has calculated the time of its return; should it not come back at that time, he may get apprehensive, and send another one out to look for it; whereby both men and horses will be unnecessarily fatigued.

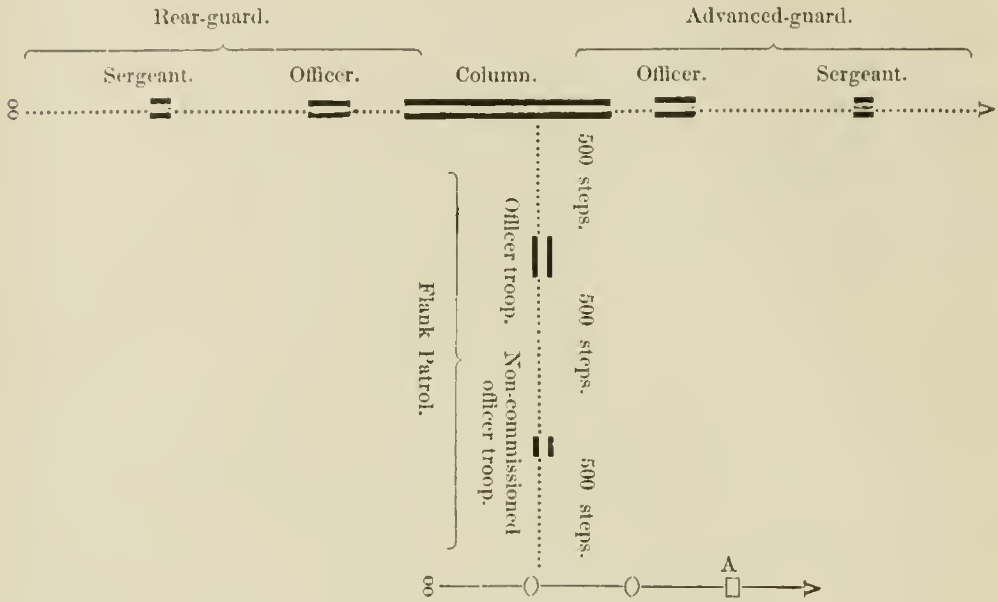

Fig. 1.

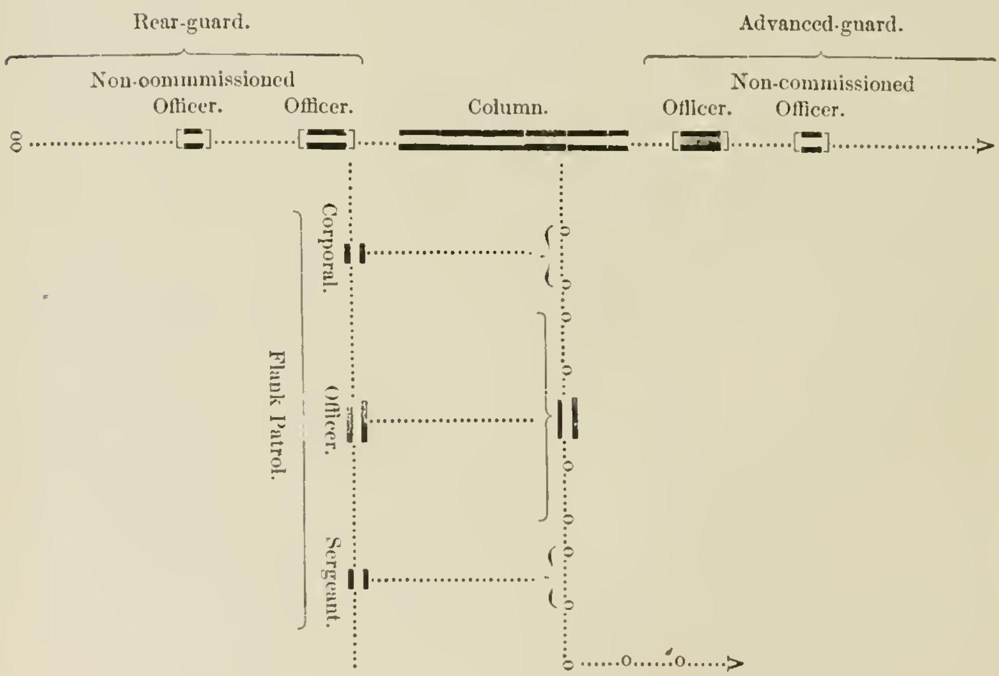

Fig. 2.

In passing, at night, any village which the enemy may have occupied, the patrol is to halt about five or six hundred yards from it. When no vedettes of the enemy are visible, a few men are sent to the right and left, who approach stealthily, to ascertain if the entrances to the village are occupied by troops, and to try and pick up an inhabitant, whom they may bring back with them. If nothing can be learned in this way, the patrol cautiously moves on.

When a patrol is ordered to ascertain, by night, whether a village is occupied, and how, three of the best mounted men are picked out for the lead; eight others follow at a distance of twenty-four yards; and the remainder of the patrol, at a hundred yards. The enemy's vedettes are then approached without noise, and as soon as one challenges, the three men in advance bear down on him at full speed, to take him prisoner. Should they not succeed, they with the other eight must make a dash at the guard, to bring off a prisoner, with whom they retire. The alarm will be given in the village to a certainty, and the sounding of trumpets or beating of drums, will enable the patrol to judge by what kind of troops it is occupied. If a patrol go so far as to be obliged to feed, it must never stop to do so in a village, but always in an open country under some trees, and, while halting for this purpose, must never omit to throw out vedettes. The horses must be watered and fed by detachments—never *all* at the same time—so as to guard against surprise. Provisions and forage, if it be necessary to get them out of villages, must be brought out by the inhabitants. On such occasions, as on all others, the inhabitants are to be treated with kindness; any attempt to rob or ill-treat them, must be promptly and most severely punished. But the object had in view by the patrol, and the direction of its route, must be carefully concealed from them. Guides that are sent home, must, if possible, be deceived, by the patrol's marching in a false direction, until they are out of sight. If information about the road be wanted, the inquiry must embrace several roads, that the true one may not be suspected. See *Patrols* and *Secret Patrols*.

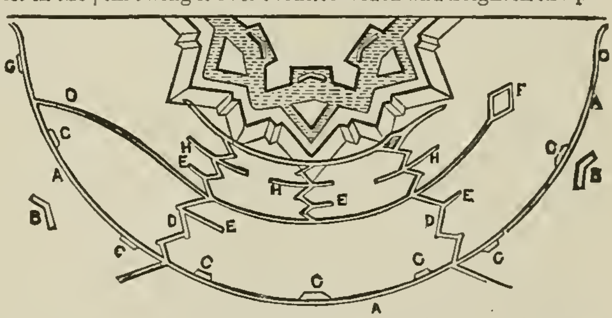
SIDE-RIB.—The rod at the side of a carbine to which the sling is fastened.

SIDE-SCREW.—One of the screws by which the lockplate is secured to the stock. They pass through the stock, and are held by the side-screw plate or by side-screw washers.

SIDE-TACKLE.—A purchase hooking into an eye-bolt on a naval gun-carriage and an eye-bolt in the ship's side, and serving to train the gun to point forward or abaft the beam, and to run it out of the port. Each carriage has side-tackle on each side.

SIEGE.—The sitting of an army before a hostile town or fortress with the intention of capturing it. With certain elements, the success of a siege is beyond a doubt; the result being merely a question of time. These elements are: first, the force of the besiegers shall be sufficient to overcome the besieged in actual combat, man to man. If this be not the case, the besieged, by a sortie, might destroy the opposing works, and drive away the besiegers. The second element is, that the place must be invested; so that no provisions, reinforcements, or other aliment of war can enter. The third element is, that the besiegers be undisturbed from without. For this it is essential that there shall not be a hostile army in the neighborhood; or, if there be, that the operations of the besiegers be protected by a covering army able to cope with the enemy's force in the field. The ancients executed gigantic works to produce these effects. To complete the investment, they built a high and strong wall around the whole fortress; and to render themselves secure from without, they built a similar wall facing outwards, beyond their own position. The first was circumvallation, the second contravallation. It was thus that Cæsar fortified himself while besieging Alexia, and maintained 60,000 men within his ring. In modern warfare, it is considered preferable to establish strong posts here and there round the place, and merely sentries and vedettes between.

Let us now assume that a fortress of great strength has to be reduced, and that the force of the enemy in the vicinity has been either subdued or held in check by a covering army. By rapid movements, the place is at once invested on all sides. This step constitutes merely a blockade; and if time be of little importance, is a sufficient operation, for hunger must sooner or later cause the fortress to surrender; but if more energetic measures are required, the actual siege must be prosecuted. Advantage is taken of any hidden ground to establish the park of artillery and the Engineer's park; or if there be none, these parks have to be placed out of range. The besieging force is now encamped just beyond the reach of the guns of the fortress; and their object is to get over the intervening ground and into the works without being torn to pieces by the concentrated fire of the numerous pieces which the defenders can bring to bear on every part. With this view, the place is approached by a series of zigzag trenches so pointed that they cannot be enfiladed by any guns in the fortress. In order to accommodate the forces necessary to protect the workers, the trenches at certain intervals are cut laterally for a great length, partly encircling the place, and affording safe room for a large force with ample battering material. These are called *parallels*, and they are generally three in number. The distance of the first parallel will increase as small-arms become more deadly; but with the old smooth-bore muskets it was usual to break ground at 600 yards from the covered-way of the fortress, while at Sebastopol ground was broken at 2,000 yards, and in the Siege of Paris by the Germans the lines were begun at least 4 miles from the city. The locality of the parallel being decided on, a strong body of men is sent to the spot soon after nightfall. The attention of the garrison is distracted by false alarms in other directions. Half the men are armed cap-à-pie, and lie down before the proposed parallel; while the other half, bearing each a pick and shovel, and two empty gabions, prepare for work. Each man deposits the gabions where the parapet of the trench should be. He then digs down behind them, filling the gabions with the earth dug out; and, after they are filled, throwing it over them to widen and heighten the parapet.



Before daylight the working-party is expected to have formed sufficient cover to conceal themselves and the troops protecting them. During the day, they—being concealed from the garrison—widen and complete their parallel, making it of dimensions sufficient to allow of wagons and bodies of troops with guns passing along. During the same night, other parties will have been at work at zigzags of approach from the depots out of range to the first parallel, which zigzags will be probably not less than 1,000 yards in length. Usually the defenders will not expend ammunition on the first parallel, for its extent (often several miles) will render the probability of doing material damage extremely small. For this reason also, the dimensions of the parapet and its solidity are of far less importance in the first parallel than in the more advanced works of attack. The first parallel, AAA, being completed, the engineers select points near its extremities, at which they erect breast-works, BB, to cover bodies of cavalry, who are kept at hand to resist sorties from the garrison. The length of the parallel is usually made sufficient to embrace all the works of two bastions at least. Sites are then chosen for batteries, CC, which are built up of fascines, gabions, sandbags, and earth. They are placed at points in the parallel formed by the prolongation of the several faces of the bastions, ravelins and other works of the fortress, which faces the batteries are severally intended to enfilade by a ricochet fire. Other batteries will be formed for a vertical fire of mortars and shell-guns By these means it is hoped that the traverses on the hostile ramparts will be destroyed, the guns dismounted, and the defenders dispersed, before the final approaches bring the assailants to the covered-way. The sappers will now commence their advance toward the points, or salient angles, of the two bastions to be attacked. If, however, the trench were cut straight toward the fortress, its guns could easily destroy the workmen and enfilade the approach. To prevent this, it is cut in short zigzags—as at D—the direction always being to a point a few yards beyond the outmost flanking-works of the garrison. The side of each trench nearer the fortress is protected by gabions and sandbags, as in the case of the parallel. At intervals, short spurs of trench, incipient parallels, are cut, as at E, to contain small-arms-men, who act as guards to the sappers. The second parallel is about 300 yards from the enemy's works,and has to be more strongly formed than the first. It often terminates in a redoubt, F, to hold some light artillery and a strong force of infantry, who could assail any sortie in flank; or it may run into the first parallel, as G, giving easier access for troops than through the zigzags The second parallel is revetted with sandbags, in which the loopholes are left for musketry. After passing the second parallel, the angles of all the zigzags become more acute,to prevent enfilading. At about 150 yards, certain demi-parallels, H, are cut, and armed with howitzer batteries, to clear the covered-way, while riflemen also act from it. The third parallel is at the foot of the glacis. Thence the place, after being sufficiently battered, is taken by a storming-party, who make their way over the glacis, or the covered-way is topped by the double-sap, which is a safer plan for the army generally, though much more deadly to the sappers. When the crest of the covered-way has thus been reached, batteries of heavy artillery will be there established, for the purpose of breaching the walls of the ravelin and bastion; while at the same time miners will first seek to destroy the defender's counter-mines (which would otherwise be likely to send these batteries into the air), and then will excavate a tunnel to the ditch, at the foot of the counterscarp. If the breach becomes practicable, a storming-party will emerge from this tunnel or gallery, and seek to carry the opposite work by hard fighting. If inner works still subsist, which would tear assailants to pieces, the double sap may be still continued across the ditch, if a dry ditch, right up the breach, that counter-batteries may be formed. If the ditch be wet, means must be adopted for a causeway or a bridge. By these means, however obstinate may be the defense, if the besieging force be sufficiently strong, and aid do not arrive from without, the ultimate success of the attack becomes certain. Vauban raised attack to a superiority above defense, first by the introduction of the ricochet fire, which sweeps a whole line: and secondly, by originating parallels. Before his time the whole attack was conducted by zigzag approaches; in which the troops actually in front could be but few, and were therefore unable to withstand strong sorties of the garrison, who, in consequence, frequently broke out and destroyed the works of the besiegers, rendering a siege an operation of a most uncertain character. See *Besiege*.

SIEGE AND GARRISON AMMUNITION.—Ammunition for siege and garrison service consists of cartridges of sizes varying according to circumstances, and the following projectiles, viz: *Shot* for 15, 10, and 8-inch columbiads (model 1861). *Shells* for 15, 10, and 8-inch columbiads, 13, 10, and 8-inch mortars; also the Coehorns and 8-inch siege-howitzer. *Spherical case-shot* and *canister* for 10 and 8-inch columbiads, and 8-inch siege-howitzer. The shells and spherical case-shot (except for the 8-inch siege-howitzer) are attached to sabots; the other projectiles are not strapped.

Canisters are made and filled like the canisters for field-service, except their dimensions, and. instead of being attached to a sabot, the lower end of the cylinder is slit with longitudinal cuts, .5 inch long and from .25 to .38 inch apart according to the caliber. The strips thus formed are turned down over a cast-iron bottom plate .5 inch thick. The cover for these canisters is of sheet-iron, .1 inch thick; it has a handle 3.75 inches long by 1.72 inch wide,made of iron wire No. 9, fastened to the cover by a strap of sheet-iron 2 inches long, 1.75 inch wide, secured by two rivets .15 inch thick. Canisters for 8-inch siege-howitzer are attached to sabots made to conform to the bore.

A stand of grape consists of 9 shot, placed together by means of 2 cast-iron plates, 2 rings, and 1 bolt and nut. The square of the nut is 2 diameters of the bolt; and its thickness 1 diameter. The head of the bolt is countersunk flush with the bottom of the lower plate, which has a slot to prevent the bolt from turning when the nut is screwed on. Each plate has on the inside 3 beds for the shot,of a depth equal to half the thickness of the plate. They are made in the form of a spherical segment,the curvature of which is the same as that of the shot; their centers are on equidistant radii, midway between the edge of the bolt-hole and that of the plate. In the upper plate are 2 holes .25 inch diameter placed opposite to each other at .5 inch from the edge of the plate to receive a rope handle. For the 8-inch siege-howitzer the stand of grape must be attached to a sabot as for canisters. The sabot may be fastened to the lower plate with screws, or the bolt may be made long enough to pass through it, or else the sabot may be inserted into the piece separately from the stand of grape.

The following implements are required for filling shells:—1 *pair of shell-hooks;* 1 *handspike;* 2 *hand-hammers;* 2 *scrapers*, (pieces of sword-blade); 2 *tow-hooks;* 2 *pairs of pincers; rags;* 1 *chisel* and 1 *mallet*, to clean the shells and break up any hard substances that may be found in the interior; 2 *searchers*, for sounding cavities; *shell-gauges;* 1 *grate*, to dry the shells on; 1 *fuse-saw;* 1 *gimlet;* a *ring of rope*, or a *hollow block;* 1 *funnel; powder-measures;* 1 *tub* or a *vessel* for powder; 2 *baskets*, for the composition and fuses; 1 *rasp;* 1 *fuse-setter;* 1 *mallet;* 1 *fuse-reamer*. The shells are cleaned inside and out, gauged, and examined that they have no defects that would cause their rejection; that the fuse-hole is not defaced; if there be water in the cavity,the shell is dried by gentle heat and cooled slowly.

To fill shells for guns or howitzers.—A helper places the shell on the block or ring of rope, the fuse-hole uppermost; inserts the fuse-plug and drives it in till the top is flush with the surface of shell. The principal reams out the hole to its proper size,the helper holding the shell to prevent it from turning. The helper inserts the pipe of the funnel in the fuse-plug, and the principal pours in the powder and closes the hole with a wad of dry tow rammed in securely,leaving a portion of it projecting out. When cylinders of rock fire or other combustibles are used, they are inserted before the fuse-plug is driven.

To fill mortar-shells.—The shells are generally filled and the fuses driven in the battery-magazines as they are required. The helper places the shell on a ring of rope and inserts the pipe of the funnel in the fuse-hole; the principal pours in the bursting-charge, introduces the cylinders of rock-fire and pushes them aside with a small stick, that they may not be in the way of the fuse when driven in. He then inserts the fuse, which should enter to within half an inch of the top, and with a mallet and fuse-setter drives it so that the end of the fuse shall project not more than .2 inch. The fuse is cut to the proper length, according to the range, before it is driven into the shell, by resting it in a groove made in a block to

receive it and to hold it steady, the saw running in a cut made for it; or the fuse may be bored through to the composition with a gimlet, at the proper length.

To fire 12-pounder shells from mortars of a large caliber.—This kind of fire is intended only for short distances, as in the defense of a breach, and supersedes the use of the stone mortar. Take a strong tub or half-barrel, provided with two strong rope handles, add a second bottom on the outside, bringing it flush with the ends of the staves to which it is nailed. To this bottom nail another, made of a single piece of wide 2-inch plank of a sufficient length to support the ends of the staves. A block of light, dry wood, of the diameter and length of the bore, is attached to the bottom of the barrel or tub by nails, and the lower end of the block which goes next to the charge is covered with sheet-iron. The fuses of the shells are cut, driven, uncapped, and the shells placed in the barrel, the fuses turned down. When the bottom tier is finished a second one is laid, and so on to the last, which is covered over with hay, which is rammed in to keep the projectiles in place. The charge of powder is put in the mortar, the proper elevation and direction are given, and the barrel or tub, loaded, is raised by the handles, the block wiped clean and introduced into the bore and set home. See *Ammunition*, *Cartridge-bags*, *Sabot*, *Strapped Ammunition*, and *Wads*.

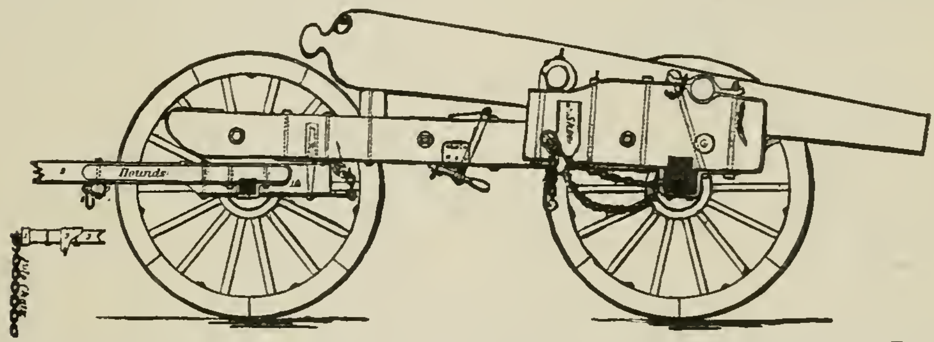
SIEGE-ARTILLERY.—In siege operations, the use of different kinds of cannon and projectiles, and of various kinds of fire, depends upon the end to be attained and the relative positions of the besieger's guns and the works to be attacked. The position to be occupied by the siege-batteries is determined by the object to be accomplished by each battery, by the nature of the ground and of the attack, and by the power of the besieger's artillery as compared with that of the besieged. In the Franco-German War of 1870, siege-batteries were constructed at distances of 4,000 yards and more, in order to drive the besieged from his outworks and to engage his artillery with such effect that a second and nearer position should be tenable. At this limit, which was the extreme range, was reached oftener than had been expected; the Germans have since introduced pieces sufficiently powerful to attain a range of 9,300 yards with 40° of elevation. With these the enemy's artillery can be engaged, with decisive results, up to 5,000 yards, his works enfiladed up to 5,500 yards, and bombarded beyond 8,000 yards. Breaching-batteries were formerly established about forty yards from the point to be breached, but in recent years the distance has been as great as 4,000 yards. Siege cannon are employed: 1st. To destroy all buildings and *matériel*, and to keep down the fire of the work so as to facilitate the establishment of the lines and batteries of attack. 2d. To dismount the artillery and to destroy its cover. 3d. To form breaches. 4th. To silence Infantry fire, effect lodgments, and clear terrepleins. 5th. To defend the batteries against sorties, and to drive from their position troops that prevent or delay the progress of the siege-works. 6th. To prevent the enemy from repairing damages, and to cover and support the assaulting columns. *In the defense*: 1st. To prevent the establishment of lines and batteries of attack, and to counteract and silence the fire of the enemy's batteries. 2d. To destroy established works, to dismount the enemy's artillery, to interrupt communication between different parts of his works, and to retard the progress of his works. 3d. To drive the enemy from outworks he may have captured, to cover and support sorties, and to prevent the enemy from following too closely the troops returning from a sortie. The fire of the besieged will be, at least for a time, more powerful than that of the enemy.

In the attack, solid shot are used principally for dismounting artillery and forming breaches, and *in the defense*, for dismounting artillery and against the head of a sap; but even for these purposes they are not necessary, and they are being replaced generally by shells, except when the latter have not the power to do the required work. Shells with large bursting charges and using time or percussion-fuses, which depend upon the object fired at, are employed more generally than any other projectiles in siege operations. This fire should from its nature be massed on distinct portions of the object. In shell fire from guns, the percussion-fuse is the best. Shells may be employed for breaching and demolishing masonry, for destroying buildings, earthworks, etc., for dismounting artillery, and for injuring the *personnel* of the enemy. In breaching, a special battering-shell may be used to destroy the face of a revetment, etc., and thus allow the common shell, with its larger bursting charge, to be employed. Shells striking masonry and bursting on impact, produce but little effect; when fired without fuses they will explode, but not before some penetration has been accomplished. For dismounting artillery, the fire should be enfilading, as a direct fire is comparatively harmless. Howitzer-fire is employed for bombarding purposes, for destroying *matériel* and penetrating the roofs of bomb-proofs and magazines, and for breaching or demolition when indirect fire has to be employed. In the latter case, the maximum charge or one closely approximating to it must be employed, though the charge and elevation must within limits be adjusted to suit the range and conditions of fire; the shell must clear the intervening obstacle, and yet strike the wall at the proper point. Shrapnel, being of value against animate objects only, cannot be employed by the besiegers to so great an extent as by the besieged. It is of little effect against troops behind earthworks unless they can be enfiladed, but will generally be used against working parties, sorties, etc., and at points where the enemy may be expected to expose himself during day or night. It is used to silence temporarily the enemy's fire by driving off the gunners; in this case, its effect is greatest when fired from mortars. This fire should be distributed over the whole extent of the object fired at, and it should preferably be parallel or oblique to some line of the work. Grape and canister are of use only to repel sorties and to clear the parapets of men when the range permits. Canister is used at ranges within 600 yards. Machine-guns also would be employed for these purposes.

When the end is to be accomplished by range, accuracy, or hard hitting, or when shrapnel is used, the direct fire is employed. If the point to be reached be behind a protecting mass, the direct fire must be curved, and reduced charges and preferably shells must be used. This allows projectiles to be thrown into a work close at hand, and renders it possible to form a breach at a point concealed from view. The principal use of the ricochet fire is to enfilade the terrepleins of the faces, curtains, etc., and render them untenable, at the same time injuring or destroying the unprotected *matériel*. By this fire certain lines of the work would be taken in reverse. Ricochet fire can be used only when the works of the besiegers have not approached sufficiently near to interfere with the rebounds of the projectile. *In the attack*, and also *in the defense*, the importance of vertical fire cannot be overestimated, and too much care cannot be taken to render it effective. For this fire, shells from smooth-bored mortars have generally been used; but large shells and shrapnel with heavy bursting charges are now being introduced, thrown from rifled mortars, howitzers, and even guns. Although this fire is not effective in dismounting cannon and forming breaches, it is of the greatest value in reaching parts sheltered from direct and ricochet fires, in destroying magazines, barracks, bomb-proofs, and the masses of troops. In this way the enemy's positions can be thoroughly searched, and the fire of his artillery be diminished or even for the time suppressed, the latter requiring, however, a continuous fire from a large number of pieces. There is no time when the besiegers or even the besieged may not employ this fire, but on account of the limited extent of the besieged work it can be used to more advantage by the besiegers; they may be able to advance their works of attack without permanently silencing the artillery of the enemy, and light mortars can be placed in the most advanced works. The moral effect produced by vertical fire is far greater in proportion to its destructive effect than that of any other kind of fire. See *Ordnance; Siege-gun*, and *Siege-mortar*.

SIEGE-CARRIAGES.—The greatly improved facilities of late years for transporting heavy guns by railways, steamers, etc., have rendered it practicable to use for siege purposes guns which would have been regarded a few years ago as entirely beyond the range of possibility for such uses. At that time, a gun throwing a 30-pound projectile was the largest siege-gun to be found in any service, while now it would be difficult to fix a limit to the size of the guns that may be used against besieged places. The gun-carriage must of necessity conform to the gun for which it is constructed, and we see now constructed for siege purposes carriages which differ in no material point from those made for garrison and seacoast defense, so less clearly have the distinctions between the different classes of guns been defined.

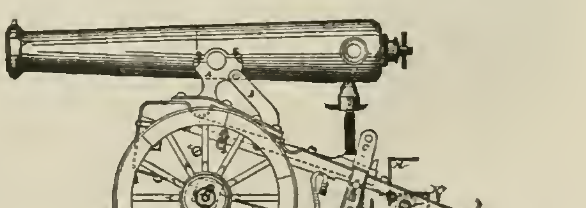
United States.—In this Service the siege-carriages are the 24-pounder and 8-inch howitzer-carriage; the 18-pdr. smooth; 30-pdr. rifle; 12-pdr. smooth, 4½-in. rifle; mortar-wagon; limber; and mortar-bed.



The construction of the siege-gun carriage is similar, in most of its details, to the field-gun carriage. It differs, however, in the greater strength of the parts, and in the mode of attaching to the limber, and by the absence of the parts used for carrying the implements. The position of the trunnion-beds is often such that when the carriage is limbered up, the weight of the piece is thrown too much on the rear wheels for convenience of transportation; another set of trunnions is therefore formed at the rear end of the cheeks, by enlarging the heads of the cheek-bolts, and the piece is shifted to them in transportation. They are called the "*traveling trunnions*." The breech of the piece rests in a groove formed in a block of wood, called the "*bolster*" and the elevating screw is disposed of by reversing it in its nut. To prevent it from unscrewing by the motion of the carriage, one of the handles is then slipped through a leather loop attached to the under side of the stock.

The same kind of limber is used for all siege-carriages. It is composed of a *fork*, the *pole*, the *axletree*, the *pintle*, the *hounds*, the *splinter-bar*, and also the *friction-circle*. The fork then constitutes the main part of this carriage, and to it are attached the pintle, the pole, the splinter-bar, the axle-tree, and the friction-circle. As the carriage is not subjected to the shock of firing, the axle-tree is not imbedded in wood to give it stiffness, as in the gun-carriage. The pintle is placed far enough in rear of the center of the axle-tree to enable the weight of the stock of the gun-carriage to act as a counterpoise to the pole, and give it steadiness when the carriage is in motion. The friction-circle acts as a sweep-bar for the *shoe* of the trail when the limber turns around its pintle. The attachment of the two carriages is secured by a lashing *chain and hook*. See *Siege-mortar Wagon*.

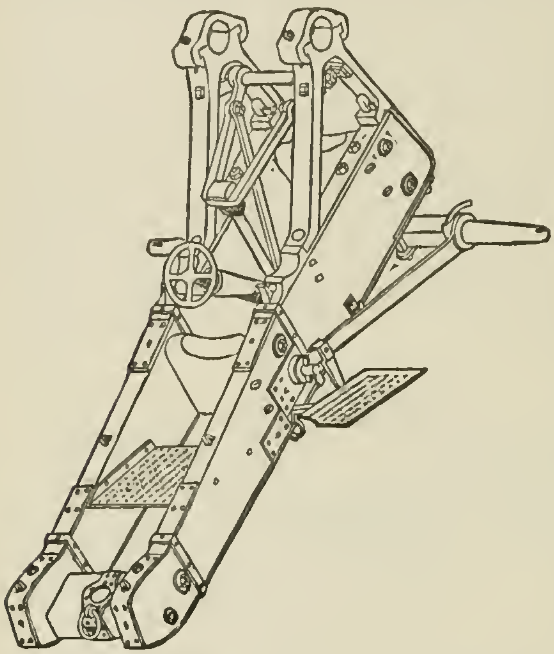
Austria.—With the view of affording greater protection to the gunners serving siege-guns, a modification has recently been made in the siege-carriage. This change consists in raising the gun about a foot and a half higher above the ground than in the old carriage. No new constructions have been made, but, to gain the proposed advantages of this new improvement at the least expense, it was determined to alter the old carriages on hand by adding to the height of the cheeks. This has been done by making a strong forged-iron frame which fits closely in the trunnion-bed of the old carriage, and has a trunnion-bed in its upper face. This iron frame is firmly bolted to the top of the cheeks of the old carriage, leaving it in all other respects unchanged. The frame is made in two parts, held very firmly together by a bolt. The elevating apparatus, instead of having a stationary female screw, has one attached to the movable elevating-quoin of wood resting between the cheeks, to which its front end is hinged by a bolt passing through the cheeks, so as to turn freely around it. The rear end of this quoin is held by another cross-bolt running through the two iron uprights *c* on the outside of the cheeks. There are three holes for this bolt in the cheeks and iron plates so that the position of the quoin may be shifted according to the elevation desired, affording a ready means of giving very different degrees of elevation to the gun, at the same time using only a short elevating-screw, by raising or lowering the seat of the female screw. Two separate female screws are attached to the elevating-quoin, so as to accommodate guns of different lengths, which may be mounted in turn on the same carriage, thus having only one carriage for the siege-gun and rifled howitzer. An iron



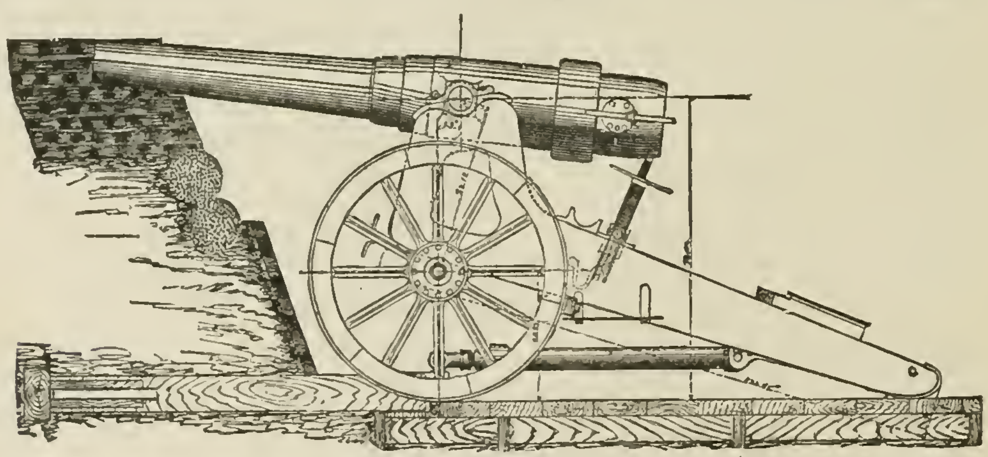
step, M, for the gunner is placed above the middle transom, and when not in use can be turned over in the position of M¹. This style of carriage is used for the 12-centimeter and 15-centimeter siege-guns and 12-centimeter howitzer. The axis of the piece is 62 inches above the ground. The carriage will admit of an elevation of 34° and depression of 17°. It weighs 3,540 pounds for the 15-centimeter (6-inch) gun, and 2,850 pounds for the 12-centimeter ($4\frac{3}{4}$-inch) gun. A wheel weighs 320 pounds. The width of track is 48.4 inches.

Height of the trunnions..................	72 inches.
Weight of the carriage with wheels...	2,750 pounds.
Width of track..............................	65 inches.

Germany.—The Prussian siege-carriage resembles much in its general appearance that just described. It is a wooden carriage of old pattern, well ironed with a strong wrought-iron frame firmly keyed and bolted to the cheeks, to support the gun, raising it high above the platform. The cap-squares are made



with projections which fit over lugs on the trunnion-beds, and are kept in place by an eye-pin. The elevating apparatus consists of one long screw with a wheel-handle, working in a female screw with long arms terminating in trunnions which fit in beds on top of the trail. The lower end of the screw turns in a collar secured to an upright on which the breech of the gun rests. The head of the upright is supported by two rods which turn on a cross-bolt just under



Prussian 15 centimeter Carriage.

the trunnions, and its foot by rods which are hinged to the first supporting-rods. The screw has an inclined position, and rises when the gun is depressed in rear of the breech. The gun may be elevated 31° and depressed 10°. The axle is iron, and is supported at the shoulders by two strong supports which connect it with the trail. Steps are provided, one between the sides of the trail for the gunner to stand on while pointing, and one on the side to enable him to mount on the carriage.

The Krupp siege-carriage for the 21-centimeter (8.26-inch) gun is made of wrought-iron and consists of a top-carriage and chassis, with a hydraulic buffer to check the recoil. The top-carriage is essentially the same as his carriage for sea-coast guns. The gun can be elevated from 6° depression to 26° elevation. The chassis differs in some minor particulars; it has an inclination of 4°; the rails are rolled each in a single piece; the front traverse-wheels are omitted; and the chassis has a bolster on the front transom, which rests on the pintle-plate, the pintle entering the bolster. The crane and hydraulic buffer are similar to those used in the sea-coast carriages. The traverse-wheels have the face hollowed out so as to fit over the traverse-circle (which is not flat but semi-circular in cross-section), and have holes in the face to receive the end of a truck-handspike to traverse the carriage. On the outer side of the rails, toward the front end, there is bolted to each rail a lifting apparatus, consisting of a screw worked by a wheel and worm, and an iron stirrup to receive a strong axle provided with a pair of large iron wheels, used in transporting the gun and carriage. The axle has a square body. The wheels have bronze felloes, shaped thus ⌴ and cast in sections; the spokes are iron rods.

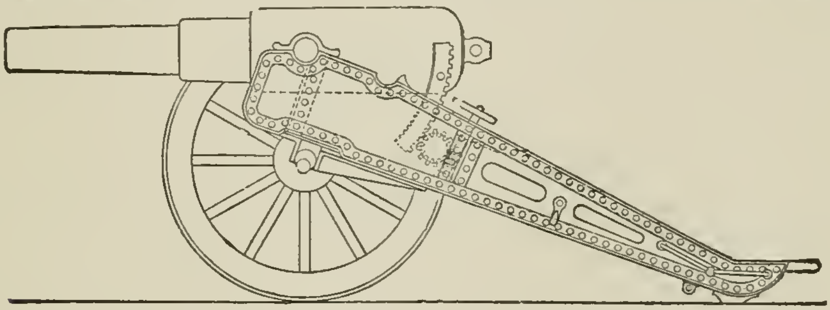
To prepare the carriage for transportation the top-carriage is run back nearly to the counter-hurters, the chassis is raised from off the pintle by means of the lifting apparatus, the transport-axle is secured in the axle-stirrup on top of the rails, and the transport-wheels are put on. These are 80 inches in diameter and have a 7 in. tread. The traverse-wheels are then removed, and the rear end of the chassis is raised and secured to the limber. The traverse-wheels may be then carried in another wagon to lighten the load of the gun and carriage. The crane is removed and secured against the side of the carriage. A shoe is provided to lock the wheel in going down hill. The platform is made of oak timbers bolted together. The cast-iron pintle-block and the traverse-circle are bolted to the platform. For transportation the platform is taken to pieces, and may be carried in an ordinary baggage-wagon. To establish the gun in battery, the ground is first leveled and rammed until it be firm, the platform is laid and the pintle-block and traverse-circle are bolted down: the gun is brought over the platform, the front bolster over the pintle, and the chassis supported by the lifting apparatus ; the transport-wheels and axle are removed, the traverse-wheels are put in place ; the limber is removed, and the chassis lowered in place.

	Pounds.
Weight of top-carriage	2,033
Weight of chassis	3,810
Weight of the gun limbered up	18,000
Weight of platform complete	4,586

The 15-centimeter (6-inch) carriage is made of wrought iron, except the wheels, which are of wood, with bronze nave-boxes. The cheeks, which are unusually high, the center of the trunnion-beds being 6 feet above the platform, and are made of boiler-plate, strengthened with angle-irons riveted all around the edge ; the cheeks continued to the rear, parallel to each other, and joined by transoms, form the trail. The traveling-trunnion-beds are placed on the trail, bringing the center of gravity of the gun, when it is on the road for transportation, as low as possible. The elevating apparatus consists of a single-screw with a rim-wheel handle, and a female screw with projecting arms terminating in trunnions which fit in journal-boxes in the sides of the trail. In order to obtain a great range of elevations without increasing inconveniently the length of the screw, two sets of journal-boxes are provided ; one on the top, the other in the sides of the trail. The carriage admits of elevations up to 35° and depressions down to 5°, with a screw of moderate length. The striking peculiarity of this carriage is the application of the hydraulic buffer for checking the recoil in carriages of this kind, by which means the recoil is controlled within the limits of about one yard. The cylinder of the buffer is placed under the middle line of the carriage, between the cheeks, to which its rear end is fastened by a cross-head, at a distance from the rear end of the trail of about one-third its entire length, and may be elevated or lowered within narrow limits. The piston-rod is fastened by a pivot-bolt to a timber anchored in the parapet, and can be moved vertically as well as horizontally to accommodate different positions of the carriage. An ordinary wagon-brake is provided to control the motion of the carriage down hill. It acts on the tread of the tire, and the pressure is applied by means of a screw attached to a cross-head on the front ends of the cheeks. Two iron brackets are fastened to the outside of each cheek, opposite the breech of the gun, for a step or platform for the gunners to stand on while loading the gun. The platform provided is the ordinary siege platform, laid down horizontally instead of sloping up to the rear end. Weight of carriage, 4,068 pounds; height of wheels, 62 inches.

Russia.—The Russian carriage is in most respects like the mortar-carriage, consisting of a top-carriage mounted on a wooden chassis. The cheeks of the top-carriage are made of a single thickness of boiler-plate about ½-inch thick for the 24-pounder-gun, strengthened by angle-irons riveted to it around its outer edge. The trunnion-plates are riveted to the cheeks. The transoms, six in number, are wrought-iron sleeves over the bolts which pass through the cheeks, and are held by nuts on the outside. The two rear bolts hold two iron stirrups, to which is attached a wooden block in which is placed the female screw for giving the elevation of the gun. The axle, which is large, with a square body, is placed close to the front edge of the cheeks. This is put in all carriages, whether used in garrisons or for siege purposes, though of use only for the latter. The wheels are made entirely of wrought-iron. The spokes, eight in number, are cut from two wide bars about one inch in thickness, leaving the bar at their middle uncut. The two pieces are placed, the one on the other, at right angles to each other, and firmly riveted together; an additional piece is riveted on each side, and a hole is bored through the four thicknesses which constitute the nave. There are no proper felloes, but the tire is in two pieces, each a complete hoop, the one shrunk on over the other. The tenons of the spokes extend through only the inner thickness. Holes are drilled through the tire, at regular intervals, for truck-handspikes. The chassis is composed of two wooden rails connected with transoms, just like that for the mortar-carriage, and rests on the platform without traverse-wheels or other mode of traversing than handspikes or snatch-blocks.

England.—The English siege-carriage is made like the field-carriage. The trail-plates have parts cut out so as to lighten them, and are riveted to the inner side of the angle-iron frame. The elevating apparatus is composed of a circular rack attached to the breech of the gun, worked by a pinion on the inside of the right cheek, a friction-wheel holding the rack against the pinion, which is worked by an endless screw with a wheel-handle projecting above the top



of the trail. The endless screw is inclosed in an iron box on the outside of the right cheek. The elevations that can be given are embraced between 35° elevation and 5° depression. An iron box is provided in the trail to carry the circular rack when the gun is in the traveling-trunnions. The lock-shoe and chain are on the left of the carriage. The limber is formed entirely of iron.

	40-pounder.	64-pounder.
Weight of carriage	2,744 lbs.	3,416 lbs
Weight of limber	1,246 "	1,246 "
Width of track		62 inches.

See *Krupp Sea-coast Carriages, Moncrieff Depression Carriages, Platforms,* and *Sea-coast and Garrison Carriages.*

SIEGE-GUN.—A siege-gun is constructed to throw a solid projectile with the highest practicable velocity, in order to penetrate the masonry of revetments, and to lessen the curvature of the projectile's flight, thereby increasing its chances of hitting objects but slightly raised from the ground. Rifled guns having been found to fulfill these conditions more fully than smooth-bored guns, they have entirely superseded the latter for siege purposes. A siege-gun, properly so called, is one that can be mounted on a siege-carriage which serves both for the purposes of transportation and for firing. Very large guns, as the 10-inch columbiad and the 8 and 10-inch rifle-guns were used in the siege operations of the late war, but they are not technically siege-guns, for no suitable carriages have been yet provided for their transportation over common roads. Whenever railroad or water communications will permit them to be transported, the largest guns may be employed in siege operations with great effect. The two siege-guns now in use in the United States, are the 4½-inche and the 30-pdr. rifles.

The 4½-inch rifle-gun is made of cast-iron, cooled from the exterior; the great length and small size of the bore rendering the water-cooling process impracticable. Its form is similar to that of the 3-inch field-gun. The principal weight and dimensions of this gun are as follows, viz.:

Designation.	No.	Lbs.	Inch.
Caliber	....	.. ....	4.5
Length of piece	....	....	133.

Horses to transp't (good roads)	8.	....	....
" " (inferior roads)	10.	....	....

This piece is mounted on the 12-pounder carriage, slightly modified and represented in the article *Siege Carriages*. The gun, on its platform, admits of 9° 30′ elevation and 10° 30′ depression. On level ground it admits of 12° elevation and 10° depression. By digging a trench for the trail to run in, a still greater elevation may be obtained.

The 30-pounder rifle-gun is made of cast-iron reinforced, after the plan of Captain Parrott, with a band of wrought-iron. Its bore is 4.2 inches in diameter, and its length about 28 diameters. Its weight is 4,-200 lbs., and it is carried on the 18-pounder siege-carriage. The weight of its projectile and charge of powder are the same as for the 4½-inch gun. It has no preponderance, and has been found to be a very accurate and reliable gun in service. See *Ordnance* and *Siege-Carriages*.

SIEGE-GUN BATTERIES.—Experience has shown that the 4½-inch siege-gun can readily accompany an army in the field and with almost the same facility as the 12-pounder. Its great range, power, and accuracy endow it with many advantage when used as a heavy field-piece, and it should form a portion of the artillery of every army organized for campaign purposes. For this service the pieces are organized into batteries of four or six guns each, and equipped after the manner of light field batteries. Each piece is furnished with two caissons of the usual pattern, having, however, only two partitions in each half-chest; these are parallel to and 4.5 inches from each side—the outer spaces for projectiles, the inner for cartridges. This arrangement allows 16 rounds for each chest, 48 per caisson, and 96 per gun. A tray in each chest serves to carry pouches, primers, and the fuses. One spare wheel is carried for the caissons of each two pieces. Caissons not carrying spare wheels, carry picket-ropes and forage. A picket-rope should be in sections; each section long enough to accommodate the horses of one piece and its two caissons, together with a proportional share of spare and other horses. This requires each section to be 35 yards long. The ends of the ropes should be provided with hooks; these, besides enabling them to be used more conveniently as picket-ropes, allow of their being used as drag-ropes for extricating carriages from any difficult places on the march. Light-artillery harness is used, but, owing to the weight of the pole, breast-hooks of extra strength are provided for the wheel-horses. The swing team being attached to lead-bars, wheel-traces are required for it.

The implements for the piece are as follows: Six *handspikes;* small ends under sweep-bar, resting on axle, large ends resting on splinter-bar, and secured by a leather strap passing from the hounds, through loops on the handspikes, to buckles on the fork; or by a rope passed through rings on the handspikes and around through staples of the hounds and fork. One *short-roller;* on the stock between theglunette bolts; secured by a rope passing through a hole in the axis of the roller and fastened to the stock. One *trace-rope;* two half-hitches in the middle around the cascable; the ends turned around the maneuvering bolts, and crossing to take up the slack. This secures the piece from sliding on its carriage. The sponge and rammer-heads are upon the same staff, which is cut to the shortest practicable length. Two sponges and rammers are allowed to each piece, and, together with one worm for each two pieces, are carried upon the sides of the piece, secured with two stout leather straps buckled around the chase and the body of the gun. The service of the piece, so far as sponging and ramming are concerned, is similar to that for light field-pieces. The sponge-bucket is carried in the same manner as for light field-pieces. One fuse-wrench, one fuse-gauge, one fuse-knife, one fuse-reamer, and one pair of gunner's pincers for each piece are carried in the trays of the limber chests of the caisson. A cartridge-pouch is used instead of a pass-box, and is carried by No. 4 suspended from the left shoulder to the right side.

Large and heavy horses, particularly for wheel-teams are used for the guns. Except where the roads are unusually good, ten are allowed to each piece. Each horse, both for piece and caissons, is provided with a nose-bag, carried as for a light field battery, and one watering-bucket is allowed for each pair of horses, carried—those for the pieces on hooks attached to the rear axle; those for caissons as in light artillery. One lifting-jack for each two pieces is carried on one of the caissons belonging to these pieces. The lifting-jack weighs 160 pounds, and is carried on a caisson having no spare wheel. Each caisson is supplied with axes, shovels, picks, paulines, etc., as for a light field battery. Two hundred rounds of ammunition are allowed for each piece, and that not contained in the caissons is carried in transportation-wagons. One spare gun-carriage, with limber complete, drawn by six horses, accompanies each battery. Three spare poles for the limber of the piece, ironed and fitted ready for insertion, are carried on the spare carriage. Each battery is furnished with a battery-wagon and forge. The spare carriage, battery-wagon, forge, ammunition, and baggage-wagons form a train, and, on the march, usually accompany the light-artillery train. The cannoneers carry their equipments and march by the side of the piece' as in a light field battery. In place of the shoe (which is entirely useless) a stout rope, attached to the ring-bolt of the lock-chain, is substituted. This rope is passed around the felly with two or three turns, is held by a cannoneer walking by the side of the piece. In this manner he is enabled to let the wheel go as it approaches the bottom of a descent.

The battery-wagon herein mentioned is that furnished from the arsenals; but,being cumbersome and quite unsuitable for field service, it is better to utilize its body and limber-chest by placing them on the running gear of the army transportation-wagon. The limber-chest can be attached to the front part of the wagon-body by strong iron brackets, and serves as a seat for the driver. A similar chest can be placed in like manner, on the rear end in place of the forage-rack. In the front chest is carried all the carriage-maker's outfit, and in the rear one that of the saddler. On the middle of each side of the body may be attached a small chest for horse medicines, or for such other small articles as may be required of easy access. When the wagon is thus arranged it is as easily drawn by four horses as the other by six, and one driver, using double lines, is sufficient. The arrangement for attaching the draught-horses to siege-gun carriages being similar to that for the army transportation-wagon, the harness used with the latter will answer for the former. A driver is required for each pair of horses, as in light field-artillery.

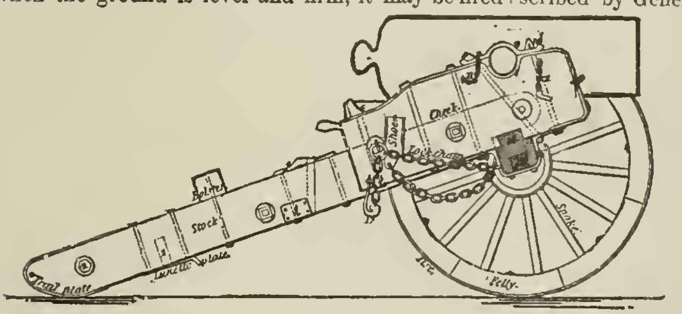
SIEGE-HOWITZER.—The *siege-howitzer* is principally employed for a *ricochet* firing, and for the purpose of battering the earth and fragments of masonry which are left standing after the fire of the breaching guns has ceased.

The following table shows the principal weights and dimensions of the 8-inch United States Service howitzer:

Designation.	No.	Lbs.	Inch.
Caliber			8.
Weight		2,600.	
Length			60.
Diameter (maximum)			17.5
Diameter (minimum)			15.
Length of bore (calibers)	5.81		
Windage			9.12
Charge (cannon powder)		4.	
Shell (empty)		45.	
Preponderance		380.	
Weight of piece, carriage, limber, and implements		6,660.	
Horses to transport	8.		

The bursting charge of the shell is one pound, and the charge to blow out the fuse-plug is four ounces. The howitzer on its platform admits of 13 degrees elevation and 10 degrees depression.

In works, it is fired from a wooden platform; but when the ground is level and firm, it may be fired without. It is used chiefly in field-works for flank defense.



The size of the trunnions and the distance between the rimbases are made the same as in the 24-pounder gun, that it may fit the 24-pounder siege-carriage, in which case a *quoin* is used for elevating instead of the ordinary screw. It would be an improvement in the working of this piece were it without preponderance. It has the advantage over the old siege-howitzer that the projectile always rests in contact with the powder, however small the charge, and the consequence is that the ranges are greater for the smaller charges.

This piece fires mortar-shells, spherical-case, grape and canister shot. By taking off the wheels of the carriage, and reversing the piece in its trunnions, and supporting the whole with strong timbers, this piece may be used as a mortar, in which capacity it gives very long ranges. As it is sometimes fired over the heads of men in the advanced trenches, no sabot or cartridge-block should be used in it except for canister. See *Siege-gun*.

SIEGE-MORTAR.—Siege-mortars comprise the *common mortars* and *Coehorn mortar*. The stone mortar was formerly used for siege purposes, but is now laid aside. The common siege-mortars are of two sizes, the 8 and 10-inch, so called from the diameters of their bores. They have no preponderance, and elevation and depression are effected by a lever the point of which acts in a ratchet cast on the breech. The fulcrum of this lever is attached to the rear transom of the mortar-bed. The chamber is elliptical as in the siege-howitzer, and for the reason given in the description of that piece, all the new mortars give longer ranges than the old ones. The bores of these mortars are about two diameters long,and the weight about 22 times that of the projectiles, respectively. To prevent the primers from pulling out of the vent, there should also be a grooved pulley attached to the *clevis-lug* for the lanyard to pass over. The vertical field of fire lies between 30° and 60°. The angle at which mortars are often fired is 45°. This gives very nearly the maximum range for a given charge of powder. The exterior form of the siege-mortars is cylindrical; consequently the natural line of sight is parallel to the axis of the bore,—a position of great convenience in aiming. The line of sight should be permanently marked on the piece while it is in the boring-mill.

Siege-mortars are used to attain those portions of a work,by vertical fire,which are defended against the direct and ricochet fires of guns and howitzers, such as the covered-way, the ditch with its communications,and the roofs of magazines,casemates, etc. The projectile principally used in mortars is the shell, which for the 8-inch weighs 44 lbs., and for the 10-inch 88 lbs. General Bormann, of the Belgian Army, some years ago proposed to convert the 10-inch mortar-shell into a spherical case-shot by filling it with balls about the size of 12-pdr. canister-shot, and a bursting-charge sufficient to rupture the shell; the fuse to be timed so that the projectile would burst about 50 feet from the ground. The effect of such projectiles at the siege of Petersburgh is thus described by General Abbott, the Commander of the siege-batteries: "This battle was probably the first in which spherical case-shot from heavy mortars was used. The expedient of putting the thirty 12-pdr. canister-shot under the bursting-charge of the 10-inch shells was of great utility,their fire keeping quiet the most dreaded flanking batteries of the enemy's line." From its lightness,and consequent mobility,the 8-inch mortar may be usefully employed in reaching an enemy sheltered by temporary field-works. See *Eight-inch Siege-mortar Mortar*, *Siege-gun*, and *Ten-inch Siege-mortar*.

SIEGE-MORTAR WAGON.—The mortar-wagon is employed to transport siege projectiles, mortars and their beds, and spare guns. It is composed of a limber and a body. The body consists of two middle-rails, united so as to form the stock, and two side-rails. These pieces rest upon the axle-tree, and are strongly connected together by cross-pieces of wood and straps of iron. At the rear of the body is placed a windlass, which aids in the mounting of guns and mortars. Stakes are placed around the sides of the body, to sustain the side and end boards which are used in transporting projectiles.

The lightness of the mortar, and the high angle under which it is fired, render it unsafe to be fired from a carriage; it is therefore, mounted on a bed, which rests directly on a platform. The siege-mortar-bed is made of wrought-iron. The different parts are the cheeks and the two transoms which connect the cheeks together. There are two projections at the end of each cheek, underneath which the handspikes are placed for moving the bed in aiming; also one maneuvring-bolt, for the same purpose. The sea-coast mortar-beds have an eccentric truck-wheel for facility of maneuver. To insure accuracy of fire with heavy guns and mortars, it is absolutely necessary that their carriages and beds should rest upon solid and substantial platforms. The platforms for siege-pieces, being transported with an army, should have the greatest lightness compatible with strength to endure the shocks of long-continued firing.

SIEGE–TRAIN.—The men, guns, and material collected together for the conduct of a siege. The following shows the proportion of *personnel* and *matériel* of a siege-train of 105 pieces.

55 rifled 64-pdrs. } on traveling-carriages
20 rifled 40-pdrs. } with siege-limbers ;
30 rifled 8-inch howitzers on traveling-carriages.

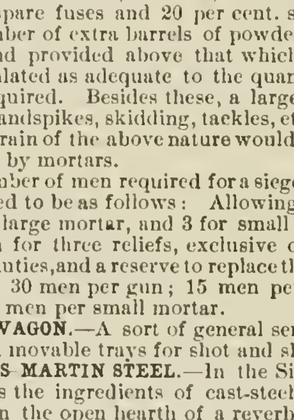
The number of rounds per gun, as well as the charges to be employed, varies according as these are intended for direct, ricochet, or curved fire. Ten per cent. spare fuses and 20 per cent. spare tubes, and a number of extra barrels of powder, should be allowed and provided above that which may have been calculated as adequate to the quantity of projectiles required. Besides these, a large proportion of guns, handspikes, skidding, tackles, etc., are provided. A train of the above nature would be also supplemented by mortars.

The number of men required for a siege equipment is computed to be as follows : Allowing 10 men per gun, 5 for large mortar, and 3 for small mortar, the proportion for three reliefs, exclusive of magazine and store duties, and a reserve to replace the casualties would be : 30 men per gun ; 15 men per large mortar; and 9 men per small mortar.

SIEGE WAGON.—A sort of general service-wagon fitted with movable trays for shot and shell.

SIEMENS-MARTIN STEEL.—In the Siemens-Martin process the ingredients of cast-steel are melted together on the open hearth of a reverberatory furnace of special construction, and a certain proportion of manganese necessary to make a sound and practically malleable steel added. The usual plant consists of a gas-producer, regenerators, furnace, auxiliary reverberatory furnace, with ingot-molds, etc.

The gas-producer, shown in the drawing, is a large chamber of triangular section, capable of holding



several tons of fuel. The charging is effected through a hopper at the charging-hole, A. The coal travels slowly down the inclined wall, B, becoming gradually heated, and parting with its volatile matters until it reaches the narrowest part of the grate. The combustion here goes on slowly, the small amount of carbonic oxide produced being immediately decomposed by the thick column of incandescent fuel above so that the contents of the chamber are gradually converted into inflammable gas, chiefly carbonic oxide, which, diluted with the nitrogen of the air remaining after combustion, is subsequently employed as fuel. The gas evolved from the producer passes through the valve, G, into the stack, H, whence it issues at a temperature of about 200°. In traversing the horizontal pipe, P, it loses one-half its heat so that its density is sufficiently increased in the descending pipe to establish a continuous draught from the gas-producer towards the furnace without the use of a special chimney.

The regenerators are placed under the furnace, and are four in number, two for the air and two for gas. They consist of vaults built in the foundation, which are filled up with fire-brick closely stacked, so that a large number of small rectangular openings are left between them, forming chambers for the blast and gases to circulate. They are worked in pairs, two being heated by the waste flame, while the others are giving up their heat to the cold air and gases ; owing to the large amount of surface presented by the bricks, the absorption of the surplus heat is effected with comparative rapidity, and the temperature of the current escaping to the chimney is reduced to the boiling point of water : they all communicate with the furnace at one end, and at the other end they are fitted with valves by the reversal of which they communicate either with the chimney carrying off the products of combustion which have parted with their heat to the bricks, or with the pipes of air and gas to which they give up their heat, thus raising the temperature of the blast and the fuel to a very high point before they enter the furnace. As soon as the brick-work has attained the proper temperature in two of the chambers, the current is turned into the adjoining pair by reversing the valves, and the heat accumulated in the brick-work is abstracted by cold air passing through one and gas through the other until the second pair is heated, and so on the process being kept up continuously notwithstanding the intermittent action of the regenerators. The bed of the furnace is flat, and is made of fine sand consolidated by pressure and strong heating, and supported on cast-iron plates, which are kept cool by a circulation of air underneath. The bed has a slight inclination towards the tap hole, which is generally placed in the middle of the furnace at the back. The furnace has a bridge at each end, which becomes alternately the fire-bridge and flue-bridge. There are three or four working-doors on the front, which are used for charging. The casting trough or ladle, and ingot, are worked in much the same manner as in the Bessemer plant, except that the ladle is attached to the furnace, and the ingot-molds are arranged on a revolving platform, by means of which they are brought successively under the ladle.

The materials for charging are pig-iron, steel, and wrought-iron scrap, and spiegeleisen or ferro-manganese. The proportions of the different material charged are determined by the requirements of the steel to be made. The charges weigh from 2 to 8 tons depending on the size of the furnace. All the materials are heated to a bright red in the auxiliary furnace. The pig is charged first and is soon melted, as soon as it arrives at a white heat, the wrought-iron or steel is added in charges of about 200 pounds at a time, each charge being raised to a white heat by exposure to the stream of gases at the flue-bridge before being immersed in the bath. After two or three additions, ebullition commences and continues till the carbon is wholly removed from the pig. The exact condition of the metal is ascertained from small proofs taken from the charge after each addition of iron towards the end of the operation. These are run into a small ingot-mold, and when cooled to the proper heat, hammered into a plate about ⅜-in. thick, and 5 in. wide. When the decarbonization is completely effected, these proofs will bend double cold, and show a fracture quite fibrous. A quantity of manganiferous pig, from 40 per cent to 10 per cent. of the charge, according to the desired hardness for the steel, is then added. When this is melted, the bath is stirred to insure homogeneity, and the final proof taken, which is treated in the same manner as the others, and gives reliable evidence of the state of the metal before pouring. This enables the quality to be adjusted to the degree of hardness required; should it be too soft, more pig is added; should it be too hard, waiting for a quarter of an hour will materially soften the material. When the metal is brought to the required condition, it is tapped off into ingot-molds.

In the Bessemer process the steel produced from a given charge of pig is less than the quantity of pig used by some 15 per cent, and to this extent any impurities are concentrated, and therefore proportionately greater in the finished product. In the Siemens-Martin process, on the other hand, the weight of the finished product is about equal to the pig-iron charged, the loss of the latter being made up by the reduction of the pure ores charged into the bath; and under these circumstances there is no such concentration of the original impurities of the pig. See *Bessemer Steel* and *Steel.*

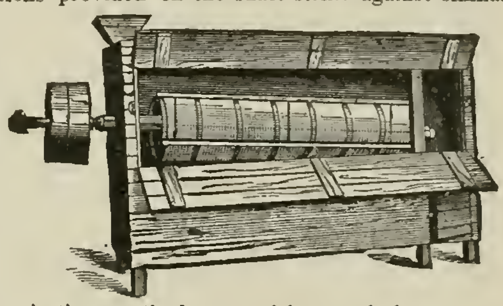
SIEMENS REGENERATIVE GAS-FURNACE.—A furnace much used in the making and melting of steel, and noted for its economical consumption of fuel. It consists of two parts: one of these contains the "Regenertors," or, as Dr. Percy calls them, the "Accumulators;" the other, which may be either quite near or more than 100 feet apart, contains the "Gas-producers" or source of the heat. In the regenerative portion, when the furnace is to be employed for the production of iron or steel, there is a melting-hearth or bed. Immediately below this hearth there are two pairs of arched chambers filled with fire-bricks placed sufficiently far apart to let air or gases pass freely between them, and at the same time expose a large surface to absorb heat. One pair of these chambers or regenerators communicates by separate flues with one end of the hearth, the other pair with the opposite end of it. Thus we have in duplicate, so to speak, a chamber through which gas and another through which air can be admitted. The furnace being in operation; while the gas and air are being admitted to the hearth through, say, the left pair of these chambers, the highly-heated products of combustion pass through the open brick-work of the corresponding pair on the right before reaching the chimney. What would pass up the chimney as waste heat in an ordinary furnace is thus absorbed by the bricks of the regenerators. After a given time—usually from 30 to 60 minutes—by means of suitable pipes and valves, the arrangement, or if we may so call it, the current, is reversed. Gas and air are now sent through the freshly-heated pair of regenerators, while the "waste heat" in turn passes into the other pair. In this way, by reversing the valves at intervals, hot currents of gas and air, in suitable proportions, are always reaching the hearth where combustion is effected at a very high temperature.

The advantages claimed for this furnace are:—1. Saving of fuel, amounting to 40 to 50 per cent. in the quantity, besides which inferior qualities of fuel, such as slack, coke-dust, lignite, and peat may be employed, producing a money saving in many instances amounting to 75 per cent. 2. Unlimited command of heat without intense chimney draught, owing to the principle of accumulation involved. 3. Great purity and gentleness of flame, which greatly diminishes the oxidation or deterioration of the material heated in the furnace and improves the quality of the produce. 4. Increased durability of the furnace and the perfect uniformity of the heat throughout the furnace. 5. Saving of space within the buildings and great cleanliness of operation, the fuel being converted into gas in the yard. 6. Complete and immediate command of the intensity of the heat and of the chemical nature of the flame, which may instantly be changed from a reducing to an oxidizing flame, or the reverse; thus tending to facilitate and improve all metallurgical operations. 7. No smoke from the stack, owing to the perfect combustion of the fuel, which renders this furnace beneficial to the public in all the large towns.

This furnace was, however, found at the time to be expensive in prime cost and somewhat costly in repairs. In the manufacture of ordnance continued changes in the direction of increased weight are often made. It thus becomes unadvisable to be hampered with an elaborate system of furnaces very difficult to adapt to ever-varying conditions. Under more stable conditions in the future, it may become desirable to revert to this system. See *Furnace.*

SIEVE.—A netted utensil for separating the smaller particles of substances from the grosser. In the manufacture of gunpowder, sieves are indispensable for separating the different sizes of grain. They are made of wire of different dimensions, and are known by the number of meshes to the linear inch.

SIFTING-REEL.—A machine employed in the manufacture of gunpowder. After the materials, whether saltpeter or sulphur, are ground they are shoveled into tubs and emptied into a hopper placed above a sifting-reel, which is similar in all respects to the charcoal-reel. As the reel revolves, certain projections provided on the shaft strike against similar



projections on the bottom of the trough that conveys the material from the hopper to the reel, and as this trough is slung under the hopper it is made to vibrate and cause the material to be shaken gradually from the hopper to the reel. The fine particles pass through a wire cloth of thirty-two meshes to the inch and fall into a bin provided; the coarse particles are thrown out at the end into another bin, whence they are taken and reground. See *Gunpowder*, *Saltpeter*, and *Sulphur.*

SIGHT.—1. The power of the eye for distinguishing objects far and near. In judging distances, good eyesight is most necessary; in fact defect in a soldier's vision renders him unable to shoot, and no recruit should be admitted into the Service if the power of his eyesight is not adequate to meet the demand made upon it consequent on the increased range of small-arms of the present day, the length of which is about 1,000 yards. This maximum range, or even an intermediate one, requires that the soldier who uses such weapons shall have a clear vision, and shall be able to judge correctly the distance of an object, the size of a man, in any position up to that extent of range. The Medical Officer who examines the recruit is able to judge of his fitness or otherwise for the Service as regards his eyesight, and is responsible that, before the recruit is admitted, he has undergone the proper examination and test.

Good eyesight recognises masses of troops at 1,700 yards. At 1,300 yards, infantry may be distinguished from cavalry, and the movements of troops may be seen, but the horses of cavalry are not quite distinct. A single individual may be seen at 1,100 yards, but his head does not appear as a round ball beyond 700 yards. At 600 yards, white cross-belts may be seen. At 500 yards, the face seems a light-colored spot; the uniform head, body, arms, and their movements, can be made out. At 250 yards, buttons may be seen, and officers distinguished from men. Officers with bright scabbards and men with fixed bayonets can be discovered, on a clear day, at a distance of 1,500 yards. 2. A small piece of metal, fixed or movable, on the breech, muzzle, center, or trunnion of a gun, or on the breech and the muzzle of a rifle, pistol, etc. by means of which a gun is levelled on the object to be struck. In smooth-bore guns, *quarter-sights* are cut on the upper quarter of the base ring, and numbered up to 3°.

Heavy smooth-bore ordnance are provided with *Millar sights*, which consist of a graduated tangent-scale at the breech, and a dispart sight in front of the second reinforce. A wooden tangent-scale is also used for elevation over the *clearance*-angle.

Heavy B. L. R. guns (Armstrong) are sighted with a *barrel-headed* and a *trunnion* sight on each side of the piece; the barrel-headed sight is held in a tangent-ring or in a socket according to the nature of the gun, the slots of the tangent-ring inclining to the left at an angle of 2° 16.′

A *barrel-headed sight* consists of a bar, elevating-nut, cross-head, two thumb-screws, and leaf. The whole is made of gun-metal, except the bar, which in most guns is made of steel. The bar is graduated on one side in degrees, on the other in yards. The degrees are divided into 6 parts of 10′ each, and any number of minutes up to 10′ each can be given. The cross-head is horizontal, and is graduated to give ½° of the deflection either to the right or left, and this ½° is also divided into three parts of 10′ each on both sides; at each end of the slide is a graduated nut divided into minutes up to 10,′ and these nuts are connected by a screw crossing the bar at right angles. A leaf with the sight-notch slides along the scale, and can be moved either right or left by either nut. These sights will become obsolete, on the guns to which they are attached being no longer required.

The *trunnion-sight* is of two kinds, viz., *drop-sight* and *screwed-in-sight*. Certain guns have the former, other guns the latter. The drop-sights consists of a gun-metal socket, collar, and pillar, and a steel leaf. The socket fits into the gun, the collar locks into the socket, and the pillar, at the top of which the leaf is screwed, fits into the collar. The *screwed-in* sight is made of steel, and has a steel leaf dove-tailed into its top and screwed into a hole above the trunnion. The leaf is hog-backed in shape, and its rear surface roughened to prevent the reflection of the light interfering with laying the gun.

The sights attached to heavy English M. L. R. guns are very similar to those of breech-loaders, with this difference, that, instead of the barrel-headed sight, they have a simple cross-head with sliding-leaf and clamping-screw attached to the *tangent-sight* bar, This sliding-leaf head gives 30′ deflection right or left, and is only for use when one wheel is higher than another, or to allow for wind or some other inaccuracy. They have also a trunnion fore-(drop) sight on each side of the gun, an hexagonal tangent-scale (graduated to 5°), and a dispart or fore-(drop) sight on top of the piece; the breech tangent-sights fit into sockets let into the side of the breech, and are inclined to the left, like those of a B. L. R. gun, but at different angles, the inclination of sight for the 7-inch gun being 3°, for the 8-inch 23′, for the 9-inch 44′, and for the 10-inch 1° 10′. The 64-pr. and 80-pr. converted guns are each provided with a breech and trunnion-sight on each side of the gun, but they have no top-sights; a wood side-scale is also supplied. The 64-pr. wedge-gun (Armstrong) has an *hexagonal brass sight* (tangent-scale), graduated to 5°, and a dispart or fore (drop) sight; the former on the top of the breech, the latter on the top of the trunnion-ring. The 40-pr. and 25.-pr. are side-sighted, having two tangent-sights and screw trunnion-sights of the usual pattern. The field-guns are sighted as follows: The 16-pr. is side-sighted, and has two tangent-sights set at 1° 50′ to the left, and two steel trunnion-sights screwed in. The tangent-sights have rectangular steel bars with gun-metal sliding-leaf heads, and are graduated with degree, yard, and fuse scales. The 9 and 7-pounders are central-sighted.

SIGHT-POUCH.—A long, slender case, used sometimes for carrying the breech-sight. It is suspended from the shoulder.

SIGNAL-ROCKET.—This rocket, designed specially for signalling has a cylindrical case of paper or metal, *a*, as shown in the drawing, attached to one extremity of a light wooden rod, *f*, and containing an inflammable composition, *b*, which, being fired, shoots the whole of the arrangement through the air, by the principle that an unbalanced reaction from the heated gases which issue from the openings in fireworks, gives them a motion in the opposite direction. The principal parts of a signal-rocket are: the case, *a*; the composition, *b*; the head, *c*; the decorations, *e*; and the stick, *f*.

The case is made by rolling stout paper covered on one side with paste around a *former*, and at the same time applying a pressure until all the layers adhere to each other. The vent is formed by choking one end of the case while wet, and wrapping it with twine. The paper case is covered outside with paste, and enclosed in a cylindrical case of tin, $1\frac{3}{16}$ inches in diameter and 9 inches long. The lower edges of the tin case are turned under slightly, to keep the paper case from going through.

A variety of compositions are employed for signal-rockets; the best can only be determined by trial, as it varies with the condition of the ingredients. The following proportions are used in the Naval Laboratory.

Niter	4 lbs. 8 oz.
Sulphur	1.2 oz
Charcoal	2 lbs.
Mealed powder	4 oz.

To increase the length and brilliancy of the trail, add steel or cast-iron filings.

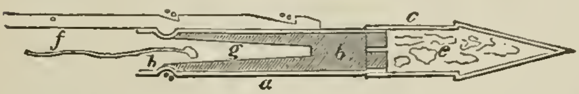
The case is placed in a bronze mold, which has a conical spindle attached to the center of its base to form the bore, *g*. This spindle is made of steel, $6\frac{1}{2}$ inches long, and goes up through the vent into the center of the case, having a hemispherical bottom to fit the choke, *h*. The composition is driven with a screw-press regulated to a pressure of about 5 tons. The first and second drifts are made hollow to fit over the spindle, and the third is solid. A small ladleful of pulverized clay is first put in and pressed down around the spindle, forming a bottom ¼-inch thick. The composition is next put in, a ladleful at a time, each one pressed down separately. The top of the case is closed with clay, which is one diameter thick, and perforated with a small hole for the passage of the flame from the burning composition to the head; through this hole a strand of quick-match is placed.

The rocket is primed by inserting one end of the strand of quick-match, about eight or ten inches long, through the vent into the bore, and coiling the remainder in the recess formed by the choke. A piece of paper is pasted over the end to protect it.

The head is formed by a tin cylinder $1\frac{3}{16}$ inches in diameter and $2\frac{1}{2}$ inches long, joined to a hollow tin cone $2\frac{1}{2}$ inches high, making the length of head 5 inches. The long tin case goes about ½ inch into the cylindrical part of the head, and a piece of paper is pasted over the joint. The object of the head is to contain the decorations, which are scattered through the air by the explosion which takes place when the rocket reaches the summit of its trajectory. The explosion is produced by a small charge of rocket composition, which is put into the head with the decorations. When the composition is consumed, the bursting-charge explodes the head and ignites the decorations, which, falling, produce a brilliant light that can be seen at a great distance.

Stars for decorations, are formed by driving the composition moistened with alcohol and gum arabic in solution in port-fire molds, or molding it in brass cylinders of the desired diameter. It is then cut into short lengths and dredged (sprinkled) with mealed powder. The gum arabic is intended to give such consistency to the stars that the explosion of the head of the rocket may not break them in pieces, thereby destroying the effect. The following is the white star composition:

Niter......	$3\frac{1}{2}$ oz.
Sulphur...	$1\frac{1}{2}$ oz.
Mealed powder...	$\frac{3}{4}$ oz.



The stick is a tapering piece of pine, about nine times the length of the case, and the large end is tied to the side of the case, so as to guide the rocket in its flight, as it has no rotary motion. The common center of gravity of the rocket and stick is a little below the former. The stick counteracts by the resistance of the air upon it and tendency to turn over, and so maintains the rocket, during its flight, as nearly as possible in the direction in which it is fired.

The object of having the cavity or bore in the interior of the rocket is, that a large surface of composition may be at once ignited when the rocket is fired, and so great a quantity of gas generated in the case that it cannot escape from the vent as quickly as formed, and it therefore exerts a pressure in every direction on the interior surface of the rocket. The pressures on the sides of the rocket mutually balance each other, but the pressure on the head is greater than that on the base, in consequence of the escape of gas from the vent; it is in this excess of pressure on the head over that on the base which causes the rocket to move forward, this being merely a similar action to the recoil of a gun. The force which produces motion in a rocket is therefore different from that which acts upon a projectile fired from a piece of ordnance; the former is a *constant* force producing accelerated motion in the rocket until the resistance of the air is equal to the force or the composition is consumed; while the latter may be considered merely as an impulsive force, which ceases to act upon the projectile when it has left the bore of the piece.

A few rockets are always kept mounted and ready for use. To fire a rocket, the stick is placed in a *trough*, or in a tube, as a guide; a musket-barrel will answer the purpose. The paper covering the bottom is torn off, exposing the priming. Holding the guide vertical or nearly so, a slow-match is applied to the priming, which ignites the composition. The inflamed gas issues violently from the bottom of the case as the rocket ascends.

The time of ascent is from 7 to 10 seconds, and they will attain a height of about 500 yards.

Under favorable circumstances a signal-rocket may be seen within a circuit of from 30 to 40 miles. In mounting rockets the stick is attached so that it will hang end down, when supported, close up alongside the bottom of the rocket. See table on page 86.

SIGNALS.—Signals are the means of transmitting intelligence to a greater or less distance by the agency of sight or hearing. Incomparably the most powerful medium yet known for this purpose is the electric current. Sound-signals are obviously but a short circuit. The electric current requires fixed apparatus establishing an actual communication between the two points; and is therefore inapplicable to the ordinary cases of ships interchanging signals with each other or with the shore; and, except under unusual circumstances, it would not apply to armies maneuvering in the field. For these purposes, so far as present knowledge extends, signals by sight or sound must always be the resort. The ancients seem to have elaborated a fair system of night-signals by torches for military purposes; but in naval affairs the ships sailed so close together that orders could be communicated by word of mouth, while the turning of a shield from right to left sufficed as sailing directions to the several lines. In modern times signaling between ships has become indispensable; but there is probably no department of practical science in which progress has been slower, and every so-called system of signals has been distinctly without any system whatever. In the time of James II. a signal could only be expressed by flags, in confusing number, hung in different parts of the vessel. By the beginning of the present century, thanks to Sir Home Popham and other inventors, the system had been adopted of hanging a number of flags under one another, each symbol or combination thus employed having an arbitrary conventional meaning attached to it. Alterations in the specific flags have been made from time to time, but essentially this is the system now in use. The flags are either square, triangular of the same length, or pendants which are pointed and longer. These are of black, white, red, blue, and yellow (in the Austrian Service alone green is added) in mass

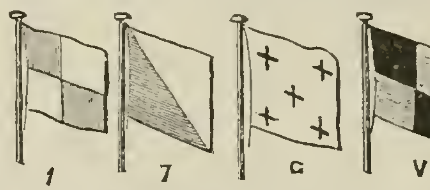


Fig. 1.

or in combination. Specimens of the flags in use are shown in Fig. 1. The signalmen find, however, that at a distance blue, red, and black are not readily distinguishable, nor yellow from white. It has consequently been the recent tendency, and apparently most justly, to reduce all the signs to black and white, singly or in combination, trusting to shape for the different signals. There are, however, disadvantages at

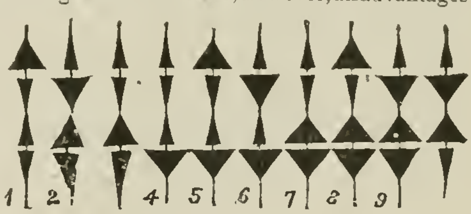

Fig. 2.—Cone System.

tending flags. In a still day they are difficult to read; or the wind may so blow that they will be only seen end on. At sea the motion of a ship will generally neutralize these drawbacks; but the case is otherwise on shore, and it may consequently occur that the ship can communicate to the land, but cannot get a reply. To obviate this, signals representing solid

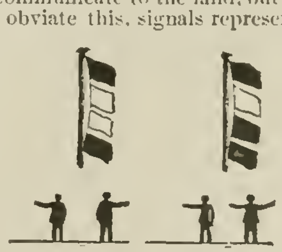

Fig. 3.

figures are sometimes employed. To fulfil their conditions they must appear the same in whatever lateral direction seen. But this limits the shapes to cylinders, cones, and the sphere, or the combinations of those figures; and as the total number of distinguishable signs is reduced, signaling becomes reduced from the word-signal to the telegraph. This distinction should be clearly understood, as much is involved in it. A word-signal, as in the present system, is where the whole word or message is sent up at once, and flies simultaneously; a telegraph signal is one in which the letters composing the word or numbers representing the signal are shown separately, and each is removed before another is shown. At sea the word system is best, for it involves no act of memory; and memory, even from signal to signal, is found difficult by signalmen in the turmoil of perhaps storm or fighting. On the other hand, the telegraph system involves far simpler apparatus, and the changes can be effected more rapidly. As regards the actual time required for a message, the word-system has the advantage in a message short enough for the whole to be shown at one time; but otherwise the difference

The following table shows the dimensions and weights of rockets and their ornaments :—

	Interior diameter of rockets.

is not material. If all advantages be balanced, it is probable that the telegraph system will eventually supersede the other entirely. Whether the word or the telegraph system be practiced, another question is, whether to spell each word, or to use numerals and a code. Under the latter principle about 14,000 of the words and sentences most commonly sent are arranged for easy reference in the signal-book. With the addition of 1 or 2 repeating symbols the 9 numerals and 0 give combinations 4 together to this number. A combination of figures is arbitrarily assigned to each expression; and the expression is communicated by representing those figures in their proper order. With the book of reference at hand, and an intelligent signalman, there can be no very great doubt of the superior rapidity of the "code." A code has also this further advantage, that, the signals representing things and not words, it can be made international, the same symbols representing the same idea in every language. It is then only necessary for universal signaling that each nation should concur in the meaning to be attached to the several signs. Many gentlemen of ability have devoted their attention of late years to the simplification of signals among whom conspicuous positions must be assigned to Colonel Grant, Colonel Bolton, Mr. Redl, and Captain Colomb, R. N. Their principal object has been so to simplify the telegraph system that signals may be made with any apparatus, or without apparatus at all. To accomplish this they have, to a great extent, abjured all color and resorted to form and motion. Among the form telegraphs there is the principle of the old semaphore, in which each letter or number is shown by the position of two arms. The arms are heavy, and involve mechanism; besides which they are not always clear on a ship in motion beyond a short distance. Very superior in visibility and simplicity is Redl's System of Cones. This consists of 4 cones fixed to a mast. The cones are collapsable, and are formed in a similar manner to umbrellas. Their usual condition is shut, and they can only be held open while a rope attached to each is pulled. With cones of 3 feet base, signaling is rapid and clear up to 5 miles, and the mast can be inserted at any place. The system is very simple: each cone represents a number, 1, 2, 3, or 4; then 1 and 4 shown represent 5; 2 and 4, 6; and so on, as in Fig. 2. This very elegant system can be applied in military or naval operations. But its chief beauty is that a person understanding it can make the same signals without the cones; for example, if a black flag represent an open cone, and a white flag a shut cone, a ship with 4 black and 3 white flags can make every signal. Again, the arm raised horizontally may represent the open cone; against the body, the shut cone; then two men standing on a cliff are as good as any signal-post—see Fig. 3. Or if one person only be present, he may represent an open cone by raising his arm with a handkerchief extended, and a shut cone by his arm without the handkerchief. He has only then to raise his arm four times in quick succession, with or without the handkerchief, to make the required signal. We have thus arrived at a universal system of the utmost simplicity, which in war, and especially during invasion, might be of inestimable benefit to the nation. The code of signals cannot be generally diffused by the Government. It only remains to apply the same system to night-signals. The old naval principle has been to hang dingy lanterns in various shapes—triangles, squares, crosses, etc. Besides requiring large bases to be at all visible, this has been found from the motion of a ship to be nearly useless. Redl's system has been applied by hanging four lanterns in a vertical line to represent the cones, and obscuring those which corresponded to shut cones. An improvement was found in introducing a red or green light in the middle, to show the relative positions of the four. The best night-signals are, however, flashing lights, as introduced by Colonel Bolton, and more elaborately by Captain Colomb, and adopted in the English Navy. This consists of a bright light, covered over by a shade, which shade, by mechanism can be lifted for any given time, exposing the light meanwhile. A flash of about half a second's duration is negative: a line of 1½ seconds, positive. Four exhibitions of the light then represent a symbol as in Redl's cones. It will be seen that this system produces results similar to Morse's electric telegraph. If the distance be within a mile or so, and the weather be still, a bugle will answer equally well, long and short notes representing the positive and negative cones. The fundamental principle of the foregoing system of universal telegraphy, applicable by night or by day, by sight or by sound is to employ two signals only—one positive and one negative—and to regulate their exhibition by periods of time. Heliography is now largely used for military signaling where there is plenty of sunshine. The heliograph is simply a mirror on a stand, capable of being swung horizontally as well as vertically, with a small hole in the mirror to look through, so as to direct it accurately. Two trained sappers with heliographs can easily flash signals to one another at a distance of 50 miles, and so communicate even without the help of a telescope. See *Semaphore*.

MARINE SIGNALS.

It is certainly very desirable to have in use a system of marine signals by which communications between vessels may be easily made, promptly read and clearly understood.

The systems now in general use in the merchant service perhaps answer well enough under favorable conditions of wind, weather and distance, that is to say, having a wind from the right direction strong enough to blow out the flags, with weather clear enough to enable you to distinguish colors, to recognize diagrams, or to discern outlines, and with moderate distances for maintaining communication. But to every one who is familiar with the meteorology of the sea, and the experience of the sailor, it is well known that signals which depend upon differences of color, upon diagrams, or upon outlines for correct interpretation, fall far short of the demands that are made upon them. Vessels are sometimes in sight of each other for many hours, separated by a distance of only one or two miles, yet they are entirely unable to express their wishes so as to be understood through such inadequate means. We herewith present the outlines of a new system of marine signals, designed by Mr. S. P. Griffin. With this system it is thought possible to communicate at distances so remote that distinctions in color are lost, diagrams are impossible to trace, and outlines are rendered obscure; or when color, or haze, or dimness of light intervenes to bring about similar results, without materially impairing the simple visibility of objects.

With this system, in order to convey intelligence clearly and rapidly between vessels, it is only necessary to be able to see the flags or other objects used in place of them, their combinations and their changes are so simple, and are so easily made, that errors in reading signals cannot very well occur.

There are three classes of marine signals; namely, day-signals, night-signals, and fog-signals. They address themselves to the eye and ear. Day-signals, as a rule, are made with flags, as these furnish the simplest, and probably the best, medium of communication whenever objects can be made out and vessels are beyond hailing distance; shirts, blankets, sails, barrels, in fact, any objects that can be readily discerned and handled, are useful for making signals, and there are a number of different plans of using these various objects, each of them possessing some merit For night-signals, lights at once suggest themselves as being the best. The plain white light can be substituted for flags in this system with entire success. Fog-signals are necessarily made by sounds; they may be used as day or night-signals also, but in practice, owing to their want of volume, they are not nearly so useful as flags or lights, and as they address the ear only, a sound-signal alphabet must be made for them —with the use of instruments that are capable of producing continuous sounds, like the bell, the trumpet, the horn, and the whistle, there need not be any trouble in transmitting intelligence, combinations of short and long sounds will satisfy any demand that can arise within the limits of hearing. As long as objects can be seen or sounds heard and we can control them, so long may signals be transmitted simplicity of arrangement is, of course, a consideration of great importance. Mr. B. F. Greene introduced a plan of signaling by measuring intervals of time between exhibitions. General A. J. Myer, Signal Officer of the Army, in speaking of it says, "thoroughly understood and skilfully used it will render intelligent communication and co-operation practicable under circumstances which have made them hitherto impossible." Undoubtedly Mr. Greene's plan of signaling is of great value, but it is not very well adapted to the requirements of the merchant service, a few simple objects, and two simple sounds without complex combinations seen or heard and understood at once, without the necessity of precise admeasurement of time intervals, are better. On board men-of-war, besides the ordinary instruments furnished to merchantmen, they have guns of suitable caliber, an abundance of pyrotechnic contrivances, and numerous officers to detail to look out and mark time.

Under this system, flag signals may be displayed from one, two, three or more places as may be agreed upon beforehand. As ships and barks are most engaged in over sea voyages, and are most given to the use of signals, the first arrangement will be for them, using their three masts as signal places and nine flags. It is not necessary that masts shall be used, or that brigs and schooners cannot be included in the first arrangement; masts are the best places, other things being equal, but two masts and a gaff, the fore and aft stays, the back stays, anywhere to show three separate and distinct hoists of flags at once will do. Let it be understood that signals must be read from forward aft, from aloft down, from starboard to port. The vessel that desires to signal, must first call attention by a hoist; let this hoist also indicate the number of places she means to use: in this first arrangement, it will be done by displaying three flags, one under the other. As soon as she is answered by a hoist of one flag, which means an affirmative, all right, go ahead. She will then hoist the signal for the international code letters, the alphabet, or numerals, as she chooses. An answer of two flags means, a negative do not understand, repeat. As this system of signaling is not intended to supersede other systems already in use, but to supply their deficiencies, it is well to conform to what is already known and practised as nearly as can be done; therefore, the alphabet and the signal dictionary of the "International commercial code of signals" will be adopted. The flags of that code as objects easy to discern may also be used. In clear weather, at moderate distances, colors, diagrams, and outlines may be used with good effect in signaling. But as soon as it is found impossible or difficult to make them out, resort may be had to this system, with the same flags, with the same letters, having the same meaning, the difference being that each letter requires a separate hoist or a combination of hoists. It may be desirable at times to be able to spell words, to construct sentences, wherefore an alphabet arranged for this system is given. The use of abbreviations in marine signals will greatly facilitate communication between vessels. In the formation of words certain letters may be understood, and in the construction of sentences whole words may be omitted. Some words and parts of sentences are so much used at sea that an allusion, however slight it may be, will indicate them without any danger of ambiguity. By writing the message to be transmitted by signals, an inspection of it will suffice to show the number of letters and of words that may be safely left out, and still convey to the eye and to the ear its full meaning. Communications by the use of numbers are easier and quicker than those by words and sentences, hence it is desirable to have a numeral signal dictionary. One can be easily made which will contain all that the exigencies of the sea requires. So may the names of vessels and places be arranged numerically in groups designated by their rig and their initial letters.

Object Signals.—First Arrangement for three signal places and nine flags, see Fig. 4, the flags are numbered in the Fig. merely for illustration. Attention signal indicating the number of places to be used, three flags one under the other in one hoist.

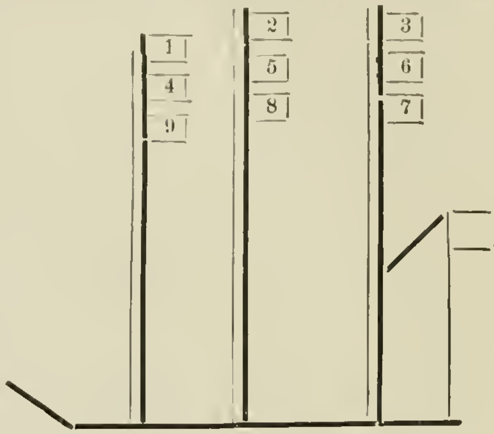

Fig. 4.—International Code Signals and Numerals.

Third Arrangement for one signal place, using five flags on one mast, or on a gaff, etc. Attention signal indicating the number of places used, one flag.

Fig. 6.—International Code, Letters, and Numerals.

In practice there will not be any trouble experienced in reading signals with blank spaces in the hoists, for the blanks will be measured at once by the flags above and below them. In daylight, when a vessel desires to communicate with another by signals she can indicate her choice of any one of the three preceding arrangements as directed, and if she chooses to use the alphabet of this system, she indicates it by hoisting signal W. flags, 2, 5, 8, running the hoist up three times for the first arrangement. Fig. 6. By hoisting signal G, flags, 2, 4, running the hoist up twice for the second arrangement. By hoisting signal F., four flags, running it up once for the third arrangement. Or the numerals by five flags in one hoist, run up and down twice, immediately after attention and place signal is answered and hauled down. It is understood that the international code letters will be used unless expressed to the contrary as above written. Signals must be kept flying until they are answered.

Sound Signals.—A whistle, trumpet, horn, bell, or any other instrument that is capable of producing continuous sound may be used. One short and one long sound are all that are necessary. The length of the dash or line indicates the relative duration of sounds.

B.	No. 1.	North	— — —
C.	" 2.	South	— ——
D.	" 3.	East	—— —
F.	" 4.	West	— — ——
G.	" 5.	N. E.	— —— —
H.	" 6.	S. E.	— —— ——
J.	" 7.	N. W.	—— — ——
K.	" 8.	S. W.	—— —— —
L.	" 9.	N. N. E.	— — — ——
M.	E. N. E.		— — —— —
N.	E. S. E.		— —— — —
P.	S S. E.		—— — — —
Q.	S. S. W.		— — —— ——
R.	W. S. W.		— —— —— —
S.	W. N. W.		— —— — ——
T.	N. N. W.		—— — —— —
V.	Stopped		—— —— — —
W.	At Anchor		—— — — ——

A short sound is half the duration of a long sound, and may be indicated by the time it takes to count slowly one, two. A long one by counting slowly one, two, three, four; intervals between sounds of the same group will be indicated by one, two, and intervals between groups by one, two, three, four. With a little practice this plan of signaling can be successfully conducted; the man who operates the instrument to produce the sounds, say with the whistle, will very soon acquire correctness in his short and long sounds, and in his blanks or intervals. The attention signal, with the sound-producing instrument, will be five short sounds, thus — — — — —, the answering and affirmative signal one long sound, —— the negative signal, two long sounds, —— ——. It is understood that the international code of letters and definitions will be used unless the alphabet is desired by signal F, two short and one long sound, — — ——, repeated three times, or numerals by signal L, three short and one long sound — — — —— repeated three times. As compass fog-signals are of great importance at sea, and as it is customary on board steamers to sound the whistle during fogs, it will be easy to indicate the course by this arrangement, instead of making only an unintelligible noise. The signals stopped and at anchor are obviously of great use under circumstances of common occurrence in the experience of the navigator. Signals are given for sixteen compass courses only, as it is believed that they will be enough in practice: to give a signal for each of the remaining sixteen points would extend the length of it too much. Besides, if you are steering, say N. by E., make the north and N. N. E. signals alternately: if you are steering N. by E. half E., make the N. N. E. signal, it being within half a point of the course, and practically near enough to it and the same for the other courses for which no special signal is given.

RAILWAY SIGNALS.

In considering the means to be employed for directing and ensuring the safety of the traffic upon railways, it became evident that among other things some plan should be devised for giving instructions and information to drivers and guards of trains as to the state of the road in advance of them, or of the nearness of a preceding train, so that the speed and progress might be judiciously regulated; the plan ultimately adopted as most suitable was that of signals. These chiefly consist of variously shaped boards, painted a bright red color on one side to indicate danger, and in some cases green on the other to indicate caution; these boards are fastened to a pole or mast attached to a post in such a manner as to admit of their being turned round, raised and lowered, or otherwise altered in position so that in addition to representations by colors certain movements are executed. In most cases the engineers or the traffic managers arranged their particular system of signals, fixed or portable, without consideration of those used on other lines, and the natural result is that the forms and systems in use are considerably diversified; the first railways had signals placed only at the principal stations and junctions, the intermediate portions of line were regulated by policemen who had certain beats assigned to them, and who gave manual signals to the drivers as necessity demanded; danger was indicated by facing the approaching train and elevating both hands above the head; the go slow or caution signal was given by one hand similarly held and all right or the line clear by extending the right hand from the body horizontally. Red, green, or blue, and white flags were used in many instances in conjunction with and also instead of the manual signals; gradually station or home fixed signals were introduced throughout each railway, then distant or auxiliary signals worked by wires having their levers concentrated at one locality, frequently in a cabin or signal-box, for facilitating operation by the men in charge; this latter method has now to a great extent given place to a system of interlocking the mechanism for moving the points and signals, and especially at junctions and large stations: these inventions for locking prevent the possibility of an all-right signal being given when the road governed by that signal is fouled in consequence of a train being wholly upon it, or through its being intersected by a train passing from another road.

The most general form of signal is that of the semaphore; it is an imitation of, the old telegraphy systems, the first of which appears to have been invented by a Dr. Hooke in 1684, Fig. 7, and revised by a Rev. Mr. Gamble about 1795; it was then styled the radiated telegraph, Fig. 8; further improvements were made in the year 1804, and also in 1810 by Pasley, by Rear-Admiral Popham in 1816, Fig. 9, and by Pasley or Macdonald in 1822, when the system was termed the Universal Telegraph, Fig. 10; it was similar in detail to the French coast semaphore in use in 1803. The semaphore signals as used on the railways are constructed with arms upon both sides of a mast fixed upon a center-pin free to move up and down; those on the left-hand side, as seen when facing the signal, are as a rule to govern the left roads, and there are as many arms as roads or descriptions of trains to be regulated. It has been found desirable to further distinguish the arms by numbers or letters painted upon them, or by affixing pieces of shaped iron or board corresponding with the understood number or letter of the several roads.

Among the early attempts in signal construction, three may be noted as possessing some novelty. In 1838 a disc signal was in use at Vauxhall Bridge, Birmingham, the invention of a Dr. Church; it was connected to the points and stood about 5 ft. high; two discs, 2 ft. in diameter, were fixed on the top at right angles to each other, and surmounted by a lamp showing two red lights, one blue and one white; the discs were painted with colors to correspond. In 1842, C. Hall introduced a system on the Great Eastern line; the signal consisted of five leaves placed in the shape of a fan on a mast, and colored yellow, green, red, and white; each leaf indicated the time a train had passed it; a green post was fixed at the side of the line 100 yds. in advance of the signal, beyond which no train was to pass if the fan exhibited the red leaf; a green and white striped post was also fixed at one mile beyond the signal; and if the fan showed the seven or nine minute color when passed, the driver might put on moderate or full speed on reaching the striped post. These signals were in use several years. On the Greenwich Railway plain posts were fixed to each road at half a mile on either side of the junction, on reaching which the driver opened the engine whistle, and the switchman notified by hand-flags which train was to proceed on to the main line. The construction of self-acting, or rather train-actuated signals, has claimed the attention of a very large proportion of inventors of signals, but

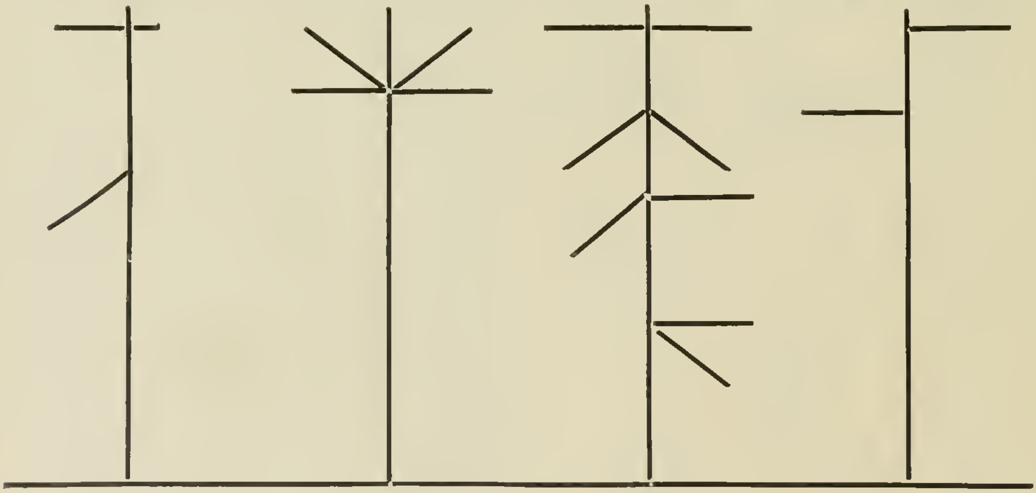

Fig. 7. Fig. 8. Fig. 9. Fig. 10.

very few systems have been tried, and many of those were found practically unreliable and therefore useless. Whitworth's signals were used on the Brighton line, at some of the tunnels on the Lancashire and Yorkshire, Whiston Bank, near Liverpool, and several other situations. In 1858 Baranowski obtained permission to test his automaton distant signal between Hackney and Kingsland, on the North London line. It was set to danger by the passing train pressing down a lever which actuated the mechanism of the signal; and when the train reached a distance of 1100 yds. it pressed down another lever, causing the danger signal previously set to be released. Although many hundreds of trains successfully worked it, its failure on one occasion is supposed to have caused an accident which led to its being removed. The Midland Company erected an indicator at Kegworth in 1863, showing the time a train had passed up to fifteen minutes. It was set in motion by a treadle being depressed by a passing train. At the expiration of fifteen minutes the pointer returned to zero. This signal was subsequently removed as unreliable. So soon as the few inventions at all trustworthy for locking signals and points had proved their advantages over previous systems, they were rapidly adopted by many of the railway companies.

A very satisfactory plan was introduced by R. C. Roper in 1869. The advantages of this system are, that the locking is accomplished without any moving bolts, cranks, or screws, the long bars on the point levers which effect the locking are in sight, and the operator can see which levers can be moved and which cannot. A bar is mounted on the point levers extending between the signal levers, dividing them into sets, and as respects each point lever in motion either way separating the single levers, which must precede the point levers in their movements from the others. The levers are all arranged in a frame in the usual way; one side of the frame is termed permission for main line, and the other permission for branch line. On each point lever is fixed a bar, the bar on one set being lower or higher than that on the other, extending as above described, and so coupled with the signal levers that if there be arranged on that side of the frame called permission for branch line all those signal levers and levers belonging to the main line, and on the opposite side of the frame those signal levers which belong to the branch line, all the signals will be then at danger. The bars on the point levers extend over the point levers in such a manner, that on either point being brought over to one side of the frame, the bar upon it rests against those signal levers which ought to be locked by it when in this position, and the signal levers which are ranged on other side of the frame are no longer locked by this lever. The side of the frame which gives permission to the main line gives danger to the branch, and the reverse; but in no case can the signal levers be moved before the point levers. A system invented by Wm. Bains, is in use at the somewhat complicated junction at Lindal Cote, it having a cross-over road running into both up and down main lines, two branch lines, on one side, and three lines on the other. There are catch-points on the up side, which have to be kept closed for the cross-over road and open for the catch-siding so that the main lines may not be fouled by traffic on the branch lines; these catch-points can only be opened for the cross-over road when the signals have been set to danger for the main lines and the branch lines on the opposite side; consequently nine points and seven signals have to mutually interlock with the one set of points. The levers are all centerd on the main shaft, and above this is a smaller shaft, which passes through a quadrant arc in the foot of each lever, thus allowing the required range of motion. On this shaft are loosely slipped a number of short tubes or rockers; these have cams upon them, which act against projecting tappets fixed one upon the bottom of each locking bar, and when the cam is held up under of one these tappets it prevents the bar from being pushed down, in which case the detent of that lever cannot be raised out of the quadrant notch. The practical result of this arrangement is, that before the lever has been moved ⅛-in. in the quadrant the locking of the second lever is perfectly effected; the pressure upon the several parts is very small and they do not require oiling.

The existing arrangements for working the traffic on the London Metropolitan Railway and at the Victoria and Cannon Street stations are good examples of the application of locking gear to signals and points, and the facilities for safety afforded thereby have been recognized by the English Board of Trade, and strong recommendations are embodied in the regulations issued by that Department that all railway companies should adopt such means for the prevention of accidents. See *Signal Tactics.*

SIGNAL SERVICE.—At the time of the organization of the Department of Meteorology of the Army Signal Office, there was no general system in operation for "Simultaneous Meteorology," and the one ever since in use was devised and carried into effect by General Myer, Chief Signal Officer. By this system the innovation was introduced of observing and reading off the instruments, "at the same moment of actual (not local) time." By this arrangement the Signal Office at Washington can call for and receive reports from all parts of the country, taken at each of the stations, at any hour of the day or night. Thus, the exact condition of the atmosphere over the whole field of inquiry is set down at a given instant, establishing the existence of conditions on which predictions may be and are fearlessly made. In November, 1871, a comparison of the tri-daily forecasts, or "probabilities," as they were styled, showed a verification of 69 per cent, which rose to 76.8 per cent by 1872. These results "afforded the best elucidation and the most complete demonstration of the law of storms and the movements of cyclones that had ever been obtained in any country." In 1872 and 1873 the expansion of the work of the Signal Office was very great; extending, through the cordial aid of agricultural societies, into a comprehensive Weather Bureau sustained in the interest of agriculture; and, through its connection with life-saving and signal-stations, becoming a most certain and effective agent for saving life and property endangered by storms on the sea. "Indication" and "Cautionary Signals," based upon three series of simultaneous weather-reports telegraphed to Washington daily, are issued from the office of the Chief Signal Officer three times each day, and are printed in all newspapers where it may be important to do so, and otherwise made public. The preparation of a graphic weather-map embodying the telegraphic data furnished to the Chief Signal Officer every eight hours, preserves an accurate picture of the existing aerial phenomena, and the conditions on which storm predictions are made. The "Farmers' Bulletins" are reprinted by the Signal Service Observers in many cities, and the telegraphic forecasts are circulated among many thousand subcenters in agricultural communities, and thence distributed among farmers. As the predictions cover twenty-four hours, and often hold good for twice that period, they reach the denser rural populations sometimes a day and a half and always as much as fourteen hours before the period to which they apply expires. The railroad system has co-operated in this service, and nearly all the railway companies distribute daily reports to the railway stations, without charge. Cautionary signals are of two kinds: 1. Those premonishing dangerous winds to blow from any direction. 2. Those premonishing off-shore winds, likely to drive vessels out to sea. The first distinctively termed the "Cautionary Signal," consists of a red flag with a black square in the center, for warning in the day-time, and a red light by night. The second, or "Cautionary Off-shore Signal," consists of a white flag with black square in the center shown above red flag with a square black center by day, or a white light shown above a red light by night, indicating that while the storm has not yet passed the station, and dangerous winds may yet be felt there, they will probably be from a northerly or westerly direction.

The *London Times* has said "the weather is by no means a subject which should be regarded merely as a matter of conversation for the multitudes of people who find it difficult to talk about any thing else. The subject is, in reality, one of great national importance; and of far more importance than many others which occupy the time and the thoughts of the public; and it is only neglected on account of the obscurity behind which the causes of weather changes have been hitherto concealed, and of the consequent apparent futility of discussing them. If any scientific investigation could bring the subject of weather changes within the region of actual knowledge, so that reasonable forecast might be made concerning them, it would at once become manifest that scarcely any other subject would vie with them in universality of interest. The power of foreseeing the weather of the next few days would do much, the power of foreseeing the weather of the next season would do almost everything, to take away from agriculture the uncertainty which is now its greatest hinderance; and a bad harvest season would then no longer, as at present, entail upon the nation a loss which must be estimated by millions." The accuracy attainable in foretelling the weather of at least the next few days, the forecasts being based upon local indications taken in connection with the general information furnished by the Signal Service, will agreeably surprise any one who will test the matter for himself. In our active, working life, who does not consult the weather, and what branch of every-day life and its varied pursuits is not influenced and affected by its changes? The practical application of weather knowledge to all classes of industry, to all professions, handicrafts, and processes of animal and vegetable life, is steadily increasing. Physicians and boards of health are enabled, from telegraphic weather reports, to detect dangerous atmospheric conditions, to investigate the origin and spread of diseases and epidemics, and to give timely warnings or hopeful encouragement, based on the knowledge of coming changes. The subtile, mysterious influence of the weather governs and controls us, and, because we pay so little attention to its changes, sends many of us to our long home. The important question, will it be clear or cloudy, warm or cold, rain or snow, on the morrow, involves so much of our health and comfort, as well as success, in nearly every practical walk of life, that all should be, as all may be, able to answer it for themselves. That a local, isolated observer, without instruments, but with some general knowledge of the elements of meteorology, and with the aid of telegraphic reports of weather conditions, especially to the westward, whence most of our weather comes, can foresee his own weather for the morrow, is beyond doubt. No farmer need suffer loss or damage from the coming rain; no merchant need risk his perishable cargo; no speculator his money, and no traveler his safety and comfort.

Weather prophecy, that covers a period of time in advance, and that specifies certain dates in the future upon which certain conditions are, or are even likely to prevail, is simply a delusion, and the alleged prophets should be regarded as materialized spooks and noisy cranks, who blow their horns, of greater or less dimensions, emitting sounds signifying nothing. Some of these manage, by extensive advertisement and an occasional chance hit, to attract the attention of the over credulous; but they sooner or later fade away and disappear from public attention. No man can, by any reasoning whatever, or upon any hypothesis, foretell the weather beyond a few days, or rarely a week in advance. Long range predictions, whether based on the position of the planets, the influence of the moon or of sun spots, or on the assumed law of periodicity, are unreliable, and amount simply to good, bad, or indifferent guess-work. It is not complimentary to the intelligence of the times, or the diffusion of knowledge, that the absurd vaticinations of the professional weather wizards should always be accepted with more or less credibility. Failures do not seem to have any effect upon the minds of the unthinking, while a chance success is heralded throughout the land, even by the press, whose business it should be to be intelligent. Arago, a French astronomer, said that no scientific man, who cared for his reputation, would venture upon a weather prediction. And yet the leading weather prophets of our time are men who base their predictions upon the occurrences of astronomical events; upon the theory that the planets exercise a controlling influence over the weather of our earth; that planetary perihelion and aphelion passages, oppositions, and conjunctions, produce changes and interruptions in the electric currents undulating between them, causing various grades of meteoric disturbances in our atmosphere.

The only reliable, as it is the only reasonable, system of forecasting the weather, is that of our Signal Service. But, while the Weather Bureau at Washington is making great progress in reducing meteorology to an exact science, the geographical areas for which predictions are made are too large, and entirely different weather may prevail in different portions of the same district. To say that local rains will occur on a given day in, for instance, the Ohio valley, is not altogether satisfactory to residents in different portions of the valley. To anticipate, by way of illustration of this: Suppose a storm is central over the western plains—weather generally travels in an easterly direction—the Signal Service announcement would be local rains for the upper Mississippi valley on the morrow, and on the next day for the Ohio valley. Now, those in different portions of either district, who have some knowledge of local signs and indications, can supplement this official announcement for their district, and determine for themselves whether the coming rain is or is not likely to reach their particular locality during the day. A little practice will enable the merchant or the farmer to read between the lines of the necessarily brief and sometimes misinterpreted government report with good results.

The Signal Service system is also employed in Great Britain and among other European nations. It consists in taking careful and simultaneous observations at a great number of representative points of the pressure and temperature of the atmosphere, the direction and velocity of the wind, the degree of moisture or saturation of the air, the cloudiness, etc., at each point. In our country, these observations, made several times each day, are promptly reported by telegraph to the central office at Washington, and there projected upon a map of the country, which then shows at a glance the distribution of sunshine and cloudiness, of warm and cold, of fair and foul weather at the time, just as the geographical map shows the distribution of mountains and valleys, plains and river courses, land and water. Our present weather science dates from the time of making simultaneous observations at numerous and widely scattered places, and the use of the telegraph in transmitting the results. Without the weather map, it would not be possible to predict weather for the various geographical divisions of the country from any central point, as is now done with great success. Without a knowledge of the principles of meteorology, the established laws and generalizations, weather reports are of little value in respect to making any deductions therefrom. There is no limit to the utility of such knowledge, and it is not difficult to acquire. There is nothing mysterious attaching to it. When once leading facts are mastered and borne in mind, there is a wonderful simplicity in meterology. There is an absorbing fascination in the constantly changing conditions, as revealed from day to day by the weather map. From the study of this map are made the forecasts for the various geographical, or rather meteorological districts, for short durations of time. These forecasts, or "Indications," are based upon established laws of storms.

The atmosphere which envelops our earth is the great factory in which all the meteorological phenomena occur. The ever varying pressure, temperature, and moisture of the air, are the three *keys* with which to unlock the weather mystery, which ceases to be a mystery when these principal elements constituting *weather* are understood. Moisture, manifesting itself in various ways, is perhaps the principal element to be considered in determining local weather changes. The air is never quite dry, and at times it is so full of moisture that a fall of rain is almost inevitable. Increasing heat increases the capacity of the air for holding moisture. Evaporation, or the conversion of visible water into invisible vapor, is constantly going on to a greater or less extent. A simple saucer full of water exposed to the open sky, and protected from interference, will, by the more or less rapid diminution of the quantity of water through evaporation, give indications of the weather. Dryness, or fair weather, is connected with a rapid rate of evaporation, and dampness, or wet weather, with a slow or more or less suspended rate of evaporation. Any intelligent, practical observer, can get satisfactory results in local weather predictions by simply watching the clouds and the varying humidity of the air, as indicated by two common thermometers suitably arranged and called a hygrometer.

The instruments should be perpendicularly secured on a piece of board about ten or twelve inches apart, and both should show the same temperature. Then cover the bulb of one of the thermometers with a wick leading into a small covered vessel, fastened to that side of the board and at some little distance from the bulb, containing preferably rain water. The readings of that thermometer, called the "wet bulb" will usually be found to be lower than those of the other. This is due to the water absorbed by the wick rising by capillary attraction to the end of the wick over the bulb and evaporating, causing cooler air around that bulb, and thus lowering the mercury in the tube. In dry weather evaporation goes on rapidly. In very damp weather evaporation is slow. When the air is thoroughly saturated with moisture, evaporation from the wick ceases, and the two thermometers read alike. That is to say, the moisture in the air, when thoroughly saturated, has the same effect upon the "dry bulb," as the water held by the wick has upon the "wet bulb." Should, for instance, the dry bulb read 60°, and the wet bulb 50°, the percentage of relative humidity would be 44 or low. By relative humidity, is meant the proportion of vapor in the air at any given time compared with what the air could contain at that time if thoroughly saturated. Saturation being expressed by 100, the above, it will be seen, would be low, less than one-half, indicating dry weather. On the other hand, should the dry bulb read 60°, and the wet bulb 58°, the percentage of humidity would be 88, or high. Should both read alike, care always being taken that the vessel is kept supplied with water and the wicking clean, the percentage of humidity would be 100—that is, the air would be quite thoroughly saturated with moisture. The greater the difference in the readings, the drier the air, and the less chance for rain.

But a knowledge of the mere percentage of existing moisture is not of so much practical importance to the farmer or others, whose business pursuits depend largely upon weather conditions, as the fact whether dampness is increasing and rain therefore probable, or whether the air is drying and fair weather likely to ensue. These facts are admirably indicated by the little instrument above described. The approaching or separating thermometers, taken in connection with the wind direction and local signs, together with the information furnished by the weather reports, should enable any one to satisfy himself as to his probable weather for at least a day or two in advance.

The air deposits a portion of its vapor on all bodies that are colder than itself, and the temperature at which such a deposit of moisture is made is called the dew point. The dew point may at all times be found by calculations with a set of factors.

The rule is: *Multiply the factor opposite the reading of the dry bulb into the difference of the dry and wet bulb thermometers, the reading of the dry bulb thermometer, less the product found, will be the dew point.*

TABLE OF FACTORS FOR COMPUTING THE DEW POINT.

Dry Bulb.	Factor.	Dry Bulb.	Factor.	Dry Bulb.	Factor.
20°	8.1	29°	4.6	38°	2.4
21	7.9	30	4.2	39° to 41°	2.3
22	7.6	31	3.7	42 to 45	2.2
23	7.3	32	3.3	46 to 50	2.1
24	6.9	33	3.0	51 to 56	2.0
25	6.5	34	2.8	57 to 64	1.9
26	6.1	35	2.6	65 to 73	1.8
27	5.6	36	2.5	74 to 86	1.7
28	5.1	37	2.4	87 to 90	1.6

EXAMPLE.

Suppose the dry bulb reads	65°
Wet bulb	59°
The difference	6°
Factor (from the table 65°)	1.8
Product	10.8
Dry bulb reading	65°
Less product	10°.8
Dew point	54°.2

Suppose the dry bulb reads 60.5°, and the wet bulb 60°. This would show that the air is very highly saturated, and, by reference to the Relative Humidity Table, it would be found that the percentage of humidity was 97. Rain could be expected, because the air contained nearly as much moisture as it was capable of sustaining. Computing the dew point, or temperature required to condense the vapor, in this case we find it to be 59.5°.

$(60.5°-60=.5°\times1.9=.95;\ 60.5-.95=59.5°+)$

That is to say, the temperature of the air in this case has to sink less than one degree, in order to produce rain.

As a guide to the probability of rain, the application of this method becomes interesting, and is generally found reliable.

If the mercury in both bulbs rises as the day advances, rain is likely, since the temperature of the air will naturally fall with the decline of the sun. In sultry weather clouds and other "signs" of rain may mislead us, but if we look at the evening sky and see there the fair weather red, as well as consult our hygrometer, and find there a considerable difference in the readings, we need not apprehend rain on the morrow. A rapid increase in the difference between the two thermometers in the morning foretells a fine day. An increasing difference between the temperature of the air and the temperature of the dew point, accompanied by the fall of the latter, is a certain sign of fair weather. But diminished heat and rising dew point foreshow rain. Fog and mist, resulting from the difference of temperature between the surface of the earth and the overlying strata of air *ascending*, is a sign of rain, as so much more vapor is being added to the amount already contained in the air. When the upper regions of the air are saturated with vapor, as indicated by *halos* around the sun or moon, it is a well-known sign of rain—the larger the halo the nearer the rain. Air saturated with vapor is much more transparent than dry air, and unusual clearness or transparency is therefore a sign of rain. Under such conditions distant objects are seen with greater distinctness, which is an indication of rain. *Lights* appear brighter and nearer before rain. The refracting power of the air becomes greater through the increasing aqueous vapor in it, and distant objects, especially over water, *loom*, or have an apparently increased elevation. On the other hand, when there is a deficiency of this vapor, and there are commingling strata of air of different temperatures, there is *haziness* indicating dry weather.

Clouds are simply aggregations of the particles of vapor in the air assuming well-defined forms and peculiarities. They appear and disappear, and assume their various shapes, according to the state of the atmosphere in respect to moisture, temperature, and movement. With their various forms all are acquainted by observation. Being merely packed particles of moisture, they are subject to temperature and wind, as the latter are governed by pressure, as we shall see further along. *Cirrus* clouds resemble locks of hair or feathers with parallel diverging fibers. They are the highest and least dense. They sometimes cover the sky as a mere transparent haze, and sometimes form themselves into collections of parallel threads, assuming an infinite variety of wavy fibrous shapes. They mostly consist of icy spicule or the frozen vapor of the upper regions. They are the first to make their appearance after a period of fair weather, and are the forerunners of coming foul weather. When the ends of these "cats' tails" curl and point *upward*, rain can be expected; when *downward*, fine weather. In the former case, a warm ascending current is attended by the decomposition of vapor preceding rain; in the latter, a cool descending current produces evaporation, and, consequently, fair weather. When these clouds sink and become denser, the result of increasing moisture in the upper air, they assume the appearance somewhat of carded cotton, and this change foretells rain.

Cumulus clouds are produced by warm currents of air ascending and expanding. They are associated with fine, warm summer weather. So long as these preserve their regularity and float along in their accustomed serenity, the existing fair weather is not likely to be interrupted. The volume of these sometimes majestic clouds is greater on warm, moist days, than when the weather is cold and dry, for evident reasons. When the edges or outlines of these clouds are sharp and well defined, it shows a dry atmosphere, and therefore presages fair weather. As all atmospheric disturbances are due to a disturbed equilibrium of the air, it is a sign of fair, normal weather, when the under surface of these massive and majestic clouds is uniform and level, showing that the equilibrium of the air strata upon which they float is unbroken.

Stratus is the extended, uninterrupted *sheet* of cloudiness that prevails in threatening, dismal, rainy weather. The hurrying *scud* cloud is a reliable sign of rain. When small clouds disappear, there will be no rain that day. If they increase in size, and unite, falling weather is at hand. The reason is plain. When the air is charged with electricity clouds are attracted to each other, and combinations are formed which result in showers, or heavy rains, according to the intensity of the conditions. When the electricity is passing off, or is diffused, clouds break up, and are dissolved. A "mackerel sky," which is a combination of *cirrus* and *cumulus* clouds, indicates fair weather for the day; but presages rain within a day or two after. The French have a proverb, "A dappled sky and a painted woman don't last long."

To produce rain, there must be a combination, in some form, of the upper and lower cloud formation —the icy vapor uniting with the vesicular. The *halo* around the moon shows the saturation of the upper regions of the sky—the descent of the icy *cirrus*. The larger and more complete, or better defined, the circle, the greater the degree of saturation. A warm south wind now bringing up the stately *cumulus*, rain results from the union of these two principal types of cloud, on the same principle that pouring ice in a glass tumbler, on a warm, moist summer day, will cause a deposit of water on the outside of the tumbler. The temperature to which the glass had been reduced by the ice at the moment the vapor of the surrounding air began to condense on its sides, is the *dew point*. In wide-spread rain storms, there are two or more layers or strata of clouds, the upper stretching out in advance of the lower, but merging into it over the region where rain is falling most copiously.

Suppose our locality is *e*, Fig. 1. The upper layer *b* has reached us, and we are beginning to see the approaching lower layer *a*. We can expect rain. If, now, an extended rain storm having set in, our locality is *d*, and there be breaks in the lower laye we cannot see the sky through them, because of the intervening upper layer. Our heaviest rain is probably yet to come. But if our locality were *c*, and breaks occurred in the clouds, we would be able to

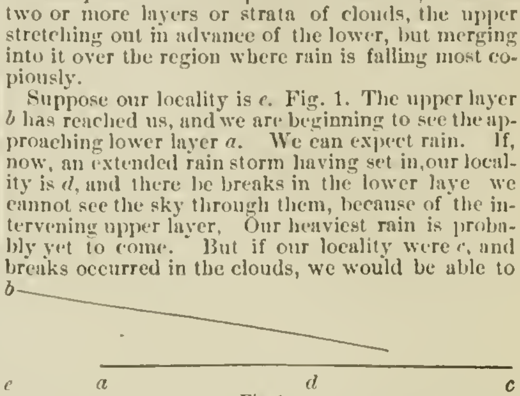

Fig. 1.

see the blue sky, the upper layer having passed beyond us; and we could expect an early end of the rain, and the return of fair weather. The character of the clouds, their combinations and movements, are important elements in forecasting all local weather. They are the effects of movements of aerial currents, and show, by their kind and changes, the pressure, temperature, and moisture at higher altitudes; and, by their movements, the prevailing currents of air, indicating whether the weather is likely to be warm or cold. If properly interpreted, clouds are sure indices of coming weather.

Rain is the vapor of the air condensed and precipitated This condensation is the result of a cooling of the air below the temperature of the dew point. This cooling takes place through radiation, the mingling of warm and cold masses of air, the opposition of winds of different temperatures, or any cause that produces condensation, either gradual or sudden. When variable winds prevail, light rains may generally be looked for. The amount of water received by the earth, from the clouds, is interesting and surprising. This amount can be very accurately ascertained by the usual rain-gauge. A rain-gauge may consist of a funnel-shaped collector and a cylinder, made of stout tin; the former securely fitting into the latter, as shown in the cut. It should be securelyplaced, with an exposure as clear as possible, and with the top of the funnel on a level. If the top of the funnel is ten inches in diameter, and the diameter of the cylinder about 3.16 inches, or the square root of 10 inches, the proportion between the cylinder and funnel will be as one is to ten; and ten inches of rain collected in the cylinder would equal one inch in the funnel, or one inch actual rain-fall. Fifteen inches in the cylinder would be one inch and a half actual rain-fall. One inch in the cylinder would equal *one-tenth of an inch* rain-fall. The length of the cylinder is immaterial; the longer the better, as it lessens the chance of overflow in case of specially heavy rains. The measuring rod—a thin, narrow strip of wood of the length of the cylinder—is graduated in inches and lengths of inches; and, when making an observation, the funnel is removed, the rod inserted in the cylinder, and the depth of water accurately noted; after which the water is emptied: and the funnel replaced Should the rod indicate a depth of twelve inches of water in the cylinder, the actual rainfall would be one inch and two-tenths. It is an easy matter to calculate how many *gallons* of water in the cylinder, the actual rain-fall would be one inch and two-tenths. It is an easy matter to calculate how many *gallons* of water fell during any rain storm, or any season, upon any given area of surface. As before stated, the amount will be found to be surprising.

Frosts should not take the farmer or the horticulturist by surprise. The probability of their occurrence can be known with almost as much certainty as the arrival of an express train. For practical use, one of the most important meteorological instruments is the common *hygrometer* by means of which can be ascertained at any time the *dew point*, and the approach of low temperature, or of frost, thus foreseen and provided against. If on a fair day, toward evening, the dry bulb, which would also be the temperature of the air, indicated 50° and the wet bulb 38°, the dew point at the time would be about 25°, and frost could of course be expected. If, on the other hand, the dry bulb were 50° and the wet bulb 48°, the dew point then would be about 46°, and no frost need be feared under the circumstances. The rule and table of factors for computing the dew point is given on page 93. The temperature of the air need not necessarily sink to 32° to produce frost, since plants and other good radiating bodies may become cooled by radiation considerably below the temperature of the surrounding air, and a heavy frost may occur when a thermometer above the surface indicates only 36° to 40°. A light frost may occur when the same thermometer indicates as high as 45°, or even 50°, of temperature. The formation of frost depends upon the dew point. Dew and frost, like rain and snow, are formed under the same circumstances, excepting the difference in temperature. Severe frosts, in their season, are found in the cooler, evaporating air attending the advance of areas of high barometer, and the approach of such areas may always be known by an intelligent reading of the weather reports.

The rule is, that *the force of the wind varies as the square of its velocity*. The force of a wind blowing at the rate of twelve miles per hour would, therefore, be just four times as great as that of a wind blowing six miles per hour, or .72 of a pound per square foot. The calculation can be carried on indefinitely. A wind blowing 24 miles per hour would exert a pressure four times as great as one blowing 12 miles per hour, or 2.88 lbs. Wind blowing 48 miles per hour would exert a pressure four times as great as one of 24 miles, or 11.52 lbs. 96 miles per hour, which would be a tremendous hurricane, would exert a pressure four times as great as 48 miles, or 46.02 pounds on every opposing *square foot* of surface. The Signal Service designates winds of 1 and 2 miles per hour as *light;* 3 to 5 miles, *gentle;* 6 to 15 miles, *fresh;* 16 to 25 miles, *brisk;* 26 to 40 miles, *high;* 41 to 60 miles, *gale;* 61 to 80 miles, *storm;* 81 to 150 miles, *hurricane*. The force of a wind blowing at the rate of 150 miles per hour would be equal to a pressure of 112.5 pounds per square foot.

The causes of winds are:

1. *Unequal atmospheric pressure* This creates motion in the air. With uniform pressure over any extent of country, there is very little, if any, motion or wind. The wind blows from regions where the pressure is greatest, to regions where it is least. Storms are areas of lowest pressure; therefore, the wind blows toward storms from all directions.

2. *Unequal specific gravity in the air.* This results from differences of temperature and humidity. Denser or colder air will flow toward regions where lighter or warmer air prevails, underrunning and displacing the latter. A storm is a concentration of heat, causing the air to expand, become lighter, and ascend. Cooler or colder air, according to the season, therefore, flows into the storm region to re-establish an equilibrium, and hence the change of temperature after a storm preceded by warm weather. The specific gravity of vapor is much less than that of dry air, and air, therefore, flows from dry to moist localities.

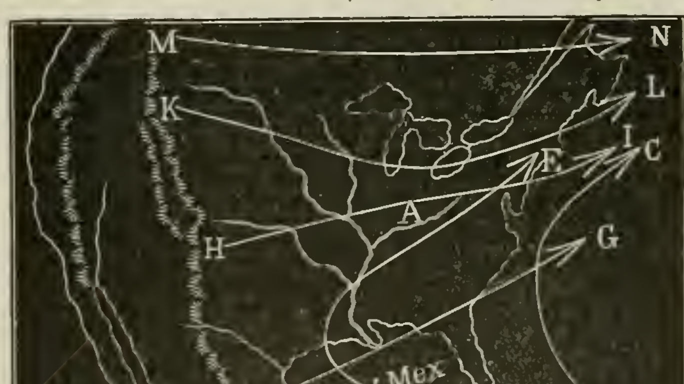

Fig. 2.

Wind is simply air in motion. Capricious as wind seems to be, it is nevertheless subject to definite laws. The *direction* of the wind is determined by the vane, and its *velocity* by an instrument called an *anemometer*. The indications of the latter are expressed in pounds of pressure per square foot of exposed surface. The pressure (in pounds per square foot) of wind velocities of from one to ten miles per hour is as follows:

Miles per hour.	Pressure per sq. ft.	Miles per hour.	Pressure per sq. ft.
1	.01 lbs.	6	.18 lbs.
2	.02	7	.24
3	.04	8	.32
4	.08	9	.40
5	.12	10	.50

The rotation of the earth has a relative effect upon the motion of the air. The velocity of the earth's rotation around its own axis every twenty-four hours is different in different parallels of latitude. At the equator the velocity eastward is 1036 miles per hour; in latitude 15°, 1000 miles; 30°, 887 miles; 45°, 732 miles; 60°, 518 miles; 75°, 268 miles; and at either pole nothing. There being but two primary motions of air, north and south—the other relative motions, due to the greater or less velocity or rotation of different parallels of latitude, will be readily understood. The *temperature* of the wind depends, of course, upon the quarter from which it blows and the distance it traverses from such quarter.

Each particle of the elastic air exerts a pressure upon those beneath it, and the weight and pressure of the entire mass upon the surface of the earth is recorded by the barometer. Atmospheric pressure varies as the motion, depth, density, moisture, and temperature of the atmosphere varies. Increasing or higher pressure means a flow of deeper, dryer and cooler air over a given region, as shown by the *rising* mercury in the barometer tube. Decreasing or lower pressure means a diminishing weight of the air, because it is then lighter, warmer, moister, and ascensive, and the mercury in the barometer tube sinks correspondingly. The term "area or *high* barometer," means a region of country over which there is an excess of air. The term "area or *low* barometer," means a region of country over which there is a deficiency of air. The former is, as a rule, attended by fair and the latter by foul weather. *Storms* are areas of *low* barometer, and as they approach our locality our barometer falls, that is, the mercury within the tube *sinks*, by reason of the influence of the coming storm, which draws the air toward its center, where it ascends. The fall of the mercury is according to the severity of the storm. If we happen to be in the path of the storm, our barometer will be lowest when the storm center passes over us. As the storm center passes by us, the barometer begins to rise, because there is a mass of air rushing over the locality after the depression or storm center, on the same principle that water seeks a level. Central areas of storms pursue paths across our country approximately shown in Fig. 2. If our locality is A (the Ohio valley), we are within influential distance of all storm centers taking the tracks, K L, H I, D E, and sometimes F G, and B C. B C, and D E, are West India cyclones, the latter out of their regular course.

When the barometer is reported lowest in a certain region, it means that there is a storm central there. When it is reported highest in a certain region, it means that that is the central region of the fair weather area. When the construction of the barometer—the difference between dry, cool, bracing and heavy, and moist warm, enervating and light air, as well as the fact that the atmosphere is forever seeking an equilibrium—that areas of low and areas of high barometer are constantly chasing and changing their relations to each other—is understood, this matter will be clear. It is a common mistake to say that the air is *heavy* in damp, wet weather, and *light* in fair, normal weather. The opposite is the case. Some of the effects of low barometer, or stormy weather, upon man and beast, have already been alluded to. When high takes the place of low, a grateful change is experienced, and the duration of the new condition can be approximately anticipated by reference to, and a study of, the weather reports. A high and steady barometer indicates, as a rule, dry, clear, fine weather. A low and fluctuating barometer indicates cloudy, windy, or wet weather. Changable weather is indicated by a quick rise, followed by a quick fall, in the barometer, or the reverse. Fair, still weather is the normal condition of the atmosphere just as health is the normal condition of living beings. Changes from this normal condition of the atmosphere are the results of forming, approaching, or passing disturbances. There is no uniformity or regularity in the intervals between these changes of conditions. The beginning, or first appearance, of a change can always be detected in the weather reports. The elements to be considered in any locality, in determining the immediate future of the weather, are atmospheric pressure, temperature, wind, moisture, the appearance of the sky, and (as announced by the telegraphic reports) the fact of precipitation elsewhere, whether in the form of rain or snow.

Areas of high barometer and areas of low barometer, are attended by their own system of winds circulating around them, towards and into the Low, and from and out of the High.

The direction of the wind is one of the main elements to be considered in weather predictions; and it can be known with reasonable certainty what winds will prevail, if it is known where the barometer reads highest, and where lowest, and this information the weather reports usually give. The rule is: "*Stand with your left hand toward the region where the barometer is lowest, and your right hand toward that where it is highest, and you will have your back to the direction from which the wind will blow during the day.*" Or, knowing the region of lowest pressure, and we stand *facing* it, our wind will blow from some point on our left to some point on our right. Not knowing the region of lowest pressure, if we stand *facing the wind*, the storm center will be on our right. Stand anywhere around the area facing the *center*, and the wind will be found to blow on your right side. Stand anywhere around the area of "Low," *facing the wind*, and the storm-center (*Low*) will be on your right side. The opposite holds good in the case of high. The former is a *cyclonic*, and the latter an *anti-cyclonic* system of winds. The lower clouds indicate the true direction of the wind better than the vane, since local surface winds may be diverted from the general direction by the topography of the earth or other obstructions. Air has primarily but two motions, northward and southward. But common observation shows us that the wind blows in every possible direction; and we have seen that there are two entirely opposite *systems* of circulation of air around areas of high and low barometer. The wind does not usually blow *directly* into a region of low, or out of a region of high, barometer; but is, in both cases, deflected toward the right; and this deflection is increased according to the size or extent of the area, whether of low or high pressure, around which the wind is blowing. Professor Ferrel has demonstrated that this deflection to the right is a mathematical necessity arising from the influence of the earth's daily rotation, causing every thing moving on its surface to deflect to the right in the northern hemisphere, and to the left in the southern hemisphere. The air, then, has a sinuous, spiral motion inward, toward the center of a region of low pressure, and at the center it flows upward from the surface. The friction of the earth's surface may retard this deflected or tangential motion of the air, and, in storms of great energy, the wind may be found to blow more nearly directly toward the center of the disturbance.

The wind, then, in any locality, may be expected to be—Easterly, when high is in the north, or low in the south. Southerly, when high is in the east, or low in the west. Westerly, when high is in the south, or low in the north. Northerly, when high is in the west, or low in the east.

By drawing lines upon a weather chart, or map, connecting the places where the barometer readings indicate equal pressure, we are enabled to definitely locate the position and extent of the areas of low and high barometer, and, with some practice and experience, to determine about when such areas, with their attendant weather, will reach and overlie our own locality. Such lines are called *isobars*. To locate an area of *low* barometer, seek out the places where the barometer reads the lowest, and encircle them, as far as possible, by an isobar. Take, for example, a report projected on the *Cincinnati Commercial Gazette's* weather map. At the time of that report, we find that, at Chicago, the barometer reads 29.77 inches; at Indianapolis, 29.74 inches, and at Louisville, 29.78. Now, simply trace a line representing approximately 29.80, from a point near Toledo to one west of Cincinnati, east of Louisville, thence around Louisville, on the south, and curving north-westward through Vincennes; thence slightly west of Chicago, and on, north-eastward, over Lake Michigan. You have here inclosed the region of lowest pressure on the map, which, in this case, however, is not the storm center, but the southern *extension*, or southern portion of the oval storm area, whose center is over the lake regions. Then trace a line for one-tenth of an inch higher pressure, or 29.90 inches, beginning west of Pittsburg; thence south-westwardly, keeping slightly north of Nashville and Memphis, passing *through* Little Rock; thence around Fort Gibson, and again north-eastward, passing slightly east of Keokuk and Davenport, describing a curve around the west of La Crosse, and running the line north-eastward again, beyond the limits of the map. This line incloses the usual barometric trough accompanying a storm movement, and generally lagging behind in the eastward movement of the storm.

If the map included and reports were had from British America, the northern portion of this storm area could be inclosed in a manner similar to that here shown. At Chattanooga and Vicksburg, it will be observed, the barometer reads over 30 inches. A line for 30 inches of pressure, drawn through Salisbury, Decatur, Grenada, and Alexandria, and leaving Chattanooga and Vicksburg east of that line, will show a portion of the western edge of an area of *high* barometer that preceded the storm movement above partly inclosed. High and low, like waves of a tempest-tossed ocean, follow each other across the country, their paths varying over higher or lower latitudes, according to the season of the year. On the map the increasing high barometer, with its colder northerly and north-westerly winds and clearing weather, is at once observed in the Missouri Valley.

It is the study of these areas of high and low barometer, as they succeed each other in their transit across the country, that is of importance. Predictions for the various geographical districts are based upon the result of such a study. Predicting the approach of a storm (*low* barometer), or a period of fair weather (*high* barometer) after a storm, is in this way comparatively easy. The *duration* of either condition depends upon its extent and rapidity of movement. The things to be considered are the position or location of the coming condition, its rate of progress, its probable path, and whether or not and *when* it will reach our own locality. Local signs will generally help to settle the last point.

Treating of storms and their causes, Professor Loomis says: "Storms are caused by a strong and extensive upward motion of the air, by which means its vapor is condensed by the cold of elevation. The atmosphere receives heat from the sun, and it loses heat by radiation. Only about one-fourth of the rays of the sun are absorbed in passing vertically through the atmosphere. The remaining three-fourths are absorbed by the earth's surface, by which means its temperature is raised, and heat is thence communicated to the air which rests upon the earth. The atmosphere thus receives its heat chiefly at the bottom, and, in consequence of radiation, loses it most rapidly at the top. Since the density of the air is diminished by an increase of heat, the atmosphere is in a state of unstable equilibrium, and the lower strata tend continually to rise and take the place of the upper. Such ascending currents are formed on every tranquil day. As the air ascends, it comes under diminished pressure and expands; and, as it expands, it cools at the rate of about 38 degrees for two miles of ascent. This ascending air carries with it the vapor which it contained at the earth's surface, and, if it rises high enough, the cold produced by expansion will condense a portion of this vapor into cloud. The height to which the air must ascend before it will become cold enough to form cloud, depends upon the difference between the dew point and the temperature of the air. If the dew point be ten degrees below the temperature of the air, cloud will begin to form when the ascending current has risen about 1500 feet."

After a period of fair weather, whose duration depends upon the dimensions and rate of movement of the area of high barometer causing it, the first indications of a storm are generally to be looked for in the western semicircle. These indications are condensation in the form of long threads of cirrus cloud formation, the ordinary cloud bank at night-fall, or the extensive and general condensation in which is formed the circle around the sun or moon. The formation of a storm center, or "area of low barometer," is due to moist, warm, and light air, having an ascensive motion. This moist rising air ascends into the upper regions, where the temperature is low, and, passing the dew point, its moisture is condensed and assumes the form of clouds; and the pressure of the air upon the barometer, or the surface of the earth, wherever this operation may be going on, is gradually lessened, and the mercury in the barometer tube sinks. Or, the warm, light, vaporized air may move high over the land, frequently over strata of dry cool air, in great volume, from the central meteorological zone, gradually sinking down and forming the germs of barometric fields of low pressure, which spread and develop into extensive storm areas. It is in such fields that the heat of the sun is concentrated and storm centers originated. The earth absorbing electricity from the air, electric disturbances of more or less violence, according to the intensity of the condition, are experienced. The absorbtion or withdrawal of electricity from the vaporized air produces sudden condensation, excessive precipitation, and a change of temperature. Wherever a storm is forming or approaching, the surface air within influential distance is attracted toward it. This movement begins first nearest the center of disturbance, each separate and individual particle of air being in turn attracted and set in motion, until the whole mass flows toward the storm center from all directions. Thus, if a storm is central in the Mississippi valley, the winds in the Ohio valley will be easterly, while in the Eastern States they may still be dominated by another system. As the storm progresses eastward and becomes central in the Ohio valley, the winds in the Eastern States will come under its influence and shift to easterly. When the storm has passed, a north-to-west wind is felt, and this follows up the disturbance, filling up the atmospheric depression and restoring normal weather. Storm areas are generally in the form of elongated ellipses, or are trough-like, much greater in length than in breadth. The shifting of the wind to the clearing-up quarter during the passage of a storm, whether through the north or the south points, will indicate to the observer whether the center of the disturbance is passing by on the south or north of his locality. If the wind sets in from the westward, having shifted through the *north* point, the depression is passing eastward, *south* of the observer; if through the *south* point, *north* of the observer.

An ordinary storm's path is generally in an eastward or north-eastward direction. The storm area extends from north to south, has more or less of an oval shape, moves eastward side foremost, its northern portion moving faster than the southern. Its diameter from north to south is of great and sometimes unknown length, while from east to west it is comparatively small. American storms are of a rotary character, they are progressive whirlwinds, moving forward in the line of an increasing spiral, and revolving from east to west in the northern, and from west to east in the southern hemisphere. An area of low barometer, wherever it may exist, is the place where opposing currents meet. The larger this area the longer the storm, and the more extensive the rain area. The rain area is under the slope of one current over the other. The size of areas of low barometer varies from a few square miles, as in local storms and tornadoes, to hundreds of miles square, as in extensive cyclones. The heaviest gales attend the most crowded isobars, or lines of equal pressure. These can always be traced on the weather map, and the approach of strong winds be anticipated. In severe storms, the wind is found to blow nearly toward the center of the disturbance. The more violent winds usually follow the rear of an advancing storm; those that precede the storm are apt to be most dangerous, by reason of being in the area of rain, fog, etc. The wind velocity is calculated from the relative pressures surrounding the central depression. If the central depression is considerably lower than surrounding pressures, it is evident that there will be a violent rush of air into this depression. If a storm-center were moving over a given place, and the atmospheric pressure there were unusually low, while at points one hundred and seventy miles distant the barometer read one inch higher, the wind velocity would be great enough to demolish houses and damage shipping. Cases of hurricanes, tornadoes, etc., are instances of these steep slopes or gradients. The steeper the gradient, that is to say, the nearer together the isobars are found to lie, the more dangerous the wind. In winter these slopes are more gradual, as the light, moist, warm, ascensive current climbs far over the other. In summer they are more steep, as the cold downward current, from its weight, banks up against the warm one.

Warmer weather is associated with a falling barometer, if the depression that induces the fall is to the west or north of your locality. As before stated, the air flows from regions of high to regions of low barometer. The weather report always announces where the barometer stands lowest. If the barometer is reported highest in the south and lowest in the north, your weather will be warm, but not as warm as it would be if there were no elevation of barometer in the south, because then the southerly air will not have traveled far. An excessively hot, dry summer, like that of 1881, is caused by the tracks of storms, or areas of low barometer, being invariably far to the north. Lows moving along extremely northern latitudes, will generally attract the southerly air toward them, and the succeeding Highs remain too far north to materially affect the weather in the interior of the country. The result is a high degree of temperature, and possibly serious drouths, since the moisture is carried over and beyond us without meeting opposing currents to condense and precipitate it in the form of frequently much needed rain. In that case we say: "All signs fail in dry weather."

The telegraph and the newspapers tell us of the effects of tornadoes; and the frequency of these recitals is probably due to the increasing facilities for gathering information, rather than the more frequent occurrence of tornadoes now than formerly. They are most frequent and severe between the 35th and 45th parallels of latitude, and between the Allegheny Mountains and Kansas and Nebraska, and they are of more common occurrence in the United States than in Europe. Theoretical meteorologists tell us that the tornado is a *column*, and the cyclone an extensive *body*, of gyrating air. Their destructive difference is due to the difference in their velocity of gyration. The important element of the tornado is its spiral movement, and this movement is inaugurated by a local mass of heated air, fed by moist surface currents ascending and forming a partial vacuum, into which the surrounding air is drawn, necessarily acquiring a gyratory motion. There being less resistance in the upper strata of air, this gyratory motion begins there first, and the well known trunk or *funnel* is there initiated and elongated downward, the main and most rapidly revolving mass being above ordinary obstacles on the earth. This column-like downward projection of the tornado cloud is not necessarily at all times visible. Distinguished meteorologists further tell us, that in the central area of the tornado the tendency of the air is spirally upward, as tourists ascend the Tower of Pisa. On the outside of this area, the tendency is downward, and the pressure increases. These opposite tendencies, therefore, produce a closing spiral at the earth end of the trunk, and an opening spiral at its conjunction with the cloud, giving it the shape of an inverted *cone*. This cone is assumed to be hollow, with quiet and rarified air along its center. Objects drawn into the vortex are raised and hurled outwardly from the ascending whirl. When at times a tremendous rain-fall, or "cloud burst," occurs, it is due to the weight of the water having become greater than the ascensive power of the air that held it in suspension.

The conditions that are favorable for the production or development of tornadoes, are an unusual elevation of temperature for the season, sultry and electric conditions of the atmosphere, a low barometer, and the conflict of opposing winds of different temperature. They are composed simply of northerly and southerly lateral currents acquiring a curving direction, the southerly one (in front) westward and inward, and the northerly one (in rear) eastward around and into the center, thus producing a whirl, on the southern side of which trees and other objects are blown toward the *east*, and on the northern side toward the *west*. The direction of movement of tornadoes, which happily are local and short lived, conform to the general law of all storms—that is, from left to right. The southerly current is the strongest, and covers the greatest area. The tornado is apt to occur immediately after the passage of the lowest barometer. The heated air in front, or on the east (sun rise) side of a vortex ascends, and in the rear the air descends, bringing with it the temperature of the upper regions. This downward sloping rush of colder air, coming in contact with the upward sloping flow of warmer air, the friction and electric action set in motion, produce the tornado, whose incipient formation is in the air above. Like a ravenous bird of prey it descends, striking the earth with an already established gyratory motion around its own center, and then, in accordance with the law of all storm movements, bounds and rebounds with greater or less velocity and destructive force, in a generally easterly direction. There is usually a black and somber cloud ranging perhaps less than a thousand feet above the surface, to which is imparted a gyratory motion, giving rise to a funnel shaped projection of the under surface of the cloud toward the earth, and this terrible funnel or trunk is more or less developed and destructive, according to the condition of the cloud and the character of the locality over which it is being dragged; now apparently fastening its enormous and powerful leech-like mouth upon a grove of trees or a row of buildings, then snatched away and lifted upward by some impulsive movement of its parent cloud only to sink again to surprise, throw into consternation, and, perhaps, lay in ruins some thriving town that may happen to lie in its path. It has its origin in the enormous electric tension caused by the friction of opposing atmospheric currents of different temperature: and electricity is undoubtedly the active agent producing the appalling effects of tornadoes. Except in a general way, tornadoes can not be predicted in advance. Their formation or approach may, however, be recognized by local indications. The most marked indications are a sultry, oppressive atmosphere, a peculiar stillness, and the appearance of fierce looking clouds approaching each other from opposite directions. It is the collision of these clouds, borne by opposite currents of air of different temperature, that causes the terrific whirl and the visible funnel shaped tornado cloud. Much has been written about means of escape from the tornado, but nothing that has been suggested appears thoroughly practicable. Cellars, caves or "dug-outs," it is claimed, will afford protection; but it is doubtful whether there is any way of escape, except, when possible, running away from its line of movement, and out of its influence. Fortunately tornadoes are short-lived, and their tracks are narrow.

Forecasting the weather by the Signal Service system, as has already been shown, is done by simply taking the atmospheric conditions throughout the country, locating the existing areas of low and high barometer, and estimating their probable direction and speed of movement, and announcing, on a basis of well established rules and scientific deductions, what changes in respect to pressure, temperature, wind, and weather are likely to occur in the various districts in consequence of such movement. Any one possessing some knowledge of natural forces, and understanding the nature of the weather, can, with the aid of weather reports, foretell, from an approaching condition, the character and probable duration of his own local weather. If the prediction based on this system is not fulfilled, there is good and sufficient cause for it. Unexpected changes sometimes occur; retarding, counteracting, or dissipating influences appear; so that, perhaps, entirely different weather may ensue. The mysterions force in nature, which we call a low barometer, sometimes performs wonderful freaks, and pursues apparently erratic paths. The Signal Service prediction of general and severe frosts for the North-west, the Lake Regions, and thence southward to Tennessee, on the 20th and 22nd of September, 1823, the mere announcement of which, more especially as it was emphasized by the injunction to "Give utmost publicity," had such a marked effect upon speculation in crops, especially corn, which was then in jeopardy, was a case in point. The prediction was based upon the appearance of a very high and threatening barometer; that is to say, an unusual accumulation of unseasonably cold air in the extreme North-west. No other prediction could have been made under the rules at the time, excepting, perhaps, that it might have been more conservative in tone. The reason for the non-fulfillment of the prediction, as afterward revealed, was simply the appearance of a new storm, whose place of origin was in the lower portion of the Ohio valley, and whose path was northward, but, being barred from making any *easterly* progress by a High overlying the North-east, it curved *westward* over the lake regions. In the meantime, the frost-threatening High in the North-west had pressed down over the regions west of the Mississippi river. The storm now curved *southward*, and fought its way through the eastern borders of the great body of cold air overlying the entire West, and traversing Iowa and the Lower Mississippi valley during the day, attended by heavy rains and violent north-west winds in its rear, returned almost to the place of its origin, thus describing a great loop, after which it slowly passed off north-easterly.

The effect of this unusual movement was to delay, counteract, and in a great measure *dissipate* the high barometer that threatened the frosts predicted. The country is divided into various meteorological districts, the extent and location of which may be recognized by their designations. Atmospheric waves of disturbance are generally first perceived in the Far West, and then usually move in an easterly direction with greater or less speed, covering successively districts, or portions of districts, according to the latitude along which the center of disturbance moves, and the enlarging or contracting area of the field of disturbance. If the barometer is very low at the center of the storm area, high winds and severe gales will prevail over an area of country of about two hundred miles radius during the winter months, and probably less than one hundred miles during the summer months. There is an old saying—

"If the glass falls low, prepare for a blow."

If an energetic storm center is located in Dakota or Minnesota, with a considerable extension of the storm area southward across the Missouri valley, the whole traveling eastward, the winds in the Ohio valley will be successively south-easterly, southerly, south-westerly, westerly, and north-westerly, as the depression in the north passes to the eastward of our meridian. The depression having passed into the North-east, or the St. Lawrence valley, an opposite condition, or area of high barometer, will follow, coming perhaps from over the Rocky Mountain regions, or perhaps from western British America. If from the latter, and it pursues the usual south-easterly path of high pressure areas, we can prepare for a change of temperature, possibly according to the season, a severe cold wave, and our winds will continue to shift around the compass in the regular way; that is, to north, north-east, east and south-east, when evidences of another depression will very likely again be seen in the reports from the Far West. In this case, we will have a period of fair weather, whose duration may be known by the character, extent and rate of movement of the high barometer causing it. If the wind is northerly and steady, and the sky becomes clear and bright, we need expect no change of weather until we see the fore-runners of the next storm, in the form of streaks of cloud appearing above the horizon of the western semicircle. In winter, the storm will follow the first appearance of these thin, hazy, feathery clouds in several days in spring and autumn generally in about one day. Now, if our barometer, or the pressure in our locality as shown by reports from neighbouring stations, is high and steady for some time, there is a surplus of air, the weather will be dry and fine, and no disturbance can take place. The passage of an area of high barometer over a given locality may occupy several days, or a week—occasionally longer—from the time that "first rise after low" (which foretells stronger blow) reaches the locality until the next rain. Or, if the high pressure was of rapid birth, and unsteady character, it may pass away or become dissipated very quickly. Weather waves may be likened to the waves of the ocean; sometimes grand in their proportions, and steady and regular in their movement; at other times choppy and uncertain. Storms, areas of *low barometer*, have a warm or hot area on their east side, with easterly or south-easterly winds, and a cool or cold area on their west side, with northerly or westerly winds. If a storm is central in the upper Mississippi valley, the highest temperature of the month may occur in the Ohio valley, while the lowest temperature of the month prevails in the Missouri valley. We may be sweltering in a moist atmosphere of 80° or 90° on the hot side of a storm, and in a dry be subjected, all unprepared perhaps, to the chilling winds and cold air following the storm. In this matter, at least, we can know what "a day may bring forth," and there is no excuse for our disregard of the changes that are inevitable: changes sometimes sudden, great, and fatal, bringing disease and suffering and death, results that may be avoided by proper precautions.

The Signal Service, then, is able to announce, with general accuracy, what the weather indications are, from day to day, in the various districts, by keeping itself well informed of the movements of low or high barometers, and the influences opposing, retarding, or modifying such movements. Storms traverse the country along higher or lower parallels, according to the season of the year, caused by the difference of the earth's position to the vertical rays of the sun. In winter and early spring, these storm paths lie along lower latitudes, and we look to the *south-west* for all indications. The lower the line of transit, the colder our winter; because the cold northerly air, in the rear of storms, preponderates. In the latter part of spring and early summer, these belts of condensation have moved further north, with the apparent motion of the sun; and we look to *west* for indications. In summer and autumn they are in the north: and the further north, the warmer our summer and longer our autumn: because the warm southerly air, in their *front*, preponderates. We then look to the *north-west* for indications. If a south-western Low appears, it is likely to travel eastward, or north-eastward, across the country, according to the most favorable conditions in its front. East and south-east to south-west winds, warmer, increasingly cloudy weather, and rain, will successively prevail over the regions in front, or on the east side, of its line of march; while north-east to west winds and much colder weather, with clearing rains, caused by the very cold winds under-running and changing the previous current, will follow as a belt of cloudiness, generally moving about *south-eastward* over the country. If this movement of the cool wave (advancing high barometer) is slow, and clearing weather does not set in as quickly as anticipated, it is because their is high pressure in the south opposing its progress. When a western low appears, it is likely to move in some easterly direction, attended by the same system of winds and weather. If a northwestern low appears, it is also likely to move eastward over, or north of, the Lake Region. Our warmmest weather, and periods of drouth, are in connection with storms passing by in the far north. Very often the conditions following a storm, in such case, do not reach us. Storm centers seek moist, warm regions, where the pressure gives way most readily; and the force of the wind in any locality depends mainly upon the rapidity with which the pressure is changing, decreasing in front, and increasing in rear, of the storm. The Signal Service predictions are reduced to the simple "determination of the path pursued by the central area of low pressure, and the rapidity with which this will extend its influence in any given direction."

Local intimations of the approach of a storm, even without instruments, are abundant, and easily read. In a period of bright, clear weather, when the atmosphere is in a normal state, we are under the condition of high pressure; and this can be distinguished very readily by our feelings alone. This fair, pleasant and agreeable condition gradually passes off with rising temperature, haziness, growing dampness, freshening southerly winds, and increasing cloud formation. There is a storm somewhere in the West, and its influence is slowly extending over us. The increase in temperature is a sure sign of an approaching storm. It shows that the central area of barometer has passed beyond us, and that the southerly current is again sinking to the surface, and warming up the earth and lower strata of air. More or less haziness may attend this change, which, counteracting the tendency to cloud formation, may prolong our fair weather. Then, as the storm or rain belt approaches, evaporation ceases—we feel the humidity of the air increasing, in consequence of the rising temperature and the prevailing wind. The barometer is gradually falling; the thready cirrus clouds appear; condensation increases; the wind freshens, blowing towards the coming storm; our feelings begin to tell us of the approaching change; the air begins to feel close and sultry; animals become restless; all substances affected by moisture show the change; odors are concentrated; fires do not burn brightly; water boils more rapidly; halos appear; distant lights are brighter, and sounds more distinct; there is a *foul* sunset, and rain is evidently at hand. High pressure, with its usual attendant, fair weather, has passed away, and low pressure, with its foul weather, prevails. Meanwhile, the weather map or weather reports will have kept us informed just where the Low was central, from time to time, and whether the center of the disturbance, or only the borders, and which borders, of its area were approaching our locality. When we consider the importance and utility of practical weather knowledge, it is surprising that a portion of the time and effort devoted in our schools and universities to acquiring a smattering of sciences that have little or no practical bearing upon the ordinary pursuits of life, is not applied to a study of those that have, prominent among which is meteorology—the science of the weather, the study of the atmosphere. The time when mere notions and superstitions respecting the weather had possession of men's minds has passed away.

The relative positions of the planets, the changes, phases, and appearance of the moon, the actions of the ground-hog, the beaver, or the intelligent pig, the gabbling of geese, and the migration of birds, all old-fashioned "signs," have been superseded by a steadily increasing knowledge of the laws governing the wonderful phenomena occurring in our atmosphere. Effects have been traced to their causes. Drouths or wet spells, excessive heat or cold, storms or sunshine, are susceptible of explanation, anticipation, and, therefore, preparation against their coming. The wind no longer blows where it listeth. We know whence it comes and whither it goes. The study of meteorology would soon place students in possession of inductive generalizations, that would give them an insight into the nature of the changes that are constantly taking place. The weather map—reports from different places of pressure, temperature, moisture, wind, and cloudiness, projected upon a map of the country, or even the common blackboard, is an object lesson second to none in point of interest and value. The Government furnishes these reports every eight hours. They could be multiplied for distribution among learners, for practical work in connection with the study of the subject, and for purposes of prediction of local changes. In connection with the study of the text-book, time and practice in locating the fields or areas of different weather, over the country, as shown by the reports, would soon enable the learner to comprehend the processes of nature, and the ever-moving weather conditions. Those of our readers wishing to pursue this interesting subject into further detail are referred to the excellent work—"*The Weather*," by S. S. Bassler, from which the substance of this article is taken.

The Signal Service, as at present organized in the United States, consists of one Chief Signal Officer, with the rank, pay and emoluments of a Brigadier General; ten Second Lieutenants, and 400 enlisted men. See *Field Telegraphy* and *Meteorology*.

SIGNAL TACTICS.—Sending messages by mounted men is always liable to accidents, and at times circumstances may preclude the possibility of doing so. During an action or the execution of movements in the presence of an enemy, orders can be sent with rapidity and silence, by night or by day, by means of signals, and in the same way communication can be maintained between parties on shore and on water.

The electric telegraph and telephone are, during war, constantly liable to interruptions, so it is essential to have the power of supplementing them by a system of signaling that is independent of elaborate apparatus; but very constant practice is necessary to enable one to transmit and receive messages accurately and quickly. A good signal-man must know several systems of signaling and different cipher systems, but for common work the General Service Code for the Army and Navy is used. Lieutenant Hugh T. Reed, U. S. Army, having had varied experience in teaching military signaling in the Army, has prepared a most valuable and concise text-book, conveniently arranged for the ordinary instruction in the elements of military signaling. In preparing this work he has endeavored to overcome the difficulties encountered in the past, by adopting the same company formation and system of maneuvering that is used in the other branches of the service, thus making the forms of drill for a squad or company of signalmen as nearly as possible like those in use for other troops. The substance of what follows is taken from this work.

GENERAL SERVICE CODE FOR THE ARMY AND NAVY.

The General Service Code, a code of two elements, is made by a certain combination of the two elementary signals "1" and "2" placed opposite to each letter of the alphabet and to each of the ten digits, the whole number opposite to each standing for that letter or digit. The elementary signal "3" is a pause signal used merely to denote the end of a word, sentence, etc. This code is used with the wand, flag, torch, telegraph and heliograph instruments. When used on telegraph instruments, seventeen words per minute is rapid sending by this code. Red and green lights may also be used with the General Service Code: the red indicating "one," the green "two," and both together "three."

A...... 22	H...... 122	O...... 21	V......1222
B......2112	I 1	P...... 1212	W 1121
C...... 121	J...... 1122	Q...... 1211	X......2122
D..... 222	K 2121	R...... 211	Y...... 111
E...... 12	L...... 221	S...... 212	Z 2222
F 2221	M...... 1221	T...... 2	
G 2211	N...... 11	U..... 112	
1......21112	4......22212	6......12222	8......11112
2......12221	5......22221	7......11222	9......11211
3......22122			0......22222

The following are a part of the conventional signals used with the General Service Code, to wit:

3— End of word. 33— End of sentence.

333— End of message. 22, 22, 22, 333— Cease signaling..

22, 22, 22, 3— Signal of assent: "Acknowledge," "I understand," or "Message is received." "I see your signals," etc.

121, 121, 121, 3— Repeat. 212121, 3— Error.

211, 211, 211, 3— Move a little to the right.

221, 221, 221, 3 – Move a little to the left.

The "call signal" is made by swinging the wand, flag, or torch, from right to left until acknowledged. a..after b..before c....can h..have n..not r...are t...the u....you ur.your w.word wi.with y.why

The signals "number 21" and "number 2121," mean "O. K.," and are often used in reply to messages.

The following four conventional signals are used with the General Service Code when the signals are made with the wand, flag, or torch, to wit:

The *first* precedes and the *second* terminates the body of the message; the *third* precedes numerals used in the message, and the *fourth* terminates them. To make these signals, being at *position*, the Instructor commands:

1. *Message*, 2. Follow.

Drop the wand in a vertical plane to the front 120°, then move it horizontally to right 90°, then vertically to the left 240°, then horizontally to the front around to the right 180°, then again to the left 240°, then horizontally to the front 90°, then up to *position*.

1. *Signature*, 2. Follow.

Make in same manner as for message follow, only reverse the movements, passing from right to left.

1. *Numerals*, 2. Follow.

Drop the wand in a vertical plane to the front 120°, then move it horizontally to the right 90°, then vertically to the left 240°, then horizontally to the front 90°, then up to *position wands*.

1. *Numerals*, 2. Ended.

Make in same manner as for numerals follow, only reverse the movements, passing from right to left.

Signal numbers are read thus:

THE LETTERS.

A...Twenty-two
B..Twenty-one—twelve
C..One—twenty-one
D...Two—twenty-two
E..................................... ....Twelve
F...................................Twenty-two-twenty-one
G...Twenty-two—eleven
etc., etc., etc.

THE NUMERALS.

1................................Twenty-one—one—twelve
2................................Twelve—two—twenty-one
3........................ Twenty-two—one—twenty-two
etc., etc., etc.

THE CONVENTIONAL SIGNS.

End of word..Three
End of sentence ....Thirty-three
End of message.........................Three-thirty-three
Acknowledge..
Twenty-two-twenty-two-twenty-two-three
Cease signaling ....
Twenty-two-twenty-two-twenty-two-three-thirty-three
Error. Twenty-one—twenty-one—twenty-one—three
Move to the right...
Two-eleven—two-eleven—two-eleven—three
etc., etc., etc.

21112, 12221, 22122, etc., when preceded by "numerals follow" and followed by "numerals ended," are numerals, while at other times they are conventional signals.

AMERICAN MORSE CODE FOR TELEGRAPH INSTRUMENTS.

The American Morse Code, the code of four elements, is made by a certain combination of four elementary signals, the dot (-), the dash(—), the long (——), and the space (an extra distance between certain dots), placed opposite to each letter of the alphabet and to each of the ten digits; the combination opposite to each standing for that letter or digit. This code is employed on telegraph and heliograph instruments.

EUROPEAN MORSE CODE FOR TELEGRAPH INSTRUMENTS.

The European Morse Code, a code of two elements, is made by a certain combination of the two elementary signals, the dot and the dash, placed opposite to each letter of the alphabet, and to each of the ten digits; the combination opposite to each standing for that letter or digit.

This code may be used on the heliograph instrument, and it may also be used with the wand, flag, or torch, by making a "1" for the "dot," a "2" for the "dash," and a "3" for the "pause signals."

THE ENGLISH SIGNAL CODE.

The code adopted by the British government, a code of two elements, is made by a combination of the two elementary signals "-" and "—" placed opposite to each letter of the alphabet and to each of the ten digits; the whole number opposite to each standing for that letter or digit. The elementary signals are termed "short" and "long" flashes, or "dots" and "dashes." At night signals are in all cases made by the obscuration and exposure of a single light; in daytime by flags or other apparatus.

GENERAL SERVICE HOMOGRAPHIC CODE.

This, a code of ten elements, is made by certain combinations of the ten digits, placed in sets of two opposite to each letter of the alphabet, and in sets of one opposite to each of the ten digits; the whole number opposite to each standing for that letter or digit. The additional element (the 3 of the General Service Code.) is a *pause signal* used merely to denote the end of a word, sentence, etc.

Conventional, practical, and cipher signals, are the same as those used with the General Service Code; the disk (or lantern) in the right hand being used to make all except the *pause signal*, and to make it both disks should be used together. In ordering conventional signals, the Captain should precede each by the cautionary command, "*Code*"; thus—1. *Code*, 2 THREE; 1. *Code*, 2. REPEAT, etc. A *disk* is eighteen inches in diameter, made of canvas on a heavy wire fastened to a handle six inches long. The "*position*" and "*carry*" are same as for *lantern drill*, described hereafter.

Being at position, the Captain commands:

1. *Motion*, 2. ONE; or 1. *Figure*, 2. ONE.

Extend the right arm diagonally up to the right and immediately return it.

1. *Motion*, 2. TWO; or 1. *Figure*, 2. TWO.

Extend right arm to the right and return.

1. *Motion*, 2. THREE; or 1. *Figure* 2, THREE.

Extend right arm diagonally down to right and return.

1. *Motion*, 2. FOUR; or 1. *Figure*, 2. FOUR.

Extend left arm diagonally up to the left and return.

1. *Motion*, 2. FIVE; 1. *Figure*, 2. FIVE.

Extend left arm to the left and return.

1. *Motion*, 2. SIX; or 1. *Figure*, 2. SIX.

Extend the left arm diagonally down to the left and return.

1. *Motion*, 2. SEVEN; or 1. *Figure*, 2. SEVEN.

Extend both arms diagonally up on the sides and return.

1. *Motion*, 2. EIGHT; or 1. *Figure*, 2. EIGHT.

Extend arms to the right and left respectively and return.

1. *Motion*, 2. NINE; or 1. *Figure*, 2. NINE.

Extend arms diagonally down on the sides and return.

1. *Motion*, 2. TEN; or 1 *Figure*, 2. ZERO.

Extend both arms above the head, cover right disk with the left; and return.

On page 102 is a table of some of the signal codes at present used.

Numerals.—When numerals are made by the wand, flag, or torch, *without* the signals of "numerals follow" and "numerals ended," they are conventional signals, and have the meanings placed opposite to them, for the General Service Code, as follows:

1................Wait a moment.
2................Are you ready?
3................I am ready.
4................Use a short pole and small flag.
5................Use a long pole and large flag.
6................Work faster.
7................Did you understand?
8................Use white flag.
9................Use black flag.
0................Use red flag.

WAND DRILL.

In the position carry wands, the wand is in a vertical position in the right hand, resting in the hollow of the right shoulder, the arm nearly extended, the thumb and forefinger embracing the lower end of the wand; thumb against the thigh, the other fingers extended and joined in rear; the left hand by the side.

Being at a carry, the Instructor commands:

1. *Position*, 2. WANDS.

Bring the wand with the right hand vertically in front of the center of the body, the hand at the height of the breast; at the same time move the fingers in rear by the side of the forefinger, back of hand to the right.

Being in position, the Instructor commands:

1. *Motion*, 2. RIGHT.

Drop the wand in a vertical plane to the right by turning the right hand and forearm till the wand makes an angle of about 120° from the vertical, then instantly return it to the vertical.

1. *Motion*, 2. LEFT.

Make in the same manner to the left.

1, *Motion*, 2. FRONT.

Make in the same manner to the front.

Being in position, to make the "call signal," the Instructor commands:

1. *Swing*, 2. WANDS. 3. STAND.

Drop the wand in a vertical plane to the right, by turning the right hand and forearm, till the wand makes an angle of about 120° from the vertical—then pass it instantly in a vertical plane to a corresponding position on the left—back to right—left—and so continue, till the Instructor commands: 3. STAND, when position will be resumed.

Being in position, the Instructor commands:

1. *Carry*, 2. WANDS.

Resume the carry with the right hand.

To Rest.

Being at a *carry*, the Instructor commands:

1. *Squad*, 2. REST; or, 1. *In place*, 2. REST.

To resume the carry, he commands:

1. *Squad*, 2. ATTENTION.

There are two methods used in ordering letter signals; the first by numerals—the second by letters.

Examples by the first method.

Being at position wands, the Instructor commands:

1. *Number*, 2. ONE.

Make in same manner as *motion right.*

1. *Number*, 2. TWO.

Same as *motion left.*

1. *Number*, 2. THREE.

Same as *motion front.*

1. *Number*, 2. ONE.

Same as *motion right.*

1. *Number*, 2. TWO—TWELVE.

Make "two"—"one"—"two," without pausing.

1. *Number*, 2. THREE.

Same as *motion front.*

1. *Number*, 3. ELEVEN—TWENTY-ONE.

Make "one"—"one"—"two"—"one," without pausing.

1. *Number*, 2. TWELVE.

Make "one"—"two," without pausing.

1. *Number*, 2. TWO—TWENTY-ONE.

Make "two"—"two"—"one," without pausing.

1. *Number*, 2. THIRTY-THREE.

Make "three"—"three," without pausing.

Examples by the second method.

The Instructor commands:

1. *Letter*, 2. A.

Make "two"—"two" without pausing.

1. *Letter*, 2. B.

Make "two"—"one"—"one" —"two," without pausing.

1. *Letter*, 2. C.

Make "one"—"two"—"one," without pausing.

Etc. Etc. Etc.

A message to be signaled should be written thus:

"FORT HALE, D. T., December third.

"To C. O., Fort Randall:

"Indians are reported near you. X. Y."

or, when in the General Service Code, thus:

"2221, 21. 211, 2, 3, 122, 22, 221, 12, 3, 222, 3, 2, 3, 222, 12, 121, 12, 1221, 2112, 12, 211, 3, 2, 122, 1, 211, 222, 3,2, 21, 3, 121, 3, 21, 3, 2221, 21, 211, 2, 3, 211, 22, 11, 222, 22, 211, 211, 3,—1, 11,:222, 1, 22, 11, 212, 3, 22, 211, 12, 3, 211, 12, 1212, 21, 211, 2, 12, 222,3, 11, 12, 22, 211, 3, 111, 21, 112, 333,—2122, 3, 111, 333."

The signalman is ordered to *position wands;* the Instructor then orders the signals one at a time, giving the second after the first is signaled, and between "Fort Randall" and "Indians" he orders "*message follow*," and after "333," "*signature follow*" then "X" —"3"—"Y"—"333" "*carry wands.*"

Numerals are signaled in words or figures. When in figures, and in position, the Instructor commands:

1. *Numerals*, 2. FOLLOW.

Supposing the number to be 19, he next commands:
1. *Figure*, 2. ONE; or, 1. *Number*, 2. TWENTY-ONE—ONE—TWELVE.

Make "two"—"one"—"one"—"one"—"two, without pausing. 1. *Figure*, 2. NINE; or, 1. *Number*, 2. ELEVEN—TWO—ELEVEN.

Make "one" "one"—"two"—"one"—"one" without pausing.

The Instructor then commands:

1. *Numera's*, 2. ENDED.

When numerals in a message are to be signed *in figures*, the message is proceeded with as far as the numerals—then the signals for "*numerals follow*" is made—then the numerals—then the signal for "*numerals ended*," and then the message is proceeded with as before.

TO READ AND TO RECORD SIGNALS.

After a recruit has been taught to make signals, he should be instructed to read and record signals made by another person, and for this purpose two recruits are sent about 50 yards from a man making signals. One of the two sent out reads the signals of the man signaling, and calls them aloud, while his companion records them, either in letters or in signal numbers, as called. If the signals are called and recorded in signal numbers, it may be necessary to refer to the General Service Code to know their meaning.

Thus—1, 2, 3, 1, 212, 3, 1121, 12, 221, 21, 33, and by reference to the General Service Code, we find that they mean "It is well."

FLAGS ATTACHED TO POLES.

Pieces of sheeting or bunting, 1 to 2 feet square, tacked to poles 6 to 8 feet long, make good flags for short range signaling.

A squad or detachment, equipped with flags *attached to poles*, is drilled by similar commands and means as those used in wand drill in the position *carry flags*.

The pole (flag attached) is in the right hand; pole nearly vertical and resting in the hollow of the right shoulder; arm nearly extended; thumb and forefinger embracing the pole about 18 inches from the butt, the other fingers extended and joined in rear; the left hand by the side.

Being at a carry, the Instructor commands:

1. *Position*, 2. FLAGS.

Bring the pole with the right hand vertically in front of the center of the body, the hand at the height of the breast, and move the fingers in rear by the side of the forefinger, back of the hand in the front; at the same time grasp the pole with the left hand at the butt, the forearm horizontal and resting against the body. 1. *Carry*, 2. FLAGS. Resume the carry with the right hand; slip the left hand up the pole to the right shoulder, fingers extended and joined, the thumb close to the forefinger, back of the hand to the front, elbow close to the body. (Two.) Drop the left hand by the side.

MANUAL OF THE KIT.

The *case* is of canvas, and when open it is 4 feet long and 2 wide, with two rubber pouches for the torches and wormer; there are short straps to hold the three parts of staff in place; the two flags are folded and laid over the whole. The kit, rolled up, is fastened by three other straps. The *canteen*, of copper, holds a gallon. The *haversack*, of rubber, holds the small articles, shears, pliers, etc. A *telescope*, with ball and socket holder (carried in the haversack), completes the signalman's outfit. In the position *carry kits*, the kit is in the right hand, nearly vertical, the butt resting in the right hand; the arm hanging nearly at its full length, near the body; the thumb in front, the fingers closed together underneath and embracing the butt; the left hand by the side. 1. *Right shoulder*, 2. KITS. Being at a carry, raise the kit vertically with the right hand, grasp it with the left hand 4 inches below the middle strap, and raise this hand until it is at the height of the chin. (Two.) Raise the kit and place it on the right shoulder, the top elevated and inclined to the left. Slip the left hand over the kit on the shoulder. (Three). Drop the left hand by the side. 1. *Carry*, 2. KITS. Carry the butt slightly to the left and lower the kit with the right hand; grasp it with the left hand 4 inches below the middle strap, the hand at the height of the chin. (Two.) Resume the carry with the right hand. (Three.) Drop the left hand by the side. 1. *Kits*, 2. PORT. Being at a carry, throw the kit diagonally across the body, grasp it smartly at the same instant with both hands; the right at the lower, the left at the middle strap, the kit sloping upward, and crossing opposite the point of the left shoulder, the butt proportionately lower. The palm of the right hand is above, and that of the left is underneath the kit; elbows close to the body. 1. *Carry*, 2. KITS Resume the carry with the right hand. (Two.) Drop the left hand by the side. 1. *Sergeants*, 2. SALUTE. Being at a carry, raise the left hand and arm horizontally to the front, palm of the hand down, the fingers extended. (Two.) Bend the left elbow, carry the hand around till the forefinger strikes the kit in the hollow of the right shoulder, retaining it there until the salute is acknowledged. (THREE.) Return to the position of the first motion. (FOUR). Drop the left hand by the side. 1. *Order*, 2. KITS. Being at a carry, grasp the kit with the left hand immediately above the middle strap; let go with the right hand; lower the kit quickly with the left, regrasping it with the right above the middle strap; the hand at the height of the thigh; the butt about three inches from the ground; the left hand steadying the kit from the right. (Two.) Lower the kit gently to the ground near the right hand, drop the left hand by the side, elbow close to the body, the back of the hand to the right, the fingers extended and joined; the kit between the thumb and fingers, extended along the kit; the butt against the toe of the right foot; the kit vertical. *To Rest.* At an order kits, the Instructor commands: 1. *Squad*, 2, REST; or, 1, *In Place*, 2, REST. To resume the order, he commands: 1. *Squad*, 2. ATTENTION. 1. *Carry*, 2. KITS. Raise the kit vertically with the right hand; grasp it at the same time with the left, below the right; resume the carry with the right hand. (Two.) Drop the left hand by the side.

The kits should be habitually carried at the *right shoulder* during drill when marching. Signalmen equipped with the wand, the flag, or torch, salute as prescribed for Sergeants' salute with the kit.

The detachment with and without arms is maneuvered the same as a troop of cavalry, or a company of infantry, and when equipped with kits, movements herein prescribed are added.

Deployments.

By the flank.—Being formed in line, the Captain commands:

1. *Form signal line*, 2. *Guide center*, 3. MARCH, 4. *By the left* (or *right*) *flank take intervals*, 5. MARCH, 6. *Detachment*, 7. HALT. At the *second* command, the director (an experienced Sergeant previously designated) places himself quickly by the shortest line, 5 yards in front of the center of the detachment. At the *third* command, the director and rank march forward; the file-closers stand fast. The director and rank having marched 15 yards, the fourth command is given, at which they halt and face to the left when the rank does. At the *fifth* command, the left file steps off, and, conducted by the left guide on his left, marches in the prolongation of the former front of the detachment; the other men follow successively at the proper interval, each steadily in the trace of his predecessor; the director and file-closers maintain their relative positions. The movement is continued till all the intervals are taken. At the *seventh* command, all of the signalmen halt, face to the front, and align themselves to the right (the point of rest) without command. The Captain and guides take their posts. This formation is termed a *signal line*. In double rank, at the *third* command, the rear rank stands fast, then faces to the left with the front rank; at the *fifth* command, the left file of the rear rank steps off at the same time the left file of the front rank does, and marches parallel with him; the other men of the rear

rank follow successively, each man stepping off with his front-rank man.

The Posts of Officers and Sergeants in Signal Line.

The *Captain* is 15 yards in front of the center; as Instructor, he goes wherever his presence is necessary; the *First Sergeant* is on the right of, and 1 interval from the rank; the *Second Sergeant* is on the left of, and 1 interval from the rank; the *Lieutenants* and the *other Sergeants* are in the line of file-closers as in line. In double rank, the right and left guides are 1 interval from their flanks of the front rank; the file-closers are posted as in line. During drill with flags or torches, the file-closers and the right and left guides go wherever their services may be required. At the close of this drill, they resume their posts, by the command of the Captain: 1. *Guides*, 2. Posts.

By both flanks. Being in line, the Captain commands:

1. *Form signal line*, 2. *Guide center*, 3. March, 4. *By the right and left flanks take intervals*, 5. March. The *first*, *second*, and *third* commands are executed as explained by the flank. At the *fourth* command, the center file and those to the right face to the right, and those to the left face to the left. The men who have faced to the right are designated *right signalmen;* those who have faced to the left, *left signalmen.*

At the *fifth* command, the deployments by both flanks are executed as explained by the flank. When the center file has his interval, the First Lieutenant commands: 1. *Right signalmen*, 2. Halt: and when the rear signalman on the left has taken his interval, the Second Lieutenant commands: 1. *Left signalmen*, 2. Halt. The right and left signalmen face to the front after halting, and all align themselves on the center (the point of rest) without command.

When the deployments are made by one or both flanks from line on the march, the file-closers halt at the *third* command. In double rank, the rear rank halts at the *third* command. In signal line, the habitual *interval* between signalmen is 5 yards. In double rank, the habitual *distance* between ranks is 15 yards. For inspection of kits, intervals are two yards. In double rank, the distance between ranks is 5 yards. Greater or less than the habitual interval may be had by adding the words "*to* (so many) *yards*" between the words "*by the left* (or *right*, *flank*," and "*take intervals*," in the fourth command In double rank the front rank may be marched less than the habitual distance, by the fourth and fifth commands being given sooner. Two parts of staff are used at five-yard intervals, and the intervals should be increased 1 yard when an additional part of the staff is used. The *staff* is of hickory, 12 feet long, tapering from 1 inch at the butt to ½ inch at the tip, and is divided into three equal parts, which are provided with brass ferrules for joining the whole together. The first, or tip part, is that to which the flag is attached; the second, the one to which the torch is attached, is covered with the ferrule 6 inches long at its upper end, to protect it from the flames of the torch. Another, a larger part of staff, 4 feet long, is sometimes strapped on the outside of the kit, and then 12 feet of the staff may be used with the torch, and 16 feet with the flag.

The Assembly.

Being at a halt, the Captain commands: 1. *Form line*, 2. *Guide center*, 3. March, 4. *Assemble on right* (or *left*) *signalman*, 5. March. At the *third* command, the file-closers close to the rank. At the *fifth* command, the right file stands fast and at a *carry:* the others face to the right, close upon the right file, and form on his left in their order, face to the front, and come to a *carry*. The officers, guides and director, take posts in line. In double rank, at the *third* command the rear rank closes to the front rank and at the *fifth* command the right file of both ranks stand fast; the others all face to the right and close in as in single rank. The assembly on the center signalman is similarly executed, the center file stands fast at a *carry*. If marching to the front, the rank halts at third command. If marching to the rear, the detachment assembles as when marching in advance; the assembly completed, the detachment is faced about. In double rank, the front rank only, halts at the third command; if marching to the rear, the rear rank forms in front; the assembly completed, the detachment is faced about.

FLAG DRILL.

The ordinary *signal flags* are 4 feet square, of white bunting, with red centers 16 inches square, or red, with white centers, each flag having on one side strings or ties 6 inches long, sewed in couples 1 foot apart, for attaching flag to the staff.

Being in single line, kits at a carry or an order, the Captain commands:

1. *Unstrap*, 2. Kits.

Place the kit upon the ground with both hands, 12 inches in front of the toes, butt to the right; at the same time carry the right foot 3 inches to the rear; unswing the canteen without rising, and place it immediately to the left of the kit, nozzle to the front; unstrap and open the kit, and then take the position of the soldier.

1. *Attach*, 2. White (or Red) Flags.

Advance the left foot 9 inches, putting it under the kit; take out the parts of staff to be used (usually two), the largest first; pass the butt end to the left and rear, and connect them together; take out the flag designated and attach to the top of the staff, tying top signals first; the flag attached, pass the staff to the front with both hands, and place it on the ground, the butt resting on the kit in front of the feet, and then take the position of the soldier.

1. *Detachment*, 2. On Post, 3. March.

At the *second* command, place the left foot 1 yard to the front; take up the staff with both hands, the left at the butt, the right about 18 inches from the left, advance the right foot 1 yard.

At the *third* command, raise the staff to position (vertically) in front of the body; the left hand at the height of the waist: at the same time advance 2 yards further to the front, using the guide on the right.

Being on post at position flags, the Captain commands:

1. *Motion*, 2. Right.

Drop the flag in a vertical plane to the right, using both hands, till the staff makes an angle of about 120° from the vertical, then instantly return it to the vertical.

1. *Motion*, 2. Left.

Make in the same manner to the left.

1. *Motion*, 2. Front.

Make in the same manner to the front.

Being on post at position flags, to make the "call signal," the Captain commands:

1. *Swing*, 2. Flags, 3. Stand.

Drop the flag in a vertical plane to the right, using both hands, till the staff makes an angle of about 120° from the vertical; then pass it instantly in a vertical plane to a corresponding position on the left; back to the right—left—and so continue till the Captain commands: 3. Stand, when *position flags* will be resumed.

When at position flags, the Captain may order any signals he desires.

Being on post, the Captain commands:

1. *Down*, 2. Flags.

Step backward 3 yards; at the same time lower the flag and place it upon the ground; then stand erect.

To Rest.

Being at down flags, the Captain commands:

1. *Detachment*, 2. Rest: or, 1. *In place*, 2. Rest.

To resume attention, and post in rear of the kit, he commands:

1. *Detachment*, 2. Attention.

Being at attention in rear of the kit, to repack kits, the Captain commands: 1. *Repack*, 2. Kits. Advance the left foot 9 inches, putting it under the kit: pass the staff to the left and rear with both hands; return all the articles used to their proper places in the kit; strap up the kit, fastening the middle strap first; sling the canteen without rising; pick up the kit, and then take the position of *order kits*. The kits are brought to a *carry* and *right shoulder*, and the line assembled, as explained in the assembly. If the command *repack kits* be given when *on post*, hold the staff vertically in both hands; face about, and with guide left return to place in rear of the kit, halt, face about, and return all articles, etc., as just explained. Being on post, at position flags, to change from flag to torch drill, the Captain commands: 1. *Return*, 2. Flags. Hold the staff vertically in both hands, face about, and with guide left return to place in rear of kit, halt, face about, detach flag and return it and the top part of the staff to the kit; drop the other part on left side; leave the canteen and the kit open on the ground, and take the position of the soldier. When the flags are *down*, the command *return flags* is executed after the post in rear of the kit is taken. The commands for torch drill are executed as explained under that head.

TO OPEN STATION.

Being in double rank, to establish signal communication between the front and rear ranks, the Captain designates the senior Lieutenant (or Non-commissioned Officer) to take command of the rear rank. The Captain marches the front rank one hundred yards or more to the front, takes intervals, faces it about, unstraps kit, etc., to *attach flags* (or *torches*). The Lieutenant (or Sergeant) cautions the rear rank to stand fast; then gives the same commands as the Captain for taking intervals, etc., to *attach flags* (or *torches*). The Captain then commands: 1. *Front rank*, 2. Open, 3. Station. At the *second* command, the front rank marches *on post* and *swings flag* till the flags of the rear rank are seen; then *stands flag*; then acknowledges (22, 22, 22, 3); then makes the signals for "to A. B.," and the signal for "message follow;" then takes the position of *stand*, the Lieutenant, seeing the "call signal" of the front rank, commands: 1. *Rear rank*, 2. On post, 3. March, 4. Acknowledge; the rear rank makes 22, 22, 22, 3, then *down flag*, and is ready to receive messages from the front rank. Communication between any two stations is opened in a similar manner.

TO CLOSE STATION.

Being in double rank, in signal line, the ranks facing each other, to form line, the Captain commands: 1. *Front rank*, 2. Close, 3. Station, 4. Stand. At the *second* command, the front rank marches *on post*; at the *third*, *swings flag*, and as soon as *acknowledged* by the rear rank, the Captain commands: 4, Stand; and immediately after: 5. *Cease*, 6. Signaling, 7. *Repack*, 8. Kits, 9. *Carry*, 10. Kits, 11. About, 12. Face; and he also gives the commands for the *assembly*. The Lieutenant seeing the front rank "call," commands: 1. *Rear rank*, 2. On post, 3. March, 4. Acknowledge. 5. *Cease*, 6. Signaling, 7. *Repack*, 8. Kits, 9. *Carry*, 10. Kits; and causes the rear rank to execute the Captain's commands to assemble.

PRACTICAL SIGNALS.

Signal stations are generally on hill-tops, roofs of buildings, mast-heads of vessels, etc., and so far apart (from 1 to 30 miles) that it is necessary to use a telescope or marine-glass to read the motions of a signal flag or torch. There should always be at least two men to each signal-station, who have a practical knowledge of signals. Now, suppose there are two such men at each of two different stations, and those at the first station designated by A and B, and the two at the second by C and D, and it is desired to signal a message from the first to the second station. At the first station A takes his flag (or torch) and calls by waving it successively from right to left. B, seeing the flagman at the second station make 22, 22, 22, 3, commands A to "stand"—"acknowledge," which A does by first coming to "*position flag*," and then making 22, 22, 22, 3. B then calls off the message signal by signal, and A makes them, pausing for a second after each signal, after making the signature he makes 333, and puts his flag down. At the second station, when A's call is seen, C takes his flag and makes 22, 22, 22, 3, and puts it down. D reads A's signals and calls them off, one at a time, to C, who writes them down. If the message is received correctly and read, C acknowledges it by flagging 22, 22, 22, 3, and putting his flag down if the answer is not to be signaled at once. If the message is not received correctly or understood, C flags 121, 121, 121, 3, 22, 3, (repeat after), or 121, 121, 121, 3, 2112, 3, (repeat before), and the signals for a word in the message that is received. If none of the message is understood, C flags 121, 121, 121, 3, 22, 221, 221, 3, (repeat all) and then puts his flag down; at the first station. B, seeing C's flag, orders A to "*acknowledge*," and calls out the signals to be repeated. If A makes an error while flagging, he at once makes 212121, 3, and then the correct signals, beginning at the word or number in which the error was made. Communication between any two stations is conducted in a similar manner.

TORCH DRILL.

The *flying-torch* is of copper, 18 inches long and 1½ inches in diameter. It has two screw fastenings for attachment to the staff, and a place near the close end for filling it. The *foot-torch* is also of copper, 18 inches long and 2 inches in diameter. The flame shades and extinguishers for both are also of copper. Being in a signal line, kits at a carry or an order, the Captain commands: 1. *Unstrap*, 2. Kits. Place the kit upon the ground with both hands, 12 inches in front of the toes, but to the right; at the same time carry the right foot 3 inches to the rear; unsling the canteen without rising, and place it immediately to the left of the kit, nozzle to the front, unstrap and open the kit, and then take the position of the soldier. 3. *Prepare*, 4. Torches. Advance the left foot 9 inches, putting it under the kit, take out the torches; place them in front of the kit, foot-torch on the right, and both pointing to the front; take the canteen in the left hand, the funnel in the right, and fill the torches, the foot-torch first; return canteen and funnel—take out flame shades, remove extinguishers, put flame shades on the torches, and extinguishers in the haversack—then take the position of the soldier. 5. *Foot-torch*, 6. Place. Take the foot-torch in the right hand; march forward, guide right, 4 yards, halt, place it on the ground near the feet, wick to the front, and before rising take a match from the haversack and light the foot-torch—then stand erect, face about, and with guide left return to place in rear of the kit, halt and face about. 7. *Attach*, 8. Torches. Advance the left foot 9 inches, putting it under the kit; take out the parts of staff to be used (usually two), the larger first, pass the butt-ends to the left and rear, and connect them together; take the flying-torch in the right hand and fasten it to the top of the staff; the torch attached, pass the staff to the front with both hands and place it on the ground, the butt resting on the kit in front of the feet, and then take the position of the soldier. 9. *Detachment*, 10. On post, 11. March. At the *tenth* command, place the left foot 1 yard to the front; take up the staff with both hands, the left at the butt, the right about 18 inches from the left; advance the right foot 1 yard, and light the flying-torch at the flame of the foot-torch. At the *eleventh* command, raise the staff to a vertical position in front of the body; the left hand at the height of the waist; at the same time advancing 2 yards farther to the front, with the guide on the right.

TO RECEIVE A MESSAGE.

Being on post, the Captain commands:

1. *Down*, 2. Torches.

Step backwards 3 yards; at the same time lower the torch and place it upon the ground in rear of the foot-torch; step up on the right to the flying-torch and put the extinguisher on it: then stand erect near the flying-torch.

TO REST.

Being at down torches, the Captain commands: 1. *Detachment*, 2. Rest; or, 1. *In Place*, 2. Rest. 1. *Detachment*, 2. Attention. Remove the extinguisher, and take post in rear of the kit.

Being at attention, in rear of the kit, to repack kits, the Captain commands:

1. *Repack*, 2. Kits.

Take the canteen in the left hand to the right of the foot-torch; empty any turpentine both torches may contain into the canteen; sling the canteen; take foot-torch in the right hand; step backward 2 yards; take the staff in the left hand, hold it vertically, and return to the rear of the kit; return all articles to their proper places; strap up the kit, fastening the middle strap first; pick up the kit, and take position of *order kits*.

If the command *repack kits* be given when *on post*, first execute "*down torches*," and then above. Being on post, at position torches, to change from torch to flag drill, the Captain commands: 1. *Return*, 2. Torches. Execute what is prescribed for *down torches*, then what is prescribed for *repack kits*, except that the canteen is unslung and placed again at the left of the kit; the upper part of staff is dropped at the left side, and the kit left open upon the ground. The command *return torches* may be given from a *down*. The commands for *flag drill* are executed as explained under that head. Any signals that are made with the flag can be made with the torch, and by the same commands. If it be necessary for the man signaling to stop to fill a torch, or to stop for any other purpose, he will, at the end of a word, lower the flying-torch to the ground on his *left*, fill the torch requiring it, and then raise the flying-torch from his left and continue the message where he left off.

LANTERN DRILL.

As it is often impracticable to use torches, especially on board ship, lanterns may be used for night signaling at short ranges, and each signalman should use three, one a colored or more brilliant light than the other two, well fastened at his waist for a reference light, and the other lanterns held one in either hand against the breasts for the "*position*" or "*carry*," these two positions being the same with lanterns or disks. The General Service Code is used. Being in signal line, at position, the Captain commands: 1. *Motion*, 2. Right; or, 1. *Number* 2. One. Extend right arm to the right and immediately return it. 1. *Motion*, 2. Left; or, 1. Number, 2. Two. Extend the left arm to the left and immediately return it. 1. *Motion*, 2. Front; or, 1. *Number*, 2. Three. Extend both arms down and immediately return them. The conventional, practical, and cipher signals of the General Service Code are about the same as those used with the torch; the lantern in the right hand being used to make all except the pause signal, and to make it both lanterns should be used together. Lanterns may be used to make the signals of the General Service Homographic Code. A squad or detachment of signalmen equipped with lanterns and maneuvered by similar commands and means to those already explained. As the whole number opposite to a letter or digit should be made without a pause, the right and left motion must be combined in making it.

INSPECTION OF THE DETACHMENT.

The Captain deploys the signal line, and then commands: 1. *Officers and Non-commissioned Officers to the front*, 2. March, 3. Front. At the *second* command, the file-closers pass through their nearest intervals in the ranks, and they and the guides place themselves in their order, the Officers 10, and the Non-commissioned Officers 5 yards in front. All dress toward the point of rest. The Captain superintends the alignments, commands *front*, and then: 4. *Unstrap*, 5. Kits. Place the kit upon the ground with both hands, 12 inches in front of the toes, butt to the right; at the same time carry the right foot 3 inches to the rear; unsling the canteen without rising, and place it immediately to the left of the kit, the nozzle to the front; unstrap and open the kit, and then take the position of the soldier.

6. *Inspection*, 7. Kits. Advance the left foot 9 inches, putting it under the kit; take out the torches; remove extinguishers; put on flame-shades; place torches in front of the kit; foot-torch on the right, and 2 feet from flying-torch, both pointing to the front; lay the wormer, extinguishers, funnel, pliers, and shears between the torches; take out all parts of staff, pass the butt-ends to the left and rear, and connect them together, and lay the staff, on the ground; lay the white flag on the kit, strings from you; fold in the middle toward the strings; fold again in the same way; the flag on the front half of the kit; fold the red flag in the same manner, immediately in rear of white flag, with the strings to the front, the flags nearly covering the kit; take the staff in the left hand, stand erect, holding it vertically on the left side, left hand at the height of the breast, butt of staff against the left toe. The accouterments and dress of each soldier having been minutely inspected, the Captain commands: 8. *Open*, 9. Haversacks; and examines them. The Captain then commands: 10. *Repack*, 11. Kits. Advance the left foot 9 inches, putting it under the kit; pass the staff to the left and rear with both hands; return all articles used to their proper places; strap up the kit, fastening the middle strap first: sling the canteen without rising, pick up the kit and then take the position of *order kits*. The next commands are: 12. *Carry*, 13. Kits, 14. *Officers and Non-commissioned Officers to your posts*, 15. March. At the *fifteenth* command, the Officers and Non-commissioned Officers face about and return to their posts in rear.

An instrument called the heliograph, heliostadt, or sun-telegraph, constructed with small mirrors made to turn upon both a horizontal and vertical axis, mounted upon a tripod, so arranged as to reflect the sun's rays in any direction, and to make the flashes appear and disappear in rapid succession, is to a limited extent used in the Army; and by it messages may be transmitted much faster than with flags or torches, and it can be used at long ranges. It is manipulated by a key, similar to the electric telegraph instrument. Mirror signaling was first used by the North American Indians. There are several styles of heliographs used in the Army. The manner of using two kinds will be given in this place.. They are both mounted on tripods, and are quite portable. The following conventional signals may be used with both instruments.

"Call"........................A succession of flashes.
"Error"................ " "
"Adjust instrument"......5 flashes.
"G. A."........... ....Go ahead.
"G. S.".........................Go slower.

THE MANSE HELIOGRAPH.

The mirror turns on a vertical axis by a tangent-screw, and on a horizontal axis by a rod (with a thread on it) from the top of the mirror to the base or top of the stand of the tripod, which supports the whole. *To sight the instrument:* Place it, so that by turning the mirror vertically and horizontally when the sun shines upon it, the dark spot in the center of the mirror (or a piece of paper wetted and put on center), as seen by a person standing nearly in front of and looking into the mirror, is in a line with and covering the distant station; then put up a half-inch rod, so as to be in line with the spot and distant station, mark the place on the rod covered by the shadow of the spot. The rod usually has a sliding brass button to mark the shadow spot, and a disk of pasteboard made to slide along the rod, and upon which the reflection falls when the key of the instrument is not depressed, and when it is not wished that the reflection be thrown to the distant station. Then by moving the mirror either horizontally or vertically, without changing the position of the instrument, the signalman may always know that whenever the shadow of the center spot of the mirror covers the mark on the vertical rod, (usually from 2 to 20 feet distant from the instrument that the reflection of the sun is thrown on the distant station. And whenever the reflection of the sun from the distant station is seen, this reflection, the marked place on the rod, and center spot of the mirror, may be seen by looking into the mirror from the position chosen in setting it up.

THE GRUGAN HELIOGRAPH.

The "sun-mirror" has a hole at its center. The "flashing-mirror" has a disk at its center. Set the tripod firmly on the ground; clamp the bar to the tripod; clamp the *sun-mirror* to the bar, and turn up the sighting-rod. Ease the bar-clamp, and, sighting through the hole in the mirror, move the bar and raise or lower the sighting-rod until its disk accurately covers the distant station; then reclamp, being careful not to disarrange the alignment. Move the mirror by means of its slow-motion screws until the reflection of the hole in the mirror (shadow spot) falls upon the disk of the sighting-rod. The flash will then be visible at the distant station. *The shadow spot must be kept in the center of the disk while signalling.* Place the screen, clamped on its tripod, close to and in front of the sighting-disk, so as to intercept the flash *when the key is depressed* (obscuration system). Working the screen in the same manner as a telegraph key, will cause the flash to disappear and appear to the distant observer. The screen may be worked and the adjustment kept by a single operator.

TWO GRUGAN MIRRORS.

Set the tripod firmly on the ground; clamp the bar to the tripod; clamp both mirrors to the bar. Place the bar diagonally across the line of vision to the distant station; the *flashing-mirror* facing the distant station, the *sun-mirror* facing the sun. Stooping down, the head in rear of and near the flashing mirror, turn the *sun-mirror* by means of the slow-motion screws until the whole of the *flashing-mirror* is seen reflected in the sun-mirror, and the reflected disk and hole accurately cover each other. Still looking in the sun-mirror, turn the flashing-mirror (by its slow-motion screws) until the distant station is brought into position, which will be when the reflected disk, the hole, and the reflection of the distant station are accurately in line, or cover each other. Now, stepping behind the *sun-mirror*, throw upon the flashing mirror a full flash from the sun-mirror, and adjust the latter until the shadow spot falls upon the center of the disk. The flash will then be visible at the distant station. *The shadow spot must be kept in the center of the mirror-disk while signaling.* Place the screen, clamped on its tripod, so as to intercept the flash *when the key is depressed*, and in a convenient position for keeping the sun-mirror adjusted.

INTERNATIONAL SIGNALS.

The necessity for a uniform and comprehensive system of signaling at sea, and to shore stations on the coasts of the United States, and other countries, has led to the adoption of the "International Commercial Code of Signals," for their naval as well as for their merchant ships, by the following nations, to-wit:

United States,	Russia,	Spain,	Germany,
England,	Greece,	Portugal,	Holland,
France,	Italy,	Brazil,	Sweden,
Denmark,	Austria,	Belgium.	

Messages received at all telegraphic signal stations and life-saving stations in the United States will be transmitted and delivered to the adress on payment, either at the Station or at the place to which adressed, of the telegraphic charge. All messages received from or adressed to the War, Navy, Treasury, State, Interior, or other official department of Washington are telegraphed without charge.

Signal stations have been established at some of the most important points on the coast of the countries above named, at which the International Code is the *only* code recognized; and vessels of any nation, which make their names known by means of this code on passing these stations, are immediately reported.

Ship owners should see that their vessels are provided with the "International Commercial Code Signal Book" and the requisite number and kind of flags for signaling purposes according to this code. The flags represent 18 consonants, B, C, D, F, G, H, J, K, L, M, N, P, Q, R, S, T, V, W, each of which has its special flag or pennant of varied forms and colors. The day signals of this code are made by hoisting, in the same hoist, 1, 2, 3, or 4 of these flags; the meaning of any combination of flags in a hoist is given in the code book; some combinations stand for a whole sentence, some for single words, others for separate letters of the alphabet; hence, it is not difficult to establish communication, especially now that the meanings of a large number of combinations are translated into so many different written languages. Examples:

Combination.	Meaning (in English).
H. B	Want immediate assistance.
H. F	We are coming to your assistance.
H. W	Engine or machinery disabled.
K. P	Bar impassable.
M. F	Hold on until high water.
P. N	Want a steam tug.
B. P. W	Do you wish to be reported?

Cautionary Signals.

The U. S. War Department (through the Signal Bureau,) prescribes that the following "Cautionary Signals" be displayed, as occasion may require, at all active Signal and Display Stations of the Signal Service.

Cautionary Signal, *i. e.*, a square, red flag, with a square, black center by day, or a red light shown at night, calls for caution in view of an approaching storm, and is so "cautionary" with reference to winds blowing from any direction.

Cautionary Off-Shore Signal, *i.e.*, a white flag with black square in the center, shown above a red flag with black square in the center, by day, or a white light shown above a red light by night, is "cautionary" with reference to winds expected to blow from a northern or western direction or off-shore, at or near the place at which it may be.

SIGNALS ON THE WATER.

The United States Treasury Department published, Feb. 17, 1877, the following circular, to wit:

Every vessel of the mercantile marine navigated without complying with the instructions of this circular, will be liable to a penalty of $200, for which sum the vessel may be seized and proceeded against.

Rule 1. *Steam and Sailing Vessels.* Every steam-vessel which is under sail and not under steam, shall be considered a sail-vessel; and every steam-vessel which is under steam, whether under sail or not, shall be considered a steam-vessel.

Rule 2. Lights. The lights mentioned in the following rules, and no others, shall be carried in all weather between sunset and sunrise.

Rule 3. *Lights for Ocean-going Steamers and Steamers carrying Sail.* All ocean-going steamers, and steamers carrying sail, shall, when under way carry —(*a.*) At the foremast head, a bright white light, of such a character as to be visible on a dark night, with a clear atmosphere, at a distance of at least 5 miles, and so constructed as to show a uniform and unbroken light over an arc of the horizon of 20 points of the compass, and so fixed as to throw the light 10 points on each side of the vessel, namely, from right ahead to 2 points abaft the beam on either side.

(*b.*) On the starboard side, a green light, of such a character as to be visible on a dark night, with a clear atmosphere, at a distance of at least 2 miles and so constructed as to show a uniform and unbroken light over an arc of the horizon of 10 points of the compass, and so fixed as to throw the light from right ahead to 2 points abaft the beam on starboard side.

(*c.*) On the port side, a red light, of such a character as to be visible on a dark night, with a clear atmosphere, at a distance of at least 2 miles, and so constructed as to show a uniform and unbroken light over an arc of the horizon of 10 points of the compass, and so fixed as to throw the light from right ahead to 2 points abaft the beam on her port side.

The green and red lights shall be fitted with inboard screens, projecting at least 3 feet forward from the lights, so as to prevent them from being seen across the bow.

RULE 4. *Lights for Towing-Steamers.* Steam-vessels, when towing other vessels, shall carry 2 bright white masthead lights, vertically, in addition to their side lights, so as to distinguish them from any other steam vessels. Each of these mast-head lights shall be of the same character and construction as the masthead lights described by Rule 3.

RULE 5. *Lights for Steamers not Ocean-going nor Carrying Sail.* All steam-vessels other than ocean-going steamers carrying sail, shall, when under way, carry on the starboard and port sides lights of the same character and construction and in the same position as are prescribed for side lights by Rule 3, except in the case provided in Rule 6.

RULE 6. *Lights for Steamers on the Mississippi River.* River steamers navigating waters flowing into the Gulf of Mexico and their tributaries, shall carry the following lights, namely: 1 red light on the outboard side of the port smoke-pipe, and one green light on the outboard side of the starboard smoke-pipe. Such lights shall show both forward and abeam on their respective sides.

RULE 7. *Lights for Coasting Steam-vessels, and Steam-vessels navigating Bays, Lakes, and Rivers.* All coasting steam-vessels, and steam-vessels other than ferry-boats, and vessels otherwise expressly provided for, navigating the bays, lakes, rivers, or other inland waters of the United States, except those mentioned in Rule 6, shall carry the red and green lights, as prescribed for ocean-going steamers, and, in addition thereto, a central range of 2 white lights, the after light being carried at an elevation of at least 15 feet above the light at the head of the vessel. The head light shall be so constructed as to show a good light through 20 points of the compass, namely, from right ahead to 2 points abaft the beam, on either side of the vessel, and the after light, so as to show all around the horizon.

The Lights for Ferry-boats shall be regulated by such rules as the Board of Supervising Inspectors of Steam-vessels shall prescribe, to wit:

Lights for Ferry-boats. The lights for ferry-boats with rudders on both ends, shall be such as, in the opinion of the supervising inspector of the district in which the boats are running, are best adopted to the character of the navigation and to the prevention of accidents by collision or otherwise.

Globe Lights. A globe light may be used in place of the torch mentioned in Rule 25, when the use of such torch would be likely to endanger the safety of vessel or cargo.

Fog-signals. It is recommended by the Board of Supervising Inspectors of Steam-vessels that, whenever there is a fog by day or night, sailing-vessels and every craft propelled by sails upon the ocean, lakes, and rivers, when on the starboard tack, shall sound, with intervals of not more than 2 minutes, *one* blast of the fog-horn; when on the port tack, *two* blasts; when with the wind free, *three* blasts; and that, when lying-to or at anchor, they shall sound the bell, with the same intervals.

Fog-horns. The selection of an instrument to be employed in making the fog-signals required by law must, in every case, be left to the master or owner of the vessels, it being only necessary that the Department shall so far regulate such selection that instruments not effective for the purpose shall be excluded. Any instrument or device for this purpose which produces a sound equivalent to that of a steam-whistle, will be considered sufficient for the the purposes of the law.

RULE 8. *Lights for Sailing-vessels.* Sail-vessels, under way or being towed, shall carry the same lights as steam-vessels under way, with the exception of the white masthead light, which they shall never carry. (See Rule 3, *b* and *c.*)

RULE 9. *Exceptional Lights for Small Sailing-vessels.* Whenever, as in case of small vessels during bad weather, the green and red lights cannot be fixed, these lights shall be kept on deck on their respective sides of the vessel, ready for instant exhibition, and shall, on the approach of or to other vessels, be exhibited on their respective sides in sufficient time to prevent collision, in such a manner as to make them most visible, and so that the green light shall not be seen on the port side nor the red light on the starboard side. To make the use of these portable lights more certain and easy, they shall each be painted outside with the color of the light they respectively contain, and shall be provided with suitable screens.

RULE 10. *Lights for Steam-vessels and Sailing-vessels at Anchor.* All vessels, whether steam-vessels or sailing-vessels, when at anchor in roadsteads or fairways, shall, between sunset and sunrise, exhibit where it can best be seen, but at a height not exceeding 20 feet above the hull, a white light in a globular lantern of eight inches in diameter, and so constructed as to show a clear, uniform, and unbroken light, visible all around the horizon, and at a distance of at least one mile.

RULE 11. *Lights for Pilot-vessels.* Sailing pilot-vessels shall not carry the lights required for other sailing-vessels, but shall carry a white light at the masthead, visible all around the horizon, and shall also exhibit a flare-up light every fifteen minutes.

RULE 12. *Lights for Coal-boats, Trading-boats, Rafts, and all other like Craft.* Coal-boats, trading-boats, produce-boats, canal-boats, oyster-boats, fishing-boats; rafts, or other water-craft, navigating any bay, harbor, or river, by hand-power, horse-power, sail, or by the current of the river, or which shall be anchored or moored in or near the channel or fairway of any bay, harbor, or river, shall carry one or more good white lights, which shall be placed in such a manner as shall be prescribed by the Board of Supervising Inspectors of Steam-vessels.

RULE 13. *Light for Open Boats.* Open boats shall not be required to carry the side lights required for other vessels, but shall, if they do not carry such lights, carry a lantern having a green slide on one side, and a red slide on the other, and, on the approach of or to other vessels, such lanterns shall be exhibited in sufficient time to prevent collision, and in such a manner that the green light shall not be seen on the port side, nor the red light on the starboard side. Open boats, when at anchor or stationary, shall exhibit a bright, white light. They shall not, however, be prevented from using a flare-up, in addition, if considered expedient.

RULE 14. *Lights on Vessels of the United States Navy.* The exhibition of any light on board of any vessel-of-war of the United States may be suspended whenever, in the opinion of the Secretary of the Navy, the Commander-in-Chief of a squadron, or the Commander of a vessel acting singly, the special character of the service may require it.

RULE 15. *Fog Signals.* Whenever there is a fog or thick weather, whether by day or night, fog signals shall be used, as follows:

(*a.*) Steam vessels under way shall sound a steam-whistle placed before the funnel, not less than 8 feet from the deck, at intervals of not more than 1 minute.

(*b.*) Sail-vessels under way shall sound a fog horn at intervals of not more than 5 minutes.

(*c.*) Steam-vessels and sail-vessels, when not under way, shall sound a bell at intervals of not more than 5 minutes.

(*d.*) Coal-boats, trading-boats, produce-boats, canal-boats, oyster-boats, fishing-boats, rafts, or other water craft, navigating any bay, harbor, or river, by hand-power, horse-power, sail, or by the current of the river, or anchored or moored in or near the channel or fairway of any bay, harbor, or river, and not in any port, shall sound a fog-horn, or equivalent signal, which shall make a sound equal to a steam-whistle, at intervals of not more than 2 minutes.

RULE 16. *Sailing-Vessels.* If two sail-vessels are meeting end on, or nearly end on, so as to involve risk of collision, the helms of both shall be put to port, so that each may pass on the port side of the other.

RULE 17. When two sail-vessels are crossing, so as to involve risk of collision, then, if they have the wind on different sides, the vessel with the wind on the port side shall keep out of the way of the vessel with the wind on the starboard side, except in the case in which the vessel with the wind on the port side is close-hauled, and the other vessel free, in which case the latter vessel shall keep out of the way. But if they have the wind on the same side, or if one of them has the wind aft, the vessel which is to windward shall keep out of the way of the vessel which is to leeward.

RULE 18. *Steam-Vessel Meeting.* If two vessels under steam are meeting end on, or nearly end on, so as to involve risk of collision, the helms of both shall be put to port, so that each may pass on the port side of the other.

RULE 19. If two vessels under steam are crossing, so as to involve risk of collision, the vessel which has the other on her own starboard side shall keep out of the way of the other.

RULE 20. *Sail and Steam-Vessels Meeting.* If two vessels, one of which is a sail-vessel and the other a steam-vessel, are proceeding in such directions as to involve risk of collision, the steam-vessel shall keep out of the way of the sail-vessel.

RULE 21. *Steam-Vessel approaching another Vessel, or in a Fog.* Every steam-vessel, when approaching another vessel, so as to involve risk of collision, shall slacken her speed, or, if necessary, stop and reverse; and every steam-vessel shall, when in a fog, go at a moderate speed.

RULE 22. *Vessel overtaking another.* Every vessel overtaking another vessel shall keep out of the way of the last mentioned vessel.

RULE 23. Where, by Rules 17, 19, 20, and 22, one of two vessels shall keep out of the way, the other shall keep her course, subject to the qualifications of Rule 24.

RULE 24. *Special Instructions.* In construing and obeying these rules, due regard must be had to all dangers of navigation, and to any special circumstances which may exist in any particular case, rendering a departure from them necessary, in order to avoid immediate danger.

RULE. 25. *Sailing Vessels to be furnished with Signal-Lights, and to show Torches.* Collectors, or other chief officers of the customs, shall require all sail-vessels to be furnished with proper signal-lights; and every such vessel shall, on the approach of any steam-vessel during the night-time, show a lighted torch upon that point or quarter to which such steam vessel shall be approaching.

Conflicting Rules. Any directions heretofore given by this Department, conflicting with the above instructions, have been revoked.

Ciphers should be as simple as possible, with the object of not having a letter or end of a word appear twice by the same signal. Any cipher can be deciphered, but the time generally required to make out a cipher message often renders it useless to an enemy. The persons interested rearrange the code used by changing the signal characters, the one with another. A copy of the code thus arranged is furnished to at least one person at each signal station. The message is written out in the signal characters of the new code and signaled, character by character, or combination by combination, by a man at one station, and recorded at the other station, and then deciphered by the person knowing the code used.

Whenever the General Service Code is used, the signal for "*cipher follows*" must *always precede* a cipher message. To make the signal "cipher follows," drop the flag in a vertical plane to the front 120°, make three complete circles to the right, keeping the staff in the same inclined plane, then up to position flags. When the cipher part of the message is completed, make the signal "cipher ended" by a reverse movement.

There are a great many methods used in cipher signaling. Examples of a few methods will be given. A *signal disk* consists of two circular plates of cardboard or other material, fastened concentrically together, so that one may revolve on the other, or be clamped together in any position; the top plate is a little smaller than the other. Both plates are ruled from the center, and have thirty sub-divisions; in each of these spaces on the small disk is written, in a prearranged order, a "*letter of the alphabet*," "*end of word*," "*ing*," "*tion*," and "*and*," and in each space of the other disk is written, in a prearranged order, "*one combination*." The disks may be clamped in thirty different positions, thereby giving thirty codes of signals.

A *signal disk*, furnished by the Chief Signal Officer of the Army to commissioned officers under his instruction, may be used for transmitting messages with flags and torches in the General Service Code, by the following rules, to wit: Three front motions stand for end of message, while pause signals from the disk are used for end of word or sentence.

1st Case. Known: Adjustment letter and key number. Adjust the letter to the key number.

2nd Case. Known: Adjustment letter (when not preconcerted, R generally). Not known: Key number. Then place adjustment letter to coincide with any selected number for the key number, send number selected from the disk, followed by a pause signal from the disk (not the front motion), and go on with message.

3d Case. Not known: Adjustment letter and key number. Then send adjustment letter by code signals (as 2112 for B), followed by a front motion. Adjust the letter (B in this case) to some combination on the disk; send this combination, followed by a pause signal from the disk (not a front motion); go on with message.

4th Case. To change adjustment letter while sending message; Make two pause signals from disk; follow with combination which coincides with new adjustment letter as disk stands, then two more pause signals from disk, then change disk so that new adjustment letter stands opposite the key number; continue the message.

If a party of signalmen desire to communicate by signals with an unknown party on a distant station, equipped with signal flags and torches, and it is ascertained that the two parties do not use the same alphabetical codes, a code may be arranged if both know the method of "sixes." For convenience the stations will be designated by A and B respectively: A takes "*position*," C does the same. A swings his flag in a vertical plane to the right, back to the left, right, left, right, left, up to "*positon*" (which, by the General Service Code, is 121212.) C does the same. Both flags are then put down. A arranges a code, as explained in the last paragraph, and takes "*position*" again. C resumes "*position*. A makes six times the signal for "one"; a pause of six seconds; six times the signal for "two"; a pause of six seconds; six times the signal for "three," and puts his flag down. This is to indicate to C that the code contains two elements and a pause signal. C makes the same signals the same way, and puts his flag down. A takes up his flag and makes, in alphabetical order, the signal numbers of his code, with a pause of six seconds after each combination. At the end of the alphabet he makes "333" of his code, and puts his flag down. C, having previously written down the letters of the alphabet, records opposite to each in their order the signal numbers received. He then takes his flag and makes "22, 22, 22, 3" of the new code, and the signal numbers in the order he has received them. At the end of the alphabet he makes "33'? of the new code, and puts his flag down. If correct, A makes "22, 22, 22, 3" of the new code. If, in exchanging the alphabets, either A or C fails to make out one of the signals made by the other, the receiver at once makes a "stop" signal by waving his flag from side to side. The sender stops immediately, and makes "22, 22, 22, 3" of the new code, and the signal *preceding* that one questioned, and then continues. In like manner alphabets of any number of elements may be made and communication established. Communication may be established in a similar manner by parties using heliograph or telegraph instruments.

CIPHER SIGNALING BY TRANSPOSITION.

Take the message:

"We can hold out two days,"

and before signaling write it thus:

"days two out hold can we:"

or by another transposition, thus:

"ew nac dloh tuo owt syad,"

or by any other transposition agreed upon.

CIPHER SIGNALING BY ROUTE.

Take the sentence:

"We have driven all the Indians of this vicinity into their agencies."

Make three, four or more columns, thus:

	1	2	3	4
1	we	in	this	Friday
2	have	Indians	vicinity	came
3	driven	the	into	Jackson
4	all	of	their	agencies.

and write the message in regular order in these columns, one word under another in some columns, and one above another in the other columns, placing the corresponding words on the same horizontal lines; and if there are any places left in the last column, add unimportant words.

The message is signaled as it appears in the horizontal lines, thus:

"We in this Friday have Indians vicinity came driven the into Jackson all of their agencies."

Before the message is written in columns a *blind* (either the same or different word each time) may be written after the *fifth*, *tenth*, *fifteenth*, etc., words of the message, thus:

"We have driven all *wheat* of the Indians in *corn* this vicinity into their *have* agencies;" and now one more column or one more lines will be required, thus:

1	2	3	4
We	corn	this	up.
have	in	vicinity	going
driven	Indians	into	is
all	the	their	grain
wheat	of	have	agencies.

and the message to be signaled is:

"We corn this up have in vicinity going driven Indians into is all the their grain wheat of have agencies."

The number of columns and the order of using them, and where the blind words are to be placed, must be prearranged.

CIPHER SIGNALING BY SCALES.

Instead of using the disk as described in another place, the letters and numbers that are on the disk are written in two separate columns in the same order of succession as on the disk and by comparing the letters in the left hand column of the scale with the letters of the disk, it will be seen that they are the same and that the numbers opposite are the same also. The *letters* are written *once* and the *numbers twice*, one set immediately under another, so that by writing the letters on a slip of paper placed over the letters on the scale, this strip may be moved so that each and every number will come opposite to each and every letter, thereby having the same changes made with the disk. Hence it is immaterial which a person uses, a disk or a scale. A new scale is easier made than a disk.

......111	H......111
......112	A......112
......122	S......122
......121	Q......121
......1111	G......1111
......1112	D......1112
......1121	V......1121
......1122	M......1122

L 2	2
W......1	1
I 11	11
O......12	12

Select any letter on the scale for an *adjustment letter*, and any number on the scale for a *key number;* then, to use the scale, move the strip containing the letters up or down till the adjustment letter comes opposite to the key number selected, and a message may be sent on this key. When no adjustment letter is given "R" is understood. Example: Take the letter "R" as the adjustment letter, and "1212" as the key number, move the slip so that "R" is opposite to "1212."

To signal the adjustment letter and key number (sent after the signal for "cipher follow") make the General Service signal for the adjustment letter—then 3, by General Service Code—then a number from the *scale*—then 333, General Service Code, thus: Signal "1121, 3, 1122, 333," which means that the adjustment letter is "W" and the key number "1122." Move the strip to place "W" opposite "1122," and the key is set.

To signal a cipher message, with "R" to be the adjustment letter, station A calls C, C acknowledges by "22, 22, 22, 3." A signals the key number (any one he wishes to use) "2122," C makes "22, 22, 22, 3,—2122—333," A and C adjust their scales (or disks) by making the letter "R" coincide with "2122," and messages may now be exchanged. Example: To signal "Black Hills," A signals "22, 2, 112, 1221, 2211, 2121, 111, 11, 2, 2, 122, 2121."

To change the key *number* while sending a message, at the end of a sentence make "33, 111, 33," which shows that each adjustment letter is to be placed opposite to "111," the new key number. The receiving station will make "22, 22, 22, 3—111—333," and thus the key number may be changed often.

There should be preconcerted plans for changing both the adjustment letter and key number, given to the persons required to use them. These instructions should be committed to memory, then destroyed.

CIPHER SIGNALING BY SUBSTITUTION.

Make substitutions as follows;

A	B	C	D	E	F	G	H	I	J	K	L	M	N	O	U	Y
1	7	8	9	2	0	.	:	3	;	,	!	?	-	4	5	6

Use the ordinary letters where no cipher is given When punctuation points are used to punctuate, they should be enclosed in parenthesis. Example:

W:2- t:2 92v3! w1s s38,(.) T:2 92v3! 1 s13-t w45!9 76(;) 75t w:2e t:2 92v3! w1s w2!!(,) T:2 92v3! 1 s13-t w1s :2(.)

By substitution, using a dictionary of any edition agreed upon, such as Webster's "Pocket Dictionary of the English Language." To encipher a message, find the first word of it in the dictionary, and substitute for it the word on the corresponding line one or more pages forward or back. Proceed in the same manner with the remaining words till the whole message is turned into cipher. To decipher a message one must know the dictionary used, and the number of pages turned. A different number of pages must be turned for each word of the message; thus, for the first word suppose one page is turned, for the second word two pages, for the third three pages, and so on to the end of the message. Geographical proper names may be substituted for tell-tale words.

Another method:—Select for a key-word a word of 6 or 7 letters that has no letter repeated in it; draw a square, divide it into 25 smaller squares, number them as shown in the diagram, and then, beginning at the upper left hand corner, and passing from

M	2 A	3 J (I,	4 E	5 S
8 T	9 Y	10 B	11 C	6 D
7 F	12 G	H	12 K	7 L
6 N	11 O	10 P	9 Q	8 R
5 U	4 V	3 W	2 X	1 Z

left to right, in each square write one letter, first the letters of the key-word (majesty) in their order, and then those of the alphabet, omitting all letters used in the key-word.

To encipher. Find each letter of the message in the diagram, see the number of its square, and substitute for it the letter in the square having the corresponding number; the letter in the center square having no number, it has no substitute.

The cipher may be written with the letters in groups.
Example: Majesty—key-word.
Message.................... *W e a t t a c k a t n o o n .*
Message enciphered....I v x r r x o g x r d c c d .

To decipher. Reverse the process of enciphering.

Another method. Select for a key number a number of seven or more figures; write the message, and, beginning at the first letter, put under it the key number, one figure under each letter in rotation, and repeat the key number till there is a figure under each letter. *To encipher.* Substitute for each letter of the message the letter of the alphabet that is a certain number from it, this number being determined by the figure under each letter of the message; when there is not the number of letters near the end of the alphabet indicated by the figure under any letter of the message, add on as many letters as may be required from the beginning of the alphabet in regular order; letters of the alphabet having o under them, have no substitutes.

The cipher may be written with the letters in groups.
Example: 4,631,870—key number.
Message.................. *W e a t t a c k a t n o o n .*
Key number.............4 6 3 1 8 7 0 4 6 3 1 8 7 0 .
Message enciphered...a k d u b h e o g w o w v n .

To decipher. Reverse the process of enciphering.

The Cipher Table is composed of 784 squares of equal size, with a combination of two characters in each square. Beginning at the upper left hand corner, the first diagonal passes through one square, the second through two, and the third three, and so on—the number of squares increasing one at a time to the twenty-eighth, and then decreasing one at a time to the fifty-fifth diagonal, which passes through the square in the lower right hand corner. There are twenty-eight characters used, *i. e.*, the letters of the alphabet, the comma, and dash, giving 28 times 28 combinations of two characters each. In the 1st square is (AA), in the 2d (AB), 3d (AC), etc., in the 28th (A—), 29th (BA), 30th (BB), 31st (BC), etc., and so on to the 784th, which has (— —). The twenty-eight characters are next placed in two series of squares with one character in each square: one series is arranged vertically, the other horizontally, so that the former will be to the left of, and the latter above the squares of the table: the two characters opposite to (AA) make the key—the first being the one in the vertical, and the second that in the horizontal series. HR is the key of the accompanying table. When the charecters in the series are placed in their natural order the key is termed *regular*, and when the characters are not so placed the key is *irregular*. See page 112.

RULES FOR USING THE CIPHER TABLE.

To encipher a message in the General Service Code, write it in words without punctuation marks; point it off into periods of two characters each, counting every letter and space between *consecutive words* as separate characters; set the key; then, beginning with the first group of the message, find the first character of it in the vertical series on the left, the second in the horizontal series at the top of the table; the two characters in the small square of the table at the intersection of the straight lines bounding the two in the vertical and horizontal series respectively, will be the first two characters of the message in cipher. Proceed in the same manner to find the corresponding ciphers for the other groups.

MESSAOE ENCIPHERED.

Key: HR.

To deciper a message in the General Service Code. Point it off into groups of two characters each, counting every letter, (,), and (—), as separate characters; set the key; then, beginning with the first group of the enciphered message, find the two characters of it in one of the small squares of the table; the character in the vertical series on the left, and that in the horizontal series at the top of the table, will be the first and second letters, respectively, of the message. Proceed in the same manner to find the corresponding letters for the other groups.

"Flag Station, eleven A. M.
"Post Adj. Fort Apache:
"Three freight wagons from Holbrook have arrived.
"Corp D."

A double cipher, or a cipher in a cipher, is one of very difficult solution. For instance, a message enciphered by one method may be itself enciphered by another method. See *Signals.*

SIGNAL TELESCOPE.—The telescope of the Signal Corps pattern has been determined by experience as the best for general uses. These telescopes are of about thirty powers. They have a focal length of twenty six inches. The tube is cased in leather, in place of wood or metal. The draw is of four joints, bronzed black, in order that there may be neither glitter to attrack the enemy, nor glare to disturb the eye of the observer. Leather caps are fitted over both eye and object-glasses, and the whole is supported by a strong leather strap, long enough to pass over the shoulder, and connecting the caps and glass in such way that there are no loose parts. This glass is strong and portable. It has power sufficient for any ordinary use, and is of a size to be conveniently handled. It is habitually worn slung over the shoulder, by the Signal-officer, wherever he may be, in the field. At permanent stations, the largest and most powerful glasses, mounted upon stands, and with accurate machinery, compasses, scales, etc., may be used. The varieties of pocket-glasses may be used at distances of from five to ten miles. A glass known as the carbineer-glass is not larger in diameter than the finger, and may be carried in the vest pocket.

Binocular-glasses (marine-glasses) have, with a low magnifying power, an extensive field of view, and give much light. They are for use in observation of extensive movements, where large tracts of country must be taken in one field of view, to find the tents of the enemy, his wagons, etc., or other objects to be afterward more closely examined with the telescope. They are employed on ship-board, or in boats, where the rolling motion interferes with the use of the telescope. They are used for observations to be made on horseback, or in hasty examinations made on foot or in trees, and generally for all observations not critical, or those to be made under circumstances where the telescope cannot be conveniently handled. The marine-glass ought to be held by both hands when in use; and to steady it, the arms should be kept close to the body. In following a moving object, to keep it in the field of view, the head ought to be turned with the glass. For reading signals at short ranges, as, say up to five miles, these glasses are better than the telescope. Signals have been frequently read with glasses of this description at the distance of ten miles.

Telescopes ought never to be allowed to fall into the hands of the enemy. Officers, on dangerous stations, should conceal their glasses when not in use. When a glass is to be hidden for precaution, the object lens, or one joint of the telescope, should be hidden separately from the body of the telescope. A single joint or one lens is so small an object, that it can be concealed almost beyond the possibility of discovery. If an officer is in danger of capture, and there are no means of concealment, the telescope-glasses should be shattered or rendered worthless rather than surrendered. To adjust a telescope to its proper focus, view with it some object with well-defined outlines, at a distance of about half a mile, lengthening or shortening the eye-glass joint until the object is seen with the sharpest distinctness. To adjust a glass at night, fix it upon some brilliant star. Glasses which are to be used in the field, should have plainly marked on one of the eye-glass slides a focus-mark, so that they may be adjusted at any time without an especial adjustment in every case. Telescopes, the object-glasses being equal in size, diminish light, as a general rule, in proportion as their magnifying power is great. The most powerful glasses are, therefore, to be used for minute observations on the clearest days, or when there is a strong light on the observed object. When the light is fading, or there is little light upon the observed object, the clearer view will be had with glasses of large field and low magnifying power. When telescopes are fitted with a double adjusting focus, the short focus is to be used when the light is dim, the long focus when strong.

The following is a simple method by which to estimate approximately the power of a telescope: When the object-glass of a horizontally placed telescope is turned toward the light, a luminous point or spot appears on the eye-glass. The diameter of this spot must be carefully measured. Measure then the diameter of the object-glass. The power of the glass is that number given as quotient when the diameter of the object-glass is divided by the diameter of the luminous spot. Thus if x = diameter of object-glass, and y = diameter of luminous spot, the Power $= \frac{x}{y}$. See *Telescope*.

SIGN LANGUAGE.—A pantomimic system of communicating ideas, extensively used by North American Indians. The range of its use is not exactly known, but it is common among all the tribes of the Plains and many of those beyond the Rocky Mountains. It is in one sense the Court language of the Indians, being the only means of communication between tribes not speaking a common dialect. The following signals will serve to show the nature of the method of communication: "*Who are you?*" is signaled by waving the right hand to the right and left several times in quick succession; "*We are friends*," by raising both hands and grasping the left with the right, as in shaking hands; "*We are enemies*," by closing the right hand and placing it against the forehead, or by waving a blanket (usually red) in the air. To say by signs "*that after a certain journey a good camp will be found, and that game may be found along the road*," first indicate the course of the sun, from its rising to the point at which it will appear on reaching the camp; then straddle one finger of the left hand with two fingers of the right, trotting them in imitation of the motions of pony and rider; then act as though halting, dismounting and tiring; then remount and proceed on the way; finally stop, bow the head, rest it on the hand and close the eyes in imitation of sleep. To intimate that "*such a one is dead*," place one hand over the other and then quickly slip it beneath (gone under); that "*such ones are husband and wife*," point to each and place the forefingers in contact throughout (meaning one); that "*such ones are brothers and sisters*," point to each and place two fingers in the mouth (meaning nourished at the same breast); that "*such ones are good friends*," point them out and fold the arms over the breast, etc. The various tribes are indicated by making the representation of some totem peculiar to each. The Comanches, or "Snakes," by a gliding motion, like a crawling snake. The Crows, by imitating the flapping of wings. The Sioux, or "Cut-throats," by drawing the hand across the throat. The Kiowas, or the "Prairie Men," by imitating the drinking of water. The Pawnees, or "Wolves," by placing the hands at the sides of the head, like the ears of a wolf. The Arapahoes, or "Smellers," by laying hold of the nose. The Utes, or "Dwellers among the Mountain Tops," by pointing upward. The Cheyennes or "Cut-arms," by drawing the hand across the arm, etc.

The Indians have a system of signaling by means of smokes during the day, and fires at night. The color (light or heavy), the volume (thin or dense), and the varying brilliancy of flame, are all significant signals. Every tribe jealously guards the secrets of its code of signals. Smokes may be raised several hundred feet in a vertical column by making a fire without very much blaze and piling on green boughs, grass, and weeds. By confining the smoke and permitting it to escape at intervals, puffs may be sent up at will. Owing to the very clear mountain air, the elevated "buttes" and mountain ridges may be seen at a great distance, and may serve the purpose of signal-stations. The Indian alphabet is very similar to ours, being made up of long and short lines. By spreading a blanket over the column of smoke and quickly displacing it, the length or shortness of the columns, as well as their frequency, may be regulated. See *Trail*.

SIGN-MANUAL.—The subscription of the Sovereign, which must be adhibited to all writs which have to pass the Privy Seal or Great Seal. When attached to a grant or warrant, it must be countersigned by one of the principal Secretaries of State, or by the Lords of the Treasury. The sign-manual, in practice, consists but of the initial of the Sovereign's name, with the letter R added, for *Rex* or *Regina*.

SILENCE.—To cause to cease firing by a vigorous cannonade. In an action, "To silence the fire" of the enemy's guns is to disable his artillery in such a way that he is unable to reply.

SILICON.—Next to carbon, silicon, or *silicum*, is the commonest and most abundant constituent of all cast-iron. Its effect is very similar to that of carbon and its tendency is to reduce the percentage of carbon. It is an element that is always present in every form of iron, although at times its quantity is very minute; the proportion of silicon being higher in the gray than in the white variety, and the greater the quantity of graphite in the crude iron, the larger the amount of silicon. The best common iron contains from one to one and one-fourth per cent. of silicon. Such iron has a smoother face than inferior pig, and when struck with a hammer rings: it is brittle and crystalline; whereas inferior pig contains only ½ or ⅜ of silicon, is rough on the face, breaks with less ease than the crystalline pig, and when struck sounds dead like lead, without ringing at all. Silicon exists in cast-iron sometimes combined and sometimes separate, and is derived from silica in the ore or in the fuel. Silica is a combination of silicon with oxygen; and when the latter is abstracted by the carbon at the high temperature of the blast-furnace, the silicon enters into combination with the iron. The presence of a large proportion of silicon in cast-iron is generally considered injurious to its quality. In refining iron the silicon is oxydized before the carbon, and in some cases the silicon is separated completely from the metal, existing only as traces. The time required to refine iron seems to depend upon the amount of silicon present in the pig: thus, gray iron requires much longer time than white, and when very silicious white iron or glazed gray-pig is used, it is almost impossible to refine it. See *Cast-iron*.

SILL.—In fortification, the inner end of an embrasure.

SILLADAR HORSE.—Indian irregular cavalry, raised and maintained on the principle of every man furnishing and maintaining his own horse, arms, equipments, etc., in return for his pay.

SILLON.—In fortification, a work raised in the middle of a ditch, to defend it when it is too wide. It has no particular form and is sometimes made with little bastions, half-moons, and redans, which are lower than the works of the place, but higher than the covered-way. It is frequently called an *envelope*.

SILURES.—A powerful people in Britain, inhabiting South Wales, who long offered a formidable resistance to the Romans, and were the only people in the Island who at a later time maintained their independence against the Saxons.

SILVER-RAIN.—The small cubes of a composition which emits a white light in burning; used as decorations for the pots of rockets, etc.

SILVER STICK.—The title given to a Field Officer of the Life Guards, when on duty at the Palace. The *Silver Stick* is in waiting for a week, during which period all reports are made through him to the *Gold Stick*, and orders from the *Gold Stick* pass through to the Brigade. In the absence of the *Gold Stick*, on levees and drawing-room days, he goes to the Royal Closet for the parole. See *Gold Stick*.

SIMULATION.—The vice of counterfeiting illness or defect, for the purpose of being invalided.

SINCH.—A strap whereby the loop on the end of the girth of a Spanish saddle is laced to the loop on the saddle. The Spaniards and Mexicans do not use a buckle, but pass a strap, rope, or raw-hide over and over around the loops and tuck the end in.

SINE DIE.—A term signifying "Without Day." When a Court or other body rise at the end of a session or term, they adjourn *Sine Die*. In law this does not preclude further proceedings by the same Court.

SINGLE COMBAT.—The "Holm-gang," or island duel of the old Norsemen. A great many quarrels were settled by single combat, when to guard against interference, the principals went alone to some small island (or holm), and there settled their quarrel by strength and skill. The idea is as old as war. In the Bible we read of Goliah challenging any Israelite to single strife. In the Iliad, Ajax challenges any opponent, and furthermore defies heaven. It was not uncommon in England, and was particularly invoked in charges of treason. The idea finds its modern and despicable expression in dueling.

SINGLE-STICK.—A cudgel used in fencing or fighting. Also, a game at cudgels, in which he who first brings blood from his adversary's head is pronounced victor.

SINISTER.—In Heraldry, the left-hand side of a shield. As shields are supposed to be carried in front of the person, the sinister side is that which covers the bearer's left side, and therefore lies to the spectator's right.

SINOPLE.—In Heraldry, a term meaning the same as *vert*. See *Vert*.

SIOBOOKATANA.—A Japanese saber having a long straight handle, but without any guard, quillons, or counterguard.

SIR.—A term originally corresponding to *Dominus* in Latin, and which has come, when appended to the Christian name and surname, to be the distinctive mark of knighthood. It was at one time the practice to use the same title in addressing the Clergy, a familiar instance being Sir Hugh Evans in the *Merry Wives of Windsor*. To so great an extent did this usage obtain, that a "Sir John" came to be a common sobriquet for a Priest. "Sir" was here a translation of *Dominus*, the term used for a Bachelor of Arts, originally in contradistinction from the *Magister*, or Master of Arts, but eventually extended to the Clergy without distinction. Used along with the Christian name and surname, "Sir" is now applied exclusively to Knights and Baronets. When standing alone, it is a common complimentary mode of address used without much consideration of rank or social status. "Sire" is another form of the same monosyllable, which has been adopted from France as a mode of addressing Royalty.

SITE.—The ground occupied by a work is denominated the *site*, or *plane of site*. The *command* is the height of the interior crest above the site; and the *relief* is the height of the same line above the bottom of the ditch. See *Field-fortification*.

SIXAIN.—In the Middle Ages, an order of battle, wherein six battalions being ranged in one line, the second and fifth were made to advance, to form the van-guard; the first and sixth to retire, to form the rear-guard; the third and fourth remaining on the spot, to form the corps or body of the battle.

SIX-SHOOTER.—A pistol with six barrels, or capable of firing six shots in quick succession; especially a six-barreled or six-chambered revolver.

SIZE.—In a military sense, to take the height of men for the purpose of placing them in military array, and of rendering their relative statures more effective.

SIZE ROLL.—In the British Service, a list containing the names of all the men belonging to a troop or company, with the height or stature of each specifically marked.

SKAIN—SKEAN.—A Celtic word which signifies a knife. It was a weapon in the shape of a small sword or knife, and was worn by the Irish in early times. Also written *Skeen*, and *Skeine*.

SKELETON.—A term applied to the diminished state of a regiment from casualties in the field or as the result of sickness.

The term is also applied, in conjunction with the word drill, to *skeleton-drill*, which is a method of instructing Officers and Non-commissioned Officers in drill, when a sufficient number of men cannot be collected to form a battalion in single rank. A skeleton battalion is formed of companies composed of two, four, or eight men each, representing, if there are two, the flanks of the company; if there are four, the flanks of half-companies; if there are eight, the flanks of sections. The intervals between the flanks are preserved by means of a piece of rope held at the ends to its full extent. By this means any set or number of maneuvers may be performed.

SKELP.—The rolled metal or welding of wrought-iron, from which certain gun-barrels are made. The skelp is passed between rollers, which first bend the plate longitudinally, and afterwards convert it into a tube. The tube is then heated to a welding heat, a mandrel is pushed into it, and it is passed through the welding rolls, which weed the edges and at the same time taper and lengthen the tube. The boring and turning are afterwards done in lathes. See *Gun-barrel*.

SKEW-BRIDGE.—A bridge placed obliquely so as to cross a road or river at an angle not a right angle. Such bridges, built of stone, are not easy of constuction, owing to the peculiar twisted forms which the voussoirs assume, and were scarcely ever used till the necessities of railway curves compelled their introduction. They are evidently a great improvement on the old-fashioned mode of twisting a road, first to the right and then to the left, in order to get the bridge at right angles to the place to be crossed. Since the introduction of iron girders as the support of bridges, skew-bridges have become easy of construction, and are now quite generally used.

SKID.—A rectangular beam of wood used extensively in all operations connected with the movements of heavy artillery. All blocks and skids should be sound, free from knots, and perfectly true in dimensions. When the edges become splintered and rounded by wear, they should be discarded, as with such it is impossible to erect safe and stable scaffolding and supports. They should not be painted; the thickness of each should be marked on both ends. In erecting a scaffold or other support, a level foundation is of the first consideration; the blocks should then be laid crossing each other in alternate tiers, and the weight supported should be made to bear equally upon all sides of the base.

The term skid is frequently employed to denote any timber which is used as a base to keep one object from resting on another. Thus, a row of cannon in store will be kept from the ground by skids.

The term is also applied to the drag which is put on the wheels of carriages in going up hills, to prevent rolling backward.

SKIDDING OF ORDNANCE.—All cannon should be placed, according to kinds and calibers, on skids of stone, iron, and wood. Permanent skids, made by building small square pillars of brick, about 18 inches high, with old railroad rails laid on the top of them, end to end, are best and cheapest. The ground selected should be hard, well-rammed, and covered with a layer of cinders or other suitable material to prevent any vegetation. *Guns and long howitzers* should rest on the skids in front of the base-ring and in rear of the muzzle; the axis is inclined at an angle of 4 or 5 degrees with the horizon, the muzzle lowest; the trunnions touching each other; or, if space be wanting for that arrangement, the trunnion of one piece may rest on the adjoining piece so that the axis of the trunnions is inclined about 45° with a horizontal line, the muzzle closed with a tompion or a plug of dry wood saturated with oil or grease; the vent down, stopped with a greased wooden plug or with putty or tallow. If circumstances require it, the pieces may be piled in two tiers, with skidding placed between them, exactly over those which rest on the ground, the muzzles of both tiers in the same direction and their axes preserving the same inclination. *Short howitzers and mortars* should rest upon thick planks or on good flagging, standing on their muzzles; the trunnions touching; the vents stopped. *Iron ordnance* should be covered on the exterior with a lacquer impervious to water; both the bore and the vent should be greased with a mixture of *oil* and *tallow* or of *tallow* and *beeswax* well melted together and boiled to expel the water. The lacquer should be renewed as often as required, and the grease at least once every year. The lacquer and grease should be applied in hot weather. The cannon should be frequently inspected, to see that moisture does not collect in the bore.

SKINNERS.—A name assumed by a predatory band in the Revolutionary War, who, professing allegiance to the American cause, but influenced by a desire to plunder, roamed over the "neutral ground" lying between the hostile armies, robbing those who refused to take the oath of fidelity.

SKIRMISH.—A slight fight in war; a light combat between detachments from armies which are yet at a considerable distance from each other, or between detached and small parties.

SKIRMISHERS.—Soldiers operating in loose array, two together—*i. e.*, front and rear, having a lateral distance of about six paces between the files. When the army advances, the ground in front, and for some distance on each flank, is usually covered by skirmishers, to prevent surprise. If cavalry come suddenly on them, they rush together, and form small squares, called rallying squares. Skirmishers fire independently at their own discretion; but the rule is, that one of the two men composing a file should always have his rifle loaded. Orders are communicated by the sound of bugle. The employment of skirmishers dates from the wars of the French Revolution, when France, assailed on all sides, supplied great numbers of conscripts, who, from the want of instruction and practice in discipline, were thrown out to fight in a loose order, where coherence and precision were not so much wanted as intelligence and courage. Skirmishers, to perform their work satisfactorily, must act together and with vigor, either to break the enemy's lines or to repulse, according to circumstances, the counter-attacks of the enemy: they must be maintained in a regular order, "order in disorder," as a foreign writer expresses it, and be regularly reinforced by the supports, which, being placed at a certain distance in rear, are always ready to advance and feed the first line when the time comes. To prepare for the final charge, by crushing the enemy with their fire, is the first aim of skirmishers; to support them when weakened, to push their line by successive bounds till they reach the enemy's positions, is the duty of supports. The reserve follows in rear, becoming in its turn supports, according to circumstances, ultimately joining the skirmishers in the last attack, assisting in penetrating the enemy's position, striking the final blow, and in pursuing the enemy with its fire.

SKIVER.—An old form of dirk used for stabbing purposes.

SKOTTEFER.—A name formerly applied to an archer.

SKULL CAP.—The small German bassinet, of the thirteenth century. It was worn over the *camail* and under the *heaume*.

SKY-ROCKET.—A species of fire-work composed of a mixture of niter, sulphur, and charcoal, tightly rammed in a stout paper case—which is caused to ascend when the compound is ignited at the lower end. It is provided with a stick which is attached to the case at one side. See *Rockets*.

SLAGS.—Fused compounds of silica in combination with lime, alumina, or other bases which result as secondary products from the reduction of metallic ores. More or less of the metal always remains in a slag; in the early days of iron-smelting the proportion of metal thus wasted was so great that some old slags have been profitably smelted in recent times.

Slags being silicates, are of the nature of glass, and externally have a glassy, crystallized, or stone-like character. Beautifully crystallized specimens are occasionally to be met with at smelting-works. They vary very much in color, and are sometimes so prettily veined and marbled, that attempts have been made to apply them to ornamental purposes. Millions of tons of slag are annually produced at the iron smelting-works of Great Britain, but almost the only use to which it has yet been successfully applied is in the making of square blocks or bricks for building purposes. The slag is run into molds, either as it issues from the blast-furnace, or after being re-melted; and it is found to be a very durable material. Broken slag is also used as a covering for roads, but its brittleness and sharpness are objectionable qualities for this purpose Several patents, beginning so far back as 1728, have been taken out for casting slag into articles of a more ornamental nature, but hitherto they have not been commercially successful.

In an archæological point of view, slags are interesting as pointing out the sites of ancient smelting-works, and as affording a clue to the primitive methods of obtaining the metals from their ores.

SLANT-FIRE.—A name applied to the fire when the shot strikes the interior slope of a parapet, *forming* with it a horizontal angle, not greater than 30°.

SLASH.—1. A term formerly employed to express the pieces of tape or worsted lace which were placed upon the arms of Non-commissioned Officers, in order to distinguish them from privates. 2. To strike violently and at random with an edged instrument; to lay about one indiscriminately with blows. 3. To cut in stripes or lines. Hence, the *slashed* sleeves and pockets, which are peculiar to the British Cavalry, when the officers or men wear long coats.

SLASHING.—In compliance with the principle that all houses, trees, brush-wood, etc., within range of the work, which could be used as a shelter and a place of concealment by the enemy's sharp-shooters should be removed, it is essential that the trees within six hundred yards of the work be cut down. As it is not practicable to remove immediately the trees from the spot, it is the custom to cut them down so that they shall form, while lying on the ground, an obstacle which may be used in the defence of the work. Trees cut down so as to fall in all directions, form what is known as a slashing. It is better, where the trees are intended to be used as an obstacle, that they be cut so as to fall towards the enemy; and, in the case of the smaller trees, which might be moved by several men, the trunks should not be cut entirely through, but only enough to allow the trees to fall. A thick and well arranged slashing forms an excellent obstruction to an enemy's free movements. It has the serious defect of being easily burned when dry. See *Abatis*.

SLAT-BAR.—The bar of a seige-howitzer limber between the splinter-bar and bolster, and connecting the futchels.

SLEEPER-RIFLE.—A breech-loading small-arm having a fixed chamber and a peculiar breech-mechanism. It is opened by pressing an eccentric lever on the right side of the butt-stock, and thus throwing out the spring-butt-plate, so as to release the rear end of the chamber-lever, and to allow it to be then thrown down by the spring included between it and the stock. By closing the chamber-lever until its rearmost end engages with the butt-plate, the forward end catches the cartridge, as would be done by a pair of tongs.

SLEEPERS.—Small joists of timber, which form a foundation for the platform of a battery, and upon which the boards for the flooring are laid. Also, the undermost timbers of a gun or mortar. Sleepers must pe well embedded in cuts or trenches, and firmly fixed or pinned into the earth, and then covered with blanks, and finally completed with ribands and rack-ashings on each side.

SLEETS. The parts of a mortar extending from the chamber to the trunnions, to strengthen that part.

SLEEVES.—Sleeves of flannel or serge, drawn over the coat-sleeves of the gunners and other cannoneers to prevent them from being soiled while loading the mortars.

SLEIGH.—A particular pattern of carriage used for the transport ot artillery in countries where much snow falls, such as in Canada. The carriages of the country are termed "sleds," and when artillery was sent to Canada in 1862, the sleds were found very useful and better adapted than the sleighs. The term *sleigh* is also given to the carriage on which heavy guns are moved when in store. The mode of moving this nature of carriage is by means of rollers being placed underneath the sleigh and worked by hand-spikes.

SLEWING.—To slew a gun or mortar, when, strictly speaking, is to turn it on its axis without moving it from the spot on which it rests. If the piece to be slewed rests on skids, a handspike is placed close to it on each skid, bevel up, and on that side of it towards which it is to be turned. This is then called "scotching" or "chocking."

SLIDE-REST.—An appendage to the turning-lathe, so contrived as to hold a tool firmly to the work, and while cutting a shaving from the bar in the lathe, the tool is slid gently along and the bar is turned quite true. There are two slides to the rest, by the separate or combined motions of which the tool can be made to act along or across the work with great accuracy; the attendance of a workman may even be dispensed with, by attaching a *star* to the wheel, and an iron *finger* to the end of the work in the lathe; as the work revolves, the finger will bear down one of the points of the star, the effect of which is the same as turning the screw-handle, by which the tool is so moved along the surface of the work.

SLIDING-CALIPERS.—An instrument used for measuring the specimens of metal to be tested. Its sliding-scale is divided into twentieths of an inch. A vernier is attached containing fifty divisions, which cover forty-nine divisions on the sliding-scale, and it reads to thousandths of an inch. It will measure space not exceeding two and a half inches, giving the result to the nearest one thousandths of an inch. The accuracy of its adjustment may be readily verified by pressing the points together gently, and noting whether the zero points coincide. If from the wearing of the steel points, or from other cause, the adjustment should become incorrect, it may be re-adjusted by turning the screw which forms one of the points.

When the instrument is designed for both outside and inside diameters, the vernier is then on the slide, which is moved along the scale. An attachment for communicating slow motion to the slide is also added. The scale is divided into fortieths of an inch. The vernier contains twenty-five divisions, which cover twenty-four divisions on the scale, and reads to thousandths of an inch. The extent of the scale which can be used by the vernier, when including the clamp, is 6 inches. In measuring an inside diameter it is necessary to add 0 2 inch to the reading of the instrument for the thickness of the measuring points. See *Calipers* and *Microscopic Gauge*.

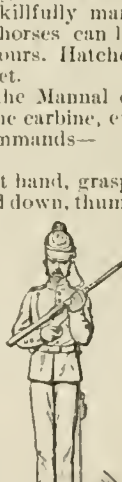
SLIDING-CARRIAGE.—The carriage mounted on a traversing platform and much used in coast batteries where rapidity of traversing is required, the objects fired at from such batteries being seldom stationary.

SLING.—1. A leather strap attached to a musket serving to support it across the soldier's back, as occasion may require. 2. A weapon much in use before the introduction of fire-arms, formed of a piece of leather, with a round hole in the middle, and two cords of about a yard in length. A round pebble being hung in the leather by the cords, the latter were held firmly in the right hand, and swung rapidly around. When the stone had attained great speed, one string was disengaged, on which the stone flew off at a tangent, its initial velocity being the same as it had at the last moment of revolution. This velocity gives far greater range and force than could be imparted in mere throwing. 3. A construction employed to hoist horses on board the ship. It is made of stout web, or double No. 1 canvas. It is 5 feet long and 2 feet wide, secured at each end by a stick of strong wood 2 inches in diameter. The sides are bound with strips of canvas doubled, thus making the edges four thicknesses. Loops of 4-inch rope are attached to each stick. The loop attached to one stick is 9 inches long; that attached to the other is 2 feet 11 inches, and has an iron eye—3 inches, inside measurement—fixed in the end. Breast and breech ropes (2-inch) 9 feet long are fixed to each side, and are tied together when the sling has been put under the horse. The slings should be tested by an excess of weight. A donkey-engine is used for hoisting. Five men are required to sling a horse quickly and well. One man holds the head guy, which is attached to a neck-collar; two men, one on each side of the horse, pass the sling under his belly; both then hold up the ends over his back, passing the long loop through the shorter one and hooking on the eye of the former to the lifting tackle, continuing to hold up the sling until the horse's legs leave the ground; another man stands at the breast and fastens the breast-rope, while the fifth stands at his rump and fastens the breech-rope. The officer superintending commands: HOIST AWAY. The first man slacks away at the guy-rope, holding it just sufficiently taut to keep the horse's head steady. When hoisting, no delay should be permitted; it should be done in the shortest time compatible with safety. At the commencement, after a certainty that all is right, it should be done rapidly to raise the horse off his feet and free him from surrounding objects before he has time to do any injury by kicking. After attaining the necessary height, he is carefully and steadily lowered to the deck. Care should be taken to have two or three careful and active men stationed to seize the horse and prevent his plunging until the slings are removed. While one holds him by the head stall, another rapidly unhooks the tackle purchase, and two others let loose the breech and breast-bands, or ropes. When the horses are to be lowered through a hatch to a deck below, the combings of the hatch, as well as stanchions about it, should be well padded. As an additional precaution, a head-collar should be provided, with a large pad on top to prevent injury should the horse strike his head against the deck beams when lighting on his feet. Everything being in readiness and skillfully managed, an average lot of one hundred horses can be hoisted on board in from two to three hours. Hatches for horses must be at least 10 by 10 feet.

SLING CARBINE.—A command in the Manual of Arms, when troops are armed with the carbine, executed as follows: The Instructor commands—

1. *Sling*, 2. CARBINE.

Throw the piece briskly into the left hand, grasping it at the rear-sight, back of the hand down, thumb along the groove, elbow close to the body, barrel to the rear, the muzzle pointing to the left and front, left hand as high as and opposite the shoulder; slip the swivel to the front with the right hand, and bear on the springs to open it; engage it in the ring and grasp the small of the stock with the right hand. (Two.) Let go with the left hand, dropping it by the side; lower the muzzle, passing the carbine behind the right hip, push the butt to the rear, and drop the right hand by the side. See *Manual of Arms* and *Unsling Carbine*.



SLING CART.—The contrivance used for moving pieces of heavy artillery, or other objects short distances. They are of two kinds: one, the garrison sling-cart for heaviest weights, is attached by its pole to a siege or a field-limber, and may be drawn by horses; the other, the hand sling-cart, is designed for moving lighter weights and siege-pieces to the trenches by hand. The siege-limber may also, in case of necessity, be used as a sling-cart. With the hand sling-cart, the weight is raised by first attaching to it a sling, and then applying to the sling the hook upon the rear of the axle, by raising the pole of the cart. The pole is used as a lever, the axle and wheels being the fulcrum. It may be used for any weights not exceeding 6,000 pounds. With the garrison sling-cart, the weight is raised by first attaching to it a sling, and then applying to the sling the hooks forming the lower part of a powerful screw passing up through the axle of the cart. Above the axle is the nut of the screw, provided with long handles. Power is applied to these handles and the screw is run up, thus raising the weight. This sling-cart is capable of carrying 20,000 pounds; but with such heavy weights the handles of the screw are difficult to turn. To overcome this difficulty, a modification has been made in the cart by substituting for the screw a hydraulic-jack.

Through the axle-body two vertical mortises are now cut each at a distance of twenty inches from the middle of the axle-body. Through these mortises slide two stout bars of iron, with hooks below for the sling-chain, and holes above for pins to support them as they are raised; the pins pass through the bars above the axle-body. A strong cross-bar connects the upper bars near their tops; under this the head of the jack is applied, the jack resting on the axle-body.

The efficiency of the wooden sling-cart has lately been much increased by the introduction of a new *hoisting apparatus*. This modification consists in the use: 1st, of a *hoisting bar*, composed of two parallel bars that pass through mortises in the axle and terminate in hooks—a cross-bar as a brace is welded immediately above the hooks; 2d, of a *hydraulic jack*; that stands on the axle over the mortise, for the old hoisting-screw; 3d, of an iron *cross-head* that slips over the hoisting-bar and rests on the head of the jack. The branches of the hoisting-bar are pierced with holes for movable pins. In using this apparatus the rings or chains by which the weight is slung are hooked to the lower ends of the hoisting-bar; pins are passed through those holes on each branch which appear immediately above the cross-head; the jack is worked and the weight is raised to the required height; a pin is placed in the lowest available hole of each branch, and the jack let down till the weight is born by the pins resting on the axle. If one lift of the jack be not sufficient, the operation is repeated as often as necessary.

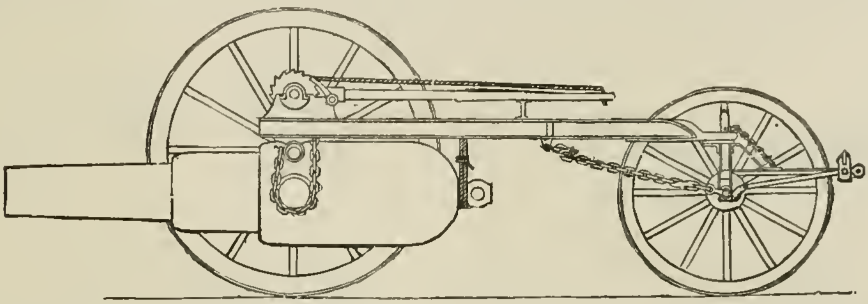
The English iron sling-cart is composed of a perch, two sides and two cross-pieces, two cheeks, an axle, and axle-body. The perch and sides are of girder-iron, and are connected by a cross-piece, also of girder-iron, riveted to them in front, and by the axle which is riveted to them in rear; also, by a stay of round-iron from the perch to each side.

The axle is arched, to give greater room under it, and has in the middle two lugs which receive the perch and rivets to secure it, also, a projecting piece at the shoulder for riveting it to the side. The cheeks are of T-iron, and are riveted to the sides; they support the windlass directly over the shoulders of the axle. The perch has a lunette by which the rear wheels are connected with the limber. A windlass of elm, cylindrical except at the ends, where it is octagonal, is provided with both ratchets and handspike sockets. It has a hook at its middle, to take an eye in the middle of the sling. Two similar hooks are on each end of the axle-bed, to take the ends of the sling. The handspikes are 80 inches long; two of them have 15 feet of a 2-inch rope made fast to the small end. The windlass is worked, in raising the load, from the rear of the wagon.

The limber is wholly of iron. The axle-body is built up by riveting two plates on the sides of the axle, with the pintle between them, and covered with a top-piece. The three futchells of T-iron are riveted to the axle-body, and bolted to the splinter-bar; this is made of plates, trough-shaped, and strengthened by a stay of round-iron at each end, connecting it to the axle-body. The wheels are wooden, with bronze nave-boxes and wrought-iron flanges. The principal weights and dimensions are as follows:—

Weight of sling-wagon..............	4,760 pounds.
Weight of sling-wagon wheel.....	777 pounds.
Diameter of sling-wagon wheel...	7 feet.
Diameter of limber-wheel..........	5 feet
Width of tire of wagon-wheel.....	6 inches.
Width of track.........................	71 inches.

See *Garrison Sling-cart*, *Hand Sling-cart*, and *Mechanical Maneuvers.*

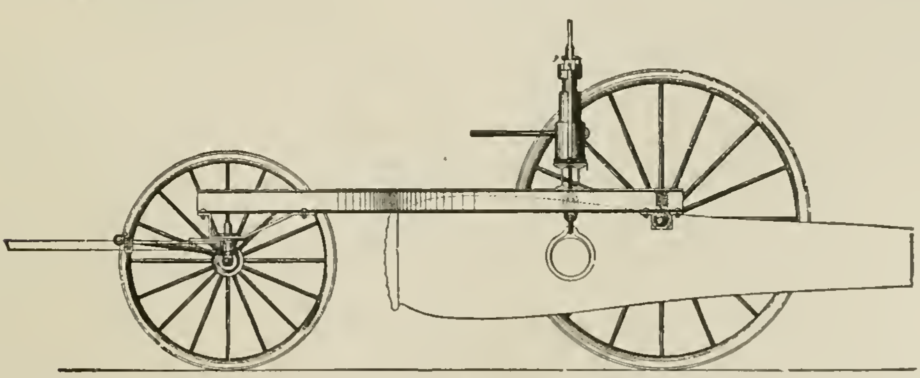


SLING-CHAIN.—A chain used in mechanical maneuvers, and for various purposes. It is composed of 69 *links*, 1 *ring* at one end, and 1 *hook* at the other. The links are made of .75-inch round-iron, and are 5 inches long. The ring is of 1-inch iron, and 6 inches diameter (exterior). Whole length of chain, 256.25 inches. The sling-chain is carried wound around the stock. It may be used for a lock-chain, the one provided with a shoe being dispensed with.

SLINGERS.—The common name for the men who used the sling. The inhabitants of the Balearic Islands were celebrated for their skill with this weapon. The Greeks, Romans, and Carthaginians, as well as the Germans, had each their regiments of slingers. The use of the sling has continued even among European armies until the 16th century, at which time they were employed to hurl grenades.

SLING-ROPE. A rope used in packing. It is usually a hand-laid Manila rope, one-half or three quarters of an inch in diameter and fifteen or sixteen feet long. See *Packing.*

SLING-WAGON.—The sling-wagon which is proposed as a substitute for the present sling-cart, is represented in the drawing which shows its construction, and the mode of using the hydraulic-jack for slinging the load. The body of the wagon is made of 6″ rolled-iron beams, simply and cheaply framed together. The bolster on which the jack stands and the load is supported is formed of two 6″ beams placed side by side, and is held in place by clamp-bolts, which admit of it being shifted at pleasure, so as to throw the weight of the load more or less on the front wheels, as circumstances may make it desirable. The wheels are steel, except a part of the nave, which is made of malleable cast-iron, the felloes being sheet-steel, and the spokes steel, rolled tapering and hollow, or + shaped in cross-section. The front axle is made so as to take a field-carriage wheel should it at any time be necessary.

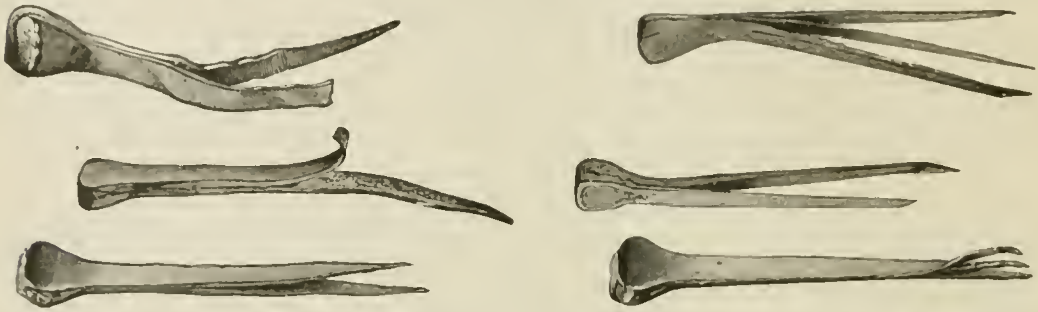


To use the hydraulic-jack in slinging the load, place the elevating-bar in position, the jack standing on the middle of the bolster and the cross-head resting on the head of the jack. Pass the trunnion-rings over the trunnions of the gun or the sling under the load to be carried, and hook the ends on the lower ends of the hoisting-bar. Insert the pins in the lowest holes that they will enter and commence pumping. When the load is raised sufficiently high, put in the pins in the lowest hole; let down the head of the jack until the weight is brought to rest on these pins. The jack may be removed or carried where it rests, ready for further use. The load can be carried suspended from the hoisting-bar as safely as if it were slung from the hooks on the screw. If the weight of the load to be transported be great, increase the strength of the front wheels and throw more of the weight upon them by carrying the bolster further forward. In this way a wagon for carrying a 15-inch gun can be constructed without making the wheels and exles excessively heavy. See *Mechanical Maneuvers* and *Sling-cart.*

SLIPPED.—In Heraldry, a term of blazon applied to a leaf, branch, or flower, which is represented with a stalk, and torn from the parent stem.

SLIPS.—Wrought-iron cylindrical cases about 4½ feet long by 2 feet 5 inches in diameter, in which the wood for gunpowder purposes is distilled; the cases are fitted with lids, and are made to fit into iron retorts, which are imbedded in masonry in such a manner that the heated air from the furnace shall circulate freely round them, and thus convey an equable heat to all parts of the retort throughout the operation of charring. In each slip there are two holes, which correspond with similar holes in the retort, and through which the gases from the wood pass off in the process of distillation. The charge of dhall stalk (the wood used in India) for a slip depends upon the size of the wood. If of large size, the slip will hold 150 lbs., medium 70 lbs., and small size 50 lbs.

SLIVERING. In farriery, the term applied to the longitudinal splitting of horse-shoe nails cut from *cold-rolled* iron. The compression of shearing holds the edges of such a nail together, and *slivering* does not show itself until the nail is driven into the hoof, when



the horny fibers cause the sections to separate. The drawing shows *slivered* nails, which were taken from horse's feet, in the American Service. These nails were all formed by the cold-rolling, punching, and shearing process, which was employed in America, until the introduction of the Putnam nail of *hot-forged* and *hammer-pointed* construction. See *Horse-shoe Nails*.

SLOPE ARMS.—A word of command, in the British Service, for placing the musket upon the shoulder with the butt advanced. In marches, soldiers are almost invariably permitted to slope arms.

SLOPE BLOCK.—In setting the ground sills of the frames in ascending or descending galleries, a small cubical block of wood, termed a *slope-block*, is used, the height of which is equal to the difference of level between the ground sills of an interval. To determine the height for any portion of a gallery where the intervals are equal, or nearly so, the difference of level or of reference of the two extremities of this portion must be divided by the number of intervals. Thus suppose that in the portion of a gallery from A to C, there is an ascent of 5 ft. or 60 in., and twelve intervals; the edge of the slope-block will, therefore, be $\frac{60}{12} = 5$ in. In a portion from C to D, if there is a fall of 4 feet 1 in. or 49 in., and thirteen nearly equal intervals, the edge of the slope-block will be 3 ft. 7 in. nearly. See *Gallery*.

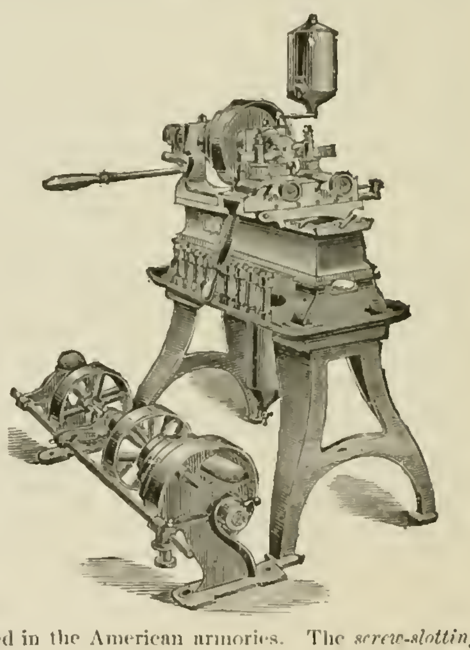
SLOPES.—In fortification, the inclination given to the earth in the formation of the ramparts and parapets, such as the *exterior* and *interior* slopes, and expressed usually by fractions in which the numerator represents the height and the denominator the base of the slope. Thus a slope described as $\frac{2}{1}$ (or verbally as two on one) is one in which the vertical height is twice the base; whilst that expressed by $\frac{1}{2}$ (or verbally as one on two) is, on the contrary, one in which the base is double the vertical height.

Slopes of hills or mountains are expressed in topography by vertical or horizontal *hachures*. Uphill at 15°, slopes are accessible for guns, but at that degree their fire would be useless; at 30°, it would be difficult for cavalry to ascend, and at 10° to charge; at 20°, infantry cannot ascend in order, but slopes are accessible for skirmishers at 45°, at 60° inaccessible for infantry. Downhill, they are suitable for attack or defense for infantry at 10°, artillery 4°, and cavalry not more than 5°.

SLOPING SWORDS. In the British Service, a position of the sword among cavalry, when the back of the blade rests on the hollow of the right shoulder, the hilt advanced.

SLOW TIME. The same as *common time*, by which troops on foot march at the rate of ninety steps per minute.

SLOTTING-MACHINE.—A machine much used in gun manufacture and mechanical engineering for the cutting of slots, or square grooves, in metal. It is of great importance, and many very ingenious inventions have been perfected for facilitating the process. The principle is, however, very simple, and is the same in all. It consists of a cutting-tool, or chisel, held very firmly in an arm, which is pressed down and raised alternately. The tool is thus made to pare off a thin portion of the metal each time it descends, until it has cut a slot of sufficient size. Water is continually thrown on to prevent the metal from becoming overheated by the friction. The drawing represents the Pratt and Whitney machine which is much



used in the American armories. The *screw-slotting machine* has a head carrying a cone-pulley of three grades, and the spindle has a longitudinal adjustment. In the plain machine the screw, held in a chuck mounted on a slide, is raised, by means of a hand-lever, pinion, and rack, to the cutter revolving in the spindle for simply sinking a nick in the head. See *Milling* and *Shaping-machine*.

SLOW MATCH.—Slow-match is a prepared rope which is used to keep and carry fire; it burns slowly with a firm, hard coal and is not easily extinguished. The materials required for slow-match are: *Hemp* or *flax rope* of three strands, slightly twisted, about 25 yards long, and of a uniform diameter of 0.6 inch; acetate of lead (sugar of lead), water. The utensils for preparing, are: 1 *kettle*; 1 *tub*; 2 *wooden spatulas*; *levers*; *twisting-winch*; *mats* or *hair-cloth*. Slow-match is prepared in two ways: 1. Boil the rope for 10 minutes in water holding in solution one twentieth of its weight of acetate of lead; remove it with spatulas into the tub; or let it remain in the cold solution until it is thoroughly saturated. First twist it over the kettle, and then, by attaching one end to the hook of a twisting-winch, twist it hard, keeping it stretched by means of a stick passed through a loop at the other end, at the same time rubbing it smartly, always in the same direction from the hook, with coarse mats, hair cloth, or cuttings of buff leather, until the diameter of the match is reduced 0.1 inch, and it has an uniform twist and hardness. Stretch it on poles or on a fence to dry, and put it up in neat coils, well secured. Match thus prepared burns 4 inches in an hour. 2. If sugar of lead cannot be procured, the rope may be simply leached. For this purpose it is put into a leach-tub and steeped in pure water for 12 hours; this water is then drawn off and replaced by lye prepared in a boiler, with a quantity of ashes equal to half the weight of the rope, to which 5 per cent of quicklime is added. This lye, with the ashes, is put, after being warmed, into the hopper of the tub, and then when it has run through and remained some time in the tub it is drawn off, heated again, and then poured back on the ashes. This operation is repeated several times in the course of 24 hours, which is the time required for the rope to be well leached. After being taken out and twisted with sticks, it is steeped for 5 minutes in hot water, being stirred at the same time, and the operation is finished as before. Match prepared in this manner burns 5 inches in an hour. Cotton rope, well twisted, forms a good match without any preparation. A slow-match may be made of strong paper by immersing it in a warm solution of niter, of about 1 pound to 2 gallons of water. When dry, roll each sheet separately, pressing it firmly, and pasting the last turn. A half-sheet thus prepared will keep fire for three hours. Slow-match weighs from 3 to 5 ounces to the yard.

Slow match is packed in tight casks or boxes. A cask 40 inches high, 24 inches diameter (weighing 60 pounds), contains 150 pounds of match. The casks and boxes should be marked with the kind and quantity of match, place and date of fabrication. Dimensions of a box to hold 200 pounds of hemp or 220 pounds cotton match; 44 inches long, 28 inches wide, 18 inches deep; weight, 87 pounds. It is made of boards 1 inch thick, ends $1\frac{1}{4}$ inch, and has corner-pieces of hard wood, 2.25 inches square. See *Fireworks*.

SLUE.—A term often used in mechanical maneuvers. To *slue* a piece or other object, *end for end*, is to turn it round, not allowing it to revolve on its longer axis. See *Mechanical Maneuvers*.

SLUG.—1. An extemporized leaden projectile formed by cutting bar or sheet lead into irregular masses; used in case of necessity as a substitute for balls or shot. 2. In breech-loading arms, which carry a bullet slightly larger than the bore of the barrel, the bullet, when forced to assume the sectional shape of the bore in the act of firing, is said to *slug* or to be *slugged*.

SLUGGED.—In breech-loading pieces, the bore consists of two separate parts, viz., the barrel, which is rifled, and the chamber immediately behind it, the bore of which is larger than that of the barrel. In this part, the charge and ball fit. When the ball is forced into the barrel by the ignited powder, it enters the grooves and becomes what is termed *slugged*.

SLUICE-GATE.—In fortification, a strong vertically sliding door, placed in a batterdeau, for regulating the flowing of the water in the ditch. Sluice gates are used besides for retaining and raising the water of a river or canal, and, when necessary, to give it vent.

SLUING TRUNNIONS.—*To slue the trunnions* is to turn the piece on its axis so as to bring the trunnions into any necessary position. This is done by first placing the piece on skids perpendicular to its axis. A fulcrum is placed near the trunnion to be raised; upon this a handspike or other lever is used, the piece, meanwhile, being chocked on the opposite side. Or a trunnion-loop may be passed around the trunnion to be raised, and a handspike or lever passed through it, with the butt-end resting on the top of the piece; the power is applied by lifting at the other end, the piece being chocked as before. Or, by passing the bight of a rope once or twice around the piece, and placing the butt of a handspike or lever through the bight, and bearing down or lifting up, using the piece as a fulcrum, the ends of the rope being held to prevent them from slipping. All three of these methods may be used at the same time. The skids should be well greased under the piece, as likewise should be the chocks. When the piece is of great weight, the hydraulic-jack or gin is advantageously used, provided the axes of the trunnions are not vertical. The former is placed under and the latter over the trunnion to be raised. When the axes of the trunnions are vertical, or nearly so, a rope is then passed around the upper one and hauled upon by means of tackle.

SLUR-BOW.—A species of cross-bow formerly used for discharging fire and arrows.

SMALL ARM BARRELS.—Barrels in the English Service for the conveyance and storage of small-arm cartridges. They are of three sizes, *half*, *quarter*, and *eighth*. The half-size is used for blank cartridges, and contains 2,000 rounds; the quarter for ball cartridges, 700 rounds of Snider or Martini-Henry ammunition; and the eighth for small supplies. The quarter-barrel is being superseded by boxes.

SMALL-ARM FACTORIES.—The establishments in which the small-arms of the service are made, viewed, and repaired. The English Government has a factory at Enfield, where the arms issued to the Regular and Auxiliary Army are made, the factory being able, when in full work, to turn out, daily, a thousand and upwards of complete arms, tested and ready for use; at Birmingham, the Government has also a large establishment for viewing the arms supplied by contract, and at Pimlico there is an establishment for repairing damaged arms, and for training Armorer Sergeants for detached service with regiments. All arms are made on the interchangeable system, so that the parts of any one rifle will fit the parts of any other when thrown promiscuously together.

SMALL-ARM PRACTICE.—Ammunition should only be expended in action; in defense of life or public property; in target practice or hunting; in the instruction of recruits; for authorized salutes, and for the subsistence of scouts and other civil employés when they are obliged to rely on their arms, to sustain life. In the United States, the Army is allowed at the rate of 20 ball-cartridges per man per month for target practice, and in the Cavalry service this number is divided between the carbine and revolver, at the discretion of the Commanding Officer. When not expended in target practice, the ammunition may, in the discretion of the Post Commander, be expended in hunting. This allowance need not be expended in each month, but may accumulate, not longer, however, than to the end of the fiscal year, and thus be used under the most favorable circumstances. That unexpended at the end of the fiscal year (June 30) is no longer available. Guards on being relieved should not necessarily discharge their pieces, but should withdraw the cartridges and replace them in the box. On the frontier, where hunting for large game is practicable, the men are encouraged to hunt and, for this purpose, Captains of companies may sell cartridges to their men in limited quantities, according to the supply on hand, and account for the sales and the money received with their quarterly returns of ordnance.

SMALL ARM PROJECTILES.—These projectiles, in great variety, are described under specific headings Only a few of the most prominent will be briefly noticed in this connection.

The bullet used in the United States Service, is derived from that of the *Carabine à tige*, chiefly, by making a conical cavity in its base. The shape of the first cavity employed, was that of a frustum of a cone; but this was found defective when used in the rifle-musket, inasmuch as it rendered the bullet too weak at the juncture of the two exterior surfaces. For arms with reduced charges of powder, as in the carbine and pistol, the large cavity is most suitable. A distinguishing feature of the musket-bullet is, that no patch of any kind is used in loading; in nearly all other modern bullets a greased patch of cloth, or paper, envelops them when placed in the bore.

The British bullet (sometimes known as the Pritchett bullet) has a perfectly smooth exterior. A conical plug of box-wood is inserted into the opening of the cavity, it is said, more for the purpose of preserving the form of the bullet in transportation than aiding in the expansion. The diameter and weight of this bullet are nearly the same as in the United States bullet.

Two distinct bullets are employed in the French Army. The first is heavy, and is intended to have great force and accuracy at long distances. It is used by troops armed with the *carabine à tige*, as the Chasseurs and Zouaves. The second bullet is light, and without much accuracy, describes a flattened trajectory, which increases the chances of hitting a line of men at the usual fighting distance. This bullet is used by troops of the line, who are not supposed to be skilful marksmen.

The Austrian bullet belongs to the class of solid expanding projectiles. In this particular case, expansion is effected by the crowding up of the disks, formed by cutting two deep grooves around the cylinder. A portion of the Austrian rifles (those carried by Non-commissioned Officers, and men of the third rank, who act as skirmishers) have a spindle attached to the breech-screw; the object of which is, not to aid in expanding the bullet, but to give it an invariable position with reference to the powder, and thereby secure uniformity of action.

The bullet used in the Swiss Service is solid, and is forced by a cloth patch tied around the grooves. The position of the bullet with reference to the powder is constant; this is determined by a notch on the ramrod—the notch being so arranged as to leave an interval between the powder and the bullet. The diameter of this bullet is much less than that of any other Service; and, in consequence of its lightness, it is fired with a larger proportional charge of powder. Within the usual range of small-arms, it is said to have a flatter trajectory, and a greater accuracy, than any other small-arm projectile; but at extreme ranges it loses its velocity very rapidly.

The proper charge of powder, for a small-arm, depends on the caliber, windage, length of the barrel, weight of the piece, and character of the projectile. The charge of the old smooth-bored musket was not far from one-third the weight of the projectile; this was necessary to make up for the loss of force by a great windage, and to give the round bullet the necessary momentum. When the elongated bullet was introduced, it became necessary to reduce the charge to prevent too severe recoil; besides, the mass of the bullet being increased, a diminished velocity sufficed to produce the same effect.

In the case of expanding bullets, too small a charge will be insufficient to force the lead into the grooves of the barrel; at the same time, it is shown by experience that, if the charge be increased beyond a certain point, the bullet is liable to be disfigured by *upsetting*, and its accuracy is diminished. *The proper charge for elongated expanding bullets varies from one-tenth to one-seventh the weight of the projectile.* See *Forcing* and *Projectiles*.

SMALL ARMS. The ancient small-arms might be classed as follows: 1st. *Hand-arms*, for close conflict. 2d. *Projectile-arms*, to attain an enemy at a distance. 3d. *Defensive-arms*, to protect the body. Hand-arms comprised the *war-club*, *battle-axe*, *pike*, *sword*, and *saber*. The *war-club* was a stout stick, the large end of which was armed with blades, or points of metal; that used by foot-soldiers was from 7 to 8 feet long, and weighed from 20 to 30 pounds. It was extensively used in the Middle Ages, and is still employed by certain oriental cavalry. The *battle-axe* was at first made of stone or bone, and afterward of metal. This weapon was much used by the Celts and Gauls, but principally by the Franks, who hurled it with great skill and effect against an enemy. The *pike* was generally employed both by infantry and cavalry. That for the infantry was very long, as in the case of the Macedonian lance, or the *sarissa*, the length of which was about 20 feet. In some countries this weapon continued to be used as late as the seventeenth century. The cavalry lance was shorter and lighter than the preceding; it is still used by certain kinds of cavalry.

The Roman *javelin* was a short pike, about 6½ feet long, which was thrown against the enemy. The *spontoon* or *half-pike*, was carried by French infantry officers as late as the time of Louis XV. The *halberd* and the musket, with its bayonet fixed, are pikes.

Swords and sabers have varied much in character with the manner of fighting of different nations; for instance, the Gauls and the Germans, who defended themselves with shields made of willow, or other light wood, made use of long and flexible swords, while the Greeks and Romans, who all wore breastplates and helmets of metal, used short and stout swords. The knights of the Middle Ages carried long and heavy swords, which they wielded with both hands.

The principal projectile-arms, before the invention of gunpowder, were the *sling*, *bow*, and *cross-bow*. The *sling* was formed of a leather cap suspended by two cords; a stone placed in the cap, a rapid rotary motion was communicated by the hand, one of the cords was set free, and the stone escaped in a tangential direction, and was thrown to a distance varying from 200 to 300 steps. The *bow* was formed of a piece of highly elastic wood, confined in a bent position by a strong cord attached to its extremities; it possessed the power of projecting arrows to long distances. This weapons played a very important part in all ancient warfare, and continued to be used by civilized nations to a comparatively late period. In the Middle Ages, it was said, that a skilful archer could fire twelve arrows in a minute, and strike a man at a distance of 100 yards. If certain English authors are to be believed, an archer who could not perform this feat, was disgraced. According to their statements, an arrow had sufficient force to penetrate an oak plank, two inches thick, at a distance of 200 yards. The *cross-bow* was a bow attached to a stock having a channel to guide the arrow. It is said to have been introduced into Europe from Asia, during the Crusades, by Richard Cœur de Lion, who armed the English troops with it. At present, the use of the bow is confined to the barbarous tribes only; the skill and dexterity with which it is managed by the Prairie Indians of this country, make it an exceedingly formidable weapon at short distances.

Armor, which was employed to protect the most exposed part of the body, naturally followed the introduction of offensive-arms. At first it was made of wood, the skins of certain animals, the scales of serpents, shells of turtles, etc., and subsequently of metallic plates, or of a cloth folded in layers. The body was also protected in the rear by movable obstacles, as shields, bucklers, etc. Among the Romans and Greeks, the infantry of the line wore the helmet, the breast-plate, a species of half-boot protected with iron, and the buckler; the cavalry, ordinarily, wore a cuirass formed of bands of leather, covered with plates of bronze. In the time of Charlemagne, coats of mail, formed of small chains, were much worn. These were followed by complete suits of metallic armor, which were worn until the introduction of fire-arms.

Portable fire-arms were invented about the middle of the fourteenth century. At first they consisted simply of a tube of iron or copper, fired from a stand or support. They were loaded with leaden balls, and were touched off by a lighted match held in the hand. They weighed from 25 to 75 pounds, and consequently two men were required to serve them. The difficulty of loading these weapons, and the uncertainty of their effects, as regards range and accuracy, prevented them from coming rapidly into use, and the cross-bow was for a long time retained as the principal projectile-weapon for infantry. Breech-loading small-arms, similar in principle to the cannon described elsewhere, were introduced about the same time, but they were soon thrown aside for want of strength and solidity. The difficulty of aiming hand-cannon, arising from their great weight, was in a measure overcome by making them shorter, and supporting them on a tripod, by means of the trunnions which rested in forks. The breech was terminated with a handle which was held in the right hand, while the match was applied with the left. Thus improved, this fire-arm was called the *arquebuse;* it was employed in sieges; and to defend important positions on the field of battle. The next improvement in the arquebuse, was to make it lighter, and enclose it in a piece of wood, called the *stock*, the butt of which was pressed against the left shoulder, while the right hand applied the match to the vent. It was still very heavy, and in aiming, the muzzle rested in the crotch of a fork placed in the ground. To give steadiness to the aim while applying the match to the priming, a species of lock was very soon devised, which consisted of a lever holding at its extremity a lighted match. In firing, the lever was pressed down with the finger until the lighted end of the match touched the priming. This apparatus, known as the *serpentine*, continued in use until it was replaced by the *wheel-lock*, which was invented in Nuremburg, in 1517. The wheel-lock consisted of a grooved wheel of steel, which acted through a half-revolution on a piece of alloy of iron and antimony, placed near a priming-charge of powder. The sparks thus evolved fell upon and ignited the priming-charge. The first pistol was a wheel-lock arquebuse, so small that it could be held and fired from the extended hand. It was invented in 1545, in Pistoia, a city of Tuscany; hence its name. The petronel was a wheel-lock arquebuse of large caliber and of lighter weight than its predecessors. To diminish the effect of the recoil, the butt of the stock was much curved, and had a broad base, which was pressed against the breastplate of the cuirass when the piece was fired. Two sizes of the petronel were used, one for infantry and one for cavalry. The musket was first introduced by the Spaniards, under Charles V. The original caliber of the musket was such that eight round bullets weighed a pound; the piece was, consequently, so heavy that it was necessary to fire it from a forked stick inserted in the ground. The size of the bore was finally reduced to eighteen bullets to the pound; and from this arm was derived the late smooth bore musket.

It is generally stated that the rifle was invented by Gaspard Zoller, of Vienna, and that it first made its appearance at target practice at Leipsic, in 1498. The first rifle grooves were made parallel to the axis of the bore, for the purpose of diminishing the friction of loading forced or tightly-fitting bullets. It was accidentally discovered, however, that spiral grooves gave greater accuracy to the flight of the projectile, but the science of the day was unable to assign a reason for this superiority, and the form, number, and twist of the grooves, depended on the caprice of individual gun-makers. About 1600, the rifle began to be used as a military weapon for firing spherical bullets. In 1729, it was found that good results could be attained by using oblong projectiles of elliptical form. The great difficulty, however, of loading the rifle, which was ordinarily accomplished by the blows of a mallet on a stout iron ramrod, prevented it from being generally used in regular warfare. The improvements which have been made in the last thirty years, principally by the officers of the French Army, have entirely overcome this difficulty, and rifles are now almost universally used in place of smooth-bored arms. The rifle has ever been a favorite weapon in this country, arising, doubtless, from the peculiar circumstances which surrounded its early settlers and pioneers, and on more than one occasion has it proved, in the hands of the irregular troops, a formidable weapon to its enemies. Until 1855, the mass of the American infantry was armed with smooth-bored muskets, but since that time it has been wholly armed with rifles. In spite of the advantages which fire-arms possessed, they, like the arms which preceded them, were not suited to resist the charge of cavalry. The bayonet, and firing in closed ranks, were unknown; the most skilful Captains of the age, however, sought to combine fire arms with pikes, in such a manner that one might afford protection to the other. The French Army was thus arranged in six ranks, four with muskets and two with pikes; on the introduction of the bayonet, it was reduced to four, and finally to three ranks. The bayonet derived its name from Bayonne, where it was first made, in 1640. At first it was formed of a steel blade attached to a handle of wood, which was inserted in the bore of the barrel, except in the operations of loading and firing. Thirty years afterward the wooden handle was replaced by a hollow socket, which fitted over the muzzle of the barrel; this change rendered the musket at all times a pike as well as a fire-arm, and led to the formation of modern infantry. The flint-lock was derived from the wheel-lock, by substituting flint for the alloy of iron and antimony, and a steel battery for the wheel. It was generally introduced into the French Army in 1680, and continued to be used in all military services, until about 1842, when it gave way to the percussion-lock. In proportion as fire-arms were improved, the rapidity of fire increased. In 1703, the loading of the musket was performed in twenty-six times and the fire of infantry was necessarily slow. In 1744, the employment of fine powder for priming was dispensed with, and the cartridge (said to have been the invention of Gustavus Adolphus) was adopted in its place. See *Care of Small-arms, Fabrication of Fire-arms, Fabrication of Swords and Sabers, Hand-arms, Inspection of Small-arms, Ordnance, Packing Small-arms, Portable Fire-arms, Royal Small-arms*, and *Springfield Rifle*.

SMALL-ARM VELOCIMETER.—The velocimeter may be very conveniently applied in studying the law of the recoil of a musket in order to estimate the accelerating forces developed in an arm of small caliber by the combustion of the powder. As it is important to diminish the weights set in motion, in order to obtain a greater amplitude of tracings, the barrel is separated from the stock, and the breech fermeture is replaced by a simple screw-plug, with a pin passing through it, which serves to ignite the cartridge

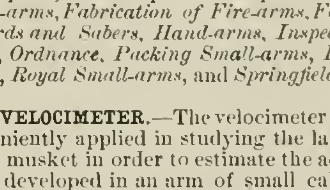


Fig. 1.

arranged for inflammation by electricity. The gun-barrel is clasped between two collars, Fig. 1., furnished with ears, which serve to guide it in the grooves of two metallic rules, secured parallel to each other on a wooden stand. These collars are formed each of two pieces insulated from the gun-barrel by an India-rubber ring and united by two screws, also insulated by means of an ivory washer; one of the ear-guides belongs to the upper piece and the other to the lower piece. The rear collar is furnished in addition with two friction springs, resting on the upper face of the guide-rules, and both secured on the upper piece; lastly, the two rules are in communication with the common circuit formed by the return wires of the registers. It results from this arrangement that, during the recoil movement of the piece, the electric circuit of these registers is each instant completed by the movable piece of the collar which bears the friction piece. The right rule has, also, fitted at a point suitably chosen, about a millimeter from the initial position of the spring, a rather small insulating tongue, which this friction piece encounters and passes over as soon as it is displaced; we thus obtain a simultaneous rupture of the currents of the registers, immediately followed by their reëstablishment; we then realize the conditions necessary for obtaining, at the very moment of the experiment, the measure of the functional retardations of each of these registers, as has been previously stated. The gun recoils freely in its slides, over a length of about 50 centimetres (19.685 inches); it then strikes a wooden hurter, which also slides on the rules, serving for guides, and which is held by means of two extended India-rubber thongs, placed symmetrically right and left, and which tend the more to deaden the effect of the shock. A toothed rack of brass, fixed between the slides, and whose obliquely-cut teeth give a hold to a pawl with a spring fixed in the buffer, serves to keep this latter in the extreme position to which it is brought by the shock, and prevents the gun-barrel from being sent back with violence to the front.

The ribbon, in the form of a tablet, designed to receive the tracings, is fixed directly on the gun-barrel; it has at its extremities two notches narrowed at the rear end, in which are engaged two large-headed pins fixed on the barrel. Above this tablet are placed two horizontal axes, turning, with a stiff friction, in their bearings, and which have, one the electrically-supplied vibrating fork, the other the registers. The fork is arranged as usual, but owing to the inconsiderable portion of the recoil of the gun, which corresponds with the passage of the ball through the bore, it must give a great number of vibrations if we wish to study, with sufficient precision, the law of the movement in this passage. A fork giving 2,000 simple vibrations per second is generally used; a fork with 3,000 vibrations is sometimes employed, but the setting of it in operation is very difficult. The electric registers are designed to give the velocity of the musket-ball. As this velocity, in consequence of the forcing of the ball, may be obtained by noting simply the moment of the rupture of a wire stretched before the muzzle and that of its arrival on a disjunctor target, it is usual to employ only two registers, one placed in the circuit of the wire at the muzzle, the other in the circuit of the target. In order to avoid any displacement of the gun at the moment of the inflammation, fire can be communicated to the cartridge electrically, as shown in Fig. 2. This result is obtained by transforming the primer of the cartridge into an electric primer. The ordinary primer is replaced by a sensitive composition contained in a small capsule, in the center of which is a small obturator-plug of brass, the rod of which passes through a very small ivory insulating ring. A small spiral of very fine platinum wire is soldered, one part to the plug, and the other to the edge of the metallic cap, and is imbedded in the sensitive composition. It suffices, then, to put the conductors of the firing battery in communication, one part with the rear end of the insulated plug, the other with the body of the gun, which itself communicates electrically with the cartridge and the cap, that by closing the current we may cause the incandescence of the wire and the inflammation of the primer and the charge. The communications are established by means of a small special connection at the extremity of a flexible cable, with two conductors, which end at the terminals of an insulating plane-table, on a column, placed on the side of the stand of the apparatus. The length of this flexible cable is sufficient to permit the free recoil of the gun. The terminals and the commutators, placed also on the stand of the apparatus, permit of establishing conveniently the circuits of the fork and the registers, of interrupting at will that of the former, and of reuniting in one common circuit the egress wires of the latter. We could replace electric ignition by a blow, causing the inflammation of a cap, by arranging the apparatus in such a manner that the shock might have no other effect than that of forcing the gun-barrel harder against a shoulder, limiting its movement towards the front; but with a fire-lock gun it would be more simple still to effect the inflammation of the cartridge by the application of some inflamed body; communicating the fire to a small quantity of priming-powder put in the vent, we would thus avoid all prejudicial disturbance before the leaving of the shot. See *Benton Thread Velocimeter* and *Velocimeter*.

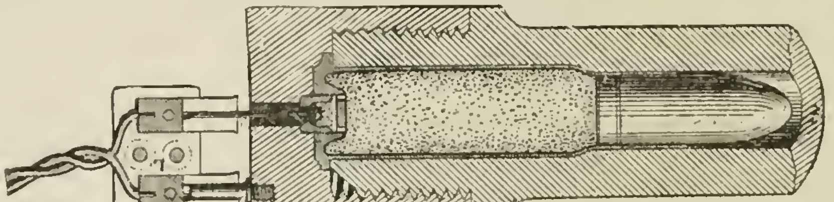

Fig. 2.

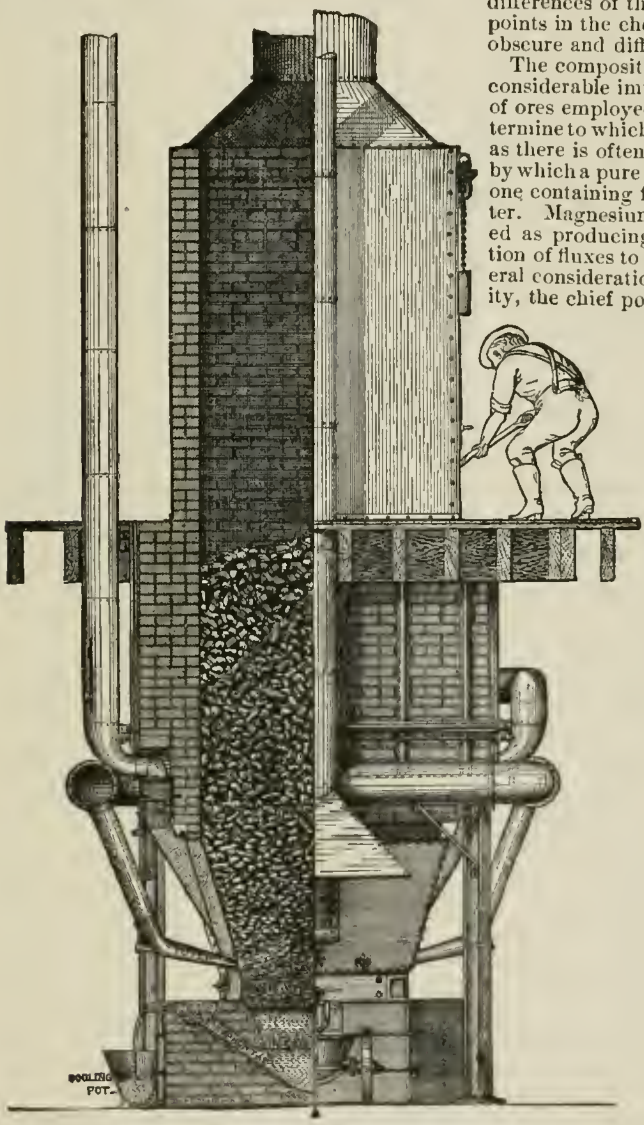
SMALL PICKETS.—An obstacle consisting of straight branches of tough wood cut into lengths of two and a half or three feet. They are driven into the ground in a quincunx order, about twelve inches apart, and project irregularly above it, not more than eighteen inches. Interlaced with cords, wires, grape-vines, brambles, prickly shrubs, etc., they form an excellent *entanglement*. See *Accessory Means of Defense*.

SMART MONEY.—In England, a sum paid by a recruit to free himself from his engagement. This is done in the presence of a Magistrate, and previous to attestation. The amount is 20s., which includes the enlisting shilling; the Enlisting Sergeant receives one-half (9s. 6d.), the remainder is credited to the public. A recruit cannot legally be attested until 24½ hours have elapsed from receipt of the enlisting shilling; he can claim 95½ hours' grace before attestation. If the enlister neglects to have him attested within 96 hours after enlistment, the engagement is void and the recruit free. Sundays, Christmas Day, and Good Friday, do not count as time against a recruit, but though he may, if he wishes, allow them to count; thus a recruit enlisted on Saturday night cannot be attested against his will on the following Monday, although, if willing, he may be attested.

SMELTING.—Smelting is the process by which iron or some other metal is reduced to the metallic state, and separated from the refractory substances with which it is combined in the ore. It consists in raising the ore to a high heat, in contact with carbon and a suitable *flux*, in the blast or smelting-furnace. The *flux* unites with the earthy matter of the ore, so forming a glassy substance called *slag* or *cinder*, and the carbon, as carbonic oxide, unites with the oxygen of the ore, setting the iron free; which, in turn, unites with a portion of the carbon, and forms a fusible compound called pig or cast-iron.

In practice, very few ores are ever found to contain earthy ingredients in proportions sufficient to form readily fusible slags alone, and it therefore becomes necessary to supply the deficiency. This may be done, either by mixing ores of dissimilar composition in such quantities as shall yield slags of the desired composition, or by the addition of calcareous or aluminous minerals not containing iron. The first of these methods is certainly to be preferred, as by it



the slag is formed without unnecessarily reducing the percentage of iron in the charge or burden, taken as a whole; whereas, the addition of fluxes increases the weight of material to be passed through the furnace for the same produce of metal; but it can only be carried out in localities having a large and varied command of minerals. Usually, therefore, a combination of both methods is used, the best mixture of ores obtainable being supplemented by the addition of earthy minerals.

The reduction of iron ores can be effected practically only by carbou or carbonic oxide. The principal flux employed in iron-smelting is carbonate of lime in the form of limestone. As a very high temperature is necessary to effect the reduction, the metal almost always combines with a greater or less proportion of the reducing agent, as well as of other elementary substances, such as the silicon, sulphur, and phosphorus, that may be present either in the ore, the fuel, or the flux; so that the ultimate result is never a pure metal, but is a compound of iron with carbon, silicon, sulphur, phosphorus and sometimes manganese, and occasionally traces of other baser elements, as titanium, etc. Small traces of foreign elements exert a very marked influence on the metal; and it is these small, and in many cases unnoticed, differences of the composition, that render so many points in the chemistry and practical working of iron obscure and difficult to be understood.

The composition of the limestone to be used is of considerable importance, and depends upon the kind of ores employed. Chemical analysis alone can determine to which class a particular limestone belongs, as there is often nothing in the external appearance by which a pure limestone may be distinguished from one containing forty or fifty per cent. of foreign matter. Magnesium limestone is especially to be avoided as producing a very refractory slag. The addition of fluxes to the blast-furnace is regulated by several considerations. When the ores are of good quality, the chief point to be considered is the production of the most fusible slag, with the smallest addition of non-ferriferous matters; this is more especially the case with charcoal-furnaces. When mineral fuel is used, however, it is necessary to form a slag that is capable of absorbing sulphur, which would often otherwise be taken up by the iron; and, for this purpose, a larger quantity of flux is used than that indicated by theory, as giving the greatest fusible product. The quality of the iron produced depends greatly upon the kind of flux employed.

Slag is the vitreous mass which covers the fused metal in a smelting-hearth. The physical character of slag, such as color, texture, fluidity, etc., varies with the composition and the working condition of the furnace, so that it is not possible from inspection alone to determine the character of the metal produced, except after considerable experience of the individual furnace; and the relation between the slag and metal in one locality may be totally different in another. The fuel used in iron-smelting varies in different localities and also with the purposes for which the iron is intended. Charcoal is said to make the most superior iron, and is always used in the manufacture of iron for ordnance purposes. Coke is generally used, and bituminous and anthracite coals are also employed.

The Lane and Bodley smelting-furnace, with one-half in section, is represented in the drawing. The mixed ore, fluxes, and fuel are fed into the furnace and gradually settle down through the brick shaft until they reach where the sides are made of steel boxes, called "water jackets," and kept cool by a continuous supply of cold water; therein the combustion takes place, a high heat being obtained by air from the blower near the engine, which drives it. The blast enters the furnace through the *tuyeres*, at the mouth of which the last of the fuel is entirely consumed, the fluxes and foreign matter whilst melting uniting into *slag*. From the bottom of the crucible a channel passes diagonally upwards, terminating in a bowl in the top of the masonry outside of the water jackets, thus forming what is known as the "*syphon tap*." At the bottom of one of the water jackets is an opening, stopped with clay, which is occasionally removed to allow the slag to escape into slag-pots, where it is allowed to congeal.

It is in the smelting-furnace that the character of the iron is fixed. Iron of good character and high susceptibility may be spoiled by its treatment at the foundry; but this, with ordinary experience and intelligence, ought rarely to occur. It is impracticable, with our present knowledge, to make good and reliable guns from iron that leaves the smelting-furnace with bad qualities. The smelting of iron is a purely chemical process, and should be conducted with the same regularity and precision as any other important chemical process. There are so many disturbing causes tending to affect its character and qualities, that, after every precaution shall have been taken to remove them, perfect uniformity in the quality of the iron produced from day to day cannot be effected, yet a near approximation to uniformity is practicable.

All the stock for a "blast" of gun-iron should be carefully prepared and housed before beginning to "blow." The ore should all be roasted and also well mixed so as to be as nearly uniform, as to size of lumps and all other qualities, as possible The charcoal should all be made as nearly as possible from the same kind of wood, of the same uniformity as to quality, and well mixed together after charring. All the stock should be carefully weighed, and supplied to the furnace at regular intervals of time. The pressure, temperature, and hygrometrical condition of the blast, should be kept as nearly constant as possible. The temperature of the blast may be kept very nearly constant without using what is termed a hot-blast, by warming it just sufficiently to bring it above the highest summer temperature.

Suppose a standard of quality to have been determined, with the stock all prepared for a given number of guns, and having determined by comparison with the *standard* the quality of iron required, a further approximation to identity in quality of the metal in the guns may be made by casting each run of metal from the smelting-furnace into a number of pigs of equal size, something greater than the number of the guns to be made, and piling them in separate piles; each run of metal furnishing one pig to each pile. Each pile should contain metal enough for one gun and one test-cylinder; and be kept separate and distinct from all others in transportation, and be repiled in the the foundry-yard in the same order as at the smelting-furnace; one gun being made from each pile, after the treatment which the iron should receive at the foundry shall have been determined by experiments made on the iron in the surplus piles. The pigs should be cast in molds as prepared from a pattern, so as to be smooth and free from adhering sand as possible.

The difference between iron as it exists when presented for use in pigs and when in the body of the finished gun is very great, sometimes amounting to a difference in density of more than 20 pounds per cubic foot, and in tenacity more than as 1 to 2. This serves to show how unreliable the tests of the first fusion pig-iron are, as a means for determining the quality of iron and its suitableness for making cannon. The quality of cannon may be improved by endeavoring to ascertain the different qualities of the metal used in making them, and the best methods of treating it in the processes of melting, casting, and cooling. It is found that some kinds of iron are susceptible of very great improvement, by the different methods of treatment at the foundries; while other kinds are at their maximum strength in the crude pigs. The cause of this difference in the susceptibility for change and improvement will doubtless be found in the qualities of ores used, and in the methods of smelting them.

Usually the quality of iron is greatly modified and improved by remelting and a long continuance in fusion. But all kinds of iron are not affected in like manner by these processes. In examining the effects of the different treatment of iron at the foundry, such samples should be chosen as will best exhibit the following particulars and characteristics, viz.: 1st. The properties which distinguish the different grades of iron made from the same ores at the same furnace. 2d. The changes in the mechanical properties of iron produced by repeated meltings of one of these grades, separately, showing the changes effected at each melting. 3d. The changes produced by repeated meltings of the different grades of iron and of different fusions mixed. 4th. The changes produced in iron of the same melting and quality, by casting it into masses of different bulk, and by different methods of cooling. The softest kinds of iron will endure a greater number of meltings with advantage than the higher grades. It appears from Major Wade's experiments with Greenwood iron that when it is in its best condition for casting into proof-bars of small bulk, it is then in a state which requires an additional fusion to bring it up to its best condition for casting into the massive bulk of cannon. In selecting and preparing iron for cannon, we may proceed by repeated fusion, or by varying the proportions of the different grades and different fusions, until the maximum tenacity is attained.

An increase of density is a consequence which invariably follows the rapid cooling of cast-iron, and, as a general rule, the tenacity is increased by the same means. The density and tenacity usually vary in the same order. It appears that the tenacity generally increases quite uniformly with the density, until the latter ascends to some given point; after which an increased density is accompanied by a diminished tenacity. The turning-point of density at which the best qualities of gun-iron attain their maximum tenacity appears to be about 7.30. At this point of density, or near it, whether in proof-bars or in gun-heads, the tenacity is greatest. As the density of iron is increased, its liquidity when melted is diminished. This causes it to congeal quickly, and to form cavities in the interior of the casting. See *Iron*.

SMITH AND WESSON REVOLVER.—Prior to the recent war in the United States, no revolver had been adopted by the military authorities in which metallic cartridges were used; but the advantages of this arm were so apparent that thousands of these revolvers were bought by officers in the Army and Navy, and so great was the demand for them that orders were upon the books of this Firm for all their possible production for two years in advance. At the Paris Exposition this weapon attracted an unusual attention and from that time a demand arose which has constantly increased, resulting in large shipments to Japan, China, England, Russia, France, Spain, Peru, Chili, Brazil, Cuba, and to almost every nation on the globe. Within the last few years, improvements have been added, resulting in the production of a revolver far superior, especially for military purposes, to anything of the kind ever manufactured.

The drawing shows the construction of this arm. The frame with its handle and lock is made as formerly, except that the frame has but a single limb projecting forward from the under-side of the recoil-shield or breech. To the front end of this limb the barrel is hinged, so as to tip forward and downward in opening, as shown in Fig. 1. The barrel, with its hinge-arm or projection, is formed from a single solid piece of steel, and it also has a solid arm or strap at its upper side, which projects back over the cylinder when closed, and is locked to the breech by a spring-latch, *A*, which operates automatically when the barrel is swung into position. The cylinder is mounted on a tubular center-pin, *n*, which is screwed into the rear end of the projection under the barrel, so that the cylinder is attached to, and swings with the barrel, when opened and closed, as is shown in Fig. 1. This center-pin, *n*, is made a little shorter than the cylinder, as shown in Fig. 2, and the central hole through the cylinder is bored out round as far as the pin, *n*, extends; but in rear of the extremity of the center-pin, the hole in the cylinder is made rectangular in form, for a purpose which will be presently explained.

The arm is provided with an extractor, *D*, which consists of a plate fitted into a central recess in the rear end of the cylinder, and which extends radially to near the center of the chambers—it, of course being cut away at its edges, so as to conform in shape and size to the chambers, thus leaving them unobstructed, so that when the extractor is in its seat, the rear end of the cylinder has the appearance of an ordinary solid cylinder, which has the chambers simply bored through it. The extractor, *D*, is provided with a stem made in the form of a square bolt, and of a size corresponding with the rectangular opening in the rear end of the cylinder, previously referred to, so that when the extractor has its stem inserted into or through this opening, it is free to slide back and forth therein, but must turn with the cylinder, thus keeping the extractor always in place in relation to the chambers. The square stem is nearly as long as the cylinder, so that, when the extractor is shoved out in the act of extracting the shells, it will not pass out of the square opening, and is of such a diameter externally, as to permit it to turn freely within the tubular center-pin, *n*, while the cylinder turns upon the center pin, the cylinder and extractor thus always turning together. To this square stem of the extractor, there is secured a round stem or bolt, *B*, which extends forward through the center-pin and for some distance into a hole bored longitudinally from the rear end forward, into the lug or projection underneath the barrel, as is shown in Fig. 1. This stem *B*, is reduced in diameter towards its front end, to afford ample room for a spiral spring, which being mounted on the stem, serves to draw the extractor back to its seat after it has been operated to expel the shells. This stem, *B*, directly over the point where the barrel is hinged to the frame, and from thence forward to the spring, is provided with a series of teeth, which are cut entirely around the stem and which engage with corresponding teeth on a ratchet-wheel, *C*, that is located vertically at the center of the front end of the arm to which the barrel is hinged; this ratchet-wheel being inserted in a slot formed in the front end of the arm, and pivoted upon the same screw which forms the axis of the joint—the front end of the arm being made of a size and shape to correspond with this wheel, whereby also a large

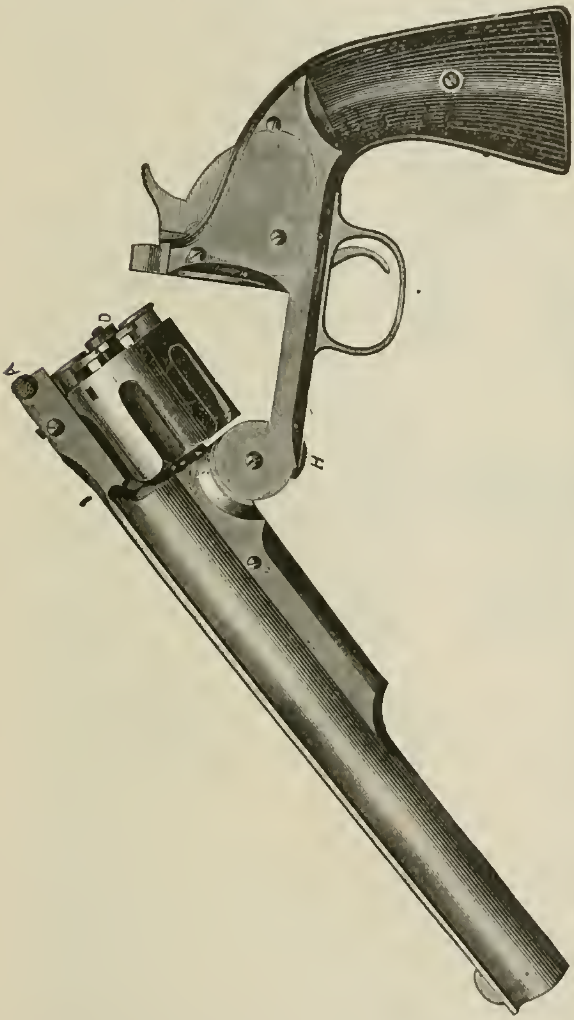


Fig. 1.

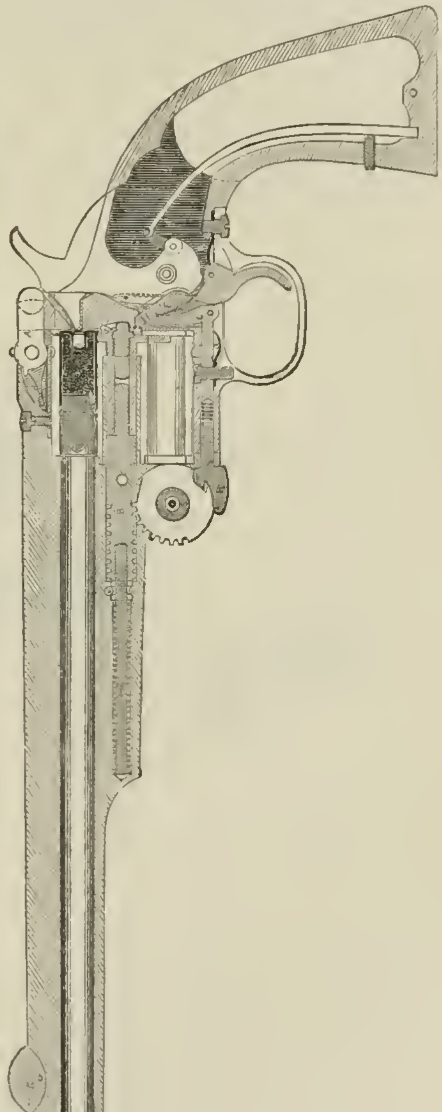

Fig. 2.

bearing is afforded for the joint, which tends to prevent wear and keeps the parts snug and firm. A pawl, *H*, is fitted in a recess bored for it in the arm of the frame, and is so located as to engage in a notch cut in the rear edge of the ratchet-wheel, *C*, by which said wheel is locked fast, and thus prevented from turning when the barrel is swung over forward—a spiral spring at the rear end of the pawl, *H*, serving to press it forward and hold it in contact with the wheel, and also to cause it to automatically engage therewith again, after same has been released. This pawl, *H*, also has a roughened projection at the under side of the arm near its front end, by pressing back on which, the pawl can be at any time disconnected from the ratchet-wheel, when of course, the latter will not act on the extractor.

The operation is as follows: The arm is held by the handle in the right hand, while with the thumb of said hand, the latch, *A*, is raised, thereby unlocking the barrel from the breech. The barrel is then swung over forward, either by the left hand, or if operations are automatic to a greater extent than in any similar arm in existence.

As a military revolver, it is believed that it has no equal. Its accuracy and penetration are shown by the following diagram of a target made at Springfield, Massachusetts, at forty yards distance; the penetration of the ball was through five inches of pine boards. Fig. 3.

The United States use this arm for cavalry, and the Government of Russia have adopted the same model for their cavalry service, an order for 20,000 having been recently executed. The system of inspection adopted by Messrs. Smith and Wesson is such that the least imperfection in material or workmanship is detected, and for which the piece is condemned.

During the past fifteen years Messrs. Smith and Wesson have by constant experiments and attention to details, largely improved their arms. One of the special improvements effected in the new model for the better protection against accidents is a rebound-

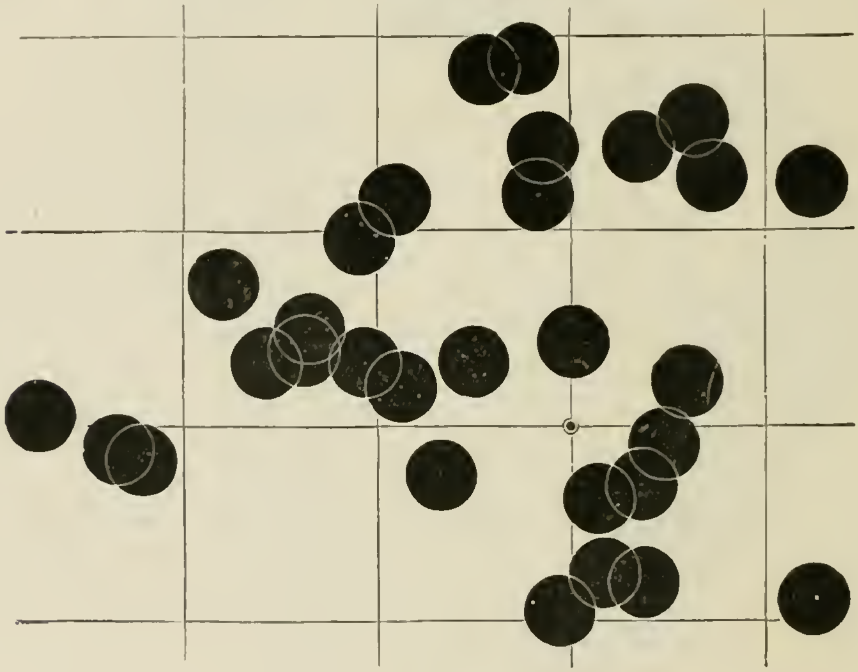

Fig. 3.

that be so engaged, by pressing the top of the barrel against any object. Now, as the ratchet-wheel is held from turning by the pawl, *H*, it follows that the teeth of said wheel engaging with the teeth of the stem, *B*, as the barrel swings forward, causes the extractor, *D*, to protrude from the rear end of the cylinder, carrying the shells out with it. The size of this wheel, *C*, is such that the extractor is caused to move enough so as to push the shells *entirely out of the chambers;* and just as this operation is completed, the shoulder of the pawl, *H*, comes in contact with the projection on the under side of the barrel, by which means the pawl is shoved back, and thereby disconnected from the ratchet, *C*, when the spring on the stem, *B*, immediately returns the extractor to its seat while the arm is still open, ready to be reloaded. When loaded, it is only necessary to swing the barrel back to its position, when the latch, *A*, automatically locks the parts together, and it is ready for firing. Figure 1, represents the arm in position for loading. It will thus be seen that while the arm is strong and consists of comparatively few parts, it accomplishes far more than any revolver ever before invented; and that its ing-lock. Although this feature has been adopted in connection with shot-guns, and now universally used, it has never before been applied to revolvers. These arms, more than any other class, are liable to premature discharge, caused by a chance blow upon the hammer when left, by carelessness, resting upon the cartridge head. By this new improvement the hammer is made to rebound automatically to a safety catch where it is held without the addition of a single piece for that purpose. The pistol is by this means *absolutely safe* in the hands of a soldier, as it cannot under any circumstances from a blow or jar be unexpectedly discharged. By several changes nine pieces have been dispensed with, and the arm materially improved, at the same time the cost being reduced to a very considerable extent. Nearly all these improvements have been patented by Messrs. Smith and Wesson in this country and Europe, and are all owned by the Firm.

It is one of the objects of this Firm to take advantage of all new inventions or suggestions, and to that end the use of hard rubber has been adopted for the construction of the handles, especially of the smaller grade of pistols. Of late a demand has sprung up for a more rapid-firing pistol than the one regularly made by Messrs. Smith and Wesson, and to meet this demand a new arm has been designed and manufactured. The drawing (Fig. 4) shows all the details of this weapon. There is also a very slight difference in the form which will be recognized in comparison with the earlier model. Upon an examination of all the details in this drawing, however, it will be seen that the new arm is very simple in its construction, and that special attention has been paid to securing for it the greatest safety possible. This arm retains the distinctive feature of the Smith and Wesson system, viz.:—the automatic extractor. One of the most important advantages of this pistol over ordinary double-acting pistols is, that instead of being made as heretofore in such a manner as to permit the cylinder to revolve after discharge of the cartridge, which releasing it, admits of the possibility of snapping upon the cartridge already discharged. It is arranged with a cylinder-stop so constructed as to firmly hold the cylinder in position except when being revolved for the act of cocking. This is accomplished by the action of the cylinder-stop, as shown, placed upon the trigger-pivot, the rear end of which rests in one of the stop-notches shown in the drawing, while the trigger is drawn back in the act of firing, the front end of the stop resting in one of the recesses of the cylinder, as shown in the drawing, while the trigger is forward.

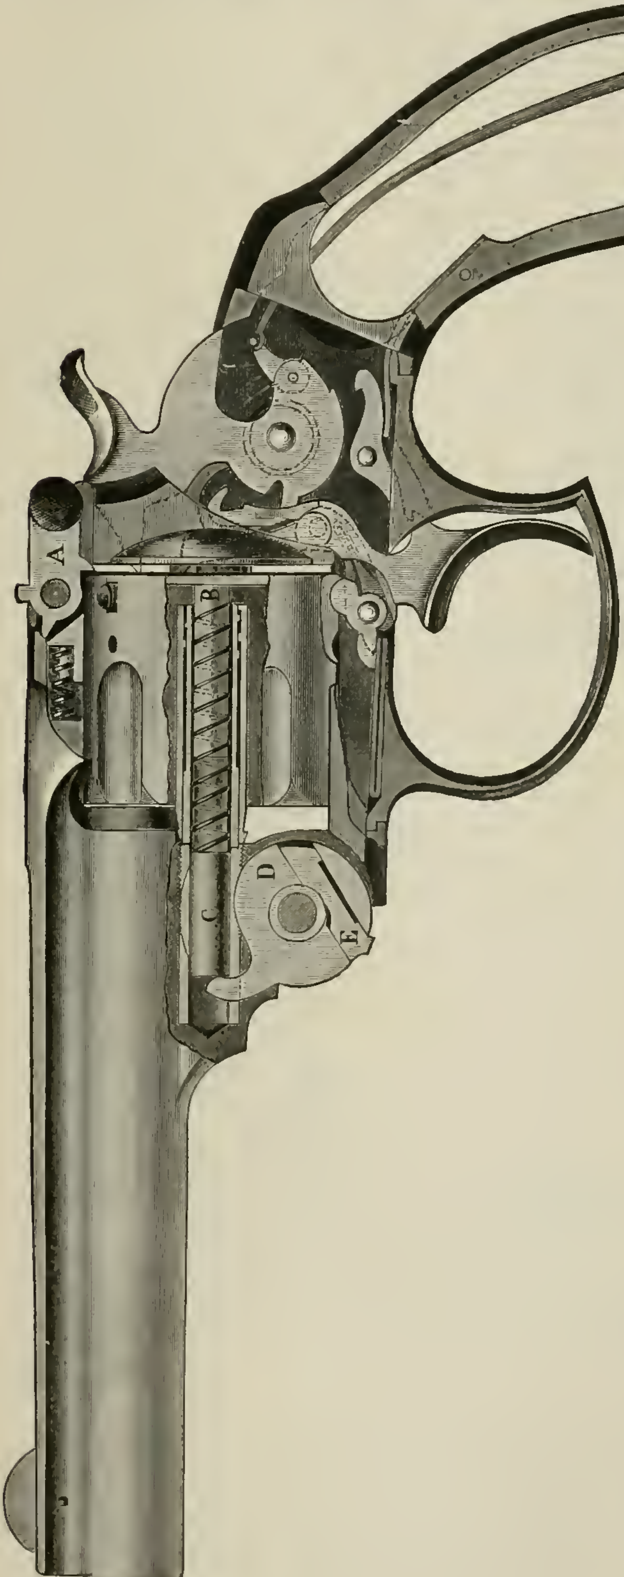

Fig. 4.

Most careful attention has also been paid to reducing the number of parts comprised in the lock of this pistol. There being but seven in all, viz., hammer, front and rear-sears, hand-trigger, cylinder-stop, and two springs. The extractor cam, D, and the extractor catch, E, differ from those used in former pistols made by Smith and Wesson, being much stronger and more simple. The full-page steel engraving represents the latest model 38, No. 2, caliber 38-100, 5 shot. See *Schofield-Smith and Wesson Revolver*.

SMOKE-BALL.—A paper shell having one vent (the thickness of the paper depending on the nature of the shell); the shell is filled with a composition which, upon igniting, evolves a large volume of smoke. It is thrown into mines or other confined situations, to suffocate the enemy's working parties. It has also been used as a signal in the Arctic Regions.

SMOOT GUN.—A breech-loading rifle, having a fixed chamber closed by a movable breech-block which rotates about a horizontal axis at 90° to the axis of the barrel, lying above the axis of the barrel and in rear being moved from above. The piece is opened by cocking the hammer and drawing back the thumb-piece of the cam-lever. A projecting stud on the cam-lever playing in the cam-recess of the breech-block draws it down into the position of loading. By simply reversing the movement of the cam-lever, the stud will act on the other side of the cam-recess, and throw up the block until it is met and stopped by the front shoulder of the cam-lever striking against a corresponding shoulder near the front of the block. The motions of loading and closing may be combined by striking the thumb-piece with the palm of the right hand as the cartridge is passed into the chamber. The piece is then locked by the position of the breech-block and also its friction against the head of the cartridge when it is fixed, by means of a double mainspring center-lock of the most usual pattern. Extraction is accomplished by a sliding extractor, a stud on the inside of which plays in a cam-recess on the outer side of the cam-lever. After passing a certain point in opening the piece, the direct pull on the extractor ceases and the ejection is secured by the acceleration which is impressed on the extractor by the action of the ejector-spring on a cam formed on the lower surface of the ejector-lever. The upper end of which lever, striking a shoulder on the extractor, throws it into a groove connected with the cam-recess, driving the shell up the inclined surface of the breech-block until it is clear of the gun.

SNAFFLE BIT. A slender bit, having a joint in the part to be placed in the mouth. It is the most common bit in use in the military service. See *Bit* and *Bridle*.

SNAKING.—When the spiral motion of rotation of an elongated projectile round its original direction (caused probably by an irregular resistance and want of homogeneity) becomes of exaggerated extent, the projectile may be seen to describe a sort of helix round its primary direction, and the accuracy of shooting is greatly influenced by the part of the helix which may first happen to be in contact with the ground. Projectiles subject to this influence are technically said *to snake*.

SNAP-CAP.—A very small leather cylinder with a metal top of the size of the hammer of the percussion musket, and fitting closely to the nipple. It is used to preserve the nipple from the action of the hammer. The snap-cap used with the Martini-Henry rifle may be described as follows:

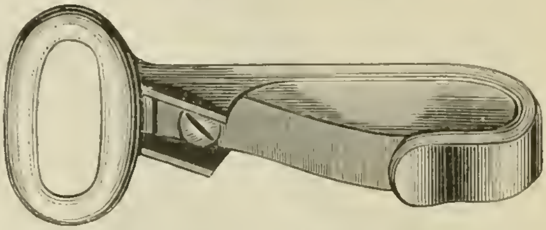
The body of the snap-cap consists of an iron tube surrounded by one of brass, the latter being made somewhat elastic. Longitudinal slits are cut to allow of sufficient compression to insert the snap-cap into the bore of the rifle.

The base is made similar to the base of a breech-loading rifle cartridge, but having a portion of the sides of the flange cut away to allow the horns of the extractor to pass, when the snap-cap is used at snapping-drill.

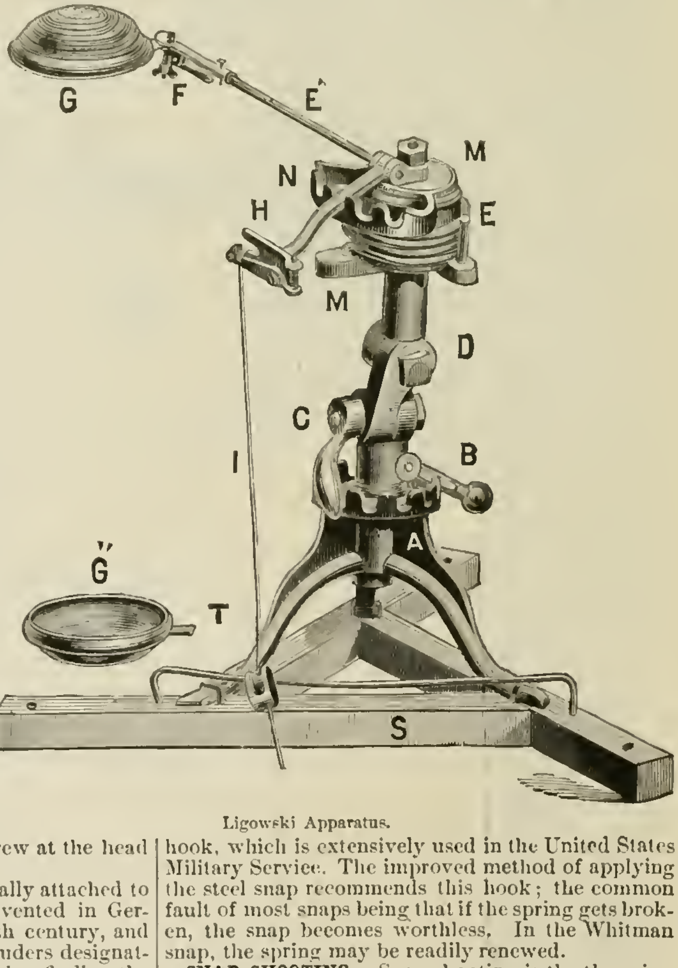
The interior of the snap-cap consists of a spiral spring, supporting a piece of ebonite, which receives the blow of the striker. The spiral spring is kept in its place by a screw at the head of the snap-cap.

SNAPHAUNCE.—A flintlock originally attached to muskets. It is said to have been invented in Germany about the end of the fourteenth century, and was so called by a set of Dutch marauders designated "Snaphans," or poultry-stealers, who, finding the light of the match betrayed them in their marauding trips, and the wheel-lock too expensive, used a lock consisting of a piece of steel, furrowed like the wheel of a wheel-lock, set on a steel post, and which moved on a pivot, and a cock in which was fixed a flint instead of a piece of pyrites; the priming-pan was provided with a cover, which, when it was required to fire the arm, was pushed on one side, and the steel bent down over the pan; on the trigger being pressed, the cock with the flint fell on the steel, and forced it back from the pan, evolving at the same time sparks which fired the priming. The improvement on this lock gave us our flintlock, which has now become an arm of the past. Also written *Snaphance*.

SNAP HOOK.—A hook having a spring-mousing by



which it is prevented from accidental disengagement with the object to which it is attached, as the bit-ring, hame-ring, or breeching-ring. The mousing formerly consisted of a spring, but a spring latch-piece is now the common form. In some snap-hooks a spring forms the latch;· in others the spring actuates the latch. The drawing represents the Whitman snap-hook, which is extensively used in the United States Military Service. The improved method of applying the steel snap recommends this hook; the common fault of most snaps being that if the spring gets broken, the snap becomes worthless. In the Whitman snap, the spring may be readily renewed.



Ligowski Apparatus.

SNAP-SHOOTING.—Snap-shooting is the throwing of both the rear and front sights of a gun into line between the eye and the target and pulling the trigger, all in one motion, and is distinguished by that name from any shooting where the aim is leisurely taken, by bringing the piece to the shoulder, getting the sights in line, hunting the target and pulling the trigger when the aim is most steady. All armies are maintained for offense and defense, and the principal weapon used is the rifle, with an imperfect knowledge of its use, the army is truly ineffective. In action, at least 99 per cent. of the shots go wild, generally in consequence of over-aiming. As an instance of this, the experience of the British troops in Zulu Land, where only one per cent. of the bullets dispatched hit the mark, may be cited. It is certainly important that all troops should be practiced in *Snap-shooting*. Practice in hitting moving objects inspires a confidence which can not be obtained in any other way, and the repetition of the three motions of loading, extracting, and aiming and firing, habituates the learner to a free use of the arms and a confidence in pulling the trigger. In the German Army they aim and snap an unloaded piece repeatedly as an exercise, considering the pulling of the trigger a necessary finish to the motion of aiming. Aided by a minimum expense, light report, easily-acquired range facilities, and a most-fascinating system, might not the practice be carried to firing and hitting, which is the desired result? This need not at all interfere with the manual, but can be practiced as an outside exercise; and the result of adopting it would be felt immediately by a company, not only in the ease and quickening of motion and improved marksmanship, but in the increased interest it would create among the members.

Mr. George Ligowsky has perfected a moving object, which is thrown from a trap in such a manner as to imitate exactly the flight of a pigeon, and which practically solves the problem of finding a suitable substitute for the live bird. The drawing illustrates the device: A, is a tripod stand with a circular rack; B, is a pawl attached to a swivel standard engaging with the circular rack upon A, for obtaining horizontal angular adjustment; C and D form an universal joint for obtaining vertical angular adjustment; M, is a head carrying the exterior spring, E, clamp-arm, E″, and segmental rack, N, which latter engages the pawl, having at its outer end the lock or trigger, H, to which the line or rope, I, is attached; F, is the clamp at the end of the swivel arm, E″, for the tongue, T, of the pigeon; G represents the pigeon in position, and G″ a reverse view of the pigeon on the ground. The weight of the trap is 17 pounds, and its height 18 inches.

To use this apparatus pin the base of the trap firmly to the ground; or what is far better, bolt the base to a plain frame-work of inch plank, about four feet long and two feet wide; secure this latter frame-work to the earth by driving two wide wooden pins on each side and nailing same to the latter. Insert the tongue, T, of the pigeon (convex side of the pigeon being upward) in the clamp, F, from the leftside perpendicular to the clamp-arm, until it rests against the check-pin and the spring-pin; pull back the clamp-arm, E″, with the left hand until caught by the pawl-trigger H, held in place by right hand; then pull the line and the bird flies from the trap. *To increase the velocity of the bird*, engage the pawl, H, farther back upon the segmental rack N. *To obtain a horizontal flight*, keep the clamp-arm, E″, nearly horizontal; to increase the *vertical* angle of flight, incline the lower joint one, two or more points (or notches) until the requisite angle of flight is obtained. *In case of violent wind*, incline the upper joint, D, one or more notches toward the wind until the pigeon alights upon its flat bottom or rim. *To change the horizontal angle of flight*, (that is, from right to left, etc.) raise the pawl, B, and throw the whole swivel-standard around until the clamp arm, E″, points in the direction towards which it be desired to throw the bird; then clamp the set or lock-screw on the tripod.

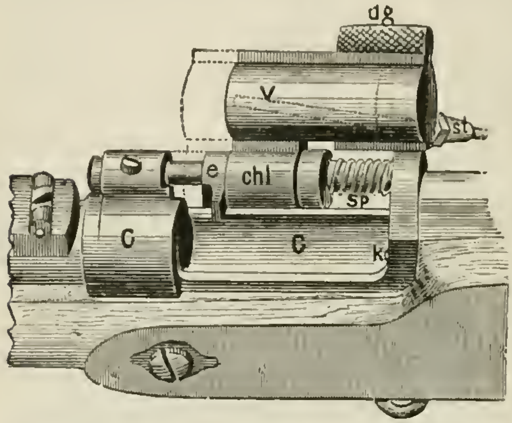
A brief study of these points will readily enable the most unskilled to send the bird at any desired angle; horizontal or vertical. The clamp, F, requires careful adjustment, but when once set must not be disturbed; if (the arm, E″, having been pointed in the direction in which it is desired to throw the same), the bird flies too far to the right, then loosen the tension of the clamp, F, by unscrewing, slightly, the binding-nut; if, on the other hand, the bird flies too far to the left, then tighten the tension.

SNARE-DRUM.—The smaller, or common military drum, as distinguished from the large bass-drum: so called because (in order to render it more resonant) there is stretched across its lower head a catgut-string

or collection of strings. These are generally used by infantry regiments to perform the beats in camp or garrison. In the French Army the drum is now, to some extent, abolished. See *Band*.

SNELL GUN.—A breech-loading rifle having a fixed chamber closed by a movable breech-block, which rotates about an axis parallel to the axis of the barrel and on the right side. It is opened by bringing the hammer to the full-cock; by firing the piece the hammer falls behind the cartridge-head, and locks the piece by engaging in a groove in the frame. The piece is fired by a center-lock, the hammer striking a side-fire cartridge directly, by a projection near its outer edge. Extraction is accomplished by a sliding-piece operated independently by the hand, and serving to guard the cartridge against an accidental fall of the hammer while loading. The friction-spring over the point of which the rim of the cartridge rides in loading, serves to keep the cartridge in the chamber while the hammer is cocked. This arm has been modified to receive a center-fire cartridge, which is ignited by a firing-pin in the form of a bent lever, pivoted on the front and left side of the hammer. As the hammer falls, the forward arm of the firing-pin strikes the right side of the frame, and throws the left arm around to the front with sufficient force to ignite the cartridge; the striking of the forward arm of the firing-pin on this frame being so timed that the fulminate shall be ignited just as the breech is closed.

SNIDER RIFLE.—The converted Enfield or "Snider" rifle was selected in 1865-66 by the British Government from the specimens submitted at an open competition of inventors. It is an extremely simple weapon, and though by no means free from faults, has given very satisfactory results up to this time. The ordinary Enfield barrel is shortened by about 2½ inches and the heel of the remainder is screwed into a strong shoe, with which is connected by a powerful hinge, the solid breech-piece, which, when shut, completely closes the breech. Through this passes the piston or striker; the normal position of the piston is maintained by a spiral spring within the nipple. Given the breech open, the cartridge is inserted and pushed forward into the barrel, where its metal rim fills the groove left around the barrel's heel. The breech-piece is closed down, the hammer drawn to full-cock, and the piece is ready for discharge. The breech-piece is securely locked by the spring bolt, which enters a recess in the false breech, and can only be withdrawn on the lever thumb-piece being



pressed by the thumb in the act of again lifting the breech-block. On the trigger being pulled, the hammer falls, drives in the piston, and out against the detonating cap of the cartridge, with a sharp blow, firing off the charge. The hammer is drawn back to half-cock, the piston flies up to its former position; the breech-piece is thrown back, and slid on its hinge along the pin until occurs a process during which a small catch hooks back into the breech, by its projecting rim, the empty cartridge-case. The canting of the rifle to one side now throws this out, a spring within the hinge moves the breech-piece to its former place, and the gun is ready for another charge.

The cost of altering an "Enfield" to a "Snider" varies from 15s. to 20s. During the transition period, upwards of a million were converted in this way, besides a large number of new arms made for Government service; but conversion and manufacture are now suspended both in the Government factories and by the large small-arms companies. The Government factories were capable of converting 1,100 rifles daily. At first, the firing of the Snider was inferior to the old Enfield; but, by alterations in the bullet, effected by Colonel Boxer, in the direction of decreasing the specific gravity at the apex by the insertion of a wooden plug (which is now, however, dispensed with, and the point of the bullet spun over the mouth of the cavity), this condition has been well reversed, and the Snider now fires 30 per cent. better than the old Enfield. Of course, these changes add some to the cost of the cartridge, which has, however, these great perfections—first, that it is absolutely impervious to wet; and, second, that fire can scarcely be communicated to it otherwise than through the detonating cap. A single cartridge has been fired within a barrel of loose cartridges without exploding any of the others. Adverting to the Snider cartridge, the whole is enclosed in a roll of thin brass foil, outside which is a covering of paper, and having for its base an iron disk, in front of which is a double cup of thin brass, while a round of millboard or pulp encircles the chamber containing the percussion-cap, which communicates with the powder. Between the powder and the ball is a layer of wool. The ball has, as explained above, the point spun over a cavity in its front, and a conical hollow is made at the base; into the wider part of this is dropped the wooden plug. For a detailed description of the action of this gun, see *Tabatière Gun*, reference being made to the drawing above. See *Needle-guns*.

SNOECK FUSE.—The construction of this fuse is based upon the property which cast-zinc possesses, of being hard and tenacious at ordinary temperatures, but very brittle when heated from 160° to 200°, Reaumer, (417° to 482° Fahr.) Hence, a zinc fuse might resist, when cold, the shocks of the charge, and balloting in the bore; but when heated sufficiently by the burning composition, would break from the shock of the falling projectile, and communicate fire to the charge. The fuse consists of a very short wooden fuse-plug, fitted in the interior with a cork collar, through which the fuse passes; and the fuse proper, which consists of a zinc tube of a truncated conical form, having at the top a projecting band, which secures the tube in its position, and at the bottom a solid portion, which, by its weight, assists in breaking the tube when the shell strikes. This tube is filled with ordinary fuse composition.

It will be noticed that this fuse is constructed on a principle very similar to the *Splingard*, but its success has been much less satisfactory. See *Fuse*.

SNOW-SHOE.—1. A species of shoe much used by the Esquimaux, Laplanders, and others who inhabit those regions where snow prevails for a great portion of the year. It consists of a flat frame, of a lanceolate form, from 8 to 14 inches in breadth at its widest part, and of great length—sometimes as much as 7, though generally about 4 feet. It is either wholly of wood or is a wooden frame filled in with wicker-work or thongs, and has cross-straps on the upper surface to attach it to the foot. The broad surface prevents the foot from sinking in the snow. 2. A snow, mud, and trotting-shoe, shown in Fig. 2, patented and made by Messrs. Shoenberger & Co., of Pittsburgh. The concave ground surface of this shoe positively prevents balling, and it will not pull off by the suction of mud or clay. No gravel or other hard substance can find its way under the shoe. Figures 1 and 2 show the Wheeler Anti-snowball Pad and Hoof-protector, a contrivance to prevent horses from "balling" and slipping in winter and from pick-

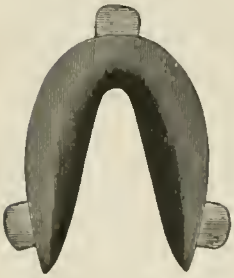


Fig. 1.—Form of Pad.

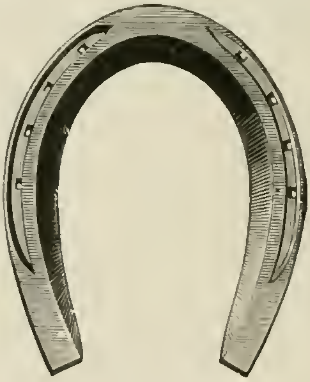

Fig. 2.

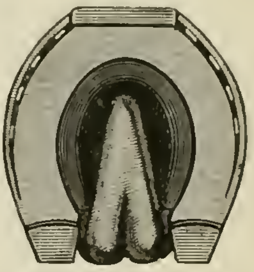

Fig. 3.—Adjusted Pad.

ing up stones in summer. It is made in sizes to fit any foot and is fitted without removing the shoe. It is made of vulcanized rubber, into which a spring of brass with catches is molded. Neither straps nor nails are required. When properly sprung into position (the frog uncovered) it cannot be thrown out by the strongest-actioned horse.

SNYDER DYNAMITE-PROJECTILE.—A newly invented shell charged with a powerful explosive and designed to be propelled from an ordinary cannon. Since the time (1805) when Robert Fulton, in an experimental trial, blew up a brig in Deal Harbor, England, with two torpedoes, filled with 180 pounds of gunpowder, by means of clock-work, the subject of torpedoes, especially for naval warfare, has commanded the attention of civilized governments, and inventions and improvements in this line have been the study of many inventors. England, from the time Fulton made his torpedo experiment, has looked with a jealous eye upon inventions in this direction. Earl St. Vincent, in speaking of the subject to Fulton, said of Sir William Pitt, who had encouraged Fulton in his trials, that he (Pitt) "is the greatest fool that ever existed, to encourage a mode of war which they, who commanded the seas, did not want, and which, if successful, would deprive them of it." That this anxiety still exists, not only in England, but among all other maritime powers, is shown by the large expenditure of money that is constantly being made in the manufacture of torpedoes.

The invention of nitro-glycerine and its adjuncts, nitro-gelatine, dynamite, forcite, giant powder, etc., gave torpedoes a fresh impetus, its destructive effect being much greater than gunpowder. But nitro-glycerine, with its kindred compounds, is of such a sensitive nature that a sudden blow or shock will cause its explosion. Consequently their uses heretofore for war purposes have been solely confined to what are known as fixed submarine mines, floating and spar torpedoes, and torpedoes propelled by machinery contained within them, or by rockets.

Fixed mines, especially when placed under water, are unreliable, and should a vessel pass over them, they could seldom be exploded at the right moment, if at all. Floating torpedoes are quite as apt to injure friends as foes, and the invention of machine-guns and electric lights renders the destruction of spar torpedoes or the thwarting of their operation easy and certain by skilled gunners before they could come into dangerous proximity to a vessel.

Locomotive, or machine torpedoes, likewise have their defects. Their manipulation is intricate and uncertain, and their range short. Of this class is the Fish or Whitehead torpedo, and notwithstanding the fact that millions of dollars have been expended in their construction and trial in war, we understand no vessel has yet been destroyed or injured by one of them. The late Commodore Wm. N. Jeffers, of the U. S. Navy, in speaking of this class of torpedoes, very aptly remarked: "They will go like the devil, but where in the devil will they go to?"

What is known as the Lay, or controlable, torpedo, has overcome many of the objections that apply to the others, yet in that implement many improvements must be made before it can be considered an effective and reliable weapon of war, and even then, like its associates, it would only be applicable to naval warfare.

Realizing the importance of torpedoes for coast defense, the United States Government has encouraged their development, and for the torpedo stations of their Army and Navy—at Willett's Point and Newport—there was appropriated by Congress during the years 1871 and 1879, inclusive, the sum of two million sixty-nine thousand dollars.

It has never been disputed by those whose opinions were worthy of consideration that, if shells or projectiles, charged with dynamite or analogous highly explosive compounds, could be safely fired from cannon, it would revolutionize the present system of warfare, especially of a maritime character. An invention has recently been perfected by which dynamite can be made to play a more important part in offensive and defensive land or naval warfare than it has hitherto been possible to attain. It consists in loading a shell or projectile with glycerine, dynamite or other high explosives, and firing the same from any ordinary gun or cannon without explosion until it strikes the object at which it is fired. The inventor accomplishes this purpose by the mechanical devices that are absolutely certain in their operations; far more so than the shells charged with gunpowder and exploded by time-fuses or other devices, and attended with less danger to those who use them. Repeated tests of this invention have been made, which, in the opinion of experienced naval and military officers who have witnessed the trials, place the utility of the system beyond the realm of doubt. By this system sufficient dynamite to sink the heaviest armored iron-clad ever floated can be fired in a single projectile.

No special kind of ordnance is required, as the invention is applicable to either breech or muzzle-loading, smooth-bore, or rifled-cannon.

By this system no shock is produced upon the projectile, and consequently less strain upon the gun than in the ordinary methods of firing. The inventor is prepared to demonstrate that with uniform weight projectiles, a longer range and greater accuracy is attainable with the same gun than by the usual methods of firing. It is confidently believed, and the United States Dynamite Projectile Company is willing to prove, by competitive tests, that they can produce a more destructive effect with a gun of six-inch caliber, using the Snyder dynamite-projectile, than can be produced with a cannon of the largest caliber ever fabricated, using the ordinary projectile or solid shot. When the saving in weight of armament of a war vessel, that may be attained by this invention is considered, its benefits will be appreciated, especially when increased speed and facility of maneuvring is desirable.

The effect produced by firing shells charged with dynamite into an enemy's camp, or fortified position, or city, can easily be imagined by any one familiar with the terrible destructiveness of exploded dynamite. However, those who have never witnessed its explosion when fired from cannon, will have a very meager conception of its havoc, as the tamping or solidifying it receives at the point of contact and explosion, by reason of the velocity with which the shell is driven, intensifies the deflagration, and augments its destructive effect. It will, furthermore, be readily apparent that the concussive effect produced by the explosions of dynamite shells would be disastrous to life within a very considerable radius.

It has been suggested that explosive compounds, in the manufacture of which nitro-glycerine is used as a base or component part, will be extra hazardous to transport or handle. This objection may seem reasonable to those having little knowledge of its nature, yet it is well known by those familiar with its character, that in many respects there is far less danger attending its transport, handling, and storage, than there is with ordinary gunpowder, as properly manufactured compounds of nitro-glycerine coming in tact with fire, if unconfined, will simply burn, while gunpowder will instantly explode. Furthermore, many of the glycerine compounds, notably nitro-glycerine, for storage, may be placed in water, for instance, in the hold of a vessel, out of the way of an enemy's shot, where it may remain for years without deterioration, or until required for charging the projectiles.

The preliminary trial at the Washington Navy Yard of the Synder dynamite-shell, using gunpowder as the projectile agent, was had very recently under the auspices of the Senate Military Committee. The gun used was a six-inch rifled breech-loading howitzer of the Moffat pattern. The shell was loaded with twelve pounds of explosive gelatine, containing 95 per cent. of pure nitro-glycerine. The firing-charge was the maximum that the gun would take, and was of common hexagonal powder. The projectile struck the target, exploding with a force that completely shattered both target and backing. The concussion of the air in the vicinity was terrific.

SNYDER SHELTER KNAPSACK.—This knapsack, the invention of Captain J. A. Snyder, of the U. S. Army, consists of ½ a shelter-tent; 3 sections of a tent-pole, with ferrules; 1 extra section suitable for top, center, or bottom piece; 1 bag, for clothing; 4 small tent-pins; 1 guy-rope; 1 set of straps. By combining two knapsacks a complete tent is made. The sections of the tent-pole are secured to the canvas by leather loops, and the sections of the pole are arranged in the loops in the shape of a square, making a sort of frame on one side. The 4 pins are secured in loops, inside of the sections of the pole. The pack, thus formed, has two straps on top, to which may be secured the overcoat, blanket, or poncho. The whole is carried on the back, well up on the shoulders by means of a broad neck-yoke tapering down toward the waist-belt. About half way between the shoulder and waist the piece forming the neck-yoke terminates in two straps, one going to the waist-belt and the other behind under the arms, hooking by brass loops to hooks in the knapsack. The knapsack is suspended by a ring on the top to a brass hook in the neck-yoke.

SOCIAL WARS. Wars with *Socii* or Allies. The most important Social War was between Rome and Italian peoples, such as the Samnites, Peligni, Marsi, etc., who desired to be admitted to the rights of citizenship. M. Livius Drusus, who had been the advocate of the Italian nationalities, was assassinated B. C. 91. The Italian allies of Rome at once revolted, and the Three Years' War that followed—during which over 300,000 men are said to have lost their lives—though the Romans, under Marius and Sulla, inflicted terrible losses upon the allies, was substantially a victory for the latter, who eventually were granted the rights demanded. Athens had two Social Wars, the first with the allied cities of Cos, Chios, and Byzantium, whose independence was secured B. C. 357-55; the second between Athens and the Ætolian and Achæn Leagues B. C. 220-17.

SOCKET.—A term generally employed to mean any hollow pipe that receives something inserted. The socket of a bayonet is the round hollow near the bend or heel of a bayonet, into which the muzzle of a fire-arm is received when the bayonet is fixed.

SODA WATER BOTTLES.—Bottles issued in India to European troops on the march, instead of wooden canteens, for holding drinking water. The bottles are covered with leather, and have a strap attached, by which the soldier can sling the bottle over his shoulder. A water bottle has lately been introduced into the service termed the *Italian* pattern. It is of wood, cut from the solid, and is furnished with a metal stopper. This pattern bottle is to be issued to all men in the dismounted services, and will be considered the universal pattern for general service.

SOD REVETMENT.—Sod-work forms a strong and durable revetment. The sods should be cut from a well-clothed sward, with the grass of a fine short

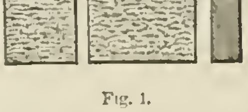

Fig. 1.

blade, and thickly matted roots. If the grass is long, it should be mowed before the sod is cut. Sods are of two sizes (Fig. 1.); one termed *stretchers*, are twelve inches square, and four-and-a-half inches thick; the others, termed *headers*, are eighteen inches long, twelve inches broad, and four-and-a-half inches thick.

The sod revetment (Fig. 2) is commenced as soon as the parapet is raised to the level of the tread of the banquette. A course of sods is then laid, either horizontally or a little inclined from the banquette; the course consists of two stretchers, B, and the one

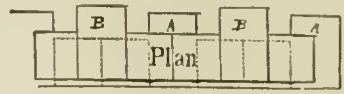

Fig. 2.

header, A, alternating, the end of the header laid to the front. The grass side is laid downward to facilitate the trimming of the top surface to a level or plane; and the sods should protrude a little beyond the line of the interior slope, for the purpose of trimming the course even at top, before laying another, and to make the interior slope regular. The course is firmly settled, by tapping each sod as it is laid with a spade or wooden mallet; and the earth of the parapet is packed closely behind the course. A second course is laid on the first, so as to cover the joints, or as it is termed, to *break joints* with it; using otherwise the same precautions as with the first. The top course is laid with the grass up; and in some cases pegs are driven through the sods of two courses to connect the whole more firmly, which is by no means necessary to form a strong sodding. When cut from a wet soil, the sods should not be laid until they are partially dried, otherwise they will shrink, and the revetment will crack in drying. In hot weather the revetment should be watered frequently, until the grass puts forth. The sods are cut rather larger than required for use, and are trimmed to a proper size from a model sod. See *Revetment*.

SOLAKS.—Bowmen or archers belonging to the personal guard of the Grand Seignor. They were always selected from the most expert bowmen that were among the Janissaries. Their only arms were the saber, bow, and arrows.

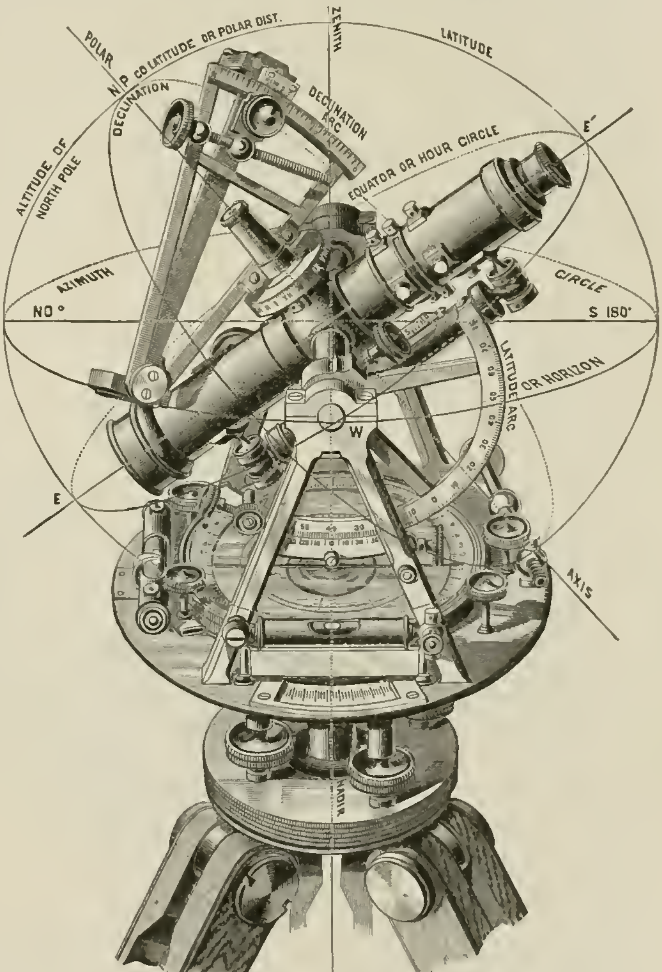
SOLAR ATTACHMENT.—An appartus placed upon a transit in order to determine the true meridian and deviation of the needle. The value and operation of the solar attachment will be better understood by a reference to the accompanying illustration. The apparatus is applied to the mountain transit, and the circles shown, represent in miniature those supposed to be drawn upon the concave surface of the heavens. When the telescope is made horizontal by its spirit level the hour-circle will be in the plane of the horizon, the polar axis will point to the zenith and the zeros of the vertical arc and its vernier coincide. In this position of the instrument, if the arm of the declination arc be placed at zero, and one lens directed to the sun, his image will be seen between the lines on the silver plate of the opposite block, as shown in the drawing, and will indicate his position in the heavens, on an instrument placed at the north pole of the earth at the time of equinoxes, or when the equator is in the plane of the horizon. Now if we incline the telescope as shown in the cut, the polar axis will descend from the direction of the zenith. The angle through which it moves, being laid off on the vertical arc, and shown by its vernier to be 40°, will be the co-latitude of the place where the instrument is supposed to be used, the latitude itself being found by subtracting 40° from 90°, making it just 50°. Now, if the declination-arm remains at zero, and the lens be again directed to the sun, his image will appear on the opposite plate as before, the instrument being used at the time of the equinox and at a latitude of 50°. When, however, the sun passes above or below the equator, his declination or angular distance from it, as given in the ephemeris, can be allowed for and set off upon the arc, and his image brought into position as before. In order to do this, however, it is necessary not only that the latitude and declination shall be correctly set off upon their arcs, but also that the instrument should be moved in azimuth until the polar axis points to the pole of the heavens,or,in other words,is placed in the plane of the meridian, and thus the position of the sun's image will indicate not only the latitude of the place, the declination of the sun for the given hour,and the apparent time, but also determine the meridian or true north and south line, passing through the place where the observation is made.

The adjustments of the solar attachments are as follows: 1. The solar lenses and lines are adjusted precisely like those of the ordinary solar,the declination-arm being first detached by removing the clamp and tangent-screws, and the conical center with its two small screws, by which the arm is attached to the arc. The adjuster,which is a short bar furnished with every instrument, is then substituted for the declination-arm, the conical center screwed in its place,at one end,and the clamp-screw into the other,being inserted through the hole left by the removal of the tangent-screw, and thus securing the adjuster firmly to the arc. The arm is then turned to the sun, as described in the article on the Solar Compass, and reversed by the opposite faces of the blocks upon the adjuster, until the image will remain in the center of the equatorial lines. This adjustment is very rarely needed, the lenses being cemented in their cells,and the plates securely fastened.

2. The vernier of the declination-arc is adjusted by setting the vernier at zero, and then raising or lowering the telescope by the tangent-screw until the sun's image appears exactly between the equatorial lines. Having the telescope-axis clamped securely, carefully revolve the arm until the image appears on the other plate. If precisely between the lines, the adjustment is complete; if not, move the declination-arm by its tangent-screw, until the image will come precisely between the lines on the two opposite plates: clamp the arm and remove the index error by loosening all the screws that fasten the vernier; place the zeros of the vernier and limb in exact coincidence,tighten the screws, and the adjustment is finished.

3. *To adjust the polar axis.*—First level the instrument carefully by the long level of the telescope,using in the operation the tangent movement of the telescope-axis in connection with the leveling-screws of the parallel plates until the bubble will remain in the center during a complete revolution of the instrument upon its axis. Place the equatorial-sights on the top of the blocks as closely as practicable with the view of a distant object; and having previously set the declination-arm at zero, sight through the interval between the equatorial-sights and the blocks at some definite point or object, the declination-arm being placed over either pair of the capstan-head screws on the under side of the disc. Keeping the declination-arm upon the object with one hand, with the other turn the instrument half around on its axis, and sight upon the same object as before. If the sight strikes either above or below, move the two capstan-head screws immediately under the arm, loosening one and tightening the other as may be needed until half the error is removed. Sight again and repeat the operation, if needed, until the sight will strike the same object in both positions of the instrument, when the adjustment of the axis in one direction will be complete. Now turn the instrument at right angles, keeping the sight still upon the same object as before; if it strikes the same point when sighted through, the axis will be truly vertical in the second position of the instrument. If not,bring the sight upon the same point by the other pair of capstan-head screws now under the declination-arc, reverse as before and continue the operation until the same object will keep in the sight in all positions. when the polar axis will be made precisely at right angles to the level and to the line of collimation of the transit.

It should here be noted that, as this is by far the most delicate and important adjustment of the solar attachment, it should be made with the greatest care,



the bubble kept perfectly in the center and frequently inspected in the course of the operation.

4. *To adjust the hour arc.*—Whenever the instrument is set in the meridian, the index of the hour arc should read apparent time. If not, loosen the two flat-head screws on the top of the hour circle, and with the hand turn the circle around until it does; fasten the screws again, and the adjustment will be complete. To obtain mean time, of course the correction of the equation for the given day, as given in the Nautical Almanac, must always be applied.

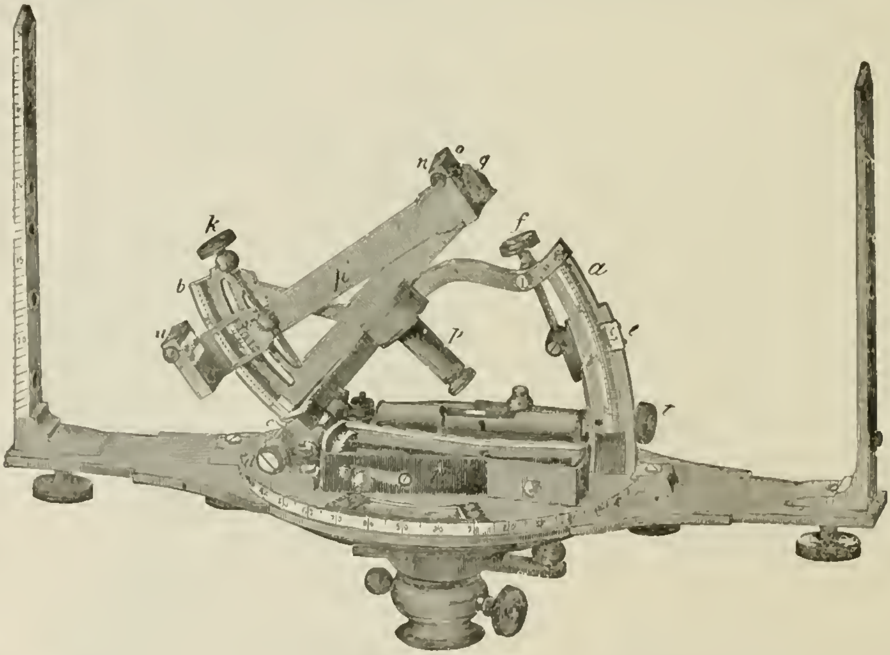
From the foregoing it will be readily understood, that good results can not be obtained from the solar attachment unless the transit is of good construction —furnished with the appliances of a level on a telescope, clamp and tangent movement to axis, and vertical arc with adjustable vernier, and the sockets or centers in such condition that the level of the telescope will remain in the center when the instrument is revolved upon either socket.

The solar attachment may be employed to run lines with great accuracy. Having set off the complement of the latitude of the place on the vertical arc, and the declination for the given day and hour as in the solar, the instrument being also carefully leveled by the telescope-bubble, set the horizontal limb at zero and clamp the plates together, loosen the lower clamp so that the transit moves easily upon its lower socket, set the instrument approximately north and south, the object end of the telescope pointing to the north, turn the proper solar lens to the sun, and with one hand on the plates and the other on the revolving arm, move them from side to side until the sun's image is brought between the equatorial lines on the silver plate.

The lower clamp of the instrument should be fastened and any further lateral movement be made by the tangent-screw of the tripod. The necessary allowance being made for refraction, the telescope will be in the true meridian, and being unclamped, it may be used like the sights of the ordinary solar compass, but with much greater accuracy and satisfaction in establishing meridian lines. Of course when the upper or vernier plate is unclamped from the limb, any angle read by the verniers is an angle from the meridian, and parallels of latitude or other angles from the true meridian may be established as with the solar compass. The bearing of the needle, when the telescope is on the meridian, will also give the variation of the needle at the point of observation. If the instrument has a movable compass circle, the variation of the needle can be set off to single minutes, the needle kept at zero, or "with the sun," and thus lines be run by the needle alone when the sun is obscured.

From what has been already said the intelligent surveyor will readily understand that the more perfect horizon obtained by the use of the telescope level, and the use of a telescope in the place of sights, render the new attachment more accurate than the ordinary solar compass. It can also be put on the telescope of any good transit at comparatively small cost, and thus enable the surveyor to establish the true meridian, to determine the correct latitude, and to obtain true time very nearly. Its adaptation to the purposes of illustration and instruction in practical astronomy in Colleges and Schools, will occur to every teacher; and we believe that for the Government Surveyor it furnishes a long-sought and much-needed instrument, superior, in many respects, to the solar compass now so commonly used. In experiments made, an error of about one-quarter of a minute in the direction of the true meridian, or in latitude, could be easily detected by observing the sun's image by a magnifier. See *Engineer's Transit* and *Saegmuller Solar Attachment*.

SOLAR COMPASS.—This instrument so ingeniously contrived for readily determining a true meridian or north and south line, was invented and patented in 1836. It has since come into general use in the surveys of U. S. public lands, the principal lines of which are required to be run with reference to the true meridian. The invention has long since become public property, and for over twenty years the solar compass has been manufactured by the Messrs. Gurley, with improvements of their own, which have made it increasingly popular and efficient. The arrangement of its sockets and plates is very similar to



that of the transit, except that the sight-vanes are attached to the under plate or limb, and this revolves around the upper or vernier plate on which the solar apparatus is placed. The limb is divided to half degrees, is figured in two rows, as usual, and reads by the two opposite verniers to single minutes. The divisions of the limb and all other arcs of the solar compass are made upon solid silver so as to avoid tarnishing.

The solar apparatus is seen in the place of the needle, and in fact operates as its substitute in the field. It consists mainly of three arcs of circles, by which can be set of the latitude of a place, the declination of the sun, and the hour of the day. These arcs, designated in the drawing by the letters *a*, *b*, and *c*, are therefore termed the latitude, the declination, and the hour-arcs respectively.

The latitude-arc, *a*, has its center of motion in two pivots, one of which is seen at *d*, the other is concealed in the drawing. It is moved either up or down within a hollow arc, seen in the drawing, by a tangent-screw at *f*, and is securely fastened in any position by a clamp-screw. The latitude arc is graduated to quarter degrees, and reads by its vernier, *e*, to single minutes; it has a range of about thirty-five degrees, so as to be adjustable to the latitude of any place in the United States.

The declination-arc, *b*, is also graduated to quarter degrees, and has a range of about twenty-eight degrees. Its vernier, *v*, reading to single minutes, is fixed to a movable arm, *h*, having its center of motion at the end of the declination-arc at *g*; the arm is moved over the surface of the declination-arc, and its vernier set to any reading by turning the head of the tangent-screw, *k*. It is also securely clamped in any position by a screw, concealed in the foregoing engraving. At each end of the arm, *h*, is a rectangular block of brass, in which is set a small convex lens, having its focus on the surface of a little silver plate, A, fastened by screws to the inside of the opposite block. On the surface of the plate are marked two sets of lines intersecting each other at right angles; of these, *b b* are termed the hour lines, and *c c* the equatorial lines, as having reference respectively to the hour of the day and the position of the sun in relation to the equator. On the top of each of the rectangular blocks is seen a little sighting-piece, termed the equatorial-sight, fastened to the block by a small milled head screw, so as to be detached at pleasure. They are used in adjusting the different parts of the solar apparatus.

A.

The hour-arc, *c*, is supported by the two pivots of the latitude-arc, already spoken of, and is also connected with that arc by a curved arm, as shown in the figure. The hour-arc has a range of about 120°, is divided to half degrees, and figured in two series, designating both the hours and the degrees, the middle division being marked 12 and 90 on either side of the graduated lines.

Through the center of the hour-arc passes a hollow socket, *p*, containing the spindle of the declination-arc, by means of which this arc can be moved from side to side over the surface of the hour-arc, or turned completely round as may be required. The hour-arc is read by the lower edge of the graduated side of the declination-arc. The axis of the declination-arc, or indeed the whole socket, *p*, is appropriately termed the polar axis.

Besides the parts shown in the drawing, there is also an arm used in the adjustment of the instrument as described hereafter, but laid aside in the box when that is effected. The parts just described constitute properly the solar apparatus. Besides these, however, are seen the needle-box, *n*, with its arc and tangent-screw, *t*, and the spirit levels, for bringing the whole instrument to a horizontal position.

The needle-box, *n*, has an arc of about 36° in extent, divided to half degrees, and figured from the center or the zero mark on either side. The needle, which is made as in other instruments, except that the arms are of unequal lengths, is raised or lowered by a lever shown in the cut. The needle-box is attached by a projecting arm to a tangent screw, *t*, by which it is moved about its center, and its needle set to any variation. This variation is also read off by the vernier on the end of the projecting arm, and reading to three minutes a graduated arc, attached to the plate of the compass.

The levels, as seen with the solar apparatus, have ground-glass vials, and are adjustable at their ends like those of any other instruments. The edge of the circular plate on which the solar work is placed, is divided and figured at intervals of ten degrees, and numbered as shown, from 0 to 90 on each side of the line of sight. These graduations are used in connection with a little brass pin, seen in the center of the plate, to obtain approximate bearings of lines, which are not important enough to require a close observation. The inside faces of the sights are also graduated and figured, to indicate the amount of refraction to be allowed when the sun is near the horizon.

The interval between two equatorial lines, *c c*, as well as between the hour lines, *b b*, is just sufficient to include the circular image of the sun as formed by the solar lens on the opposite end of the revolving arm, *h*. When, therefore, the instrument is made perfectly horizontal, the equatorial lines and the opposite lenses being accurately adjusted to each other by a previous operation, and the sun's image brought within the equatorial lines, his position in the heavens, with reference to the horizon, will be readily defined with precision.

Suppose the observation to be made at the time of one of the equinoxes; the arm, *h*, set at zero on the declination-arc, *b*, and the polar axis, *p*, placed exactly parallel to the axis of the earth. Then the motion of the arm, *h*, if revolved on the spindle of the declination-arc around the hour circle, *c*, will exactly correspond with the motion of the sun in the heavens, on the given day and at the place of observation; so that if the sun's image was brought between the lines, *c c*, in the morning, it would continue in the same position, passing neither above nor below the lines, as the arm was made to revolve in imitation of the motion of the sun about the earth.

In the morning, as the sun rises from the horizon, the arm, *h*, will be in a position nearly at right angles to that shown in the cut, the lens being turned towards the sun, and the silver plate, on which his image is thrown directly opposite. As the sun ascends, the arm must be moved around, until when he has reached the meridian, the graduated side of the declination-arc will indicate 12 on the hour circle, and the arm, *h*, the declination-arc, *b*, and the latitude-arc, *a*, will be in the same plane. As the sun declines from the meridian the arm, *h*, must be moved in the same direction, until at sunset its position will be the exact reverse of that it occupied in the morning.

Let us now suppose the observation made when the sun has passed the equinoctial point, and when his position is affected by declination. By referring to the Almanac, and setting off on the arc his declination for the given day and hour, we are still able to determine his position with the same certainty as if he remained on the equator. When the sun's declination is south, that is, from the 22d of September to the 20th of March in each year, the arc, *b*, is turned toward the plates of the compass, as shown in the engraving, and the solar lens, *o*, with the silver plate opposite are made use of in the surveys. The remainder of the year, the arc is turned from the plates, and the other lens and plate employed. When the solar compass is accurately adjusted, and its plates made perfectly horizontal, the latitude of the place, and the declination of the sun for the given day and hour, being also set off on the respective arcs, *the image of the sun cannot be brought between the equatorial lines until the polar axis is placed in the plane of the meridian of the place, or in a position parallel to the axis of the earth.* The slightest deviation from this position will cause the image to pass above or below the lines, and thus discover the error. We thus, from the position of the sun in the solar system, obtain a certain direction absolutely unchangeable, from which to run our lines, and to measure the horizontal angles required.

This very plain principle is not only the basis of the construction of the solar compass, but the sole cause of its superiority to the ordinary or magnetic instrument. For in a needle instrument, the accuracy of the horizontal angles indicated, and therefore of all the observations made, depends upon "the delicacy of the needle, and the constancy with which it assumes a certain direction, termed the magnetic meridian."

The principal causes of error in the needle, briefly stated, are the dulling of the pivot, the loss of polarity in the needle, the influence of local attraction, and the effect of the sun's rays, producing the diurnal variation. From all these imperfections the solar instrument is free. The sights and the graduated limb being adjusted to the solar apparatus, and the latitude of the place and the declination of the sun also set off upon the respective arcs, we are able, not only to run the true meridian, or a due east and west course, but also to set of the horizontal angles with minuteness and accuracy from a direction which can never change, and is unaffected by attraction of any kind.

The adjustments of this instrument, with which the surveyor will have to do, are simple and few in number, and will now be given in order.

1st. To adjust the levels.—Proceed precisely as directed for the mountain transit by bringing the bubbles into the center of the tubes by the leveling-screws of the tripod, and then reversing the instrument upon its spindle, and raising or lowering the ends of the tubes, until the bubbles will remain in the center during a complete revolution of the instrument.

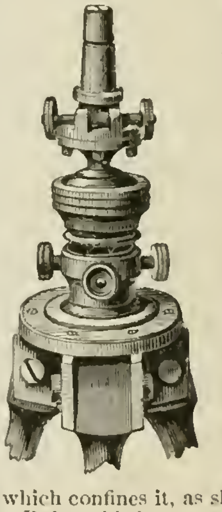
2d. To adjust the equatorial lines and solar lenses.—It is necessary, first, to detach the arm, *h*, from the declination-arc by withdrawing the screws shown in the cut from the ends of the posts of the tangent-screw, *k*, and also the clamp-screw, and the conical pivot with its small screws, by which the arm and declination-arc are connected. The arm, *h*, being thus removed, attach the adjuster in its place by replacing the conical pivot and screws, and insert the clamp-screw so as to clamp the adjuster at any point on the declination-arc. Now level the instrument, place the arm, *h*, on the adjuster, with the same side resting against the surface of the declination-arc as before it was detached. Turn the instrument on its spindle so as to bring the solar lens to be adjusted in the direction of the sun, and raise or lower the adjuster on the declination-arc, until it can be clamped in such a position as to bring the sun's image as near as may be between the equatorial lines on the opposite silver plate, and bring the image precisely into position by the tangent of the latitude-arc or the leveling-screws of the tripod. Then carefully turn the arm half way over until it rests upon the adjuster by the opposite faces of the rectangular blocks, and again observe the position of the sun's image. If it remains between the lines as before, the lens and plate are in adjustment ; but if not, loosen the three screws which confine the plate to the block, and move the plate under their heads, until one half the error in the position of the sun's image is removed. Again, bring the image between the lines, and repeat the process until it will remain in the same situation, in both positions of the arm, when the adjustment will be completed. To adjust the other lens and plate, reverse the arm end for end on the adjuster, and proceed precisely as in the former case, until the same result is attained. In tightening the screws over the silver plate care must be taken not to move the plate. This adjustment now being complete, the adjuster should be removed, and the arm, *h*, with its attachments, replaced as before.

3d. To Adjust the vernier of the declination-arc. —Having leveled the instrument, and turned its lens in the direction of the sun, clamp to the spindle, and set the vernier, *v*, of the declination-arc, at zero, by means of the tangent-screw at *k*, and clamp to the arc. See that the spindle moves easily and yet truly in the socket, or polar axis, and raise or lower the latitude-arc by turning the tangent-screw, *f*, until the sun's image is brought between the equatorial lines on one of the plates. Clamp the latitude-arc by the screw, and bring the image precisely into position by the leveling-screws of the tripod or socket, and without disturbing the instrument, carefully revolve the arm, *h*, until the opposite lens and plate are brought in the direction of the sun, and note if the sun's image comes between the lines as before. If it does, there is no index error of the declination-arc ; if not, with the tangent-screw, *k*, move the arm until the sun's image passes over half the error ; and again bring the image between the lines, and repeat the operation as before until the image will occupy the same position on both the plates. We shall now find, however, that the zero marks on the arc and the vernier do not correspond, and to remedy this error, the little flat-head screws above the vernier must be loosened until it can be moved so as to make the zeroes coincide, when the operation will be completed.

4th. To adjust the solar apparatus to the compass sights.—First level the instrument, and with the clamp and tangent-screws set the main plate at 90° by the verniers and horizontal limb. Then remove the clamp-screw, and raise the latitude-arc until the polar axis is by estimation very nearly horizontal, and if necessary, tighten the screws on the pivots of the arc, so as to retain it in this position. Fix the vernier of the declination-arc at zero, and direct the equatorial-sights to some distant and well marked object, and observe the same through the compass sights. If the same object is seen through both, and the verniers read to 90° on the limb, the adjustment is complete ; if not, the correction must be made by moving the position of the verniers.

It should be remarked that since the solar work is attached permanently to the sockets, and this adjustment is made by the maker, it will need no further attention at the hands of the surveyor except in case of serious accidents. The other adjustments are of course also made in the process of finishing the instrument, and are liable to very little derangement in the ordinary use of the solar compass.

For more rapid leveling of the solar compass, the



Messrs. Gurley have recently devised an arrangement represented in the drawing, which is screwed into the top of the tripod like the ordinary leveling head. This can be used either with a simple ball-spindle, or with the compound ball with tangent-screw as shown in the drawing. The instrument is leveled very nearly upon the ball, and finally made truly horizontal by the leveling-screws. It also revolves upon the spindle as upon the ordinary compass-ball, but it can be clamped at pleasure to the spindle, and then by the tangent-screw be directed precisely to any object. A simple ball with extra cap is also supplied, which can be easily substituted for the compound ball, by unscrewing the cap which confines it, as shown in the drawing.

Before this instrument can be used at any given place, it is necessary to set off upon its arcs both the declination of the sun as affected by its refraction for the given day and hour, and the latitude of the place where the observation is made.

The declination of the sun, given in the ephemeris of the Nautical Almanac from year to year, is calculated for apparent noon at Greenwich, England. To determine it for any other hour at a place in the U. S., reference must be had, not only to the difference of time arising from the longitude, but also to the change of declination from day to day. The longitude of the place, and consequently its difference in time, if not given directly in the tables of the Almanac, can be ascertained very nearly by reference to that of other places given, which are situated on, or very nearly on, the same meridian. It is the practice of surveyors in the States east of the Mississippi to allow a difference of *six* hours for the difference in longitude, calling the declination given in the Almanac for 12 M., that of 6 A. M., at the place of observation. Beyond the meridian of Santa Fe, the allowance would be about *seven* hours, and in California, Oregon, and Washington Territory very nearly *eight* hours. Having thus the difference of time, we very readily obtain the declination for a certain hour in the morning, which would be earlier or later as the longitude was greater or less, and the same as that of apparent noon at Greenwich on the given day. Thus, suppose the observation made at a place, say, five hours later than Greenwich, then the declination given in the Almanac for the given day at noon, affected by the refraction, would be the declination at the place of observation for 7 o'clock, A. M.; this gives us the starting-point. To obtain the declination for the other hours of the day, take from the Almanac the declination for apparent noon of the given day, and, as the declination is increasing or decreasing, add to or subtract from the declination of the first hour the difference for one hour as given in the ephemeris, which will give, when affected by the refraction, the declination for the succeeding hour; and proceed thus in making a table of the declination for every hour of the day.

To set off the latitude, find the declination of the sun for the given day at noon, at the place of observation as just described, and with the tangent-screw set it off upon the declination-arc, and clamp the arm firmly to the arc. Observe in the Almanac the equation of time for the given day, in order to know about the time the sun will reach the meridian. Then, about fifteen or twenty minutes before this time, set up the instrument, level it carefully, fix the divided surface of the declination-arc at 12 on the hour circle, and turn the instrument upon its spindle until the solar lens is brought into the direction of the sun. Loosen the clamp-screw of the latitude-arc, and with the tangent-screw raise or lower this arc until the image of the sun is brought precisely between the equatorial lines, and turn the instrument from time to time so as to keep the image also between the hour lines on the plate. As the sun ascends, its image will move below the lines, and the arc must be moved to follow it. Continue thus, keeping it between the two sets of lines until its image begins to pass above the equatorial lines, which is also the moment of its passing the meridian. Now read off the vernier of the arc, and we have the latitude of the place, which is always to be set off on the arc when the compass is used at the given place. It is the practice of surveyors using the solar compass to set off, in the manner just described, the latitude of the point where the survey begins, and to repeat the observation and correction of the latitude-arc every day when the weather is favorable, there being also nearly an hour at mid-day when the sun is so near meridian as not to give the direction of lines with the certainty required.

Having set off in the manner just given the latitude and declination upon their respective arcs, the instrument being also in adjustment, the surveyor is ready to run lines by the sun.

To do this, the instrument is set over the station and carefully leveled, the plates clamped at zero on the horizontal limb, and the sights directed north and south, the direction being given, when unknown, approximately by the needle. The solar lens is then turned to the sun, and with one hand on the instrument, and the other on the revolving arm, both are moved from side to side, until the sun's image is made to appear on the silver plate; when by carefully continuing the operation, it may be brought precisely between the equatorial lines. Allowance being now made for refraction, the line of sights will indicate the true meridian; the observation may now be made, and the flagman put in his position. When a due east and west line is to be run, the verniers of the horizontal limb are set at 90°, and the sun's image kept between the lines as before. The solar compass being so constructed that when the sun's image is in position the limb must be clamped at 0 in order to run a true meridian line, it will be evident that the bearing of any line from the meridian, may be read by the verniers of the limb precisely as in the ordinary magnetic compass; the bearings of lines are read from the ends of the needle.

In running lines, the magnetic needle is always kept with the sun; that is, the point of the needle is made to indicate 0 on the arc of the compass-box, by turning the tangent-screw connected with its arm on the opposite side of the plate. By this means the lines can be run by the needle alone in case of the temporary disappearance of the sun; but, of course, in such cases the surveyor must be sure that no local attraction is exerted. The variation of the needle, which is noted at every station, is read off in degrees and minutes on the arc, by the edge of which latter the vernier of the needle-box moves.

When very long lines are run by the solar compass, either by the true meridian, or due east and west, an allowance must be made for the curvature of the earth. Thus, in running north or south, the latitude changes about one minute for every distance of 92 chains 30 links, and the side of a township requires a change on the latitude arc of 5′ 12″, the township, of course, being six miles square. This allowance is of constant use where the surveyor fails to get an observation on the sun at noon, and is a very close approximation to the truth. In running due east and west, as in tracing the standard parallels of latitude, the sights are set at 90° on the limb, and the line is run at right angles to the meridian. If no allowance were made for the earth's curvature, these lines would, if sufficiently produced, reach the equator, to which they are constantly tending. Of course, in running short lines either east or west, the variation from the parallel would be so small as to be of no practical importance; but when long sights are taken, the correction should be made by taking fore and back sights at every station, noticing the error on the back sight, and setting off one half of it on the fore sight on the side towards the pole.

The time of day is readily ascertained by the solar compass when the sun is on the meridian, as at the time of making the observation for latitude. The time thus given is that of apparent noon, and can be reduced to mean time, by merely applying the equation of time as directed in the Almanac, and adding or subtracting as the sun is slow or fast. The time, of course, can also be taken before or after noon, by bringing the sun's image between the hour lines, and noticing the position of the divided edge of the revolving arm, with reference to the graduations of the hour circle, allowing for minutes of time for each degree of the arc, and thus obtaining apparent time, which must be corrected by the equation of time as just described.

In using the compass upon the sun, if the revolving arm be turned a little one side of its proper position, a false or reflected image of the sun will appear on the silver plate in nearly the same place as that occupied by the true one. It is caused by the reflection of the true image from the surface of the arm, and is a fruitful source of error to the inexperienced surveyor. It can, however, be readily distinguished from the real image by being very much less bright, and not so clearly defined.

When the bearings of lines, such as the course of a stream, or the boundaries of a forest, are not desired with the certainty given by the verniers and horizontal limb, a rough approximation of the angle they make with the true meridian, is obtained by the divisions on the outside of the circular plate. In this operation, a pencil, or thin straight edge of any sort, is held perpendicularly against the circular edge of the plate, and moved around until it is in range with the eye, the brass center-pin, and the object that is observed. The bearing of the line with great exactness is then read off at the point where the pencil is placed.

The solar compass, like the ordinary instrument, can be used at all seasons of the year, the most favorable time being, of course, in the summer, when the declination is north, and the days are long, and more generally fair. It is best not to take the sun at morning and evening, when it is within half an hour of the horizon, nor at noon, as we have before stated, for about the same interval, before and after it passes the meridian.

It will readily occur to all who have read the preceding description of the solar compass, that while it is indispensable in the surveys of public lands, it also possesses important advantages over the magnetic compass, when used in the ordinary surveys of the military engineer. For not only can lines be run and angles be measured without regard to the diurnal variation, or the effect of local attraction, but the bearings being taken from the true meridian, will remain unchanged for all time. The constant uncertainty caused by the variation of the needle, and the litigation to which it so often gives rise, may thus be entirely prevented by the use of the solar compass in determining all Government lines. It is also said by those familiar with the use of this instrument, that, in favorable weather, surveys can be more rapidly made with it than with the ordinary needle instrument; there being no time consumed in waiting for the needle to settle, or in avoiding the errors of local attraction. When the sun is obscured, the lines may be run by the needle alone, it being always kept with the sun, or at 0 on its arc, and thus indicating the direction of the true meridian. The sun, however, must ever be regarded as the most reliable guide, and should, if possible, be taken at every station. It is with the design of making the principles and use of the solar compass intelligible to all in the military service, that we have given a very extended account of this instrument, believing that when its merits become better understood, it will come into general use.

We have described the standard instrument of the United States, as made by Messrs. W. & L. E. Gurley, and it may be well to state briefly its points of superiority.

1. A motion of the horizontal plates almost entirely free from friction, combined with perfect solidity.

2. A fine clamp and tangent movement to the divided limb, as shown under the plate.

3 A tangent movement with clamp, for the declination-arc, as shown at *k*.

4. A tangent movement with clamp to the latitude-arc, as shown at *f*

5. A tangent motion for the whole instrument about its sockets, as shown in the last drawing.

6. Great facility of adjustment, and, consequently an important saving of time. See *Compass*, *Dial-compass*, *Engineer's Transit*, *Plain Compass*, and *Pocket Solar Compass*.

SOLAR TELEGRAPH.—A telegraph in which the rays of the sun are projected from and upon mirrors. The duration of the rays makes the alphabet, after the system of Morse. It was proposed to apply it to the use of the French Army in Algeria, the posts to be established at twenty leagues from each other. See *Heliostat*.

SOLDAN.—The title of the Lieutenant Generals of the Caliphs, which they bore in their Provinces and Armies. These officers afterwards made themselves Sovereigns. Saladin, General of the forces of King Noureddin of Damascus, was the first that took upon him this title in Egypt, 1165, after having killed the Caliph Caym.

SOLDER.—An easily fusible alloy used for joining metals. Solders are of various kinds, suited to different metals. They always require to be used with a flux, such as borax, resin, chloride of zinc, sal-ammoniac, etc. The following are the principal solders: *Pewterers' solder*—bismuth, 2 parts; lead, 4 parts; tin, 3 parts. This can be used for coarse work by the direct application of naked fire; but for fine work, requiring the protection of a muffle-furnace, the composition must be bismuth and lead, of each 1 part; tin, 2 parts. *Plumbers' solder* for coarse work—tin, 1 part; lead, 3 parts. For finer work—tin, 2 parts; lead, 1 part. *Spelter solder*—12 parts zinc to 16 parts of copper. *Soft spelter solder*—equal parts of copper and zinc. When solders are applied in the common work of plumbers and tinmen, a tool called the soldering-iron is used; this is made red-hot, and affords a convenient means of applying fire direct to the solder and flux. Although called the soldering-iron, the portion of the tool to be heated must be of copper. In many manufactures, a flame produced by a mixture of atmospheric air and coal-gas is used to melt the solder; and for fine work, the common blow-pipe is often used.

SOLDIER.—One who enters into an obligation to some Chieftain or Government to devote for a specified period his whole energies, and even if necessary his life itself, to the furtherance of the policy of that Chief or Government. The consideration may be immediate pay, or prospective reward; or the contract may be merely an act of loyal devotion. The acknowledgement of the service by the employer constitutes the man a recognized soldier, and empowers him to take life in open warfare, without being liable to the penalties of an assassin and a robber. The fact of being mercenary, that is, of receiving wages for killing and being killed, does not render a soldier's trade less honorable. He bears arms that others may be enabled to do without them; he is precluded by the exigencies of military training from maintaining himself by peaceful occupation; and it is therefore but fair that those whom he protects should support him, and give him, over and above actual maintenance, reasonable wages for the continual risk of his life. If a man willingly enlist himself as a soldier in what he believes to be an unrighteous cause, it is an act of moral turpitude; but when once enlisted, the soldier ceases to be morally responsible for the justice or iniquity of the war he wages; that rests with his employer. Obedience, implicit and entire, is his sole virtue. The maxim is, "The military force never deliberates, but always obeys."

SOLDIER OF FORTUNE.—During the frequent wars which occurred in Italy, before the military profession became so generally prevalent in Europe, it was usual for men of enterprise and reputation to offer their services to the different States that were engaged. They were originally called condottieri, or leaders of reputation. They afterwards extended their sphere of action, and under the title of *Soldiers of Fortune*, sought for employment in every Country or State that would pay them.

SOLDIERS' DAUGHTERS' HOME.—An Institution founded March 8, 1855, at Hampstead, for the maintenance and education, on the principles of the Church of England, of the daughters of soldiers, whether orphans or not. Every girl receives a supply of uniform clothing on admission, and an outfit of the value of nearly £8, including a Bible and a Prayer-book, when placed in service. Nearly one thousand girls have been received into the Asylum since its foundation, of whom 6 have been trained as Schoolmistresses and Assistant Teachers, and 261 have been placed in service, and have generally done well; 138 rewards of £2 and £1 each have been distributed among the girls in service for 2 years' continuance in one place with certified good conduct. There are now in the Home, where accommodation can be found for 200 girls, 170 girls, of whom 21 are supported by kind friends and by regiments, the remainder exclusively by the income of the Home.

SOLDIERS' FRIEND.—A term in the military service which is generally applied to such officers as pay the strictest attention to their men; granting them reasonable indulgencies without injuring the service; seeing their wants relieved, and above all things, enforcing just dealings and prompt settlements.

SOLDIERS' HOMES.—The first Institution of this character established by the United States Government was founded by Act of Congress passed March 3, 1851—"to found a Military Asylum for the relief and support of invalid and disabled soldiers of the Army of the United States." The funds to conduct this Institution originated in tribute levied by General Scott on the City of Mexico, after its capture, for the benefit of the United States Army. The Act referred to above defined the beneficiaries thereof to be soldiers who had served 20 years; pensioners, after surrendering their pensions; and persons disabled by wounds or sickness incurred in the military service of their country. Besides the sum of money already named, the Act appropriated an unexpended balance of a previous appropriation to the same purpose, and placed the Institution in charge of a Board of Commissioners, to include the General of the Army and those General Officers commanding the Eastern and Western Military Divisions; and the Chiefs of the Medical, Pay, Commissary, and Quartermaster's Departments, and the Adjutant General of the Army. This portion of the Act was revised by the Act of March 3, 1859, reducing the number of Commissioners to include only the Adjutant General, Surgeon General, and Commissary General of Subsistence.

The following funds are, at present, set apart for the maintenance of the *Soldiers' Home*:—All stoppages or fines adjudged against soldiers by sentence of Courts-Martial, over and above any amount that may be due for the reimbursement of government or individuals; all forfeitures on account of desertion; all moneys belonging to the estate of deceased soldiers, which may be unclaimed for the period of three years subsequent to the death of said soldier or soldiers, to be repaid by the Commissioners of the Institution, upon the demand of the heirs or legal representatives of the deceased; also the sum of 12½ cents per month is stopped from every Non-commissioned Officer, musician, artificer, and private of the United States Army.

Applications for admission to the Soldiers' Home are made to the Adjutant General of the Army for reference to the Board of Commissioners. When a soldier, by reason of old age and long service, or of disability contracted in line of duty, becomes a candidate for admission to the Soldiers' Home, his Company Commander so reports, through proper military channels, to the Adjutant General of the Army, giving all details that may be needed for a full understanding of the case. This report is referred to the Board of Commissioners of the Home, and if, in their opinion, the soldier is entitled to become an inmate, the necessary authority is then given to order him to Washington for temporary admission to the Soldiers' Home. The Governor of the *Home*, in less than thirty days, reports the man's physical condition to the Adjutant General, with a view to his return to duty or discharge from the service. The descriptive list, *which should be sent by mail*, gives full particulars in regard to physical condition and the circumstances under which any disability may have been contracted.

It is expected that men already discharged from the Army, and entitled to admission to the Home, will bear their own expenses in reaching it. Urgent exceptional cases may be reported to the Adjutant General for decision of the Secretary of War. The transportation, by the Quartermaster's Department, of persons to the Soldiers' Home is forbidden, unless it is ordered by the Secretary of War on the application of the Board of Commissioners of the Soldiers' Home. Inmates of this Institution receive a small allowance of pocket-money per month, and they are also paid for any labor they can perform. About $8 per month is allowed to old soldiers, who, having families, are permitted to live elsewhere than at the Home.

Various temporary Asylums were erected or leased between 1851 and 1857. In 1851 a purchase of land was made for this purpose in the City of Washington, distant about 3½ miles from the Capitol; including, with later purchases, about 460 acres. This is, in fact, the only permanently established Soldiers' Home under the Act of 1851. It comprehends a farm, orchards, gardens, park, etc.; the building of white marble calculated to accommodate about 500 inmates at one time; and a chapel, well-stocked library, and hospital complete the excellent service of the Institution. The number of inmates of this Establishment up to the year 1878 was in the neighborhood of 2,000. Besides this one there were founded under the Acts of 1865 and 1873 Homes for the volunteer soldiers of the war of 1861–65 in Chelsea, near Augusta, Maine; Hampton, Virginia; Dayton, Ohio; and Milwaukee, Wisconsin. Appropriations are made annually by Congress for the support of these Institutions. Similar Institutions are the Chelsea Hospital, in England, Kilmainham Hospital, near Dublin, and similar establishments in Berlin. See *Royal Military Asylum* and *Hôtel des Invalides*.

SOLDIERS' THIGH.—When tight breeches were worn in the British Army, the term had its peculiar military application, from the notorious poverty of Army men. *Soldiers' thigh* figuratively means an empty purse; or, speaking familiarly, a pair of breeches that fit close and look smooth, because the pockets have nothing in them.

SOLDIERY.—Soldiers collectively. A body of soldiers. The military.

SOLDURIERS.—A term anciently used among the French, to signify those persons who attached themselves to some particular General or Military Knight, whose fortunes they followed, in consequence of being paid and supported by him.

SOLE.—1. A veterinary term. That portion of a horse's foot which, together with the bars and frog, comes in direct contact with the ground. 2. In fortification, the foot or bottom of the embrasure. This is frequently termed *solid*.

SOLERET A LA POULAINE.—The first recorded pointed soleret. It was used in the first half of the 14th century, and is so called *poulaine*, from the prow of a galley. See *Solerets*.

SOLERET ARC TIERS POINT.—The form of soleret worn from 1450 to 1485. See *Solerets*.

SOLERET BEC DE CANE.—This form of soleret was employed about 1560, and must not be confounded with those called *ogivale tiers point* of the fifteenth century. See *Solerets*.

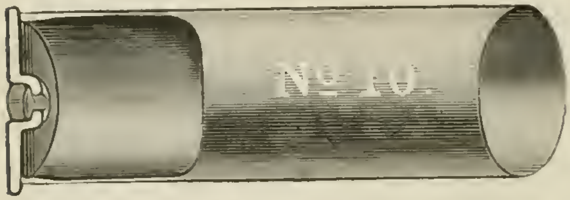
SOLERET DEMI-POULAINE.—The form of soleret worn in the latter part of the 14th century. Sometimes called *ogivale de lancette*. See *Solerets*.

SOLERET DEMI-SABOT.—The variety of soleret worn about 1480 and 1485. It forms part of the Maximilian fluted suit. The shape of this soleret indicates the end of the 15th, and slightly the beginning of the 16th century. See *Solerets*.

SOLERET PIED D'OURS.—A style of *soleret* shaped like a bear's paw, belonging to fluted armor and worn from 1490 to 1560. It was followed by the form *Bec de cane*. See *Solerets*.

SOLERETS.—Articulated plates or coverings for the feet in iron. They do not appear to date farther back than the first of the 14th century. The first known *soleret* is pointed (*soleret à la poulaine*). This shoe, towards the middle of the 14th century, made way for the *demi-poulaine* or *ogivale de lancette*, and reappeared toward the close of the century. In the 15th century, appeared the styles or shapes—*arc tiers point*, *demi-sabot*, *pied d'ours*, and *bec de cane*. This last soleret was replaced by the boot and top boot. Also written *Soulière*.

SOLID HEAD SHELL.—The construction of this shell, shown in section in the drawing, is extremely simple. The fulminate is in a cap, and is struck by a firing-pin when the hammer descends. Both the center and rim-fire cartridges require the firing-pin of the gun to be specially arranged, in order to strike the cartridge at the proper point, though cartridges have been devised in the United States to be both rim and center-fire, and guns have also been made to fire either or both kinds of cartridges. The idea of using sheet-metal for this purpose seems to have originated with the French. In 1826, Cazalat patented a shell of this kind, having a receptacle with a covering patch of water-proof paper for the fulminate at its base. A hole in the bottom of the cup admitted fire



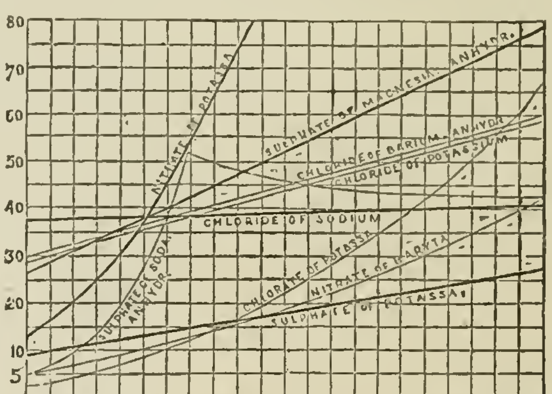
Solid Head No. 10—shot shell cut open.

to the charge. This appears to have been in advance of the age, being drawn from a single piece of copper, and being *center-fire*. See *Cannon-primers*, and *Center-fire Metallic-case Cartridge*.

SOLID SHOT.—Solid projectiles are used in guns and small-arms, and produce their effect by impact alone. When used in heavy guns they are known as *solid shot, round shot*, or *shot*. They are made of cast-iron, and on account of their very great strength and density, and the comparatively large charges of powder with which they are fired, are used when great range, accuracy and penetration are required. They are the only projectiles that can be used with any great effect against very strong stone walls, or floating batteries covered with wrought-iron plates. Solid shot for guns are classified according to their weight, which, in the United States' land service, is as follows, viz.; Field service, 6 and 12-pounders; siege service, 12, 18, and 24-pounders; sea-coast service, 32 and 42 pounders. Solid shot for columbiads are classified according to the diameter of the bore, as 8 and 10-inch solid shot. These projectiles are very often made of steel. The only *solid* shot used in the English service for rifled guns are the Paliser shot of the following calibers: 12½-inch, 12-inch, 10-inch, 9-inch, 8-inch, and 7-inch, and they are only intended to be used against iron-clad vessels. See *Bullet, Projectiles, Shot, Studded Projectiles*, and *Weight of Projectiles*.

SOLID SQUARE.—A square body of troops; a body in which the ranks and files are always equal.

SOLUTION.—A substance is said to undergo solution, or to become dissolved, whenever the force of adhesion between it and a liquid in which it is immersed is sufficient to overcome the force of cohesion between the solid particles. Thus sugar or salt is dissolved by water, camphor or resin by spirit of wine, and silver by mercury. The liquid which effects the solution is termed the *solvent*, or sometimes *menstruum;* and some solutions have special names, for example, the term *syrup* is applied to a solution of sugar in water; *tincture* to solution of a solid in alcohol. If a solid body be introduced in successive small portions into a definite quantity of a liquid capable of dissolving it, the first portions disappear the most rapidly, and each successive portion dissolves more slowly than its predecessor, until a point is reached at which the liquid ceases to possess any further solvent power. When this occurs the forces of cohesion and adhesion are balanced, and the liquid is said to be *saturated*. Solution is promoted by increasing the extent of surface in a solid, or by reducing it to powder. An elevation of temperature, by diminishing cohesion, will generally also increase the solvent power of the liquid; but there are exceptions to this rule—as for instance, in the case of lime and its salts, water just above the freezing-point dissolving nearly twice as much lime as it does when boiling. A compound of lime and sugar, very soluble in cold water, is separated from the solution almost completely if heated to boiling. But the most remarkable case of the kind occurs in sulphate of soda (Glauber's salt), which in its crystalline form dissolves in about ten times its weight of ice-cold water, and rapidly becomes more soluble as the temperature rises until it reaches 91°, from this point until the solution boils the solubility slightly decreases, the boiling liquid retaining, however, about four-fifths of the quantity which was dissolved at 91°. Carbonate and seleniate of soda, and sulphate of iron, exhibit the same peculiarity in a less marked degree. "These anomalous results may be partly explained," says Dr. Miller, "by the consideration that heat diminishes the force of adhesion as well as that of cohesion. Generally speaking, cohesion is the more rapidly diminished of the two, but not uniformly so, and in these cases it would appear that the adhesive force decreases in a greater ratio than the cohesion of the saline particles." The accompanying diagram shows the unequal solubility of various of the more common salts in water of different temperatures. The *lines of solubility* cut the verticals raised from points indicating the temperature upon the lower horizontal line, at heights proportional to the quantities of salt dissolved by 100 parts of water. For example, 100 parts of water dissolve—at 32°, 8 parts; at 122°, 17 parts; and at 212°, 26 parts of sulphate of potash. Water which has been saturated with one substance—that is, which refuses to dissolve any more of that substance, will very often continue to dissolve others. In true or simple solution the properties, both of the solid and the solvent, are retained. When, however, any chemical action ensues between the solid and the liquid, the resulting solution commonly presents perfectly new and distinct features; as, for example, when the metals are dissolved by acids, or oils by the alkalies (as in soap-making). The uses



of solution in laboratory processes are numerous. By the difference in degree of their solubility we can separate one substance from another; and by dissolving a body we can purify it, either by filtration or by crystallization. Moreover, when it is required that two bodies shall react on one another, they do so with incomparably more force in their dissolved than in their solid state.

SOMERSET.—A saddle for the wounded, padded before the knee and behind the thigh. The first saddle of this kind was made for Lord Fitzroy Somerset who had lost his leg below the knee at the battle of Waterloo, and from whom it took its name.

SORN.—Formerly a servile tenure in Scotland, by which a Chieftain might, with all his followers, live upon his tenants at free quarters.

SORTIES.—These, if well timed, will generally decide the fate of the affair. They should be made when the assaulting column is thrown into confusion, or shows any signs of irresolution in its movements;

or when its flank or its rear is carelessly exposed. They are sometimes made to alarm the enemy for his own safety; or to make a diversion in favor of expected succors in blockaded posts. Cavalry is the best arm for a sortie, on account of the rapidity of its movements, and the violence of its shock. When infantry is employed for this purpose, it should use the bayonet alone. Should the enemy succeed in forcing his way into the work, the reserve must attack with the bayonet, before he has time to form; but it must be confessed that success oftener crowns an offensive movement, on the part of the assailed, in endeavoring to regain possession of their works, than any effort to drive back the enemy at the moment, when flushed with success, he has the hope of a certain victory. The only well-grounded prospect that the assailed have of repelling the assault, when the enemy has gained the top of the scarp, is to meet him in an offensive attitude at the point of the bayonet on top of the parapet. The particular arrangements of the defense consist in defending all obstacles, such as abattis, palisadings, etc., by a warm well-aimed fire, as the particular object of all these obstacles is to keep the enemy exposed for a longer time to the fire. Large stones, heavy round logs, and the loaded hollow projectiles, should be in readiness to be rolled over on the enemy whilst he is in the ditch endeavoring to mount the scarp. Large branches of trees prepared as for an abattis, with chevaux-de-frise, and other obstacles, should be at hand to obstruct the breach. Finally, in an isolated post, if the enemy, after having been repulsed makes a show of blockading it, or of renewing his attack, and there is no prospect of succor arriving, the garrison should attempt an escape by night.

In siege operations, the policy of the besiegers is to expose as little as possible to the chances of hand-to-hand conflicts, but to endeavor to gain their ends by the action of their artillery, and by skill and perseverance, pushing forward their trenches until they reach the last position that the besieged can take up, still keeping under cover. The besieged, however, are often constrained to a bolder course; sometimes to open the way for succors to reach them; and sometimes to avail themselves of opportunities presented by the very great mistakes of the besiegers trying to drive them from their trenches, spike the guns of their batteries, and even destroy their depots. The parallels and their guards are to provide against such attacks; and, with proper measures and due vigilance, they ought never to succeed, but the besieged be made to pay dearly for each attempt. In past sieges, when the first parallel was usually opened at about 600 yards from the defenses, a sortie against it was regarded as a very uncertain operation, and only to be attempted when the garrison was strong and had a respectable force of cavalry and of light batteries to act with their infantry in the sortie. This contingency, however, should be guarded against by having the flanks of the first parallel secured by a redoubt armed with field-guns; with the epaulments for cavalry thrown up a few hundred yards to the rear of the flanks; and by a suitable reserve ready to move forward at a moment's notice to the support of the troops in the parallel. After the first parallel is completed and occupied by the guards, the besieged will seldom attempt a sortie in force before the ground is broken upon the position of the second parallel, and the besiegers should be prepared for this probability by having an extra force in and near the first parallel, to support the few guards who may be in the advanced boyaux for the protection of the workmen from the sorties of small bodies. So soon as a serious movement of the besieged beyond their defenses is observed, the working parties should be withdrawn in a prompt and orderly manner, taking with them all their trenching-tools, along the approaches, the guards in these covering their movement to rear, thus leaving the front of the first parallel unmasked to deliver its fire on the sortie. No effort is made to check the sortie except by the fire of the trenches until the troops composing it have reached the advanced trenches, when a charge may be made over the steps made for that purpose in the trench and parapet of the parallel, or through breaks left in the parallel itself of sufficient width for the passage of a column of infantry. From the completion and occupation of the second parallel, none but sorties of small bodies, seldom exceeding fifteen men are to be apprehended, with the object of temporarily stopping some approach.

SOUGH.—A small drain at the foot of an embankment, to convey the surface water from it into a side drain. Also, an *adit* or *day-level* for carrying off the water.

SOUND.—The impression produced on the ear by the vibrations of the elastic medium, such as air or water, in which it is plunged. That this is the case is proved, *first*, by the fact that a bell or tuning-fork *in vacuo* gives no sound when struck; *second*, by the fact that the mere currents, as such (winds, running water, etc.), do not produce the sensation of sound until they are frittered down into vibratory motions by obstacles. The general nature of the mechanical process by which sound is propagated in the air will be illustrated, and compared with the other cases of wave-motion, in our article on WAVES. Meanwhile, it is only necessary for us to observe that, as the velocity of sound is ten times greater than that of wind in the most violent hurricane, it is not the *air* itself which is transferred from place to place, but a *state of disturbance* (condensation or rarefaction) of the air.

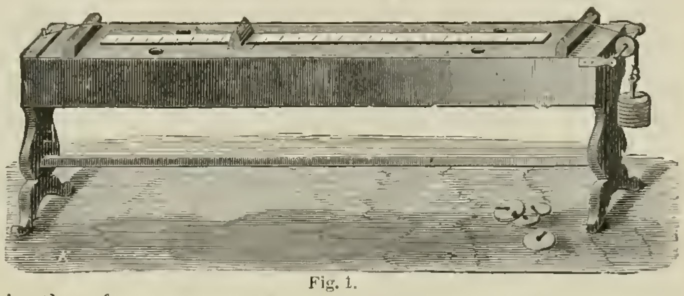


Fig. 1.

Each successive layer of air in the path of the sound suffers this disturbance in turn, and by virtue of its elasticity passes it on to the next. Newton was the first who attempted to deduce from mechanical principles the velocity of sound, but only for the particular case in which each particle of air in the path or the sound is supposed to move backward and forward according to the same law as the bob of a pendulum. He showed that this species of motion is consistent with the elastic properties of air, as given by Boyle's or Mariotte's law, viz., that the pressure of air is proportional to its density. The velocity of sound in this case is of course to be found from the time which elapses between the commencement of the motion of any one particle of air, and that of another at a given distance from it, in the direction in which the sound is moving. The numerical result deduced by Newton with the then received experimental data for the compressibility of air, was 979 ft. per second. This investigation was very defective, applying, in fact, solely to the special case of a pure musical note, continually propagated without lateral divergence; yet the solution obtained by Lagrange from a complete analysis of the question, gave precisely the same mathematical result. But, by direct measurements, carefully made, by observing at night the interval which elapses between the flash and the report of a cannon at a known distance, the velocity of sound has been found to be considerably greater—in fact, about 1,090 feet per second, at the temperature of freezing water. Newton seeks for the discrepancy between theory and observation in the idea that the size of the particles of air is finite compared with their mutual distance; and that sound is instantaneously propagated through the particles themselves. Thus, supposing the particles to have a diameter $\frac{1}{9}$th of the distance between them, we must add $\frac{1}{9}$th to the space traveled by sound in a second, *i.e.*, to the velocity—which will thus be brought up to $(1+\frac{1}{9})$ 979 feet.=1088 feet, nearly, which is a very close approximation to the actual value given above.

This is not one of Newton's happiest conjectures—for, independent of the fact that such an assumption would limit definitely the amount of the compression which air could undergo, and, besides, is quite inconsistent with the truth of Boyle's law for even moderate pressures, it would result from it that sound should travel slower in rarefied, and quicker in condensed air. Now, experiment shows that the velocity of sound is unaffected by the height of the barometer; and, indeed, it is easy to see that this ought to be the case. For in condensed air the pressures are increased proportionally to the increase of condensation, and the mass of a given bulk of air is increased in the same proportion. Hence, in a sound-wave in condensed air, the forces and the masses are increased proportionally, and thus the rate of motion is unaltered. But the temperature of the air *has* an effect on sound, since we know that the elastic force is increased by heat, even when the density is not diminished; and therefore the velocity of sound increases with the temperature at the rate of about $4\frac{1}{2}$ feet per Fahr. degree, as is found by experiment. Newton's explanation of the discrepancy between theory and experiment being thus set aside, various suggestions were made to account for it; some, among whom was Euler, imagining that the mathematical methods employed, being only approximate, involved a serious error. The explanation was finally given by Laplace, and is simple and satisfactory. When air is *suddenly* compressed (as it is by the passage of a sound wave), it is heated; when suddenly rarefied it is cooled, and this effect is large enough to introduce a serious modification into the mathematical investigations. The effect is in either case to *increase* the forces at work—for, when compressed, and consequently heated, the pressure is greater than that due to the mere compression—and, when rarefied, and consequently cooled, the pressure is diminished by more than the amount due to the mere rarefaction. When this source of error is removed, the mathematical investigation gives a result as nearly agreeing with that of observation as is consistent with the unavoidable errors of all experimental data. It is to be observed that, in noticing this investigation, nothing has been said as to the pitch or quality of the sound, for these have nothing to do with the velocity. It must, however, be remarked here that, in the mathematical investigation, the compressions and rarefactions are assumed to be very small; *i.e.*, the sound is supposed to be of moderate intensity. It does not follow, therefore, that very violent sounds have the same velocity as moderate ones, and many curious observations made during thunder-storms seem to show that such violent sounds are propagated with a greatly increased velocity. It is recorded that in one of Parry's Arctic voyages, during gun-practice, the officer's command "Fire" was heard at great distances across ice *after* the report of the gun.

Since sound consists in a wave-propagation, we should expect to find it exhibit all the ordinary phenomena of waves. Thus, for instance, it is *reflected* according to the same law as light. It is *refracted* in passing from one medium to another of different density or elasticity. This has been proved by concentrating in a focus the feeble sound of the ticking of a watch, and rendering it audible at a considerable distance, by means of a lens of collodion films filled with carbonic acid gas. Sounds *interfere* to reinforce each other, or to produce silence; just as the crest of one wave in water may be superposed on the crest of another, or may apparently destroy all motion by filling up its trough. The simplest mode of showing this is to hold near the ear a vibrating tuning-fork and turn it slowly round its axis. In some positions, the sounds from the two branches reinforce, in others they weaken, each other. But if, while the sound is almost inaudible an obstacle be interposed between the ear and one of the branches, the sound is heard distinctly. Beats form another excellent instance.

The most untutored ear distinguishes at once between a mere *noise* and a *musical note*. It of course distinguishes a *loud* sound from a faint one. Moreover, it distinguishes musical notes from one another by their shrillness or gravity, or, as it is technically called their *pitch*. Again, as in the case of vowel-sounds sung to the *same* musical note, or as in the case of different instruments (flute and violin for instance) playing the same note it distinguishes something further—which is called the *quality* of the note. It is on the pitch of notes that the theory of music is based, for the quality is only of importance in giving variety as in band music—or in giving richness of tone in a solo. The most perfect *music*, so far as theory goes, may be executed on the poorest instrument, but it gives little pleasure from the want of richness or quality. In the same way a singer may possess faultless intonation, yet the performance, though *musically* perfect, may, from the harsh quality of the voice,

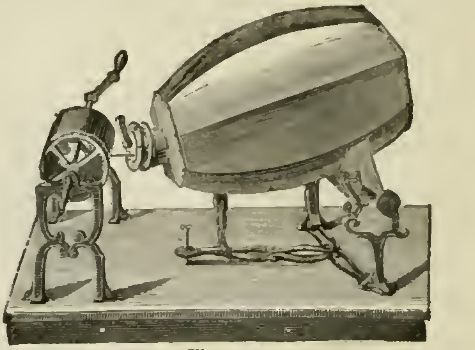

Fig. 2.

be unpleasant. Many interesting experiments may be made with the sonometer, a simple form of which is shown in Fig. 1. This instrument will serve to determine the number of vibrations made by a string emitting musical sound. It is provided with a series of weights, to vary the tension of the string. The scale is divided to correspond to the modified chromatic gamut, the true chromatic gamut, or the French meter divided to thousandths, at pleasure. By means of the phonautograph, represented in Fig. 2, phonetic sounds may be recorded automatically by diagrams in a manner analogous to that in which the indicator-diagram of a steam-engine records the pressure of the steam. The future of this instrument is undetermined. It would be possible to so connect the style with electrical devices that its excursions, both as to distance and continuity, might be exactly repeated at any distance by the telegraphic circuit; or the instrument might be made to operate a type-writer, and so the words spoken might become a record printed in ordinary letters on paper.

The various simple sounds which can be obtained from a string are called *harmonics* of the fundamental note; the latter being the sound given by the string when vibrating as a whole. For each vibration of the fundamental note, the harmonics have two, three, four, and etc. Of these, the first is the octave of the fundamental note; the second the twelfth, or the fifth of the octave; the third the double octave; and so on. Thus, if we have a string whose fundamental note is C, the series of simple sounds it is capable of yielding is:

C, C_1, G_1, C_2, E_2, G_2, (B $flat_2$) C_3 D_3 E_3, etc.

Of those written, all belong to the ordinary musical scale except the seventh, which is too flat to be used in music. This slight remark shows us at once how purely artificial is the theory of music, being founded not upon a physical, but on a sensuous basis. To produce any one of these harmonics with ease from a violin string, we have only to touch it lightly at $\frac{1}{2}$, $\frac{1}{3}$, $\frac{1}{4}$, etc., of its length from either end and bow as usual. This process is often employed by musicians, and gives a very curious and pleasing effect with the violoncello or the double-bass. The effect of the finger is to reduce to rest the point the string touched; and thus to make it a point of no vibration, or as it is technically called, a *node*. In the case of a piano-forte wire, a blow is given near one end, producing a displacement which runs back and forward along the wire in the time in which the wire would vibrate as a whole. The successive impacts of this wave on the ends of the wire (which are firmly screwed to the sounding-board), are the principal causes of the sound.

The theory of band instruments is quite as simple. Thus, in a flute, the sound is produced by a current of air passing across an orifice at the closed end. This produces a wave which runs along the tube, is reflected at the open end, runs back, and partially intercepts the stream of air for an instant, and so on. Thus the stream of air is intercepted at regular intervals of time, and we have the same result as in the sirène. In this case, there is but *one* node, viz., at the middle of the pipe. If we blow more sharply, we create two nodes, each distant from an end by $\frac{1}{4}$ of the length of the tube. The interruptions are now twice as frequent, and we have the first harmonic of the fundamental note. And so on, the series of harmonics being the same as for a string.

SOUTH BOSTON FOUNDRY.—The South Boston Foundry possesses the only works for heavy ordnance existing in this country, and can cast guns weighing ninety tons in the rough. The West Point Foundry makes the production of coiled wrought-iron tubes a specialty, and produces medium and light ordnance. Both make all varieties of guns and projectiles, but the South Boston Foundry has, also, with the Ames Company, of Chicopee, Mass., been since 1836 recognized contractors for bronze guns. The survival of the existing ordnance-works has been due not to chance but to their excellent work, and, failing proper support on the part of Congress, to their engaging in other lines of manufacture. The South Boston Iron Company, for instance, was the first maker of chill rolls in this country, Mr. Alger having patented the method in 1811; also improvements in plows and cylinder stoves for anthracite before 1840, later, fine statuary castings in iron; and heavy machinery was made from the first or since 1828. At all times many foundry specialties, such as gearing, pulleys, kettles, etc., have been made. About forty years ago almost all the machine-shops of Boston and vicinity drew their castings from "Alger's Foundry." Captain Thos. A. P. Catesby Jones writes in 1835 concerning the different foundries: "The Boston Foundry, owned by Mr. Alger, has not, I believe, cast *any* guns for the Navy, nor am I certain that he has for the Army; but for shot he had a considerable contract with the Ordnance Department in 1833, and his specimens were the best I have ever seen. And from the extensive plan, perfect machinery, and the experienced workmen connected with that work, I should place great confidence in the productions of that Foundry."

All the cannon and shot required for the gradual increase of the Navy were cast at the Columbian, Bellona, and the West Point Foundries. The quality of the castings of these three works does not materially differ, but the shot turned out by the West Point Foundry are greatly superior in all respects to those cast at the Bellona and Columbian Foundries. Lieutenant Wahlback states, in his Annual Report in 1847, that "the cannon furnished by the South Boston Iron Foundry have all been cast since the revised regulations of 1840, and are not, therefore, included in the foregoing. The few trials I have made of guns from this Foundry have afforded the most favorable results, and the quality of the metal is unsurpassed." About 1840 the character of "gun-iron" used for ordnance became definitely fixed, largely due to the efforts of Major Wade. Previous to that time, each foundry used its own iron in its own way, taking either hot or cold-blast, and of the grade the founder thought best. But it was found about that time that only cold-blast charcoal-iron carefully made, properly mixed, and refined in air furnaces, gave uniformly good and very reliable results. A knowledge of the mechanical properties of metals was first exactly obtained by Major Wade's testing-machine, which has gone all over the world as the American testing-machine. Originally called the "Metallo-Dynamometer," it was built by Mr. Alger about 1840 under the directions of Major Wade, and the original machine is still in daily use at the foundry, giving accurate results. The knowledge thus gained enabled the value of new guns to be fixed, from the character of their metal, without subjecting them to the damaging proof previously applied to each gun. Their reliability was shown by a few rounds of service charges, and American guns cast under the United States regulations since 1840 have had the highest reputation for strength and endurance.

The South Boston Iron Company began to cast heavy guns about 1839, and erected in 1842 what was then the heaviest shop in the country for ordnance. Previous to that time many light guns of bronze and cast-iron up to twenty-four-pounders had been made. Beginning at that period it had the advantage of all previous failures and avoided the hap-hazard methods of the earlier foundries. About 1836 Cyrus Alger patented and made the first guns of malleable iron, cast and converted in an oven, supplying fifteen of them during 1837 and 1838. The first gun rifled in America was rifled at the Foundry in 1834. About 1840 Mr. Alger invented the following improvements in fuses and in casting shell, all of which have been adopted and are still in use in the United States service and abroad, but for which he received no compensation whatever from the Government.

First.—The use of a fuse composition rammed in a paper case fitting into a wooden or metal plug inserted in the shell. *Second.*—A safety-plug of lead fitting like a cup in the bottom of the paper case, the top edges of the cup are thin enough to expand tightly against the paper, but be easily detached and the cup thrown into the shell cavity by the shock of discharge. The cup will thus ordinarily shut off the fuse from the powder, but opens the passage as soon as the fuse begins to burn. *Third.*—A safety-cap to ensure the ignition of the fuse under all circumstances combined with a leaden disc, and removed when loading, to prevent ignition out of the gun. *Fourth.*—Placing the holes for the escape of gas from the burning fuse in a metal plug and obliquely, and in such a position that the fuse is not extinguished by mud nor by ricochetting on water. *Fifth.*—The use of a metal bushing in connection with a hollow core-arbor to receive the fuse, "that is, a bushing, with a small hole to receive fuse, which is placed directly upon the core-arbor, and, is retained in place as a part of the shell by the metal cast around it."

These fuses were immediately adopted, as leaving nothing to improve for a time-fuse for smooth-bores of the heavier classes. They were used in the Mexican War, and ever since in the United States for all smooth-bore ammunition. The metal bushing has been extensively copied everywhere, and a chilled-cored shot could not be made without it. The earliest piece of what would now be called heavy ordnance, cast at the South Boston Foundry, was the ten-inch Columbiad. This gun marked, at the same time, a departure from old ideas and the introduction by Col. Bomford of horizontal shell fire of great power. It was cast 6th September, 1839, under Col. Bomford's superintendence, and was copied soon after by Gen. Paixhan, in France. Its dimensions were in extreme length, 111 inches; length of the bore, 90 inches; weight of the gun, 14,500 pounds; weight of the shot, 130 pounds; of the shell, 90 pounds; and of powder charge, eighteen pounds. In 1839 a Board of Ordnance Officers was sent to Europe to inspect European ordnance and ordnance-works. It purchased 6 and 12-pounder cast-iron guns, and 12 and 24-pounder iron howitzers from Swedish, French, and English foundries.

These guns were subjected to extreme proof at Fort Monroe, 1841-42, with the result that the Finspong guns proved themselves the best of all tried, including West Point guns of similar sizes. The proof of the Finspong 6-pounder was as follows, the gun bursting at the last fire. The charges had two wads in each:

Series.	Pounds powder in each round.	No. of balls in each round.	Rounds.
First.	2	1	20
Second.	3	2	20
Third.	3	3	10
Fourth.	6	7	2
Totals.	142	104	52

The Stäfsjo gun stood forty-nine rounds in similar series, the Aker, forty-seven rounds, the West Point thirty-nine rounds, and the Gospel Oak gun thirty-eight rounds, respectively. There were twenty rounds each in the first and second, and ten in the third series; the Finspong gun only reached the fourth series.

In March, 1844, the South Boston Foundry submitted a 6-pounder cast-iron gun, No. 7, of their own make, for extreme proof, which took place at City Point, South Boston. In strength and endurance it was found superior to the Finspong as above mentioned.

Rounds.	Powder charge, pounds.	Number of balls each round.	Number of balls.
16	2	1 to 16	136
4	2½	13 to 16	58
2	3	14 and 15	29
14	3	16 each.	224
2	6	7	14
38	102		461

The result of this and other proofs was so much to the credit of the South Boston Foundry, that it again cast for the Army, ordnance on 8th July, 1846, the first twelve-inch Columbiad of Colonel Bomford's design. This gun weighed, finished, 25,510 pounds; for the period it was truly a colossal gun and was the largest that could be made in the country at that date. The weight of its shell was 172 pounds, with twenty pounds of powder, and ten degrees of elevation; the shell ranged 2,770 yards, and its extreme range with maximum elevation was 5,761 yards, or three and one-half miles. The weight of the gun precluded it from sea service at that period. This twelve-inch seacoast gun remained the limit of size of our Army guns till 1860.

About 1844 Mr. Alger, taking advantage of Colonel Bomford's experiments on the pressure exerted by fired gunpowder at different points of the bore, then brought out a 32-pounder which was the first gun wholly plain in outline, and was the original of what is now known as the Dahlgren gun. This 32-pounder gun was known as Alger's 32-pounder, and after its proof and trials was carefully preserved and still exists at the South Boston Foundry. On comparing its outline with the Dahlgren it will be found to differ no more than is due to the powder pressure curves of the respective charges, and to the absence of the tulip muzzle. The trunnions were cast hollow so as to diminish the "shrink" due to their mass of metal.

In connection with this gun Mr. Alger submitted a "port-carriage" to the Navy Department, involving a friction-compressor binding the wooden chassis and the now universally adopted *eccentric axle* for the wheels of the carriage itself. By this arrangement the gun-carriage slides back upon firing—the whole weight of the gun, creating friction, and when raised off the chassis and on its wheels by turning the eccentric axles, rolls back easily into the firing position. Major Wade witnessed about 1843, "in Boston, the trial of several devices for checking the recoil of cannon by friction—by means of clamps, compressors, and eccentric axles—designed by Captain Van Brunt of the Navy, and by Mr. Cyrus Alger. The eccentric axle designed by Mr. Alger, caused the gun-carriage to *slide* in its recoil and to move on *rolling wheels* when returning to battery. This appeared to be the best of the methods then tried."

During the course of the improvements of our Navy guns by the late Admiral Dahlgren, the South Boston Foundry made many guns remarkable for their strength and endurance. Admiral Dahlgren said that Cyrus Alger "possessed that rare quality, sagacity, which constitutes in truth the highest attribute of the intellectual man, and enabled him to arrive at results which others sought by disciplined study and often in vain." The shell-guns of Dahlgren design were introduced largely into our Navy not long before the Civil War, and the safe limit of charge for the eleven-inch gun was not known till investigation was compelled by the failure of the "Monitor's eleven-inch guns, which were made at the South Boston Foundry to penetrate the armor of the Merrimac." It was perhaps not expected they would be brought against armor, or if the idea was broached it was answered by the statement that "the occasions on which shot could be advantageously used are so rare as hardly to warrant their being considered as part of the regular allowance." The South Boston nine and eleven-inch shell-guns exhibited endurance, which bore a comparison with the best forged Armstrong guns of 1862.

A cast-iron eleven-inch gun, if fired with thirty-one pounds of powder and ninety-three pounds of shot, would be doing more proportional work than the Armstrong wrought-iron gun which in April, 1862, pierced the Warrior target with a round 156-pound shot and fifty pounds of powder, afterwards bursting under that charge. It is proper to say here, we do not know but that between the two dates it had fired greater charges. But an eleven-inch of South Boston make (No. 1,262 S. B. F. 1862) was fired 155 times as follows: 22 rounds, twenty pounds of powder; 101 rounds, twenty-five pounds of powder; 32 rounds, thirty pounds of powder; shot from 165 to 169 pounds each. After this proof the gun exhibited no marks of a strain or of defects of any kind. Another eleven-inch gun was fired 170 rounds in two successive days without injury, although the gun became so heated that it was found warm eighteen hours after the last round.

The trial gun, for extreme proof, of a contract in 1857 (No. 1,098 S. B. F. 1857) a nine-inch Dahlgren shell-gun, 9,090 pounds in weight, endured the following proof before its destruction, a series of 1,532 rounds. [See table on next page.]

With twenty pounds of powder and 343½ pounds weight of shot, the gun recoiled nineteen feet; with twenty pounds powder and 469 pounds shot, the recoil was thirty-three feet; and with twenty pounds of powder and 636½ pounds of shot, the recoil was twenty feet up a steep slope, although the breech of the gun had been completely buried before firing. With ten shot the bore was nearly filled, the fronts of the last being seven and three-fourths inches from the muzzle. At bursting the gun was torn in two from cascabel to middle of chase, the part blown off, about two-fifths the circumference, being broken into five large fragments. The proof-firing was extremely rapid, 500 rounds being accomplished in four successive days. The enlargements due to firing were inconsiderable, the bore remaining in serviceable condition, and the endurance was reported on the 1,527th round as "really astonishing." Nothing could exceed the confidence these guns inspired in the War, and their efficiency on the new Ironsides is a matter of history. The Monitor was armed with eleven-inch guns fired with 169 pound shot and fifteen pounds powder. It was not known then that the charge could be increased to thirty pounds, as was afterward proved safe in case of necessity. This increase would give a shot of 169 pounds, an initial velocity of 1,400 feet, and a similar increase of charge of the nine-inch gun from ten to thirteen and one-half pounds of powder, would give an initial velocity of about 1,290 feet to its shot. The low velocity of her shot was consequently the reason why in all probability the Monitor failed to sink the Merrimac.

Rounds.	Powder charge.	Number of shot each round.	Tot'l wei'ht shot each round.
1	15 pds.	1 shot	91 pounds.
9	10 "	1 shell	72 "
1,500	10 "	1 "	72 "

1	20 "	8 "	724 "
1	20 "	9 "	812 "
1	20 "	10 "	903 " and burst.

In 1860 the fifteen-inch gun of 49,000 pounds was cast, and proved in 1861. Being demanded for both naval and sea-coast armament in great numbers, the South Boston Iron Company erected a new ordnance-foundry and machine-shop, and began in 1863 to apply the Rodman method to the production of fifteen-inch guns. This shop was designed to cast and finish the largest guns then thought practicable. During the War the service demands prevented any extended experiments on the strength of the gun. But after the War, and armored ships had to be met, it was found safe to fire 100 pounds of powder with the 450 shot instead of fifty pounds, the heaviest service charge during the War. The initial velocity was thus increased to 1,600 feet per second. It is a fact that a fifteen-inch Rodman gun made at South Boston Foundry has endured twenty-six rounds with 140 pounds of mammoth powder and 450 pounds shot without bursting.

Perhaps the best instance of the reliability of both guns and shot, made by American methods will be found in the history of the fifteen-inch Rodman gun of South Boston, model made by Cyrus Alger & Co., in 1867 for the British Government (S. B. F. No. 186). The report of the Ordnance Select Committee during its trial at Shoeburyness was understood to have stated "that it was doubtful if the Rodman gun can be burst with *any charge* of American powder, as it will not burn more than 100 pounds, which it has fired without injury."

The trial of the gun lasted a year from June 1867, during which it was tried against all the armor-shields in use. It was fired thirty-six times; fifteen rounds of these were with charges of 100 pounds mammoth powder or its equivalent (83¼ pounds R. L. G.) The velocities of the shot at impact were 1,174 to 1,500 feet per second, and it was shown that at 200 yards the gun could not penetrate eight-inch armor nor materially injure the nine-inch Hughes elastic shield. This conclusion caused the gun to be regarded as a formidable weapon, but not especially dangerous to the British men-of-war as the Admiralty had previously adopted heavier armor. If, however, the force of the shot failed to meet the expectations of American officers, yet their material—gun-iron—also that of the gun itself, exhibited its wonderful tenacity in the best light. A shot which struck the Gibraltar target with a velocity of 1,174 feet per second and making an indent four inches deep, rebounded twelve feet to the front nearly entire. The striking face was flattened and a few largish fragments splintered off. Many others exhibited similar behavior, the shot rebounding to the front, set up and disfigured. Their toughness induced the belief that they must in some way be made partially of wrought-iron. They were of course entirely of cast-iron, but cast-iron in its most perfect state, combining all the hardness possible for cast-iron. The essential characteristic of gun-iron is its elasticity, which it exhibits to a limit of 9,000 to 12,000 pounds per square inch, an amount somewhat less than that of ordinary bronze and nearly half that of average wrought-iron.

The South Boston Foundry has made, since 1836, a specialty of producing bronze guns, and turned out for the United States and Massachusetts probably the first sound ones made in this country. Bronze cast in sand is liable to many defects—porosity, and separation—often the gravest, and the Company is entitled to the credit of at least the application of cast-iron molds for guns, and it believes it made the first discovery of that improvement before 1855. In sand molds it made gun bronze, the average tenacity of which was 41,270, and density 8.64, which is considered now a first-class bronze. But after the adoption of chill-casting very high results were obtained. The average density of 24-pounder navy howitzers, between S. B. F. Nos. 1,417 and 1,693 of 1863–64, was 8.72, and the average tenacity 50,041 pounds per square inch. Nine guns included in the above series exhibited an average density of 8.80 and an average tenacity of 60,610 pounds to the square inch. These are believed to be the highest recorded qualities of bronze gun metal.

In 1869 Mr. S. B. Dean, while Engineer of the South Boston Iron Company, discovered that bronze guns could be greatly improved and rendered highly useful as rifles by rough-boring the gun, and then forcibly expanding the bore to its finished size by means of mandrels successively enlarging in diameter. This process he patented here, in France, and unwisely perhaps in Austria, where it has been pirated by the Austrian artillery under the name Uchatius System." All the field-guns and many siege-guns of the Austrian Army are now made of so-called "steel bronze," a very good name, considering the fact they should be the "Dean bronze" guns. The effect of the Dean method is to bring the exterior of the gun under tension while the interior is hardened and rendered capable of resisting the wear of the rifled projectile. The first condition renders the gun stronger, all portions helping each other against the explosion, and is the counterpart of the Rodman process where the exterior is put under tension by shrinking it, as it were, on the more quickly cooling interior of the gun. The hardening effect is great and highly valuable.

The following table of properties of similar cylinders, one of them cut from the chase of a three and one-half inch Dean rifle after the process of "condensing," clearly exhibits the improvement effected.

	Uncondensed.	Condensed.
Hardness,	1.40	5.12
Density,	8.35	8.70
Tenacity,	35,810 lbs.	51,571 lbs.

In 1863 Mr. Francis Alger, son of Cyrus, patented the use of a bag or pouch to hold the bursting-charge of a Shrapnel or a shell. He made the bag waterproof and attached it to the fuse. This method has been widely adopted, and in large shells is an essential safeguard against the explosion of the bursting-charge by the shock of the explosion, and consequent friction of the powder against the shell. Various improvements in fuses for rifled shell were experimented with and Mr. F. Alger patented in 1862 a combined time and percussion-fuse of merit.

During the Civil War the South Boston Iron Company furnished the Government with over 1,700 guns, including 700 bronze guns and howitzers, about 700 solid cast-guns of eleven-inch caliber and less, 332 Rodman guns of ten-inch caliber and over, and only 19 rifled-guns of all sizes. This record will show how largely the war was fought with smooth-bore guns. The Rodman guns were barely fifteen-inch guns for the Army, and to meet the demand a new ordnance-foundry and machine-shop put into operation in 1863, which is now the only works for Heavy Ordnance in the United States, and is capable of turning out large guns of about fifty tons in weight. During the War it made nothing heavier than fifteen-inch guns of 49,000 pounds. It might be expected that the foundry would have many interesting records of so busy a period, but its energies, as of the Ordnance Bureaus of the Army and Navy, were almost wholly devoted to producing guns of serviceable design. Even the usual proofs were dispensed with, so great was the need for ordnance, and after the trial gun of a class had fired 1,000 rounds in proof the rest of the class were accepted according to the tests of their material.

In respect to the projectiles, however, the Company did good work. The need of good rifle projectiles became decided when rifles began to be appreciated, as our artillerists became more experienced. Many experimental projectiles claimed attention and the Company decided on the Schenkle plan as affording the best solution of the difficulty. The projectile was cast with a conical base over which a papier mâché sabot fitted almost half the length of the shot. The explosion drove the sabot up, the cone thus compressing it between the shot and the gun, and causing it to take the grooves. In service eighty-two per cent. took the grooves most perfectly in the Parrott gun, for which they were not intended. Being light it fell off almost immediately in the flight without danger to the troops over whom it was fired. The shot was thoroughly rotated and was considered most reliable until it was found that the sabot, under influence of moisture, often swelled so much as to refuse to enter the gun. The South Boston Foundry furnished some 500,000 rounds of ammunition of all sizes to the Government, of which some 400,000 were Schenkle projectiles. Although the question of a perfect projectile remained unsolved, yet the Schenkle percussion-fuse furnished with the shot was one of the unqualified successes of the War. It was found absolutely certain in action, and combined extreme simplicity with perfect safety. It now remains the standard fuse of our Navy, and requires very slight modification to render it equal to all requirements. During actual service in the Civil War eighty-two per cent. proved perfect.—*Norton's American Inventions and Improvements in Breech-loading Small-arms, Heavy Ordnance, and Munitions of War.* See *Foundry*, and *West Point Foundry*.

SOVEREIGN.—The name applied in politics to the person or body of persons in whom the legislative power of a State is vested. In limited Monarchies, Sovereignty is in a qualified sense ascribed to the King, who, though the Supreme Magistrate, is not the sole legislator. A State in which the legislative authority is not trammeled by any Foreign Power is called a Sovereign State. The States of the German Empire were all designated *Mi-Souveraines*, because their sovereignty was qualified by their subordination to the Imperial Authority; and the same term may be applied to the States of the American Union.

SOW.—The main trough (or the body of metal contained therein) leading from the tap-hole of a cupola or smelting-furnace, and from which ramify the passages leading to the separate molds in casting; or to the shallow ditches in the floor which receive the *pigs* of cast-metal. 2. A kind of covered shed formerly used by besiegers in filling up and passing the ditch of a besieged place, sapping or mining the wall, and the like. It had its name from its being used for rooting up the earth like swine, or because the soldiers therein were like pigs under a sow.

SOWAR.—A trooper in an Indian cavalry regiment.

SPACE.—Room; the interval between troops when drawn up in line or column. In a battle, the amount of frontage which would be required for troops to act in. Most Generals make 1,000 yards as a fair calculation for every 6,000 or 8,000 men of all arms.

SPADE-BAYONET.—A very broad-bladed bayonet; it may be used in digging shelter-holes or rifle-pits. See *Bayonet*.

SPADROON.—A sword much lighter than a broadsword, and made both to cut and thrust.

SPAHIS.—The cavaliers furnished by the holders of military fiefs to the Turkish Army, and who formed the *Elite* of its cavalry. The Spahis, along with the Janissaries owe their organization firstly to Orchan, the second of the Ottoman Sultans, finally to Sultan Amurath I.; and when levied *en masse*, could number 140,000, but such a levy was seldom called for. In the field, they were divided into two classes, distinguished by the colors (red and yellow) of their standards; one class had pistols and carbine, the other a bow and arrows, and both carried a saber, lance, and *jerid*, or javelin. They were excellent irregular troops; but when European organization was introduced into the Turkish Army, they were replaced (1826) by regular horse. At the present time, the French have numerous regiments of Spahis, raised from among the native tribes of Algeria and from France in about equal proportions; the dress, especially of the indigenous soldiers, partakes very much of the Arab character. The natives are allowed to rise to any grade below that of Captain; but all the superior officers must be of French descent. See *Zouaves*.

SPANCELLED.—In Heraldry, the term applied to a horse, two of whose legs are strongly fettered by a log of wood.

SPANDAU FIRING-SCHOOL.—This School for the instruction of the Prussian soldier in the use of the musket was created in 1851, and it is to the influence exerted by the teaching given there that the remarkable skill shown by the Prussian infantry is specially due. It is established at Spandau, and is provided with large buildings, embracing shops, laboratories, magazines for ammunition, lecture and model-rooms, and sheltered grounds for drills and gymnastic exercises. The object of the School is to perfect, by the constant study and practice of those having it in charge, the arms and munitions in use in the Army; the thorough trial of all arms adopted in the service of foreign nations; the experimenting with new inventions; and finally, the instruction of teachers, intended to impart a thorough knowledge of fire-arms and their use to the whole Army. Its permanent organization consists of a Superintendent, 4 Captains, 8 Lieutenants, 1 Adjutant, 1 Paymaster, 1 Armorer, 4 Sergeant Majors, and 5 Sergeants. Four Lieutenants are added for temporary duty as Instructors, and are always selected from those who have passed through the course; they are changed every year. The detail sent annually to the School is divided into two classes: the first remains one year, and the second

only six months. The second class consists of 69 Lieutenants, 130 Non-commissioned Officers, and 244 soldiers, with the necessary number of buglers, drummers, orderlies, tailors, and shoemakers. The first class is composed of 1 Sergeant, candidate for Paymaster, 17 Non-commissioned Officers, 138 soldiers, and the necessary buglers, drummers, etc. They are engaged during the winter in making experiments, and in the current work of the School.

The course of practical instruction commences on the 1st of April, and embraces the following subjects: 1*st Course.*—Preparatory drill. Aiming from a rest. Aiming from the shoulder. Firing. Estimating distances. Description of the musket and targets. The Officers and Non-commissioned Officers are also instructed in the fabrication of arms and in making ammunition, etc. 2*d Course.*—This is devoted entirely to firing under the different circumstances of actual service. 3*d Course.*—This is only for Officers and Non-commissioned Officers, and serves to develop the knowledge already gained. The Officers are occupied, in addition to their other duties, in assisting in teaching the theoretical course, the history of fire-arms, their manufacture, the fabrication of cartridges, and finally in considering the different arms adopted in foreign armies. The Non-commissioned Officers and soldiers are occupied with gymnastic exercises, bayonet-fencing, and from time to time with the manual of the musket. The target-ranges, 13 in number, are on a tract of ground covered with a young growth of pines, through which avenues are cut, varying in length from 80 to 1,600 meters, and terminating in a rise of ground, which serves as a butt to stop the balls. Wires for telegraphic communication connect targets and firing-stands with the Officers and principal workshops. The targets are made of wooden frames covered with a thick card-paper; they are both fixed and movable, and have the most varied forms, representing detached men, some standing or kneeling, others half concealed, a company of infantry or cavalry, a battery of artillery, or even a battalion of troops.

The soldier is taught to fire not only at movable targets, but also at such as appear unexpectedly at some point of the field. For this purpose the target is mounted on a car which travels on rails laid across the range, and is drawn at variable speeds by men stationed on either side, behind traverses, pulling on a rope attached to the car. The troops, acting as skirmishers, debouch suddenly from the woods, and fire at the different targets, at unknown distances, some stationary, others movable. Thus the soldier is accustomed to estimate distances, to do it promptly, and to judge of the rate of motion of movable objects, and the allowance to be made in aiming at such. Besides, this kind of practice has the effect to teach the soldier to preserve his composure when an enemy, whatever it may be, appears unexpectedly before him. The Officers, by such exercises, have the opportunity of learning what is required of them, and studying the art of directing troops upon the field. While at the School, the men receive extra pay of one thaler per month, and as a distinction wear on the cuff of the coat a button bearing a special device. Those who prove themselves to be good marksmen wear, as a badge of their skill, two white stripes on the coat-collar. Those who have passed through the course of instruction given at the School return to their several regiments to act as Instructors of Musketry to the regiment. Each soldier is allowed to fire 100 cartridges annually, and encouragement to become expert marksmen is given by the State granting large sums for premiums for the best shots.

SPANISH RIFLING.—The Spaniards have modified the French system by adopting a uniform twist, and placing the studs upon the projectile in pairs. Three grooves are used; the cast-iron guns are reinforced with hoops having definite initial tension.

SPANISH SYSTEM OF FORTIFICATION.—The construction of the Spanish system was nearly the same as the Italian system—but the lines of defense were directed on the curtain angle. See *Italian System of Fortification.*

SPANISH TUTANIA.—An alloy composed of 24 parts of tin, 2 of antimony, and 1 of steel.

SPANNER.—A screw-wrench, used for the purpose of tightening nuts upon screws.

The spanner used in the field is "McMahon's 15." It has a fixed and a movable claw for use as a wrench. The movable claw can be set at any distance from the fixed claw by means of a thumb-screw.

SPAR BRIDGE.—A light bridge for crossing broken arches, rivers with steep banks etc., in which it is not practicable or convenient to obtain supports for the bridge from the bottom or on the surface of the river. Works on military bridging give the following as the best known for spanning all intervals with timber:—

Single-lever bridge.—Composed of two frames locking into each other, and not meeting at a greater angle than 120°. This nature of bridge is not suitable for a greater span than 30 feet.

Double-lever bridge.—Suitable for spans of 40 feet; it consists of two frames locking into a connecting frame or two or more longitudinal pieces, with cross transoms. The opening is thus divided into three spaces, and the span of the road bearers is about 14 feet.

Single-truss bridge.—This can be used for spans up to 50 feet; it consists of two frames locking into each other in the same manner as the single-lever bridge, and provides three points of support, viz., one on each frame, and a third suspended by the ropes from the head of the frames.

Lever-truss bridge.—Suitable for spans of about 50 ft.; it is a combination of the single and truss bridges.

SPARE GUN-CARRIAGE.—This is merely an ordinary gun-carriage, fitted up so as to carry four axletrees, the iron-work for a spare gun-carriage, a pair of shafts, two sponges, one wadhook, and other spare articles for the battery.

SPARTHE.—An Anglo-Saxon term for a halbert or battle-axe.

SPARUM.—A kind of dart, which was used by the ancients in war, which was shot from a cross-bow. The wound it occasioned was extremely dangerous, as its point was triangular. Several of these darts were discharged in a volley.

SPATHA.—A long sword, with but one edge and a sharp point, used by the Romans. It was borrowed by the early Romans from some barbarous tribes, and then introduced among others. Its presence does not prevent the simultaneous appearance of the various short swords.

SPATTERDASHES.—A kind of covering for the legs of soldiers, made of cloth, or of a coarse linen waxed over, and buttoned tight, by which means the wet was kept off.

SPATTS.—A variety of spatterdashes that reached only a little above the ankle.

SPAVIN.—A disease of horses, which occurs under two different forms, both interfering with soundness. In young, weakly, overworked subjects, the hock-joint is sometimes distended with a dark-colored thickened synovia or joint-oil. This is bog or blood spavin. Wet bandages, occasional friction, a laxative diet, and rest should for several weeks be diligently tried; and if such remedies prove unsuccessful, the swelling must be dressed with a strong blistering ointment, or be fired. The second variety of spavin is the more common and serious. Toward the inside of the hock, at the head of the shank-bone, or between some of the small bones of the hock, a bony enlargement may be seen and felt. This is bone-spavin. At first there is tenderness, heat, swelling, and considerable lameness; but as the inflammation in the bone and its investing membrane abates, the lameness is less perceptible, although the animal continues to drag his leg and go stiffly. In recent and slight cases, cold water should be applied continuously;

but in serious cases, when the limb is swollen and tender, hot fomentations are best. For several days they must be perseveringly employed. When the limb is again cool and free from pain, an iodide of mercury or fly-blister should be applied, and the animal treated to three months' rest in a small paddock, the end of a barn, or a roomy loose-box. In persistent cases, firing or setoning usually gives much relief.

SPAYADE.—In Heraldry, a stag in his third year; a spay.

SPEAKING-TRUMPET.—An instrument which, on being applied to the mouth, carries sound to a considerable distance. It was formerly used in all large armies; and at the siege of Gibraltar, General Elliott (afterwards Lord Heathfield) caused all the words of command to be given through a speaking-trumpet.

SPEAR.—A weapon having a wooden shaft mounted with a very sharp steel point. It has been known and used from time immemorial, first as a hand or missile-weapon, and subsequently as a pike or lance. In the early Norman period, A. D. 1066-1087, the spear was a well-known military arm. It was sometimes ornamental, like the lance of the present day, with a small flag fixed just below the metal point, and termed, in the language of that day, the *gonfanon* or *gonfalon*. See *Javelin*, *Lance*, and *Pike*.

SPECIAL DUTY.—Soldiers may be employed on duties not strictly military, when the exigencies of the service require it, for the reason that they are incident to the operation of an army; as, mechanics, laborers, cooks, and attendants in hospitals, clerks, scouts, etc. Soldiers, when detailed on these duties are generally reported on special or extra duty, but are required to attend the regular inspections and musters, and if not proficient in drill, should be required to attend drills until they know their duties as soldiers. Officers, when placed on duty which temporarily relieves them from duty with their companies, as Acting Commissaries and Quartermasters, or on Court-Martial duty, etc., are reported as being on *special duty*.

SPECIAL ORDERS.—Such orders as do not concern the troops generally; such as relate to the march of some particular corps, the establishment of some temporary post, the detaching of any individuals, the granting requests, and generally such matters as need not be published to the whole command. See *General Orders* and *Orders*.

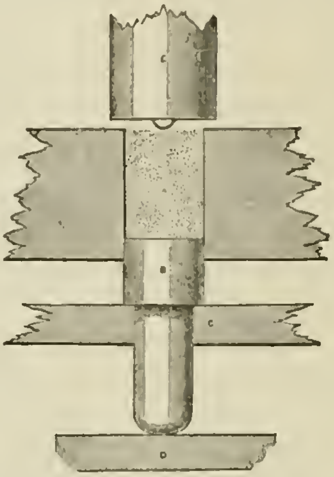
SPECIAL POWDERS.—For some years, it has been a recognized fact, that the ignition, combustion, and explosive effect of gunpowder depend, in a great degree, on the size, shape, and the density of the grain, and that guns of different calibers require for their most efficient service all powders differing in these features, in order to secure the best results. The rapid increase in weight of projectiles with the increase in caliber of guns, and the comparatively smaller power of resistance of the guns, render it necessary that the rate of combustion of the charge be regulated, so as to reduce the strains on the guns as much as possible, while at the same time preserving high initial velocity to the projectile, thus rendering practicable the use of the heaviest guns, projectiles, and charges.

The amount of gas evolved at the first instant of inflammation and combustion is measurably controlled by the size and form of grains, offering a lesser surface of ignition, and the increased density, offering greater resistance to the penetration of the hot gases through the grains, graduates its rapidity of burning. The from of grain affecting the amount of surface exposed to combustion—that shape which offers a comparatively small surface at the first instant of ignition, increasing progressively, is theoretically the best.

Experiments by all civilized nations have settled beyond cavil the important part played by powders suited in the above qualities to the guns in which they are to be used, and have led to the adoption of large-grain powders in heavy guns, resulting in the production, among the best, of mammoth, pebble, cubical, hexagonal, and perforated prismatic powder; the honor of the first investigation and practical results in this direction, being universally awarded to the late General Rodman, United States Army.

Special powders are readily made by machinery, and the fundamental parts of every such machine are: (1) a mold in which to place the powder-meal; (2) a punch accurately fitting the mold, with which to compress the powder; and (3) some appliance for pressing the finished pellets out of the molds.

A safe arrangement for combining these three is shown in the drawing. A, is a small charge of powder



placed in the mold; B, a punch which fits it accurately. This punch has a shoulder on which it rests quite loose on a second plate, C, underneath the mold-plate. The lower end of this punch rests on the upper surface of the hydraulic ram, D. An upper descending punch, E, of larger diameter than the mold, can be brought down to the surface of the mold-plate either by a screw or by a hydraulic pressure so as to close the mold.

With such an arrangement a pellet can be very safely made; firstly, by bringing the top punch down on the plate, and fixing it there so as to confine the powder; secondly, by raising the lower punch, by means of the ram, till a proper amount of compression has been given to the powder; thirdly, by stopping the pressure from beneath, raising the upper punch; and, fourthly, by raising the finished pellet out of the mold by the pressure of the ram underneath. It is plain that any form can be given to the pellets by altering the shape of the molds and punches, and that hollows or perforations can be made in the pellet if required. There is no difference really in any of these powders, except in the shape.

Nearly all the great Powers of Europe have powder-mills under the immediate supervision of their own officers and agents; and the quality of powder made at them is held deservedly in high estimation. While these mills are insufficient for supplying all the wants of the respective Governments, the great care in selection and manipulation of the best materials, and close attention to every detail of manufacture, serve to maintain a high standard of quality of powder, and regulate the price and excellence of that amount obtained from private manufacturers. The United States would profit by following so excellent an example, by establishing a powder-mill, under official directon, of a limited capacity. The Royal Gunpowder Factory of England is located at Waltham Abbey; those of Russia are the Ohktenskoi; the Michael-Schosta (saltpeter district), the Kazan (at which most powders for the military and naval service are made). Germany obtains her powders, in part, from the Government factories at Spandau and Neisse; the standard quality of that procured from private factories being regulated by the former. France now has five gunpowder-works—Ripault, Bouchet, Saint Chamas, Angoulême, and Esquerdes. Belgium has a large powder-mill at Wetteren and produces large gunpowders of most excellent quality. See *Compensating Powder, Hexagonal Powder, Pebble Powder, Prismatic Powder*, and *Progressive Powder*.

SPECIFICATION.—In preferring charges great care should be used to specify the date and locality of the alleged offense. When doubt exists, it may be alleged that the act specified was committed "at or near" a certain place, and "on or about" a certain date. Before charges are forwarded to Department Headquarters for trial by any General Court, Post Commandants should investigate the character and force of all the testimony on which they are based, and be reasonably assured that the alleged facts can be fully established; and also, *that the offenses charged are of so grave a nature that a Garrison Court cannot adjudge a sufficient penalty*. Charges should be laid under the specific Articles of War pertaining to the offense.

Charges cannot be legally preferred under the 62d Article of War when the offense committed is in violation of any other Article. In an absence from any appointed parade, drill or other exercise, but not from the limits of the post, the specification should usually be charged under the 33d Article of War —but otherwise under the 32d, and sometimes under both. Soldiers found drunk on any guard, party, or other duty, after having been actually placed on such duty, and in the ranks, and not until then discovered to be drunk, should be charged with violation of the 38th Article of War—but otherwise under the 62d Article, as when unable to turn out for or attend guard-mounting.

Charges laid under Articles of War which prescribe possible capital punishment, such as the 21st or 39th Articles, are not properly cognizable by a Garrison or Regimental Court, nor should *degrading crimes*—like theft, to the prejudice of good order, etc.—be tried before such tribunals, because they cannot sentence to dishonorable discharge. Persons convicted of any criminal offense cannot be enlisted into the Army, and this policy of the law suggests the propriety of dishonorably discharging all convicted of degrading crimes of a felonius nature.

The non-performance of any stated duty enjoined in regulations or standing orders is *not*, in itself, a "disobedience of orders in violation of the 21st Article of War". Such a charge should be laid under the 62d Article, and would, if but a slight neglect of duty, be cognizable before a Garrison Court. To support the charge of "disobedience of orders under the 21st Article," and thus make it solely cognizable by a General Court-Martial, there must be shown, in the performance of such stated duty, such an intentional disregard of authority as is evinced by a willful refusal or omission to comply with the specific command of a Superior Officer.

In time of peace, under the 47th Article of War, the crime of "desertion" is *not* a capital one. If a charge against an enlisted man for this offense is to be referred to a Court for trial more than two years after date of his unlawful abandonment of the military service, the fact that he was not amenable to justice within that period should, under present rulings, be made to appear affirmatively in evidence, so that the proceedings, findings, and sentence may not be liable to be set aside. The better practice would, therefore, seem to be to insert in the specification, after allegation of apprehension or surrender, the further allegation, required by the 103d Article of War, as to the manifest impediment which prevented the prisoner from being amenable to justice within two years of the commission of the offense.

In preparing several specifications under a charge, the date and place of the alleged offense should be written in each, and not merely in the final specification, of which the prisoner may be acquitted.

SPECIFIC GRAVITY.—The specific gravity of any substance is the proportion which the weight of a certain bulk of that body bears to the same bulk of another body, which is taken as a standard. The standard for substances solid and liquid is distilled water at the temperature of 62° Fah., barometer 30 inches; and the weight of a cubic inch of this standard is given in the Parliamentary Reports for 1825 as 252.456 troy grains, hence a cubic foot of it weighs 997.129 avoirdupois ounces, or 62.32 avoirdupois pounds. It is convenient to remember that a cubic foot of water weighs about 1,000 ounces avoirdupois, as the error resulting from employing this estimate does not amount to much more than the $\frac{1}{350}$th of the whole. For aëriform bodies, the standard is atmospheric air, a cubic inch of which, at a temperature of 32° Fah., weighs .32698, and at 60° Fah., .30935 grains troy. The specific gravity of solid bodies is best measured by the hydrostatic balance, which gives the weight of a volume of water equal in bulk to the solid, by which it is only necessary to divide the weight of the solid in air to obtain the specific gravity; that of liquids may be obtained by the areometer, or by comparing the weight lost by a solid body in the liquid and in water, and dividing the former by the latter—or by means of the *specific-gravity bottle*, which holds exactly 1,000 grains of distilled water in its standard condition. The bottle is emptied of water, filled with the liquid, and is then weighed; the result gives the weight of a volume of the fluid equal in bulk to 1,000 grains of the standard, and hence this weight divided by 1,000 gives the specific gravity. The specific gravity of an aëriform fluid is determined by weighing a glass globe filled first with the fluid, and then with atmospheric air. Following is a table of the specific gravities of the substances most frequently dealt with in the arsenal and laboratory:

SOLIDS (METALS).

	Sp. Gr.		Sp. Gr.
Iridium (ham'ered)	23·	Iron	7·78
Platinum	20·15	Tin	7·29
Mercury	14·	Zinc	7·19
Lead	11·35	Antimony	6·70
Silver	10·74	Arsenic	5·76
Bismuth	9·82	Aluminium	2·67
Cobalt	7·81	Calcium	1·58
Copper	8·78	Sodium	·97
Manganese	8·01	Potassium	·86

LIQUIDS.

	Sp. Gr.		Sp. Gr.
Sulphuric Acid	1·84	Champagne Wine	1·
Nitric Acid	1·5	Burgundy Wine	·99
Aqua Regia	1·23	Whiskey, average	·92
Oil of Cinnamon	1·04	Oil of Turpentine	·87
Oil of Cloves	1·03	Brandy	·84
Milk	1·03	Alcohol, pure	·80
Tar	1.01	Ether, Sulphuric	·72

GASES.

	Sp. Gr.		Sp. Gr.
Hydriodic Acid	4·34	Oxygen	1·11
Chlorine	2·44	Olefiant Gas	·98
Sulphurous Acid	2·22	Nitrogen	·97
Cyanogen	1·80	Prussic Acid	·94
Carbonic Acid	1·52	Ammonia	·59
Muriatic Acid	1·28	Hydrogen	·07

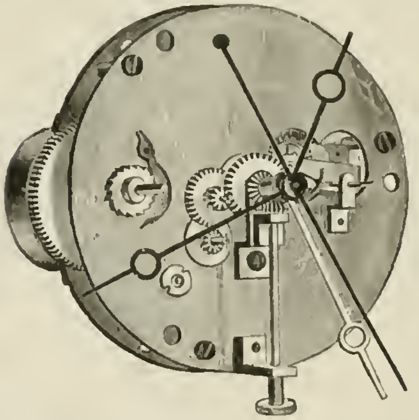
See *Areometer*, and *Hydrometer*.

SPECKLE SYSTEM OF FORTIFICATION.—In this system, the bastions are large, with orillons and cavaliers, the flanks are triple, and parts of the middle and upper ones are perpendicular to the lines of defense. There are cavaliers on the curtains. The covered-way is *en cremaillère*, and flanked by places of arms. Beyond the glacis there is an advanced ditch. The walls have counter-forts 5 yards apart, connected at the top by arches, which bear the parapet and render breaching difficult. It is the modern revetment "en décharge." When this method is reinforced, the flanks are perpendicular to the lines of defense, and the ravelin is made very salient.

SPECTROSCOPE.—The instrument by the aid of which spectral phenomena may be most conveniently studied. It consists essentially of, first, an illuminated slit, from which parallel rays of light proceed; secondly, a prism or train of prisms, to separate the differently refrangible rays; and thirdly, a telescope, to view a magnified image of the spectrum produced.

SPECULUM METAL.—An alloy of copper and tin, used for making the reflecting surfaces of reflecting telescopes. The best consists of 126.4 parts copper to 58.9 tin. To obtain a perfect alloy, and to cast it successfully, is a matter of great difficulty, requiring much skill and experience. See *Telescope*.

SPEED INDICATOR.—A device for indicating the number of revolutions made by a shaft in a given time. The instrument mostly used in the United States is shown (inside view) in the drawing, and is made by the American Steam-gauge Company, Boston. It consists of a nicely made eight-day Howard clock movement, fully jewelled, and placed in one of the eight and a half inch dial nickel-plated steam-gauge cases. Upon the face of the clock are shown four hands, all moving from the center; viz., hour, minute, second, and fourth the *speed* hand, which is made of a different color to distinguish it from the others. The *speed* hand is wholly independent of the clock proper, being driven by a bevel-gear connected with a shaft leading to the outside of the case. On the shaft is placed a ratchet-wheel with a number of teeth in it to correspond with the number of revolu-



tions the engine makes per minute; for instance, if the engine makes fifty-seven revolutions per minute, there must be fifty-seven teeth in the ratchet-wheel; or, whatever number of revolutions the engine makes per minute, there must be a corresponding number of teeth in the ratchet-wheel. By this it will be seen that when the engine has made fifty-seven revolutions, and there are fifty-seven teeth in the ratchet-wheel, it will have caused the speed hand to make one revolution around the dial of the clock, and the second-hand will also have made one revolution around the dial of clock. The second hand that is used is quite long, extending from center of dial to the outside circle of same. If the engine makes more revolutions per minute than it ought to, it will be detected by an increase in the movement of the speed hand; or, if the engine makes less revolutions per minute than it should, it will be detected by a decrease in the movement of the speed hand. When the engine stops, of course the speed hand will stop, but the clock will continue to move at its regular rate. After the engine is started and attained its usual speed, if the speed and second hands are at some distance apart, place the thumb and the forefinger upon the knurled wheel on shaft connecting the ratchet and bevel-gear, and move it forward until the speed and the second hands are brought together. In connecting the speed-indicator with the engine, it is only necessary to take the motion from some part of the engine most convenient, in the same manner that a revolution-counter is connected; and if a revolution-counter be used, the motion can be taken from it, which is the most convenient.

SPENCER LEE MAGAZINE GUN.—In this arm, the breech-block is supported against the pressure of the gas, when the piece is fired, by a recoil-block, solid with the guard, which has a circular recess concentric with the rear of the breech-block. The latter is slipped in the recess sideways and has, when assembled, a motion of rotation in a vertical plane. The recoil-block is in turn supported by the rear of the receiver. The trigger and the hammer are pivoted in the guard-plate, the nose of the former or the sear being held in position in the notch of the latter by the sear-spring. The main-spring is connected with the hammer and the under rear of the breech-block by swivels. When the trigger is pulled the head of the firing-pin is struck by the upper end of the hammer. The breech-block is operated by a cam-pin, with friction roller on the inside of the rear end on the left of two sliding bars, connected by the hand-grasp. The cam-pin travels in the groove on the left side of the breech-block, which also has a frog or switch, pivoted near its rear. When the cam-pin enters the groove, as it does when the forked side is forced to the rear, it rolls over the incline of the frog. The pin cannot rise, since the bars of the slide travel in grooves on the inside of the receiver. Hence the frog must be pressed downward, and its point in turn, pressing on the bottom of the groove in the block, compels the latter to descend. When the pin passes out of the groove to the rear, the front of the breech-block would rise above the receiver under the pressure of the mainspring, if not held down by the extractor, as explained later on. When the slide is returned to its first position, the cam-pin travels on the lower side of the groove, the frog turning freely about its pivot, and the front of the block is forced to descend to the level of the chamber. The piece is cocked in the act of opening the breech-block by the cam-pin coming in contact with the hammer and pressing it back until the nose of the sear enters the notch. At the front of the breech-block is a movable face or head, which is forced against the base of the cartridge during the closing of the breech. On the opening of the latter the head drops away, and thus facilitates extraction of the shells.

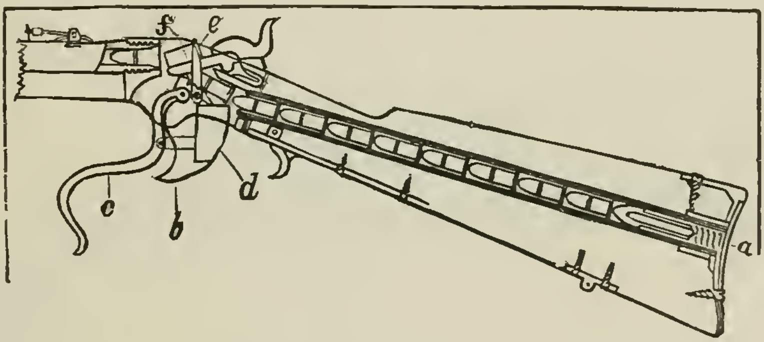
A device for locking the hammer until the breech-block is closed is interposed between the head of the hammer and a shoulder on the shaft. Closing the breech-block rotates the shaft and withdraws the shoulder from the front of the locking-bar. The latter is free to move to the front to the extent permitted by the recess in which the tenon on the bar enters, and the hammer can fall if the trigger be pulled.

The magazine is that known as the Lee, with very slight modification. It is attached to the under side of the breech-block, and rises and falls within. The breech-block is recessed on its under side sufficiently to receive a single cartridge. When this cartridge is drawn forward into the chamber another from the magazine takes its right place in the block. It will be seen then that the complete backward motion on the slide causes the block to descend, the shell to be pushed out on its upper surface, and then the block to fly up and eject the empty shell; the forward motion then carries a cartridge from the magazine into the chamber and causes the block to descend to its proper position in rear of it. A cut-off may be so turned as to limit the backward motion of the side, thus preventing the extractor passing beyond the shoulder. The block then cannot rise and bring the cartridges from the magazine opposite the chamber. The piece may then consequently be used as a single-loader. When the cut-off is turned vertically downward, the piece may be used as a magazine-gun. If turned upward to its farthest extent, a small pin, on its under side, will enter a notch in the slide and lock it, and therefore the breech-block. Three motions are necessary to operate this piece as a magazine-gun, viz., the movement of the slide to the rear, to the front, and the pulling of the trigger. In addition, when used as a single-loader, loading. See *Magazine-gun*, and *Spencer-Roper Small-arms*.

SPENCER LINE-THROWING GUN.—The Spencer line-throwing gun is a smooth-bore, and consists of the body, the trunnion-ring and the breech-plug or fermeture. The body is made of low steel, forged solid, and afterward bored out. The exterior of the body is divided into three principal parts viz., the first reinforce, the second reinforce, and the chase. The *first reinforce* is a frustum of a cone with the larger base turned toward the muzzle of the gun. The *second reinforce* is a short frustum, generated by revolving about the axis a convexo-concave line whose middle point touches continually a circle having its center on, and its plane perpendicular to, the axis. This reinforce conjoins the first reinforce and the chase. The *chase* is a frustum of a cone, terminated in front by the face of the piece without swell of the muzzle or a muzzle-band. The *trunnion-ring* is a cylindrical ring of wrought-iron, which embraces the first reinforce near its rear end. This ring bears the trunnions, which are forged solid with the ring, and then turned down and properly aligned. The *breech-plug* is made of low steel. It is divided into two symmetrical parts by a meridian plane, which is horizontal when the fermeture is in position for firing. One of the halves has four dowel pins, two on each side, that fit into corresponding holes in the other half. These dowels or pins serve to preserve the relative positions of the parts when put together. The front end of the breech-plug, as a whole, is recessed to form the small hemispherical chamber that terminates the bore.

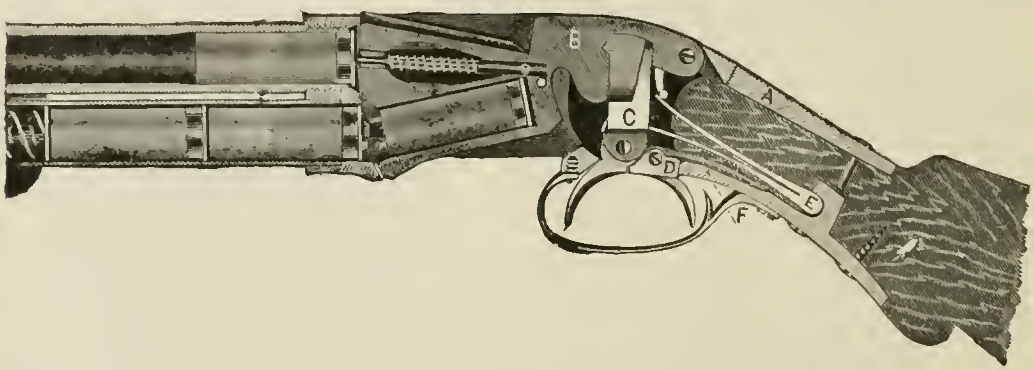
The axial portion of the breech-plug is cut away, forming a funnel-shaped cavity connecting with the chamber at its forward and smaller end. The bounding lines of this cavity, as seen in the longitudinal section, are curves, convex toward the axis of the bore prolonged. The hole through the fermeture is made of this form to guide the line as it passes through the bore of the gun and prevent cutting it off. The head of the fermeture, or part which projects beyond the posterior terminal plane of the gun, is slightly rounded for the same reason. Two holes perpendicular to the axis are bored in this basal projection to receive the cylindrical projection on the spanner-wrench used to close the fermeture. The cylindrical exterior of the body of the breech-plug is divided into eight equal parts, four sectors being armed with sectional screw-threads and four being blanks. The sectional screws and blank spaces alternate. The rear end of the bore of the gun is counterbored, and has sectional screw-threads and blanks to correspond with those in the breech-plug. The plug is inserted by turning it to the left until the threads on the block come opposite a blank space in the gun, then press the plug forward until it reaches the bottom of the counterbore, when an eighth of a turn to the right with a spanner-wrench engages the threads on the block with the corresponding ones on the inner surface of the counterbore, and brings the block firmly to its seat, at the same time locking the system. To withdraw the plug, give it an eighth of a revolution to the left, and *pull out* the plug. The vent is perpendicular to the axis of the bore, and is placed 1″ .6 in front of the trunnion-ring. It is obvious that the gun has a large muzzle preponderance. The projectiles are made of cast-iron. They are cylindrical in form, with short ogival points. The rear ends are rounded off. An axial hole is drilled in the base of the shot to receive the base-screw, used to connect the projectile with a spiral spring. Three sizes of projectiles are made, differing only in length and weight.

SPENCER RIFLE.—The magazine of the Spencer repeating-rifle lies in the butt of the stock, and is capable of holding seven copper case cartridges. A follower (*a*) impelled by a spiral spring pushes the line of cartridges towards the chamber of the barrel. When the chamber is closed, the point of the foremost cartridge rests against the *carrier-block* (*b*). When it is opened which is done by depressing the *lever-guard* (*c*), this cartridge is pushed forward into the position shown in the figure. By raising the lever-guard the cartridge is carried around and pushed into the mouth of the chamber, which is firmly closed



by the *breech-block* (*d*). The *extractor* (*e*) is a flat lever attached to the left side of the carrier-block, and withdraws the empty case by pressing against the under side of the rim. Another small lever, called the *guide* (*f*), falls into the space occupied by the carrier-block, and forms an inclined plane, up which plane the empty case moves to clear the piece. A *key* (not shown in the figure) has lately been introduced into this arm, by which the supply of cartridges can be cut off or let on at pleasure, and enables the soldier to reserve all the cartridges in the magazine for an emergency. When the magazine is locked, the piece can be loaded directly from the cartridge-box, as a simple breech-loader. The operation of this key is simply to prevent the carrier-block from falling so far as to uncover the magazine: at the same time it falls far enough to uncover the chamber for the insertion of a cartridge by hand.

SPENCER ROPER SMALL ARMS.—The most recent and novel principle developed in arms of great precision, whether for fowling or campaigning purposes, is exemplified in a shot-gun, the joint production of the inventors—C. M. Spencer and Sylvester H. Roper. The name of the former is a tradition of the Civil War, his repeating-rifle, which first appeared during the concluding years of that great struggle, and was issued in large numbers by the Federal Government, being esteemed by careful students of military annals an important factor of the Union triumph. Mr. Roper, if less world-wide known than his fellow-worker, has long been recognized in this country among the masters of mechanical motion, and has patented several devices particularly tending to the natural and rapid manual of small-arms. It is now some three years since the first outcome of the two inventors' efforts, to produce a fowling-piece which should take the place of the two double-barrel guns in a ducking trip, or be good for three quails out of a covey, was in working shape. The long experience of the sportsman combined with the shrewd application of the inventor, at once discarded all possibilities of improving the double-gun beyond its present perfection, or of successfully adapting the repeating systems of military and sporting-arms. The solution of the problem was to be sought in a path hitherto unexplored. Obviously the only resort was to a theory never before considered, which would call into exercise a change of manual while necessitating a change of mechanism.



The distinctive feature of the Spencer-Roper principle is, that for the first time in the history of small-arms, the left hand is available for something more than a support to the barrel and as a regulator of the aim ; but retaining these functions becomes an essential factor of the system, relieving its neighbor of a large portion of its duties while itself actuating the retaining processes. The original model, developing Messrs. Spencer & Roper's idea, carried 11 cartridges, which could be discharged at "will" in 4 seconds. The model, as recently perfected, has a capacity of 6 cartridges, (experience having demonstrated that to be the suitable number for use and the best working of the piece) of which 5 are held in the tubular magazine beneath the barrel, and one placed in the chamber. The gun has no fore-arm, or tip, of wood ; but about 6 inches in front of the frame, embracing the magazine, and well insulated from the possibly heated barrel is placed a bulge, of the same material as the stock or of hard-rubber, termed the hand-rest, which connects with the flat side-bars or switches, occupying the interval between the barrel and the magazine. The manipulation of the gun is exceedingly simple. When once the magazine is filled, the piece is brought to the shoulder, and the fingers of the right hand in position about the trigger-guard, while the left hand grasps the hand-rest and poises the piece. A backward and forward movement of the hand-rest throws a cartridge into the carrier-block, cocks the hammer, projects the charge into the gun, and the trigger is pulled. The rapidity of emptying the magazine being limited only by the natural dexterity and the experience of the operator. This manual and the action of the arm will be better understood by a reference to the sectional drawing of the piece, when in condition for firing, having one cartridge in the chamber and the magazine supposed to be filled. A, indicates the outline of the frame or receiver ; B, the block which serves both to carry up the cartridge and close the breech ; G, the firing-pin, in position to strike the cap of the cartridge, when actuated by the hammer, D, which is at cock; C, the trigger; E, indicates the mainspring, engaged; and, F, the trigger-spring in the same position.

The sectional drawing does not illustrate the operation of the extractor, which is positive, or the relation of the slides, or the switch-action to the locking-system. The extractor is pivoted in a slot of the right slide, and can not be seen in a left-sectional view. The operation of the backward and forward movement is exerted through the left side of the system, the slide in its backward passage traveling in a groove of the receiver, or frame, and actuating by a cam the downward movement of the breech-block until the position of the extractor on the right side of the system is such as to relieve the main-spring and cause the block to re-ascend. It will be observed that the elements of safety are at the *maximum* in this system. While the receiver is of the most durable design, the breech-block, pivoted at the rear, takes up the recoil in a plane in a direct line with the shock, and is itself supported by the solid back of the receiver. While the gun is, as the term implies, "hammerless," it is essentially safer than other arms so named, it being possible when the gun is cocked and loaded, to let down the hammer to the safety-notch and cock it again when desired, by introducing the two fingers gently between the projection of the hammer and trigger.

The organization of machine-plant and factory-room for the production of small-arms, on the American system of gauges and interchangeable parts, requires so large an expenditure of time and labor, that it is quite possible the publication of this first extended analysis of its distinctive merits will anticipate the commercial introduction of this latest achievement in small-arms. The aim of its inventors and promoters has most wisely been, so far as possible, to perfect their new gun before offering it to the public. With this view a number of guns, made by hand, have been, since the production of the original model placed in the hands of experts with the request that they should be submitted to the most difficult requirements of sporting service and subjected to the severest usage. To this *exigeant* testing the present perfection of the invention owes very much in the way of suggestion and consequent improvement. There is no such thing as perfection in any field of invention without arduous study and thorough experience of the difficulties to be encountered; no *Deus ex Machina* except in classic tradition.

The production of a new repeating-rifle was not contemplated by either of the inventors of the repeating shot-gun. In the early spring of 1881, however, there was issued from the Army Head-quarters at Washington an order for a Board of Officers to assemble in New York, "to examine and consider all magazine-guns that may be brought before it, and recommend such (one or more) of these guns as in its opinion are suitable for the military service." About the commencement of 1882, the Board having in the meanwhile prosecuted its trials of various models at Springfield, and adjourned to New York to conclude its labors, Mr. Spencer was strongly urged to adapt the system of the shot-gun to military purposes. In March the new repeating-rifle was introduced to the Board. In this evolution of a shot-gun into a military arm, the inventor following the lessons of long experience in repeating-arms, eschewed everything in the shape of a magazine which should be a part of the arm itself or in which the position of the reserve ammunition should permit the projectile of one cartridge to impinge upon the head of another. The model subjected was practically a single-loading breech-loader, with a receiver open at the bottom to receive and operate the Lee detachable magazine. The magazine referred to has been considered at length in another part of this work. The action of the Board of Officers was most complimentary to this arm. In the resumé of trials it was found that while in the generality of the tests, the Spencer-Lee was very rarely beaten, in that of "rapidity with accuracy," the recognized test for the efficiency of magazine-guns, it was very far from having an equal.

The model of the Spencer-Lee submitted to the Board was, with such very slight alteration, as was required by the substitution of a detachable for a tubular fixed magazine, generally similar in design to the original Spencer-Roper shot-gun, the breech-block pivoted at the rear and falling in a vertical plane, and the slides having a like function in opening and closing the action. Since the report of the Board was rendered, for considerations of length of system, a breech-block moving laterally, has been substituted for the original design. The models thus far produced have met an uniform approval. Considering the extraordinary merits of the Spencer-Roper shot-gun, it would certainly seem that a military arm, based upon a like theory of accuracy wedded to great rapidity should take the place of the single-loaders now in use. The infantry and cavalry arm of the future must be that one which will deliver the most shots in a very limited period, bounded by seconds rather than by minutes. An English authority has within a short time, uttered the *dictum*, "that as the fighting machine, which it is desirable to bring to the highest perfection, consists of two parts, a man and a rifle, the mechanical part, *i. e.*, the rifle, should be the quickest and best attainable: and the man, the other part should then be levelled up to it by careful instruction." Henceforth there can be no discipline of Woolwich, or instruction at Hythe, which can lift a man up to the level of his half of the fighting-machine, if he knows his enemy possesses the more rapid weapon. Within a few weeks the improved Spencer-Lee rifle has delivered 70 shots in one minute and three-quarters, of which each one would have struck its man. See *Lee Magazine-gun*, and *Magazine-gun*.

SPENT.—A projectile is said to be spent when it reaches an object without sufficient force to pass through it, or otherwise to wound than by contusion.

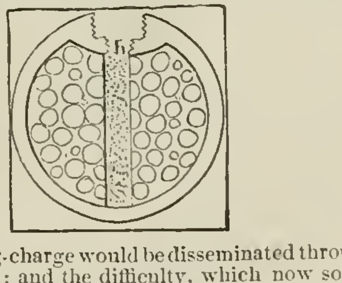
SPEW.—In gunnery, to run at the mouth; applied to a gun when, from too quick firing, it bends at the chase, or the muzzle droops.

SPHERE.—A regular solid figure, every point of whose surface is equally distant from its center; and whose outline is traced by a circle revolving round its diameter. All sections of a sphere by a plane are necessarily circles, and all sections by planes passing through the center, or by planes cutting the sphere at equal distances from the center, are equal. The former sections are called *great*, and the latter *small circles*. Small circles may vary in size between a mere point and a great circle, approaching either limit as nearly as we please. The surface of a sphere is equal to that of four of its great circles, or (taking x for the radius of the sphere) to $4\pi x^2$; and its volume to that of a cone whose altitude is twice that of the sphere, or $4x$, and whose base is a great circle of the sphere, the formula for it being $\frac{4x}{3} \times \pi x^2$, or $\frac{4}{3} \pi x^3$. The most remarkable geometrical property of the sphere is the relation which its surface and volume bear to those of the circumscribing cylinder, *i. e.*, a cylinder whose length and diameter of each end are each equal to the diameter of the sphere, and in which, therefore, the sphere will be exactly contained. The concave surface of such a cylinder is exactly equal to the surface of the sphere; and not only so, but if a section parallel to the base of the cylinder be made through both cylinder and sphere, the curved surfaces of the portions cut off are equal; whether such portion be cut off from one end or be intercepted between two parallel sections; it follows from this that the curved surface of any section of a sphere with parallel ends is equal to the product of the circumference of a great circle of the sphere by the height or thickness of the section, and that the curved surfaces of all sections of a sphere are proportional to the thickness of such sections. The volume of the sphere, also, is equal to two-thirds of that of the circumscribing cylinder.

SPHERICAL CASE-SHOT.—Though projectiles similar to spherical case-shot were used in France as early as the time of Louis XIV., the credit of perfecting them is due to Colonel Shrapnel, of the British Army. They were first successfully used by the English against the French, in the Peninsular War.

The envelope in the spherical case-shot, is a thin cast-iron shell, the weight of which, when empty, is about one-half that of the equivalent solid shot. To prepare this shot, it is first filled with round musket-balls, 17 to the lb., and the interstices are then filled up by pouring in melted sulphur or resin; the object of which is to solidify the mass of bullets, and prevent them from striking, by their inertia, against the sides of the case and cracking it, when the piece is fired. A hole is bored through the mass of sulphur and bullets, to receive the bursting-charge; and, in order not to displace too many bullets, and not to scatter them too far when the shot bursts, the bursting-charge should only be sufficient to produce rupture.

If the iron, of which the case is made, were always of suitable quality, and the cavity filled with bullets snugly packed in, there would be no necessity for sulphur to prevent accidents. In this case, it would not be necessary to remove any of the bullets,



as the bursting-charge would be disseminated through the interstices; and the difficulty, which now sometimes arises from their adhering to fragments of the case, would be entirely obviated.

To increase the effect of a small bursting-charge, the lower portion of the fuse-hole, *b*, is partially closed by screwing into it a disk perforated with a small hole for the passage of the flame from the fuse. The spherical case-shot mostly used for field-service is the 12-pounder; it contains about 80 bullets; its bursting-charge is 1 oz. of powder; and it weighs when finished 11.75 lbs.,—nearly as much as a solid shot of the same caliber.

The rupture of a spherical case-shot may be made to take place at any point of its flight: and in this respect it is superior to the canister and grape-shot, which begin to separate the moment they leave the piece. See *Case-shot* and *Projectiles*.

SPHERICAL CHAMBER.—This chamber consists of a sphere, joined to the bore of the piece by means of a cylinder, which serves as a channel to the gases. As this cylinder decreases in diameter, the gas finds more difficulty in escaping, and greater force is developed. This chamber is more objectionable than the cylindrical chamber, from its liability to break the projectiles, although it gives a very great range. This form of chamber is not now in use, as it is hard to make and soon becomes foul, when used.

SPHERICAL PROJECTILES.—These projectiles are commonly used in all smooth-bore guns, and for this purpose possess certain advantages over those of an elongated form. 1st. They present a uniform surface to the resistance of the air as they turn over in their flight. 2d. The centers of figure and inertia coincide. 3d. They touch the surface of the bore at only one point; they are therefore less liable to wedge in the bore and endanger the safety of the piece. 4th. Their rebound on land and water being certain and regular, they are well suited to ricochet-firing. See *Projectiles* and *Shot*.

SPHERICAL-SHOT MACHINE.—A machine for imparting a truly spherical form to steel or iron cannon-balls. The ball, hot from the molds or from subsequent heating, is placed in cups which are preferably caused to rotate in opposite directions and at different speeds. One of the cups is upon a spindle at the end of a shaft which has longitudinal motion by a tail-center, actuated by a hydraulic press or otherwise, and serves to press the cups together. The other cup-spindle is fixed. The cups are slacked off at times during the operation, to briug fresh surfaces of the ball under operation.

SPHERO-HEXAGONAL POWDER.—This is a molded powder, the grain, which is shown in the drawing, differing from the ordinary hexagonal powder by being formed of two hemispheres, instead of two pyramidal frustums united upon a hexagonal zone or base. It was thought that the nearly spherical form of the grains would insure very uniform results.

The granulation is the same for all, viz., 123 to the pound, but the density varies as follows:

	Density.
H. A	1.75
H. B	1.73
H. C.	1.72

These powders have been thoroughly tested, and contrary to all expectation, the results obtained with the H. B. and the H.C. powders, which from their lower densities should be quicker-burning powders, were very much inferior to the H. A. as regards both pressure and velocity. A sphero-hexagonal powder, I. B., of density 1.728, and granulation 123, was employed in recent experiments with the 3.17-in., chambered rifle, and with most excellent results.

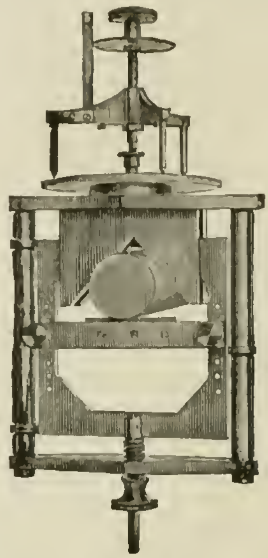
The following is a mean summary with the maximum charge employed:

Nature of gun.	Kind of powder.	Weight of charge.		Weight of projectile		Initial velocity.	Pressure.
		Lbs.	*Ozs.*	*Lbs.*	*Ozs.*		
3.17-inch chambered rifle.	I. B. sphero-hexagonal.	5	13	10	8	2,026	30,000

The amount of air-space allowed in the chamber with the above charge was about 32 cubic inches per pound of powder. See *Gunpowder*.

SPHEROMETER.—An instrument for measuring the curvature of surfaces. It consists of a three-armed frame, standing on three steel pins, which usually form with each other an equilateral triangle; in the center of the instrument is a vertical screw with a fine thread, and having a large graduated head. The screw is turned downward until its point reaches the surface on which the instrument stands; if this is a true plane, the index of the graduated screw-head should mark zero; if, on the contrary, it is either a convex or a concave, the corresponding positive or negative reading indicates the degree of sphericity.

The drawing represents an exceedingly accurate instrument, designed by Fauth & Co., for measuring the inequality of pivots. It is much more reliable and expeditious than the contact-level. It is made to measure pivots from $2\frac{1}{4}$ inches down to the smallest size. The round glass disc on which the three



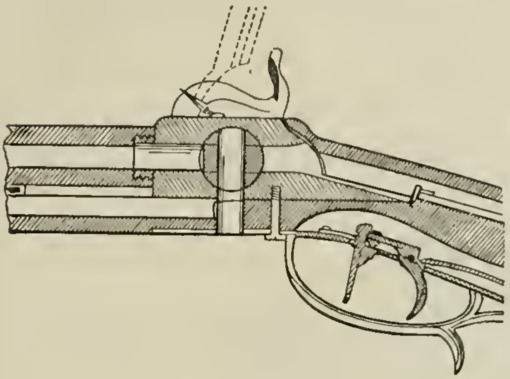
legs rest is perfectly flat; the screw is made with the utmost exactness, bearing on a jewelled center, and the nut is so constructed that there can be no dead motion.

SPICULUM.—A pilum, with a shaft $5\frac{1}{2}$ feet long, which, when impelled by a strong arm, was able to transfix a foot-soldier through his shield, or a horseman through his breast-plate.

SPIDER.—In casting a gun the core is lowered into the mold of the gun. To center and secure the core-barrel in position it is necessary to have a frame, usually termed a "*spider*," to support and hold rigidly in place the core when properly centered. It is made of cast-iron, about two and one-half feet high, having three legs, each of which has a projection at the bottom, fitted with an adjustable screw, which rests upon the upper flange of the flask; there is also a funnel or sleeve fitted in the central part of the top, through which the core-barrel passes and fits closely, holding it firmly, so that any movement of the frame will produce a change in the position of the core. See *Molding*.

SPIDER HELMET.—The casque of the French soldiers under Henry IV. It has a peak or flat vizor, with iron strips or ribbons all round.

SPIGGOT BREECH.—What has been called the "faucet" or "spiggot" breech was at one time considered a promising form of breech-closing device, and is believed to have been the very first American breech-loader. The breech-block or plug is perforated, and is in fact like the closing plug of a spiggot. The cartridge must be thrust entirely through the breech-piece, when made in the form shown in the drawing, before the breech can be closed. This form of breech was a good one for a gun using destructible cartridge-cases, but a metallic shell could not be easily withdrawn. Some heavy guns are still made on this principle. There is another form of faucet or spiggot-breech in which the cartridge is held in the breech-plug, and fired therein when in line with the barrel. In such construction the breech-plug is not generally bored through. As the plug must be greater in diameter than the length of the cartridge, this breech mechanism has not been very much used.



Spiggot Breech.

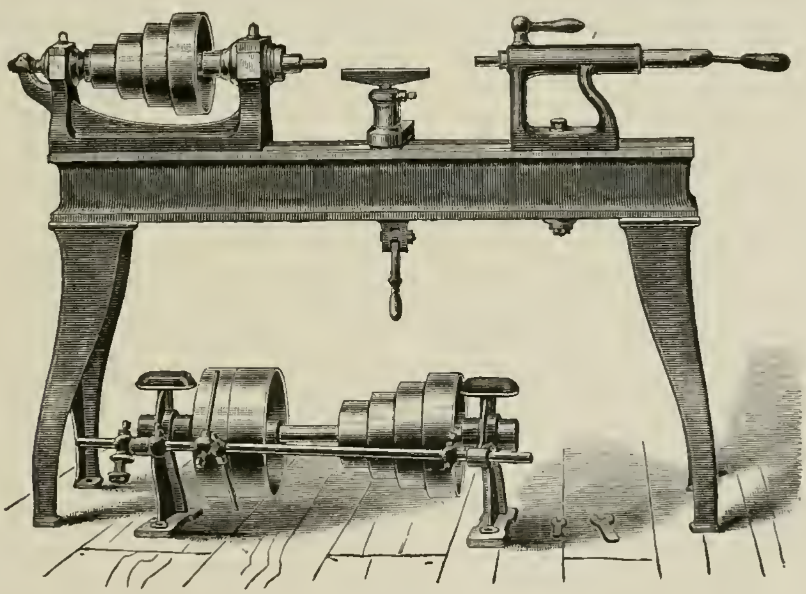
SPIKE.—A spike employed to temporarily disable a cannon should be made of hardened steel, with a soft point that it may be clinched on the inside. A nail without a head, or a bit of ramrod, may be used in place of a regular spike. To spike a piece, drive in the spike flush with the outer surface of the vent, and clinch it on the inside with a rammer. To prevent the spike from being blown out, wedge a shot in the bottom of the bore by wrapping it with cloth or felt, or by means of iron wedges, driven in with a bar of iron; wooden wedges might be easily burned out by means of a charcoal fire lighted with a pair of bellows. When a piece is likely to be retaken, a *spring-spike* is used, having a shoulder to prevent its being too easily extracted. See *Disabling Cannon.*

SPINDLE.—1. The *arbor* or the *mandrel* of a lathe. The *live* spindle is in the *head-stock*, the *dead* spindle is in the *tail-stock*, where its function is merely to center and support the object, and not to partake of its movement or impart motion. 2. The tapering end or *arm* on the end of an axle-tree. The hub of the wheel is slipped on the *spindle*, and is secured there by the linch-pin or nut. 3. The pin on which the pattern of a mold is formed.

SPIN HAY.—To twist it up in ropes, very hard, for an expedition, by which means it is less bulky and also less troublesome for the Cavalry to carry behind them. An expert horseman can spin five days' forage into a very narrow compass.

SPINNING-LATHE.—A form of lathe used in armories. The drawing shows the Pratt and Whitney pattern. The machine generally employed for britannia work, has a swing of 16 inches. Cone-pulley of four grades, largest diameter is 10 inches, for 2½-inch belt. Front bearing of head-stock spindle, 1⅝ inches diameter, 5 inches long. Screw-thread for face-plate 1½ inches diameter, 8 pitch. Pulleys countershaft 7 by 3 inches. Footstock spindle operated by lever or screw, as may be desired. Distance between centers of 6-feet bed, 3 feet 4 inches. Weight, with countershaft, 750 pounds.

For spinning sheet metals up to 15 inches in diameter and 30 in length the lathe with a double-head is used. The work is secured and released by the combined action of a treadle, rack and pinion, and weight, the treadle extending the entire length of the lathe. There are two heads, each carrying a cone of four grades, and the front support of the long spindle may be secured at any point on the slides. The lathe has a bed 5 feet in length, swings 15 inches, and weighs, with T-rests, countershaft having two cones, etc., 675 pounds. See *Lathe.*



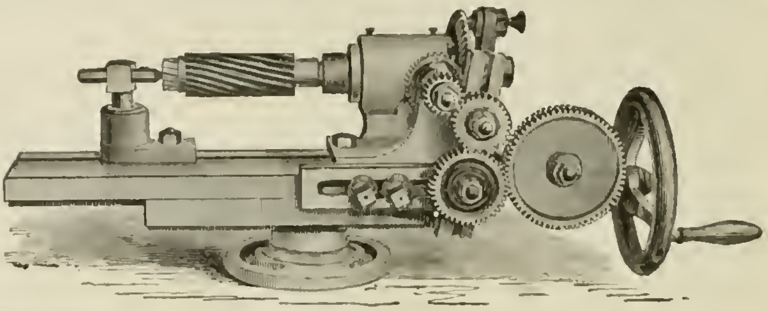
Spinning-lathe.

SPIRAL.—In geometry, the name given to a certain class of curves which, during their gradual regression from a point, wind round it repeatedly. Their equations are generally expressed in terms of polar co-ordinates, and are all necessarily of the form $r=f(A)$, where A never signifies a function of the angle, but the angle itself or a multiple of it. Several such curves have received distinguishing epithets, either on account of the properties they possess or from their inventor; the chief of them are—the *equable spiral* or the *spiral of Archimedes*, whose equation is $r=aA$ and which commencing at the origin, circles round and regrades from it with unvarying uniformity; the *hyperbolic* or *reciprocal spiral* ($rA=a$); the *logarithmic* or *equiangular spiral* ($r=ab^A$), which recedes from the center or origin with a velocity increasing as the distance, and always cuts the radius vector at the same angle; etc.

SPIRAL BIT.—A gun implement used for clearing the vents of ordnance when choked, after the gun drift has failed to do so.

SPIRAL-CAM.—A portion of the firing mechanism in certain machine-guns. See *Gatling Gun* and *Cam-ring.*

SPIRAL-CUTTER.—An attachment for the milling-machine, used in the armories to perform a great variety of work in the fabrication of small-arms, etc. The device, shown in the drawing, will originate and cut spirals 8 inches in length, right or left hand, and of any pitch, from one turn in 2 inches to one turn in 6 feet. Four gears go with the device, making 12 changes, as each can be used either as driver or driven, and all the studs are alike in size. If other pitches are required, common lathe gears can be used by fitting a bushing to them. A table of changes, angles and pitches, with rules for cutting any desired pitch



Spiral-cutter.

accompanies the machine. The piece to be cut can be held either upon centers, upon an arbor fitted to spindle, or one end in a chuck screwed upon a spindle. The spindle is hollow, allowing a $\frac{15}{32}$ inch rod to pass through it. To meet occasional wants, the spiral-cutter is sometimes made automatic and capable of cutting a conical spiral 9 inches long, supporting the outer center while cutting. See *Milling*.

SPIRALE.—A piece of ordnance used in France in the fifteenth century.

SPIRAL SPRING COILING-MACHINE.—A contrivance for coiling wire. The machines used in most armories for this purpose, are made in two sizes by the Pratt and Whitney Company, and are suitable for coiling from $\frac{1}{4}$-inch and smaller wire, springs of a minimum diameter of eight times the diameter of the wire. No. 1 machine has one set of rolls, and will coil wire of $\frac{3}{32}$-inch and smaller diameter. No. 2 machine has two sets of rolls and back-gears, and will coil wire of $\frac{1}{4}$ to $\frac{3}{32}$-inch diameter. The wire in the original coil may be placed on a reel, one end inserted between the rolls into the former, and the whole or any part wound into one continuous spring. Great care should be taken that the rear end of the wire does not pass beyond the grip of rolls; if it does so, there will be much difficulty in clearing the former. To avoid trouble, the spring should be cut close to the former at the point of exit, and the rolls reversed in motion to draw the wire back through the former. Close or open coils can be wound according to pitch of the former used. The first former of any pitch is apt to be expensive, as trials are usually necessary to attain the desired result. Countershafts are suitably arranged.

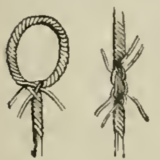
SPITHEAD FORTS.—The troubled state of European politics which gave rise in 1859 to the Volunteer Movement, led also to the recommendation of an extensive plan of defenses for the Arsenals and Coast. A Board of Commissioners drew up a scheme for these defenses, to cost about £5,000,000, of which a sum of £2,000,000 was for Portsmouth, Spithead, and the neighboring Coast. At present the entrance to the important Arsenal and Dockyard at Portsmouth is defended by Fort Monckton on the Gosport side, Southsea Castle on the other side, Cumberland Fort at the entrance to Langston Harbor, and Lumps and Eastney Forts between the two last named, and some defensive lines between the Island of Portsea and the mainland. £580,000 was voted in 1860 as a beginning, to increase the number and strength of these forts, to build detached forts on shoals in the sea between the mainland and the Isle of Wight, and to raise fortified lines on Portsdown Hill (the principal work being Fort Southwick), wholly northward of Portsmouth Harbor. The works were commenced but the often-conflicting lessons furnished by the American war led to much delay and endless variations of plan.

The National Defense Commissioners had proposed five advanced forts on the shoals known as Horse Sand, Noman or No Man's Land shoal, Sturbridge shoal, Spit Point, and a point intervening between Horse Sand and Portsea Island. But after much discussion and numerous alterations of plan, it was only in 1864 that it was determined to proceed with the foundations at least of two—the Horse and the Noman forts. The foundation of each fort consists of rings of stone-work, laid on the levelled bed of the shoal, tapering a little upward from a width of 54 ft. to one of 43 ft., the outer diameter of the ring gradually lessening from 231 to 213 feet. From 20 to 15 ft. of submarine masonry is required. Outside the rings of stone are layers of rubble to protect the stone-work from the action of tidal rush. Two years later similar forts were begun on Spit bank and St. Helens shoal. In 1865 a mortar-battery had been erected at Puckpool in the Isle of Wight, commanding at long range the approach to Spithead. In 1868, after it had been found impossible to secure a foundation for a fifth fort on the Sturbridge shoal, Puckpool battery was strengthened and armed with 30 mortars and 4 guns of 25 tons.

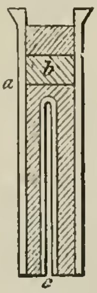
All this time the Government had not determined which of three modes to adopt for constructing the forts—whether to form them entirely of iron, or of granite faced with iron, or simply of granite, leaving the facing for after-consideration. The plan most in favor with the Government in 1866 was to erect on each of the foundations at Spithead a *revolving* iron fort or tower of enormous magnitude. Circumstances in 1867 induced the Government again to pause. Experiments on the Rodman 15-in. and 20-in. guns led the Engineers to believe that no iron casing for forts could resist shot of 500 lbs. to 1,100 lbs. from such ordnance; while the rolling of an armor-plate 15 inches thick revived the hopes of those who believe that armor will eventually vanquish guns. Finally, the forts were finished, of a granite core, surrounded by a great thickness of iron plates. Above each fort are revolving turrets carrying 35-ton guns, which throw shells of 700 lbs. The inner line of defense has been strengthened by new works at Gilkicker, Southsea Castle, etc., and by the increase of the size of the guns, and the addition of iron shields in the embrasures.

SPLENT—SPLINT.—The bony enlargement on the horse's leg, between the knee and fetlock, usually appearing on the inside of one or of both fore-legs, frequently situated between the large and the small canon bones, depending upon concussion, and is most common in young horses that have been rattled rapidly along hard roads before their bones are consolidated. When of recent and rapid growth, the splint is hot and tender, and causes lameness, especially noticeable when the horse is trotted along a hard road. A piece of spongiopiline saturated with cold water should be applied to the splint, kept in position with a light linen bandage, and wetted with cold water or a refrigerant mixture each hour. Perfect rest must be enjoined for ten days or a fortnight. When the limb is cool, and free from tenderness, the swelling, which will still remain, may be greatly reduced by some stimulating applications, such as the ointment of the red iodide of mercury, the common fly blister, or the firing-iron. See *Splints*.

SPLICE.—To join the two ends of a rope together without a knot, or to unite the end of a rope to any part thereof, by interweaving the strands in a regular manner. The instrument used for the purpose is a marline-spike. There are two kinds of splice, *short* and *long*. To make a *short splice*, untwist from 4 to 8 inches of each of the two ends of the rope, and interlock the strands up to the close parts of the rope, those of the two ends alternating; hold in the left hand one end of the rope with the loose strands in the front, and cross each strand of that end over the strand of the other end which is to the left hand of it; then by means of the marline-spike pass it under the same strand of the second end, and draw very firmly on the strand which is passed through. Pursue the same course with all the strands of the second rope. To increase the strength of the splice, pass each strand round the one on its left a second time, and cut off the loose ends. The short splice is used for slings, block-straps, or when the rope is not intended to pass through blocks. To make a *long splice* for a rope which is to pass through a pulley, the short splice being too thick, untwist about 8 inches of the two ends, and interlock as before, untwist a strand of one end from the close part of the rope and replace it by the strand of the other rope which comes to hand; cross the end of the latter strand over the one which is replaced, and pass it under the adjacent strands. Substitute, in this manner, every other strand of the other rope, and cut off the loose ends. The long splice is used to unite two ends of a rope which is to pass through a block. See *Cordage* and *Knots*.



SPLINGARD FUSE.—A concussion-fuse is made to operate either by the shock of the discharge, or by the shock experienced in striking the object, and is applicable to spherical projectiles. One of the simplest, as well as one of the most effective, concussion-fuses is that invented by Captain Splingard, of the Belgian Service. It is composed of two principal parts—the wooden plug, and the paper fuse. The chief peculiarity lies in the arrangement of the paper fuse. The case (*a*) is made of paper, rendered incombustible by a solution of sulphate of ammonia and alum, and filled with fuse composition (*b*) of variable quickness of burning. A long cavity is formed in the lower part of the composition, by driving it around a spindle, as in a rocket; this cavity is filled with moist plaster of Paris, and a long needle is inserted in it, nearly to the bottom of the plaster, forming a tube (*c*) enclosed in and supported by the composition. The composition is ignited in the usual way, at the top, and, as it burns away, leaves a portion of the plaster tube unsupported; when the shell strikes its object, the shock breaks off the unsupported part of the tube; the flame of the composition communicates with the bursting-charge; if the tube do not break, the composition burns up, and the bursting-charge is ignited, as in an ordinary time-fuse. The upper portion of the composition burns away quickly, in order to leave the tube unsupported soon after the projectile leaves its piece. See *Concussion-fuse* and *Fuse*.

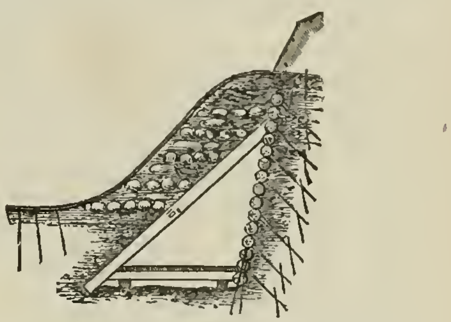


SPLINTER-BAR.—A transverse horizontal bar to which the shafts, or the pole and traces, are attached. It should be well supported throughout its length by the futchells (or frame sides and summers where no under-carriage is used), at short intervals, to neutralize the straining moments from the *traces*. If the ends project far beyond the futchells or sides of the carriage, stays must be added across the angles.

SPLINTER-PROOF.—The mouth of a magazine is usually covered by the *splinter-proof* shelter. This is constructed by taking scantling eight by ten inches, cut into suitable length and placing it in an inclined position, so as to cover the mouth, and leave an easy access to it. The pieces usually are inclined 45°, and are placed side by side; they are covered by at least two feet of earth, or sods; and hides or tarpaulins are thrown over the whole.

The magazines here referred to are only suited for works which are not expected to be occupied but for some weeks, and are not exposed to an attack of any but light field-guns. In all cases where lumber is abundant, it will be best to cover at top by a foot in thickness of pieces laid in juxtaposition, and to give a covering of at least six feet thickness of earth on the most exposed side, and place the magazine entirely underground.

Splinter-proofs for the trenches and enclosed works faced with timber from eight to twelve inches diam-

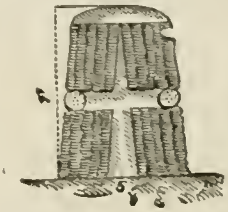


eter, and covered with a sheeting of thick boards and from four to six feet of earth, which are supported by uprights at the back, having a board flooring as shown in the figure, have been recently used in our field-works and trenches with great benefit in the saving of life.

The drawing shows a cross section of a splinter-proof shelter laid against the side of a traverse. The traverse is revetted with fascines, and the timber-work is thoroughly covered with sandbags and tarpaulins, or raw hides.

Splinter-proofs made after the foregoing plan, but smaller, may be placed against the parapet between the guns. These not only afford shelter for the men, but give a place to keep implements and a few rounds of ammunition ready for immediate use.

SPLINTER-PROOF TRAVERSE.—This traverse, intended to be used only as a protection against splinters and the fragments of shells scattered around by their explosion, is not so thick as other traverses. The usual height is the same as that of the parapet, and the thickness at the base is from seven to eight feet. The length varies, being in some cases only ten feet, and in others as much as sixteen feet. As a rule, a traverse of this kind is not joined to the parapet, but is separated from it by a narrow passage which can be used by the men to pass from one side of the traverse to the other. It is usually constructed as follows:—A rectangular space is marked upon the ground for the base of the traverse. A row of gabions is then placed in juxtaposition along the line representing the base of the traverse, and is given a slope inwards, either by setting the gabions on the slightly inclined excavation in the ground, or by raising the outer edges by means of fascines laid along on the ground. The gabions are then filled with earth, and also the interior space enclosed by them. When the earth has risen above the top of the gabions, two rows of fascines are laid upon the top of the gabions to form a base for a second row of gabions. The second row is then filled with earth, and the process of filling with earth continues until the earth is high enough. The top is rounded off, or is made ridge-shaped, and the traverse is completed. The same method may be used for the construction of traverses required for defilade, when there is a very pressing emergency for them. Splinter-proof tra-



verses are placed between the guns along a line of parapet which is exposed only to a direct fire from the enemy, and are only intended to confine the effects of bursting projectiles to a limited space. They are usually constructed only when there is a necessity for them, and then hastily. Gabions, sand-bags, fascines, or any of the materials used for revetments, may be employed in their construction.

SPLINTS.—1. In ancient armor, the small overlapping plates for defence of the bend of the arm; they constituted part of the suit called the *almaine-rivets*, which was worn for the defence of the lower part of the body. 2. In surgery, certain mechanical contrivances for keeping a fractured limb in its proper position, and for preventing any motion of the fractured ends; they are also employed for securing perfect immobility of the parts to which they are applied in other cases, as in diseased joints, after resection of joints, etc. See *Surgery*.

SPOILS.—Whatever is taken from the enemy in time of war. Among the ancient Greeks, the spoils were divided among the whole army, the General taking the largest share. Among the Romans, the spoils belonged to the Republic.

SPOKES.—The small bars inserted in the nave of the wheel and which serve to support the felloes. The *working-spoke* is exposed to all the chief strains and shocks. The general transverse section of the spoke is fixed by the pressure due to traction sustained by the working-spoke. This pressure, P, varies as

$$\frac{W}{\cos d - c \sin d};$$

in which d is the angle contained between the vertical drawn through the center of the wheel, and the radius through the obstacle; c the co-efficient of friction of arm and pipe-box, and W the weight of the load on the wheel. On inspecting the equation

$$P = \frac{W}{\cos d - c \sin d},$$

we see that when $d = 0$, $P = W$; hence the pressure on the working-spoke is never less than W, and it increases greatly as the height of the obstacle increases. The first shock from side-thrusts has to be sustained by the spoke, the strain upon which increases towards the nave. Hence the section of the spoke in the plane of side-thrusts (perpendicular to the face of the wheel) should deepen as it approaches the nave. But this increase of strength at the foot of the spokes is limited by the dimensions of the nave, and other considerations of weight and manufacturing convenience; and it has been found, on account of these limitations, insufficient of itself to meet the entire straining moment from the more severe natures of side or diagonal-thrust, the most injurious effect of which can be removed by arranging the spokes so that their longer axes, lying on the surface of a cone, are directed to its apex, which is in the axis of the wheel, the face of the wheel forming the base of the cone. In this construction the spokes cannot be bent back by side-thrusts without extending the tire. By increasing the *angle of dish* and decreasing the *strut* we will lessen the strain on the spoke; but experience has shown that a *dish* of not less than ½ inch per foot of the wheel's diameter is necessary for heavy carriages destined to travel at speed over rough country. The *strut* generally adopted is about ½ inch in a 5-foot wheel. The spokes may be as numerous as is consistent with securing a strong and rigid junction with the nave. The more numerous, the less the strain on each spoke. See *Wheel*.

SPOKESHAVE.—A small iron plane something like a penknife, set in the middle of a frame, which can be used with both hands. It works easily in the direction of the grain, and is used for shaping and smoothing small rounded surfaces. This instrument is used by the carriage-maker, cooper, saddler, and other artisans.

SPONGE.—A mop for cleaning the bore of a cannon after a discharge. The sponge-head is a wooden cylinder covered with a fabric, of which the warp is hemp and the weft woolen yarn, woven in loops like a Brussels carpet. Alum-dressed sheep-skin with the wool on is sometimes used. In field-service, the *rammer* is at one end of the staff and the sponge at the other. Fig. 1. represents the ordinary sponge, and Fig. 2, a choke-bore cleaner, for small-arms. Fig. 3. shows a hair-brush used for this service with rifled

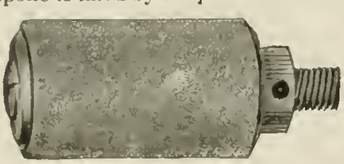


Fig. 1.

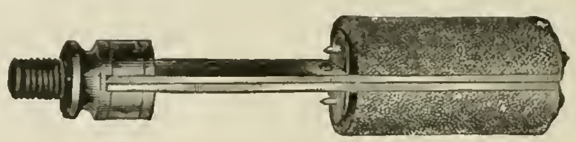

Fig. 2.

Fig. 3.

Fig. 4.

Fig. 5.

guns. Figures 4 and 5 show the ordinary forms of rubber cleaners for small-arms.

SPONGE-BUCKET.—A sheet-iron bucket, for washing the bore of the piece. The top and bottom are turned over the sides and fastened with rivets; or the bottom may be fastened to the sides by a double fold, and stiffened with a hoop shrunk on above the seam.

SPONGE-CLOTH.—A peculiar kind of cloth, moist with oil; it is employed to clean the screws of Armstrong guns, and is made of cloth so woven that no fiber comes off in use by which the worms of the screw could be clogged.

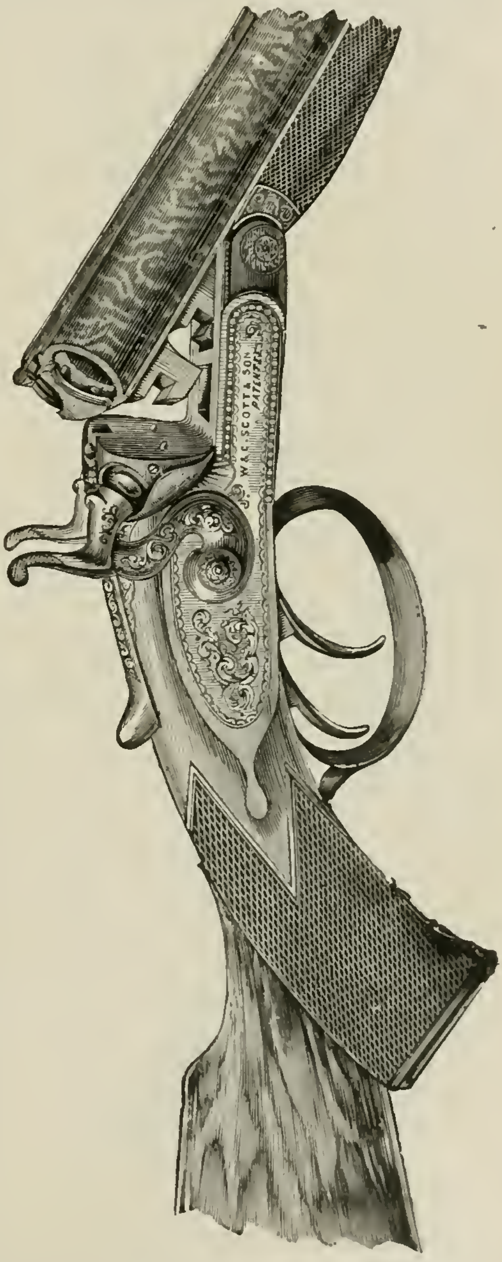
SPONGE-COVER.—A strong bag of linen or canvas, used to protect and preserve the sponge. The diameter of the bag is equal to that of the bore of the gun, and the length sufficient to allow the mouth to be drawn together, around the staff, by means of a cord inserted in the hem. A loop of canvas sewed to the bottom, serves as a handle by which to pull the cover off. The covers are marked with the caliber of the piece to which they belong.

SPONTANEOUS COMBUSTION.—Taking fire of itself. This phenomenon is known in the mineral and organic world. Frequently cases are stated of coals becoming ignited of their own accord. This is more often seen on board ships laden with coal, where, from the heat of the hold, and the moisture from water which a ship takes in from leakage, or other causes, the coal becomes heated and moistened, and from the conjunction of pyrites in the coal, in which the protosulphide is associated with the bisulphide of iron, it takes fire. New-burnt charcoal, and particularly new-ground charcoal, is very liable to spontaneous combustion. Phosphorus is another mineral subject which, in its dry state, is very liable to burn spontaneously. Articles of cotton or wool saturated with oil (vegetable), and heaped together, are very liable to burn spontaneously, oil having always an affinity for oxygen, and thus causing ignition. Many of the disasters which occur in powder-houses, when the houses have been closed and an explosion has taken place, may possibly have occurred from cotton-waste containing oil being left collected in a corner of the house.

SPONTOON.—A weapon bearing resemblance to a halberd, which, prior to 1789, was borne instead of a half-pike by officers of British infantry. It was a medium for signaling orders to the regiment. The spontoon planted in the ground commanded a halt; pointed backward or forward, advance or retreat; and so on. The ungraceful and grotesque shape of the weapon points out very accurately the time of its invention—the period of wigs and three-cornered hats. The last *spontoons* known in France were those carried by the French Guards in 1789.

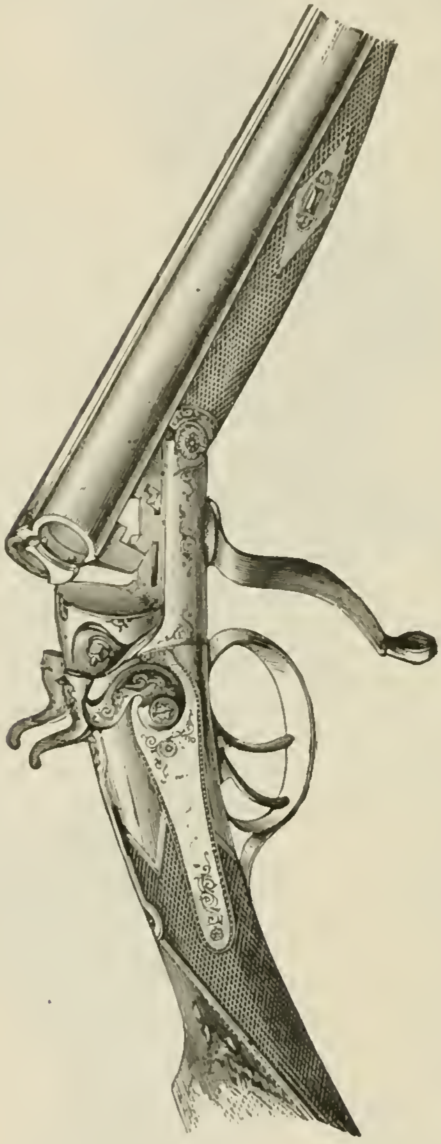
SPORTING-ARMS.—This teeming subject to be adequately treated would require much more space than could possibly be given it in a work like the present. We must content ourselves, therefore, with a brief outline of the history of game-shooting, some hints on the selection, handling, and use of guns, and a list of the game resorts in the United States. From the time of Nimrod to the present day the capture of wild animals has always afforded man the keenest enjoyment, and no occupation is more healthful, invigorating, or beneficial. Although over-indulgence in anything is hurtful and brings satiety, nothing is less prone to pall than shooting. The ping of the rifle-bullet or crack of the shot-gun has charms that never tire. It would be idle to describe the pleasures of the field and forest; the votaries of the chase are even now too numerous, and each year sees an alarming increase in their number, whilst unfortunately game (especially the large mammalia) is rapidly decreasing.

It is doubtful at what time guns were first used as sporting-arms, but early French and Italian works seem to indicate the close of the 14th century. We find a curious illustration in an old manuscript entitled "Ye Gonne and howe to Use itt," dated 1446. This curious sketch is evidently a caricature, but it is sufficient to show that all fire-arms were used for game-shooting in the early part of the 15th century. We get notices of the same in several records of that century, and by the close of the 16th the gun seems to have become so general a sporting weapon as to necessitate special regulations in several European countries. About 1580, an Italian work informs us,



Scott Top-lever, Double-bolt.

shooting at birds flying and animals in motion was first practiced, but this could not have been to any great extent. It was not until the close of the 18th century that shooting on the wing became at all common; since that time it has been so universally practiced as to make shooting at any fixed object with a shot-gun unsportsmanlike. The well-balanced and light guns made by the crack gunsmiths of the early part of this century greatly favored snap-shooting, and many of the sportsmen of those days, if they did not make such large bags as those of to-day, enjoyed sport into a good old age, and were hale and hearty to the last. So much for the days of flint and steel. It is seldom sportsmen shoot alone now. Drives or *battues* are much more in vogue; otherwise sportsmen, as a rule, shoot in company, very often substituting markers for pointers and setters, and contenting themselves with a retriever, and not always that. This method of walking the game is not half so pleasurable as shooting over well-broken dogs, but when



Leader Breech-loader.

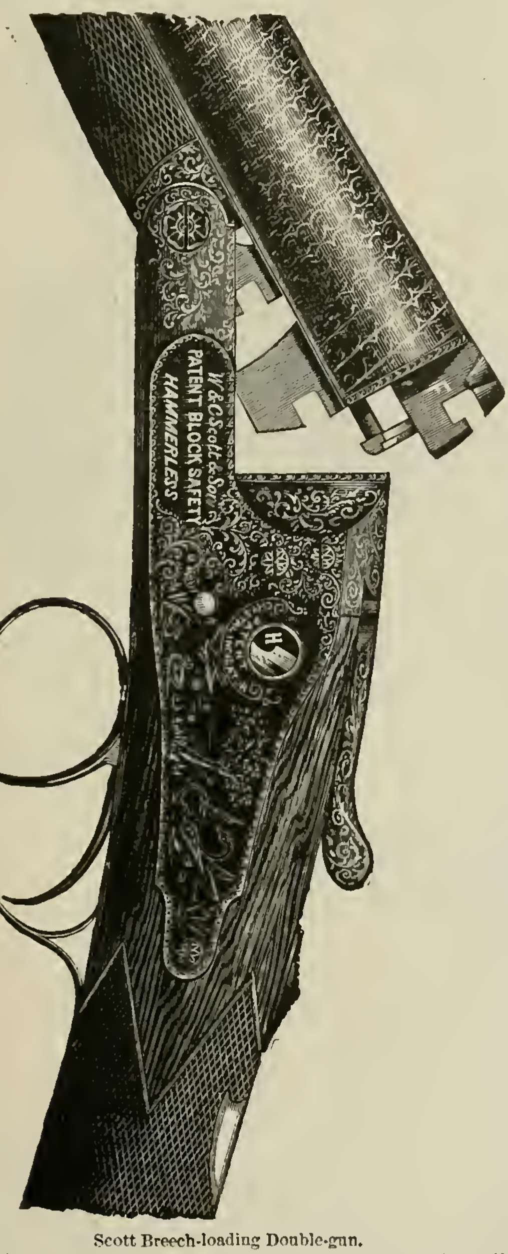
properly carried out it invariably insures a larger bag.

In his selection of a rifle or a shot-gun for game-shooting in this country, the sportsman is frequently puzzled on account of the contrariety of opinion existing among some of the crack shots. In the following paragraphs, which we take from a work by an experienced hunter, he may find some hints to assist him in his choice.

For a timber gun, or rifle at short-range, the improved Winchester, model 1876, should be selected. It is a close, clean shooter, is easily kept in order, and is handily packed while in the woods, or carried on a saddle. When cartridges are carried in the magazine for several days, the ends of the balls become battered, but they can easily be trimmed up with a knife or file. . . . For large game and long-range shooting, the Sharp's and the Remington rifles should be recommended. They both shoot close, hold the same cartridges, and are of equal merit. The vertical movement of the breech-block is safe, easy, and not liable to get out of repair; it is easily removed and cleaned, and there are no screws to be misplaced or lost. The barrel can be wiped from the breech, thus removing all dirt from the working parts, and in shooting it is second to none. The Remington rifle of all grades shoots admirably, . . . and is a great favorite with marksmen upon the various shooting-ranges of the East. . . . When shooting rapidly, the Sharp's rifle is very conveniently loaded, as the cartridges naturally fall down into the barrel. With some other makes it is often necessary to set the cartridge with the fingers. The Maynard rifle shoots well, and does good shooting when hunting antelope and other large game. The shells of long, heavy cartridges will stick in most rifles when a little foul. A breech-loading rifle should never be used when dirty. When having been shooting rapidly, wipe out the rifle at the first opportunity; and clean, with a greasy cloth, the dust from a few of the cartridges in the front of the belt. When riding over the dusty plains it is almost impossible to keep cartridges greased and clean. The needle-gun and Winchester rifle are superior to others in throwing shells clean from the barrel. The Winchester will throw the shells clean from the hunter's shoulder, and when firing rapidly at running deer, at long-range, a second shot is often fired before the first shell strikes the ground.

Sportsmen nowadays are very fastidious, and buy many imported shot-guns; and it is to be regretted that the home manufacture is not more encouraged. American rifles are the finest in the world, and our shot-guns might be if the manufacturers were sufficiently patronized. We have a dozen good makers in the United States that would turn out beautiful guns if sportsmen would pay for the work in them. The different grades of the Remington guns are an example. These cost less than forty dollars. They shoot hard and close, and work admirably. They are the gun "for the million," and are the best breech-loaders in the market. The Fox gun differs from all others, having a side action when loading, thus doing away with the clumsy fall of the barrel which occurs when charging other breech-loaders. It is not so liable to wear, being unlike the greater number of breech-loading shot-guns in having no hinge for the barrels to work on. The now well-known Baker gun has grown very popular, and its utility will make it the deer-hunter's favorite. In this gun we have a heavy, strong-shooting breech-loading rifle and a fine double breech-loading shot-gun. With a heavy ball in the rifle-barrel, a charge of loose "buck" in one shot-barrel and a wire cartridge of buckshot in the other, the hunter is well "fixed" for all emergencies. The sights of this gun are directly over the rifle-barrel, and the hunter has only to calculate on the trajectory.

The shooting qualities of breech and muzzle-loading guns are subjects of great discussion. Our experience is that the muzzle-loader shoots the stronger and better, particularly with light charges. The greater portion of breech-loading guns will recoil when long, crimped cartridges are used, the crimping appearing to make the difficulty. The metallic shells, if properly charged, shoot stronger and with less recoil than the crimped paper ones; and yet the metal shells often stick in the best of guns, and cause much trouble. Many sportsmen shoot too much shot, and use that which is too coarse. Equal bulk of powder and shot are good proportions, except when shooting very coarse shot, when a few extra pellets may be added. It is necessary to use more powder when shooting cartridges than when using the muzzle-loader. When hunting ruffed grouse in timber, in their wild, shy season, charge the right-hand barrel with No. 7 shot, and the left-hand barrel with No. 6. Use No. 5 shot for pinnated grouse on the Prairies. Every gun has its specific charge for good shooting, and is regulated by its weight and bore. Practice only will determine this point; and when decided upon, do not deviate from the proper load. A gun will make the most regular pattern when clean; when



Scott Breech-loading Double-gun.

dirty it very often sends the shot quite irregularly, in bunches; and when an occasional long shot is successful, the amateur sportsman might think a gun is most reliable when foul. Experience, however, teaches one that a clean gun shoots the better. When shooting rapidly from the muzzle-loading gun, if it becomes foul and begins to recoil, the charge may be slightly lessened, as the dirt in the barrels causes the wads to fit tightly, and the strength of the powder is more fully used than in a clean gun.

It is now acknowledged that it is better to make use of both eyes, and to pay no attention whatever to the gun whilst aiming. In short, the *eye*, *hand*, and *trigger* must act in perfect unison, and without any consideration having to be given to either. On a bird rising, the hand should *intuitively* raise the gun until it covers the object, from off which the eyes are not taken before the trigger is pulled. This only requires practice; and if such is forthcoming, and the body kept in perfect health, a good wing-shot is sure to result. Health is undoubtedly of the greatest importance to professional shots, and is necessary to good shooting. It cannot be expected that one who has not the power over his muscles to keep the hand steady can exert them to raise at once a gun and to level it to the greatest nicety. It is now the prevailing notion that most misses are caused by shooting behind or below the mark that is aimed at. To remedy this, straight stocks are recommended, and the following method has been devised to ascertain whether the gun is properly brought up. The shooter is to place himself three or four yards from a good-sized mirror, and aim at his own eye, raising the gun repeatedly, steadily but quickly, as in shooting at the bird. Upon looking into the mirror, with the gun as brought up to the shoulder, if the two round holes, or end elevation of the muzzle, are alone discernible in the mirror, the fit and handling of the gun are theoretically correct; if a little of the lower or under side of the barrel is likewise to be seen, so much the better; but if any of the top rib, or top side, of the barrels figures in the mirror, the chances are that nine shots out of every ten will be below the birds.

With fast-flying birds, and game running at full speed, it is a much disputed point among all who use the gun whether the shooter should hold "on" or "ahead." The latter appears to have the best of the argument, theoretically and practically. To prove that either plan is the correct one would be next to impossible; but says Greener: "With due deference to the majority of sportsmen, we hold with the practice of holding on." A great deal of difference is doubtless caused by the manner of bringing up the gun the shooter has acquired; some bring up the gun with a swing in the direction the mark is moving, others bring it up and follow the object, while the majority of good shots put up the gun and, it is supposed, fire ahead. Now, those who shoot with the gun on the swing, and who *intuitively* increase the speed of the swing in the same ratio as the increase in the speed of the mark, never require to hold ahead, even in the opinion of the strongest supporters of the hold ahead theory. The second class of poking shots are generally most uncertain in their aim, and the habit is detrimental to becoming an expert snap-shot, whilst we cannot but believe that many who imagine they hold ahead in reality hold on.

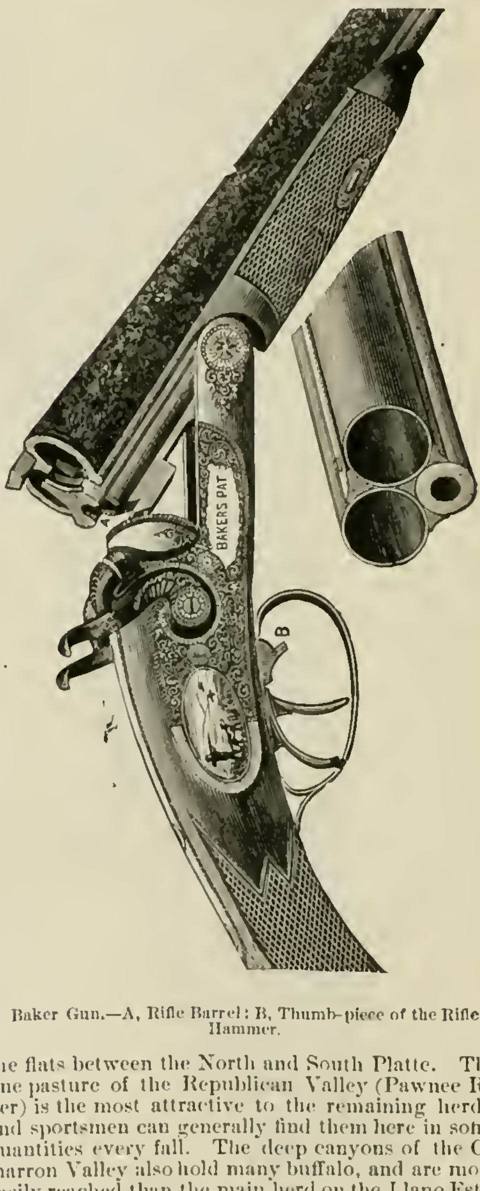
In the first place, having practiced raising the gun and perfecting the handling so that it shall intuitively follow the eye, it must be most difficult to point the gun away from the object at which both of the eyes are staring; and if the eyes are then removed from the object to some distance ahead, it is impossible to accurately tell what distance the line of aim is from the bird. This is especially the case when gazing at the sky; and for a shooter to be able to aim ten or fifteen yards ahead, as is advised by some wild-fowlers, is next to impossible to do with regularity. When gazing at no fixed object, it is as easy to move 30° across the sky as ten yards, and that without being aware of the discrepancy. Those who hold on, by shooting very promptly, prove the truth of the theory that it is necessary for the hand and eye to act in unison; whilst they who hold ahead, although agreeing that the hand must follow the eye, yet so shoot that the hand must point the gun in a different direction from the object on which the eye is fixed. An ordinary full-choke possesses a killing circle of at least thirty inches in diameter at thirty yards. Assuming a bird crossing to be fired at by a holder-on, the shot, traveling at the rate of 225 yards per second, would reach the bird at thirty yards in less than one-fifth of a second from the instant of pulling the trigger; so that it would indeed be a fast-flying bird to get without the killing circle in that time. The time required from the instant of pulling the trigger to the explosion of the cap is greater than that occupied by the shot traveling fifty yards; but with hammerless guns the time is less than with hammer guns, the blow given being much shorter, and direct instead of being conveyed by an exploding-pin. Some quick shots, however, anticipate the time it takes to *fire* the gun, and pull the trigger whilst raising the gun up to the shoulder. This requires a considerable practice to perfect, and the gun must, of course, be within an ace of the proper position; but, however the practice may be deprecated, it is certainly *au fait* for trap as well as general snap-shooting.

In grasping the gun, a disputed point is the position of the left hand. As a rule, sportsmen grasp the barrels in the very weakest place, viz., just in front of the cartridge-chambers. Others again, to shield themselves as far as possible from danger, grasp the front of the trigger-guard by the left hand. This position is wrong, as but little command is obtained over the gun, the liability of injury by the breaking of the breech-action is not at all lessened, and usually a piece of horn has to be attached to the trigger-guard, spoiling the beauty and handiness of the gun. To have full command over the gun, and at the same time exposing the hand and arm to a minimum of risk in case of a burst, *grasp the gun well forward*—if close to the fore end tip so much the better—but do not bring the hand any nearer to the breech than six inches, and keep the elbow well depressed. By having a proper command over the gun, it can be raised quickly and easily, and even a heavy or clumsy gun may be manipulated with tolerable success.

GAME AND GAME RESORTS.

Large Game.—The buffalo is considered the first game of North America. Although rapidly decreasing in numbers, there are still several millions distributed over the United States and Canada. Buffalo-hunting as a sport is tame after the excitement of killing the first half-dozen, for no more skill is required to kill twenty or one hundred buffaloes than to kill one. The Indians still hunt the buffalo with bows and arrows, and consequently get to close quarters. A ball-gun is sometimes used by other hunters, but a rifle is preferable; a brace of saddle-pistols or an army revolver is generally carried in addition. There are at present two buffalo-ranges in the United States—the southern, extending from 32° to 37° 32′ north latitude and from 99° to 104° west longitude; or, roughly speaking, from the Arkansas River on the north to the rivers Brazos and Colorado on the south. The western limit is the Rio Pecos; the eastern, the Washita Mountains in the Indian Territory. This vast tract includes part of Texas, Indian Territory, New Mexico, Kansas, and Colorado, and several Indian Reservations. The northern buffalo-range cannot be exactly defined. It extends from the Missouri River on the north and east to the Rocky Mountains on the west and the South Fork of the Big Cheyenne River on the south. This tract also includes parts of Montana, Wyoming, and Dakota, and numerous Indian Reservations. The abundance of buffalo may be judged by the fact that it was estimated that 4,500,000 buffaloes were killed during the three years 1872–74, and in 1878 over 60,000 buffalo-robes were shipped down the Yellowstone River. In the season of 1880 a professional robe-hunter killed 2,000 head of buffalo in Montana. Many buffalo are likewise to be found in broken herds between the two buffalo-ranges we have mentioned. Some thousands inhabit the country between the Arkansas and the South Platte, and in 1874 a large number crossed over to

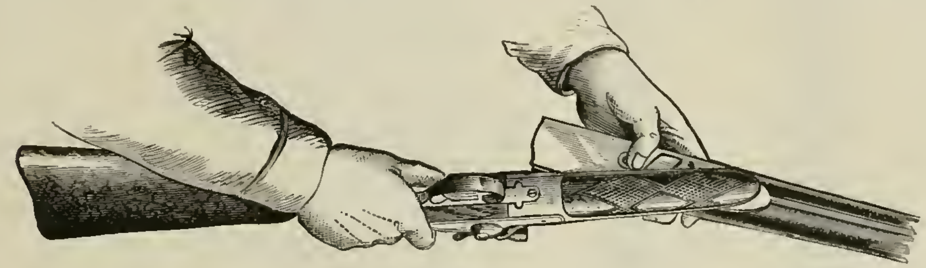
Sporting Rear-sight.



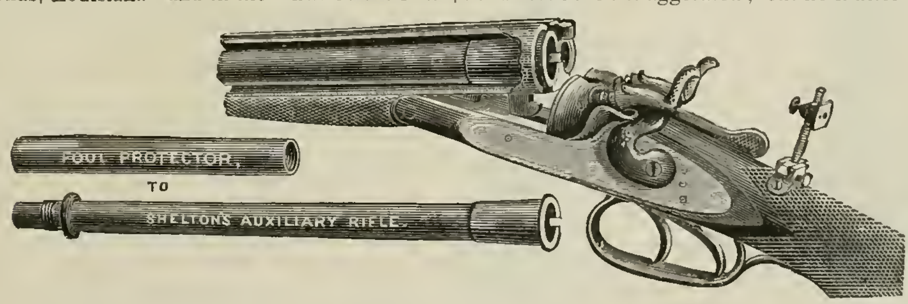
Baker Gun.—A, Rifle Barrel: B, Thumb-piece of the Rifle Hammer.

the flats between the North and South Platte. The fine pasture of the Republican Valley (Pawnee River) is the most attractive to the remaining herds, and sportsmen can generally find them here in some quantities every fall. The deep canyons of the Cimarron Valley also hold many buffalo, and are more easily reached than the main herd on the Llano Estacado, or Staked Plain. In the northern range, the valleys of the Yellowstone, Bighorn, Tongue, Powder, Sweetwater and Wind Rivers are the most favored localities for the buffalo, as well as elk, deer, antelope, and other "Injun cattle." The "Rocky Mountain buffalo" is smaller and shaggier than the buffalo of the plains, and is far more difficult to stalk. It inhabits the deepest, darkest defiles, or the craggy, almost precipitous sides of mountains inaccessible to any but the most practiced mountaineers. Its size makes it easily distinguishable from the ordinary buffalo, which, generally speaking, may be found on all the eastern slopes of the Rockies not yet taken into cultivation. Wild cattle are shot by ranchmen in Texas and Mexico; the sport is more dangerous and exciting than buffalo-hunting. The American elk is found all over North America where civilization has not exterminated it. Montana, Wyoming, Kansas, and Indian Territory are known to be simply alive with these animals, and doubtless other Territories are stocked in a similar manner. An excellent country for the elk, deer, bear, antelopes and mountain-sheep is that near the Bear, Snake, and Upper Cache-La-Poudre Rivers, on the south side of the Union Pacific Railroad. The Upper and Middle Parks in Colorado are also very well stocked with all sorts of game.

In all the States westward of the Rockies to the Pacific Coast, game may be found in sufficient numbers to satisfy even an inordinate sporting appetite. In California, deer and bear constitute the chief varieties of large game, and these, particularly the former, are very plentiful in nearly all parts of the State. Nevada is the worst hunting-ground of any of the Western States. Eastward of the Mississippi the hunting of large game is confined to a few moose and fewer panthers, and the black bears, which are only plentiful among the canebrakes of some Southern States, and the wilds of Northern Maine and Michigan. They are, however, frequently found in Eastern Tennessee, Western Pennsylvania, North Carolina, and Virginia, and are sometimes seen in even more thickly settled portions of the country. Panthers are mostly found in the canebrakes of the South—Florida, Texas, Louisiana—and in the wilds of the Alleghanies, Cumberland, and the Blue Ridge Mountains. The moose is only found in the northern portions of Maine and Michigan, and in British territory. Other deer, the black-tailed, and the white-tailed or the red deer, are found throughout the States. Northern Wisconsin, Michigan and New York, Western Pennsylvania, West Virginia, Virginia, Tennessee, and North Carolina are well stocked, and in all the States South and West there is deer-shooting galore in districts remote from the settlements. For antelope the plains of the Southern and Western States are best suited. Northern Texas, Kansas, Colorado, and Montana abound with antelope; but the rapid settling up of the country, especially sheep-farming, is making this game far less plentiful. The bighorn, or Rocky Mountain sheep, is to be found among the highest peaks of the Rockies and the Black Hills. This animal is considered the finest sporting animal in the United States, its habits being similar to the European mouflon. Great care and judgment are required to stalk it successfully. The American hare, or jack-rabbit, is common throughout the East as well as the South and West. A blue hare is found in the Rocky Mountain range. Besides these animals the hunter on the Plains may meet with the cougar, puma, or Mexican lion, which, if he is a good, unerring shot, he may attack. If at all nervous, the hunter had better leave the animal alone, as it is one of the strongest and most dangerous of the carnivora. They are great destroyers of game, and, like wolves, coyotes, foxes, otters, skunks, lynxes, wolverines, panthers, and bears, should never be spared upon a favorable opportunity offering itself. For bear-hunting, dogs are a valuable acquisition, and without them a hunter might often travel the woods for weeks without bringing one to bag. Dogs are likewise of the greatest service in cougar and panther hunting. All bears, including the grizzly, as well as panthers and cougars, will, if possible, get out of the way of man, and will rarely attack unless wounded, or in defense of their young. The grizzly bear is common in California, and often met by hunters after the bighorn in the Rocky Mountains. It is the most formidable of all the bear tribe, and often attains gigantic proportions; one specimen exhibited weighed some 2,000 pounds. It is very tenacious of life, and should be hunted with dogs, a large-bore rifle, and in company. Stories of the "bar-fites" coming from California are doubtless much exaggerated; but no hunter once in the clutches of a dying or wounded grizzly can hope to escape scathless; and no man dare close with the grizzly, as is regularly done in Scandinavia with the common brown bear. According to Caton the American deer are of eight kinds: "The moose, wapiti or elk, woodland caribou, mule-deer, Columbia black-tail, common or Virginia deer, barren-ground caribou, Acapulco deer." Hunters make but four distinctions: moose, wapiti, caribou, and blacktail.



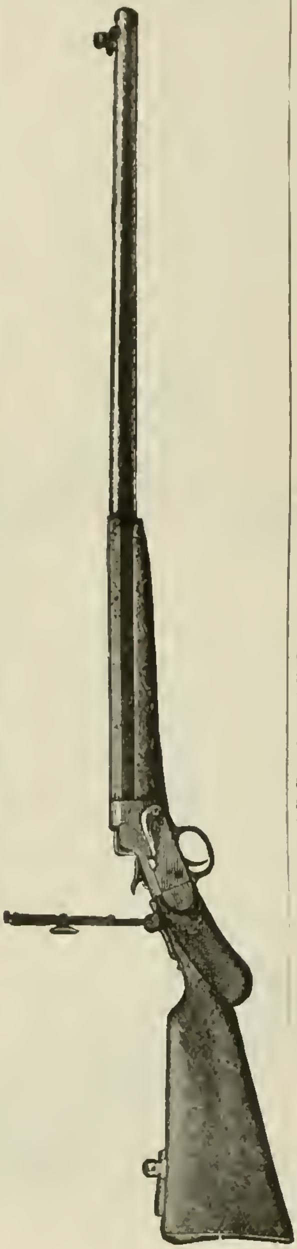
Fox Gun.



Shelton's Auxiliary Rifle.

Game for the shot-gun abounds in every State, the chief game-birds being quail, grouse (five varieties), woodcock, snipe, wild-turkeys and wild-fowl. For *quail-shooting* in the East, Ohio, Indiana, Virginia, North Carolina, Kentucky, Tennessee, Arkansas, Wisconsin, Missouri, Illinois, and Iowa offer the greatest inducements. In California it is not unusual to bag fifty couple in one day's shooting; but there two varieties are known, both differing from the Eastern quail, and called respectively the mountain and val-

Remington Magazine-rifle.

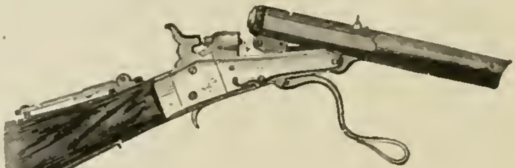


Remington Long range Creedmoor Rifle.

ley quail. The former are by far the more numerous. The favorite haunts of the latter are the valleys and foot-hills of the Sierra Nevada and coast mountain ranges. In size they are about equal to the bob-white or Eastern quail, while the mountain quail is considerably larger, and is to be met with in the more elevated regions.

Grouse-shooting.—The blackcock is generally known by frontiersmen as the sage-cock. The best localities are on the eastern slopes of the Rockies. Fort Fred Steele is said to be the best center for the hunting-grounds of this grouse. The dusky, blue, black, or mountain grouse is found in almost all of the mountainous regions of the West, inhabiting the mountain-slopes from an altitude of 6,000 feet to the snow-line. His close-lying, solitary habits seem to indicate that he belongs to the same branch of the *Tetraonidæ* as the European ptarmigan. He affords no better sport, but is rated an equal delicacy for the table. The sharp-tailed grouse, so commonly known as the willow-grouse, is more common in British territory, but has penetrated from the North to the Canadian and the Missouri Rivers; it is also found in the West. The ruffed grouse is common in most of the States East; it is not often found on the Southern Plains, but it may frequently be met with on the foot-hills in timber, it being essentially a covert bird. A very large number has been killed in the Black Hills and also the surroundings of the Laramie Plains. Pinnated grouse, or prairie-chickens, are most abundant in all parts of Wisconsin, Minnesota, Iowa, Nebraska, Kansas, Missouri, Indian Territory, and Texas. In some parts of Michigan, Illinois, and Indiana they are to be found in limited numbers, but are fast disappearing in all parts of the Eastern States, and, strange to say, appearing in Western States, where a few years ago they were unknown; they may now be found in some parts of Utah and Nevada, and in great numbers up the Arkansas Valley. *Wild-turkeys* afford the best sport of any American birds, being constantly on the alert, and possessing a most acute sense of smell. Full-grown cocks frequently weigh as much as 20 or 25 lbs. They are most abundant in the less inhabited portions of Western Virginia, North Carolina, Tennessee, Missouri, Arkansas, Mississippi, and Texas. A few are met with in Michigan and Illinois, more in some of the Southern States, and very many in some portions of New Mexico and Arizona; but in those States situated north of Kentucky and east of Indiana they are rarely, if ever, met with. A species of *rock-partridge* is said to frequent North-western Texas and South-eastern New Mexico. They weigh about 1 lb., and resemble in shape and plumage the bob-white. Their favorite resort is the grassy tops of limestone mesas; they are found in coveys, and lie well to the dog. *Woodcock shooting* is to be had all along the valley of the Mississippi and its tributaries, from Minnesota to the Gulf of Mexico. This is the choicest woodcock-ground, but bags of ten to twenty birds are frequently made in most all Eastern States, as hereafter detailed. None are to be found in California, or, to the best of our knowledge, in any of the Pacific Coast States. *Jacksnipe* are found in quantities in resorts mentioned for duck-shooting.

The *wild-fowl* of the United States comprise the trumpeter swan; Canada and white-fronted geese, canvas-back, ring-necked, red-headed, scaup, dusky shoveler, gadwell, buffle-headed, wood or summer, pin-tail, and common wild ducks; blue and green-winged teal, the widgeon, and many other birds. Duck or mallard-shooting is found in the marshes in the fall, in the corn-fields in winter, and in timber in the spring. Decoys, sinks, and other devices are common. The wild-rice ponds are the best feeding-ground for ducks in the fall; they are often of wide extent, and, as it is impossible to see over the top of the rice, care is required in "taking the bearings," or the wild-fowler may be lost. A pocket-compass is an article of necessity in wild-fowl shooting. The wild-fowl resorts in the United States are so numerous that we have deemed it more simple to take each



Maynard Improved Rifle.

State separately, and to give the places most recommended not only for wild-fowl, but also of every other kind of shooting, and to include accounts of such local methods of taking the game as we think may prove of use or interest. We *italicise* those places in which game is most plentiful. In the Atlantic States the best places for big bags of wild-fowl are on the

Parker Gun.

Chesapeake Bay and its tributaries, Currituck and Albemarle Sounds, the rice-swamps of South Carolina, and the glades of Florida. To the westward they are found in fewer numbers, until we reach Indiana and Michigan.

In *Maine*, Piscataquis County affords the best of shooting. The *Moosehead Lake* region is the most renowned: here may be found an occasional moose, a few bears, with more caribou, wolves, rabbits, and plenty of small game—ducks, geese, ruffed grouse. Mount Spencer and *Brassua Lake* are the best localities in this region. Sebec Lake in the same County, affords very fair sport at ducks, grouse, and small game.

New Hampshire.—The northern portion of this State affords fair shooting. In Carroll County there are deer and bob-whites; in Cheshire County the lakes about *Keene* abound with ruffed grouse, ducks, jack-rabbits, and small game. In Coos County, the forests near the Connecticut lakes are said to contain moose, deer, otter, mink, and small game. For these lakes go to *Island Pond Station*.

Vermont.—Essex County, in the north-eastern portion of the State, reached from Island Pond Station, is a comparative wilderness, and abounds in small game, but nothing very attractive.

Massachusetts.—There is good wild-fowl shooting on many parts of the coast and the Elizabeth Islands. In 1880 woodcock and quail were plentiful near West Boylston. The best points for wild-fowl are Buzzard's Bay, Chatham, Cotuit Port, Marshpee, and No Man's Land. The State is very thickly populated; and, although the wild-fowl shooting is very good, there is nothing to attract sportsmen from distances.

Rhode Island.—All wild-fowl shooting along the coast is fair. Block Island, Souh Kingston, and Watch Hill are the best resorts.

Connecticut.—In Middlesex County there is good duck-shooting at *Saybrook Point*, and snipe and duck near New Haven; in Litchfield County, good wild-fowl, grouse, quail, and wood-cock shooting near the Twin Lakes at Canaan; and good duck-shooting at Noank, New London County.

New York.—In the northern portion of this State there is a favorite resort of all sportsmen, the Adirondack Wilderness, in extent seventy-five square miles, abounding with small game; its qualities have, however, been overrated, and it is much thronged with sportsmen. It is best approached from Martin's, on the Lower Saranac. Deer-shooting is practiced here in a most unsportsmanlike manner: the bucks being driven into the lakes, and sportsmen following in boats. The deer are often shot within ten feet of the boat, and it is said that in some instances the boatman has had hold of the deer's tail before the the hunter fired. Grouse, snipe, and woodcock are plentiful, and quail and ducks in season. On Long Island there are deer, quail, ducks, and ruffed grouse. The northern portion of the Island is fair ground for shooting, also the Great South, Peconic, and Shinnecock Bays; but all are too easy of access. Good snipe-shooting is to be had near Cayuga Lake, in the Montezuma Marshes. Wild-fowl abound at the Thousand Islands, where there is woodock, quail, and snipe shooting. Alexandria Bay is the chief resort at these Islands. Others are Goose, Eel, and Halstead Bays. The north-eastern part of Ulster County is noted for ruffed grouse.

New Jersey offers few inducements to sportsmen. There is wild-fowl on the sea-coast, and duck and snipe shooting in *Atlantic*, *Ocean*, and Morris Counties.

Pennsylvania.—Many parts of this State abound with game. Near to the Blue or Kittatinny Mountains, the Sideling Hills and the Alleghanies are the best game resorts. In Blair County, Altoona is the point for good deer, partridge and woodcock ground, with an occasional bear. Other good ground lies in Cameron, *Clinton*, McKeon, Pike, and Potter Counties. Wolves and panthers are sometimes met with. Deer are not at all scarce, and ruffed grouse, bob-whites, woodcock, and small game are also found in abundance.

Virginia and West Virginia.—The latter of these two States offers great inducements to the sportsman. The Alleghany and Cumberland Mountains cover innumerable deer and a few panthers and bears. Smyth County, in Virginia, and Morgan and Tucker Counties, in West Virginia, are noted for sport. *Hoys Wilderness* and the Blackwater region, in the latter County, are plentifully stocked. Oakland Station, on the B. and O. R. R., is a good starting-point. Sport in West Virginia comprises black-tailed and other deer, wild turkeys, ruffed grouse, woodcock, quail, and other small game. On the coast of Virginia is Chesapeake Bay, the famous wild-fowl resort; Cobb's Island, and the mouths of the Rappahannock, Mattapony and Pamunkey Rivers, are also visited by large numbers of wild-fowl.

North and South Carolina.—These States are practically destitute of large game, and offer no inducement for the sportsman to leave the better ground in West Virginia. The coast of North Carolina is thronged with wild-fowl. *Beaufort*, in Carteret County, *Newberne*, in Craven County, and Carrituck County, especially near Knott's Island, are the best quarters; in the first and last canvas-back ducks are met with, and in all black and other ducks, geese, snipe, etc. South Carolina has similar wild-fowl, and a few deer and foxes inland.

Georgia.—The sea-coast is similar to that of the two preceding States. Wild-fowl are quite numerous; and in the County of Bartow there is turkey and quail shooting.

Florida is at present a sportman's paradise Wild-fowl are particularly numerous, especially south of Lake Okeechobee. The other game consists of panthers, bear, red and Virginia deer, jackrabbits, turkeys, quail, woodcock, and snipe, besides foxes, raccoons, and other minor game in abundance and variety. The St. John's River is a good point, about the center of the peninsula. The *Indian River Country* up the St. John's River abounds with game. Titusville and Mellonville are good places to start from, but a cruise of some weeks round the south and the western parts of the peninsula is most successful for all shooting. The snipe and duck-shooting is not to be excelled. Hernando County and Homosassa are very good districts, and fairly easy of access. The southwestern and southern part of the peninsula is, however, the best; to the southwest of Lake Okeechobee to Charlotte Harbor, and along the Calooeahachee River, turkey and deer are unusually numerous. In the western part of the State good shooting may be had from Pensacola, consisting of bear, deer and turkey. In the Grand Lagoon there are myriads of wild-fowl.

Alabama is fairly stocked with game: the deer and turkey in abundance, and wild ducks, geese, bears, and foxes in goodly numbers. Choctaw County, in the western part of the State, is good ground for deer, bear, opossums, turkeys, etc. Clarke County has the same, and along the Alabama River there is plenty of wild-fowl. Lauderdale County is also very good, and the muscle-shoals on the Tennessee River swarm with wild-fowl. In the northern portion of the State, at the foot of the Alleghanies, game of all kinds is plentiful.

Mississippi is abundantly stocked with wild-fowl in the western portions. The forests are fairly stocked with turkeys, deer, bears, and small game. Corinth, in Alcorn County, Coldwater, in DeSoto County, Panola, in Panola County, and Hudson and *Austin*, in Tunica County, are near good grounds; wild-fowl are plentiful down the Mississippi River and in the St. Francis Lakes.

Tennessee is fairly stocked with deer, opossums, foxes, wild-fowl, small game, and a few bears and turkeys. The famous Reelfoot Lake is in this State, near Tiptonville. The lake is thirty miles long, and from three to ten wide; and besides excellent duck, snipe, and wild-fowl shooting there is good *bass-fishing*.

Davis Breech-loader.

Kentucky is only famous for its fox-hunting in the English style. There is a fair quantity of small game and ducks, etc., down the Ohio, Tennessee, Cumberland, and Mississippi Rivers.

Illinois is a similar State, but abounding with wild-fowl. We will mention a few good grounds. They are: Henry, Chillicothe, Spring Lake, Liverpool, Havana, Beardstown, and Naples, on the Illinois River; Annawan, near the Winnebago Swamps; on the Calumet River near Chicago; near Quincy; *New Boston;* Grand Tower; near the mouth of the Big Muddy River; and at numerous other places, particularly along the Mississippi River. In Du Page County there is also very fair pinnated-grouse, quail, woodcock, bob-white, and similar shooting.

Indiana has but little large game, but pinnated-grouse, rabbits, wild-fowl, and small game are abundant. Wayne is near good grouse, quail, and fair deer ground. Blackford, Knox, and Laporte Counties are also well stocked with ruffed grouse, quail, snipe, woodcock, etc. Vincennes and Montpelier are first-rate headquarters for the sportsman. For wild-fowl, English, Beaver, and Wolf Lakes, the swamps bordering on Michigan, the Calumet, etc., have been strongly recommended.

Ohio.—This is not an attractive State for a sportsman, and he must for the most part be content with wild-fowl and small game, such as quail and snipe. The best shooting is on the shores of Lake Erie, near Sandusky City or Cleveland,

Michigan is one of the finest resorts accessible to the general sportsman. Northern Michigan is best for sport. Near *Negaunee* there is fair deer shooting, and the whole country beyond Escanaba is fairly stocked with deer, fur-bearing animals, and also small game. In the northern and more inaccessible part of Michigan both bear and deer are plentiful, and good sport is to be had. Good wild-fowl shooting is to be had almost anywhere along the borders of the great lakes, and especially on the *St. Clair Flats*, near Detroit. There are many islands in the lakes famous for shooting, notably Royal Island, St. Ignace, and the Apostle Islands (twenty-seven in number).

Wisconsin is fairly stocked with large game, and has wild-fowl and small game in abundance. For wild-fowl the best resorts are Horicon, *Puckawa*, and *Koshkonong* Lakes, also Lake Winneconne, and the numerous shallow inlets and bays along Lake Michigan, and the lowlands of the Chippewa, St. Croix, and Mississippi Rivers. For large game the north and the northeastern districts are likely to prove the most successful.

Minnesota.—This Land of Lakes, undoubtedly the fisherman's paradise, is very fairly stocked with large game, and abounds with wild-fowl, fur-bearing animals, and small game. The Northern Pacific Railway runs through some of the best hunting-grounds of North America. Duluth is a good place to start from; Detroit and Fargo, on the North Red River, are excellent starting-points farther west. The Red Lake region and Fort Pembina are recommended for large game; while for duck-shooting one cannot go wrong, there being more suitable feeding-ground for water-fowl in this State, probably, than in any other State in the Union. There are likewise grouse, woodcock, and snipe in abundance.

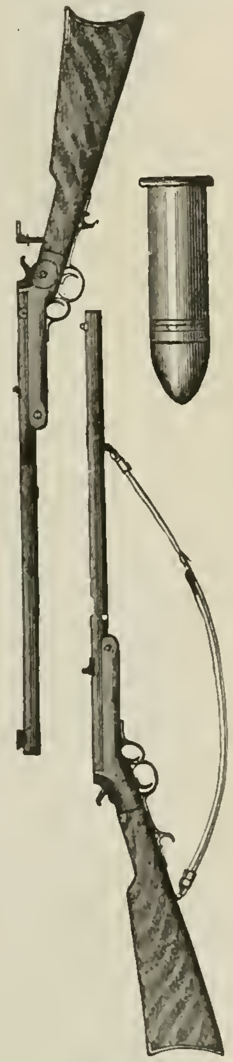
Iowa is not celebrated for large game, but is excellent for its pinnated-grouse and duck-shooting. For ducks and wild-fowl, *Comanche*, on the Mississippi, is a good center; but all along that river, and the Missouri, and the hundreds of small, muddy-bottomed streams and ponds throughout the State, the sportsman can scarcely fail to make a large bag.

Missouri.—The southeastern part of this State is excellent wild-fowl ground. In some of the forests north and west there is a fair sprinkling of deer and a few turkeys. For wild-fowl the Mississippi offers the best ground, and also the *Little*, Black, and *St. Francis* Rivers, and all about the sunken lands near New Madrid. These grounds extend into Arkansas, and along the Castor, St. Francis, Black, White, Little Red, Arkansas, and Washita Rivers, and at other numerous lakes along the Mississippi, as the Big, Swan, and Cottonwood Lakes. Farther north there is good shooting near Hannibal and Lagrange.

Arkansas is well supplied with large and small game; but to reap the full benefit it is requisite to camp out. Start from *Texarkana* for bear, deer, wild turkey, and grouse-shooting; or *Forest City*, forty miles below Memphis, for large game and innumerable wild-fowl. Small game is general throughout the State.

Louisiana is very fully stocked with game. The

Smith and Wesson's Repeating-rifle.



F. Wesson's Breech-loading Rifle.

north is well timbered, and intersected with numerous *bayous*. In the south, the many bays, lagoons, marshes, and canebrakes swarm with wild-fowl and alligators. For wild-fowl the mouths of the Mississippi are without parallel. In the canebrakes are many bears and turkeys, both of which are hunted by dogs. The north and center abound with deer, turkeys, and rabbits, while bears are numerous, and, in the season, snipe, woodcock, and quail in very large numbers. Alexandria is strongly recommended for its shooting.

Texas.—This State, with an area of nearly 240,000 square miles, contains some of the finest hunting-grounds in the world, but, for the most part, difficult of access. The coast all along, and especially about Galveston and the mouth of the Rio Grande del Norte, abounds with various kinds of wild-fowl. Houston is a much-visited center for deer, grouse, and quail-shooting. Bears, deer, and like game are general in the wooded parts of the State. Northern Texas is the home of the buffalo, but the ground is best approached from Kansas. This and Western Texas are very well

English Side-action, Bar-locks.

stocked with all kinds of game found on the Plains; but owing to the numerous Indians, and the still more numerous white thieves, none but a large and well-escorted party dare cross the Llano Estacado or the Rio Pecos. The most available ground from the south lies to the west of San Antonio. In Texas "fire-hunting" is practiced for deer, and antelope are in some districts very numerous.

Indian Territory abounds with game of every description. It is, however, against the law of the United States for any white man to kill game on Indian Reservations.

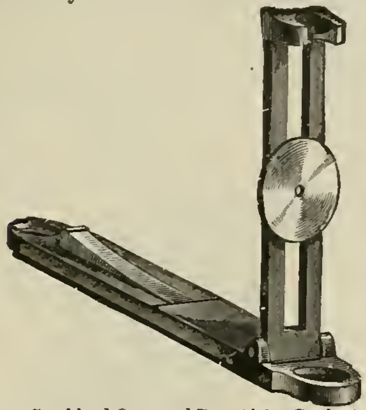
New Mexico likewise abounds with game, but is infested with robbers and difficult of access. Excursions may be made from the advanced posts on the Atchison, Topeka, and Santa Fe Railway with fair

Lefaucheux System.

success, but the toil in most cases would exceed the sport.

Arizona is well stocked with game and water-fowl. Yuma is now easily reached by rail from California. It is a mountainous country, and up to the present is chiefly occupied by miners. The next few years will doubtless open up this country wonderfully, when it will be the finest hunting-ground west of the Rockies. Camping-out in large companies will, however, be necessary for several years, and the best districts are most difficult and dangerous to get access to.

California abounds with many varieties of game. Nevada County is one of the most accessible for game,



Rear Combined Open and Peep Sight, Graduated.

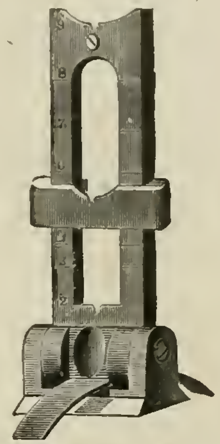
and the regions of Lakes Tahoe and Independence (reached from Emigrant Gap Station, U. P. Railway) are famous for bear (grizzly) and large game. The

Remington Sporting and Target Rifle.

Oregon Branch of the C. P. Railway runs through a fine shooting-region. The San Joaquin Valley is also good ground, and from Los Angeles may be reached the *Big Pine Mountains*, where game of all kinds is very numerous. There is also a good district near *Humboldt Bay*, in the north, reached by steamer from San Francisco. The peninsula of Lower California is too wild and remote a region to offer special inducements to sportsmen. In many parts of California wild-fowl are so numerous as to necessitate the posting of guards about newly sown grain-fields to protect the crops. The resorts are very numerous, some of the most celebrated being the San Joaquin and Sacramento Rivers, the mouth of Feather River, Cash Creek, Tomales, Suisun, Sonoma, and San Francisco Bays, Tulare and Clear Lakes.

Nevada is not an attractive country to the sportsman, being for the greater part desert land. The best game resorts lie within an easy distance of the C. P. Railway. The Humboldt range is fairly stocked with game; the Sierra Nevada is a favorite resort, and reached by stage from Reno. *Washoe County* is the best stocked: good starting-places and headquarters being Verdi, Washoe City, and Wadsworth. Winnemucca, Wells, Carlin, and Elko are in the midst of a good antelope, deer, grouse, and duck country. At the first there is also the chance of blackcock and bighorn.

Utah does not abound with large game, but is fairly stocked with antelope, blackcock, and other grouse;



Common Musket Rear-sight.

and on the Great Salt Lake there are plenty of geese, ducks, swans, and wild-fowl. Ogden has fair sport in its neighborhood.

Colorado is and is not recommended for large game shooting. It seems that in Colorado, game, although not scarce, is by no means so plentiful as in Wyoming and Montana. Near Denver there are grouse, quail, geese, and turkeys. For larger game the North and Middle Parks have been recommended. Manitou, Estes Park, and Central City are in the neighborhood of antelope, bear, deer, and a little wapiti shooting. There are several varieties of ducks and geese, but wild-fowl and small game are not so abundant as in other States.

Kansas was once the sportsman's paradise, but is so rapidly settling up that it is not safe to recommend it for large game. There are, or were, plenty of antelope, but the inclosure of the land for sheep-farms has greatly interfered with the habits of this retiring animal. Some of the best shooting may be had from the Stations on the Kansas Pacific and the Atchison, Topeka and Santa Fe Railways. Hutchinson, on the latter, is a good starting-place for the antelope country. Fort Dodge is also in a good country. Turkeys are not scarce, and grouse and quail may be shot anywhere west of Salina.

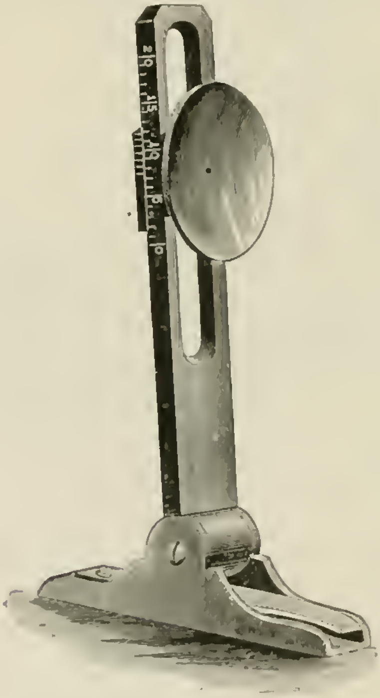
Nebraska is fairly stocked with elk, deer, antelope, turkeys, and goodly numbers of grouse, rabbits, and wild-fowl. For elk the Loup Fork of the Platte River is said to be very good; other Stations are in Dawson

County. Near the borders of Wyoming, deer and antelope are fairly plentiful. Antelope and *Ogalalla* Stations have good ground in their vicinity. For wild-fowl the Elkhorn Valley is a good district, but they are pretty numerous throughout the State.

Wyoming is, as we have already mentioned, the best locality for large game in the States; wapiti, buffalo, deer, antelope, bears, moose, and mountain sheep being numerous in some districts. The Laramie Plains, the Fremont Peak, and especially the Bighorn Mountains, Wind River and Yellowstone Valley regions are, it is reported, alive with game. Buffalo are found chiefly in the northern section; bears chiefly in the Black Hills; antelope, deer, and small game everywhere.

Dakota.—This Territory contains the larger portion of the northern buffalo range; it is sparsely settled, and contains large and numerous Indian Reservations. Bismarck, on the Northern Pacific Railway, is a good starting-point. The ground may be reached from Rawlins on the U. P. Railway. There is game in abundance, but camping out is necessary.

Montana.—This Territory also includes part of the buffalo range. Game is in great abundance throughout the Territory. Rawlins or Bismarck may be made starting-points. Helena is a good center to work the



Vernier Peep Sight.

Missouri Valley. The finest natural scenery and sport are to be found in this Territory, but at present it is difficult of access.

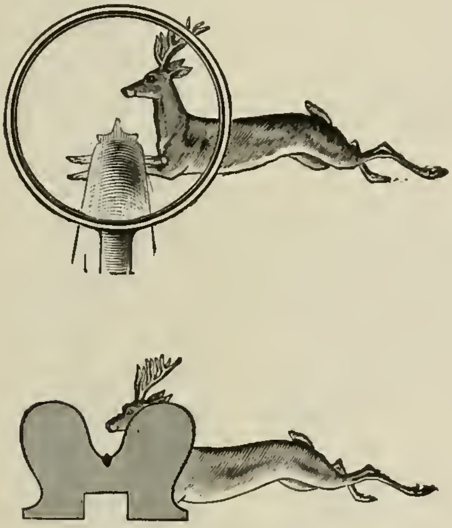
Idaho.—This mountainous Territory is but little known. For good sport it is second only to Montana. Buffalo will not be found in quantities, if at all; but there are plenty of deer, wapiti, bears, and a few panthers and antelope; wolves, foxes, and fur-bearers are in any quantity. Its inaccessibility makes it more the paradise of the trapper than that of the sportsman. Sportsmen usually start from Kelton Station, on the U. P. Railway, and fit out at Idaho City or at Boise. The Snake River region is one of the best and most accessible. Consult *Farrow's Mountain Scouting*, New York, 1881.

Oregon is a fine field for sportsmen, but difficult of access. In most of the valleys large numbers of elk and three other varieties of deer roam almost unmolested. The Yaquina Valley and Cascade Mountains are the finest regions; antelope are very numerous in the latter; quail and grouse abound in great numbers, whilst there are myriads of geese, ducks, and other wild-fowl. The country is rich in the common fur-animals, and also silver foxes, and pumas or cougars.

Washington Territory also abounds in large game, fur-bearing animals, and all kinds of feathered game. The only difficulty is the trouble of getting there, and then getting safely back to the settlements with the spoil. Vancouver is a good place from which to fit out.

Remington Heavy Model Double-gun.

Alaska.—This very recently acquired territory of the United States is in regular communication with San Francisco by steamer. It is a wild, boggy country, rich in fur-bearing animals, notably the fur-seal; and fish, bears, and deer are fairly plentiful; but it can never be recommended as a sporting locality, as it rains almost incessantly nine months out of every twelve, and its inhabitants are among the most degraded of Aborigines. Of the unexplored country inland it is conjectured much must be valuable and habitable, but near the coast the average rainfall is 96 inches yearly. The various military and sporting-arms at present manufactured and possessing great merit are illustrated and described at length under

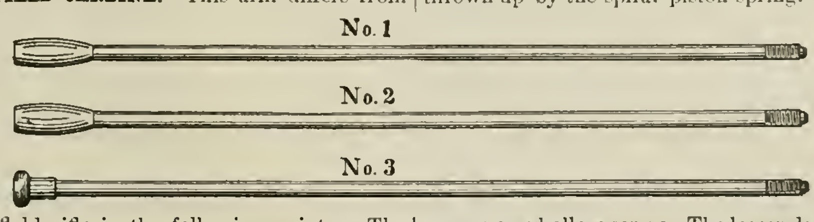


Lyman Sight.

the irrespective titles throughout this work. These descriptions, together with the illustrations given in this article, will enable the reader to readily comprehend the merits and distinguishing features of the different arms and systems. See *Baker Gun*, *Breech-loader*, *Parker Gun*, *Remington Rifle*, *Small-arms*, *Spencer-Roper Small-arms*, and *Springfield Rifle*.

SPREAD-EAGLE.—In Heraldry, an eagle, or the figure of an eagle, with its wings elevated and its legs extended; often met as a device in Heraldry, upon military ornaments, and the like.

SPRINGFIELD CARBINE.—This arm differs from



the Springfield rifle in the following points:—The barrel is 22 inches long; the thickness of metal at the breech and at the muzzle is not changed. It has a half stock; but one band, which has a hook-swivel for stacking; and has no ramrod. It is slung by a ring which plays on a bar attached to the left side of the stock, opposite to the lock. The front sight is removable, so that it can be replaced in case of wear; it is secured to the stud by a pin; the base of the rear sight is graduated to 500 yards, and the leaf to 1200 yards. The tumbler has an additional notch, the *safety (locking) notch*, on which to carry the hammer when the breech is closed, as it then overlies the firing-pin-guard and prevents the block from opening. The drawing represents the three parts of a *jointed ramrod*, which is intended to be used for cleaning the carbine, and, with the aid of the headless shell-extractor, removing burst cartridge-shells. No. 1 and No 2 joints are alike, and have a male screw at one end and a female screw at the other. The third joint has a head at one end and a male screw at the other. To prevent cutting away too much of the stock, the receptacle for the ramrod is formed of three small holes instead of one large hole of sufficent diameter to contain three joints. The total length of the arm is 41.3 inches, and its weight 6.87 lbs. See *Small-arms* and *Springfield Rifle*.

SPRINGFIELD-JONES MAGAZINE-GUN.—This arm is the well-known United States Service Springfield rifle, with several alterations and additions as follows: The firing-pin guard has been removed, and the outer end of the thumb-piece slotted in the direction of the axis of the barrel. This slot receives one end of a lever, which is secured by a pin about which it may turn in a direction toward the under side of the thumb-piece. A flat spring lying in a groove in the upper surface of the thumb-piece—to which it is secured by a screw, bearing on a flat and against a shoulder on the upper extremity of the lever, returns it to position and limits its motion in the reverse direction. An arm, securely attached by the tumbler-screw to the hammer, on which a shoulder has been cut to prevent rotation, bears against the lower end of the lever and raises the thumb-piece when the hammer is brought to the half or full-cock, and thus unlocks the breech-block. A piston, pivoted to the left side of the breech-block, is surrounded by a spiral spring, the rear end of which finds a bearing on a metal plate attached to the left hand side of the stock, the front of which is bent at right angles to the receiver. A hole through the plate admits the rear end of the piston. When the breech-block is unlocked by the cocking of the hammer the spiral spring throws up the block and extracts the empty shell. The well of the receiver has been deepened at the rear, and the lower part of the breech-pin cut away to form a channel through which the cartridges may feed from the magazine, which is in the butt-stock. The ejector-stud has been replaced by a movable one, which is depressed to the bottom of the receiver at the instant the cartridge leaves the magazine. This stud is pivoted at its rear to a block just above the trigger-mortise. A short distance in advance of its pivot it passes through a pin, which bends about the magazine-tube and enters the tang-screw hole above. The magazine proper consists simply of the familiar-tube, spiral spring, and piston, and requires no comment. The operation of the magazine system is as follows: The piece having been cocked and the breech-block being thrown up by the spiral piston spring, the operator presses on a hollow screw. The lower detent then descends, and the first cartridge, under the pressure of the magazine spring, slips by and enters the chamber. As the lower detent is depressed the upper one also descends, checking the second cartridge. When the pressure on the hollow screw is relieved a spring returns the detents to the original positions: the second cartridge then passes the upper and is checked by the lower detent. As a single-loader the piece is operated in the ordinary manner, the lower detent serving as a cut-off to the magazine. As a magazine-gun three motions are necessary to operate it, viz., opened, closed, fired. As a single-loader four distinct motions are necessary, viz., opened, loaded, closed, fired. This gun carries five cartridges in the magazine and one in the chamber. See *Magazine-gun*.

SPRINGFIELD RIFLE.—The small-arms employed in the United States Service are the *rifle* for infantry, and a *carbine* and *revolver* for all mounted soldiers. After a series of exhaustive experiments and a full trial, the *Springfield* system was adopted for the rifle and carbine, with a caliber of 0.45-inch. The barrel of the rifle is of low steel. Its length is 32.6 inches;

the thickness of metal at the breech is 0.297-inch; from this point it gradually diminishes (the exterior element being a slightly re-entering curve) to the muzzle, where it is 0.14″-inch. The rifling consists of three plain concentric grooves, 0.235 inch wide, equal in width to the lands, 0.005-inch deep, with a uniform twist of one turn in twenty-two inches. The grooves start from the center of the throat, the bottom of them is therefore not continuous with the surface of the chamber. The chamber extends 2″.155 from the base of the bore, and is made slightly conical so as to facilitate the withdrawal of the cartridge-case. The contraction of the chamber, caused by the difference in diameter of the cartridge-shell and of the bullet, is known as the *throat*. At the mouth of the chamber a *counter-bore* is cut for the head of the cartridge, and a slot is cut in the barrel for the reception of the ejector. Fig. 1 represents a section—nine-tenths size—of the breech-loading system, by a vertical plane passing through the axis of the receiver, with the several parts projected thereon, and showing their relative position.

A, is the bottom of the receiver; B, the *barrel*, with screw-thread; C, the *breech-screw*, with its circular recess to receive the cam-latch; E, the *hinge-pin* around which the *breech-block* (D) turns; F, the *cam-latch*, that locks the breech-block in place; G, the *cam-latch spring* to press the cam-latch into the recess; H, the *firing-pin*, which transmits the blow of the hammer to the priming of the cartridge; I, the *firing-pin spring* (no longer used), to press the firing-pin back whenever the hammer is raised; J, the *extractor*, to withdraw the empty cartridge-shell after firing. K, is the *ejector-spring spindle*. When the breech-block is closed, the point of the ejector-spring spindle presses against the extractor above the position of the axis of the hinge-block, and no motion takes place. When the breech-block is raised so as to press against the *lug* (M) of the extractor, the point (J) moves slowly to the rear, withdrawing the shell—the upper part of the extractor meanwhile compressing the ejector-spring. When the direction of the pressure of the spring passes below the center of the hinge, the extractor moves rapidly and throws the shell clear of the receiver. L is the *ejector-stud*, which serves to deflect the shell upward and thereby clear the *well* of the receiver, as seen in the drawing.

Fig. 2 represents a side-view of the breech-block; full size. A is the *hinge*; B is the *face* of the block; C is the *arch* (now filled in to give the block greater stiffness), D is the *comb*; E is the *breech-block cap recess* and *screw-hole*; F is the *cam-latch recess* and *cam-shaft hole*, the latter being a loose fit for the cam-shaft which passes through it; J is the *hammer-guard*; K is the *hinge-pin hole*, which is slightly elongated horizontally.

When the piece is fired, the horizontal elongation of the hinge-pin hole permits the breech-block to slide bodily backward under the influence of the discharge. By this means, and by the enlargement of the cam-shaft hole, a direct bearing is obtained by the interposition of the *cam*, which, abutting against the front surface of its recess in the block at one end transfers the recoil directly to its recess in the face of the breech-screw at the other end, wthout subjecting the shaft on which it turns to any strain. The bearing of the cam is above the center of the breech-screw, and its resistance consequently tends to press the rear end of the breech-block downward and forward.

The tendency of the front of the block toward lifting, in case of an escape of the gas from the cartridge, is prevented by the engagement of its forward end under the ears or hinges of the receiver, as shown in the drawing.

The *hammer-guard* on the breech-block is intended to prevent the accidental striking of the firing-pin by

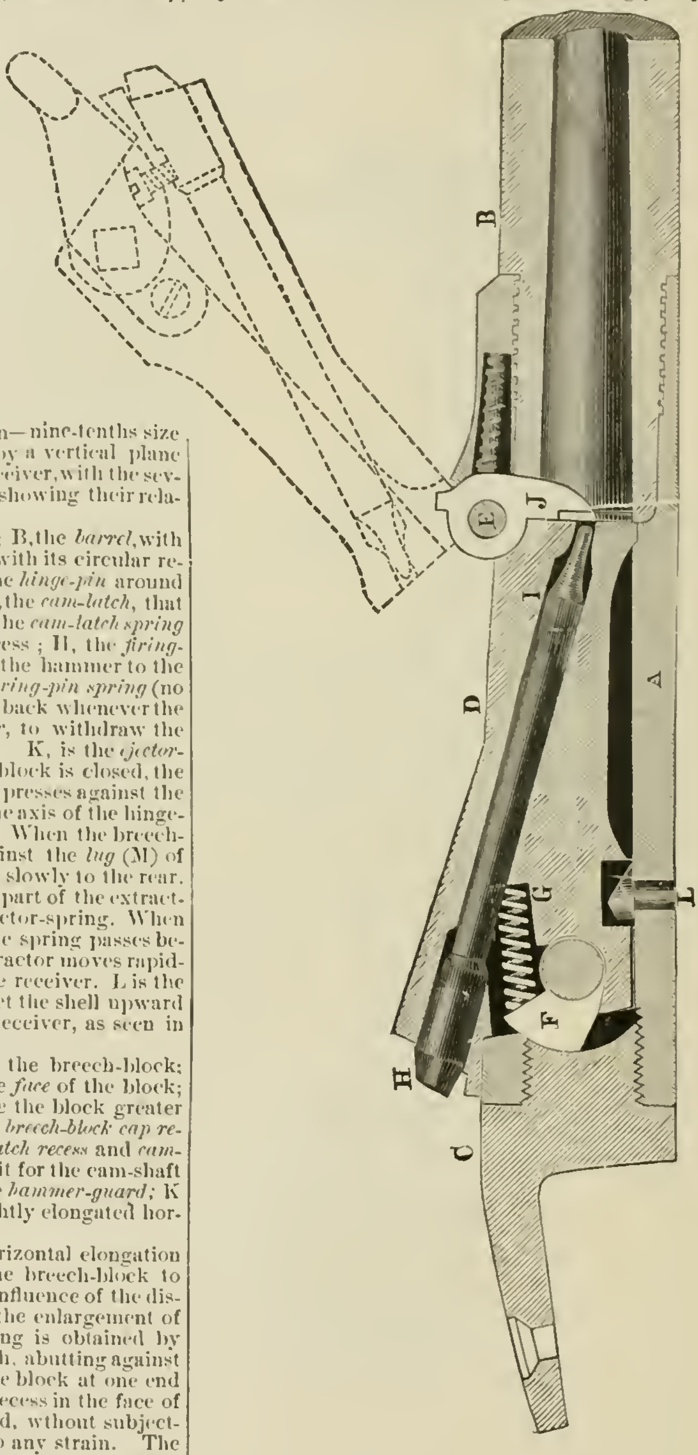


Fig. 1.

the hammer when by the act of closing the piece, the firing-guard is thrown up. Neither the hammer-guard nor the firing-pin guard is intended to hold down the breech-block by catching under the hammer. The tendency of the block to rise is felt, if at all, at the forward end. The *breech-screw* closes the rear of the receiver; it is composed of the *body*, *tenon*, which fits into a mortise in the stock and prevents the barrel from turning in its bed, and the *tang*, which assists in securing the receiver and barrel to the stock, and for this purpose is pierced with a hole for the *tang-screw*, which also passes through the stock and screws into the guard-plate.

Fig. 3 represents the firing-pin, full size. It is kept in place by the firing-pin screw, which projects into the *slot* (A) on its under side. The position of this screw is shown in the broken lines representing the raised position of the breech-block (see Fig. 1).

3d. The highest portion of the base and the lowest graduation-mark of the leaf correspond to the same range, thereby obviating a blank space in the old sight.

4th. For greater convenience in manipulating the sight, the graduation-marks are placed on the left-hand side of the base.

5th. The shape and size of the rifle and carbine-sights are the same; they differ only in the position of the graduation-marks, and are distinguished by the letters R and C stamped on the respective bases.

The construction of the inside of the lock is shown, half-size, in Fig. 6. The *tumbler* (B) passes from the inside through the lock-plate, and is connected

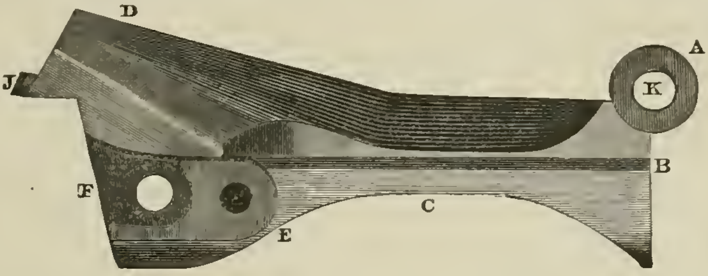

Fig. 2.

Fig. 4 represents front and side-views of the front-sight and bayonet-stud, three-fourths size, which is brazed on to the barrel. A is the *sight;* B, the *stud*, by which the bayonet is fastened to the barrel.

Fig. 5 represents a side and rear-view of the rear-sight, full size. It consists of the *base* (A), the *leaf* (B), and the *slide* (C). The base is fastened to the barrel by two screws. To prevent the unnecessary removal of the base, these screws are made without any slit in the head. The leaf is hinged to the base by means of a pin. It is held firmly when either closed or raised by the rear-sight base-spring. The slide (C) moves easily on the leaf to which it is made friction-tight by the rear-sight slide-spring. For distances up to 500 yards the graduation-marks are stamped upon the side of the base, and the leaf is turned down so that the slide may rest upon the mark which gives the desired range. For distances greater than 500 yards the leaf stands upright, and the slide is adjusted so that its top edge will indicate the desired number.

D represents a cross-section of the *base* through the front screw-hole, while the *dovetail mortise* indicates the manner in which the base-spring is fastened.

Fig. 4.

The rear-sight here represented was adopted in 1877. It differs from the original sight for the .45″ caliber rifle and carbine in the following particulars, viz:

1st. The shape of the sighting-notch is more open, or like a "buck-horn" sight, and its center is more clearly defined by a slight vertical cut.

2d. The steps are removed from the base, and the number of graduations on the leaf are increased so as to give ranges between each 100 yards.

by the square and tumbler-screw to the *hammer* (A). The small end of the tumbler is held in place by the *bridle* (C), which is fastened to the plate by the *bridle-screw* (D). The *sear* (E) is held in place by the *sear-screw* (F), which also passes through the long arm of the bridle. The *sear-spring* (G) keeps the sear in the tumbler-notch, and is held to the lock-plate by the *sear-spring screw* (H). The *main-spring* (I) abuts against the bolster, and is connected to the tumbler by the *swivel* (J). K K are the side-screw holes.

Fig. 7 represents the lock-plate, half-size, showing the position of the holes, etc. A is the cam-latch notch; B, the *bolster;* C, main-spring notch; D, mortise for main-spring pivot: E, hole for arbor of the

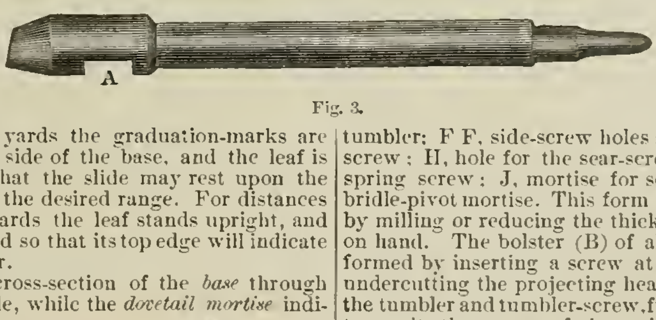

Fig. 3.

tumbler; F F, side-screw holes; G, hole for bridle-screw; H, hole for the sear-screw; I, hole for sear-spring screw; J, mortise for sear-spring stud; K, bridle-pivot mortise. This form of lock-plate is made by milling or reducing the thickness of the old ones on hand. The bolster (B) of all *new* lock-plates is formed by inserting a screw at the same point and undercutting the projecting head. Fig. 8 represents the tumbler and tumbler-screw, full size. The tumbler transmits the power of the main-spring to the hammer. A is the *body*; B is the *arbor*, which passes through the lock-plate. The part of the arbor exterior to the lock plate is called the *square* (C). It fits into the tumbler-hole of the hammer; in the end of the arbor is a hole (F) into which the tumbler-screw (I) is screwed, fastening the hammer to the tumbler. The *pivot* (D) supports the other end of the tumbler in the bridle. At the front end of the tumbler is a slot into which the main-spring swivel fits, and is connected with a tumbler by a rivet passing through the *hole* (E). On the under side are the *safety-notch* (K), the *half-cock notch* (H), and the *cock-notch* (G), into which the sear catches when the hammer is drawn back to safety, half, and full-cock positions, respectively. Fig. 9 represents a side and bottom-view, half size, of the guard-plate which supports the trigger and strengthens the weak part of the stock. A is the *strap;* B B, the *bolsters;* C C, the *trigger-stud* and *mortise*. D D, holes for *guard-bow*. E E, holes for *wood-screws;* F, hole for *trigger-*

screw; G, hole for *tang-screw.* The trigger is attached to the guard-plate by a screw about which it moves The pressure exerted by the upper part of the blade of the trigger against the tang of the sear, disengages the nose of the sear from the notch of the tumbler, relieves the main-spring, and brings down the hammer with force upon the firing-pin. The ramrod is divided into the *head,* slotted and grooved for the wiping rag; the *notch* which catches against the ramrod-stop and holds the rod in place; and the *cannelures,* for the purpose of giving the fingers a firm grip in cleaning the piece. All the metallic parts of the rifle are browned, except those which are case-hardened; these are blackened. The total length of the arm, without bayonet, is 51.9 inches and its weight 8.38 lbs The trigger is adjusted to pull off at from 6 to 8 lbs.

The model of the Springfield rifle for officers has a

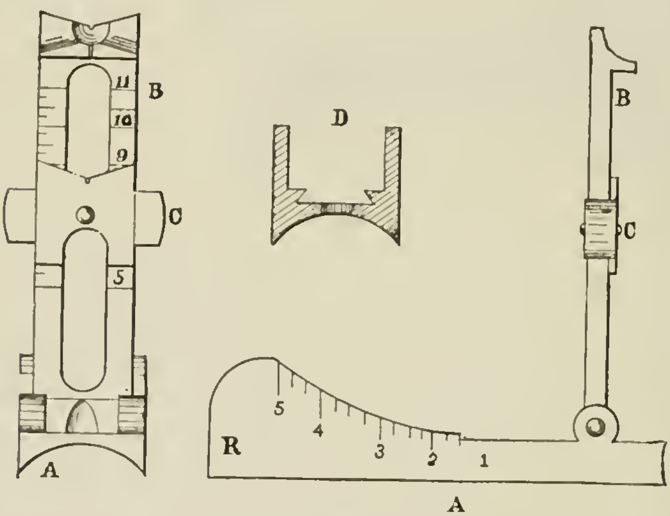

Fig. 5. Rear Sight.

weight of 8 pounds, varying with the density of the wood used in the stock. The length of the barrel is 26 inches. The stock is checked "fore and aft" the breech, and is tipped with white metal. The rifle has a plain "buck-horn" sight on the barrel, graduated like the service-sight, and also has peep and globe-sights. The globe-sight can be folded down on the barrel when its pin becomes an open front-sight, which is used with the buck-horn sight. The peep has a lateral as well as a vertical motion, and by turning the screw and loosening it, may be adjusted to counteract any deviation to the right or left. When at the bottom of the slide, the peep is adjusted for a range of 50 yards; when at the top, it is adjusted for a range of 1,100 yards. The peep sight may be folded down on the barrel either forward or backward. In the former position, the peep should be pushed to the bottom of the slide, or the hammer—in being cocked—will strike it. The globe-sight is distant from the buck-horn and peep sights just 20.8 inches and 32.75 inches, respectively. The rifle has a "single-set" trigger. When *set,* it is a hair-trigger; when *unset,* it is the ordinary service-trigger, requiring a pull of about four pounds. The trigger should be set by pushing it forward with the thumb, *after cocking the hammer*—never *before.* A "fly" in the tumbler carries the sear over the half-cock notch when the trigger is set. The ramrod is of wood, both ends being ferruled with brass, nickel-plated. The ferrule on the smaller end has a slot for the admission of a wiping-rag; that on the larger end has a milled head for convenience in drawing out the rod. A small pin in the under side of the barrel, entering a hole in the rod just below this milled head, prevents the rod from slipping out of place. The breech-block, receiver, hammer, lock, band, and the heel of the butt-plate are all plainly engraved. The description and dimensions of the parts of the rifle, other than those above mentioned, are the same as those of the corresponding parts of the Springfield rifle, caliber .45". All of these rifles made after April, 1877, have a detachable pistol-grip handle; and the peep sight, as well as the buck-horn sight, are graduated with *approximate* accuracy for the Frankford rifle-cartridge. The lowest elevation on both sights corresponds to 50 yards range.

The following directions for using the Springfield breech-loading system should be carefully observed: 1. Raise the breech-block by pressing against the thumb-piece upward and forward till the breech-block rests on the receiver; if there be an empty shell in the chamber, it will be loosened from its place by the extractor and thrown out by the ejector-spring. Place the cartridge in the chamber with the thumb and two forefingers; then seize the thumb-piece with the thumb and forefinger—the other fingers in front of the breech-block—and close it down; the breech-block will press the cartridge home. The cam-latch will spring into its place and lock it; but, to make sure of this, it may be well that the soldier acquire the habit of pressing the thumb on the thumb-piece as the hand is withdrawn. 2. The surface of the cam-latch and that of the recess in the breech-screw should be kept free from dust and rust, to prevent sticking in opening the breech after each discharge; these surfaces should be well oiled occasionally and *then wiped dry.* The force of the discharge is exerted against both ends of the body of the cam-latch; and to insure this, the arbor and body of the cam-latch shaft are made purposely to fit their bearings loosely. 3. The hammer should habitually be carried at the safety-notch, and great care should be taken that the motion of the firing-pin be not obstructed by dust or rust. 4. Should the extractor cut through the rim of the shell and thereby fail to withdraw it, draw the ramrod and drive the shell out. 5. The chamber should be kept clean, and great care should be observed to prevent cartridges fouled with dirt, and particularly sand, from being inserted or discharged in the piece, as the expansion of the shell presses the sand into the metal

Fig. 6.

and mars the surface of the chamber, and thus causes the shell to stick. Care should also be taken in cleaning the chamber to wipe away all *free oil,* as its presence is found to lead to a pulling apart of the cartridge-shell somewhere between its head and the seat of the bullet. The shell of an exploded cartridge should not be allowed to remain in the chamber any length of time for fear it may adhere by corrosion. 6. Should the thumb-piece interfere with the head of the hammer in raising the breech-block, it is probable that either the tumbler or sear-screw is too loose or broken. 7. It should be borne in mind that the ejector, cam-latch, and firing-pin springs are *convenient* rather than *essential*; and that the breaking of one or all of them does not necessarily unfit the piece for further service. The extractor alone will loosen

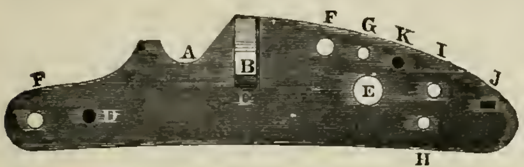

Fig. 7.

the shell so that it can be easily removed by the fore-finger, or it will fall to the ground if the muzzle be elevated when the breech is open. 8. Should the head of a cartridge come off in the act of firing—*a*. Insert the headless-shell extractor (spring-point foremost) into the rear end of the cartridge-shell, and push it forward with the thumb until the rear end of the extractor is flush with the end of the barrel. Turn the back of the hand toward the well of the receiver, and with the finger push in the extractor until its base is flush with the rear end of the headless shell. This insures the hook-prongs being at least four-tenths (0″.4) of one inch beyond the front end of the shell. The length of the headless shell is only 2 inches, while that of the extractor, from the base to the hooked shoulder of prongs, is 2″.4. *b*. Leaving the breech-block open, draw the ramrod, or cleaning-rod, insert it in the muzzle of the piece, lower it carefully until it rests upon the head of the extractor; then press down gently upon the rod, and it will push the extractor before it until the prongs strike the edge of the shell. Now press down firmly, but without shock, and the hooks of the prongs will grip the forward end of the shell. The resistance to any further motion will indicate that the hooks have come to a bearing. Spring the ramrod—the first time gently—and the extractor and shell will be ejected together. The breech must be so placed that the block will not interfere with the ejection.

To replace the broken and defective parts, as well as to facilitate the cleaning the arm, the soldier should learn the proper method of taking the rifle apart and putting it together. The parts should always be dismounted in the following order:—1. Unfix the bayonet. 2. Put a plug of soft wood in the muzzle of the barrel. 3. Draw the ramrod. 4. Turn out the tang-screw. 5. Take off the lock. To do this, first put the hammer at half-cock: then unscrew partially the side-screws, and, with a slight tap of the head of each screw with a wooden instrument, loosen the lock from its bed in the stock; then turn out the side-screws and remove the lock with the left hand. 6. Remove the side-screws; taking care not to disturb the washers. 7. Take off the upper band. 8. Take off the lower band. 9. Take out the barrel. In doing this, turn the rifle horizontally, with the barrel downward, holding the barrel loosely with the left hand below the rear sight, the right hand grasping the stock by the handle; and if it does not leave the stock, tap the plug in the muzzle gently against the ground or floor, which will loosen the breech end from the stock. This is preferable to lifting the barrel out by the muzzle, because if the tang of the breech-screw should bind in the wood, the head of the stock would be liable to be split by raising the muzzle first. 10. Remove the hinge-pin by pressing on its point with the point of the tumbler-punch until the end carrying the arm projects sufficiently far to enable it to be grasped and removed by the fingers. 11. Remove the breech-block carefully, so as not to allow the extractor and ejector-spring to fall to the ground. 12. Remove the extractor and ejector-spring. 13. Remove the cam-latch by unscrewing the breech-block cap-screw, and loosening the cap with the point of the screw-driver. 14. Remove the cam-latch spring. 15. Turn out the firing-pin screw, then take out the firing-pin and spring from the breech-block. The foregoing parts are all that will usually be found necessary to be taken off or dismounted. The soldier should never dismount the *band-springs*, *guard*, *side-screws*, *washers*, *butt-plate*, or *rear-sight*, except when an officer considers it necessary. The breech-screw should only be taken out by an armorer, and never in ordinary cleaning. The lock should not be taken apart, nor the bayonet-clasp taken off, except when absolutely necessary in the opinion of an officer. The parts which are especially assigned to be dismounted by an experienced armorer will be stated in their regular order following No. 15, viz: 16. Take out the upper and lower band-springs, using a wire-punch of proper size. 17. Take out the side-screws. 18. Take out the guard, using care to prevent injuring the wood at each end of the guard-plate. 19. Take out the side-screw washers with a drift-punch. 20. Take out the butt-plate screws with the largest blade of the screw-driver, and remove the butt-plate. 21. Remove the rear-sight by turning out the rear-sight screws with a clamp screw-driver. 22. Remove the receiver. In doing this, be particular to see that the extractor is removed beforehand. 23. Turn out the breech-screw by means of a "breech-screw wrench," suited to the tenon of the breech-screw. No other wrench should ever be used for this purpose, and the receiver should be held during the operation in neatly-fitting clamps. 24. The lock is taken apart in the following order: *a*. Bring the hammer to full-cock and clamp the notch of the screw-driver over the two branches of the main-spring. Remove the spring from the lock-plate, being careful not to let it go from the notch of the screw-driver. *b*. Turn out the sear-

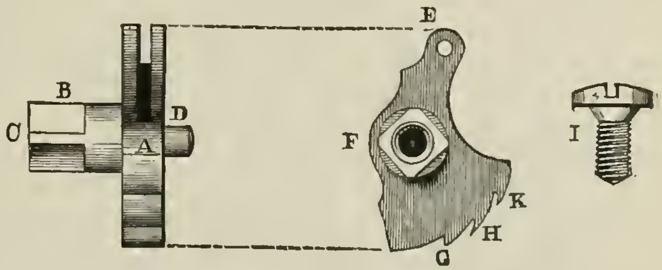

Fig. 8.

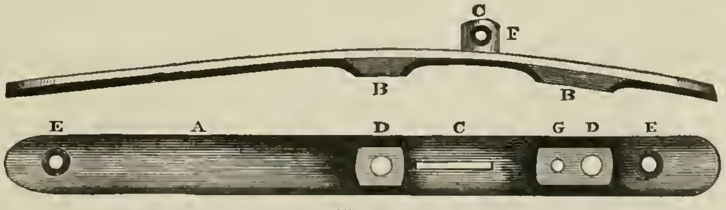

Fig. 9.

spring screw. Before turning this screw entirely out, strike the elbow of the spring with the screw-driver so as to disengage the pivot from its mortise; then remove the screw and spring. *c.* Remove the sear-screw and sear. *d.* Remove the bridle-screw and bridle. *e.* Remove the tumbler-screw. *f.* Remove the tumbler. This is driven out with a punch inserted in the screw-hole, which at the same time liberates the hammer. *g.* Detach the main-spring swivel from the tumbler with a drift-punch. See *Fabrication of Fire-arms*, *Headless Shell-extractor*, *Portable Fire-arms*, *Small-arms*, and *Springfield Carbine*.

SPRINGFIELD RIFLE MODIFIED. Besides the very well-known model 1870, described above, there are various modifications, differing from each other in points of mechanism and action.

In the *Springfield-Stillman*, the lock is set in a prolongation of the tang of the breech-screw, and is altered mainly from the Sharps lock. The firing-pin screw is replaced by a stop-pin kept in place by the breech-block cap.

In the *Springfield-Allin*, the cam-latch and thumb-piece are in one piece instead of being riveted together as in the 1870 model. It is fired by a center-lock, the main-spring of which lies under the receiver, being dovetailed into it at its forward end. The firing-pin screw is replaced by a stop-pin, which is kept in place by the breech-block cap.

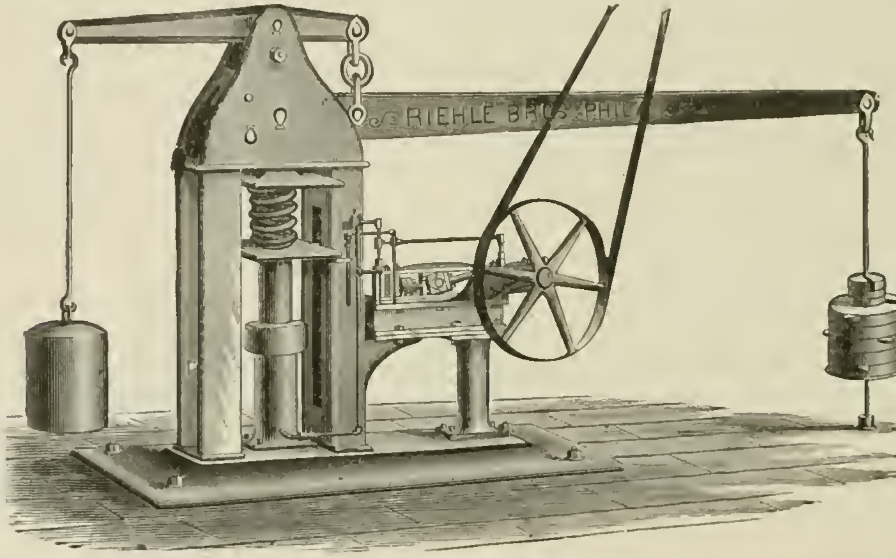
In one model, the lock-plate is of uniform thickness, about one half that of the 1870 model, the main-spring bolster being replaced by a screw. The shape of the hammer and of the surrounding parts of the stock are changed, so as to promote economy of manufacture and ease of manipulation.

In another model, the shape of the ejector-stud is modified, and a lining inserted into the receiver, with the intention of facilitating the introduction of the cartridges.

SPRINGS.—Elastic contrivances designed to facilitate the movement of carriages over rough roads. Their action may thus be explained: As the carriage advances along an even road, the spring is constantly deflected to that extent which balances all the weight of the carriage. As soon as the wheel encounters an obstacle, the motion of the axle-tree is changed suddenly from a horizontal to a circular path; the center of the circle, or the axis, being the point of contact between the wheel and obstacle. If A be the angle contained between the radius from this point and the vertical, V the original velocity of the carriage which the horse has to maintain; then, the velocity of the axle-tree in its new path $= V$ sec. A and the vertical component of this new velocity $= V \times$ tan. A, which is the velocity with which the axle-tree is impelled upwards towards the carriage, the wheels being deflected in proportion. But if there be no springs, the *carriage itself* must be given this new vertical velocity; and the carriage offers a resistance to rising proportional to its mass and to the *square* of the velocity of the new motion. And the additional resistance experienced by the horse is proportional to this, causing a jerk on the traces and making the work heavier. By using springs, however, the vertical motion of the axle-tree is applied to the spring with a *gradually increasing* pressure, producing a correspondingly increasing deflection until the inertia of the carriage is overcome; in the meanwhile, if the speed be considerable, the obstacle is passed over before any material effect is produced upon the carriage. Experiment points to the following conclusion: For carriages calculated to travel at a walking pace, springs are of little or no use. Their value, however, is at once felt when the pace increases to a *trot*, and is augmented with each increment of speed, especially upon hard, rough roads.

SPRING SPIKE.—A spike having a shoulder and spring to prevent its being too easily extracted. It is used when guns are spiked temporarily and are likely to be retaken. See *Spike*.

SPRING TESTER.—A machine for ascertaining the elasticity of springs under pressure. The drawing shows an improved machine of this class with the following:



DIMENSIONS.

Extreme height	5 ft. 8 in.
" length	11 ft.
" width	5 ft.
Weight	5,300 lbs.

Capacity 10,000, 25,000 and 30,000 pounds.

ADAPTATION.

Compression Surface above	16 in. × 16½ in.
" " below	16½ in. × 5 ft.
Space between Surfaces	1 ft. 10 in.
Dynamic Motion	1¼ in.
Motion of Plunger	10 in.

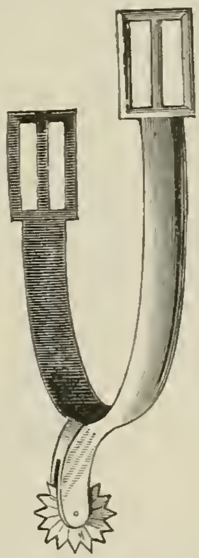
The power-pump is operated by a pulley and belt. A lug projects from the corner of the lower table or compression surface; this lug intercepts a pawl that is connected with a valve that controls the flow of the liquid, and when the long table moves upward to the desired height, the fluid is diverted from under the plunger back into the reservoir, thus securing a uniform test.

The upper table bears against weighing levers, and is comparatively motionless, while the lower table moves upwards and communicates the pressure through the springs to the upper table, and thence to the lever and weights as shown. The lower table is well extended so as to take in a long spring. See *Testing-machine*.

SPRITES.—Wooden arrows which were anciently projected from muskets.

SPRUE.—Strictly, the hole through which melted metal is poured into the gate, and thence into the mold. The term is applied to the waste pieces of metal cast in this hole. See *Molding*,

SPUR.—1. An apparatus fastened to the heel of a horseman, for goading the horse. It is much less used than formerly. All cavalry soldiers wear spurs; but their use, except in the heat of an actual charge, is discouraged as much as possible. In the days of chivalry, the use of the spur was limited to knights, and it was among the emblems of knighthood. "To win his Spurs," was for a young man to earn knighthood by gallant conduct. The degradation of a knight involved the hacking off of his spurs; and the serving before a knight of a pair of spurs on a dish, was a strong hint by his host that he had outstayed his welcome.



In the United States Army, all the mounted officers wear spurs made of yellow metal or gilt with ornamentation, and the cavalrymen wear the same pattern with a plain surface.

2. A tower or block-house placed in the outworks before the port.

3. A wall that crosses part of a rampart and connects to the interior work.

SPUR-NECK.—The part of the spur projecting from the shank and holding the rowel. About the 15th century, when tournaments were greatly in fashion, the *spur-neck* was extravagantly long. It became shorter again in the 16th century, when the spurs had very often rowels of twelve, fifteen and even eighteen points.

SPUR-TUBES.—Quill priming-tubes filled with inflammable composition, and ignited by applying the match. The body of the tube is filled with a composition of mealed powder moistened with camphorated alcohol until a thick paste is formed; the composition is introduced into the quill by pressing its lower end into the paste, thus taking up a portion of it, and repeating the operation until the quill is filled. A small wire is then run through the axis of the tube, and allowed to remain there until the paste is dry, when it is withdrawn, leaving the composition perforated throughout its entire length. The object of piercing the composition is to expose more surface to the action of the flame; the ignition of the whole contents of the quill is thus rendered instantaneous. The head of the tube, or spur is formed by inserting a strand of quick-match, about an inch long, into the composition through a hole near the head of the quill. This is protected by a small tube of stiff paper lashed at right angles to the quill. The end of the quick-match is covered with a paper cap, and the whole is shellacked over to protect it from moisture.

SPY.—A person who secretly, in disguise or under false pretense, seeks information with the intention of communicating it to the enemy. The spy is punishable with death by hanging by the neck, whether or not he succeed in obtaining the information or in conveying it to the enemy. If a citizen of the United States obtains information in a legitimate manner, and betrays it to the enemy, be he a military or civil officer, or a private citizen, he shall suffer death.

Spies have been used in all wars from the time when Moses sent Joshua on such a purpose to the present time. Their employments are quite recognized by the law of nations as interpreted by Grotius, Vattel, and Martens; nor is it held to be any dishonor to a General to avail himself of their services. On the other hand, the spy himself is looked upon as an outlaw, and one devoid of honor. If taken by the enemy, he is put to death ignominiously and without mercy. As, however, the calling is so dangerous, and so little redounds to honor, it is never permissible for a General to compel by threats, etc., any person, whether of his own or the hostile party, to act as spy; but he is at liberty to accept all such services when proffered. A spy is well paid lest he betray his employer. In the British Army spies are usually controlled by the Quartermaster General. Martial law, though distinct enough in ordering the death of a spy, is not clear in defining what constitutes a spy. A man—not of the enemy—within the enemy's lines, and in the enemy's uniform, would presumably be a spy. If in a civil dress, and unable to give a good account of himself, his chance of hanging would be considerable; but if found in one camp in the uniform of the opposite side, he might not be treated otherwise than as a prisoner of war, or at least as a deserter from the enemy.

Both as regards honor and penalties, it would seem that spies ought in fairness to be divided into two classes—first, those who betray their own country to an enemy; secondly, those who, being enemies, contrive surreptitiously to obtain information by penetrating into the opposing army. The first class are traitors of a deep dye, for whom no ignominious death is too bad; but the second class are often brave men, who dare much in the service of their country, It is unfair to accord to them the same treatment as the traitors.

SPY-GLASS.—In order that all the advantages gained by the use of the spy-glass may be more fully understood, we shall here briefly consider the optical principles involved in its construction. The object-glass, receiving the rays of light which proceed from all the points of a visible object, converges them to a focus, and there forms a minute, inverted and very bright image, which may be seen by placing a piece of ground-glass to receive it at that point. The eye-piece, acting as a compound microscope, magnifies this image, restores it to its natural position, and conveys it to the eye. The visual angle which the image there subtends, is as many times greater than that which would be formed without the use of the spy-glass as the number which expresses its magnifying power. Thus, a spy-glass which magnifies twenty times increases the visual angle just as much, and therefore diminishes the apparent distance of the object twenty times; or, in other words, it will show an object two hundred feet distant, with the same distinctness as if it was distant only ten feet from the naked eye. The drawing will give a correct idea of the manner in which the rays of light coming from an object are affected by passing thorogh the several glasses of a spy-glass. We shall only consider the rays which proceed from the extremities. These, after passing through the object-glass are converged to that point—the common focus of the object and eye-glasses. At this place the rays cross each other, and the image is then inverted. The rays next come to the object-lens, and passing through it are refracted so as again to cross each other, and come thus to the amplifying lens. By this they are again refracted, made more nearly parallel, and thus reach the large field-lens. After passing through this, they form a magnified and erect image in the focus of the eye-lens. By the eye-lens the image is still further magnified, and at last enters the eye of the observer, subtending an angle as much greater than that at the point, O, as is the magnifying power of the spy-glass. The United States Signal Service instrument, made by Messrs. Queen & Co., embodies the three most important qualifications of a good spy-glass, viz., great defining power, lightness, and portability. This glass will, under ordinary circumstances, enable the observer to make out signals at a distance of twenty-six miles, read the name on a light-ship at nine miles, make out wild fowl at sixteen miles, show shot marks at very longest ranges, the time by a church clock at six miles, and persons walking at ten and one-half miles. It is fitted with two leather caps, to which is attached a strap, thus forming a light and efficient case. See *Object-glass.*

SQUAD.—Any small number of men assembled for the purposes of drill or inspection. A troop or company of soldiers should be separated into as many squads as there are Officers or Sergeants at hand to drill them. The *awkward squad* comprises recruits not yet fitted to take their places in the regimental line.

SQUAD-BAGS.—Canvas bags provided for troops (one for every 25 men), for the purpose of relieving a soldier from carrying a complete kit on the line of march or in the field. In India, where knapsacks are not carried by the soldier on the march, a small squad-bag is issued to each soldier.

SQUAD-BOOK.—In the British Service, the roll of a squad, containing, besides the names, the trades and other particulars of the men.

SQUADRON.—In military language, two troops of cavalry. It is the unit by which the force of cavalry with an army is always computed. Three or four squadrons constitute a regiment. The actual strength of a squadron varies of course with that of the component troops; but it ranges from 120 to 200 sabers.

In naval affairs a squadron is a section of a fleet, and constitutes the command of a junior Flag Officer or Commodore.

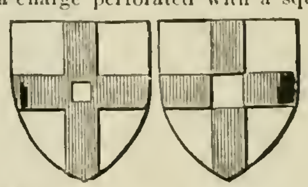
SQUAMATA.—A flexible cuirass composed of small iron or bronze scales sewed on linen or leather, and first worn by cavalry soldiers in the time of Polybius. Also written *Squammata.*

SQUARE.—In military evolutions, the forming of a body of men into a rectangular figure, with several ranks or rows of men facing on each side. With men of ordinary firmness a square should resist the charges of the heaviest horse. The formation is not new, for a Grecian syntagma was a solid quare of 16 men in every direction; but in modern warfare the solid square, having been found cumbrous, has been abandoned for the hollow square, with officers, horses, colors, etc., in the center. The front rank kneels, and the two next stoop, which enables five ranks of men to maintain a rolling fire upon an advancing enemy, or to pour in a murderous volley at close quarters. The application of the *solid square* to resist cavalry appears to have been introduced in 1798, when the French Army in Egypt, being weak in cavalry, was opposed to overwhelming hordes of Mamelukes. At the battles of Chebreifs and of the Pyramids, Bonaparte formed his infantry echeloned in squares against the Egyptian horse.

A large square has not proportionally a greater fire than a small one, and it is no stronger. In a charge of cavalry, that portion only which attacks the face of a square is to be dreaded. If the face is much extended the number of cavalry that can bear down against it is augmented in like manner. A square of three thousand men is not then any stronger than a square of one thousand. It would therefore be absurd to form three thousand men in one square, because they can be more readily formed into three or four squares, which will mutually protect each other, and form, as it were, a system of redoubts. And if one of these combined squares is broken by cavalry, the cavalry becomes disordered in the act, and the remaining squares are left intact. Besides, in presenting a small front to the attack of cavalry, horses, fearing to charge against the shower of balls which welcome them, are apt to oblique to the right or to the left. If the face of the square is extended they cannot do so, and the shock must fall on some part of the face, but the smaller the faces of combined squares the greater will be the intervals, and the more certain the success of the defense.

From these considerations, it is apparent that large squares ought not to be used, but that squares of a single battalion are worthy of all commendation. The formation of troops in two ranks is the prescribed order of the United States infantry tactics. Marshal Marmont says: "Nothing can be said in favor of a third rank. Persons of experience know that if one can, at a review, fire a volley in three ranks, it is impossible in war. It is better, therefore, to adopt the two-deep formation, and to render it permanent." The tactics direct that the divisions, as a general rule, shall always be formed before forming square. Marshal Bugeaud is of opinion that the square formed from the column by company, which would give a depth of four or six men to the different faces of the square, is greatly to be preferred. Apart from the fact that such squares are more expeditiously formed, the face of the square is reduced one-half, and the square is strengthened by the reduction.

SQUARE-PIERCED.—In Heraldry, a term used to designate a charge perforated with a square opening, so as to show the field.



Square-pierced. Quarter-pierced.

A cross square-pierced is often improperly confounded with a cross quarter-pierced, where the intersecting part of the cross is not merely perforated, but entirely removed.

SQUARE POWDER.—The grain of this powder is formed of two quadrangular pyramidal frustums united on a square base. The side of this base is about 1.25 inches, and the thickness of the grain 1.30 inches.

These powders were intended as experimental powders for large calibers, and were made of three different densities, but of the same granulation, viz;

	Granulation.	Density.
G. S.	11	1.775
G. T.	11	1.760
G. W.	11	1.715

The tests were made in a 11-inch rifle, using as high as 85 pounds of G. S., with a 505-pound projectile. The results demonstrated that the density of the G. S. was too high for the granulation. G. W. proved too violent owing to its low density, even with the moderate charge of 70 pounds.

The results obtained with G. T. were as follows:

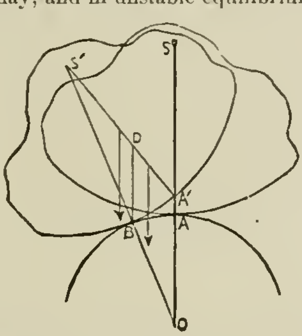
Nature of gun.	Kind of powder.	Weight of ch'rge	Weight of pr'jec.	Vel'ty at 110 feet.	Pressure
		Lbs.	*Lbs.*	*Feet.*	
11-inch rifle.......	G. T. square.	70	505	1245	31500
		75	505	1314	33000

These results, though only fair, yet indicate that the charge might safely be increased to 80 pounds, with the promise of much better results; since for an increase of 5 pounds, *i. e.*, from 70 to 75, the velocity has been increased 71 feet, while the pressure, on the other hand, has run up only 1,500 pounds. See *Gunpowder*.

SQUIRE.—The name formerly given to an attendant on a warrior.

STAB.—To pierce with a pointed weapon; as, to be stabbed by a bayonet, dagger, etc.

STABILITY.—When a body rests upon a surface in such a manner that a vertical from its center of gravity falls within the largest polygon which can be formed by joining the various points of contact of base and surface, it will stand; but if the contrary is the case, it will fall, unless extraneously supported. If the base of the body be a plane, and the supporting surface convex, or *vice versa*, or if both base and surface be convex, there will then be only one point of support, and if the body be at rest, its center of gravity must be vertically over the point of contact. Should a body so placed receive a slight impulse, it will either oscillate to and fro, ultimately returning to its original position, or remove further and further from its original position, showing a tendency not to return, or appear indifferent to any one position. In the first case, the body is said to be in *stable*, in the second case, in *unstable*, and in the third, in *neutral* equilibrium. It will appear at once that the predetermining cause of equilibrium being of one rather than of another of these species, is the tendency of the center of gravity of every body to seek a lower position. In stable equilibrium the center of gravity of the body may, and in unstable equilibrium may not,



attain a lower position, while in neutral equilibrium its position continues unaltered. In illustration of the mode in which the species of equilibrium possessed by a body which has received a slight impulse is determined, let us take the case of a body with a spherical base resting upon a spherical surface; let S and O be the centers of the spherical surfaces respectively, and let A be their point of contact (the center of gravity being consequently in the line SA, or in it produced toward S, and after displacement, in the line S'A', produced if necessary), let the new position of S, after the body has been slightly displaced, be S', and the new point of contact B; join OS, OS' S'A', and draw BD vertically, that is, parallel to OS.

Then A'D : A'S' :: OB : OS', or $A'D = \frac{A'S' \times OB}{OS'}$,

that is, A'D= the product of the radii of the two surfaces divided by their sum. Now should the center of gravity of the displaced body fall between D and A', it will have a moment round B tending to restore the body to its former position (*stable equilibrium*); should the center of gravity be beyond D from A', its moment round B will tend to increase the displacement (*unstable equilibrium*); while, if it fall in the line BD, it will still be above the point of contact, as it was at first, and there will be no tendency either to return to, or to move further from, the original position (*neutral equilibrium*). These conditions may be briefly expressed by the following formulæ, in which R is the radius of the supporting surface, *r*, of the spherical base of the body, and X the distance of the center of gravity from the point A; when equilibrium is stable, X is less than $\frac{R \times r}{R + r}$; when unstable, X is greater than $\frac{R \times r}{R + r}$; and when neutral, $X = \frac{R \times r}{R + r}$. From these formulæ, the conditions of equilibrium of a body, with a spherical base on a plane surface can be at once deduced by making $R = \infty$. the three species of equilibrium being then represented in order by X less than *r*, X greater than *r*, and $X = r$; the simplest illustrations of these being respectively a segment of a sphere, a tall cone on a spherical base, and a sphere.

STABLE HORSE.—A name formerly applied to that part of the Tippoo Sahib's cavalry which was best armed, accoutered, and most regularly disciplined.

STABLES.—Foul air is the cause of many diseases of the horse. Hence the importance and economy of spacious, clean, and well-ventilated stables. Ceilings should be twelve or fifteen feet high, with large ventilators through the roof, and a window or side-aperture in each stall. If possible, the building should have no upper story or loft. In stables with a loft, ventilation from the top is always insufficient, and there must be side-openings well above the horses, so that the draught will pass over their heads. These openings must never be closed except on the windward side, to keep out rain or snow.

On the southern frontier, a cavalry-stable is best constructed on three of four sides of a rectangle so as to inclose a stable-parade or court. First build an exterior stone or adobe wall, twelve or fifteen feet high: resting on this wall, and on posts or columns set back some fifteen feet in the interior, is a roof so pitched as to shed the rain outside of the inclosure; the stalls are arranged along the wall, with a window opposite each horse. In cold weather, the spaces between the posts can be partly boarded up, and the window-shutters fastened. The forage and store-rooms are constructed at the angles, taking advantage of the inclosure-walls, which form two sides of the rooms. A hospital-stable should be somewhat isolated, and have a large yard for turning-out invalids, who should be protected from sun and high winds by an open shed against one side of the inclosure.

A picket-line is established in the immediate vicinity of every company-stable; the horses being tied on each side of a timber framed on posts, to a rope passed through the posts. There should be shallow trenches behind the horses to carry off rain, and the ground on which they stand having just slope enough to let water run into the trenches. Constant attention must be paid to maintaining the ground about the picket-line in good order.

A Non-commissioned Officer is detailed, in each company, to take immediate charge of the police and sanitary condition of the stable, picket-line, etc. He is the custodian of the forage and stable property generally. The stable is to be kept thoroughly policed, free from smells, and well whitewashed. There must be no accumulations of manure or foul litter inside or near the doors or windows without. The feed boxes are washed out from time to time, and kept clean. The ground about the picket-line is swept daily, and all dung, etc., carried to the manure-heap.

Except at night when the horses are bedded down, no manure or urine should remain in the stalls; the stable-police remove it as fast as it accumulates. If practicable, all wood-work within reach of the horses and not protected by sheet-iron or any other metal, is painted every four months with thin gas-tar, to prevent its being gnawed. The same precaution must be followed with regard to the troughs, picket-posts, and picket-line. One or more lamps should be hung in each stable, to burn during the night. Saddles generally rest on strong pins in the heel-posts; bridles on smaller pins below them. The name of each horse,and that of his rider,should be placed over his stall. Horses should always stand on earth. Clay is the best for this purpose,as it packs well. Gravel, or sandy earth, is not suitable. Each man is held responsible for the renewal of the earth, and also the leveling of the floor of his stall. The sloping of the floor of stalls, from the manger to the heel post,is injurious and uncomfortable to the animal, who stands in an unnatural position, with the forelegs higher than the hind ones. When earthen floors are not level, they give more trouble, as the horse will paw a hollow for his fore-feet unless he can elevate his hind-legs by backing out of the stall.

Whenever the horses go out of the stable,the windows of their stalls should be kept open,unless necessary to exclude rain or snow, or when cold draughts affect the animals in contiguous or opposite stalls. Stable-doors are never closed in the daytime, except to keep out wet or exclude cold winds which blow on the horses. If the doors be in a single piece,bars are put across the door-way; if divided in half, it will be usually sufficient to open the upper part. At night, except in very hot weather, they should be closed and locked, communication with the stable being kept up by a man-hole.

Except in very cold windy weather, or in very hot weather where there is no shade,horses should stand most of the day at the picket-line,as they have better air and are less confined, while the stables become drier and more healthful. In ordinary climates,military stables must be kept as cool as possible. If the horses do not stand directly in the draught,the colder the stable the less will they suffer if called suddenly to take the field. For the same reason,horses should never be blanketed in the stable, except in the excessively cold weather of a high latitude.

Stable-guards are for the protection of the horses, equipments, and forage, as well as for the enforcement of the special regulations in regard to stables and horses.

The sentinels of the stable-guards are posted and relieved like those of other guards. They are forbidden to strike or otherwise punish horses; and, if consistent with safety,wear the saber-belt only when on post at the stable or picket-line.

The employment of stable-guards for *police* and *fatigue duty at the stable*, is strictly forbidden; but this does not prohibit men not on post from being called upon to groom their own horses, or to assist in feeding grain before reveille.

It is recommended that morning stable-duty be always after the men have breakfasted. Evening stable duty should be one hour and a half before retreat. Horses are groomed twice daily, at morning and at evening stable-calls. The grooming is always at the picket-line, except in stormy weather. The men are marched to the horses, and get to work as soon as the command COMMENCE GROOMING is given by the First Sergeant. In garrison,two or more men in each company, called the *stable police*, are usually kept at work between morning and evening stable-calls, in removing manure, policing generally, feeding, etc. In camp,as a general rule,the whole company polices the picket-line, feeds hay, etc.,at such times as may be most convenient.

To groom the horse, take the curry-comb in right hand, fingers over back of comb; begin on the near side at the upper part of the neck, thence proceed to the chest, arm, shoulders, back, belly,flank,loins, and rump. Then go to the off side, taking comb in left hand, and proceed as before. The curry-comb is not applied to the head or very tender parts, and must not be used on the legs from the knees or hocks downward, except to carefully loosen matted dirt. In cold weather, or when the hair is long,the curry-comb is freely used; at other times but little, particularly when the horse is changing his coat. It must always be applied very gently to horses with tender skins and short coats. Next take the brush in left hand, and change curry-comb to right; begin at the neck, and on the near side,and proceed in the same order as in currying, brushing also the parts not touched by the comb; on the off side take brush in right hand, curry-comb in left. In places difficult to clean, apply the brush backward and forward, finishing by leaving the coat smooth. After every few strokes, clean the brush from dust with curry-comb. Having done with the brush, rub or dust off the horse with the grooming-cloth, and wipe about the eyes and nostrils,and clean the dock. The skin under the flank and between the hind-quarters must be soft,clean,and free from dust. Curry-combs, cards, or common combs, must never be applied to the mane or tail; but the brush, fingers, and cloth are freely used on both. A wisp is used for wet places; it is rubbed against the hair until the places become dry.

In garrison,it is recommended that grain be fed at first call for reveille by the Non-commissioned Officer in charge of the stables,assisted by one or two members of of the stable-guard, or men detailed for the purpose. The grain, in a box on wheels, is rolled in front of each stall, whence it is transferred to the feed-boxes by allowance-measures. Grain is fed again at evening stable-duty as in the morning, but not until after the hay has been fed and the stable swept up. In camp or on the march,grain is fed at morning and evening stable-duty. The men are marched to the forage-wagon,or other grain depository, where the Non-commissioned Officer in charge, with an allowance-measure, issues to each in turn.

Hay, in garrison, is fed thrice daily; immediately after morning stable-duty, in the middle of the day, and at evening stable-duty; at the evening feed each animal should have at least one-half of his daily allowance. The dust must be well shaken out of the hay before it is put in the mangers. During the short days of winter, the feeding at noon may be omitted without injury to the animals.

Hay, in camp, is fed at the picket-rope, morning, noon, and evening; but on the march,in the evening only. The occasional use of bran is important for stabled horses. In spring, or in early summer, they should have grass for at least a week or ten days, during which time they ought not to be much worked. Salt should be given once a week. When forage cannot be obtained,grazing should be allowed at every spare moment, especially early in the morning, when the dew is on the grass. The daily allowance of oats, barley, or corn, is twelve pounds to each horse; that of hay fourteen pounds; the allowance of straw for bedding is one hundred pounds a month to each animal. Good oats weigh about forty pounds to the bushel; barley about forty-eight pounds; corn about fifty-six pounds. Pressed hay weighs eleven pounds per cubic foot. The average weight of a bale of hay is from three hundred to three hundred and twenty-five pounds. The standard bushel used in the United States contains 2150.4 cubic inches. A cubic yard contains 21.69 bushels. A box 16 × 16.8 × 8 inches holds one bushel; a box 12×11.2×8 inches holds half a bushel; a box 8×8.4×8 inches holds one peck.

Horses must be watered quietly and without confusion; the manner in which this duty is performed is a good test of the discipline of any mounted command. They are led or ridden, at a walk, to and from water, depending upon its distance from the stable. At the drinking-place, no horse should be hurried,or have his head jerked up from the water, until he has done drinking. In the field, or on the march, the watering is from the most convenient running water; in garrison, it is usually from troughs. In warm weather, water drawn from a cold well or spring before being used, should stand long enough for the chill to pass off. During the hot months, horses are watered thrice daily; in the morning, at noon, and just before grooming in the afternoon. At other times, two waterings are enough; after the morning and at evening stable-duty. In very cold weather, once a day, at noon, is sufficient. It is to be always remembered that a horse will rarely drink enough very early in the morning. The daily allowance of water for a horse is four gallons. On the march, horses are watered with buckets carried on the carriages; the oftener the better, as it is not usually known when another watering-place will be reached. When horses have to make a day's march without water, they will be watered after they are fed, just before leaving camp in the morning. If a mounted command have to march a long distance without water, so that it will be necessary to encamp *en route*, the animals are well fed but denied water until just before starting, when they are permitted to drink freely. The command marches in the afternoon, and does not encamp until it has accomplished at least half of the distance, and moves early the next morning to reach water.

STACK ARMS.—A movement in the *Manual of Arms*, for setting up rifles or muskets together, with the bayonets crossing one another, and forming a sort of conical pile. The movement is thus executed: The men being in line and at *order arms*, the Instructor commands:

1. STACK, 2. ARMS.

At the command *stack*, each even number of the front rank carries his piece with the right hand diagonally in front of the center of the body, and grasps it with the left hand above the lower band, the barrel to the rear, the muzzle opposite the right arm: he then grasps the piece of his rear-rank man with his right hand above the lower band, and places the shank of the bayonet upon that of his own, the barrel to the right; the odd number of the front-rank, with the right hand, then places the shank of his bayonet in the angle formed by the bayonets of the other two pieces, the barrel to the front, retaining his hold on the piece above the lower band; the butts of all the pieces about six inches from the ground.

At the command *arms*, the even number of the front-rank, with his right hand, passes the butt of the musket of the rear-rank man thirty inches to the front, passing it between the butts of the other two pieces; the stack is then lowered, the butt of the musket of the even number striking the ground just to the left of his left toe, that of the odd number striking the ground between his feet.

The stack being formed and aligned, the command, *lay on loose pieces* is given; at which the remaining pieces in the rear-rank are passed to the even numbers of the front-rank, who lay them on the stacks. The pieces of the file-closers are laid on the stacks at the same time. The stacks are broken in an inverse manner.

If in single rank, number two of each four makes the stack, and at the command *stack*, takes the piece of number three with the left hand above the lower band and uses it as explained for the piece of the even number rear-rank man; the stack is completed as in two ranks, after which the piece of number four is passed to the right and placed upon the stack.

In breaking the stack, the piece of number four is first passed to him; the stack is then broken as when in two ranks, except that number two grasps his own piece with the right and the piece of number three with the left hand. See *Hook-swivel.*

STACKET.—An old term for stockade. See *Stockade.*

STACKING-SWIVEL.—The swivel attached to the upper band of a breech-loading rifle or carbine, to enable stacks to be formed without attaching the bayonet or using the wiper.

STACK OF ARMS.—A number of muskets or rifles set up together, with the bayonets crossing one another, forming a sort of conical pile.

STADIA.—A very simple aid in estimating distances consisting of a small stick, held vertically in the hand at arm's length, and bringing the top of a man's head in line with the top of the stick, noting where a line from the eye of the observer to the feet of the man cuts the stick, or *stadia*, as it is called. To graduate the stadia, a man of the ordinary height of a foot-soldier, 5 ft. 8 in., is placed at a known distance, say 50 yards; and the distance on the stick covered by him when it is held at arm's length is marked and divided into 8 equal parts. If the distance is now increased, until the man covers only one of these divisions, we know he is at a distance equal to 50 yds. $\times 8 = 400$ yds. This instrument is not very accurate, except for short distances. A much more accurate stadia is constructed by making use of a metal plate, having a slit in it in the form of an isosceles triangle, the base of which held at a certain distance from the eye, will subtend a man, (5 ft. 8 in.) say at the distance of 100 yards. A slider moves along the triangle, being always parallel to the base, and the length of it comprised between the two sides of the triangle, represents the height of men at different distances, which are marked in yds., on the side of the triangle, above or below, according as the object looked at is a foot-soldier or horseman. In order to keep the stadia always at the same distance from the eye, a string is attached to the slider, the opposite end having a knot tied in it, which is held between the teeth while using the instrument, which is held in the right hand, the slider being moved with the left-hand finger. The string should always be kept stretched when the instrument is used, and the line in a vertical position. It must be graduated experimentally, by noting the positions in which the slider represents the height of the object. The instrument used is not, however, reliable. Its uncertainty increases in an equal ratio with the distance of the object observed. At the extreme ranges it is quite useless. At the School for Firing at Vincennes, therefore, they rely entirely on the eye alone for the judgment of distances, and great pains by careful practice and instruction is taken to perfect that judgment. A simple instrument by which distances can be determined is, therefore, still a great desideratum. See *Range-finder.*

STADIMETER.—An instrument invented by Messrs. Paucellier and Wagner, of the French Topographical Corps, for ascertaining the distance between any two points. It consists of a horizontal, graduated rule, mounted on an upright staff. It is viewed through an intervening telescope provided with a micrometer. The number of divisions of the micrometer that cover a certain number of the divisions on the rule indicates the distance between it and the telescope.

STADOMETER.—A contrivance for estimating distances, usually employed on the drill-ground, to save measuring. It consists of a bar 5 feet 2 inches long, marked with an index having a sliding sight and a cross-head at one end extending at right angles to its length, and is supported at a convenient height by legs at each end. Two fore-sights, one at two inches and the other at four, are placed on the head.

In using this instrument the sight on the index-bar is aligned upon the desired point. A flag is then placed at 40 yards at right angles from that point (the angle being obtained by the use of a cross-staff having two sets of sights), and the sliding-sight on the index-bar slipped down until the fore-sight on the head is aligned on the flag, when the scale will show the distance, as every four inches represents 40 yards. To measure over 600 yards, the inner fore-sight on the head is used, and the distance on the scale doubled, since at that angle every 2 inches would represent 40 yards.

The author has contrived a *stadometer*, the principle of which is based on the proportionality of the corresponding sides of similar triangles and an application of the plummets. It does good work on an undulating and broken drill-ground, where actual chain-measurement would be impracticable if not impossible. Prolonged practice and experience, in the appreciation of distances, are necessary to give the *coup d' œil* that insures sufficient accuracy. The practice should be conducted over smooth, broken, and undulating ground, and frequently from elevated points. The distances should frequently be estimated in all directions as regards light and the condition of the atmosphere.

STAFF.—The staff of an army consists of a body of skilled officers, whose duty it is to combine and give vitality to the movements and mechanical action of the several regiments and drilled bodies composing the force. The distinction between an officer on the staff of an army and a regimental officer is that the latter is concerned with his own regiment alone, while the former deals with his army, or section of an army exceeding a regiment, and regulates the combined action of the several arms and bodies of men. A good staff is all-important to the success of a military enterprise.

In the British Service the *General Staff* of an army comprises the General in actual command, with the subordinate Generals commanding the several divisions and brigades, and as assistants, the officers of the Adjutant General's Department—*i. e.*, the Adjutant General, his deputy, assistants, and deputy-assistants if the army be large enough to require all. Similarly, the officers of the Quartermaster General's Department; the Brigade Major; the Provost Marshal; and the Judge Advocate; and the Controller (at the head of the Civil Departments), the functions of all of whom are described under their respective heads. The head of the General Staff of the British Army is at present a Field Marshal Commanding-in-Chief, whose headquarters are at the War Office, of which Department he is an *ex officio* member. He is responsible for the discipline of the Army, and is assisted by the General Officers in command of the military districts in England and Scotland, the semi-independent Commander-in-Chief in Ireland, and the Commanders-in-Chief in the various foreign possesions and colonies. India forms a nearly independent command, under a Commander-in-Chief, whose headquarters remain in Bengal. There are subordinate Commanders-in-Chief in Bombay, and Madras; and in each Presidency there are several military divisions. A certain period of military service, and certain qualifications, are required in an officer before he can be appointed to the General Staff, and a proportion of the posts is given to officers who have passed the Staff College. The fact of having passed through it, however, is not held to constitute any claim to a Staff appointment.

The *Personal Staff* consists of the Aids-de-Camp and Military Secretaries to the respective General Officers. These officers are appointed, within certain limits, by the Generals whom they serve.

The *Garrison Staff* consists of the officers governing in fortresses and garrisons; as Commandants, Fort Majors, Town Majors, Fort Adjutants, and Garrison Adjutants.

The *Civil or Department Staff* includes those non-combatant officers who have to provide for the daily requirements of the troops. These are the Commissaries for supplies and stores, Chaplains, Medical and Veterinary Departments.

The *Recruiting Staff* consists of an Inspector General (at the War Office), and of the officers of the several brigade depots. The *Pensioner Staff* includes only the Staff officers of the enrolled force. The *Regimental Staff* includes the Colonel, Lieutenant Colonel, Adjutant, Paymaster, Quartermaster, Inspector of Musketry, and Medical Officers.

In the French and in most Continental armies the Staff is divided into the Etat Major, or General Staff and the *Intendance* put under an *Intendant General*, which comprises all the Civil Departments. There is a Regimental Staff in addition. The want of concentration of the Civil Departments often felt in the British Service, led to the creation, in 1869, of the Control Department, subsequently split into two branches, the Commissariat and the Ordnance Store Departments.

In the United States Service, the General Staff consists of the officers of the several Military Bureaux.

The Staff of Division and Department Commanders is limited to the following: The authorized Aides-de-Camp. One Assistant Adjutant General, or an officer to act as Assistant Adjutant General. One or more officers of the Inspector General's Department, if available; if none are available, an officer may be assigned to these duties with the sanction of the Secretary of War. One Judge Advocate, or an officer assigned to that duty with the sanction of the Secretary of War. One Chief Quartermaster and one Chief Commissary of Subsistence, who shall also take full charge of the depot and purchases for their respective departments at the place where the headquarters are located. One Medical Director, who shall also perform the duty of Attending Surgeon at the place where headquarters are established. A Chief Paymaster, who shall make his proportion of payments in the command. An Engineer and an Ordnance Officer when needed.

As far as practicable, all appointments and details on the Staff are equalized among the several regiments. General Officers appoint their own Aides-de-Camp. Brevet Brigadier and Major Generals on duty as such may, with the special sanction of the War Department, be allowed the Aides-de-Camp of their brevet grades. An officer shall not fill any Staff appointment, or other situation, the duties of which will detach him from his company, regiment, or corps, until he has served at least three years with his regiment or corps; nor shall any officer (Aides-de-Camp excepted) so remain detached longer than four years. An officer of a mounted corps shall not be separated from his regiment, except for duty connected with his particular arm.

The Commander of a regiment appoints the Adjutant from subalterns of the regiment, nominates the Regimental Quartermaster to the Secretary of War for appointment, if approved. He also appoints the Non commissioned Staff of the regiment; and upon the recommendation of the Company-Commanders, the Sergeants and Corporals of companies. A regimental Staff Officer who accepts a detail for recruiting or other service which will remove him from the discharge of his Staff duties for any considerable time is held to have vacated his Staff position from the date he accepts the detail. This does not apply to details on Courts-Martial, Boards, or any such like duty.

It is necessary that a General Staff Officer should have a knowledge of horsemanship—he should also not be ignorant of the sword exercise; he should have some knowledge of topography; he should be familiar with foreign languages, should have studied military administration and also castrametation; but above all, he should possess a complete knowledge of tactics, and be able to judge skilfully of military positions. An officer grown old in the silence of a Bureau would hardly, in the tumult of battle, or under critical circumstances, second his General by aiding him intelligently concerning all warlike operations. Can he interrogate spies; watch over the observance of order in military trains; draw up orders and instructions; mark out military positions; improvise a fortification; organize and conduct foraging parties; direct markers for grand maneuvers? Open the march of armies? Vault at the head of the light cavalry? Stimulate and enlighten the troops by his interpretation of the orders he carries, by his intuitive knowledge of their tactical position, by his coup d'œil, by the propriety of his counsels, and by the vigor of his impulsions? None but officers whose experience has been gained by service with troops, can do these things with promptitude and effect; but these are the important duties of the General Staff, and service with troops, therefore, is the true criterion of merit in such Staff Officers. In organizing a permanent General Staff Corps, it consequently becomes necessary either to employ in peace that large body of officers necessary in war for the Staff duties, upon duties entirely foreign to their functions in war, or else leave them in idleness. Either course must unfit them for the services required of them on campaign, and it therefore follows, that a permanent General Staff involves a useless number of officers in time of peace, and a deficiency of experience, instruction, and aptitude for their duties in time of war. It is impossible to avoid this vicious circle with a permanent General Staff. The only true system of Staff organization, then, is that which admits of supernumerary General and Regimental Officers, selected temporarily for Staff duties by Commanders of troops, as provided by the Act of Congress of 1799, drawn by Alexander Hamilton. "The leading qualifications which should distinguish an officer selected for the Head of the Staff (says Napoleon), are to know the country thoroughly; to be able to conduct a *reconnaissance* with skill; to superintend the transmission of orders promptly; and to lay down the most complicated movements intelligibly, but in few words, and with simplicity."

STAFF ADMINISTRATION.—The supply and payment of the Army, and the direction of the expenditures of the appropriations for its support, are by law committed to the Secretary of War. He exercises control through the several Bureaus of the War Department and the several branches of the military service and the officers thereof. He determines where particular supplies shall be purchased or contracted for; where they shall be delivered, inspected, and stored, and how distributed—whether at general depots for the use of the whole Army, or at particular posts or headquarters for parts thereof. He decides, also, through and by means of what officers within the laws these purchases and contracts shall be made.

All officers of the Staff who are assigned to the command of a General or other officer remain under that officer's military command, and are under his supervision, control, and command in all their official acts relating to matters within his command, and to all matters, acts, and things not specially excepted from his command and control under the law and by the Secretary of War, in accordance with the Regulations and General Orders published by the War Department or issued by the Secretary of War from time to time.

It is the duty of every Commanding Officer to enforce a rigid economy in the public expenses, and to correct all irregularities and extravagances which he may discover; to see that all disbursements are prudently and economically made; that public property is properly cared for, and not lost or destroyed through neglect; to carefully scrutinize all contracts and disbursement accounts submitted for his approval, and to see that the public interests are fully protected.

The administrative control exercised by Department Commanders when troops are in the field, devolves on the Commanders of Divisions; or, when the command is less than a Division, on the Commander of the whole. See *Staff*.

STAFF COLLEGE.—A Government Institution established in 1858, about two miles from Sandhurst. The following are the more important regulations governing this Institution.

I. The Staff College is open to officers of all arms of the Service, and shall consist of 40 students; admission to the College being determined by a competitive examination. Only one officer at a time can belong to the College from a battalion of infantry, or a regiment of cavalry, and only ten officers at a time from the two corps of Royal Artillery and Royal Engineers, but, so far as the exigencies of the Service shall permit, there will be no limitation to the numbers allowed to compete for admission. Every application to study at the Staff College must be made whilst the officer making it is present and serving with his regiment, through the Commanding Officer. No application from an officer on leave will be entertained, and officers are not to be granted leave to be absent from their regiments or depots with the view of preparing themselves to compete for admission to the Staff College.

II. Twenty vacancies will be offered for competition annually, three of which may be filled by officers of the Royal Artillery and two by officers of the Royal Engineers, provided they are among the twenty candidates highest on the list. The principle under which officers are allowed to enter the Staff College being that of pure competition, it follows that candidates who may be found qualified at any examination, but who, from want of a sufficient number of vacancies, cannot then be admitted, will not have any claim to subsequent admission without undergoing another competitive examination.

III. No payment is required from students to the funds of the College, beyond an entrance fee of £3 from an unmarried and £1 10s. from a married officer, as a contribution to the College mess funds in addition to the regulated quarterly subscription; and an entrance subscription of £3 3s. to the College library.

IV. The qualifications requisite for admission are:

(*a*) A service of not less than five years, previous to examination, exclusive of leave of absence. This is not to apply to the usual leave of absence annually granted to officers on home service.

(*b*) A certificate from his Commanding Officer, that the candidate is in every respect a thoroughly good regimental officer.

(*c*) A report on the following questions, to be confidentially answered by a Board, consisting of the Commanding Officer and the two next senior officers of the candidate's regiment, viz.:

Is his conduct marked by steadiness and prudence, and is he temperate in his habits? Is he extravagant in his mode of living? Does he display zeal, activity, intelligence, and discretion in the performance of his duties, and does he take an interest in his profession?

[Any other characteristics of the officer which render him suited or otherwise for the duties of a Staff Officer, are reported].

Is his disposition such as would enable him to perform those duties with tact and discrimination, and in a manner calculated to ensure their being cheerfully carried out by those to whom orders would be conveyed by him; or are his manners and temper objectionable, and likely to cause him to disagree with those with whom he might be associated or brought in contact? Is he active in his habits? Is he a good (fair or indifferent) rider, and is he short-sighted?

(*d*) A certificate that the candidate, if not a Captain, has passed the examination for a troop or company.

(*e*) A medical certificate of good health and fitness for the active duties of the Staff.

Officers on half-pay whose regiments have been disbanded are, if possible, to obtain answers to these questions from the three senior officers under whom they have most recently served.

V. Every application to study at the Staff College must be forwarded through his Commanding Officer, whilst the officer is present and serving with his regiment. No application from an officer on leave will be entertained.

VI. Every candidate, before being admitted to the entrance examination, will, if practicable, be attached for a month to the Staff of a General Officer commanding a brigade or division, who at the expiration of this period will report confidentially upon the candidate's general fitness for Staff employment, and especially upon his aptitude for business and for conducting official correspondence.

VII. The competitive examination for entrance to the Staff College comprises the following subjects, the relative value of each at the examination being shown by the number of marks attached to it:

Mathematics, limited to arithmetic, algebra, geometry, plane trigonometry, and elementary mechanics	900
Military history and geography	900
French	300
German	300
Hindustani	300
Fortification	600
Military drawing	300
Geology, exclusive of mineralogy	300
Chemistry, heat, electricity, and magnetism	300

A qualification will be exacted from every candidate in—

1. Mathematics. 400 marks will be allotted to arithmetic, the first four books of Euclid, and algebra as far as simple equations inclusive; and of this number, at least 250 must be obtained for qualification.

2. Either French, German, or Hindustani. The qualifying minimum is, in French, 150 marks; in German or Hindustani, 100 marks.

3. Elementary field-fortification. One-third of 150 marks, to be assigned to a simple paper, will be required as the qualification in this subject.

VIII. The remaining subjects, as well as the higher portions of mathematics, may be taken up or not, at the option of the candidate, the marks gained therein and in the obligatory subjects, after deducting 60 from the marks gained in each voluntary subject, being reckoned in determining his position in the list of competitors.

IX. In regard to military history, early notice will on each occasion be given of the special campaigns on which questions will be set at the next ensuing examination.

X. The examination of officers serving in the United Kingdom, for entrance to the Staff College, is held in London, about the month of June, under the direction of the Director General of Military Education. (See par. xxix.)

XI. In the case of officers serving abroad, the examination is conducted by means of the same printed questions as are set for the examination of candidates in London. These questions are to be answered in writing in the presence of a Board of Officers, which will be appointed by the General Officer in command, and which will certify that the candidate has obtained no assistance from books, or help of any kind in the examination. (See par. xxx.)

XII. Notice will be given of each examination, and detailed instructions for the guidance of candidates will be published annually in the General Orders of the Army. Candidates are recommended to obtain the reports of the past examinations for admission, with copies of the examination papers, published by Taylor & Francis, Red Lion Court, Fleet Street.

XIII. The College course of study commences annually on or about the 1st of February. The transmission of the printed examination papers to stations abroad is so arranged that the examinations may be held simultaneously, and the merits of the candidates decided upon in time to admit of those who are successful joining the Staff College by the 1st of February next ensuing.

XIV. A synopsis of the course of study will be forwarded to any officer on application to the Director General of Military Education, War Office.

XV. The following are the subjects of instruction at the Staff College, viz.:—

OBLIGATORY.

1. Mathematics (first year only). 2. Fortification and field-engineering. 3. Artillery. 4. Topographical drawing, military surveying and sketching, and road making. 5. Reconnaissance. 6. Military art, history, and geography. 7. Military administration and law. 8. French, or German, or Hindustani. 9. Riding.

Instruction in mathematics is limited to the first year, and will comprise mensuration, the mode of determining heights and distances by ground problems, and by the ordinary trigonometrical calculations with the aid of logarithms, the use of the sextant, and elementary mechanics.

VOLUNTARY.

1. The two languages not selected as obligatory. 2. Geology, exclusive of mineralogy. 3. Experimental sciences. 4. Photography. 5. Military telegraphy.

Officers desirous of showing their proficiency in any or all of the above subjects, as well as in other modern languages not taught at the College, and in landscape drawing, may be examined therein, and a special report of their qualifications in each subject will be made to the Field Marshal Commanding-in-Chief, provided they obtain three-fifths of the maximum allotted to that subject; but they will not be allowed to count any marks thus gained at the final examination.

XVI. The course of study occupies two years, which period is not to be exceeded except in case of illness, and then only with the sanction of the Field Marshal Commanding-in-Chief. The Commandant, in arranging the details of the course of instruction, will be assisted by a College Board composed of the Professors.

XVII. The yearly course is divided into two terms, viz., from the 1st February to the 15th July, and from the 1st September to the 15th December, the intervening periods constituting the vacations.

XVIII. Confidential reports as to the character and abilities of every officer at the College, and his qualifications for Staff employment, will be forwarded at the end of every term by the Commandant to the Field Marshal Commanding-in-Chief, and any student who is reported unlikely to make an efficient Staff Officer will be required to leave the College. Examinations are held at the end of every half-year; the summer examinations being conducted by the Professors of the College, and the winter examinations by Examiners independent of the Establishment.

XIX. The examination at the end of the second term is probationary, and any student will be required to withdraw from the College who shall fail to obtain the minimum aggregate of marks. The marks gained at this examination will not be carried on to the credit of students at the final examination, except those gained in mathematics.

The subjects of the probationary examination, with the proportions of credits attached, will be as follows:

1. Mathematics	3
2. Fortification	3
3. Military history	3
4. Topographical drawing, military surveying and sketching	2½
5. Military administration	3
6. French, German, or Hindustani	2

The minimum aggregate required to pass at the probationary examination is .55. The counting minimum in each subject is .4.

XX. Should, moreover, any marked case of deficiency or neglect be brought under the notice of the Director General of Military Education, at any half-yearly examination, or at any other period, the student so reported will be liable to removal.

XXI. At the end of the second year a final examination will be held for the purpose of testing the general proficiency of the students in the obligatory subjects of the College course, as well as the qualifications of other officers who, under par. xxv., may be admitted to the examination.

Credit will be given to each subject at the final examination in the following proportions:

1.	Fortifications, field engineering, and artillery	6
2.	Military drawing and surveying, etc.	2½
3.	Reconnaissance	4½
4.	Military art, history, and geography	6
5.	Military administration	4
	Military law	2
6.	French, German, or Hindustani	4
7.	Mathematics	3

XXII. In the examination in modern languages great stress will be laid on original composition, and on colloquial knowledge.

XXIII. For qualification the students will be required to obtain .55 on the aggregate allotted to the seven obligatory subjects mentioned in par. xxi., the counting minimum in each subject being .4. For "honors" they must gain .8 on that aggregate of marks. For "special mention" in any subject .9 must be obtained.

XXIV. After the final examination the Director General of Military Education will draw up and submit to the Field Marshal Commanding-in-Chief a list of the passed candidates, arranged in the order of seniority of their regiments, distinguishing those who have gained "honors."

XXV. Officers of all branches of the Service shall be allowed to pass the final examination at the Staff College (subject to the following restrictions), without having gone through the course of instruction at the College. Candidates presenting themselves for the final examination without having gone through the course of instruction must have a previous service of seven years, and similar qualifications in other respects to those exacted (in par. IV.) from candidates for admission to the Staff College.

Previous to the time appointed for the final examination, they must reside at the College for such a period in the months of October and November, as may be necessary to allow of their taking part in the examination in reconnaissance, and of their being tested under the direction of the Commandant in the practical subjects of instruction at the College.

They must also pass the qualifying examination in mathematics prescribed in par. VII. They will also be tested in riding.

XXVI. Officers who have passed their final examination at the Staff College will either—

1. Be attached for three months, during the following summer drill season, to the Staff of a General Officer at some camp where all the three arms of the Service are present. During this period they shall be regularly employed as acting Staff Officers, and shall be required to make themselves acquainted with the organization of the several arms, and with the combined movements of troops. At the end of three months a confidential report shall be forwarded by the General Officer, stating minutely their abilities, the manner in which they have performed their duties, and the department of the Staff for which they appear to be most fit; or—

2. Be attached, during the following summer drill season, to other arms of the Service, for the purpose of acquiring instruction in those duties and field movements which are not common to their own. Certificates of their efficiency therein will be forwarded to the Adjutant General by the officers commanding the corps to which they have been attached.

Officers of cavalry and infantry will attend at Woolwich, or such other station as may be named, for instruction in artillery for a period of two months.

Officers of cavalry will be attached to infantry for two months.

Officers of artillery, horse-artillery excepted, will be attached to cavalry for one month, and officers of engineers and infantry for two months.

Officers of artillery and engineers will not be required to be attached to infantry.

XXVII. Candidates who shall have proved their fitness for employment in the Topographical Department of the War Office, by a superior knowledge of French and German, as well as of topography, will be named in the report of the Director General of Military Education as qualified for employment in that Department.

XXVIII. Officers who fail either at the probationary examination, or at the final examination, whether they have or have not gone through the course of instruction at the College, will not be allowed to present themselves again, either for admission to the College or at the final examination under par. XXV.

XXIX. Officers serving in the United Kingdom who are desirous of entering the Staff College must, before a date which will be made known, inform their Commanding Officers, by whom the certificates from (*a*) to (*e*), par. IV., will be prepared and forwarded through the usual channel to the Adjutant General of the forces. General Officers, in transmitting these applications, will record their opinions as to the fitness or otherwise of the applicants for Staff work, should they be able to do so from their personal knowledge of them.

If these certificates are satisfactory, orders will be issued for carrying out the test prescribed in par. VI. General Officers will report not latter than 20th May upon the candidates then attached to their Staff; after which date the officers, if approved, will receive, from the Director General of Military Education, the rules to be observed at their examination. The examination will take place in London on a date which will be made known by the Civil Service Commissioners.

XXX. General Officers commanding abroad will issue their own local orders specifying the date up to which applications will be received by them from officers wishing to be examined. Care should be taken that sufficient time is allowed for the qualification described in par. VI. to be obtained, so that all the necessry papers and certificates may be received at the Horse Guards on or before the 1st May.

General Officers in forwarding these applications, will carry out the instructions laid down in par. XXIX.

The examination papers will be sent out for those officers only whose applications shall have been thus received.

XXXI. The examination will commence on the 8th June, or as soon after that date as the examination papers shall be received from the Director General of Military Education; but no examination can be allowed to commence after the 30th June.

A Board of Officers will be appointed at the most convenient station of the district, by the General Officer in command, and will consist of three officers; one of them to be, when practicable, a Staff Officer, having the rank of Field Officer, and the other two, if possible, not under the rank of Captain. One of these officers will belong to one of the scientific corps, where any such officer can be obtained.

The questions are to be answered in the presence of the Board.

The Board will give to each candidate a number, which he will affix to each of his examination papers, instead of his name. He will retain the same number throughout the examination.

The Board will give to each candidate a paper of the printed examination questions on each subject, at the time specified for the examination in that subject.

The candidates will write their answers to the questions in the presence of the Board, and their papers, together with the printed examination questions, will be collected at the hour appointed, and made up into a packet, which will be sealed before being taken from the examination room.

The Board will, immediately on the conclusion of the examination, forward the papers of the candidates to the General Officer Commanding, for transmission to the Director General of Military Education, accompanied by a certificate that the candidates obtained no assistance from books, or help of any kind, in their examination. The Board will, at the same time, forward the names of the candidates, corresponding with their index numbers in the examination, in a separate envelope, for transmission to the Director General of Military Education. See *Royal Military Academy.*

STAFF CORPS.—Formerly an organized regiment of officers, many of whom served under the Duke of Wellington on the Staff. After the close of the Peninsular War, the Corps died out. The Staff Corps, as now known under that name, is that in India, which is formed into three Corps, one in each Presidency, and which was raised after the mutiny of 1855-58. The Corps are made up chiefly of officers of cavalry and infantry of the late Indian Army, and vacancies are filled up by young officers from her Majesty's European regiments.

STAFF PAY.—Pay given to officers and soldiers in the Government Service, who perform duties either on the Permanent Staff of an army or in Regimental or Departmental employment. Following is a table of salaries allowed for English Staff Officers and Departments of the several Presidencies in India. (See next page). See *Pay.*

STAFF SERGEANTS.—Non-commissioned Officers employed on the Staff of a Regiment, District, or Division. The following are classed under the above head, in the English Army:—

The Master Gunner, Sergeant Major, Schoolmaster, Bandmaster, Quartermaster Sergeant, Sergeant Instructor of Musketry, Sergeant Instructor in Fencing and Gymnastics, Sergeant Assistant Instructor of Gunnery, Farrier Major, Drum, Trumpet, Pipe or Bugle Major, Paymaster Sergeant, Orderly-room Sergeant, Armorer Sergeant, Hospital Sergeant, Saddler Sergeant, Collarmaker Major, and Wheeler Major. The above Staff Sergeants are entitled to lodging, fuel, and light allowance, when there is no barrack accommodation.

STAFF SLING.—This form of sling was composed of a shaft about one yard in length, and a leathern sling fixed on to one end. The slinger held it in both hands, and could hurl stones with a great violence. This weapon was subsequently employed to throw grenades.

STAIRS.—Except for temporary purposes, the stairs in fortifications are constructed of stone; each step is a solid block, which is 6 feet long in the clear; its breadth at top or the tread 12 inches, and its height or rise 8 inches. Stairs are usually placed along the counterscarp and gorge-walls of the outworks, forming a communication, for infantry only, between the ditch and the terre-plein of the work to which they lead. They are also used within the enceinte in positions where there is not sufficient room for ramps, or where, for greater security from surprise, it is desirable to present a narrower and more difficult defile to the assailant. In cases where room is wanting and the communication not in habitual use, the width of the stair may be reduced to 4 feet. See *Communications.*

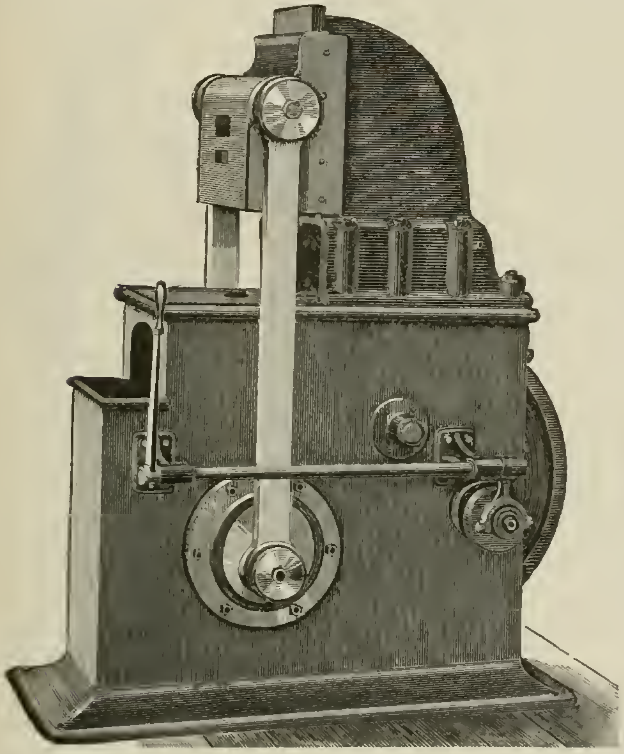
STAKES.—Small pieces of wood, either formed by hand or cut from the small branches of abatis. They are used as an obstacle against the advance of an attacking force, being sharply pointed and driven into the ground until only 1 or 2 feet project. They should be placed either in front of the counterscarp or in the ditch.

STAMPEDE.—Terror and confusion among flying troops, horses, etc. It is a favorite trick of Indians to stampede the stock upon their first arrival in camp, when the attention of every one is preoccupied and more or less confusion reigns. They seldom attempt a stampede at night, preferring the daylight for such work, and invariably select the early dawn of day or some moment when the command is in a probable state of confusion. A stampede is one of the most dreaded disasters that can happen. Frequently, the animals are not only widely scattered, but irretrievably lost; and much damage follows the rush of the infuriated herd through the camp, frequently trampling the men and tents, and killing themselves by coming in contact with trees and projecting rocks. When attempting a stampede, a few Indians will sometimes steal into camp, go to the bell-mare, remove the bell, place it on one one of their fleetest animals, and ride out of camp (before noticed) being followed by the entire herd. Again, they sneakingly approach as near the herd as possible, and dash into it, with their horses at full speed, at the same time terrifying them by the most hideous yells, and succeed in driving off the stock before any effectual resistance can be made. It is often effected by starting an Indian pony into the herd or the camp, with a buffalo robe dangling at his heels. The alarm is soon communicated to all the animals. When the herd is once started, it is pushed forward as rapidly as possible for a few days, so as to make distance between it and the pursuing party, while many Indians pass to the rear to offer resistance to the pursuers, if close at hand. Horses, and especially mules, that have been once stampeded, cannot be trusted beyond the control of the herders. They will, at very unreasonable moments, stampede in the most frantic manner without any apparent good reason. Even the passage of a deer, wolf, strange horse or herder among them will cause them to take alarm and scatter all over the country. The herders cannot be too diligent; they should at all times be ready for every emergency, and whenever the animals take fright they should hasten with the bell-mare in advance of them and gradually turn them in the direction of camp.

STAMPING-MACHINE.—There are many different types of stamping-machines for the great variety of work encountered in the Armory. For the ordinary and lighter work, a stamping-machine is employed, of which the essential portions are a *die*, a *reverse* or counter-die, and a *hammer*. A toothed rack, with arrangement for catching the hammer after it rebounds, is only used for special purposes. The die, which is made of cast-iron or steel, is fixed to the bottom of the stamp, and the reverse is attached to the hammer, which works between two guides. Pieces of thin rolled brass are cut to size, and one placed upon the die; the hammer, with the counter-die, is now raised to sufficient height by a windlass and rope, or other means, and allowed to fall, and thus force the thin plate into the die. The plates from the first blow are then annealed. Repeated blows and annealings follow until the article is "brought up," slight alterations in the reverse being from time to time required. Sometimes as many as 30 blows are necessary, but 10 or 12 strokes will suffice for an object with a considerable depth of raising. Globular articles are stamped in two or more pieces, and then soldered together.

The drawing represents the Pratt & Whitney double connection power-press, which is very extensively used in the manufacture of the parts of small-arms, etc. It is intended for heavy punching and for cold-drawing pieces which are difficult or costly to finish by milling or filing. It is capable of a resistance of 400,000 pounds. The driving-wheel, 36 inches diameter, carries a belt 4½ inches wide. On its shaft is a pinion engaging with a large gear-wheel on an intermediate shaft. A pinion on this shaft gears with another wheel on a shaft that carries the eccentrics which produce the stroke. The machine may be stopped or started instantly at any point of its stroke by means of the Pratt friction-clutch. The opening in the bed for the reception of dies is 9 inches square. The machine is built with a stroke of from 1 to 6 inches, as may be required. The weight of the machine, including countershaft, with 30 by 5½ inch pulleys, is 6,000 pounds.

The stamping process was first adapted to the production of hollow shapes in sheet-iron by Mr. T. Griffiths in 1841; and since then, the manufacture of a great variety of shapes has been improved and extended to a surprising extent. In the case of a dish-cover, for example, a single sheet of iron is brought to the required shape by the repeated stampings and



burnishings upon a chuck. It is afterward tinned with great ease, there being no joints to interfere with the operation; and for the same reason, iron basins stamped out of the single sheet can be readily enameled. The old way of forming these articles by hand-labor was very tedious and clumsy. German silver is too brittle a metal to be stamped like brass or iron, consequently it has only hitherto been made into small objects, such as spoons and forks, by this process. But the Messrs. Elkington, of Birmingham, are now making articles of considerable size in this material, by means of a stamping-press worked by hydraulic power. A number of the graduated dies are used for one object, each pair coming very gradually nearer the desired shape, but none of them making an impression deep enough to strain the metal. See *Die-sinking*.

STANCHION-GUN.—A small cannon, mounted on a pivot; also, a boat-gun, mounted on the gun-wall.

STAND.—This word, primarily signifying the act of opposing, is employed in various military phrases. *To stand one's ground*, is to keep the ground or station one has taken. *To stand fire*, is to receive the fire of arms from an enemy without giving way. *To make a stand*, is to halt for the purpose of offering resistance to a pursuing enemy. *To stand at ease*, is to enjoy, when in the ranks, a certain indulgence with regard to bodily position, with or without arms. *To stand fast*, is the term used as a caution to some particular part of a line or column, to remain quiescent while the rest are moving. *To stand to the guns*, is to prepare for action by taking station at the guns. *To stand to arms*, is a cautionary command, when soldiers are put upon the alert.

STANDARD.—In its widest sense, a standard is a flag or ensign under which men are united together for some common purpose. The use of the standard as a rallying-point in battle takes us back to remote ages. The Jewish Army was marshaled with the aid of standards belonging to the four tribes of Judah, Reuben, Ephraim, and Dan, and the Egyptians had ensigns with representations of their favorite animals. The flag of Persia was white, and, according to Xenophon, bore in his time a golden eagle with expanded wings; it was fixed on a chariot, and thus conveyed to the field of battle. Æschylus, in enumerating six chiefs who, headed by Polynices, set themselves in battle array against Thebes, describes the device on the standard of each. In the earliest era of Roman history a bundle of hay or fern is said to have been used as a military standard, which was succeeded by bronze or silver figures of animals attached to a staff, of which Pliny enumerates five—the eagle, the wolf, the minotaur, the horse, and the boar. In the second Consulship of Marius, 104 B. C., the other animals were laid aside, and only the eagle retained; and down to the time of the later Emperors, the eagle, often with a representation of the Emperor's head beneath it, continued to be carried with the legion. On the top of the staff was often a figure of Victory or Mars. Each cohort had also an ensign of its own, consisting of a serpent or dragon woven on a square piece of cloth, and elevated on a gilt staff with a cross-bar. Under the Christian Emperors, the *labarum* was substituted for the imperial standard. Various standards of great celebrity occur in mediæval history, among which may be enumerated the Flag of the Prophet; the standard taken from the Danes by Alfred of England; and the Oriflamme, originally belonging to the Abbey of St. Denis, and borne by the Counts of Vexin, which eventually became the standard of the French Kingdom.

In strict language, the term standard is applied exclusively to a particular kind of flag, long in proportion to its depth, tapering toward the fly, and except when belonging to Princes of the Blood Royal, slit at the end. Each Baron, Knight or other Commander in feudal times, had a recognized standard, which was distributed among his followers. The length of the standard varied according to the rank of the bearer. A King's standard was from 8 to 9 yards in length; a Duke's, 7 yards; a Marquis's, 6½ yards; an Earl's, 6 yards; a Viscount's, 5½ yards; a Baron's, 5 yards; a Banneret's, 4½ yards; and a Knight's, 4 yards. There was never a complete coat-of-arms on the standard; it generally exhibited the crest or supporter with a device or a badge of the owner, and every English standard of the Tudor era had the cross of St. George placed at the head. Standards were registered by the Heralds, and the charges on them selected and authorized by an Officer of Arms.

The so-called Royal Standard of Great Britain is more properly a banner being a square flag with the national arms covering the entire field without any external accessories. The so-called cavalry standards in use in the British Army are also in strictness banners. They are small in size: their color is determined by the color of the regimental facings, and they are charged with the cipher, number, insignia and honors of the regiment. The banners of the Household Troops are, however, all crimson and richly embroidered with the Royal ensignia of England. Corresponding to the standards of the cavalry are the colors of the infantry regiments, of which each has "a pair," one, called the Queen's Color being the Union Jack, charged with some ornamental device; the other, the Regimental Color, with the cipher, number, device, motto, and honors of the corps, cantoned with a small Union Jack. When a regiment obtains new colors, they are usually given by the wife of the Colonel or some lady of distinction.

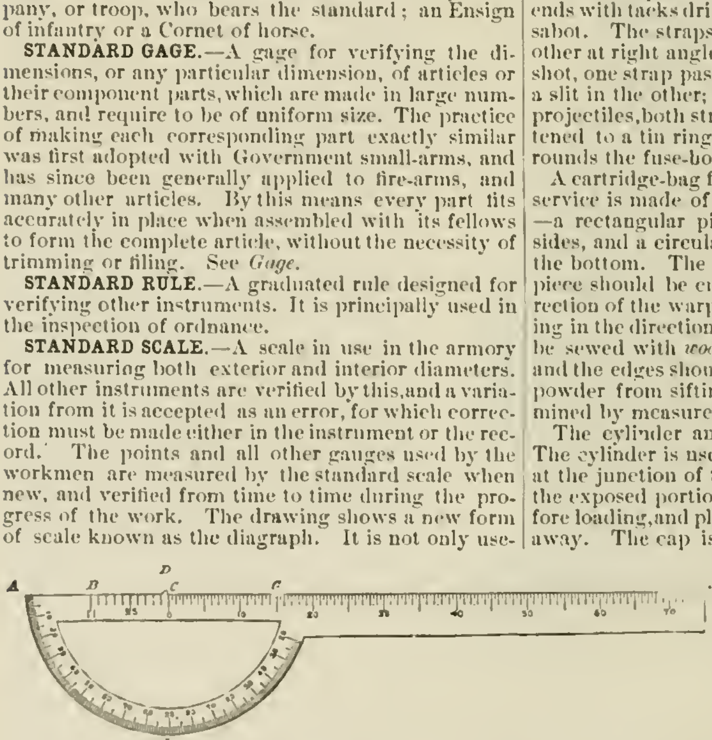
In the United States, each mounted regiment has a silken standard, and each company a silken guidon. The standard bears the Arms of the United States, embroidered in silk, on a blue ground, with the number and name of the regiment in a scroll underneath the eagle. The flag of the standard is two feet five inches wide, and two feet three inches on the lance, and is edged with yellow silk fringe. See *Banner*, *Colors*, *Flags*, *Guidon*, and *Labarum*.

STANDARD-BEARER.—An officer of an army, company, or troop, who bears the standard; an Ensign of infantry or a Cornet of horse.

STANDARD GAGE.—A gage for verifying the dimensions, or any particular dimension, of articles or their component parts, which are made in large numbers, and require to be of uniform size. The practice of making each corresponding part exactly similar was first adopted with Government small-arms, and has since been generally applied to fire-arms, and many other articles. By this means every part fits accurately in place when assembled with its fellows to form the complete article, without the necessity of trimming or filing. See *Gage*.

STANDARD RULE.—A graduated rule designed for verifying other instruments. It is principally used in the inspection of ordnance.

STANDARD SCALE.—A scale in use in the armory for measuring both exterior and interior diameters. All other instruments are verified by this, and a variation from it is accepted as an error, for which correction must be made either in the instrument or the record. The points and all other gauges used by the workmen are measured by the standard scale when new, and verified from time to time during the progress of the work. The drawing shows a new form of scale known as the diagraph. It is not only use-



ful in the verification of measures, but is very handy in drawing patterns and diagrams with great rapidity. With the addition of compasses for circles, it will be found an improvement upon an entire box of ordinary instruments, doing the same work with greater accuracy and facility. See *Corrective Gauges*, and *Inspection of Ordnance*.

STANDING ARMY.—An army which is kept up by a country, and is liable to every species of duty, without any limitations being fixed for its service.

STANDING ORDERS.—Certain general rules and instructions, which are to be invariably followed, and are not subject to the temporary intervention of rank. Of this description are those orders which the permanent Commander may judge fit to have inserted in the order books, and which are not to be altered by the temporary Commander.

STANDING SAP.—A method of sapping less irksome but not quite so rapid as the ordinary method of advancing. The squad consists of three men. No. 1 leaves a turn of 18 inches, and digs a trench 18 inches wide and 3 feet deep. No 2 widens this trench 18 inches and No. 3 widens No. 2's work 18 inches.

STAND OF AMMUNITION.—A stand of ammunition is composed of the projectile, the sabot, the straps, and the cartridge-bag. The projectiles used in howitzers are shell, shrapnel, and canister.

The sabot is a thick, circular disk of wood, to which the cartridge-bag and projectile are attached. For a spherical projectile, the sabot has a spherical cavity and a circular groove to which the cartridge-bag is tied; in the canister-sabot, the spherical cavity is omitted, and a circular offset is added. The effects of a sabot are:—1st. To prevent the formation of a *lodgement* in the bore. 2d. To moderate the action of the powder on the projectile. 3d. To prevent the projectile from moving from its place. In consequence of the scattering of the fragments, it is dangerous to use the sabot in firing over the heads of one's own men.

The projectile is secured by two tin straps, fastened at the ends with tacks driven into the sabot. The straps cross each other at right angles; for solid shot, one strap passes through a slit in the other; for hollow projectiles, both straps are fastened to a tin ring which surrounds the fuse-hole.

A cartridge-bag for the field-service is made of two pieces —a rectangular piece for the sides, and a circular piece for the bottom. The rectangular piece should be cut in the direction of the warp, to prevent the bag from stretching in the direction of its diameter; the seams should be sewed with *woolen* yarn, 12 stitches to the inch, and the edges should be basted down, to prevent the powder from sifting through. The charge is determined by measurement.

The cylinder and cap are made of a stout paper. The cylinder is used to give stiffness to the cartridge at the junction of the sabot and bag; the cap covers the exposed portion of the bag, and is drawn off before loading, and placed over the projectile, or thrown away. The cap is made by cutting off a portion of the cylinder, and choking one end. The cartridge-bag is attached to the projectile by tying it around the grooves of the sabot with twine.

As soon as the ammunition is finished it should be ganged to see that it is of the proper caliber; it is afterwards packed in well seasoned pine boxes, so disposed that the sabot may rest on a ledge in the box, leaving the charge below free from any pressure. The shell, shrapnel, and canister for the 12 pdr. howitzers are packed in boxes containing nine each. A fuse-cutter (for the Bormann fuse) is placed in the rim of each box containing loaded projectiles. The boxes are painted black and marked with the contents. The lids are fitted with hinges and secured with screws. A key is becketed to each box for unscrewing the lid. In consequence of the objection to packing powder in wood, thereby rendering it more liable to deterioration, various plans have been suggested for fitting the cartridge to be attached to the sabot at will, and stowing them separately; and it has been ordered that this be done. See *Ammunition*, and *Field and Mountain Ammunition*.

STAND OF ARMS.—A complete set for one soldier, whether horse or foot: as a rifle and bayonet, cartridge-box and belt, etc. Frequently the rifle and bayonet alone.

STAND OF COLORS.—The common expression for a single color, or flag.

STAND TO HORSE.—A position assumed by troopers preparatory to mounting. The horses being equipped with blankets and watering-bridles, the Instructor commands: STAND TO HORSE. At this command, each soldier stands face to front, on the near side of the horse, his breast on a line with the lower jaw, takes the position of the soldier dismounted, except that his right hand, nails down, grasps both reins, six inches from the bit.

STANG-BALL.—A projectile made up of two half-balls united by a bar. See *Bar-shot.*

STAR.—1. The star is of frequent occurrence as a heraldic bearing; it sometimes represents the heavenly body so called, and sometimes the rowel of a spur. In the latter instance, it is blazoned a *mullet.* Stars of more than five points should have the num-

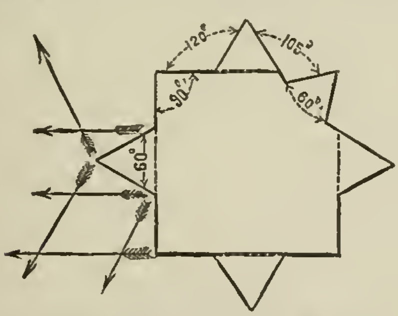
Stars.

ber of points designated, and the points may be wavy. A star, or *estoile*, with wavy points, is often designated a blazing star: and when the points are more than six in number, it is usual to represent only every second point as waved.

The star is a well-known ensign of knightly rank. A star of some specified form constitutes part of the insignia of every order of knighthood.

2. The Order of the Star was an order of knighthood formerly existing in France, founded by John II. in 1350 in imitation of the then recently instituted Order of the Garter in England. The ceremony of installation was originally performed on the festival of the Epiphany and the name of the Order is supposed to have been allusive to the Star of the Magi.

STAR FORTS.—Star forts in plan consist of a polygon having alternately salient and re-entering angles. The object of this disposition is to obtain cross-fires on the approaches upon the salients, and to remove the dead space in the portions of the ditch at the salients. This can only be effected in star forts having at least eight salients. In all other cases, when the salients are limited to 60°, the re-entering angles become too obtuse to admit any but a very oblique fire from the faces in the direction of the salients. The star fort is sometimes planned by placing redans on the middle of the faces of a square redoubt, as shown in the drawing, thus presenting alternate salients of 90° and 60°. In some special cases the salients of 90° are reduced to 60° by prolonging



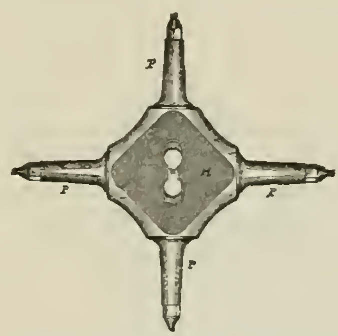
Plan of Star Fort for a polygon of eight sides.

inwards the faces of the redans. When the site is horizontal there is no good reason for making the work irregular in its parts. The star fort, from its imperfect flanking dispositions, is but little if at all superior in strength to the redoubt. For the same interior space for the uses of the garrison, the star fort presents a much longer line of parapet than the redoubt, to be defended. It is therefore only on irregular sites, or broken ground, that an application will be found for it. Since the introduction of modern improved arms, but little regard has been given to flanking arrangements in field-works, experience having developed the fact that they are of very little practical advantage. Lines and groups of works are now laid out so as to cover each other by flank and cross-fire. A work entirely detached, should, however, have within itself proper flanking arrangements. See *Field-works* and *Inclosed Works.*

STAR-GAUGE.—An instrument for measuring the diameter of the bore of a gun at any part. The head is made of brass, with four steel sockets for the measuring points, used in gauging smooth-bore guns or tubes, two of the sockets being soldered fast into the head and the other two movable. The two stationary points act simply as guides, and are held horizontally in the bore, while the movable or the measuring points are held and act vertically.

A wedge or tapering plate, *W*, the sides of which are cylindrical, runs through a slit in the head; an aperture in the inner end of the movable sockets, *AA*, embraces the cylinders, so that when the wedge is moved forward or backward, the sockets are projected or withdrawn.

The tapering of the wedge has a certain known proportion to its length, so that if it is moved in either direction a given distance, a proportional movement is imparted to the sockets. The sides of the wedge incline 0.35 inch in a length of 2.2 inches, so that by pushing it the thirty-fifth part of this distance (about 0.06 inch), the distance between the two sockets is increased .01 inch. There are four steel measuring-points, *P*, for each caliber, fitted with very strong shoulders at one end, below which threads are cut



for screwing into the sockets in the head. A wrench is made to fit the shoulders, so as to turn the points firmly into their places; when two of these are screwed into the fixed sockets, the distance between their extremities is equal to the true diameter of the bore.

In front of this set are three movable sockets, used when gauging rifled guns. These are capable of a lateral motion to enable them to be adjusted for use with guns of any size or of any number of grooves. The staff, to which the head is permanently attached, is a hollow brass tube, made in three or more sections, and graduated for its entire length into inches and quarters, beginning at the measuring-points (smooth-bore), so as to indicate the distance of the latter from the muzzle of the gun. Through the staff passes a square steel rod, divided into the same number of sections as the staff, and which are arranged with threads, so as to be screwed together.

The handle is a brass tube, and is secured on to the rear of the square rod. It has a sliding motion along the end of the staff to which it is fitted. Toward the front part is a slit, on the side of which is marked a scale to indicate the movements of the measuring-points. Each joint of the staff carries a mark made on a small silver plate, which shows through the slit the zero point upon the scale, when the measuring-points are adjusted to the true diameter of the bore. For purposes of adjustment the rear half of the handle can be moved by screwing backward or forward along the front half, and it can be secured, when desired, by a clamp-screw.

A ring-gauge—being a simple steel ring of sufficient thickness to insure stiffness—is used for each caliber in connection with and for adjusting the gauge. Each ring-gauge is accompanied by a set of measuring-points, which are screwed into the sockets by an ordinary wrench. A rest in the form of a T is placed in the mouth of the gun to support the instrument in the axis of the bore. The upright branch is movable for convenience in packing, and each carries a slide which can be adjusted for different sizes of bore. To facilitate the adjustment of the rest, the positions of the slides on the different branches are permanently marked for different calibers of guns.

To adjust the instrument, the ring-gauge of the required diameter is so held as to surround the corresponding points which have been fitted to the sockets. The points are then pushed out by the handle till in contact with the ring; and if the zero points do not coincide, the clamp-screw is loosened and the rear part of the handle is screwed backwards or forwards till the coincidence is effected. The clamp-screw is then tightened and the instrument is ready for use.

Before and after every set of measurements the adjustment of the instrument must be similarly verified. Where more than two lengths are used, the staff must be supported when taking measurements near the muzzle of the gun. In rifled pieces the measurements should be made at intervals of $\frac{1}{4}$ of an inch from the bottom of the cylindrical part of the bore to the front of the seat of the shot, and at intervals of 1 inch from that point to the muzzle. The measurements are at first taken from land to land, and afterward from groove to groove. See *Inspection of Ordnance*.

STAR OF INDIA.—The Order of the Star of India is an order of knighthood instituted by Queen Victoria in June, 1861, with the view of affording the Princes, Chiefs, and people of the Indian Empire a testimony of her Majesty's regard, commemorating her Majesty's resolution to take on herself the government of India, and rendering honor to merit and loyalty. The Order consists of the Sovereign, a Grand-master, who is to be the Governor General of India for the time being, and 25 knights, together with such extra and honorary knights as the Crown may appoint. The members of the Order are to be military, naval, and civil officers who have rendered important service to the Indian Empire, and such native Chiefs and Princes of India as have entitled themselves to her Majesty's favor. The insignia consist of a collar, badge, and star. The *collar* of the Order is composed of the heraldic rose of England, two palm branches in saltire tied with a ribbon, and a lotus-flower alternating with each other, all of gold enameled, and connected by a double golden chain. From an imperial crown, intervening between two lotus-leaves, depends the *badge*, consisting of a brilliant star of five points, and hanging from it an oval medallion, with an onyx cameo profile bust of Queen Victoria, encircled by the motto: "Heaven's light our guide" in gold letters, on an enriched border of light-blue enamel. The *investment badge* is similar to the collar-badge, but with the star, the setting of the cameo, and the motto all of diamonds; it is worn pendent from a ribbon of pale blue with white borders. The *star* of the Order is a five pointed star or mullet of diamonds on an irradiated field of gold. Around it, on an azure fillet bordered with gold, is the same motto in diamonds, the whole encircled by wavy rays of gold.

Star of India.

STARS.—Decorations for rockets. There are several varieties :—*White stars* consist of 16 parts of niter; 8 parts of sulphur; and 4 parts of mealed powder. *Blue stars* usually consists of 69 parts of potassium chlorate ; 24 parts of sulphur ; and 7 parts of copper sulphate. *Red stars* consist of 32 parts of strontium nitrate ; 9 parts of good sulphur ; 8 parts of potassium chlorate; and 2 parts of lamp-black. *Green stars* consist of 18 parts of barium nitrate ; 6 parts of sulphur; 4 parts of potassium chlorate ; and 1 part of lamp-black. *Purple stars* consist of 24 parts of potassium chlorate ; 4 parts of sulphur ; and 3 parts of copper sulphate. *Yellow stars* consist of 1 part of charcoal ; 1 part of sulphur ; and 6 parts of sodium nitrate. *Five-pointed stars* consist of 7 parts of sulphur, and 10 parts of mealed powder.

To prepare the composition, reduce the materials to the finest powder; mix them with the hands; pass them three times through the sieve, mixing them each time with the hand. Moisten the composition with whisky in which gum has been dissolved, so that the composition shall retain its form when pressed in the hand. Fill the mold by pressing it in the composition spread out in a wooden bowl : push out the star with the piston, letting it fall lightly on a sheet of paper dusted over with mealed powder. *Colored stars* are made in the same manner as white ones, using the compositions indicated in the table. See *Compositions*, *Fireworks*, and *Signal-rocket*.

STAR-SHELL.—A thin iron shell used with light muzzle-loading guns, filled with stars, and intended to light up an enemy's position at night. It contains six stars of magnesium-light composition, burning about 13 or 14 seconds, and seven stars of signal-light composition, burning about 34 or 36 seconds. It is complete in itself, having the burster ($\frac{1}{2}$ drachm of powder) with quick-match priming arranged in the interior, and only requires the time-fuse to be prepared and fixed when required for action. By adopting a code where certain words are represented by different colors, a complete system of communication might be kept up between two bodies of troops at a considerable distance from each other.

STATANT.—In Heraldry, a term applied to an animal standing still, with all the feet touching on the ground. If the face be turned to the spectator, it is said to be *statant gardant*, or in the case of a stag, *at gaze*.

STATE.—In the British Service, a statement of the number of officers and men of any body of troops, distinguishing those present, those employed, absent, or sick, and the different ranks under separate headings.

STATICS.—The science of the equilibrium or balancing of forces on a body or system of bodies, has gradually advanced from the days of Archimedes to the grand developments it has now acquired. Singularly enough, though most of its simpler theorems are very generally known, are almost popular, in fact, there is no science in which elementary teaching is so defective. The ordinary proofs of its fundamental principles, such as the *parallelogram of forces*, the *principle of the lever*, etc., are usually founded on the supposition that a body in equilibrium is *absolutely at rest*. Now, any one who knows that the earth rotates about its axis, that it revolves about the sun, that the sun is in motion relatively to the so-called fixed stars; that *they* are, in all probability, in motion about something else which is itself in motion, etc., will at once see that there is no such thing as absolute rest, and that *relative rest* or motion, unchanged with reference to surrounding bodies, is all that we mean by equilibrium. He will then, at once, see that the foundations of all statics are to be sought in the laws of motion. And, in fact, Newton's second law of motion gives us the necessary and sufficient conditions of equilibrium of a single particle under the action of any forces; while his third law, with the annexed scholium, gives these conditions for any body or system of bodies whatever.

The simplest statement of the conditions of equilibrium of a rigid body which can be given, is that furnished by this scholium of Newton's, which is now known by the name of the principle of energy (see FORCE) or work. It is as follows: A rigid body is in equilibrium if, and is not in equilibrium unless, in *any* small displacement whatever, no work is done on the whole by the forces to which it is subject. In the case of what are called the *mechanical powers*, this is equivalent to the statement that work expended on a machine is wholly given back by the machine—or that the work done by the *power* is equal to the work spent in overcoming the *resistance*. It is shown in the geometrical science of kinematics that any motion whatever of a rigid body can be reduced to *three* displacements in any three rectangular directions, together with *three* rotations about any three rectangular axes—so that the equilibrium of a rigid body is secured if no work be done on the whole in any of these *six* displacements. There are thus six conditions of equilibrium for a rigid body under the action of any forces—and these are reduced to *three* (two displacements and one rotation), if the forces are confined to one plane; and to *one* (a displacement) if the forces act all in one line.

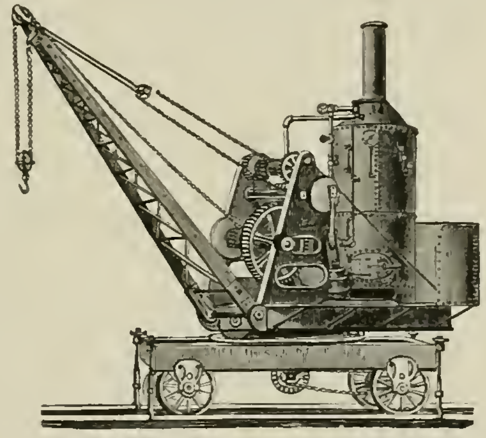
Equilibrium may be *stable*, *unstable*, or *neutral*. It is said to be stable if the body, when slightly displaced in any way from its position of equilibrium, and left free, tends to *return* to that position. It is unstable if there is any displacement possible which will leave the body in a position in which it tends to *fall further away* from its position of equilibrium. It is neutral if the body, when displaced, is still in equilibrium. It is easily shown, but we cannot spare the space for the proof, that a position of stable equilibrium is, in general, that in which the potential energy (see FORCE) of the body is a minimum—of unstable equilibrium, where it is a maximum (for some one direction of displacement at least)—of neutral equilibrium, where the potential energy remains unchanged by any small displacement. Thus a perfect sphere, of uniform material, is in neutral equilibrium on a horizontal plane—while an oblate spheroid, with its axis of rotation vertical, is in stable equilibrium; and a prolate spheroid, with its axis vertical, is in unstable equilibrium on the plane. Similar statements hold for other than rigid bodies. Thus, a chain, or a mass of fluid, is in stable equilibrium when its potential energy is least, *i. e.*, when its center of gravity is as low as possible. This simple statement is sufficient for the mathematical solution of either question.

STATION.—A locality chosen for the garrisoning of troops. The name of *stationes*, or stations, was given by the Romans to the guard which was kept in the day time at the gates of the camp, and at the intrenchments. The *statio agraria* was an advanced post to prevent surprise, insure the safety of prisoners, etc. The chief use was to keep the military *sway* secure from hostile incursions, whence we find them at the concurrence of roads. The term is also extensively applied to the old military stations of the Romans, when encampments of towns existed. The *statira castra* were encampments for a short time; the *aestiva castra* were the same, but might be occupied only for one night. The *hyberna castra*, or winter camps, were elaborately fortified, even with stone walls, houses within, etc., so that many towns grew out of them. See *Post*.

STATUS IN QUO.—A treaty between belligerents, which leaves each party *in statu quo ante bellum*, that is in the state in which it was before the war. Also written *status quo*.

STAYS.—Bars, generally of round or angle-iron, spanning an angle in frame-work, to neutralize the bending moment about the junction of two beams forming the angle. Stays are of frequent necessity in the construction of artillery carriages.

STEAM-CRANE.—The application of steam to the working of cranes was an obvious one, and is now universal where much hoisting-work has to be done; it not only effects a great saving in labor, but causes the work to be much more quickly done, a consideration quite as important. Steam-cranes and winches are now almost invariably used at foundries. When working on a wharf, and in many other situations, it is often very convenient that the crane should be movable, so that it may go to its work in the multitude of cases where that arrangement is more convenient than the converse. For this purpose it is mounted on a plain railway truck, either of wood or iron, the truck being generally provided with clamps at the ends, by which it can be firmly secured to the rails when lifting the weights. The balance construction, now universally adopted for portable cranes, was invented or suggested by the late Mr. R. W. Thomson, C.E. in 1856—its essential feature being the use of the boiler as a counterpoise to the weight to be lifted. The principal parts of a steam-crane are: 1. The boiler, which must be of some very simple construction, as it has so frequently to be worked with excessively dirty water. 2. The framing, which is generally made



of cast-iron, and supports the boiler, the engine and gear, and the jib. 3. The engine (which has almost always two small cylinders, and is fitted with reversing gear), and the pinions, wheels, drums, etc., for the hoisting and other motions. 4. The "jib" (either of wood or iron), over a pulley in the top of which the chain passes, and the purpose of which is to enable the different objects to be lifted quite clear of the ground, and deposited, when necessary, on trucks, etc., 5. The pillar, which is firmly attached to the truck, and which, passing upward through the center of the frame, forms the pivot on which it turns round. 6. The truck itself, which supports the whole machine. If the crane is stationary, the truck, of course, is not required, the bottom of the pillar being imbedded in masonry; and for large cranes the boiler is generally made separate from the machine itself, and sometimes the engines also. A portable balance steam-crane is when complete fitted with the following motions.—1. Gear for hoisting generally with two or more speeds, to be used according to the weight to be lifted; 2. Gear for raising or lowering the outer end of the jib; 3. Gear for slewing the jib (with boiler and frame attached to it); 4. Gear for propelling the truck along the rails. A complete and well-designed crane of this kind, made by Messrs.

Williamson Bros., will lift from 5 to 7 tons, according to the position of the jib. The revolving base has a tank under the boiler, from which the feed-water is supplied by means of an injector. At the sides and the back end of boiler, a sheet-iron frame is fitted for use as a coal-bunker; or, if required, iron or other ballast can be placed in it, to assist in balancing heavy loads. The carriage or truck is constructed of wrought and cast-iron, to which are fitted rail-clamps; and, where the crane is for a narrow gauge, can be fitted with cross-girders to increase base.

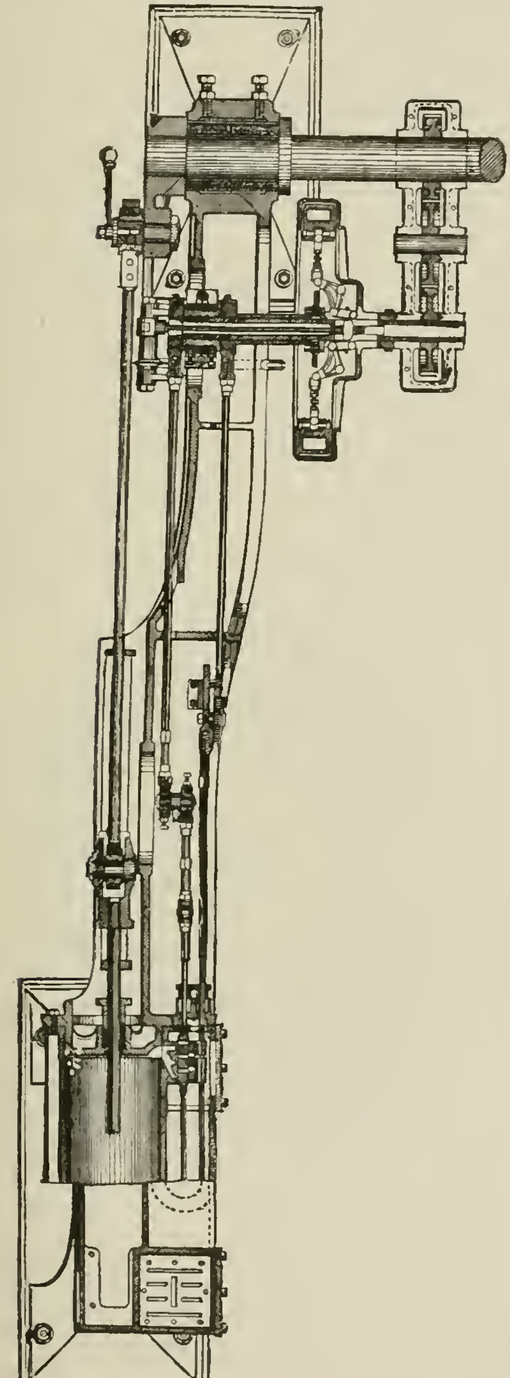
STEAM-ENGINE.—Steam-engines, in their infancy, were known as fire-engines; and in point of fact the older term is the more correct, because the water or steam is only used as a convenient medium through which the form of energy which we call heat is made to perform the required mechanical operations. In modern engines, sufficient heat is added to the steam to raise it to a very high pressure, and the excess of this pressure over the pressure opposed to it (either atmospheric pressure or the still lower pressure in a condenser) is both the cause and measure of the work done by the engine. In earlier machines, however, the steam was raised only to atmospheric pressure, and admitted into the engine only to be at once condensed by a jet of cold water. The excess of the atmospheric pressure above the pressure in the partial vacuum caused by the condensation was then the direct cause of work. Engines of this kind are not now used; they were called atmospheric engines. As a source of power, steam has several advantages over wind and water. It is independent of the weather, may be applied anywhere, affords a constant equable motion, and is capable of indefinite increase. Its invention, therefore, has caused a new era in the arts; and the revolution which it has brought about in industry of all kinds, as well as the influence it has had on civilization in general, and must yet have in a higher degree, are altogether incalculable.

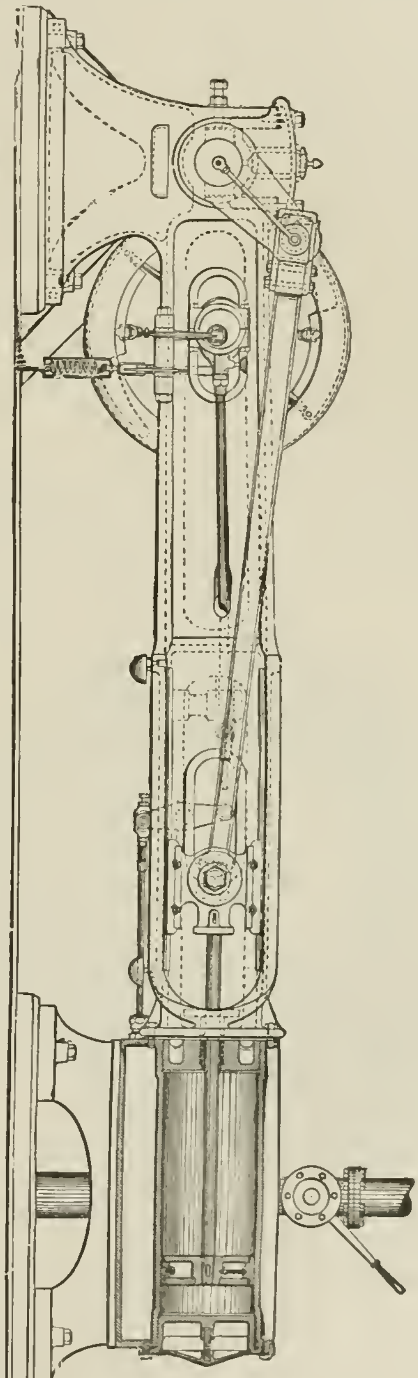
The invention of steam as a propelling power is claimed by various nations: but the first extensive employment of it, and most of the improvements made upon the steam-engine, the world indisputably owes to the English and the Americans. It would appear that as early as 1543 a Spanish Captain, named Blasco de Garay, showed in the harbor of Barcelona a steamboat of his own invention. It is most likely that Blasco's engine was on the principle of the Æolipile of Hero, invented 130 B.C., in which steam produces rotatory motion by issuing from orifices, as water does in Barker's Mill. The preacher Mathesius, in his sermon to miners (Nuremberg, 1562), prays for a man who "raises water by fire and air," showing the early application of steam-power in Germany; and the German engineer, Sol. de Caus, in the service of the Elector Palatine in Heidelberg, describes in his work, *Les Raisons des Forces Mouvantes avec Diverses Machines*, 1615, a steam-machine, which was merely a contrivance for forcing the water contained in a copper ball through a tube by applying heat. An Italian engineer, G. Branca, invented, in 1629, a sort of steam windmill; the steam being generated in a boiler, was directed by a spout against the flat vanes of a wheel, which was thus set in motion.

In England, among the first notices we have of the idea of employing steam as a propelling force, is that contained in a small volume, published in 1647, entitled *The Art of Gunnery*, by Nat. Nye, mathematician; in which he proposes to "charge a piece of ordnance without gunpowder," by putting water instead of powder, ramming down an air-tight plug of wood, and then the shot, and applying a fire to the breech "till it burst out suddenly." But the first successful effort was that of the Marquis of Worcester. In his *Century of Inventions*, the manuscript of which dates from 1655, he describes a steam-apparatus by which he raised a column of water to the height of 40 feet. This, under the name of "Fire-waterwork," appears actually to have been at work at Vauxhall in 1656. Sir Samuel Morland, in 1683, submitted to Louis XIV., a project for raising water by means of steam, accompanying it with ingenious calculations and tables. The first patent for the application of steam-power to various kinds of machines was taken out in 1698 by Captain Savery. In 1699, he exhibited before the Royal Society a working model of his invention. His engines were the first used to any great extent in industrial operations; they seem to have been employed for some years in the drainage of mines in Cornwall and Devonshire. The essential improvement in them over the older ones was the use of a boiler separate from the vessel in which the steam did its work. One vessel, in all former engines, had served both purposes. He made use of the condensation of steam in a close vessel to produce a vacuum, and thus raise the water to a certain height, after which the elasticity of steam pressing upon its surface was made to raise it still further in a second vessel.

In all the attempts at pumping-engines heretofore made, including Savery's, the steam acted directly upon the water to be moved without any intervening part. To Dr. Papin, a celebrated Frenchman, is due the idea of the *piston*. It was first used by him in a model constructed in 1690, where the cylinder was still made to do duty also as a boiler; but in an improved steam-pump invented about 1700 he used it as a diaphragm floating on the top of the water in a separate vessel, or cylinder, and the steam, by pressing on the top of it, forced the water out of the cylinder at the other end. The next great step in advance was made about 1705 in the atmospheric engine, conjointly invented by Newcomen, Cawley, and Savery. This machine held its own for nearly seventy years, and was very largely applied to mines.

The next essential improvements on the steam engine were those of Watt, which began a new era in the history of steam-power. The first and most important improvement made by Watt was the separate condenser, patented in 1769. He had observed that the jet of cold water thrown into the cylinder to condense the steam, necessarily reduced the temperature of the cylinder so much that a great deal of the steam flowing in at each upward stroke of the piston was condensed before the cylinder got back the heat abstracted from it by the spurt of cold water used for condensing the steam in the cylinder. The loss of steam arising from this was so great that only about one-fourth of what was admitted into the cylinder was actually available as motive power. Watt, therefore, provided a separate vessel in which to condense the steam, and which could be kept constantly in a state of vacuum, without the loss which arose when the cylinder itself was used as a condenser. This device, which now looks simple enough, was the greatest of Watt's inventions, and it forms the foundation of his fame. His genius was such that in a few years he changed the steam-engine from a clumsy, wasteful, and almost impracticable machine into a machine practically the same as we now have. The principal improvements since his time have been either in matters relating to the boiler; in details of construction consequent on our increased facilities, improved machinery, and greater knowledge of the strength of materials; in the enlarged application of his principle of expansive working; or in the application of the steam-engine to the propulsion of carriages and vessels. His principal inventions were as follows: 1. The condensation of steam in a vessel separate from the cylinder, so as to avoid the cooling of the latter. 2. The use of a pump, designated an "air-pump," to withdraw the condensed water, and mixed steam and air, from the condenser. 3. To surround the cylinder either with a steam-jacket, or with some non-conducting body, in order to prevent radiation of heat (these three, with others, were included in the specification of 1769). 4. To use the steam expansively in the way explained further on in this article (this was invented before 1769, but not published till 1782); and 5. The now universally used double-acting engine, and the conversion of the reciprocating motion of the beam into a rotary motion by means of a crank (both these were invented before 1778, the engine being patented in 1782, but the crank having before that date been pirated and patented by another. Watt also patented and published his parallel motion, throttle-valve, governor, and indicator; all four of which are still used.





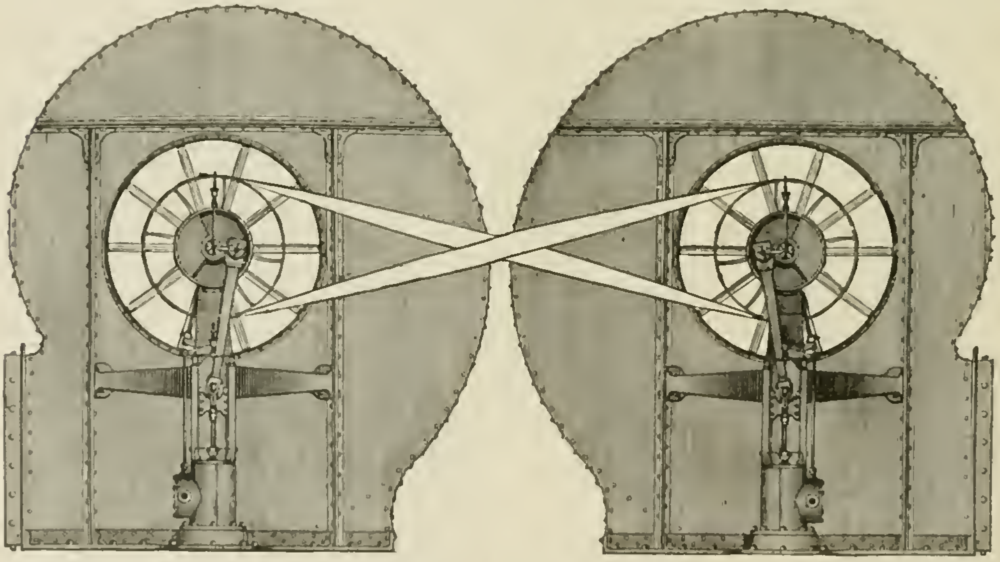
It would be inconsistent with our limits to enter into any description of the constructive details of steam-engines; we can only afford to give a general notion of the way in which the motion is originated, and to explain the chief principles on which the motive-power and economy of engines depend. For the purpose of our illustration we have selected the Cummer Engine—one of the most perfect and satisfactory engines ever designed. The illustration herewith presented shows an elevation and a part of the vertical section of this standard automatic engine, and also a horizontal section which shows the form of the girder and cylinder, and clearly exhibits the various working parts, in their relation to each other. In the elevation there appears a section of the piston and there is shown the form of cross-head, connecting-rod, and crank. The horizontal section further details the cross-head, the sub ends of the connecting-rod, and crank. The main bearing with its quarter-boxes, shoes and means for adjustment is clearly detailed, and there is shown the train of three gears which drives the governor-shaft from the main-shaft; the governor also appears in section showing the weights, the bell crank, and attachments to the shaft-rod. The elevation and plan exhibits the large bell crank, to the vertical arm of which the thrust-rod is attached, while the horizontal arm supports all the hanging weights, and has attached to it the spiral spring which appears in the elevation. Referring once more to the horizontal section, it will be noticed that the main eccentric is attached directly to the governor-shaft, and the cut-off eccentric is attached to a long sleeve, which by suitable connection with the governor-weights, is made to rotate the eccentric forward or backward, and thus change the point of cut-off. The main eccentric operates the main-valves and also the exhaust-valves through the intervention of a rock-arm. The eccentric-rods and valve-stems have means for adjustment of length, these, with the joints at the rock-arm and the slide to prevent vibration of the cut-off valve-stem, as well as the mode for attaching the valves to the valve-stems, are all shown in the horizontal section.

The lower right hand portion of this section, shows that part of the cylinder where the exhaust-valve for this end is situated. The piston rod stuffing-box is bushed with brass. In the vertical section appears a novel form of cylinder-head which projects within the cylinder and reduces the clearance to as low an amount as possible. The forward head is formed by the end of the girder-frame, but in the larger sizes the head is made separate and bolted to the frame. Objections have been made against this deep form of cylinder-head, on the ground that the annular space between the head and counterbore affords so much more condensing surface than the ordinary form of cylinder-head; but, in point of fact, this objection does not hold at all, because the cylinder-heads are made a true fit for one inch or so at the outside bearing and a sliding fit for all the rest of the length. The space between the counterbore and the head, which is about the thickness of a piece of paper, becomes, when in use, completely filled up with a deposit from the oil used to lubricate the cylinder, which is driven in by the steam and effectually prevents any condensation from this cause. The various details alluded to in this general description, will be found more thoroughly illustrated and described under specific headings. See *Cylinder*, *Fly-wheel*, *Governor*, *Indicator*, and *Piston*.

STEAM-FAN.—A fanner driven by steam. These machines have a wide range of application, being employed for blowing furnaces of all kinds provided with grate-bars, such as steam-boilers, steamboat, gunboat, ironclad and steam yacht boilers, iron melting, heating, puddling, and nail furnaces. Coal-screenings and all kinds of refuse coal, tan bark, sawdust, etc., may be successfully used for fuel by the use of blast from these fans. For heating dry houses and rooms for drying lumber of all kinds, and all materials manufactured from wood; leather, glue, grain, fruits, fish, herbs, paints, cotton, wool, knit goods, and all other textile fabrics. For cold storage where the air is drawn over ice for cooling and preserving meats of all kinds, fish, fowls, dairy products, etc. Also, for any and all other purposes where a large volume of hot or cold wind is required.

The larger sizes are particularly adapted for cooling and ventilating mines, casemates, manufacturing establishments, work-shops, chemical-works, powder-mills, tanneries, slaughter-houses, store-houses, warehouses, vaults, offices, hospitals, cell-houses in prisons, public-halls, assembly-chambers, court-rooms, school-houses, cook-rooms, hot fire-rooms on steamers, and all kinds of ships of war, cooling men working near hot furnaces in rolling-mills, steel-mills, etc.

The drawing shows two of Sturtevant's steam-fans coupled so as to economize power and save the unnecessary wear and tear of engines. By reducing the speed 20 per cent. it is possible to run with half the power—one engine running both blowers or fans. When blowers are used for warming and ventilating buildings, it is frequently the case that for very many reasons it is desirable to use two, located not very far apart. Sometimes one of these is used for blasting in, while the other is used for exhausting out, both being of the same size, and the situation such as to require both fans to run at the same time. In most of these cases it is not necessary to run both engines. For example, suppose, by running both engines, both fans could be made to run at 200 revolutions; by uncoupling one engine and driving both fans by the other, the two fans will then make 160 revolutions in place of 200. Then in case only 100 to 120 revolutions are needed, the valve can be adjusted to cut off shorter and not let the engine take so much steam. This saves running both engines in mild weather; in fact, two blowers can be run at half speed with one engine cutting off very short, while it would require both engines cutting off at one-half or two-thirds to



run at full speed. In the case of large blowers, for all very heavy work, say from 8 feet to 25 feet diameter of the fan, it is found to be more satisfactory to build them entirely of wrought-iron, using the best beam and angle-iron for the frame, and plate-iron for the housing. It will be seen that this mode of construction is applicable to any size. These blowers can be built very light or very heavy, for light or heavy work. By light work is meant warming and ventilating buildings. Those used for blowing furnaces in iron-mills, etc., require to be built very heavy and strong. In this class of blowers it is necessary to use thicker plates and heavier beam and angle-iron. See *Blower*, *Fanner*, and *Iron*.

STEAM-GUN.—A gun whose projectile-force is derived from the expansion of steam issuing through a shotted tube. Mr. Henry Bessemer has proposed a steam fire-engine to throw bullets instead of water. He calculates that it will throw $181\frac{3}{4}$ pounds, representing 2540 rifle-bullets per minute, to the distance of one mile, with a consumption of 5 pounds of coal and 3 gallons of water. The calculation for steam at 150 pounds pressure is that it would escape at an initial velocity of 1,900 feet per second, and, acting upon a two-ounce leaden ball. presenting an area of $\frac{1}{8}$ of an inch, would exert a force upon it of 90 pounds. Mr. Bessemer suggests a universal joint tube for delivering a sweeping fire; and a mantlet to shield the gunners.

The idea of employing the expansive force of steam for propelling projectiles is not a new one, but its application has seldom met with success, since penetration has been sought for. Among other contributions to the subject is a paper " On the Numerical Expression of the Destructive Energy in the Explosions of Steam Boilers, and on its Comparison with the Destructive Energy of Gunpowder," by Mr. G. B. Airy. He reaches the conclusion that the destructive energy of one cubic foot of water, at the temperature which produces the pressure of 60 pounds to the square inch, is equal to that of one pound of gunpowder.

In Richardson and Watts' "Chemical Technology," Vol. I., Part IV., page 523, London, 1865, we also find the following:—"High-pressure steam is exceedingly well adapted to the performance of this kind of work; unluckily it would require high pressure steam of 400 atmospheres or 5,000 lbs. pressure on the round inch to perform this duty, and as such steam could only be generated in a furnace intensely heated, it is scarcely probable that boilers will be found sufficiently strong and durable to work continuously under such pressure. If they were found to be practicable, nothing more would be necessary than to bring a steam pipe from the boiler to the breech of every gun in a fortress or a ship, and the admission of the charge of such steam into the chamber by a valve would be sufficient to discharge the missile of the 68-pounder with a speed of 1,600 feet a second." The well-known Mr. Perkins studied this subject carefully, but applied it somewhat differently. He found that steam of this pressure could be generated only by water nearly red-hot; and instead of throwing the steam into the breech by a pipe, he threw the red-hot water into the breech of his gun, allowing it when there to expand itself into steam and expend its force in giving speed to the ball. This expedient of Perkins is well worthy of study. It has both the defects and advantages of a gunpowder-gun. The red-hot water thrown into the barrel would have the fault of being too powerful at the beginning of its expansion and too weak at the end. The barrel would be filled partly with water and partly with steam; and as the water grew into steam it would lower its temperature and its pressure, so that the explosive force would fall off very much towards the end of the stroke. This is the inevitable evil of allowing the water to become vapor in the gun. When the steam is generated in a separate boiler, and freely admitted into the breech of the gun, there is reservoir enough of heat and steam to maintain the even pressure in following up the ball from the breech to muzzle. It is the evil of charges converted into gas within the breech of the gun, that their temperature and pressure are too high at starting and too low at the end. The steam-gun would in this respect be the best of our projectile forces.

Compressed air has many of the advantages and some of the defects of steam; and the frequent use of the air-gun has shown its convenience as well as its efficiency. Air can be compressed into a reservoir by mechanical force, just as steam can be raised in a boiler by heat; and by compressing 400 times the natural quantity of air into a given space, a pressure of 400 atmospheres might possibly be obtained in this way. If an air-pipe communicated from this reservoir to the breech of the gun, air of 400 atmospheres of pressure would certainly be able to follow up the 68-pounder shot, with pressure and velocity able to discharge it with a speed of 1,600 feet per second. and, therefore, to do our work; but the apparatus would be full of mechanical difficulties. Liquid gases are known to be receptacles of enormous mechanical power. Carbonic acid gas, liquefied and shut up in a reservoir, generates large volumes of gas with great rapidity the moment it is permitted to expand. Other gases expand with still greater rapidity and force; and if we could ever conceive liquid gases to be easily made, safely carried, and comfortably handled, a charge of liquid gas bottled up in the breech of a gun would be a very effectual propelling power, and quite able to generate the force we want, and to apply it within the time we require. This system, however, is also beset with mechanical difficulties.

The preceding illustrations of steam, compressed air, and liquid gases lead us on very instructively to the manner in which fire has become necessary to do the work of a gun. A supply of heat is essential to the expansion of a gas, and a rapid supply is indispensable to the rapid performance of the work. In steam, the fire is not only external to the gun but external to the boiler in which the steam is generated. In gunpowder, the fire is introduced into the inside of the gun, for the purpose of supplying the heat that is wanted to raise the gases to their elastic pressure, and to maintain them at that pressure while expanding. Red-hot steam introduced into the breech of the gun rapidly cools down and loses its heat and power in expanding. If we could introduce fire into the breech of the gun at the same time, to maintain the heat of the steam and the water, the steam would become an admirable propelling force. Carbonic acid gas expanding rapidly from the liquid into the gaseous state cools down so suddenly as not only to lose its mechanical power, but to freeze into solid flakes of snow. If we could charge the breech of the gun with fire as well as with liquid gas, the fire would give it the heat it wants, prevent its congelation, and maintain its power to the end of the discharge. What gunpowder and gun-cotton do is really to provide a reservoir of gas and a fire to heat it simultaneously and in the same chamber. In the case of gunpowder the fire is fed with charcoal, in the case of gun-cotton the fire is fed with gun-cotton wool, another form of carbon. In gunpowder, large quantities of carbonic acid gas are generated, possibly in the liquid state, and are heated by the internal furnace of the charge, possibly red-hot. In like manner in a gun-cotton charge, red-hot water or steam is introduced with other gases, possibly also liquids, together with an internal furnace of flame; and thus the work is done—first, by the release of the gases themselves, and, secondly, by the continuance of the elasticity of those gases by the internal supply of heat. This is how gunpowder and gun-cotton really do the work of a steam-gun, a carbonic acid gun, or any other kind of gas-gun.

STEAM-HAMMER.—Properly called a steam-operated hammer. The term is usually, however, restricted to one working vertically by the attachment of its rod to a piston in an upright cylinder above. The steam-hammer has doubtless contributed much more than any other mechanical invention of modern times in developing the wonderful resources of the iron trade, and is still looked upon as a marvel of engineering skill and ability. The cannon-forging steam-hammer at the Springfield Arsenal, that at Woolwich for use in the Royal gun factories, and the wonderful hammer (capable of working a mass of steel of 100 tons) at the works of Krupp, of Essen, are a few of the monster machines employed in the manufacture of the present heavy ordnance. The first idea of a steam-hammer appears to belong to James Watt, the great father of engineers, and was patented by him in 1784. In 1806, William Deverell, "described as an Engineer of Surry," also took out a patent for a steam-hammer; but in neither case does it appear that steam-hammers were actually constructed. From this time till 1837, the idea seems to have been entirely lost sight of, when it was again taken up by Mr. James Nasmyth, of the Bridgewater Foundry, Patricroft, near Manchester, as the result of an application made to him by Mr. Francis Humphreys, engineer to the Great Western Steamship Company, who had been unable to induce any forge-master to undertake the forgings required for the paddle-shafts of the *Great Britain* steamship, then in course of construction. Mr. Nasmyth sent a sketch of his hammer plan to Mr. Humphreys, who, along with Mr. Brunel and others, heartily approved of the scheme, but in consequence of an alteration being made in the propelling arrangement of the great ship, the paddle-shaft was not required, and the hammer was not then constructed. The scheme was offered to many of the large forge-masters and engineers; but while all seemed to admire the idea they failed to appreciate its value and the hammer remained a mere sketch in Mr. Nasmyth's "Scheme-book" till 1842, when, in December of that year, Mr. Nasmyth secured a patent for his invention, and the first steam-hammer was made in accordance with his plan at the Bridgewater foundry early in 1843, but although considered by some as an improvement upon the old "helves" hitherto used for forging purposes, it was very far from being a perfect or even a marketable tool. The hammer was worked by means of an ordinary slide-valve and a long lever, requiring great labor and constant attention in order to give the blow required; so that some contrivance was necessary, capable of an adjustment, in order to have complete command over the power of the blow, and that, the instant the blow was struck, the block should rise again, so that not only no loss of time should ensue, but that the heat in the mass of iron on the anvil might not be reduced or carried off by the cold face of the block. The peculiar difficulty of securing a true automatic arrangement will be seen when it is considered that the instant of percussion must vary with almost every blow that is struck; for the piece on the anvil becomes thinner and thinner by each succeeding blow, and in flat bars a blow is first given on the flat side and then on the edge, the difference in the fall of the hammer in the two cases being oftentimes several inches; and further, that the hammer must be under perfect control at all times.

Mr. Nasmyth, after very many and protracted trials, failed to produce the motion required, and, as a consequence, the whole hammer scheme was on the point of being abandoned. In this dilemma, and during Mr. Nasmyth's absence from the works, his partner, Mr. Gaskell, applied to their engineering manager, Mr. Robert Wilson, who afterward became managing partner and successor to Mr. Nasmyth, to endeavor to solve the problem which had hitherto baffled the skill of Mr. Nasmyth. Mr. Wilson took the matter in hand, and in little more than a week, a motion was invented and attached to a hammer upon which former experiments had been made, and was at once found to answer most admirably every condition required. Under the influence of this very beautiful mechanical motion every variety of blow could be given, from the gentlest tap up to the heaviest blow within the compass of the hammer, and that, too, perfectly self-acting in every respect, the long lever and the hard work before referred to being now entirely banished. By simply altering the position of the tappet-lever by means of two screws, a blow of the exact force required could be produced and continued so long as steam was supplied. So completely was the hammer now under control, that it became a favorite amusement to place a wine-glass containing an egg upon the anvil, and let the block descend upon it with its quick motion; and so nice was its adjustment, and so delicate its mechanism, that the great block, weighing perhaps several tons, could be heard playing "tap, tap" upon the egg without cracking the shell, when at a signal to the man in charge, down would come the great mass, and the egg and glass would be apparently, as Walter Savage Landor has it, "blasted into space." On Aug. 18, 1843, the first hammer was delivered to Messrs. Hird, Dawson, and Hardy, of the Low Moor Iron Works, near Bradford, Yorkshire, and gave such satisfaction, that orders for

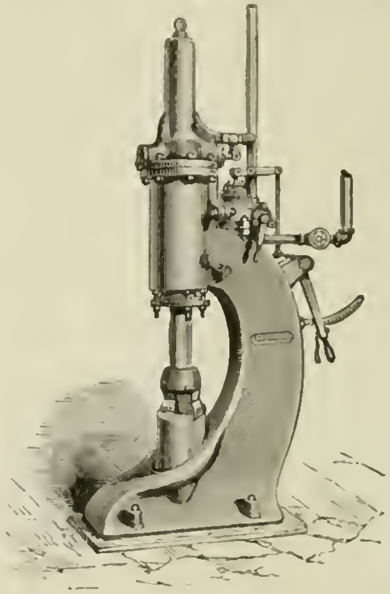


Fig. 1.

this remarkable tool began to flow in from all parts of the country. The hammer remained in this condition, with the exception of a few minor details, from 1843 to 1853, when Mr. Wilson (who in the interim had removed to the Low Moor Iron Works) invented, patented, and applied to the hammers at Low Moor and elsewhere, what is called the "circular-balanced valve."

The modern steam-hammers are much simplified and are variously constructed in detail. Fig. 1, shows a single upright steam-hammer, as made by William Sellers and Company. This hammer is a modification of the Morrison steam-hammer, provided with automatic valve gear and ranging in size from 300 pounds up to 2,500 pounds. In these hammers, the motion to work the valve has been obtained from a diagonal groove in the upper end of the hammer bar. In early practice this diagonal groove was planed in the flat surface, which surface Mr. Morrison adopted as a means of preventing the bar from turning; but as this slot so made was found to cause a slight tendency to rotate the bar back and forth, it has been abandoned, and inclined grooves, diametrically opposite to each other, are made to work a brass yoke, whose line of vibration is through the central axis of the bar, thus entirely obviating the above objection, and very much increasing the extent of wearing surface, and permitting the guiding of the bar by brass keys in these opposite grooves. The ports in the steam chest have been so modified, so as to use a supplemental valve to throttle the exhaust below the piston, without impeding the free exhaust above the piston. This enables the hammer to strike quick, light blows for finishing; in other words, the hammer can go up as quickly, but when coming down its force may be gauged by the steam cushion upon which it descends, which steam, thus condensed in bulk, re-expands in the up stroke, to the manifest economy of steam used. To fully appreciate the importance of this improvement it must be borne in mind that any attempt to gauge the intensity of the blow by throttling the ingress of steam to the cylinder, slows down its speed and renders its automatic blows irregular without proportionately decreasing their force, as in many cases the weight of the bar alone is too great for the character of work in progress. A slow motion of the working-lever will permit a corresponding slow raising of the hammer and its slow descent, with a squeezing force upon the work, so that it permits its advantageous use as a squeezer for bending and holding work between the dies. In short, the valve motion with the one working lever enables the workman to have as perfect control of the rapidity, force, and character of the blow as is possible with a hammer held in his hand and controlled by his will. These hammers up to and including 2,500 pounds weight of ram are made with one upright only; those of 1,000 pounds and under are so made as to inclose in their base the top of the anvil block, which block rests on a separate foundation, and thus relieves the frame from shock.

Fig. 2, represents a single frame steam-hammer

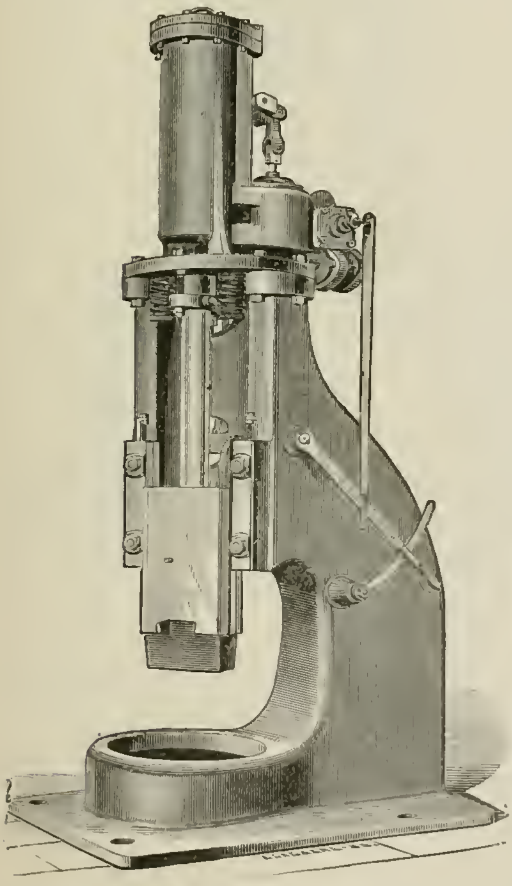

Fig. 2.

made at the Machine Tool Works of Mr. Frederick B. Miles, Philadelphia. In Fig. 3, we have a double frame steam-hammer by the same maker. These hammers are of distinctively American origin. Their general design and arrangement, valve gear and minor details, are all of native invention, not copied from foreign models. This valve gear, of but three moving pieces, takes up its own lost motion by gravity, and having no connection with the ram, it escapes all concussion. It is managed so as to produce every variety of effect by a single lever with no extra gear. The latest improvement made in them is *adjustable guides* for taking up the wear of ram, keeping the dies matched, and preventing the breakage of piston rods. In the single frame hammers there are detached anvils, and the valve gear, both hand and self-acting, is arranged for top steam. The ram and guides are set *diagonally* to the frames at the proper angle for the drawing and finishing. The weights of drop are 200, 300, 500, 700, 1100, 1500, 2400 lbs. The diameters of cylinders are 4$\frac{3}{4}$, 5$\frac{1}{2}$, 6$\frac{1}{4}$, 7, 10, 12$\frac{1}{2}$, 14, inches. The length of strokes are 13, 16, 20, 22, 27, 44, 56 inches. They can be fitted, when required, with a treadle, by which the hammer-man can work the valve gear with his foot. The hammer can be started upward off the anvil, or made to hang *suspended* and start with a *downward blow*. In the double frame hammers the valve gear, arranged for top steam, is both hand and self-acting. The safety buffers prevent damage from careless handling, and enable the piston packing to be examined or renewed without disconnecting. The steam and exhaust connections have stuffing-box joints, and are placed at the side, leaving two fronts clear for cranes. The common weights of drop are 1200, 1500, 2000, 2500, 3000, 4000, 5000, 6000, 8000, 10000, 15000, 20000, and 30000 pounds respectively. The diameters of cylinders are 10, 10$\frac{3}{4}$, 12, 14, 15, 18, 20, 22, 22, 25, 30, 36 and 40 inches. The length of strokes are 30, 30, 36, 36, 48, 48, 54, 54, 60, 72, 84, 96, and 108 inches. The hammers are rated in size according to the weight of the ram and piston. This takes no account of the top steam, which enormously multiplies the force of the blow; nor has it any reference to the entire weight of the machine.

The foundations are simple and inexpensive. They consist of one long pier for the anvil seat, and two smaller ones to support the bed-plate. The drawing, Fig. 4, shows the arrangement. The anvil rests upon a separate foundation pier in order to reduce the effect of concussion upon the frame. This pier is made long, extending beyond the hammer on each side, so as to get plenty of area to rest upon; and the ends are left open for convenient access, in case the anvil should settle and require re-adjustment. In marshy places the piers should rest on piles or on timber platforms, and the anvil should be raised 2 or 3 inches higher than in the drawing, to allow for settlement. A warning mark, on the guides, shows when the piston touches the bottom of the cylinder. Before this mark is reached, the anvil must be raised, or a higher anvil die used.

The 80-ton steam-hammer of Creusot is a monster in this line. It consists of four distinct parts: the foundations or sub-structures, the anvil and its supports forming the superstructure, the steam-cylinder and various valves, and finally the moving mass which constitutes the hammer. The foundations consist of a bed of masonry laid in cement, and resting at a depth of 36 feet below the ground upon solid rock, and of a cast-iron anvil base filled in between with oak timbers designed to lesson by its elasticity the vibration transmitted from the hammer. The masonry bed contains 784 cubic yards; its upper face covered with layers of oak about 3.3 feet thick, laid horizontal, upon which rests the anvil base. At the Works at Perm it was found more convenient to make the anvil base in a single piece, and to mold and cast it on the very site upon which it was to be finally used. The Messrs. Schneider & Co. decided that this arrangement would be inconvenient, and, moreover, as it would not be possible to transport to its selected site a mass weighing 720 tons, they decided to make the anvil base in six horizontal layers resting one upon the other. Each layer is formed of two pieces, except the upper one, which carries the anvil block, which is a single piece weighing just 120 tons. The anvil base, which has a total thickness of 17.4 feet and is 108 feet square at bottom and 23 feet square at the top, is formed of 11 pieces, the pieces constituting a layer being firmly united, and the layers themselves being secured each to the other above and below. The space between the anvil base and the walls of the pit containing it, is filled in with oak timbers driven in on end. As is seen, the anvil base is independent of the frame for the hammer branches of the frame. The latter, inclining toward each other in the shape of the letter "A," rest upon foundations and are keyed to a bed-plate sealed in the masonry surrounding the anvil base; they are united at the top by the entablement. They are hollow castings with a rectangular cross-section, and each branch is made in two sections, which are united half way up by straps and bolts. The slides are also attached to their respective supports by means of bolts. Finally, the frame is strongly braced by four wrought-iron plates which also secures the slides. The height of the frame is 32.91 feet and its weight, together with that of the slides, is 250 tons. The plates for stiffening the frame weigh altogether about 25 tons, and the supporting bed-plates weigh just 90 tons. This arrangement of the frame, so connected by iron plates, is of great rigidity, as has been shown since the hammer commenced work. This frame, as has been previously stated, supports the entablement (table), the weight of which is 30 tons; upon it is placed the steam-cylinder composed of two sections, each 9.84 feet in height, connected together by clamps and bolts. The circulation of steam is attained by means of two valves and the action is of single effect. The diameter of the cylinder is 74.8 inches, from which is obtained a surface of 4,238 square inches after deducting the area of the rod, which has a diameter of 13.27 inches. This, for a steam pressure of 5 atmospheres, permits an effort upon the piston of about 140 tons.

As the weight of the hammer is 80 tons, it is apparent that the power is more than sufficient to raise it, and its weight may consequently be increased. The stroke of the piston is 16.4 feet. This fall multiplied into 176,400 pounds—the weight of the falling mass will give a working-force of 2,893,200 foot-pounds. The 50-ton hammer at Essen, the stroke of which is only 9.84 feet, has a working force of only 1,081,950 foot-pounds. Supposing the two hammers acting upon an ingot 4.92 feet in height, the hammer at Creusot would still have available 2,025,240 foot-pounds, while that at Essen would have at its disposal only 542,475 foot-pounds, from which it is very evident that the former hammer in this particular instance would be more than three times more powerful. The width between the branches is about 24.61 feet and the height under the braces is 10.5 feet, which secures an ample space for the manipulation of large masses of metal. The height of the hammer from the foundation plate to the top of the cylinder is 61 feet, and adding 18.4 feet for the anvil base and 19.7 feet for the foundation on which it rests, it is seen that this colossal structure is in all nearly 100 feet high. In spite of this condition so unfavorable to stability, in spite of the enormous effect resulting from the shock of 2,893,200 foot-pounds, the structure, constructed of parts skillfully proportioned, does not vibrate, and the foundation, cushioned by the filling of timbers previously mentioned, transmits to the ground slight vibrations less sensible than those from a hammer of much less power. The valves are worked by rods attached to one branch of the frame and descending to a point about 10 feet above the ground; the workmen who manipulates these stands upon a platform and is protected, not only from the intense heat of the forging but from the sparks, etc., thrown off under hammering.

The four cranes for use with the hammer are all of the same type, and differ from each other only in their power. As we have before stated, three of them have a capacity of 100 tons and the fourth a capacity of 160 tons. They belong to that class which have only a lower pivot, and their shape is that of the swan's neck. They are made of plate and angle-iron. They turn about their pivot, resting on the ground-level upon a friction circle. This circle forms part of a kind of tubing in cast-iron firmly secured to the masonry foundations. This tubing is itself united to the cast-iron plate which supports the hammer frame. As this arrangement is applied to each of the four cranes, their foundations thus become, as well as that of the hammer, solidly united together over a very extended surface, thereby giving to the whole structure very great stability. From the pivot to the top of the jib each crane, as a total height of 57 feet composed as follows: From the pivot to the ground level, 27.5 feet, and from the ground to the top of the jib, 29.5 feet. The swing of the cranes are 30.6 feet. Each of these cranes has four movements, given by steam-engines attached to the cranes themselves, which, with two cylinders, have a capacity of 60 horse power with 250 strokes per minute. These four movements are as follows, viz: *First*—Swinging the cranes. *Second.*—Raising the charge. *Third.*—Traveling the charge. *Fourth.*—Turning the load. There is nothing special in the first three movements; they are given by means of gearing which permits the direction of the motion to be readily changed. The load is attached by a system of movable pulleys, over

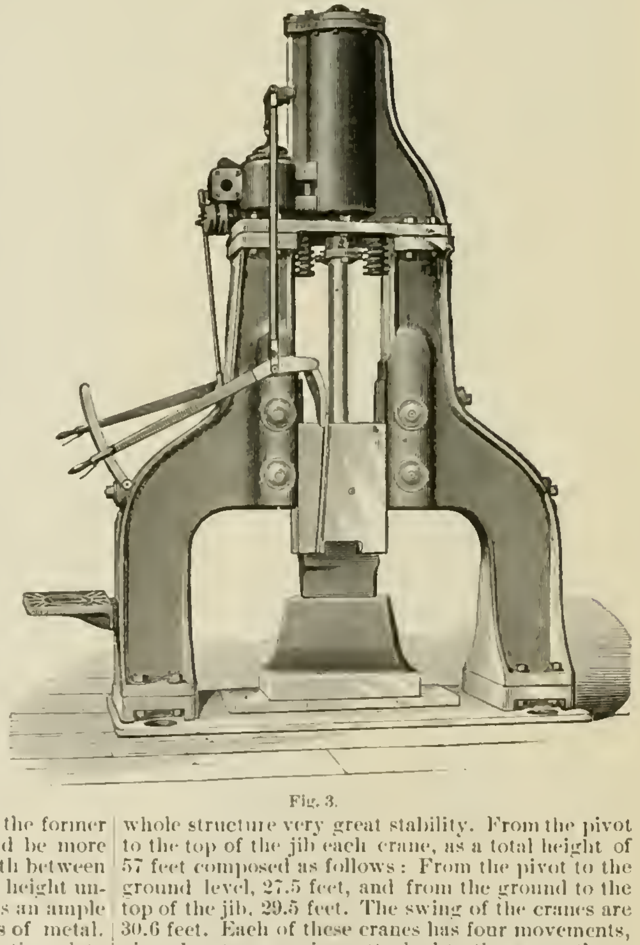

Fig. 3.

which passes the chain, which is also wrapped about the drum with helecoidal grooves attached to the body of the crane. The traveling of the load is effected by means of a small truck running upon rails placed upon the anus of the cranes. The most peculiar movement is that of turning the load. With small hammers this is done by hand by the aid of levers and a large gang of men; but such an operation would not be any longer practicable in handling a piece weighing 100 tons or more, such as this hammer is intended to work.

The 80-ton hammer at the Saint Chamond Works (Loire) should receive a passing notice. The following gives the weight of the pieces entering into the composition of the hammer and also gives the principles of its construction and its functions:

Anvil base	1,102,500	pounds.
Plates of courses	269,010	"
Legs	595,350	"
Table and cylinder . . .	326,340	"
Piston distributer, platform, sheathing plates, assembling parts, hammer-carrier, hammer.	352,850	"
Total	2,646,050	"

Weight of moving mass . .	176,400	pounds.
Maximum fall	15.75	feet.
Work of fall	1,240	ft.-tons.
Spread of legs	21.65	feet.
Breadth of hammer . . .	6.23	"
Height disposable for forging	13.12	"
Diameter of cylinder . . .	6.23	"
" " shaft . . .	1.11	"
" " receiving-valve .	1.14	"
" " discharging-valve	1.64	"
Steam pressure	95	lbs. per sq. in.
Pressure to raise 80,000 kilos	43	" " " "

The cranes used with the steam-hammer are pivoted above and below. To provide the journals for the upper pivots there is placed around the hammer a metal *gallows* of which the base is anchored in the ground and the top of which carries the collars to receive these pivots. This gallows is composed essentially of two horizontal beams of sheet and T-iron, bound by a latticed straining piece at right angles to their extremities. Buried in the ground they find their bearings in metal platforms formed equally of intertied beams. The platforms are laid down in the massive masonry, monumentally formed and provided for the fitting in of the vertical beams of the gallows, and secure by their weight the stability of the cranes. These are constructed in sheet T of soft steel. The pivots and pieces for fitting are of cast-steel. They each carry a steam-engine of two cylinders which provide for four kinds of movements, viz: 1st. The movement for elevating the charge. 2d. The movement for traveling the charge upon the cranes. 3d. The circular movement of the crane around its axis. 4th. A movement of "*virage*." This last movement, invented there some years ago by M. Fouchére, Master Mechanic of the great forging shop of the Company, allows the piece suspended by the crane to turn over and over in such a manner as to easily present all the points of its surface successively to the blows of the hammer. One man standing upon a platform moving with the crane is sufficient to control all these various movements. Besides the three, the hammer possesses a fourth crane (smaller), serving for putting in and out of place the necessary woking tools.

This Work altogether contains 5,219,200 pounds of metal divided as follows:

Shop, gallows, cranes . .	1,719,900	pounds.
Hammer	2,646,000	"
Furnace, generators, boilers	771,750	"

And 17,920,000 pounds of masonry and notwithstanding all that it has been built with a remarkable promptness. The preliminary designs date only in fact from the month of January, 1878; matured ones only from March, 1878, and the Works were opened in the month of May of the same year. The first trials were made on the 4th of August, 1879, which actually gave a total of from 14 to 16 months from beginning to the completion of the undertaking. The skillful conduction of this immense undertaking and its completion with such rapidity is a high testimony

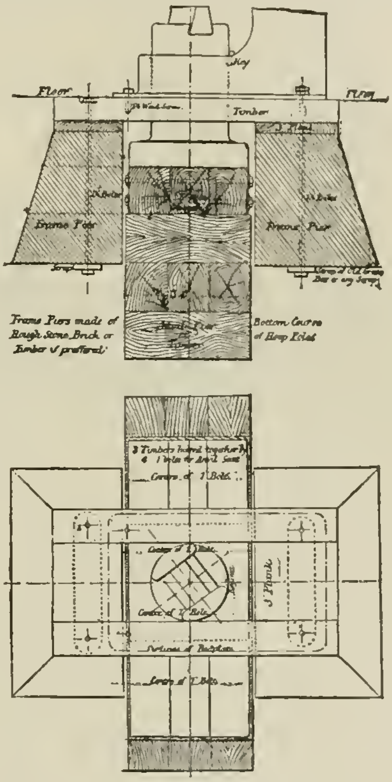

Fig. 4.

to the ability of the engineers of the Company, who have fully contributed to their portion of the work. Since it has been in operation the 80-ton hammer has to-day already forged a number of large pieces, among which we may mention the following: Three ingots of 45 tons, 5.2 feet diameter, for tubes for use in the 42-cm. (16.5 inches) cannon. These tubes have a length of 32.8 feet and a diameter of 2.46 feet. One ingot of 45 tons, 4.92 feet diameter, for front portion of the 42-cm. cannon. One ingot of 70 tons, 6.5 feet diameter, for rear portion of the 42-cm. cannon. The functions of the 80-ton hammer has left nothing to be desired during this period, and the forgings are of a most satisfactory character.

STEAM-PUMP.—This application of the steam-engine to pumping purposes is most useful to the military engineer. In its simplest form, a tube through which the steam is forced enters a hollow globe to a little beyond its center. On either side of this tube are openings into the globe for the entrance of water. These openings are much larger than the steam-pipe. Opposite the latter is the exit tube for the mixed steam and water, which has a trumpet-shape and a length of about once and a half times the diameter of the globe. The rush of steam across the semi-diameter of the globe and through this funnel produces exhaustion in the lateral halves of the globe, into which spaces the water is forced by the external pressure of the air. The first direct acting piston-pumps were probably invented by Mr. H. R. Worthington, of New York, while making experiments for canal steam navigation in 1840. He patented a steam-pump to feed marine boilers in 1844. The steam-cylinder was fed through a pipe which had a valve at the other end within the boiler. To this valve there was adjusted a float which controlled the supply of steam, which extended the cylinder through a slide valve which was acted upon by a spring controlled by the motion of the piston. The present Worthington and Baker pump was evolved from this apparatus. It is a combination of pump and steam-cylinder, driven

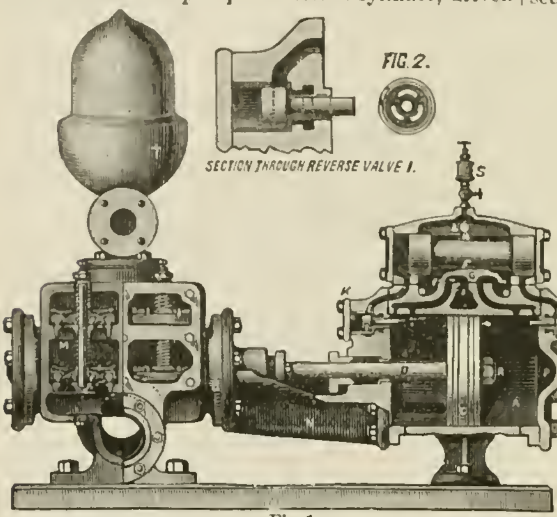

Fig. 1.

by direct action and without intervention of fly-wheel or any appliance for producing rotary motion. The steam-cylinder has the usual arrangement for the entrance and exit of steam, and the rod and piston is attached to a plunger of a double-acting pump. At the middle of the piston-rod, between the pump and steam-cylinder, there is attached an arm which, in passing to and fro, strikes the long end of a lever, which changes the steam-valves so as to alternately admit steam on one side or the other of the piston. Various improvements have been made to control the action of the slide-valve. One method is the employment of a secondary cylinder and piston, to which steam is admitted by a sub-valve, acted upon by the main piston, near the end of the stroke. Another method is the employment of a fly-wheel. We will first mention those pumps having an attached crank and fly-wheel. Of these an example is furnished by the Eclipse steam-pump, made at Pittsburg, Penn. The crank-shaft actuates a rocking-lever, by which is moved the slide controlling the admission and exhaust of steam. The Clayton pump, made at Brooklyn, N. Y., has a yoke which couples the piston and pumping-rods, and answers for the support of the crank-shaft journal. One end of the shaft, by suitable attachments, controls the valve, while the other supports the fly-wheel. These fly-wheel pumps have the advantage of a perfect control of the steam valve. The direct-acting pumps have been the subject of many inventions, the principal object sought being the arrest of the piston at any rate of speed at a proper distance from the cylinder-head. This has been accomplished by various devices. We have not space to describe the different forms of apparatus, but will mention the following as good examples :—Knowles's steam-pump, which employs an auxiliary piston-valve or chest-piston, which has a reciprocating and rotary motion, which imparts motion to the main valve; Blake's steam pump, in which both the main and the auxiliary valves are plain, flat slide-valves, the auxiliary valve being a continuation of the ports of the main cylinder, and therefore forming a movable valve-seat; the Cameron steam-pump, in which the steam-piston, at the end of the stroke, acts upon valves at either end of the cylinder, alternately admitting and exhausting steam; the isochromal steam-pump, made at Hamilton, Ohio, which has a governor to regulate the strokes of the piston; and the National steam-pump, in which the valve-gear consists of a main piston-valve, doing the work of an auxiliary piston, the valve stem performing the office of an auxiliary valve.

The Cameron steam-pump, so universally employed in foundries, arsenals, and garrisons, is shown in section in Fig. 1. A is the steam-cylinder shown in the section; C, the piston; D, the piston-rod; L, the steam-chest; F, the plunger; G, the slide-valve; H, a starting-bar connected with a handle on the outside; I I, are the reversing-valves, and K K the bonnets over the reversing-valves; N is the body-piece connecting the steam and water-cylinders; B is the water cylinder with the valve-chest bonnet removed; M is a valve-seat shown in section —the valve over it is also shown in section; T is the discharge-air vessel. Fig. 2 shows an enlarged sectional view of the reversing-valve chamber with phosphor-bronze lining. The operation is very simple:

Suppose the steam-piston, C, moving from right to left; when it reaches the reversing-valve, I, it opens it and exhausts the space on the left-hand end of the plunger, F, through the passage, E, which leads to the exhaust-pipe; the greater pressure inside of the steam-chest changes the position of the plunger, F, and slide-valve, G, and the motion of the piston, C, is instantly reversed. The same operation repeated at each stroke makes the motion continuous. The reversing-valves, I I, are closed by a pressure of steam on their larger ends, conveyed by an unseen passage direct from the steam-chest.

Fig. 2, shows the pump complete with boiler-feed, boiler-base, smoke-bonnet, section of smoke-stack, grate-bars, gauge-cocks, steam-gauge, water-gauge, safety-valve, globe-valves, blow-off cock, steam and

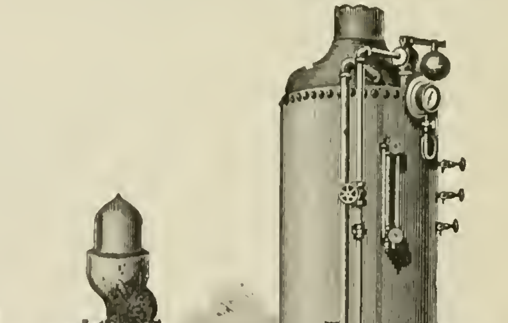

Fig. 2.

exhaust-pipes, boiler-feed connection, valves, unions, etc.

The table (page 205) shows the approximate pounds pressure due to columns of water from 50 to 200 feet in height; also the number of gallons of water that will be delivered per minute, and the height in feet to which it will be discharged through nozzles from

The loss by friction in 2½-inch rubber hose, throwing a 1-inch stream 100 feet high, is 15 pounds for each 100 feet of hose.

⅝ to 1¼ inches in diameter, under heads from 50 to 200 feet in height, or the corresponding pounds pressure. See *Hydraulic Power* and *Pumping-engine.*

STEAM-SAPPER.—The steam-sapper or road-traction engine can be used as a locomotive on rails by changing the road driving-wheels. There are two sizes of these engines in the English Service, one 6 tons and the other 8 tons weight; 80 per cent. of the weight is borne on the driving-wheels. The steam-sapper is specially made for drawing loads on roads and across country; on good roads they will draw three times their own weight up a slope of 1 in 12; when used on rails (at 4 ft. 8½ in. gauge), they can ascend a gradient of 1 in 20 with a load equal to their own weight; and they can go round curves of 2 chains radius. They are constructed to travel on road or on rails at two speeds, four miles and eight miles an hour. Some of these steam-sappers have been provided with a crane equal to lifting and moving about with 5 tons weight; there are also some with a winding drum and 400 yards of steel wire rope, which enable them to draw loads up a slope of 1 in 2: the ones fitted with the crane are invaluable in artillery parks, being able to move about with a load suspended and to deposit it in a fresh site. These road-traction engines are a valuable auxiliary to an army in the field. In the event of a railway having to be constructed for a military expedition, they can be advantageously employed in hauling the materials for the line to where they may be required over the open country, or as steam-cranes at the point of disembarkation to land the heavier portion of the railway plant. "Steam-sappers" can also be used as winding stations at the tops of inclines, where the trains cannot be drawn up either by animal or steam-power. Road-traction engines made in the way previously mentioned, and of almost exactly the same pattern as has been adopted in H. M. Service, are used by France, Russia, and Italy in their army transport-trains. It is, however, desirable to confine these useful machines to the work they are specially designed for, that is, drawing good loads on a road or in an open country, and for lifting weights; locomotives for traction on rails require particular construction to get all the work possible out of them. See *Railway Communications*, and *Traction-engine.*

STEAM-SHEAR.—A machine used for slitting metal plates. The plates, 20 to 30 feet long and 6 or 7 feet wide, are placed on a table provided with rollers and guides, which is advanced toward the knives until a strip of the desired width and of the whole length of the plate is severed. One used by the Otis Iron and Steel Company, weighs about 80,000 pounds, has knives 87 inches long, and shears 1¼-inch steel plates at a single stroke.

STECHEN.—A passage at arms. A description of tournament practiced at the close of the 12th century.

STEEL.—To give a brief definition of steel is a difficult task. Until lately, steel has been usually defined to be iron containing a small amount of carbon, an amount smaller than that present in cast-iron, but greater than the maximum quantity to be found in characteristic wrought-iron; *i. e.*, iron containing between 0.3 per cent. and 2 per cent. of carbon was termed steel. This proportion of carbon is, however, only approximate, and Dr. Percy gives from 0.5 to 0.65 per cent. of carbon as the limit at which, when free from other foreign matter, iron may be considered as passing into steel, so that when hardened by quenching in water it will strike fire readily with flint. According to this definition, where carbon is present "in certain proportions, the limits of which cannot be exactly prescribed, we have the various kinds of steel, which are highly elastic, malleable, ductile, forgeable, weldable, capable of receiving very different degrees of hardness by tempering, and fusible in furnaces." Owing, however, to the gradual development of new modes of manufacture, and to the enormous increase in recent years in the production of cast-steels of all kinds, the arbitrary definition of steel above given leads to much confusion and serious mistakes, and though it may be called a mere question of words, the above definition has no doubt exercised a deleterious effect upon the introduction of steel in place of worked or wrought-iron for many purposes for which it is well suited.

A simpler definition of steel seems likely to be adopted, a definition which possesses the advantages of precision, and is in harmony with the current modes of manufacture. According to this, *steel is an alloy of iron, cast while in a fluid state into a malleable ingot.* It is held, according to this nomenclature, that steel and wrought-iron cannot always be distinguished by a chemical analysis (for the same proportions of carbon, manganese, silicon, etc., may exist in any malleable alloy of iron), and that the fundamental and essential difference between steel and all compounds of iron, merely worked or wrought, is a structural difference easily determined. All malleable products of iron industry—that is so say, all varieties of iron, except cast-iron—may be divided into piled-metal (wrought-iron) and ingot-metal (steel); the former embracing all malleable-iron or alloys of iron produced without fusion of the metals while in a malleable state, and the latter applying to all irons, however produced, which are cast into a malleable ingot. These two classes differ more widely in mode of manufacture, appearance, and in many important properties than the varieties of each class among themselves, and form two parallel and continuous series, the corresponding members of which are chemically identical, differing only in mode of production and in mechanical structure, and rising in each series from the purest and softest iron to the hardest and most highly carbureted varieties.

M. Adolph Grenier, of Seraing, adopting this definition of steel, classifies the two parallel series of products, the irons and the steels, as follows:

Percentage of carbon.

0. to 0. 15	0.15 to 0. 45	0.45 to 0. 15	0.55. to 1.50 or more.

Series of the irons.

Ordinary irons.	Granular irons.	Steel irons or puddled steel	Cemented steel, Styrian steel

Series of the steels.

Extra soft steels.	Soft steels.	Half soft steels.	Hard steels.

is homogeneous throughout and free from flaws or intermixed impurities.

We now can understand fully what steel means in accordance with either of the definitions given of the term, whether depending merely upon its chemical constitution as to the amount of carbon present or upon the physical treatment of the metal, which must be melted and cast into a malleable mass. In either case it is evident that the properties of the metal must vary very much, but more especially if we adopt the second definition. The soft or low steels approximate, like ordinary wrought-iron, to pure iron, and the hard or high natures of steel approach cast-iron in their properties. Over wrought-iron steel has always the advantage of being homogeneous, but it is unfortunately uncertain in quality, a surprising fact when we think how it is produced; still it is so, and we find that ingots of this metal of the same chemical constitution, produced in the same way and from identical materials, often differ much from one another in the properties of elasticity and tenacity. Many nostrums have been proposed for overcoming this de-

The production of the more highly carbureted varieties of the iron group, such as puddled-steel or cement steel, except with the view to casting the metal subsequently, is now carried on upon a comparatively limited scale, while that of the steels proper, or cast-steel, is increasing enormously each year. For the construction of ordnance, we may say that cast-steel is at present and will in the future be as a rule employed, so we may safely take the new definition of steel and look upon this metal *as a melted malleable alloy of iron produced in any way whatever, and containing a smaller proportion of carbon or other hardening element than is contained in cast-iron.* Steel may be produced in a variety of ways, by more or less decarbureting cast-iron under such conditions as to obtain a melted product. By dissolving wrought-iron or steel-scrap, or spongy reduced iron in melted cast-iron. By the direct melting or puddled-iron, or other variety of iron of the requisite degree of hardness (the hardness referring to the amount of carbon in the iron). By melting a mixture of soft wrought-iron, or iron-sponge, with carbon or with cast-iron or of malleable-iron, which is too hard for the variety of steel required, with oxidizing agents, or by directly melting together a mixture of iron ore and carbon as a single operation.

The processes by which steel-making is practically carried out are by melting in pots or crucibles, giving "pot" or "crucible" steel; on the open hearth or bed of a reverberatory furnace, giving Siemens or Siemens-Martin steel; or by blowing the air through molten cast-iron, producing Bessemer steel. In whatever way made, the material is essentially the same, depending on its chemical composition and physical structure for its properties. It differs much from wrought-iron, even when chemically the same metal, because a mass of wrought-iron is made up from a number of bars or of blooms heated and welded together, each of these again being composed of separate granules with impurities interposed, such as slag, etc., entangled so that the mass is unavoidably full of flaws and imperfect welds. Steel, on the other hand, has been brought into a state of perfect fusion, and cast while liquid into a malleable ingot, which

fect, which appears to be due to the molecular condition of the metal as affected during the melting and the subsequent treatment of the ingot.

It is in modification and improvements of the latter that quality appears to lie, and already many plans are being attempted for the insurance of greater certainty in the quality of steel, such, *e. g.*, as casting it under pressure to get rid of the bubbles or blow-holes.

Steel will not, like wrought-iron, stand a high welding heat, especially if it be of a "hard" or "high" nature. If hammered at too great a heat the ingot will fall to pieces. After being cast, steel is hammered or rolled, and it acquires a fibrous structure during this process, as may be easily shown if a bar of this metal be acted on by a strong acid. When first cast, steel, excepting the higher varieties, is comparatively soft and inelastic, and can thus be treated in a similar manner to any wrought-iron; but, with the exception of the very low or soft varieties, it may be subsequently hardened by what is called "tempering," when the metal is heated and plunged into mercury, water, oil, or some other liquid. in order to cool it more or less quickly. The effect of such tempering depends very much upon the amount of carbon present in the steel, as well as upon the degree of heat it is previously raised to, and has a marvelous effect in increasing both tenacity and elastic limit in the case of good steel. Besides the great uncertainty of steel, we must remember that it is very inferior to wrought-iron in another important point, that of being easily weldable. The importance of this property with regard to facility and economy in working large masses of metal can hardly be exaggerated.

The qualities of steel may be summed up as follows: In tenacity it varies, roughly speaking, from 30 to 60 tons per square inch, and its limit of elasticity lies between 13 and 30 tons. The softer the steel the more ductile it is, the less readily can it be tempered, the lower in its limit of elasticity and tenacity. All other things being equal, the more rapidly it is cooled the harder it becomes; but at the same time the higher natures are rendered more brittle. When cooled in a comparatively bad conductor of heat, such as oil, the mass parts with its heat slowly, and is not only made more elastic and harder, but also toughened; while in any case the limits of elasticity and tenacity approach one another more nearly. The effect of tempering upon the metal is, of course, comparative; thus experiments have shown that certain soft steels containing from 0.15 per cent. to 0.22 per cent., or 0.24 per cent. of carbon, were very decidedly toughened by heating to a red heat, and then being quenched in water. The steel used for Woolwich gun-barrels, containing about 0.3 per cent. of carbon, would be made very hard, but also very brittle, if so heated; therefore it is tempered in oil, as being a worse conductor of heat than water, and is thus toughened.

This is shown well by the following table given by Mr. Kerkaldy:

Nature of specimen.	Tenacity (tons per square inch).	Elongation per inch.	Character of fracture.
1. Highly heated and cooled in water.	30	0	Entirely granular.
2. Highly heated and cooled slowly	36½	22	Entirely fibrous.
3. Moderately heated and cooled in oil	53	14½	One-third granular, two-thirds fibrous.
4. Highly heated and cooled in oil.	68	2½	Almost entirely granular.

Should the steel be too highly carbureted, or be in too large a mass, it is liable to fracture during the process of toughening. With the higher natures we can obtain very great strength and elasticity, though we lose in ductility, and have a more brittle material. We have also the great advantage of hardness and homogeneity, giving us, when required, a very smooth surface quite free from flaws. Until further improvements are made, the advantages are counterbalanced by great uncertainty as to the behavior of the material, especially in the higher or harder steels. The greater cost of steel of sufficiently good quality is also one disadvantage when we compare it with wrought-iron. The brittleness and uncertainty of this material prevent us employing steel as a sole material for any gun save the small 7-pounder for boat and mountain service. Although, however, steel is not such a material as we should employ for the sole manufacture of a gun, yet it is admirably suited for the inner barrel, as it is very strong and gives a hard, clean surface, while its limit of elasticity is high, so that even a heavy strain does not stretch it permanently and deform the bore. It may indeed split if subject to too great a pressure when not properly supported by the exterior layers, but by putting a wrought-iron jacket outside we prevent any danger from that cause; for, should the steel-tube burst, the wrought-iron exterior will prevent any explosive rupture. The lower table exhibits the mechanical properties of United States steel as made at the Midvale Works. See *Annealing, Bessemer Steel, Blistered Steel, Cast-steel, Crucible-steel, High Steel, Iron, Low Steel, Mild Steel, Natural Steel, Puddled Steel, Semi-steel Shear Steel, Siemens-Martin Steel, Steel Works, Tempering, Tilted Steel,* and *Whitworth Metal.*

STEEL-BRONZE.—An alloy of tin and copper, so hardened as to render it as durable and strong as the steel; hence its name. The mode of treating this alloy is the invention of a Frenchman, M. Lavessière. It has been of late improved on by General Uchatius, Director of the Royal Arsenal at Vienna, and is employed by him in the manufacture of light field guns. It takes its name, not from any steel entering into its composition, but is simply given to signify that the metal does possess, in some degree, the properties of steel, so as to qualify it as a substitute for that metal in gun-making. It is also alleged that there is no phosphorus in it. The composition of steel-bronze differs only slightly from that of ordinary bronze (90 per cent. of copper and 10 per cent. of tin), the alloy consisting of 92 per cent. of copper and 8 per cent. of tin. The great secret of producing this metal lies in the manner it is cast, and this comprises two op-

erations, viz.: (1) casting in an iron mould; around a metallic core; and (2) passing the metal, when cold, through the rolling mill. The moulds are of cast-iron and 3.9 inches thick; in the center of each is placed a wrought copper core, 1.9 inches in diameter, around which the metal is cast and chilled. See *Dean Gun.*

STEEL-BRONZE GUN.—A gun lately introduced into the Austrian service, and made of steel-bronze. The mode of manufacture is as follows: The metal having been prepared as shown above, the cylinders are bored to a diameter smaller than that required for the bore of the gun. For this purpose the cylinders are placed vertically on a support, then steel punches or cones are forced into the aperture by the means of a powerful hydraulic press. The size of these cones increases gradually, so as to produce a progressive widening of the inside of the bore; six cones are sufficient to alter a diameter of 3.15 inches into one of 3.425 inches. In the formation of the gun in the process adopted, the surface of the bore acquires a hardness equal to that of steel, and the strain given by the distension of the interior is far greater than can be given to the powder chamber on the explosion of the greatest charge it can be made to hold. General Uchatius states in his report the reasons that led him to adopt the above process, in the following words:—"The work done by the powder to the detriment of the gun at the commencement of the shooting, namely, the enlargement of the bore, must be exerted by mechanical pressure beforehand, and to a still greater degree than the work done by the strongest occurring powder-gas pressure, whereby the elastic power of resistance of the barrel will be so increased that the subsequent smaller powder-gas pressures will exert no further effect, and the metal immediately surrounding the surface of the bore must be given the necessary degree of hardness by subjecting it to a process analogous to that of rolling out." Thus is repeated what is done in the manufacture of the Nacomber gun, with this difference, that that gun is "built up" of wrought-iron discs, "set" by means of a powerful hammer, and the breech encircled with heavy steel rings. General Uchatius further says of his gun: "All metal strata surrounding the bore concentrically are in a state of elastic tension, and exert a pressure, from without inwards, equal to the pressure exerted by the hydraulic press ramming from within outwards, and which the table of pressures shows to correspond very nearly with a state of about 2,400 atmospheres."

The experiments made with these new guns have shown that the *bronze-steel*, as it is also called, is not only as hard as cast steel, but far more elastic, and the action of the powder-gas seems to injure the gun very little; further, it is less liable to damage from atmospheric action than steel. The initial velocity is very little less than that of the Krupp gun, and to these advantages must be added the great difference in price (cost of construction), which is stated to be only £35 per gun. The dimensions of this new gun are the same as the Krupp gun of 8.7 centimeters, from which it was copied, the only difference being in the length of the bore, which is 6 feet 5 inches. The wedge and the vent bush are also slightly different; the bore is provided with a copper Broadwell ring, and closed with a flat wedge of Uchatius' construction; the vent bush is bored in a copper screw, and is perpendicular to the axis of the bore. The Austrian Committee of Artillery, after the late experiments with the steel-bronze gun, reported as follows: "The steel-bronze B.L.R. gun, throwing a projectile of about 14 lbs., with a charge of 3.3 lbs., showed great durability; after 2,147 rounds had been fired from it almost without interruption, the melting of the tin particles was considerably less than the burning out of the breech surface of the Krupp gun of the same caliber that was tried along with it: and, besides, the erosion did not exceed the admissible limits. The comparative firing showed that the steel-bronze gun possesses the same accuracy as that of the cast-steel gun. Notwithstanding the melting of the tin particles, the accuracy of the firing was in no way diminished, and the projectile that was purposely allowed to burst in the bore after 2,121 rounds damaged the parts but little where the explosion took place, and even then, the firing was not inferior to what had taken place. The extreme durability of the bore is due not only to the excellence of the material, but also to the construction of the loading chamber, as well as to the construction of the projectile. The projectiles used in the trial were of two kinds: a common shell and a bolt-shaped shell, with double case, of 2½ calibers in length, with four belts of copper wire or guide-ring incased in its cylindrical portion.

Competent artillerists in Germany, it is stated, have shown themselves favorable to the steel-bronze, and the Committee of Artillery at Berlin has caused two pieces of this metal to be manufactured for the purpose of carrying out experiments. If these give good results, it is proposed to employ steel-bronze in the manufacture of garrison and naval guns, and thus utilize the large stock of bronze ordnance possessed by the German Artillery.

STEEL GUNS.—As the name implies, guns made of steel. In the British Artillery, guns entirely made of that metal have not been adopted, except for one nature of mountain gun. The M.L.R. guns of the service have the inner barrel made of steel. The mountain gun above alluded to (7-pdr.) is made from a solid block of steel, rough bored and shaped, then toughened in oil, and afterwards finished in the usual manner. The bore is 3 inches, and rifled with three grooves on the French system, having a twist of one turn in 20 calibers. This rifling differs from the modified French system (as applied to the 9-pdr. and 16-pdr.) in not having the corners rounded, and in the curve of the bottom of the groove being described concentric to the bore. The grooves are 0.6 inch wide at the bottom and 0.1 inch deep.

Since the introduction of rifled ordnance in Europe and America, special attention has been directed to steel as a material capable of withstanding the immense strain to which rifled guns are subjected; but English artillerists found an objection to this metal chiefly on account of its brittleness and want of endurance, the trials made with steel guns in England and on the Continent, some years ago, not having been considered satisfactory. The want of confidence in steel guns arose probably from the fear that manufacturers had not yet attained to the perfect method of forming the gun or the want of knowledge in the manufacture of the metal itself; but the system lately pursued by Sir J. Whitworth, of compressing steel in its fluid state by hydraulic pressure, has produced guns which afford all the endurance and strength that can be desired. In the compression of this metal, all the cavities or air cells are driven out, and it becomes perfectly homogeneous. Steel possesses important advantages over wrought-iron, such as elasticity, tenacity, and hardness, but it is more expensive.

Steel, as a metal for the manufacture of ordnance, has been adopted by most Continental Nations, the chief manufacturer being Mr. Krupp, of Essen, in Prussia, whose guns have been adopted not only by Germany, but also by Russia, Belgium, Holland, Italy, Spain, Egypt, Turkey, and even Japan. Austria, for a time, carried on experiments with some of Krupp's guns with the view of introducing them into her service; but preference has since been given to steel-bronze, which is stated from experiments to be superior to steel. Krupp's guns of a small caliber are manufactured from one solid block; those above 8-inch caliber are compound, being weighted and strengthened by external rings in the manner described under the head of Krupp guns.

The uncertainty of some of Krupp's heaviest guns was shown some years ago, particularly in the trials made in Russia. Two burst after firing a comparatively few number of rounds, one 66, the other 109 rounds: the former is stated to have burst from the jamming of the shot; the latter, it is inferred, from defective metal, although the contrary is reported. Four guns were then tested for endurance; two of which, M.L.R. guns, withstood, the one, 215, the other 286 rounds. The other two were S.B. guns, and withstood 1,025 and 790 rounds respectively None of them burst, but they were all worn and eaten into the seat of the shot, by gas, to such an extent that the Committee considered that the service of the rifled guns could not with safety be assigned a higher duration than 250 rounds. An 11-inch cast-steel Krupp gun, tried in 1871 at Cronstadt, burst at the muzzle after the ninth shot, this result being probably due, in the opinion of the committee, to a flaw in the metal near the muzzle. During the war of 1870-71, many of Krupp's light guns are stated to have become unserviceable, but probably they became so, not so much from any fault in the metal, as from a mechanical derangement in the breech-loading apparatus, which has doubtless since been remedied. The Krupp guns lately manufactured for the German Army appear from the reports to be very satisfactory.

Such are a few of the principal results attained in the manufacture of the early steel ordnance. Whether guns of this metal will eventually be introduced into the British Service, it is difficult to say; as far as can at present be seen, no change is likely to be made. Another drawback, besides the uncertainty of the metal resisting the strain of the charge, is the great cost involved in melting and casting the material, together with the expense of turning and boring such a hard metal, all which add greatly to the price of the gun.

The relative cost of steel guns compared with those of pieces manufactured of other materials has been computed as follows:—

	Per ton.
Cast-iron guns.	£21
Armstrong (original construction), wrought-iron with steel tube. . .	100
Armstrong (Fraser construction) . .	65
Steel, on Krupp's or Whitworth's plan	170
Gun-metal	190

Russia has large steel factories at Aboukoffsky and at Oberchoff. In England, the Sheffield Works and the Vavasseur Factory in London manufacture steel guns. See *Steel Works*.

STEEL-PRESS.— A press for solidifying molten steel. The suggestion is embodied in one of Bessemer's early patents, but has been developed by Sir Joseph Whitworth and by Révollier, Biétrix, & Co., of St. Etienne, who adopted it in 1867, having built steel-works specially arranged for it in connection with furnaces for making steel by the Siemens-Martin process. According to the plans adopted by Révollier & Co., the metal was run from the furnace into a ladle, which, by means of a turn-table crane, was conveyed to the ingot-molds, and the metal turned into the latter. The molds were placed on an ingot-carriage, and after filling they were run under an hydraulic press.

STEEL PROJECTILES. — Projectiles of this class have proved more efficient than those of any other metal, but their expense has heretofore been too great to warrant their general use. For rifle projectiles they are made from the solid ingots of steel turned to form, and bored out for shells. They are hardened by heating and cooling quickly, the head being to a certain extent chilled. The manufacture is expensive and tedious, and the tempering is a matter of difficulty, the shells being liable to crack. In order to overcome this difficulty hollow shot have been devised, the hole through the center allowing the sudden shrinkage to take place without the injurious effects above alluded to.

The operation of forming a cavity in a solid steel projectile is done in a machine or lathe, of peculiar construction. The solid projectile is first bored out from the base to the top of the cavity in the ordinary way. It is then put in a chuck and a cutter inserted in the hole thus formed. The cutter is firmly fixed to the rest, and its point is bent at right angles to its length. As the cavity enlarges, new cutters with longer points are employed until the desired size is obtained. A former of peculiar shape guides the feed-motion of the cutter and gives form to the cavity. The point of the projectile rests in the cavity of the center-piece of the lathe and the base is held firmly by jaws.

Whitworth's steel shells are formed from ingots of steel cast in the form of hoops, and drawn down to the necessary size under the hydraulic press. The ends are closed with screw-plugs. They are therefore less costly than might be thought. See *Chilled Projectiles*, *Projectiles*, and *Whitworth Projectile*.

STEEL WORKS.—Iron-smelting is the largest and most important in the whole domain of metallurgy, and at first sight, presents a remarkable contrast to all other branches of the smelter's art. For in case of most of the other metals employed as such in the arts, we have, as sources of supply, a numerous class of minerals varying greatly in richness and composition, and susceptible of reduction to the metallic state by processes also differing greatly among each other; while, in the case of iron, the few minerals that can be made useful as ores are restricted within much narrower workable limits, and form only one class of chemical compounds, namely, oxides, whose reduction can be effected practically only by one agent—that is, carbon or carbonic oxide. But as a very high temperature is necessary to effect the reduction, the metal almost always combines with a greater or less proportion of the reducing agent, as well as of other elementary substances, such as silicon, sulphur, and phosphorus, that may be present either in the ore, the fuel, or the flux, so that the ultimate result is never a pure metal, but a series of compounds, varying in properties from great hardness to perfect malleability, and from ready fusibility to almost absolute infusibility.

Practically speaking, absolutely pure iron may be said to be of no commercial value. But, on the other hand, extraordinarily small traces of foreign elements exert a very marked influence on the metal, and it is precisely these small, and, in many cases, unnoticed differences of composition, that render so many points in the chemistry and practical working of iron obscure and difficult to be understood. When it is considered that the investigation of such problems calls for researches involving the utmost refinements of analytical chemistry, it is not remarkable that contradictory statements and opinions still abound on many points of the chemistry of iron-making. The mechanical considerations involved in this subject are almost as important as the chemical; for, unlike the smelter of other metals, who is able by fusion alone to bring his finished product to a merchantable state, the iron smelter has to deal with pasty infusible masses, which require to be compacted and moulded by pressure by powerful machines, such as hammers, presses, rollers, etc., before they can be made available for consumption.

Iron is employed in the arts under three several states, whose variable properties are mainly due to differences in the quantity of carbon present, and in a much lesser degree to that of other foreign matters. When alloyed with a maximum of the latter element, an amount which in ordinary smelting does not exceed 6 per cent., or fall below 2 per cent., the substance obtained is known as cast iron or *pig metal*. This is a hard and comparatively brittle substance, which can be readily fused at a high temperature, and is susceptible of being moulded into solid forms by casting, but also in most modern iron works forms an intermediate product in the manufacture of the other classes. According as the metal may be most adapted for founders' or forge-masters' use, it is distinguished as forge or foundry pig.

Wrought or Malleable Iron is the nearest approach to the chemically pure metal that can be obtained on the large scale, may be almost absolutely free from carbon, and never contains more than 0.25 per cent. It is a soft, malleable, and extremely tenacious substance, infusable, except at the extreme temperatures obtainable in furnaces of special construction, but capable of being agglomerated by pressure, when at a white heat, to a compact state by the process of welding. When heated and suddenly cooled, it retains its softness. It may be produced either directly from the ore or by the conversion of pig iron. The varieties of the malleable iron are distinguished by many different names, but these have reference rather to form and destination than to differences of composition.

Those varieties of iron in which the amount of carbon is above the maximum of malleable, and below the minimum of cast metal, are known as *steel*. The distinguished property of this class of products is the power of being hardened or softened at pleasure, by sudden or rapid cooling, by the process known as *tempering*. Being intermediate in position between wrought and cast iron, steel is both fusible and malleable, but requires a higher temperature for fusion than the latter, and greater compressing power, owing to its lower welding temperature, than the former. Those varieties that are richest in carbon are the hardest and most fusible, and are known as *strong steels*, while those that are nearer malleable iron in composition are distinguished as *mild steels* or *steely irons*. Steel may be obtained either direct from the ore at one operation, or indirectly by a variety of processes of greater or less complexity from either cast or wrought iron.

The history of the production of iron is probably almost co-extensive with that of the human race; at least, it goes back far beyond the periods of authentic history. According to the Pentateuch (Gen. iv. 22) the discovery of iron is attributed to Tubal Cain, who is said to have been sixth in descent from Adam. Pagan tradition assigns the discovery to Vulcan, placing it about the time of Deucalion's deluge. There can be little doubt that the discovery was made at a very early period, as the production of small masses of malleable iron is one of the simplest of all metallurgical operations, requiring only a small furnace without blowing apparatus, such as can be made by digging a hole in the side of any bank exposed to the prevailing wind, a supply of easily reducible ore, and charcoal for fuel. Such processes as these have been described as in use in Africa by Mungo Park, and are still employed in Birmah; and probably something of the same kind is indicated by the tradition which ascribes the discovery of iron in Scythia to the effects of forest fires in districts containing iron ores, when portions of the reduced metal are said to have been found among the ashes of the burnt trees.

It may have been, however, that the masses of iron referred to were meteorites, whose existence was first made apparent by the clearing of the ground. Homer refers several times to iron and steel. Thus in the twenty-third Illiad, Achilles, at the funeral games of Patroclus, gives a disc of iron as the prize; and in the ninth Odyssey, the hissing of the burning stake that Ulysses plunges into the eye of Polyhemus is compared to the noise produced when steel is hardened by quenching it with water when at a red heat. Probably the first important improvement in the manufacture was the introduction of the artificial blast, which is of great antiquity. In Egyptian sculptures of the reign of Thothmes III. (1505 B. C.) smiths are represented working at a forge, which is provided with two simple leather bellows, worked by the pressure of men's feet for the exhaust, and inflated by strings pulled by hand, in a manner exactly similar to that still employed in Birmah. Aristotle (B. C. 384-322) describes the process of making cast steel used in India, which is still produced under the name of *wootz*; and also the manner in which the Chalybes of the Euxine procured iron. Pliny (A. D. 2379) mentions the great masses of iron ore still worked in Elba, Styria, and Spain, and describes the methods of making iron and steel, especially remarking that the quality of the latter depended upon the water used in quenching, and that small tools were tempered in oil. ("Natural History," bk. xxxiv. chap. 41.) Diodorus (B. C. 60-40), in describing the iron works of Elba, states that the ore was reduced to small pieces and heated in furnaces; the charge, when properly softened, was removed and divided into small masses, which had a spongy appearance (blooms), and were exported to main land of Italy for conversion into tools.

Galen (A.D, 131) remarks that knives made of Indian iron (steel) were remarkable for their strength and hardness, but were often so brittle that the cutting edge splintered off, owing to their having been very improperly tempered. According to Franquoy, bellows with valves were introduced by the Romans into Gaul during the fourth century A.D. These, although single acting and made of leather, were a considerable advance upon the savage form, which required strings for their inflation. The wooden double bellows, which are still in use in some parts of the Continent, may be regarded as the precursors of the cylinder blowing engine, and were introduced into the Harz about 1620, either from Franconia or Thuringia.

During the Middle Ages the great improvement consisted in the gradually increasing height of the furnace, consequent on the use of ores of an infusible and difficultly reducible character. This necessitated a special means of withdrawing the reduced mass of iron (lump or bloom), which was effected through a lateral opening in the hearth, or lower part of the furnace, instead of being lifted out from above, as was done with the ordinary open fire. With the increased length of the operation, the reduced metal being left for a considerable time in contact with the fuel, facility was given for a greater absorption of carbon, resulting in the formation of a larger quantity of molten pig iron, which was run out with the slag, than was the case with the open fires. The increased height of the furnace is well seen in Agricola ("De Re Metallica," lib. xii. edit. 1546), who describes two different methods of iron-working as common in his time. The text is not very clear, but the engravings represent, in the first case, an ordinary bloomery, in which malleable iron is produced directly from the ore, together with a certain quantity of hard or pig iron; while, in the second method described as in use with refractory ores, the furnace has a shaft of such a height that the furnace-man requires to ascend a short flight of steps to reach the throat, or charging-place. It is surprising that this author makes no mention of foundry work; but as he states that the "hard iron" of the bloomery was useful for stamp heads, he was probably acquainted with the use of iron castings, but not with their mode of manufacture. The omission may also be accounted for by supposing that no foundries existed in Saxony, to which country most of Agricola's descriptions refer, until sometime after their establishment in the Rhenish and Low Countries. The subject of iron-founding is noticed by Lazarus Ercker in his "Probierbuch," published in 1574. Karsten supposed that the *Stückofen*, or high bloomery furnace above referred to, was of Eastern origin, and was first introduced into Styria, travelling thence westward to Burgundy and Alsace, subsequently returning eastward into Bohemia and Saxony; and that the later forms of *Blauofen* and high furnace (the proto-types of the modern blast furnace) were invented in the Netherlands. The first indication of the latter are found in Lorraine and in the German Rhineland. Franquoy, who seeks with patriotic zeal to establish the priority of invention of the blast furnace to the Liége district, states that according to documentary evidence the *hauts fourneaux* at Vennes and Grivegnée in that country were established before A.D. 1400, and also that the furnace at Marche les Dames was built by William, Count of Namur, A.D. 1340. Karsten, on the other hand, states that although the knowledge of pig iron dates from time immemorial, its use and systematic production for foundry purposes cannot be traced back with certainty to an earlier period than the end of the fifteen century.

In England, the blast furnace was probably in use at a very early period, as we have evidence, accord- to Lower, of ornamental castings being made in Sussex some time in the fourteenth century. The principal seats of the iron trade at that period in England were in the great forests of Sussex, Gloucestershire, and South Wales, where, under the older forms of bloomeries, iron works had existed since the days of the Romans. The gradual diminution of the forests of Sussex under the demands of the furnace, a process of destruction which may be seen going on at the present time with increased rapidity in Sweden, North America, and other countries producing charcoal iron, led to the passing of a stringent act in 1584 (27th Elizabeth) forbidding the further erection of iron works in the Weald of Sussex except under certain limitations. With the commencement of the seventeenth century came the first attempts at smelting with mineral fuel, the pioneer of this particular improvement being Dud Dudley, who in 1619 produced both pig and wrought iron with coal in Worcestershire; but the scheme was unsuccessful, owing to the opposition of the charcoal iron masters, so that after trials in several localities extending over upwards of thirty years, all of which ended unfortunately, the inventor finally abandoned the subject. A similar trial was made in Hainault by Octavius Stada, a native of Bohemia, in 1625, who obtained a monopoly of the invention for twenty-five years, but it lead to no practical results. It was not till more than a century later, namely, in 1735, that the problem of smelting with coal was successfully solved by Abraham Darby, of Colebrookdale, who was the first to use coke in the blast furnace, an improvement which spread rapidly into all other iron-producing districts situated on or near the coal measures. The last furnace in the Weald of Sussex, at Ashburnham, was blown out in 1829, and there are now only two or three scattered representatives of the ancient charcoal furnaces remaining in the whole United Kingdom. The century following the success of Abraham Darby is marked by the introduction of the two great inventions which especially distinguish the modern period of iron manufacture; that is, the substitution of the reverberatory furnace for the open fire in the forge, and the use of heated air in the blast furnace. The former change effected by the puddling process, invented by Cort in 1784, has almost superseded all the older methods of making malleable iron; and the latter, due to Neilson and Condie, and first used at the Clyde iron Works in 1828, has greatly increased the productive power of the blast furnace, with a diminution in the consumption of fuel.

Since the introduction of the hot blast, the chief improvement in the blast furnace is that of intercepting the gases, which were formerly allowed to burn to waste at the throat, and leading them off by distributing pipes, to be usefully employed as fuel under steam boilers, hot blast stoves, &c. This was patented in France in 1811 by Aubertot, the gases being employed for heating steel furnaces. In 1832 the waste gases were used for heating the blast at Wasseralfingen, in Bavaria, and a similar apparatus was first erected in England in 1848 by J. P. Budd, at Ystalyfera, in Glamorganshire, since which time various modifications of the same plan have been adopted to a considerable extent, especially in those furnaces that are obliged to draw their fuel from a distance, but in other districts, as for example in South Staffordshire and Scotland, the old flaming throats still prevail. Within the last few years, the chief invention and improvements have been in steel manufacture, and many new processes have been introduced. Prominent among these is that named after its inventor, Henry Bessemer, which, although only of a few years' standing, has already effected important services by the production of a material admirably adapted for use in railway and other engineering work in place of wrought iron. Perhaps the problem of most immediate interest at present is that of the economical substitution of mechanical for manual power in the process of puddling, so as to enable the forge-master to manipulate larger masses of malleable iron at a time, and thus to put him more nearly on an equality with cast-steel makers than is now the case.

With the exception of the Weald of Sussex, very little change has taken place in the position of our principal iron-working centers from the earliest time down to the present day. Since the great expansion of railways several new and important localities have been brought into work, the ores being carried to the fuel or the reverse, according as might be most advantageous. In this way the great northern coal field of England, which is almost absolutely without ironstone, gives rise to the largest production in the kingdom by feeding the Cleveland district with coal and coke, and drawing ironstone for its own furnaces in return. The prevalence of cheap ores in the oolitic districts has brought the blast furnace to within fifty miles of London in Northamptonshire, and the pastoral districts of Wiltshire have been invaded by the same visitor. It need not, therefore, be a matter of much surprise if at some future period the Wealden furnaces were to be re-lighted, as they could be easily supplied with fuel from the western coal fields should the supply of ore be sufficient to warrant the attempt, especially as on the opposite coast of France large furnaces have been established for smelting ores out of the same formation, and which are supplied with fuel from England.

Under the various headings in this ENCYCLOPEDIA, the properties and uses of steel for gun construction, etc., have been given. In this article, considering steel as the intermediate link between ordinary cast and malleable iron, we will dwell at length on the methods of its production, its analysis, mechanical properties and tests. For a still more elaborate essay on the subject, the reader may consult *Bauerman's Metallurgy of Iron*, from which the substance of this article is taken. Steel may be produced in many different ways, of which the following are the more important:—

1. By the Catalan forge directly from the ore.
2. From pig iron, by fusion and partial oxidation in the hearth finery.
3. From the same metal, by a similar process in the puddling furnace.
4. By exposing bar iron to the action of solid or gaseous carbonaceous matter at a temperature below its melting point. This method is known as conversion by cementation, and the amount of change produced is mainly dependent upon the time employed. When merely a surface coating of steel is required, the process adopted is known as case-hardening; while, on the other hand, if sufficiently long continued, the iron may be completely converted into cast iron. A process which may be regarded as the reverse of cementation is practised to a certain extent upon cast iron. A process which may be regarded as the reverse of cementation is practised to a certain extent upon cast iron, by exposing it to heat in closed vessels filled with finely-powdered hematite. The surface of the casting is decarburised at the expense of the oxygen of the peroxide of iron, with the production of a malleable coating. This is known as the method of making malleable cast iron. In the above processes steel is produced without melting, and is converted into bars by hammering and rolling, in a similar manner to that adopted in the manufacture of malleable iron. A more homogeneous product may be obtained by fusion, according to the following methods:

5. The cemented or blistered steel produced in No. 4 is broken up into small pieces and melted in crucibles, with or without fluxes, in quantities of from 60 to 80 lbs. This is the original method of making cast steel introduced by Huntsman, in the neighborhood of Sheffield, and is still largely used in the same district for the production of the higher class of cutlery and tool steel.

6. By blowing air through molten pig iron until it is wholly or partially decarburised. In the former case the necessary amount of carbon is restored by the addition of highly-carburised pig, such as spiegeleisen, in small quantity. This is what is known as Bessemer's process.

In addition to the above processes, several new methods of making cast-steel have been proposed and adopted to a certain extent, but not generally. The essence of these methods consists in fusing cast-iron with oxidising, or wrought-iron with carburising additions or by fusing cast and wrought-iron in proper proportions alone, as in the last step of the Bessemer process. The following are some of the more prominent:—

Uchatius Process. This consists in melting in crucibles granulated pig iron with peroxide of iron, produced from roasted spathic iron ore, and a small quantity of oxide of manganese. By varying the proportions of metal and ore, and especially by the addition of a certain quantity of malleable scrap iron, a softer or milder steel may be obtained.

Obuchow's method of producing cast-steel is generally similar to that of Uchatius. White pig is fused with malleable iron or steel scrap, with variable additions of magnetic iron ore, titaniferous black sand, such as is obtained in gold-washing, arsenious acid, niter, and clay, or with arsenious and magnetite alone. The operation is concluded as follows:— The scrap iron, magnetic oxide, and clay are placed in a large clay crucible which has been previously brought up nearly to a white heat; the cast-iron is then run in melted from a cupola, and the crucible is heated until the contents are perfectly fluid; the remaining ingredients, namely, arsenious acid and niter, are then added, the whole being well stirred. The steel is cast in closed cast-iron moulds, and the ingots, as soon as they have cooled down to a red heat, are removed, and taken at once to the hammer and tilted.

Price and Nicholson's process consists in melting malleable iron with refined metal, that is pig iron free from silicon, the relative proportions of the two metals being adjusted according to the character of the steel that it is desired to produce.

Indian cast-steel or *wootz*, is made from malleable iron cut into small pieces, which are charged in quantities of about 1 lb. weight in clay crucibles, together with about 10 per cent. of dried wood of *Cassia auriculata*, and two or three leaves of *Asclepias gigantea*. The covers of the crucibles are luted on with clay, and when dry, some twenty are heated together in a charcoal hearth for about two hours. On breaking the crucible after fusion, a round cake of steel is obtained, about 1 inch in thickness and 5 inches in diameter, which is perfectly smelted, and usually presents a series of finely-radiating striations on its upper surface. Wootz is extremely hard, containing a large amount of carbon, and requires great care in tempering and forging.

The addition of charcoal or other carbonaceous matter in the fusion of blister steel furnishes a ready method of controlling the hardness of cast-steel, and is commonly practised, especially where a proportion of malleable-iron is added to the charge. The same effect may be produced by the use of crucibles made of blacklead instead of clay, the carbon required for the conversion of the malleable iron into steel being furnished by the substance of the crucible: the latter modification is said to be largely used by Krupp at Essen, in Westphalia.

In making the so-called *natural steel* in open fires, a method that was formerly practiced to a considerable extent in Styria, Westphalia, and other parts of Europe, but which is now being rapidly superseded by more improved processes, the hearth differs from that used in making malleable iron by having less depth, while the twyer is at a lower level and more strongly inclined, as the molten mass is not brought directly before the twyer, but is decarburized under the combined influence of the blast and slag, with an increased expenditure of time and fuel. As a rule, about double the quantity of coal and one half more time is required to convert a charge of pig-iron into steel than would be the case if the same weight was operated upon for malleable iron. The best varieties of pig iron for the purpose are those containing a considerable quantity of carbon, such as spiegeleisen, or the strongly mottled variety called *blumige floss*, containing flowers or spots of gray upon a white ground. Dark gray pig can be used, but should first be subjected to refining.

In Styria the process is conducted on hearths, with a bottom of charcoal dust about 12 inches thick. The first portion of the charge, weighing 120 lbs., is melted down with a small quantity of cinder, the latter being strewed over the coals, the reheating of the blooms (*masseln*), about ten or twelve in all, from the former operation, going on at the same time. When only two blooms are left, a further addition of pig iron is made to the extent of from 30 to 60 lbs., and the blowing is continued until the hearth is filled to within one or two inches of the twyer. The fire is then allowed to go down quickly, the slag is tapped through a hole in the front plate into a trough filled with water, and the lump of crude steel remaining in the hearth is allowed to cool, out of contact of the air, by covering it with a shovelful of moistened cinders. In about a quarter or half an hour after stopping the blast, the lump is lifted out of the furnace, and is then divided under the hammer into ten or twelve pieces, which, as has already been stated, are reheated during the fining of the next charge.

The bars drawn under the hammer are hardened by quenching in cold water, and broken, in order to test their quality. They are sorted according to hardness into several classes, distinguished by special names. The best are known as chisel or tool steel, noble steel, and crude steel, below which come a variety of steely irons, used for scythe-making, wagon-wheel tires, and similar purposes. Usually the forges are small, each containing two fires and a hammer, having three water-wheels, two for the bellows, and one driving the hammer, which weighs from 5 to 6 cwt., making from 70 to 120 strokes per minute, with a maximum lift of about two feet. When small-sized bars or scythes are made in the same forge, a lighter tilt-hammer of 3 or 4 cwt. is generally used. With both fires at work, four men produce about 12 or 15 cwt. of crude steel blooms in sixteen hours. The consumption of charcoal is about 30 cubic feet per cwt. under ordinary conditions, but may be reduced to between 22 and 25 cubic feet by using covered hearths and hot blast. The proportional yield of the different kinds of steel is as follows for every 100 parts of pig iron treated:—

60	parts	of steel of all kinds (crude, noble and chisel steel.)
20	"	mock, or over-refined steel, containing soft iron.
10	"	steely iron of different kinds.
10	"	loss.
100		

The Carinthian process is carried out with much larger quantities of pig iron at one time than is the Styrian. The charge, weighing about 5 cwt., is melted down in a hearth some 2 feet square, with an effective depth of from 7 to 9 inches below the twyer. The bottom of the hearth is lined with charcoal dust or brasque in the usual way. The twyer is about $1\frac{1}{4}$ inches wide, and plunges from 10° to 16°. The charge is kept melted before the blast for three hours, as in the ordinary process of refining, and after removal of the slag, is converted into thin plates by throwing water on the surface, and stripping off the chilled metal in crusts or discs of about 1 or 1½ inch thick. After the fire is made up, the first portion of the bloom obtained in the preceding operation is reheated and hammered—an operation requiring about an hour and a half. A quantity of from 40 to 70 lbs. of pig iron, with a little cinder, is then melted down gradually, and upon this the refined metal of the first operation is added by small quantities at a time, until the whole charge forms a more or less pasty or imperfectly fluid mass (*sauer*) on the hearth bottom, which is broken up with a bar and piled into a heap in the center. The amount of working depends upon the feel of the iron. If it *dries* too rapidly, fresh pig iron must be added, while in the opposite case of being too fluid, oxidation is promoted by the addition of hammer scale. The upper portion of the mass, being under the influence of the blast, loses its carbon; while the lower part, being in contact with the glowing charcoal lining the hearth remains in the condition of cast-iron. After making up the pile, the second portion of the previous bloom is reheated, and when this is finished, the contents of the hearth, having subsided to a uniform level surface, are found to be sufficiently fined to allow the formation of a fresh bloom, which is broken out and divided into two parts for further treatment. The half blooms are again divided, and finally finished into bars, which are hardened, broken and selected in the same way as in Styria. It will be seen that the same hearth is, in addition to its proper work, made to do duty alternately as a refinery and reheating fire, an arrangement that must be attended with considerable waste both of time and fuel. The loss upon the pig iron is from 20 to 30 per cent., including the reheating; the consumption of charcoal is from 40 to 50 cubic feet per cwt. About 75 per cent. of the produce is good steel, which is reheated in special small fires, and drawn under light hammers into bars, which are packed in cases and sold as Brescian steel.

The so-called true Brescian process practised at Paal, in Styria, differs in certain details of manipulation from the preceding, the most important point being, that in reheating the blooms, they are plunged into the bath of molten pig iron, whereby they undergo a kind of surface hardening by cementation.

In Siegen, where spiegeleisen is, or was, formerly treated in the open fire, the charge is melted down in small quantities of 60 or 80 lbs. weight upon a bottom of mottled iron. As soon as the fusion commences the slag is tapped to within 2½ inches of the bottom, and further additions of spiegeleisen are made in diminishing quantities, from 40 lbs. at the fifth to 20 lbs. at the seventh and last charge. It is sought as much as possible to keep the mass at the consistency of soft butter during the entire operation. The bloom (*schrei*) ultimately obtained weighs 4 cwt., the time required being about eight hours. It is divided into seven or eight pieces, which are tilted into bars, with a loss of about 20 per cent. Reckoned upon the pig iron, the loss is 30 per cent., 100 lbs. giving 70 lbs. of steel, of which about three-fourths are of good quality, and capable of being properly hardened, and the remainder mild steel or steely iron. It is doubtful whether this process is still practised, having latterly been superseded by the method of steel puddling.

Puddled Steel. There is no essential difference between the methods of making wrought-iron and steel in the puddling furnace, other than the degree of decarburization to which the pig iron is subjected. The most highly-carburized varieties of pig iron, especially those containing manganese, such as spiegeleisen, are best adapted for the process. The furnace is usually of a somewhat smaller size than that employed for making malleable iron; or rather, the size of the bed is diminished in proportion to that of the fireplace and stack, in order to be able to command a very high temperature. The charge does not usually exceeed 3 or 3½ cwt., which is introduced in fragments as nearly as possible of the same size and thickness, and spread out so as to expose a large surface to the flame, in order that fusion may be effected uniformly and without much oxidation. The use of only one kind or class of pig iron is also necessary, otherwise, supposing white and grey iron to be mixed, a portion of the charge would probably fine and come to nature while the more fusible part was still unchanged. This is exactly the reverse condition to that required in puddling for malleable iron, where a mixture of two different kinds of pigs has an advantageous effect in accelerating the process. In all steel puddling, on the other hand, the charge is rendered perfectly fluid, and covered with molten slag, in order that the fining may go on very slowly and uniformly. The presence of protoxide of manganese in the slag is important, as contributing fluidity without increasing the decarburising influence. By keeping the contents of the furnace well stirred together during the second part of the process, the iron separated in malleable condition may, in the event of its becoming too much decarburised, be brought back to the proper condition by dissolving it in the unaltered pig iron below, in a somewhat similar manner to that which is practised in the Siegen open fire process, where the iron is prevented from drying to too stiff a consistency by the addition of fresh quantities of pig iron at intervals. In order to induce fining in the molten mass, the damper must be closed until the charge thickens and commences to rise, when the heat must be carefully raised during the time of stirring, which usually takes from thirty-five to forty-five minutes, or somewhat longer than is the case in puddling for malleable iron. The high temperature prevailing in the furnace keeps the contents of the hearth well melted, and by continued stirring, fresh particles of metal are constantly brought to the surface of the fluid covering of slag. The appearance of fine, white, brilliant grains is a sign of the process going on well, and indicates the formation of steel of good quality and uniform texture. If, on the other hand, the separated grains are large, and resemble snowflakes, the product is likely to be of a coarse fracture, and imperfectly refined. The slag must be less basic than that formed in puddling for malleable iron, as the presence of a large excess of oxides of iron not only reduces the fluidity, but acts too energetically on the removal of the combined carbon from the pig iron.

The balling of the granular clots of steel as they come to nature is an operation requiring considerable skill; it must be done in a neutral or non-oxidizing atmosphere, such as is obtained by shutting the damper, and keeping the hearth filled with flame and smoke with an ordinary furnace, or shutting off the top blast when a gas furnace is used. The balls are shingled at a lower temperature than those of malleable, and when they cannot be immediately taken to the hammer, are protected against oxidation by rolling them in the melted slag, so as to obtain a superficial crust or varnish, which excludes the air from contact with the heated metal. The slowness of the fining process, and the extra amount of stirring required, are sufficient to explain the apparent anomaly that a partial should require longer time than a complete decarburisation. Under ordinary circumstances the time required for working off a heat is in either case as follows:—

	Fibrous Iron.	Steel.
Melting down...........	30 to 40 min.	40 to 50 min.
Stirring	30 " 35 "	45 " 50 "
Boiling and fining......	25 " 30 "	20 " 25 "
Balling......................	10 "	10 "
	85 115	105 135

As originally fully described in the specifications of Riepe, by whom the process was introduced into

England; the charge recommended to be used is 280 lbs., which is to be exposed to a red heat until the metal begins to fuse, when the temperature is reduced by lowering the damper. Forge or mill cinder, to the extent of twelve or sixteen shovelsful, is then added, and when the whole was melted, a small quantity of peroxide of manganese salt and clay ground together. After this mixture has acted for a few minutes the damper is fully opened, and about 40 lbs. of pig iron is placed upon an elevated bed of cinder near the fire-bridge. When this begins to trickle down, and the boiling of the contents of the furnace commences, it is raked into the hearth, and the whole mass is well mixed together. When the grains of steel begin to break through the cinder, as already described, the damper is to be partially closed, and the operation of stirring below the cinder commenced, taking care that the heat be not raised above cherry redness, or the welding temperature of shear steel. The remainder of the process of balling is done with a closed damper, as already described. It appears to be doubtful, according to the statements of most of the recent writers on the subject, whether the process can be properly conducted at the low temperature specified. The use of the highest heat attainable in the puddling furnace was afterwards claimed by another patentee, and on subsequent litigation, the term "cherry redness" was explained as meaning a bright red heat when the furnace was illuminated by direct sunlight. Parry states that if the heat be too high during the boiling, the mixed cinder and metal separate from each other, and the decarburisation proceeds slowly; while, on the other hand, if the temperature be too low, the cinder and metal cannot be properly mixed, being of too stiff a consistency, and the steel will not be homogeneous. The temperature must be raised to a full yellow heat on the appearance of the floating granules in the slag. The fire should be made up at the end of the boiling process, in order to prevent the passage of air by opening the fire-hole during the balling. It is necessary to shingle the balls as soon as possible, in order to prevent the decarburising action of the rich slag retained by capillary attraction upon the spongy particles of steel. When the slag is poor in protoxide of iron it sets very quickly, and when more basic, acts powerfully in removing carbon. The presence of oxide of manganese is advantageous, as communicating fluidity without increasing the oxidizing effect—a point of considerable importance, as the shingling takes place at a lower temperature than is the case with malleable iron. In some cases an addition of peroxide of manganese is made immediately before balling, or the mixture of peroxide of manganese, clay, and salt, already mentioned as being recommended by Schafhaütl for improving ordinary iron, is added at intervals after the melting down of the pig iron during the stirring. At Lohe, in Siegen, twelve heats of $3\frac{1}{2}$ cwt of white fibrous "steel" pig iron are puddled in the turn of twelve hours. Each charge yields from seven to eight balls, weighing 40 lbs. each. The loss upon the pig iron is 9 per cent. in puddling, with a further amount of 11 per cent. upon the reheating, which is done in covered hearths with a single twyer, somewhat like the South Wales hollow fire. The blooms are drawn into bars under a tilt hammer. The produce is assorted according to the fracture: 78 per cent. is good hard steel, capable of being broken when cooled in water; the remaining 22 per cent. is more or less mixed with soft iron. The total expenditure of coal is double the weight of the steel produced; out of this 84 per cent. goes for puddling, and the remaining 16 per cent. for reheating. These quantities refer to Ruhr coal, which is not of a very high quality. The total production for twelve hours is about 31 cwt. When grey pig iron is used, either alone or mixed with mottled, it is necessary to add from 10 to 15 per cent. of scale and cinder. In such cases the consumption of coal may be somewhat increased, as the process lasts a little longer than when working with iron melted from spathic ores. In Styrian works using lignite, with the advantage of good pig iron, the consumption is from 32 to 42 cwt. per ton of steel blooms made, without counting charcoal or wood for reheating. The use of gas furnaces is said to be of great advantage in the steel puddling process, both as regards the saving of fuel and diminishing the waste of iron. At Kirchhunden, in Siegen, the saving is stated at from 35 to 40 per cent. in the coal, and from 9 to 10 per cent. on the amount of iron burnt. According to observations made in several localities, the consumption of fuel is diminished when the sides of the hearth are cooled by a circulation of air instead of water. The chemical changes going on in the process of steel puddling have been investigated by Schilling and other chemists in a similar manner to that followed originally by Calvert and Johnson. The following are Schilling's results of the composition of the metal and slag at the different points of the process, as carried out at Zorge, in Hanover. The charge consisted of white pig iron from Gittelde, and grey from Zorge, mixed in equal weights. The fuel employed in the blast furnace was charcoal, the consumption being at the rate of 100 lbs. for every 87 lbs. of pig iron produced. See table below.

The metal of the sample No. III. was tough and strong cast-iron; No. IV., taken after five tools had been heated in rabbling, was stronger than the preceding, but of a tin-white color; No. V. was very cellular, and much resembled white pig iron, but was

No. I. White pig iron from Gittelde.
" II. Grey pig iron from Zorge.
" III. Mean composition of charge.
" IV. Charges after melting down $47\frac{1}{4}$ minutes from the commencement of process.
" V. Metal at the commencement of rising, $18\frac{1}{2}$ minutes from the preceding.
" VI. Metal during boiling 14 min. later.
" VII. Another sample taken during boiling, 17 minutes later than No. VI.
" VIII. Granules of steel commencing to separate, $14\frac{3}{4}$ minutes later.
" IX. Sample taken at the formation of the first ball, 9 minutes later.
" X. Sample taken at the formation of the last ball, 9 minutes later.

slightly malleable. No.VI. was decidedly malleable and apparantly possessed most of the properties of steel, notwithstanding the large amount of carbon present. No increase of carbon was observed in the earlier stages of the process, as recorded by Calvert and Johnson and Lan. Schilling ascribes this difference to the use of a gas-furnace, and the introduction of an excess of air into the furnace by the top blast:

In these slags, which are nearly uniform in composition throughout, the oxygen ratio of acid to bases is as 11·687: 18·212, or nearly 1 : 1½ that of a sesquibasic silicate. This is supposing the peroxide of iron to be in combination with silica, and not replacing it. The large and constant amount of phosphoric acid is ascribed, not to the oxidation of phosphorus contained in the pig iron, which is obviously in too small a quantity to produce such an effect, but to the ash of the wood burnt in the gas generator, and carried over by the draught, owing to the defective arrangement of the ash pit. It is evident, therefore, that even the above elaborate series of analyses does not furnish us with an exact idea of the changes going on during the process.

Production of Steel by Cementation. This process consists essentially in the exposure of bars of malleable iron, in close contact with charcoal, to a high and long-continued heat, the air being excluded. The furnace, employed for this purpose, is an oblong chamber with a semi-cylindrical roof, containing two large chests or converting pots, also of rectangular form, which are heated by a fire grate, placed below them, and running along the entire length of the chamber. The flame is distributed uniformly by a system of transverse rectangular flues, across the bottom and up the sides of the pots,and finally passes through a number of short vertical chimneys in the sides of the chamber into a tall covering hood or stack, of conical form, like that of an ordinary glass-house furnace or potter's kiln. The size of the boxes varies in different localities, according to the weight of iron heated at one time, from 8 to 15 feet in length, and from 2½ to 3 feet in breadth and height, corresponding to a capacity of between 8 and 12 tons of bar iron, with the necessary quantity of the cementing powder. In Yorkshire they are usually built of sandstone flags, but in other places ordinary fire-bricks and lumps or slabs of the same material are used. The introduction and withdrawal of the charge are affected through man-holes, in the shorter side walls of the covering chambers, placed above the level of the top of the boxes; these holes are of course walled up with brickwork when the furnace is lighted. In some instances, where the furnace is of small size,the roof of the chamber is made in several pieces, so as to be easily removed at the end of the operation, in order to facilitate the withdrawal of the cemented bars. Two small square holes, communicating with the interior of the boxes, are placed a little lower down on the same side of the furnace; these contain the trial bars used in determining the progress of conversion.

Bar iron smelted from Swedish magnetic ores is used in the production of the best kinds of cement steel at Sheffield, and, as a rule, hammered bars are preferred to those made by rolling. The most esteemed brands are those produced at the small forges in the eastern part of Sweden, in connection with the Dannemora mines; that of Löfsta having the highest reputation. The ordinary sizes of bars employed are from 2 to 5 inches in breadth, and from one-third to three-quarters of an inch in thickness; the flat form being preferred to those of round or square section. In filling the pots, an allowance is made for the expansion of the iron by heat; a space of about 2 inches in the direction of the length, and a little less transversely, being left between the edges of each layer of bars and the walls, and in like manner the butt ends of adjacent bars in each line must not be brought in contact with one another.

The cementing material is in all cases charcoal, in the form of a coarse powder obtained by sifting through a riddle with ½ or ¾-inch meshes. No special variety of charcoal is necessary, that of the hardest wood obtainable in the neighborhood being generally used; as, for example, birch in Sweden, beech in Rhenish Prussia, and oak in England. Hard-wood charcoal is said to be advantageous on account of the large amount of alkaline salts in the ash, which are regarded as favoring the production of cyanogen compounds. For the same purpose, an addition to the charcoal of small quantities of carbonate of baryta, alkaline carbonates, yellow prussiate of potash, animal charcoal, or organic matter containing nitrogen, has been recommended at different times, and tried experimentally; but none of these substances are in general use, except in the superficial converting process of case-hardening.

In charging the pots, the bottom is first covered with a coating of charcoal, and upon it the bars are arranged in tiers lying on the flat sides, and separated from each other by a layer of charcoal about half an inch thick. About one-third of the total cubic contents of the pot is occupied by the iron, the remaining two-thirds being filled with charcoal. When the whole charge has been introduced, the top of the pot is covered with a layer of clay or other refractory material. At Sheffield, grinder's waste, or wheelswarf—a mixture of finely-divided, partially-rusted steel with quartzose sand, produced by the waste of the grindstones employed in grinding the cutlery—is generally used. It is plastered over in a damp state, and frits together to a kind of glaze when strongly heated, forming a covering impervious to the air. A certain proportion of fresh charcoal, to the extent of one-half or two-thirds of the total quantity, must be used in each operation; that remaining from a former charge requires to be subjected to washing and sifting before it can be used again. The mixture of the two kinds is found to give a better result than when fresh coal is used alone, and the conversion is more rapidly effected.

When the furnace is charged, all the apertures are carefully stopped with brickwork or fire-clay, to prevent the access of air. The fire is then lighted, and in about twenty-four hours the chests are raised to a red heat, and in about two or three days more will have attained the proper temperature. According to the nature of the steel required, the fire is kept up for a period of from seven to nine or eleven days: the hardest quality for melting purposes requiring the longest, and spring and shear steel the shorter time. Conversion begins at a temperature of about 1,000°, but goes on more actively at the melting-point of copper, about 1,170°: at higher temperatures cast-iron is produced.

The progress of the conversion is determined by the appearance of the trial bar; the first is taken out after about a week's firing. When there is no longer an unaltered kernel of soft iron apparent in the center, the conversion is considered to be complete, the fire is allowed to go down, and the furnace is left to cool for three days; the man-hole stoppings are then removed, and on the sixth day the withdrawal of the cemented bars is commenced, and takes one or two days more, so that the whole operation requires from seventeen to twenty days. The physical properties of the iron are considerably modified by conversion; the color of the fractured surface changes from the original bluish tinge of malleable iron to a somewhat reddish white, like that of bismuth, and at the same time the luster is very considerably diminished. The texture is in all cases scaly crystalline. The finer the grain and the darker the color, as a general rule, the more highly carburised or harder will be the steel produced; at the same time, both specific gravity and tenacity are reduced. A more decided peculiarity of the converted bars, however, is the blistering of the external furnaces, whence the term *blister steel* is derived. When the blisters are small, and tolerably regularly distributed, the steel is of good quality; but when large, and only occurring along particular lines, they may be considered as indicative of defective composition or want of homogeneity in the iron employed. The cause of this phenomenon is not quite clearly made out. The most probable explanation is, that it is due to the irregular action of the cementing material upon included particles of slag, consisting of basic protosilicate of iron, which is reduced to the metallic state with the evolution of carbonic oxide, which blows up the surface of the metal when in a softened condition from the heat of the furnace. The average increase of weight in the conversion of bar iron into blistered steel is from $\frac{1}{2}$ to $\frac{3}{4}$ per cent. The fuel necessary per 100 lbs. of the latter is as follows:—

Coal	75 to 90 lbs.
Lignite . . .	160 " 210 "
Peat	200 " 300 "
Wood . . .	300

Blister-steel bars may be used for common purposes, such as steeling the faces of hammers, without further treatment; but more generally they are subjected to one or more reheatings in packets or faggots, and weldings by hammering or rolling, whereby the texture becomes more uniform, and strength and elasticity are increased, but with a progressive diminution of hardness. Spring steel is produced by heating blistered bars at an orange-red heat, and drawing them down either under the hammer or by rolling. *Shear steel* is a better quality, obtained by drawing the original bars to lengths of 3 feet, which are piled together in faggots and welded, the reheating being effected in a hollow fire. The surface of the faggot is covered with clay, which forms a cinder in the heating process, and prevents the blast from acting on the combined carbon of the crude bars. The product of this operation is known as *single shear*. It may be further refined by doubling the bars, and repeating the process of heating and welding, making double-shear steel. The best and most uniform quality of steel can, however, only be obtained by fusing the blistered bars in crucibles.

Case-hardening, or the production of a thin superficial layer of steel upon malleable iron, is a rapid process of cementation carried out on a small scale. An iron box, heated in a smith's forge, is used as a cementation chest. The charcoal is usually obtained by carbonising animal matter, such as bones, horn, or leather. The articles to be case-hardened are embedded in the charcoal in the ordinary way, and are then exposed to heat for a short time, taking care not to use too high a temperature. Under the most favorable circumstances the cemented layer may attain a depth of about three-eighths of an inch in four or five hours. The work when removed from the fire, is hardened by plunging it while in a heated state into cold water, if it is required to be uniformly hard over the whole surface, otherwise it is allowed to cool, and the steeled surface is removed by turning down such parts as are intended to remain malleable, and the other portion is subsequently hardened by heating and quenching in water as before.

The following is the most rapid method of case-hardening:—The piece of iron to be treated, after being polished, is raised to a bright red heat, and the surface to be hardened is rubbed or sprinkled with finely-powdered yellow prussiate (ferrocyanide of potassium). As soon as the powder has volatilised or disappeared, the work is quenched in cold water in the usual way. If the process has been properly conducted, the surfaces covered by the salt will be found to have become hard enough to resist the file.

Malleable Cast-iron. The process of annealing, or rendering the surface of cast-iron articles malleable, so that they may be filed or hammered, is a kind of inverse cementation, finely-divided peroxide of iron being employed to remove the carbon from the surface of the casting. Cast-iron smelted from the red hematite is generally preferred for this purpose, especially that made with charcoal. The fusion takes place in crucibles in an air furnace, such as is used in for smelting cast-steel, good coke being used as fuel. The castings, when removed from the moulds, are very brittle, and cannot be touched with the file. They are then packed in cast-iron crucibles containing powdered red hematite, which are arranged in rows one above another in a furnace of rectangular section, somewhat similar in character to an ordinary cementation chamber. When the furnace is charged, all the apertures are carefully closed, and heat is applied gradually, so that the whole contents may be be brought up to a red heat in twenty-four hours; the firing is then continued for from three to five days more, according to the depth of the malleable skin required on the finished work. Articles of irregular thickness that are intended to be bored out must be subjected to the process a second time, in order to obtain the proper degree of alteration.

The appearance of the finished articles, when drawn from the furnace, is similar to that of malleable iron, but lighter in color; the density is about the same as cast-iron, the increased specific gravity of the malleable portion being counteracted by its porosity. The fractured surface is white and finely granular, with a very high lustre, occasionally presenting a grey silky appearance, recalling that of soft steel. When the thickness of the object is more than half or two-thirds of an inch, a kernel of very soft grey cast-iron is left in the center. In the latter case the central portion may sometimes be broken by bending the object without the external skin giving way.

Malleable castings, prepared in the above manner, may be easily wrought cold, but become very brittle when heated, breaking to pieces under the hammer at an incipient white heat; at a higher emperature the kernel or unaltered cast-iron melts, so that articles that have been subjected to the process cannot be united by welding, but may be brazed without difficulty. On account of the more refractory nature of the material, the use of malleable cast-iron crucibles has been suggested for melting silver in mints, instead of the cast-iron pots ordinarily used for that purpose. The principal application of the process is, however, to small articles of hardware, such as keys, buckles, gun-furniture, etc. Recently, however, it has been applied on a larger scale by M'Haffie, of Glasgow, to parts of machinery, such as toothed wheels and screw propellers, the latter having been successfully adopted in steamers employed in the whaling and sealing trade in the Greenland seas, where ordinary cast-iron screws are especially liable to be broken by the floating ice. The malleable skin may be partially converted into steel by case-hardening in the same way as ordinary soft iron, so that these different states of cast-iron, malleable iron and steel may be combined in the same object. Common articles of cutlery made in this way are distinguished as *run-steel* goods.

Production of Steel by Fusion. In all the preceding methods, the steel produced, whether by fining or cementation, is, as a rule, very unequal in quality; and uniformity can only be attained by repeated faggoting and welding, steps which are necessarily attended with a loss of carbon, and consequent reduction of hardness. The requisite uniformity of composition may, however, be obtained by breaking up the crude bars produced in the forge, or by cementation, and exposing them to a strong heat in crucibles out of contact with the air. The product, when melted, is poured out into cast-iron moulds, forming ingots of *cast-steel*, which are much more regular in composition and texture than the original material.

The practise of melting steel was introduced at Sheffield by Huntsman about the year 1740, and is still carried out in substantially the same manner at the present day. Although a simple operation, it is an expensive process, owing to the large consumption of fuel and crucibles required for a comparatively small production of ingot.

The crucibles generally used in a steel-melting-house are made of mixtures of different kinds of fire-clay from the coal measures, with a certain proportion of ground potsherds and coke dust; the usual size is from 16 to 18 inches in height, and from 5 to 7 inches in diameter at the mouth, with a slight belly at about two-thirds of the height from the bottom. The capacity varies from 35 to 80 lbs. Usually two pots are placed in a furnace; they stand upon cylindrical discs or cheeses of fire-brick resting on the grate bars. Previously to being used they require to be gradually heated to redness in an open fire or annealing grate, which is done by placing them in batches of twenty, bottom upwards, together with their covers, upon a bed of red-hot coal in the grate; and the intermediate space is then filled with coke, and the fire is urged until the necessary heat has been obtained. The pots are then removed to the melting furnaces, and fixed in position on their stands. The fires are replenished with coke, and as soon as they have been brought up to a strong heat, which takes place in about twenty minutes, the charge of blister steel, properly assorted and broken into small pieces, is introduced through a wrought-iron funnel; after which the cover is placed on the top of the pot, and the full heat of the furnace is given for about three and a half hours, during which time fresh fuel must be added every three-quarters of an hour. When the fusion is complete, which is ascertained by removing the cover and searching the contents of the crucible with a pointed rod, in order to ascertain whether any hard unmelted lumps remain, the crucible is cleared from adherent slaggy masses by stirring below the grate, and is then lifted out by the furnaceman with a pair of curved-nosed tongs. The ingot mold, made of cast-iron, is blackened by coating it with train oil and heating; or, in some cases, a thin wash of fire-clay, mixed with water to the consistency of cream, is used. When the pot is removed from the furnace it is deposited in the teaming hole, a small pit filled with broken pieces of coke, and the lifting bags are changed for those used in casting. The contents of the crucible are allowed to cool for a short time before pouring. When the ingot mold is filled, its mouth is covered with a plug of cast or wrought-iron, or a shovelful of sand, in order to prevent the top of the ingot from becoming spongy by the escape of gases before solidification.

After the first cast the crucible is cleared from adherent clinker, and returned to the furnace for a second melting. The charge is somewhat reduced, and the consumption of coke, as well as the time of fusion, is diminished in a similar proportion. Thus the first melting takes from four to six hours, while the second and third only require from two to two and a half hours each. The furnace is allowed to cool after from three to five meltings have been made, as there is no advantage to be gained by keeping it constantly heated, owing to the corrosion of the lining bricks produced by the very high temperature, whereby the capacity and the power of the consuming fuel is increased, without any corresponding increase in the amount of steel melted. Under ordinary circumstances the total amount of coke burnt is from three to three and a half times the weight of the ingots produced, when of a good quality; but when made from inferior varieties of coal, it may be as high as five or six times the weight.

In France furnaces are used capable of containing a large number of crucibles which are not brought into direct contact with the fuel, but are arranged in series in a chamber, which is heated by a fireplace similar to that of a reverberatory furnace. The chambers, which are made to hold from four to nine pots, are covered with a square lid in the usual way. In addition to the chimney draught, a blast is used below the grate, and a portion of the waste heat is sometimes applied to raising steam for the hammers and rolling-mills used in finishing the ingots. Siemens' regenerative gas-furnace has also been applied with considerable advantage to steel melting, and by its use the consumption of fuel per ton is reduced from 3½ tons of coke to 1½ tons of inferior slack.

When very large masses of cast-steel are required, the contents of all the crucibles are either poured into the foundry ladle before filling the mold, or the pouring is so arranged that by bringing up relays of fresh pots, a constant stream may be kept up without intermission. In this way large castings, up to as much as 40 tons, are made by Krupp, in Essen, from crucibles containing 70 lbs. of steel. The furnaces hold from 2 to 24 pots each. The materials used are reported to be puddled steel and wrought-iron scrap, with an addition of carbonaceous matter, in order to render the malleable iron fusible, a somewhat similar process to that adopted in making the native Indian steel, called wootz. The drawing of the crucibles from the furnace is also facilitated by placing them on a platform, which is raised by a mechanical lifting apparatus placed below the ash-pit, thus doing away with the use of the lifting-tongs.

At the River Don Steel Works in Sheffield, cast-steel is largely made by the method introduced by Mushet in 1801, which consists in melting malleable scrap-iron with charcoal and oxide of manganese in crucibles directly, without using any blister-steel. The furnaces are 288 in number, each of sufficient size to contain two pots charged with 100 lbs. With the whole number at work, a casting of 25 tons weight may be made, the pouring from the 576 pots being completed in five minutes. In order to keep up the supply, the pots are conveyed from their melting-holes to the casting-place on small barrows, instead of being carried by the tongs, as was formerly the custom. The steel produced is to a great extent employed in making castings for direct use, such as railway crossings, wheels, and bells, instead of merely running it into ingots, which are subsequently worked up under the hammer. The molds used for this purpose are made sufficiently refractory by the use of a thin layer of burned clay, produced by grinding old metal pots, which is applied immediately over the pattern, the remainder of the box being filled with ordinary molding sand. This method of steel casting was first practiced at Bochum, in Westphalia, where it is still carried out on a rather large scale. Castings made to pattern, which are not intended to be subsequently hammered, must be annealed and allowed to cool very slowly.

An addition of manganese, either as a carburet reduced by heating the oxide with carbon at a very high temperature, or a mixture of black oxide of manganese with carbonized pitch or resin, is very commonly used for improving steel in the process of melting. This is the celebrated process of Heath, which formed the subject of long and protracted litigation a few years back. The appearance of fracture of ingots of cast-steel varies with their hardness or relative proportion of carbon. The softer kinds are bright and finely granular. The harder qualities often show crystalline plates of a certain size, arranged in parallel stripes or columns at right angles to the surface of the mold, so that in a square ingot the columns intersect, forming a cross. In all cases the ingots are more or less unsound, being filled with small vesicular cavities, so that they require to be reheated and hammered before they can be converted into bars. This is done in the manner already described for making shear-steel, care being taken to effect the reheating at as low a temperature as possible, and to prevent the metal from burning by keeping it out of access of the air while in the fire.

Bessemer's Process. This, one of the simplest methods of producing cast-steel in large quantities, combines the action of the puddling and ordinary steel-melting furnace into one operation. The essence of the process consists in injecting large quantities of air into a bath of molten cast iron through a large number of small orifices, in order that the combustion of the carbon and other matters in combination may take place rapidly and uniformly. By this means a very high temperature is developed in the converting vessel, the heat being sufficient to melt the decarburised malleable iron, instead of producing same in a pasty, weldable condition, as is the case in the puddling-furnace. This great increase of temperature is obviously due to the rapidity of combustion, owing to the intimate contact of the air, which is injected at a much higher pressure, from 15 to 20 lbs. to the square inch, than is used in the ordinary operation of iron-melting, with the molten metal, instead of the decarburised iron merely taking place at the surface of the bath, or where the pasty metal is in contact with particles of scale, cinder, or similar oxidizing agents, as is the case in puddling. It will be remembered that, in the latter process, the temperature of the puddling furnace has to be artificially reduced by closing the damper, in order to bring about the reactions between the different portions of the charge, which only go on very slowly when the contents of the hearth are in a liquid state. In Bessemer's process, however, the increase of temperature goes on progressively from the moment the blowing commences until the conclusion of the operation, the heat produced being developed by combustion going on in the molten mass, in the order in which the combined foreign substances are removed being similar to that observed in puddling and refining. After the whole of the carbon has been eliminated; the heat is kept up, if the blowing be prolonged by the combustion of the iron, giving a product exactly similar in general properties to the *burnt iron* which is obtained when malleable iron is too often or too highly heated in the process of welding.

This process is, therefore, not adapted for the production of soft malleable iron, but, with certain modifications, is capable of producing steel of good quality, within a considerable range of composition and hardness. This may be done in two ways: the first is that practised in Sweden, where the blowing is interrupted after a partial decarburisation of the charge, the proper moment for stopping the operation being determined by the appearance of the flame issuing from the mouth of the converting vessel; or the metal may be completely decarburised, and then brought back to the composition of steel by the addition of highly-carburised melted pig iron, such as spiegeleisen, in sufficient quantity to restore the necessary amount of carbon. The latter modification of the process is due to Mushet, and is now generally preferred to the older method as being more certain in result.

The varieties of cast-iron best adapted for conversion into steel by the Bessemer process are those smelted from hematite or magnetic ores not below No. 2 in greyness. White iron can only be treated with difficulty and increased waste, partly owing to its imperfect fluidity when melted, which increases the resistance offered to the passage of the blast, but more particularly on account of its deficiency in carbon and silicon. The carbon being in the combined state, the production of carbonic oxide takes place at too early a stage of the process, and not being present in sufficient quantity, prevents the attainment of the proper temperature in the converting vessel.

The chief essentials in the chemical composition of the pig iron are almost absolute freedom from sulphur, phosphorus and copper, as neither of these ingredients is sensibly reduced in the amount by the process; silicon and manganese, on the other hand, may be almost completely removed, and their presence is beneficial within certain limits. As long as manganese remains scarcely any iron is oxidized, the silica produced from the silicon of the metal uniting with protoxide of manganese to form a slag, which is very fluid, but also is very destructive to the siliceous linings of the converting vessels.

The best English pig iron for use in the Bessemer process is that smelted from Cumberland hematite, about No. 1 or No. 2 in greyness. It should contain from 1½ to 2 per cent. of phosphorus. At Essen, in Westphalia, the limiting quantities of foreign matters in the pig iron preferred for Bessemer steel-making are as follows, according to Jordan. The metal generelly used is smelted from mixtures of spathic ore and Nassau hematite.

Manganese, maximum	1.00	per cent.
Sulphur "	.04	"
Phosphorus "	.06	"
Carbon, minimum	5.00	"
Silicon "	2.00	"

The furnaces, or *converters*, employed in the process are of two different kinds. The oldest, or fixed form, which has been used to a certain extent in Sweden, is a cylindrical vessel of refractory brickwork, somewhat similar to a foundry cupola, but broader and lower in proportion. Near the bottom, which is made with a slightly forward incline towards the tap-hole, is placed a series of small twyers, which are arranged at equal distances around the entire circumference. The top of the vessel is covered by a dome, terminating in a conical neck, turned towards a hood placed above it, for carrying off the flame and sparks given out during the blowing.

The second, or movable, form of converter, which is now almost universally adopted, consists of an egg or pear-shaped vessel suspended upon trunnions, and provided with appropriate moving mechanism, whereby it may be rotated vertically through an angle of about 180°. The outer casing or shell is made of wrought-iron plates riveted together, and, as originally made, was not unlike a soda-water bottle in shape, supposing the pointed end to be flattened, and the neck turned over at an angle of about 30° to the body. In the newer forms, however, especially those intended for working with large charges, increased capacity is obtained by making the body and lower part cylindrical, thus approximating in outline to the older fixed converters.

The suspension is effected by means of a stout hoop of wrought-iron or steel carrying two trunnions, which is shrunk on to the body of the converter at the widest part. One of these trunnions, which run in bearings supported by cast-iron standards, is solid, while the other is hollow, forming a passage for the blast, and carries a spur pinion.

The interior lining of the converter must be made of the most refractory material at hand. Fire-brick or clay may be used; but in Sheffield, and in England generally, a nearly pure siliceous sandstone from below the coal measures, known as ganister, is found to be better adapted for this purpose than any other substance. It is prepared by grinding to a fine powder, and may be used alone or mixed with a certain proportion of powdered fire-brick; in either case a small quantity of water is used, sufficient to make the powder slightly coherent, which is then rammed hard between the inside of the shell and a wooden core, which is afterwards removed. The old form of vessel is made in two parts, which are united by screw bolts, and can be taken apart for convenience in lining. In the cylindrical-bodied form, the lower part is made removable, the union being effected by eye-bolts and cotters.

The bottom of the converter is in either case flat, and contains the twyer-box. This is a cylindrical chamber, connected by a curved pipe with the hollow trunnion. The twyers are cylindrical or slightly tapered fire-bricks, each perforated by seven parallel holes, about half an inch in diameter. Usually from five to seven of these bricks are used, which are arranged vertically and at equal distances apart in the lining of the bottom of the converter. Their lower ends pass through a perforated guard plate in the top of the air chamber, the vertical position being maintained by stops bearing against the horizontal arms, which may be turned on one side, when it is necessary to remove or replace the bricks, without being obliged to take out the bottom of the converter.

In the earlier Bessemer works two converters are placed opposite to each other with a deep cylindrical casting pit between them. In the center of the pit is fixed another water-pressure engine, with a vertical cylinder and solid plunger piston, carrying at its upper end a cross-arm, formed of two parallel girders strongly braced together, to one end of which is attached the ladle,the overhanging weight being supported by a counterpoise attached to the opposite end. The ladle, which is similar to that used by iron founders, but considerably larger,is made of wrought iron lined with fire-clay, having a small hole in the bottom for running out the melted steel into the ingot molds placed below. The hole is closed by an iron rod coated with fire-clay. The opposite end of the rod passes through a slide bar on the outside of the ladle, and may be raised or lowered by means of a hand lever. In order to traverse the ladle about the central pillar, so as to bring the center of the hole over each of the molds in succession, the top platform is provided with spur gearing, so that it may be moved like a railway turn-table. This motion is worked by a man standing on the platform, as is also another for reversing the ladle on its bearings, in order to remove the waste after the end of the cast. The valve of the central engine, which raises and lowers the ladle, is in charge of the same man who works the tipping engines for the converters. He is usually stationed in a box at one side of the converting house, raised a sufficient height above the ground to command a clear view of the whole of the apparatus. The power for working the engines is obtained from a small steam-engine driving the necessary force pumps, which deliver their supply into two accumulators for equalising the pressure.

The method of conducting the process is as follows:—The charge of pig iron, which may be of any weight between 1½ and 10 tons—3 to 8 tons are now generally used in preference to the smaller weights—is melted in a cupola, or brought melted in a ladle from the blast furnace. The converter, having been previously brought up to a red heat by filling it with ignited coke, is reversed in order to remove any unconsumed fuel, and afterwards turned back to a horizontal position to receive the charge of molten metal, which is run in through a movable gutter of wrought-iron lined with sand. It is then slowly brought back to the vertical position, and the blast is turned on. At first the flame issuing from the neck is of a yellowish or reddish color, but slightly luminous, with only a comparatively small amount of sparks. During this period, lasting from four to six minutes, the action going on is similar to that in the refinery in the first stage of puddling, namely, the conversion of graphitic into combined carbon, and the oxidation of silicon, with the formation of a silicate of protoxide of iron and manganese. In the second or boiling period, when the oxygen of the blast begins to attack the carbon, the action becomes very violent, the flame increases in brilliancy, and great showers of sparks, fragments of burning iron, and finely-divided slag are thrown out, owing to the rapid ebullition produced by the evolution of carbonic oxide from all parts of the melted metal. This lasts for about six or eight minutes longer, when the sparks diminish and the action goes on more quietly without the production of sparks. The flame gives the characteristic bluish violet of carbonic oxide, and is intensely hot—a point marking the last or fining stage. When the last trace of carbon is burnt away, the flame suddenly drops, and is succeeded by a stream of luminous white-hot gas, consisting principally of nitrogen, the heat being kept up from this moment, if the blowing be continued, entirely by the combustion of the molten decarburised iron. As soon, however, as the flame indicates that the whole of the carbon is removed, the converter is turned back to the horizontal position, and the proper quantity, usually about 10 per cent., of molten spiegeleisen, or other similar compound of iron, carbon, and manganese, is run in from the air furnace in the same manner as the original charge. Formerly the blowing was resumed for a few minutes after addition of the spiegeleisen, but this is now discontinued, and the contents of the converter are emptied into the ladle, which has been brought into the proper position by lowering the central pillar of the crane. The ingot moulds usually employed are made of cast-iron, open at both ends, of an octagonal or circular form of base, and somewhat smaller in diameter at the top than the bottom. They are arranged in a a semi-circle on the floor of the casting pit. The ladle is raised to a sufficient height to clear the top of the moulds, and is turned so as to bring the hole over the center of each one successfully; the plug is lifted, and the molten steel flows out in a stream about an inch thick. Care must be taken to prevent the stream from striking against the side of the mould, in which case the ingot is likely to be unsound. When the mould is filled a small quantity of sand is thrown on the surface of the metal, which is then covered by a piece of thin sheet iron, and the whole is secured by a cross bar passing through two eyes on the top of the mould. After the converter is charged, the blast must be admitted before it is turned back to the vertical position, otherwise the moulten metal would run down through the twyers. A pressure of from 5 to 6 lbs. per square inch is required to overcome the hydraulic head of the liquid column of metal, and from 9 to 14 lbs. more to force the air through at the proper velocity, or from 15 to 20 lbs, per square inch total pressure. An arrangement for opening and shutting the valve by the rotation of the converter is provided. The valve, which is of a double-beat form, has its stem prolonged upwards, and carries a weight tending to keep it pressed against its seat. The lifting mechanism consists of a lever worked by an eccentric disc attached to the axis of the converter. When the latter is lowered for filling, the pressure of the eccentric is taken off the lever, and the valve closes; but when the motion takes place in the opposite direction, the cam part of the disc lifts the lever, and with it the valve. By this arrangement, the opening and shutting of the valves at the right moment, a point of great importance, are made completely independent of the action of the man working the converter.

In both Sweden and Austria the process is usually conducted without remelting the pig iron, which is tapped directly from the blast furnace into the converter. In the former country the addition of spiegeleisen was formerly dispensed with, the blowing being only continued for a very short time after the more rapid boiling has ceased. The uncertainty of being able to stop the process at the right moment has led to the more general adoption of total decarburisation, and the addition of spiegeleisen in the manner already described.

Although spiegeleisen as now made usually contains much more manganese, 20 per cent. and above, than that formerly produced from spathic ores, its use has in great part been superseded by the richer alloys, known as *ferro-manganese*, which contain up to as much as 87 per cent. of the latter metal. They are especially valuable in making extra soft steel where it is desired to add a proportion of manganese without increasing that of carbon, as is done in the production of the so-called phosphorus steel. Another alloy, containing about 10 per cent. of silicon and 20 of manganese (*silico ferro-manganese*), is also specially applied in the production of steel castings, a certain proportion of silicon causing the metal to set in the mould without developing blow-holes.

It need scarcely be said that the reactions going on in the Bessemer converter are substantially similar to those observed in puddling and hearth fining. The following, one of the earliest complete series of analysis of products taken at different stages of the process that was published, refers to the Austrian Government Works at Neuburg, in Styria. The pig iron operated upon is smelted from the spathic ores of the Erzberg with charcoal.

ANALYSIS OF METAL.	I.	II.	III.	IV.	V.
Carbon, graphitic	3.180	—	—	—	—
" combined	0.750	2.465	0.919	0.087	0.234
Silicon	1.960	0.443	0.112	0.028	0.033
Phosphorus	0.040	0.040	0.045	0.045	0.044
Sulphur	0.018	trace	trace	trace	trace
Manganese	3.460	1.645	0.429	0.113	0.139
Copper	0.085	0.091	0.095	0.120	0.105

No. I. Original pig iron.
" II. Metal taken at end of first stage.
" III. " " after the boil.
" IV. " " end of the blowing.
" V. " restored to steel by addition of pig iron.

COMPOSITION OF SLAGS.	II.	III.	IV.	V.
Silica	46·78	51·75	46·75	47·27
Alumina	4·65	2·98	2·80	3·45
Protoxide of iron	6·78	5·50	16·86	15·43
" manganese	37·00	37·90	32·23	31·89
Lime	2·98	1·76	1·19	1·23
Magnesia	1·53	0·45	0·52	0·61
Potash, Soda	traces throughout			
Sulphur	0·04	trace	trace	trace
Phosphorus	0·03	0·02	0·01	0·01

These analyses are numbered to correspond with those of the metal taken at the same time.

It will be seen from the above analyses that the iron is not oxidized by the blast to any great extent until nearly the whole of the manganese and carbon have been removed. The retention of the entire quantity of phosphorus contained in the original pig iron in the finished steel is in accordance with observations made in other countries. Newer methods of conducting the process, whereby steel of good quality can be produced from Cleveland and similar brands of pig metal rich in phosphorus, are described further on.

In Sweden and Austria the finished steel is classified by numbers, according to the hardness and percentage of carbon, commencing with the most highly carburised. The amount of carbon is determined by Eggertz's colorimetric method. The following is the proportion of carbon in Bessemer steel from Heft:

No.	Specific gravity.	Carbon.	Silicon.
II.	7·791	1·35	0.02
III.	7·828	1·15	trace
IV.	7·848	0·85	0·02
V.	7.856	0·72	0·03
VI.	7·836	0·53	trace
VII.	7·872	0·11	trace

In Sweden a similar basis of classification is adopted; but instead of arbitrary numbers, the qualities are distinguished by the actual percentages of the carbon.

At Seraing, in Belgium, the follwing scale is used. It applies only to the milder qualities.

Class.	Carbon per cent.	Tensile strength. Kilog. per sq. m.m.	Elongation per cent.	Properties.
Extra soft	0·25—0·35	48—56	20 to 25	Welds, but does not harden.
Soft	0·35—0·45	56—69	10 to 20	Welds and hardens imperfectly
Semi-hard	0·45—0·55			
Hard	0·55—0,65	69—105	5 to 10	Hardens, but does not weld.

Ingots with more than 0·65 per cent. are classed as extra hard, but they are not produced in the regular system of working.

The slags of the Bessemer process vary considerably in composition from those of the puddling-furnace, being much more acid and approximate to the pyroxene formula $RO\ SiO^2$. At Hörde, in Westphalia, a crystallized slag has been obtained which yielded by analysis—

Silica	41·73
Protoxide of iron	20·59
" manganese	32·74
Lime	1·58
Magnesia	0·17
	99·76

Oxygen, ratio of silica : bases = 23.85 : 12.43.
Specific gravity, 3.08.

The crystals were found to be of the angular augite form, the angles being intermediate between those of the natural minerals Pajsbergite and Babingtonite as is also their composition.

The enormously high temperature developed by the action of the cold air on moulten cast-iron in the Bessemer process is obviously due to the extreme rapidity with which the operation takes place, and the advantageous form of the converter for concentrating the heat developed. For, although the reactions, and consequently the heat produced, are in no way different from those of other finery processes, whether in the open fire or reverberatory furnace—carbon, silicon, manganese, and some iron being burnt in either case, with the productions of carbonic oxide, silicate of protoxide of iron and manganese, and malleable iron—we have, in the blowing of a charge weighing five tons, an amount of work done in about twenty minutes that would require from two and a half to three days in its performance in the puddling-furnace. It has been pointed out by Jordan that the principal part of the heat developed in the process is due to the combustion of the silicon, which, when oxidized to silicic acid, combines with protoxide of iron and other bases, and remains in the bath in the form of slag; while in the case of carbon a portion of the heat is expended in volatilizing the carbonic oxide produced, which escapes at the temperature of the melted metal, and burns to waste at the mouth of the converter. Should the calorific power of silicon be assumed to be the same as that of carbon, the amount of heat produced by the combustion of one kilogramme of silicon to silicic acid will be 8,000 units when burnt in pure oxygen, or 6,382 in air; the difference between the two quantities corresponding to the amount required to heat up the inert nitrogen. Under the latter condition, one kilogramme of carbon will produce only 475 effective units, being the difference between 2,473 units theoretically developed, and 1,998 units carried off by the gaseous products, carbonic oxide and nitrogen, supposing them to escape at a temperature of 1,400°. The use of steam instead of air as an oxidizing agent, is, in the case of combustion of iron or carbon, always disavantageous, on account of the great amount of heat required to free the oxygen from its combination with hydrogen, which is not reproduced to the same extent in the subsequent formation of carbonic oxide or protroxide of iron. With silicon, however, the conditions are somewhat different, as there is a small sensible gain. This will explain the reason why the use of steam in the refinery is only recommended for a few minutes at the commencement of the operation—that is, as long as free silicon remains in the pig iron under treatment.

By applying the quantities given above to the calculation of the amount of heat developed in the blowing of one ton of Bessemer pig iron of the ordinary quality produced in the South of France, which is the following composition per ton of 1,000 kilog.—

Carbon . . .	42.50
Silicon . . .	20.00
Iron and manganese.	937.50
	1000.09

Jordan arrives at the following results —

Kilogr.	Units of heat.
The combustion of 20 of silicon produces	127,648.
The combustion of 42.5 of carbon produces	20,176
The combustion of 87.5 of iron and mang. produces	66.237.
Or a total of	214,061.

If we take the specific heat of molten and malleable iron at 0.16, the amount of heat developed will be sufficient to raise the temperature of the metal, which is supposed to be completely decarburised, about 1,350 degrees above that of the cast-iron when run into the converter.

The great heating power of silicon is therefore to be regarded as the reason for the use of dark grey iron in the Bessemer process; under all ordinary circumstances, about 2 or 2.5 per cent. silicon being considered as essential. Jordan states that in the steel works in the south of France the process could only be carried out by running the cast-iron directly from the blast-furnace into the converter, the amount of silicon being not sufficient to allow of remelting of the pigs—an operation which is usually attended with a loss of about 1 per cent. of silicon. The place of silicon as a heat-producer in the Bessemer process may be, to some extent, taken by manganese, as is the case in Styria, where the cast-iron used is smelted from the spathic ores. It is, however, less advantageous, because the deficiency in silica, which is required to flux the protoxide of manganese formed, can only be supplied by the destruction of the siliceous lining of the converter.

Although silicon is an essential component of good Bessemer pig iron, it is of importance that the amount per cent. should be somewhere above the same as, or not very much more than, that of the carbon. An excess of the former element works prejudically in two ways—first, it gives rise to an increased waste of iron in the slag; and, secondly, it cannot be completely removed before the whole of the carbon is burnt away, so that it may happen, in the blowing of such metal, that, although the process is apparently complete as determined by the usual indication of the cessation of the flame from the converter, sufficient silicon is retained in the decarburised metal to render the finished steel brittle and useless. Snelus gives the following analyses in illustration of this point. (See table at head of page.)

	I.	II.	III.	IV.
Carbon	0.445	0.515	0.550	0.490
Silicon	0.814	0.270	0.640	0.009
Sulphur	—	—	0.067	0.033
Phosphorus	—	—	0.038	0.036
Manganese	—	—	0.554	0.576
Copper	—	—	0.554	0.025

Analyses I., II. and III., are examples of underblown and brittle steel, rich in silicon; IV. is the ordinary composition of good Besemer rail-steel made at Dowlais.

The following series of analyses, by the same chemist, of metal taken at different stages of the blow, show very distinctly the gradual removal of the carbon along with the silicon: :

	I.	II.	III.	IV.	V.	VI.
Carbon, graphitic	2.070	—	—	—	—	—
" combined	1.200	2.170	1.550	0.097	0.566	0.519
Silicon	1.952	0.795	0.635	0.020	0.030	0.030
Sulphur	0.014	trace	trace	trace	trace	trace
Phosphorus	0.048	0.051	0.064	0.057	0.055	0.053
Manganese	0.086	trace	trace	trace	0.309	0.309
Copper	—	—	—	—	0 039	0.039
Ratio of carbon to silicon	1.6: 1	2.7: 1	2.4: 1	4.8: 1	19: 1	17: 1

I. melted charge of pig; II. metal at end of first stage, 6 minutes from start; III. metal after blowing 9 minutes; IV. over-blown metal, 13 minutes from start, before adding spiegeleisen; V. steel from ingot; VI. steel from finished rail.

It will be noticed on comparing these analyses with the similar series from Styria that the observed phenomena are substantially the same in both instances. The difference in the amount of copper, which is much larger in the Styrian steel than in that from Dowlais, is to be attributed to the fact that the pig iron used in the former is entirely smelted from spathic ore, while in the latter only the spiegeleisen is due to that source. Copper pyrites, in small quantity, is almost invariably present in spathic carbonates, and, however carefully they may be roasted and weathered, some copper, as a general rule, is reduced, and passes into the iron in the blast furnace.

The progress of the conversion of the charge can be controlled to some extent by observing the spectrum given by the flame with the spectroscope; and more particularly the moment of complete decarburisation may be determined with considerable accuracy, especially if the flame be bright and free from smoke. The spectrum produced when combustion is most active is characterized by groups of numerous lines in the yellow and green portions, that of sodium being the most prominent and the first to appear among the former. There is also a well-defined group of lines in the blue field, and under the most favorable conditions the violet and red lines of potassium and lithium, together with an extra violet line accompanying the former, are seen. For this, however, an instrument of great defining power, and an extremely bright flame are essential. When the metal is completely decarburised, the yellow and green lines disappear, but the sodium is persistent, sometimes even after the tipping of the converter. On the addition of the spiegeleisen, the whole of the lines reappear with great brilliancy. When there is much manganese in the cast-iron employed, as is the case in Styria, the use of the spectroscope is difficult, owing to the brown smoky character of the flame.

At Seraing, it has been found that the disappearance of the dark absorption-bands, which alternate with the bright lines, can be much more readily determined than the latter, which often reappear after their apparent extinction, and is therefore to be preferred as admitting of much closer and easier observation. The exact chemical character of the spectrum of the Bessemer flame has not as yet been made out, although it has been the cause of considerable controversy, there being two different opinions as to its origin. One of these supposes the lines to be due to carbonic oxide and their cessation to the complete combustion of the carbon, while the other considers that they are mainly produced by manganese, and that their sudden disappearance may be accounted for by the diminution in the amount of the metal volatilized until the quantity present in the flame is reduced below that necessary to produce them, it having been found that for the detection of manganese by the spectroscope much larger quantities must be employed than are sufficient to produce the ordinary reaction with soda on platinum foil before the blowpipe.

Another indication of the progress of the operation, is that afforded by the character of the slag. This has been employed in Austria and Sweden. An iron rod is inserted into the converter, and when brought out a portion of the slag adheres to the point. So long as any carbon remains unconsumed a peculiar brownish tint is observed, but as soon as the point of total decarburisation is reached, the slag assumes a dead black color, with a peculiar metallic lustre characteristic of the presence of protoxide of iron in considerable quantity. This test is said to be capable of great precision in the hands of experienced workmen.

At Seraing the following relations have been observed between the color of the converter slag and the temper or proportion of carbon in the blown metal.

Lemon yellow .	0·75 per cent and above
Orange . . .	0·60 " "
Light Brown . .	0·45 " "
Dark brown . .	0·30 " "
Bluish black . .	0·15 " "

In the earlier period of the working of the process at Sheffield, the yield of ingots was 77½ per cent., on the weight of the pig iron charged, 15 per cent. being lost in the converter and 7½ per cent. in the remelting in the reverberatory furnace. With three-ton converters the lining required renewal after blowing 250 tons, but the endurance of the twyers was much less, and they required to be replaced after every third or fourth operation. This was done by knocking out the stumps of the worn twyers and inserting new ones, the joint being made tight by pouring in a semi-fluid paste of ganister, or letting the vessel cool so as to be able to send a man to ram the crevices up with the mixture. With this arrangement the number of blows that could be obtained with a pair of converters was only from about six to eight in twenty-four hours, as, although the actual blowing did not require more than fifteen or twenty minutes, much time was consumed in the necessary operations of casting, and especially the placing and removal of the ingot molds. For more rapid work it is necessary, therefore to save time in the subsidiary operations of—(*a*) smelting the pig metal; (*b*) repairing or replacing the converter linings, wholly or in part; and (*c*) handling, *i. e.*, placing, filling, and removing the ingot molds. The first of these requirements is met by the provision of a large number of cupola melting furnaces, or by taking the metal directly in the melted state from the blast-furnaces. The former method is practised in America, the latter being confined to European works, where it is becoming general when the conditions are favorable for its use. Where the works are small, as in Sweden, the converters may be placed close to the pig beds and below them, so that the molten iron may have the smallest possible distance to travel; but in England, where the steel works are necessarily at a distance from the blast-furnaces, the metal is lifted into a ladle mounted upon wheels, which is drawn to the converter by a locomotive, and is either delivered at such a height that it may be tapped directly into the converter, or is lifted by a hydraulic lift The railway for the ladle usually runs the whole length of the range of the blast-furnaces in a tunnel below the level of the ordinary pig beds, and the charge is drawn from two or more blast-furnaces to obtain uniformity in the quality of the metal. At Barrow the melted metal is taken by a line, which is nearly two miles in length, between the blast-furnace and the steel works, but it is not appreciably chilled by the journey. At Givors, in the South of France, by a combination of this kind a very great economy in fuel has been attained; with two blast-furnaces and two converters about 24,000 tons of steel ingots are produced annually without any further expenditure of fuel than the coke consumed in the blast-furnaces. The metal is run directly into the converters, and the waste gas of the furnace tops is sufficient to drive the smelting and Bessemer blast-engines and the hydraulic cranes connected with the converters, as well as to heat the blast by the use of Cowper's stove.

For facilitating the repair of the twyers, which are subjected to rapid corrosion by the action of the slag, it is now customary to attach the bottom to the body of the converter by eye-bolts and cotters, so that it can be easily detached and replaced when necessary. Particular attention is paid to this point in America, where a special hydraulic lift is placed below the converter for the purpose of facilitating this operation. In the new process of Thomas and Gilchrist, the lining of the converter-body, being very rapidly acted upon, requires more frequent replacing than in the older method, and therefore it is necessary to arrange for the substitution of new converters for worn ones without stopping to cool down. This may be done by making the body detachable from the trunnion-belt, so that when the converter is reversed it may be dropped upon a lift and lowered to a railway truck, the new one in the same way being lifted into its place, mouth downwards, when it is keyed up and turned over into the working position. This is the plan devised by the late A. L. Holley, in America. At Eston, the more direct method of lifting the entire converter out of the trunnion bearings by a steam-crane traveling on an overhead railway has been adopted.

The third requirement, that of an increased facility in handling the ingots, has been obtained by modifying the arrangement of all the different parts of the plant, and more particularly in the position of the converters with reference to the ingot moulds. In the original arrangement, where the two converters were placed with their mouths turned towards each other, at opposite ends of the diameter of the circle swept by the center crane, the space for the moulds was restricted to a semi-circle or less; while by placing them side by side, with their axes parallel, or but slightly converging, a much larger space, up to three-quarters or more of the entire circle, is rendered available for placing moulds, and the number of ingot cranes may be increased. This arrangement was first adopted in America, where it is combined with the further improvement of restricting the central ladle crane entirely to the service of the converters, the ladle, when the melted steel is poured, being transferred to a second crane, commanding a pit of larger radius containing the moulds. The transfer is made by bringing the arms of the two cranes into the same line, and moving the ladle, which is mounted on wheels, by hand gearing or by a hydraulic piston mounted on the frame of the larger crane. It is also found more convenient to work with the moulds at the natural level of the ground, so that in all new works the sunk pits are no longer used, the converters being mounted on piers or cast-iron standards. The following are the principal working results obtained in two English and two American works, in 1880:—

Dowlais, S. Wales. Two converters, 10-ton charges pig iron, with 1.2 per cent. manganese and 8 per cent. of spiegel, with 15 per cent. manganese; and 13 twyer bricks, with 13 air channels of ⅝ inch, giving a twyer area of 487 square inches per ton of metal blown. Blast pressure of 15 to 25 lbs. per square inch. The bottoms last 12 blows without any intermediate replacing of twyers. Length of blow 18 minutes. Number of casts per day 28. Make of ingots per week 1,600. Yield 88 per cent.

Rhymney, S. Wales. Three converters, 8-ton charges pig iron, 2 per cent. manganese, and 10 per cent. spiegel, with 20 per cent. manganese; 16 twyer bricks, with 13⅜-inch holes. Twyer area per ton 2.87

square inches. Blast pressure 30 lbs. The bottoms last from 16 to 30 blows, with the consumption of 24 extra twyer bricks. Length of blow from 13 to 15 minutes. Number of casts per day 36. Make per week 1,600 to 1,800 tons. Yield 85 per cent.

Bethlehem, Pennsylvania. Two converters. 7-ton charges pig iron, with 1.5 per cent manganese, 10 per cent. steel scrap, 10 per cent. spiegel, with 15 per cent. manganese; 12 twyer bricks each with some 12 ⅝-inch holes. Twyer area 2.48 square inches per ton. Blast pressure 25 pounds per square inch. Bottoms last 8 to 9 blows, with 12 extra twyer bricks per week. Length of blow 15 to 16 minutes. Number of casts 45 to 46 per day. Make per week 1,800 to 2,000 tons. Yield 90 per cent.

Cambria, Pennsylvania. Two converters, 7-ton charges pig iron, with 1.5 per cent. manganese, 18 to 20 per cent. steel scrap, 7 per cent. spiegel, with 15 per cent. manganese; 11 twyers, with 12 $\frac{7}{16}$-inch holes. Twyer area 3.19 square inches per ton. Blast pressure 28 lbs. Bottoms last from 10 to 19 blows. Time of blow 17 minutes. Number of casts 72 per day. Make per week 2,600 tons. Yield 90 per cent.

The average production of each of the 24 converters at work in America, in the month of November, 1881, was 5,400 tons. The Edgar Thompson and Bethlehem works, Pittsburg, each with a pair of 8-ton converters made in the year 1881, 16,235 tons and 16,729 tons respectively. At the former works 496 casts were made in the week ending December 3rd, 1881, giving 3,813 tons of ingots, the largest make in twenty-four hours being 700 tons. It is not, however, considered by European steel-makers that these very high working results could be imitated with advantage on economic grounds.

Basic-Bessemer Process. The method of conducting the Bessemer process described above, and requiring for its success a rich pure pig metal essentially free from phosphorus and sulphur, but containing a notable proportion of silicon, was, with certain modifications in detail, alone practised up to within two or three years of the present time. As the proportion of such pig metal available is comparatively small as compared with the inferior ores of the more highly phosphuretted kinds smelted from the newer sedimentary formations in Cleveland, Luxemburg, and elsewhere in Europe, the discovery of means of utilizing the latter for steel-making has long been sought by different investigators. In 1872 Snelus determined by experiment that the retention of phosphorus by the metal was intimately related to the character of the slag (which, as has already been shown, is essentially a normal silicate of the form of $ROSiO^2$), and that when this could be rendered of a more basic character the greatest part of the phosphorus could be eliminated in the slag in the same way as in the puddling furnace. This he did by the addition of lime and oxide of iron, and more particularly by substituting for the ordinary siliceous converter lining of ganister, one in which lime and magnesia were the essential constituents, the best results being obtained with bricks made of magnesian limestone which had been burnt at a very high temperature. These experiments, made upon Cleveland pig iron with 1 to 2 per cent. of phosphorus, showed that good steel could be made from it with only 0.1, or not sensibly more than in that made from hematite. But they were unpublished until the announcement of similar results having been obtained by Thomas and Gilchrist, at Blaenafon, and subsequently as a working experiment at Eston, in Cleveland, where it has since been carried out on the largest scale in regular practice, as well as at Hörde and Ruhrort, in Westphalia, and several other works in Germany and Eastern France. The process is now conducted in the following manner: The converter, which is lined either with bricks made of hard burnt dolomite set in tar asphalte, or with the same rendered plastic and rammed round a core, is heated by a fire off coke breeze, and a quantity of quick-lime equal to 15 to 20 per cent. of the weight of the charge of metal is thrown in. The latter may contain any amount of phosphorus, but should be as free as possible from silicon and sulphur, the latter being corrected by a proportion of manganese when white iron is used. It should be poured in as hot as possible. The blowing is conducted in the ordinary way until the whole of the carbon is burnt off, which requires about ten minutes, when, instead of casting, the blast is kept on for two or three minutes longer, which causes a great increase in the temperature of the bath with a thickening of the converter smoke. This so-called *afterblow* is the period of dephosphorisation; its duration is controlled by taking a test of the metal in a ladle, which is cast and flattened under a steam-hammer, cooled in water, and broken, which can be done in five minutes. When the desired malleability is obtained the converter is tipped to run out the slag, and spiegeleisen or ferromanganese is added in the usual way. The removal of the slag is important, as a portion of the phosphorus may be reabsorbed if it is left in contact with the melted metal.

At Eston the converter linings are made of dolomite carefully ground and burnt, mixed with tar which has been well boiled to deprive it completely of water. The upper part is removable, and is lined separately; the body is, however, relined in place by inserting a tapered cast-iron plug heated by a coke fire, and corresponding in size to the inside dimensions of the new lining. The space between this and the old lining, which is not allowed to wear thinner that 3 or 4 inches, is filled with the mixture of tar and dolomite, which becomes plastic when heated. When the blow is finished both the metal and slag are poured into a ladle, and a proportion of hematite pig, very rich in silicon, equal to 4½ per cent. of the charge, is run in through a spout. This causes a very violent reaction, the whole bulk of the slag being blown out and run into a proper receptacle. The spiegel is then added and the metal is cast. The bottoms are made by ramming a mixture containing less tar than that used for the body lining around a series of ½-inch core pins which occupy the place of the twyer bricks. They last eleven blows, as compared with eight when made of ganister. Nearly 1,000 tons of steel can be made without relining the body. According to Thomas's summary of the general results obtained, the production of steel for lining is considerable less than in the original process, and therefore for a given make the number of converters or the facilities for changing them should be increased, but no increase of engine-boiler or crane power is necessary.

With three converters from 22 to 24 charges are blown each day in Germany. The linings require considerable repairs after a number of charges varying from 40 to 70 (average 56) have been blown; the bottoms may last from 8½ to 21 blows (average 14). The average consumption of basic material in lining is rather under 1 cwt. per ton of steel, and for preparing it 24 cwt. of coal or 16 cwt. of coke is required. The consumption of the lime for slag-making is about 3 cwt. per ton of the steel. This slag contains about 50 per cent. of lime, iron 10 per cent., phosphoric acid 12 per cent., silica 15 per cent. in maximum, and variable quantities of manganese according to the source of the metal. It is now returned to the blast-furnace as flux. The loss upon the weight of the pig charged varies from 13 to 19 per cent., averaging 15 per cent. as compared with 12 when working hematite iron. The duration of the operation, including the afterblow, varies from thirteen to twenty-five minutes, not including time for sampling, which when practised takes from three to four minutes more. White pig iron is now generally preferred, but white, grey, or mottled metal may be used indifferently. The amount of phosphorus in eleven varieties actually treated varied from 1 to 3 per cent., that of silicon from 0·5 to 1·3 per cent., and of manganese from 0·35 to 2·0 per cent. Where the silicon exceeds about 1 per cent. the metal may be best treated by blowing it first in an ordinary ganister-lined converter for a few minutes, and then transferring it to the basic-lined one, whereby the wear of the latter is sensibly diminished.

The progressive transformation of the metal during the operation has been studied by several chemists. The following is an example given by Jordan of the blowing of a charge at the Rhenish Steel Works, in Westphalia:—

	A	B	C	D
Carbon	3·276	0·590	0·026	0·302
Silicon	0·476	0·022	0·002	0·016
Manganese	1·131	0·122	0·197	0·540
Phosphorus	2·600	2·064	0·062	0·092
Sulphur	0·062	0·139	0·051	0·040

A. Original metal melted from cupola.

B. After blowing ten minutes, the silicon is almost entirely, and the carbon nearly, removed, while the phosphorus is almost unchanged. The ordinary blow lasted $13\frac{1}{4}$ minutes, when the carbon had diminished to 0·124 per cent.

C. After two minutes' overblow, the phosphorus is rapidly oxidized together with the iron, the carbon and silicon not being further changed.

D. After addition of spiegeleisen. This augments the carbon and silicon, and, to a slight extent, manganese and phosphorus—the latter by the reducing action of the carbon of the metal upon the phosphoric acid of the slag. In this case the proportion of sulphur retained is rather high; usually about one-half is eliminated.

The final slags were of the following composition:

	E	F
Silica	8·05	8·22
Phosphoric Acid (P_2O_5)	18·55	17·15
Iron, Protoxide	8·37	9·24
Manganese	4·45	6·27
Lime	56·54	56·03
Magnesia	3 10	3·29
Sulphur	0.33	0·29

E. At the end of the blow. F. After the addition of the spiegeleisen.

Open-hearth Processes. The production of cast-steel by dissolving the malleable scrap in molten cast-iron without the use of crucibles was patented by Heath in 1845, and a similar method in 1855 by Price and Nicholson. The first actual fusion of cast-steel in the bed of a reverberatory furnace was effected by Sudre, in France, in 1860, when quantities of tool steel up to two tons at a time were run into ingots from a furnace analogous to that used in iron melting, the heat being intensified by a forced draught under the grate, with the result of rapidly destroying the furnace. The introduction of the regenerative furnace, in which the highest temperature can be obtained without strong draught or cutting flame, has, however, furnished the required solution of the problem, and in 1862 it was applied by Attwood, of Towlaw, and Martin, of Sireuil, in France, and subsequently with improvements and modifications in the furnaces and the modes of manipulation by Siemens, Pernot, and others. As it was first worked on the large scale by Messrs. Martin, the name Martin-Siemens process is generally used on the Continent; the modification, using iron ore instead of scrap-iron, is known as the Siemens' process; and latterly the general name of open-hearth process has come into use for both.

In the newer forms of this furnace the roof is made with a strong slope from the flue ends to the center, giving a more plunging flame. The ventilating space below the bed is much enlarged. The gas ports for equal area are made longer and narrower, and the regenerators of increased size are roofed with semi-circular instead of segmental arches, in order to give a larger exhaust flue for the flame, and thus to moderate its temperature before it reaches the regenerator. The size and capacity are also greatly increased, the original charges of 35 cwt. to 5 tons having been increased to 8, 10, or in some instances 15 tons. The materials used are very good pig iron from hematite, which need not be as grey as that required in the Bessemer process for the initial bath, malleable iron in the form of blooms, sponge, or puddle bars, clean scrap, whether of iron or steel, old rails, and iron ore of good quality, as additions, and spiegeleisen and ferro-manganese for the final tempering.

The first operation consists of forming the bath by charging the required qualities of pig iron, to which, when melted, additions of iron or steel are made in small quantities at a time; they are charged cold on the hinder flame bridge, and when strongly heated are turned into the bath. This is the English practice; on the Continent an auxiliary-heating furnace is generally used, the scrap being made red-hot before charging. The direction of the draught in the melting furnace is changed every half-hour. The proportion of scrap used depends upon its character and the condition of the furnace. With an almost neutral flame, No. 1 grey pig iron will dissolve ten times its weight of Bessemer scrap with 0.3 or 0.4 per cent. of carbon, but No. 3 will not take more than three or four times its weight of soft puddled iron, and when the flame is cutting, a considerably less proportion.

When the charge is melted the metal is tested from time to time by taking samples in a ladle, which, after cooling in water, are hammered and broken. When the required pitch, as indicated by the toughness and fracture, has been attained, from 6 to 9 per cent. of spiegeleisen or ferro-manganese is added, and when this is melted the charge is tapped out into the ladle and cast into ingots, in the same way as in the Bessemer process. The time required for working a 5 to 6 ton charge is from nine to eleven hours. The loss in melting Bessemer scrap with No. 3 hematite pig is from 4 to 5 per cent. of the total weight of the charge. The coal used is from 13 to 14 cwt. per ton of steel made.

In the Siemens' process, with iron ore, the bath of pig iron is decarburised by the addition of rich pure hematite or magnetite, in about 2-inch lumps. This causes a violent boiling, which is kept up until the metal is nearly soft enough, when it is allowed to stand for a short time to allow the iron to clear from the slag, a small quantity of limestone being added at intervals to throw down some of the iron. The spiegel is then added, about 1 per cent. more being used than in the scrap process. From 20 to 24 cwt. of ore are used in a 5-ton charge; about one-half the metal is reduced and passes into the steel, so that the yield in ingots is from 1 to 2 per cent. in excess of the weight of pig metal and spiegeleisen charge. The consumption of coal is rather larger than in the scrap process, or from 14 to 15 cwt. per ton of steel. The two processes are often combined, both scrap and ore being used in the same charge. The latter is obviously of value as a tempering material.

At Saint Chamond, in France, the Siemens' process is carried on at a very large scale in Pernot's furnace. This furnace has a circular bed on wheels that can be rotated when heated, and is removable for repair. The bed, made of sand upon an iron-plate bottom, is contained in a frame made of cast-iron staves, kept together by a stout iron hoop. It is inclined about six degrees to the horizon, and is supported by a central spindle and conical friction rollers, upon a cast-iron traveling-frame, with four or six wheels, running upon a railway. By means of gearing wheels the bed is rotated at from two to four revolutions per minute. The pig iron and scrap are heated to redness before charging, and as the position of the different pieces of the latter is constantly changing, be ing alternately brought under the full action of the flame and plunged into the liquid, the fusion is very rapid. One-half of the bed being also exposed to the flame by the slipping of the charge at each revolution, the bottom heat is continuously renewed, and the chilling or sticking of the charge on the bottom is prevented. The removable hearth allows repairs of the roof to be more readily and quickly made than is the case with those of fixed construction. The diameter of the hearth within the lining is about 7 feet in the 8-ton, and 13¾ feet in the 20-ton furnace; the depth of the bath being about 8 or 9 inches in the center. The former melts from three to four charges, and the latter two, in the twenty-four hours.

The following represent the progressive steps in the melting of a charge in the 20-ton furnace:—

Hour.	Pig iron Tons.	Steel Waste Tons.	Puddled Iron Tons.	Ferro-manganese Tons.	Carbon in bath Per cent
2.10 a.m.	5,000	5,000	—	—	—
4.45 "	—	3,000	—	—	0.5
7.0 "	—	3,000	—	—	0.4
9.40 "	500	—	2,000	—	0.25
11.50 "	—	—	1,000	—	0.25
1.25 p.m	—	—	—	0,693	0.12
1.30 "	Metal tapped out	.	.	.	0.35

The pig iron contained 3.35 per cent., and the ferro-manganese 50 per cent. of manganese. The coal used is about 1.5 cwt. in the heating-furnace, and 5 to 5.2 in the melting-furnace, per ton of the ingots, or only about one-half of that of the fixed furnace. The loss upon the weight of the charge is 4 to 5 per cent. on hard, and 6 to 7 per cent. on soft steel.

In Ponsard's modification of the rotatory heart furnace, or "Forno Convertisseur," a wind chest is added to the bottom spindle, and twyers are inserted in the side lining, so that a decarbonizing blast may be injected as in the Bessemer process. This has been used experimentally with fair results, but has not been adopted in the large scale.

The dephosphorising process by means of lime may also be carried on in the open-hearth furnace. Experiments have been made in this direction at the Alexandrowsky works, in Russia. The bed of the furnace is made of a mixture of calcined dolomite and tar, which burns to a very hard mass. The composition of the charge was as follows:—

		Per Cent.
Iron Ore from Sweden .	Fe 48 per cent.	6.7
Lime	. . . .	6.7
Cleveland Pig Iron .	P. 1.62 "	25.0
Broken Ingot Molds .	" 0.70	4.5
Malleable Scrap .	. " 0.30 "	44.5
Hematite Pig . . .	. . . .	6.7
Spiegeleisen . .	. Mn 15.0 "	5.4
Ferro-manganese .	. " 75.0 "	0.5
		100

About two-thirds of the lime and ore were first charged with the pig iron and part of the scrap, the remainder of the former and the latter following at short intervals. When a test-piece of the metal, after cooling in water, can be bent double without breaking, the hematite pig is added, and, after its complete incorporation and a fresh testing of the metal, then the spiegel and ferro-manganese. Before tapping, and before each ddition to the charge, care must be taken to remove the highly phosphuretted slag. The proportion of phosphorus in the original metal equals 0.571 per cent.; that is reduced to 0.06 in the ingots.

Fluid Compression of Steel.—Large masses of cast-steel, whether from the crucible, Bessemer, or open-hearth furnace, are rarely solid throughout; the tops of large ingots being generally pitted or honeycombed with small holes for some distance down, and the unsoundness increases with the softness of the metal. It was formerly supposed that these bubbles were due to the evolution of carbonic oxide, produced by the reducing action of combined carbon upon oxide of iron taken up in the metal in the last stage of the process; but the researches of Parry, Muller, and other chemists have shown that the gas included is steel is almost entirely nitrogen, which is absorbed in large quantities by the fluid metal and given out on solidification in the same way as oxygen is absorbed by melted silver. Muller considers that the beneficial effect of the final addition of spiegeleisen is in part due to the sudden large evolution of carbonic oxide, which sweeps out much of the dissolved hydrogen. This is borne out by the experiments of Allen, who finds that Bessemer metal gives sounder ingots when it is stirred by a rotating paddle lowered into the ladle before the casting, than when poured in the ordinary way. A large amount of gas is given off in stirring, which fires on meeting the air.

Another method of obtaining sound ingots is that of causing the metal to solidify under a pressure. This was first adopted by Sir Joseph Whitworth, who had molds built up in segments of cast-iron with numerous perforations for the escape of gases, and bound together with a strong tube of cast-steel. The interior of the mold is lined with sand. When the metal is run in, the piston of a hydraulic press descends upon the upper surface, and a pressure of about 6 tons to the square inch is applied. The ingots are considerably shortened as compared with those cast in open moulds, but it has been questioned whether their soundness is invariably increased.

A simpler method of consolidation has been applied by Captain Jones, who subjects the top of the liquid metal in a closed mould to steam pressure. A steam drum is fixed to the side of the ingot-crane, having a number of cocks corresponding to those of the moulds, and also india-rubber connecting pipes. The moulds and bases are kept together by clamps attached to long iron rods fitting over projecting lugs at the bottoms. At the upper end of the mould a conical seat is turned, which carries the pouring cup. When the mould is filled, the lid, with a coupling and flexible steam pipe, is substituted and wedged down, the conical seat giving a steam tight joint. The steam, which may be from 80 to 150 lbs. pressure per square inch, is then turned on, and is allowed to act until the metal has set. The highest pressure is required with mild steel. The ingots are perfectly sound, and are 1½ to 1 inches shorter than those cast in the ordinary way with sand stopping.

In a modification of the above method recently patented by Krupp, the pressure of carbonic acid gas is substituted for that of steam. The acid in the liquid state is contained in a bottle communicating with the mould near the top, by a pipe of small bore. The mould, hooped with steel, is connected with the cover by bolts and wedges, an expanding copper ring helping to make the joint gas tight. The feeding hole in the cover is closed by a sliding wedge. When the metal is poured the surface is covered with a layer of sand, slag, or other bad-conducting material, the feeding hole is closed, and the gas tube opened. The pressure exacted depends on the temperature of the fluid acid, which is immersed in a cistern of water, which may be artificially heated or cooled as required. The tension of carbonic gas increases very rapidly with the temperature, it being 52 atmospheres at 15 degrees, 82 at 35 degrees, 400 at 100 degrees, and 800 at 200 degrees.

Manipulation of Steel Ingots. It was formerly customary to subject all heavy ingots, whether from the Bessemer or open-hearth process, to the action of a steam-hammer before rolling, but this is now given up, at least in rail manufacture, for which purpose the bulk of the steel so produced is applied. The ingots, when returned from the mould are conveyed while stil hot to a reheating-furnace, usually of the Siemens, Bicheroux, or some equivalent form, and when at a good orange-red heat are passed through the "cogging" mill, corresponding to the blooming mill of the puddling forge, which reduces them from a pyramidal to a parallel-sided form with a corresponding elongation. These are then returned to the furnace, and when reheated are finished at one operation in the rail mill. As the crop ends and pieces of irregular lengths are more difficult to dispose of than those of malleable iron, it is now customary to use large ingots giving finished bars long enough to cut into several rails with only one pair of crop ends. At Eston ingots of 35 cwt. giving four rail lengths are used. At Workington ingots giving three rails are passed nine times through the cogging mill, and thirteen times through the rail mill to obtain the finished section. The hammer is still in general use for ingots intended for rolling into plates as well as for billets for wire-making, and also in forging the large ingots intended for heavy gun tubes. For this latter purpose hammers from 50 to 80 tons falling weight have been constructed. Two of the latter weight are in use, one at Creusot and the other at Saint Chamond, in France.

Pointed steel projectiles for piercing armor plates are made at Terre-Noire from open-hearth steel, with carbon 0.45 to 0.60, silicon 0.25 to 0.3, and manganese 0.5 to 0.6 per cent., by casting in metal moulds with a contracted sunk head of sand above. They are made solid, and if required as shells are bored out afterwards. In the hardening process the projectile is heated to redness, and the point is dipped into water until the redness has disappeared, when it is transferred to an oil bath and allowed to cool. The weight of the oil in the bath should be at least four times that of the piece immersed. The oil adhering to the hardened piece is removed by a gentle tempering heat. Large objects must be annealed vertically to avoid warping by unequal lateral contraction.

Combining Steel with Wrought-iron. Compound armor plates for ships are now made by casting melted steel upon a wrought-iron base and rolling the combined mass when sufficiently cooled. For a compound plate of the finished size, 16 feet by 6½ feet and 8 inches thick, a foundation plate of wrought-iron, 9¾ feet by 6 feet and 12½ inches thick, is prepared, and a mild steel plate, 2 inches thick, made from a 50-cwt. ingot of open-hearth steel, containing about 0.45 per cent. of carbon, is attached to it by distance pieces and steel screws, leaving a hollow space of 5 inches between the two plates. This when brought to a strong red heat is placed upright in a rectangular moulding box, the steel side being placed close to a thick cast-iron plate, the remaining sides being filled with foundry sand, and the bottom built up with fire-brick. The space between the plates is then filled with melted open-hearth steel poured from a 5-ton ladle at the highest attainable temperature, the metal being run through several feed-holes in a gutter lined with fire-clay fixed above the mould, which is sunk in a pit in the usual way. When the casting has cooled to a red heat it is lifted by a crane and rolled to the required dimensions at once. The resistance of these plates to penetration is about 20 per cent. greater than that of soft iron plates of equal thickness. The adhesion between the two metals is perfect, a layer of steely iron being formed at the junction, while the outer steel face retains its full temper. The latter is about one-third of the total thickness in the heavier plates, and somewhat more in the lighter ones, or about 3 inches in an 8-inch and 4 to 4½ inches in a 14-inch compound plate. If the plate is to be curved, the soft cover is placed on the convex side. The wrought-iron side-pieces and screws are removed in the process of planing the plate to the finished dimensions.

The following are the analyses of the constituents of a good compound plate:

	Steel Face.	Iron Foundation.
Carbon	0.573	0.040
Silicon	0.173	0.117
Manganese	0.617	0.090
Phosphorus	0.054	0.165
Sulphur	0.046	0.010
Copper	0.026	0.016

Hardening and Tempering Steel. The property of becoming hardened by sudden cooling from a high temperature is possessed by all varieties of malleable iron containing more than 0.25 per cent. of carbon. The degree of hardness imparted by the operation is dependent partly on the amount of carbon present, and partly, but in a greater degree, on the difference of temperature between the heated metal and that of the fluid employed in hardening, and the rapidity with which the cooling takes place. Those fluids that possess the highest conducting power for heat produce the greatest hardening. Thus, mercury is most efficacious in this respect, whereas alcohol is entirely without action. The specific gravity of steel is diminished by hardening. According to Hausmann, hard unweldable cast-steel from Solingen was reduced from 7.844 to 7.760, and a softer welding quality from 7.858 to 7.801, by quenching from a red heat in cold water. The change of volume is not uniform even for objects of a regular form. Caron found, by repeating the operation on the same bar for many times in succession, that hammered bars contracted in their length and increased in the other dimensions. With rolled bars and sheets, on the other hand, an increase in length was observed. After thirty hardenings, the specific gravity was diminished from 7.817 to 7.743.

The process of tempering consists in reheating hardened steel to a temperature varying with the degree of hardness required, and cooling it by immersion in the same manner. The proper temperature is indicated by the color of the thin film of oxide formed on the surface of the heated steel, according to the following scale:—

Temperature.	Color.	Proper temper for
220°	Pale yellow.	Lancets.
230	Straw yellow.	Razors and surgical instrum'ts
243	Golden yellow.	Common razors and pennkniv's
255	Brown.	Cold chisels, shears, scissors.
265	Brown dappled with purple.	Axes, planes, &c.
277	Purple.	Table knives, large shears.
288	Bright blue.	Swords, coiled springs.
293	Full blue.	Fine saws, augers, &c.
316	Dark blue.	Hand and pit saws.

The reheating is generally effected in baths of molten metals, or metallic alloys having definite fusing points. Thus, alloys of tin and lead, in varying proportions, may be used up to a temperature of about 300°; above which, boiling linseed oil and pure lead are to be employed. Steel gun-tubes and projectiles are tempered in oil, whereby their tenacity is considerably increased.

The chief points required to be determined in the analysis of the different kinds of metallic iron and steel for commercial purposes are carbon, distinguishing the graphitic from that in the combined state, silicon, sulphur, phosphorus, manganese, and copper, while the remaining common heavy metals, and those of the alkaline earths, are of less importance, as occurring only in minute quantities, and requiring the use of refined analytical methods, which involve too great an expenditure of time and materials to be employed except in special inquiries.

Determination of the total amount of Carbon. When iron containing carbon in the state of combination is dissolved in hydrochloric acid, protochloride of iron is formed with the evolution of hydrogen, which in the nascent state combines with a portion of the carbon set free, at the same time forming volatile hydrocarbons, which escape, giving a fetid odor to the gas. If, however, instead of hydrochloric acid, a metallic chloride, reducible by iron, is used, no evolution of hydrogen takes place, and the whole of the carbon goes down in an insoluble form, and may be collected. The uncombined or graphitic carbon is not in any way attacked by the acid. The reagent generally used is protochloride of copper, $CuCl^2$, which was first introduced by Berzelius. About 100 grains of the metal in a finely-divided state, usually drill chips, borings, or filings, are treated with a moderately strong solution of protochloride of copper until the whole is decomposed. Protochloride of iron is formed, and metallic copper, which remains undissolved, together with the carbon and silicon. The insoluble residue is collected on a filter, and washed, first with weak hydrochloric acid, then with a solution of potash, and lastly with water, leaving only the carbon and copper behind, which, when dried, are burnt with oxide of copper in a hard glass tube, according to the ordinary method adopted in organic analysis. As the graphite is difficultly combustible, it is best to burn it off in a current of free oxygen. The total amount of carbon is deduced from the carbonic acid produced in the combustion, which is absorbed by caustic potash in the usual way. In Richter's modification of the above process a solution of the double chloride of copper and sodium, $NaCl + CuCl^2$, is employed instead of chloride of copper alone. By properly proportioning the amount of the double salt employed, the separation of metallic copper may be prevented, which is retained in solution as subchloride.

Regnault's method of burning the iron directly with oxide of copper, or chromate of lead, can only be adopted when the substance under examination is susceptible of being reduced to a fine powder, an operation of considerable difficulty with many varieties of iron. Weyl's method, which does not require the sample to be powdered, consists in effecting the solution of the iron with hydrochloric acid, aided by a weak galvanic current. A lump of the iron to be treated is partly immersed in weak hydrochloric acid, in connection with the positive pole of a single Bunsen cell, the negative pole being formed by a plate of platinum. The distance between the poles must be regulated so that no sesquichloride of iron is formed, a point that may be readily determined by the appearance of a yellow tint in the liquid. As soon as the immersed portion of the iron is dissolved the remainder is removed, washed, dried, and carefully weighed: the difference or loss on the original weight gives the amount of iron dissolved. The carbon and other insoluble matters are collected on an asbestos filter, and treated in a similar manner to that already described.

Ullgren's method depends upon the oxidation of the total amount of carbon to carbonic acid without heat by means of chromic acid. The first operation consists in treating the finely divided iron with sulphate of copper, producing metallic copper and protosulphate of iron, carbon and other insoluble substances being precipitated. The precipitate is washed by decantation, and removed into a flask with the smallest possible quantity of water. Strong sulphuric acid is then added, and after the liquid has cooled, a certain quantity of chromic acid, which is decomposed by the carbon, producing carbonic acid, which is collected in a weighed tube containing caustic potash in the usual way. This method was reputed to give good results, but, according to Schnitzler, is not available for the analysis of steel, the results indicated being inferior in accuracy to that of Berzelius, and in some instances as much as 30 per cent. too low on the total amount of carbon contained.

A new method, suggested by Fresenius, of dissolving the iron in hydrochloric acid, and leading the carburetted hydrogen formed over ignited oxide of copper, so as to convert it into carbonic acid, is said to give good results with steel and dark grey pig iron containing but little combined carbon. The graphitic portion remaining in the residue is then estimated by a second combustion. Schnitzler gives the following estimation of carbon in the same steel by different methods as a measure of their relative accuracy:—

	I.	II.	III.	IV.	V.	VI.	VII.
Combined carbon, per cent.	—	—	—	—	—	0·19	0·18
Graphitic carbon per cent.	—	—	—	—	—	0·78	0·74
Total carbon.	0·74	0·75	0.68	0·93	0·96	0·92	0·92

Nos. I., II., III. Determinations by Weyl's methods Nos. IV., V. by Berzelius's method with chloride of copper. Nos. VI., VII. by Fresenius's method of determining the combined carbon directly. The latter is not applicable to such irons as contain a large amount of combined carbon, such as spiegeleisen, which, when dissolved in acid, deposit hydrocarbon oils that are not carried off by the hydrogen evolved

Boussingault uses bichloride of mercury in the determination of carbon, for the solution of the iron, which is converted into protochloride of iron, without the decomposition of water, so that no gas is given off capable of combining with the carbon as it is liberated, and the consequent formation of volatile hydrocarbons is avoided. The iron, finely powdered or in fillings, mixed with fifteen times its weight of bichloride of mercury and sufficient water to form a thin paste, is triturated in an agate mortar for half an hour. When thoroughly incorporated, the paste is transferred to a hard glass flask, and heated to 80° or 100° for an hour, when it is thrown on a filter and washed with warm water, to remove the soluble protochloride of iron. The residue on the filter, consisting of protochloride of mercury, with carbon and the other insoluble matters of the iron, is dried in a water-bath, transferred into a platinum boat, and introduced into a tube communicating with a generator or gas-holder supplying a stream of dry hydrogen. The tube is gradually heated to redness, when the protochloride of mercury, is volatilized without decomposition, leaving the carbon in the form of a black powder, which is allowed to cool in hydrogen, and then weighed. When the boat is slightly heated, the carbon fires in the air and burns like tinder; if, however, graphite is present, it must be borne in a current of oxygen. The siliceous residue, after the combustion of the carbon, is due to the combined silicon of the iron, but the quantity obtained does not represent the whole amount, because the first action of the bichloride of mercury is to produce chloride of silicon, which is transformed by water into hydrochloric acid and silica, and the latter being partly in the soluble form, passes away with the wash-water, in the filtration.

Graphite, or uncombined carbon, is determined in the insoluble residue remaining after solution in hydrochloric acid, which is digested with a strong solution of caustic potash to remove the silicon produced from the oxidation of the silicon. The black residue, after the solution of the silica, is repeatedly washed until perfectly free from alkali, dried, weighed, and calcined at a strong heat in a current of air until the whole of the carbonaceous matter is burnt off. The weight of the small amount of residue is then determined, and deducted from that obtained previously. The difference gives the quantity of graphite. The combined carbon is obtained by deducting the last result from that of the total amount of carbon by one of the preceding methods.

Silicon is determined by weighing the insoluble residue of the hydrochloric acid solution after it has been ignited to a strong red heat in a current of air to remove the whole of the carbon. This residue is nearly all silica, but its purity must be tested by dissolving in caustic potash. The insoluble portion, if any, is collected, and its weight is deducted from that obtained at the former weighing.

Determination of Phosphorus.—A weighed portion of the metal is digested in aqua regia evaporated to dryness, and the residue redissolved in hydrochloric acid. The solution is then treated as in the analyses of iron ores, the determination being made as pyrophosphate of magnesia, or preferably as phospho-molybdate of ammonia.

Sulphur may be estimated in grey pig iron by collecting the sulphuretted hydrogen gas evolved by the action of hydrochloric acid, and passing it through a solution of acetate of lead. The precipitate, sulphide of lead, is collected, washed, and converted into sulphate by digesting with nitric acid, evaporation to dryness, and gentle ignition. The amount of sulphur is calculated from the weight of sulphate of lead so obtained: it contains 10·55 per cent of sulphur. The above is not applicable to white iron, owing to the difficulty of acting upon it with hydrochloric acid; but aqua regia may be used, and the sulphur is then directly converted into sulphuric acid, and may be precipitated with chloride of barium, and weighed as sulphate of baryta in the usual way. Another method of oxidizing the sulphur consists in fusing the finely-divided metal with niter and carbonate of soda in a gold crucible; the fused mass is extracted with water, and the sulphuric acid existing in the solution as an alkaline sulphate is precipitated by chloride of barium as before.

It is rarely necessary to determine the amount of iron. When required, the volumetric methods by solutions of permanganate or bichromate of potassium described under Assaying are to be used. Manganese may be determined as in the analysis of ores. Arsenic and copper are precipitated from the hydrochloric acid solution by sulphuretted hydrogen, care being taken to reduce the whole of the iron to the state of protochloride. The two sulphides may be separated by digestion in sulphide of potassium, which dissolves the sulphide of arsenic, leaving the sulphide of copper untouched. Nickel and cobalt, if present, will be found in the solution obtained after the removal of arsenic and copper by sulphuretted hydrogen. The iron is first converted to a persalt, and is then separated as peroxide by a slight excess of carbonate of baryta; after which nickel and cobalt are precipitated by sulphide of ammonium. Chromium and vanadium are to be looked for in the carbonaceous residue obtained by dissolving a considerable quantity of the iron in weak acid. The ignited residue is fused with niter at a gentle heat for an hour, and when cooled, the mass is powdered and boiled with water. Vanadate and chromate of potash pass into the solution, are converted, by means of chloride of barium, into the corresponding baryta salts, which are insoluble, and are collected upon a filter. The chromate and vanadate of baryta are decomposed with sulphuric acid, whereby chromic and vanadic acid, are set free, and remain as such in the filtrate after separation from the sulphate of baryta. The filtrate is neutralized with ammonia, concentrated by evaporation, and a fragment of chloride of ammonium is placed in it. In proportion as the solution becomes saturated by the latter salt, vanadate of ammonia is deposited as a white or yellowish crystalline powder, which may be collected and subjected to further treatment by the blowpipe or otherwise, in order to verify its properties. The chromic acid is precipitated from the solution by means of acetate of lead as a yellow chromate of lead.

Eggertz's methods of determining small quantities of sulphur and phosphorus may be conveniently used for estimating these substances in pig irons of high quality, such as those produced in Sweden, but are not applicable to the bulk of the iron produced with mineral fuel from the ores of stratified deposits.

For sulphur, one-tenth of a gramme of finely divided pig iron is placed in a stoppered bottle, with 1 gramme of water and half a gramme of sulphuric acid. A clean bright plate of silver is suspended by a wire in the upper part of the bottle, and the discoloration in a given time (about fifteen minutes) is proportional to the amount of sulphuretted hydrogen evolved. As this is very small, the plate, instead of being blackened, is tarnished with very thin films, presenting the same order of color as those observed in tempering steel according to their thickness varying from straw-yellow to bright blue. No absolute measure of quantity is obtained, the result being determined by comparing the color on the plate with a standard series, obtained previously by experimenting upon samples whose composition has been determined by analysis. Thus, a blue color indicates that the metal will yield a sensibly red-short iron when converted into malleable iron in the hearth finery; but if the plate is only browned, the sulphur is not in sufficient quantity to affect the quality of the iron.

In the determination of small quantities of phosphorus, 1 gramme or 15 grains of the iron or steel to be examined is reduced to a fine powder, and treated with strong nitric acid at the heat of boiling water. When the metal is dissolved, the solution is evaporated to dryness, the residue moistened with 4 cubic centimeters of aqua regia made of equal volumes of hydrochloric and nitric acids. After standing for about an hour, an equal volume of water is added, and the solution filtered. The filtrate and wash-water should not exceed 20 cubic centimeters.

The precipitation of the phosphoric acid is effected by a solution of molybdate of ammonia, containing 60 milligrammes of molybdic acid per cubic centimeter. It is added to the solution of the iron in the proportion of 2 cubic centimeters per milligramme of phosphorus supposed to be present, and digested, with occasional stirring, at about 40° for three hours. If no precipitate is formed, a further addition of molybdate of ammonia is made. The yellow crystalline precipitate, which contains 1.63 per cent. of phosphorus, is collected in a filter, washed with water acidified with nitric acid, and weighed after drying in a water bath. If, however, the quantity is very small, the determination may be made by measuring the volume of the precipitate in a narrow glass tube with a scale made especially for the purpose.

Eggertz's method of determining combined carbon in iron or steel depends upon the discoloration produced by carbon in solution of pernitrate of iron, which, under ordinary circumstances, is colorless, or at most of a slightly greenish tint. The standard series of colors is made by dissolving quantities of 1 decigramme of steel of known composition in nitric acid at very low temperature, and diluting with water to a standard volume. The solutions, which give different shades of brown, are preserved in glass tubes. A similar weight of the steel to be examined is dissolved in pure nitric acid under the conditions observed in making the standard series. The solution is decanted from the residue, poured into a burette of the same diameter as the tubes containing the standard series, and diluted with water until it matches one of the tints. The amount of carbon is then found by calculation from the relative volumes of the solutions. Steel, with a medium amount of carbon, say 0.8 per cent., will give a yellowish-green solution; a very hard variety, with 1.5 per cent., brownish red; and the softest, with 0.40 per cent., only a slight greenish tinge.

The Swedish classification of Bessemer steel by numbers, based upon the percentage of carbon determined by the above process, is as follows:—No. 1 contains 2 per cent.; No. 1.5, 1.75; No. 2, 1.5; and so on up to No. 4.5, with only 0.25 per cent., below which point the scale is not extended.

The following determinations of carbon in various kinds of iron and steel made in Sweden are by Eggertz:—

Softest Swedish Bessemer iron contains	0.08	per cent. of carbon.
Soft steel . "	0.75	" "
Best quality of cast-steel . contains	1.4 to 1.5	" "
Natural forge steel contains	0.99 " 2.44	" "

Cement steel contains 0.50 " 1.90 " "
Cast steel " 0.86 " 1.94 " "
Hardest welding cast-
steel . contains 1.80 " " "
Malleable cast-iron
contains 0.88 " 1.52 " "
Draw-plate steel
contains 3.30 " "

The following modification of this process is adopted at Seraing, in Belgium, for the determination of carbon in mild Bessemer steel. Two samples, each weighing 0.2 grammes, of the ingot to be tested are taken; one being in the state of filings, and the other of borings. These are treated with 20 cubic centimeters of nitric acid, of specific quartz 1.2; the solution being effected in a water-bath at 80°. For the test-standard, the same weight of two different samples, of the hardest steel made in the works, whose carbon has already been determined, and containing 0.61 and 0.63 per cent. respectively, are dissolved up in the same manner. The whole of the four solutions are then brought down to one tint by adding water to the darker ones, care being taken to conduct the operation in tubes of exactly the same diameter. The amount of carbon can then be computed from the volume of the solutions. If the difference in the results given by the two samples does not exceed 0.03 per cent., the arithmetical mean between them is adopted as the true amount; but should it be larger, the operation is repeated.

In order to obviate the necessity of making standard solutions for every set of determinations, different colored liquids have been employed with a view of obtaining a permanent scale of colors. Among these may be mentioned caramel, or burnt sugar, which gives various shades of yellow and brown, but alters very quickly; and partially decomposed solution of indigo in sulphuric acid, which is said to keep its characteristic color without alteration for a considerable time. Another recommended by Hetman consists of a mixture of bichromate of potash and nitrate of cobalt. In most cases, however, the direct system of comparison with solutions obtained from steel of known compositions is to be preferred.

Silicon. The determination of silicon in iron and steel is a matter of some difficulty, as the mere weighing of the ignited insoluble residue from the hydrochloric acid solution and calculation of the silica found, as silicon, depends upon the assumption that the iron is free from silicates, which is often contrary to the fact, especially in malleable iron, which may contain a notable amount of intermingled slag that has not been perfectly expelled in the welding, and exists as a mechanical impurity, having no relation whatever to the real composition of the metal. This defective interpretation of the ultimate analyses is probably the cause of the contradictory statements current as to the amount of silicon that may be present beneficially in malleable iron. Eggertz has introduced a method of determining silicon in the presence of slags, which is based upon the fact that when iron is slowly acted upon by bromine, a solution of iodine, it dissolves, and the silicon set free is converted into silica, which is completely soluble in a boiling solution of carbonate of soda, while that in combination in the slag, if any be present, is not acted upon. The same method may be employed with cast-iron, as blast furnace slag, which sometimes occurs in it as a mechanical impurity is not sensibly acted upon either by iodine, bromine, or carbonate of soda.

The process is conducted as follows: Three grammes or 45 grains of iron in the state of filings or borings, sufficiently small to pass through a sieve with meshes $\frac{1}{70}$ of an inch in diameter, is treated with five times its weight of iodine, in a volume of fifteen cubic centimeters of water contained in a beaker of about six or seven times that capacity. Water that has been boiled to free it from air is used, and the operation must be performed at as low a temperature as possible, in order to prevent oxidation of the iron by the air, it is usual, therefore, to keep the beaker cool by the use of ice. When the iron is completely dissolved, the solution is increased to three times the original volume by the addition of very cold water in order to prevent the separation of basic salts of iron, and is well stirred and left to settle. The lighter scales of graphitic carbon remain in suspension, and are poured off with the bulk of the liquid into a filter 2 inches in diameter, with only about one-tenth of the original quantity of the insoluble residue which forms a heavy powder at the bottom of the beaker. A few drops of hydrochloric acid are added, and the liquid stirred with a glass rod; if this produces a disengagement of gas the whole of the iron is not dissolved, and a little iodine and carbonate of soda is added in order to complete the solution. The acidified water must be poured quickly on the filter in order to prevent the decomposition of the slag. When the whole of the residue is transferred to the filter it is washed with cold water until the whole of the iron is found to be completely removed when tested by a solution of ferrocyanide of potassium. The filtrate is evaporated to dryness with the addition of hydrochloric acid in order to recover any small amount of silica that may have gone into solution with the iron. The original residue which may contain graphite, silica, and slag is transferred without drying into a large platinum crucible, and after concentrating the wash-water to 6 cubic centimeters, a saturated solution of carbonate of soda is added, and the crucible is heated for one hour in a water-bath, the liquid being stirred from time to time with a platinum spatula in order to divide any lumps in the insoluble residue. The solution is then carefully poured from the insoluble mass in the crucible on to a small filter, and a fresh quantity of carbonate of soda solution is added and boiled for another hour, when the whole contents of the crucible are thrown upon the filter and washed. The alkaline solution of silica is acidified with hydrochloric acid, added to that containing the iron, and evaporated in a water-bath. This operation is repeated with the addition of fresh acid until the silica is perfectly freed from iron, when it is filtered, dried, ignited, and weighed as often as may be necessary to ensure its complete purity, which must be further tested by heating it with hydrochloric acid. When 3 grammes of iron are treated, 0.016 grammes of silica correspond to 0.001 gramme of silicon. The insoluble residue from the carbonate of soda solution may contain graphite slag, oxide of iron, and titanic acid. There is no way of distinguishing the amount of oxide of iron present as such, in addition to that in combination with silica, except by assuming the composition of the slag to be constant, which is not the case.

Eggertz found by the use of this process, that the amount of silicon in good bar iron may vary from 0.01 to 0.10 per cent, ; but into samples of Krupp's cast-steel it was as high as 0.30 per cent. Slag has been found usually in mere traces in cast-steel, but in one instance it amounted to 0.2 per cent. Malleable iron, however, contained much more. In wire iron from a charcoal hearth 0.33 per cent. was found, in armor-plates from 0.75 to 3.00 per cent., and in a rail as much as from 4.00 to 5.00 per cent.

Special Methods of Determining Manganese.—According to Pattinson, manganese is completely precipitated as hydrated dioxide from a hydrochloric acid solution when a certain proportion of ferric chloride is present, by the addition of solution of bleaching powder, or bromine, and carbonate of lime in excess, at a temperature of 50 to 70 degrees. The dark brown precipitate, when filtered and washed until all traces of chlorine or bromine are removed, is transferred on the filter to a beaker containing a measured volume of a solution of ferrous sulphate in sulphuric acid, whose contents of iron are known, in which it readily dissolves, the maganese dioxide producing manganous sulphate, and converting its equavalent of ferrous into ferric sulplate. The amount of ferrous sulphate remaining in the solution is then ascertained by a standard solution of bichromate of potash, as in the assaying of an iron ore. The difference gives the amount peroxidized by the second atom of oxygen in the manganese dioxide, and from it the amount of the latter metal is calculated according to the following equation:—

$$2\,FeO\,SO^3 + MnO^2 + 2\,SO^3 = MnO\,SO^3 + Fe^2O^3 3SO^3,$$

each unit of ferrous salt corresponding to 0.18 of its weight of manganese. In determining the standard of the iron salt solution a filter of the same size as that used in separating the manganese should be added, in order to compensate for any possible reducing action due to the paper. The original solution should contain at least half as much iron as manganese. The method is equally applicable to the analysis of ores or metal.

In America the precipitation of maganese as dioxide by boiling a nitric acid solution with chlorate of potash is much used in the analysis of pig iron and steel. In the former case carbon and silicon must be removed by a preliminary filtration of the nitric acid solution through asbestos, but with steel this is not necessary. The precipitated manganese dioxide is filtered upon asbestos, and after washing is dissolved in dilute sulphuric acid in the presence of a known excess of a standard solution of oxalic acid, the amount of which remaining unchanged is determined by a standard solution of permanganate of potash. The reaction is:—

$$MnO^2 + SO^3 + C^2O^3 = MnO\,SO^3 + 2\,CO^2,$$

each unit of oxalic acid corresponding to 0.763 of its weight of manganese. This method is proposed by F. H. Williams, who recommends the use of a permanganate solution of which one cubic centimeter corresponds to one milligramme of iron and one of oxalic acid, requiring three times its volume of the former solution to oxidize it.

Ford adopts a direct method of determination in connection with this process. The precipitated dioxide of manganese is dissolved in hydrochloric acid, rendered neutral, with ammonia; acetate of soda is added, and the solution is boiled and filtered. An excess of phosphate of soda and ammonia is added to the filtrate, which is made slightly ammoniacal, when on stirring a finely crystalline precipitate of phosphate of ammonia and manganese goes down, which on ignition is converted into pyrophosphate of manganese.

The quality and character of malleable iron or of steel may to some extent be judged by the appearances presented by fractured surfaces, which are fibrous and comparatively dull in the softer kinds, while in the harder ones they are brilliant and granular or crystalline in various degrees, The fineness and uniformity of the grain is most marked in the harder varieties of tilted cast-steel, especially those containing tungsten and manganese in considerable quantity, which are nearly glassy in fracture, while unwrought ingots are usually of coarsely crystalline structure, somewhat resembling that of antimony. The nature of the fracture may vary, however, with the manner in which the rupturing strain is applied. If this be very sudden the broken surfaces are almost invariably crystalline, as is seen in coupling-hooks and pins broken in railway accidents, although they are usually made of iron which ordinarily shows a fibrous fractuure when broken by strains progressively augmented. The crystalline structure of melted or balled iron or steel is very considerably modified by the process of lamination, the crystalline masses becoming distorted and elongated by the action of the rolling-mill, fiber being developed in the direction of the length of the bar. At each successive piling the grain becomes finer and more regular, owing to the breaking down and rewelding of the fibers in the bars forming the pile. Tresca has compared the effect of forge rolling to that of the process of carding and drawing cotton, the result in both cases being the production of parallel fiber. When the work is done upon the metal in a plastic state at a high temperature, the density is increased; but when a powerful tractive strain is exerted, as in wire drawing or planishing bars by cold rolling, the metal elongates more rapidly than its transverse section diminishes, and the density is diminished while the tenacity is considerably increased. The softness and lower tenacity, together with the original higher density, may be restored by annealing.

The changes referred to above are illustrated by the following results taken from Kirkaldy's experiments on wrought-iron and steel made at Glasgow in 1858–61; from which it appears the diminution in specific gravity in bars stretched by a severe tensile strain varied from 0·7 to 1.2 per cent. By cold rolling the diminution amounted to 0·7 per cent. for bars, and 0·36 per cent. for plates.

Mark or Name.	Specific Gravity.	Tensile Strength.
Govan puddled bar . .	7·450	20·9 tons per sq. in.
" hammered bar . .	7·764	28·7 " "
" rolled bar, 1½ in. square	7·720	25·6 " "
" " reduced to 1¼ in.	7·729	25·4 " "
" " " 1 "	7·722	25·6 " "
" " " ¾ "	7·702	25·9 " "
" " " ½ "	7·685	26·6 " "
Blochairn best rolled bar .	7·636	27·1 " "
" " cold rolled .	7·582	30·6 to 30·5 "
" " annealed .	—	25·2 to 27·8 "
" best boiler plate .	7·566	20·5 lengthways; 19·2 crossways
" " cold rolled	7·539	39.7 lengthways; 36·0 crossways
" " annealed	—	22·7 lengthways; 21·7 crossways

The same observer found in 1858—61 that the tensile strength of the best brands of British bar-iron varied from 24 to 27·5 tons per square inch: bars of irregular section bear a somewhat similar strain, or from 24 to 27·4 tons. The strength of plates varied from 20·4 to 24·6 tons lengthways, or in the direction of the greatest longtudinal extension produced by rolling, and from 18·5 to 22·6 tons crossways. The specific gravity varies from 7·531 to 7·760, being greatest in Yorkshire iron, which is made almost entirely under the hammer.

The relation between the composition of malleable iron and steel and their resistance to strains of different kinds has of late years been investigated by many observers. The following table, showing the limits of elasticity and tensile strength of various kinds of malleable iron and steel, is taken from one of the earliest of these investigations made in Sweden for the Jernkontor, by Styffe:—

Percentage of Carbon	Specific gravity Soft.	Hardened.	Tensile strength, tons per square inch.
1·5	7·785	7·736	34—39
1·2	7·832	7·771	37—40
0.9	7·874	7·808	56—59
0·6	7·879	7·807	37—41
0·4	7.893	7·839	30—34

The absolute strength appears to be greatest when the steel contains from 1 to 1¼ per cent. of carbon.

The following table contains the relation between the specific gravity and tensile strength of Bessemer steel of various degrees of carburisation made at Sandviken, in Sweden. (See next page.)

An elaborate series of experiments on the effect produced by varying single constituents in steel as regards mechanical properties has been published by the Terre-Noire Company, at the Paris Exhibition, in 1878. The metal investigated was principally open-hearth-steel. In the first series five charges were made with different proportions of carbon, phosphorus and manganese being kept as nearly uniform as possible; in the second series, manganese was varied; and in the third, phosphorus. These were subjected to the different tests of flexure tension, impact, and compression, both in the natural state, and when

tempered in water and oil. An abstract of the results obtained with the natural metal is contained in the following table.

than that of the best bar iron: that is, it will stand a greater transverse strain without fracture, but it is more rigid, or for equal increments of weight, takes a smaller permanent set. The latter was for square bars of the best wrought-iron, 4 inches in the side and 39½ inches between the bearings, under a strain of 30 tons applied in the center, 1.6 to 1.9 inches, while for similar bars of No. 59 it was only 0.4 inch. The elasticity and ultimate strength appear to be in direct proportion to the amount of carbon, as is also the rigidity, the latter property in the harder varieties appearing as fragility under impact. Increase of manganese has generally the same effect as augmentation of carbon, the elastic limit and ultimate tensile strength being increased, while the elongation before fracture is diminished.

Chromium has a remarkable influence upon the resistance of the metal to compression. The same test piece of No. 278, when water-tempered, and twice subjected to a pressure of 200 tons per square

Column F contains the breaking strains of bars 39½ inches between the points of support, and loaded in the middle. E, the limits of elasticity. T, the ultimate tensile strength, all expressed in tons per square inch. L, the percentage of elongation on the original length of bars broken by tension. I, the energy of blow producing fracture in foot-lbs. in the falling weight test. C, compression expressed in loss per cent. of original height, under a load of 200 tons per square inch in the series I. to IV., and the crushing strain in tons per square inch in series V. ? signifies the fracture was not produced by the highest available stress.

From these experiments it appears that the flexibility of very mild steel, such as No. 59, is greater inch, was only shortened about 2.5 per cent.

Phosphorus, when present in notable quantity in steel, increases the rigidity, and sensibly diminishes the power of resisting impact. Such metal, however, can only be rendered workable by keeping down the proportion of carbon, which is effected in practice by the use of high ferro-manganese, with the necessary result of introducing a large proportion of manganese. This condition is involved in the manufacture of the so-called *phosphorus-steel*, which has been successfully made on the large scale for some time, it being more particularly applied in the re-manufacture of old iron rails in the open-hearth furnaces.

Series IV. contains the tests of steels cast with a considerable addition of silicon as well as manganese, which has the property of giving ingots free from blow-holes. This gives a very strong metal suitable in the harder varieties for all armor-piercing projectiles.

Series V. shows the gradation of cast-iron into steel by the progressive diminution of carbon. No. 156 is a dark grey pig metal, whose low mechanical resistance is to be ascribed to the large amount of silicon present, as No. 161, containing the same amount of carbon, is sensibly stronger. With 2 per cent. of carbon, the metal may be hardened by chill-casting, but below this point there is not much difference between objects cast in sand or metal moulds. The property of malleability appears in No. 104, with 1.5 per cent. of carbon which can be forged and drawn under the hammer, and also tempered to some extent, and may be considered to be steel, although it is extremely rigid, and breaks under a tensile strain almost without elongation.

In comparative tests of iron and steel it is essential that all the samples should be subjected to exactly similar treatment; that is, the test-pieces must be of the same dimensions, especially as regards length and thickness. For equal quality of material a thin section gives a proportionately higher resistance per unit of surface than a thicker one. This is especially seen in steel wires, which may be obtained of a tensile strength of 100 to 140 tons to the square inch. The proportional elongation before fracture is also greater with short than with long test-pieces, and the lengths of those used by the different investigators vary very considerably; 4, 6, or 8 inches being, however, common. The figures in the foregoing table refer to cylindrical pieces of 4 inches long and 0.4 inch diameter.

Another method of estimating the toughness of steel consists in measuring the area of the fractured surface and comparing it with that of the original transverse section. These will always differ, the differences being greatest in the softer kinds of metal. Thus the difference between the original and fractured surfaces was 65.7 per cent. in No. 59, while in No. 82 it was only 12.4 per cent. It is matter of controversy whether the toughness of the metal is best evidenced by contraction or by elongation; the latter is the more convenient test, as the determination of the area of fracture is rather a troublesome process.

Working Tests. The tensile strength alone is not a sufficient measure of the quality of malleable iron or steel, as, especially with the latter, a metal of great strength may be deficient in softness and incapable of working properly under the hammer. Whenever, therefore, where the metal is to be subjected to further treatment, such as punching and drilling for riveting holes in boiler or shipbuilding works, special forge tests, both hot and cold, and in the case of steel tempering tests, are adopted, examples of which are given below.

Another useful supplemental test, especially in the case of welded iron, is obtained by polishing a section of the bar or plate, and then etching it with some corrosive liquid which brings out the lines of junction of the different elements of the pile and cinder patches or other defects. Either weak hydrochloric acid applied upon blotting paper, or a very dilute solution of chloride of platinum, may be used as an etching fluid.

Rails which are subjected to heavy percussive strains in use are tested in England for safety by allowing a heavy weight to fall upon them from a height which varies with the weight per yard and the character of the metal. For iron rails, according to Sandberg, a proper safety-strength is given by the product of the weight in cwts. into the fall in feet which should equal the weight per yard. Thus a 56-lb. rail supported on bearings 3 feet apart should not be indented more than $\frac{3}{4}$ inch to 1 inch by a weight of 7 cwt. falling 8 feet. For steel rails a heavier weight and higher fall are necessary to prevent the use of too hard a metal, and the former is therefore increased to a ton and the latter to 15 feet with light or 20 feet with heavy sections.

The prescription of a particular chemical composition for steel rails has been proposed by Dr. Dudley for the Pennsylvania Railway Company, who gives us the following as permissible limits:—

Phosphorus, not above	. .	0.10 per cent.
Silicon	" . .	0.04 "
Carbon	0.25 to 0.35, preferably	0.30 "
Manganese	0.30 to 0.40, "	0.35 "
Sulphur and Copper	. .	not specified.
Other impurities	. . .	only traces.

Minimum tensile strength, 29 tons per square inch.
Minimum elongation, 20 per cent.

This specification is founded upon the results of the analysis of a considerable number of worn rails, some of which had broken in use while others had not. At the same time the theory was propounded that the hardening properties of the phosphorus, silicon, carbon, and the manganese were to each other in the proportion of $1 : \frac{1}{3} : \frac{1}{3} : \frac{1}{5}$, and that the sum of the phosphorus and of the respective fractions of the other constituents expressed in hundredths per cent. gave a measure of the hardness in so-called *phosphorus units*. By this method the number of such units in good rails varied from 20 to 36, while in those that broke in use it varied from 33 to 53. This theory has, however, not found general acceptance, mainly from its being founded upon too small a number of observations; but the conclusion that great hardness is detrimental to the wearing power of steel rails accords with the previous experiments of J. T. Smith, who found that on the Furness line the loss of weight of rails that had been eight years in use averaged only 13.54 per cent. when the steel contained 0.30 per cent. of carbon, while with harder ones with 0.44 per cent. of carbon the average wear was 15.18 per cent.

The German Union of Railway Managers in 1880 proposed the following scheme of classification for steel used in railway materials, which has subsequently been adopted in its main points by the German and Austrian Government lines:—

1. According to quality and temper:—

First Class.	Kilograms per sq.m.m.	Contract'n per cent.	Qualitative fact'r
Hard .....tensile strength	65	25	90
Medium " "	55	35	90
Soft...... " "	45	45	90
Second Class.			
Hard .... " "	55	20	75
Soft...... " "	45	30	75
2. According to uses:—			
Axles.....tensile strength	50	30	90
Engine tires " "	60	25	95
Car'ge&wagon tires "	45	35	90
Rails...... " "	50	20	85

The qualitative factor in the last column is the sum of the other two with in some cases the addition of an arbitrary quantity. The above scheme, which is based on the tensile strength only, is by many persons regarded as unsuited for practical requirements, and the Society of German Ironmasters has propounded a more complete one, as being better fitted for the use of both producers and consumers. An abstract of this will be found in the Proceedings of the Institute of Civil Engineers, vol. lxvii., p. 484.

The following are the tests prescribed by the Admiralty for the plate iron intended for use in the Navy and may be taken as indicating the average strength of iron of fair quality. See next page.

Plates should be tested, both hot and cold, on a cast-iron slab having a fair surface, with an edge at right angles, the corner being rounded off with a radius of half an inch. The portion of plate tested to be 4 feet in length across the grain, and the full width of the plate with the grain. The bend should be made from 3 to 6 inches from the edge. All plates to be free from lumination and injurious surface defects.

PLATE IRON, FIRST CLASS, OR B. B.			SECOND CLASS, OR B.	
	Length-ways.	Cross-ways.	L'ngth-ways.	Cross-ways.
Tensile strength, per square inch.	22 tons	18 tons	20 tons	17 tons
Forge test, hot. All plates of 1 inch in thickness and below must be capable of bending hot without fracture thro'gh an angle of......	125°	90°	90°	60°
Forge test, cold. All plates should admit of bending cold without a fracture as follows:—				
1 in. thick to angle of	15	5	10	—
$\frac{3}{4}$ " "	25	10	20	5
$\frac{1}{2}$ " "	35	15	30	10
$\frac{1}{4}$ " "	70	30	55	20
$\frac{3}{16}$ in. and under to angle of..........	90	40	75	30

The tests to be applied to one plate of each lot of fifty of the same thickness.

The tests specified for steel are as follows:—Strips cut lengthwise or crosswise to have an ultimate tensile strength of not less than 26 or more than 30 tons per square inch of section, with an elongation of 20 per cent. in a length of 8 inches. Beam, angle, bulb, and bar steel to satisfy such forge tests, hot and cold, as may be sufficient to prove soundness of material and fitness for service. Strips cut crosswise or lengthwise $1\frac{1}{2}$ inches wide, heated uniformly to a low cherry red heat, and cooled in water at 82° Fahr., must stand bending in a press to a curve whose corner radius is $1\frac{1}{2}$ times the thickness of the plate. The strips are all to be cut in a planing-machine, and to have the sharp edges taken off. The durability of every bar or plate supplied to be ascertained by the application of one or both of these tests to the shearings, or by cold bending under the hammer. All steel to be free from lamination and injurious surface defects. Lloyd's rule specifies 26 to 31 tons as the limit of tensile strength, with an elongation of 16 per cent. on 8 inches for steel ship plates. Angle iron must bear flattening under the hammer and doubling back cold. In other respects the tests are similar to those of the Admiralty.

We will conclude this article with some observations on *blast furnaces* and their accessories together with a brief notice of their capacities. In the very early days of iron-smelting the only merchantable product was bar or malleable iron obtained directly from the ore; cast-iron being a subsequent discovery, consequent upon the employment of larger furnaces and higher temperatures in the treatment of more refractory minerals. In process of time, it was found that the production of cast or pig metal, as an intermediate stage in the manufacture of malleable iron, was attended with advantages not possessed by the older method, so that at present it is followed exclusively; the latter being confined almost entirely to a small and constantly diminishing area in Europe, besides being more extensively practised in Africa and India.

The subject, therefore, naturally divides itself into two main heads:—

I. Direct method, or extraction of malleable iron from the ore, and

II. Indirect method, or production of pig iron from the ore, and subsequent conversion into malleable iron by some form of finery process.

The difference between the two processes is mainly due to the height of the furnace. In the direct method, where a low charcoal hearth or forge is used, a portion of the ore is reduced to the metallic state at a comparatively low temperature, while another part combines as protoxide with any silica that may be present, forming a highly fusible and basic slag, into which the reduced spongy mass sinks, any excess of carbon taken up being removed by the oxidizing agency of the slag aided by the blast which is introduced through an inclosed nozzle or twyer, so as to impinge directly upon the metallic bath.

On the other hand, the furnace used for the production of cast-iron is mainly distinguished by its great height, and may be described in general terms as a conical hearth, whose walls are continued upwards into a chimney or stack of increasing but variable section; the blast-nozzle being laid horizontally instead of in an inclined position. The height of the upper portion, *i. e.* above the twyer level, may be from ten to twenty times as great as that below, or hearth proper. When the furnace is at work, or, as it is technically termed, *in blast*, it is kept filled to the top or *throat* with alternate layers of fuel, ore, and flux, the latter being mixed in proper proportions to produce the most fusible combinations of the earthy matters, a constant stream of air being maintained through the twyers, at a sufficient pressure to pass freely through the contents of the furnace. Part of the incandescent fuel subjected to the blast is completely consumed, burning to carbonic acid with a development of the maximum of heat, whereby the matters immediately adjacent are melted, and fall into the hearth, where they separate by liquation into the metal and slag; the latter, being specifically lighter, rises to the surface, and protects the former from the decarburising action of the blast. The carbonic acid formed in the first instance, encountering fresh fuel, is reduced to the state of carbonic oxide, a process that is attended with a great absorption of heat, so that the region in which a temperature sufficiently high for the fusion of metal and slag prevails does not extend more than a very short distance from the point of introduction of the air. The carbonic oxide so produced, and the unaltered nitrogen of the air, when brought in contact with an oxide of iron at a red heat, is again oxidized to carbonic acid, with the simultaneous production of metallic iron, which becomes carburetted by further contact with carbonaceous matters in its descent towards the hearth. The alternate production of carbonic acid and carbonic oxide, by the reciprocal action of carbon and oxides of iron upon the gases, is continued in the upper part of the furnace as long as the temperature remains sufficiently high, the quantity of the former gas being augmented by the decomposition of the limestone flux generally used. Ultimately, however, a sufficient amount of carbonic oxide remains in the so-called waste gases, either to form a great body of flame at the throat of the furnace when the current is allowed to flow freely into the air, or a valuable fuel, yielding sufficient heat for all the accessory operations of the furnace, when collected and utilized. The shaft of the blast furnace may, therefore, be considered as combining within itself, and performing the functions of, several distinct furnaces; thus the hearth is devoted entirely to fusion, while the middle region is essentially a concentration chamber, and the top parts, when raw fuel and flux are used, combine the functions of a limekiln with those of a coke oven. Taken as a whole, therefore, the reactions in the manufacture of pig iron are more complex than those of the open-fire process of making malleable iron direct from the ore; but, as the latter is only one out of many methods by which the same product is obtained, it will be more convenient to defer its consideration, and commence with a description of the former.

In its original or what may be considered typical form, the blast furnace consists of a shaft or chamber formed of two truncated cones, joined by their bases. The upper and more acute of the two cones is placed upright; and is known as the *stack*, while the lower and more obtuse one is inverted: the line of junction forming the widest part of the furnace is called the boshes, possibly a corruption of the German *bauch*. Sometimes the lower cone is continued down to the level of the ground, but more generally the lower part of the furnace is enlarged, forming what is known as the *hearth*, in which the molten materials collect below the level of the twyers or pipes through which the blast is introduced. In France, the space between the twyers and the broadest part, or top, of the boshes is known as the laboratory or working place (*ouvrage*). The top, or throat, of the furnace is surrounded by a platform for the convenience of charging, and is in many cases covered by a short cylindrical chimney, which leads off the flame escaping at the throat; this portion of the furnace is known as the *tunnel head*.

In the newer forms of furnaces, the conical or spindle-shaped body and cylindrical hearth, with their sharply-contrasted divisions, are, for the most part, superseded by more flowing forms, the straight slopes of the sides being converted into curves, giving a more or less barrel-shaped outline to the stack. The same terms are, however, alike applied to the different parts, the boshes being taken as indicating the widest part of the stack, and the hearth that lying below the twyers.

The construction of blast furnaces varies very considerably in different localities, in regard to size and proportion of parts to each other, as well as material employed. In the early days of pig-iron manufacture, when a square horizontal section was in general use, the external form was usually that of a square base, pyramidal tower, tapering uniformly from the ground upwards, which became modified, on the introduction of the circular stacks, to a conical or cylindrical form, the lower portions near the ground, and surrounding the hearth, still retaining the square base. Both of the above forms are characterized by extremely massive construction, the lower parts, or stack pillars, forming solid four-sided blocks of masonry, braced with iron rods, and united by cylindrical arches into the so-called twyer houses, a complete circular passage being usually formed through the mass of the pillars. When the whole furnace is of rectangular section it is braced by a similar system of tie rods through the entire height, but in conical or cylindrical forms iron hoops, placed at short distances apart, are used for the same purpose. With every increase of size the massive character of the external casing of the blast furnace has diminished by the reduction of the mass of masonry, and the substitution of cast and wrought-iron whenever it is possible to do so. Thus in many modern English furnaces the old stack pillars and twyer houses have been replaced by cast-iron columns or standards, arranged in a circle, whose entablature is a cast-iron ring, carrying the whole of the superstructure, or stack, so that the hearth casing, instead of being accessible only at the twyers, is now freely exposed all round. In like manner, the old solid stack casing of masonry and hooping has given place to a cylinder of wrought-iron plates riveted together. The latter class are known as cupola furnaces, from their resemblance to the common iron founder's furnace of the same name. Examples of these different forms of construction may be seen in almost every iron-making district. The older kinds, with massive stacks, are, as might be expected, to be found chiefly in the older districts, such as South Wales, Staffordshire, and Scotland; while in the newer furnaces of the north-eastern counties and Lancashire, the iron-jacketed cupola type is more commonly seen.

The shaft, or stack, of the furnace, *i.e.* the upper part above the boshes, is constructed at the same time as the casing. It is now invariably formed of fire-bricks, which are moulded to the proper curve of each ring. The thickness of the shaft or ring wall is about 15 or 18 inches, the joints being brought to a fine face and set in fire-clay. A second wall is, in the more massive class of furnaces, placed immediately outside the first; this may be either of common or seconds fire-brick, and set in cement; outside of all, comes the exterior casing, which, as has been already stated, may be either of iron, brick, or masonry.

A small annular space, filled either with loose sand or small fragments of broken slag, is usually interposed between each successive lining, in order to allow for any alterations of form produced by the expansion of the inner one. In the outer casing a number of square holes are often provided for the escape of moisture; these are more especially used in furnaces which only remain in blast for a certain period of the year, as is the case in Sweden, but in those that work continuously, they are often omitted.

The lower portion of the furnace, including the hearth and boshes, is built after the completion of the stack. The foundation of the hearth varies with the nature of the ground, and may sometimes require to be commenced, in concrete and rubble work, at a considerable depth below the surface; the hearth bottom consists of a thick layer of fire-brick, or sandstone, in blocks, or as large a size as can be obtained, or in some cases both materials are used. The bricks for this purpose are laid in the form of an inverted flat arch, in order that they may not be forced up in the event of the molten metal finding its way through the joints. When a bed of masonry is used below the hearth bottom, it is generally built with a system of channels or flues intersecting at right angles, through which air circulates, and prevents the access of moisture from the ground to the hearth.

The sides of the hearth and boshes, up to their junction with the stack, require to be made of refractory material, and also of considerable thickness, having to withstand a very high degree of heat, in addition to the common action of the molten slags. When the rectangular hearth was used, it was customery to build these parts of sandstone similar to that employed for the hearth bottom, but for the circular form brick is generally adopted, and is in almost all cases to be preferred.

In Sweden and Germany the hearth and boshes are often formed of a mixture of finely-crushed quartz or ground fire-brick, and fire-clay, applied in a plastic state, and rammed tight between the casing walls and a wooden core or mold of the proper shape of the cavity required, which is afterwards removed. This kind of hearth, which is represented in the Swedish furnace, is found to answer very well in all practice for furnaces of small diameter, but requires to be carefully dried before being heated, in order to prevent irregular shrinkage and cracking.

A short distance above the ground level the passages for the introduction of the blast are perforated through the wall of the hearth. These are known as the *twyer holes*, and vary in number from two to six. On the front or working side of the hearth, a square or flat-arched opening extends from the hearth bottom to a little above the level of the twyer holes. The vertical sides of this opening are prolonged outwards for a short distance into a rectangular cavity, known as the fore-hearth, which is bounded in front by a wall of refractory material, called the *dam*. The arch covering the opening is called the *tymp arch*.

The exterior of the hearth, and the faces of the numerous apertures pierced through it, are strengthened with cast-iron plates and wrought-iron bracings. The under side of the arch is, in large furnaces, usually protected by a cast-iron box or block, having a wrought-iron serpantine pipe inside, through which a current of water is kept flowing, in order to protect the brickwork from destruction by the intense heat to which it is exposed, and the corrosive action of the molten slag which is constantly flowing through it.

The dam in front of the hearth is formed of fire-brick, and carried up to the twyer level. Externally it is supported by a cast-iron plate, called the dam plate. A semicircular furrow in the top edge, known as the cinder notch, forms a passage for the slag, which is now often moulded into large blocks by receiving it in a shallow square-bodied railway truck, having movable sides of wrought-iron. When the truck or *cinder tub* is full, it is removed, and the block of slag, weighing in some instances as much as 7 tons, is, as soon as it has cooled sufficiently to become solidified, removed and thrown away. In charcoal and other small furnaces the front of the dam is generally formed into a gently-sloping inclined plane or *cinder fall*, where the slag as it runs out solidifies in a comparatively thin layer, and may be broken up and removed by hand. In Staffordshire, the slag is allowed to collect in a shallow basin in the floor of the casting house, called the roughing hole, where it consolidates to an irregular disc-shaped lump, which is afterwards lifted out by a crane, and sent off on a truck to the slag bank or cinder tip.

The tap hole for withdrawing the molten iron from the hearth is a narrow vertical slit pierced through the dam, and extending from the hearth bottom about 12 or 15 inches upwards. During the time that the hearth is filling, it is stopped by a packing of sand rammed in tight, which can be easily perforated by a pointed bar, at the time of casting. The space between the top of the dam and the tymp arch is also stopped with sand or brick, a small passage being left for the escape of slag. Sometimes the dam is raised above the level of the twyer, so that a greater depth of melted slag is retained in the furnace, and flows out continuously, the top of the fore-hearth not being stopped. At either side of the tymp there are often fixed to the hearth-casing a series of cast-iron plates with vertical racks or notches, which form points of support or fulcra for the heavy tools used in clearing the hearth and other operations in the interior of the furnace; these are known in France as *gendarmes*.

In Styria furnaces are built without fore-hearths or tymp arches, the hearth being entirely closed, and the slag and metal are allowed to accumulate, and are tapped off together at short intervals. This construction is now becoming general in other countries, with the addition of a passage for the slags, which is kept constantly open. For the latter purpose, Lurman's slag twyer is used. This is a large water-cooled bronze twyer of $7\frac{1}{2}$ inches bore in the place of the tymp, into which is inserted another of $1\frac{1}{2}$ or 2 inches aperture, through which the slag runs.

The upper end of the stack, or throat of the furnace, is surrounded by a platform or charging plate sufficiently broad to give room for working the barrows used in filling ore, fuel and fluxes. In the older square-stacked furnaces, sufficient space for this purpose could usually be found between the ring wall and the external casing; but in the more taper cylindrical or conical forms of modern times, additional surface is necessary. This is provided by an overhanging gallery carried upon brackets, constructed entirely of cast and wrought-iron. When two or more furnaces are placed adjacent to each other, their galleries are united by bridges, which communicate with the lifts for bringing up materials to the furnace top.

When the gases are allowed to burn at the throat, it is necessary to provide a chimney in order to carry the flame clear of the charging place. For this purpose a short cylinder of brickwork hooped with wrought-iron, or even of cast-iron, is used, known as the *tunnel-head*. The charging holes are rectangular apertures, varying in number with the diameter of the throat, in the lower part of the tunnel-head, through which the charges of ore, fluxes, and fuel are introduced. Except at the time of charging they are generally closed by wrought-iron shutters. The arrangements of the head of the furnace when the gases are collected are somewhat more complicated, and will be described further on.

Lifts.—In hilly countries, where the valleys are deep, it often happens that blast furnaces can be placed below the general level of the ground, supplying the ores and fuel, so that all materials necessary for working may be delivered at the furnace top without any special appliances. In flat ground, on the other hand, such as prevails in most of the iron districts of England, it becomes necessary to resort to mechanical lifts for raising the charges. The following are some of the forms more generally employed.

Inclined Planes. These are mostly to be found in old works, the more directly vertical lift being generally preferred at the present day. They are usually made with a double line of railway, or with a single line and crossings for the return trucks, carried on trestle work. The inclination is usually not more than 25 or 30 degrees. The most convenient form of truck is a triangular frame, with two pairs of wheels of unequal height, supporting a horizontal platform of sufficient size to carry four or more of the iron wheelbarrows used in charging, with their loads. The motive power is usually a steam engine of from 10 to 20 horse power, working a pair of winding drums. The load is drawn either by wire ropes, or in Staffordshire by flat-linked chains, such as are used in the same district for drawing in collieries.

At the Barrow Iron Works, in Lancashire, two inclined planes are used for the supply of seven furnaces. They are carried by bow and string girders of wrought-iron, and extend from the ground to the top of the furnace, with only one intermediate support. The platform-wagon, carrying the barrows, is received into a recess in the charging platform, and a similar one below, so that the barrows with the loads may be wheeled on and off on their arrival at either end. The motive-power is a high-pressure steam engine placed behind the furnaces, working a wire-rope drum. About 4,000 tons of materials are lifted weekly by each plane.

The most approved form of lift, where large quantities of material have to be raised to a considerable height, is a cage moving between vertical guides exactly similar to those used in collieries. As the load is comparatively quickly raised, it is a useful precaution, where steam-power is used, to have no self-acting valve gear, but to let the engine be entirely worked by hand, in order to prevent the chance of accidents from overwinding.

The water balance is an old and favorite form of lift for small furnaces. It consists of two cages moving vertically and guided, united by a rope or chain passing over a guide pulley; below the floor of each cage is fixed a water-tight box, provided with a discharge valve in the bottom. When the empty cage is at the top of its stroke, water is allowed to flow into the box until the weight is sufficient to pull up the other cage with a fresh load, the speed being regulated by a brake on the guide pulley. As soon as the return cage reaches the ground, the projecting stalk of the discharge valve strikes against a catch, and is driven up; leaving a passage for the water, which runs out, and the cage is ready for another ascent when loaded. The chief merit about this plan is its extreme simplicity and the large useful effect got from the water, especially if a natural fall can be used, otherwise it must be pumped up by special machinery. The principal objection to it is the difficulty of keeping the water boxes tight, the lift houses being generally damp and sloppy from leakages.

A more perfect kind of hydraulic lift is that constructed upon Sir William Armstrong's system, where the lifting cage is connected to a water-pressure engine by means of a chain passing over a system of compound pulleys, so that when the engine makes a stroke of 6 or 8 feet the load is lifted through a height six or eight times greater, according to the multiplying purchase of the tackle.

Pneumatic lifts are now used to a considerable extent in England, as the necessary power, compressed air, may be readily obtained from the main blast engines supplying the furnaces. The simplest form is a wrought-iron cylinder, open at the bottom and closed at the top, about 6 or 8 feet in diameter, and somewhat longer than the height of the furnace, suspended in a tank by counter-balance weights passing over pulleys in a manner exactly similar to an ordinary gasometer. A pipe for the admission of air at 3 or 4 lbs. per square inch above the atmospheric pressure, is introduced through the tank. The wagon to be lifted is carried on the top of the bell, and as the whole of the moving parts of the apparatus are balanced, the amount of power required is only that necessary to raise the additional load. For the return stroke, the air within the bell is allowed to escape by opening a valve communicating with the atmosphere, the weight of the empty wagon being sufficient to lower the bell in the tank.

In Gjers' pneumatic lift, which is much used in the newer Cleveland furnaces, the motive power, instead of being taken from the main blast engine, is furnished by a pair of double-acting air-pumps, the lift being effected by the pressure of the atmosphere acting against a vacuum in a cylinder, while the empty wagons are returned by compressing air under the piston. The Jacob's ladder, or endless chain system of lift, usually described in older works, is probably no longer in use.

The use of cast-iron cylinder blast-engines has almost everywhere superseded the ruder contrivances of wooden chests with square pistons, bellows, etc. In Sweden, for small furnaces and forges, the single-acting form of engine is much used, being cheap and economical in working and maintenance. Usually three inverted vertical cylinders are employed, of about 3½ or 4 feet diameter and length of stroke carried on cast-iron or wooden standards, and driven directly by a water-wheel.

The cylinder is provided with an air-tight piston, to which a reciprocating motion is imparted by appropriate mechanism. Two sets of valves are placed on the cylinder cover: the longer series open inwards as the piston recedes, given a passage for the admission of the external air, and at the change of stroke are closed by the compressing force exerted by the piston on the included air; and the second series, or discharge valves, which are in connection with the blast reservoir open, and allow the compressed air to pass out. In the single-acting engine only one end of the cylinder is covered and provided with valves; while in the double-acting form both ends are similarly arranged, so that one side of the piston is drawing the air through the intake valves, while the other is compressing the volume taken in at the preceding stroke, and driving it over into the reservoir through the discharge valves.

The valves employed are generally oblong rectangular plates, with their shorter sides placed vertically—one of the long sides forming the hinge. In order to combine rigidity with lightness, it is usual to make them of a combination of thin sheet iron, with contact surfaces of felt, leather or india-rubber. The hinge may be either of metal, very accurately fitted, or merely a flexible leather flap. The seats or boxes to which they are affixed are usually rectangular tubes projecting from the outer face of the cylinder cover. In order that the valves may close by their own weight when relieved from the pressure of the air, it is usual to fix the beating face of the seat in an inclined position, or counter-balance weights or springs of steel or india-rubber may be used for the same purpose.

As the motion of the valves is similar to that of the pendulum, the time required for opening and shutting them is dependent on their vertical length, so that the piston cannot be driven beyond a certain speed, unless mechanical means, capable of being increased *pari passu* with the speed of the engine, be employed. This has been attempted in the so-called slide-blowing engines, where the flap valves are replaced by a slide similar to that used in steam engines, which travels at the same rate as the piston, and places the apertures at either end alternately in communication with the external air and the blast reservoir. The system of construction has been adopted at different times both in England and on the continent. The best-known form is Slate's engine, where the slide is annular, and placed outside of the vertical blast cylinder, receiving motion by means of a pair of parallel rods connected with the rotary shaft of a steam engine below. The form of the slide is the solid of revolution produced by the rotation of an ordinary -∽- shaped slide valve about a vertical axis, formed by the center line of the steam and blast pistons. In Thomas and Laurent's arrangement the cylinder is horizontal; the air passages are of a retangular form, and are, together with the slide, placed laterally in the same manner as the steam ports and slide valve in an ordinary horizontal steam engine.

In Fossey's engine, the side valves are replaced by discs with radial perforations, which are put in slow rotary motion by gearing from tne fly-wheel shaft. A jacket is cast round the cylinder, with an interspace forming the passage from the cylinder to the reservoir. The apertures in the disc are sixteen in number, a corresponding series being formed in the cylinder ends, which are alternately opened and closed by the rotation of the disc in conformity with the motion of the piston. In the former position the external air is admitted, while in the latter the volume enclosed is driven over into the jacket and reservoir. In practice the use of the slide blast engine has not been found to be advantageous; owing to the large amount of mechanical effect consumed by the friction of the slide against the rubbing face of the cylinder, which would be great in itself, on account of the high speed at which they require to be driven, but is materially increased, owing to the dusty state of the atmosphere almost unavoidable in iron works.

In the ordinary form of engine with flap or clack valves it is necessary to provide as large an area of air ways as can be got out of the surface of the cylinder cover. The intake passages should be made, if possible, equal to one-half, and the outlet about one-eight, of the area of the piston. As it is impossible in large engines to use single valves of these dimensions, on account of their weight, and consequent liability to give rise to injurious shocks in working, it is customary, therefore, to employ a number of small valves, whose united areas make up the required amount of surface.

The question of the relative advantages of the horizontal and vertical blast cylinders has been discussed at considerable length by engineers, both in England and on the Continent. As in many other matters depending upon practical experience, there is much to be said on either side. For engines of small dimensions the horizontal form is cheaper, and may be worked with the least amount of clearance from the vertical position of the cylinder covers, which may be pierced through like a gridiron, giving a bearing for the valves, without any overhanging parts or valve boxes. The required foundations may also be less massive than in the vertical form, owing to the longer bearing of the framing, when a horizontal direct-acting steam-engine is the motor; this, of course, necessitates the comparatively larger surface for the engine-house. On the other hand, the difficulty of lubrication is increased, as the powdered graphite, which is generally used for this purpose, instead of being uniformly distributed round the pistons, is apt to fall to the bottom of the cylinder, while the upper side works dry, and the cylinder wall is worn irregularly, and becomes ovalised. The difficulty of keeping the weight of the piston off the bottom, and producing the same kind of unequal wear, is also urged against the use of large horizontal cylinders; but this objection which has also been applied in the case of horizontal steam engines, does not appear to be productive of any practical disadvantage in the larger modern engines used for screw propulsion, whose diameters are quite equal to those of the average of blast cylinders.

In regard to vertical beam engines the chief disadvantages are their very great length and expensive character of construction, and the extra amount of clearance, equal to the volume of the valve boxes, rendered necessary by the horizontal position of the cylinder covers; on the other, they have the great advantage of stability, and may be made of any dimensions; thus, in South Wales, engines are in use with blast cylinders up to 12 feet in diameter. In engines giving small volumes of blast at very high pressure, such as are used in Bessemer's process, the valves require to be made extremely light: the construction employed in such cases is a plain ring or plate of india-rubber covering a perforated plate, which opens and shuts by its own elasticity when exposed to, or relieved from, pressure.

In Coulthard's blast-engines the air passages are circular holes in the cylinder, similar to those used by Bessemer, but the valves are light wooden balls covered with india-rubber, which are arranged on inclined and grooved seats, sloping in a direction contrary to that of the current of air, so that when the pressure is sufficient to drive the balls up the incline the air way is opened; but as soon as it is relieved, they roll down again, and stop the passage.

The combination of the blast and steam cylinders, when steam power is used, is effected in various ways. The large vertical engines of modern date in this country are beam engines, the main bearing being supported either on the engine-house wall or on an entablature carried by cast-iron columns. The piston-rods are attached by the ordinary parallel motion. On the steam side, the beam is often continued beyond the point of articulation of the piston-rod, and turned upward into a short crane neck, to the end of which the connecting-rod working the fly-wheel is attached. This arrangement permits the use of a long light connecting-rod, without unduly increasing the surface occupied by the engine.

In Belgium, direct-acting engines with vertical cylinders are much used, the blast cylinder being placed uppermost. In an engine of this class built at Seraing, Evans's beam, with an oscillating center, is adopted, in order to keep the working parts within a comparatively small space, the length of the base of the engine-house being little more than the radius of the fly-wheel, or about 25 feet. The height, owing to the two cylinders being placed one above another, is considerable, being not less than 40 feet. The steam cylinder is 41½ inches, and the blast cylinder 66 inches; the length of stroke 88 inches. When working with steam of 30 lbs. pressure, and blowing air at 4½ lbs. above the atmosphere in sufficient quantity for a large furnace burning coke, the work done is equal to between 80 and 100 horse power. In the newer kind of engines built at the same works, the vertical direct-acting form is preserved, but the piston-rods are guided by sliding blocks instead of the older and more complicated arrangement of Evans.

In Austria a class of small direct-acting engines of the same character is used for charcoal furnaces, having the steam cylinder placed uppermost, which, together with the framing for the guides, is bolted on to the top flange of the blast cylinder. They are usually of small dimensions, averaging from 25 to 30 horse power, and delivers from 2,300 to 2,500 cubic feet of air per minute.

In Siegen, and other parts of Rhenish Prussia, horizontal blast engines are preferred. The commonest pattern has both cylinders placed in the same line; the rod which carries the two pistons goes through both covers of the blast cylinder, and is guided on either side. Usually two engines are coupled together upon the same fly-wheel, but the construction is such that they may be disconnected if only the power of one engine is wanted. For charcoal furnaces from 30 to 40 horse power is considered sufficient, but with the larger ones, working on coke, from 80 to 100 horse power is found to be necessary, as in other districts.

The same kind of horizontal engine is generally adopted in new works in Sweden and Lapland, having only a single charcoal furnace.

The working limits of blast pressure vary with the nature of the fuel employed, and the burden of the furnace, etc. Thus, in some of the small charcoal furnaces of Northern Europe, it does not exceed half or three-quarters of an inch of mercury above that of the atmosphere; while in American anthracite furnaces as much as 15 inches, or 7½ lbs., is used. In England 2½ or 3 lbs. is used with cold blast and tender fuel, but 3½, 4, or 5 lbs. is common with hard coke. In Bessemer's process of steel-making, by forcing air through a column of molten pig iron, a pressure of from 15 to 20 lbs. per square inch is used.

The largest blast engines hitherto constructed are those at Dowlais and Ebbw Vale, in South Wales; the former, which was erected by the late Mr. Truran, has a cylinder 144 inches in diameter, with the same length of stroke; the area of the admission valves is 56 square feet, that of the discharge valves 16 square feet, the former being equal to half the surface of the piston. The steam cylinder is 55 inches in diameter, with a piston making a stroke of 13 feet, the motion being transmitted by an unequal-armed beam. Owing to the large area of the air ways a very high speed, as many as 20 strokes per minute, can be obtained. The volume of blast delivered is about 51,000 cubic feet, at a pressure of 3½ lbs., sufficient for the supply of six large furnaces and four refineries. The main blast pipe is 5 feet in diameter. The Ebbw Vale engine has a blowing cylinder of the same size, but the steam cylinder is 72 inches in diameter.

The practice of blowing several furnaces by one engine of a large size, though mechanically advantageous, is attended with considerable risk, as the safety of the furnaces may be endangered in the event of a break-down, unless there be a reserve of blowing power. It is therefore preferable to divide the work between two or more engines, according to the number of furnaces in blast. Where there is only a single furnace, as is usually the case in charcoal-smelting, two small engines coupled together, but capable of being worked independently of each other, may be used, for the same reason.

The air or blast issues from the blowing cylinder in an irregular stream, owing to the variation in pressure at different points of the stroke, the supply being intermitted during the period of actual compression after the closing of the intake, and before the opening of the discharge valves. In order, therefore, to produce a steady current in the furnace, it is necessary to use some means of equalizing the pressure. This may be done either by receiving the blast into a reservoir whose volume is several times that of the blowing cylinder, or by delivering it into a second cylinder containing a loaded piston, which rises when the supply of blast is greater than the amount required by the furnaces; but when the quantity diminishes the piston falls, and exerts a compressing force, until the equilibrium is restored by increasing the speed of the engine. The same effect may be produced, with less loss from friction, by the use of a loaded bell, or gasometer, floating in a water tank.

Fixed reservoirs are usually made of wrought-iron formerly a spherical, or balloon-shaped form was commonly adopted, but they are now more generally made cylindrical, with flat ends like high-pressure steam boilers. The thickness of the plates, of course, depends upon the pressure and dimensions employed, as well as on the form adopted: from one-twelfth to one-eighth of an inch may be taken as sizes commonly used. The volume of the regulator may be from twenty-five to fifty times as great as the amount of blast in cubic feet delivered by the engine per second, when it is placed near the furnace, but this may be considerably diminished when a long blast main is used. Indeed, it often happens that sufficient uniformity can be got in the latter case, especially when several engines are used, by blowing into the main direct, without the use of a special regulator. Regulators in masonry or brickwork are usually lined with cement in order to protect the air from taking up moisture. A regulator of this character consisting of a chamber cut out in the solid rock, was applied at Devon Iron Works, in Scotland, as early as 1792.

The use of heated air in the blast furnace, which was first introduced by Neilson in 1828, has been found to be attended with a great economy of fuel, and at the same time the working power of the furnace is increased. It is therefore employed at the present day in iron-making districts all over the world, almost to the exclusion of cold blast, the latter being retained only for certain special makes which command an extra price, and may therefore be produced without the strict regard to economical considerations which is necessary when working on an article of lower repute.

The amount to which the temperature of the blast may be raised with advantage does not appear to have any practical limit, every fresh increase being attended with further saving of fuel; thus, in the first instance, 100° were found to be an advantage over air at the ordinary temperature; then came temperature of 200°—400°, up to the melting point of zinc; and now it is actually used at a visible red heat, or about 700°. Thus it was found that a saving was produced of 5 cwt. of coke per ton of iron made by using air heated to about 650°, instead of the lower temperature of 350° or 400°, previously employed. The difficulty of keeping the apparatus tight, and the rapid destruction of metal pipes when heated to redness in air, render a special construction necessary for the production of such extremely hot blast economically. The greater number of blast-heating apparatus in use at the present time, and known as *hot blast ovens* or *stoves*, consist essentially of a series of parallel, or spiral tubes, arranged in a chamber of fire-brick, and heated externally by a fire. The opposite ends of these tubes are connected with two mains intersecting them at right angles. One of these supplies cold air, while the other, or hot blast main, removes the heated air.

In the older forms of stoves, such as that originally adopted at Calder, in Lanarkshire, the fireplace is an oblong rectangle in plan. The two mains, which are placed parallel to the longer sides, are of a circular section, and cast with a number of circular sockets for the heating pipes. These are arched, horse-shoe, siphon, or inverted U pipes, also circular in section, placed with the arched portion upright, and luted into the sockets on the mains. The fire-grate runs along the whole length of the bottom, and the flame, after playing on the undersides of the tubes, passes between and around them, by means of appropriate flues, into the chimney, while the cold air, entering by the main on one side, flows continuously through the arched pipes, where it becomes heated, and passes off to the furnace by the opposite main.

To obviate the defects of this apparatus, many special modifications have been introduced. Thus, in order to get a greater amount of heating surface, the horse-shoe pipes are now usually made of flattened elliptical, or rectangular, instead of circular section. A smaller radius of curvature for the arch has been obtained by the use of inverted V pipes, and more uniformity in heating, by the introduction of stops at intervals in the entry main, so that the air is made to pass alternately backward and forward several times across the arch, instead of moving only in one direction, as was the case in the original form. Whatever system of construction is used, the air should pass through the apparatus in the reverse direction to the flame, entering cold, at the end farthest from the hottest point of the fire. Arch-headed pipes are very easily broken by irregular expansion at the crowns, if a certain freedom of motion is not allowed to the ends; this is equally provided against by placing one of the mains loose on its bed, supporting it by spherical bearings, so that it may travel outward to a slight extent as the pipes become heated.

Round and oval ovens have been introduced to obtain a more uniform heat than can be got by the old rectangular form. These terms refer to the shape of the base, or fire-place. The mains are replaced by a cast-iron box of a square or trapeziform section, divided by a central partition, one division corresponding to the cold, and the other to the hot blast main. The vertical pipes, instead of being arched at the top, are united by a short horizontal one, the limbs being close together. This variety is much used in Staffordshire and Lancashire.

A modification somewhat similar to the last, known as the *pistol pipe*, is used in Scotland, Cleveland, and other districts in this country, and is also rather in favor in France and Germany. The two vertical pipes or limbs are replaced by a single one, divided by an internal partition reaching nearly to the top. It is closed at the upper end, and is either straight, slightly bulbed, or bent over into a half arch. One of the divisions is connected with the intake, and the other with the exit, so that the cold air rises on one side, and passes through the bulbed chamber at the top, down the other, heated to the furnace. When the curved head is used, it is usual to place two series of pipes in opposite directions, with the heads, meeting so as to form an arch for mutual support; but, of course, the question of unequal expansion does not arise, as each half of the arch is independent of the other. The term pistol pipe is derived from the resemblance of the curved head to a pistol stock, the straight portion corresponding to the barrel.

All the preceding forms of stoves are characterized by the use of air ways presenting continual changes of form; thus the blast passes from the main through the heating pipes alternately backwards and forwards. In what are known as spiral-pipe ovens, the heating is effected in tubes of uniform section, arranged similarly to the worm of a still. Among these may be mentioned the apparatus in use at Ebbw Vale, a horizontal coil of cast-iron pipes exposed to a fire running the whole length of the axis. The pipes are formed in segments corresponding to one-half of a complete turn of the screw, and are united by ordinary socket joints. The union of the pipes and mains in stoves is always effected in the same manner, the latter being cast with sockets for receiving the ends or feet of the pipes, which are often made slightly conical, spigot fashion. The joint is made air-tight by rust cement.

Stoves with straight or serpentine horizontal pipes are much in vogue in Germany, and are known after the name of the works at Wasseralfingen, in Wurtemberg, where they were first introduced. In the original construction a number of straight pipes of circular bore, placed horizontally, extend from side to side of the walls of the fire chamber in a manner exactly similar to the tubes of a locomotive, and are united into a continuous serpentine coil by external arched bends not exposed to the fire. In this way the difficulty arising from the tendency of the pipes to break at the bends, owing to irregular expansion when heated, is avoided. The newer forms differ chiefly from the foregoing in the section of the pipes, which are now usually elliptical instead of circular. The position of the longer axis may be either horizontal or vertical; the latter, being the most advantageous arrangement, is usually adopted.

Thomas and Laurent's stove, used in several of the newer French furnaces, consists of three vertical tubes of a large diameter, united by external horse-shoe pieces placed externally, as in the Wasseralfingen apparatus. In order to obtain a larger heating surface, the inner side of the tube is studded with projecting radiating ribs about 3 inches high, the remaining interior space being filled with a cylindrical core of cast-iron or fire-brick. These ribs are not continuous in the same place throughout the entire height of the tube, but are interrupted at different levels, the series above and below being arranged so as to break joint with the central one. By this means the air is forced to travel in a somewhat deviating course through the passages enclosed between the core and the ribs. A very considerable heating effect is claimed for this arrangement, which is similar to that of the stoves known as "gill calorifiers," used for warming large rooms; but it is attended, owing to the irregular section of the air ways, with a notable loss of pressure from friction. In considering hot blast stoves, we have hitherto assumed that the heating of the air is to be effected by means of fuel burnt on a grate below the pipes. This is still done to a considerable extent, but the substitution of the waste gases of the furnace is now almost equally common, especially in furnaces using fuel brought from a distance. For this purpose it is necessary to bring a branch pipe to the stove from the main gas conduit, which terminates either in a series of jets, or more commonly in a rectangular mouth-piece, a special aperture of a similar character, for the admission of air, being placed immediately above or below. It is generally advisable to have a grate with a small fire, which insures ignition of the gases; without this, in case of the flame becoming extinguished, air would be liable to get back into the gas main, where it would most probably produce an explosion.

Pressure-gauges. For low-pressure blast, such as is used in small charcoal furnaces, or for determining the tension of the waste gases, a water gauge is generally used, but for the more highly compressed air used in furnaces on mineral fuel, mercury gauges are necessary. When the blast is at a very high temperature, it is necessary to make the observations as quickly as possible, or to cool the air down by passing it through a tube placed in a current of water, before allowing it to come in contact with the mercury. By multiplying the indications of the mercurial gauge in inches by 13.59, the corresponding height measured in water is obtained, and conversely, inches of water gauge may be reduced to mercurial inches by dividing by the same constants. When, as is usually the case, the height of the water gauge is expressed in feet and inches, it may be reduced to the corresponding pressure in inches and lines of mercury by multiplying by 0.882. The amount of blast passing through a twyer is found by multiplying the velocity of the current passing per minute or second, as deduced from the pressure, by its sectional area. The result, of course, must be corrected for temperature, atmospheric pressure, and moisture, and for the contraction of the jet at the point of efflux. The latter correction varies in amount with the form of the nozzle, and is somewhat greater for cylindrical than conical pipes, and also increases with the pressure employed. As a general rule, the diminution of volume from this cause may be taken at about 3 per cent., and the real amount found by multiplying the theoretical quantity by 0.92. The determination of the amount of blast carried into the furnace, from the observations given above, may be approximately found by the following formula, given by Weisbach, as a simplification of the more exact one deduced by him from Poisson's law, checked by actual experiment:—

$$Q = 1179F\sqrt{\frac{h}{b}} \times \frac{1.018}{(1 + 0003672\,t)^{\frac{1}{2}}} \qquad (1)$$

where Q = the number of cubic feet discharged per second, reduced to the temperature of 10° Centigrade, and 30 inches barometrical pressure, F = area of twyer, h = observed height of pressure gauge in inches of mercury, b = observed height of barometer. The second part gives the correction for the heat of the blast, when t = its temperature in Centigrade degrees.

In the first part of the above formula, F is taken in square feet, by dividing by 144, or, putting F = 1 square inch, we obtain the following expression:—

$$Q = 8.2\sqrt{\frac{h}{b}} \qquad (2)$$

which gives the volume of the blast per second per square inch of the sectional area of the twyer. The following table gives the value of Q for different values of the fraction $\frac{h}{b}$ in formula (2):—

$\frac{h}{b}$	Q	$\frac{h}{b}$	Q
0.01	0.82	0.30	4.49
.02	1.16	.35	4.85
.05	1.83	.40	5.19
.10	2.59	.45	5.50
.15	3.18	.50	5.80
.20	3.67	.55	6.08
.25	4.10	.60	6.35

These quantities require to be corrected for the temperature when hot blast is used by the second part of formula (1);

The quantity of air passing into a furnace may also be decided from the composition of the waste gases when the furnace works with a closed top, and the whole of the volatile products are collected.

Determination of the Temperature of the Blast. Mercurial thermometers cannot be used in determining temperature much above 200° or 250° with accuracy, owing to the irregular expansion of the mercury when very near its boiling-point. For measuring the high temperatures prevailing in blast furnace operations, metallic pyrometers of various kinds are employed, depending either on the expansion of a single metal, or a combination of two, such as iron and copper or platinum. These, although convenient, are liable to give inaccurate results after a time, from the metals becoming permanently expanded when repeatedly heated.

In practice the temperature of the blast is generally determined by its power of fusing metal. This is done by exposing a thin rod of the metal to the current in the tywer, a hole being made for the purpose in the elbow of the branch pipe connecting the twyer with the blast main.

The following are the reputed melting-points of the metals available for determining the temperatures of hot blast:—

	Degrees.
Tin	245
Bismuth	250
Lead	330
Zinc	410
Antimony	512

In experiments on the temperature of the interior of the furnace, such as those made by Tunner in Styria, and Rinman and others in Sweden, alloys of gold and silver, and silver and platinum, are used, the increase of the melting-point being assumed as directly proportional to the increase in the amount of the more refractory metal. This method was also used by Plattner in determining the temperature of slags.

Pouillet's pyrometric method, which consists in observing the increase of temperature produced in a weighed quantity of water by plunging into it a mass of metal, whose weight and specific heat are known, heated to the temperature to be measured, has also been applied to the construction of pyrometers for blast-furnaces; a ball of copper is used for medium, and platinum for higher temperatures. From the increase in the sensible heat of the water, the loss experienced by the metal may be found by the following formula:—

$$t' = \frac{w\ t}{w'\ s}, \text{ where}$$

w = weight of water, t = its increase of temperature, w' = weight of metal ball, s = its specific heat. To this result must be added the observed temperature of the water in order to get at that of the furnace.

Siemens' pyrometer, which is used to a considerable extent for measuring hot blast temperatures, is of this kind, and is thus described by the inventor:—

It consists of a portable vessel, formed of three concentric cylinders of thin copper plate, the space between the inner and middle one being filled with cowhair, and that between the middle and outer one with air, so as to prevent as perfectly as possible the loss of heat from the interior. A delicate mercurial thermometer is fixed in the interior of the vessel, being protected by a perforated shield, and furnished with a movable sliding-scale, showing pyrometer degrees, each of which is equal to 50° of the ordinary thermometric scale. For obtaining the temperature, balls of copper or platinum are used, which are so adjusted that fifty of them would be equal in thermal capacity to an imperial pint of water. Each ball is perforated by a hole, through which a rod is passed in exposing the same to the action of the heat to be measured. Immediately before using the instrument, an imperial pint of water is poured into it, and the slide is so moved that the zero point of its scale corresponds with the top of the mercury in the thermometer. The ball, after having been exposed to the heat for two or three minutes, is plunged into the water. The mercury will then be observed to rise, and the absolute measure of the temperature is obtained by adding the reading on the pyrometer scale opposite the new level of the mercury to the original temperature of the water before the ball was introduced. With a little practice very satisfactory results may be obtained with this instrument; but its application is limited to the heat at which the metal ball is deteriorated; nor can it be used for measuring the temperature of inaccessible places.

Another pyrometer, recently invented by Mr. Siemens, is based upon the property possessed by pure metals of offering an increased resistence to the passage of an electric current in proportion as their temperature increases. A platinum wire of known resistance is wound upon a helical groove on the surface of a cylinder of fire-clay, and enclosed within a cylindrical casing of platinum if the temperature to be measured exceeds the welding point of iron, or copper for lower temperatures. The two ends of the coil are brought endways, and are attached within the tube to thicker wires of copper, insulated for a short distance by a coating of pipe clay, and further on, when beyond the influence of the heated space, by india rubber or gutta percha. These wires communicate with the measuring instrument, which may be placed at any convenient distance. The latter is a specially constructed galvanometrical arrangement, and is so graduated that a reading in degrees on a divided scale may be at once obtained. These do not give an absolute measure of temperature, but the final result is taken out from a table calculated for each instrument. The pyrometer coil may be either fixed permanently, if it is desired to have a means of continuously determining the temperature of a particular place, or it may be introduced into the furnace through a door or other opening for a minute or two, which is sufficient time to obtain a reading. The latter is the only method available for very high temperatures; for by continuous exposure the protecting case, even when of platinum, would be ultimately destroyed. The electrical resistance of platinum wire is increased fourfold by a rise of temperature from 0 to 1650°.

It is in all cases desirable to place the stoves as near to the furnace as is consistent with the other requirements of the works, in order that the blast may lose as little of its acquired heat as possible, by not having to travel a long distance through pipes exposed to the air. In some instances, especially in small charcoal furnaces, where the stoves are heated by waste gases, they are placed on a level with the furnace top, the gases being led in by a short flue in order to economise their sensible heat, as well as the much greater quantity derived from their subsequent combustion. The hot blast main is then carried down vertically to the twyers. This practice is tolerably common in Swedish and German charcoal furnaces, and appears to be very general in the United States, where the blast-engine boilers are often carried on the top of high-vaulted structures in the same manner. Much greater regularity of draught, and especially freedom from choking by dust, can be obtained when the stoves are placed at the ground level, and the gases are brought down by a suitable conduit.

The blast coming from the stove passes through a ring main, which, in the old square-cased furnaces, is carried through the circular passage traversing the stack pillars; but in the newer forms is generally attached to the columns, surrounding the hearth at a certain distance above the ground. A vertical branch pipe, or *goose neck*, is led off opposite to each twyer hole, and at the proper level is turned over at right angles into a horizontal arm, to which the blast nozzle, or blowpipe, is attached. A throttle, or slide valve, for stopping or regulating the blast, is attached to each branch, as well as to the main near the stove. In cold blast furnaces the air is led through a conical copper nozzle, attached to a branch pipe by a flexible leather tube; but with hot blast it is requisite to make all the fittings of metal, and the necessary means of adjustment are provided by interposing a sliding or telescopic tube and a ball-and-socket joint between the end of the branch pipe and the twyer. By the former the twyer is set to the proper length, while the latter allows the direction of the entering blast to be varied, so that it be made level, plunging or rising at pleasure. When hot blast is used, it is necessary to protect the walls of the hearth from the intense heat generated by the energetic combustion going on immediately in front of the twyers. This is done by the use of water twyers, which are hollow, conical, or tapering D-shaped tubes, with double walls, which are kept cool by a current of water circulating through the interspace.

The number and arrangement of twyers vary very considerably. The smaller charcoal furnaces have often only two, placed on opposite sides of the hearth. Three is a more usual number, one being placed at the back; *i. e.*, opposite to the tymp, and the others at the sides of the hearth. When a larger number is used, they are generally placed at equal intervals all round the hearth. This method is usually adopted in cupola furnaces; but in South Wales, where there are many large furnaces with only three twyer arches, they are sometimes arranged in series; thus, two will be put through each of the side openings, and the same number at the back, or three at the sides, and one or two at the back, etc. This is done to avoid the use of twyers of an excessive diameter, and, by multiplying the points of contact with the fuel, to make the combustion more uniform over the entire area of the hearth. Sometimes a special twyer is added on the tymph side, for the purpose of removing irregularities caused by local cooling, and is only used in case of the hearth becoming obstructed.

In small charcoal furnaces, working with an open throat, the gases are often taken off by wrought-iron pipes perforating the wall of the furnace about 10 or 12 feet below the top. This plan is commonly used in Sweden for supplying gases to mine kilns, hot-blast stoves, etc., but can only be practiced on a small scale. The supply is apt to be somewhat irregular, from the stoppage of the holes by the descending charge. A more perfect method for the same purpose, is that of contracting the throat by the insertion of a cast or wrought-iron cylinder of somewhat smaller diameter than the ring-wall, so that an annular space at the top is kept clear the materials of the charge, and forms a connecting flue for the gases. In order to prevent the charges from blocking up the lower part, it is usual to increase the diameter of the shaft by the amount required to form the flue, and the tube restores the furnace to its original section.

When it is desired to collect the whole of the gases given off at the top of the furnace, it is necessary to work with a closed throat. The most generally used, and, at the same time, one of the simplest contrivances for this purpose is that known as the cup and cone. It consists of an inverted conical cast-iron funnel fixed to the top of the furnace, whose lower aperture is of about one-half of the diameter of the throat. An upright cast-iron cone is placed in the furnace below the cup; it is suspended by a chain attached to its apex, so that it may be raised or lowered at pleasure; in the former position it bears against the bottom of the cup, and forms an air-tight stopper, preventing the escape of any gas from the top of the furnace, which then finds its way out by proper passages through the wall of the furnace in the space above the charges enclosed by the cup; but when lowered it allows the charges in the cup to be dropped into the furnace, and at the same time acts as a distributer. Only the small amount of gas that is lost during the time of charging is allowed to escape, and as this operation is very quickly performed, the current through the mains is kept up with great regularity. The cone is suspended by an arch-headed lever, carrying a counterbalance at the end of the opposite arm. The rising or lowering is effected by a pinion, moved by a hand-wheel gearing into a segmental rack attached to the counterbalance weight. The gas passes through a lateral flue into a square wrought-iron main-pipe, or conduit, which distributes it to the various pipes feeding the boiler fires and hot-blast stoves. A modification of the cup and cone is in use in Cleveland, where the cone is replaced by an external cylinderical stopper, which is lifted during the charging time, and lowered when the throat is stopped, the object being to allow the charges to occupy the space which is necessarily kept empty for working the cone on the old system. It was found, however, that the working of the furnace was injured from the want of a proper distributer for the charges, on account of the absence of the cone; when this was supplied by suspending a conical ring by three chains to the bottom of the plug, regularity in charging was restored.

In the charcoal furnaces of Lake Superior and Styria, a charging barrow is used, which is constructed exactly in the same manner as the cup and cone. The body of the barrow is an inverted eight-sided pyramidal cup, the bottom being an upright cone, which, when dropped by a lever attached to its summit, leaves an annular space for the materials to pass out into the furnace, at the same time they are directed towards the circumference of the throat, in sliding over the surface of the cone. At Rhonitz, in Hungary, charging barrows are used having sliding cylindrical sides in addition to the dropping conical bottom, so that the charging takes place in a ring towards the sides of the furnace as well as at the center.

Büttgenbach's system of furnace construction originally adopted at Neuss on the Rhine, has been followed to some extent in France and Germany. In this neither red-brick nor sheet-iron casing is used, the stack wall being formed of single rings of moulded fire-bricks, with a few wrought-iron hoops. This is carried upon cast-iron columns, or brick-piers, the hearth being entirely independent and accessible on all sides. The charging platform is carried by the gas down-comer, which, instead of being a single large tube, is diverted into several smaller ones, which together form a kind of scaffolding to support the top of the furnace, part of it being carried by the stack wall, which is free to expand and contract under changes of temperature, as it is relieved from the downward pressure of the heavy structure at the top.

In a furnace at Schwechat, near Vienna, the stack consists of a single thickness of fire-brick hooped with iron rings, carried upon arches uniting piers of red brick-work 23 feet high, upon a base 40 feet square. The upper end of the stack is cased with sheet-iron for a height of about 12 feet, and the hoops are united together by flat bars of iron, forming a casing which, while it allows the bricks to be freely exposed to the air, is sufficiently strong to bear a part of the weight of the top of the furnace, the remaining support being given by the gas down-comers. The hearth has seven courses of water-blocks built into it between the twyers and the junction with the stack. These are flat cast-iron boxes covered with sheet-iron and open behind. Water is introduced by a pipe into the uppermost series, and flows downward through the lower ones; the cooling action tends to preserve the brick-work of the boshes from corrosion, especially when the ore contains much manganese. The gas brought down from the furnace top is received in a ring-shaped tube, partly filled with water and open at the side. The water is raised in the opening by the pressure of the gas, and forms an air-tight joint. The furnace is $61\frac{3}{4}$ feet high, $18\frac{1}{2}$ feet diameter in the boshes, and $7\frac{1}{2}$ feet in the hearth; the capacity is 9990 cubic feet, and the daily make 45 to 50 tons of Bessemer iron from the spathic ore of Styria.

In laying out new works at the present time it is usual to build the furnaces of a more or less skittle or tub-shaped section, all sharply contrasted slopes being avoided, the diameter increasing continuously from the throat to the boshes, and then being contracted in a similar manner down to the hearth-bottom, without having a cylindrical hearth. The form of the body of such a furnace is well represented by a common soda-water bottle, supposing the neck and the pointed bottom to be removed. In Scotland the same kind of section is used, with the addition of a broad cylindrical hearth. In Cleveland slightly-curved stacks, with conical boshes and cylindrical hearths, are the rule. In South Wales the latter conditions are often reversed, the lower part, up to the top of the boshes, being made conical, while the stack, which is for a certain distance cylindrical, is terminated by a strongly-curved dome. In all cases of the above, however, the hearths are of considerable breadth.

In French, Belgian, and German furnaces curved sections are less common than in this country. A more especial characteristic is, however, the small diameter of hearth generally adopted, the sides being brought in from the boshes in a strongly-curved convex sweep. This type, which is usually combined with an extremely massive construction of hearth, is very similar in form to an inverted claret-bottle, having the bottom and the greater part of the neck removed; the body, which increases from the bottom upward with a slight taper, representing the stack, the shoulder the sweep of the boshes, and the narrow neck the hearth. Swedish charcoal furnaces are generally of considerable height when compared with their diameter; the hearth and boshes form part of the same cone, usually very acute. The stack is either wholly or in part cylindrical. In Styria the charcoal furnaces used for smelting spathic ores resemble those of Sweden by their considerable height, as compared with the breadth and the steep slope of the conical parts, but are specially distinguished by their narrow throats, which often do not exceed $2\frac{1}{2}$ feet.

The height and other dimensions of blast-furnaces vary very considerably in different localities with the nature of the ores and fuel. No special rules can be laid down as to the form best suited for a particular class of ore, experience having shown that the requirements of each class are to be met by special arrangements. The most useful guide in the construction of new furnaces is furnished by the condition of those that have been blown out after working upon the same kind of ore. It was by comparisons of this kind that the modern barrel-shaped furnace was elaborated by Gibbons, in South Staffordshire, from the older conical form, the section of the newer furnace being modified wherever the action of the fire was found to be strongest: thus square hearths were burnt out to a circular form, and the sharp angle at the joining of the hearth and boshes was also removed. It was therefore apparent that, by altering these parts in conformity with the indications, a double advantage was attained, a certain amount of materials being saved, while the furnace was sooner brought to its best working condition than was the case when it had first to be cut into shape by the heat.

If we consider the nature of the work done in the blast furnace with reference to the amount of iron produced in a given time, it will be evident that an increase of such production can only be obtained from the same ores by passing a large number of charges through in the same time; this, however, depends upon the facilities possessed for withdrawing them by fusion at the bottom; for, however great the cubic contents may be, it is clear that new materials can only be supplied in proportion to the speed with which those charged before them are removed. The power of fusion is, however, to be measured by the space offered for combustion of fuel by the blast, and as in the best condition of work, this space should be confined as much as possible to the plane of the twyers, it follows that increase of space for more active combustion is to be got mainly by augmenting the width of the hearth. The amount of such an increase is to be determined by the power of the blast, which must be of sufficient tension to penetrate to the center of the hearth.

Greater height may be given to a furnace, either to increase its capacity, or to intercept more completely the enormous quantity of heat carried upward by the gaseous products of combustion. Strictly speaking, there should be no combustion of fuel, except in the region of fusion, and the space immediately adjoining, where the carbonic acid produced at the twyers is converted into carbonic oxide. The latter gas, and the nitrogen of the air consumed, are charged with the reduction of the oxides of iron in the ore to the metallic state, and the progressive heating of the materials in the upper region of the furnace. The greater the distance, therefore, of the upper end of the column of materials from the level of most active combustion, the more perfectly will the heat be abstracted from the gases; therefore, we might expect that the greatest economy of fuel would be found in the tallest furnaces, and this is practically the case, as exemplified in the newer furnaces in Cleveland, which have been successively increased from a height of 50 or 60 feet to 70 feet and upwards, in one instance attaining as much as 96 feet, with an increased saving of fuel in each case. Of course only the sensible heat is abstracted from the gases,—an amount that is quite independent of the further and much larger quantity that may be got by burning them in air.

The conditions limiting the height of the furnace are mainly due to the character of the ores and fuel, as regards their power of resisting crushing when exposed to the pressure of a tall column of materials, and the initial velocity of the blast. The favorable results given above, as obtained in Cleveland, are due to the extremely hard character of the coke employed, which, according to Bell, is capable of resisting a crushing strain of 5 cwt. per square inch. Very tall furnaces, therefore, can scarcely be used with tender fuel, such as soft charcoal, or coal, and pulverulent ores. Much of the anthracite of South Wales is in the same condition, as it decrepitates, and is apt to choke up the furnace, if not removed by an extra-powerful blast. The furnaces, therefore, worked with this fuel, though of large diameter, and provided with a great number of twyers, are usually of small height.

The time occupied in the descent of the materials from the throat to the hearth is chiefly dependent upon the capacity of the furnace. It is of the greatest importance that this should be so regulated as to insure an early commencement of the reduction of the ore to the metallic state at a low temperature, otherwise, in the event of protoxide of iron and silica coming in contact with each other in a more highly-heated atmosphere, a silicate is formed, which is easily fusible, but difficultly reducible, and, running down into the hearth, forms what is known as a scouring or black cinder, at the same time giving rise to white iron. The harder a furnace is driven, therefore, the greater is the tendency to deterioration in the quantity of the metal produced, owing to the quicker descent of the charges; and it will, therefore, be apparent that when an increased make is desired, larger furnaces should be used.

The difficulty of insuring uniformity of temperature in circular hearths of large character has led to the proposal of a more elongated form, such as an ellipse or oblong rectangle: the latter being adopted in Rachette's furnace, which was introduced in Russia a few years back, and has been tried experimentally in other parts of Europe. The oblong hearth is combined with a shaft, increasing regularly in diameter upwards, the section at the throat being from two and a half to three and a half times as large as that measured at the level of the twyers. The object of this arrangement, which gives a furnace similar in form to a calcining kiln, is to produce a more prolonged contact between the gases and the materials of the charge, by reducing the velocity of the upward current. The use of drying flues is another new feature in Rachette's furnace; these are a series of ramifying rectangular passages, traversing the outer casing of the stack at different levels, which are in connection with a similar chamber placed below the hearth. Before blowing in, a fire, placed in the chamber, warms up the whole of the masonry uniformly, and more quickly than can be done on the old system; afterwards the flues may be used for the reverse purpose of cooling the masonry by the circulation of cold air. The twyers, from twelve to sixteen in number, are arranged in two rows, breaking joint with each other, on the opposite long sides of the hearth; a dam and tapping place are provided on each of the short sides, so that the removal of slag and iron may be effected from either end.

In the simplest of the preceding cases the charge is dropped into the center of the throat, and forms a conical heap, sloping outwards to the circumference at an angle varying, with the nature of the materials, from about 35° to 40°, the latter being the maximum inclination of the talus formed by coke. Owing to differences of form and density, the fragments of ore and fuel take up different positions in the furnace, the former usually remaining in the place where they first strike the surface of the column, while the lighter and more voluminous masses of fuel roll down the slope until they have established a talus at the proper angle of repose. It will easily be seen, therefore, that this is the worst possible combination, the fuel being mainly distributed towards the circumference, where there is a comparatively free passage for the gases, while the ore remains in a dense column, impenetrable at the center, and descends without being properly heated. When coke is used, the friction of the fragments against the wall is so very great as to increase the tendency to form obstructions, or *scaffolds*, and their attendant evil. known as slips, when the charge falls, owing to the removal of the obstruction, by gradually increasing pressure from above, and by the removal of supports below. The ore in the center, by its greater velocity of descent, passes through the fuel charged before it, producing an inversion of charge, so that the slags change irregularly from white to black, according to the preponderance of the ore or fuel at the twyers.

When the charges are thrown in close to the circumference of the throat, the surface of the column of materials forms a conical cup, the lighter fragments rolling inwards towards the center, while the ore remains at the outside. The tendency is, therefore, for the fuel and larger masses of ore to collect in the middle, where it forms a column, which, on account of its ready permeability as compared with, the more densely-packed ore at the sides, gives a more equable draught over the entire horizontal section of the shaft, at the same time that the bulk of the ore descends slowly through the region of maximum heating by the gases, both conditions tending to uniformity of working and economy of fuel. When the throat is very wide, however, and the furnace low, the draught at the center may become too strong, leading to an unnecessary consumption of fuel by diverting the gases from the sides. The continual contact of metallic oxides has also an injurious effect upon the lining of the furnace, as the silica of the bricks is liable to combine with protoxide of iron, forming a fusible silicate, by which they are rapidly destroyed.

When a conical funnel or charging plates are used, the surface of the column in the furnace presents an annular ridge, sloping both towards the center and the circumference, the ores occupying the crest of the ring, while the fuel and larger blocks are intermixed at either side. This is by far the most favorable condition for uniform working, as then the charge and fuel are more perfectly mixed than by either of the preceding methods. The use of the movable cones below the funnel, is in the ordinary cup-and-cone arrangements, corrects the tendency to accumulations at the center, which is experienced when the charging funnel is too much contracted at its lower end.

Tapping. The molten metal accumulating in the hearth of the furnace is removed at regular intervals by tapping, or piercing a hole through the lower part of the dam, and allowing the metal to flow into the sand or cast-iron moulds placed in front of the furnace. Before tapping, the blast is shut off, and the tymp stopping removed. The tap-hole is opened by driving in the point of a wrought-iron bar, which is held by one man, while another strikes the end with a sledge hammer if necessary. The moulds, or pig beds, usually consists of a series of furrows in the sand of the casting floor, moulded by wooden cores of a D-shaped section. The curved side is placed downwards, and usually has the name or mark (brand) of the works attached to it. The moulds are arranged in parallel series on either side of a central feeder, known as a sow; and as soon as one series is filled, the current is allowed to flow into the next, and so on until the cast is completed. In Sweden cast-iron moulds are generally used instead of sand.

When the ore contains lead, a certain quantity may be obtained in the metallic state by tapping the hearth at the lowest possible point, or by making a hole below the hearth bottom, and collecting the metal which finds its way through the joints of the stones. In the latter case a small fire is kept burning in the hole to prevent the lead from solidifying, and it is then allowed to accumulate until a sufficient quantity has been obtained for a cast.

Blowing in. When a furnace is quite new, the whole of the masonry must be very carefully dried before it can be lighted. This may require several weeks, according to the state of the atmosphere and the nature of the materials employed. When perfectly dry the hearth is filled with wood, and the upper part of the furnace, to the top of the boshes, with coke, which is then lighted from below. As soon as the fire has burnt through to the surface a light charge of ore is given, which is repeated when the fire reappears at the top. Twelve hours after lighting, a grating of bars, carried by an external bearer laid across the rack plates of the hearth, is placed within the furnace, a little below the level of the tymp; the column of materials being thus supported, the cinders and ashes of the coke filling the hearth are then removed, and the air passing through the grate bars, revives the combustion in the upper part of the furnace. When the lower part of the mass is glowing, the bars are withdrawn, and the ignited materials are allowed to fall into the hearth. The fire is then slackened by stopping up the forehearth as before. The same process is repeated at the end of every twelve hours, or if it is desired to get the furnace in blast quicker, every six hours. As soon as the first charge gets down to the hearth the dam and twyers are fixed in position, and the blast is turned on, cold air, and nozzles of a reduced diameter, being adopted at first. The furnace is then filled to the throat, as if in regular work; but the weight of the charges, as well as the temperature of blast and diameter of twyers, must be gradually increased, so as to get to the proper burden in about seven or eight days. When several kinds of ore are at hand it is well to begin with the poorest, as for the same volume of charge the burden will be lighter. The above is the old method of scaffolding, which is still used in France. In England a more rapid plan is adopted. The top of the wood in the hearth is covered by a considerable quantity of coke, followed by alternate layers of coke and limestone, the latter for fluxing the ash of the fuel, until the furnace is one-third full. When the fire is well started, and small charges of ore are added, the blowing is commenced with twyers of a very reduced area. If properly managed, grey iron and clean cinders may be obtained from the beginning; but for this purpose it is essential not to increase the burden too rapidly, or to drive too hard at first.

Blowing out. When a furnace is to be put out of blast, it is advisable to reduce the charges as much as possible for a short time before, in order to get the hearth as hot as possible, so as to remove any metallic obstructions. The gas tubes, and all metal fittings of the throat, are then removed, and the charging being stopped, the contents of the furnace are entirely liquefied by the last charge of fuel. The last tapping must be made from as low a point as possible. The sides and bottom of the hearth are often found to be covered with masses of imperfectly-agglomerated malleable iron, the so-called bears, wolves, or sows, and isolated crystals, or even large masses of a copper-red compound, formerly supposed to be metallic titanium, but which has been shown by Wöhler to be a cyano-nitride having the composition $Ti\ C^2N + 3\ Ti^3N$.

Stoppage of Furnace. It may sometimes happen, through failure of the blast engine, or a deficiency of materials, that a furnace must be stopped for some time. This is done by closing up the throat and all the twyer holes hermetically with sand or clay. If the charges have been previously diminished to a certain extent, so as to keep a good body of fuel in the furnace, it may be stopped for about a week without serious inconvenience; but if the blast be interrupted for a longer period, the cooling takes place to such an extent that the furnace becomes blocked up, and would probably be obliged to be abandoned.

The greatly-increased production of modern, as compared with older furnaces, is due partly to their much larger size, and partly to more rapid driving, produced by giving more blast. No general rule can be laid down as to the time necessary for complete reduction of the ores previous to their actual fusion and the separation of metal and slag by liquation, as it is obviously dependent upon many variable elements, such as the greater or less density of the ores and fuel, the richness of the former, whether they are readily reducible, or have a tendency to scorification, etc. This point must, therefore, be determined by actual experiment for each particular furnace, by varying the amount of blast and the burden of ore and fluxes, until the particular result required, either in respect to quality or quantity of produce, is obtained. Other things being equal, the time of reduction will be lessened the more perfectly the materials are exposed to the action of the upward gaseous current. It therefore becomes of the greatest importance to render the flow of gases as uniform as possible throughout the mass, by the use of proper charging and gas-collecting appliances. Especial care must be taken that no hindrance is offered to the free efflux of the current at the top of the furnace. For this reason, these methods, based upon the collection of the gases above, or in the center of the charge, are to be preferred to such as employ lateral flues, penetrating the wall below the level of the throat, whereby the current is diverted, without being allowed to give up its heat to the upper part of the column of materials above the flues. An increase in the volume of blast, keeping the pressure constant, has a tendency to put the furnace on white iron. By increasing both pressure and temperature, on the other hand, especially with refractory ores, greyer or more highly-carburised iron is likely to be produced.

The nature of the work done by blast-furnaces can only be understood by examining the conditions of production prevailing in different districts. The following example gives some of the working details of a furnace selected merely for the purpose of illustration.

At Eisenerz, in Styria, the furnaces consist of two truncated cones, with a very narrow throat, and are distinguished from the ordinary blast-furnace by being without a fore-hearth, the metal and slag being allowed to collect in the hearth, which is comparatively shallow, and are tapped off together at short intervals, the number of casts varying from 5 to 16 in twenty-four hours. The ores are chiefly spathic, poor in manganese, partly pure, and partly altered into brown hematite. In order to get rid as completely as possible of the sulphur due to the presence of pyrites in small quantities, they are allowed to weather for two, three, or more years after roasting. The amount of iron varies from 35 to 55 per cent. The object sought to be attained is the production of white iron, for conversion into bar iron, from rich and easily-reducible ores, with a minimum expenditure of fuel (charcoal). This is done by working under a very heavy burden, the tendency to obstructions caused by this proceeding being counteracted by giving charges of fuel alone at regular intervals. Some varieties of ore are of the self-fluxing kind; but as a rule they contain a considerable quantity of lime, requiring the addition of siliceous and aluminous fluxes, such as clay or clay slate. The following are the charges and yields of two furnaces, taken as a sample :—

1. *Von Fridau's Furnace, Vordernberg.* The charge consists of 5 to 6 cwt. of roasted ore, 10 per cent. of clay, and 8 to 10 lbs. of washed metal, *i. e.* granulated pig iron, recovered from the slag by stamping and washing. The fuel is measured; 2 tubs, or 15$\frac{1}{2}$ feet, or about 101 lbs. of soft pine-wood charcoal being employed per charge. The burden of ore is gradually raised from 3 to 6 cwt. per charge, and then diminished similarly, a blank charge of fuel being given at each change. The daily production is from 18$\frac{1}{4}$ to 20 tons. The twyers plunge or incline at an angle of 5°, so that the furnace fulfils, to some extent, the functions of a refinery.

2. *Von Fischer's Furnace, Vordernberg.* This is one of the smallest furnaces in the world. The usual charge includes 223 lbs. ore, 15 lbs. clay, and 4 lbs. of washed metal, to 1$\frac{3}{4}$ tub (13$\frac{3}{4}$ cubic feet or 95 lbs.) of charcoal. The daily production is 7$\frac{1}{4}$ tons; the furnace is tapped at intervals of one and a half hours, fourteen charges being made during the same period, including a blank one, *i. e.* of fuel without burden.

These furnaces are driven at a very high speed. The first tapping takes place twelve hours after lighting, and afterwards at intervals of two to two and a half hours. The burden of ores smelted per tub of 7$\frac{3}{4}$ feet of charcoal varies from 170 to 220 lbs. with cold, and from 220 to 250 lbs. with hot blast. The consumption of charcoal is from 65 to 70 per cent. of the weight of the metal produced, or from 13$\frac{1}{2}$ to 14 cwt. per ton. See *Steel.*

STEVENS GUN.—Messrs. J. Stevens & Co. of Chicopee Falls, Mass., have obtained a special reputation for their sporting-arms. Fig. 1, represents the combined central-fire rifle and shot-gun, the shot-barrel fitting in the same stock. Fig. 2, represents the new model Hunter's Pet, which is much used as a *pistol-carbine*, and for accurate shooting at short range. This arm weighs from 2 pounds for a 10-in.

Fig. 1.

Fig. 2.

barrel to 2$\frac{3}{4}$ for an 18-in. A heavier pattern weighs about 5$\frac{1}{4}$ lbs., and is good for all shooting up to 40 rods.

The Stevens' shooting-gallery rifle is a specialty and challenges the world. There are more of them used in shooting-galleries than of all others combined. The Austin Bros., Boone Bros., Frayne Combination, Capt. Joe Rambolt and wife, Baughman and Butler, Buffalo Bill, Wild Harry, Fanny Herring, and others always use them when shooting apples from the heads of each other. In some cases the marksman points the rifle over the shoulder, and takes aim by the reflection in a small looking-glass before him. They give this rifle decided preference over all other weapons in performing these dangerous feats.

The Stevens gun can be easily taken apart and carried in a valise or trunk, which is a great advantage over other styles. This point is greatly appreciated by those who travel long distances, as the arm once carefully packed with other traps, needs no further attention until required for use. This is a strong point with all the Stevens arms, viz.:—their great portability. Another good feature is, unless specially ordered otherwise, they are all chambered for the ordinary rim-fire ammunition, which can be had in any village in the land. Absolutely no traps at all are required except a wiping-rod, which should be frequently used with a woolen rag wet with oil to keep the barrels in the best condition for fine shooting.

STEP.—In a military sense, step signifies pace, or progression by one removal of the foot. The term is also figuratively used to signify promotion; thus, the *step* from a Lieutenant to a Captain, and so on to higher grades. To *step out*, is to lengthen the step, without altering the cadence. To *step short*, is to diminish or slacken the pace, according to the tactics. These phrases are frequently used in military movements when it is found necessary to gain ground in front, or to give the rear of a column, etc., time to acquire its proper distance. *Balance-step*, is so called from the body being balanced upon one leg, in order to render it firm and steady in military movements, etc.

In the United States Service, the length of the direct step, in common and in quick time, is twenty-eight inches, measured from heel to heel; and the cadence is at the rate of ninety steps per minute for common time, and one hundred and ten steps for quick time. The principles of the direct step are taught by means of the *balance-step*; during its execution the Instructor requires the recruits to keep the body, shoulders, arms, and hands in the position of a soldier.

The Instructor commands: 1. *Balance-step*, 2. *Left foot*, 3. FORWARD, 4. REAR, 5. HALT. At the command *forward*, bend slightly the left knee, and carry the left foot, without jerk, about fourteen inches to the front, the knee straightening as the foot is brought forward, the toe turned out and slightly depressed, the sole of the foot about three inches from the ground the body balanced firmly on the right foot, and inclining slightly forward. At the command *rear*, carry the left foot, without any jerk, to the rear, the knee slightly bent, the toe on a line with the right heel, and inclining slightly downward. The steps may be continued by alternating the commands, *forward* and *rear*. At the command *halt*, given after the command *rear*, plant the foot by the side of the other. The balance-step with the right foot is similarly executed. To execute the balance-step, gaining ground to the front, the Instructor commands, 1. *Balance-step*, 2. *Left foot*, 3. FORWARD, 4. GROUND, 5. HALT. At the command *forward*, advance the left foot as previously explained, at the command *ground*, plant it without shock, the foot advancing as the weight of the body is brought forward, the left heel twenty-eight-inches from the right; the right foot is then advanced without command to the position of *forward*, and similarly planted at the word *ground*. The movement is continued by the command *ground*, until the command *halt*, when the foot in advance is planted and the one in rear brought to the side of it. The command *ground*, is at first given in very slow cadence to allow each recruit to balance himself on the foot that is planted, and is afterward gradually increased to common time.

The principles of the balance-step being thoroughly understood, to march in the direct step, the Instructor commands: 1. *Forward*, 2. *Common time*, 3. MARCH. At the command *forward*, throw the weight of the body upon the right leg without bending the left knee. At the command *march*, move the left leg smartly, but without jerk, carry the foot straight-forward twenty-eight inches from the right, measuring from heel to heel, the sole near the ground, the toe a little depressed, the knee straight and slightly turned out; at the same time throw the weight of the body forward, and plant the foot without shock, the weight of the body resting upon it; next, in like manner, advance the right foot, and plant it as above; continue the march, without crossing the legs or striking one against the other, keeping the face direct to the front. The Instructor indicates from time to time the cadence of the step by calling out, *one, two, three, four;* or *left, right*, the instant the left and right foot, respectively, should be planted.

Being in march, to shorten the step, the Instructor commands: 1. *Short step*, 2. MARCH. At the second command the length of the step is reduced to fourteen inches, the squad resuming the full step at the command: 1. *Forward*, 2. MARCH. Being in march to mark time the Instructor commands: 1. *Mark time* 2. MARCH. At the second command given the instant one foot is, comingto the ground, continue the cadence and make semblance of marching, without gaining ground, by alternately advancing each foot about half of its length, and bringing it back square with the other. To resume the direct step the Instructor commands: 1. *Forward*, 2. MARCH. Being in march, to change step, the Instructor commands: 1. *Change step*, 2. MARCH. At the command *march*, given the instant the right foot comes to the ground, the left foot is advanced and planted; the hollow of the right is then advanced against the heel of the left, the recruit again stepping off with the left. The change on the right foot is similarly executed, the command *march* being given when the left foot strikes the ground. Being in march, to march to the rear the Instructor commands: 1. *To the rear*, 2. MARCH. At the command *march*, given as the right foot strikes the ground, advance and plant the left foot: then turn on the balls of both feet, face to the right about, and immediately step off with the left foot.

Being at a halt to side step, the Instructor commands: 1. *Side step to the right* (or *left*), 2. MARCH. At the command *march*, carry the right foot six inches to the right keeping the knees straight and the shoulders square to the front; as soon as the right foot is planted, bring the left foot to the side of it, and continue the movement, observing the cadence, until the commands: 1. *Squad*, 2. HALT. Side steps are always executed in quick time, unless common time be specified. Being at a halt to back step the Instructor commands: 1. *Backward*, 2. MARCH. At the command *march*, step off smartly with the left foot fourteen inches straight to the rear, measuring from heel to heel, and so on with the feet in succession till the commands: 1. *Squad*, 2. HALT. At the command *halt*, bring back the foot in front to the side of the one in rear.

The length of the double step is thirty-three inches; the cadence is at the rate of one hundred and sixty-five steps per minute. To teach the principles of the double step, the Instructor commands: 1. *Double step*, 2. MARCH. At the first command, raise the hands till the forearms are horizontal, fingers closed, nails toward the body, elbows to the rear. At the command *march*, raise the left leg to the front, bending and then elevating the knee as much as possible, the part of the leg between the knee and instep vertical, the toe depressed; replace the foot in its former position, and execute the similar movement with the right leg. The Instructor, placing himself seven or eight yards in front of the recruit and facing him, indicates the cadence by the commands, *one, two*, given alternately as the left and right foot touch the ground, beginning in common time, and increasing gradually to double time. The alternate movement of the feet is continued till the commands: 1. *Squad*, 2. HALT. At the command *halt*, bring the foot, which is raised, by the side of the other, drop the hands, and resume the position of the soldier.

The recruit being established in the principles of the step the Instructor commands: 1. *Forward*, 2. *Double time*, 3. MARCH. At the command *forward*, throw the weight of the body on the right leg; at the second command, raise the hands until the forearms are horizontal; at the command *march*, carry forward the left foot, the leg slightly bent; the knee somewhat raised, and plant the foot, the toe first, thirty-three inches from the right; then execute the same motion with the right foot; continue this alternate movement of the feet; throwing the weight of the body upon the foot in advance and allowing a natural swinging motion to the arms. The double step under urgent circumstances may be increased to one hundred and eighty steps per minute. At this rate a mile can be passed over in ten or eleven minutes. The recruits are also exercised in running, the principles being the same as for double time.

In marching in double time and at the run, the men breathe as much as possible through the nose, keeping the mouth closed; experience has proved that, by conforming to this principle, men can go much farther with less fatigue.

Recent and interesting experiments in cadence and step have been made at West Point by Colonel H. C. Hasbrouck, U. S. Army. The Cadets at the Military Academy are arranged according to size throughout the battalion; the files on the outer flanks of the flank companies are over six feet, and on the inner flanks of the center companies about five feet in height.

Measurements of the cadence and length of step were taken many times for each company and under all circumstances, in column of fours and platoons, with right and left in front, in line, maneuvering, and marching in a straight line over a measured course of 300 yards, and at quick and double time; also with and without music by the Academy Band. As it was supposed possible that a step that was suitable and natural for the active but not yet fully developed young gentlemen that compose the Corps of Cadets might not do for the soldiers of the Army, measurements of the cadence and length of step of a Company of Engineers, a very well instructed and fine appearing Company were also taken.

The results obtained were as follows:

Battalion of Cadets.	
Average length of step, quick time	30″.2
Slowest cadence, quick time without band	115
Shortest step, quick time	28″.6
Longest step, quick time	31″.3
Slowest cadence, quick time, without band	109
Fastest cadence, quick time, without band	119
Average cadence, quick time, with band	120
Average length of step, double time	37″.2
Average cadence of step, double time, without band	184
Shortest step, double time	35″.5
Longest step, double time	38″.9
Slowest cadence, double time, without band	181
Fastest cadence, double time, without band	188
Average cadence, double time, with band	180
Company of Engineers.	
Average length of step, quick time	31″.5
Average cadence of step, quick time	120
Average length of step, double time	37″.
Average cadence of step double time	178

It will be noted that the shortest step taken in quick and double time is longer than the step prescribed in the Tactics. The slowest cadence viz., 109, was made in marching against a very high wind. It is believed that an increase in the length and cadence of the step, in both quick and double time, is desirable. Probably, a length of 30″ and cadence of 120 for quick time; and a length of 36″ and cadence 175 for double time, would be a great improvement and would prove practicable and suitable for all the men in service.

STER HYDRAULIC PRESS.—A press in which a powerful hydrostatic pressure is obtained by introducing into the cylinder of a hydraulic-press already filled with liquid, not an additional amount of liquid by successive impulses, as in the case of the hydraulic-press, but a solid substance, usually a solid cord, by a steady, uninterrupted movement.

STERRO METAL.—An alloy used in gun-making. It derives its name from the Greek word signifying "firm." It consists of copper and spelter, with very small portions of iron and tin; and to these latter its peculiar properties are attributed. It has a brass-yellow color, is close in grain, is free from porosity, and has considerable hardness, whereby it is suitably adapted to bearing-metal, or to other purposes, where resistance to friction is needed. *Sterro-metal* possesses another quality, which, in reference to its application for guns, is regarded as more important than its high tenacity, namely, great elasticity. The inventor proposes that, in heavy ordnance, the interior should consist of a tube of *sterro-metal*, and, over this, wrought or cast-iron should be shrunk from the breech to beyond the trunnions. The following is the composition, as given by Baron Rosthorn, of the Imperial Arsenal, the inventor:

Copper	55.04	or	57.63
Tin	0.83		0.15
Zinc	42.36		40.22
Iron	1.77		1.86

It differs from *Keir's metal*, mainly in having a small quantity of tin.

STETSON MAGAZINE-GUN.—This rifle has a fixed chamber closed by a movable breech-block, which slides in the line of the barrel by indirect action, being moved by levers from below. The arm resembles externally, in its operation, and in many of its features, the Winchester. It is locked in the act of closing the lever-guard, by a projection on the bolt being thrown upward in front of a shoulder in the upper portion of the frame. The empty shells are ejected through the same lateral opening by which the magazine is charged. It is provided with a cut-off for the magazine, by which it can be reserved for an emergency while the arm is being used as a single-loader.

STICKLER.—A sidesman to fencers, or second to a duelist.

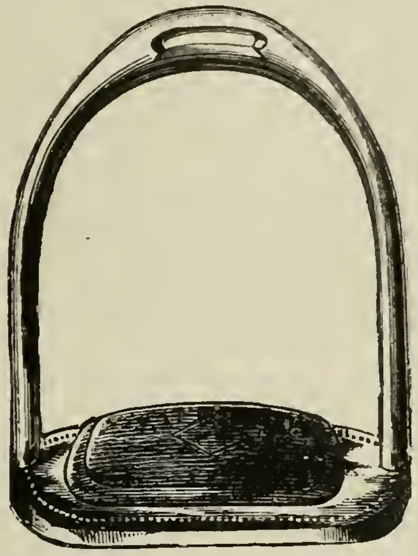
STILETTO.—A small poniard which came into use during the Middle Ages, and which is of common use even at this day. The blade is round and pointed.

STILLMAN MAGAZINE.—The comb of the butt-stock is counter-bored for four musket cartridges. They are kept in place by a lid swinging backward, which is kept open when raised, and shut when closed by a flat spring which bears on corresponding flat surfaces on the hinge. When the lid is raised the cartridges are kept from accidentally falling out by copper bushings, as in the *Benton magazine*. This magazine has been modified so as to allow the lid to swing sidewise in opening.

STINK POT.—In warfare a shell, often of earthenware, charged with combustibles, which, on bursting, emit a foul smell and suffocating smoke. It is useful in sieges for driving the garrison from their defenses; also in boarding a ship, for effecting a diversion while the assailants gain the deck. The stink-pot is a favorite weapon of the Chinese. Under the more elegant title of Asphyxiated-shell, the French and other modern nations have experimented considerably on this mode of harassing the enemy. Also written *Stink-ball*.

STIRRUP.—The iron hoop fastened to the saddle by a leather strap, to enable the rider to mount and dismount, and support his foot while in the saddle. The present English stirrups are similar to those attached to a hunting-saddle. The stirrup-irons are made of shear-steel. The lance-stirrup has a leather bucket attached to it, for the butt of the lance. The stirrup was not used till the 14th century. Its shape has varied very much, according to the time and the people. At first it was only a strap, to which was subsequently added a flat piece of wood or metal; and afterwards it was of a triangular shape, as may be seen in the frescoes of the Cathedral of Brunswick. The stirrups used in battle in the 15th century, which took the place of the *soleret*, were closed at one end so as to prevent the passage of the foot.

The drawing represents the Whitman stirrup, which



possesses the advantage of keeping the rider's foot in place by means of a solid rubber mat. See *Saddle*.

STOCCADO.—A push or thrust with a rapier.

STOCK.—1. A term variously applied in ordnance to signify the nave of a wooden wheel, the handle of a tool, the whole of the wooden part of a rifle or pistol, a part of the gun-carriage, etc. 2. The usual neck-gear of a soldier in some armies, generally made of black leather, answering the double purpose of keeping the cold out and the soldier's head up. The stock is not worn by the enlisted men in the United States Army, but is worn by Cadets. See *Cravat* and *Gun-stock*.

STOCKADES.—A line of stout posts or trunks of trees firmly set in the ground, in contact with each other, and arranged for defense. A stockade is used principally when there is plenty of timber and little or no danger of exposure to artillery fire. It is frequently used to close the gorge of a field-work, and to guard against the work being carried by a surprise, by bodies of infantry attacking the work in rear. The timbers of a stockade may be either round or square. When round, they are hewed to a flat surface on two of the sides so that the posts, when placed in position, shall have a close contact of at least four inches. The top of a stockade should be at the least eight feet above the ground on which it is placed, and it should have the upper ends of the timbers sharpened (Fig. 1), arranged with spikes, or fixed in some way to offer an obstruction to climbing over the top. A stockade is arranged for defense by cutting loop-holes, which can be used by a soldier when firing. The height of the loop-hole may be just four feet and six inches above the ground, or higher. In the former case, the soldier stands upon the natural surface of the ground in the act of firing; in the latter case, he stands upon a banquette of earth or some temporary arrangement which raises him to the proper height. The exterior opening of the loop-hole should be not less than six feet above the ground on which the enemy may stand when he is close to the stockade, so that he can not make use of the loop-hole. Some obstruction must therefore be placed in front of the loop-hole, keeping the enemy away from it; or the ground immediately in its front should be deepened by digging a trench. If the loop-hole can be placed six feet above the ground, it will be practicable to arrange the loop-holes so as to furnish a double tier of fire.

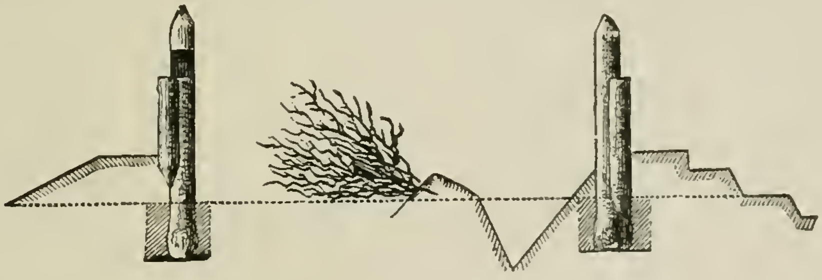


Fig. 1.

The loop-holes of the lower row should be arranged so that they cannot be used by the enemy. They should not be higher than eighteen inches above the ground on the outside; on the inside, the ground must be cut away or a trench dug in rear of the stockade, so as to allow the use of the loop-holes by the defense. The stockade is frequently strengthened by a second row of timbers, as shown in Fig. 2. In this drawing, is seen the method of making loop-holes, by cutting away a strip from two adjacent posts, leaving an interval through which the men can fire. Loop-holes are usually made about two feet and six inches apart. See *Accessory Means of Defense*.

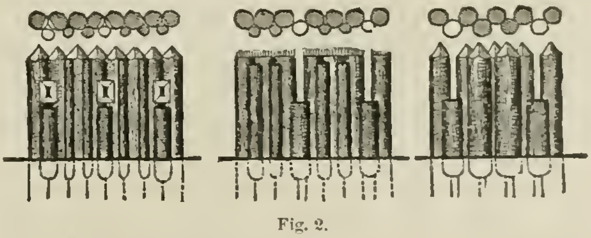

Fig. 2.

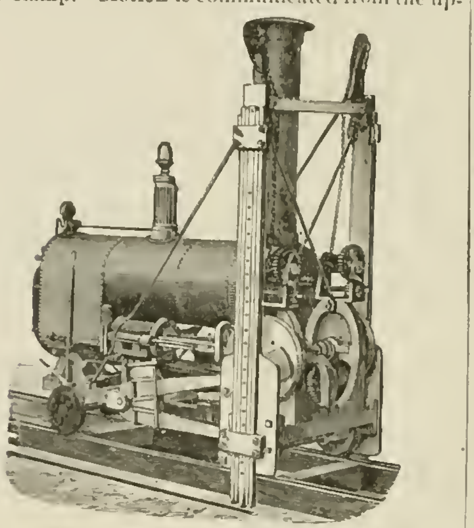
STOCK-PURSE.—In the British Service, a certain saving which is made in a corps for regimental purposes.

STONE-BOW.—A cross-bow which was formerly used or designed for throwing stones.

STONE-CUTTING.—The plans as at present adopted by Military Engineers, for constructing permanent fortifications, require a thorough knowledge of the art of stone-cutting. Stone, as employed for military purposes, is a substance which in none of its varieties is easily operated on by machinery, owing chiefly to its brittleness, its unequal hardness, and the natural cracks which so frequently impair its solidity. Accordingly though many ingenious machines have been invented for working stone, it is as yet only in some of the plainer kinds of work that they can be said to have entirely superseded hand operations. Some stones and slates are soft enough to be cut with ordinary toothed saws much in the same way as wood is cut. More generally, however, the sand-saw is employed, which we shall presently describe in noticing marble cutting. For the cutting of common kinds of stone, which are not to receive a fine polish, a machine, which promises to be very efficient, has been recently patented by Mr. George Hunter, of Maentwrog, Caernarvon, and is now in operation at various large quarries, both of stone and slate. The cutting portion consists of a circular disk, round the circumference of which a number of pointed steel tools are fixed into sockets, thus giving it the appearance of a large toothed saw. This machine will cut sandstone at the rate of 5 to 6 in., slate at 3 in., and soft limestone at 3 in., per minute, supposing these to be in blocks each 2 ft. thick.

The American Wardwell double-gang machine, extensively used and adapted for every kind of stone, except grit-sandstone, is represented as mounted upon a steel rail track on the bed of the quarry. The frame which supports the boiler, engine and other machinery consists of one piece of forged iron, weighing nearly a ton, thus furnishing great durability. The engine is of six horse power, its shaft carrying a balance wheel on each end to which is attached an adjustable wrist-pin plate. The levers which operate the gangs of cutters are pivoted at their rear ends to an extension of the frame. The free end of the upper lever passes through a sliding-stirrup, or swivel attached to the wrist-pin plate (not shown) giving an up and down motion to that end of the lever, as the balance-wheel revolves. The free end of the lower lever passes through a mortise in the back side of the lower clamp. Motion is communicated from the up-



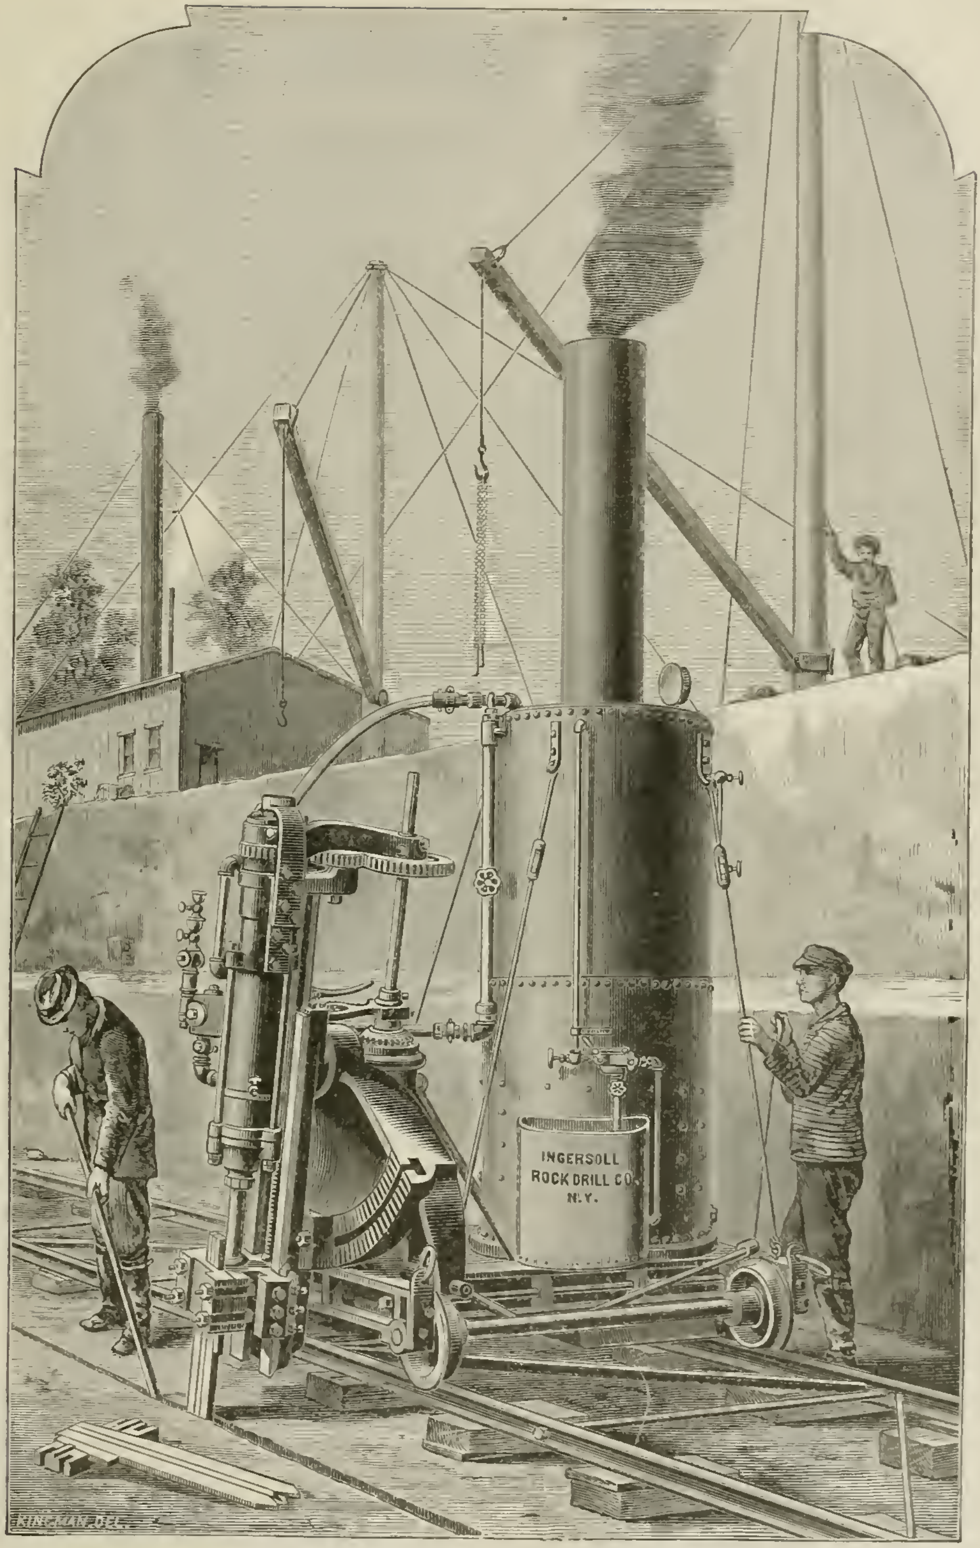
Wardwell Double-gang Machine.

per to the lower lever by means of clasps, between which the rubber springs are placed, as shown in the drawing. The free end of the lower lever actuates the gang of cutters, which consists of five bars of the best cast-steel, sharpened at their lower ends, and clamped together by head and foot clamps; the whole sliding freely on the standard. Of the five cutters, two have diagonal cutting-edges and three have their edges transverse. The center cutter extends the lowest and they altogether form a stepped arrangement each way from the center; thus when the machine is moving forward the three cutters, which includes the center one, operate, and while moving in the opposite direction the other two with the center one perform the work. The object of the diagonal cutting edges is to insure an even bottom to the channel. These bars of steel are from seven to fourteen feet in length, according to the depth of the channel to be cut. The upper end of these bars are grooved to match corresponding grooves in the head clamp, for the purpose of preventing displacement of the cutters. The worm on the main-shaft actuates the worm-gear upon the feed-shaft. The feed-shaft extends diagonally downward to the rear of the machine, where it terminates in a bevel-pinion: upon the rear axle are placed two bevel-gears. By means of the lever shown, either of these bevel-gears may be thrown into action with the pinion. It will be readily understood that the motion thus communicated, serves to turn the axle either backward or forward, according to which wheel engages the pinion. When the machine is required to be stationary these bevel-gears are so placed as not to engage with the pinion. The short lever locks these bevel-gears in either of the desired positions. The windlasses on each side of the machine are for changing the gangs.

So far as sawing or slicing of stones is concerned, the great tendency of late years is to rely on the use of the diamond—the black variety which is of no use as a gem. Some American stone-cutting machines have saws with teeth set with these diamonds, and are said to cut ordinary sandstone at the rate of 75 sq. ft. per second for each saw. Machines for dressing the face of stones by means of a series of chisels, in imitation of the handiwork of the mason, have recently been tried and have given fair results. It is considerably more than a century since machinery for sawing and polishing marble were first established at Ashford, near Bakewell, in Derbyshire, that country being still the seat of the principal marble manufacture of England. Marble is cut into slabs by means of a series of thin plates of soft iron used like saws, but having no teeth. The saw-blades are fixed into a rectangular frame, to which a reciprocating horizontal motion is given. The block of marble to be cut rests on a carriage below the frame, and a small rill of mixed sand and water is constantly falling into the saw-cuts. After the marble has been sawn into slabs it is cut up into narrow pieces, when so required, by means of small circular saws with smooth edges, sand and water being employed as above. The sawn slabs are next submitted to the grinding process. This, for pieces of moderate size, is usually done upon a large circular cast-iron plate, called a *sanding-bed* or *grinding-bed*, mounted upon an upright spindle, and supplied with sand and water. The workman places the piece of marble with its face downward upon the grinding-bed, and exerts the proper amount of pressure. The marble is held in its place by means of guide-rods stretched across the plate. Slabs too large to be manipulated in this way are ground with plates of iron operating upon their surface.

Cylindrical objects, such as columns or vases, are first formed roughly into shape with a hammer and chisel, and then turned, with a pointed steel tool, upon a lathe, to which a slow motion is given. When thus brought to an accurate form, a rapid motion is given to the lathe, and the tool-marks ground away by the use of coarse, and then fine, and still finer sandstones—the polishing being completed with emery and putty-powder while the object is still upon the lathe. Machinery is also applied to the production of flat objects with curved and molded outlines. The machine for this purpose operates by the use of a rotatory cutter, which is guided in its action by a template formed accurately to the intended shape of the article. The cutter is of steel or stone, and is attached to the lower end of a spindle driven by beveled wheels. There is a flange which allows the cutter to penetrate the marble till it reaches the template and no further. In the process of cutting, the marble is constantly drawn up against the cutting-tool by two weights, the one pulling the table in one direction, the other the carriage on which the table rests, in a direction at right angles to the former, thus compelling the cutter to follow the outline of the template. The shape of the cutting-tool is, of course, exactly the reverse of the moulding to be formed.

In the cutting of granite, the machinery and processes are so nearly the same as those employed for marble, that it is unnecessary to describe them separately. Suffice it to say, that all objects to which the sawing apparatus cannot be applied, require to be worked to shape with great care by means of steel chisels and iron mallets, which only remove a small

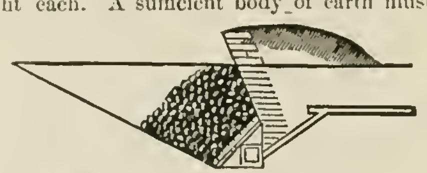


Improved Ingersoll Stone Channeler.

portion at a time. Owing to the great hardness of the material, any defect in the chiseling greatly increases the labor of polishing. So slow, indeed, are the operations with granite, that a saw-blade will not cut through one inch in depth during a whole day, and a good-sized sawn slab will take a week to polish.

A most important operation in the quarrying of stone is that known as "channeling," by which is meant the process of cutting long, narrow channels in the rock for the purpose of freeing the sides of large blocks of stone. Formerly this work, like all other operations of quarrying (excepting the hoisting and loading), was performed by hand; but of late special machines have been devised for the purpose, which are rapidly finding their way into use. When the proper number of channel-cuts have been made around a block of stone in the quarry, it is necessary to undercut the blocks in order to raise them. This is done by drilling,or "gadding," a series of holes at varying distances apart, according to the nature of the stone, along the bottom of the block, and releasing it by the splitting action of wedges. The large illustration exhibits an improved form of channeling-machine recently introduced by the Ingersoll Rock Drill Company. The machine is self-contained, and mounted upon a carriage which is made to traverse a tramway laid alongside of the cut about to be made. The boiler is of an improved design, with submerged flues, and has a water-tank attached. The engine is unusually powerful for the work required. It is the well-known Ingersoll rock drill, provided with channeling-cutters in place of the usual drilling-bit, and operates by percussion, as in the usual form of the drill. It is provided with a steam-cushion, by which the force of the blow is completely controlled. The framing by which the engine is attached to the carriage is made amply strong to secure the requisite stability for channeling in hard and tough stone, and by means of suitably disposed gearing the machine can be adjusted to a desired angle in a vertical plane. The stability of this machine has been fully tested and demonstrated by successful work in all kinds of stone. One of the machines has been doing successful work during the season on the massive green serpentine rock of Hartford County, Maryland, and has not cost a cent for repairs. This rock is as hard as fluorspar (harder than granite). The makers give the record of their machine as follows: In sandstone, 260 feet channel in 10 hours; in oolitic limestone, 230 feet.

STONE-FOUGASSES.—A stone-fougass is made by excavating a shaft 6 feet deep, inclined to the horizon at an angle of about 45°. At the bottom place a charge of 55 lbs. (a cubic foot) of powder, then a strong shield of wood at least 6 inches thick, in front of the charge, and over the shield throw in three or four cubic yards of pebbles, of not less than half a pound weight each. A sufficient body of earth must be



placed vertically above the charge and retained over the upper part of the shaft, near the edge, by a revetment of sods, to insure the effect taking place in the right direction. Fougasses are usually fired by means of an augot, or casing tube, containing a hose or saucisson, etc., led up the side of the pit or shaft, and then parallel to the surface of the ground, at a depth of two or three feet; or they may be fired, at the proper moment, by means of a loaded musket with its muzzle in the powder, and a wire or string fastened to the trigger. See *Fougasses*.

STONE MORTAR.—A mortar designed to project stones a short distance, not exceeding 250 yards; it also threw 6-pounder shells up to 150 yards. The stones which were used in this mortar were put into a basket fitted to the bore and placed upon a thick oak plank, which covered the mouth of the chamber. This plank had a number of holes bored through it, to allow the passage of the flame. When shells were fired, they were laid in beds with their fuses placed outwards, and cut to burn 15 seconds. The mortar was primed with a piece of quick-match long enough to allow the cannoneers to get out of the way of any fragments which might fall in the battery. When firing stone, the angle of elevation was 60°; but, with shells, this angle was about 33°, to prevent the shells from having too great a force when falling, by which they would be buried in the ground, and their explosion become less effective.

STONE SHOT.—Shot used with guns up to the sixteenth century. The class of ordnance from which they were discharged was comparatively weak as compared with that of the present day, and consequently the projectiles were of no great size. Stone shot were also discharged from mortars.

STOP IRONS.—Pieces of iron at the ends of the side-pieces of a platform to prevent the carriage running off it.

STOPPAGE OF PAY.—When by report of the Second Comptroller of the Treasury, or of any Bureau of the War Department, it is ascertained that an officer of the Army has been overpaid, or is indebted to the United States for money, property, or supplies, or has failed properly to account for the same, the Paymaster General notifies the officer of the charge.

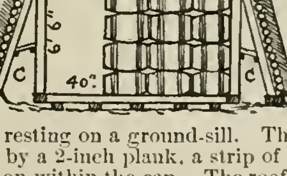
If a refundment or satisfactory explanation be not made within a reasonable time, the Paymaster General, on the order of the Secretary of War, gives notice of the stoppage of the officer's pay until the overpayment or indebtedness is satisfied. Should the officer in his explanation appeal to the Secretary of War, the Paymaster General submits the case for decision before enforcement of the stoppage. The notice of stoppage of officers' pay takes the form of a monthly circular to all Paymasters, advising them of stoppages in force at its date. This circular is submitted to the Secretary of War for his approval prior to publication. When an officer's name is borne upon this circular, no payment of salary is made to him which is not in accordance with the stoppage entry in the case. Paymasters disregarding this requirement in any case are held liable for the amount of the stoppage. Overpayments to an officer are deducted on first payment after notice of stoppage, even if the pay accounts have been assigned. The assignee takes the account subject to all risks of stoppage. The officers against whom the pay is stopped may demand a suit, and the agent of the Treasury is required to institute a suit within sixty days thereafter.

STOPPAGES.—Certain deductions in the British Service made from the pay of officers and men, in consideration of supplies made to them, or in aid of certain institutions. These stoppages were formerly more numerous than now. Thus, every officer and man had to pay toward Chelsea and Greenwich Hospitals, and a soldier had to pay for his own kit by a stoppage from the bounty. These stoppages have been remitted. Those at present remaining are, under usual circumstances, limited in the Navy to payment for slops (*i.e.*, clothing) when issued to men, or for willful damage: in the Army, for forage, 8½d. each ration by cavalry officers, and 6d. for artillery officers (though their horses eat the same); for messing on board ship; for diet in hospital, if sick through the man's own fault; for cost while in a prison; for damages to barracks: and as a fine for drunkenness.

STOPPER.—1. A plug placed in the muzzles of muzzle-loading small-arms, not in breech-loaders, to keep the bore free from rust, and to prevent dirt from entering into the barrel. It is made of cork or India-rubber, having a brass-top. To make it thoroughly serviceable, the cork or India-rubber should be covered with serge or flannel. 2. A gasket or short piece of rope used to keep any weight suspended, or to take the strain off a rope, one end being always attached to some fixed object. It must be stronger than the rope it has to hold.

STORAGE MAGAZINE.—The magnitude of the storage magazine will depend upon the number and caliber of pieces in the work and the number of charges to be kept for each. This data being known, the amount of storage room required will be determined by allowing 5,780 cubic inches for each barrel containing 100 pounds of powder. Projectiles and cartridges for siege and field-guns are put up in boxes, and are stored in magazines kept especially for this kind of ammunition. Each box of siege-gun ammunition contains four projectiles and four cartridges, and it measures about 2,950 cubic inches. Each box of field-gun ammunition contains ten projectiles and cartridges, and measures about the same. From this it is easy to obtain the storage capacity required for any amount of these kinds of ammunition. The dimensions of the interior of the magazine should be so regulated as to entail no unnecessary loss of space in storing its contents. The exterior dimensions of a powder barrel are: Length, 20 inches; diameter at bilge, 17 inches. With the barrels stored in the usual way, on the side, a magazine 6 feet 6 inches high would afford space for four tiers, leaving 8 inches on top for handling room. A magazine 10 feet wide will give room for four rows, leaving 40 inches for passageway; therefore each 17 inches of length of a magazine 10 feet wide by 6.5 feet high will contain 16 barrels. A magazine of this height and width and 30 feet long would store 400 barrels and leave a space of about one yard in width, extending across it, at the entrance. At the rate of 100 rounds for each 15-inch gun, a fair allowance for such guns in any field-works, a magazine of the foregoing dimensions will give storage for a supply of powder for four pieces. The number of rounds per gun should increase as the caliber diminishes. It would, however, seldom be necessary to have more than 300 rounds for any caliber above 100-pounders. An ordinary packing-box containing the number of rounds previously specified measures, in exterior dimensions, 19 inches in length, 13.5 inches in width, and 11.5 inches in height. These dimensions allow the boxes to be compactly packed in a magazine of any ordinary shape, and it requires only a very small calculation to determine the storage-room required for any given number of rounds for the guns of these calibers. It is best not to exceed, for any one magazine, the dimensions above laid down, namely, 30 by 10 by 6.5 feet. When greater storage room is required, two or more should be constructed. Precautions to secure drainage are of the utmost importance. Generally the ground is sufficiently undulating to effect this by means of a covered drain leading from the bottom of the magazine. Where this is not practicable, the bottom of the excavation must be formed so as to collect the water at one point, whence it may be removed by pumping or bailing.

The drawing illustrates the best method of constructing a storage magazine. The sides of the interior of the magazine are formed of 12 inch logs, either square or round, placed vertically in juxtaposition, and resting on a ground-sill. These are capped on top by a 2-inch plank, a strip of the same being spiked on within the cap. The roof is formed of 15-inch logs, laid across, in juxtaposition, each having a shoulder of 3 inches to fit it to the cap and inside strip. Longitudinal logs with varying diameters are laid on these, so as to give a proper pitch to the roof. Earth is solidly packed upon the top and between the roof logs, receiving the proper slope for the roofing boards. These boards, carefully joined, are laid on in two thicknesses, each being covered with a coating of asphalt or coal-tar; and upon these boards rest the covering of earth. The flooring is of joists and boards. The sides of the magazine are all surrounded with an air-chamber formed of inclined



logs supported on a ground-sill and resting against the top logs; these are placed at three or four feet apart, each one being braced at the middle to resist the flexure from the pressure of the earth. The air-chamber is covered in by saplings laid upon each other horizontally. Ventilators are placed between the magazine and the air-chamber, near the top, and also between the latter and the external air, the two not being opposite, and the usual precautions to guard against sparks, by covering the mouth with wire cloth or perforated tin, are taken. The whole is covered with earth, the thickness of which will depend on the character of the enemy's artillery. In no case should it be less than 14 feet on the exposed side; 10 feet will be sufficient for the other sides and the top. The entrance may be either upon an end or side, depending upon how the magazine has been located with reference to the enemy. In all cases the entrance must be on the side from the enemy, and should be secured by a bomb-proof covering. The magazine-chamber should, if practicable, be placed at least two-thirds of its height below the surface of the ground. In this and in all similar structures railroad iron is a highly serviceable material for roofing, the bars being laid in juxtaposition in place of the logs before mentioned. See *Powder Magazine*, and *Service Magazine*.

STORE-HOUSE.—Every post furnished with heavy artillery has one or more store-houses for the preservation and safe-keeping of equipments, implements, and such machines as should not be exposed to the weather. They should be light, dry, well ventilated, and furnished with shelves, racks, and tables for the accommodation of the stores kept therein. The articles are sorted according to their natures and arranged in appropriate places. These places are distinctly labeled, and, furthermore, each article, as far as possible, should be marked, so that under no circumstance there may be mistakes or confusion.

Cartridge-bags are preserved from moth by packing them with an hydraulic press; by enveloping them in paper bags hermetically sealed, the paper being similar to that used for preserving army clothing; or by heading them up in tight casks. A mild infusion of colocynth will preserve them from the moth. The bags are steeped in it, afterwards dried, and then packed away. *Sponges* are preserved from moths and packed away in the same manner as cartridge-bags. They should not be kept on the head of sponges in store, as they are then always damaged by rats and moths. Sponge-covers should never be put on the sponge-head unless both are clean and dry; after using, the sponge should be washed clean and dried, and then the cover put on. *Sponges, rammers, worms*, and *ladles* are generally placed on racks, with supports, not over three feet apart, to prevent the staves from warping.

Articles composed of brass are spread on shelves, and are kept clean and free from verdigris. It is forbidden by the regulations to use oil or grease upon them; alcohol or vinegar, with rotten-stone and afterwards whiting, are the most suitable polishing materials for them, and all scouring should be avoided. A good lacquer for brass rticles is composed of: Alcohol, 95 per cent., 2 ounces; seed-lac, 1 ounce. Put the mixture in a glass vessel for five or six days, exposed to the light; shake well once each day, and apply with a brush while the article is as hot as it can be made without injury.

Steel or iron implements should be painted black or kept bright, according to the use for which they are intended. For polishing, use crocus-cloth, oil, and rotten-stone; after which, oil with sperm oil. For the preservation of the bright parts of machinery, elevating screws, etc., when not in use, the following preparation is used, viz.: One pound white-lead and 0.25 pound tallow or lard oil, heated and mixed together. This is applied warm with a brush or cloth. It is removed by rubbing off with the cloth, using a little turpentine.

Leather equipments are hung on pegs in a cool, airy place. Those of russet leather should be taken down three or four times a year and brushed off to prevent accumulation of mould. Those of black leather should once or twice a year be washed with castile soap and water, well rubbed, and before thoroughly dry oiled with a mixture of neat's-foot oil and tallow; lamp-black may be added to the oil for blacking. *Fuses*, *friction-primers*, and *water-caps* are kept, as far as possible, in their original packages, and are stored in the driest and safest place in the store-house.

Pulley-blocks are hung up or piled where they have free circulation of air; those of wood are occasionally oiled with raw linseed oil. The *hooks*, *checks*, and *partitions of iron blocks* are painted black. *Journals* should be coated with black-lead, or if this is not available, lubricating oil must be applied before using. The greatest care must be observed to keep them free from sand or other gritty substance. *Rollers*, *maneuvering blocks*, *shifting-planks*, *chocks*, *cradles*, *capstans*, and *capstan-bars* are stored in dry places. They should not be painted, but are occasionally oiled with raw linseed oil.

Gins are painted olive, with the iron parts black. The windlass, however, should never be painted, but oiled with linseed oil. As strict uniformity is not observed in the construction of gins, each one should be numbered and its parts so marked that if parts of different gins become mixed they may be readily separated. Each gin should be placed by itself, the braces fastened to the legs by their bolts and keyed up; the clevis and clevis-bolt are left on the pry-pole.

Trunnion-rings, *sling-chains*, etc., are hung on pegs and preserved from rust by a thin coat of black paint.

Hydraulic-jacks should be kept filled. The ram or piston and the journals are frequently oiled to prevent rusting, but when used the head of the ram, to prevent slipping, should be free from oil or grease. The outside of the jack may be painted.

Gatling guns are kept in dry store-houses, and require the greatest care to preserve them from rust. The use of emery-cloth or any other scouring material must be avoided. They must be kept covered, and well oiled with a mixture of about equal parts of good sperm and kerosene oil. Every two or three days they should be wiped off, a rag passed through the barrels, and fresh oil applied. The journals are oiled through the oil-holes in the breech-casing. The carriages, limbers, and caissons are painted and cared for as other wooden carriages.

Gun-lifts are painted olive and when not in use are kept under cover. *Hand-carts*, *sling-carts*, *garrison-trucks* and *wagons* are painted the same as siege-carriages, and should be kept under sheds. The small sling-cart, being entirely of iron, excepting the pole, is painted the same as iron carriages.

Paints, *turpentine*, *oils*, *lacqueurs*, etc., are kept in a room separate from other stores; a cellar or casemate is preferable. The floor should be covered with two or three inches of fine sand, which should be renewed occasionally. Sawdust should *never* be used for the floor. *Volatile oils*, such as kerosene or benzine, must never be kept stored in the paint and oil room, but in such place that the least possible damage will arise from it should it take fire.

Paint brushes, when new, and before using, should be wrapped, or, as painters term it, bridled with strong twine, and soaked in water to swell them. After using, they should be cleaned with spirits of turpentine and put away in a vessel containing water to keep them from drying and becoming unpliable.

STORES. All public stores taken in the enemy's camp, towns, forts, or magazines, whether of artillery, ammunition, clothing, forage, or provisions, shall be secured for the service of the United States; for the neglect of which the Commanding Officer is to be answerable. See *Military Stores*.

STORE TRUCK.—An efficient vehicle for removing single packages of a considerable weight; the bar in front being insinuated under the box, for instance, which is then tipped so as to balance back slightly against the bed, in which position it is transported upon a pair of heavy wheels of small diameter. It is an indispensable assistant in the armory, arsenal, and packing-rooms. The term truck is sometimes applied to certain hand-carts and two-wheeled barrows. It is not easy to make the distinction in some cases, and is perhaps not very important. The store-truck is used mostly in the United States Service for moving boxes, and in embarking and disembarking stores, is quite light and has two strong rails rounded at the ends for handles.

STORE WAGON — A wagon consisting of a body and limber, employed to carry the various stores of a field-battery, such as the wheelers', collar-makers', and farriers' stores.

STORM. To storm is to make a vigorous assault on any fortified place, or on its outworks. The storming-party is a select body of men, who first enter the breach, and are, of course, imminently exposed to the fire of the enemy.

STORM FLAG.—In the United States Army, the storm flag is the National flag. It is eight feet fly and four feet two inches hoist, is furnished to all occupied military posts and National Cemeteries, and is hoisted in stormy or windy weather. This flag is also used as a recruiting flag. See *Flags*.

STORM GAS CHECK.—This invention consists of a loose tubular lining, which fits into the barrel of the weapon, and covers the junction between the barrel proper and the breech-piece; and being capable of an endway movement, by reason of the expansive force of the ignited powder, will completely seal the joint between the breech and barrel. The gun may be smooth-bore or rifled, and shot or shells of any suitable construction may be used. See *Gas-check*.

STOVE BARRELS.—A variety of barrels used when carrying powder from one manufacturing department to another.

STRAGGLERS.—Individuals who wander from the line of march. It is part of the rear-guard's duty to pick up all stragglers.

STRANGLES —A contagious eruptive disorder peculiar to very young horses. It is ushered in by sore throat and cough, muco-purulent nasal discharge, and the eruption of a swelling in the space between the branches of the lower jaw. In about ten days this swelling comes to a head, bursts, and in favorable cases, the patient is soon well again. From exposure to cold, poverty, or other causes, the swelling, however, occasionally appears in less favorable situations, as about the glands lying within the shoulder, in those of the groin, or even in those of the mesentery. Such irregular cases are apt to be protracted, accompanied by much weakness, and sometimes prove fatal. Bleeding, physic, and irritant dressings are always injurious. Good food and also the best nursing, with fomentations to the throat, and steaming of the head, favor the healthier maturation of the swelling. When there is debility, coax the animal to eat by offering him at short intervals small quantities of scalded oats, malt, bran, or green food, and allow him several times daily a pint of sound ale.

STRAPPADO. A punishment formerly inflicted upon foreign soldiers by hoisting them up with their arms tied behind them, and then suddenly letting them down within a certain distance of the earth.

STRAPPED AMMUNITION.—In large field-howitzers, it is not convenient to unite the cartridge bag and projectile, on account of the difficulty of packing them in the ammunition-chests; the bag and projectile are, therefore, carried separately. The projectile is attached to a sabot without grooves; and, to give a proper form to the cartridge-bag the mouth is closed with a *cartridge-block*, which resembles a sabot; hence the name *strapped ammunition*.

Straps are made of sheet-tin. For shot there are two straps crossing at right-angles, one passing through a slit in the middle of the other; for shells there are four straps fastened to a ring of sheet-tin and pierced with four slits, through which the ends of the straps are passed and folded down on the under side. The sheet of tin is first cut to a length equal to that of the straps, and, if the straps are for shot, a line is drawn dividing it into two equal parts, to mark the place for the slit. The straps are cut with circular shears. If such be not at hand, the width of the strap is marked on the sheet, cut with tinner's shears, and straightened on a bench with a mallet. The slits are made with a cold-chisel on a block of lead, and a strap not slit is passed through and set flat by a blow of the hammer.

The following implements are required to strap shot and shells: One *bench*; 2 *pans*, containing *nails* .55-inch long, with strong, flat heads .2-inch diameter; *boxes* and *barrels*, for straps and sabots; 4 *hammers*, for strapping; 1 *common hammer*; 4 *punches*; *shot-gauges*, of each caliber; 1 *gauge* for each caliber, .04 in. greater than the largest shot-gauge, through which the shot should pass after it is strapped; *tow* or *rags*, for wiping the balls; 1 *wheel-barrow*; 1 *paulin*, if the shops have not a plank floor.

A helper knocks off the scales from the balls with a hammer, cleans and dries the interior of the shells, if requisite, wipes the balls, and gauges them, both before and after they are strapped. The workman sitting astride the bench, places the shot or shell in the cavity of the sabot, the roughest part of the shot down, the fuse-hole of the shell on top, in the axis of the sabot. The ball should rest on the bottom of the cavity (it can be told from the sound, by striking on the bottom of the sabot with a hammer); if it do not the sabot is rejected. The workman places the junction of the straps in the axis of the sabot, or the ring concentric with the fuse-hole of the shell; beginning with the strap which is not slit, he forces the end of it into the groove of the sabot with the back of the hammer, punches it, and nails it; he then draws the other end tight, punches it, and nails it, in the same manner. He disposes the other strap perpendicular to the first, nails it to the sabot as he did the first, cuts off the superfluous length, and with the hammer and side of the cold-chisel sets the straps in close to the ball at the top of the sabot.

The boxer mode is as follows:—Bore a hole, 2 inch in diameter, .15 inch deep, in the shot; enlarge the hole at bottom. Take a copper rivet, .2 inch in diameter, hollow out the end, leaving the length of the rivet .25 inch greater than the least thickness of the sabot; bore a hole in the center of the sabot for the rivet, with a countersink for the head; place the shot in the sabot, the hole down; insert the rivet in the sabot, making it enter the hole in the shot: strike the head of the rivet a blow with a hammer to upset the end of the rivet and fasten the sabot.

If tin or sheet iron cannot be procured, straps may be made of strong canvas, 1 inch wide, sewed at the point of crossing. The part of the ball which is to be inserted in the sabot is dipped in glue; the straps are also glued to the ball; the ends are doubled into the groove and secured by 2 nails in each end. Another method is to wrap round the ball a band of canvas 1 inch wide, one-half of which is glued to the ball, the other to the sabot; or the shot may be kept in place by merely tying the cartridge-bag over the top of it.

When strapping shells for siege and garrison service, the straps are cut and made as prescribed for shot for the field-service, changing their dimensions. Two rings or loops of tin, .38 inch diameter, are attached securely to the slit strap of the howitzer and columbiad shells, for the purpose of attaching a handle made of cord .15 to .25 inch thick. A slit is made in the strap through which the ends of the tin loop are passed and soldered on the under side of the strap. For the handle, pass a piece of marline through both loops and tie the two ends together, leaving such a length that the hand can embrace both branches. The shells are placed in the sabot, and the straps put on in such a manner that the fuse-hole may fall in one of the angles, between two straps, and that the axis of the fuse-hole may stand at an angle of about 45° with that of the sabot. The eyes of the shell should not be covered by the straps. The straps are fastened at each end with 2 nails in the side and 2 in the bottom of the sabot. In loading the piece care must be taken to place the fuse-hole in the upper part of the bore. See *Ammunition*, *Field and Mountain Ammunition*, and *Siege and Garrison Ammunition*.

STRAPS.—Decorations made of worsted, silk, gold, or silver and worn upon the shoulders, without epaulettes.

STRATAGEM.—In war, any scheme or plan for the deceiving and surprising of an army, or any body of men.

STRATARITHMETRY.—The art of drawing up an army, or any given number of men, in any geometrical figure, or of estimating or expressing the number of men in such a figure.

STRATEGICAL FRONT.—The portion of the theatre of war in front of any position occupied by an army as it advances, is termed the *front of operations*. That part which is directly in front of an army, or which can be reached in two or three days, forms simply a *front*. When the whole extent lying between the two hostile armies is considered, the term *strategical front* is applied. See *Strategy*.

STRATEGICAL LINES.—The lines followed by an army in making a strategical movement. Temporary lines of operations, or maneuver lines, therefore, are strategical lines. *Lines of operations* are important strategical lines. In general, lines connecting two or more strategical points, which lines can be used by an army, and which allow of easy communication between these points, are strategical lines. A base of operations is a strategical line. See *Strategy*.

STRATEGICAL MARCHES.—Marches made in the theatre of war, near an enemy whose position is not exactly known, having in general for their object the completion of some strategical combination. They are used to conduct an army to a position from which an attack can be made on the enemy, or to a position in which the army can remain and receive an attack, in other words, to a position immediately in the presence of the enemy. The marches are either *ordinary* or *forced*, and are used principally to mass troops at some stated point on the theatre of operations before the enemy can make arragements to prevent it or can prepare counter-movements to weaken or nullify the effect of the movement. Secrecy, celerity, and good order are indispensable requisites for success in all marches of this kind. See *Marches* and *Route Marches*.

STRATEGICAL OPERATIONS.—It is by preparatory movements, by marches skilfully conducted, so as to throw our forces on the vulnerable point of the enemy's line, that all such grand results are obtained, which flow from a single victory. A battle gained is always a fine thing; but the consequences resulting from it may be very different, according as, by our previous measures, we are able to cut the enemy's line of communications; separate him from his base; disperse his forces, or simply force him to retreat without further loss than that on the battle-field. In the first case, victory is complete if the first success is promptly followed up. In the second, the enemy will soon be able to rally his forces, and offer a new battle. Vigor on the field and rapidity of pursuit should go hand in hand for great success. The latter is of as great importance as the former. Marshal Saxe was so thoroughly pervaded with this conviction, that he laid it down as an axiom, that "*military success resided in the legs of the soldiers*." A *dictum* that is ably enforced by all authentic military history.

A march, regarded as a strategical operation, may be either towards or from the enemy; either a *forward* movement, or one in *retreat*. In either case the army, if numerous, is necessarily divided into several corps, which move upon separate roads, either to subsist more easily, or to have all the space necessary for all deployments, and the other preparatory movements for delivering battle. The different columns of march should be kept the closer together, as the enemy is known to be the more bold and active in his movements. If there is danger of an attack, the columns should be kept in supporting distances of each other, and they should not be thrown into any position where an obstacle might prevent their being brought together at any desirable moment on the field of battle. At the same time discretion must be shown, so that so simple a rule may not be pushed to an absurd extreme, by keeping the various columns so close to each other that parallel roads will have to be made for them with the axe and pick, when those already in use cannot be turned to account. Any attempt of this kind would, except in rare cases, so greatly retard our movements that the least enterprising enemy would take advantage of it. Military history offers epochs where this circumspect course was pursued by armies, but no truly great General has ever submitted to such trammels. So long as a march is not made within cannon-range of the enemy, more or less interval can be left between the columns whilst executing the marches which are to bring them into position on the battle-field, according to the nature of the locality. The only limit to be fixed is, that the intervals shall not be so great as to prevent any corps reaching the battle-field on the day prescribed.

Each column should adopt all the usual precautions to prevent a surprise. Neglect in doing so has brought on some of the greatest disasters recorded in history. Of all marches, those which are most likely to produce the most splendid results are the ones that are concealed from the enemy, and therefore termed *secret marches*. Well-planned and executed, they enable an army to throw itself unexpectedly on the enemy's flank, threaten his base of operations, surprise his cantonments, etc. A country cut up with forests, water-courses, and like natural obstacles, lends itself best to the operations of a secret march; as these both conceal the movements of troops, and lead the enemy into fancied security from the character of the locality, and cause him to neglect the usual precautions to guard against a surprise. It cannot be too strongly impressed upon every soldier that, with his patience and a determined will, there is no natural obstacle that troops cannot overcome, when there is no enemy to interrupt our work. In this respect, in looking back on military history, it may with truth be said that nothing is impossible to a determined will.

Speed is one of the chief characteristics of strategical marches, as it is of the ordinary movements on the battle-field. In this one good quality resides all the advantages that a fortunate initiative may have procured; and by it we gain in the pursuit all the results that a victory on the battle-field has placed in our hands. By rapidity of movement, we can, like the Romans, *make war feed war*, by remaining so short a period in any one spot as not to exhaust the resources around us, however unequal to a prolonged sojourn. By this means, we disembarrass ourselves of those immense trains which are otherwise indispensable for the ordinary daily wants of an army; we carry along with us only what is indispensable, obliging the soldier to keep himself always supplied with a few days' rations of bread in his knapsack, driving along with the army herds of cattle in sufficient numbers to furnish the meat ration. In this manner, an army, freed from all of the *impediments* that might retard its motions, will be able to accomplish the most stupendous labors in marching and fighting. No great success can be hoped for in war in which rapid movements do not enter as an element. Even the very elements of nature seem to array themselves against a slow and over-prudent General. The Chevalier Folard has very well remarked, "that the slow and heavy in war will partake of as little of the glory of this world, as the lukewarm will of the glory of the world to come."

Under another heading in this work the advantages of interior lines of operation were pointed out. Marches which lead to this result deserve the close study of the General. If the enemy, for example, is moving on an extended front, upon our army, with the purpose of surrounding it, the true resource for safety is for us to move in mass upon some very weak point of his center, and, having thus separated his wings, beat them both in detail. In this manner we shall not only foil the enemy's plan, but scatter and force his forces on divergent lines of retreat; the more disastrous to him at the moment, and the less advantageous for his concentration later.

If the enemy's forces are concentrated, we may direct a movement of our army towards each one of his flanks, so as to induce him to separate in his center for the purpose of securing each of his flanks, when, having done so, we may reunite our separated forces and rapidly concentrate them on the one of his fractions the most accessible to us. A movement of this kind cannot be attempted with a prospect of success unless the topographical features are of such a character as to mark our movements. For example, supposing a river to lie between our force and that of the enemy, so as to prevent him from moving on our center, we might direct two fractions on the extreme right and left of the enemy's position, and, if he does weaken himself on his center to reinforce his wings, we might take advantage of this to cross the river rapidly on his center, everything having been prepared for it, and thus, holding a point between his wings, concentrate on either and overwhelm it before it could receive succor from the other. Here everything depends on rapidity of movement, and subsequent vigorous action. An hour's delay in such combinations may not only cause the failure of the best-laid plan, but entail disastrous results. A single hour may suffice for the enemy to gain the strategical point and overwhelm us with superior forces. If fortune is on the side of the heavy battalions, she also frequently grants her favors to superior activity and audacity.

From the preceding discussion, if based on sound principles, and historical precedents are strongly in its favor, it follows that to defend with advantage a frontier menaced on several points, the true rule is not to attempt to hold every point in force, but to watch every outlet by small corps, just of sufficient strength to check and delay the enemy, and to hold the chief portion of our forces concentrated at some central point, from which they can operate rapidly against any very considerable fraction of the enemy's forces. For example, let us suppose an army of 80,000 acting on the defensive against one of 120,000 separated into three corps of 40,000 each. To oppose to the enemy three corps of equal strength we should have but about 26,000 in each, and consequently we would find ourselves inferior in numbers on all points. If, instead of this, we opposed to each fraction of the enemy a corps of from 12,000 to 15,000, it would be sufficient to hold 40,000 in check, whilst our main body, consisting of from 35,000 to 40,000, holding a central position, could move on the point first menaced, and, being joined by the corps of observation, would offer to the enemy an effective force of about 50,000 combatants, which, with all other things equal, should beat the enemy. See *Strategy*.

STRATEGICAL POINTS.—The points of operation are also termed *strategical points;* and under this appellation are comprised not only those which may be regarded as the chief end to be attained, but also those by the occupation of which any army will receive incontestable advantages. The capital city of a country is in Europe regarded as a strategical point of great importance, chiefly from political considerations, arising from the influence which the seat of government exercises over the whole country. This, to a certain extent, is true of our own country; for although Washington city,in a military point of view, might have but little influence on the results of a war, and has no controlling influence over public opinion at home,still its loss would be regarded by Europeans in a European point of view,and hence its possession, whether by a foreign or domestic enemy,would have a damaging effect abroad, besides exercising a certain moral one at home.

A point is strategical that gives us entire control of several important roads,the course of a river,or which guards some important passage. In a flat country there are usually few strategical points. Those which hold this position usually owe it to fortifications by which they are surrounded, and by those various resources for military purposes which they can furnish. Wooden,hilly,and well watered regions present many such points. In high mountain ranges, strategical points are very restricted in number, but are usually of a very decided character. They are met with behind the narrow mountain passes at the points of junction of several valleys along which roads have been made. They are also found at elevated points where the ridges of several chains seem to come together.

Troops occupying such points can choose the roads by which they think best to descend from;their movements, in such a case, are from the center towards the circumference, whilst those of an opponent can only be made,with a prospect of success, by making wide circuits, to turn the spurs which obstruct any lateral movement. See *Strategy*.

STRATEGOS.—A series of American games of war, based upon military principles and designed for the assistance both of beginners and far advanced students, in prosecuting the study of tactics, grand tactics, strategy, military history, and the various operations of war.

Strategos is far more comprehensive than the German game "Kriegsspiel," or than its English version "Aldershot," both of which have now become so famous among foreign soldiers. Unlike these games, which have little in common with the ordinary soldier, the subaltern, and the private military student, and were designed for the almost exclusive use of the best-informed and most advanced members only of the military profession, the *American* game of war possesses an absorbing interest for those *of every grade* in the profession of arms; while in its most advanced application, Strategos embodies all the more valuable features of these foreign games,introducing also at the same time very many noticeable improvements upon both of them, and being thoroughly American even in its necessary similarities thereto.

Strategos begins with the novice at the very threshhold of *minor tactics*, and accompanies him upward through all its varying phases as applied to each of "the three arms." It yields readily to all the requirements of "dummy" instruction, and from the simple squad or detachment up through the company,battery squadron, and battalion,even to the army corps itself, considered as a tactical formation, it well affords a ready means of practical and unlimited elucidation never before offered to the military profession. This application of the outfit will prove of inestimable value in the practical study of tactical problems, its scope being such as to cover every possible demand for object study.

Advancing a step beyond this one, its elementary application, the same outfit may be most profitably employed by the student of *strategy* and *grand tactics* in his deeper studies. With it he can more readily,and understandingly master both definitions and principles of the science of war, and upon these as a foundation still further investigate the many considerations which affect and vary their application in the practical experience of campaigning. In this connection it may be stated that the topographical capacity of the outfit is such that it is an inexhaustible source of very ready illustration for every *text book* or authority—such as Jomini, Hamley, Wolseley, Halleck, Mahan, Wheeler, Dufour, etc., upon military principles and precepts, so that diagrams which are utterly beyond the scope of even such books can, with its aid, be realized in the simplest, most expeditious, and lucid manner.

Again the Strategos outfit will afford valuable companionship to those who are interested in the study of *military history*—battles and campaigns can be *analyzed* with its assistance, and followed step by step, and detail by detail, in a manner which it would be utterly impossible to realize even with the most extensive system of maps and diagrams. The power of *illustrating any military historical topic* will be limited only by the subject itself, while it surely will at the same time possess the peculiar advantages of both the tableau and the panorama, any and every feature of which may be modified at will. The above varied uses to which the outfit of this new game can be applied will appeal directly to the great majority of American military aspirants, and satisfy a want that has long been felt, especially in our country, *and one which the extremely complicated and advanced foreign games have utterly failed to appreciate.* With an outfit, therefore, of such elastic capacity, there can certainly be no difficulty experienced when representing the various ancient and modern armies in any of their phases of formation, either tactical, grand tactical,or as influenced by any topographical considerations,in accurately delineating the several orders of battle, and even of studying the latter over against each other either arbitrarily or according to the principles laid down under the head of the "Battle game."

The "Battle game" is an application by which a most entertaining and instructive *game*, based upon military principles and precepts,can be played. Upon the game board used in this application of the outfit, two armies of any size and organization can be represented with proper regard to lines, distances, and order of battle, by squadron, battery and battalion, and(the various pieces having special moves and powers, and the whole progress of the game being governed by carefully compiled rules)a miniature and bloodless battle can be fought, far less trying to ordinary patience than the "Advanced game," and yet gradually educating the players up thereto. The various features of the "Battle game" have been calculated with special reference to the subject illustrated ; the aim has been to make the rules, etc., *suggestive*; and although the game is necessarily far more extensive than ordinary parlor pastimes, it is yet simple enough to be fully within the capacity of any military student already even moderately familiar with the elements of the science of war, while a mere military novice cannot but be benefited, though seeking therefrom perhaps entertainment only for an evening. It is intended particularly—1, to give practice in organizing large forces, in making dispositions, and in forming lines and orders of battle; 2, to *familiarize* the player with the natural run of affairs during action; 3, to *sharpen* the *coup d'œil*; 4, to fix in the mind the *individuality* of each of the arms, their relative importance, and the necessity of their combined use; 5,to suggest practical and decisive *concentrations* at opportune moments; 6, to afford field and opportunity for comprehensive battle plans; 7, and finally, in a word, to inculcate *generalship*.

The several applications of the Strategos outfit thus far enumerated do not come within the scope of any game of war now known. By them, these applications are all completely overlooked in the haste to present an advanced and necessarily very complicated game *to those few* special students whose interest and professional studies may lead them to it. The *great mass* of American military students will thus always fail to find interest in these foreign games on account of their very complexity; and this fact, in no small degree, accounts for the extreme slowness with which Kriegsspiel, though now some seventy-five years old, becomes known in our own country even among all officers of the regular army, who alone perhaps as a class can afford to be constant players of it. But Strategos, having advanced thus far with the subaltern and the student, is not open to these objections; nor does it by any means neglect the special wants of the few whose extensive knowledge of the military art, science and history, and whose more than passing object in studying these matters, would demand the highest and most scientific application of the outfit. With such an application, embodying all that is valuable in the German and English games, and introducing many new and noticeable improvements in the matter of method, men, tables, adaptability to American requirements, etc., etc., the game of strategos may naturally and does appropriately terminate. Its "Advanced game" thus affords to the professional military man every opportunity that could be desired for pursuing studies *commenced in more elementary fields* to their legitimate termination.

In this, the last branch of the subject, therefore, all arbitrary assignments of values and moves is of course entirely out of the question, and improper. The whole game is required to base itself upon actualities, upon the results of careful investigations, and upon the tabulated statistics of experience, of actual practice, and of former battles and campaigns. Everything in such a game must be subjected to the most searching military scrutiny, and nothing is allowed upon the map which does not conform to the very best of military information possessed and attainable. Each of the essential elements of distance, time, and topography must have its peculiar weight duly considered, and throughout the directions, rules, order of procedure, tables, etc., etc., devoted to the playing of the "Advanced game," the constant endeavor will be seen to represent the mimic battle or campaign in all its features save the dreadful wastes of blood and iron.

The text-book contains all the rules for the use, and minutely describes the employment of the outfit in each of its several applications. It also serves as a sort of general military "hand-book," being replete with references, precepts, rules, suggestions, data, and tables, all of which have special and intrinsic statistical value over and above their mere uses in the game room. Considered by itself, it is, in fact, a study of the bearing of military statistics upon war, on field and map, and is a most comprehensive military work. See *Kriegsspiel* and *War Game*.

STRATEGUS.—The title of any Athenian General Officer. Also written *Strategos*.

STRATEGY.—In tracing out the movements of ancient armies, as far as we have the means of doing so, and from the often very obscure narratives of historians, it will be observed that in some features they conform very closely to those of modern armies, whilst in others they differ most essentially from them. Those in which this conformity is seen, and which pertain only to the general operations of a campaign belong to that branch of the military art which has received the appellation of *strategy*. Whilst those in which a marked difference is noticeable, such as the manner of conducting marches, dispositions for battle, the arrangements of encampments, etc., belonging to the domain of *tactics*. For example, the famous expeditions of Hannibal and Napoleon over the Alps present more than one point of resemblance in their general features; whilst the battles and combats which afterwards followed have no points of comparison. The reason of this is, that general operations are controlled by the topographical features of the seat of war; whilst those of a partial character, mere evolutions, or, in a word, tactical combinations, depend solely upon the weapons with which troops have been armed at different epochs. The study of military history thus becomes very instructive in a strategical point of view, whilst, on the other hand, in endeavoring to apply the notions, gleaned from the same source, on the tactics of the ancients, to our modern armies, errors of the most grave character might be committed. Every servile imitation in this latter case—an error which more than one man of talent has fallen into, from not having sufficiently weighed the enormous difference that exists between what are known, in the present day, as firearms, and the weapons for like purposes used by the ancients, and the consequences which must necessarily ensue from this cause in the arrangement of troops for combat—is greatly to be deprecated

From the forgoing remarks, it will be inferred that strategy is, in a peculiar sense, the science of Generals in command of armies; whilst tactics, in all its ramifications, from the elementary drill of the soldier to orders of battle, from the *bivouac* of an outpost to the encampment of an army, now belongs to officers of all grades. Yet with these marked differences, it is sheer pedantry to pretend to define the precise limits of these two prominent branches of the military art, as they present a multitude of exceptions in which they approach and run into each other. Tactics if we restrict its meaning to the evolutions and maneuvers of troops on the field of battle, may be taught with mathematical exactness, because every movement is accurately prescribed, and the more so the lower we descend the scale of this branch of military knowledge. But this is far from being true of strategy, because, in the calculations involved in its operations, a great many considerations enter which do not admit of exact computation, and thre upon which success or failure essentially depend; as time, the character of the roads over which the army has to move, the nature of the obstacles which lie between it and the enemy, the moral qualities and activity of the enemy's forces, etc., etc.

The following extracts from *Edmunds' Art and Science of War*, will give the reader valuable information concerning the main principles of *strategy* and their application in modern warfare:

A point is said to be *strategical* when it is so situated that its possession will be of decided advantage to an army. Cities at the junction of large rivers, or controlling the crossing of a river or a pass through the mountains, or at the meeting of several important roads, are good examples of this class of points. It is evident that these places are more numerous and of more consequence in a broken than in a level country. In the latter place a point might become strategical by being strongly fortified.

Owing to the extensive system of railroads now operated in nearly all countries, and to the great facility they offer for the movement of troops and supplies, a railroad center is now a point which it may be very desirable to occupy.

In our own country, New York, Philadelphia, Chicago, St. Louis, Vandalia, Cincinnati, etc., are all prominent illustrations of such points, and there are many others whose position will not apparently have much influence on a campaign, but by being brought by its accidents within the sphere of operations of an army, must be held at all hazards. In every country there are always some places which are more important than others, the possession of which by an opposing force would usually be decisive.

The following are some of the reasons why the occupation of great railroad centers in the theater of operations would be advantageous to the General in command of an army. They enable him to draw his supplies and re-enforcements from a great extent of country, to separate his troops for subsistence, and to concentrate them for battle; to gain rapid and early information of the enemy and his movements, for there are always telegraph lines along the railroads centering at a common point; to move his forces rapidly to any point threatened by the enemy, etc.

In a mountainous country, the strategical points, although few in number, are generally very prominent The junction of several valleys, or roads along the crests of several ridges, would naturally be of great value to an army occupying it, as the forces might operate in any one of the valleys or along any of the roads with an equal facility, while the enemy, once committed to one line, could not change to another without great labor and loss of time, necessitated by the retrograde movement resulting from the difficulty of crossing the intervening spurs or valleys.

In the campaign of 1796-97, in Italy, Bonaparte, by causing the redoubt which closed the pass of the Montenotte to be occupied by one thousand two hundred men, was able to interpose his army between the armies of the allies—Austrians and Sardinians—and whip them in detail. At this time the allies, numbering about sixty thousand men, were operating in three columns by three roads separated by very difficult mountainous country. Bonaparte, with about thirty thousand men, holding the middle road, the pass of the Montenotte, very successfully accomplished his plan of attacking in succession the columns of the enemy. The campaign was thus decided from its inception, and the redoubt of Montenotte, seconded by a small and brave garrison had great influence upon the final result.

The capital city of a country is usually a very important strategical point. This may proceed, not from its influence on the military operations of a campaign or from its position, but from the fact that it is the seat of government the occupation of which by the enemy may have a lasting and damaging effect in a political point of view. During our civil war great importance was attached to the capture of the city of Richmond, and all the campaigns of the Army of the Potomac were made with that city as the objective point, with the idea that its fall would put an end to the war. This was undoubtedly too much to expect; for the bulwark of the rebellion was not the city of Richmond, but the Confederate armies, and their capture or overwhelming defeat was necessary before the fall of the city would be a decisive cause of the close of the war. The supplies and re-enforcements of the Confederate army were nearly all drawn from the States south of Virginia, and as long as the avenues of supply remained intact the cohesion of the army was assured and it remained a menacing force.

War having been decided upon, it then becomes the duty of the Commanding General to determine and lay out a *plan of campaign*. In forming this plan everything the enemy may do should be foreseen, and measures should be taken to prevent the accomplishment of his plans. In an offensive war the plan of campaign consists in the selection of an objective, theater of operations, base, and lines of operations. The determination of the objective usually decides the theater of operations; for it will necessarily be that part of the frontier which is near the objective. The principles of strategy already laid down comprise all the considerations which will usually govern a General in making his selections of these different objects. Sometimes, however, there may be political questions which cannot be overlooked by the General when drawing up his plan.

In choosing an objective, which is usually the point first determined in the plan, the capital of the enemy's country is naturally the subject taken into consideration on commencing the work. Its possession will generally have such a decided effect, both upon the nation itself, and abroad, that its capture will become the primary object of the campaign. This statement is based on the fact that, when the capture of the enemy's capital becomes a matter of such great importance, it is presumed that the hostile army will make every exertion and sacrifice to prevent the accomplishment of this purpose: that it must be fought and conquered, before the capital itself is reached. In November, 1862, General Burnside assumed command of the Army of the Potomac, which at that time was concentrated in the neighborhood of Warrenton. General Lee's forces were scattered, one wing of his army being near Culpepper and the other in Shenandoah Valley, and separated by two marches. It was possible for General Burnside, by a single march, to interpose his forces between the two wings, and he was already in a position favorable to a decisive action. Instead of following this plan, which had been the purpose of General McClellan, his predecessor, he announced his intention of making a change of base to Fredericksburg and of making "a movement upon Richmond from that point." Swinton remarks as follows: "It would be difficult to explain this determination on any sound military principle; for while the destruction of the hostile army was, in the very nature of things, the prime aim and object of the campaign, General Burnside turned his back on that army, and set out upon a seemingly aimless adventure to the Rappahannock, whither, in fact, Lee had to run in search of him. If it be said that Richmond was General Burnside's objective point, and that, regarding this rather than the hostile force, he choose the Fredericksburg line as one representing fewer difficulties than that on which the army was moving (the line of the Orange and Alexandria railroad), the reply is, that an advance against Richmond was, at this season, impracticable by any line; but a single march would have put him in position to give decisive battle under circumstances eminently advantageous to him."

The marches of the troops necessary for concentration, the points where they are to assemble, and the arrangements for the needed supplies of all kinds, will also be considered in drawing up the plan. It is thus seen that it is only the general features that are settled upon in determining the plan of campaign: that the marches of each day, the place for camping, etc., are details which do not enter into this problem, but are decided upon as the time comes for their accomplishment or selection. In drawing up the plan the outline maps of the country are made use of; those that show only the boundaries, principal cities, rivers, mountains, and roads are the best for the purpose. The topographical maps are resorted to when indicating the minor details of the march and camp, and also in studying the natural features of positions where it is expected to deliver battle.

A thorough knowledge of the geography of a country is then indispensable, both in planning a campaign and in conducting the minor operations of the war. The Archduke Charles says: "It is by studying the theater of war, that the objective points are learnt, and the means which the nature of the ground presents for taking possession of and maintaining them. By the aid of this knowledge operations are combined, that is to say, the way is examined by which it is possible to arrive more certainly at the proposed end, and the result to be expected awaited." Frederick the Great fought the battle of Leuthen on ground with which he was thoroughly familiar, having previously hunted over it. It was thus possible for him to make dispositions by means of which, with a force of thirty thousand men, he disastrously defeated the Austrian Army of eighty thousand men. "In 1796, Moreau's Army, entering the Black Forest, expected to find terrible mountains, frightful defiles and forests, and was greatly surprised to discover, after climbing the declivities of the plateau that slope to the Rhine, that these, with their spurs, were the only mountains, and that the country, from the source of the Danube to Donauwerth, was a rich and very level plain. "In 1813, Napoleon and his whole army supposed the interior of Bohemia to be very mountainous, whereas there is no district in Europe more level, after the girdle of mountains surrounding it has been crossed, which may be done in a single march." The Union armies labored under very great disadvantages during the rebellion from not having a proper knowledge of the statistics and topography of the Southern States, and ignorance of these subjects was a fruitful cause of grave errors and great loss.

The plan of the campaign, in the case of an army carrying on a defensive war, is called the *plan of defense*.

The character of the war to be carried on by the defence will depend upon the national characteristics of the people, the nature of the country, the number and discipline of the troops, etc. All these points will receive attention when developing the plan of defence.

The question whether an army acting on the defensive will await the hostile forces within its own frontiers or carry the war into the enemy's country, will also be decided. In the first case the army can take positions for receiving battle which have been selected, studied, and strongly fortified before hand; the enemy is obliged to make large detachments from his forces to hold places that it might be dangerous to leave unoccupied in his rear; the people can be relied upon to give timely information of the enemy's movements; facilities are offered for obtaining guides and spies; the army can operate in any direction with the certainty of finding a base or strong points of support. In case of disaster the difficulties and dangers of retreat are much lessened, while for the enemy, under adverse circumstances, the perils are greatly multiplied. The great objection to this system is that it makes the country sustain all the burdens of the war.

In the second case these relative advantages and disadvantages will be reversed, but the consideration of making the enemy contribute the means of carrying on the war may outweigh all others, and cause this system to be adopted. Particularly will this be the case when your forces, although not equal in numbers to the enemy, are well disciplined, and not inferior in other respects.

In the plan of defense it will be determined whether to meet the enemy on the frontier and dispute his advance, or to allow him to penetrate into the interior, and then concentrating all energies, make the results of a defeat overwhelming. In the campaign of 1812, in Russia, Napoleon was drawn on towards Moscow, which place he found in flames and then began the horrors of that terrible retreat, which deprived him of a large proportion of that magnificent army with which he had started out only a few months before.

Positions that are to be held to the last extremity, or that are to be abandoned after a certain amount of resistance; roads that are to be kept ready for all emergencies; points on which to fall back in case of disaster; places where stores and supplies are to be accumulated; all these will be designated in the plan of defense.

The army should be kept well together, ready to assume the offensive at the first favorable opportunity; for a passive defence seldom leads to passive results.

Movements in war, whether offensive or defensive, must always be based upon a calculation of time and distance. But the applications of this principle are easier in defensive than in offensive war. In the latter the operations are vaster, the conditions more variable, the elements of the calculation more uncertain. At any moment one may be forced to change his part, to abandon an attack in order to defend himself and to escape great perils. There is needed, therefore, a greater genius, to be always ready to vary his projects, to execute new combinations. In a defensive war, the theater is more contracted; the operations are upon familiar ground, the nature of which may be exactly appreciated. The combinations being less in number, it is easier to arrange for them and to confront them. In an offensive war genius must supply the want of experience, and guess at the character of the country in which the operations are made; the points of support upon which we count, vary and sometimes disappear. In defensive war we act upon a field prepared and studied; we have fixed pivots of operation; everything may be calculated with precision. A superior genius is then more necessary for offensive war, while a great knowledge of the profession, the talent to choose judiciously the points of support, an extreme foresight, with indefatigable activity, may suffice for the needs of defensive war.

Nevertheless, this kind of war is far from being easy, because properly speaking, a General is only reduced to act on the defensive when the means at his disposal are inferior to the enemy. Now, in modern wars, with equality of arms, instruction and experience, numbers are of chief avail.

In a military point of view, the offensive has its good and its bad side. Strategically an invasion leads to deep lines of operation, which are always dangerous in a hostile country. All the obstacles in the enemy's country, the mountains, rivers, defiles and forts, are favorable for defence; while the inhabitants and the authorities of the country, so far from being the instruments of the invading army, are generally hostile. However, if success be obtained, the enemy is struck in a vital point; he is deprived of his resources and compelled to seek a speedy termination of the contest. For a single operation, which we call taking the *initiative*, the offensive is almost always advantageous, particularly in strategy. Indeed, if the art of war consists in throwing the masses upon the decisive points, to do this it will be necessary to take the initiative. The attacking party knows what he is doing and what he desires to do; he leads his masses to the point where he desires to strike. He who awaits the attack, is everywhere anticipated; the enemy falls with large forces upon fractions of his force; he neither knows where his adversary proposes to attack him, nor in what manner to repel him. Tactically, the offensive also possesses advantages, but they are less positive, since, the operations being upon a limited field, the party taking the initiative cannot hide them from the enemy, who may detect his designs, and by the aid of good reserves cause them to fail. The attacking party labors under the disadvantages arising from the obstacles to be crossed before reaching the enemy's line; on which account the advantages and disadvantages of the tactical offensive are about equally balanced. Whatever advantages may be expected either politically or strategically from the offensive, it may not be possible to maintain it exclusively throughout the war; for a campaign offensive in the beginning may become defensive before it ends.

The offensive confers, at the outset, the power of concentrating on the flank or center of the enemy's line of defence, and so turning or breaking it. The defender must either oppose the enemy with an inferior force at first, or abandon territory in order to assemble his forces at some point further back. On the other hand, offensive war demands great resources, and success itself, if not absolute and decisive, entails fresh difficulties on the invader. And when he has penetrated very far within the defender's territory, the situations of the antagonists differ greatly, inasmuch as the army on the offensive is bound to its base, be that base wide or narrow, while the defensive forces may base themselves on any portion of the territory which will supply them and which their front protects.

It is evident, that when one belligerent power feels secure behind an unassailable frontier, and holds many issues into the enemy's territory, either by command of the sea or otherwise, it can assemble its forces unknown to its antagonists upon some point selected by itself, from whence to make an eruption into the theater of war. And if the belligerents be divided only by a frontier line—a river such as the Rhine or Potomac, or a mountain range such as the Alps—the army that passes it will nearly always find itself immensely superior to the force that can immediately interpose. For the defender's army has by the conditions of the defensive been spread so as to guard all possible avenues by which the attack might be made. Thus, in the Waterloo campaign, Wellington and Blucher, being on the defensive, were guarding all the roads from the French frontier into Belgium, along a front of a hundred miles. Napoleon suddenly assembled his whole army upon the center of their line, and, on first entering Belgium, was greatly superior to any force which the opposing General could interpose between him and his object, Brussels. During the American civil war, Richmond being the point arrived at by the principal Northern army, the Federals could, behind the screen of the Potomac, concentrate their forces and advance either from the Upper Potomac down the Shenandoah valley; from Washington along the Orange railroad to the Rappahannock; from Acquia Creek by the Fredericksburg and Richmond railway; by the peninsula between the York and James rivers adopting either stream as a base; or from the south side of James river by Petersburg. They used all of these lines, and frequently advanced at first with numbers greatly superior to those which the Confederates could assemble to oppose them. Thus, the great advantage conferred by the offensive, is the *power of concentration*.

A defensive war is not without its advantages when wisely conducted. It may be passive or active, taking the offensive at times. The passive defence is always pernicious; the active may accomplish great successes. The object of a defensive war being to protect as long as possible the country threatened by the enemy, all operations should be designed to retard his progress, to annoy him in his enterprises by multiplying obstacles and difficulties, without, however, compromising one's own army. He who invades does so by reason of some superiority; he will then seek to make the issues as promptly as possible; the defence, on the contrary, desires delay till his adversary is weakened by sending off detachments, by marches, and by the privations and fatigues incident to his progress. An army is reduced to the defensive only by reverses or by a positive inferiority. It then seeks in the support of forts, and in natural or artificial barriers, the means of restoring equality by multiplying obstacles in the way of the enemy. This plan when not carried to an extreme, promises many chances of success, but only when the General has the good sense not to make the defensive passive; he must not remain in his positions to receive whatever blows may be given by his adversary, he must, on the contrary, redouble his activity, and be constantly upon the alert to improve all opportunities of assailing the weak points of the enemy. This plan of war may be called the *defensive-offensive*, and may have strategical as well as tactical advantages. It combines the advantages of both systems; for one who awaits his adversary upon a prepared field, with all his own resources in hand, surrounded by all the advantages of being on his own ground, can with hope of success, take the initiative, and is fully able to judge when and where to strike.

At the commencement of a campaign, to *advance* or *not to advance* is a matter for grave consideration, but when once the offensive has been assumed, it must be sustained to the last extremity. However skillful the maneuvers, a retreat will always weaken the *morale* of an army, because in losing the chances of success, these last are transferred to the enemy. Besides, retreats always cost more men and *matériel* than the most bloody engagements; with this difference, that in a battle the enemy's loss is nearly equal to your own, whereas in a retreat the loss is on your side only. We will suppose an army taking the field; the first care of the Commander should be to agree with the head of the State upon the character of the war; then he must carefully study the theater of war, and select the most suitable base of operations, taking into consideration the frontiers of the State and those of its allies. The selection of this base and the proposed aim will determine the zone of operations. The General will take a first objective point; he will select the line of operations leading to this point, either as a temporary or a permanent line, giving it the most advantageous direction, namely, that which promises the greatest number of favorable opportunities with the least danger. An army marching on this line of operations will have a front of operations and a strategic front. The temporary positions which the *corps d'armée* will occupy upon its front of operations, or upon the line of defence, will be strategic positions. When near its first objective point, and when it begins to meet resistance, the army must either attack the enemy or maneuver to compel him to retreat: and for this end it will adopt one or two stragetic lines of maneuver, which, being temporary, may deviate to a certain degree from the general line of operations, with which they must not be confounded. To connect the strategic front with the base as the advance is made, lines of supply, depots, etc., will be established. Strategical points and lines are inseparable, and exist conjointly; a point is not decisive for military operations unless accessible for all armies, and a line is not considered as being advantageous, so much as the object to which it leads. The frontiers of States, are either large rivers, or chains of mountains, or deserts. Of all these obstacles to the march of an army the most difficult to overcome is the desert; mountains come next, and large rivers occupy the third place.

Some authors have represented that high ranges of mountains are. in war, inaccessible barriers. Napoleon, on the contrary, in speaking of the Rhetian Alps, said that, "An army could pass wherever a man could put his foot." Generals no less experienced than himself in mountain warfare have united with him in this opinion, in admitting the great difficulty of carrying on a defensive war in such localities, unless the advantages of partisan and regular warfare can be combined; the first to guard the heights and to harass the enemy, the second to give battle at the decisive points—the junction of the large valleys. When you are occupying a position which the enemy threatens to surround, collect all your force immediately, and menace him with an offensive movement. By this maneuver you will prevent him from detaching and annoying your flanks, in case you should judge it necessary to retire. It is an approved maxim in war never to do what the enemy wishes you to do, for this reason alone, that he desires it. A field of battle, therefore, which he has previously studied and reconnoitered, should be avoided, and double care should be taken where he has had time to fortify or intrench. One consequence deducible from this principle is, never to attack a position in front which you can gain by turning. Previous to the battle of Austerlitz, Napoleon put in practice this rule, which he himself gives in his memoirs: "When you have resolved to fight a battle, collect your whole force, dispense with nothing. A single battalion sometimes decides the day." Napoleon had carefully arranged for the concentration of forty thousand men at Vienna, or sixty-five thousand at Brunn, according as circumstances should permit. The Russians, on the contrary, attacked the French without waiting for General Essen, who was only a few days' march distant, and who was bringing with him nearly ten thousand men. The allies did exactly what Napoleon had wished. No force should be detached on the eve of a battle, because affairs may change during the night, either by the retreat of the enemy or by the arrival of large re-enforcements to enable him to resume the offensive, and counteract your previous dispositions.

With the purpose of dispersing the forces of the enemy, we must harass him particularly upon those points essential to his safety, and promplty seize the moment in which he has yielded to our feints, to attack him upon a weak point with *superior* numbers. This is just what is called a feint in fencing phrase, with the sword in hand, when in single combat. Two or three slight partial advantages open the way for the more considerable ones which decide the fate of the campaign. It is thus clearly seen how extremely important it is for a General to assume the *initiative* in all of his movements; thus he overrules the design of his enemy, and a first success frequently gives an ascendancy which is never lost. But the favorable moment must be clearly discerned. Too great a disproportion in the force and in the various means, would be an insurmountable obstacle. We should wait until the confidence of the enemy leads him into error.

Profiting diligently by the occasion when offered, the skillful General may always obtain an advantage which will permit him to turn the tables on his adversary, and to pass from defensive to offensive.

This is what happened, remarkably, in 1796, in the immortal campaign of Italy. The French army, having arrived at the frontiers of the Tyrol, and in a defensive position, found itself much inferior to the Austrian army, augmented as it was by the re-enforcements led by Wurmser in person. The enemy's General, when attacking, had divided his force; the French General reunited his own, and soon a first success enabled him to assume the offensive in turn. Afterwards a series of victories succeeded in combats where the French army was almost always superior in numbers upon the field of battle. To sum up, all in one word, this division of the art of war which applies to the general movements of armies, it should be observed, that it is always founded upon a calculation of time, distance, and celerity of movement.

During the late civil war in North America, General Jackson was quartered in the Shenandoah valley with about fifteen thousand or twenty thousand men. Opposite to him was a Northern army entering the valley from Harper's Ferry, under General Banks; another army under General Fremont, on the west side; and another army, under General Siegel, just on the east side of Manasses Gap. General Jackson descending the valley rapidly, first encountered the head of General Fremont's column near this point. General Jackson retreated rapidly for a day or two, until he had drawn the head of Fremont's army away from the main body, and then he fell on that and defeated it. The two Generals, Milroy and Schenck, were beaten and fell back on Fremont, who had just sent off despatches to Washington announcing a victory, but who was very glad to get over the mountains and make his escape. He was disposed of for a few days. Jackson proceeded down the valley, and moving rapidly on Manasses Gap, fell on a detachment of General Banks troops, and defeated them. General Bank's, who was down at Winchester, hearing of what had happened, came up speedily, and tried to support his unfortunate detachment. He met with Jackson under disadvantageous circumstances, and was beaten on the two days following, and was driven right over the Potomac into Washington.

During the Continental war, in 1866, like the two invading armies in Bohemia, so the two foes of Austria—Prussia and Italy—on a great scale, were assailing her on a double line. In all circumstances the rule must hold, that the defender in such a case ought not, except with forces superior to both, to attempt to make head against both attacks. The policy of retarding the attacks of one enemy, and operating in force against the other, is the only decisive mode of operation. For this reason Colonel Hamley maintained, before hostilities began, that Austria should at first have taken that step which circumstances afterwards forced on her, and, withdrawing all the forces disposable for the field, should have held only the fortresses and mountain passes, secure that, when once she had crushed her German foe, she could always, by Verona, issue upon the Italian army in Venetia and drive it over the Po.

Battles have been stated by some writers to be the chief and deciding features of war. This assertion is not strictly true, as armies have been destroyed by strategic operations without the occurrence of pitched battles, by a succession of inconsiderable affairs. It is also true that a complete and decided victory may give rise to results of the same character when there have been no grand strategic combinations. The results of a battle generally depend upon a union of causes which are not always within the scope of the military art; the nature of the order of battle adopted, the great or less wisdom displayed in the plan of the battle, as well as the manner of carrying out its details, the more or less loyal and enlightened co-operation of the officers subordinate to the Commander-in-Chief, the cause of the contest, the proportions and quality of the troops, their greater or less enthusiasm, superiority on the one side or the other in artillery or cavalry, and the manner of handling these arms; but it is the *morale* of armies, as well as of nations, more than anything else, which makes victories and their results decisive." When the march of an army has been so conducted, that, when it meets the enemy on the field of battle, it has a decided advantage over him, the battle which follows will usually be more decisive than in the contrary case. A single battle well fought under the foregoing condition, has frequently been decisive of the whole campaign, and even of the war. The battle of Jena gave Napoleon advantages, which, vigorously followed up in the manner so peculiar to him, soon placed the kingdom of Prussia at his feet, and left him free to turn his attention to the Russians.

Battles are classed as offensive, defensive, and as a combination of these two, viz., offensive-defensive or defensive-offensive. *a.* In an offensive battle, the army moves to attack the enemy wherever found. "It must be admitted that the assailant generally has a moral advantage over the assailed, and almost always acts more understandingly than the latter, who must be more or less in a state of uncertainty." *b.* In a defensive battle, the army selects a position in which to receive the enemy, and does not leave it. Gettysburg was, for the Union troops, a strictly defensive battle; for the Confederates, it was an offensive battle. *c.* When, in the first case, the army leaves its position at any time during the battle in order to attack the enemy, it then fights a defensive-offensive battle; while for the enemy, the battle is offensive-defensive. The battle of Chancellorsville was offensive-defensive for the Union troops, and the reverse for the Confederates. In the same manner that a nation may be restricted to a defensive war, a General may be required to fight a defensive battle. Owing to inferior numbers, having troops inferior in discipline to the enemy, or armed with an inferior weapon, a General may be constrained to take a position and await the attack of the enemy. By taking a strong position, this inferiority may be counterbalanced; and, by assuming the offensive at the proper time, he may gain a great advantage over the enemy, which, properly followed up, may give him the victory. The Austrians were restricted to the defensive at the battle of Königgratz, because they were armed with a muzzle-loading rifle, and were inferior to the Prussians in numbers and discipline; the latter were armed with the breech-loading needle-gun. A pure defence can never win a battle, it may perhaps enable the troops acting on the defensive to preserve their position, but the most that can be hoped for from a pure defence is a drawn battle, not a victory. The improvements in modern arms have undoubtedly added much to the power of the defence, but the attack has been advanced also.

At first sight, it would appear that the defence would gain more from the peculiarities of improved fire-arms than the attack. An army acting on the defensive, may have it in its power to choose such a position, as to oblige the enemy to cross an open plain; it will also probably have time to ascertain the distance of certain fixed points, so as to produce the greatest effect from its fire. On the other hand, the advantages that an attacking force possesses are also very considerable. As its Commander has only to consult his own judgment, he regulates his movements according to the disposition of the enemy. He, being the assailant, has a definite object before him, and chooses his own way of obtaining it; while the defender has first to find out his adversaries intentions, and then to make the best arrangements for frustrating them. On the one side, confidence and resolution, on the other, uncertainty and anxiety. The defender, if he wish to bring about a decisive result, must eventually himself become the assailant; but here the question arises, whether before advancing to attack, he should not exhaust all the material advantages to be gained from stationary fire, by employing it to the very last moment.

When two armies come in contact the one that acts on the offensive or takes the initiative has the power of selecting the point for attack, and of arranging against that point a superior force. The defender does not know where he will be attacked, and has to provide for several possible, nay probable contingencies. He is liable to be deceived, induced to disseminate his force, and seek to be strong at all the threatened points, while the assailant need be strong at one and that the decisive point. Increased range and accuracy in weapons have given the attacker the power of selecting far more advantageous positions for covering and supporting his attack than formerly. Ground which in the days of old artillery might be simply ignored must now be held by the defender, thus compelling him to extend and therefore weaken his whole line; or it must be abandoned to the enemy, who will quickly make use of it as a *point d'appui* for an attack; and as the area operated over has thus increased at a much quicker rate than the actual effective range of the weapons, the assailant benefits considerably.

When the enemy's line is found to be equally strong along the entire front, so that no favorable point of attack can be found the possession of which will carry with it advantages proportionate to the losses which would follow upon its capture, then the better plan would be to flank or turn the enemy, and compel him to abandon his position. The attack is seldom confined to one point, but, having selected the place where the great effort will be made, endeavor to mislead the enemy by one or more *false* or *feint* attacks, to keep him in doubt as to your real intentions, and to prevent him from concentrating his troops to meet your forces making the main attack. Tactical and strategical considerations both enter the problem of determining the point of attack; the consideration which will govern in any particular case will depend upon the results which are expected to

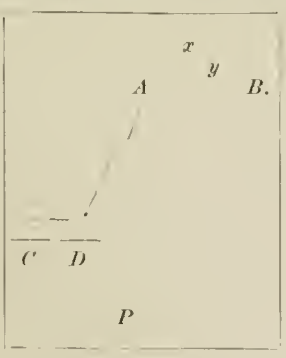


Fig. 1.

follow the defeat of the enemy, or the risks to be run in attaining these results. The tactical considerations relate to the advantages which can be gained on the field of battle; and the strategical to the consequences of victory. The strategical conditions are more important than the tactical, unless the difficulties of the ground are too great, and the results expected to follow do not justify the risks to be taken.

Let the army *P* in Fig. 1, find the enemy in the position *AB*, with one flank resting on a hill and the other on a river, with an impassable marsh in front. The point *A* is both the strategical and tactical point of attack; for its capture would command the field of battle, force the enemy from his line of retreat, *xy*, and throw him back on the impassable obstacle opposite the left flank. *AC*, with the right re-enforced would be a better position for the assailed to take, as in this case an attack at *A* would compel the assailant to fight with an obstacle at his back, and an attack at *C* would give the assailed the full benefit of the height. The position *AC* is also objectionable, as it presents a salient *D*, always a weak point in a line, because it renders both faces liable to be enfiladed.

Suppose an army, acting on the defensive, to have the position *XY*, Fig. 2: its right uncovered, and its left resting on an impassable obstacle. The strategical point of attack is *Y*; for, if the left is forced back, the line of retreat *AB* is exposed. But the selection of *Y* as the point of attack, forces the assailant to fight with his back to the obstacle *Z*, which would be very dangerous unless greatly superior to the enemy. Rather *X* select as the point of attack, and depend upon vigorous fighting and pursuit for great results. Combined attacks, like combined marches, cannot be relied upon for success. They should only be undertaken when the natural features of the country are such that the enemy can easily be checked if he attempts to make a counter-attack,

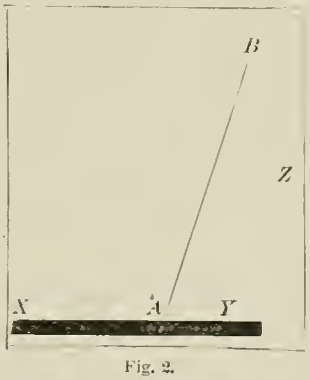

Fig. 2.

and when the preliminary movements of the troops are concealed from his view. When the features of the country are such that the detachments can, by taking up naturally strong positions, hold the enemy in check, the main body can operate with safety against the flank; for, in case of repulse, its main line of retreat would not be compromised. Much depends upon the character of the opposing General; if he be alert and always ready to act promptly and vigorously, any extended movements would be dangerous, although it might under other circumstances be successfully carried out. Movements may be made with troops that are superior in numbers or in discipline, which would be very rash when the opposing forces are nearly equal, or the Commanders of the same capacity.

There are really but two ways in which a battle can arise. *a.* When one army is on the defensive, and holds a strong post, the other moving forward to attack it. *b.* When the two armies meet, both being in movement. Auerstadt, Solferino, Mars-La-Tour, are all examples of this latter kind of battle, but in every case the *rôle* of attacker or defender falls to one side, sometimes to each alternately, and it may vary in different portions of the field, the same army being on the defensive in one place and on the offensive in another. However a battle may actually come about, the order of march of the troops forming the army must be intimately connected with the action of the troops in the line of battle; consequently the order of march must be invariably detailed so as to allow of the armys first required being near the head of the column. If the way in which battles begin is considered, it will be found that the cavalry of the advanced-guard usually find the enemy and report his position; if he is in a defensive position, they report the circumstance; if on the move, they report the force immediately in front of them. In all probability they will be driven in on the main body of the advanced-guard, the Commander of which must then take up the best defensive position he can, to cover the deployment of the troops in his rear. If the enemy are holding a defensive position, he will not be very much troubled, because few Generals will like to leave a carefully prepared position and to give up too soon the advantage of acting on the defensive, or to move until the plans of the attacker have declared themselves. In such a case the Commander of the advanced-guard, knowing that the enemy is to be attacked, must take up such a position that he may protect and cover the advance of the main body to the attack.

If the enemy are not holding a defensive position, he will in all likelihood be hardly pressed, and have some difficulty in maintaining a *point d'appui* on which the troops in rear are to form up to the right or left, such as Hassenhausen, held by Gudin at the battle of Auerstadt. Consequently it follows that those arms of the service which can best facilitate the formation, should be near the head of the column. Hence there is a very close connection between the tactical action of troops on a field of battle, and their order of march, and it is essentially requisite that the order of march, be subordinated to the deployment of the army into line of battle, and this becomes all the more important as the troops approach the actual point of collision. As they do so, the number of roads on which they are moving must be reduced, by the mere convergence of the columns, and hence, the order of the troops in those columns becomes of the utmost importance. It is further manifest that there should be no definite order of march, but the actual order in which the troops stand should be regulated by the work to be done, and the nature of the country.

It is manifestly the object of the officer commanding the advanced-guard to find a position such as will compel the enemy to develop a considerable force to attack him, and at the same time enable him to make head against such an attack. Such a position can generally be found; it is often desirable to occupy a small village or town, loop-hole some houses or buildings, or form some trenches, which will enable the advanced-guard to remain in possession of the ground. It is requisite in many cases to open passages to the right and left for troops to move through and facilitate the formation; a strong body of engineers should therefore move with the advanced-guard. If the enemy is in position, and does not show any inclination to attack, a portion of the engineers may be detailed to remove obstacles, form any small bridges that may be required, such as those that were needed for the passage of the Bistritz and Sauer, and facilitate the advance of the troops beyond the position taken up by the main body of the advanced-guard. But as the line of advance of an army acting on the offensive will, if defeated, be generally its line of retreat, it will be always well to strengthen some points which in case of disaster may afford a rallying place to troops that are worsted. But no position can be properly defended without artillery, consequently the Commander of the advanced-guard should have a strong force of artillery with him, which he must use boldly, to search out the enemy's position, compel him to unmask his guns, and declare himself. The Commander of the artillery of the advanced-guard has a very responsible office thrown on him. He must not only find positions for his own guns, but he should, from the fire of the enemy, be able to select places for the corps batteries as they come up; and to facilitate this object he should place his batteries so as to leave room for others to come up in support of them.

The battle of Mars-La-Tour offers an excellent example of the action of an advanced-guard on a large scale, when meeting an army on the move. The object of the Germans was to hold the French fast, and prevent their retreat on Verdun, while the remainder of their army came up. Thus the troops that first attacked the French were really acting like all other advanced-guards, they were covering the front and giving time for the deployment of the army. The German General, Alvensleben, learning from his reconnoitering officers that the French were encamped between Vionville and Rezonville, determined to attack them with his own corps, the third, and what other troops were near. At nine A. M., the Germans established between Tronville and the road by which the French were retreating, four horse-artillery batteries and three cavalry regiments, which surprised the French encampments, compelled the French to retire and deploy, facing west across, and at right angles to the Verdun road. At eleven o'clock Vionville was taken by the Prussian infantry and immediately strengthened by two companies of engineers, and it at once became a *point d'appui* round which the whole Prussian line pivoted throughout the day. The four horse-artillery batteries were soon supported with four batteries, which fired on the French infantry masses, causing them to suffer severely; soon, however, the German ammunition columns began to be exhausted, and the ammunition columns left at Gorge, although ordered up in time, could only come up the ravine with great difficulty and under a shower of French shells. Then the corps artillery came into action to the east of Tartleville. The operation was no easy one. Once in position it was received with a terrible infantry fire from Flavigny. But the batteries held their ground, being shortly supported by four more batteries, which extended the line of guns to the left towards Vionville. The fire of the French infantry, at nine hundred to one thousand two hundred yards, caused great loss, covering the batteries with a rain of bullets. The eight batteries in position near Vionville, and the seven near Flavigny, now concentrated their fire on Flavigny and the Cistern wood; these fifteen batteries completely cleared that important position, which fell to the Germans about twelve o'clock without any serious infantry fighting. The second French corps, shaken by the terrible artillery fire, called on its cavalry for support, and a sharp cavalry action ensued, under cover of which nine of the fifteen German batteries advanced beyond the Flavigny road so as to embrace that place in the German line of battle; three other batteries advanced almost simultaneously along the main road between Rezonville and Vionville; but these movements were only executed at the cost of heavy losses; some batteries losing all their officers, others many of their horses.

It will be seen by this abridged account, that the German guns were not advancing in line with or following in rear of the infantry. But the movements of the artillery, so far from being rigidly tied down to conform to the rules of the infantry, were tactically independent, that is to say, both the arms were working each according to its own special peculiarities for the attainment of one object. Long before the Prussian infantry could come on the ground in any force, the artillery was in position, preparing the way for it, protected on its flanks by cavalry and a small force of infantry. The manner in which the German artillery was used to extend the line of battle, fill up a great gap in its center, and so not only occupy a longer front themselves, but attack their enemy over a larger front, is well worthy of notice: they were working tactically together with the cavalry and infantry to debar the French from the Verdun road, and give time for the deployment of the German army. The attack of the French cavalry on the German batteries was at once met by the German cavalry, and the fire of the guns being then masked, both as regards their own, and to a certain extent their opponent's fire by the cavalry fight, the batteries seized the opportunity and dashed to the front. At one o'clock the Prussians had two cavalry divisions, one corps, and twenty-one batteries in action, the French had one cavalry division, two corps, and twenty-six batteries. The whole of the Prussian guns were really in three batteries, of nine, seven, and five guns respectively, while the French guns were scattered about. After one o'clock the French took the offensive, and drove back the Prussian wings; the center, however, held fast to Vionville. In this action the use made of artillery and engineers to check the French and gain time, the action of the artillery especially, in seizing advantageous places, and rapidly bringing up fresh batteries, and in concentrating masses of fire on certain points, are well worthy of close examination. If the guns had not been with the advance, the same result could never have been obtained. It is worth noticing where the guns marched. The artillery had no special escorts, one battery marching with the cavalry brigade forming the advanced-guard, and the other three with the main body of the division; all the divisional artillery of the third corps marched between the brigades of the leading division, the corps artillery between the divisions. Notwithstanding the eighth Prussian corps hardly came into action at all, a large number of its batteries coming in towards the close of the day, supported the exhausted artillery of the tenth and third corps. We have said that no matter how a battle may begin, the *rôle* of attacker and defender will usually fall to one side, and perhaps change several times during the course of the day, depending on the number of men engaged at one place, the strength of the positions, the mode of handling the reserves, and the number of men defending the position.

To conduct a retreat successfully in the presence of a victorious or superior enemy is the most difficult operation in war. This is owing to a great extent to the effect produced on the *morale* of the troops as soon as their backs are turned on the enemy. The magnitude of the distances and the nature of the country to be traversed, the resources it offers, the obstacles to be encountered, the attacks to be apprehended, either in rear or in flank, superiority or inferiority in cavalry, the spirit of the troops, are circumstances which have a great effect in deciding the fate of retreats, leaving out of consideration the skillful arrangements which the Generals may make for their execution. It is upon the rear-guard in retreats that the safety of the army depends, and the efforts and sacrifices made by it should be unlimited when necessity calls for them. The officer to command the rear-guard should be selected with regard to his coolness in emergencies, his prudence and judgment in making dispositions. "He should be feared and respected by his enemies." A retreat is always a necessity after a lost battle or after an unsuccessful enterprise. When a retreat is inevitable, the troops engaged must first be withdrawn. This, when possible, should be done by alternate lines, the movement being protected, as much as possible by the artillery, a portion of which remains with the line nearest the enemy for this purpose. A *rear-guard* of the freshest troops is organized as soon as possible; the pursuing enemy is checked or forced to deploy, when the retreat is stopped and the troops reorganized, and order restored. The army is then again in condition to confront the enemy. The sooner all this can be accomplished, the less will be the losses from the consequences of defeat. The losses in battle are small when compared to those of a disorganized, routed army on the retreat. The nature of the retreat will depend entirely upon the nature of the pursuit. A vigorous enemy, following up his advantage with energy, will soon entirely disperse or capture a defeated army. At the commencement of a retreat it frequently becomes necessary to decide whether a forced march will be made, or whether the retreat will be conducted by regular marches. With a large army it may be set down as a general rule that short marches should be made, placing the main reliance for safety upon the rear-guard. A forced march with a large army is a very difficult operation under the most favorable circumstances, but when made by a beaten, dispirited, disorganized army, it may lead to the most disastrous results.

There are five methods of arranging a retreat: The first is to march in a single mass and upon one road. The second consists in dividing the army into two or three corps, marching at the distance of a day's march from each other, in order to avoid confusion, especially in the *matériel*. The third consists in the marching upon a single front by several roads, nearly parallel, and having a common point of arrival. The fourth consists in moving by constantly converging roads. The fifth, on the contrary, consists in moving along constantly diverging roads. A retreat conducted in accordance with the first method would evidently be a dangerous operation with a very large force, and especially so if the enemy should make a vigorous pursuit. The danger would arise from overcrowding, which might soon convert the retreat into a rout. The second method might be followed when the enemy does not push the retreating army too hard. When the roads are good the fourth method would be most excellent, for the army, as it marches onward in retreat, is constantly concentrating, a very desirable object to attain. In regard to the fifth method there are only two cases in which divergent roads can be followed: 1st. When an army has experienced a great defeat in its own country, and the scattered fragments seek protection within the walls of fortified places. 2d. In a war when the sympathies of the whole population are enlisted, each fraction of an army thus divided may serve as a nucleus of assembly in each province; but in a purely methodical war, with regular armies, carried on according to the principles of the art, divergent retreats are simply absurd.

Usually a retreat should be regulated by the same rules as a forward movement, viz., the different corps of the army should move on parallel roads within mutual supporting distances. This is a point of the greatest importance, for the army should always be prepared to meet an enemy ever on the alert for a favorable chance to attack. The crossing of a large stream by an army on the retreat is usually an operation of extreme difficulty. The trains should first be crossed, and well cover their passage the army should take a strong position some distance in advance of the point selected for the crossing. The march of the rear-guard should be so regulated that it will reach the point intended for it to cross just after the last of the main body has passed. After the rear-guard has crossed, the bridge should be destroyed. A retreat conducted parallel to a frontier may often lead to very decisive results. As this operation usually exposes a flank to the enemy, it can only be resorted to with safety when the natural features of the country greatly favor it. When the line of retreat is along a large river, or along a mountain, the bridges and defiles of which are under the control of the retreating army, the advantages are very great. When this line of retreat is through the enemy's country, the army can subsist at his expense, and cause him to bear the full weight of the war; and when the army's line of retreat is within its own frontier, the enemy is drawn on without gaining ground towards the interior, is forced to expose his flanks to attacks from those directions, and is forced to march through a hostile country, the inhabitants of which are always ready to assist his opponent.

After a battle is gained the defeated army should be pursued unceasingly. You have won a great battle, and the enemy are in full retreat: run after him; hammer him with guns, charge with cavalry, above all things pass round his flanks, and keep pushing him and hitting him from morning until night. His forces will soon cease to be an army. The French after Waterloo, when well beaten by the English, and pursued without intermission by the Prussians, flocked back across their frontier a disorganized mass without arms. The General who, in pursuit, acts with precaution, who maneuvers instead of charging, will never inflict much harm upon an enemy: caution is out of place when you have a beaten army before you. This conduct, which by some may be termed reckless, may at times occasion losses to the pursuer, but unless it is practised, you can never expect to crush a retreating enemy. This is the time for cavalry and mounted infantry, if you have any of the latter. When the pursuit is vigorously made many risks may be taken, for it is safe to presume that the enemy cannot in this case make a decided stand, or turn on the offensive with very much prospect of success. The communications of the defeated army should be seized, if possible, because when they are gained the whole *matériel* of the enemy is at your mercy, and a position may be taken to bar his further retreat or attack him in flank. The latter operation will usually be the safer one, because the efforts of a desperate foe may accomplish much in the former case. A great effort should be made to separate the forces of the retreating army, as in this case a larger fraction of it may be destroyed or captured, while in the contrary case little damage would be inflicted. A road parallel to that taken by the retreating forces offers many advantages to the pursuing army; for, by following this road, opportunities may be presented of making a flank attack. A retreat, from its moral effects, always gives certain advantages to the pursuing force, even when made by an army in good condition.

A description of Soult's retreat, after leaving Oporto, is taken to illustrate the difficulties which may be surmounted in operations of this nature. The 15th, Sir Arthur reached Braga. Murray was at Guimaraens on his right, and Beresford, who had anticipated his orders, was near Chaves, having sent Sylveira towards Salamonde, with instructions to occupy the passes of Ruivaens and Melgassy. But at this time Soult was fifteen miles in advance of Braga, having, by a surprising effort, extricated himself from one of the most dangerous situations that a General ever escaped from. To understand this, it is necessary to describe the country through which his retreat was effected. We will observe that the Sierra de Cabirera and the Sierra de Catalina line the right bank of the Tamega; but, in approaching the Douro, the latter slants off towards Oporto, thus opening a rough but practicable slip of land, through which the road leads from Oporto to Amarante. Hence, the French in retreating to the latter town had the Douro on their right hand and the Sierra de Catalina on their left. Between Amarante and Braga, which is on the other side of the Catalina, a route practicable for artillery runs through Guimaraens, but it is necessary to reach Amarante to fall into this road. Thus, Soult, as he advanced along the narrow pass between the mountains and the Douro, rested his hopes of safety entirely upon Loison's holding Amarante. Several days, however, had elapsed since that General had communicated, and an aide-de-camp was sent on the morning of the 12th to ascertain his exact position. Colonel Tholosé, the officer employed, found Loison at Amarante, but neither his remonstrances, nor the after-coming intelligence that Oporto was evacuated, and the army in full retreat upon the Tamega, could induce that General to remain there, and, as we have seen, he marched toward Guimaraens on the 13th, abandoning the bridge of Amarante without a blow, and leaving his Commander and two-thirds of the army to what must have appeared inevitable destruction. The news of this unexpected calamity reached Soult at one o'clock on the morning of the 13th, just as he had passed the rugged banks of the Souza river; the weather was boisterous, the men were fatigued, voices were heard calling for a capitulation, and the whole army was stricken with dismay. Then it was that the Duke of Dalmatia justified by his energy that fortune which had raised him to his high rank in the world. Being by a Spanish pedlar informed of a path that, mounting the right bank of the Souza, led over the Sierra de Catalina to Guimaraens, he, on the instant, silenced the murmurs of the treacherous or fearful in the ranks, destroyed the artillery, abandoned the military chest and baggage, and loading the animals with sick men and musket ammunition, repassed the Souza, and followed the Spanish guide with a hardy resolution. The rain was falling in torrents, and the path was such as might be expected in those wild regions, but the troops made good their passage over the mountains to Pombeira, and, at Guimaraens, happily fell in with Loison. During the night they were joined by Lorge's dragoons from Braga, and thus, almost beyond hope, the whole army was concentrated.

If Soult's energy in command was conspicuous on this occasion, his sagacity and judgment were no less remarkably displayed in what followed. Most Generals would have moved by the direct route upon Guimaraens to Braga; but he, with a long reach of mind, calculated upon the slackness of pursuit after he passed Vallonga, that the bulk of the English army must be on the road to Braga, and would be there before him; on that, at best, he should be obliged to retreat, fighting, and must sacrifice the guns and baggage of Loison's and Lorge's corps in the face of an enemy—a circumstance that might operate fatally on the spirit of his soldiers, and would certainly give opportunities to the malcontents; and already one of the Generals (apparently Loison) was recommending a convention like Cintra. But, with a firmness worthy of the highest admiration, Soult destroyed all the guns and the greatest part of the baggage and amunition of Loison's and Lorge's divisions; then, leaving the high road to Braga on his left, and once more taking to the mountain paths, he made for Carvalho d'Este, where he arrived late in the evening of the 14th, thus gaining a day's march in point of time. The morning of the 15th he drew up his troops in the position he had occupied just two months before at the battle of Braga; and this spectacle, when twenty thousand men were collected upon the theater of a former victory, and disposed so as to produce the greatest effect, roused all the sinking pride of the French soldiers. It was a happy stroke of generalship, an inspiration of real genius! Soult now re-organized his army; taking command of the rear-guard himself, and giving that of the advanced-guard to General Loison. Noble, the French historian of this campaign, says, "The whole army was astonished"; as though it was not a stroke of consummate policy that the rear, which was pursued by the British, should be under the General-in-Chief, and that the front, which was to fight its way through the native forces, should have a Commander whose very name called up all the revengeful passions of the Portuguese. *Maneta durst not surrender;* and the Duke of Dalmatia dexterously forced those to act with most zeal who were least inclined to serve him; and, in sooth, such was his perilous situation, that all the resources of his mind and all the energies of his character were needed to save the army.

From Carvalho he retired to Salamonde, from whence there was two lines of retreat. The one through Ruivaens, by which the army had marched when coming from Chaves two months before; the other, shorter, although more impracticable, leading by the Ponte Nova and Ponte Miserella into the road from Ruivaens to Montalegre. But the scouts brought intelligence that the bridge of Ruivaens, on the little river of that name, was broken, and defended by one thousand Portuguese, with artillery; and that another party had been, since the morning, destroying the Ponte Nova on the Cavado river. The destruction of the first bridge blocked the road to Chaves; the second, if completed, and the passage well defended, would have cut the French off from Montalegre. The night was setting in, the soldiers were harassed, barefooted, and starving; the ammunition was damp with the rain, which had never ceased since the 13th, and which was now increasing in violence, accompanied with storms of wind. The British army would certainly fall upon the rear in the morning; and if the Ponte Nova, where the guard was reported to be weak, could not be secured, the hour of surrender had certainly arrived. In this extremity, Soult sent for Major Dulong, an officer justly reputed for one of the most daring in the French ranks. Addressing himself to this brave man, he said, "I have chosen you from the whole army to seize the Ponte Nova, which has been cut by the enemy. Do you choose one hundred grenadiers and twenty-five horsemen; endeavor to surprise the guards, and secure the passage of the bridge. If you succeed, say so, but send no other report; your silence will suffice." Thus exhorted, Dulong selected his men, and departed. Favored by the storm, he reached the bridge unperceived of the Portuguese, killed the sentinel before any alarm was given, and then, followed by twelve grenadiers, began crawling along a narrow slip of masonry, which was the only part of the bridge undestroyed. The Cavado river was in full flood, and roaring in a deep channel; one of the grenadiers fell into the gulf; but the noise of the storm and the river was louder than his cry; Dulong, with the eleven still creeping onwards, reached the other side, and falling briskly on the first posts of the peasants, killed or dispersed the whole. At that moment, the remainder of his men advanced close to the bridge; and some crossing, others mounting the heights, shouting and firing, scared the Portuguese supporting posts, who imagined the whole army was upon them; and thus the passage was gallantly won.

At four o'clock, the bridge being repaired, the advanced-guard of the French commenced crossing; but as the column of march was long, and the road narrow and rugged, the troops filed over slowly; and beyond the Ponte Nova there was a second obstacle still more formidable. For the pass in which the troops were moving being cut in the side of a mountain, open on the left for several miles, at last came upon a torrent called the Miserella, which breaking down a deep ravine, or rather gulf, was only to be crossed by a bridge, constructed with a single lofty arch, called the *saltidor*, or leaper; and so narrow that only three persons could pass abreast. Fortunately for the French, the *saltidor* was not cut, but entrenched and defended by a few hundred Portuguese peasants, who occupied the rocks on the further side; and here the good soldier Dulong again saved the army; for, when a first and second attempt had been repulsed with loss, he carried the entrenchments by a third effort; but at the same instant fell deeply wounded himself. The head of the column now poured over, and it was full time, for the English guns were thundering in the rear, and the Ponte Nova, was choked with dead. Sir Arthur Wellesley, quitting Braga on the morning of the 16th, had come, about four o'clock, upon Soult's rear-guard, which remained at Salamonde to cover the passage of the army over the bridges. The right was strongly protected by a ravine, the left occupied a steep hill; and a stout battle might have been made, but men thus circumstanced, and momentarily expecting an order to retreat, will seldom stand firmly; and, on this occasion, when some light troops turned the left, and General Sherbrooke, with the guards mounting the steep hill, attacked the front, the French made but one discharge, and fled in confusion to the Ponte Nova. The French reached Montalegre on the 17th. Sir Arthur, with the main body of the army, halted that day at Ruivaens. The 18th he renewed the pursuit, and a part of his cavalry passed Montalegra, followed by the guards; the enemy was, however, drawn up behind the Salas in force, and no action took place. Sylveira, indeed, had entered Montalegre, from the side of Chaves, before the British came up from Ruivaens; but instead of pursuing, he put his men into quarters; and a Portuguese officer of his division, who was despatched to Marshal Beresford with orders to move from Villa Perdrices upon Villa del Rey, loitered on the road so long that all chance of intercepting the French line of march was at an end; for, though Beresford, on the 19th, pushed Colonel Talbot with the Fourteenth dragoons as far as Ginjo, Francheschi turned in force, and obliged that officer to retire, and thus the pursuit terminated.

Soult, on the 19th, entered Orense, but without guns, stores, ammunition, or baggage; his men exhausted with fatigue and misery, the greatest part being without shoes, many without accouterments, and in some instances even without muskets. He had carried fifty-eight pieces of artillery into Portugal, and he returned without a gun; yet was his reputation as a stout and able soldier nowise diminished. When General Loison abandoned Amarante, he relinquished all claims to military reputation, as a simple statement of facts will prove. The evening of the 12th he wrote to Soult that one regiment had easily repulsed the whole of the enemy's forces; yet he, although at the head of six thousand men, cavalry, infantry, and artillery, that night, and without another shot being fired, abandoned the only passage by which, as far as he knew, the rest of the army could escape from its mighty perilous situation with honor. The marches and encounters, from the 14th to the 17th, were excellent on both sides. Like the wheelings and buffeting of two vultures in the air, the generals contended, the one for safety, the other for triumph; but there was evidently a failure in the operations of Marshal Beresford. Soult did not reach Salamonde until the evening of the 15th, and his rear-guard was still there on the evening of the 16th. Beresford was in person at Chaves on the 16th, and his troops reached that place early on the morning of the 17th. Soult passed Montalegre on the 18th, but from Chaves to that place is only one march. Again, Marshal Beresford was in possession of Amarante on the 13th, and as there was an excellent map of the province in existence, he must have known the importance of Salamonde, and that there were roads to it through Mondin and Cavez shorter than by Guimaraens and Chaves. It is true that Sylveira was sent to occupy Ruivaens and Melgacy; but he executed his orders slowly, and Miserella was neglected. Major Warre, an officer of the Marshal's staff, endeavored, indeed, to break down the bridge of Ponte Nova and Ruivaens; and it was by his exertions that the peasants, surprised at the former, had been collected; but he had only a single dragoon with him, and was without power to execute this important task. The peasantry, glad to be rid of the French, were reluctant to stop their retreat, and still more to destroy the bridge of Miserella, which was the key of all the communications, and all the great markets of Entre Minho e Douro; and therefore sure to be built up again, in which case the people knew well that their labor and time would be called for without payment. It is undoubted that Soult owed his safety to the failure in breaking those bridges; and it does appear that if Major Warre had been supplied with the necessary escort and materials he would have effectually destroyed them. "Sylveira did not move either in the direction or with the celerity required of him by Beresford; there seems to have been a misunderstanding between them; but allowance must be made for the numerous mistakes necessarily arising in the transmission of orders by officers speaking different languages; and for the difficulty of moving troops not accustomed or perfectly willing to act together." Instructive lessons may also be learned from the following: Soult from Spain in 1814 (parallel retreat); Frederick the Great from Moravia in 1758 (parallel retreat); Napoleon from Moscow in 1812 (parallel pursuit); Grouchy after Ligny in 1815 (pursuit); retreat of the Austrian army after Koniggratz in 1866; retreat of the English army from Quatre Bras on Waterloo in 1815; Johnston's withdrawal before Sherman's advance through Georgia in 1864; Lee before Grant in Virginia the same year, etc.

The conduct of the advance-guard and the manner of executing the marches will always materially influence strategical operations. The strength of the advanced-guard will depend upon the nature of the country, the strength of the main body, the quality of the troops, the season of the year, and upon the duty required of it. If an attack is expected, or it is required to take or hold a certain position, it will be stronger than under the ordinary conditions of march. As a rule its strength will vary from *one-fifth* to *one-third* the total force. The fact that, when very strong, the duty would recur so often as to greatly fatigue the men, and if too weak, it might become an object to the enemy to make an attempt to cut it off from the main body and capture or destroy it, should also be considered when determining the strength of the advanced-guard The duty should be so regulated that it will fall in turn to all the different divisions of the army, in this way simplifying the details of the service, familiarizing all the troops with the duty, and keeping them under the command of their proper officers, which will have a good effect on the discipline of the command. The plan of making details for this duty from the different regiments tends to relax discipline by bringing men under officers with whom they are not accustomed to serve. The composition of an advanced-guard is usually the same as that of the body of troops which it is designed to cover and protect. The advanced-guard of an *army* is generally composed of the three arms, viz.: infantry, cavalry, and artillery; the relative proportion of each depending upon the nature of the country and the resistance it may be required to make. Following the general rule, the cavalry will predominate in an open country; in fact in such a country, nearly all the cavalry of an army on the march should be thrown well to the front and on the flanks, thus affording the best protection from a surprise, gaining information of the enemy's movements and designs, and covering those of its own army, enabling the General to make any desirable dispositions without the enemy's knowledge. In a broken or rugged country the *main force* will consist of *infantry*, such ground being best adapted to the movements and methods of fighting of this branch of the service. The cavalry in this case should be employed in scouting, and in conveying information to the rear.

The principle of the formation of an advanced-guard is that it is made up of a number of detachments, increasing progressively in strength from the front to the rear. The object of each of these detachments is to guard against surprise the stronger body which follows immediately in rear, and to give the latter time to prepare for attack. This consideration regulates the distances to be preserved between strong detachments. When the detachments are small, the distances need only to be sufficiently great to prevent the possibility of the rear detachment being suddenly brought under fire without notice. The advanced-guard should be divided into the *advanced party* with its *support*, the *reserve* of the advanced-guard. The strength of the *reserve* should be from *one-third* to *one-half* of the whole advanced-guard. The remainder will make up the *advanced party* and its *support*, being in the proportion of about *one-third* for the *advance party* to *two-thirds* for the *support*. "The extreme front of the advanced-guard

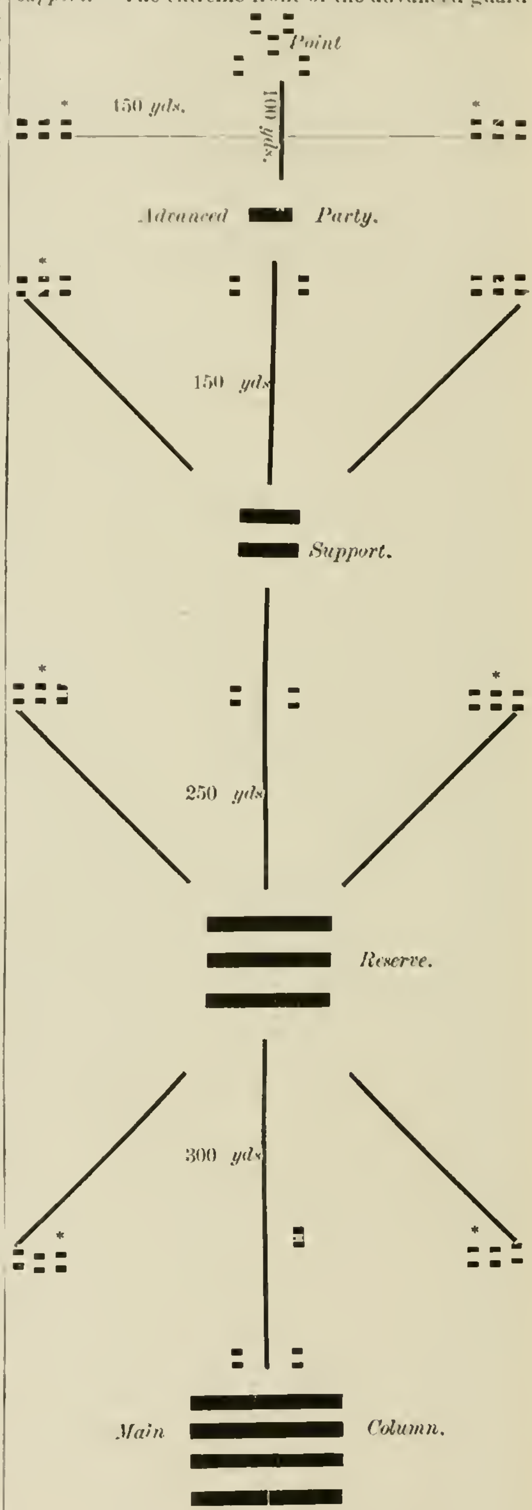

Fig. 3.

will always consist of a leading group, or point, of three or four men, under a Non-commissioned Officer if possible, sent forward from the advanced party."

To illustrate the general dispositions of an advanced-guard—which are about the same for all, whatever their strength and purpose—the manner of arranging a guard of one hundred and fifty men, infantry, will be taken. First,—Fig. 3—a leading group of four men under a Corporal, flanked by two groups of three or four men each to the right and left rear, not more than one hundred and fifty yards off the main route. The remainder of the advanced party follows at one hundred yards from the point. At one hundred and fifty yards, a connecting file between, the support follows, detaching, when required, two small flanking groups, to support and keep in sight the flankers of the advanced party. At two hundred and fifty yards, connecting files being between, the reserve follows, consisting of half the force. It may detach to either flank, when desirable, one group of men thrown forward, and another group thrown rather back supporting the former. None of these flanking groups should extend their distance laterally from the main route over four hundred yards, under ordinary conditions. A distance of three hundred yards separates the reserve from the main body, which is thus eight hundred yards, or nearly half a mile, from the leading group of the advanced-guard.

In the case of an advanced-guard or cavalry of about the same strength as the foregoing, the lateral distances would be increased to two hundred, three hundred, or even a greater number of yards, depending upon the nature of the country; and the distances between the different portions of the guard would be increased in proportion, until the total distance from the point of the advanced-guard to the *main* column would be one thousand five hundred or two thousand yards or even more in a very open country. The Commander of the advanced-guard remains with the reserve. It marches on the main route always ready to move quickly to the front or flank if required. When possible, flanking patrols from the reserve move on each flank. They are to examine houses, farms, etc., standing back from the route, and preserve connection with any columns that may be advancing on other roads to right and left. Should there be any fighting it is done by the reserve. The advanced parties, feel, observe, and reconnoiter, but when it comes to pushing home an attack the reserve must be brought up as quickly as possible. This does not mean that the advanced parties will not usually be able to sweep back the enemy's feelers and scouts if they are encountered. So much they will doubtless be able to effect, but should more serious resistance be met with, it is their duty, even at the cost of delay, to obtain re-enforcements, or to fall back on the larger body in their rear, so as either to ensure the advance being pushed successfully, or that such obstacle to the enemy's nearer approach be offered, as shall give the main body time to prepare for action. The principle on which such rules for action are based is that it is the essence of the duty of an advanced guard to be *successful* in repulsing the enemy or in holding him back a sufficient time. The distance of the head of an advanced-guard from the main column varies according to circumstances, and cannot be dictated by rule. It may, however, be fairly remarked with reference to the principal duty of the advanced-guard, that if the main body requires to be afforded a long time to prepare for the engagement—in other words, if the column of the main body be deep, and would take much time to form up—the distance of the head of the advanced-guard must be a long way in advance. But if the country is difficult to traverse, and the enemy's advance can be easily retarded, the head of the advanced-guard need not be so far in front as if the country is open, and the advances of the enemy would be uninterrupted. Or, if the advanced-guard is strong, and can hold the enemy, it need not be so far in advance as if it were weak, and liable to be driven rapidly back. Again in thick or foggy weather, or at night, the distance in front of the head of the advanced-guard, would be reduced, as would also the breadth of front of the scouts, or flanking parties. Under such circumstances a long extended advanced-guard would be useless, and the proper direction of march might be lost. The enemy could also easily pass through a widely extended front, undetected, in a dark or foggy state of the atmosphere.

A very rough rule is sometimes followed of ascertaining approximately what the distance should be from the head of the advanced-guard to the head of the main column. The distance is to be equal to the length of the column of the main body *en route*, on the assumption that the rear of the column would then have time to form up for action, before the enemy could pass from where he encountered the head of the advanced-guard, to the position taken up by the column to receive the attack.

The division of the advanced-guard into advanced party, support, and reserve, admits of a sub-division of duties which is very desirable. The nature of these duties leads us naturally to fix the position in the advanced-guard of the several arms when combined. Mobility is undoubtedly necessary for the advanced files, and reconnoitering their duty, cavalry must therefore be at the head; and not only at the head but to reconnoiter to the flanks, for infantry employed on this service, to any distance, would delay the advance, and the men be soon exhausted by the extra fatigue. The advanced party, and also the leading portion of the support, would therefore, be *cavalry*. But cavalry should not compose the whole of the support, as cavalry meeting hostile infantry would naturally be checked. The support, then to fulfill its complete mission, should include infantry. A few engineers should accompany the support, in order to be near at hand when required to repair a broken bridge or assist in removing an obstacle to the advance. The pioneers of infantry would also march with the support, to render like service. The reserve would be composed of all the three arms, in order to withstand the enemy and fight him. Infantry at the head, followed by the artillery, then by more infantry, and finally by the remainder of the cavalry not employed in the advance. The engineers not with the support, would bring up the rear of the advanced-guard. The circumstances under which guns would require to take a more forward place in the march of an advanced guard are of rare occurrence. In a mountainous or hilly country, much enclosed, a few guns might perhaps accompany the support. In such a country they would be comparatively safe from sudden attack or reverse, the enemy being hampered in his movements by the ground, and they would be close at hand when required for any special service, such for instance as silencing the enemy's guns brought to bear on points which must be passed by the advanced-guard. A couple of guns are also sometimes of use with the support, in order to clear the road in front without loss to the infantry.

Marches are of two kinds. 1. Those made beyond striking distance of an enemy, called *route* marches. 2. Those made in the immediate vicinity of the enemy, called *strategical* and *tactical* marches the latter being in sight of the enemy. Marches of the second class are termed *strategical* because they are usually made in connection with some *strategical* combination. In marches of the first class the comfort of the men is an object of the first importance, unless there is some urgent reason for rapid concentration, when every other consideration must give way to it. In the second case comfort must give way to security. In both cases the marches should be so conducted that the troops will arrive at their destination with as little fatigue as possible. Great care should consequently be exercised to see that the troops are not obliged to make any unnecessary movements. Particularly discouraging is a counter-march without any object accomplished, as when caused by false information; it is fatigue endured without return. Success in war will depend in a great degree upon the manner in which the marches are conducted. The General, who at a given time, can have the greatest number of troops at a given point and in the best condition for fighting, is bound to be successful. General Wolseley says: "Let me see two armies on the march, and I believe I could tell you the respective fighting value of each. The fitness of troops for the great final struggle, when they at last meet their enemy, must ever depend greatly upon the manner in which their marches have been arranged. Men overmarched, or whose health and comforts have not been duly attended to whilst on the march, can never be expected to go in at an enemy whose men have been well cared for by an able staff administration." One general principle should be followed in all marches, viz., to have as many columns as possible and march them upon the greatest possible front. This will be decided by the number and nature of the roads leading in the desired direction. The greater the distance from the enemy the more closely may the above rule be followed; as the enemy is approached, the more nearly should the marching approach the battle front. Several roads, sensibly parallel, and but a few miles apart, fulfil this condition most favorably.

The following general rules should be observed in all marches: 1. The several branches of the service should afford each other mutual protection, and their position on the line of march should depend on the nature of the country. 2. The order of march should be such, that by short, simple, and rapid movements, it can become the order of battle. 3. That at no time, and under no pretext whatever, should the slightest deviation from the strictest discipline be permitted. The march of an army corps over a single road is a very tedious and fatiguing operation. The march of the several divisions should be so regulated that they will not interfere, and so the short delay of one will not affect the others. Let us suppose the case of an army corps of thirty-five thousand men, marching on a single road, and see what space would be taken up by it. The advanced-guard—consisting of a brigade of cavalry, four regiments of infantry, two batteries of horse artillery, a company of engineers, and a pontoon train—from the extreme front to the extreme rear, would cover about four miles of road; the main column about thirteen miles; the train four miles. Allowing an interval of one mile between the advanced-guard and the main column, and twenty per cent. for opening out on the march, and the corps will cover about twenty-five miles of road. The rear-guard would have to make a forced march in order to reach the extreme head of the column in one day. General McClellan, referring to the disadvantages arising from the use of a single road for the march of a large army, says: "If I had marched the entire army (about one hundred thousand men) in one column along the banks of the river instead of upon five different parallel roads, the columns with its trains would have extended about fifty miles, and the enemy might have defeated the advance before the rear could have reached the scene of action."

A march is said to be *forced* when it is longer than the ordinary marches, and is made for the attainment of some particular object. Forced marches are very fatiguing, and they should therefore be resorted to only in cases of urgent necessity, and then but few such marches should be made in succession. On the eve of a battle they are frequently necessary in order to facilitate the concentration of troops. Especially will this be the case with the large armies of the present day, which cover a great extent of country while on the march. Depending upon the condition of the roads and weather, and the size of the column, infantry will march from one to two and one half miles an hour. Allowing ten hours as the limit of the greatest ordinary march, and time for the necessary halts—which should be made for at least five or ten minutes each hour—infantry can march from ten to twenty miles a day. The latter distance will therefore be the longest ordinary march for troops of this branch of the service; a longer march than twenty miles will then be a forced march. Cavalry at a walk will usually march three miles an hour; moving at a trot it can make five miles for a few hours. Forced marches, continued for several days, are more severe for cavalry than for infantry. When it is possible, cavalry and horse artillery should march by a different road from the infantry, as it is very fatiguing to horses to keep pace with men on foot. If this cannot be done, large intervals should be allowed between the mounted and dismounted branches of the service when on the march. Unless the country is deep or very much cut up by canals, cavalry can generally make its way across the fields, having a detachment of mounted sappers with tools carried on pack-horses for the purpose of opening ways through and over obstacles. The pace at which the troops at the head of a long column march is far from being a matter of indifference; it should be uniform and slow. If the rate of marching at the head of the column is not uniform, the troops in rear will be unnecessarily fatigued, as they will be obliged to go alternately fast and slow in order to keep the proper distances. If the rate is too fast, the column will be drawn out and the number of stragglers greatly increased.

Route marches become marches of *concentration* when made for the purpose of bringing different bodies of troops together at a specified place or places at a time fixed upon before hand. *Strategical* marches become marches of *maneuver* when so made that they render untenable the position occupied by the enemy, forcing him either to abandon it or to accept battle under adverse circumstances. In this class of marches secrecy, celerity, and good order are the first essentials of success. The campaign of 1805 furnishes a most notable example of these two classes of marches. At the opening of the campaign, Napoleon's entire army was distributed from the Texel to Brest along a front of about five hundred miles. By most admirably planned marches of *concentration*, he brought the first and second corps—thirty-seven thousand men—from Hanover and Holland to Wurtzburg, between September 18th and 20th; the third, fourth, fifth, and sixth corps and the reserve—one hundred and thirty-eight thousand men—from France to the Rhine, between Manheim and Strasburg, between September 21st and 24th. The seventh corps was to reach the Rhine at Strasburg after the others. With the corps in these positions the marches of *concentration* were completed. Each corps moved in three divisions on three consecutive days. The Austrians, at Ulm, expected Napoleon to make a front attack, by passing through the defiles of the Black Forest. Their grounds for this belief were based upon the operations of previous campaigns. But Napoleon's plan of campaign was entirely different from any that had previously been followed. The main body of the French force being on the right helped to fix Mack, the Austrian Commander, in his error. Napoleon, making a strong demonstration in front of the Austrian position, pivoted on his right, and concentrated his entire force on the Danube, between Donauwerth and Ingolstadt, in the rear of Ulm, thus separating the Austrians from the Russians who were already coming up the Danube to their relief. Ulm was thus rendered untenable and Mack was so compelled to capitulate. The marches of the French army from the Rhine and Wurtzburg were marches of *maneuver*, aiding by their direction a strategical combination.

A *flank* march is one whose direction is parallel, or nearly so, to the enemy's position. Such a march, when made in the immediate presence of the enemy, is usually a very delicate operation to successfully accomplish, and should rarely be resorted to. As the distance from the enemy is increased the difficulties of a flank march diminish, and when they are made at a distance of several marches from him, with good protection for the exposed flank, they will not differ from ordinary marches. One of the most brilliant examples of a successful flank march in the presence of the enemy, was that of the rebel general Stonewall Jackson, made during the battle of Chancellorsville, May 2d, 1863. General Hooker determined to fight a defensive battle and strengthened his position for this purpose. General Lee, Hooker's opponent, finding a front attack on his position impracticable, sent General Jackson with about twenty-two thousand men to attack Hooker's right and rear. The position of the Union forces is shown in Fig. 3, also the direction of Jackson's flank march. The column on the march was at no time more than two miles from the Union lines, but was concealed from them by intervening timber. It is said that General Lee, previous to the battle, had a road cut through the timber from Jackson's position to the Brock road, with a view of making this maneuver. The full effect expected from this flank movement was not realized, owing to the loss of General Jackson, who was mortally wounded and taken from the field just as he was about to follow up the advantage given by his new position in the line of battle. This march and the subsequent attack had, however, a decided influence on the fight, and, in connection with other events, determined General Hooker to withdraw his forces across the Rappahannock river. The Union force controlled by General Hooker numbered about one hundred and twenty thousand men; the Confederates had about fifty thousand men.

Combined marches are those made for the purpose of attacking two or more points of the enemy's position at the same time; or, they may be undertaken in order to have several corps, marching from different directions, reach a certain point at a fixed time. The nearer this point is to the enemy the more difficult will be the operation, owing to the opportunities offered of attacking the separated corps in detail. These operations are open to the same objections as diversions, their object frequently being defeated by similiar causes. Marches through obstructed country depends for success upon the manner in which they are conducted. The difficulties to be encountered by the advanced-guard will in this case be increased, and upon its efficiency will depend the safety of the army. Forests, streams and mountains will have to be crossed and defiles traversed. The disposition to be made for the accomplishment of these objects will depend upon the circumstances in each particular case; whether the enemy is present in strength, is strongly posted, and the opposisition that he will probably make. It is the province of the advanced-guard to develop all these facts, so that suitable arrangements may at all times be made by the Commanding General. The general rule is not to compromise the safety of any considerable body of troops in such positions, and therefore they should not be entered until the country has been thoroughly scouted in every direction. Each division should act as a support to the one that precedes, and the march should not be resumed until all the troops have traversed the dangerous zone. The safety of the trains pertaining to an army on the march is a consideration of the first importance. In a forward movement they follow the columns of march, and if the flanks of the army are protected they may follow either indifferently, or both. Under other circumstances they should follow the flank which affords the best protection, otherwise they should be placed in rear of the center. On a retreat the trains will be in advance of the army. Night marches with large forces are very difficult operations for obvious reasons. They are, however, a necessity in certain cases, as on the retreat in order to gain a march on the enemy, when making diversions, etc.

In moving an army it is desirable, if possible, that only one division should march by each road. The largest unit that can at all conveniently march by one road in a continuous column is an army corps; but its pace will be very slow, and great fatigue will be entailed upon men and horses. Orders for a march should contain: 1st. General direction and object of march. 2nd. Date, hour, and order of the march, and the roads to be followed by each division, etc. 3d. Formation of advanced or rear-guards, and special instructions for flanking parties and detachments of all sorts. 4th. Instructions for field hospitals, reserve ammunition, engineers, pontoons, and military portion of the train generally. 5th. Instructions for supply of troops and orders for baggage and provision columns. 6th. Position of General on the march, and of headquarters for the night. It is quite evident that as the success of strategy is mainly dependent on accurate calculation of the powers of marching, the most brilliant conceptions, and the most profound combinations, must fail if the troops do not move over the distances calculated on, and do not occupy the prescribed relative positions to each other. Similarly, when the head of a column is attacked, the most skilful tactics will not help it, if the artillery, cavalry or infantry that are required for any particular action cannot be found, if the roads are blocked, and re-enforcements cannot be brought up, or ammunition be got at; consequently the art of marching forms a most important portion of the science of war. The increased power of weapons enables a small body of men, who know they will be supported, to hold a position longer than formerly, this enables an advanced-guard to check an enemy, compel him to deploy, and bring up his artillery before he can make an impression; consequently the distance apart of columns on the march, or the front of an army moving in proximity to an enemy, may now be enlarged to an extent that formerly would have been unsafe. It is a matter of no little importance as affecting rapidity of marching and punctuality of supply.

The functions of outposts are to hold an enemy in check until the army is prepared for action and is ready to receive him; to enable the army to rest by securing it from surprise by the enemy; and to prevent the enemy's reconnoitering parties from approaching sufficiently near the position of the army to gain any information concerning it. Armies in actual presence of each other form order of battle, and in this case outposts cease their function. Armies at a distance from each other, when the nature of the country and their means admit of it, cover their front and flanks with cavalry, one or two or more marches in advance; and in this case, since these troops would give notice of the enemy's movements and time for preparation, the other outposts behind these would, for the moment, find their uses limited to preventing the passage of deserters on the one side, spies on the other, and to giving protection from sudden raids of parties of the enemy which might break through the cavalry cordon. It is when the cavalry line does not exist, or has been withdrawn, while armies, though not in presence, are within striking distance, that outposts assume their full value. The withdrawal of the cavalry may follow either from the force of that arm on one side being overmatched, or because one army awaits the other in position. In this last case, when the opposing lines of cavalry covering their respective armies come into collision, the cavalry of the army which takes position, even though for the moment victorious, must in the end give way; because the advancing army will push on troops of all arms, while the stationary army cannot do so, seeing it intends to fight elsewhere, and cavalry alone cannot oppose a combination of arms. The army in position therefore, places its outposts, and its cavalry retires through them. The enemy's cavalry is checked by the outposts. The enemy thereupon either proceeds at once to reconnoiter and attack the position, or himself takes position, covered by *his* outposts, with the intention of attacking next day, or at a more convenient time, or of maneuvering. To observe his (the enemy's) approach from a distance, and to recognize, if possible, its true character; to resist up to a certain practicable point, and then fall back in concert and good order, continuing to retard the enemy, —such are the functions which are demanded from a line of posts extending across valleys and over ridges, sometimes in wooded ground, sometimes in enclosures, sometimes in an open country, sometimes along a front the issues of which are close defiles—each variety of the conditions calling for an appropriate disposition; while the whole attenuated line, which thus opposes itself to the onset of an army, is to maintain concentrated action throughout.

The arrangement of the different component parts of the outposts is similar to that of the advanced-guard, and their duties have much the same character, differing, however, essentially in matters of detail and mode of execution. In order to perform these duties properly, efficiently, and with the minimum amount of fatigue, the combined action of the two arms, infantry and cavalry, is absolutety necessary. The infantry is required to resist the enemy's advance, and the cavalry to watch him, obtain information of his movements, and to promptly transmit the knowledge gained to the rear. The relative proportion of these two arms in any case will be determined by the nature of the country in which the army is operating. If the country is level and open the cavalry can be employed to the best advantage, and it would therefore be largely used, especially during the day, but at night it should be replaced by infantry as far as practicable. In a rough, close, or broken country infantry would be principally employed at all times. Infantry and cavalry on this duty should never be placed together in the same line, on account of the danger which would result from a flank attack on the former, rendered possible by the latter being forced back from its position. Owing to the similarity of the two duties—advanced-guard and outpost—it is desirable that the names of the component parts should as far as practicable be the same for each. In many instances, after the day's march is finished, the advanced-guard, when not too much fatigued, is also required to perform the duties of outposts, in which case very little change would be necessary in its formation in order to adapt it to its new service. There are two systems of outposts, viz., the *cordon* system and the *patrol* system. In the first system a line of sentinels is so arranged that the enemy, either singly or in parties, cannot by any possibility pass it; in the second case constant patrols are made, which are expected to detect parties of the enemy attempting to pass, without calculating to entirely bar the way to individuals. When the weather is clear and the country comparatively open, the *cordon* system is very effective, but in a very broken country, or when the weather is stormy or foggy, the large number of men required to properly perform the service makes the duty very arduous. The *patrol* system under these circumstances would probably be preferred, sentinels being placed on all the avenues of approach, and a thorough system of patrols being employed to prevent the enemy from penetrating the lines. Under all conditions of country and weather, a combination embracing the best qualities of each system might be devised. To illustrate the manner of arranging and placing outposts, let us suppose that an army corps has taken position in fairly open ground, and the necessary arrangements are to be provided for its security. For this purpose the troops detailed for outpost duty will be posted in four lines, as follows: 1. *Sentinels.* 2. *Pickets.* 3. *Supports.* 4. *Reserve.*

Each picket furnishes a chain of double *sentinels* to watch the country in front, and to connect with the neighboring pickets. No more posts should be established than are absolutely necessary. In fairly open ground by day they may be from two hundred to four hundred yards apart for infantry, and up to six hundred yards for cavalry mounted sentries called *vedettes.* Sentries should not be more than four hundred yards in advance of their pickets. Vedettes may be as far as six hundred yards from their pickets. Sentries or vedettes should have clearly in view all the men of the posts on each side of them, and no ground in front of the two adjoining posts should be unseen by the sentries of both posts. At night, sentries should be placed so as, if possible, to bring any advancing person against the skyline, they themselves remaining in shadow; but, as it is impossible to continue the cordon system with strict effect at night, sentries would in general be only placed on the roads, and other lines of approach. Vedettes would be withdrawn altogether at night, unless there were no infantry available, in which case they would then be placed on the roads or the passages through which an enemy is most likely to advance.

The strength of a picket will be determined by the number of posts for which it furnishes sentries or vedettes, in addition to the men required for detached posts, and for patrolling duties. The picket acts as a support, or a sort of anchor, to the sentries, vedettes, or detached parties which it furnishes. It is therefore posted in their rear, if possible centrally, and on a main route or thoroughfare. A mounted orderly or two should be attached to an infantry picket. Patrolling duties must always be allowed for, the number of men required being determined by the Commander of the outposts according to circumstances; with cavalry pickets the proportion would generally require to be large, about *one-fourth* to *one-third* of the whole picket. Detached parties are of a strength proportioned to the duty upon which they are sent. From two to four double sentries are quite sufficient for an infantry picket to furnish and two to three double vedettes for a cavalry picket. It follows that the infantry picket would observe from six hundred to eight hundred yards of front, whilst the cavalry picket would watch a front of one thousand to one thousand five hundred yards. The pickets themselves may be from four hundred to eight hundred yards from their supports in the case of infantry, and from one thousand two hundred to two thousand yards in the case of cavalry. Infantry pickets would thus be from six hundred to eight hundred yards from one another, whilst cavalry pickets would be from one thousand to one thousand six hundred yards apart.

These figures are of course purely approximate, as the nature of the ground and other circumstances must immensely affect the dispositions in any particular case; in a perfectly open country, in clear weather, for instance, the distance and intervals would no doubt be much increased. The principles however, by which they should be calculated are simple, and ought to be borne in mind. The pickets, whilst being placed centrally as regards their sentries, should be close enough to aid and support one another in retreat, an efficient flanking fire being mutually provided for in the case of infantry. They should not be too close in front of their supports, as the latter might in such case be demoralized by the pickets being suddenly driven in upon them, nor, on the other hand, too far distant to prevent the supports from advancing in time, to aid the pickets when hardly pressed. From twenty-five to fifty men for infantry, and from twenty to thirty for cavalry, are generally sufficient for ordinary pickets. Where large detached parties are furnished by a picket, its strength must be proportionally increased. A picket should be, if possible, posted on the route by which the enemy will probably advance, and a cavalry picket should have ground in advance of its position favorable for action, in case it may be necessary to take the offensive in order to check the enemy. The position of the picket ought to be so far concealed that the enemy can only discover it by attacking; but, there must be free movements in all directions, and especially easy means of communication, both with the flanking pickets and the supports in rear. In all cooking, eating, feeding, and watering arrangements, *two-thirds* of a picket of either arm must always be ready for immediate action, and none of the men should stroll at a distance from the arms.

The line of resistance—that is, the line where the first important stand is to be made—having been decided upon in the first instance, the supports are also placed at convenient positions thereon, as centrally as subdivision, therefore, in the one case, would be, for the reserve one-third, for the support one-third, for the pickets one-third; in the other case, for the reserve one-half, for the support one-fourth, for the pickets one-fourth, of the whole strength. The reserve ought to be placed out of sight of the enemy, occasionally divided into two parts, on a principle route or routes of retreat to the main body. Its functions are to move to the re-enforcement of the supports if necessary, or to occupy a good defensive position for the troops to fall back upon if required. The distance from the line of supports must vary considerably according to circumstances, but would range

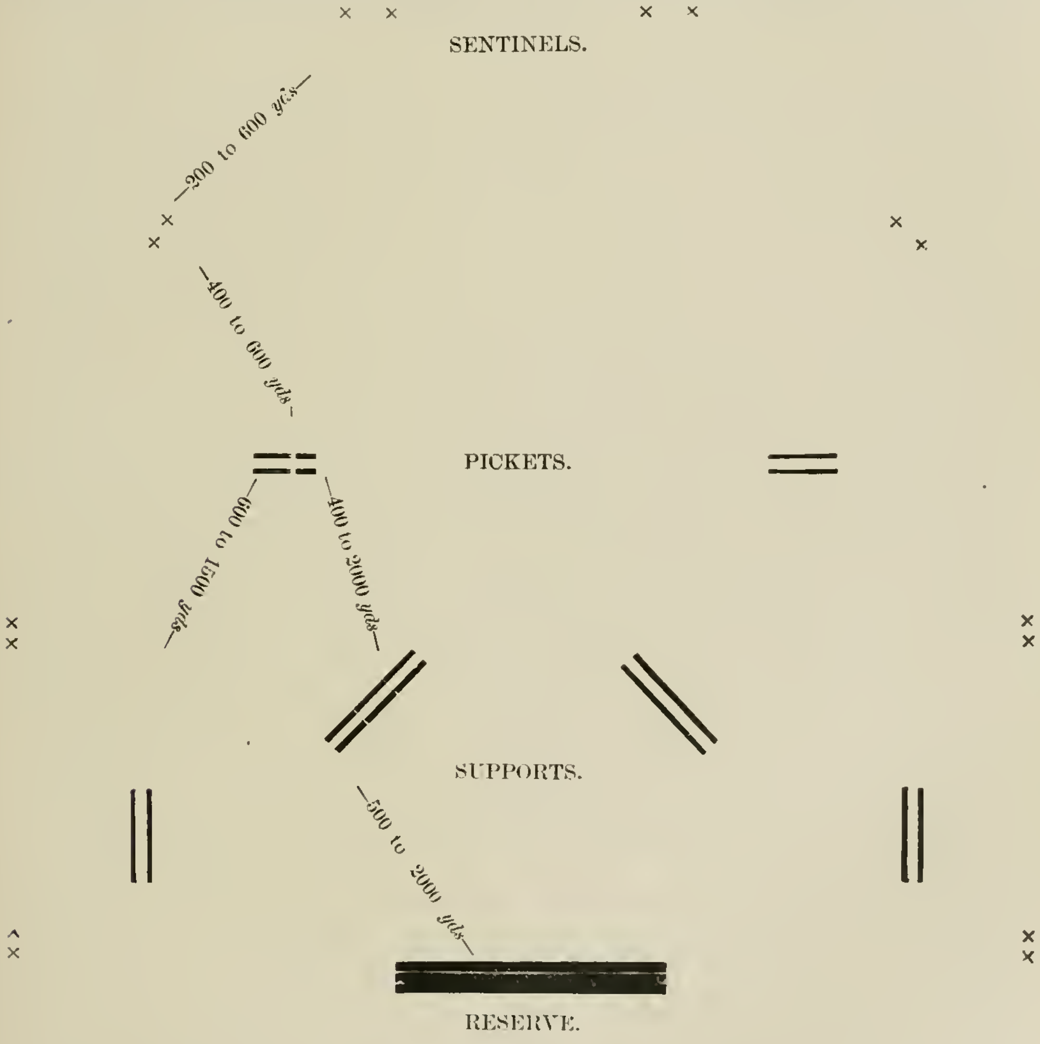

Fig. 4.

possible to their own group of pickets in front, and close to or on the main avenues of approach. Supports should be of a strength equal to all in front of them, and one support to every two or three pickets will be sufficient. The strictness of routine laid down for the pickets may be somewhat relaxed in the case of the supports; but they must be always ready to march, day or night, at a moment's notice to any point required, or to stand on the defensive.

The reserve is intended as a general support to the lines of pickets and supports. It consists generally of from one-third to one-half of the whole strength of the outpost. This leaves, for the supports and pickets, either two-thirds or one-half the whole. The under the more ordinary conditions from five hundred yards to one thousand yards for infantry and from one thousand two hundred to two thousand yards for cavalry. The reserve may bivouac, rest, cook, eat, and smoke, but should always be ready to act at the shortest notice. Fig. 4 represents the outposts arranged in accordance with the foregoing principles.

When the enemy is able to bring his artillery into action the attack may be considered to have commenced. As it is the duty of the supports to hold the enemy in check until the army is ready to receive him, it follows that they must be placed beyond effective artillery range of the position, which may be taken as two thousand five hundred yards. The line of sentinels would then be from three thousand three hundred to three thousand seven hundred yards in the case of infantry, and from four thousand three hundred to five thousand one hundred yards in the case of cavalry, in advance of the main body. No rule can be determined which will regulate these distances for all occasions and under all conditions. The distances in all cases will also depend upon the nature of the country, the objects to be obtained by the outposts, and other peculiar circumstances always attending each particular case. Changes in the position of a portion of the outpost line will usually become necessary at night. They should be carefully arranged before dark, and put into execution just as the light is failing so as not to be observed by the enemy. Bridges, main routes, and obligatory points of passage should be occupied by the pickets, the supports being pushed close up to them. Advanced sentries being of little use during the dark hours, except on the roads, footpaths, and other avenues of approach, the number of double sentries in a close country can usually be reduced at night. If extra men are thus set free they should be employed on patrol duty, which must be more frequent in front of the line as the double sentries are fewer in number. On the other hand, in a comparatively open country, the number of approaches to be watched may even exceed the number of day posts. Here there would be no saving of sentries, but the patroling would probably not require to be so incessant. In order to make these dispositions it may become necessary to contract the outpost line, but in such case the original posts would be resumed on the approach of daybreak. This should, however, be effected with as much care and preliminary examination of the ground as at the previous occupation.

With a mixed force cavalry would usually be withdrawn from the front at night. This would be especially the case in a difficult or enclosed country. But should it be necessary to retain them during the night on account of the absence of infantry to replace them, they must undergo a thorough change of position. The posts with wide extended view suitable for the cavalry vedette by day are valueless at night, and stationary mounted men can only watch roads or defiles after dark.

Cavalry pickets which have been in open ground during the day must now be placed on the roads, where they can have free movement from front to rear, double vedettes being immediately in front of the pickets advanced a short distance up each approach. Principal reliance must be placed upon the watchfulness of the patrols, which are kept constantly in motion during the night. The enemy can only himself move in any force upon the roads; and if these are vigilantly watched and examined for some distance to the front during the dark hours, a certain amount of security against surprise is thereby obtained.

Patrols from outposts are of three kinds: 1. Visiting patrols. 2. Reconnoitering patrols. 3. Strong patrols. *Visiting patrols* consist of an Officer, or a Non-commissioned Officer, and one or two men. They are sent out from each picket between reliefs, and their duties consist in keeping up the communication between the picket and its neighboring pickets, as well as with its support in rear, and with its detached parties in advance. Visiting patrols are especially necessary in a close country and in bad weather. In an open country, with clear weather, they may be much less often sent out during the day.

Reconnoitering patrols are sent forward a limited distance, not exceeding from half a mile to a mile for infantry, in advance, to examine ground which cannot be watched by the sentries, and to give notice of the enemy's approach. They commonly consist of an Officer or Non-commissioned Officer, and two to four men. Cavalry may be safely despatched to a much greater distance than infantry. The Germans and French call the smaller of these patrols by names which signify crawling or creeping in the case of infantry, and secrecy in the case of cavalry. *Strong patrols* are of the same character as the last, but of larger force and not necessarily secret. If of greater strength than a dozen men they would be furnished from the supports or reserve. Sometimes a company or troop, or even a larger body, would be despatched on such duty. They should not proceed farther than about a mile for infantry, from the line of sentries, and even then with mounted orderlies attached, for the purpose of conveying information rapidly to the rear. The object of strong patrols would generally be to obtain early information of the enemy's movements when he is at a distance, to ward off his patrols, and to prevent surprise; sometimes to engage a post, in order to ascertain the enemy's strength, thus acting on the offensive. Above all things, strong patrols should avoid unnecessary firing. Firing signifies, to those in rear, that the patrol has not only seen the enemy, but that the enemy has seen the patrol, and is advancing. An incessant fire, kept up in retiring, intimates that the enemy is in force and is pressing the pursuit, but this signal should be abstained from unless it is necessary to arouse the troops in rear; the outpost line must be most careful not to occasion false alarms, which are hurtful to the *morale* of the army. As a general rule, it would be best to retire steadily, if possible unperceived, as soon as the enemy is touched upon; but sometimes, if opportunity serves, a prisoner or two may be captured, in order to obtain information.

Artillery with outposts. Artillery, if added, would usually be with the reserve, when the guns should be posted so as to cover the retreat of the advanced portion of the outposts, or else be held in readiness close to a main route to proceed at once to any required point as the attack of the enemy develops itself. Guns are, however, occasionally more to the front, when, without unduly risking their safety, they can be placed so as to command ground which must be passed by the enemy in his advance. The enemy may thus be forced to lose time by deploying when still at a considerable distance. The guns posted near the front line should be safe from surprise, and either out of range of the enemy's effective rifle fire, or protected from it by skirmishers thrown out in advance of the guns. With proper precautions an artillery outpost may often be placed in an advanced position, probably on a flank, where, being well covered by the guns of the main body, it need not retire until it has accomplished its object, supporting the infantry as they fall back from point to point. For this and other purposes of delaying the enemy, however, advanced guns must avoid taking position within artillery range of ground which the enemy's batteries could reach and take post on unperceived. Horse-artillery acting with cavalry may sometimes, if well supported, be pushed still farther to the front, for the purpose of making the enemy develop his attack early in the day.

The chain of outposts should cover not only the front of an army, but should also extend well around the flanks, in order to guard every avenue by which the enemy might by any possibility approach. When the army remains in one place for any length of time it is advisable to strengthen the outposts by means of abattis, slashings, etc. All the heights from which the enemy could obtain a commanding view of the country in the vicinity of the army should be included within the chain of outposts, and if this is not practicable, then should such heights be occupied by detached bodies of troops to prevent the enemy from making use of them for the purpose of reconnoitering. When an army has to withdraw at night from the presence of the enemy it becomes an object to conceal the movement as long as possible, and for this purpose the outposts are usually left in position until daylight. Under these circumstances the sentinels should be particularly on the alert, and patrols should frequentlymade to prevent spies o ber deserters from giving the enemy information of the movement. The troops should constantly be prepared for an attack, which would certainly follow should the departure of the army be discovered. It also becomes a part of the duty of the outposts to keep the fires burning as usual so that the suspicions of the enemy may not be aroused.

Fig. 5.

Particular care should be taken not to post troops on any point from which they cannot reach the enemy with their fire, and from which they cannot move to the assistance of the troops at other points. Nor should troops be placed in advance of the general line where they might be liable to be cut off by the enemy, without providing for their safe retreat by holding with a strong force all the roads leading to the position. To illustrate the dangers almost certain to result from an improper arrangement of troops in position, reference is made to the battle-field of Gettysburg, Fig. 5. The result of the Confederate reconnaissances was to fix upon the ground opposite Longstreet—that is, the left and left center held by Sickles' corps—as the most practicable point of attack. * * * In the original ordainment of the line of battle, Sickles' corps (third) had been instructed to take position on the left of Hancock, on the same general line, which would draw it along the prolongation of Cemetery Ridge, towards the Round Top. Now, the ridge at this point is not very well defined, for the ground in front falls off into a considerable hollow. But at the distance of some four or five hundred yards in advance, it rises into that intermediate crest along which runs the Emmetsburg road. General Sickles, thinking it desirable to occupy this advanced position—which he conceived would, if held by the enemy, make his own ground untenable—assumed the responsibility of pushing his front forward to that point. The motive that prompted General Sickles to this course was laudable enough, yet the step itself was very faulty; for though to superficial examination the aspect of this advanced position seems advantageous, it is not really so; and prolonged to the left, it is seen to be positively disadvantageous. It affords no resting place for the left flank, which can be protected only by refusing that wing, and throwing it back through low ground, towards Round Top; but this, in turn, presents the danger of exposing a salient in a position which, if carried, would give the enemy the key-point to the whole line. General Sickles' disposition of his troops had precisely this character. * * On this obtruding member, General Lee determined to make his attack; for, as he states: "It appeared that if the position held by it could be carried, its possession would give facilities for assailing and carrying the more elevated ground and crest beyond." This eccentricity in the placing of Sickles' corps did not become known to General Meade until about four o'clock, when he arrived personally on the field; and though he then saw the danger to which that corps exposed itself, it was thought to be too late to correct the error; for just at that moment, Longstreet, under cover of a powerful artillery fire, opened his attack, and all that remained for General Meade was to support Sickles as far as could be done in the emergency. The final result of this attack was to carry the position occupied by General Sickles, after serious losses and a stubborn resistance on the part of the Union troops; but there then remained the line which should have been occupied in the first instance, and the efforts to carry which resulted in Lee's defeat.

Rivers, like mountains, strengthen the relative defence; but one of their peculiarities is, that they are like implements of hard and brittle metal, they either stand every blow without bending, or their defense breaks and then ends altogether. When the river is very large, and the other conditions are favorable, then the passage may be absolutely impossible. But if the defense of any river is forced at one point, then there cannot be as in mountain warfare, a persistent defense afterwards; the affair is finished with that one act, unless that the river itself runs between mountains.

The other peculiarity of rivers in relation to war is, that in many cases they admit of very good, and in general of better combinations than mountains for a decisive battle. Both again have this property in common, that they are dangerous and seductive objects which have often led to false measures, and placed Generals in awkward situations. Positions may be selected near rivers either for the defensive, to prevent an enemy from passing, or for the offensive, to force a passage. In selecting a position to guard a river or an extended line of frontier, when menaced by the enemy, it will not be advisable to divide the army into several equal portions and endeavor to watch each point suitable for crossing, or each pass by which the enemy may *débouche* ; but, placing the main body in a central position, watch the different bridges and passes with strong detachments, and, when the enemy has developed his point of attack, advance with the main body to meet him and dispute his passage. For example, let us suppose an army of eighty thousand acting on the defensive against one of one hundred and twenty thousand separated into three corps of forty thousand each. To oppose to the enemy three corps of equal strength, we would have but about twenty-six thousand in each, and consequently would find ourselves inferior in numbers on all points. If, instead of this, we opposed to each fraction of the enemy a corps of from twelve thousand to fifteen thousand, it would be sufficient to hold forty thousand in check, whilst our main body, consisting of from thirty-five thousand to forty thousand, holding a central position, could move on the point first menaced, and, being joined by the corps of observation, would offer to the enemy an effective force of fifty thousand combatants, which, all other things equal, should beat the enemy. The principle is not the less true, and the rule not the less imperative, even when the disparity of force is far greater. It may happen that, with every effort, we may not succeed in obtaining the preponderance of numbers on any point; still the only chance of success lies in concentrating all we can, and trusting to skill, promptitude, vigilance, and audacity, to do the rest. History furnishes brilliant examples of what a great General can accomplish, even under apparently the most discouraging state of things, by promtitude and rapidity of movement in throwing his reserve first on one and then on another of the enemy's fractions. Napoleon's campaign of 1814, in France, fully illustrates the application of these principles.

The passage of an unfordable river in the presence of an active enemy is an operation of the most difficult nature. A crossing may be forced, or stratagem may be resorted to for the purpose of deceiving the enemy as to the point selected, and thus the undertaking may be successfully accomplished before the enemy can concentrate to vigorously oppose it. As on the defensive, it is not best in this case to separate the army into several corps in order to force a passage at several points, but menacing several, to select one or two, and then by a rapid march to endeavor to reach them and effect the passage before the enemy is fully prepared to prevent it. In selecting a point to cross a river, it is well to bear in mind that in the bends the current is not so rapid as elsewhere ; also that small islands are generally located there, which may greatly aid the crossing and the construction of the bridge.

The following general rules embrace nearly all the points to be observed in the passage of a river in the vicinity of the enemy :

1. It is essential to deceive the enemy as to the point of passage, that he may not accumulate an opposing force there. In addition to the strategic demonstrations, false attacks must be made near the real one, to divide the attention and means of the enemy. For this purpose half of the artillery should be employed to make a great deal of noise at the points where the passage is not to be made, whilst perfect silence should be preserved where the real attempt is to be made.

2. The construction of the bridge should be covered as much as possible by troops sent over in boats, for the purpose of dislodging the enemy, who might interfere with the progress of the work ; and these troops should take possession at once of any villages, woods, or other obstacles in the vicinity.

3. It is important also to arrange large batteries of heavy caliber, not only to sweep the opposite bank, but to silence any artillery the enemy might bring up to batter the bridge while building. For this purpose it is convenient to have the bank from which the passage is made somewhat higher than the other.

4. The proximity of a large island near the enemy's bank gives great facilities for passing over troops in boats and for constructing the bridge. In like manner, a smaller stream emptying into the larger one near the point of passage, is a favorable place for collecting and concealing boats and materials for the bridge.

5. It is well to choose a position where the river makes a re-entering bend, as the batteries on the assailant's side can cross their fire in front of the point where the troops are to land from the boats, and where the end of the bridge is to rest, thus taking the enemy in front and flank when he attempts to oppose the passage.

9. The locality selected should be near good roads on both banks, that the army may have good communications to the front and to the rear on both banks of the river. For this reason those points where the banks are high and steep should be carefully avoided.

The rules for preventing a passage, follow, as a matter of course from those for effecting it, as the duty of the defenders is to counteract the efforts of the assailants. The most important thing is to have the course of the river watched, without attempting to make a defense at every point. Concentrate rapidly at the point threatened, in order to overwhelm the enemy, while a part only of his army shall have passed.

A long line of river cannot be successfully defended against the passage of an enemy who is provided with a sufficient pontoon train. On this account the army defending the river should be well concentrated, with its line of retreat well secured, and inflict as much damage as possible on the enemy at the point of crossing. The passage of a large river by an army on the retreat, when hardly pressed by the enemy, is one of the most difficult operations to be performed in any war. The points selected for the passage should present the most favorable features to enable a small body of troops to hold a larger body in check for a considerable time, so the enemy cannot press too hard upon the troops that have to pass last. Every precaution should be taken to deceive the enemy as to the point of crossing, which, when once selected, should be reached as soon as possible. The march should be so arranged that there shall be no crowding at the crossing, each body of troops reaching the designated place when the bridge is clear.

The passage of the Douro, by Wellington, May 12, 1809, illustrates all the details of such an operation, and shows with what small means it can be successfully accomplished. The passage of the Douro, by Sir Arthur Wellesley, 12th of May, 1809, was immediately after the river had been passed by the French, under Soult, continuing their retreat, and destroying the bridge across it from Villa Nova to Oporto. Soult, at Salamanca, would be more formidable than Soult at Oporto, and hence the ultimate object of the campaign, and the immediate safety of Beresford's corps, alike demanded that the Douro should be quickly passed. But, how force the passage of a river, deep, swift, and more than three hundred yards wide, while ten thousand veterans guarded the opposite bank? From the summit of the height of Sarca, the English General searched all the opposite bank and the city and country beyond it. He observed horses and baggage moving on the road to Vallonga, and the dust of columns as if in retreat, and no large body of troops was to be seen under arms near the river. The French guards were few, and distant from each other, and the patrols were neither many nor vigilant ; but a large unfinished building standing alone, yet with a short and easy access to it from the river, soon fixed Sir Arthur's attention. This building, called the Seminary, was surrounded by a high stone wall, which coming down to the water on either side, enclosed an area sufficient to contain at least two battalions in order of battle; the only egress being by an iron gate opening on the Vallonga road. The structure itself commanded everything in its neighborhood, except a mound, within cannon shot, but too pointed to hold a gun. There were no French posts near, and the direct line of passage from the height of Sarea, across the river to the building, being to the right hand, was of course hidden from the troops in the town. Here, then, with a marvellous hardihood, Sir Arthur resolved, if he could find but one boat, to make his way, in the face of a veteran army and a renowned General. A boat was soon obtained; for a poor barber of Oporto, evading the French patrols, had, during the night, come over the water in a small skiff; this being discovered by Colonel Waters, a Staff-officer of a quick and daring temper, he and the barber, and the prior of Amarante, who gallantly offered his aid, crossed the river, and in half an hour returned, unperceived, with three or four large barges. Meanwhile, eighteen or twenty pieces of artillery were got up to the convent of Sarea; and Major-General John Murray, with the German brigade, some squadrons, and two guns, reached the Barca de Avintas, three miles higher up the river, his orders being to search for boats, and to effect a passage there, also, if possible. Some of the British troops were now sent towards Avintas, to support Murray; while others came cautiously forward to the brink of the river. It was ten o'clock; the enemy were tranquil and unsuspicious; and an officer reported to Sir Arthur Wellesley that one boat was brought up to the point of passage. "Well, let the men cross," was the reply; and upon this simple order an officer and twenty-five soldiers entered the vessel and in a quarter of an hour were in the midst of the French Army.

The Seminary was thus gained without any alarm being given, and everything was still quiet in Oporto; not a movement was to be seen; not a hostile sound was to be heard. A second boat followed the first, and then a third passed a little higher up the river; but scarcely had the men from the last boat been landed, when a tumultuous noise of drums and shouts arose in the city; confused masses of the enemy were seen hurrying forth in all directions, and throwing out clouds of skirmishers, who came furiously down on the Seminary. The citizens were descried gesticulating vehemently, and making signals from their houses; and the British troops instantly crowded to the bank of the river: Paget's and Hill's divisions at the point of embarkation, and Sherbrooke's, where the old boat bridge had been cut away from Villa Nova. Paget himself passed in the third boat, and mounting the roof of the Seminary, was immediately struck down, severely wounded. Hill took Paget's place; the musketry was sharp, voluble and increasing every moment as the number accumulated on both sides. The enemy's attack was fierce and constant; his fire augmented faster than that of the British, and his artillery, also, began to play on the building. But the English guns, from the convent of Sarea, commanded the whole enclosure around the Seminary, and swept the left of the wall in such a manner as to confine the French assault to the side of the iron gate. Murray, however did not appear; and the struggle was so violent, and the moment so critical, that Sir Arthur would himself have crossed, but for the earnest representations of those about him, and the just confidence he had in General Hill. Some of the citizens now pushed over to Villa Nova with several great boats; Sherbrooke's people began to cross in large bodies; and, at the same moment, a loud shout in the town, and the waving of handkerchiefs from all the windows, gave notice that the enemy had abandoned the lower part of the city; and now, also, Murray's troops were seen descending the right bank from Avintas. By this time three battalions were in the Seminary: and Hill, advancing to the enclosure wall, opened a fire upon the French columns as they passed, in haste and confusion, by the Vallonga road. To the left, General Sherbrooke, with the brigade of the guards, and the Twenty-ninth regiment, was in the town, and pressing the rear of the enemy, who were quitting it. In the center General Hill, holding the Seminary and the wall of the enclosure, sent a damaging fire into the masses as they passed him; and his line was prolonged to the right, although with a considerable interval, by General Murray's Germans, and two squadrons of the Fourteenth dragoons. The remainder of the army kept passing at different points; and the artillery, from the height of Sarea, still searched the enemy's columns as they hurried along the line of retreat. The passage of the Douro, at Oporto, would, at first sight, seem a rash undertaking; but, when examined closely, it proves to be an example of consummate generalship, both in the conception and the execution. The careless watch maintained by the French may, indeed, be called fortunate, because it permitted the English General to get a few men over unperceived; but it was not twenty-five, or twenty-five hundred soldiers that could have maintained themselves, if heedlessly cast on the other side. Sir Arthur, when he so coolly said, "Let them pass," was prepared to protect them when they had passed. He did not give the order until he knew that Murray had found boats at Avintas, to ferry over a considerable number of troops, and, consequently that that General, descending the Douro, could cover the right flank of the Seminary, while the guns planted on the heights of Sarea could sweep the left flank and search all the ground enclosed by the wall around the building. If General Murray's troops only had passed, they would have been compromised; if the whole army had made the attempt at Avintas, its march would have been discovered; but in the double passage all was secured; the men in the Seminary by the guns, by the strength of the building, and by Murray's troops; the latter by the surprise on the town, which drew the enemy's attention away from them. Hence, it was only necessary to throw a few brave men into the Seminary unperceived, and then the success was almost certain; because, while that building was maintained, the troops in the act of passing could neither be prevented nor harmed by the enemy. To attain great objects by simple means is the highest effort of genius.

Other celebrated examples of the successful passage of rivers in the presence of the enemy are given below. It is the details of these operations which should be particularly studied, in order to render the lessons derived from them instructive and useful. Passage of the Rhine at Tholhuys, by Louis XIV, in 1672; the Rhine at Kehl, and the Danube at Hochstadt, in 1800; the Danube at Essling and Wagram in 1809, by Napoleon; the Beresina at Borisov in 1812, by Napoleon; the Danube at Satonnovo, by the Russian army, in 1828; the Rappahannock at Fredericksburg, by Burnside, in 1862; the Rapidan, by Grant, in 1864, etc., etc.

With respect to the proportions of the different arms of the service of which every army is composed, regard is had to the relative importance of each. Infantry is placed first in order, and usually comprises about four-fifths of the entire strength. The proportion of cavalry depends upon the nature of the country in which the army is to operate, being larger in an open country, which is favorable for its action, than in a broken or wooded country. It generally forms about one-fifth the entire force. Artillery, ranked third in the order of importance, is in the proportion of about three guns to one thousand men. An army, therefore, of one hundred thousand men, would consist of eighty thousand infantry, twenty thousand cavalry, and three hundred guns. The proportion of artillery depends upon the character of the troops, and the nature of the country in which they are to be employed. The greater the efficiency of the troops, the less may be the number of guns. The proportion would also be less in a wooded or broken, than in an open or level country; the former being less advantageous for the efficacy of the artillery. The proportion of light to heavy guns is also regulated by similar causes. When operating in a country with but few good roads, the former should predominate, otherwise, the heavy guns will vary in number from one-third to one-half the total. In the campaign in Bohemia, in 1866, the Prussian army was constituted as follows: Elbe army, forty thousand men and one hundred and thirty-five guns; first army, eighty-one thousand men and two hundred and seventy guns; second army, one hundred thousand men and three hundred and sixty guns.

A careful reconnaissance is important in both tactical and strategical operations. A general reconnaissance has for its object the obtaining of detailed and accurate information of countries and their armies that will be of assistance in case of war. It comprises within its scope our own as well as other countries, for the data obtained may be used in prosecuting military studies, and as an aid to a General in drawing up his plan of operations, which includes the movements of troops necessary for concentration as well as their employment after this has been accomplished and they are ready to meet the enemy. Tables of statistics, giving population, manufactures, industries and concerning the roads, railroads, canals, rivers, important improvements, head of cattle, and the sections of country where they are most numerous, etc.; geographies, general and military; reports, of all kinds, etc., will all be found of great assistance in compiling the required information. But, however complete and exhaustive these sources of information may be, officers of the army should frequently be sent to different countries to examine and report not only upon their military systems, but upon any subject which may become important in a military point of view. This method not only serves to retain possession of much that might be of great utility in planning military operations, but it enables officers to gain personal experiences of peoples and their customs, which might be invaluable to them and to their country, in the event of war. In a reconnaissance of this nature great care should be taken to particularly notice those subjects which cannot be found in published reports, statistics, etc., and to make the examination and report most thorough in these respects. The course of study preparatory to those journeys necessarily imposed upon officers to fit them for the duty, would also be of great assistance in the training proper for their profession. Canada and Mexico being contiguous to our frontiers, we might derive great benefits from a thorough knowledge of these countries.

Special reconnaissances are made with reference to the actual military situation at the time, and a report of them is usually made at once, frequently upon the spot. They are divided into two classes, viz., *topographical* and *armed*.

Topographical reconnaissances are undertaken for the purpose of obtaining accurate and detailed knowledge of the theater of operations. This knowledge obtained, the General in command is enabled to arrange his troops on the march with the condition of mutual support fulfilled; to select positions for giving or receiving battle, when acting on the offensive or defensive; to select suitable camping places; and to prepare the means for passing or avoiding those obstacles which are always to be found on the line of march of an army, as rivers, marshes, etc. It is important that officers should follow a regular system in preparing reports of reconnaissances, otherwise, what would be perfectly clear and intelligible to them at the time, might mislead the person who is to depend upon them for information. For this reason the following definitions are given:

1. *Ground.* By the word ground is meant the surface of the ground, as far as its nature or character in a military point of view is concerned. Ground may be divided into the following kinds: *Even ground*, the nature of which offers no obstacle whatever to any kind of formation or movement of troops; *cut up ground* would be precisely the reverse of this. *Open ground*, the nature of which offers no obstacle to the vision in any direction; *concealed ground* is the reverse of this. *Passable ground*, or ground the nature or character of which offers no obstacle to the passage of troops; *impassable ground* is the reverse of this. It is evident that these definitions have not only an absolute but a relative meaning as well, when applied exclusively to the different arms. *Level ground*, in a mathematical sense, does not exist at all; the expression, however, is used to designate ground in which there appears to the eye to be no perceptible change from rise to fall, which does not affect the action of the three arms, and which prevents the formation or movement of troops under cover. A *hill*, an isolated elevation of ground, with slight slopes. *Heights*, or *ridge of heights*, extensive elevations, with slight slopes. A *mountain*, an isolated elevation of considerable height over the surrounding country. A *plateau*, an extensive elevation of the ground, having a summit with a nearly flat surface. In reconnaissance reports it is desirable that either absolute or relative altitudes should be given. Depressions in the ground are the reverse of elevations, and may be classed as a *depression*, *gorge*, *ravine*, and *valley*, and should be especially described, both as regards their dimensions and steepness of slope. *Hilly ground* belongs to a flat country or where a flat country merges into a mountainous one; the elevations in the ground are slight both as regards height and steepness of slope, and affect the movements of troops only to a small extent, but at the same time enable troops to be formed and moved up under cover. The action of the three arms is similarly affected, inasmuch as by choosing certain elevated points a greater field for the action of firearms may be obtained. *Mountainous country* affects the movements and action of troops to a very great extent by high elevations on the ground, steep slopes, and the rugged character of the surface, and very often restricts troops to the roads or to the patches of passable ground found here and there in the valleys. There is also great difficulty in housing and feeding troops on the country, and in very high mountains (over three thousand meters) it is only possible in the case of small detachments. Large bodies of troops would have to depend almost entirely on supplies brought from a distance, especially as regards food. As regards the nature of the surface of the ground, it is usually described as having a rocky, clayey, loamy or sandy sub-soil, which is generally covered with a layer of mould of variable thickness, on which vegetation takes place. Ground is described as *rocky* when the rocks protrude beyond the surface uncovered with earth or soil, and as *stony* when the surface is covered with a layer of loose stones. *Soft* or *wet* ground may be described as ground not having a firm surface. The marsh, bog, or swamp are to be considered as tracts of ground left in their natural state; they may generally be looked upon as tracts of wet country that are impassable.

2. *Slopes.* Slopes may be either gentle up to 5°, steep over 20°, and very steep over 30°. Slopes are best given in degrees. Gentle slopes offer no obstacle to the movement of troops. A slope of 10° has a considerable effect on the movements of infantry in close formation; cavalry cannot charge downhilll, and only wtih difficulty uphill; artillery can only move uphill with difficulty, and the drag or brake has to be applied going downhill. The movements of cavalry and artillery cannot be carried out in an orderly manner on any slope of 20°, except as single horsemen. Slopes of 30° may be considered as impassable for the infantry in close formation; on the steeper slopes, *i.e.*, up to 45°, single men can only

climb up with the very greatest difficulty, if at all.

3. *Water.* Water as belonging to the natural features of a country, is also important in a military point of view. Water may be either *running* or *still.* Running water may be classed according to the size and importance of the stream, as *river, rivulet, stream* or *brook.* Still water may be classed as *sea, ocean, bay, lake, pond,* or *pool,* and as parts of the sea, as *gulf, bay, harbor,* or *roadstead.*

4. *Roads, etc.* Among the artificial features of a country land communications are of special importance, especially railways, which may be classed as *railways* or *tramways.* The military importance of the latter is almost *nil;* but, on the other hand, the former are of the very highest importance. Next come the *high-roads* of a country, *i.e.*, the roads that have been scientifically constructed and have been regularly kept in repair. The expressions, *country-roads, cross roads, forest roads,* and *meadow roads,* all convey their own meaning, inasmuch as all of them serve for some particular purpose, which their names indicate, and do not directly join two important towns or villages. *Paths* or *tracts,* that can only be used by foot passengers, may be styled *foot-paths.* A *hollow road* is a road, the level of which is sunk below that of the adjoining ground. A *pass* may be considered as the road over a chain of mountains joining the two countries or tracts of country divided by such chain. A *defile,* as generally accepted, means the contraction or narrowing of passable ground, such as a mountain defile, the defile over a dam, over a bridge, etc. *Rivers,* etc., are crossed by means of *bridges, ferries,* or *fords.* The former may be classed as permanent or floating; and again, according to the materials they are constructed of, and the plan of construction. Ferries vary according to the nature of the floating means of conveyance and method of transit from one bank to the other. *Land* may be classed as park, garden, meadow, plough, grazing, or uncultivated land, and woods or forests. Woods that have been regularly planted and laid out are called forests. *Habitations* may be classed as either towns, market towns, villages, or hamlets, and as single houses. *Fortifications* may be classed according to the size and the particular object of the work, as *battery* (intended for guns only), *redoubt* (a field-work intended chiefly to be used by infantry), *fort,* a closed permanent work of small dimensions, *fortress* (a permanently fortified town). The expression *before, behind, this side of, that side of,* etc., should always, if possible, be avoided, as the meaning they convey almost invariably depends on the position of the observer at the time. In by far the greater number of cases it is advisable to use geographical expressions (such as north, south, etc.) instead. But on the other hand, in the case of a water-course running, for instance, from east to west, the expressions north bank and south bank should never be used, but invariably the words *right* and *left* bank, as well as the expressions above and below. Similarly, in speaking of a ravine, the expressions right side and left side of the ravine should be used. In this case the observer should invariably fancy himself at the highest point of the stream or valley, and facing towards the mouth or opening, when using these expressions.

The following are the main points which should be considered by officers making reconnaisances for the guidance of a General in command of an army:

ROADS.

Their classification and length; their breadth, which will regulate the front of the column of march, and any contraction, or enlargement of the road should be noted; the nature of the road-bed, stating whether the necessary materials for repairs can be found in the vicinity; the inclines, stating the gradient and whether difficult parts of the road, can be avoided: the defiles, their nature, length, breadth, etc., and in the case of bridges, the materials of which they are constructed, the weight they will safely bear, the nature of the stream they cross, etc.; whether bordered by fences—stone or wood—ditches, hedges, etc.; the nature of the country on either side of the road, whether open, wooded or cultivated, and the nature of the crops; the distance between prominent points, both in miles and the time required on the march; good positions for the defensive, and the probable number of troops that can be placed in them to advantage; towns, etc., through which the road passes; points where other roads cross or join; their direction and condition, etc.

RAILWAYS.

1. The *line.* Whether single or double throughout, or double for certain distances; the location and length of the sidings; general condition of the road-bed, class of rails used, and length of time constructed and worked, which will determine the weight of the trains that can be safely run; the bridges, tunnels, and crossings on the line, giving the materials of which they are constructed, the width and height of each in the clear. The construction of important bridges and tunnels on the line should be considered in connection with the question of how long their destruction, either intentionally or by the enemy, would interfere with the working of the road. The *guage.* Whether broad or narrow. *Gradients.* State the length and difference of level of each. The gradients will affect the size of the trains that can be safely run over the road, and the traction power required to haul them. *Curves.* The radius of each curve should be given. The number of sharp curves on the line will influence to some extent the speed of trains. *Distance between stations.* On single lines only those stations will require attention which are provided with sidings where trains can pass. On double lines the distance between telegraphic stations will regulate the intervals between consecutive trains.

2. *Stations.* Number of tracks from which cars may be loaded or unloaded at each station; number and location of turn-tables and switches; platforms available for loading or unloading supplies and troops of all arms, or facilities for making platforms, and spaces suitable for forming troops while loading; number and capacity of storehouses, and their location with respect to the lines of the road; extent and location of water supply, and whether available for men and animals; places where refreshments can be procured, etc.

3. *Means of carrying on the traffic.* The watering stations with the means and quantity of supply; fuel stations, with kind and quantity of fuel usually kept on hand; number and location of construction and repair shops; location and capacity of the engine houses; system of telegraphs and signals, with the number of lines available for military purposes.

4. *Rolling stock.* Number, condition and power of engines; number and condition of cars of all kinds suitable for carrying troops of all arms, supplies and animals; materials for repairs, etc.

5. *Administration.* Personnel of the stations, lines, engines and trains.

6. *Division of the line.* Give the usual runs of the engines, stations where the personnel of the engines and trains is changed, and where the trains pass under the control of other lines.

7. *Duties.* The personnel of day and night service; the roster, and length of the tours of duty; order of duties and extra duty: ordinary and extra traffic, etc.

When railroad lines are to be used for military purposes, it is very desirable that the personnel of the roads should be continued in service; that the management of the lines should not be changed except when absolutely necessary: for in this way will the assistance of those who are accustomed to the duties be secured to the best advantage.

RIVERS.

1. Length of the portion of the river to be reconnoitered, the general direction, and any very great deviations from it.

2. Breadth, viz., the average breadth and the breadth at passages over the river and at towns or villages of importance.

3. Depth in deepest places in the stream, average depth, as well as the depth at points of special importance (as mentioned under 2).

4. The banks, height above mean level of the river, slope and peculiar character, embankments or artificial banks.

5. Bed and character of the bottom, whether rocky, stony, gravel or mud. Periodical changes in the bed.

6. Islands, whether cultivated or passable.

7. Fall and rapidity of the current per second. The fall is *slight* if the rapidity of the current is from 11.8 to 27.5 inches, *moderate* if from 2.2 to 3.2 feet, *rapid* if from 3.2 to 6.5 feet, and *very rapid* if 9.8 feet or more per second.

8. Whether navigable for ships or boats, together with data on the waterfaring population, boats, ferries, and ships, especially steamers, and purposes for which used. Any alteration in the volume of water according to the time of year should be noted and given.

9. Artificial arrangements such as sluices, dams, weirs, etc., giving their position and construction and the effect they have on regulating the volume of water in the river.

10. Tributaries should, if necessary, be similarly described.

11. *The valley of the river.* The depression and extent, whether passable or crossed by roads; cultivated towns and villages, especially those situated on the banks of the river, stagnant pools or creeks, and marshy places; elevations on the ground, dams and dykes, should be especially noted. Sides of the valley, distance from the river and from each other, relative heights, nature of the ground, whether steep or passable; roads and cultivation.

12. *Permanent bridges.* Materials (wood, stone, brick or iron; construction, on piles, arches, girders, etc.); breadth, length, and height of roadway above mean water-level; whether any part can be temporarily drawn up or removed; the weight the bridge can support, and whether passable for the different arms; the approaches on either bank, whether easily destroyed and restored.

13. *Floating bridges.* Such as bridges of boat, pontoons, or rafts, giving size, construction, and weight the bridge is capable of supporting, the number of boats, etc., the bridge is formed of, and the time taken in opening and closing the bridge.

14. *Ferries and flying bridges.* Weight the ferry or bridge can support, giving the time taken in crossing, together with the number of men, horses and guns that can be taken over at a trip.

15. *Fords.* Giving position, direction, depth, bottom. A ford 3.28 feet deep is passable for infantry, 4.71 feet deep by cavalry, and 2.85 feet deep by artillery.

16. *Favorable positions for throwing military bridges.* Giving approaches on either bank, construction, and whether assistance could be obtained on the spot in the way of bridging materials, workmen or transport.

CITIES, TOWNS, VILLAGES, ETC.

Inhabited places are of importance as points of *d'appui* in fighting, and as places where troops may be housed, fed, or equipped. Large towns or villages are important in the latter sense, whereas small places are more so for fighting purposes, because the latter only are so situated (though rarely it is true) as to command all the surrounding country. Large places are generally situated in valleys, and moreover, require a large force to be effectually held. It should also be stated in a reconnaissance of a place whether it is suited for defense, and more especially independent defense; *i.e.*, if the intended garrison could hold out unassisted for any considerable time against a superior enemy. As regards the latter question, the following points should be considered:—

1. Buildings (stone, wood, mud).
2. How enclosed (walls, hedges, banks and ditches).
3. Entrances (number and description).
4. Streets and squares (extent and position as regards each other; any obstacles to communiation).
5. Large solidly constructed buildings, well adapted for reduits, such as churches, etc.
6. Weak points in the defense, and how far capable of being remedied.
7. The surrounding country, whether favorable to the attack or defense. The number of troops considered necessary for an obstinate defense of the place, or the distribution of troops for the same, would not be given unless required by special order.

As regards giving the troops the use or benefit of the place, the following points should be considered: 1. Number of houses, with the number of men, etc., they would contain. 2. Number, occupation, and trades of the inhabitants. 3. Stores, depots, factories, bakeries, mills. 4. Facilities of transport by rail, river, road, or canal.

WOODS.

The following points should be considered in making a reconnaissance of woods: 1. Position and extent. 2. Nature and configuration of edges. 3. Roads, paths, tracks, and vistas. 4. The kinds of trees and undergrowth, with thick and clear spaces, clearings. 5. Nature of the soil with reference to the ground being passable off the roads, etc. 6. Obstacles to movements, such as streams, water, marshy places, etc. 7. Villages, etc., in the woods, with any clear spaces round them.

VALLEYS, AND LOW LYING GROUND.

A reconnaissance report on the above should give information as regards: 1. Situation and extent. 2. Nature or character of the ground, whether cultivated; peat-bogs, marshes, ditches, etc. 3. Roads, paths and tracks. 4. Whether the ground off the road, etc., is passable for the different arms, and how far the state of the ground varies at different seasons of the year.

MOUNTAINS.

The reconnaissance of mountains is a very difficult undertaking, inasmuch as the vision is generally much obscured, especially when the mountains are wooded. Good maps are consequently indispensable. Very particular attention should be paid to places where troops can to a certain extent deploy for action; otherwise the chief points to be considered are whether or to what extent troops can be moved, housed and fed. The reconnaissance report should furnish information of the following points:

1. Position, extent, shape and relative heights. Main and secondary ridges or spurs, plateaus, chief and secondary valleys should all be considered, giving the steepness of the various slopes.

2. Surface. The actual surface or covering of the mountains (rock, stones, debris, earth, etc.), marshy or rocky places, cultication (forest, ploughland, meadows,) towns, villages, etc., with the resources they contain.

3. Water, lakes, rivers, streams, etc.

4. Roads, tracts, paths and passable ground, especially noting ground where troops in formation could move off the roads, etc., (generally only found in valleys, or on ridges).

5. Special military considerations, such as positions, places for bivouacking, or where defiles, passes, etc., could be blocked, etc.

FORTRESSES.

1. The past history of the fortress should be thoroughly studied, especially that of its constructions, and of any sieges that it may have undergone, certain of the most important details of which should be given in the reconnaissance report.

2. Next, general geographical and strategical questions should be gone into and examined. This entails a reconnaissance of the surrounding country, which

should be made from an intending besieger's point of view, that is the best way of obtaining a correct insight into the defensive properties of the place, at least as regards how far an enemy's approach can be best observed, the ground round the fortress commanded, and an investment prevented or obstructed.

3. Next, in the reconnaissance of the interior of the place, the general system of defence, the *enceinte* with its ditches, outworks, advanced works, detached forts, and covered communications, should all be considered, both as regards plan, section, and system of fortifications. Casemated covers, caponnières, powder magazines, reduits, casemates for the garrison, bomb-proof hospitals, arsenals, and stores for provisions, have of late years gained much in importance.

4. Next the sluices belonging to the place regulating the level of the water in the ditches and ground near the works, the system of counter-mines if any, the entrenched camp, whether partially formed or projected, together with any works of defence that would be undertaken to give additional strength to the place were a siege expected, should be gone into and described, giving the time the latter would require with the labor and materials available on the spot. Similarly the artillery armament of the place should be examined and described.

5 Finally, the town itself surrounded by the fortifications should be examined separately by itself as a place of habitation, and any considerations which might affect the defense of the place, either advantageously or disadvantageously, should be studied and described; also, whether with due reference to all the above considerations, the proposed garrison of the place appears sufficiently strong.

6. In conclusion, a general *résumé* should be made, showing the advantages and disadvantages presented by the works of the place, and the neighborhood of the fortress, in the case of investment or blockade, attack "*de vive force*," by surprise or escalade, bombardment, artillery attack, or regular siege with breaches and assault, with special reference to the weak fronts of the fortress.

LARGE TRACTS OF COUNTRY.

1. In the reconnaissance of large tracts of country, the first object should be to examine and describe the general character of the country for military purposes.

2. For this purpose a country has very often to be divided into sections according as the latter are favorable or otherwise to military requirements, as regards the marching, fighting, quartering, feeding, etc., of troops. The country should be considered both as regards its orography and hydrography, paying special attention to important rivers, etc., and the general character and configuration of the ground (mountainous, hilly, and flat country).

3. Next, the communications both by land and water should be carefully examined, *i. e.*, railways, highroads and navigable rivers and canals. The state of cultivation of a country is also of importance and large tracts of forests or woods, valleys and low-lying ground, etc., should be specially reported on. Finally, the inhabitants (numbers, nationalities, religion, occupation, characteristics, etc.) should be considered, together with the towns, villages, etc., with population of each, paying of course, special attention to fortified places or points otherwise of military importance.

STATISTICAL RECONNAISSANCES.

1. Statistical reconnaissances complete the detailed series of reconnaissances just given. But it would be a mistake to fancy that the necessary information for the same could be collected during a tour from observation only. Consequently a preparatory study, going thoroughly into the question by collecting information from every kind of book and printed matter, must first of all be undertaken.

2. Work of this description is nowadays rendered comparatively easy by the publication of certain works on statistics, but as a rule, the information thus obtained has generally to be differently grouped to be of value for military purposes. The following points should then be considered.

3. *Quarters and camps.* Number and description of the towns, villages, etc., giving the number of inhabitants and the number of fireplaces in each; the public buildings and supplies of wood and straw should be noted in each separate place.

4. *Provisions.* Produce of cultivation and meadows, head of cattle, stores, mills, industries and trades, especially bakeries, breweries, distilleries, wine and tobacco produce.

5. *Clothing and equipment.* Linen, cotton, cloth, and leather factories.

6. *Sanitary establishments.* Hospitals, infirmaries, and baths.

7. *Means of transport.* Rolling stock of railways, horses, mules, and yoke oxen; description of carts and carriages with draught; navigation.

8. *Arms and warlike stores.* Small-arm factories, iron foundries, stores of metal and timber, powder-mills.

9. *Money.* Monetary system, duties and taxes.

10. *Inhabitants.* Military system and organization, any special organization for the defense of the country, such as national guards or local rifle clubs; degree of education and political feelings.

11. Reconnaissances made without preparatory work can only be useful as a means of verifying military considerations of high importance, or completing our existing stock of information. As regards the latter, it is worthy of remark that documents and maps, made for local use only, and consequently but little known elsewhere, are often to be obtained on the spot itself, and afford much valuable information.

REPORT.

As regards the general form of making a reconnaissance report, it is generally advisable to make it in as abstract or even tabulated form as possible. For instance, it should not be necessary when seeking for information on a given point, to have to wade through the whole report to the end; a short index of the contents as well as a logical arrangement of the subjects facilitates the work of rapidly examining the report. It is, moreover, desirable to have a great deal of important data or information without arguments or reasoning, as the latter can only be made on definite suppositions. A report which is not definite in its information is but little better than none at all; to make an incorrect or false report amounts to a military crime; and a report which is larger or more voluminous than is necessary, often fails to fulfill the object desired. A report should be as brief as possible when it accompanies a map or sketch as "explanations." Further, it should always be borne in mind that every reconnaisance report is an official report, and that, consequently, the officer making the reconnaissance is responsible for the accuracy and truth of his personal observations. The latter should therefore be kept quite distinct from that part of the report which has been compiled from the information and observation of others.

ROUTE SKETCHING.

There is a branch of topography, which, from the importance sometimes assumed by it, should be mentioned under the subject of topographical reconnaissance, in connection with which it is frequently used, viz., route sketching. The object of route sketching is to represent the route passed over by an observer, together with so much of the country in the immediate vicinity and within view, as may in any way affect military operations. The sketch is usually accompanied by notes giving explanations of any features that strike the observer as being of particular importance. Information gained in this manner may frequently be found of great assistance in arranging the details of a campaign or of a battle. It is not proposed to treat of the subject in this work, but the details of the duty, as well as those pertaining to reconnaissance, will be found in a book entitled "Military Sketching and Reconnaissance," by Lieut.-Col. Hutchison and Captain MacGregor, of the British service.

The officer selected for the duty of conducting a reconnaissance, should be one who has been specially instructed for the purpose. The duty requires an officer who has a particularly good military judgment, and who has previously made a thorough study of the subject. He should have a mind that can readily grasp details and retain them; he should be familiar with the different arms of the service, their placing for mutual support, and their adaptability for action under the varying features of ground. The faculty of correctly estimating distances by the eye will be of great assistance to an officer in performing this duty. This faculty, although natural to some, may by practice be acquired by all. The officer should be provided with all the materials necessary for making and recording his observations; good maps of the country to be examined, a field glass, writing materials, etc.; good guides—the best will usually be found among that class of people whose duties take them about the country—a good escort, preferably cavalry, as offering the necessary essential of moving quickly, and of furnishing the means of forwarding rapidly the information obtained.

An officer familar with the duties prescribed should be able to make a general sketch of the country, giving the details set forth, during the temporary halts necessarily made on the march for the purpose of resting his escort and obtaining information. The great value to an army, of officers who are thoroughly conversant with these duties, and the great assistance to the General in command that the information gained by them is in carrying out his plan of campaign, are fully illustrated by the events of the wars of 1866, and of 1870-71. The Prussian staff was most thoroughly organized, and the influence the officers composing it, exerted in bringing the campaign to a successful issue, is readily apparent after a careful study of the detailed operations of these wars has been made.

An armed reconnaissance, when made with a small force beyond the outlaying sentinels of an army, for the purpose of obtaining information of the enemy, is usually termed a *patrol*, *scout*, or *secret, reconnaissance*. The best hour for the troops to set out on this duty is about dusk, or sometime during the night. They can at this time more easily pass between the outposts of the enemy, and when daylight comes they will then be on the ground which it is desirable to examine. Again, if the departure of the detachment is discovered by the enemy, another route can be taken during the night. The officer selected for this duty should be daring, courgeous and capable of enduring great fatigue; he should be a good horseman have good eyesight, a mind quick to grasp all details, be prompt to act, and he should have a retentive memory. He should be familiar with sketching, so as to be able to represent any portion of the enemy's works or position, or to convey a good and intelligent idea of the ground which it may be the intention to occupy. He should be provided with a good field glass, with maps, and with all the materials necessary to record the information gained. A good guide is also indispensable, one who is thoroughly acquainted with the country, the byways, short cuts, etc. The officer should be given full instructions, in writing, if necessary, of the object of his scout, and he should entirely understand them before starting out on his mission. He should know the distance taken up in column by the sub-divisions of the different arms of the service, so he can readily estimate the strength of any force of the enemy which may come under his observation. He should be furnished with a detail suitable for the work required of him. If the country is open, the escort should be composed of cavalry; if it is broken or rugged, infantry should be taken. The men should be selected from the best material the army affords, their qualifications being similar to those of the officer in charge of the party. As a general rule, the detachment should be small, as a few men can conceal their march and presence from the enemy much better than a troop or company under similar circumstances.

Great care should be exercised when approaching any place favorable for an ambuscade. Such points should be carefully examined by one or more men, detached for the purpose, before closing in on them with the party. All renconters with the enemy should be carefully avoided, as the main object is to gain knowledge of his forces, positions, and movements, without exposing the presence of the party making the scout. Even very small parties of the enemy should be allowed to pass, as the main object of the scout might be lost by an attempt to capture them, by the escape of some one member of the party, out of sight or overlooked for the moment. The detachment should avoid the traveled roads, keeping near them, however, by moving along the byways, through the woods and fields. It should be very careful about making any noise, should not be allowed to build fires or the men even to smoke at night, when in the immediate vicinity of the enemy. It keeps well together, depending upon a few men in advance, marching in dispersed order, to give timely notice of anything suspicious in the vicinity. If any considerable force of the enemy is discovered, the detachment should be entirely concealed from view, but in such a position that all the enemy's movements may be seen, and his exact composition, direction of march, and numbers determined, when a detailed statement of the information obtained should be made in writing and sent to the commanding General by two of the most reliable men of the party. General Pope, during his campaign in Northern Virginia, received accurate information in regard to the flank march of General Jackson, from Colonel J. S. Clark, of the staff of General Banks. That officer remained all day in a perilous position, within sight of Jackson's moving column, and counted its force, which he found to be thirty-six regiments of infantry, with the proper proportion of batteries, and a considerable cavalry force. If the object be to gain information of the enemy's presence or strength at a certain place, the officer, when he has reached the immediate vicinity, will conceal his detachment in the best manner possible, and taking two or three of his best men, will approach as near as he can without discovery, to gain the desired end. If essential to send information speedily, a few men may be left at intervals along the line of march, to in turn take the message and forward it. Upon the return of the officer to his station, he should make a report in writing of his scout.

A reconnaissance in force is generally made just before a battle, for the purpose of forcing the enemy to develop his strength and dispositions. The time selected is usually late in the day, in order that night may be depended upon to put an end to the fighting, and to give the commanding General an opportunity to make any change in the arrangement of his troops which the facts gathered from the reconnaissance may have rendered necessary. The enemy should be threatened in such a manner as to lead him to suppose that a real attack is intended, and to force him to discover his strength and position. During the advance reconnoitering officers should be well to the front, seizing upon every point of advantage for a good lookout, noting the details of the enemy's position, marking where his troops and guns are placed, and estimating distances. The reports and notes (rapid outline landscape sketches sometimes added) of these officers, when put together on return, will afford valuable information to the General commanding. Care must be taken that the movement does not lead to a general action for which the force is not prepared. By advancing for the reconnaissance late in the day, even should it be difficult to withdraw, darkness will enable the Commander to put a stop to the fight.

A *reconnaissance in force* may be made under the immediate supervision of the General-in-Chief, or by a detachment of troops of all arms, selected for the purpose, and under the direction of a subordinate commander. In the first case, there would be a general advance of the whole line, as if for the purpose of bringing on a general engagement, showing a strong line of skirmishers in front. The forward movement may be preceded by a charge of cavalry for the capture of some of the enemy's outposts or sentinels, from whom information of a very valuable character may sometimes be obtained, especially when they are from differennt fractions of the enemy's forces. The artillery should be brought into action in order to cause the enemy to open fire with his own, thus revealing the general disposition of his forces, key points, etc. The General follows the movement, taking station where he can most readily overlook the enemy's line, and, having gained his object, causes the troops to be withdrawn to their position. Care should be exercised that any success obtained at any point of the line, be not so closely followed up as to prevent the withdrawal of the troops at the proper time. Or, if during the movement, it is found that an important position has been gained, owing to the failure of the enemy to properly guard it, and which it may be desirable to hold, dispositions should at once be made for that purpose, by sending re-enforcements forward, causing the troops to entrench, etc. An operation of the second class is more difficult, requiring great tact and good judgment on the part of the officer in command. Depending upon the nature of the country and the object to be gained, the detachment will be formed of one or more arms of the service. The troops selected, usually a division, or perhaps the advanced guard of an army, will be handled as in the first case, the additional precaution being taken to see that the line of retreat to the main body of the army is in no way compromised. To render this secure, the flanks of the attacking body of troops should be well protected by patrols of cavalry and by skirmishers.

Minor operations made by small parties and usually called *patrols*, are continually carried on, both within and beyond the line of advanced sentinels of an army. In the first case, to examine well the ground between the sentinels, also the ground between the line of sentinels and their respective outposts. In the second case, to examine the country between the lines of the two armies, to ascertain what changes may have been made during the night. In this way small affairs of detached parties are brought on, the object being to take prisoners and thus gain information. The great objection to a *reconnaissance in force* is that, as the troops are used to unmask the enemy and make him develop his position and forces and then withdraw, the operation partakes of the nature of a retreat, and is liable to have a somewhat demoralizing effect upon them. From commanding ground, or before an enemy who is negligent in covering his front, much may be learnt by a practical General without making an actual attack. Napoleon spent part of the day before Austerlitz at the outposts, while in his front, the valley of the Goldbach, and the opposite slopes, were covered with cavalry skirmishers, amidst whom rode experienced officers, from whose observations, joined to his own, the Emperor deciphered accurately the movements and designs of the adversary.

Marmont says, "Nothing should be neglected by which we may obtain exact information; and the surest method is always to be in contact with the enemy by means of light troops, frequently to have small engagements, and to make prisoners, whose answers are almost always simple and sincere. More is learned through them than by means of the most faithful spies. The latter often confound the names of corps and of Generals, and form very inexact estimates of the strength of the troops, concerning whom they report."

"Two Prussian officers of the staff of Prince Frederick Charles, the afternoon before the battle of Königgratz, boldly approached the Austrian lines, observed the positions of the Austrian troops, and, though both pursued and assaulted by cavalry, got safe home, and brought to their General certain intelligence, which allowed him to frame the combinations which resulted in the morrow's victory."

"The eyes of the Austrian Army on more than one occasion during the campain (1866) failed. Their patrol system was very much inferior to that of the Prussians. Its inferiority seems to have been due to the want of military *education* among the officers to whom patrols were entrusted. In the Prussian Army special officers of high intelligence were always chosen to reconnoiter. The Prussian system never failed, never allowed a surprise. The Austrians were repeatedly surprised and taken unprepared."

When an enemy is at a distance and his movements are unknown, he is often more to be feared than when close at hand and under observation. He must not therefore be lost sight of because he is some way off; but on the contrary he must be watched in such a manner as to observe his movements closely with a view to estimating his designs, and at the same time to prevent his attempts at reconnaissance with like intentions. A fatal mistake is too often made by cavalry, in supposing that it is sufficient to reconnoiter the enemy and return with a report, or even to reconnoiter in a certain direction and report that no enemy is seen. It is not only necessary to find the enemy, but when found, to keep him under constant observation. For this purpose detached bodies of cavalry should be advanced to the front of an army, interposing between their own troops and the enemy a veil or screen, behind which there is immunity from surprise, and in the extreme front of which feelers, or reconnoiterers are actively employed, collecting intelligence for transmission to the rear.

These duties would be either performed by the "divisional cavalry" or else by the "cavalry division," according as the operations are on a small or on a large scale. By the former is meant the cavalry attached to a division. If several divisions are acting together, the cavalry of each would cover the immediate head of its own column on the march, reconnoiter the country to its front and flanks, and link the column to others, just as in action it would fight on the flanks of its own division, crown its success or cover its retreat. By the latter is meant the division or brigade of cavalry, which is an independent tactical body, having relations to the whole army of a similar nature to those borne by the divisional cavalry to its own division. It therefore furnishes the advanced cavalry for screening and reconnoitering duties, when several columns are moving forward in combination. Should a division or smaller column of three arms be acting by itself, a portion of its cavalry would generally be detached to the extreme front for a similar purpose.

A force of considerable strength is usually employed on this important service. The principle adopted is that of retaining a support in rear, from which smaller parties are detached to the front and to the flanks, these parties in their turn sending out smaller fractions, until the whole assumes the form of an open fan, upon the outer edge of which the patrols are reduced to a strength of some eight or ten men, which in their turn may be covered in extreme advance by groups of scouts of two or three men together. This action of the cavalry may perhaps be best appreciated by its being described as a moving outpost chain. A regiment of cavalry may thus be sent out to a distance, varying, according to circumstances, from ten miles to one or two days' march, in advance of the army it serves to cover. One squadron moves still farther to the front, one to each flank, while the remaining squadron acts as a reserve to the others. Each of these squadrons now in extreme advance sends patrols to its front and flanks, as required by the nature of the ground and supposed position of the enemy. A support, consisting of from one-third to one-half the squadron, remains in each case in rear, moving along a central route. The patrols in their turn detach scouts so that every part of the ground may be thoroughly examined. The distances to which the advanced squadrons should proceed from the squadrons in reserve, and also the intervals to be preserved between the squadron in advance, must depend so much upon the nature of the country and upon the position of the enemy, that it would be hard to frame any absolute rule on the subject.

It is, however, suggested that, while the advance should be extended as much as possible in order to avoid employing too many men upon the service, care should invariably be taken that all the bodies in front be able to fall back securely upon their supports, in case of the enemy being met in force. It is recommended that the distance to which each patrol may detach itself from its immediate support be restricted to four or five miles, or as much ground as can be passed over in one hour in ordinary country. On occasion, however, a patrol may be despatched on independent service for much longer distances, relying entirely upon its own resources. It frequently becomes necessary for scouts to be sent to considerable distances from their supporting body; but each group, though out of sight and hearing of the next, should always know the general position of the groups on either flank of its own patrol, and of the squadron from which the patrol is detached.

CONNECTING POSTS.

In proportion as a reconnaissance is pushed further to the front the necessity for maintaining some system of constant communication with the rear becomes more apparent. It must be regarded as a first essential condition, that the intelligence procured by a reconnoitering party be transmitted at once to the main body. It is also needful that a detached patrol should be in a position to receive orders from the rear as quickly as possible. Hence arises the necessity for connecting posts, when reconnaissances are being carried on at some distance in advance of the main body. The posts are placed on the main routes, generally at positions which can be found easily, such as bridges or remarkable or well-known buildings, and they are established by each advanced party as it proceeds to the front. The posts should be two or three miles apart, or the distance an orderly could, in case of necessity, pass over at a gallop without pulling up. A post should not consist of less than three men, one of whom must always be ready to mount at an instant's warning, whenever a messenger is seen approaching, for the purpose of carrying on the despatch to the next post. The orderly who brings in a message returns to his post after a short rest, and takes back with him any orders for the advanced party. The pace at which an orderly should ride, the exact place, and hour of despatch, should be written on the outside of the message.

STRONG RECONNOITERING PARTIES.

A strong reconnoitering party would be detached, either from the main body, or from the reserve of the advanced covering detachments, *i. e.*, from the reserve of the advanced-guard on the march, or from the reserve of the outposts at the halt. The Commander would receive before starting the most precise instructions as to the object to be effected. He might be ordered, for instance, to search for the position taken up by the enemy, and to ascertain the numbers of his troops by such indications as may come under observation without disclosing his own proximity; or he might be directed to feel for the enemy in a particular quarter until he should hit upon him. Or else he might be directed to report on the resources of the country, the facilities and obstacles it presents for advance, and the general lines of communication.

Strong reconnoitering parties may push their reconnaissance far beyond the zone of the smaller reconnoitering patrols. They are generally ordered out by the General or Brigadier, their force and composition depending much on the nature of their mission and of the country, and on the necessity or non-necessity of concealing the march of the party. A troop of cavalry is often sent on such a duty, a staff-officer accompanying the force. If the country is close, hilly, and wooded, infantry may be selected in preference, a few mounted men being attached as orderlies; but more usually still in a varied country, infantry is joined to cavalry as its support. The infantry would accompany the cavalry to certain points, past which the horse must fall back in retiring. These points the infantry would hold to secure the retreat of the cavalry, which latter would then advance rapidly to the front to complete the reconnaissance. The cavalry in its turn would cover the retreat of the infantry across any open ground.

The addition of infantry gives to such reconnoitering parties a strength and power of resistance which cavalry can never attain by itself. The employment of artillery tends towards a similar end, and the especial mobility of horse-artillery renders it most appropriate for such service. Artillery is nevertheless seldom added to an ordinary reconnoitering party, its use being generally confined to a reconnaissance in force, or a special reconnaissance. But although guns are not much employed upon this kind of duty, there may still be occasions where artillery would prove a useful addition to the other arms, as, by its assistance, woods or other suspicious places, within range, could be effectively examined or cleared of the enemy's presence, without the necessity of a close approach. Guns can also cause the withdrawal of parties of the enemy from small defensive positions by acting on their flank.

Whenever the several arms are combined in a strong reconnoitering party, cavalry is always well to the front in the advance, so long as the ground permits. The infantry in rear takes up successive positions favorable for defense, as it advances, so that if at any moment the cavalry is driven back it will be protected in its retreat by the infantry. In the return march the infantry takes the lead, unless hardly pressed in a close country, when the cavalry is sent on in front.

Troops are usually drawn up, or formed in two ways, viz., *a*. In *column*; the habitual disposition when on the march, and for facility of movement and maneuver. *b*. In *line*; which is now as a rule the order on the field of battle. The formation in deep columns of attack, formerly employed with such great effect on the battle field, will now very rarely be used. This change in the manner of handling troops is due entirely to the great improvement in the fire-arms of the last twenty years.

INFANTRY.

It may be said of infantry that it is by far the most important factor of an army. Cavalry and artillery certainly render important and essential service at some period of every campaign, or during some phase of every battle; but good infantry is absolutely necessary for the accomplishment of any great operation in war. Infantry is undoubtedly the main stay and the backbone of all armies, whether it be viewed in the light of numbers, or its action on the field of battle. Its fire is more deadly than that of artillery, its action is sure, while that of cavalry is fitful. On the infantry of an army the brunt of the fighting falls, it suffers more in action and more on the line of march, and to it the action of all other arms is subordinate. Artillery fire but to pave the way for an infantry attack, or to check an infantry advance. Cavalry charge but to confirm an infantry victory or to check a pursuit, engineers open roads and make bridges, to allow infantry to pass; they strengthen positions, and throw up earthworks, but to protect and cover the infantry, or to enable a small body to check a superior force. On infantry tactics the whole superstructure of military operations must be built. But it must be borne in mind that in any tactical action, one arm of the service without the other is really incomplete, and the true function of tactics, is to so apply the action of each arm, that not only its special power shall be developed, but that it shall be developed at the time and place requisite for the support of the other arms.

The Austrian infantry has always proved inferior to that of other powers with which it has recently been matched. The excellence of the other branches of the army has never been able to atone for this one fatal defect. The infantry of an army is its mainstay. A battle, it is true, may occasionally be decided by the vigorous action of cavalry, as was the case at Marengo; sometimes be influenced by the happy concentration of artillery, as was seen at Wagram and Solferino; but success can never be confidentially relied upon in war, unless the fighting powers of the infantry may be fully trusted.

The infantry by its fire disables the enemy and prepares the way for the efficient operations of the cavalry and artillery; the infantry by its charges wins battles, carries and defends positions. Infantry has great powers of endurance, is capable of giving or receiving battle in almost any position, and is peculiarly free from those casualties, which in unforseen emergencies frequently paralyze the other arms. The essential qualities of a good infantryman are: coolness under all circumstances of danger, self-reliance and independence in action, judgment in deciding when to take advantage of cover, and when to leave it in order to move forward again; he should be a good marksman, as the main reliance of infantry is the efficacy of its fire; he should know when to husband his amunition, and when to deliver his fire with the greatest rapidity; for rapidity and accuracy of fire at the proper moment are now of supreme importance in the decisive phase of a battle. The genius of the Commanding General is the greatest aid in winning a victory, infantry ranks next. The cavalry and artillery render important service on the field of battle, and in the retreat and pursuit; the infantry often finds itself in positions and under circumstances that would be most disastrous, if not supported by these arms; and by their aid successes gained by the infantry are often made complete. Infantry can win a battle, but calvary and artillery are necessary to destroy the enemy by a vigorous pursuit. The history of all wars and of all nations confirms these conclusions.

Infantry acts defensively by its fire and offensively by its charges. On the field of battle it is invariably employed in one of these ways, or in both combined. On the field of battle two bodies of infantry will seldom come into actual contact. In making an attack the assailant will either be repulsed and driven back by the effect of the fire of the assailed, or, when the former reaches a certain point in its advance, the latter will abandon its position. Infantry on the field of battle, when stationary, should always lie down; it is thus always to a certain extent concealed from the enemy's view and protected from his fire. The introduction of breech-loading rifled arms has radically modified the tactical formations of infantry; this being particularly true for offensive movements. Formerly, the fire from troops in a body was mainly relied upon to produce telling results; now, the main object is to develop to the fullest extent the independent action of each individual soldier and the fire from each rifle. It appears, therefore, that both in defensive and offensive fighting tactics, one great object is to develop the individual action of the man, whether in the use of his weapons or as a unit. For officers this development of independent action is the power of leading and handling small groups or bodies of from ten to two hundred men; but while this independence is developed, it must be held in hand and directed, it must be freedom, not license. It must be carefully watched by a Commander who has reserves in hand to support it, either by completing the victory or checking defeat; and above all it necessitates most careful training on the part of the soldier.

The first troops that come into contact with one another before battles are fought, are small detachments. Military history necessarily passes over much that is done by these small bodies; but there can be no doubt that the correct leading and handling of these small bodies, conduce greatly to bringing the action of larger bodies to a successful conclusion. At the beginning of any great battle, there are numerous struggles for important points, indeed great battles are often brought about by the necessity for supporting small detachments seeking thus to obtain some advantageous ground. Now it is undoubtedly one of the consequences that flow from the use of modern arms, that troops once actually engaged can rarely, if ever, move to the right or left. Maneuvering under fire, always difficult, may now be deemed almost impossible: once troops are really engaged it would appear that their movements must be either forward or backward. Fresh troops may be brought up from the rear to feed the fight in front, but such movements as those made by Massena at Wagram, are at the present day impossible.

The actual success of operations in war must primarily rest on the action of small bodies; good previous strategical movements, a correct formation of the order of battle, a proper selection of the points to be attacked, will make the success, when obtained, of far greater importance; but the actual success must ultimately depend on the correct handling of small bodies of men. The question how a small body of men should be handled in actual fighting has now become of far greater importance than formerly. Important as affecting the individuals concerned, perhaps more so, as reacting on larger bodies. This is one of the features of modern fighting, and one which must be carefully considered. A battle under existing circumstances is a series of small battles or fights in which bodies of troops, perhaps not greater than a brigade, are engaged, and each of these bodies must be tactically complete, must work for one object, and seek to carry one point.

It has been said that for the future no direct attack can possibly be made on troops occupying a position, and that all attacks must be made on the flanks; but experience shows that attacks on the flank, unless supported by a strong front attack, can always be met and defeated. The battle of Wagram, and perhaps still more, the counter-strokes delivered at Rossbach and Salamanca, show, that unless front attacks are made at the same time, flank attacks are unlikely to succeed; consequently, however difficult and dangerous such attacks may be, yet it is requisite that they should be made, in order that the change of front, which any well-disciplined army can make if unopposed, may be prevented.

We said that on the German side the intention was generally evident of attempting to turn the enemy. But the fight often developed itself in such a manner that, after preparing the way by artillery fire, the Germans made a vigorous attack upon the French center, without waiting for the effect of the movement on the flanks. This mode of action has often been criticised, and attention has been called to the enormous sacrifices which it has generally entailed; but these critics forget that, when you wish to force the enemy to fight, a fairly sharp attack in front is necessary to hold him fast, otherwise he would avoid the turning movement which is meanwhile going on, either by a timely retreat, or by throwing himself upon the turning column and attacking it, whilst executing its movement.

The offensive. In order that a force on the offen sive may be able to develop with effect its maximum of attacking power, and make use of it to the utmost, it should adopt a formation favorable, as far as possible, to the following requirements: *a.* To the very greatest mobility. *b.* To the greatest possible security from the effects of the enemy's fire. *c.* To the greatest possible development of its own fire.

For troops acting on the *offensive*, the great object to be attained is, to devise some means by which they can, with some degree of organization remaining, reach a point sufficiently near the enemy's position, to enable them to carry it by a grand and concerted rush forward. To contend that this result can now be obtained by troops in the old formation in column, or even drawn up in two ranks, is contrary to all the teachings of the past few years; which leads us to conclude that such an operation would be attended with the most disastrous results. The results of recent wars teach that the proper formation for troops acting on the *offensive* is in successive lines of skirmishers. The intensely effective and continuing rolling fire of the Chassepôt made it clear to all our Commanders that a strong deployment of skirmishers was absolutely necessary, so as to answer the enemy's fire in an effective manner, not to expose too strong supports to its effects, and at the same time prepare the way for our attack. In the course of a long conversation on this subject, General Skobeleff expressed himself as follows:

"The only formation in which troops can successfully assault intrenched positions is in successive lines of *skirmishers*. The division General must be perfectly thoughtless of his own comfort or safety, and put himself between the skirmishers and the reserves where he can feel the pulse of the battle and have his troops in his own hand, and judge of the moment when the sucessive battalions in reserve should be sent forward. There are in every command a small percentage of cowards who will slink away at the first opportunity, a certain number of men of rash bravery who will go too far forward and get killed, and the great majority of men of ordinary courage, but liable to waver as the fight gets hot The reserves must be sent in at the moment when the reasonably brave men have been long enough engaged and met with enough resistance to begin to feel nervous, but before they have actually begun to retreat; and it is in deciding upon the opportune moment for sending forward his reserves that the art of a division Commander consists. Such are the opinions of the General who made more open assaults than any other in this war, and who never failed in any one of them to carry the works which he was ordered to attack.

The expression "loose order" has been often employed to describe this mode of attack, but the expression is an inaccurate one. The attack is not loose, which rather means a careless haphazard action, but it is the *individual* action of the soldier fighting in extended lines; the real facts being that such a method of fighting demands not only greater individual exertion and intelligence, but far higher and more complete instruction on the part of both officers and men.

It appears generally that troops formed for attack should be formed in at least three bodies, and that these bodies should under one direction work for one object, and be closely linked together, and be of such strength, that each shall be a considerable force. We thus arrive at the formation of a skirmishing line, a supporting line, and a main body. Taken together these three form the first line. It further appears that the men placed in the skirmishing line should be extended so as to diminish loss, increase accuracy and rapidity of fire, while at the same time a heavy and destructive fire is maintained. The functions of the skirmishing line being to crush and overwhelm the enemy with bullets. The objects of the supports being to fill up gaps among the skirmishers, and so sustain the intensity of their fire. The duty of the main body being to advance the moment the enemy is sufficiently shaken, and to drive him out of his position.

The distance between these three bodies must be governed partly by the work they have to do, partly by the trajectory of the arms in use, partly by the ground; to effectively support the skirmishers, that is to say, to be able to feed them with fresh men, the supports should be two hundred to two hundred and fifty yards in the rear. The main body must be able to cross the interval that divides them from the skirmishers in about five minutes, or they must be five hundred to six hundred yards off. Consistent with the due performance of these functions the supports and main body may be in any formation that from the shape of the ground, or other circumstances, will protect them best from loss, whether that formation be extended order, line, or columns, and they must change from one formation to another as quickly as possible. The principles which govern the formation of troops for attack can only be given, their application must depend on the knowledge and ability of the Commander in adjusting his formation to suit the ground he is working over. Thus the more cover there is to take advantage of, naturally the smaller will be the loss, and consequently the supporting body, whose functions are to supply the losses of the skirmishers, may be reduced, and the length of the skirmishing line increased, at the same time that the intervals between the lines may be diminished. But the original question embraced more than the formation of the troops. It was, how shall the shot-swept zone be crossed?

Putting irregularities of ground out of consideration, this zone is swept by fire of different kinds, in different places. *a.* The artillery fire, which may be said to begin at about two thousand five hundred yards. *b.* The unaimed or random fire of the infantry, which may begin to tell at about one thousand one hundred yards. *c.* The aimed fire of the infantry, which will begin to tell at about six hundred to seven hundred yards. Artillery employed in defending a position do not fire so much on advancing infantry in the early stage as on the attacking artillery, in addition to which the actual loss by artillery fire in action is comparatively small, being from one twelfth to one fourteenth of the loss caused by the musketry fire. Hence it may, speaking in general terms, be disregarded. The unaimed infantry fire produces many losses, and it appears that the effect of such fire may be mitigated by observing where it falls most, and avoiding those places.

The fire that causes heavy losses, and checks advancing troops, is undoubtedly the aimed or directed fire of infantry. The sooner and quicker the space between, where the deployment of the troops takes place, and the enemy's position is crossed, the better; but if crossed at the double, one of the objects of the skirmishing line, crushing the enemy with bullets, would not be accomplished, hence, such a method of advance, even if it were possible to run over the two thousand yards without stopping, would be undesirable. But it seems desirable that the first one thousand yards should be crossed without firing, and as rapidly as possible. It will be shown hereafter, that the attacker's artillery usually fires on the enemy's infantry, not on his guns, hence, until the attacking troops reach the zone of dangerous infantry fire, or about one thousand one hundred yards from the position if possible, they should advance without firing, and as quickly as they can, without being disordered, once the dangerous zone of infantry fire is reached, not only will they begin to suffer, but the power of inflicting loss on the enemy by means of their own fire begins, and about this stage of the advance the skirmishers must begin to fire. How should they then advance? Bearing in mind that the function of the skirmishing line is to keep up a continuous rain of shot on the enemy, and expose themselves as little as possible, or to develop the offensive power of the breech-loader, while reducing the destructive effect it has when used on the defensive. Bearing this in mind, it appears that the advance may be made in a succession of short rushes, lying down, firing rapidly, and again running on. This maneuver may be performed in several ways ;the whole line may so act, or alternate men may so act, or alternate portions, sections, subdivisions, or companies may so act. The first method entails the disadvantage of there being a time, however short, yet a small appreciable time when the fire ceases. The second method has this objection, that the party in advance are sure to mask the fire of those in rear more or less, and that soldiers are peculiarly apt to be discouraged by losing men from their comrades' fire, and that the men are apt to get out of hand, and the officers find their control reduced. The rush forward of an extended line invariably draws the enemy's attention, and consequently his fire on that portion; this is the moment for the other portion to seize and rush on too, hence there is an advantage in the alternate rush of portions.

For what distance should these rushes be made? They should be of such a length that the men should not be exhausted and out of breath after making them, even when the distance is run over as rapidly as possible; for this reason, it would appear that these rushes should not exceed about sixty yards, but should be adjusted so as to obtain cover; if cover exists, the rush should be from cover to cover. Before advancing, the officer commanding the body about to make the rush should select the place he is going to, point it out to his subordinates, and at a given signal he should dash to the front, his subaltern and men following; on getting into his new position he will get his men under cover as quickly as possible, kneeling, lying down, or standing, as may best cover them, and will open fire at once, and fire steadily and deliberately until the company on his flank is rushing, when he should fire a few rounds as quickly as he possibly can, to cover its advance. It should be a standing rule that when any body of skirmishers is rushing to the front, those on its immediate flank should fire rapidly to cover its advance and reduce the effect produced by the cessation of its fire.

It is the function of the supports to fill up the gaps in the skirmishing line, hence, companies must get mixed up together, it is perfectly impossible to prevent it. But it is possible, by careful training to obviate, or rather to mitigate, the evils that might ensue. Meanwhile the German line of skirmishers was approaching the enemy by a succession of rushes. This was either done by taking advantage of cover,or else they would advance about a hundred paces at a run, throw themselves down, and then run on again. In this manner the line of skirmishers got part of it within four hundred paces, part to within from one hundred and fifty to three hundred paces of the enemy, according to the nature of the ground, seldom without suffering great and inevitable loss. This advance would occasion separate strokes and counter-strokes, which naturally caused the tide of battle to roll backward and forward. At this period the fight would attain its highest pitch of intensity. The fire of the breech-loaders on both sides resounded unceasingly, and the work of commanding became the more and more difficult. (The distances which we here give are modified of course by the nature of the ground and other circumstances). As a general rule the German infantry had their sharpest musketry fighting at from about five hundred to one hundred and fifty paces, under peculiar circumstances even at closer quarters.

These were doubtless the right tactics and suited to the present arms, because one should use the offensive power of the breech-loader before attacking an enemy in position. An immediate rush against such a position, even if made by strong lines of skirmishers, would as a rule fail. If fresh detachments come up from the rear during a stationary musketry fight, whether to strengthen the line of fire or to make an attack, it was necessary to double these up with the old skirmishers, because closing the latter to a flank was usually not to be thought of; thus men of many different battalions and regiments were intermingled.

Companies *will* get mixed up. Long range weapons compel an advance in extended order for long distances, and do what officers may, men under such circumstances, exposed to a heavy fire, do get out of order. There is no use blinking this fact; it is impossible that it can be otherwise, so long as human beings possess different physical and moral endowments. Some men will be eager and anxious for the work, others will hang back, and their courage gradually ooze away. Some can be influenced by example and encouragement, others cannot; some are stronger and better able to keep up than others, consequently we must expect such a mixing up of companies amongst the skirmishing line. It is better to foresee and provide by training that an evil which *will* take place may be as little of an evil as possible, than attempt to guard against what all experience shows cannot be guarded against. No army ever went into action with better drilled or steadier troops than the English did at the Alma; they were the results of years of careful drill and the finest and most perfect organization and system that any army ever had, and yet what was the force that first carried the battery at the Alma but a mob, composed of various regiments, brigades and divisions mixed up together, and such must ever be the case where a rapid advance under a heavy fire is made by a body of troops for any distance. The wisdom of introducing any complication, with the object of preventing companies being mixed, is at least questionable.

The principles on which troops should be formed, and which govern their advance, being such as have been described, it is desirable to endeavor to realize as clearly as possible the circumstances under which, and the reasons why an attack is made at the present day possible. At a distance from the enemy's position, varying according to the nature of the ground, and the state of the atmosphere, but perhaps lying within the limits of two thousand five hundred to three thousand yards, troops will have to deploy and quit the close order in which they have previously been formed. *Now an attack on an enemy presupposes a superiority of force at the place where the attack is made.* War, whether viewed tactically or strategically, is but the art of being the strongest at the right place at the right time. This superiority of force may be numerical, moral, or local, or it may be composed partly of all three, but for an attack to have a reasonable hope of success, *the attackers at the point the attack takes place must be superior.*

Now, when the first deployment takes place the attacker's infantry will suffer but slightly from artillery fire. But the assailant's artillery will shake down walls of villages, farms or houses in which the defenders are posted, thus driving the infantry out. Their artillery will consequently become the object for the defender's guns to fire at,as it will be stationary, or only advancing occasionally,and in masses of several batteries. Hence the infantry will, in this first stage, suffer but little from the direct or aimed fire,although a few losses may be occasioned by stray shots. As the infantry advances, a large portion of the artillery will advance also,not together,but by alternate batteries, or brigades of batteries; so that a fire will be always kept up. It will probably advance thus, until it gets near to the extreme range of the infantry fire,or about one thousand to one thousand four hundred yards from the enemy's position. The moment the first or skirmishing line of the infantry comes near enough to the enemy's position to become a mark for its aimed or direct fire,say about six hundred to seven hundred yards, the troops in rear, that is to say,the supports and main body,will suffer but little, except from the unaimed or random fire. The fire of the assailant's artillery and the fire of his skirmishing line will have the effect of drawing on them both the enemy's artillery and infantry fire, *and hence it becomes possible to bring up the main body, in a much closer formation than is often supposed.*

Now here is one of the strong points of the attack, and *vice versa* one of the weak points of the defense. The defenders, do what they will, instinctively fire on the troops that are doing them an injury, and consequently the main body of the attack escapes, or nearly escapes, from all but the unaimed or stray shots that have missed the skirmishing line. Hence in every attack the fire both of the artillery supporting the attack, and of the infantry skirmishing line, must be continuous, carefully directed, and brought to bear on the portion of the enemy's position, where an entrance is to be forced. But no fire, however heavy, well-directed, and continuous, will drive good troops out of position. A heavy cross-fire of musketry and artillery may shake the *morale*, and disorganize the defenders, may kill and wound many, may induce many of the less brave individuals to leave the position, but still the really brave men will remain to fight it out. So long as they have ammunition these men will hold their position, and it is only the advance of superior numbers that will finally compel them to retire.

The attack of an enemy's position is based entirely on the science of the attack of a fortress. A mass of artillery fire is concentrated on certain points; under cover of that fire the infantry advance until checked by infantry fire. Again the infantry fire is subdued by the infantry fire added to the artillery fire of the attackers, a breach is made in the enemy's position, and through that breach a formed body of men is pushed, who make a lodgment there. Such in general terms is the attack of a fortress, such in general terms is the attack of a position, with this difference, the former is the work of days, the latter that of hours. The necessity of bringing up a sufficiently strong body formed, in hand and under control, to drive out the defenders, occupy their positions and reap the results of the fire is manifest and the question arises, how shall this body be brought up? It must conform more or less to the movement of the skirmishers; at what distance from them should it be, and in what formation? The three distinct zones of fire, through which troops must pass in moving to the attack, have been already described; these zones must govern the formation of the main body. When entering the zone of artillery fire which may be said to begin at from two thousand five hundred to three thousand yards from the enemy's guns, the main bodies should be so formed as not to offer a mark sufficiently large to induce the enemy to turn his guns on them. The great object of the defense is to retard the attack, and as the attacking artillery will at this, the first stage, be partly in action, partly moving up with the skirmishing line, the defenders must, if this force be, as it should be, a powerful one, direct all their attention to it and not to the main body. Formed in such a way, and kept at from five hundred and fifty to six hundred and fifty yards behind the skirmishers, the main body may advance and experience but little loss. On arriving at from one thousand two hundred to one thousand four hundred yards, the unaimed fire of the infantry will begin to tell, and at this point the formation of the main body may be again extended. The formation requires to be such as will enable the men to advance with speed without being demoralized: and this appears to be more likely to be attained by small columns than by either a line or extended formation.

The action of the supports during the time that elapses from the troops coming under fire should be now considered. The duty of the supports is essentially to keep up the fire of the first line, and fill gaps. It is not so much for re-enforcing the skirmishers that they are requisite, the skirmishing line should originally consist of a "sufficient number," their function is to keep that line up to "the sufficient number," feeding it to fill up the gaps caused by the enemy's bullets. Hence the officer commanding the supports, must watch the front, or skirmishing line, and send up men when he sees they are requisite. The nearer to the skirmishers the supports are the more they will suffer, but if too far off they will cease to act as supports. It appears that the supports will suffer less, that is to say, they will attract the enemy's fire less if they advance in small groups. The distance at which the supports are from the skirmishers must be left chiefly to the officer commanding those supports, but then it should rarely exceed three hundred yards. As the skirmishing line advances towards the enemy, and begins to get into the zone of aimed fire, or some six hundred to seven hundred yards from the enemy, the supports must be freely pushed on, and take their places in the skirmishing line, and as the advance of the skirmishers will, from the fact of their moving in successive rushes, be somewhat slower than that of the supports, the latter will close on them, and the main body will also close somewhat on the supports (as it will experience less loss, and consequently be less retarded).

The Commander of the supports must during his advance seek to find out the places where his assistance may be most usefully sent. The best points for the attack may be found when about eighty to one hundred yards from the enemy. As the fire is kept up the main body will advance, and when it comes near the line of supports the latter should rush to the front and join the skirmishers. The following rule should become absolute, the moment the main body arrives near what is left of the line of supports. They should dash to the front and join the line of skirmishers in order to give the impulsion requisite to cross the last and most dangerous zone of all, and finally give the assault.

If an attempt be made to realize the state of affairs at this period of the attack it will be seen that the skirmishers, re-enforced by the supports, are within two hundred and fifty to three hundred yards of the enemy: that the main body is some three hundred yards in rear of the skirmishers; the divisional artillery perhaps some one thousand two hundred to one thousand four hundred yards off, supported by a portion of the corps artillery occupying advantageous places up to two thousand yards off, and all bringing a heavy cross-fire on the enemy's position; the second line of troops following up in the rear of the main body of the first line, and perhaps some five hundred to six hundred yards in rear of it, a tremendous fire being maintained by the now thickened skirmishers, and the whole front covered with clouds of smoke. Such a state of things cannot last long; the skirmishers may get a hundred yards nearer, and the main body getting closer to them, must prepare to carry the position; gradually converging, the various portions of the main body must push rapidly to the front and drive the enemy out. While the second line seeing the advance and hearing the cheers that accompany it, should push rapidly on also, ready to support the attack, meet the enemy's reserves, and confirm the success. What should the skirmishers do when the main body advances? The skirmishers, who have borne the heaviest part of the fighting, will undoubtedly have got much excited, and heated; they will have been brought close up to the enemy's position, and by that time all the men whose heart is not in the work will have disappeared. officers and men who have worked through the zones of fire that have been described, who have seen comrades and friends dropping, will be in such a state of nervous excitement that the cheer and advance of the main body, will, no matter what orders are given, carry them to the front. The idea of leaving skirmishers lying down is contrary to the fundamental principle of the attack, which is that all the disposable forces should be applied; and leaving them behind really leads to nothing This line left behind cannot fire effectively on the enemy, it cannot collect and reform the *débris* of the troops crushed by the enemy's fire, it will have done enough, and suffered too much already for that. Judging by all experience, what it must do, is to push on with the rest. To leave it lying down is in the most favorable case a useless theoretical course to pursue, generally it will be a dangerous one.

The moment the position is carried every effort must be made to hold it. The troops should be reformed. A heavy fire should be poured on the enemy as he retires, and the second line following rapidly, must endeavor to occupy the ground, and coming up in regular order can do so far better than troops whose nerves have been wrought up to the highest pitch of excitement by a successful attack.

The nature of the attack described is illustrated by Figures 6, 7, 8, 9, and 10; but although such sketches are useful as giving expression to ideas, it should be clearly understood as regards the supports and main body, that there can *by no possibility be any definite or fixed formation*. The formation to be adopted should be entirely suited to the ground, thus one

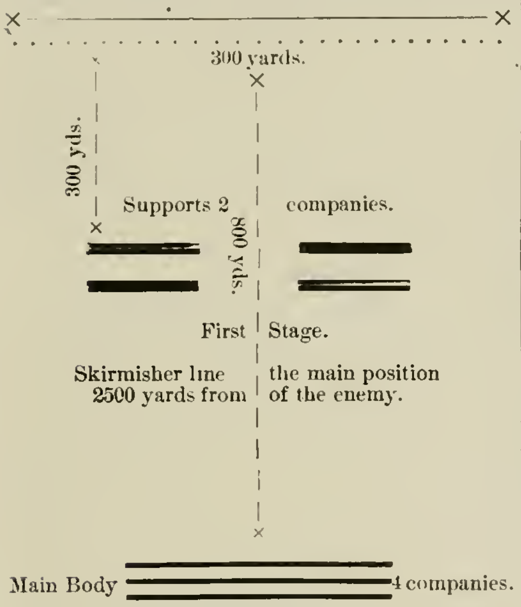

Fig. 6.

company of the supports may be in column, another in line, and after advancing one hundred yards the formations may be entirely altered, the company in column being extended, and that formerly in line now in column; similarly for the main bodies.

Von Scherff divides the attack into three stages, and lays down certain general rules to govern the formation and conduct of the troops during the progress of the attack. Every attack has to go through three stages: *a*. The period of preparations. *b*. The moment of accomplishment, and of the greatest strain on the faculties, and *c*. The period of reaction and of recovery.

The preparatory stage. This expression does not mean the same as "opening of the fight." The latter implies the several acts of reconnoitering the enemy and the ground, of gaining time for deployment, of coming to a determination upon the object to be fought for, and upon the means to be employed: that is to say, of making your dispositions and giving out your orders. In the observations which follow, we will look upon this period as passed by, and will treat of the "preparation" simply as the first step of an attack, the direction of which, and the means to be employed in making which, have already been quite settled.

1. In order to prepare the way effectively it is necessary to bring up your skirmishing line to between two hundred and four hundred paces of the enemy's position, and to overwhelm with a concentrated and uninterrupted fire the particular part of it on which you intend to direct your assault.

2. In order to do this, the attacking force should be divided into an *advance* and *main body*.

3. These two bodies should be in such proportion to one another that from one-fourth to one-half of the total strength should be alloted to the *advance*.

4. The advance is again divided into skirmishers and supports; the former bringing as many rifles into play as the nature of the ground will allow, the latter being intended to make good the losses of the former, must, on open ground, be of equal strength to them, but under favorable circumstances need only be half as strong.

5. The better the cover afforded by the ground the greater may be the extension of the skirmishers during their advance. The limits to be assigned to this extension depend on the necessity which exists of ensuring unity of command throughout the attack, and of being able to concentrate the skirmishers' fire upon one point. The front of one thousand men will range between three hundred and five hundred paces.

6. For the sake of unity of command it will be advisable for every battalion taking part in the attack to form its line of skirmishers with one company and its supports with another.

7. The skirmishers should advance from the extreme range of the artillery fire bearing upon them as far as the *extreme* effective range of the enemy's infantry fire in one body. The company which furnishes them should always be extended in one line before it becomes a target for the enemy's fire, even if at first it had formed some supports. This advance from one thousand two hundred to eight hundred, if possible, to six hundred paces of the enemy, takes

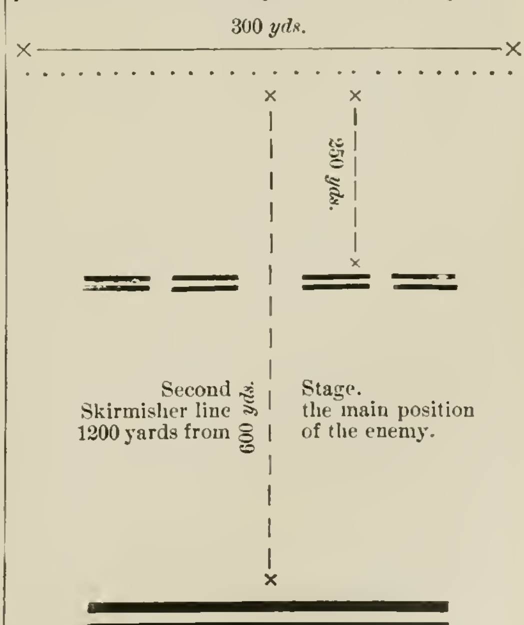

Fig. 7.

place as long as may be without opening fire, individual firing by word of command being only allowed when you can no longer dispense with its animating effect, or when special reasons for it arise (such as the necessity of driving in advanced parties of the enemy, etc.). As soon as the line of skirmishers reaches the zone of loss from *aimed infantry fire* it changes its mode of progression to that of the alternate *rushing forward* and *lying down* of separate fractions. As far as it is possible (the nature of the ground and the advantage taken of particularly favorable moments forming exceptions), these rushes are made by whole divisions, and not over more than from fifty to eighty paces at a time; whether in succession from a flank or chequer-wise is immaterial. Each time, the divisions which are halted and lying down cover by a steady, well-directed fire the advance of the others. Only when the skirmishers have advanced to within the most effective range of the enemy—say from four hundred to two hundred paces—will an unmistakable command or signal be given, upon which a *rapid independent fire*, as much concentrated as possible upon a point previously indicated, will be opened and will be maintained until the moment of the actual assault.

8. The distance of the supports from the skirmishers and their mode of advance, will be regulated as provided for the portion of the attacking force, which remains in close order.

9. The skirmishers will be re-enforced by the supports, as far as practicable, by doubling in separate fractions between separate fractions of the front line; but the details of execution will always be subordinate to producing the best possible effect upon the enemy.

The stage of execution. Whilst it was the task of the *preparation* to pave the way for the attack, the work of breaking the enemy's power of resistance by employing the greatest possible amount of striking power, devolves upon the *execution*. The conditions for successfully carrying out an attack, as far as they depend on the Commander's dispositions may be summed up as follows:

1. Every independent body of troops intended to take part in an attack should have a distinct objective assigned to it by superior authority, and should direct its efforts against this point, without cessation, with its whole strength, and in the most direct way.

2. The troops must be deployed for the attack as soon as they come within reach of the enemy's artillery. They should be divided into a main and advanced body, the former keeping within five hundred paces of the advanced skirmishers; in open ground, and under favorable circumstances, nearer to them.

3. The support of the advanced skirmishers should as soon as it becomes a mark for the enemy's guns, assume by degrees a more and more extended formation behind the skirmishers, first deploying from column into line, then spreading out so as to leave intervals between the divisions, and finally making each division expand into an open *line*. The Captain of the support will use his own discretion as to the re-enforcement of the skirmishers, both with regard to time, place, and amount, establishing himself as close as possible behind them with whatever parts of his company remain in hand, and finally throwing himself with these remnants into the line of skirmishers to take part in the heavy firing, when the main body has approached within eighty or one hundred paces.

4. The main body may get over the ground from first coming into action until reaching the zone of unaimed infantry fire, that is, until within one thousand five hundred or one thousand two hundred paces of the enemy, in little columns, if the attention of the defender's artillery is so much occupied by that of the assailant, or by his advanced skirmishers, that it cannot direct its fire on the main body.

5. From this point onwards, when either the mass attracts the fire of the enemy's guns or begin to catch his rifle balls, it should resolve itself into company columns, with intervals of from forty to eighty paces, in which formation as near an approach as possible should be made to the advanced skirmishers, say to within from six hundred to four hundred paces of them. During this advance each company may, at the discretion of its Captain, either deploy or else when wished form *open line* from division columns.

6. As soon as the main body has arrived within about fifty paces of the line of skirmishers, now re-enforced by the whole of the supports, the commanding officer gives the signal for the assault, which will be made by both advanced and main body together in double time, as lively a fire as possible being at the same time kept up by the advanced troops during the movement, which continues thus to within about twenty or thirty paces of the enemy, then terminating in a rush at full speed with a cheer, and the position is carried. The advanced troops will generally make it a point to envelop the point of entry whilst the main body converges upon it and breaks in.

7. The troops which force the position must aim at gaining the further border of it, so as to be able from thence to pursue the retreating enemy with their fire, and every portion of the attacking force will try to do this without regard to their original subdivision into advanced and main body. It will not signify if at this stage portions of the main body companies pass beyond or mingle with fractions of the advanced companies, which may yet be engaged with the enemy within the limits of the post which has been forced. An immediate rush forward beyond the border of the position is altogether inadmissible. The assailant will do much better if he at once prepares the point which he has captured for defense. As soon as the success of the attack may be considered complete, every officer must do his utmost to restore order as quickly as possible in his immediate neighborhood, and by degrees throughout the whole mass, in spite of the over-excitement or reaction which will probably prevail.

The third stage of the attack. We hardly require theoretical argument or a graphic desetription to prove that troops which have made an attack, as it necessarily must be made, in the manner above described, will have expended almost all their power for a certain time, and require a period of repose which should, at least, last until the disorder which, as we have already asserted and still confidently maintain, is inseparable from such operations has been to some extent remedied. This third stage has at all times been an extremely dangerous period for the assailant, a period in which the laurels which have been won at the price of blood, have often been again torn from the victor by a counter-attack of the enemy. Hence it has always been the aim and the task of the Commander when making his general dispositions for the attack to provide for this moment of depression, and in examining this part of the question we come to this difficult point, the subdivision of the force into separate *lines of battle*.

The following principles will be sufficient to regulate their general employment in the attack, in reference to the third stage now discussed.

1. An attacking force of more than two or three battalions must needs be formed in more than one line of battle, so as to be able to meet any counter-attack of the enemy, the possibility of which must be kept in view.

2. A second line of battle becomes necessary when the front of attack is so wide that a charge made against it cannot be met directly by the wings of the assailing force, namely, if the front exceeds the range of a rifle-ball, say from eight hundred to one thousand two hundred paces. A third line of battle is requisite to help the advanced troops to tide over the weak moment of reaction through which soldiers who have met with stubborn resistance will naturally pass, and of which the defender is likely to take advantage for making a counter-attack either on the flank of the stormers as they advance, or on the position which they have just carried. Therefore, while a second line of battle is only necessary under certain conditions, a third line can never well be dispensed with; that is to say, we shall always find it advisable to keep back a certain portion of the line to follow after the fashion of a third line.

3. From a quarter to one-third of the total force will usually be sufficient for the third line, and the second may be much weaker. The former will meet the enemy's counter-strokes by acting on his flanks, and, according to circumstances, will serve as an "outer" reserve after the position has been carried, or will undertake the pursuit; the latter will fill up accidental gaps in the front line, oppose a purely defensive action to the attempts to break through, or clear out his stragglers after the position is won.

4. The usual distance of the second line of battle from the main body of the first line will be three hundred paces, so that it may not share the losses of the latter, while the third will follow at the distance of from eight hundred to five hundred paces, so regulated that it may be at hand when its support is required. While the corps composing the second line of battle will, in accordance with the duties required of them, be disposed so as to cover the intervals of the first line, those of the third line will also be most advantageously posted on the flanks with a view to the part assigned to them, which, however, does not prevent them from being at first kept together in the center so as to be available for use on either side. But anyhow they must be drawn to a flank in the extreme case, of having to cover the retreat of the first line after its repulse.

5. The combined action of the second and third lines of battle with the first will depend too much upon circumstances to become the subject of regulation. It will generally be convenient to place the corps

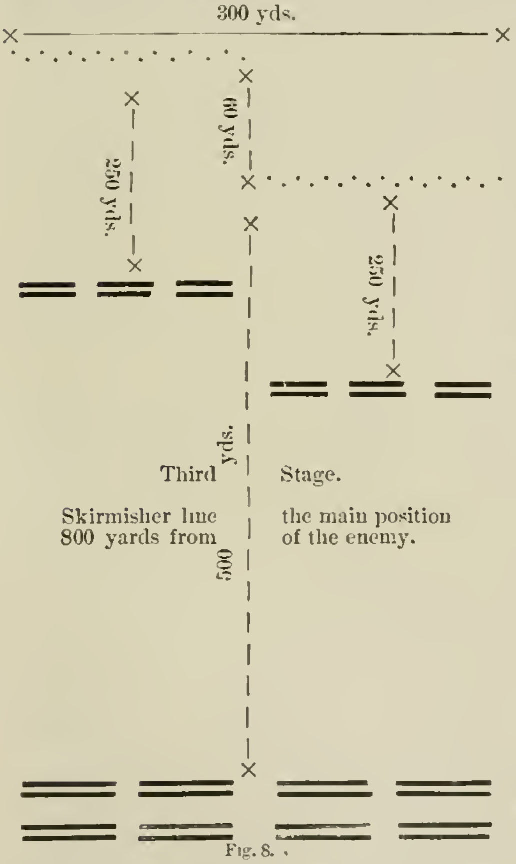

Fig. 8.

in second line, under the same command as those in front of them in the first line, while the third had better form an independent command: but the Commander of the whole force must have full discretion in the matter.

The defensive. The improvements made in fire-arms during the past thirty years seem to carry with them the conviction that the *defensive* has greatly gained in strength thereby, and this, too, at the expense of of the *offensive*. Theoretically this deduction seems natural enough, but the result of recent wars teach us conclusions entirely different. Fire-arms and gunpowder first rendered the *defensive* possible for an army operating against another in an open country. Previous to these inventions, the weaker party was forced to take refuge in walled cities and there await the enemy: and the latter was then forced to resort to siege operations. In the open field both parties took the offensive: for, had either side concluded to stand on the defensive, it would have inevitably been beaten.

In 1859, the Austrians, provided with rifled small-arms, stood on the *defensive*, and were beaten. It is true that in this war the French had rifled cannon, but their infantry was generally armed with the smooth-bore musket.

The French have usually followed the *defensive-offensive* system; that is, they have stood on the *defensive* until the enemy fully developed his plan of attack, and then, at the proper time, assumed the *offensive*, with results that are well known. The first Napoleon reaped his greatest success by following this system. Austerlitz is a brilliant example of a battle fought on this plan. In 1870, the French stood on the *defensive*—contrary both to their nature and traditions—and were beaten. In 1878-79, the Turks also stood on the *defensive*, and they in turn were beaten. Of course in all these cases there were certain causes which contributed to the choice of the *defensive*, other than the advantages supposed to be inherent in it; but still, confining the mind to the simple question of *improved weapons*, it is somewhat singular that the side which assumed the presumably stronger system, the *defensive*, was invariably beaten.

Before entering into the subject of the tactics to be followed by infantry holding a *defensive* position, it is proposed to make a simple calculation illustrative of the relative powers of the breech and muzzle-loading rifles on the defense. Let us suppose a force of two hundred infantry manning the interior crest of a redoubt. With the present breech-loading rifled musket this number of men can deliver eight thousand shots in four minutes, allowing six seconds per shot for loading, adjusting sight, and aiming. This number of shots can be delivered while the enemy is passing over a distance of about six hundred yards—limit of effective fire of the *muzzle* loading smooth-

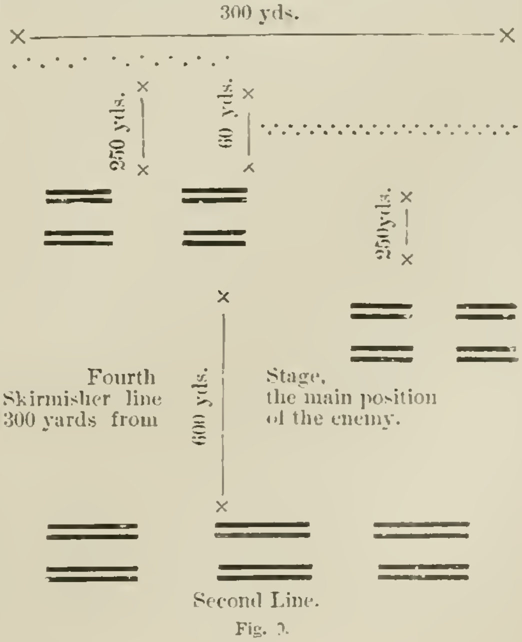

Fig. 9.

bore musket at the double time, and without any halt or delay, and under the most favorable conditions of ground. The same number of men, armed with the *muzzle*-loader, can deliver one thousand two hundred shots—allowing three shots in two minutes—under the same conditions. Supposing that one shot in twenty-five is effective, we will have three hundred and twenty men hit in the first instance, and forty-eight in the second. Then remembering that the breech-loader will prove fatal at three times the effective range of the muzzle-loader, and some idea may be formed of the great superiority of the former arm, especially when employed in positions where the distances had been previously measured and marked on the ground. We can thus see good reasons for the open order indicated for troops acting on the *offensive*, and are also enabled to form an idea of the tactics that should be followed by the *defense*.

This change in the conditions of infantry fire has reversed the relative defensive value of ground. Formerly ground that most abounded in cover was regarded as very strong, while the reverse was held of ground that was level, open, and easily approached. Now, the latter requires but comparatively few men to hold it, for no troops could live to cross it under a heavy musketry and artillery fire. The former is now the place that requires most defenders, for it is the locality where the opposing troops can find that cover so essential to protect them from the heavy fire of troops in position and protected from return fire by the works that forces on the defensive now invariably shelter themselves behind.

The power that improved arms have given to the defense is that of keeping the attackers for a longer time under a heavy fire than formerly; it is also stated that the defenders derive much advantage from the following causes: *a*. Their fire is delivered by men in position, who can take a better and more correct aim. *b*. That the force acting on the defensive may be better covered and protected than that acting on the offensive, suffer less loss, and consequently be cooler and less excited. *c*. That the ground may be better studied by the defensive than by the attacking force, and not only can advantage be thus taken of its conformation, but also additional force may be obtained by removing men from where they are of no use to important places.

If, however, these advantages, or supposed advantages, be analyzed, they will be found to have hardly the importance that they at first sight appear to possess. With reference to the first, it must not be forgotten that the assailants move rapidly and by rushes of alternate fractions, which tends to disconcert the aim of the defenders, who are ever firing at a running target, while the attackers are firing at a fixed target; therefore the superiority of the defense in this case does not seem to be very great. With reference to the second it appears that the concentration of fire on one spot so demoralizes a defender that he can be neither cool nor calm. The fire of the attacker is always convergent, that of the defender divergent. Further, the advance of troops takes them away from the dead and wounded, who are left behind. The defenders must remain in one place, and the dead and wounded can with difficulty be removed, hence the *morale* of the defenders will suffer most. With reference to the third, there can be no doubt that the defense will benefit greatly from its superiority in this respect; and it is not only in its fire, but the power to bring that fire to bear on proper places, that the defender owes his superiority.

It would appear that for the correct holding of a defensive position, arrangements should be made to bring a very heavy artillery and infantry fire on the attackers at the very beginning of the action, and to hold a few powerful reserves in hand, to attack and drive out any troops that may obtain a lodgment within the general line. The assailant to have a reasonable hope of success must be superior at the point where the attack is made. Now to counteract this superiority there must be on the side of the defense large reserves kept ready in hand to be moved the moment the attacker's project is developed, and sufficiently near to be brought up in time to drive the enemy back; not merely to check his advance after he has penetrated the position. Such reserves must be in the hands of the Generals commanding the divisions and corps, rather than those of the General-in-Chief, and hence it follows that these bodies should each form its own reserve.

On the defensive it may fairly be questioned if a deployed line is now requisite. The breech-loader enables an extended line to deliver more fire now than a closed line in former days. It will perhaps be wiser, therefore, to keep a large portion of the first line until the attack has developed itself, and then to use it in thickening the line of skirmishers where most threatened. Such a method gives much additional power to the men who see themselves supported by those behind, and who feel that they are not left alone to cope with the attackers. The sudden increase of the defender's fire, by a large reenforcement of the supports, has a powerful effect in checking the enemy's advance. It appears, from the testimony of all continental writers, to be the experience of recent war, that volley firing cannot be used, and that independent firing, which enables each man to judge its own time and aim, is far more effective.
